***Abstract*—Advancements in data capture techniques in the field of Magnetic Resonance Imaging (MRI) offer faster retrieval of critical medical imagery. Even with these advances, reconstruction techniques are generally slow and visually poor, making it difficult to include compression sensors. To address these issues, this work proposes a novel hybrid GAN-DRN architecture-based method for MRI reconstruction. This approach greatly improves texture, boundary characteristics, and picture fidelity over previous methods by combining Generative Adversarial Networks (GANs) with Deep Residual Networks (DRNs). One important innovation is the GAN's all-encompassing learning mechanism, which modifies the generator's behaviour to protect the network against corrupted input. In addition, the discriminator assesses forecast validity thoroughly at the same time. With this special technique, intrinsic features in the original photo are skillfully extracted and managed, producing excellent results that adhere to predetermined quality criteria. The Hybrid GAN-DRN technique's effectiveness is demonstrated by experimental findings, which use Python software to achieve an astounding 0.99 SSIM (Structural Similarities Index) and an amazing 50.3 peak signal-to-noise ratio. This achievement is a significant advancement in MRI reconstructions and has the potential to completely transform the medical imaging industry. In the future, efforts will be directed towards improving real-time MRI reconstruction, going multi-modal MRI fusion, confirming clinical effectiveness via trials, and investigating robustness, intuitive interfaces, transferable learning, and explanatory techniques to improve clinical interpretive practices and adoption.**

Keywords*—*Magnetic Resonance Imaging (MRI); deep learning; generative adversarial network; deep residual network; ResNet50

I. Introduction

Body organs, extremities, and different tissues were imaged using medical imaging devices such Magnetic Resonance Imaging (MRI), ultrasound, computed tomography (CT), and X-ray. Nevertheless, poor signal-to-noise ratios (SNR) and reduced contrast-to-noise ratios (CNR), as well as image artefacts, may be present in images obtained using such imaging paradigms. Especially in clinical circumstances, the impact of imperfections and noise from many sources, like those caused by magnetic fields inhomogeneities, have to be matched with the period needed for collection. Actually, since CT scans have been so much speedier than MRI scans, they are frequently chosen over MRI notwithstanding its weaker soft tissue contradiction, loyalty, and the presence of ionising energy. The average MRI session lasts between 20 and an hour for each sufferer. Contrasted to CT, individual scans take longer, and they frequently call for distinct MR patterns that react distinctly to the properties of distinct tissue kinds such as T2-weighted (T2-w) or T1-w MRI [1]. To solve these difficulties and enhance the images quality for improved visual perception, comprehension, and assessment, image reconstruction methods were created. Radionics, medical image assessment, and computer-assisted identification and assessment are a few applications of deep learning (DL) techniques that were employed effectively in medical imaging [2], [3]. During the past ten years, enthusiasm for artificial intelligence (AI) had significantly increased across almost all branches of research and innovation. The development of DL, a collection of techniques centred around artificial neural networks (ANN), which has shown to be a powerful all-purpose tool for automated processes, has played a significant role in its rise to prominence [4].

As non-linear models of the information that best match the intended objective for which it was learned, the DL networks learn the fundamental features and significant basis functionalities. It performs this completely autonomously (i.e., without operator input) as a component of an improvement procedure to identify the best attributes. In contrast to conventional statistical and machine learning (ML) techniques, DL algorithms performance improves accordingly to a power law as additional information is added [5]. Convolutional neural networks (CNNs), one of the DL approaches, have transformed imaging and computer vision since they offer a data-driven strategy for addressing a variety of difficult issues. Due to their data-driven type, DL techniques frequently outperform conventional linear analytic techniques, where these characteristics have been manually chosen and created over extensive experience and research. The term "deep" typically refers to the dimensions and quantity of "layers" that make up a neural network, every one of which has the capacity to store an enormous amount of these properties. Acquiring the interconnected neuron's weights from the initial strata to all the following ones until the final strata has been a necessary step within the optimisation procedure [6]. This procedure is typically labelled or supervised in advance. By making modest adjustments to the results, or "returning" of the system, stochastically gradient descent has been utilised during learning to determine this network weight of neurons that are optimum. Backpropagation constitutes a technique whereby inefficiencies from the identified and anticipated outcome can be reduced by changing the weights [7]. As a result, the artificial neurons can successfully generate non-linear judgements, and the system design can parameterize the problem and automatically choose features by controlling the weights among the neurons. Among the key factors driving the AI development researchers are seeing today was the development of novel networks, network structures, and neuronal connections [8].

Recently, DL, also known as representation learning [9], had received a lot of interest for the evaluation of medical images [10]. Deep learning (DL) outperformed traditional machine learning (ML) approaches because it can extract features from unfiltered data sources during the learning phase. It may acquire concepts based on inputs owing to its multiple secret layers [11]. The DL technique and its usage in several fields [2], Reconstruction of medical images has been aided by recent improvements in successful computing platforms such as cloud-based computing and graphics processing units (GPUs). The quantity of research carried out on medical image recovery has expanded dramatically in recent years. Acceleration of MRI scans is one of these applications. This problem is essential because, while MRI remains the leading diagnostic technology for a range of procedures, it is inherently slower than other methods due to the physical processes involved in data acquisition. Thus, a critical component in the MRI widespread clinical use was the lowering of scan times [12].

Conventional image reconstruction techniques have traditionally relied on broad (unsupervised) restoration techniques that make very few implications about the object being photographed. These approaches do not conveniently support methods that would greatly boost up MR deals, despite the fact that they give users trust in the pictures by providing solutions that have been typically resilient to noise and distortions. The speed factors that can be achieved for anatomical contrasting images, like T2-w and T1-w images, without taking into account prior understanding have been in the range of 2 to 4. The quality of the restoration then quickly deteriorates with obvious artefacts. Greater acceleration variables may be attained for operational contrast, like coronary MR angiography (CMRA) [13].

New prospects for dramatically increasing MR image capture and restoration speeds whilst retaining high quality have emerged with the introduction of DL-based techniques into MRI restoration. Sparse restoration, multi-contrast restoration, and parallel imaging are the three key areas where AI-based MR imaging has made progress. Compressed sensing (CS), a method for quick MR imaging predicated on the sparseness earlier, has gained prominence in recent years. Nevertheless, the repetitive solution process requires a considerable amount of effort to produce a high-quality restoration, and the regularisation parameter has been chosen empirically. Despite the fact that several numerical techniques, including Stein's Unbiased Risk Estimation (SURE) [14], were suggested to optimise the free variables in MRI, these techniques are saddled with significant computational expenses.

Additionally, just a small number of standard images are used in most systems, and the preceding information is.

The primary traditional challenge in MRI image reconstruction is to accurately reconstruct high-quality images from raw data acquired during the scanning process, while addressing issues such as under sampling artifacts, noise, and motion-related distortions [15]. These factors can lead to blurry, distorted, or incomplete images, hindering accurate diagnosis and interpretation by medical professionals. Overcoming these challenges is crucial for enhancing the diagnostic value and overall effectiveness of MRI imaging in clinical settings. The significance of this study lies in its innovative approach to addressing the challenges of MRI image reconstruction, which is crucial for accurate medical diagnosis and monitoring. While MRI is a valuable diagnostic tool, its relatively slow imaging speed can limit its practicality. This paper introduces a Hybrid Deep Learning framework that combines the strengths of Generative Adversarial Networks (GANs) and ResNet50 Deep Residual Networks to enhance the quality and speed of MRI image reconstruction. By effectively leveraging GANs for image refinement and ResNet50 for feature extraction, the proposed approach not only accelerates the reconstruction process but also ensures improved image fidelity, texture, and edge preservation. This has the potential to greatly benefit clinical practice by enabling quicker and more accurate interpretations of MRI scans, thus enhancing the overall efficiency and reliability of medical imaging for diagnosing and managing various illnesses. The study's utilization of performance metrics such as PSNR and SSIM provides quantitative evidence of the effectiveness of the proposed method, further underscoring its importance in advancing MRI image reconstruction techniques beyond the limitations of previous approaches. Through extensive experimentation and comparisons with existing methods, the research demonstrates substantial improvements in MRI image reconstruction. In prior MRI image reconstruction research, a notable issue was the inherent trade-off between image quality and reconstruction speed. Traditional methods struggled to provide high-quality images in real-time or with limited computational resources. This issue posed challenges in clinical applications where timely and accurate diagnoses are imperative. The study "Improvement of MRI Image Reconstructions through Combination of Deep Residual Networks and Generating Adversarial Networks in a hybrid Deep Learning Architecture" made the following significant contributions:

- Better Image Quality: By incorporating GANs, MRI images may be seen more clearly and have greater value as diagnostics.
- Real-time or Near-real-time Reconstructions: Applications requiring MRI reconstruction of images in actual time or near-real-time are critical in medical applications. Deep ResNets facilitate rapid MRI reconstruction of images.
- Balancing Trade-off: This study overcomes the enduring difficulty of choosing one as opposed to another in earlier approaches by striking an equilibrium between the quality of images as well as reconstruction speed.
- Clinical Utilisation: By rapidly delivering images of excellent quality, the suggested hybrid deep learning system will greatly enhance medical evaluations and support healthcare providers in making quick and precise decisions.
- Improvement of MRI Technologies: This study advances MRI technology by utilising the advantages of GANs as well as ResNets, guaranteeing that patients obtain the greatest imaging results and medical experiences.

The rest of the paper is structured as follows: Section II gives an overview of relevant studies. Section III covers the approach's research gap. The proposed approach is presented in Section IV, which describes the improving MRI Image Reconstruction by employing a Hybrid Deep Learning Mechanism based on Generative Adversarial Networks with Deep Residual Networks. Section V goes over the findings and performance analysis. Finally, Section VI summarises the contributions of research techniques to the work

II. Related Works

It is difficult to recreate a PET image regarding low-count projected data and physical consequences since the inverse issue is poorly stated and the final image has been typically noisy. GANs were recently demonstrated improved performance in a variety of computer vision applications, which has sparked significant attention in medical diagnostics. For the purpose of reducing streaking aberrations and enhancing the PET images quality, Qianqian et al. [15] suggested a unique deep residual GAN (DRGAN) framework relying on GANs. Instead of directly generating PET images, the investigators of the suggested approach taught a generator to build a "residual PET map" (RPM) for expressing images. For the purpose of requiring anatomically accurate RPM and PET images, DRGAN employed two barriers (critics). The authors created residual dense links with pixel shuffle processes (RDPS blocks), which promote feature reusing and avoid resolution loss, to better enhance the contextual data. To assess the suggested strategy, both simulated data and actual medical PET data have been employed. The quantification outcomes demonstrate that DRGAN may achieve higher performances in the bias-difference trade-off and deliver equivalent image quality when compared to other cutting-edge algorithms. The comprehensibility of the produced residual PET map (RPM) or the topographical precision of the restored PET images are not included in the description. For accurate medical evaluation and clinical choice-making, anatomy precision is just as important as comprehension. Evaluation of the quality and clinical applicability of the restored PET scans is crucial.

Using sparsely collected information to speed up MRI causes substantial artefacts that make it difficult to see the image's actual content. Fully dense attention CNN (FDA-CNN), a cutting-edge convolutional neural network (CNN), was suggested by Biddut et al. [16] to eliminate aliasing artefacts. Incorporating fully dense connection and an attention procedure for MRI restoration, researchers upgraded the Unet framework. The fundamental advantage of FDA-CNN was that every decoder strata's attention gate boosts learning by concentrating on the pertinent picture information and improves network generalisation by eliminating irrelevant engagement. Convolutional layers with close connections can also reuse map features and avoid the disappearing gradient issue. The investigator additionally employs a fresh, effective under-sampling sequence in the phase orientation that extracts high and low frequency bands both arbitrarily and deliberately from the k-space. Three distinct datasets and sub-sampling masks were used to objectively and subjectively assess FDA-CNN's performance. The suggested method outperformed five existing DL-oriented and 2-compressed sensing MRI restoration methods because it produced cleaner and more illuminated images. Additionally, FDA-CNN outperformed Unet for an accelerating value of 5 in terms of average SSIM, VIFP, and PSNR each by 0.35, 0.37, and 2 dB, respectively. The calibre and variety of the training databases have a significant impact on the FDA-CNN technique's success. The network's capacity to generalise may be hampered if the training databases have been too small or do not sufficiently cover all of the potential MRI changes.

A unique framework was created by Manimala et al. [17] to quickly and accurately restore chaotic sparse k-space information into MRI. In the suggested approach, Rician noise-corrupted MR pictures are denoised using a CNN. The technique takes advantage of signal similarities by analysing related patch collectively in order to extract local information. The CNN was learned on a GPU with the Convolutional Network for Fast-Feature Embedding system, rendering it appropriate for online restoration, resulting in a crucial drop in running time. The primary benefit of the CNN-based restoration over current cutting-edge methods has been the elimination of the need for noise level optimisation and forecasting during denoising. Different under-sampling strategies were used in analytical studies, and the findings show great accuracy and a constant peak SNR especially at twenty-fold under-sampling. Large under-sampling rates make it possible to transmit k-space data wirelessly, and fast restoration makes it possible to use our approach for virtual health surveillance. The fact that the CNN had been trained on a GPU according to the research suggests that there may be significant processing demands. In pragmatic medical situations, it is crucial to take into account the system's scalability and hardware capabilities required for real-time or online reconstruction.

The amount of time it takes to acquire data can be significantly decreased with CS-MRI. The conventional CS-MRI approach, which relies on iterations, is versatile in modelling but typically time-consuming. Because of its excellent effectiveness, the deep neural network (DNN) approach has recently gained popularity in CS-MRI. The DL method's disadvantage, however, is its rigidity. It heavily relies on the k-space data's screening process and learning images. In order to achieve speedy, adaptable, and accurate restoration, Ruizhi and Fang [18] suggested an iterative technique for MRI restoration termed IDPCNN that combines the advantages of both the conventional approach and the DL techniques. Projection and denoising are two stages of the suggested approach. A cutting-edge denoiser has been used in the denoising process for smoothing the images. The projection stage continuously adds specifics to the space domain while exploring the previously acquired frequency domain data. Under various sampling filters and rates, the restoration quality has been better than the finest MRI restoration techniques. The IDPCNN offers the possibility for broad clinical uses due to its stability, rapidity, and high restoration quality. The study makes no reference to any clinical verification or assessment of the IDPCNN technique by qualified physicians or medical professionals. To ascertain whether the reconstructed images have been diagnostically precise and trustworthy for generating medical judgements, clinical evaluation is essential.

Dynamic MRI is a valuable technique for capturing the ever-changing anatomy of various organs in the human body over time. However, its clinical utility is often constrained by practical limitations, such as limited acquisition time due to mechanical and physiological factors. Dynamic MRI is known to exhibit spatio-temporal heterogeneity in its frequency spectrum, particularly in the k-space domain. To address this challenge and expedite the acquisition process, researchers Shashidhar and Subha [19] devised a novel approach involving a cascaded Convolutional Long Short-Term Memory (ConvLSTM) framework. This technique focuses on restoring T2-weighted dynamic MRI patterns from significantly under-sampled k-space data. Specifically, it leverages a Cartesian undersampling mask to acquire less k-space data than traditionally required. The ConvLSTM framework plays a pivotal role in mitigating aliasing artifacts resulting from this undersampling process. Notably, it excels in capturing both temporal and spatial connections within the image data, surpassing the capabilities of conventional CNN-based restoration methods. While the use of medical databases, such as the Alzheimer's Disease Neuroimaging Initiative (ADNI) dataset, offers valuable insights, it also raises ethical concerns related to data privacy and informed consent. It is imperative that research endeavors adhere to rigorous ethical standards and secure the necessary permissions and authorizations for the responsible use of such data.

In the areas of neuroscience and ML sectors, there has been an increase in interest in comprehending how the individual brain functions. In earlier research, generative adversarial networks (GANs) and autoencoders were used to boost the accuracy of stimulus image restoration from functional MRI (fMRI) datasets. These approaches, however, primarily concentrate on gathering pertinent aspects across two separate data modalities, namely, fMRI and stimulus images, whereas neglecting the fMRI statistic's temporal information, which results in less than the ideal efficiency. Shuo et al. [20] suggested a temporal information-guided GAN (TIGAN) to restore visual data from the brain's activity to tackle this problem. The suggested approach is made up of three essential parts, particularly: an algorithm for image restoration that is employed to render the restored image more comparable to the unique image; a fMRI encoder for visualising the stimulus visuals into hidden space; along with an LSTM framework for fMRI characteristic mapping. Additionally, researchers use a pairwise ordering loss to organise the stimulus images as well as fMRI to guarantee strongly correlated pairings are at the highest level and poorly associated ones are at the lower level in order to better quantify the relationship between two distinct types of databases (i.e., natural images and fMRI). The empirical findings on real-time databases imply that the recommended TIGAN outperforms a number of cutting-edge image restoration techniques. GANs and LSTM architectures may be operationally taxing; learning and inference need a significant amount of computational energy and time. The TIGAN method's computational effectiveness is not mentioned in the outline, which can have an impact on its accessibility and flexibility, especially in large-scale or real-world applications.

A DL-based restoration approach was presented by Yan Wu et al. [21] to enhance image quality for fast MRI. Researchers combined a volumetric recursive deep residual CNN with the self-attention process, which recorded long-range connections across image areas. Each convolutional layer included a self-attention component integrated into it, which computed the signal at each point as the weighted average of all the attributes at each position. Additionally, data consistency has been mandated, and reasonably dense shortcut links have been used. The SAT-Net suggested network has been implemented to cartilage MRI data that was obtained employing an ultrashort TE pattern and retroactively under-sampled in a pseudo-random Cartesian sequence. The algorithm had been evaluated employing 24 images that produced better results after being learned on 336 3-dimensional images (each one comprising 32 slices). The structure is adaptable to a wide range of applications. Although it is said that the SAT-Net approach can be applied to a variety of applications, the explanation does not give any concrete examples or evidence of its usefulness outside of cartilage MRI. Validating the approach's efficacy and adaptability with diverse MRI data kinds and clinical uses is crucial.

To speed up parallel MRI with residual complicated CNN, Shanshan Wang et al. [22] introduced a multi-channel image restoration technique called DeepcomplexMRI. To learn the deep residual CNN offline, DeepcomplexMRI employs an extensive amount of previous multi-channel ground truth images as emphasise data, in contrast to most current efforts that depend on the utilisation of coil sensitivity or prior knowledge of predetermined transforms. A sophisticated convolutional network has been specifically suggested to account for the relationship between actual and fictitious portions of MRI. Additionally, among network levels, the k-space information coherence is continually guaranteed. The suggested technique can recover the intended multi-channel pictures, according to tests using in vivo databases. Its contrast with cutting-edge techniques also shows that the suggested method could more precisely rebuild the intended MR images. The utilisation of medical imaging database poses ethical questions about data usage, privacy, and informed permission. It is crucial to confirm that the research complies with ethical standards and has gotten the necessary authorization for the gathering and use of data.

The main problem with the aforementioned techniques is that they require more thorough assessment and validation with respect to both clinical application and technical excellence. These papers offer novel deep learning-based solutions for a range of healthcare imaging problems, such as MRI and PET imaging restorations; but they frequently do not have comprehensive medical confirmation, expert medical confirmation, and scalable evaluations. The evaluated methods suggest novel approaches to improving medical images. Though DRGAN emphasizes PET image improvement with residual GANs, questions arise over the clinical relevance due to inadequate focus on RPM comprehension and anatomical correctness. FDA-CNN covers MRI artifact reduction, although problems with scalability and real-time equipment needs are not explored. CNN-based restorations for unpredictable sparse MRI data offers potential for denoising but require investigation into scalability and real-world applications. IDPCNN provides excellent CS-MRI restoration, although the lack of clinical validation raises questions regarding diagnostic accuracy. ConvLSTM for continuous MRI raises ethical issues without providing details on adherence to norms. TIGAN provides fMRI recovery with temporal instructions, although the computational efficacy is not explored. SAT-Net produces promising outcomes for rapid MRI enhancement, but its wider relevance remains unsubstantiated. Deepcomplex MRI presents a unique approach for simultaneous MRI reconstructions with recognized ethical implications, emphasizing the importance of validation over several datasets and clinical contexts. Moreover, informed permission and information protection are two moral problems that have not been often handled [19]. The primary area of study deficiency is the inadequate use of these intriguing deep-learning approaches in realistic clinical contexts, where their efficacy, simplicity, and robustness must be thoroughly examined and verified. Furthermore, evaluating the actual worth and benefits of these suggested approaches in clinical settings is hampered by the dearth of studies compared with current state-of-the-art procedures.

III. Problem Statement

Previously, CNN-based techniques had trouble maintaining subtle image information and materials, LSTM-based techniques had trouble capturing long-range dependence, and conventional machine learning techniques had trouble adapting to intricate image-to-image conversions in MRI reconstructions. To solve these problems, the suggested study proposes a combination of deep learning architecture that blends Deep ResNets with GANs. Through the use of GANs, this method improves texture retention and quality of images while facilitating real-time or almost real-time reconstruction—a crucial feature for applications in healthcare. This work expands the application of MRI reconstruction to medical imaging by crossing the speed and quality of image gaps, providing a more flexible and effective means of enhancing healthcare outcomes and increasing diagnostic precision.

IV. Proposed GAN-ResNet50 Approach

Undersampling is a key method for speeding the capture of Magnetic Resonance (MR) images in Magnetic Resonance Imaging (MRI). It may shorten the duration and expense of MR scanning, minimizing patient pain. Generative adversarial network (GAN) [23] is a particularly effective MRI techniques for obtaining the original picture from undersampled images. In this work, an MRI picture and the accompanying ground truth images are used. Divide the data into training and testing sets after normalizing the intensity of pixels as part of the preprocessing. Create the ResNet50 generator and discriminator network-based GAN framework. Distinguishing between genuine high-quality MRI images and artificially produced high-quality MRI images is the goal of the discriminator. The goal of the generator is to provide excellent MRI images that can deceive the discriminator. Construct the GAN framework's loss function. A content loss must be included in the loss function together with adversarial loss, which pushes the generator toward generating realistic images. This guarantees that the generated images and the real-world images are similar. Iteratively improving the loss function will train the GAN model. The discriminator becomes more adept at distinguishing actual images from created ones, while the generator gets better at producing high-quality MRI images. Utilize quantitative criteria to assess the reconstructed images, such as peak signal-to-noise ratio (PSNR) and structural similarity index (SSIM). These parameters assess how well the reconstructed pictures match the originals. The experimental results reveal that the hybrid GAN-DRN technique achieves amazing performance with an SSIM and a PSNR, resulting in a significant improvement in picture fidelity. These findings point to the possibility of transformational uses in MRI reconstructions. However, the technique's performance needs to be evaluated in a variety of clinical circumstances to confirm its durability and practical efficacy. Fig. 1 shows the overall methodology of the Proposed Method.

Fig. 1. Overall workflow of the proposed approach.

A. Dataset

The study utilized the dataset from the MICCAI 2013 Grand Challenge to assess GAN-ResNet50 performance. T1 weighted coronal brain sections make up the dataset. For training, 6277 photos are used for validation, while 9901 images are used for testing. It presents the results of the test set in this work unless specified otherwise. Each image has a size of 256 by 256 pixels, with pixel values ranging from 0 to 1. In the experiment, the center of the original photos is cropped if the needed size is less than 256*256 in order to assess the model's ability to reconstruct images of various sizes, including 64*128, 128*256, and 256*256. To ensure that the number of photos needed for training, validation, and testing is the same for images of all sizes, thus only crop one patch per image is made. It implies that the results on photos of various sizes may be compared fairly. Additionally, when a model is tested, photos of the same size as those used to train it are used [24].

B. Data Pre-processing

For categorization, the normalization type of pre-processing is essential. The input data should be normalized to speed up the learning process. Furthermore, to avoid numerical problems like accuracy loss due to arithmetic errors, some sort of data normalization may be necessary. Following initially outweighing features with originally lower ranges, characteristics with initially big ranges would take over a gradient descent. Feature space normalization might be considered a kernel impression of pre-processing rather than, strictly speaking, a type of pre-processing because it is not introduced externally to the input matrices. In other words, by transforming the data into a usable plane, normalization is a distinct kernel mapping approach that simplifies calculations. Given the enormous amount of data points, the complex normalization algorithm requires an extended period for processing. The Min-Max normalization technique that was selected is fast and efficient.

By using Min-Max Normalisation, the real data m is translated straight into the required interval as given in (1) (max_{new}, min_{new}).

$$m = min_{new} + (max_{new} - min_{new}) * \left(\frac{m - min_x}{max_x - min_x}\right) \quad (1)$$

The method's advantage is that it maintains every connection among the data points precisely.

C. Image Segmentation

Image segmentation is a critical component of medical image processing, including MRI data enhancement. In the context of MRI reconstruction, image segmentation plays a pivotal role in isolating and delineating specific anatomical structures or regions of interest within the reconstructed images. This segmentation process is fundamental for tasks such as tumor detection, organ volumetry, and the visualization of specific tissues or pathologies. The integration of GANs and Deep ResNets within MRI reconstruction pipelines enhances the segmentation process by providing high-quality, noise-reduced images for subsequent analysis.

D. *Preprocessing for Segmentation*

Before the actual segmentation process, the reconstructed MRI images are subjected to preprocessing steps, which may include denoising, bias field correction, and intensity normalization. The integration of GANs and ResNets at earlier stages of image reconstruction inherently improves the quality of MRI data, leading to more accurate and robust preprocessing results.

Semantic and Instance Segmentation

- In the context of medical imaging, there are two primary types of image segmentation: semantic segmentation and instance segmentation.
- Semantic segmentation involves classifying each pixel in the image into predefined categories or labels. For example, it can be used to differentiate between different types of tissues, such as white matter, gray matter, and cerebrospinal fluid in brain MRI.
- Instance segmentation takes the process further by distinguishing individual instances of objects within the same category. For example, it can be used to identify and differentiate multiple tumors in an MRI scan.

1) ROI Detection: Region of interest (ROI) detection is a vital aspect of medical image analysis. GANs and ResNets contribute to the creation of sharper, high-resolution images, making it easier for automated algorithms to detect and segment ROIs accurately. This is especially valuable in tasks such as identifying specific pathologies or measuring anatomical structures.

2) Benefits of GANs and ResNets in Segmentation:

- Noise Reduction: The noise reduction capabilities of GANs help in segmenting images with minimal interference from artifacts or random noise.
- Edge Preservation: ResNets, with their deep architectures, are well-suited for preserving image edges, enabling the precise delineation of structures in the segmentation process.
- Better Contrast: GANs enhance the contrast and clarity of MRI images, making it easier for segmentation algorithms to distinguish between different regions or structures.
- Improved Generalization: By improving the overall quality of MRI images, the integration of GANs and ResNets ensures that segmentation models generalize better across different datasets and clinical scenarios.

E. *Generative Adversarial Network with ResNet50*

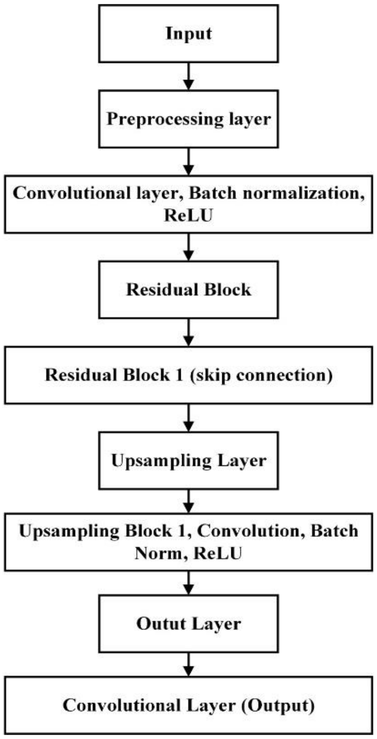
A generator G_r and a discriminator $D_r$make up a GAN. The parameters or weights of the generator are indicated as G_r and D_r, respectively. The generator reconstructs the original, completely sampled MRI (I) and labels them as real, while the discriminator is instructed to identify the reconstruction from the undersampled images (n) as false, or not real. The discriminator cannot determine if the images it reconstructs are real or artificial, that is, it is unable to differentiate the reconstructed images apart from the completely sampled ones. In contrast, the generator is trained to attain the opposite goals. The following loss function is able to be used to mathematically represent the entire process of training as a minimax activity given in (2):

$$\mathcal{L}\left(\theta_{G_r},\theta_{D_r}\right) = min_{\theta_{G_r}} max_{\theta_{D_r}} \mathbb{E}_{i\sim d(i)}[\log D_{r\theta}(i)]\mathbb{E}_{n\sim d_n(n)}[\log(1 - D_{r\theta}(G_{r\theta}(i)))] \quad (2)$$

Here the distribution of the undersampled images is represented by d_n and the distribution of the fully sampled images by d. It has been demonstrated that the generator minimizes the Jensen-Shannon divergence among the distributions of the original and reconstructed images when using an optimized discriminator. In other words, it is possible to think about GAN models as minimizing the distributional difference between completely sampled and reconstructed images.

1) Generator architecture with ResNet50: The study utilized a unique generator design to enhance training stability and speed up model convergence. ResNet50 can capture scale-invariant features based on spectral data, convolutional processes are good at capturing spatial properties. Therefore, it is preferred to take into account both the spatial and spectral data in one framework. Their main distinction is that ResNet50 operates on each subband from the preceding level. The ResNet50 feature, according to the study, may speed up feature learning. As a result, it might provide quicker convergence and more training consistency. This is the first time a deep learning model has been tried using ResNet50-based architectures.

When using ResNet-50 as the generator in a GAN framework in Fig. 2 for MRI image reconstruction, the generator network plays a crucial role in transforming low-quality MRI images into high-quality ones. The ResNet-50 architecture consists of convolutional layers, residual blocks, downsampling layers, and an output classification layer. To repurpose ResNet-50 as a generator, the architecture is modified by removing the classification layer and adapting the last layer to match the dimensions of high-quality MRI images. The modified ResNet-50 generator takes low-quality MRI images (LQ) as input and aims to generate corresponding high-quality MRI images (HQ).



Input
Preprocessing layer
Convolutional layer, Batch normalization, ReLU
Residual Block
Residual Block 1 (skip connection)
Upsampling Layer
Upsampling Block 1, Convolution, Batch Norm, ReLU
Outut Layer
Convolutional Layer (Output)

Fig. 2. Generator architecture with ResNet50.

The input LQ images pass through the initial convolutional layers, capturing low-level image features. The residual blocks, which are the hallmark of ResNet architectures, help the generator learn the residual mapping between LQ and HQ images. These blocks contain skip connections that directly connect earlier layers with deeper layers, allowing the network to learn the difference or residual between the input and target images. By incorporating skip connections and residual learning, the generator can effectively capture and preserve important image details during the upsampling process. The upsampling layers gradually increase the spatial resolution of the input, helping to generate high-quality images with fine details. The modified last layer of the generator outputs high-quality MRI images that closely resemble the ground truth images. During the training process, the generator is updated based on the adversarial loss and content loss, as mentioned earlier. This encourages the generator to produce high-quality images that can deceive the discriminator and resemble the ground truth high-quality MRI images. By leveraging the ResNet-50 architecture as the basis for the generator, the GAN framework benefits from its ability to learn complex image mappings and effectively handle attribute extraction, resulting in improved MRI image reconstruction.

2) Discriminator with ResNEt-50: The flattening layer of the discriminator employed in GAN-ResNet50 is the primary factor enforcing the input size constraint. Considering the GAN-ResNet50 discriminator is analysing a 256×256-pixel MR picture. The image is compressed by 26 = 64 times, or 4×4 pixels, after undergoing 6 convolutional procedures. The 'concat, 1024' layer has 1024 channels when it is reached. Its size at this layer could be characterized as a tensor of 4×4×1024 dimensions. The tensor from the previous layer, "concat, 1024," is unwound into a column vector of 8192 units by the following flattening layer. The following dense layer, which has 8192 input nodes, is capable of accepting it. On the other hand, if the similar model is given an image with 128*128 pixels. This image would be converted into a 2×2×1024-dimension tensor, unraveled into a 4096-unit column vector, and then layered with an 8192-unit dense layer even though there aren't enough input nodes for it. This instance demonstrates how the GAN-ResNet50 discriminator's input size limitation works.

To eliminate this constraint, the investigation replaces the flattened procedure with a global average pooling (GAP) layer. 29 GAP determines the average value of each pixel in each input way, irrespective of the image's size or pixel count. For instance, the GAP layer inputs in the simulation have 1024 channels. The result of this function is always going to be a series of vectors with 1024 units, no matter how big the tensor that was input from 'concat, 1024' is. Following that, the sigmoid is activated by applying an intense layer of 1024 units. As a result, the input size restriction is significantly lifted by the discriminator's architecture. According to the paper, this is a plan to use GAN-based MRI techniques for the first time.

While ResNet-50 is typically used for classification tasks, discriminator architecture in Fig. 3 can be designed to effectively assess the authenticity of the generated images. The discriminator architecture can be constructed by modifying the last layer of ResNet-50 to output a binary classification result, indicating whether the input image is real (high-quality) or fake (generated). By removing the classification layer and retaining only the convolutional layers and downsampled features of ResNet-50, the discriminator focuses on learning discriminative features for distinguishing between real and generated images. The modified ResNet-50 discriminator can have additional layers, such as fully connected layers and a final sigmoid activation layer for binary classification. The convolutional layers within the ResNet-50 architecture capture hierarchical image features, while the additional layers facilitate the final decision-making process. The discriminator takes input images, both real high-quality MRI images (HR) and the generated high-quality images (G(LQ)), and outputs the probability of the input being a real image. Throughout the training process, the discriminator undergoes training to minimize the binary cross-entropy loss, which measures the disparity between its predictions and the actual ground truth labels. This adversarial training strategy compels the discriminator to become proficient in discerning between authentic and synthesized images. Concurrently, the generator, which is based on the modified ResNet-50 architecture, strives to generate images that can convincingly mislead the discriminator. Through this collaborative interplay, wherein the generator and discriminator are thoughtfully adapted, the GAN framework becomes adept at learning to generate MRI images of exceptional quality. These generated images exhibit a remarkable likeness to authentic MRI scans, consequently elevating the overall standard of image reconstruction quality.

3) Adversarial loss function: Although there is an empirical rationale for the success of GAN, as mentioned in the introductory section, in practice GAN experiences non-convergence and training fluctuations. The training of the model with loss function, which we shall employ in our model, is said to solve these two issues. It is suggested to minimize the distance between the generator and discriminator as opposed to minimizing JSD. A more stable training history is said to be achieved by this (3):

$$\mathcal{L}(\theta_{G_r}, \theta_{D_r}) = min_{\theta_{G_r}} max_{\theta_{D_r}} \mathbb{E}_{i\sim d}(i)[D_r(i)] - \mathbb{E}_{n\sim d_n(n)}[D_r(G_r(n))] \quad (3)$$

If the discriminator function D_r is 1-Lipschitz, then this loss function minimizes the distance (4).

$$\|D_r\|_l \leq 1 \quad (4)$$

Weight clipping may be employed to enforce this 1-Lipschitz requirement. The distinct loss functions for the discriminator and generator, which is referred to as $\mathcal{L}_{D_r}$ and $\mathcal{L}_{G_r}$ in (5) and (6) accordingly, for purposes of simplification (3):

$$\mathcal{L}_{D_r}(\theta_{D_r}) = max_{\theta_{D_r}} \mathbb{E}_{i\sim d}(i)[D_r(i)] - \mathbb{E}_{n\sim d_n(n)}[D_r(G_r(n))] \quad (5)$$

$$\mathcal{L}_A(\theta_{G_r}) = min_{\theta_{G_r}} - \mathbb{E}_{n\sim d_n(n)}[D_r(G_r(n))] \quad (6)$$

The frequency domain loss ($\mathcal{L}_F$) and normalized root mean square error (NMSE) loss ($\mathcal{L}_N$) to the overall generator loss in addition to $\mathcal{L}_A$ is increased. In the spatial and temporal domains, accordingly, $\mathcal{L}_N$and $\mathcal{L}_F$ are anticipated to reduce the distinction among fully sampled and reconstructed image. They are characterized as (7) and (8):

$$\mathcal{L}_N(\theta_{G_r}) = \sqrt{\frac{\|i - G_r(n)\|^2}{\|i\|^2}} \quad (7)$$

$$\mathcal{L}_F\left(\theta_{G_r}\right) = \|F\{i\} - F\{G_r(n)\}\|^2 \tag{8}$$

Here F is the Fourier transform operation to convert an image to a frequency representation, often known as a k-space representation. The generator's final loss function in the simulation is (9):

$$\mathcal{L}_{G_r}\left(\theta_{G_r}\right) = \mathcal{L}_A + a\mathcal{L}_N + b\mathcal{L}_F \tag{9}$$

Here a and b are weights to balance out how much each of the three loss components contributes to the overall loss.

V. Results And Discussions

Deep learning approaches have been shown to offer significant potential for the development of MRI image reconstruction. Utilizing a wide range of various approaches, study in this field has skyrocketed over the last five years. More thorough evaluation and a broad display of proactively obtained clinical information are required to boost trust in such methods. The work proposes a novel GAN-based MRI reconstruction method that can successfully do away with the input size constraints of GAN. Using ResNet50 connections and loss functions, feature learning can be accelerated. While still working well on images of different sizes, the model has demonstrated improved reconstructing accuracy when compared to previous MRI techniques.

A. *Performance Metrics*

In the study focusing on the "Enhancement of MRI Image Reconstruction through Integration of Generative Adversarial Networks (GANs) and Deep Residual Networks (ResNets) in a Hybrid Deep Learning Framework," the evaluation of the proposed methodology is conducted through a range of performance metrics. These metrics include the Peak Signal-to-Noise Ratio (PSNR), measuring image quality by assessing the similarity between original and reconstructed images; the Structural Similarity Index (SSIM) to evaluate the preservation of structural information; Mean Square Error (MSE) and Root Mean Square Error (RMSE) to gauge the average squared differences between original and reconstructed images; Dice Coefficient for segmentation tasks, assessing the overlap in segmented regions; and considerations of computational efficiency, such as inference time, vital for real-time medical imaging applications. These metrics collectively serve as a comprehensive means to quantify the effectiveness and quality of MRI image reconstruction in the context of the hybrid deep learning framework, ensuring it meets the stringent requirements of medical imaging while optimizing computational efficiency.

- Peak Signal-to-Noise Ratio (PSNR): PSNR serves as a metric for assessing the fidelity of the reconstructed MRI images by quantifying the degree of similarity between the original and reconstructed images. Elevated PSNR values are indicative of superior image quality.

- Structural Similarity Index (SSIM): SSIM evaluates the structural information preservation in the reconstructed images. Higher SSIM values indicate that the fine details and structures in the images are retained.

- Mean Square Error (MSE): MSE measures the average squared differences between the original and reconstructed images. Lower MSE values imply better reconstruction quality.

- Root Mean Square Error (RMSE): RMSE is the square root of MSE and provides a more interpretable measure of the reconstruction error.

- Dice Coefficient (for segmentation tasks): If the MRI images are used for segmentation tasks, the Dice coefficient measures the overlap between the segmented regions in the original and reconstructed images.

- Computational Efficiency: This can include metrics like the inference time required for image reconstruction, which is crucial in real-time medical imaging applications.

These performance metrics are essential for quantitatively assessing the quality and efficacy of the MRI image reconstruction using the proposed hybrid deep learning framework, ensuring that it meets the requirements for accurate, high-quality medical imaging while considering computational efficiency.

Outcomes of several reconstruction techniques for a 256×256-pixel image are given. The term "GAN-Resnet50" which refers to the original with the loss function included. The whole set of tests demonstrates that the ResNet50-based generator and discriminator further enhance the model effectiveness whereas the addition of the loss function just minimally accomplishes it.

TABLE I. Outcome of 256*256 Pixel Images in 10%

Approaches	**Sampling Ratio of 10%**	
	PSNR	***SSIM***
WDAGAN	31.689	0.920
DAGAN	30.272	0.891
GAN-ResNet50	35.281	0.950

In Table I, the outcomes of different image enhancement approaches for 256x256 pixel images under a 10% sampling ratio are presented, along with their corresponding Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index (SSIM) values. Among the methods evaluated, GAN-ResNet50 demonstrated the highest PSNR at 35.281 and the highest SSIM at 0.950, indicating its superior ability to reconstruct high-quality images from the sparse data, which is crucial for preserving image fidelity. WDAGAN followed with a PSNR of 31.689 and an SSIM of 0.920, showcasing its competitive performance. DAGAN, on the other hand, achieved a PSNR of 30.272 and an SSIM of 0.891, indicating slightly lower image quality compared to the other methods. These results highlight the effectiveness of GAN-ResNet50 in enhancing image reconstruction quality at a 10% sampling ratio, emphasizing its potential for improving image-based diagnostic and analysis tasks in various fields such as medical imaging and remote sensing.

TABLE II. OUTCOME OF 256×256 PIXEL IMAGES IN 50%

Approaches	Sampling Ratio of 50%	
	PSNR	*SSIM*
WDAGAN	39.976	0.990
DAGAN	44.939	0.954
GAN-ResNet50	50.111	0.998

In Table II, the results for different image enhancement approaches applied to 256×256-pixel images at a 50% sampling ratio are presented, along with their respective Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index (SSIM) values. Notably, GAN-ResNet50 exhibited the highest PSNR at 50.111 and an outstanding SSIM of 0.998, indicating its remarkable ability to reconstruct images with exceptional quality, particularly in scenarios where more data is available. WDAGAN, while also performing well, achieved a PSNR of 39.976 and a very high SSIM of 0.990, highlighting its competence in preserving image details. DAGAN, on the other hand, excelled with an impressive PSNR of 44.939, demonstrating its proficiency in achieving high fidelity image reconstruction even at this increased sampling ratio, although its SSIM of 0.954 suggests some room for improvement in structural similarity. These results underscore the exceptional performance of GAN-ResNet50 in enhancing image quality at a 50% sampling ratio, emphasizing its potential for various image-centric applications where data availability is more substantial, such as high-resolution medical imaging and remote sensing tasks. Fig. 4 shows the Sampling ratio of 256×256-pixel images in 10% and 50%.

The quality of this enhancement is clearly obvious. The internal carotid artery is a bright, vertically directed line that is located slightly below the brain when compared to the equivalent region in the reconstructed image. The reconstruction inaccuracy of this artery in the 'Difference Image' in GAN-ResNet50 is significant. The error looks to be less organized and more random. This suggests that GAN-ResNet50 is performing more qualitatively. The reconstruction error of DAGAN is almost non-existent in the magnified perspective of the red box with corpus callosum and white matter tract and the green box with medial temporal cortex. On the other hand, the image created by DAGAN shows an increased error.

In Table III, the results for various image enhancement approaches applied to 64×128 pixel images at a 10% sampling ratio are displayed, along with their corresponding Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index (SSIM) values. Among the methods assessed, GAN-ResNet50 achieved the highest PSNR at 27.8 and an impressive SSIM of 78.9, demonstrating its capability to enhance image reconstruction quality even when data is sparser. WDAGAN, although with lower PSNR (24.90) and SSIM (76.5) values, exhibited competitive performance. DAGAN, on the other hand, had a PSNR of 24.22 and an SSIM of 74.4, indicating relatively lower image quality compared to the other methods at this low sampling ratio. In Table IV, the results for the same approaches are presented but for 64x128 pixel images with a 50% sampling ratio. GAN-ResNet50 once again displayed the highest PSNR at 40.4 and an outstanding SSIM of 98.1, signifying its excellent performance in reconstructing high-quality images from more abundant data. WDAGAN and DAGAN also showed substantial improvements at the increased sampling ratio, with competitive PSNR and SSIM values. These results underscore the effectiveness of GAN-ResNet50, especially in scenarios with limited data, and its ability to significantly improve image reconstruction quality, making it a promising solution for various applications, including low-resolution medical imaging and remote sensing tasks. Fig. 5 shows the Sampling ratio of 64×128-pixel images in 10% and 50%.

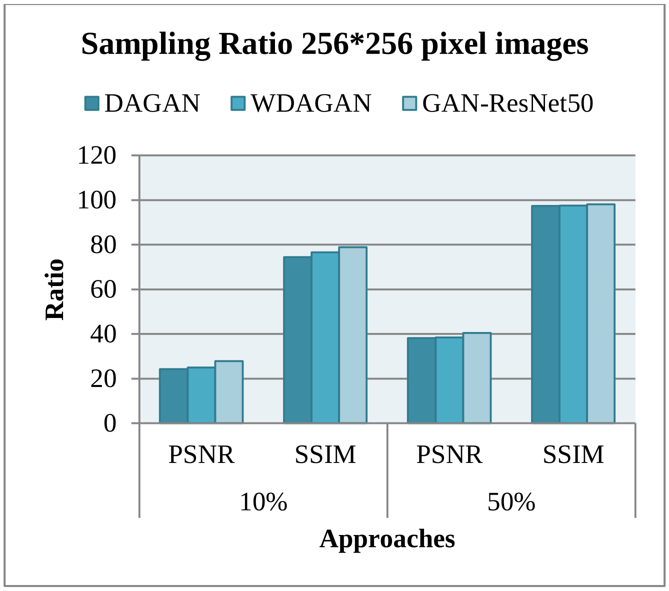

Fig. 4. Sampling ratio of 256×256-pixel images in 10% and 50%.

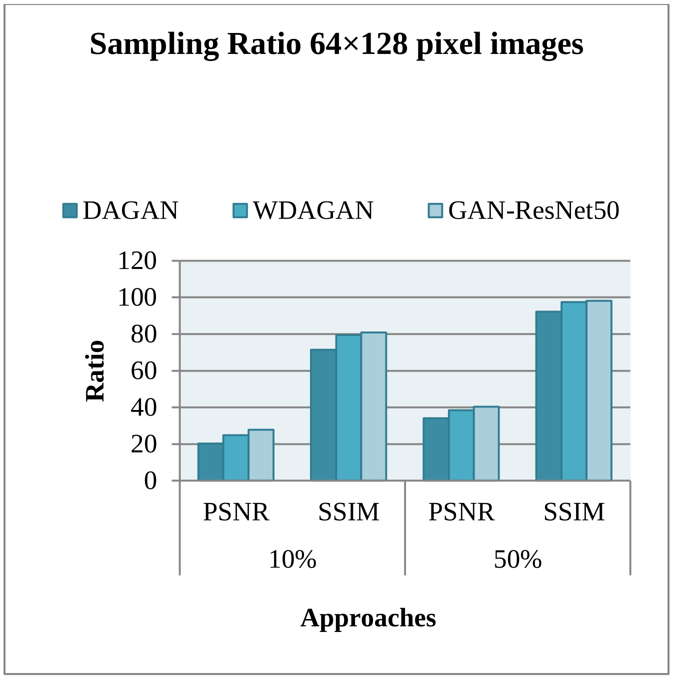

Fig. 5. Sampling ratio of 64×128 pixel images in 10% and 50%.

TABLE III. OUTCOME OF 64×128 PIXEL IMAGES IN 10%

Approaches	Sampling Ratio of 10%	
	PSNR	*SSIM*
WDAGAN	24.90	76.5
DAGAN	24.22	74.4
GAN-ResNet50	27.8	78.9

TABLE IV. OUTCOME OF 64×128 PIXEL IMAGES IN 50%

Approaches	Sampling Ratio of 50%	
	PSNR	*SSIM*
WDAGAN	38.4	97.5
DAGAN	38.1	97.3
GAN-ResNet50	40.4	98.1

This characteristic expands the variety of training samples by enabling the identical GAN-ResNet50 model to analyze an assortment of image dimensions that could be encountered in MR reconstruction. The study has introduced global average pooling to relax the input size requirement of the proposed GAN-ResNet50 framework to provide a fair comparison.

TABLE V. OUTCOME OF 128×256 PIXEL IMAGES IN 10%

Approaches	Sampling Ratio of 10%	
	PSNR	*SSIM*
WDAGAN	30.1	91.5
DAGAN	28.3	88.6
GAN-ResNet50	37.4	95.3

Table V presents the outcomes for different image enhancement approaches applied to 128x256 pixel images at a 10% sampling ratio, accompanied by their respective Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index (SSIM) values. Notably, GAN-ResNet50 exhibited the highest PSNR at 37.4 and an impressive SSIM of 95.3, signifying its exceptional proficiency in enhancing image reconstruction quality even in situations with limited data. WDAGAN also performed well with a PSNR of 30.1 and a commendable SSIM of 91.5, demonstrating its competence in preserving image details. On the other hand, DAGAN, while achieving a PSNR of 28.3, had a relatively lower SSIM of 88.6, suggesting some room for improvement in structural similarity. These results underscore the superior performance of GAN-ResNet50 in enhancing image quality at a 10% sampling ratio, highlighting its potential for various applications, particularly those involving low-resolution medical imaging and remote sensing, where data availability may be constrained.

TABLE VI. OUTCOME OF 128×256 PIXEL IMAGES IN 50%

Approaches	Sampling Ratio of 50%	
	PSNR	*SSIM*
WDAGAN	43.1	98.1
DAGAN	39.7	96.9
GAN-ResNet50	50.3	99.1

In Table VI, the results for various image enhancement approaches applied to 128×256-pixel images at a 50% sampling ratio are presented, along with their corresponding Peak Signal-to-Noise Ratio (PSNR) and Structural Similarity Index (SSIM) values. Remarkably, GAN-ResNet50 demonstrated the highest PSNR at 50.3 and an exceptional SSIM of 99.1, underscoring its remarkable capacity to substantially improve image reconstruction quality in scenarios where data availability is more abundant. WDAGAN also displayed impressive performance, with a PSNR of 43.1 and an outstanding SSIM of 98.1, indicating its competence in preserving image details even at the higher sampling ratio. DAGAN, while achieving a PSNR of 39.7, exhibited a slightly lower SSIM of 96.9, signifying a relatively lower level of structural similarity. These results highlight the outstanding performance of GAN-ResNet50, especially in situations with more data, further emphasizing its potential for diverse applications, including high-resolution medical imaging and remote sensing, where data quality and fidelity are of utmost importance. Fig. 6 shows the Sampling ratio of 128*256 pixel images in 10% and 50%.

In the context of image enhancement and reconstruction, various models have been compared based on their performance metrics, namely, the Structural Similarity Index (SSIM) and Peak Signal-to-Noise Ratio (PSNR).

In Table VII, the study conducted by Hyun et al. [25], the U-net model achieved an SSIM of 0.903, but the PSNR was not specified. Cole et al. [26] implemented an Unsupervised GAN and reported an SSIM of 0.81 along with a PSNR of 26.39. Z. Wang et al. [27] used the Unet-DSSIM model, which achieved an SSIM of 0.88 and a PSNR of 29. In contrast, the proposed method, a Hybrid GAN-DRN model, outperformed the others with an impressive SSIM of 0.99 and a remarkable PSNR of 50.3. These performance metrics highlight the significant advancements achieved by the proposed method in terms of image quality and fidelity. Fig. 7 provides a visual representation of the performance comparison, further emphasizing the superiority of the Hybrid GAN-DRN model in enhancing image reconstruction quality.

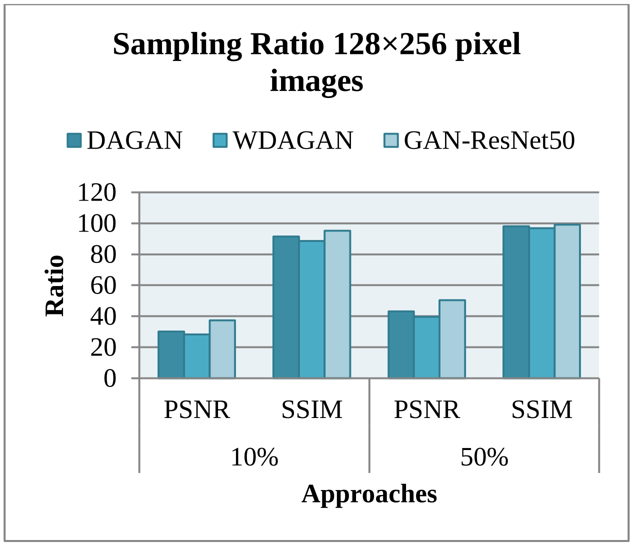

Fig. 6. Sampling ratio of 128×256-pixel images in 10% and 50%.

TABLE VII. PERFORMANCE COMPARISON

Reference	Model	SSIM	PSNR
Hyun et al [25]	U-net	0.903	-
Cole et al. [26]	Unsupervised GAN	0.81	26.39
Z. Wang et al.[27]	Unet-DSSIM	0.88	29
Proposed Method	Hybrid GAN-DRN	0.99	50.3

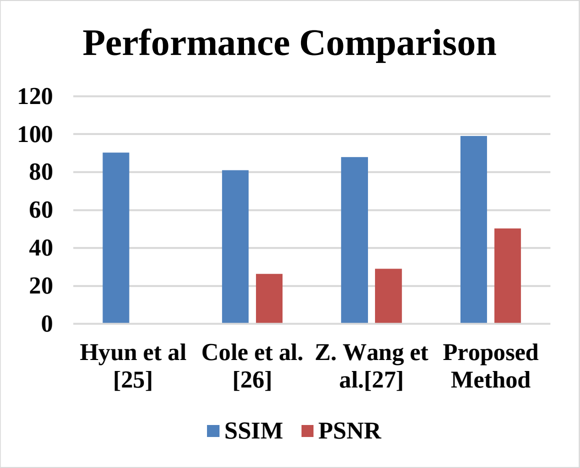

Fig. 7. Performance comparison of different methods.

The overall performance comparison among the various image enhancement methods clearly demonstrates the remarkable superiority of the proposed Hybrid GAN-DRN model. Its exceptional SSIM score of 0.99 and a remarkable PSNR value of 50.3 signify a substantial leap in image quality and fidelity. The Hybrid GAN-DRN's outstanding SSIM score indicates a near-perfect similarity between the enhanced images and the ground truth, suggesting that it effectively preserves fine image details and structural content. Furthermore, the exceptionally high PSNR value reflects a minimal level of noise and distortion in the reconstructed images, making them highly faithful to the original data. In contrast, the other methods in the comparison, such as U-net, Unsupervised GAN, and Unet-DSSIM, displayed relatively lower SSIM and PSNR values, indicating comparatively reduced image quality and fidelity. This stark performance differential emphasizes the substantial advancements achieved by the proposed Hybrid GAN-DRN model. It excels in enhancing image reconstruction quality, reducing noise, and retaining essential image features. As such, the proposed method holds great promise for a wide array of applications, particularly in fields like medical imaging and remote sensing, where image quality is of paramount importance and where it can significantly improve the accuracy of diagnostic and analysis tasks.

B. Discussion

The study of picture improvement using DRNs and GANs represents a significant advancement in reconstructed images. The study's conclusions and comparison of several methods for enhancing images offer light on the capacity of such models and demonstrate the superior results of the suggested Hybrid GAN-DRN methodology. The primary goal of the study is to compare several image improvement techniques utilizing the SSIM and PSNR, two important performance indicators. Particularly in areas like remote sensing and healthcare imaging, these measures are essential for evaluating the authenticity and quality of augmented images. The analysis of the information shows a distinct pattern: The suggested Hybrid GAN-DRN architecture works noticeably better than each of the approaches compared. This simulation attains a remarkable 50.3 PSNR and a remarkable 0.99 SSIM score. These measurements show how well the suggested approach preserves picture details, lowers noise, and improves the overall level of reconstruction of images. This is especially significant since it creates new opportunities for a variety of image-centric systems in which the precision and integrity of the reconstructions are critical. The practical implications of this research are significant, particularly in areas where diagnostics and choice-making processes are directly impacted by the quality of images. The suggested approach can lead to improved reconstruction of image quality, more precise medical diagnosis, and improved evaluation of information from remote sensing, and improved image-based systems for making decisions. To completely realize the possibilities of the suggested strategy, despite its exceptional contributions, it is imperative to highlight the necessity for additional studies and verification in medical and real-world environments. The study also emphasizes how crucial it is to comprehend and maximize the processing requirements of sophisticated models based on deep learning, particularly for large-scale or instantaneous applications. To sum up, the study of picture improvement using a combination of GANs and DRNs represents a substantial development in the area of reconstruction of images. The exceptional performance of the suggested Hybrid GAN-DRN approach, as shown by SSIM and PSNR parameters, places it in an encouraging spot for enhancing image authenticity as well as quality in a variety of uses, eventually leading to improved accuracy and confidence in image-based decision-making procedures. The benefit of DRGAN is its novel usage of a residual GAN structure to generate a "residual PET map" (RPM), which has the potential to increase PET picture quality with enhanced contextual data. However, more attention on clinical application is needed. FDA-CNN excels in removing MRI artifacts with a completely dense focus, demonstrating promising results. However, the technology requires further investigation to overcome scalability issues to assess its practical application in real-time applications.

VI. CONCLUSION AND FUTURE WORK

Ultimately, this research presents a potentially effective MRI reconstruction technique based on the GAN-ResNet50 design, tackling the crucial problem of accurate and high-fidelity reconstruction of images. The study's comparison studies show that the suggested strategy outperforms both previous approaches and cutting-edge deep learning methods for maintaining fine-grained image information. This development has significant potential to improve the fidelity and quality of MRI reconstructions, especially in the field of medical imaging because accurate diagnosis and decision-making depend on high-quality images. The acquired findings demonstrate the GAN-ResNet50 strategy's outstanding performance and its capacity for balancing image texture, border specifics, and total fidelity. Together with the GAN's discriminatory powers, the hybrid deep learning method strikes a compromise that guarantees a degree of reconstructing grade that is both visually realistic and for diagnosis. The suggested GAN-DRN-based MRI reconstruction approach may encounter difficulties in dealing with distinct anatomical variances and diseases, thus limiting generalisation across different clinical circumstances.

A. Future Work

There are a number of fascinating avenues for additional study and advancement as researchers look to the years to come. These involve leveraging the GAN-ResNet50 design to optimize real-time MRI reconstruction, verifying the method's clinical effectiveness through rigorous examinations, expanding its uses to multi-modal MRI combination for thorough assessment of patients, and investigating ways to improve robustness, interpretation, ease of use, and transferable learning abilities via explainability methods. These actions are essential for increasing the novel approach's medical acceptance and interpretation, which will ultimately help MRI imaging patients and healthcare providers.

Hybrid Vision Transformers and CNNs for Enhanced Transmission Line Segmentation in Aerial Images

Hoanh Nguyen*, Tuan Anh Nguyen
Faculty of Electrical Engineering Technology, Industrial University of Ho Chi Minh City, Ho Chi Minh City, Vietnam

***Abstract*—This paper presents a novel architecture for the segmentation of transmission lines in aerial images, utilizing a hybrid model that combines the strengths of Vision Transformers (ViTs) and Convolutional Neural Networks (CNNs). The proposed method first employs a Swin Transformer backbone (Swin-B) that processes the input image through a hierarchical structure, effectively capturing multi-scale contextual information. Following this, an upsampling strategy is employed, wherein the features extracted by the transformer are refined through convolutional layers, ensuring that the resolution is maintained, and spatial details are recovered. To integrate multi-level feature maps, a feature fusion module with a squeeze-and-excitation (SE) layer is introduced, which consolidates the benefits of both high-level and low-level feature extractions. The SE layer plays a pivotal role in augmenting the feature channels, focusing the model's attention on the most informative features for transmission line detection. By leveraging the global receptive field of ViTs for comprehensive context and the local precision of CNNs for fine-grained detail, our method aims to set a new benchmark for transmission line segmentation in aerial imagery. The effectiveness of our approach is demonstrated through extensive experiments and comparisons with existing state-of-the-art methods.**

Keywords*—*Vision transformers; convolutional neural networks; transmission lines segmentation; hybrid model; feature fusion

I. Introduction

Transmission line segmentation in aerial images is a critical task in the maintenance and monitoring of electrical power grids. It enables the automated inspection of power lines for fault detection, vegetation encroachment, and structural analysis, which are essential for ensuring the reliability and safety of electricity distribution. However, this task is fraught with challenges. Aerial images often have highly variable lighting conditions, weather effects, and diverse landscapes that can obscure the visibility of transmission lines. Additionally, the lines themselves can be difficult to distinguish due to their thin and linear nature against complex backgrounds. Another significant challenge is the presence of other linear structures, such as roads and railways, that can be easily confused with power lines by automated systems. The movement of the aerial platform, whether it's a drone or a manned aircraft, introduces motion blur and varying angles of capture, further complicating the segmentation process. Addressing these challenges requires robust algorithms capable of high precision and adaptability to a range of environmental conditions and image qualities. Traditional methods for vision-based transmission line detection and segmentation have revolved around the utilization of edge and line segment detection techniques as foundational steps. These methods generate a multitude of potential cable segment candidates by applying algorithms such as the Hough transform, Radon transform, and various other heuristic and search-based line detection strategies, such as the circle-based search, heuristic line detection, Line Segment Detector (LSD), and Edge Drawing for line segment detection (EDLines). Once edges and line segments are detected, a set of specialized rules, informed by the structural characteristics of cables and the context of their surroundings, are applied to discern correct cable segments and eliminate false positives. One of the main drawbacks of these approaches is their dependency on numerous parameters and complex rules that need to be meticulously set by hand, which hinders their adaptability to different environments. As a result, the precision and robustness of traditional methods can be significantly compromised due to environmental variations, making it challenging to maintain consistent performance across diverse scenarios. The advent of deep learning has catalyzed significant advancements in the domain of vision-based transmission line detection and segmentation. CNN-based methods have eclipsed traditional techniques, demonstrating substantial improvements in detection accuracy and computational efficiency. These deep neural networks facilitate end-to-end learning and inference, simplifying the complex parameter tuning process inherent in multistage approaches and enhancing generalizability across varied scenarios. For instance, CNNs have been trained to identify image patches containing cables, which are then further processed using traditional methods like the Hough transform for line segmentation. Moreover, some approaches have integrated fully convolutional networks with line segment regressors for direct line segment detection, particularly effective in scenarios where aerial images capture transmission lines at close range. However, when dealing with long-range and wide-angle captures that result in indistinct or slightly curved cable representations, these methods pivot towards a pixel-wise segmentation framework, employing semantic and instance segmentation techniques to provide a more nuanced cable detection and enable individual cable instance identification, which is pivotal for autonomous UAV applications.

Recent years have witnessed the rapid development of ViTs [1, 2]. ViTs leverages the transformer architecture, originally designed for natural language processing, to handle sequences of image patches as input. ViTs model relationships between these patches through self-attention mechanisms, making them capable of capturing global dependencies within an image. The combination of CNNs and ViT into a hybrid architecture aims to harness the local feature extraction proficiency of CNNs with the global context understanding of ViTs. CNNs are adept at recognizing patterns and textures within small regions of an image, making them excellent for tasks that require detailed local information, such as edge detection. ViTs, with their attention-based approach, can consider the entire image at once, which allows for a more holistic understanding of the scene. By integrating both, the hybrid model can effectively process and integrate both local and global information, leading to improved performance on complex tasks like transmission line segmentation. This synergy can provide a more nuanced understanding of images, enabling the model to be both precise in detail and comprehensive in scope, potentially overcoming limitations found in models that rely on a single approach.

This study introduces an innovative hybrid architecture for the precise segmentation of transmission lines in aerial images, leveraging the synergistic potentials of ViTs and CNNs. The core of our proposed method is a Swin Transformer backbone, adept at hierarchically processing the input image to encapsulate multi-scale contextual information. This is complemented by an upsampling mechanism that meticulously refines the transformer-extracted features via convolutional layers, crucial for preserving resolution and restoring spatial details. A feature fusion module, equipped with an SE layer, is integrated to merge feature maps from multiple levels, harnessing both the high-level and low-level extraction strengths. The SE layer is instrumental in enhancing feature channels, directing the model's focus towards the most salient features for detecting transmission lines. Our approach is designed to exploit the expansive receptive field of ViTs for global context awareness, while utilizing the CNNs' local precision for capturing intricate details, thereby establishing a new standard for transmission line segmentation in aerial photography. The method's superiority is validated through comprehensive experimental benchmarks, showcasing its advancement over current leading methodologies.

The rest of the paper is organized as follows: Section II presents related studies; Section III details our proposed model; Section IV describes the experiments and results; Section V provides the conclusions.

II. Related Work

A. Transmission Line Detection and Segmentation

Traditional approaches to vision-based detection and segmentation of transmission lines have primarily focused on employing edge and line segment detection techniques as their fundamental processes. In study [3], a real-time algorithm was developed for detecting power lines in UAV video images, where the process begins with converting video images into binary images using adaptive thresholding. Subsequently, Hough Transform identifies line candidates in these binary images, and a fuzzy C-means clustering algorithm discriminates actual power lines from these candidates. Mu et al. [4] proposed a method for automatically extracting power lines from cluttered natural backgrounds in aerial images. The approach involves using a Gabor filter to eliminate background noise, followed by the application of the Hough transform to detect straight lines in the images. Zhang et al. [5] introduced a new method for detecting and tracking power lines, starting with the use of the Hough transform to extract line segments. The method then employs K-means clustering in the Hough space to filter and identify power lines and utilizes a Kalman filter for tracking these lines within the continuity of a video sequence. In study [6], the authors presented an algorithm that capitalizes on the geometric relationships inherent to circle symmetry for line segment detection. It employs Canny and Steerable Filters to detect line segments, which are then linked in a subsequent stage for effective analysis. Sharma et al. [7] introduced a novel morphological operator and robust image space heuristics for the accurate location and complete extraction of power lines. Santos et al. [8] introduced PLineD, a new vision-based power line detection algorithm designed to robustly detect power lines, even in noisy image backgrounds. Although traditional approaches to vision-based detection and segmentation of transmission lines have achieved some success, they still have many limitations. A significant limitation of these methods is their reliance on a multitude of parameters and intricate rules that require careful manual adjustment, impeding their flexibility across various environments. Consequently, the accuracy and reliability of traditional approaches are often adversely affected by environmental changes, posing challenges in achieving uniform performance in different settings. With the outstanding advantages of CNNs, many methods using CNNs for transmission line segmentation have been proposed [9]. In [10], the authors introduced a pyramidal patch classification framework that effectively eliminates clutter without relying on additional auxiliary tools. This is achieved through a hierarchical patch partition and selection strategy, complemented by a new spatial grid pooling layer in the CNN-based classifier. Nguyen et al. [11] presented LS-Net, a rapid, single-shot line-segment detector tailored for power line detection, which is fully convolutional by design and comprises three modules: a fully convolutional feature extractor, a classifier, and a line segment regressor. Lee et al. [12] presented a weakly supervised learning algorithm for identifying power lines. The algorithm classifies sub-regions within images using a sliding window approach and a CNN. In [13], a Transmission Line Detection (TLD) algorithm, CableNet, is proposed, drawing inspiration from instance segmentation and incorporating enhancements to Fully Convolutional Networks (FCNs) [14] with overlaying dilated and spatial convolutional layers for better representation of transmission lines, and dual output branches for generating multidimensional feature maps for instance segmentation.

B. Vision Transformer-CNN Hybrid Models

In recent years, the rapid development of ViTs has significantly advanced the field of computer vision, leading to their widespread application in tasks ranging from image classification to complex scene understanding [15, 16]. Instead of simplifying ViTs, another prominent research direction involves merging components of ViTs and CNNs to create novel backbone architectures. These hybrid models combine the local feature extraction prowess of CNNs with the global contextual understanding afforded by ViTs, thus offering a comprehensive approach to image analysis. Follow this approach, [17] highlighted the adaptation of principles from the extensive literature on CNNs, particularly the use of activation maps with decreasing resolutions, to enhance the design of transformers. The study in [18] investigated the optimization challenges of ViT models, attributing the issues to their 'patchify stem' design, and proposes a solution by replacing it with stacked stride-two 3x3 convolutions. This modification significantly enhances optimization stability and model accuracy, leading to the recommendation of using a standard, lightweight convolutional stem in ViT models for improved performance and robustness. In study [19], the authors introduced BoTNet, a versatile and efficient backbone architecture for various computer vision tasks, which enhances performance by integrating self-attention mechanisms. This is achieved by replacing spatial convolutions with global self-attention in the last three bottleneck blocks of a ResNet, leading to notable improvements in instance segmentation and object detection, while simultaneously reducing the number of parameters and maintaining minimal latency overhead. ConViT [20] presented the concept of gated positional self-attention (GPSA), a novel form of positional self-attention designed with a flexible, 'soft' convolutional inductive bias. GPSA layers are initially configured to emulate the locality characteristic of convolutional layers but are also equipped with a gating parameter that allows each attention head to dynamically balance the focus between positional and content information. Guo et al. [21] proposed a novel hybrid network that synergizes the long-range dependency capturing capabilities of transformers with the local information extraction prowess of CNNs. Recently, PVTv1 [22], PVTv2 [23], LITv1 [24], and LITv2 [25] incorporate convolutional operations at each stage of ViT models to diminish the token count and construct hybrid, multi-stage structures.

III. METHOD

A. *Model Architecture*

Fig. 1 illustrates the overall pipeline of our method, which integrates a vision transformer encoder with a convolutional neural network decoder to create a hybrid model for the segmentation of transmission lines in aerial images. Input images undergo a hierarchical processing through multiple layers of the Swin Transformer [26], each reducing the spatial dimensions while increasing the depth of feature representation. These layers (Layer 1 to Layer 4) progressively transform the input, capturing intricate details and contextual information at various scales. The transformed features are then upsampled and passed through convolutional layers to refine the feature maps, ensuring that spatial information is preserved and enhanced. The upsampling process gradually restores the resolution of the feature maps, which are then combined through feature fusion steps. These fusion steps are essential as it aggregates multi-scale information, enabling the model to capture both high-level semantic information and low-resolution spatial details. A squeeze-and-excitation (SE) layer is subsequently employed to recalibrate the feature channels, emphasizing informative features while suppressing less useful ones. Finally, a segmentation head, comprising a series of convolutional layers, is responsible for generating the output segmentation map that delineates the transmission lines within the aerial images.

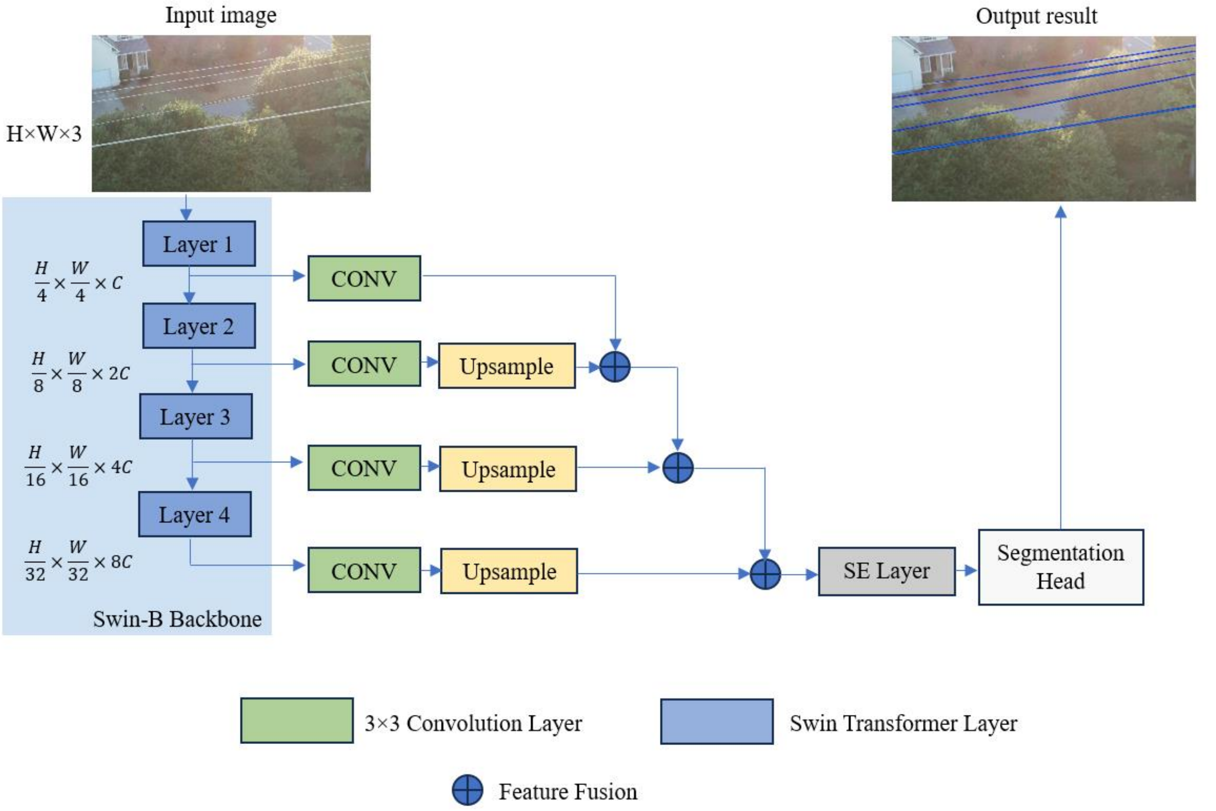

Fig. 1. Model architecture.

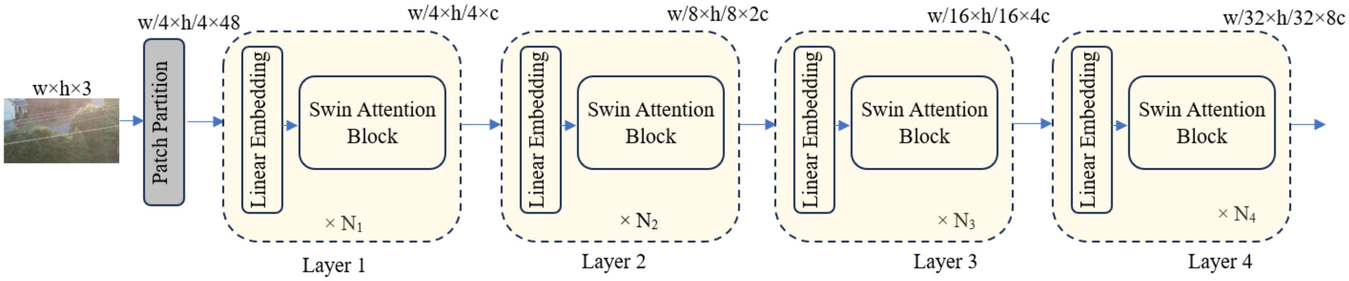

Fig. 2. The structure of Swin Transformer encoder.

TABLE I. DETAILED ARCHITECTURE OF SWIN-B

Layer	Output Size	Number of Blocks	Attention Heads	Attention Head Dimensions	MLP Ratio
Patch Partition	w/4 × h/4 × 48	N/A	N/A	N/A	N/A
Layer 1	w/4 × h/4 × 96	2	3	32	4
Layer 2	w/8 × h/8 × 192	2	6	32	4
Layer 3	w/16 × h/16 × 384	6	12	32	4
Layer 4	w/32 × h/32 × 768	2	24	32	4

B. *Swin-B-based Encoder*

Fig. 2 illustrates the structure of Swin Transformer encoder. The original input image is represented as $w×h×3$, where w and h are the width and height of the image, and 3 represents the RGB color channels. This image is then partitioned into patches. The size of these patches is 4×4 pixels, which are then flattened and linearly embedded into a higher-dimensional space (e.g., 48 features per patch). So, the input dimension to the first transformer layer is *w/4×h/4×48*. As the input passes through each Swin Transformer layer consisting consecutive N_i (i = 1, 2, 3, 4) Swin transformer blocks, the spatial resolution is further reduced, and the feature dimensionality is increased, thus enhancing the model's ability to capture more complex features at different scales. The Swin Transformer employs a self-attention mechanism within each block. The attention is computed using queries (Q), keys (K), and values (V), which are derived from the input feature maps. The formulation of self-attention within the Swin Transformer involves a sequence of operations beginning with the computation of Q, K, and V via linear transformations of the input feature map. The attention scores are then determined by calculating the dot product between Q and K. These scores are normalized using a softmax function to derive attention weights, which are subsequently used to obtain a weighted feature representation by multiplying them with V. To ensure stability in the gradients during training, a scaling factor, commonly the inverse square root of the keys' dimensionality, is optionally applied to the dot product of Q and K. Mathematically, the attention can be represented as:

$$Attention(Q,K,V) = Softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \qquad (1)$$

where, d_k is the dimensionality of the key vectors. This allows the model to focus on different parts of the image depending on the learned importance of each feature.

The Swin Transformer framework is offered in four distinct variants, namely Swin-T (Tiny), Swin-S (Small), Swin-B (Base), and Swin-L (Large), each differing in capacity and computational requirements. The choice of a particular Swin Transformer variant for a given task hinges on a balance between the model's empirical performance and the computational constraints of the available hardware. In the case of the segmentation of transmission lines in aerial images, Swin-B was selected due to its robust performance in capturing intricate details and providing a higher feature resolution necessary for the precise delineation of transmission lines, which are often slender and require fine-grained detection capabilities. Moreover, Swin-B strikes a balance between computational efficiency and model complexity, making it a pragmatic choice for tasks demanding high accuracy without exceedingly intensive computational demands. Table I provides detailed architecture of Swin-B backbone.

C. *CNNs-based Decoder*

The decoder leverages a U-Net-like structure known for its effectiveness in segmentation tasks due to its ability to combine low-level feature maps with high-level ones, thus capturing context and fine details. Each feature map output from the Swin-B backbone passes through a 3×3 convolution layer. This operation serves to refine the feature maps by applying filters that can capture spatial hierarchies within the data. After the convolution layers, the feature maps are upsampled. This process increases the spatial resolution of the feature maps to prepare them for feature fusion. The upsampling doubles the height and width of the feature maps, as is common in U-Net architectures [27] to match the dimensions of the feature maps from the encoder that will be fused. The upsampled feature maps are then fused with corresponding feature maps from earlier layers of the encoder. This step is crucial as it reintroduces higher resolution details that may have been lost during downsampling in the encoder. Feature fusion is done using element-wise addition operation. The last part of the decoder is the segmentation head, which outputs the final segmentation map. This head takes the processed feature maps and applies a combination of convolutional layers, activation functions, and sigmoid layer to generate the pixel-wise classification of the transmission lines. Given the size of the input to the decoder is $\frac{H}{32} \times \frac{W}{32} \times 8C$, the size of the output should match the original height and width of the input image $H \times W \times 2$.

D. Squeeze-and-Excitation Layer

Before the final output, we employ a Squeeze-and-Excitation (SE) layer [28] to recalibrate the feature channels by explicitly modelling the interdependencies between them. The SE layer uses global average pooling to squeeze global spatial information into a channel descriptor, then uses two fully connected layers to capture channel-wise dependencies, and finally applies the channel weights back to the original feature maps to emphasize useful features and suppress less useful ones. Fig. 3 shows the architecture of the SE layer. Let the input to the SE layer be a feature map F with dimensions $H' \times W' \times C$, where H' and W' are the spatial dimensions after upsampling and C is the number of channels. The SE layer first performs a global average pooling operation on F, which squeezes the spatial dimensions H' and W' into a single channel descriptor z with dimensions $1 \times 1 \times C$. Mathematically, this is represented as:

$$z_c = \frac{1}{H' \times W'} \sum_{i=1}^{H'} \sum_{j=1}^{W'} F_{i,j,c} \tag{2}$$

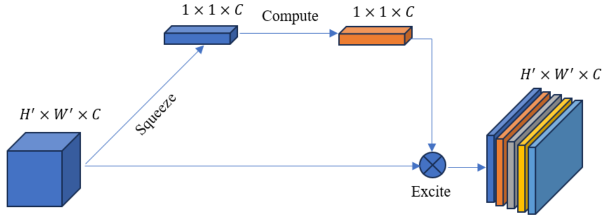

Fig. 3. The architecture of the SE layer.

where, z_c is the *c-th* element of z; $F_{i,j,c}$ is the value at position *(i, j)* in channel *c* of the feature map *F*.

The SE layer then passes *z* through two fully connected layers. The first layer reduces the channel dimensionality from C to $\frac{C}{r}$ using a ReLU activation function, and the second layer increases it back to C using a sigmoid activation function, thus generating the channel-wise weights *s* with the same dimension $1 \times 1 \times C$. Mathematically, this is represented as:

$$s = \sigma\big(g(z, W)\big) = \sigma(W_2 . \theta(W_1 . z)) \tag{3}$$

where, σ denotes the sigmoid activation, θ denotes the ReLU activation, W_1 and W_2 are the weights of the fully connected layers, and g represents the excitation function.

Finally, the SE layer applies these weights *s* back to the original feature map *F* through channel-wise multiplication, producing the output feature map F' with the same spatial dimensions $H' \times W'$ but with recalibrated channels:

$$F'_{i,j,c} = s_c . F_{i,j,c} \tag{4}$$

This operation scales each channel of the input feature map by the corresponding learned weight, emphasizing informative features and suppressing less relevant ones. The output of the SE layer is then ready to be passed to the subsequent layers in the decoder for further processing towards the final segmentation map.

E. Loss Function

Binary Cross-Entropy (BCE) loss is a commonly used loss function for binary classification tasks, such as the segmentation of transmission lines in aerial images, where each pixel is classified as either belonging to a transmission line (positive class) or background (negative class). The BCE loss function measures the distance between the predicted probabilities and the actual binary labels, penalizing predictions that diverge from the true labels. Formally, the BCE loss for a single pixel is calculated as:

$$L_i = -[ylog(p) + (1 - y)log(1 - p)] \tag{5}$$

where, y is the true label of the pixel, and p is the predicted probability that the pixel belongs to the transmission line class. The true label y is 1 if the pixel is part of a transmission line and 0 otherwise. The predicted probability p is obtained from the output of a sigmoid activation function in the last layer of the neural network, ensuring that p is in the range [0,1].

For the entire image, the total BCE loss is the average of the individual pixel losses:

$$L_{BCE} = -\frac{1}{N} \sum_{i=1}^{N} L_i \tag{6}$$

where, N is the total number of pixels in the image.

IV. Experiments

A. Dataset and Metrics

We use the TTPLA dataset [29] to evaluate the proposed method. The TTPLA dataset is a specialized collection of aerial images designed for the detection and segmentation of transmission towers and power lines. This dataset is significant for training and evaluating machine learning models, particularly in the domain of remote sensing and automated monitoring of electrical infrastructure. It includes high-resolution images that capture the intricate details of transmission towers and power lines from various angles and under different lighting conditions. The diversity of the dataset aids in developing robust models capable of accurately identifying and segmenting these structures. The dataset consists of 1,100 images with a resolution of 3,840×2,160 pixels and manually labeled 8,987 instances of transmission lines and transmission towers. For the purpose of evaluating the transmission line segmentation task, we only employ the labels of transmission lines for training and testing.

Precision (*P*), recall (*R*), Intersection over Union (*IoU*), and *F-score* are critical metrics for evaluating the performance of models in the segmentation of transmission lines in aerial images. Precision measures the ratio of correctly predicted positive observations to the total predicted positives. It is formulated as:

$$P = \frac{TP}{TP + FP} \tag{7}$$

where, TP is true positives and FP is false positives.

Recall assesses the ratio of correctly predicted positive observations to all actual positives. It's given by:

$$R = \frac{TP}{TP+FN} \tag{8}$$

with FN being false negatives.

Intersection over Union (*IoU*), also known as the Jaccard index, is the area of overlap between the predicted segmentation and the ground truth divided by the area of union. The formula is:

$$IoU = \frac{\text{area of overlap}}{\text{area of union}} \tag{9}$$

F-score is the harmonic mean of precision and recall, providing a balance between them. It's calculated by:

$$F - score = 2 \times \frac{P \times R}{P+R} \tag{10}$$

These metrics are pivotal for tuning models to the specific challenges of aerial image segmentation, such as delineating thin and often indistinct transmission lines against complex backgrounds. High precision indicates a model that reliably identifies line pixels, while high recall shows it finds most of the actual line pixels. *IoU* gives an overall sense of the model's accuracy, and *F-score* offers a single measure to assess both precision and recall.

B. Implementation Details

We leverage the strengths of transformer models, specifically building upon the Swin Transformer for the encoder component. The Swin-B model is pretrained on ImageNet-22k with a resolution of 384×384, maintaining the window size (M) as in the pretrained models. To adapt to the higher resolution requirements of the semantic segmentation task, we fine-tune these models based on the dataset's resolution. Following methodologies in the literature, relative position bias is incorporated when calculating attention scores. The decoders are initialized with random weights from a normal distribution. For optimization, the AdamW optimizer [30] is employed. The input aerial images are resized to a standard resolution of 512×512 pixels, striking a balance between preserving detail and maintaining computational efficiency. The learning rate is set at 1e-4, paired with a cosine annealing scheduler to facilitate adaptive learning rate adjustments over approximately 100 training epochs. The model's training is executed on a high-end NVIDIA RTX 4080 GPU. A batch size of 4 is used. Implementation is carried out using deep learning frameworks PyTorch. To further bolster the model's ability to generalize, data augmentation techniques including random rotations, flipping, scaling, and brightness adjustments are employed.

C. Comparison with Existing Methods on TTPLA Dataset

We compared the proposed model with six existing models on the TTPLA Dataset, as shown in Table II. It is evident that our model, which integrates a vision transformer encoder with a convolutional neural network decoder, outperforms most of the existing models in terms of precision, IoU (Intersection over Union), and F-score. These metrics are critical for assessing the effectiveness of segmentation models in aerial imagery. Notably, the proposed model achieves a precision of 0.855 and an F-score of 0.671, surpassing the UNet, UNet++, and Focal-UNet models that also use the Resnet-18 architecture. This superior performance can be attributed to the efficient feature representation and fusion enabled by the hybrid architecture of the proposed model. The Swin Transformer layers in the encoder capture intricate details and contextual information at various scales, which is crucial for accurately delineating transmission lines in complex aerial images. The use of the squeeze-and-excitation layer further enhances the model by emphasizing informative features, allowing for a more nuanced segmentation output. This is evident in the comparative improvement in precision and F-score, where the model excels in correctly identifying relevant pixels while maintaining high overall segmentation accuracy. In contrast, models like LCNN and HAWP, based on the Hourglass architecture, show significantly lower precision and F-score values, indicating a lesser ability to accurately segment transmission lines in aerial images. Their lower performance might be due to less effective feature extraction and fusion compared to the proposed hybrid model. Overall, the proposed model's superior performance across multiple metrics, especially in precision and F-score, highlights its effectiveness in segmenting transmission lines in aerial images, demonstrating the advantages of its novel architecture combining vision transformer and convolutional layers.

TABLE II. SEGMENTATION PERFORMANCE OF THE PROPOSED METHOD AND THE COMPARISON METHODS ON THE TTPLA DATASET

Models	Backbone	P	R	IoU	F-score
DeepLabv3+ [31]	Resnet-18	0.784	0.510	0.424	0.573
UNet [27]	Resnet-18	0.846	0.583	0.515	0.662
UNet++ [32]	Resnet-18	0.843	0.591	0.522	0.668
Focal-UNet [33]	Resnet-18	0.784	0.577	0.504	0.662
LCNN [34]	Hourglass	0.541	0.315	0.498	0.519
HAWP [35]	Hourglass	0.581	0.421	0.485	0.532
Our Model	Swin-B	0.855	0.579	0.522	0.671

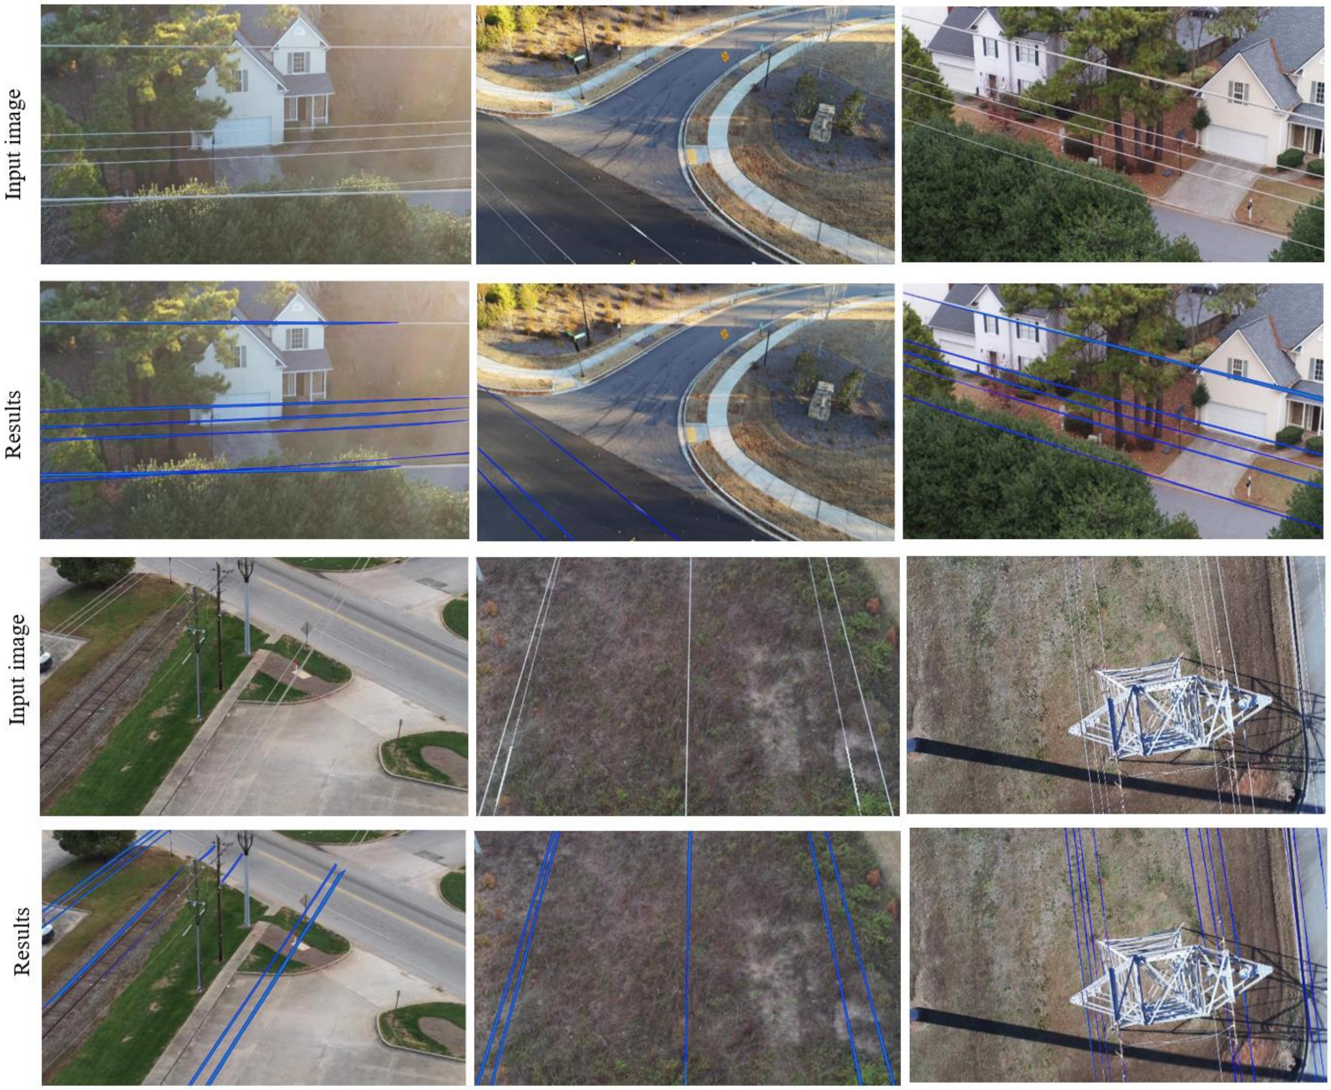

Fig. 4. Sample transmission line segmentation results of the proposed model.

Fig. 4 displays a side-by-side comparison of original aerial images against the segmentation results produced by the proposed model for transmission line identification. Across various landscapes such as residential areas, road intersections, and open fields with transmission towers, the model delineates the transmission lines with a high degree of precision, as indicated by the blue lines overlaying the images. Specifically, the model accurately identifies transmission lines in residential areas without confusion from similar-colored backgrounds, showing its precision in challenging environments. At a road intersection, the model successfully differentiates transmission lines from road markings despite visual noise, indicating strong feature extraction capabilities. In open fields, the model effectively handles contrasts and textures, maintaining accurate segmentation over uniform backgrounds like grass. These results underline the model's robustness in varied settings and its applicability in real-world tasks such as infrastructure monitoring from aerial imagery.

D. Comparison of Swin-B with Other State-of-the-Art Backbones

We conducted experiments to evaluate the performance of Swin-B encoder. Fig. 5 shows the F-score performance of various backbone architectures employed in image segmentation models. Swin-B tops the chart with an F-score of 0.671, indicating its superior ability in combining features effectively for precise segmentation tasks. Swin-T closely trails with a marginally lower F-score of 0.668, suggesting that while it is slightly less effective than Swin-B, it remains a highly competitive architecture. ResNeSt-101 and ResNet-101, both advanced iterations of the ResNet family, score 0.642 and 0.630 respectively, pointing to a proficient but noticeably lesser segmentation capability compared to the Swin architectures. VGG-16, the oldest architecture among those compared, shows its limitations with an F-score of 0.585, underscoring the advancements in backbone architectures for segmentation tasks and the importance of choosing the right one for optimal performance.

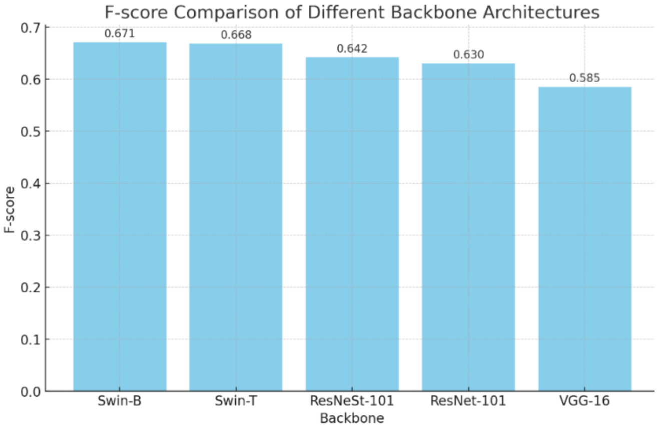

Fig. 5. F-score comparison of different backbone architectures.

V. Conclusion

This paper presents a novel hypbid architecture for the segmentation of transmission lines in aerial images. The presented hybrid segmentation model, which leverages the synergy of a vision transformer encoder and a convolutional neural network decoder, has proven highly effective in the segmentation of transmission lines from aerial images. The model's performance, as demonstrated on the TTPLA Dataset, is superior to existing models, achieving remarkable precision and F-score metrics. Its ability to handle complex backgrounds and maintain high accuracy in diverse environments showcases its robustness and adaptability. The successful application of this model paves the way for its integration into aerial survey systems, offering significant improvements in the monitoring and maintenance of power line infrastructures, potentially reducing costs and increasing operational efficiency. The research outcomes not only contribute to the advancement of segmentation techniques but also underline the transformative impact of integrating transformer architectures within computer vision tasks. For future work, we will incorporate advanced object detection algorithms to identify not just transmission lines but also associated structures such as towers and insulators. This would provide a more comprehensive analysis of the aerial imagery, facilitating detailed inspections and maintenance planning.

***Abstract*—Semantic and instance segmentation are critical goals that span a wide range of applications, from autonomous driving to object recognition in different fields. The existing approaches have limitations, especially when it comes to the difficult task of identifying and detecting minute things in intricate real-world situations. This work presents a novel method that uses a hybrid deep learning architecture with the Python programming language to smoothly combine semantic and instance segmentation. The suggested approach takes care of the pressing necessity in challenging real-world settings for accurate localization and fine-grained object detection. By combining the strengths of a Convolutional Neural Network (CNN) with a Bidirectional Long Short-Term Memory Network (BiLSTM), the hybrid model effectively achieves semantic segmentation by using sequential input and spatial information. A parallel attention method is smoothly included into the segmentation process to further improve the model's capabilities and enable the recognition of important object attributes. This study highlights the difficulties caused by changing environmental elements, highlighting the need for precise object location and understanding in addition to the complexities of fine-grained object detection. The suggested approach has an outstanding accuracy rate of 99.66%, outperforming existing approaches by 25.22%. This significant increase highlights the benefits that the hybrid design has over individual techniques and shows how effective it is at resolving issues that arise in dynamic real-world circumstances. The research highlights the importance of attention processes in deep learning and demonstrates how they might improve the specificity and accuracy of object detection and localization in intricate real-world scenarios. The improved performance of the suggested methodology is with well-known techniques like RCNN, CNN, and DNN, reaffirming its status as a reliable means of developing object localization and recognition in difficult situations.**

Keywords*—Semantic segmentation; instance segmentation; convolutional neural network; bidirectional long short-term memory; attention mechanism

I. Introduction

Fine-grained object identification in visual computing is an important topic for addressing real-world issues by concentrating on minute distinctions and subtleties among comparable things, prioritizing precision in technologies such as manufacturing, self-driving vehicles, healthcare imaging, and wildlife preservation [1]. The phrase "challenging real-world environments" in this sense refers to a wide range of elements, such as obstructions, various lighting situations, various views, and abundantly generated scenery. Gaining an improved understanding of the minute differences that set items belonging to the identical grouping apart is the main objective of fine-grained object recognition. For example, fine-grained recognition of objects goes beyond standard object recognition to distinguish between certain dog kinds or cat species. standard object recognition could distinguish among a dog and a cat [2]. Innovative strategies are required to uncover small features and patterns that are invisible to the human eye, which frequently combine learning algorithms, deep neural networks, and characteristic engineering to achieve efficient analysis. Real-world scenarios with continually changing and unexpected characteristics provide considerable challenges to a seamless object recognition infrastructure. obstacles, visual obstacles generated by extra objects or features, and variations in light, such as shadows and views, can all complicate the identification process [3]. Recognition algorithms must be adaptable to variations in size, movement, and viewpoint caused by real-world views and complicated backgrounds. Sophisticated algorithms are required to discriminate between useful items and insignificant visual characteristics in busy and patterned surroundings, providing smooth object detection in difficult conditions [4]. A comprehensive strategy comprising innovative algorithm creation, different training data sets, and in-depth knowledge of individual applications is required to increase the robustness and dependability of smooth object recognition algorithms for real-world applications.

Robots and AI systems use instance segmentation and semantic segmentation as core computer vision operations, allowing them to analyze visual input in a variety of circumstances and translate pixel-level data into useful information [5]. Semantic segmentation is an important approach for scene evaluation and object recognition that assigns pixel-level classification to certain sections of a picture. This allows computer systems to recognize object boundaries and grasp how the world is organized. Semantic segmentation improves its efficiency by distinguishing between object categories and individual occurrences, making it the cornerstone of scene interpretation [6]. In picture segmentation, each structure has a precise object mask, which is critical for robotics and AI systems to reliably discriminate and recognize instances of the same item category. This level of granularity is critical in complicated applications such as self-driving cars and healthcare imaging, where detecting unique instances in crowded settings is important. It is difficult to distinguish delicate elements from clutter limits segmentation algorithms in real-world scenarios. Conventional approaches fail to detect small-scale items accurately, while real-world difficulties like as obstructions, accessibility limits, and changing illumination conditions hamper object identification and localization even more. These issues demand unique tactics that go beyond existing approaches to provide dependable and seamless object assessment in difficult real-world scenarios. [7].

This paper introduces a hybrid deep learning architecture that combines semantic and instance segmentation capabilities to improve real-world segmentation algorithms. The framework employs attention processes to outperform existing strategies in tasks demanding precise object placement and identification. It integrates semantics and instance-level segmentation into a single framework, fixing specific flaws while maximizing benefits. The method employs numerous decoding paths and shared encoders to extract important information from input images, allowing the system to comprehend the image's overall meaning and design. This fundamental understanding facilitates scene design and relationships [8]. The framework employs a shared encoder to decrease processing needs, increase efficiency, and ensure a thorough grasp of input data. Strategic decoding branching switches the encoder, resulting in more accurate and consistent segmentation results while optimizing resource utilization and data transmission. The hybrid architecture uses attention processes to improve system efficiency, allowing it to concentrate on critical data locations, especially in complicated and crowded situations where fine-grained features are likely to be covered [9]. The system employs attention methods for segmentation, ensuring that computer resources are used efficiently and that meaningful instances are distinguished from background noise. The combination of attention processes and the shared encoder increases flexibility by handling occlusions, angles of view, and illumination conditions. This integrated technique encourages a more detailed comprehension of settings, resulting in considerable improvements in accurate item location and identification in demanding real-world scenarios [10]. The hybrid deep learning framework enhances semantics and instance segmentation through the use of twin decoding approaches. It separates pictures into relevant segments for semantic segmentation by generating pixel-wise categorization projections, allowing for comprehensive image interpretation by identifying significant portions of the image [11]. The second decoder is particularly built for instance segmentation, resulting in exact object masking to discriminate between distinct instances of objects. This method improves higher-level semantic comprehension and enables fluid localization, resulting in a more complete and accurate contextual understanding.

The framework incorporates attention processes into decoding operations to improve its efficacy in demanding settings. These tactics guarantee that just the most significant parts of a picture are analysed, allowing the algorithm to focus on areas critical for object localization and recognition. This enhances its capacity to handle complicated things, respond fast to visual cues, and function effectively in tough conditions [12]. The hybrid architecture's performance was evaluated using a variety of real-world datasets, such as interior settings, animal photos, and metropolitan landscapes. The system outperformed advanced approaches in semantics and instance segmentation, proving its capacity to handle accurate item localization tasks in demanding environments such as interior settings and metropolitan landscapes [13]. The hybrid architecture, as a flexible solution, exhibits its capacity to excel across a number of domains, providing potential paths for improvements in fine-grained visual processing and supporting applications ranging from autonomous cars to medical imaging.

The key contributions of the article is,

- The study introduces a novel pre-processing step using Gaussian functions, enhancing feature extraction and smoothing in input data, contributing to improved overall model performance.
- The research leverages a fusion of Convolutional Neural Networks (CNN) and Bidirectional Long Short-Term Memory networks (BiLSTM) for semantic segmentation, enabling the model to capture both spatial and temporal dependencies in the data, resulting in more accurate and context-aware segmentation.
- The incorporation of attention mechanisms in instance segmentation significantly refines object delineation. The attention mechanism ensures that the model focuses on relevant regions, enhancing the precision and efficiency of instance segmentation in complex scenes.

- The study offers a nuanced view of the model's capabilities by introducing a thorough performance evaluation technique that takes into account variables including segmentation accuracy, computing efficiency, and resilience.

This article's remainder is organized as follows: In Section II, a summary of related research is provided. Section III presents the problem statement. The suggested approach's methodology and architecture are explained in Section IV of the article. The findings and subsequent discussion are covered in Section V. The conclusion is covered in Section VI.

II. Related Works

Automatic recognition of objects in 3D spaces is essential to working zone security, including ensuring adherence to building codes and averting accidents and fatalities at workplaces [14]. However, a number of difficulties, including correct three-dimensional object comprehension because of size changes and a lack of indicators in the three-dimensional environment, outstanding identification, exceptional segmentation of instances, and insufficient technical object databases with masking present significant challenges. These difficulties affect conventional manual techniques. The main discovery is to calculate pseudo-light recognition and reaching point clouds for three-dimensional object recognition using two-dimensional recognition of objects, segmentation of instances, and cameras perception. On the contrary hand, an upgraded cascading masks R-CNN is used to identify boundaries and masking for every two-dimensional object, while an enhanced characteristic pyramids system is presented for obtaining additional smooth object characteristics. An additional object classes with the boundaries and masking is introduced, and the AIM database for massive machinery identification is expanded. On the contrary hand, using deep learning, autonomous camera parameters estimation, a vision-based approach, and a spatial filtering, it is possible to retrieve pseudo-LiDAR point's clouds of objects generated by boundary boxes and masking from a monochromatic image. Numerous tests and evaluations reveal that the recently developed approach can recognize three-dimensional items and autonomously assess the security working areas. On the AIM information set, the suggested object recognition system produced the most advanced outcomes, and for the enhanced information set. The fresh framework will act as a starting point for studies regarding three-dimensional object recognition for additional three-dimensional positions.

The study extends Trans10K-v1, the initial significant database for translucent item differentiation, by providing an additional, smooth database known as Trans10K-v2 [15]. The novel dataset has a number of enticing advantages over Trans10K-v1, which only contains two constrained classes. (1) It is better suited for practical use since it comprises eleven smooth classes of translucent items that are frequently seen in the average household surroundings. (2) Compared to its predecessor, Trans10K-v2 presents additional difficulties for currently sophisticated segmentation techniques. Additionally, the Trans2Seg pipelines, unique transformer-based segmented pipelines, are suggested. Initially Trans2Seg's transformers encoders, which offers an overall responsive field as opposed to CNN's localized one, outperforms standard CNN systems in terms of performance. Subsequently, the study builds a collection of accessible designs as the question parameters of Trans2Seg's transformers decoder, where every instance acquires the statistical information of a particular group in the entire data set by treating semantic segmentation as an issue of dictionaries. Researchers compare Trans2Seg with a variety of than twenty current semantically segmented techniques, revealing that it greatly exceeds all CNN-based techniques and potentially solving the problem of translucent object segmentation.

For the creation of a successful computerized diagnostic framework, the identification and fragmentation of the new coronavirus infection of 2019 abnormalities using CT images are extremely important [16]. One of the finest options for creating such an instance is deep learning. However, a number of issues, involving as information variation, a wide range in the dimensions and form of the inflammation, lesions imbalances and an absence of annotations, restrict the effectiveness of DL techniques. In order to overcome these difficulties, a unique multitasking regression networks for categorizing COVID-19 lesions is put forward in the present research. The model's designation is MT-nCov-Net. The lesions identification is formulated as a multitasking structure extrapolation issue, allowing for the sharing of low-, medium-, and excellent-quality information across multiple assignments. In order to effectively acquire tiny and substantial lesion characteristics while minimizing the semantic disparity between various scale visualizations, a multiscale characteristic learning modules is introduced. This component captures the multiscale knowledge of semantics. Also included is a smooth lesions identification module that employs an adaptable dual-attention technique to find infected regions. The inflammatory regeneration modules then segment the infected regions using the obtained position mapping and the merged multiscale depictions. By reducing the COVID-19 area's form, MT-nCov-Net can properly fragment the inflammation through absorbing all of its features. MT-nCov-Net is empirically assessed on two open multisource information sets, and the results support its general efficacy above the state-of-the-art methodologies and show how well it works to solve the issues with COVID-19 diagnostics.

Due to the intricacy of plant images, segmenting plants is a difficult automated vision problem [17]. The study has to do increasingly more challenging activities in order to tackle various real-world issues. Instead of looking at the entire plant, the study must make distinctions between plant sections. The lack of information with thorough annotations is the main obstacle to multi-part segmentation. Actively annotating databases at the object component levels takes a lot of effort and money. The study suggests using pseudo-annotation with inadequately supervised training. In the article, researchers examine the minimally supervised training techniques currently in use and offer a productive pipeline for agrarian applications. It is made to deal with close object overlaps. For the plant component example and the entire plant scenario, the pipeline outperforms the starting point solutions by twenty-three percent and forty percent, respectively. To improve simulation effectiveness, researchers also use instance-level enhancement. The goal of the method is to create a weakened segmentation masking that can be used to trim items from the source images and paste them onto fresh backdrops while the participant is being trained. On object component segmentation operations, the strategy gives us a fifty-five percent mAP gain over the initial state, and on entire plant segmentation operations, a seventy-two percent gain.

Recent developments in navigational autonomy have shown a greater preference for computation vision over conventional methods [18]. The majority of the places are built with individual movement in mind, which is how this works. They are therefore chocking full of visual indicators. In this way, the capacity to recognize objects visually is crucial for self-driving cars to prevent impediments while interacting with the outside environment. It is laborious and costly to gather information employing unmanned aerial vehicles that are capable of operating in the real environment. A database consisting of areas and conversations constitutes one of IT businesses' greatest resources as a result. Adopting an image-realistic three-dimensional simulation as the source of information is one way to address this issue. It is feasible to obtain a substantial quantity of information with this asset. Therefore, utilizing images from a frontend UAV camera moving through a three-dimensional simulator, the present study builds a collection of images for example segmentation. The Mask-RCNN, a cutting-edge deep learning approach, is used in the present research. The framework estimates per-pixel segmentation of instances from an image input. According to empirical findings, Mask RCNN performs better in the data we provide when improving the algorithm generated from the COCO dataset. Additionally, the intriguing findings in real-life information provide the suggested technique a solid generalization potential.

The inconsistent and fragmented nature of points cloud information in a non-Euclidean environment makes it difficult to fully employ smooth semantic properties [19]. A max pooling procedure is frequently employed to draw attention to particularly significant characteristics in the immediate area in attempting to illustrate the local characteristic for every centering point that is beneficial for improved contextual understanding. The max pooling method, however, ignores any additional geometrical local connections between every central location and its related neighborhood. In order to do this, the focused attention method shows promise in preserving node representations on graph-based information by paying consideration to every node in its immediate vicinity. Using stacking MLP units and a unique neural network called GA Point Net, the study offers a new method for analyzing point clouds. GA Point Net can acquire localized geometrical descriptions. To effectively utilize local characteristics, the study emphasizes various focus weights on every focal point's neighborhood. To completely retrieve localized geometrical patterns and improve the system's resilience, the study additionally mixes attentive characteristics with the regional identity characteristics produced by the focus grouping. The suggested GA Point Net structure performs at the cutting edge across the form categorization and segmentation operations when evaluated on a variety of datasets used as benchmarks.

To be more precise, the characteristics with multiple scales are combined top-down to blend specifics and broad semantics to improve tiny item detection [20]. A pyramidal tiered attention mechanism made up of channels and spatial focus is created throughout the fusion of multi-scale information in order to see the item. Additionally, enhancing self-paced learning is used to direct the model to study challenging data. Two real-world datasets, an AMMW dataset and a publicly accessible PMMW dataset, are used for validating the technique that is suggested. The results of experiments show that the suggested strategy is preferable due to its versatility in identifying various devices concealed inside clothing while remaining harmless; the AMMW scanner has become a common tool for checking the safety of people in public settings in recent years. Nevertheless, due to intrinsic image noise, unknown item kind, and ambiguous status, it is very difficult to identify all concealed objects autonomously and precisely. Recent improvements in concealed object identification have been made by various current algorithms, particularly those that utilize deep learning. These techniques are effective for finding a few specific types of huge things, but they are ineffective for finding dim or imperfect hard objects. The state-of-the-art approaches are provided in this paper as a hidden finding of objects model with SPFAFN to handle this problem. SPFAFN obtains improved results on the two datasets with Maximum Precision.

The importance of object detection for systems that drive autonomously is rising [21]. Nevertheless, the use of existing object detectors to autonomously drive is constrained by their low accuracy or low inference ability. By integrating dilated convolutions and a SAM into the YOLOv3 design, a quick and precise object detector known as SA-YOLOv3 is suggested in this study. In order to enhance the accuracy of detection, the loss functional determined by GIoU and focused loss is rebuilt. With immediate inference, the suggested SA-YOLOv3 enhances YOLOv3 by 2.58 mAP and 2.63 mAP on the KITTI and BDD100K standards, respectively. Its improved compromise in terms of quickness and - accuracy in comparison to other cutting-edge detectors suggests that it is appropriate for use in self-driving vehicle applications. It is believed that this strategy, which integrates YOLOv3 with an attention mechanism for the first time will serve as a model for upcoming studies on autonomous vehicles.

To differentiate objectives from inferior categorization is the goal of smooth visual categorization [22]. It is thought to be a very challenging assignment since smooth images naturally exhibit significant inter-class variations and tiny intra-class variability. The majority of current methods employ CNN-based systems as characteristic extractors, which results in the generated exclusive areas including the majority of the object's components and missing to identify the truly crucial components. The perception transformers, which employ a mechanism for focus to gather broad context-relevant data to create a distant reliance on the desired object and then extracts more potent characteristics, has subsequently proven its effectiveness on a variety of imagine activities. The ViT approach might function inadequately in the categorization of smooth images because it continues to place greater emphasis on overall coarse-textured data than localized smooth data. The study enhances the ViT framework and develops a concentration accumulating transformers to more effectively catch small variations across images. To improve communication between every transformer layering, the study specifically suggests an essential consideration accumulator. Additionally, the study provides an original data entropy selection to direct the algorithm in accurately obtaining discriminatory portions of the image. Numerous tests demonstrate that the suggested model architecture is capable of operating at an innovative modern facilities level on a number of widely used databases.

It's crucial and difficult to recognize facial expressions employing a DCNN [23]. Although significant efforts have been performed to improve FER accuracy using DCNN, earlier experiments have not yet been adequately generalized for use in practical situations. Conventional FER research is mostly restricted to regulated lab-posed fronted facing images, which do not encounter the difficulties associated with motion disintegrate head causes, obstructions, face distortions, and illumination under unregulated circumstances. The study suggested a SqueezExpNet architecture for extremely efficient FER systems that can tolerate fluctuations in the environment. It can benefit from global as well as local face data. The network was split into two distinct phases: a geometric concentration phase, which uses a SqueezeNet-like structure to collect localized highlighting data, and a geographic texturing phase, which consists of numerous compressed and extended levels to take use of the highest-level broad characteristics. To highlight significant localized facial areas, the study specifically developed the weighted masking of three-dimensional facial characteristics and employed element-wise combination with a geographical characteristic in the initial step. The subsequent phase of the network is then fed with the facial geographical imagine and its enhancements. To help overcome the unpredictability, a network of recurrent neural networks was created to cooperate with the emphasized data from two phases instead of only employing the SoftMax function, much like a classification system. The three top expressions databases were used in investigations encompassing simple and complex FER objectives. The technique produced cutting-edge findings and surpassed the current DCNN algorithms. Instantaneous FER could uncover possible applications in monitoring, well-being, and feedback mechanisms according to the created construction, chosen investigation approach, and published outcomes.

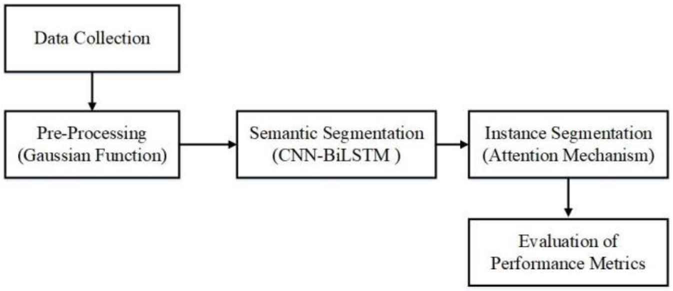
The thorough literature review explores a wide range of computer vision and deep learning subjects. By balancing camera perception, instance segmentation, and two-dimensional object recognition, the first study presents a novel hybrid deep learning architecture that adeptly tackles real-world complexities in three-dimensional object recognition. The results are promising and have significant implications for the identification of machinery and the development of autonomous driving technologies. Moreover, it presents Trans2Seg, a novel transformer-based segmentation pipeline that significantly outperforms the state-of-the-art CNN-based techniques. To enhance and broaden the research landscape in this dynamic and ever-evolving domain, the study complements these breakthroughs by creating Trans10K-v2, a novel dataset featuring a variety of translucent object classes.

III. Problem Statement

Deep convolutional neural networks (DCNNs) must operate accurately in uncontrolled, real-world contexts, making face emotion recognition an important yet difficult challenge. Advances in facial expression recognition (FER) accuracy have mostly concentrated on controlled lab environments, ignoring problems like head obstacles, motion disintegration, face distortions, and changing lighting. Effective generalization in such real-world scenarios is not possible with the current DCNN-based models [23]. In order to overcome these shortcomings, the SqueezExpNet architecture is presented in this paper. It is intended for very effective FER systems that can adapt to changes in the environment and make use of both local and global face data. The network is divided into two phases: a geographic texturing phase and a geometric concentration phase. For enhanced performance, a network of recurrent neural networks and weighted masking of three-dimensional face characteristics are included. The suggested technology outperforms existing DCNN algorithms and has potential uses in feedback systems, monitoring, and wellbeing applications.

IV. Proposed Hybrid Learning Architecture with Attention Mechanisms

The approach entails putting forth a unique architecture that combines instance and semantic segmentation to improve precise item localization and recognition in difficult real-world circumstances. The integration recognizes that although semantic segmentation delivers high-level contextual comprehension, instance segmentation offers detailed instance-level information. The CNN-BiLSTM for semantic segmentation is a novel addition that makes use of the spatial context and sequence data gathered by BiLSTMs and CNNs. In particular in complicated situations, the addition of attention processes, such as segmentation, assists in focusing on key visual areas for exact instance classification. In addition to demonstrating the architecture's superiority over stand-alone approaches and emphasizing the importance of attention processes in boosting instance segmentation's accuracy and reliability, the research makes sure to provide a thorough review of the architecture through quantitative and qualitative assessments. It is depicted in Fig. 1.



Data Collection
Pre-Processing (Gaussian Function)
Semantic Segmentation (CNN-BiLSTM)
Instance Segmentation (Attention Mechanism)
Evaluation of Performance Metrics

Fig. 1. Proposed methodology.

A. Data Collection

The VEDAI dataset, which supports the growth of fine-grained vehicle recognition algorithms in remote sensing images, is a dataset for fine-grained vehicle identification. The total number of images and occurrences in VEDAI is 1210, and each image has a 1024 by 1024 pixel resolution. The order of occurrences in this collection can be considered sparse, as can be observed by the quantity of instances and images [25].

B. Pre-Processing using Gaussian Function

When preprocessing an image using a Gaussian function, a Gaussian filter is applied to it to assist smooth it out and remove noise. The kernel or mask of the filtering procedure is the bell-shaped Gaussian function, a mathematical function. The filter operates using a Gaussian kernel, and each pixel is assigned a weight based on how near to its neighbors it is. The weights are computed using the values of the Gaussian function at each location along the kernel. By changing the Gaussian filter's parameters, such as the kernel size and standard deviation, the amount of image smoothing may be changed. While bigger kernel sizes and greater standard deviations provide more comprehensive smoothing, smaller kernel sizes and lower standard deviations maintain finer features. The final preprocessed image has a smoother overall look, less noise, and fewer high-frequency features. Gaussian filtering, a preprocessing technique frequently used in image processing, is particularly useful for tasks like demising, feature extraction, and increasing the quality of images. Because the Gaussian filter can blur and smooth images well, it is a crucial tool in computer vision and image processing applications. This filter, which gets its name from the Gaussian function, is frequently used to improve images and reduce noise. Through the use of a Gaussian kernel to convolve the input picture, the filter reduces high-frequency noise while maintaining important image characteristics. Its natural smoothing ability helps to lessen pixel-level differences, producing an output that is more aesthetically pleasant and visually cohesive. The blurring effect of the Gaussian filter also helps to emphasize important structures while minimizing unimportant details, which makes it useful in applications like edge detection and feature extraction. Because of its adaptability, the filter may be used in a wide range of domains, such as object identification, robotics, and medical imaging. As such, it is an essential tool for preprocessing and picture refinement in a variety of settings. The Gaussian function equation is shown below in Eq. (1).

$$H(y) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{\frac{x^2}{2\pi\sigma^2}} \tag{1}$$

where the standard deviation of the distribution is denoted as σ. The distribution is assumed to have a mean of 0.

C. Hybrid CNN-BiLSTM for Semantic Segmentation

Considering it effectively handles image interpretation issues by combining the capabilities of CNN and BiLSTM, the Hybrid CNN-BiLSTM architecture is essential to semantic segmentation. Through the combination of the sequential information-taking capacity of the BiLSTM and the spatial feature-capturing capability of the CNN, this innovative approach allows the model to interpret both contextual and spatial subtleties in the image data. These two components work together in the Hybrid CNN-BiLSTM architecture to significantly increase semantic segmentation accuracy and precision, particularly where precise localization and fine-grained object recognition are crucial. The resilience and reliability of semantic segmentation tasks are enhanced by this design, which makes it possible for the model to function effectively in dynamic and complicated real-world environments. This makes it vital for a wide range of applications, including autonomous driving, computer vision, and medical imaging.

A convolutional neural network (CNN) is used in this step of feature extraction and is a crucial step in deep learning for pattern and recognition of image applications. CNN is developed in order to autonomously determine organizational and discriminating qualities from the original input images. In a series of convolutional layers, tiny filters are organized over the input image to collect regional trends and attributes. These characteristics capture the edges, the surfaces, and shapes which make up the visual environment. Then, the feature maps are down sampled by pooling layers, which lessens the computational cost while maintaining important data. Fully connected layers accept the results of the learnt attributes and put them into effect future classification or similar activities.

CNNs have shown outstanding results in a range of applications involving computer vision, demonstrating modern performance in problems including object detection, image segmentation, and analysis of images in healthcare. This is because of their ability to voluntarily pick up and remember important aspects from visuals. By merging information from different methods, the CNN technique maximizes the benefits of each modality while compensating for its limitations and providing a more complete knowledge. Recurrent neural networks of the Bidirectional Long Short-Term Memory (BiLSTM) variety handle sequential information while simultaneously considering into account both past as well as future circumstances. It has both forward and backward LSTM components that create hidden states and collect data from components that come before and after them in the sequence. When combined with convolutional neural networks (CNNs), BiLSTMs can improve pixel-wise image categorization in applications like semantic segmentation. Bidirectional connections are utilized into consideration by BiLSTMs to enhance the framework's comprehension of intricate spatial and contextual interactions, producing more precise and context-sensitive semantic segmentation that benefits applications related to computer vision. The diagrammatic representation of the proposed hybrid CNN-BiLSTM method is depicted in Fig. 2 and the equations of CNN-BiLSTM are depicted in Eq. (2) to Eq. (7) below:

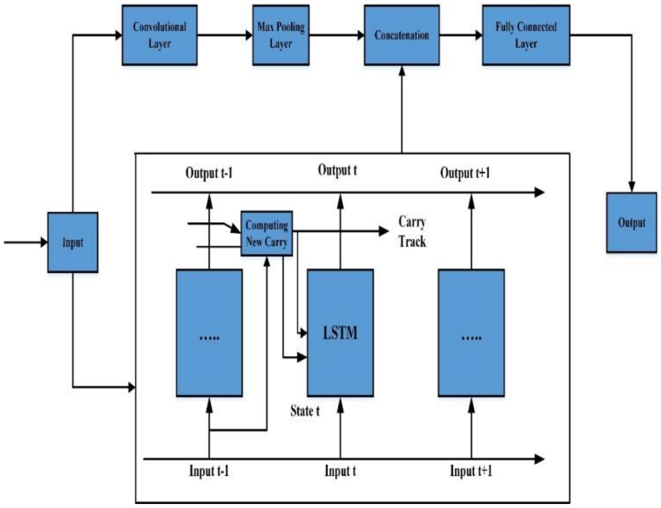


Fig. 2. CNN-BiLSTM framework.

$$g_v = \sigma(N_g y_d + K_g g_{v-1} + d_g) \tag{2}$$

$$h_v = tan_g(N_h y_v + K_h g_{v-1} + d_h) \tag{3}$$

$$j_v = \sigma(N_j y_v + K_q g_{v-1} + d_j) \tag{4}$$

$$p_v = \sigma(N_i y_v + K_p g_{v-1} + d_p) \tag{5}$$

The current qv state can be calculated by (6).

$$q_v = g_v \times q_{v-1} + j_v \times h_v \tag{6}$$

$$x_v = g_v = p_v \times tan_g(q_v) \tag{7}$$

Here, Kg, Kh, Kq, Kp signifies the weight matrices of the previous short-term state gv-1. Ng, Nh, Nj, Ni signifies the weight matrices of the current input state yd, dh, dg, dj, and dp are labelled as the bias terms, qv-1 characterizes the preceding long-term state.

D. Attention Mechanism for Instance Segmentation

The Attention Mechanism is a fundamental component of instance segmentation and serves as a basis for enhancing and optimizing object recognition in intricate visual datasets. The primary function of this method is to enhance the accuracy and precision of instance segmentation by allowing the model to recognize and concentrate on certain object features and regions. Even in congested or densely populated environments, the model can efficiently separate and isolate individual object instances because to its dynamic capacity to balance the value of different components in the visual input. This adaptable approach proves its worth in a multitude of domains, ranging from robotics and object recognition to the intricate realm of medical imaging, where it enhances instance segmentation accuracy and consistency. This paves the door for innovative developments in these domains by laying the foundation for a richer comprehension of complicated visual data and the things it includes.

The attention model improves the CNN by maintaining its context-relevant characteristics. In the prior-based model, each block's attributes are integrated into the ones from the layer below it. This method equally weights each attribute acquired from the previous CNN blocks. To learn precise feature values, important characteristics from the previous blocks must be given a high weight relative to other features. In order to facilitate the acquisition and selection of noteworthy qualities from previous blocks, a mechanism tracking attention was consequently introduced to the CNN architecture. This model generates an attention mask that equalizes the relative importance of spatial characteristics on that feature map. Leveraging an attention mechanism throughout blocks, the CNN architecture generates a weighted function for simulating activations from the prior blocks. The connections from the previous blocks that were skipped were then weighed throughout the depth axis for every single pixel in that layer's spatial range [26].

Two operational channels, H(x) and S'(x) are used to guide the layer of convolution to produce 'x' output in both the first and subsequent blocks. H(x) shows the set of methods that were implemented to take the input value "x" and just feed it forward to the block after it. The group of techniques collectively referred to as S'(x) has weighting with attention and skipping the 'x' through convolutional and maximum-pooling layers. The balanced summation is used to obtain the outputs G(x) from the CNN block and is shown in Eq. (8).

$$G(X) = H(X) + S'(X) \tag{8}$$

Eq. (9) is used to determine the functional route S'(x).

$$S'(X) = S'(X) * \varphi \tag{9}$$

where S(x)'s spatial dimensions and the attention weight matrix's parameters are equivalent. The appropriate cross-section of S(x) is multiplied point-wise (broadcast throughout the depths) by the attention matrix's weights "." CNN can incorporate the inputs from the current moment and its results from the previous instant to automatically allocate the weighting for each element of the network as a whole by including an attention method. Important image details may be focused on to improve the classification's precision and adaptability. Based on this, CNN's attention concept is added to form the Attention-CNN model. Pay attention carefully: To identify and classify the framework and airborne particulates in SEM images, CNN is used. The attention-CNN architecture consists of the input, a convolution, attention to detail, full connection, and output layers. The layer that receives input is made up of four nodes, which are the labelled images of four separate kinds of particles, as the input data is a pictorial representation of four distinct particle types. Each of the convolution layers of the four phases that together make up a single layer of convolution is followed by a layer of attention in order to successfully accomplish weight transportation. The dimensions of the convolution kernels are 8x3x3, 16x5, 32x3, and 32x3 for each layer, accordingly. A pooling layer connects the first and last convolution layers. The final result of the layer used for convolution serves as the layer's input, and the total number of nodes in the full connections layer is set to 64. The maximum number of the output layer nodes is 4, and the output layer classifies the smallest particles into four groups.

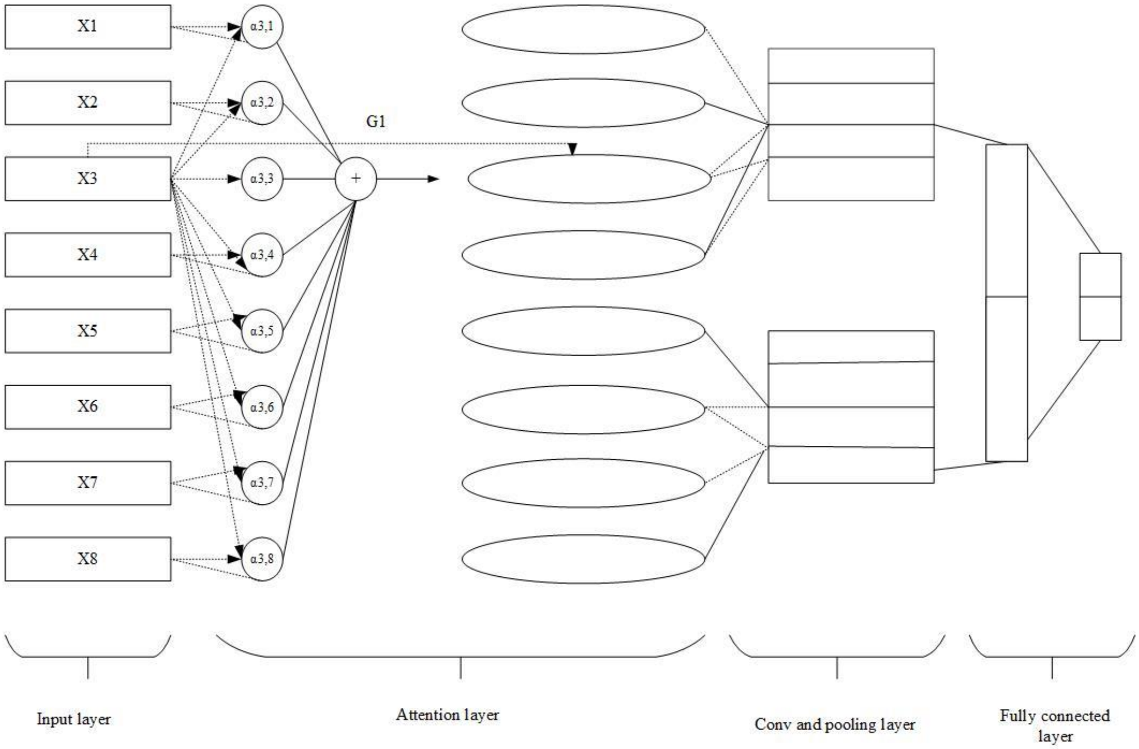

Fig. 3. Attention mechanism integration in CNN.

The CNN Attention Mechanism for Integration is shown in Fig. 3. A nonlinear relationship might be inserted amongst the different layers of an ensemble of neurons by changing the function that causes activation. The network's output no longer looks linear, which increases the network's expression and allows it to fit a wider range of patterns. The Attention-CNN model uses two activating coefficients, Relu (rectified linear unit) as well as, for its concealed and outputs components, respectively. Relu can deal with elevation dispersion throughout the element transfer process. When the value of the Relu function is greater than 0, its derivative is 1. It is simple to identify the gradient and may greatly accelerate the gradients' downward speed of convergence. Eq. (10) shows the Relu function's formulation.

$$ReLu = max(0, X) \tag{10}$$

By transferring the outputs of several neurons to the coordinates (0, 1), Softmax is able to classify data in a variety of ways. Assuming there is one, j denote the last component of an input array; the softmax value assigned to that component is determined by

$$G_j = \frac{s^j}{\sum_{i=1}^{k} s^j} \tag{11}$$

where, k stands for all of the input items. Since both the first-order and second-order instant means of the gradient are completely used by the Adam optimization approach, the forward momentum component is taken into account during the updating procedure. Adam's computation is shown in Eq. (12) to Eq. (16):

$$u_t = \alpha_1\delta_{t-1} + (1-\alpha_1)k_t \tag{12}$$

$$n_t = \alpha_2\delta_{t-1} + (1-\alpha_2)k_t^2 \tag{13}$$

$$\hat{u}_t = \frac{u_t}{1-\beta_1^t} \tag{14}$$

$$\hat{n}_t = \frac{n_t}{1-\delta_1^t} \tag{15}$$

$$k_{t+1} = k_t - \frac{\partial}{\sqrt{\widehat{n_t}}+\varepsilon}\hat{u}_t \tag{16}$$

where u_t is the first-order moment estimates that nt is the second-order momentum term, α_1, α_2 are actually dynamic values, $k_t$is the gradient of the cost operates after t iterations, u_t is the first moment's correction value, n_t is the second moment's correction value, k_t is the model's variables, and is a small amount that can circumvent the zero denominators. In neural network [24] training, the loss of functions is used to quantify the difference between the predicted result and the actual value. In addition, the effectiveness of the computational framework is evaluated using this component as a benchmark. The cross-entropy cost functioning, which may be thought of as the loss of function for Attention-CNN in Eq. (17),

$$H = -\frac{1}{n}\sum_l l_j(\rho(a) - b) \tag{17}$$

where, y is the resultant value, b is the actual value, n is the total of the samples l is the sample, and n is the sample. The following formula is used to determine the gradient.

$$\frac{\partial b}{\partial a} = \frac{1}{n}\sum_l l_j(\omega(z) - b) \tag{18}$$

where the error between the output and the actual value is $\omega(z) - b$ [27].

V. Results and Discussions

To improve accurate item localization and recognition in challenging real-world scenarios, the approach proposes a novel architecture that combines instance and semantic segmentation. The integration acknowledges that while instance segmentation provides detailed instance-level information, semantic segmentation provides high-level contextual comprehension. A novel addition that leverages the spatial context and sequence data collected by CNNs and BiLSTMs is the CNN-BiLSTM for semantic segmentation. The addition of attention processes, like segmentation, helps to focus on important visual areas for precise instance classification, especially in complex scenarios. The research ensures that the architecture is thoroughly reviewed through quantitative and qualitative assessments, highlighting its superiority over stand-alone approaches and highlighting the role of attention processes in improving the accuracy and reliability of instance segmentation.

A. *Performance Metrics*

Training and Testing Accuracy: An indicator of a machine learning model's success during the training stage is training accuracy. It displays the percentage of instances (or samples) in the training dataset that were properly predicted in relation to all of the occurrences in that dataset. In other words, the degree to which the model's predictions match the actual labels for the data it was trained on is indicated by the degree of training accuracy.

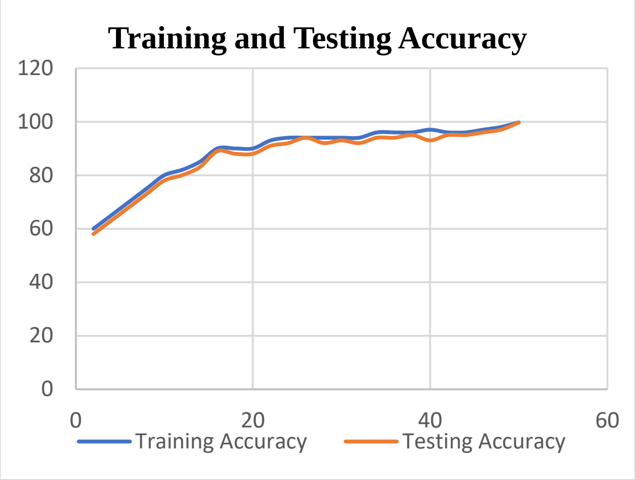

Fig. 4. Training and testing accuracy.

In this Fig. 4, accuracy refers to a performance parameter that assesses the percentage of fine-grained objects that the proposed hybrid deep learning architecture successfully recognized and localized in difficult real-world contexts. The model's excellent precision and efficacy in successfully recognizing and localizing items with complex features and difficult backgrounds are indicated by the accuracy of 99.66% that was attained.

Training and Testing Loss: A machine learning model's training loss, often referred to as the objective or cost function, is a quantifiable indicator of how well the model is doing. It shows the difference between the actual target values (ground truth) found in the training dataset and the projected values produced by the model. Making the model's predictions as near to the actual values as is practical is the main objective of training; this is to minimize this loss.

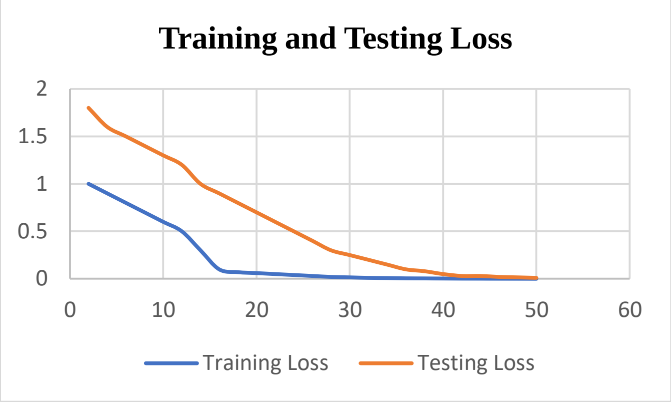

Fig. 5. Testing loss.

In Fig. 5, the gap between anticipated and ground truth values during training is measured as loss, which is shown graphically, and iteratively evolves over time for the hybrid deep learning architecture. As the model is trained, the loss curve shows how the architecture is coming together to minimize mistakes and enhance its capacity to precisely recognize and localize fine-grained objects in challenging real-world circumstances.

ROC Curve: In binary classification tasks, a graphical depiction known as the Receiver Operating Characteristic (ROC) curve is frequently used to assess how well a machine learning model is doing. As the discriminating threshold for distinguishing positive and negative occurrences is changed, it demonstrates the trade-off between the TPR, also known as sensitivity or recall, and the FPR.

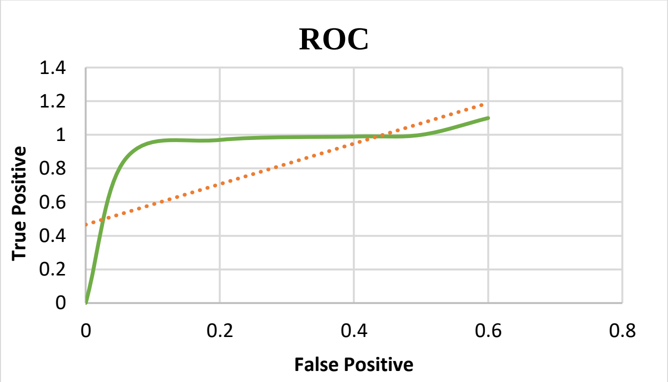

Fig. 6. ROC curve.

In Fig. 6, the best threshold for detection assessments is present; the ROC assesses the model's capacity to discriminate between the presence and absence of objects. ROC values over a certain threshold indicate a more precise object identification model. The true positive rate, also referred to as sensitivity or recall, is shown on the vertical axis, while the false positive rate is represented on the horizontal axis. The proportion of actual positive events that the classification model correctly identified is measured by the true positive rate, while the percentage of no object data that is incorrectly classified as an object is shown by the false positive rate. These rates for various classification thresholds, which specify the point at which the model classifies a data point as an event or a non-event, are plotted to create the ROC curve.

Matthews Correlation Co-efficient (MCC): The MCC is one of the most popular measures for classification effectiveness. It is generally recognized as a reliable estimate that may be used even when class sizes vary significantly. Eq. (19) contains the formula for the Matthews correlation coefficient.

$$MCC = \frac{T_P T_N - F_P F_N}{\sqrt{(T_P+F_P)-(T_P+F_N)(T_N+F_P)(T_N+F_N)}} \quad (19)$$

Negative Predictive Value (NPV): The subject-to-outcome ratio calculates the percentage of patients who have really poor test findings overall. The NPV measures the proportion of times each forecast was entirely wrong. Eq. (20) has the formula.

$$NPV = \frac{T_N}{T_N+F_N} \quad (20)$$

TABLE I. COMPARISON OF MCC AND NPV

Methods	NPV (%)	MCC (%)
RCNN	89.82	69.47
CNN	85.67	57.03
DNN	79.58	38.75
Hybrid DL-Attention Mechanism	**93.77**	**73.12**

Based on their NPV and MCC performance indicators, the various techniques are compared in Table I. The RCNN, CNN, DNN, and a hybrid deep learning (DL) model with an attention mechanism are the four techniques that are assessed. The comparison table's findings highlight the importance of the Hybrid DL-Attention Mechanism as a useful strategy for the assigned job, surpassing more established approaches like RCNN, CNN, and DNN in terms of NPV and MCC. The results highlight the rising significance of attention processes in deep learning by demonstrating their capacity to improve correlation metrics and prediction accuracy across a range of applications. It is shown in Fig. 7.

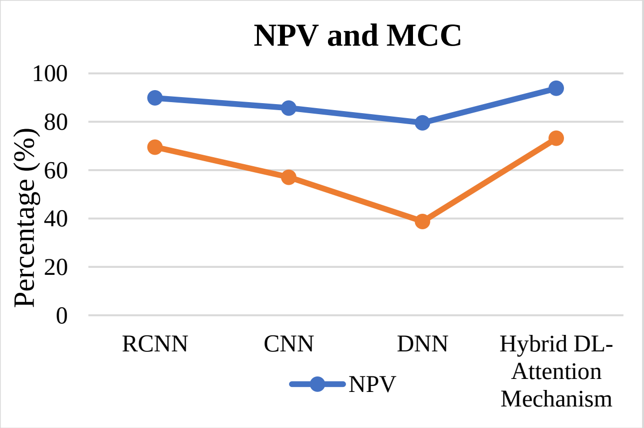

Fig. 7. Comparison of NPV and MCC.

False Positive Rate: The percentage of situations, where a favorable outcome was predicted but it did not materialize. It is illustrated in Eq. (21).

$$FPR = \frac{F_P}{T_N+F_P} \quad (21)$$

False Negative Rate: Eq. (22) displays the percentage of positive situations that were expected to be negative but ended up being positive.

$$FNR = \frac{F_N}{T_P+F_N} \quad (22)$$

TABLE II. COMPARISON OF FPR AND FNR

Methods	FPR (%)	FNR (%)
RCNN	10.17	20.35
CNN	14.32	28.64
DNN	20.41	40.82
Hybrid DL-Attention Mechanism	**3.51**	**4.44**

The contrast provided Table II highlights the FPR and FNR performance of the Hybrid DL-Attention Mechanism. The results highlight the potential of deep learning's attention mechanisms by showing how they may considerably improve the model's performance in tasks that call for striking a careful balance between reducing false alarms and missed detections. By demonstrating the advantages of attention processes in optimizing detection and classification models for practical applications, this research adds to the larger area of computer vision (see Fig. 8).

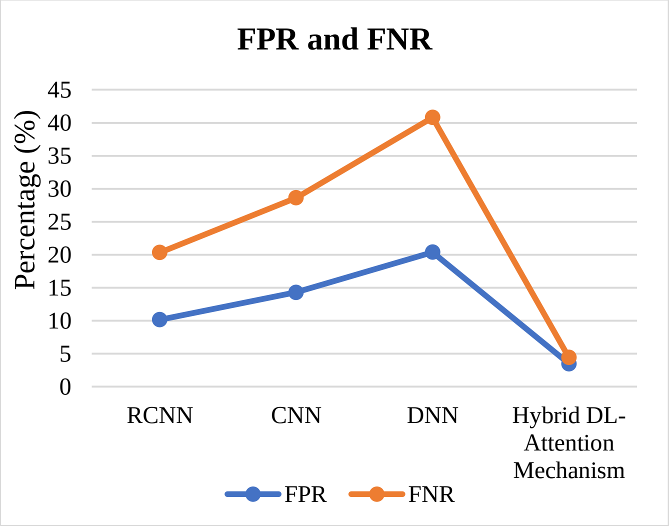

Fig. 8. Comparison of FPR and FNR.

Accuracy: Accuracy is used to evaluate the system model's performance as a whole. Every interaction can be properly foreseen is its central tenet. Eq. (23) provides the precision.

$$Accuracy = \frac{T_{Pos} + T_{Neg}}{T_{Pos} + T_{Neg} + F_{Pos} + F_{Neg}} \quad (23)$$

Precision: Precision also describes how closely two or more computations resemble one another in addition to being right. The link between precision and accuracy shows how often a judgment may be formed. Precision may be calculated using (24).

$$P = \frac{T_{Pos}}{T_{Pos} + F_{Pos}} \tag{24}$$

Recall: The percentage of all pertinent results that were effectively sorted by the procedures is known as recall. The suitable positive for such numbers is determined by dividing the genuine positive by the erroneous negative values. It is referenced in Eq. (25).

$$R = \frac{T_{Pos}}{T_{Pos} + F_{Neg}} \tag{25}$$

F1 Score: Accuracy and recall are combined in the F1-Score calculation. Eq. (26) computes the F1-Score using precision and recall.

$$F1 - score = \frac{2 \times precision \times recall}{precision + recall} \tag{26}$$

A comparison of many object identification techniques, including RCNN, CNN, DNN, and a hybrid DL architecture with attention mechanisms, is shown in Table III. Key performance indicators including accuracy, precision, recall, and F1-Score are used to assess these approaches. With an astounding accuracy of 99.66%, the hybrid DL architecture with Attention Mechanisms emerges as the most accurate technique. The accuracy, recall, and F1-Score values for this approach are also superior, coming in at 98.12%, 97.65%, and 96.54%, respectively. The outcomes highlight how combining attention mechanisms into a hybrid DL architecture has a substantial influence and leads in remarkable object detection performance. Overall, the evaluation's findings highlight the promise of cutting-edge strategies that make use of attention processes to improve object detection resilience and accuracy in difficult situations (see Fig. 9).

TABLE III. COMPARISON OF PERFORMANCE METRICS

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
RCNN	86.43	79.64	79.64	79.64
CNN	80.90	71.35	71.35	71.35
DNN	72.78	71.35	71.35	59.17
Hybrid DL-AM	**99.66**	**98.12**	**97.65**	**96.54**

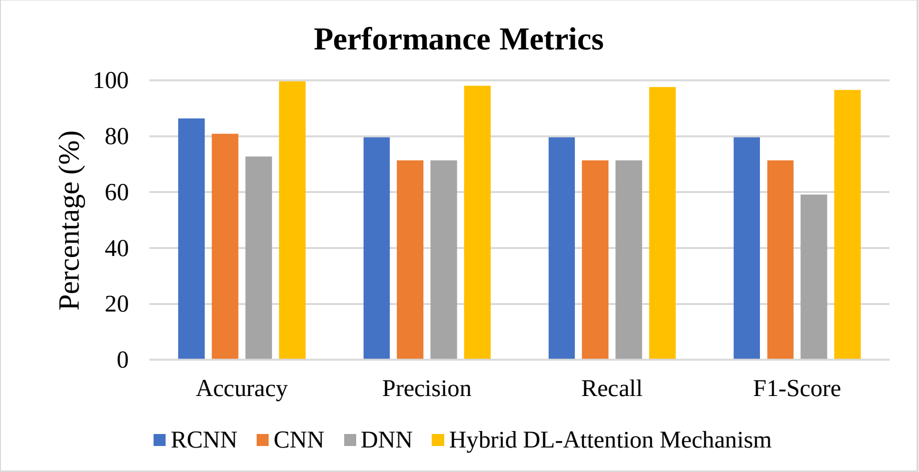

Fig. 9. Comparison of performance metrics.

VI. DISCUSSION

The paper addresses recent advances in computer vision, focusing on the application of deep learning algorithms for workplace safety, automated diagnostic frameworks for COVID-19 abnormalities [16], and plant segmentation. It also looks at navigational autonomy, proposing the use of 3D simulations in self-driving automobiles and Mask-RCNN for picture segmentation. The study also examines object detection and introduces SA-YOLOv3 for self-driving applications [21]. It also emphasizes the need of seamless visual classification through enhanced perception transformers. The study on facial expression recognition proposes the SqueezExpNet architecture [23], which efficiently solves real-world issues such as motion, obstacles, and lighting changes. The study emphasizes the ongoing advancement of computer vision techniques, as well as their potential influence on safety, healthcare, agriculture, autonomous systems, and other fields.

VII. CONCLUSION AND FUTURE WORK

This research examines the profound challenges associated with precise object localization and identification in complex real-world scenarios. The subject of computer vision has advanced significantly with the introduction of the new hybrid deep learning architecture. By integrating semantic and instance segmentation approaches with attention mechanisms to maximize their respective strengths, the strategy has demonstrated exceptional performance. Comprehensive tests and studies have clearly shown significant improvements over conventional methods in terms of precision, memory, and overall correctness. Among the notable achievements are the integration of CNN and BiLSTM for semantic segmentation and the astute use of attention processes in instance segmentation. The model can now find fine-grained objects with the maximum accuracy, even in dynamic and complicated real-world scenarios, thanks to these advancements. This discovery has extensive implications for many disciplines, including medical imaging, robotics, autonomous driving, and more, that depend on reliable and consistent object localization. With the increasing complexity of real-world environments, the hybrid design in conjunction with attention mechanisms has opened up new and intriguing possibilities to enhance the adaptability and reliability of computer vision systems. Further study in this hybrid design in several domains and situations is a potential avenue. Particular difficulties arise with applications in industrial automation, agriculture, and underwater research. More substantial advancements in computer vision could result from evaluating the architecture's resilience and flexibility under these conditions. This forthcoming study aims to scrutinize the versatility of the hybrid technique, exploring its capacity to redefine and revolutionize object localization across diverse real-world scenarios.

***Abstract*—As an infrastructure for urban development, it is particularly important to ensure the safe operation of urban rail transit. Foreign object intrusion in urban rail transit area is one of the main causes of train accidents. To tackle the obstacle detection challenge in rail transit, this paper introduces the CS-YOLO urban rail foreign object intrusion detection model. It utilizes the improved YOLOv5s algorithm, incorporating an enhanced convolutional attention CBAM module to replace the original YOLOv5s algorithm's backbone network C3 module. In addition, the KM-Decoupled Head is proposed to decouple the detection head, and SIoU is applied as the loss function. Tested on the WZ dataset, the average accuracy increased from 0.844 to 0.893 .The research method in this paper provides a reference basis for urban rail transit safety detection, which has certain reference value.**

Keywords—Railroad track intrusion detection; CBAM (Convolutional Block Attention Module) attention; activation function; decoupling probe; loss function

I. Introduction

The safety environment of urban rail transit is crucial for ensuring the safety of rail transit operations and the well-being of passengers.

With the gradual improvement of safety requirements in the urban rail transportation industry, the number of safety accidents in rail transportation has significantly reduced. However, due to natural and human factors leading to foreign object intrusion on railroad tracks, these incidents exhibit sudden and unpredictable characteristics. Relying solely on manpower cannot ensure comprehensive and timely detection. Therefore, it is necessary to establish a corresponding railroad track foreign object intrusion detection system for real-time monitoring of the running lines. This system aims to provide accurate alarm information to duty personnel, ensuring the safety of train operations. The detection of foreign object intrusions on urban rails has been a focal point of research, and an effective intrusion detection method for urban rail is of great significance for ensuring the overall safety of urban rail operations.

At present, there are two main methods for urban rail transit intrusion detection: contact detection and non-contact detection. Contact detection requires a large amount of hardware as a support and is troublesome to install, which is not easy to use on a large scale, and at the same time, when the equipment detects the intrusion of foreign objects it cannot be disposed of in time, which will seriously affect the safety of urban transportation. However, computer vision is an efficient non-contact intrusion detection method that is widely used in different transportation industries. It has the advantages of easy maintenance and intuitive results. However, the complexity and variability of urban environments and disturbances such as bad weather can lead to false alarm problems. Fortunately, with the development of deep learning algorithms, it has been possible to achieve high detection accuracy and reduce the false alarm rate to a certain extent. Deep learning algorithms excel at automatically learning complex features and patterns from large amounts of data, allowing computer vision systems to better distinguish between true intrusions and normal changes in the environment. However, deep learning algorithms are slow, take up a lot of memory, and require the support of a high-performance computer. There are many cameras in cities, but fewer cameras are used for intrusion detection in urban rail transit, and it is not practical to use a large number of high-performance computers. An efficient method for urban rail intrusion detection is needed in complex transportation scenarios.

II. Literature Review

Intrusion detection is an active research topic in the field of urban rail transit security. At present, some universities and research institutions in the United States are also conducting in-depth research in this area, such as the University of California, Berkeley, Yale University and so on. They have obtained more accurate and practical algorithmic models by introducing deep learning techniques and combining a large number of data sets for training, and target detection algorithms based on convolutional neural networks have come into being and have been gradually applied to a variety of urban environments, which are now broadly categorized into single-stage detection algorithms and two-stage detection algorithms. Common single-stage detection algorithms include RetinaNet [1], SSD [2] and YOLO [3] series. The algorithm regards localization and classification as a regression problem, realizes end-to-end detection, and has a faster detection speed, but its anchor mechanism based method [4], generates a large number of candidate frames in detection, and the number of candidate frames in which the target is detected is small. Common two-stage detection algorithms such as R-CNN [5], Fast R-CNN [6] have been widely used in this field. They aim to improve the detection performance by reducing the redundancy in the candidate frames generated by the anchor mechanism. Two-stage detection algorithms first screen out all positive samples and subsequently generate regions of interest (ROIs), and then in the second stage of these two-stage detection algorithms, the bounding frames generated in the previous stage are further

This work was supported in part by the Scientific Research Foundation of Jilin Province under Grant JJKH20230305KJ.

refined by performing region classification and positional adjustments on the regions of interest. The whole process requires iterative detection, classification and position refinement, and although two-stage detection algorithms tend to be slower compared to single-stage detection algorithms, they usually achieve higher detection accuracy. Zuoming [7] proposed a CNN model for road extraction that optimizes the extracted data to obtain comprehensive road features. Jiguang Dai [8] introduced a multi-scale CN N based road extraction method for remote sensing images. They used sub-image training model and combined it with residual linking to solve the resolution reduction and gradient vanishing problems in the extraction process. X. Zhang [9] developed a FCN network which utilizes a spatially consistent integration algorithm to determine the weights of the loss function used to extract the road regions. Xiangwen Kong [10] introduced a SM-Unet semantic segmentation network with a strip pooling module to enhance the road extraction performance. Hao Qi [11] proposed an MBv 2-DPPM model considering segmentation accuracy and speed. He and Ren [12] proposed a train obstacle detection method based on improved R-CNN. A new parallel upsampling structure and a context extraction module were added to the architecture to improve the accuracy of R-CNN to 90.6%. In order to enhance the ability to recognize small target objects, He [13] applied an enhanced Mask RCNN railroad obstacle detection method and proposed a new feature extraction network that incorporates a number of multiscale improvement techniques. The two-level target detection technique is the basis of the above method. Multiscale feature fusion by extending the sensitive domain and fusing shallow and deep features can improve the target recognition ability to some extent. However, real-time detection is not possible due to the area suggestion network. Zhang [14] proposed a high speed rail intruder detection algorithm based on YOLOv3 network. By improving this algorithm with FPN structure and extracting features with switchable hollow convolution, the false alarm rate of target detection is reduced, but the frames per second (FPS) is low, which does not satisfy the requirement of real-time detection. Literature [15] proposed a lightweight adaptive multi-scale feature fusion target detection network based on YOLOv3 to improve the performance of small target detection in complex environments, but there is a leakage detection phenomenon for occluded objects Literature [16] proposed a traffic sign recognition algorithm based on YOLOv5, comparing the detection results of the current common algorithms for the traffic signs. Overall, YOLOv5s algorithm performs better and faster in urban track detection. However, there are still some challenges, such as dealing with complex traffic situations in the city and enhancing the detection speed of the model, so the yolov5s algorithm model is chosen as the experimental base model and improved.

This paper proposes an improved method for foreign object intrusion detection in urban rail transit using YOLOv5s network as the base network. The method is designed to meet the need for real-time and accurate detection in urban rail transit environment. The YOLOv5s network model consists of several parts including Input, Backbone, Feature Fusion, Neck and Head. To enhance the input data, a mosaic [17] data enhancement method is used at the Input. This technique randomly selects four images from the image library and then rearranges them to generate a new image. By using the mosaic technique, the YOLOv5s network can benefit from the increased variation and diversity in the training data, which helps to improve its performance in object detection tasks; the proposed method also includes an improvement to the channel attention mechanism used in the CBAM [18] module. This improvement yields a new attention mechanism module called SCBAM. The SCBAM module aims to enhance the information interaction between different channels, further improving the network's ability to capture relevant features and improving the overall performance of tasks such as object detection. The proposed SCBAM convolutional attention module replaces the original C3 module, which effectively improves the model's ability to specifically characterize and recognize small target objects. Three detection layers are used in the YOLOv5s detection head [19], which are responsible for predicting large, medium and small targets, respectively. In addition, the network structure, output characterization method and boundary regression loss function of the YOLOv5s architecture were modified to improve its performance. These modifications aim to reduce the false detection and leakage rates in urban rail transit intrusion detection. By enhancing the feature extraction capability of the algorithm, the improved YOLOv5s network architecture provides more accurate and reliable detection results for long-range and small intrusion objects.

III. CS-YOLO Algorithm

A. *YOLOv5s Structural Model*

YOLOv5s target detection framework has a great performance advantage in large and medium-sized target detection, with real-time monitoring speed up to 140 fps and relatively high recognition accuracy. YOLOv5s consists of 3 main parts: backbone network, bottleneck layer and detection head, and the model structure is shown in Fig. 1.

1) Backbone network: The YOLOv5s algorithm combines the C3 and SPPF modules to enhance its performance. The C3 module focuses on reducing computation and increasing inference speed, optimizing the model's efficiency. On the other hand, the SPPF [20] module conducts multi-scale feature extraction on a single feature map, contributing to improved model accuracy. By leveraging these modules, the enhanced YOLOv5s algorithm achieves a balance between computational efficiency and accurate object detection. This makes it well-suited for various applications requiring real-time, precise recognition, and tracking of objects, thereby enhancing detection accuracy and speed for small and medium-sized objects on the track. C3 contains three standard convolutional layers and several bottleneck modules, the number of which is determined by the configuration file. The number of bottleneck modules is determined by the product of the n and depth_multiple parameters of YAML.C3 is the main module for learning the residual features and is divided into two branches, one using the specified bottleneck layer and three standard convolutional layers, and the other passing through only one of the basic convolutional modules, and finally the two branches are merged. After the Concat operation, the activation function in the standard convolution module is SiLU. This is a function that applies the Sigmoid linear unit by *elements, which is* characterized as take-anywhere, continuous, and smooth, not a monotonic function, and is suitable for representing nonlinear features. The principle of the SPPF module is basically the same as that of spatial pyramid pooling [21] but uses a different design of pooling kernels. SPP uses 4 pooling kernels by default in YOLOv5s: 5×5, 9×9, 13×13, and 1×1. SPPF uses two pooling kernels by default in YOLOv5s: 5×5 and 1×1.Spatial pyramid pooling allows fusing feature maps at different scales and in the SPP layer Apply different pooling operations to multiple scales to capture information from different receptive fields. By pooling features at different scales, the SPP layer increases the perceptual field of the network, allowing it to efficiently process inputs of different sizes. This approach allows the network to process inputs of various sizes without the need to resize or crop the image to a specific size beforehand. The SPP layer enhances the flexibility and adaptability of the network in processing inputs of different resolutions.

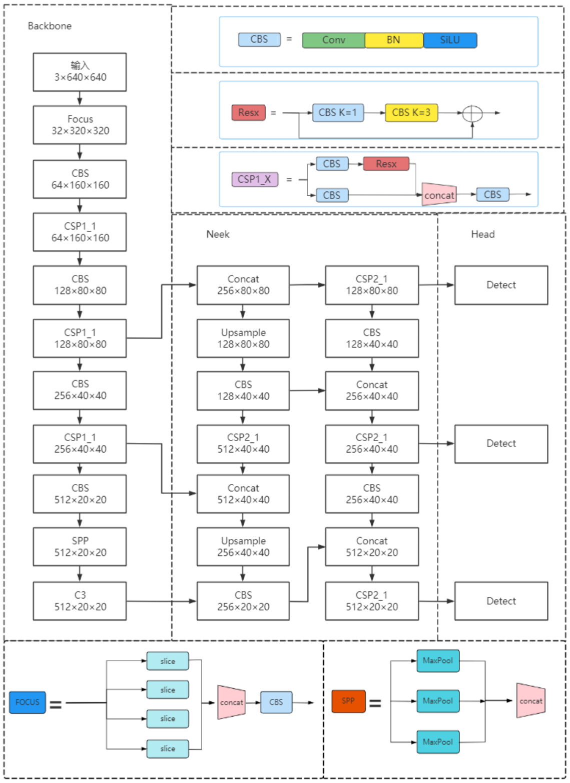

Fig. 1. YOLOv5s algorithm structure diagram.

2) Neck network: The YOLOv5s algorithm contains two key components, the Feature Pyramid Network (FPN) [22] and the Path Aggregation Network (PAN) [23]. The FPN utilizes a feature pyramid structure to integrate high-level semantic information with low-level features. This allows semantic knowledge to be passed top-down within the network. By combining the high-resolution details of low-level features with the contextual understanding of high-level features, FPN enhances the overall semantic representation of the network. On the other hand, PAN facilitates bottom-up transfer of localization information so that low-level information is propagated to higher levels in the network. PAN achieves this by fusing feature information from feature maps of different sizes. By integrating FPN and PAN, the YOLOv5s algorithm benefits from the transfer of semantic information and the effective utilization of multi-scale features. By integrating FPN and PAN, the YOLOv5s algorithm benefits from both the delivery of semantic information and the effective utilization of multi-scale features.

3) Head networks: The head networks as the detection part of the model and is mainly used to predict objects of different sizes from the extracted multi-scale feature maps. The output anchor frame mechanism extracts a priori frame scales by clustering and constrains the location of the prediction boundaries. The first is an 8-fold downsampled output with respect to the input image, which has a small perceptual range, preserves low-level high-resolution features, and facilitates the detection of small objects. The second is a 16-fold downsampled output with respect to the input image, which has a medium perceptual range and is suitable for detecting medium objects. The third is an output downsampled 32 times with respect to the input image, which has a large perceptual range and is suitable for detecting large objects.

B. *Improved CBAM-based Attention Mechanism Module*

The CBAM module is an attention mechanism that enhances spatial [24] and channel [25] attention while minimizing parameters. Its performance in classification detection on public datasets has shown improvement. However, when applied to the urban railroad track intrusion detection dataset in this paper, challenges arise. These challenges include a greater variety of vehicle classifications, a scarcity of samples, and the presence of vehicles with similar features. Consequently, the classification detection performance falls short of achieving the anticipated results. Fig. 2 illustrates the structure of the CBAM module.

The original channel attention mechanism employed global pooling operations, which included average pooling and maximum pooling on the input feature map along the width and height dimensions. These pooling operations aggregated information from all spatial locations within each channel. Following pooling, the generated features underwent processing through a multilayer perceptron (MLP). The MLP performed element-wise operations [26] to learn the importance weights for each channel. Finally, the output of the MLP passed through the Sigmoid [27] activation function to generate the final channel attention feature map. The Sigmoid function maps the values to a range between 0 and 1, representing the importance or activation level of each channel. In summary, the original channel attention mechanism comprises a pooling operation, an MLP for weighting, and a Sigmoid operation that produces the final channel attention feature map.

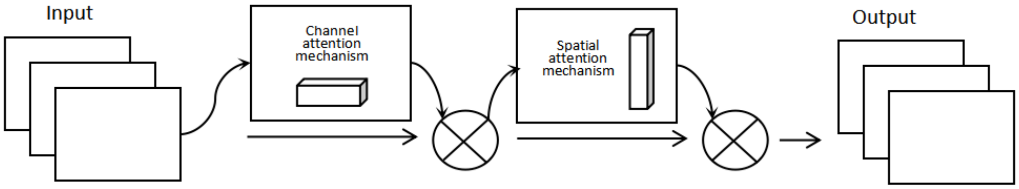

Fig. 2. CBAM structure diagram.

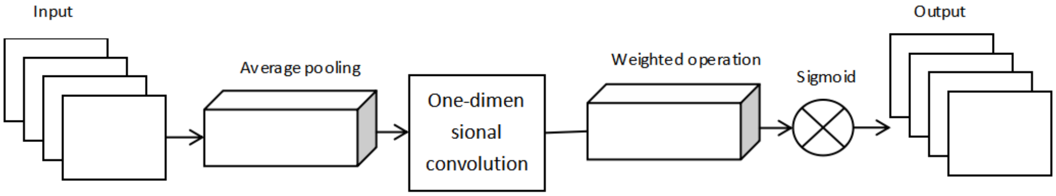

Fig. 3. SCAM structure diagram.

When information in the channel is globally and maximally pooled, this operation tends to neglect information interaction within the channel. In this paper, this paper optimizes and enhances the channel attention component of CBAM by discarding the maximum pooling operation. Instead, this paper represent the compressed features by aggregating the spatial information of the feature map through the average pooling operation. Drawing inspiration from the concept of ECA [28], this paper replaces the MLP network with a one-dimensional convolution operation in the improved version of the channel attention mechanism. Following one-dimensional convolutional processing, the ability to interact information between different channels is strengthened, and the output is subsequently simplified by a sigmoid function. In summary, as illustrated in Fig. 3, the improved channel attention module (SCAM) achieves local cross-channel interaction information of size K. This enhancement boosts the model's feature extraction capability, particularly for small and medium-sized objects.

C. *KM-Decoupled Head*

When recognizing targets on urban tracks, the task becomes more challenging due to the presence of multiple types of targets. To address this challenge and enhance the accuracy of localization and classification, this paper introduces a decoupled detection head known as KM-Decoupled Head. The primary idea behind this approach is to separate the feature channels for localization and classification tasks, specifically for bounding box coordinate regression and object classification. This decoupling enables a more precise estimation of bounding box coordinates, ultimately improving localization accuracy. Additionally, it ensures that the features used for classification are less influenced by changes in the localization task, leading to improved object classification. In essence, the goal of KM-Decoupled Head is to enhance target prediction in scenarios involving multiple types of targets and occluded targets. By decoupling the feature channels used for localization and classification, it enhances the accuracy of both tasks, resulting in more efficient target identification on urban tracks.

As illustrated in Fig. 4, the KM-Decoupled Head, a decoupled detection head, follows a specific process. First, a 1×1 convolution [29] is applied to the input feature map to reduce the number of channels and parameters generated. Subsequently, the output feature map is split into two branches to address the classification and localization tasks separately. For the classification branch, features are extracted using a 3×3 deep convolution [30]. The number of channel bits in the feature map is then adjusted to match the predicted number of target categories through a 1×1 convolution. On the other hand, the localization branch also employs a 3×3 deep convolution for feature extraction. After feature extraction, the resulting feature map is divided into two parts. One part predicts the center coordinates of the bounding box, along with the height and width of the bounding box. In summary, the KM-Decoupled Head employs a 1×1 convolution to reduce the number of channels and subsequently splits the feature map into separate branches for classification and localization tasks. The classification branch adjusts the feature map channels based on the predicted target categories, while the localization branch predicts the bounding box coordinates and confidence scores for target identification.

The decoupled structure of the KM-Decoupled Head offers several advantages over the coupled detector head, which integrates multiple types of information into a single feature map. Firstly, the decoupled design effectively avoids potential conflicts between different task requirements, thereby enhancing localization and classification capabilities. By separating the feature channels for each task, the model can focus on learning distinct representations for precise localization and accurate classification. Secondly, the decoupling head preserves information in each channel through depth and breadth operations, ensuring that valuable information is not weakened or diluted during processing steps. Additionally, this approach helps reduce computational complexity, thereby accelerating network convergence. Finally, due to the depth and breadth operations, the decoupling head achieves faster inference. In conclusion, the decoupled structure of the KM-Decoupled Head improves localization and classification by mitigating conflicts, effectively preserving channel information, reducing computational complexity, and achieving faster inference speed through depth and breadth operations.

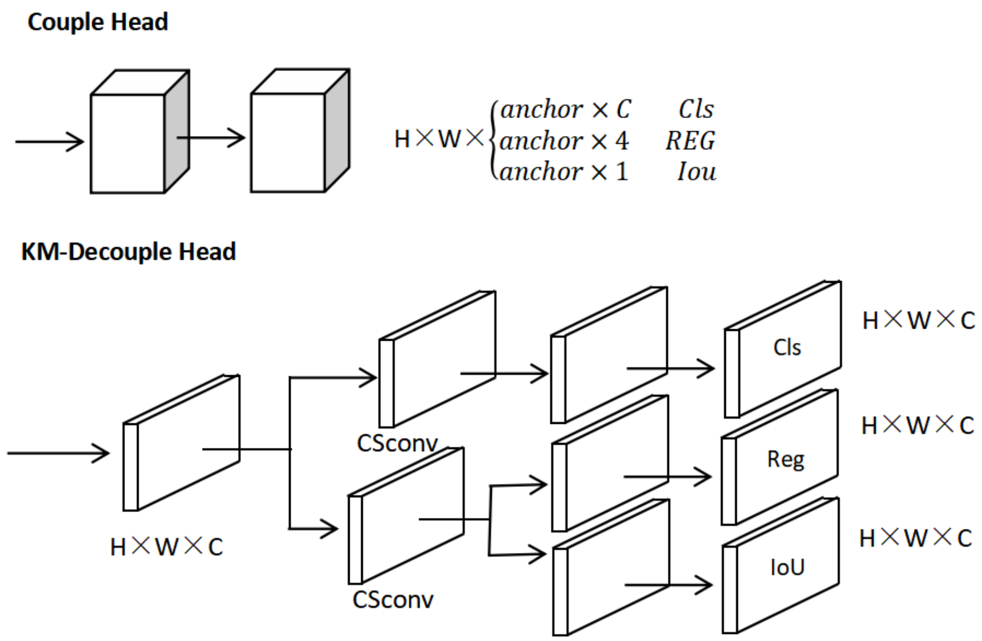

Fig. 4. Coupling head with KM-decoupled head.

D. *Loss Function SIoU*

The loss function in the YOLOv5s model is CIoU[31] :

$$L_{CIoU} = 1 - IoU + \frac{(b，b^{gt})p^2}{c^2} + \alpha v \tag{1}$$

$$v = \frac{4}{\pi^2}\left(\arctan\frac{w^{gt}}{h^{gt}} - \arctan\frac{w}{h}\right)^2 \tag{2}$$

$$\alpha = \frac{v}{(1-IoU)+v} \tag{3}$$

where IoU is the ratio of the intersection and union of the predicted and actual frames, b represents the center of the predicted point, b^{gt} represents the center of the actual frame, p denotes the Euclidean distance, c denotes the length of the diagonal of the bounding box formed by the predicted frame and the actual frame, α represents the weighting coefficient, and v represents the difference in the aspect ratio of the predicted frame and the actual frame.

CloU does not consider the direction of mismatch between the actual frames and the predicted frames, leading to slower convergence and lower efficiency. Therefore, we introduce a more balanced loss function, SloU [32], which increases the vector angle between regressions. We also redefine the cost function (penalty indicator), effectively reducing the degrees of freedom of regression, speeding up the convergence of the network, and further improving the accuracy of regression. SloU consists of four cost functions.

- Angle_Loss Angle_Cost minimizes the number of variables associated with distance. The formula is:

$$\lambda = 1 - 2 * \sin^2\left(\arcsin\left(\frac{c_h}{\sigma}\right) - \frac{\pi}{4}\right) \tag{4}$$

where σ is the distance between the center point of the real frame and the predicted frame, and ch is the height difference between the center point of the real frame and the predicted frame.

- Distance_LossDistance_Cost explores the distance of different bounding boxes at different centers as much as possible. The formula is:

$$\Delta = \sum_{t=x，y}(1 - e^{-\gamma pt}) \tag{5}$$

$$p_x = \left(\frac{b^{gt}_{c_x} - b_{c_x}}{c_w}\right)^2，\ p_y = \left(\frac{b^{gt}_{c_y} - b_{c_y}}{c_h}\right)^2 \tag{6}$$

"cw" and "ch" refer to the width and height of the minimum bounding rectangle of the actual box and the predicted box, respectively. "$b^{gt}_{c_x}$" and "$b^{gt}_{c_y}$" represent the coordinates of the center of the actual box, while "b_{c_x}" and "b_{c_y}" represent the center coordinates of the predicted frame.

- The shape loss Shape_Cost represents the deviation of the center of the predicted frame from the center of the real frame in an effort to obtain the optimal predicted frame. The formula is:

$$\Omega = \sum_{t=w，h}(1 - e^{-w_t})^\theta \tag{7}$$

$$\omega_w = \frac{|w - w^{gt}|}{\max(w，w^{gt})} \tag{8}$$

$$\omega_h = \frac{|h - h^{gt}|}{max(h，h^{gt})} \tag{9}$$

"w" and "h" represent the width and height of the predicted box, while "wgt" and "hgt" represent the width and height of the actual box,θ is the degree of concern for shape loss.

- Iou_Cost is the ratio of the intersection and the concatenation between the predicted and real boxes. The formula is:

$$\mathrm{IoU} = \frac{|B \cap B^{GT}|}{|B \cup B^{GT}|} \tag{10}$$

- the regression loss function SIoU is:

$$\mathrm{Loss}_{\mathrm{SIoU}} = 1 - \mathrm{IoU} + \frac{\Delta + \Omega}{2} \tag{11}$$

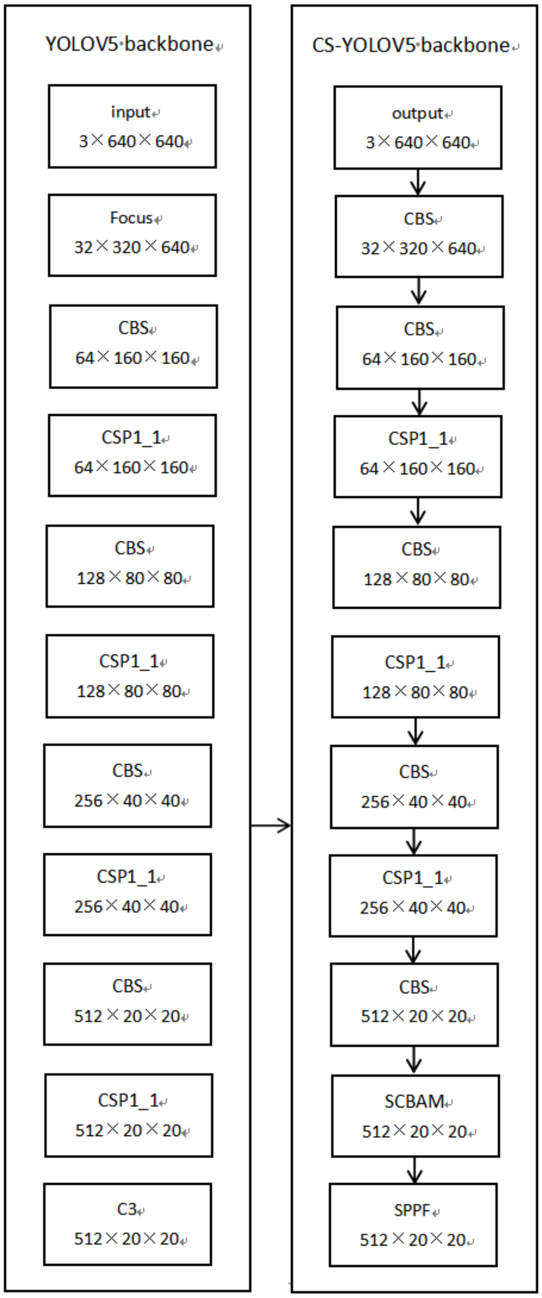

Fig. 5. Improved YOLOv5s backbone network.

E. Backbone Network Improvement

The enhanced SCBAM attention mechanism module replaces the original C3 module in the YOLOv5s backbone. It strengthens inter-channel information fusion using the channel attention mechanism and improves inter-channel information fusion through the spatial attention mechanism. The spatial attention mechanism is focused on detecting the target's location. By combining these two mechanisms, the output information becomes more concentrated on key features, enabling the model to prioritize important features during target detection. This enhances the feature extraction capability and ultimately improves the model's accuracy in detecting objects of various sizes. Additionally, this paper replaces the Focus slicing operation with a 6x6 convolution and substitutes the SPP module with the SPPF module to address the speed issue caused by parallel operations in the original model. The enhanced backbone network diagram is illustrated in Fig. 5

IV. Experimental Analysis

A. Experimental Environment and Parameter Settings

The specific experimental environment is shown in Table I.

TABLE I. EXPERIMENTAL ENVIRONMENT

Configuration name	Version/parameters
Operating system	Windows 11
Video storage	16GB
GPU	RTX4050
Memory	64GB
Python	3.7
Deep learning framework	pytorch1.11.0

During training, the network is trained using the SGD optimizer with an initial learning rate of 0.2. The learning rate is adjusted using the cosine annealing strategy. The batch size is set to 16 and the training process is performed for a total of 300 epochs.

B. Experimental Data Set

To assess the superiority of the improved target detection algorithm proposed in this paper, experiments were conducted on urban rail foreign object intrusion using the custom dataset, WZ-dataset.

As there is no publicly available dataset for foreign objects intruding on tracks in cities. This article develops a new dataset WZ-dataset. This dataset comprises 10 common types of foreign objects that may intrude on urban rail tracks, including pedestrians (person), bicycles (bike), electric bicycles (ebike), three-wheeled vehicles (tricycle), bottles, bags, cars, buses, trucks, and books. The WZ-dataset contains a total of 2,000 images, distributed across training, validation, and testing sets in an 8:1:1 ratio. Specifically, there are 1,600 images in the training set, 200 images in the validation set, and 200 images in the test set. The image size is consistently maintained around 600×800 pixels. To ensure a balanced sample size, each type of target is evenly distributed. The CS-YOLO algorithm model proposed in this paper is trained using the training and validation sets of the WZ-dataset (see Fig. 6). The model's performance is then evaluated by measuring the final average accuracy and detection speed on the test set.

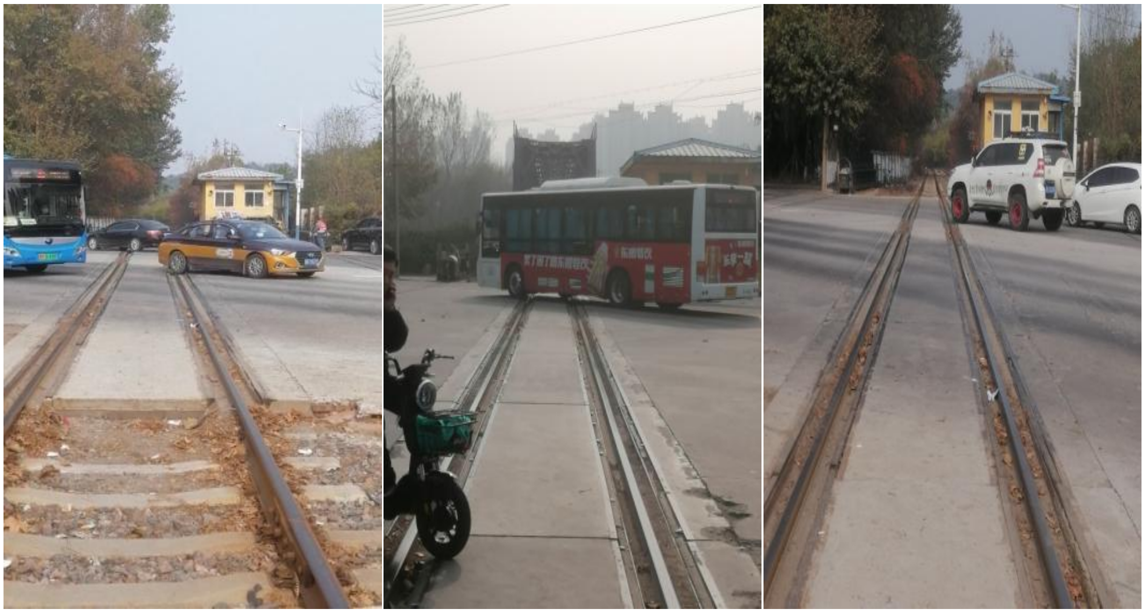

Fig. 6. Example of WZ dataset.

C. Performance Index

The performance metrics, including Precision (P), Recall (R), Mean Accuracy (mAP), Parameters, Inference Time per Image, and Frames per Second (FPS), are utilized in the experiments to evaluate the proposed algorithm's performance. The calculation formula for these performance metrics is as follows:

$$\mathrm{Precision} = \frac{\mathrm{TP}}{\mathrm{TP+FP}} \tag{12}$$

$$\mathrm{Recall} = \frac{\mathrm{TP}}{\mathrm{TP+FN}} \tag{13}$$

$$\mathrm{mAP} = \frac{\sum_{\mathrm{i=1}}^{\mathrm{N}} \mathrm{AP_i}}{\mathrm{N}} \mathrm{AP} = \int_0^1 \mathrm{P(R)dR} \tag{14}$$

$$\mathrm{FPS} = \frac{\mathrm{TotalTime}}{\mathrm{NumFigure}} \tag{15}$$

When evaluating object detection models, TP refers to true positives, representing instances where the model predicts correctly. FP stands for false positives, indicating instances where the model predicts incorrectly. Average Precision (AP) measures the area under the precision-recall curve, offering a comprehensive evaluation of the model's performance at various thresholds concerning both precision and recall. AP calculates the average precision for each category, and Mean Average Precision (mAP) is the average of the APs across all categories. mAP provides an overall assessment of the model's performance across multiple object categories. mAP0.5 represents the average precision calculated at an IoU threshold of 0.5, considering a bounding box prediction correct if the Intersection over Union (IoU) is greater than or equal to 0.5. For mAP0.5:0.95, average accuracy is calculated across IoU thresholds ranging from 0.5 to 0.95 in steps of 0.05. Frames per Second (FPS) represents the number of images processed and detected by the network model per second. It reflects the speed and efficiency with which the network model performs object detection. A higher FPS value indicates that the model can process images more quickly, enabling real-time or near real-time applications.

D. Experimental Analysis of SCBAM Attention Module

The SCBAM (Spatial and Channel Bottleneck Attention Module) is an enhanced version of the CBAM (Convolutional Block Attention Module). This paper aims to assess the effectiveness of the SCBAM attention module through five sets of comparative experiments on the WZ dataset. The experimental results presented in Table II demonstrate the efficacy of the SCBAM attention module. On the WZ dataset, the average accuracy mAP0.5 improved by 3.4%, and mAP0.5:.95 improved by 6.3%. Importantly, these enhancements were achieved while maintaining good detection speed, ensuring real-time detection performance. These findings strongly support the effectiveness of the SCBAM attention module proposed in this paper.

TABLE II. COMPARISON TESTS OF DIFFERENT ATTENTION MECHANISMS ON THE WZ DATASET

Method	mAP@0.5	mAP@0.5:.95	FPS
Baseline	0.844	0.532	85
+SENet	0.856(+1.2)%	0.556 (+2.4)%	77
+CA	0.865 (+2.1)%	0.505 (-2.7)%	90
+ECA	0.867 (+2.3)%	0.574 (+4.2)%	73
+CBAM	0.872 (+2.8)%	0.587 (+5.5)%	83
+SCBAM	0.878 (+3.4)%	0.595 (+6.3)%	91

E. Ablation Experiments

CS-YOLO is an enhanced version of the YOLOv5s network model, featuring improvements in various aspects, including the attention mechanism, output characterization method, backbone network, and bounding box regression loss function. In this paper, a series of ablation experiments are conducted to assess the impact of the proposed modules on the algorithm's performance. These experiments analyze the performance optimization achieved by individual modules, as well as the combined effect when different modules are introduced in different orders. The objective is to determine the effectiveness and contribution of each module in enhancing the overall performance of the algorithm. The results of the ablation experiments are presented in Table III.

This paper introduces three improved methods incorporated into the YOLOv5s network model (indicated by a checkmark in Table III). These methods enhance the detection accuracy on the WZ dataset to varying degrees. The CS-YOLO algorithm proposed in this paper achieves a detection speed of 78 FPS, outperforming the original YOLOv5s algorithm. On the WZ dataset, this algorithm demonstrates a 4.9% improvement in mAP0.5 and an 8.9% improvement in mAP0.5:95. Experiments conducted on the WZ dataset validate the effectiveness of the proposed algorithm in urban rail transit detection. These experiments showcase the algorithm's capability to address the challenge of foreign object intrusion detection in complex urban rail transit environments.

F. Comparison Experiments

Table IV in this paper presents experimental results comparing the CS-YOLO algorithm with several other existing algorithms on the WZ dataset. The compared algorithms include the original YOLOv5s, SSD, Faster R-CNN, YOLOv3, YOLOv4-tiny, YOLOv4, YOLOv5m, YOLOX-tiny, YOLOX-S, YOLOv6-tiny, and YOLOv7-tiny. The experimental results comprehensively analyze the performance of the CS-YOLO algorithm in comparison with these popular algorithms. For detailed information about the experimental results and algorithm performance comparison on the RS dataset, please refer to Table IV in this paper.

The experimental results in Table IV demonstrate that the CS-YOLO algorithm proposed in this paper achieves higher detection accuracy on the WZ dataset compared to other mainstream algorithmic models. Notably, the parameters of the algorithm proposed in this paper are reduced by 130%, while the detection accuracy is improved by 2.7% compared to the YOLOv5m network with a similar structure. Although YOLOV4-tiny and YOLOv7-tiny exhibit higher detection speeds (111 FPS and 119 FPS, respectively), their detection accuracies are relatively low at 75.5% and 83.3%, making them unsuitable for complex urban rail transit environments. In conclusion, the CS-YOLO algorithm proposed in this paper demonstrates the highest detection accuracy while maintaining good real-time performance, offering a significant advantage over other algorithms under consideration.

TABLE III. CS-YOLO ABLATION EXPERIMENTS ON THE WZ DATASET

Group	SCBAM	KM-DHead	SIoU	mAP@0.5	mAP@0.5:.95	Parameters	FPS
1				0.844	0.532	7.1M	85
2	√			0.878 (+3.4)%	0.595 (+6.3)%	7.1M	91
3		√		0.878 (+3.4)%	0.553 (+2.1)%	7.4M	74
4			√	0.848 (+0.4)%	0.558 (+2.6)%	7.1M	94
5	√	√		0.884 (+4.0)%	0.590 (+5.8)%	7.4M	85
6		√	√	0.878 (+3.4)%	0.592 (+6.0)%	7.4M	80
7	√		√	0.881 (+3.7)%	0.589 (+5.7)%	7.1M	78
8	√	√	√	0.893 (+4.9)%	0.621 (+8.9)%	7.4M	78

TABLE IV. COMPARATIVE EXPERIMENTS OF COMMON ALGORITHMS ON THE WZ DATASET

Method	mAP@0.5(%)	mAP@0.5:.95(%)	Parameters(M)	Inference(ms)	FPS
YOLOv5s	0.844	0.532	7.1	11.3	85
SSD	0.865	0.639	100.2	23.1	55
Faster R-CNN	0.711	0.453	136.2	46.6	23
YOLOv3-spp	0.833	0.512	9.56	12.3	81
YOLOv4-tiny	0.755	0.502	5.9	10.9	111
YOLOv4	0.817	0.528	244.8	55.2	35
YOLOv5m	0.866	0.636	20.9	19.9	70
YOLOX-tiny	0.822	0.565	5.1	16.8	43
YOLOX-S	0.848	0.591	9.0	23.5	25
YOLOv6-tiny	0.866	0.611	15.0	22.5	81
YOLOv7-tiny	0.833	0.567	6.1	8.3	119
CS-YOLO	0.893	0.621	7.4	14.8	78

In this paper, the detection performance before and after the improvement is visually compared, as illustrated in Fig. 7. The comparison results demonstrate that the CS-YOLO algorithm exhibits excellent detection performance in both sets of images. The results further highlight that the CS-YOLO algorithm effectively addresses misdetection and omission issues when detecting fuzzy and small targets in complex urban rail backgrounds compared to the initial YOLOv5s algorithm. With an FPS of 78, the CS-YOLO algorithm achieves higher detection accuracy by more accurately identifying common foreign object features while maintaining real-time detection speed. This capability meets the need for real-time and accurate detection in complex urban rail scenes.

G. Analysis of Experimental Results

The accuracy recall curve of the initial YOLOv5s and CS-YOLO are shown in Fig. 8. The horizontal axis represents the recall rate, and the vertical axis represents precision. The inset box displays the detection precision for various common intruders, with the bolded blue line representing the average precision across all detection categories. Upon comparing the detection results of the two algorithms, it is evident that the CS-YOLO algorithm exhibits lower detection precision for tricycles and trucks compared to the initial YOLOv5s. However, it demonstrates higher detection precision for all other intrusions. The average accuracy is improved by 4.9% compared to the initial YOLOv5s algorithm, indicating the significance of the proposed improvements.

V. Conclusion

In this paper, we propose the CS-YOLO algorithm model for detecting foreign object intrusions in complex urban railways. The algorithm addresses the challenges of low accuracy and poor timeliness present in existing methods. Key enhancements include the introduction of the SCBAM attention mechanism module, replacing the original C3 module in YOLOv5s. Additionally, the algorithm features the KM-Decoupled Head decoupling head, utilizes SIoU as the loss function, and modifies the backbone network structure. In comparison to other mainstream target detection algorithms, This article improves the algorithm achieves superior detection accuracy, particularly in resolving issues of false positives and missed detections when dealing with concealed and small targets. Despite the enhanced accuracy, the algorithm maintains real-time detection speed, making it well-suited for detecting foreign objects on complex urban tracks. Future research should focus on optimizing the network for easier deployment on embedded GPU platforms, ensuring its applicability in real-world scenarios.

Students' Perception of ChatGPT Usage in Education

Irena Valova, Tsvetelina Mladenova, Gabriel Kanev
Computer Systems and Technologies, University of Ruse, Ruse, Bulgaria

***Abstract*—This research article delves into the impact of ChatGPT on education, focusing on the perceptions and usage patterns among high school and university students. The article begins by introducing ChatGPT, emphasizing its rapid user adoption and widespread interest. It explores the application of ChatGPT in various fields, including healthcare, agriculture, and education. A comprehensive survey involving 102 students, both high school and university, is detailed, covering aspects like familiarity with ChatGPT, reasons for usage, self-assessment of its effectiveness, and attitudes toward informing teachers about its use. The findings reveal varied perspectives on the benefits and challenges of incorporating ChatGPT in the learning process. The article concludes by emphasizing the need for careful consideration and integration of AI technologies in education, highlighting the risks of uncritical reliance on such tools and advocating for a balanced approach to foster students' critical thinking and intellectual growth.**

Keywords*—Artificial intelligence in education; assessment; ChatGPT; Generative Pretrained Transformer 3, GPT-3; higher education; learning, teaching; Natural Language Processing (NLP)

I. Introduction

ChatGPT is a language model (chatbot) created by OpenAI that allows humans to interact with a computer naturally. A chatbot is an application used to conduct a conversation through the exchange of text messages or text-to-speech between a human and a computer/machine. These are computer programs that can hold a conversation with a user in natural language, understand their intent, and respond based on predefined rules and data. Designed to convincingly simulate the way a human would behave as a conversation partner, chatbot applications typically require constant tuning and testing. While working they are self-educating and improving.

For many researchers and for high education itself, it is important to see how high-school students (in their final years of high school) and university students perceive the idea of using such chatbots in their studies. This article is an examination of the adoption of AI by the students – how they are using it, how frequently, what type of questions they ask it, to what degree they understand the answers, and how they implement them in their class assignments.

This article is the result of an analysis of a questionnaire given among 102 Bulgarian students. It presents the questions, their answers, and some thoughts about the results. While the survey was anonymous, the respondents are students, the authors, are teaching and therefore we have first-hand observations about their problem-solving skills and their thought patterns.

It is obvious that this type of AI is here to stay, and it is up to the universities how they will be able to adopt and use it. Conducting such surveys will help them to understand it better and apply it efficiently.

II. Literature Review

OpenAI is an artificial intelligence (AI) research and Implementation Company ensuring that general-purpose artificial intelligence benefits all of humanity. The company is dedicated to putting this alignment of interests first even before profit.

The definition of AI characterizes it as a branch of computer science that deals with the automation of intelligent behavior. The degree of intelligence is difficult to define, and therefore artificial intelligence cannot be precisely defined either. The term is used to describe systems that aim to use machines to emulate and simulate human intelligence and related behavior. This can be achieved through simple algorithms and predefined models, but it can also become much more complex.

ChatGPT (Chat Generative Pre-trained Transformer) was publicly presented in the summer of 2020 and launched in November 2022. It is an object of curiosity, controversy, and scientific interest among a wide range of Internet users from all ages and stages of life. Unlike search engines (such as Google, Bing, or Baidu), ChatGPT does not crawl the web for information about current events and information, and its knowledge is limited to things it learned before January 2022. It is the subject of many comments and discussions, from the fact that some analysts see it as a threat to some professions, to the fact that others believe that this technology is extremely successful and useful. Although this is not the first application based on artificial intelligence, it can be said that it is the most tested and has generated the most interest among users. The first million users were reached in just five days, which for other platforms took months and years (for example, Facebook reached a million users in 10 months in 2004). In just three months, ChatGPT users reached one billion (see Fig. 1), [https://www.tooltester.com/en/blog/ChatGPT-statistics/]. The first reactions are obviously to test and see how this brand-new technology works, and if it works. Almost immediately after testing, reasonable questions arise as to how useful and how dangerous such technology is. Many studies have analyzed the impact on different professions and business fields [1], and the impact on different fields of study [2] and industry [3].

In study [4], the authors conclude that the presence of various AI agents such as ChatGPT will change the context of higher education, but this will not be disruptive. It is very important to realize and assess this transformation promptly and to model it appropriately.

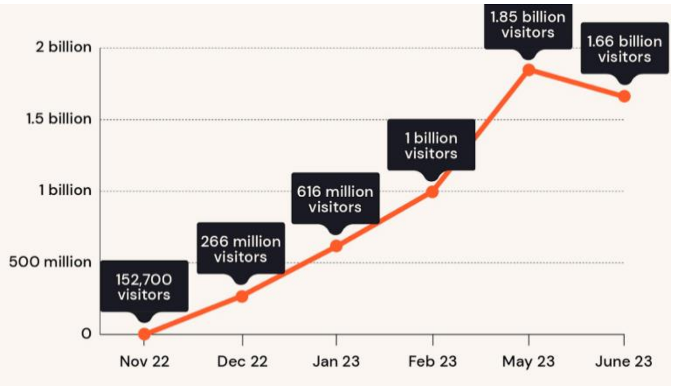

Fig. 1. ChatGPT visitors since release.

The impact of ChatGPT is examined in various fields, such as healthcare, medicine, and dentistry [5, 6]. Its impact and expectations in the field of agriculture and livestock breeding are also examined.

Today's agriculture uses various smart technologies and collects large volumes of data that can be used for crop forecasting, soil analysis, identification of crop diseases and pests, precision farming and irrigation planning, animal behavior analysis, and assessment of their condition. This can be helpful for businesses to make informed decisions and increase their profits. In study [7], the author investigates the potential positives and negatives of the application of chat GPT in agriculture. He provides examples of questions where ChatGPT can be useful in agriculture by analyzing and editing its answers. These are assessments of atmospheric conditions, soil, and air quality, diseases of different crops, and others. The author is noting the following points of ChatGPT usage that are valid for every other usage area:

- Strong dependence on data quality - if the data is inaccurate, biased, or incomplete - this will inevitably affect the responses from the agent;

- Lack of experience - ChatGPT is good at analyzing data but is not a specialist in any specific field and it is very important to have an experienced professional in the relevant field to interpret the model results and make the final decisions. The human factor cannot be avoided, and the specialists have the final say on the decisions.

Will it replace university professors or classroom teachers - this question is being asked more and more often. In research [8], the authors made a qualitative analysis based on a methodology for data collection, documentation, and drawing conclusions, which analysis shows that ChatGPT can only be a tool in training, and it is not possible to completely replace the trainer. It is more important to find an appropriate way to integrate technology into the learning process and, respectively, to develop the competencies of teachers in managing learning with such technologies.

Some researchers evaluate ChatGPT as an opportunity to increase the effectiveness of training and the motivation of students [9, 10, and 11] because the use of this new technology allows learning at an individual pace of the student and because students choose the direction of deepening their knowledge, they are much more motivated. ChatGPT provides personalized and interactive help, which engages more learners and develops self-learning skills.

It is natural to think in the direction of whether to allow or block access to ChatGPT in educational institutions [12] or whether to look for applications that detect if a given text is generated by ChatGPT. Before any measurements are taken it is interesting to see whether it is used and to what extent is used by the students.

The detailed analysis of the possibilities and limitations of ChatGPT made in [13, 14] shows that the use of this technology has great potential for application in the field of education, but it also comes with quite a few limitations and challenges. The use of ChatGPT, with all its positives and negatives, in training is in its very early stages and this assumes much more research in this area.

The results of the analysis of the use of ChatGPT in the different areas of higher education show a major problem in scientific writing [15]. Is it plagiarism to use text generated by ChatGPT and how to reference such text, what percentage of such text, relative to the total volume, is permissible in student and faculty scholarly publications are some of the topics examined by the author.

The study in [16] concluded that in the context of using ChatGPT in education, it should be noted that technology can only be a tool and cannot completely replace the role of the teacher. Therefore, it is necessary to integrate technology into learning appropriately and effectively and to develop the competence of teachers in managing learning with such technologies.

How can the use of such technologies be useful?

- Can be used to search for information and ask questions from different fields;

- Can provide help and explain different projects and problems in different areas;

- Can generate text - articles, program code, letters, poetry:

1) You can ask ChatGPT to write an article on any topic, specifying what tone or style to use - formal, casual, persuasive, descriptive, humorous, emotional, technical, and more.

2) Some programmers (IT students too) try to outsource the entire programming process to ChatGPT. It's not that this technology can't write good programming code, but it's still recommended to be used only as an additional tool in this area.

3) There is a free ChatGPT Writer extension for Gmail that can compose emails and messages by correcting grammatical errors, paraphrasing text, changing writing style, and summarizing text.

III. Problems when using ChatGPT and AI Technologies in Education

The main group of problems in the use of AI technologies in education is ethical and, more precisely, problems related to plagiarism. If the lecturer and the students have the opportunity to use similar technologies, what will stimulate them to express their position and their opinions? These technologies provide a faster and easier way to create texts on a given topic or to solve set problems or tasks. The students sort of overdo their homework and in this way, they don't acquire the habit of writing and expressing their thoughts, they don't reason, and they don't look for an explanation for the problems they are given to solve, they don't put any thought into it. They may not even read the condition of the given problem or tasks, but simply use the copy-and-paste functions and get the result.

How to make students understand that it makes sense to know the definitions from the learning material so that they can search for information, respectively ask ChatGPT. It is clear that in the modern conditions of Internet access, it does not make sense for them to learn by heart and reproduce a text, it is important to be able to solve problems and tasks and, above all, to learn to think.

The collective opinion that ChatGPT will lead to the extinction of certain professions and thus put many people out of work is relatively popular and shared among the vast majority of people. There is a fear that it will replace the programmers, and more specifically - the junior programmers. However, if it does replace them because it solves elementary tasks perfectly, where will seniors come from if they have not been junior programmers? How will the seniors be so good if they’ve missed the moment of programming elementary tasks - while they were studying at the university they missed it, and then there was no way to work as such.

ChatGPT can find applications in the learning process as an intelligent assistant. Its particular advantage is that it can provide learners with interactive help at any time and from any place. The authors in [10] specified the following guidelines in which the use of ChatGPT may be useful to students:

- Provide information and resources, answer questions, organize information, help prepare for exams, and provide feedback;
- Improve language skills - grammar, vocabulary, and style during communication with the agent, as well as use ChatGPT to check their written text for syntactic and grammatical errors;
- Provides a new interactive way of learning languages - without restrictions on when and where, and has opportunities to generate realistic dialogues in a chosen and interesting area for the learner; can exercise their foreign language skills if they communicate with him in a chosen foreign language;
- Improving cooperation and communication - if students work in a team, the use of ChatGPT stimulates communication between the participants in the teams and also between them and the teachers;
- Provide support and motivation - ChatGPT can also act as a means of support and motivation for students. They can use ChatGPT to talk about their problems and concerns or ask for advice on how to better manage their time and tasks.

It should be noted that ChatGPT is not the only natural AI agent that can understand and generate conversation in natural human language. In February 2023, Google introduced Bard, which follows the LaMDA model but has similar features and applications [17, 18]. Our research is focused on ChatGPT and therefore does not describe other similar solutions.

IV. Research Methods

A. Objectives and Contributions of the Experimental Research

The research aims to investigate the possibilities and extent of the use of ChatGPT by university students and final-year high-school students in the process of their education. Naturally, we consider all the risks and challenges of the unethical and illegal use of such tools in the learning process. The attitude of the students and their assessment of the capabilities of ChatGPT in the learning process are important because this would determine the use of these technologies in schools and universities. 102 surveyed students from the University of Ruse and students in the last year of Mathematical High School “Baba Ton-ka”, Ruse, Bulgaria took part in the research and focused on the place and role of ChatGPT as a potential source of knowledge and information for students and students. The main questions that are the aim of the study are:

R1: How familiar are the students with the capabilities of ChatGPT?

R2: What are the potential benefits and challenges associated with using ChatGPT in learning from the learner's perspective?

R3: Are students inclined to use ChatGPT in the university/school and what do they think they will achieve by using it?

R4: Can learners rate the responses received from ChatGPT?

B. Description of the Respondents

The total number of participants in the study is 102, students from the Computer Systems and Technologies specialty of the University of Ruse, Bulgaria, and students in the last year of Mathematical High School “Baba Tonka”, Ruse, Bulgaria, who, in addition to mathematics, study informatics and information technologies intensively (see Table I). It is important to specify the major of the students and the subjects they are studying since it is very likely that their IT orientation has some certain influence on the way they accept these new technologies, as well as their natural greater interest in them.

This group of students is chosen because they are students, we have direct observations on. These are students who we teach, thus allowing us to get to know them better.

TABLE I. DEMOGRAPHIC STATISTICS

	Demographic Stats		
	Possible Options	***Number***	***Percentage***
Gender	Female	44	43%
	Male	56	55%
	I don’t want to share	2	2%
Age	Under 19 years (primarily high-school students)	44	43%
	19-25 years	36	35.3%
	Over 25 years	22	21.6%

C. Data Collection

An anonymous survey was developed using Google Forms. It is distributed among students and pupils through email messages, social networks, and messages on online learning platforms used in the university and school.

The survey consists of 15 questions of different types.

The questions can be divided into groups according to the information we expect from them. The first group of questions concerned various demographics of the respondents and their possible knowledge and experience in using AI and ChatGPT. Another group of questions concerns the respondents' assessment of the benefits and harms of using such technologies, and the challenges of using them, and also a group of questions to assess the extent to which students can judge how true the answers to the chat GPT are. Questions with different types of answers were used - an open answer that requires entering the opinion of the respondent in a free text, multiple choice of one of all the indicated answers, and choice of several of many possible answers.

V. RESULTS

The first group of questions aims to answer the first research question - to assess the extent of knowledge and use of ChatGPT by the respondents. The results show that a very small percentage (13.7%) have not used ChatGPT at all, an equal number do not use it but have tried it and know what it is about. 21.6% regularly use it (see Fig. 2). In reality, only 13.7% of those polled don’t use and are not interested in ChatGPT that shows that the technology is familiar to the trainees.

It is interesting what the respondents mostly use this technology for according to the answers of the respondents to the question “What kind of problem did ChatGPT help you with?”, it was most used for research, during the development of projects in second place, and in third place for writing homework. An interesting fact from these answers is that it is also used during exams and 19% of the respondents state that it has helped them in some form during exams tasks and 17% of them - with answering exam questions. About a quarter still used ChatGPT to fill in ambiguities and gaps in their knowledge of the material they were studying.

Just over ⅓ of respondents rate ChatGPT as better than Google and other popular search engines, with almost half of them rating it not just better, but much better. Also, almost ⅓ don't care which is better, but rather getting an answer to their problem is important to them. A rather large percentage - 26.5% claim that they do not have any definite opinion on the subject, and for 14.7%, ChatGPT is in no way superior to search engines (see Fig. 3).

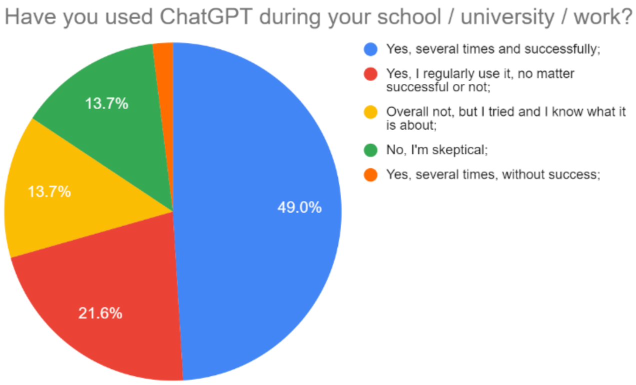

Fig. 2. Answers to "Have you used ChatGPT in your school/university/work?"

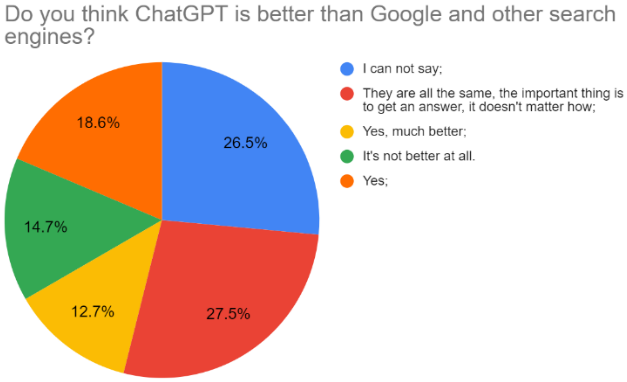

Fig. 3. Answers to “Do you think ChatGPT is better than Google and other search engines?”

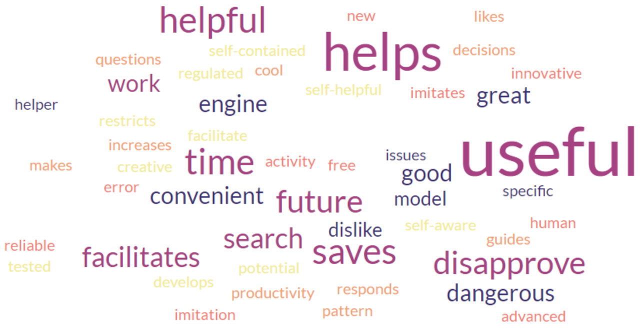

Fig. 4. Word cloud of users' opinions.

With this survey, we tried to find out what the respondents think about AI and ChatGPT and whether they think there is a difference between the terms by asking them to write in a few words their opinions. We summarized and evaluated the most frequently used phrases and words in the descriptions, and as can be seen in Fig. 4, they are aware of the differences between AI and ChatGPT, evaluating ChatGPT as a platform that uses AI. Most often rated ChatGPT as extremely useful, which they consider being the future of the field.

Regarding the second set of questions about the assessment of R3: Are students inclined to use ChatGPT in the university/school and what do they think they will achieve by using it?

As apparent from R1 the respondents surveyed have tried and used ChatGPT, it's not entirely new to them and some even have quite a bit of experience with it. We were interested to know if they were worried about having used the agent and what they think about the teaching knowing of their usage. A very large part of the respondents (53.9% do not see the point in sharing with the teacher the fact that they had to use this kind of help because they do not think it will improve the teaching or the content of the course and 15.7% are afraid to mention to the teacher, so as not to harm their final grade (see Fig. 5). In a small additional anonymous survey with ⅓ of respondents, regarding a specific homework assignment, 54.5% of participants admitted to using ChatGPT to write the source code implementing the assignment of the homework. 63.6% of the participants had to make corrections to the solution returned by ChatGPT, and the rest used it directly. 81.8% tested with different data and tried to fully verify the functionality of the returned code, and the rest admitted that they had not tested at all or attempted to test with any data, but rather trusted ChatGPT. These results show that trainees are coping and benefiting from using ChatGPT. It is worrying, however, that there are a considerable 20% who use it without thinking about the tasks set and the answers returned, and directly use them to pass them as a solution to homework.

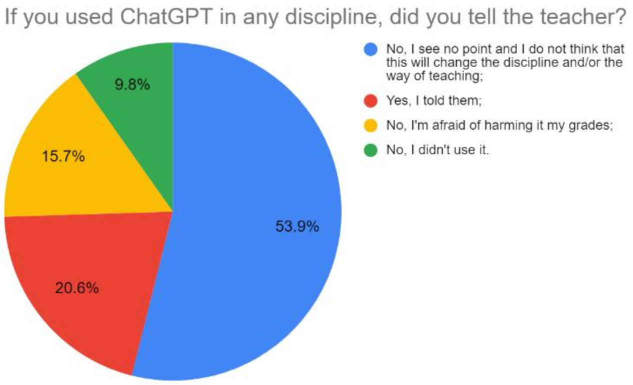

Fig. 5. Answers "If you used ChatGPT in any discipline, did you tell the teacher?"

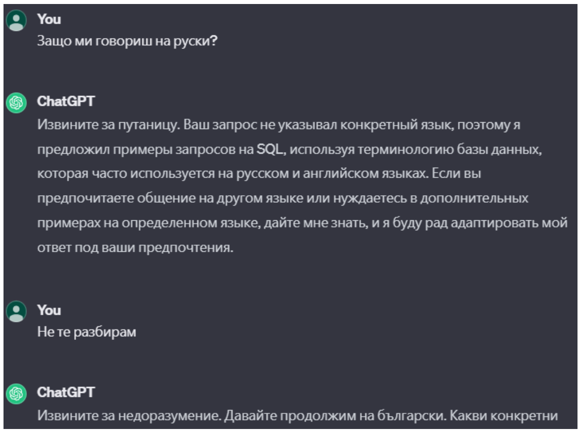
Another question in the survey gives an example of a small programming task that usually could be given as homework or in a workshop. The question itself states: “You have a task for finding the shortest path in a graph in C++…… Write the question that you would ask ChatGPT”. The answers vary from complete copy-paste of the text of the task to breaking down the steps they would take to explain their problem to ChatGPT and to paraphrase the question. Some of the most interesting answers are:

- “No question just ctrl + c and ctrl + v on the task, He understands it and if my ideas are different from his answer then I ask specific questions, but this is rarely necessary.”
- “I would like to give me the whole code so I can get the idea of how the algorithm works, then I'd try to write the code myself and if something doesn't work out I'd check from the already given answer.”
- “Make me a road map for all the algorithms for finding the shortest path in a graph, ranking them for me from good and used to not so much, taking into account speed, complexity, and all advantages.”
- “Write me some C++ algorithms that can find the shortest path in a graph from vertex A to vertex B.”
- “Algorithms for shortest path in a graph C++”.

It is interesting to note that from 102 answers, only 13 are in English. That gives the impression that the students are more willing to ask in their native language, in this case - Bulgarian, and receive the answers in the same language. While the ability of ChatGPT to understand and perceive different languages there are some cases where the agent is confused and thus susceptible to wrong answers. Fig. 6 shows a conversation with ChatGPT where the Bulgarian language is incorrectly recognized as Russian and the chat needs several interactions to understand and correct the problem.



You
Защо ми говориш на руски?

ChatGPT
Извините за путаницу. Ваш запрос не указывал конкретный язык, поэтому я предложил примеры запросов на SQL, используя терминологию базы данных, которая часто используется на русском и английском языках. Если вы предпочитаете общение на другом языке или нуждаетесь в дополнительных примерах на определенном языке, дайте мне знать, и я буду рад адаптировать мой ответ под ваши предпочтения.

You
Не те разбирам

ChatGPT
Извините за недоразумение. Давайте продолжим на български. Какви конкретни

Fig. 6. Screenshot of confused ChatGPT.

It is interesting to see if they need any additional guidance and pointers on how to use it if they are officially allowed to use AI agents. Only 8.8% felt they needed help at least in the beginning, and 66.7% would use it directly themselves without a problem (see Fig. 7).

Apart from whether they have used or would use it is interesting to see how they use ChatGPT and what types of questions they ask. The reason behind this is that a large proportion of the respondents have expressed their desire for copy able text assignments in the past. Students, and more specifically, the students who have responded to the survey, do not like assignments that are spoken and explained aloud. Here, it should be noted that the assignments in question, are simple tasks, meant to be done in the timespan of a workshop and not homework assignments.

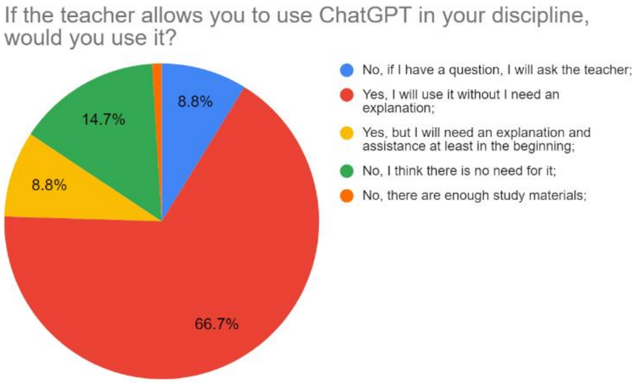


Fig. 7. Answers "If the teacher allows you to use ChatGPT in your discipline, would you use it?"

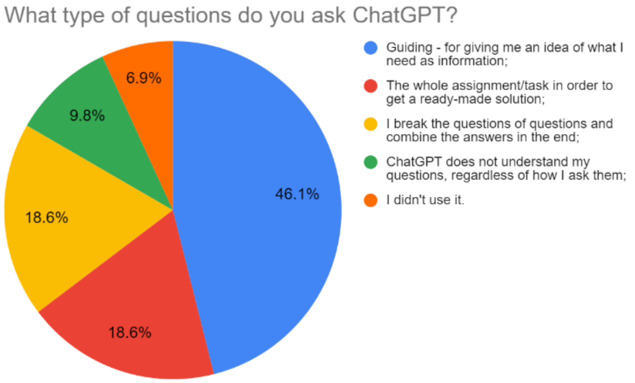

Fig. 8. Answers to "What type of questions do you ask ChatGPT?"

Pretty quickly it came as obvious to this attachment to the text format. Given an assignment with 10 tasks, some students produce the answers in less than five minutes, which under normal circumstances is impossible, as it is physically impossible to write a programming source code for such a short time. Upon close inspection of the provided answers, it is not difficult to notice that they are generated by AI, as some small details are not described in the assignments and are known by the lecturers. This whole situation is quite an obvious sign of ChatGPT usage.

Fig. 8 shows that according to the self-assessment of the respondents, 46.1% try to ask guiding questions to the agent to orientate themselves in the problem and the topic based on the answers received. Some of them (18.6%) try to break the assignment into separate problems, ask questions related to them, and then summarize and combine the information from the received answers. There are still 18.6%, who don't bother to think about the task they have and directly give it to ChatGPT to get the ready answer. There are also 10% of respondents who do not have much success using the chatbot because they cannot ask their questions in a way that it understands them correctly.

Regarding the received answers is shown in Fig. 9. 42.2% of the respondents used the chat just for pointers about their problem and the same percentage found mistakes in the answers that they corrected before submitting or using them. A relatively small percentage, but still a notable percentage – 8.8% directly used the received answers without any corrections. This raises the question about their ability and willingness to further check and dive into the problem. 6.9% answered that they had not used the solution provided by ChatGPT. While the percentage is small, it is interesting to find out why is– maybe the provided solution was not correct at all or was too complex to understand and implement, or they have just wanted to see and play around with the chat.

R4: Can learners rate the responses received from ChatGPT - According to the results shown in Fig. 10, 30.4% of respondents do not bother to check the answers received from the chatbot, with 24.5% trusting them completely. Almost 20% check each answer further, and 50% first consider whether the answer can be used and only then check it.

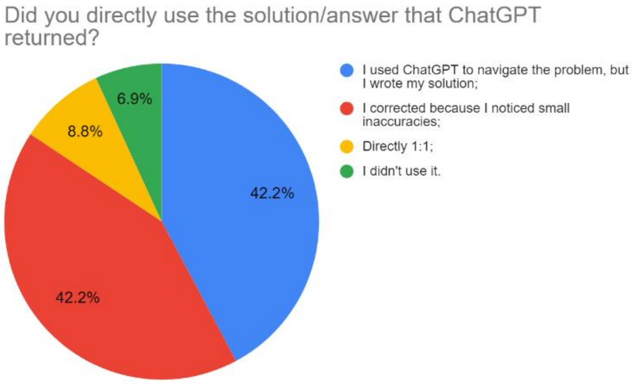

Fig. 9. Answers to "Did you directly use the solution / answer that ChatGPT returned?"

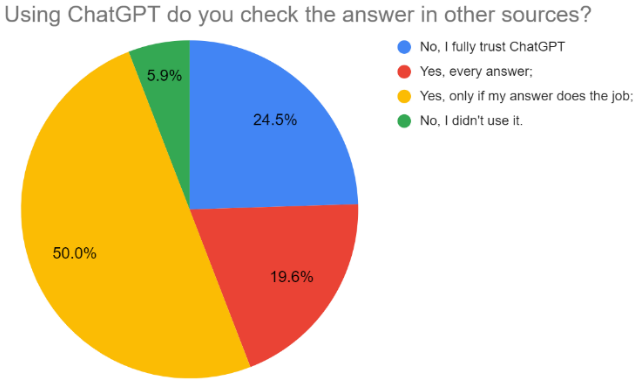

Fig. 10. Answers of "Using ChatGPT do you check the answer in other sources?"

To assess how the respondents think about the answers from the chatbot, a question in which two definitions are given for the same term (in this case it is a definition of a set). All participants are aware of the term and use it in the learning and programming process. They are given a definition of the concept that is popular in textbooks and a definition given by ChatGPT. Their task is to evaluate the two definitions. The received answers show that for the respondents it does not matter whether the definition will be strictly formulated (in this case, it is the second definition, the one from the textbooks) or it will be in a more descriptive form and with few examples (the first, from ChatGPT) - still for 38.2% the answer returned by ChatGPT is clearer and more understandable and they are more likely to trust it. For 31.4% the strictly theoretical versions is more understandable, and for 15.7% of the respondents, both are equally clear (see Fig. 11). What's worse is that for 14.7%, neither of the two definitions or explanations is comprehensible, and as we said - this is certainly something familiar to them, or at least should be.

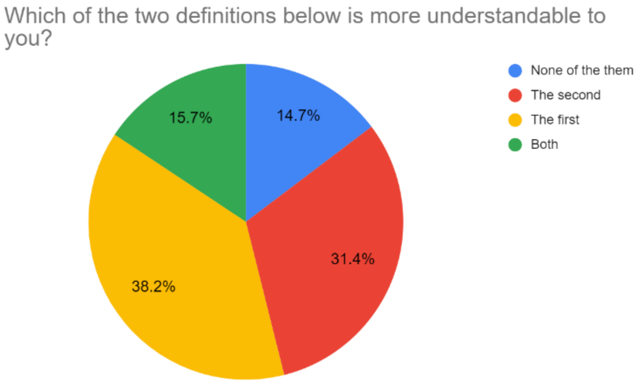

Fig. 11. Answers to "Which of the two definitions below is more understandable to you?"

VI. Conclusions

The usage of ChatGPT and similar AI-based technologies is something that is going to be more and more common. As lecturers and teachers, it is up to us to be able to navigate and adapt to it. The students have this very tempting, interesting, and easy-to-use at first glance technology. It is expected that they will be tempted to use it, after all this is an easy way to pass an exam and receive an excellent grade. While the education system does have its flaws and rewards excellent grades, the usage of these types of systems can and should be used in more efficient and effective manners to help with developing the thinking and problem-solving skills of the students.

From the experiment described in this article, the following can be concluded:

- ChatGPT systematizes sources of information found on the Internet on a given topic and saves time and effort;
- It provides personalized feedback and assistance to students anytime and from anywhere where they have access to the Internet;
- There is a real danger that students will learn false, malicious, or biased information if they rely entirely on ChatGPT without verifying the authenticity of what is written. As the survey shows, they do not pay enough attention and accept the answers as true;
- There is a real danger of fraud in the preparation of academic texts, cheating and plagiarism;
- The answers from ChatGPT can be deceiving and if the students are trusting it blindly, as this survey has proven to be the case, this can lead to bigger problems in the future. Many of today’s students are going to develop the habit of copy-and-pasting their problems in such chats and are going to stop developing their critical thinking thus limiting their intellectual growth.

This research underscores the undeniable potential of ChatGPT in reshaping educational dynamics. However, it also emphasizes the critical need for responsible integration. The findings spotlight the importance of equipping students with the skills to discern between AI-generated content and authentic knowledge. Striking a balance between leveraging AI for efficiency and preserving the essence of intellectual growth remains imperative in the evolving landscape of education.

While ChatGPT demonstrates remarkable capabilities, the study accentuates the irreplaceable role of human guidance in education. The findings highlight that, despite AI's potential to enhance learning experiences, it should be viewed as a tool rather than a substitute for human educators. The emphasis is on developing strategies to effectively integrate AI while ensuring that students receive the mentorship and critical thinking skills essential for their development.

As ChatGPT and similar AI technologies become integral to the educational experience, there is a pressing need to incorporate ethical AI education. The study underscores the importance of guiding students in understanding the ethical implications of relying on AI tools. Educators are encouraged to incorporate discussions on responsible AI use, fostering a generation that not only embraces technological advancements but also critically evaluates their impact on learning and intellectual development.

Faculty of Applied Sciences, IMIS Laboratory, Ibn Zohr University, Agadir, Morocco[2, 3]

***Abstract*—Predicting the trend of stock prices is a hard task due to numerous factors and prerequisites that can affect price movement in a specific direction. Various strategies have been proposed to extract relevant features of stock data, which is crucial for this domain. Due to its powerful data processing capabilities, deep learning has demonstrated remarkable results in the financial field among modern tools. This research suggests a convolutional deep neural network model that utilizes a 2D-CNN to process and classify images. The process for creating images involves transforming the top technical indicators from a financial time series, each calculated for 21 different day periods, to create images of specific sizes. The images are labeled Sell, Hold, or Buy based on the original trading data. Compared to the Long Short Time Memory Model and to the one-dimensional Convolutional Neural Network and the model exhibits the best performance.**

Keywords—Technical indicators; convolutional neural networks; stock trend forecasting; deep learning

I. Introduction

Predicting stock trends has been the subject of intensive research for decades, making it a challenging problem [1] [2]. Developing accurate prediction models is challenging due to the many factors that can impact price changes. In recent years, machine learning and text mining models have shown promising results in multiple applications, including stock market prediction [3]. However, deep learning techniques [4] [5] [6] have become a potential alternative due to the limited accuracy of these models. The use of deep learning in financial studies is becoming increasingly popular as its potential is demonstrated in various applications. Despite this, deep neural networks are still not widely used for stock market prediction. The main reason for this is that processing financial data is difficult and the prediction task is complex. To tackle this issue, a unique strategy is suggested that transforms financial data into image-like representations and utilizes a deep convolutional neural network (CNN) to forecast stock trends.

This paper provides a thorough explanation of the approach, encompassing the technical aspects of the model and the data pre-processing procedures. The proposal consists of converting financial data into 2D images and then feeding them into a CNN for training. In particular, 21 technical indicators for a 21-day period are computed and the 225 most pertinent features are selected, which are transformed into 15x15 images. A chronological sequence of these images is used as input to the CNN model.

The approach's effectiveness in predicting stock trends is demonstrated by the presentation of its results. The model's performance is evaluated through various metrics, such as precision, confusion matrix, F1-score, and recall. Moreover, the evaluation of the outcomes of the proposed approach against other conventional machine learning models, proving that the deep learning approach is superior. In summary, the proposed approach is a promising solution for stock market prediction, delivering a more precise and efficient alternative to traditional machine learning models.

The rest of the paper is structured as follows: Section II describes the related work; Section III details the background and the followed methodology in Section IV. Section V covers the results, and Section VI presents general conclusions. Finally future works is given in Section VII.

II. Related Work

Different approaches have been investigated in the field of predicting stock prices to improve the accuracy of forecasts. [7] It suggests employing ARIMA models, for crop price predictions. It recommended using feature selection techniques to enhance their predictive abilities. The research in [8] developed an HNN-based forecasting approach that utilized headline information as well as ARIMA model predictions to drive sales estimation and business strategic decision making for the publishing industry.

For forecasting stock price indices, [9] came up with a method integrating ARIMA model and backward propagation neural network. The resulting statistics were compared against outputs attained via back propagation neural network and a single ARIMA model approach, respectively. Similar to [10], a model was designed to measure time periods optimal for the prediction of the market price of securities within various industries in 2019. The results emphasized the importance of using large datasets while training models to predict with more precision. A hybrid CNN-TLSTM model for predicting the USD/CNF exchange rate by [11] obtained low mean absolute percentage error (MAPE) and mean squared error (MSE) showing its ability of dealing with complex nonlinear data According to [12], CNN-LSTM proved efficient as a quantitative trading strategy analyzer in the stock market capable of forecasting future movement of stocks and revealing their patterns. The study in [13] proposed the CNN-BiLSTM-AM technique for prediction of the following days' closing stock prices.

The study revealed that this model achieved greater predictive accuracy as well as performance when compared to other models using CNNs coupled with an attention mechanism. A study by [14] used an LSTM recurrent neural network to predict stock market trends, highlighting the LSTM model's capacity for accurately predicting stock prices.

III. Background

A. Background

Deep learning has become one of the most relevant mechanisms in the domain of machine learning and has been used generally in image recognition and natural language processing [15]. The most commonly used deep learning algorithms are convolutional neural networks (CNN) for feature extraction [16], recurrent neural networks (RNN) for mining time series data [17], etc. Therefore, for the purpose of making full use of their benefits, a CNN model is utilized to benefit from its power in feature extraction, which will be presented as follows.

1) Convolutional neural networks: Undoubtedly, convolutional neural networks (CNNs) (see Fig. 1) have established themselves as the most prevalent deep learning model, showcasing various network structures encompassing 1D, 2D, and 3D CNNs [18]. The 1D CNN specializes in processing sequential data [19], while the 2D counterpart excels in image and text recognition. Conversely, the 3D CNN takes the next stage in the identification of video data [20]. A standard convolutional neural network comprises an input layer, an output layer, and multiple hidden layers. These concealed layers typically house numerous convolutional layers that execute convolution through a dot product, employing RELU as the activation function. Following these convolutional layers are additional operations such as pooling, flattening, and fully connected layers [21].

2) Convolutional layer: The convolutional rlayer, a cornerstone of convolutional neural networks, shouldes the bulk of computational burden. It utilizes a set of spatially-restricted filters, each spanning the entirety of the input volume's depth. During the forward pass, these filters are slid across the input's width and height, computing the dot product between their entries and the input at each position. This process, akin to fingerprint identification, generates a 2D activation map, revealing the filter's response at every location. The network learns filters that activate to specific visual features, each producing a distinct map. These maps are then stacked along the depth dimension, forming the layer's output volume.

3) Pooling layer: Convolutional neural networks frequently employ pooling layers interspersed between convolutional layers. These interludes serve to shrink the representation's size, thereby reducing both the network's parameter count and computational demands, while simultaneously mitigating overfitting. The pooling layer independently processes each depth slice of the input, resizing it through a MAX operation. A widely used variant employs 2x2 filters with a stride of two, effectively down sampling each depth slice by a factor of two in both width and height dimensions. This translates to each MAX operation extracting the highest value from a quartet of numbers, leaving the depth dimension unaltered.

4) Fully connected layer: Fully connected layers establish connections between every neuron in one layer and every neuron in another layer. This architecture is similar to that of a traditional multi-layer perceptron neural network (MLP). In a CNN, the flattened matrix is passed through a fully connected layer to enable classification.

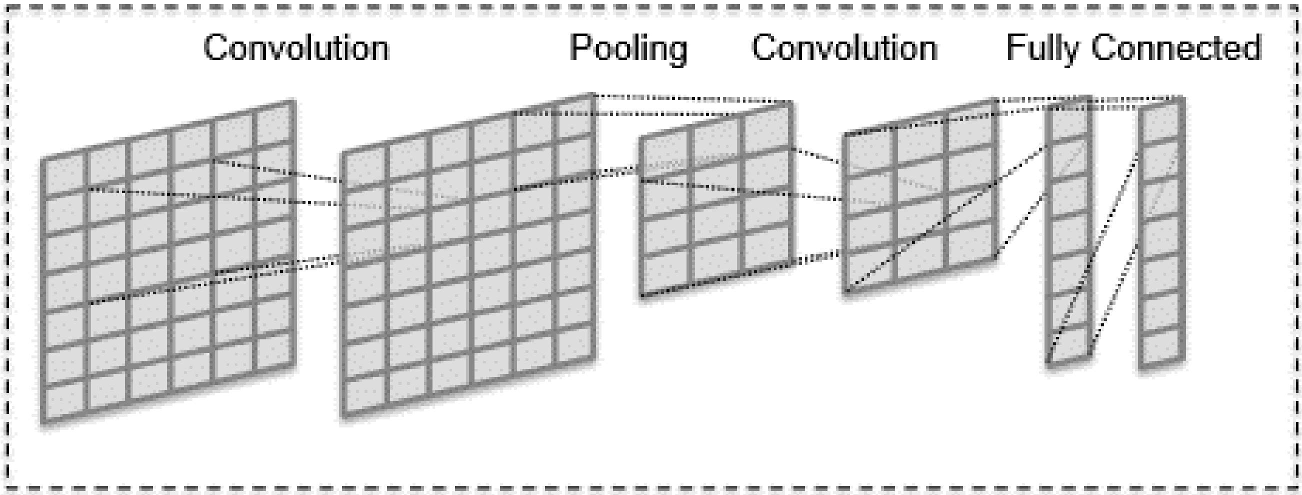

Fig. 1. CNN model architecture.

IV. Methodology

The proposal involves a model that employs Convolutional Neural Networks (CNNs) to detect favorable buying and selling points in stock prices. The model utilizes the top 15 technical indicators out of 21, using varying time intervals to generate images. As mentioned in (see Fig. 4), this approach encompasses four key stages: feature engineering, feature selection, data labeling, class imbalance handling, and image creation. The objective is to identify the most appropriate buy, sell, and hold positions in the time series of related stock prices.

1) Feature engineering: The dataset comprises features such as Date, Open, High, Low, Close, Adj Close, and Volume. To enhance the dataset's informational value, it's necessary to calculate 21 technical indicators for each day. These indicators include: RSI, William %R, MFI, MACD, PPO, ROC, CMFI, CMO, SMA, EMA, WMA, HMA, Triple EMA, CCI, DPO, KST, EOM, IBR, DMI, PSAR, and Volume values for intervals ranging from 6 to 27 days. These indicators are primarily categorized as momentum or oscillator types.

2) Feature selection: The proposed method improved the model's performance by applying a feature selection technique to the technical indicators. It selected 225 high-quality features using a univariate method that chooses variables with a strong relationship to the target outcome. It used two methods for feature selection: ANOVA F-value focusing on statistically significant differences between classes, and mutual information capturing non-linear relationships. It identified the features that both methods agreed on, then sorted the index list from the intersection of ANOVA F-value and mutual information to group similar indicators in the image.

3) Labeling data: The target was labeled by following a methodology [22] that used an 11-day window on the closing price. It checked if the middle number in the window was the highest, and if so, labeled the last day (11th day) as SELL. Otherwise, if the middle number was the lowest, labeled the last day as BUY. If neither condition was satisfied, labeled the last day as HOLD. The window was then slid and the process was repeated. This approach aimed to identify buying and selling opportunities at low and high points within each 11-day interval.

4) Handling class imbalance: The target was labeled and the data was found to be severely imbalanced. The Hold instances outnumbered the Buy and Sell instances by a large margin. The labeling algorithm used produced a relatively high number of Buy and Sell instances. Moreover, the Hold class was difficult to classify, making it hard for the model to learn meaningful insights. To solve this problem, the Sample Weights technique was adopted. This technique involved giving more weight to specific samples, which was a successful method for dealing with class imbalance.

5) Image creation: After completing all the preparatory steps, including downloading the dataset, calculating the technical indicators, performing feature selection, labeling the target, and normalizing the data, tabular data containing 225 features for each day was obtained. Subsequently, this data was converted into an image-like format. Sample 15x15 pixel images generated during this image creation process are presented in (see Fig. 2) to illustrate the visual representation of the data.

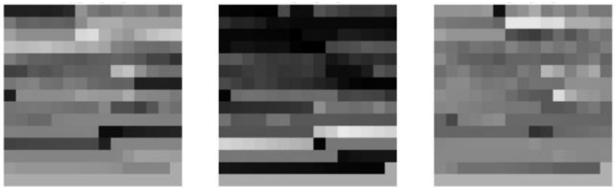

Fig. 2. Sample of generated images.

6) CNN model architerture: The proposed model consists of nine layers. The first layer, the input layer, receives images of size 15x15x3. The second layer is a convolutional layer with 25 filters, each of size 2x2. This layer is followed by a dropout layer that randomly drops out nodes during training with a 0.15% probability. Next, another convolutional layer is added, featuring 12 filters of the same size as the previous layer, stacked to a dropout layer with the same percentage (0.15%). Comes next the flatten layer, a dense layer with 100 neurons, a dropout layer with 0.15%, and the last layer which is the output layer with three neurons The model's output layer consists of three neurons, which determine the final action. The neural network uses the Adam optimizer, which is an adaptive gradient-based method that adjusts the learning rate for each parameter based on the previous gradients. It uses a learning rate of 0.001, which is a common value for the optimizer. The neural network trains for 3000 epochs, which means it sees the training data 3000 times with a batch size of 64 sample. EarlyStopping and ReduceLROnPlateau callbacks were utilized during model training. The first one stops the training when a monitored quantity (such as the validation loss) stops improving, and the last one reduces the learning rate when a monitored quantity (such as the validation loss) stops improving. (see Fig. 3) shows a recap for the CNN architecture.

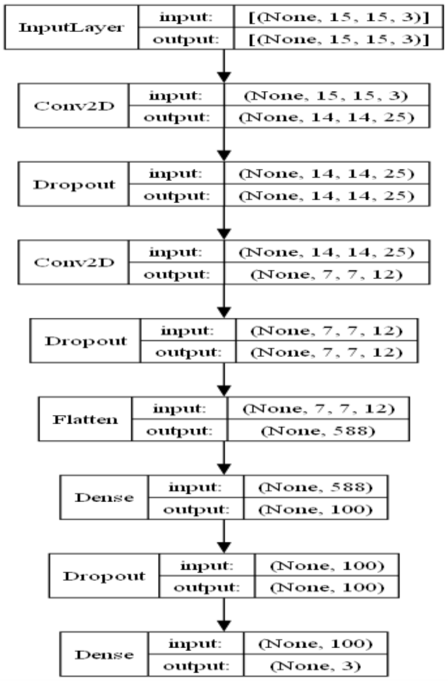

Fig. 3. Model.

a) EarlyStopping: Choosing the optimal number of training epochs is critical when training a neural network. Employing too many epochs can lead to overfitting, where the model becomes overly reliant on the training data and loses generalizability. Conversely, using too few epochs can result in underfitting, where the model fails to grasp the underlying patterns in the data. To address this dilemma, a technique called "early stopping" can be implemented. This involves training the model for a potentially large number of epochs, but proactively stopping the training process once the model's performance on a separate validation dataset ceases to improve.

b) ReduceLROnPlateau: During training, deep neural networks leverage the stochastic gradient descent (SGD) algorithm. This optimization technique utilizes randomly sampled data points from the training set to estimate the error gradient of the model's current state. Subsequently, the backpropagation algorithm is employed to update the model's weights based on this gradient information.

The learning rate governs how rapidly the model adapts to the problem it's facing. Smaller learning rates necessitate more training epochs because the weights are updated with smaller increments in each iteration. Conversely, larger learning rates propel faster adjustments, demanding fewer epochs.

However, selecting an inappropriate learning rate can lead to complications. A learning rate that's too high can cause the model to converge rapidly to a suboptimal solution, missing the optimal one. Conversely, a learning rate that's too low can cause the training process to become sluggish and potentially stall indefinitely. Consequently, selecting the optimal learning rate is crucial for effective deep neural network training.

7) Performance evaluation: The proposed model was assessed mainly by its computational performance, especially its accuracy in classifying buy, hold, and sell categories. These predicted labels guided buy, sell, and hold decisions based on stock prices. The model was trained and tested on WALMART stocks, using train, validation, and test splits. The F1-score was the main metric for performance evaluation on the test data, along with other metrics such as the confusion matrix, weighted F1 score.

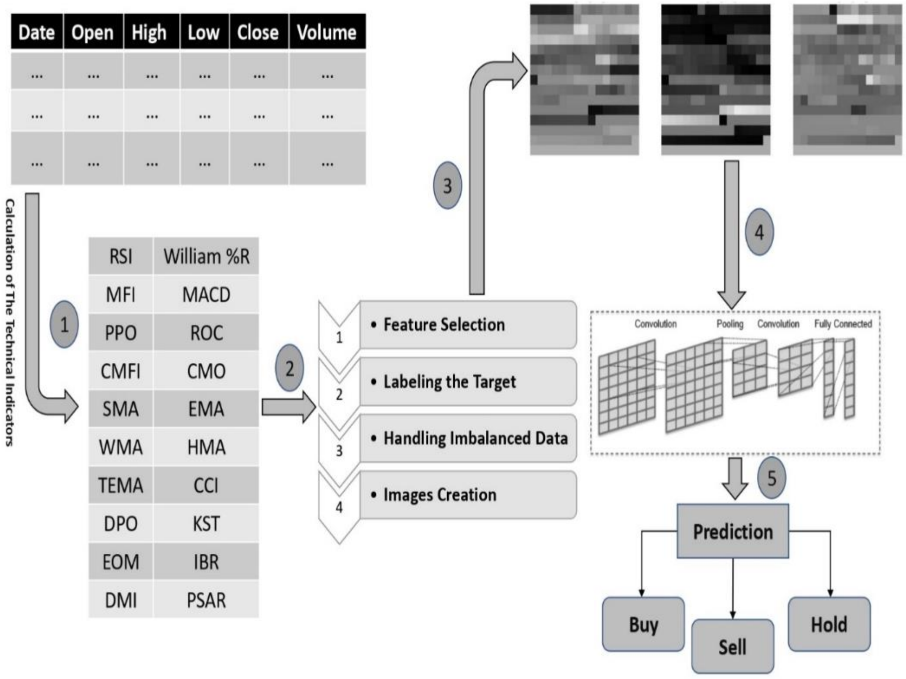

Fig. 4. Proposed method.

V. RESULTS

On WALMART test data the model gave the following result:

The model's predictive abilities were thoroughly evaluated and analyzed. Table I presents the confusion matrix for the WALMART test data, while Table II offers a deeper analysis based on these results. Notably, the precision values for "Buy" and "Sell" classes surpass those for "Hold," indicating the model's strength in capturing key buy and sell points. However, false entry and exit points arose due to the inherent rarity of these instances compared to "Hold" periods. This posed a challenge for the neural network: accurately detecting rare entry and exit points while maintaining the overall "Hold" distribution. As a consequence, the model generated false alarms for non-existent entry and exit points to capture the majority of true ones. Additionally, the "Hold" points lacked the clear definition of "Buy" and "Sell" points, leading to some confusion, particularly near peaks and valleys within sliding windows.

TABLE I. CONFUSION MATRIX OF TEST DATA (WALMART)

Predicted			
Actual	Buy	Sell	Hold
Buy	44	0	20
Sell	0	42	19
Hold	122	140	613

The F1-weighted score was used to comprehensively assess classification performance, which considered class weights for a more refined evaluation. The sample count of each class determined its F1 score weight. Multi-Layer Perceptron (MLP), Long Short-Term Memory (LSTM), and Convolutional Neural Network (CNN) methods were the baselines for stock market prediction, compared with the proposed model. Table III displayed the comparative prediction results.

TABLE II. EVALUATION OF TEST DATA (WALMART)

Total Accuracy: 0.699			
	Buy	Sell	Hold
Recall	0.6875	0.6885	0.7000
Precision	0.2650	0.2307	0.9401
F1-Score	0.3825	0.3455	0.8024
Weighted F1	0.7480		

TABLE III. THE AVERAGE OF F1-SCORE OF TEST DATA (WALMART) ON DIFFERENT MODEL

Model	AVG F1-Score
CNN	0.44
LSTM	0.57
MLP	0.45
CNN 2D	**0.74**

VI. CONCLUSION

In this study, a 2D Deep Convolutional Neural Network model was developed utilizing financial data and technical indicators to predict optimal buy and sell points. The model analyzed financial time series data, converted it into 2D images, and identified "Buy," "Sell," and "Hold" signals for profitable trades. Using WALMART stock prices as the primary data source, the model outperformed other models with the same dataset.

While the model's performance is encouraging, there's still room for improvement. Experimenting with various techniques, such as hyperparameter tuning, exploring different image sizes, alternative target labeling strategies, and utilizing additional technical indicators, could yield further gains. This research also contributes to the growing trend of applying 2D CNNs to non-image data, particularly in time series forecasting.

VII. FUTURE WORKS

The model was trained on the historical data of WALMART stocks. For future work, more stock data from different sources will be incorporated to enhance the deep learning models. Moreover, other types of deep neural networks and their combinations will be explored to achieve better performance. Furthermore, since the news has an impact on the stock price trends, the model will be augmented with sentiment analysis features to increase its accuracy. Additionally, alternative labeling methods will be experimented to improve the model outcome.

Appendix

1) *Relative Strength Index (RSI):* The Relative Strength Index (RSI), conceived by J.W. Wilder in 1978, quantifies the relative intensity of upward price movements against downward ones. This technical indicator, employed by traders to assess trend strength and identify potential reversals, offers valuable insights into momentum and potential trading signals. As price fluctuations occur, RSI values oscillate between 0% and 100%, signifying whether prices reside in the overbought (above 70%) or oversold (below 30%) territory. Equation for calculating the RSI value is provided in Eq. (1):

$$RSI = 100 - \frac{100}{1+(averagegain/averageloss)} \tag{1}$$

2) *Williams %R:* The Williams %R indicator, a stalwart among momentum-based technical tools, assists traders in identifying overbought and oversold conditions in stock prices. Its domain spans a spectrum from -100 to 0, serving as a window into market sentiment. A well-established interpretation of Williams %R values posits those readings below -80 signal an "oversold" market, ripe for potential upward reversals. Conversely, values exceeding -20 suggest an "overbought" market, susceptible to downward corrections. Eq. (2) details the calculation of Williams %R.

$$R = \frac{\max(high)-close}{\max(high)-\min(low)} * -100 \tag{2}$$

3) *Money Flow Index (MFI):* The Money Flow Index (MFI), a technical analysis stalwart, leverages both price and volume data to gauge overbought and oversold conditions in an asset, pinpointing potential trend reversals. Its values range from 0 to 100, offering a window into market sentiment. Unlike the Relative Strength Index (RSI), which focuses solely on price, the MFI encompasses both price and volume information, painting a more complete picture of market sentiment. Eq. (3) to Eq. (5) show the calculation of MFI:

$$RMI = TP \times Volume \tag{3}$$

$$MFR = \frac{14\,PeriodPositiveMoneyFlow}{14\,PeriodNegativeMoneyFlow} \tag{4}$$

$$MFI = 100 - \frac{100}{1+MFR} \tag{5}$$

4) *Moving Average Convergence and Divergence (MACD):* The Moving Average Convergence Divergence (MACD) indicator is a technical analysis tool that gauges the momentum and direction of stock prices. It measures the relationship between two moving averages of a security's price to identify potential turning points in the market.

When the MACD line crosses above the signal line in an upward direction, it suggests that bullish momentum is increasing, and stock prices are likely to rise. Conversely, if the MACD line crosses below the signal line in a downward direction, it indicates that bearish momentum is gaining strength, and stock prices are likely to fall.

The MACD indicator is a versatile tool that can be used to identify potential buy and sell signals, assess the strength of a trend, and anticipate trend reversals. However, it's important to note that the MACD indicator should not be used in isolation and should be considered in conjunction with other technical indicators and fundamental analysis. Eq. (6) and Eq. (7) show the calculations of MACD and Signal Lines:

$$MACD_{Line} = EMA_{12} - EMA_{26} \tag{6}$$

$$Signal_{Line} = EMA_{9}(MACD) \tag{7}$$

5) *Percentage Price Oscillator (PPO):* While the Percentage Price Oscillator (PPO) might appear similar to the MACD, a closer look reveals a subtle difference. While both rely on moving averages to assess momentum and trend direction, their calculation methodologies diverge. Eq. (8) and Eq. (9) illustrate the specific computations employed by the PPO to arrive at its main line and signal line:

$$PPO = \frac{EMA_{12} - EMA_{26}}{EMA_{26}} \times 100 \tag{8}$$

$$Signal_{Line} = EMA_{9}(PPO) \tag{9}$$

6) *Rate of Change (ROC):* The Rate of Change (ROC) indicator shines a light on the velocity of price movements over a defined timeframe. Eq. (10) unveils its computational heart:

$$ROC = \frac{Lasted_{close} - Previous_{close}}{Previous_{close}} \times 100 \tag{10}$$

7) *Chaikin Money Flow Indicator (CMFI):* The Chaikin Money Flow (CMF) indicator, a technical analysis stalwart, gauges the volume of capital flowing into or out of a security over time. Its values dance between 1 and -1, with proximity to 1 signifying robust buying pressure and proximity to -1 indicating potent selling pressure.

A CMF value hovering near 1 whispers of a substantial inflow of money into the security, suggesting buyers firmly grip the market reins. Conversely, a

CMF value teetering around -1 hints at a considerable outflow of capital, indicating sellers are asserting control.

However, it's crucial to acknowledge that the CMF indicator should not be a solitary oracle. Its effectiveness is amplified when combined with other technical indicators and fundamental analysis, creating a well-rounded investment perspective. For the mathematically inclined, the CMF's inner workings are unveiled in Eq. (11) to Eq. (13):

$$Multuplier = \frac{((Close-Low)-(High-Close))}{(High-Low)} \quad (11)$$

$$MFV(MoneyFlowVolume) = Volume \times Multiplier \quad (12)$$

$$CMF_{12period} = \frac{21periodSumOfMFV}{21periodSumOfVolume} \quad (13)$$

8) *Chande momentum oscillator (CMO):* The Chande Momentum Oscillator (CMO) joins the ranks of the RSI and the stochastic oscillator as a fellow momentum indicator. It too dances between -100 and 100, but with its own interpretive twist. When the CMO value waltzes past 50, stock prices are deemed to be frolicking in "overbought" territory. Conversely, a plunge below -50 suggests they're wallowing in the "oversold" zone. Eq. (14) unveils the CMO's inner workings:

$$CMO = 100 \times \frac{S_u - S_d}{S_u + S_d} \quad (14)$$

9) *Simple moving average (SMA):* The humble Simple Moving Average (SMA) reigns supreme as a fundamental indicator, capturing the essence of a security's price movement over a chosen period. Its power lies in its simplicity – it's just the average of prices during that timeframe. Its true magic unfolds when it's crossed by the actual stock price. Eq. (15) unveils the unassuming yet powerful formula behind the SMA:

$$SMA(M,n) = \sum_{k=a+1}^{a+n} \frac{M(k)}{n} \quad (15)$$

10)*Exponential moving average (EMA):* The exponential moving average (EMA) is a type of moving average indicator that places greater weight on recent price data, making it more responsive to current trends. Traders employ the EMA on trading charts to identify potential entry and exit points for trades based on the relative position of price action to the EMA. When the EMA is high relative to price, traders may consider selling, while when it is low relative to price, they may consider buying. Eq. (16) illustrates the calculation of EMA:

$$EMA(t) = (M(t) - x) \times \frac{2}{\tau+1} + x \quad (16)$$

$$\text{With } x = EMA(M, t-1, \tau) \quad (17)$$

11)*Weighted Moving Average (WMA):* While both the weighted moving average (WMA) and exponential moving average (EMA) aim to capture trends by assigning decreasing weights to past closing prices, their weighting mechanisms differ. The EMA employs an exponential decay, where the weights decline rapidly as we move back in time. In contrast, the WMA utilizes a linear decay, resulting in a more gradual decrease in weights assigned to older prices. This distinction highlights the potential for the WMA to offer a different perspective on market trends compared to the EMA, particularly in situations where recent price movements hold significant importance. Eq. (17) shows how WMA is calculated:

$$WMA(M,n) = \frac{SumOfWeighedAverages}{SumOfWeight} \quad (17)$$

12)*Hull Moving Average (HMA):* The Hull moving average (HMA) stands out among moving average indicators for its superior ability to minimize lag, a common drawback of traditional SMAs. While EMAs and WMAs attempt to address this issue by emphasizing recent data, HMA takes it a step further, achieving even better lag reduction. Eq. (19) details the HMA's calculation, highlighting its distinct approach.:

$$HMA(M,n) = WMA\left(2 \times WMA\left(\frac{n}{2}\right) - WMA(n), \sqrt{n}\right) \quad (18)$$

13)*Triple Exponential Moving Average (TEMA):* The triple exponential moving average (TEMA) tackles a persistent challenge in technical analysis: how to filter out minor price fluctuations while capturing the underlying trend. Unlike traditional EMAs, TEMA employs a layered approach, essentially applying multiple exponential weightings to price data. This sophisticated strategy, as shown in the subsequent formula, effectively smooths out short-term volatility, revealing the true market direction with greater clarity:

$$TEMA = (3 \times EMA) - \left(3 \times EMA(EMA)\right) + \left(EMA\left(EMA(EMA)\right)\right) \quad (19)$$

14)*Commodity Channel Index (CCI):* Standing out as a versatile tool for traders, the Commodity Channel Index (CCI) assesses how much a current price deviates from its typical range over a specified period. Essentially, it compares the present price to the average price within that timeframe, translating the difference into an easily interpretable value. Although fluctuating between -100 and 100, the CCI spends a quarter of its time outside this range, signifying potentially significant deviations from normalcy. Eq. (20) and Eq. (21) unveil the mathematical magic behind this indicator, revealing how it transforms raw price data into a powerful market sentiment gauge:

$$CCI = \frac{TP - 20PeriodsSMAofTP}{0.015 \times meanDeviation} \quad (20)$$

$$TypicalPrice(TP) = \frac{High + Low + Close}{3} \quad (21)$$

15)*Detrended Price Oscillator (DPO):* Unlike most oscillators chasing momentum, the Detrended Price Oscillator (DPO) takes a different path. Its unique strength lies in stripping away trend direction from price data, allowing it to focus solely on the underlying cyclical patterns. By filtering out trend noise, the DPO exposes the true rhythm of the market, highlighting peaks and troughs that hint at potential turning points. Eq. (22) unveils the secret behind this transformation, revealing how the DPO isolates cyclical swings for informed buy and sell decisions based on historical echoes:

$$DPO = \frac{PricefromX}{2} + 1periodAgo - XperiodSMA \quad (22)$$

Where X is the number of periods used for the look-back period.

16)*Know Sure Thing (KST):* he Know Sure Thing (KST) indicator, conceived by Martin Pring, addresses a fundamental challenge in technical analysis: deciphering the complexities of rate-of-change (ROC) data. KST tackles this challenge by employing a novel multi-period approach. It calculates simple moving averages (SMAs) of four distinct ROC periods, effectively smoothing out volatility and capturing momentum across various timeframes. These tamed ROC values then converge into a single, comprehensive indicator: the KST. To further enhance its interpretability, a 9-period SMA of the KST itself is employed as a signal line, generating crossover alerts for potential trading opportunities. Eq. (23) formalizes this innovative approach, unveiling the intricate interplay of SMAs and ROCs within the KST framework:

$$KST = RCMA_1 + (RCMA_2 \times 2) + (RCMA_3 \times 3) + (RCMA_4 \times 4) \quad (23)$$

where:

$RCMA_1$ = 10-period SMA of 10-period ROC

$RCMA_2$ = 10-period SMA of 15-period ROC

$RCMA_3$ = 10-period SMA of 20-period ROC

$RCMA_4$ = 15-period SMA of 30-period ROC

17)Ease of Movement (EOM): In the technical analyst's toolbox, the Ease of Movement (EOM) indicator stands out as a bridge between the ephemeral world of momentum and the tangible realm of volume. EOM seeks to capture this crucial intersection, condensing the combined influence of price movement and volume into a single, quantifiable value. This value, at its core, aims to answer a critical question: are prices moving "easily" in their current trend? EOM posits that effortless price movements, reflected in high EOM readings, hold the potential to persist and present lucrative trading opportunities. Eq. (24) to Eq. (26) unveil the mathematical alchemy behind EOM, revealing how it transforms raw price and volume data into this insightful blend of momentum and volume analysis:

$$DistanceMoved = (\frac{High+Low}{2} - \frac{PHigh+PLow}{2}) \tag{24}$$

$$BoxRation = \frac{\frac{Volume}{scale}}{High-Low} \tag{25}$$

$$1 - PeriodEOM = \frac{DistanceMoved}{BoxRation} \tag{26}$$

18)Interbank Rate (IBR): The interbank rate, often overlooked yet crucial to the financial system's smooth functioning, operates like an invisible plumbing system connecting banks. This rate dictates the interest charged when banks borrow short-term funds from each other to meet immediate liquidity needs or conversely lend out excess reserves. These interbank loans, captured in Eq. (27), typically have very short durations, often overnight and rarely exceeding a week. Understanding the interbank rate is akin to comprehending the heartbeat of the financial system, as it regulates the flow of liquidity and influences borrowing costs for all institutions within the network:

$$IBR = \frac{SumOfInterestRates}{NbrOfInterestRates} \tag{27}$$

19)Directional Movement Indicator (DMI): The Directional Movement Indicator (DMI) stands apart from conventional trend indicators by offering a multifaceted perspective. Instead of relying on a single metric, DMI deploys a three-pronged attack, harnessing the strengths of the Average Directional Index (ADX), the plus directional indicator (+DI), and the minus directional indicator (-DI). This powerful triumvirate delves deep into the trend's soul, simultaneously revealing its strength, direction, and potential turning points. DMI, with its values ranging neatly between 0 and 100, paints a clear picture of the market's underlying momentum, empowering traders to identify and capitalize on trending opportunities with greater confidence.

$$+DI = 100 \times EMA(\frac{+DMI}{ATR}) \tag{28}$$

$$-DI = 100 \times EMA\ (\frac{-DMI}{ATR}) \tag{29}$$

$$ADX = 100 \times EMA(\left|\frac{+DI- -DI}{+DI+ -DI}\right| \tag{30}$$

20)Parabolic SAR: The Parabolic SAR (SAR) acts as a vigilant sentinel, constantly scanning the market landscape for potential ambush points – where trends might stall or reverse. This dynamic indicator relies on a trio of key components: The previous SAR value, the extreme point (EP) marking the trend's peak or trough, and the ever-adapting acceleration factor (AF) reflecting the trend's sensitivity. As Eq. (31) and Eq. (32) illustrate, rising EPs fuel AF's ascent, amplifying the SAR's response to potential reversals. Conversely, falling EPs trigger AF's descent, making the SAR more cautious in a weakening trend. This intricate interplay between past, present, and future trends empowers traders to identify critical points of potential stops and reverses, navigating the market with newfound foresight.

$$PSAS + PresviousAF(PreviousEP + PSAR) \tag{31}$$

$$PSAS - PreviousAF(PSAR - PreviousEP) \tag{32}$$

An Explainable and Optimized Network Intrusion Detection Model using Deep Learning

***Abstract*—In the current age, internet and its usage have become a core part of human existence and with it we have developed technologies that seamlessly integrate with various phases of our day to day activities. The main challenge with most modern-day infrastructure is that the requirements pertaining to security are often an afterthought. Despite growing awareness, current solutions are still unable to completely protect computer networks and internet applications from the ever-evolving threat landscape. In the recent years, deep learning algorithms have proved to be very efficient in detecting network intrusions. However, it is exhausting, time-consuming, and computationally expensive to manually adjust the hyper parameters of deep learning models. Also, it is important to develop models that not only make accurate predictions but also help in understanding how the model is making those predictions. Thus, model explainability helps increase user's trust. The current research gap in the domain of Network Intrusion Detection is the absence of a holistic framework that incorporates both optimization and explainable methods. In this research article, a hybrid approach to hyper parameter optimization using hyperband is proposed. An overall accuracy of 98.58% is achieved by considering all the attack types of the CSE CIC 2018 dataset. The proposed hybrid framework enhances the performance of Network Intrusion Detection by choosing an optimized set of parameters and leverages explainable AI (XAI) methods such as Local Interpretable Model agnostic Explanations (LIME) and SHapely Additive exPlanations (SHAP) to understand model predictions.**

Keywords*—Network Intrusion Detection; deep learning; hyper parameter optimization; hyperband; CSE CIC IDS 2018 dataset; XAI methods; LIME; SHAP

I. Introduction

With cyberattacks becoming increasingly prevalent, it is imperative that businesses shift their focus towards cybersecurity. Our lives have transitioned to be internet centric after the pandemic, but cybersecurity problems are also intensifying every day. Researchers are concentrating on creating Deep Learning (DL) based Network Intrusion Detection System (NIDS) to identify zero-day attacks as new varieties of cyberattacks continue to emerge. Outdated attack traffic and no representation of contemporary attack types leads to poor representation of real time network traffic. Also, redundancy, anonymity due to privacy or ethical issues, simulated traffic, lack of traffic diversity, and the absence of an all-inclusive dataset are some issues with most of the existing datasets. Despite numerous attempts, the research community is yet to accomplish the development of systems that can handle threats without human intervention. Malicious cyberattacks create significant security risks, necessitating the development of an innovative, adaptable, and more dependable Intrusion Detection System (IDS). The number of Internet-connected devices is anticipated to reach 50 billion by the end of the decade [1]. Although, techniques for infiltration and security defences have advanced dramatically during the past decade, a significant number of organizations still use outdated cybersecurity solutions.

Considering the above challenges, the primary objective of this research article, is to implement an explainable and optimized network intrusion detection model using DL techniques. The proposed work incorporates both optimization and XAI methods. The main contributions are as follows:

- Implement hyperband algorithm on the proposed DNNHXAI (Deep Neural Network Hypertuned XAI) model to choose optimized parameters.
- Investigate explainability of the proposed model using LIME and SHAP.

II. Literature Survey

Notable numbers of works are proposed in the area of NIDS, Abdulnaser et al. used Apache Spark and DL models on the CSE CIC 2018 dataset. The authors conclude that Spark drastically reduces the training time when compared to DL models [2]. Haripriya et al. performed distributed training of deep auto-encoder including all the attacks of the CSE CIC IDS 2018 dataset. The authors achieved an accuracy of 98.96% by training their proposed model on two worker nodes. [3]. Kanimozhi et al. used Artificial Neural Networks (ANN) and used only the benign and botnet traffic of the CSE CIC 2018 dataset. They used Grid Search CV to perform hyper parameter tuning. However, the authors conclude that their proposed model can be extended to detect the remaining classes of the dataset and usage of higher end frameworks like Tensor Flow to perform hyper tuning optimization [4]. Vimal Gaur implemented Machine Learning (ML) algorithms on CICDDoS2019 dataset to detect Distributed Denial of Service (DDoS) attacks and performed hyper parameter tuning. The author concludes that hyper parameter tuning increases the accuracy by 2.01% [5]. Priya Maidamwar et al. implemented ML algorithms on UNSW-NB15 dataset and used Grid Search CV as their hyper parameter tuning technique. An improvement in accuracy and minimization of False Alarm Rate (FAR) was observed [6].

Amin et al. propose a ML based NIDS model for binary classification on CSE CIC-IDS 2018 dataset. However, they observed that minority classes are misclassified due to class imbalance and suggest researchers to use techniques like Synthetic Minority Oversampling Technique (SMOTE) [7]. Haripriya et al. effectively addressed the class imbalance problem of the CIC CSE IDS2018 dataset by using SMOTE. They used deep autoencoder to classify all the attacks of the dataset [8]. Rambasnet applied and compared various State-of-the-art frameworks on CSE CICIDS2018 dataset. Their findings demonstrate the usefulness of different DL frameworks for detecting network intrusion traffic. An accuracy of 99% was achieved. However, since the class imbalance of the dataset was not addressed, a large number of infiltration samples were misclassified [9].

Anita Shiravani et al. proposed a new method for effectively selecting features using fuzzy numbers. The authors emphasize on the fact that dimensionality reduction plays a major role in pre-processing which in turn improves the system performance [10]. Mohammad Mausam et al. proposed a NIDS framework using Bayesian Optimization (BO) with Gaussian Process (GP). They implemented their proposed method on NSL-KDD dataset and conclude BO-GP outperforms Random Search Optimization [11]. Yoon Teck et al. implemented ML algorithms on CICIDS 2017 dataset and used BO-Tree-structured Parzen Estimator (BO-TPE) as the hyper parameter tuning technique. The authors direct future researchers to apply hyper parameter optimization on DL algorithms to substitute their ML approaches [12].

Abdulatif et al. implemented ML algorithms in Kitsune dataset used in the domain of NIDS. The authors recommend Grid Search optimizer with Tree algorithm for Kitsune dataset [13]. Hyojoon et al. use Proximal Policy Optimization (PPO) algorithm on CICDS2017 and UNSW-NB15 datasets to control the hyper parameters of Deep Neural Network (DNN)-based feature extractor and K-Means cluster module. The authors conclude that feature engineering is crucial in NIDS data pre-processing and direct future researchers to carry out research using diverse datasets [14]. Sara Emadi et al. implement Convolutional Neural Network (CNN) and Recurrent Neural Network (RNN) algorithms on the NSL-KDD dataset. The authors conclude that research in the area of NIDS can further be improved by reducing the training time and using hyper parameter tuning to improve the overall performance [15]. Haripriya et al. carry out a comprehensive study on different benchmark IDS datasets and their impact on network intrusion techniques [16]. The authors insist on the fact that the quality of the dataset plays a vital role in the domain of NIDS.

Zhibo zang et al. carries out an extensive survey on different methods, categorization, research gaps and challenges of XAI in the domain of Cyber security [17]. Pieter Barnard et al. use XGBoost model on the NSL-KDD dataset. The authors use SHAP to explain their proposed model [18]. Zakaria et al. use DNN on NSL-KDD and UNSW-NB15 dataset. The authors conclude their work by using LIME, SHAP and Rule fit methods to improve the interpretability of the proposed model [19]. Shraddha Mane et al. implement DNN on NSL-KDD dataset and use XAI methods to generate explanations [20]. Basim Mahbooba et al. addressed explainability by using Decision Tree (DT) on KDD dataset [21]. Syed wali et al. implements Random Forest (RF) on CIC CSE IDS2018 dataset and used SHAP as an XAI method [22].

Studies from literature reveal that hyper parameter tuning is very important to decide on the best architecture of the DL model. Although researchers have previously worked on optimization algorithms for hyper parameter tuning, there is an increasing need to use advanced optimization algorithms for hyper parameter tuning to speed up the training process. When it comes to optimization, overlooking hyperparameter optimization altogether is the most substantial mistake one can make. Modest adjustments to hyperparameter values can have a significant effect on model's performance. Especially in the domain of network security, the main aim is to speed up the process of intrusion detection and help network administrators to take immediate action before a catastrophic attack on the network occurs. XAI methods can help minimize model bias by outlining the standards for making decisions. Therefore, monitoring the model using XAI methods help in lessening the bias and also unexpected consequences. Previous research works in the field of NIDS reveal that, researchers have either used hyper parameter optimization methods or XAI methods in the field of NIDS. It is observed that none of the researchers used both the methods. This research article leverages both hyper parameter tuning and XAI methods, thus providing hyper optimization along with a comprehensive understanding of model's predictions.

III. METHODOLOGY

The proposed framework is divided into two stages. First hyper parameter tuning is done using hyperband. Secondly, XAI methods such as SHAP and LIME are used to interpret the model predictions.

A. Dataset Description and Pre-processing

The proposed work uses the CSE CIC IDS2018 dataset. The main rationale behind choosing the CSE CIC IDS 2018 dataset is, it reflects the current attacks. Unlike the outdated KDD Cup 99 dataset, it also includes a wide range of attacks. It is very essential to choose the dataset that reflects real time network traffic comprising a wide diversity of attacks. The dataset consists of a total of 16,000,000 samples spread over 10 CSV files. The dataset was collected from Amazon Web Services (AWS) S3 bucket [23].

Data type conversion was carried out by converting 64 bit values to 32 bit values. Features containing only one variable were dropped. Also features having infinite and Not a Number (NAN) values were also dropped. Label encoding and one-hot encoding was performed on the different attack types of the dataset. It was noticed that the dataset suffers from class imbalance. It is observed that the number of samples belonging to benign (normal) were more when compared to the attack class. Class imbalance leads to "Accuracy paradox". For instance, while using training data with a very high percentage of benign samples, a model could be trained to predict normal traffic with high accuracy, but it might not be good at detecting attack traffic. Similar observations were made on all the files of the dataset. Thus, to overcome the limitations of the class imbalance, SMOTE was used in the proposed model.

B. Workflow of the Proposed Model

The entire workflow of the proposed framework is shown in Fig. 1. The CSE CIC IDS 2018 dataset is collected from the AWS S3 bucket. To help speed up the training process and improve accuracy, pre-processing is carried. Class imbalance problem of the dataset is addressed using SMOTE [24]. Then the DL model is developed by using DNN. Hyper parameter tuning is carried out using hyperband algorithm and an optimized set of parameters are chosen [25]. The performance of the model is evaluated on the test dataset.

Fig. 1. Workflow of the proposed model.

C. Importance of Hyper Parameter Tuning in the Proposed Work

The performance of any ML/DL model depends on the configuration. One major challenge in implementing any ML/DL algorithm is discovering an optimal configuration for the model and the training algorithm. Hyper Parameter Optimization (HPO) is a technique to deal with the challenge of fine-tuning DL hyper parameters. Tuning in an enormous search space is an exhausting process. Data-driven techniques must be employed to address the issues with HPO. Manual processes are ineffective. There are several hyper parameter tuning algorithms namely Random search, Bayesian Optimization (BO) and hyper band. Random search is the least efficient algorithm as it randomly selects parameter combinations from a search space rather than learning from previously tried parameter combinations. BO uses an optimization method that is sequential, and thereby it cannot be used well with parallel resources pair.

Speeding up configuration evaluation is the primary objective of an orthogonal approach to hyper parameter optimization. Hyperband can be considered as an extension of the successive halving approach; the goal of the Hyperband is to regularly apply successive halving to address the trade-off between the number of configurations and resource allocation. Additionally, it can find the ideal combination faster by using successive halving. The primary idea is to fit numerous models for a limited number of epochs and to only continue training the models that perform best on the validation set. Therefore, in comparison to commonly used hyper tuning algorithms like BO, hyperband can dramatically speed up a variety of DL and kernel-based learning tasks. All the above factors motivated us to use hyperband as the hyper parameter tuning technique in the proposed model.

D. Need for Model Explainability in the Proposed Work

Considering the large sizes of NIDS datasets, performance becomes the bottleneck. DL models are incomprehensible, counterintuitive, and challenging for people to understand. All the DL models act like black-box structures. Because DL models are so complicated, interpretability research has taken multiple avenues. Over the years, DL models evolved by improving the performance metrics to handle large data but with increasing complexity came less interpretability. Feature importance methods were used to show how each feature is important to model prediction in general. However, these methods do not give information about individual predictions. Also, which features tend to increase or decrease the prediction is not known. Understanding ML model is referred to as model explainability. There are numerous advantages of integrating XAI methods with DL algorithms. It enables individuals to mitigate the negative impacts of automated decision-making and help in more informed decisions. To identify and protect security vulnerabilities. Integrating algorithms with human values is an essential goal. As an instance, suppose a model is able to determine if the traffic is normal or malicious, the network administrators have to know what parameters the model has considered. This helps to know whether the model contains any bias. It is also essential for network administrators to understand and describe the model’s predictions once it has been implemented. Fig. 2 illustrates the importance of XAI methods in the proposed work.

IV. Experimental Setup

Table I illustrates the different hyper parameters used while training the proposed DNNHXAI model. The number of hidden units ranged from 2 to 32 with a step value of 3. The number of hidden values ranged from 2 to 10. Different activations such as relu, tanh, sigmoid were used. Relu was the most preferred activation function. The dropout values ranged from 0.0 to 0.1 with a step size of 0.05. An optimized learning rate of 0.001 was chosen. Table II gives the different general parameter values used while training. The batch size was set to 128 with 15 epochs. The loss functions used were binary cross entropy and categorical cross entropy for binary and multi-classification respectively. Adam optimizer was chosen as preferred optimizer as it helps the model to converge faster.

TABLE I. Different Parameters Used for Hyper Parameter Tuning

Sl No	Name of the hyper parameter	Range of values for different hyper parameters	Best hyper parameters given by Hyperband

1	Number of units	Min_value=2, Max_value = 32
		Step=3,
		Default=32
			Units in 0th layer = 29
			Units in 1st layer = 5

2	Number of layers	Min_value =2,
		Max_value = 10
			2

3	Activation	Dense Activation
		Values=relu,tanh, sigmoid
		Default= relu
			relu

4	Dropout	Min_value=0.0,
		Max_value = 0.1
		Default = 0.005,
		Step = 0.05
			0.1

5	Learning Rate	Values = 1e -2,1e -3,1e -4	0.001

TABLE II. Gives the Different General Parameter Values used while Training

Sl.No	Parameter	Value
1	Batch size	128
2	Number of epochs	15
3	Loss function	Binary Cross entropy Categorical Cross entropy
4	Optimizer	Adam

All the experiments were carried out using Google Colab which is a cloud-based environment. To speed up the training process, Graphical Processing Units (GPU) was chosen as the runtime option. The train – test split was set to 75% and 25 % respectively.

V. Results and Discussion

An accuracy of 96.67% was achieved without hyper parameter tuning. With usage of hyperband (see Fig. 3) as the hyper parameter tuning technique, the accuracy peaked to 98.58%.

SHAP and LIME methods are used to explain the predictions of the proposed model [26] [27]. Fig. 4 gives the waterfall plot. It shows how a positive SHAP value positively impacts the prediction. On the contrary, a negative SHAP Value has a negative impact on the prediction. The magnitude helps us understand how strong the impact is. It also illustrates the feature importance of SHAP analysis by using the summary plot by considering the CSV file containing Distributed Denial of Service (DDOS) attack. The chosen CSV file contains two classes benign (normal traffic) and DDOS (attack traffic). The Class label is encoded as '0' and '1' for Benign and DDOS attack respectively. As per the result, min packet length is the highest ranking feature.

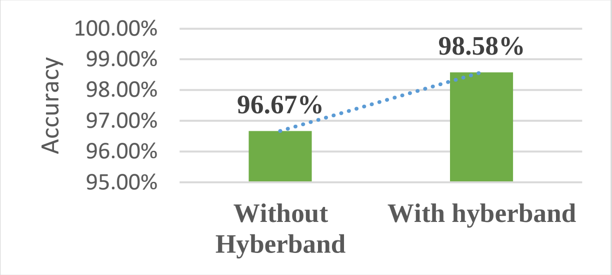

Fig. 3. Difference in accuracy with and without hyperband optimization.

Fig. 5 illustrates how LIME can be used to understand local predictions given by the model by considering the Comma Separated Values (CSV) file containing DDOS attack in the CSE CIC IDS 2018 dataset. The features shaded in blue indicate positive influence on the output. Conversely, the features shaded in orange indicate negative influence on the output. Similar experiments were conducted on the different attacks of the dataset. The key difference between SHAP and LIME is how they provide explanations. SHAP uses a game-theoretic approach to provide global explanations. Conversely, LIME is model specific that provides local interpretable explanations. In this research work, an attempt was made to investigate model interpretability using SHAP and LIME. However, it is observed that LIME explanations are not robust because of its instability. For each prediction, a new explanatory is generated by the LIME algorithm. Thus, small variations in the data lead to different interpretations. In contrast, SHAP helps in providing global explanations, therefore explaining the overall model's behavior across all the instances. Finally, we conclude that SHAP performs better than LIME.

Table III gives the comparative analysis of the proposed work with other latest works exiting in the literature. It is observed that researchers have either used Optimization or Explainability but not both. Also, outdated datasets like NSL-KDD that do not reflect current attacks are still being used. Conventional hyper parameter tuning techniques like Grid Search CV are no longer suitable as it is time-exhaustive and computationally expensive, especially if it involves a high dimensional search space. Although, Random Search CV is better than Grid search CV, a lot of variance is observed because of its randomness. Research works [3][4][5][10][11] use different optimization methods for hyper parameter tuning. Research works [17][18][19][20][21][28] use different XAI methods. Table III clearly illustrates that none of the previous works in the field of NIDS incorporated a hybrid model leveraging both hyper-parameter optimization and explainability. Comparison was based on the usage of optimization, XAI method and accuracy as the performance metric. In this research article, a hybrid approach incorporating both optimization and explainability is implemented. Advanced Optimization algorithms such as a hyperband helps in finding the hyper parameters faster with improved accuracy. Explainable methods such as LIME and SHAP help in gaining greater insights on the data by understanding model predictions and thus increasing user's trust in the model.

VI. CONCLUSION

With the advancement in technology, the number of cyberattacks is increasing exponentially. Although, DL models prove to be efficiently detect intrusions, its complexity has increased tremendously at the price of massive computational overhead. It is exhausting, time-consuming, and computationally expensive to manually adjust the hyper parameters of DL models. In this research paper, hyperband an advanced hyper parameter tuning algorithm is applied on the proposed DNNHXAI model. It is observed that the configuration of model hyper parameters has a significant impact on its prediction accuracy. Although DL models today are able to achieve very good accuracies, there is an increasing need to enhance the user's trust by using XAI methods. First, the algorithm should have the best performing parameter configured and XAI methods should be used to deduce the contributing factors. Particularly, in the domain of cybersecurity, an attacker can largely exploit a vulnerability within few seconds. To address the above stated challenges, an attempt is made to not only configure the best parameters but also to understand the model predictions in an efficient manner. A single model that can detect a variety of attacks is proposed. It is efficient to quickly differentiate between normal and attack traffic. The proposed model overcomes the problems encountered in traditional DL algorithms w.r.t hyper parameter optimization and explainability. Instance by instance explanation is done with both LIME and SHAP. The main outcome of combining hyper parameter tuning with XAI techniques is to enable network administrator to take appropriate action based on the certainty of a detected attack. Considering all the files of the dataset, an overall accuracy of 96.67% and 98.56% is achieved without and with hyper parameter tuning respectively. The framework implements efficient pre-processing techniques, addresses class imbalance, uses the latest benchmark IDS dataset that reflects recent attacks, implements advanced hyper parameter tuning techniques and leverages XAI methods to understand model's predictions. Promising results were achieved and an improvement in model's performance is observed when hyper parameter tuning is used. XAI methods are used to increase the explainability of model's predictions. As a future work, researchers are advised to leverage transfer learning techniques on the latest datasets in the domain of NIDS. Also, additional XAI methods can be used on different DL algorithms to explain model's predictions more efficiently.

Abstract—**Images in low-light conditions typically exhibit significant degradation such as low contrast, color shift, noise and artifacts, which diminish the accuracy of the recognition task in computer vision. To address these challenges, this paper proposes a low-light image enhancement method based on Retinex. Specifically, a decomposition network is designed to acquire high-quality light illumination and reflection maps, complemented by the incorporation of a comprehensive loss function. A denoising network was proposed to mitigate the noise in low-light images with the assistance of images' spatial information. Notably, the extended convolution layer has been employed to replace the maximum pooling layer and the Basic-Residual-Modules (BRM) module from the decomposition network has integrates into the denoising network. To address challenges related to shadow blocks and halo artifacts, an enhancement module was proposed to be integration into the jump connections of U-Net. This enhancement module leverages the Feature-Extraction- Module (FEM) attention module, a sophisticated mechanism that improves the network's capacity to learn meaningful features by integrating the image features in both channel dimensions and spatial attention mechanism to receive more detailed illumination information about the object and suppress other useless information. Based on the experiments conducted on public datasets LOL-V1 and LOL-V2, our method demonstrates noteworthy performance improvements. The enhanced results by our method achieve an average of 23.15, 0.88, 0.419 and 0.0040 on four evaluation metrics - PSNR, SSIM, NIQE and GMSD. Those results superior to the mainstream methods.**

Keywords—Low-light image enhancement; decomposition network; FEM attention mechanism; denoising network; detail enhancement

I. INTRODUCTION

In the field of computer vision, low-light image enhancement has perennially been a focal point of research. Images acquired under low light conditions are often affected by problems like light weakening, increased noise and loss of detail, resulting in degraded image quality and blurred image content. The identified limitations exert a detrimental impact on the efficacy of computer vision applications, presenting challenges across various scenarios, including object detection [1], driverless driving [2], medical imaging. Moreover, these deficiencies introduce inconvenience in routine image capture and sharing within everyday life.

Traditional image enhancement methods often rely on manually adjusting parameters such as brightness and contrast [3], which may not adapt well to changes in different scenes. However, due to the inability to effectively and accurately capture the features of the image, as well as its complex textures, these methods can lead to over-enhancement or the presence of shadow blocks and halo artifacts in the enhanced image. In contrast, methods based on deep learning improve adaptability and generalization by automatically learning image features, making them particularly suitable for complex environments. Specifically, deep learning methods based on Retinex theory, which separate an image's illuminance and reflectance through a decomposition network, allow for detailed adjustments through reflectance recovery and illuminance adjustment networks. These methods then merge the enhanced reflectance and illuminance images to improve brightness, contrast, and maintain natural colors, making them especially suitable for image enhancement in low-light environments. However, the decomposition network in Retinex can be affected by uneven lighting, potentially leading to loss of image detail, especially in dark and highlight areas of the image, thereby affecting the naturalness and realism of the final enhancement effect.

Although there are currently various enhancement methods for low-light images, mainly focusing on improving image contrast, it is important to note that low-light images often contain a significant amount of noise, which can greatly affect the quality and clarity of the image. Many of the current denoising techniques are applied in the pre-processing and post-processing stages of the image. Denoising in the pre-processing stage can cause the image to become blurred, while applying denoising in the post-processing stage can lead to the amplification of noise. Therefore, in the process of enhancing low-light images, how to appropriately balance the suppression of noise with the preservation of image details becomes a key challenge.

To address the aforementioned issues, this paper presents three main contributions, as follows:

1) In this paper, a decomposition network is proposed to obtain illumination and reflection maps through the decomposition of the RM and IM modules, as well as a comprehensive loss function is advanced to maintain the overall structure and consistency of the decomposed images.

2) A denoising network was proposed to remove noise in low-light images, with the assistance of images' spatial information, noise can be efficiently diminished, preserving map details, and consequently elevating the overall quality of enhanced images.

3) To effectively mitigate shadow blocks and halo artifacts in low-light images, this paper introduces an enhancement network featuring the FEM attention mechanism, which can significantly improve the restoration of image details and textures, yielding clear and natural image results.

The rest of this article is organized as follows: Section II discusses the related work. The proposed approach is detailed in Section III. Section IV provides quantitative and qualitative evaluation the method’s performance. In Section V, ablation experiments were carried out on the FEM module and the de-noising module, respectively.

II. Related Work

Over the past few decades, various conventional methods have been proposed to address the challenges of low-light image enhancement. Noteworthy among these are traditional image enhancement methods, specifically histogram equalization [4] and methods based on Retinex theory [5]. Among these methods, histogram equalization method is one of the earliest and most extensively utilized methods. It aims to enhance image contrast and brightness by redistributing the gray level of image pixel values. This approach exists the disadvantages such as the limitations of global processing and the sensitivity to noise, which can lead to unnatural effects and information loss.

To enhance the visual alignment of images with human perception, Land et al. [6] proposed Retinex theory. At the core of the theory lies the concept that an object's color is determined not only by the intensity of the reflected light but also by its ability to reflect light waves. However, this method exhibits limitations when applied to images with complex lighting conditions and strong contrasts. To address these issues, researchers introduced the Multiscale Retinex (MSR) algorithm [7], incorporating multi-scale Gaussian filters to more accurately estimate the illumination components at various scales, and suppressed the halo effect through weighted summation. Furthermore, in pursuit of preserving the natural and authentic visual characteristics of images, Gao et al. [8] proposed an improved Retinex algorithm based on the traditional Retinex algorithm, which introduced color correction and multiscale processing technology to improve image details at different scales more precisely, thereby improving the visual effect and quality of images. However, most RetineX-based methods can cause severe color distortion and struggle to effectively enhance images with relatively high dynamic range.

In recent years, the remarkable adaptive capabilities of deep learning in low-light image enhancement have established it as an effective method, contributing to the improvement of image quality and finding widespread application in various computer vision tasks. Numerous scholars have extended their efforts to constructing learning-based models based on Retinex theory. For instance, RetinexNet [9] integrates Retinex theory with deep convolutional neural networks, enhancing image contrast through brightness maps estimation and adjustment, with subsequent post-processing using Block-Matching and 3D Filtering (BM3D) for denoising. Zhang et al. [10] designed an efficient network based on Retinex theory to enhance low-light images. Lim et al. [11] introduced the Deep-Stacked Laplacian Restorer (DSLR), capable of recovering global brightness and local detail from the original input, achieving notable success in contrast improvement and noise reduction. Moreover, several non-Retinex-based methods have been proposed. Li et al. [12] developed LightenNet, a convolutional neural network employing a stacked sparse denoising autoencoder structure to learn the nonlinear transformation function for adaptive brightness and contrast enhancement in low light images. However, this method faces challenges in effectively addressing noise in low-light images conditions. Ma et al. [13] proposed a low-light image enhancement method based on a fast, flexible and robust strategy. The method combines adaptive enhancement and parameter adjustment to efficiently enhance images while preserving detail and quality. EnlightenGAN [14] employs an unsupervised deep learning approach within a Generative Adversarial Network (GAN) framework to address low-light image enhancement challenges. Depth-Aware Decomposition and Restoration Network (DA-DRN) [15] introduces a self-sensing depth Retinex network, directly restores degraded reflectance and preserves the detail information in the decomposition stage by using the dependence between reflectance and illumination pattern. Although these methods can significantly improve the brightness and contrast of images, challenges persist in noise removal and image detail recovery. Some methods may result in overly enhanced image, leading to potential distortions.

The essence of the Retinex method lies in the estimation of luminance and reflectance maps. Traditional methods, with their limited decomposition ability, often result in over-enhancement or under-enhancement. In contrast, the learning-based approach demonstrates enhanced decomposition results and effectively improves contrast. It is noteworthy that many learning-based methods primarily utilize spatial information from low-light images to generate high-quality normal-light images, often neglecting the recovery of detailed information. Therefore, the enhancement module proposed in this paper leverages the FEM attention module, embedding it into U-Net's jump connection to augment the network's learning capacity for meaningful features. This augmentation is achieved by integrating image features and spatial attention mechanisms in the channel dimension. This design not only utilizes spatial information to strengthen contrast but also prioritizes the recovering of finer detail from the image.

In low-light conditions, image quality is often constrained by the optical signal attenuation, resulting in a significant degradation of the signal-to-noise ratio and a notable increase in noise. Some methods use the denoising model as preprocessing methods for low-light image enhancement; however, this preprocessing result in the loss of details in the low-light image. Chen et al. [16] introduced a model employing two parallel CNN branches: one for extracting brightness information and the other for extracting residual noise information. Low-light Photo Denoising via a Diffusion Model (LPDM) [17] is a denoising method for low-light images that utilizes a diffusion process. Initially, low-light images are enhanced to improve their brightness and contrast, followed by noise reduction through a diffusion process.

Although this method is effective in reducing noise, it introduces certain issues, such as the loss of some image details. To mitigate the loss of detail information during the denoising process, this paper introduces a denoising network to suppress noise in the reflection map. However, eliminating noise by restraining high-frequency signals in reflectivity map may lead to the loss of inherent details.

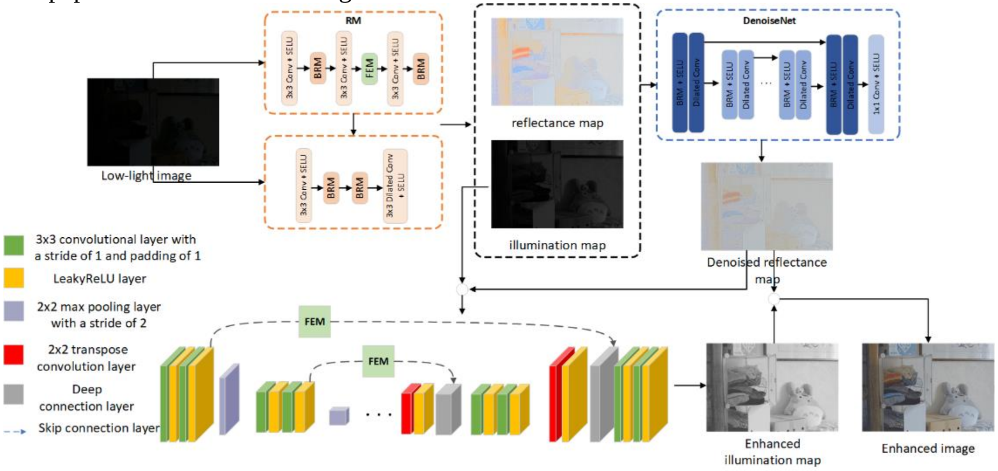

Fig. 1. The framework of the proposed method.

III. Proposed Method

As illustrated in Fig. 1, the whole pipeline is based on Retinex. Initially, a comprehensive loss function is incorporated into the decomposition network to obtain light and reflection maps. In order to mitigate the loss of detailed information, a denoising network is introduced to suppress the high frequency information in the reflection image. Finally, the FEM attention module is proposed in the enhancement network to process the light image, aiming to better preserve object details, create smoother color transitions, and yield a clearer, more natural image.

A. Decomposition Module

The loss function of decomposition network consists of perception loss function, illumination consistency loss function and global consistency loss function.

$$L = \lambda_1 \cdot L_{perceptual} + \lambda_2 \cdot L_{\mathrm{consistency}} + \lambda_3 \cdot L_{\mathrm{global}} \tag{1}$$

The values of λ_1, λ_2 , λ_3 and are 0.3, 0.4, and 0.3.

The perception loss function is designed to preserve the perceived quality of the image. Traditional pixel level loss function often falls short in accurately capturing the perceived quality of the image. Hence, we choose a pre-trained convolutional neural network to extract image features and subsequently calculate the feature difference between the generated low-light image and the target image.

$$\mathrm{L}_{perceptual} = \frac{1}{N}\sum_{k=1}^{N} \| \phi(I)_k - \phi(L)_k \|_2^2 \tag{2}$$

Where, the input low-light image is I , the target light map is L , $\phi(I)$ represents the feature map extracted by the pre-trained convolutional neural network (such as VGG16), and N is the number of feature maps, $\|.\|_2$ stands the $L2$ norm.

The illumination consistency loss function ensures the structural information's consistency between the generated low-light image and the target image.

$$L_{perceptual} = \frac{1}{N}\sum_{k=1}^{N} \| \mathrm{G}(I)_k - \mathrm{G}(L)_k \|_2^2 \tag{3}$$

The $\mathrm{G}()$ represents the gradient of the image.

The global consistency loss function elevates the overall consistency of the generated low-light image and the target image.

$$L_{global} = \frac{1}{N}\sum_{k=1}^{N} \| \mathrm{mean}(I)_k - \mathrm{mean}(L)_k \|_2^2 \tag{4}$$

The $mean()$ represents the mean of the image.

B. BRM Module

The BRM module (Fig. 2) adopts the concept of a residual network as a reference and comprises 5 convolution layers. The convolution kernel size is {1, 3, 3, 1}, and the corresponding number of the convolution kernel is {64, 128, 128, 64}. For the activation function, SELU is assigned to correspond to the convolution kernel 3, and LeakyReLu to the convolution kernel 1. Finally, a 64×1×1 convolution layer added to the jump junction.

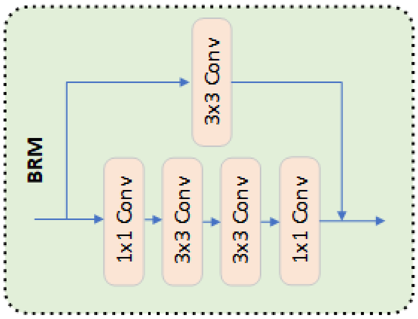

Fig. 2. The framework of BRM.

C. Denoising Module

The heavy noise in low-light images obscures essential details, structure, and other valuable information, burying useful features beneath irrelevant ones. It is these severe degradations that make the training process challenging for network learning and the recovery of useful features (such as details, structure, and corrected color information).

Previous methods often eliminate noise by suppressing high-frequency signals in the reflection map. However, those signals frequently encompass critical image details and texture information. The inhibition of high-frequency signals can lead to detail loss or blurring, resulting in visually smooth or less sharp enhanced image. In this paper, a denoising network is posed to remove noise in low-light images by considering spatial information from images. U-Net [18] has demonstrated excellent results in numerous computer vision tasks, and it is frequently employed in low-light image enhancement networks. Nevertheless, U-Net's use of multiple max pooling layers has resulted in loss of feature information. In our network, the maximum pooling layer is replaced by the extended convolution layer, enabling a broader context information range by increasing the receptive field size of the convolution kernel without reducing the feature map resolution. The BRM module from the decomposition network is integrated into the denoising network, with each sub-module of U-Net being replaced with BRM. In the denoising network's encoder part, subsampling is achieved by adding an average pooling layer with a pool core size and step size of 2 to the BRM module at the end. In the decoder part, up-sampling is realized by incorporating a deconvolution layer with convolution kernel size and step size of 2 to the BRM module. The spatial information in images often contains rich details and structural information. The denoising network proposed in this paper leverages spatial information for denoising, enhancing its ability to preserve details and resulting in clearer and more natural images after denoising.

In the denoising network, a novel loss function is proposed in this paper. By integrating the Mean Square Error (MSE) loss term with the smoothing loss term, the image's noise suppression and smoothing effect can be optimized simultaneously. The MSE loss term aids in minimizing the pixel-level difference between the real image and the low-light image, thereby mitigating the impact of noise. The smoothing loss item promotes the smooth characteristics of the low-light image, enhancing the clarity of edges and details. The specific process is as follows:

$$L = \lambda Lsmooth + Lmse \tag{5}$$

The tradeoff between smoothness and the difference at the pixel level in the denoising loss function can be controlled by adjusting the weighting factor λ for the smoothing loss term, which defaults to 0.2.

$$Lmse = ||Igi - ^{□} Igi||^2 \tag{6}$$

Where, Igi represents the grayscale image relative to the low-light image, and $^{□}Igi$ represents the grayscale image relative to the real image.

$$Lsmooth = ||\nabla^{\sim} Igi||^2 \tag{7}$$

Where, $^{□}Igi$ represents the image processed by the denoising network, and ∇ represents the gradient operator, which is used to calculate the gradient of the image. In this paper, the Prewitte operator is arranged to represent the value of the gradient operator, which can be represented by the following two matrices:

$$G_x = \begin{bmatrix} -1 & 0 & 1 \\ -1 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix}, G_y = \begin{bmatrix} -1 & -1 & -1 \\ 0 & 0 & 0 \\ 1 & 1 & 1 \end{bmatrix} \tag{8}$$

D. Enhancement Module

After denoising, residual shadow blocks and halo artifacts persist in low light images. In this paper, an enhancement module is devised to remove these artifacts while improving the quality of low-light images. Notably, the generation of shadow blocks and halo artifacts can be attributed to the U-Net's jump connection, wherein severely degraded features are directly conveyed to the up-sampled stage by linking up-sampled features with previous down-sampled features, leading to the retention of degraded features.

Inspired by SENet [19] in image recognition, the FEM attention module is incorporated into U-Net's jump connection to enhance noise removal and facilitate detail recovery. This inclusion is particularly effective in eliminating shadow blocks and halo artifacts. The FEM attention module operates by integrating image features in the channel dimension, assigning higher weights to valuable features (such as the correct color, detail, and texture features). This enabling the network to better learn these crucial features, while assigning lower or zero weights to less important features (such as noise, distorted colors, shadow blocks, and halo artifacts) or even giving no weight at all.

The loss function of the enhancement module is shown as follows:

$$L_{Re} = L_{Ren-con} + \lambda L_{Re-per} \tag{9}$$

Where λ is the weight used to balance different loss terms, the default value is 0.1. $L_{Ren-con}$ the content loss value obtained by calculating the absolute value of the difference between the enhanced image and the real enhanced image at each position of pixel, and adding the absolute value of all differences. The presented loss metric quantifies the holistic disparity between the generated enhanced image and the authentic enhanced image. L_{Re-per} is the perception loss, which is gained by computing the square difference in the perception space between the generated enhanced image and the actual enhanced image, summing across all pixel positions. To maintain a balanced consideration of the various layers within the feature map, normalization is conducted by dividing the dimensions of the feature map.

Content loss is defined as follows:

$$L_{Re-con} = \sum_{i}^{N} |□ S_{low} - S_{en}| \tag{10}$$

Where i is the index of the pixel, $\square S_{low}$ is the generated enhanced image, S_{en} is the real enhanced image. $\|$ is the absolute value symbol. $\sum$ means adding the difference of each pixel, that is, adding the difference between the generated enhanced image and the real enhanced image at each pixel position.

Perceived loss means:

$$LRe-per=\frac{1}{(CjHjWj)}*\Sigma\|\varphi j(\square S_{low})-\varphi j(S_{en})\|^2 \quad (11)$$

Where Cj represents the number of channels in the feature map of the *J-th* layer and the number of channels in the feature map of different layers used in the perception loss. Hj is the height of the feature map of the *J-th* layer, which represents the height of the feature map of the different layers used in perception loss. Wj represents the width of the feature map of the *J-th* layer, representing the width of the feature map of the different layers used in perception loss. φj represents a function that maps the image to the *J-th* layer feature map, which is used to extract the representation of the features of image on the perceptual space. $\square S_{low}$ represents the enhanced image generated. S_{en} is a true enhanced image. $\|\cdot\|^2$ represent the square of the Euclidean norm of two vectors used to calculate the square of the difference in perceptual space between the generated and real enhanced images.

E. FEM Module

In recent years, a multitude of attention modules have been proposed to incorporate learnable weights in information processing, facilitating dynamic adjustments and the assignment of significance to various parts of the input data. This approach draws inspiration from human perceive and cognitive processes, enabling models to concentrate on information that significantly contributes to a given task or problem. For instance, Hu et al. [19] propose a Squeeze-and-Excitation (SE) block, which effectively performs feature recalibration by modeling the interrelationships between channels. Recognizing the importance of positional relationships between pixels, Non-Local Network (NLNet) [20] explored a nonlocal operation to capture the interactions between any two positions, irrespective of their spatial distance. Subsequently, the Cross Partial attention Volume Transformer (CPVT) module introduces an attention mechanism that crosses partial channels and divides the input feature map into several subgroups, each encompassing a subset of the channels. The attention mechanism is applied to each subgroup, focusing exclusively on channel relationships within the current subgroup and not considering channels in other subgroups. This approach achieves a balance between computational efficiency and performance.

These methods prove advantageous in addressing complex tasks like object detection and scene segmentation. A notable example is Axial-Deeplab [21], a deep learning model designed for image segmentation tasks. It employs an Axial attention mechanism for processing large-scale images and incorporates a segmented attention mechanism to enhance the capture of relationships between objects. However, these approaches may exhibit limited impact on low-level tasks, such as image enhancement. To address this issue, we propose an FEM (Fig. 3) attention module in this paper. The module effectively removes shadow blocks and halo artifacts by integrating image features and spatial attention mechanisms in the channel dimension. Furthermore, optimized jump connections are introduced, enabling adaptive exploration of contrast information within the image and facilitating the recovery of potentially fine details in low-brightness areas.

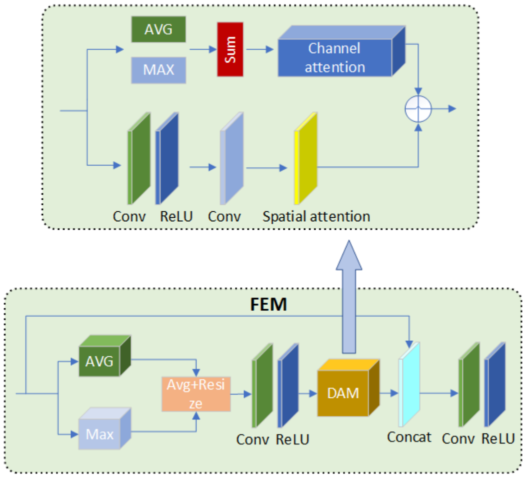

Fig. 3. The framework of FEM.

The FEM module comprises two Conv+ReLU layers, AdaptiveAvgPool2d, AdaptiveMaxPool2d, an up-sampling module and a Dual Attention Module (DAM). Specifically, for an input feature graph X with dimensions H × W × C, AdaptiveAvgPool2d and AdaptiveMaxPool2d are employed to extract representative information. The average of these two operations generates a global information feature map with dimensions 1 × 1 × C. Then, the feature map with global information undergoes amplified through up-sampling, and the number of channels is compressed using 1×1 Conv to obtain a global feature map with dimensions H × W × C1. Following this, a DAM module is introduced to extract global features from spatial and channel dimensions. The DAM consists of two input branches: channel attention branch, and spatial attention branch. For an input feature graph X with dimensions of H × W ×C, the channel attention branch employes global average pooling and global maximum pooling to generate the global average pooling feature map Cavg and the global maximum pooling feature map Cmax in spatial dimension, respectively. Their purpose is to emphasize the information regions, and these results are combined to produce the output Fc (R1×1×C) of the attention branch of the channel. The spatial attention branch aims to generate a space-based attention map. Similar to the channel attention branch, it computes Savg (RH×W ×1) and Smax (RH×W ×1) through global average pooling and maximum pooling in the channel dimension respectively. The output spatial attention map Fs (RH×W ×1) is then obtained through a convolution layer. Finally, Fc and FS are combined to rescale and optimize the global feature map, resulting in the output. The input feature map (encoding local information) and the optimized global feature map (encoding global information) are combined using the concatenate function and the Conv+ReLU function to generate an output feature map with dimensions H × W × C.

IV. Experimental

A. Parameter Setting

The experiment was conducted using PyTorch 1.8.0, with network training confined to a 256×256 patch on a single NVIDIA GTX 1080Ti GPU. The batch size was set to 2 and a total of 1×10^5 iterations were performed. Data enhancement involved random horizontal and vertical flips. Employing the Adam optimizer, the initial learning rate was set to 10^{-4} , gradually reduced to 10^{-6} through a cosine annealing strategy.

B. Data Set

The low light image dataset comprises a curated collection of specialized images tailored for the examination and evaluation of image processing algorithms in low light conditions. Typically, these datasets contain images captured in settings with insufficient illumination, offering researchers a challenging assortment for the development and assessment of algorithms aimed at enhancing the quality of low-light images. Derived real-world low-light scenes, these datasets encompass derived environments, both indoor and outdoor, capturing a range of shooting conditions and objects. These images within these datasets commonly exhibit characteristics such as low contrast, indistinct light and dark details, and elevated noise levels.

In the experiment of this paper, we utilized the LOL-v1 [9] and LOL-v2-real [22] datasets. The LOL dataset consists of 500 pairs of images, each with low and normal illumination, totaling 1,000 images. The images are captured with the same camera in varying lighting conditions, these images span a diverse array of scenes, both indoor and outdoor, and cover various shooting conditions and subjects. The dataset's diversity ensures comprehensive coverage of low-light scenes, which enhance the generalization and robustness of the evaluation algorithm. The LOL v2 dataset serves as a sequel to LOL v1, consists of two pairs of training and validation images, involving the actual shot and composite-generated images. Specifically, LOL-v2 is divided into two subsets: LOL-v2-REAL and LOL-v2-synthetic. The former includes 689 pairs of low-light/normal-light images for training and 100 pairs for testing, primarily adjusted by modifying camera parameters like exposure time and ISO. The latter is generated on an illumination distribution analysis of RAW format images.

C. Evaluation Index

1) Subjective evaluation: The method presented in this paper is compared with several advanced low-light image enhancement methods, including KIND [10], KIND+ + [23], NE [24], SCI [13] and RetinexNet [9]. Experiments are conducted using publicly available source code provided by the authors of these methods.

The results depicted in Fig. 4, The RetinexNet method overly smoothens details and even causes color deviations, making the image look unnatural. Moreover, the results of RetinexNet still contain a lot of noise. Although it uses BM3D to remove noise from the decomposed reflectance component, it cannot clearly remove the noise. The main reason is that BM3D is designed to remove Gaussian noise with a fixed noise level. However, the noise in the reflectance component is more diverse and complex than Gaussian noise. Although KIND and KIND + + introduced a recovery network to recovery color and remove noise from reflected images, the results were still inconsistent. For instance, in the first row of the Fig. 4, the KIND++ enhanced image still displays color deviation when compared to the reference image. In the second row, KIND treats a small light source as noise and removes it. In the sixth row, it is evident that KIND has unevenly enhanced the image. In the third image, the enhanced KIND ++ image still has color bias compared to the reference image. The SCI based method produces visually appealing results, it carries some undesirable artifacts (such as white walls). In contrast, upon observing the visualization results, particularly the outline of the teddy bear in the first row of Fig. 4 and the texture details of the book in the third row, our proposed method outperforms in terms of enhancement, reduced noise, and more accurate detail recovery. Conversely, other methods yield a fuzzy recovery effect due to noise interference in low light images, with the recovered images retaining significant noise. By comparing the results of different methods in the fifth line of images, our proposed method performs superior performance in restoring color saturation, presenting a more natural and vivid color enhancement effect. Moreover, in contrast to the restored color of the window in the second row of Fig. 4 and the floor in the last row, it can be concluded that our proposed method excels in maintaining color fidelity, suppressing noise, and removing artifacts.

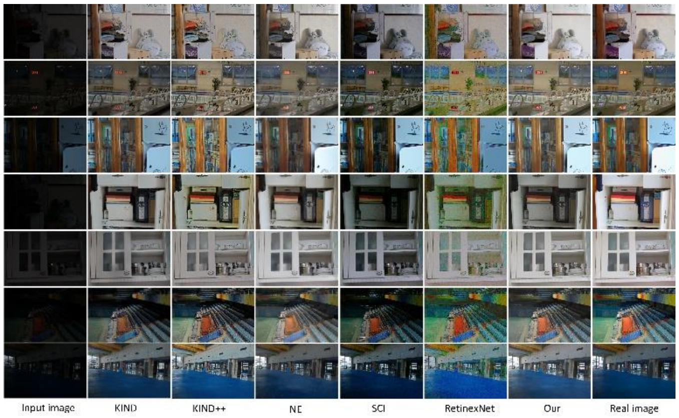

Fig. 4. Subjective comparison on the LOL-V1 dataset.

Fig. 5 illustrates the impact of the experiment detailed in this paper, along with comparisons to other experiments on the LOL V2 dataset. Although RetinexNet can enhance the low-light areas in images, it exhibits severe color distortion and halo artifacts (a significant amount of halo artifacts can be observed around the contours of the mountains in the second row of images). In contrast, our method effectively brightens the low-light areas reasonably while maintaining the realistic visibility of the result. Besides enhancing brightness, our method also successfully reduces color distortion and halo artifacts. SCI introduces and even amplifies noise after enhancement, and therefore suffers from severe noise distortion and color degradation when brightening dark areas. Conversely, our experimental results have superior color-recovery performance. KIND tends to exhibit some under-enhanced areas and apparent color distortions. Although the KIND ++ can remove noise, excessive sharpening (the surface of the mountain in the second row and the intersection of branches in the sixth picture) may introduce other problems such as loss of detail, blurring, and causing the image to unnatural. Compared to all these methods, our method can effectively enhance the brightness and display details of the image while suppressing noise, and it presents the most abundant and reasonable color information.

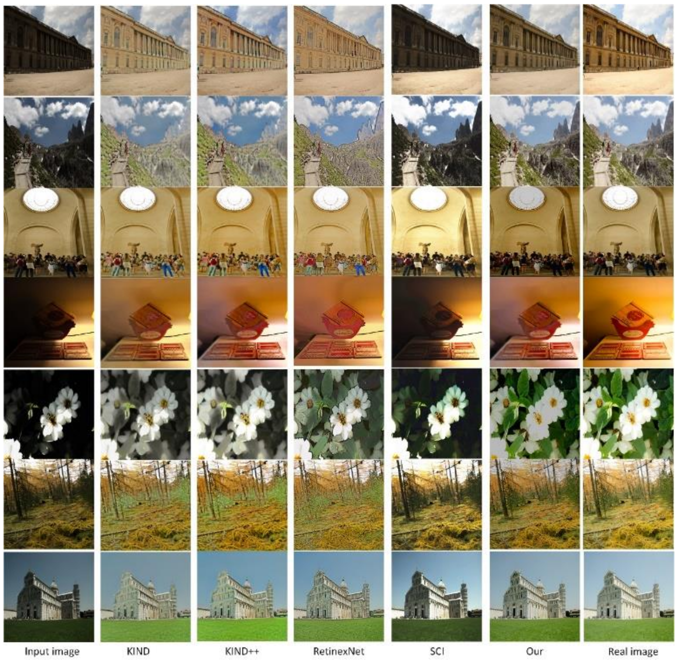

Fig. 5. Subjective comparison on the LOL-V2dataset.

2) Objective evaluation: According to Table I, our method achieves superior results, which manifests that the enhanced images obtained by this pipeline are more visually satisfactory.

To objectively evaluate the enhancement results, we employed four classical indicators, and the results are presented in Table I. Among these metrics, PSNR [25] is utilized to measure the noise level and degree of distortion between the original image and the processed image. A higher PSNR value indicates a closer result to the reference image at the pixel-level. SSIM [26] is employed to evaluate structural similarity, considering perceptual properties such as image structure and content. A higher SSIM value indicates a greater similarity in structure to the reference image. The method proposed in this paper achieves excels in both PSNR and SSIM, highlighting its advantages in lighting restoration and structural restoration. KIND and NE also achieved high PSNR values, indicating their effectiveness in restoring global illumination. GMSD [27] assesses image quality by comparing gradient amplitude difference between the original and the processed images. NIQE [28] quantifies the effect of the image enhancement algorithm by analyzing the statistical characteristics of the image and generating a continuous value score. A lower NIQE score indicates higher quality detail, brightness, and tone, indicative of a more natural appearance devoid of artifacts or pseudo-details. Consistently, our method achieves superior performance in both PSNR and SSIM. The enhanced images generated by our pipeline exhibit a more natural and vivid appearance, showcasing enhanced global and local contrast.

TABLE I. COMPARISON OF OBJECTIVE EVALUATION INDICATORS OF DIFFERENT MODELS

	KIND	KIND++	NE	SCI	RetinexNet	Our
PSNR	21.38	19.21	22.61	20.80	18.4	23.15
SSIM	0.85	0.79	0.82	0.72	0.62	0.88
NIQE	0.610	0.556	0.526	0.470	0.831	0.419
GMSD	0.060	0.106	0.091	0.063	0.137	0.040

D. Ablation Experiment

1) Comparison of the effectiveness of FEM module: To validate the efficacy of the FEM module, a model was trained with the FEM module replaced by an ordinary convolution. Fig. 6 illustrates the impact of FEM module on image enhancement. The results indicate that the model incorporating the FEM module effectively preserve object details and achieves smoother color transition in the image. Notably, in the third and fourth images, the enhanced results closely approximate the real image, aligning with the characteristics of the natural landscape. Analysis of the data presented in Table I reveals a notable improvement when utilizing models with FEM module compared to those without. Specifically, the PSNR increases by 3.74 (=20.22-16.48) and SSIM increases by 0.18 (=0.81-0.63). These finding lead to conclusion that models incorporating FEM modules exhibit superior performance in image enhancement.

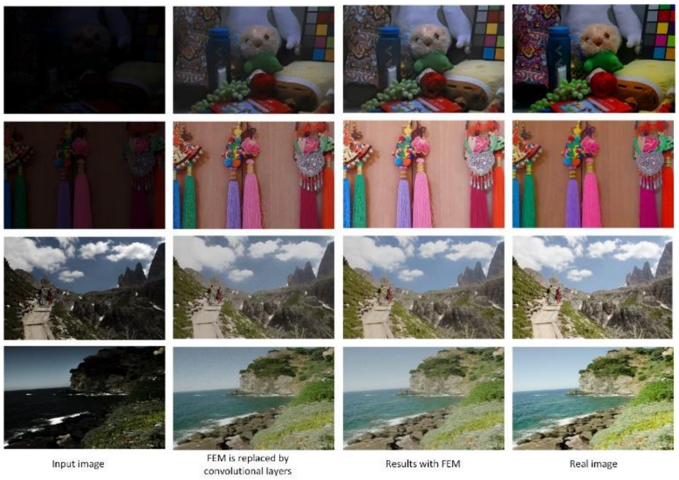

Fig. 6. Ablation experiments to verify the effectiveness of the FEM model.

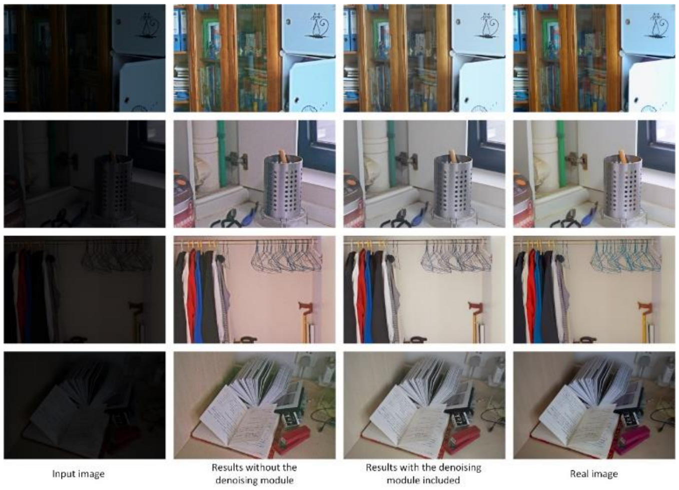
2) The effectiveness of the denoising network: To validate the efficacy of the denoising module, a comparison was made between a method trained without the denoising network and the original method. As depicted in the Fig. 7, the experimental results employing the denoising network effectively remove the noise from the image, and the results after the removal of noise contain finer details and more vivid colors. *It is* illustrat*ed* in the Table *II* that the method incorporating the denoising network improves the PSNR ratio by 2.88 (22.77-19.29) and the SSIM ratio by 0.17 (0.84-0.67). These results demonstrate the effectiveness of the denoising network in this experiment.



Input image
Results without the denoising module
Results with the denoising module included
Real image

Fig. 7. Ablation experiments to verify the effectiveness of the FEM module.

TABLE II. RESULTS OF THE OBJECTIVE EVALUATION OF THE ABLATION EXPERIMENTS

Different situations	PSNR	SSIM	NIQE	GMSD
No FEM module	16.48	0.63	0.51	0.083
FEM module	20.22	0.80	0.46	0.066
No denoising network	19.29	0.67	0.58	0.073
denoising network	22.17	0.84	0.43	0.042

V. CONCLUSIONS

This paper proposes a low light image enhancement method based on Retinex. We propose an efficient network for decomposing a low light image, incorporating an innovative loss function that integrates perceptual, light consistency and global consistency to obtain high quality light and reflection maps. The decomposition network comprises a reflection image extraction module (RM) and an illumination image extraction module (IM). Additionally, we integrate a denoising network and an enhancement module to further improve image quality. Our method not only enhances image color smoothness, reduce artifacts, but also effectively remove noise to restore image details under low-light conditions. By employing the FEM attention module instead of the convolution layer, our method successfully preserves object details. This results in a smoother color transition, yielding clearer and more natural images. Experimental results demonstrate that the proposed method achieves significant performance improvement across various low-light scenes. When compared to other existing methods, our method excels in image enhancement and detail recovery, showcasing superior noise removal and artifact suppression. In future work, we aim to extend the application of this method to other computer vision tasks, substantiating its versatility and performance advantages in different domains through comparisons with other state-of-the-art methods.

***Abstract*—Aiming at the problems of high complexity, insufficient global information extraction and easy overfitting in finger vein recognition, a finger vein recognition method based on diffusion model is proposed. Firstly, finger vein images are generated according to the dataset by diffusion model, which is used to prevent overfitting; secondly, a streamlined convolutional neural network is used to form a two-branch lightweight backbone network with an improved multi-head self-attention mechanism, which can effectively reduce the complexity of the model; and finally, in order to maximally extract the image's overall information, the convolution is used to merge the extracted local and global features, and the recognition results are output. The algorithm can reach a maximum recognition rate of 99.78% on multiple datasets, while the number of references is only 2.15M, which further reduces the complexity of the algorithm while maintaining a high accuracy compared to other novel finger vein recognition algorithms as well as lightweight convolutional neural network models. As the first attempt in this field, it will provide new ideas for future research work.**

Keywords—Finger vein recognition; convolution neural network; diffusion model; multi-head self-attention mechanism; lightweight network

I. Introduction

Lately, the focus of researchers on finger vein recognition technology has intensified, attributed to its exceptional security and precision. Since the vein network of each individual is hidden under the skin, finger vein-based biometrics has a massive advantage in live identification. As a developing technology, finger vein recognition-based biometrics is far from flawless. Various internal and external factors can impact the performance of finger vein verification. These factors include: Lighting Conditions, Finger Placement Angle, and Uniform illumination. Therefore, high-precision and high-robustness algorithms are essential for feature extraction, recognition, or verification of finger vein images. A typical finger vein recognition process includes image acquisition, preprocessing, feature extraction, and matching. In the finger vein image acquisition process, a finger vein image acquisition device consisting of an image sensor and an infrared light source is used. Preprocessing of the acquired finger vein images is carried out to facilitate the subsequent feature extraction process. Suppressing noise, improving image contrast, and performing data augmentation are common image preprocessing methods.

Feature extraction in finger vein recognition involves two main categories: traditional recognition methods and deep learning methods. Traditional recognition methods for feature extraction can be further classified into three distinct categories: template-based methods [1], representation-based methods [2], and feature-based [3][4][5] learning methods. These methods require manual labeling of parameters, depend on image quality, and have cumbersome recognition steps. Compared with machine learning methods, deep learning [6][7][8][9] based methods can achieve more stable recognition results by acquiring more profound image features through Convolutional Neural Networks (CNN). Therefore, some researchers proposed deep learning-based finger vein recognition methods. For example, Radzi et al. [10] proposed a CNN-based finger vein recognition method, Fang et al. [11] proposed a lightweight two-channel network to improve the verification of finger veins by extracting the mini-region of interest (ROI), Zhang et al. [12] proposed Domain Adaptation Finger Vein Network (DAFVN) improve the final recognition result by extracting illumination invariant features in the image and reducing the effect of light on the recognition result. Recently, researchers proposed the Vision Transformer (ViT) [13] method, which has attracted widespread attention in deep learning. Compared with CNN, ViT focuses more on global features and has shown excellent performance in several domains. In addition, researchers have proposed some improved methods, such as Liu et al. [14] proposed Swin Transformer, which obtains global and local features by constructing hierarchical feature maps and sliding windows, with better experimental results but high model complexity, and Peng et al. [15] proposed Parallel Network Architecture, which makes use of convolution and Multi-Head Self-Attention (MHS) mechanism. Head Self-Attention (MHSA) to extract local and global features in parallel, which improves the network performance but is ineffective for small datasets. Based on the advantages of Transformer, researchers started applying it to finger vein recognition. Huang et al. [16] proposed Finger Vein Transformer (FVT) model for recognition, which achieves multi-scale feature extraction by reducing the number of tokens layer by layer, but exploiting the Transformer increases the complexity and computation at the same time.

To enhance the efficiency of recognizing finger veins, some researchers have introduced data enhancement techniques to make the model better adapt to finger vein images in various scenarios. Yang et al. [17] proposed Finger Vein Representation Using the Generative Adversarial Networks (FV-GAN) model, which was the first time GAN was in the field of finger vein recognition. Choi et al. [18] proposed a Conditional Generative Adversarial Network (CGAN) to recover blurred images. They used a deep convolutional neural network for the finger vein images—a convolutional neural network for finger vein image recognition. Hou et al. [19] proposed a ternary classifier, GAN, for generating training data to improve the learning ability of the CNN classifier. Although high-quality images can be generated using GAN networks, they require more extensive databases and may be unstable during training.

Diffusion Model (DM) [20] is a recently emerged deep generative model for high-quality image generation, which is rapidly evolving and is widely used in tasks such as text-to-image generation, image-to-image generation, and video image generation. Also, one of the data enhancement methods, the diffusion model has a more straightforward training process and generates higher-quality images compared to GAN networks. Jonathan et al. [20] proposed the Denoising Diffusion Probabilistic Model (DDPM), which is used for image generation tasks, generating the image quality is higher than other generation models such as GAN. Robin [21] et al. proposed Latent Diffusion Models (LDM), which achieve image generation by introducing a cross-attention conditioning mechanism, which significantly improves the training and sampling efficiency without degrading its quality.

Summarizing the above research methods, the existing algorithms for finger vein recognition generally have high complexity, recognition accuracy needs to be improved, and the training process is unstable, so a two-branch lightweight finger vein recognition model (FV-DM) based on the diffusion model is designed to achieve finger vein image generation using the diffusion model to solve the problem of overfitting due to the small finger vein dataset. The CNN and the improved E-MSHA module are used to extract image features in parallel with the dual-branching in the feature extraction process to avoid the problem of low accuracy caused by insufficient feature extraction, while the diffusion model is used in the finger vein recognition process in order to explore a new way of finger vein recognition. The comprehensive experiments on the self-constructed dataset and three public datasets show that FV-DM all achieve better recognition results, as well as lower model parameters and computational complexity, shorter recognition time, and lower Equal Error Rate (EER).

The remainder of this paper is organized as follows. Section 2 introduces our modelling approach and explains how it works. Section 3 describes the experiments conducted to validate the performance of the model. In Section 4, we summarize the paper and make suggestions for future work.

II. Methodology

A. Diffusion Model

Recently, the diffusion model as a generative model has received more and more attention from researchers due to its powerful image generation ability. As shown in Fig. 1, the diffusion model is mainly divided into the forward noise addition process and the reverse denoising process. The solid line indicates the forward noise addition process and the dashed line indicates the reverse denoising process.

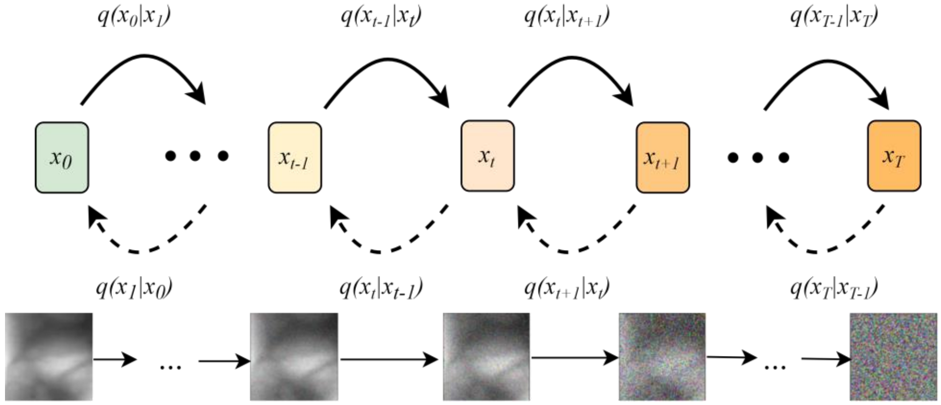

Fig. 1. Network structure diagram of diffusion model.

1) Forward noise addition process: The forward noise addition process uses Gaussian noise to gradually add noise to the input image, generating a series of noise samples $x_0, x_1, ..., x_T$ until the image becomes a pure noise image. Assuming that $q(x_0)$ is the probability distribution of the real image, $q(x_t \mid x_{t-1})$ represents the probability distribution of the current image x_t obtained by adding noise to the previous step image x_{t-1} in the forward noise addition process, and the mathematical expressions for each step of the process of adding Gaussian noise are shown in (1):

$$q(x_t \mid x_{t\text{-}1}) = N(x_t \mid \sqrt{1\text{-}\beta_t}\, x_{t\text{-}1}, \beta_t I) \tag{1}$$

Where β_t is the diffusivity and t varies with time. The formula is expressed as a mean $\mu_{\mathrm{t}} = \sqrt{1-\beta_t}\, x_{t-1}$ with a variance Gaussian $\sigma_t^2 = \beta_t$ distribution. If the final image x_T is obtained through x_0, the whole process can be regarded as a Markov chain from $t=1$ to the moment $t=T$, as shown in Eq. (2):

$$q(x_{0:T}) = q(x_0)\prod_{t=1}^{T} q(x_t \mid x_{t-1}) \tag{2}$$

In the forward noise addition process, Eq. (1) can be expressed as by the simplified way in literature [23]:

$$x_t = \sqrt{1-\beta_t}\, x_{t-1} + \sqrt{\beta_t}\, z_{t-1} \tag{3}$$

Where z_{t-1} denotes the noise at moment $t-1$. The x_t at any moment is obtained from the original image x_0 with the formula shown in the following equation:

$$\alpha_t = 1-\beta_t \tag{4}$$

$$\overline{\alpha_t} = \prod\nolimits_{i=1}^{t} \alpha_i \tag{5}$$

$$\begin{aligned} x_t &= \sqrt{\alpha_t}\, x_{t-1} + \sqrt{1-\alpha_t}\, z_{t-1} \\ &= \sqrt{\overline{\alpha_t}}\, x_0 + \sqrt{1-\overline{\alpha_t}}\, z_t \end{aligned} \tag{6}$$

$$q(x_t \mid x_0) = \mathrm{N}\,(x_t | \sqrt{\overline{\alpha_t}}\, x_0, (1-\overline{\alpha}_t)I) \tag{7}$$

z_t is denoted as a Gaussian distribution satisfying $\mathrm{N}\,(0, I)$

2) Reverse denoising process: The reverse denoising process is also known as the inverse diffusion process. The main purpose is to gradually predict the target image x_0 from the purely noisy image x_T, i.e., to derive the x_{t-1} distribution from x_t, which can be transformed into what is shown in Eq. (8) by using Bayes' formula:

$$q(x_{t-1} \mid x_t) = q(x_t \mid x_{t-1}) \frac{q(x_{t-1})}{q(x_t)} \tag{8}$$

According to the forward noise addition process, $q(x_t \mid x_{t-1})$ is known, and for $q(x_{t-1})$ and $q(x_t)$, it can be solved by adding the known condition x_0, as shown in the following equation:

$$q(x_{t-1} \mid x_t, x_0) = q(x_t \mid x_{t-1}, x_0) \frac{q(x_{t-1} \mid x_0)}{q(x_t \mid x_0)} \tag{9}$$

In the process of reverse denoising, the features in the input noisy image are predicted by the neural network, and this paper chooses U-Net as the model for noise prediction. U-Net is a U-shaped network structure, which consists of downsampling on the left side, upsampling on the right side, and cross-layer connections. The downsampling reduces the size of the feature map through the convolution operation and reduces the computational cost. The upsampling gradually restores the feature map to its original size through the inverse convolution operation, and the cross-layer connection is used to splice the features between the downsampling and the upsampling, which can effectively integrate the features of different levels of the image. For normalisation, Group Normalization (GN) is chosen. Finally, for the downsampling and upsampling operations in U-Net, the convolution with a step size of 2 and the inverse convolution are chosen, respectively. The specific structure is shown in Fig. 2.

B. Design of the Network Model

Inspired by DDPM [20], a finger vein recognition network based on a diffusion model is designed. It is shown in Fig. 3

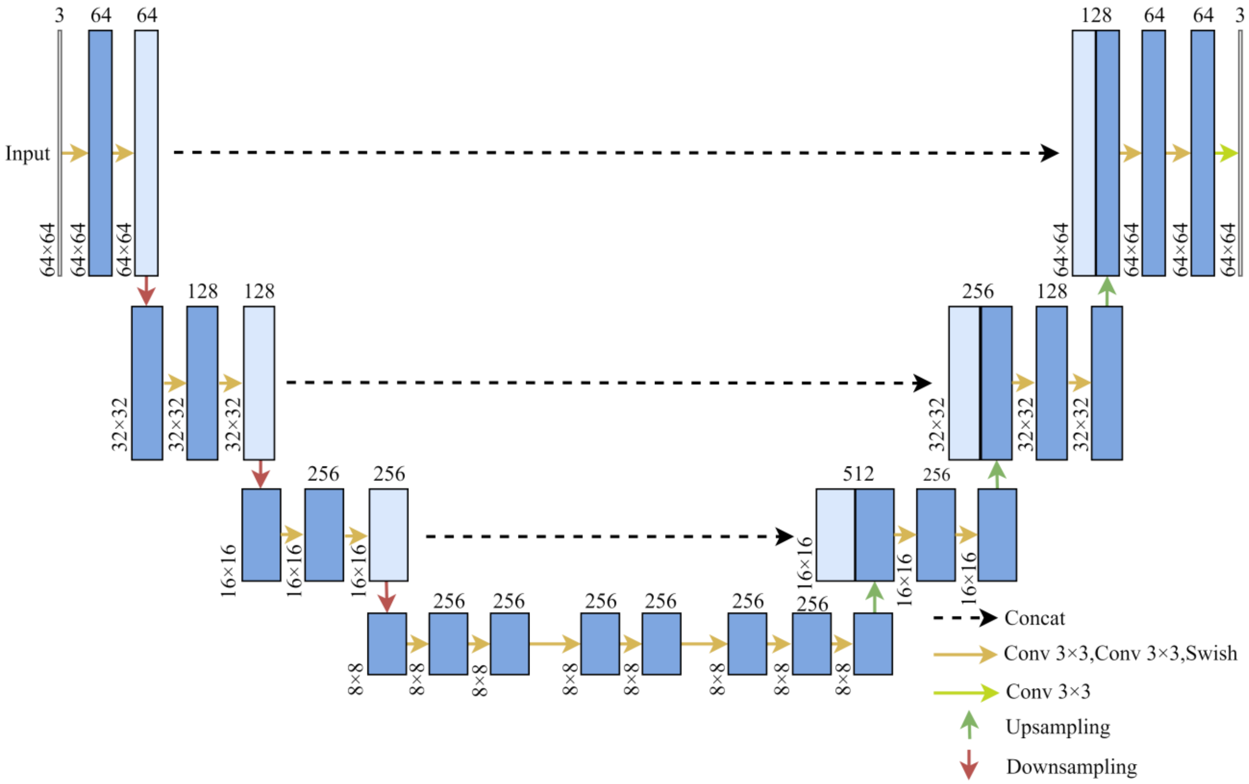

Fig. 2. U-Net Structure diagram.

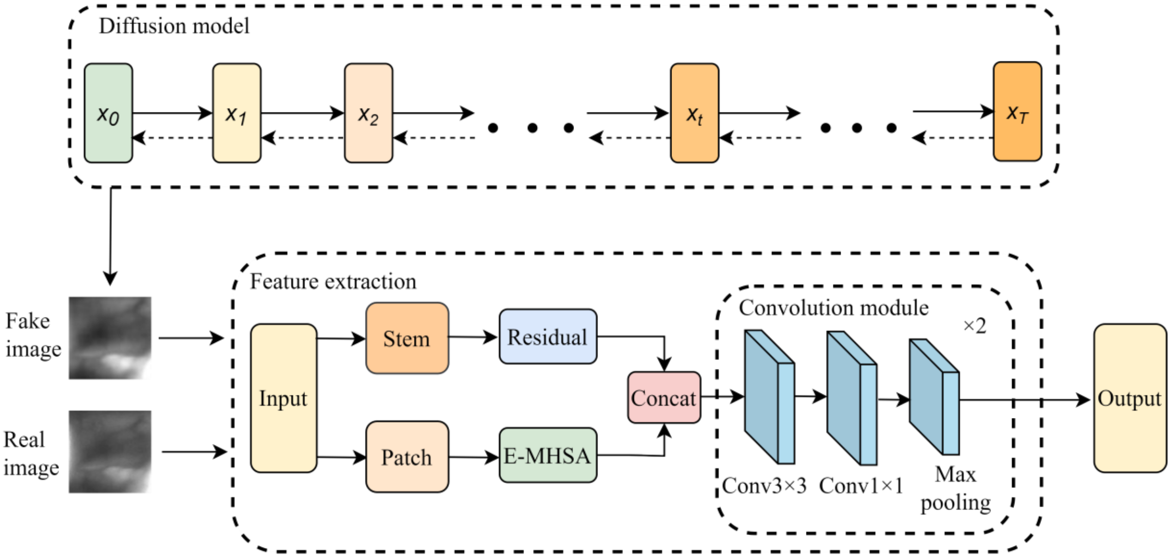

Fig. 3. Structure diagram of diffusion model.

The network structure contains two main parts: the image generation part and the image feature extraction part. Firstly, the diffusion model is used to achieve image generation by forward noise addition process and reverse denoising process. Then, the generated image is passed into the feature extraction network along with the actual image, and the Residual [22] module and the E-MHSA module extract the global and local features of the image, respectively, and stitch the features after extraction, which allows for better fusion of the features and further improves their expressive ability. The fused features are passed through the convolution module to achieve the extraction of deeper features. As shown in the figure, the convolution module consists of an ordinary convolution of size, an ordinary convolution of size, and a maximum pooling layer and is stacked twice in the feature extraction process to extract image features more comprehensively.

C. Residual Structure

The model uses a Residual module and an improved E-MHSA module for local and global feature extraction in the early stage of feature extraction. The Residual module consists of an inverted residual structure, which can effectively reduce the computational cost while extracting the local features of the image. The specific structure is shown in Fig. 4.

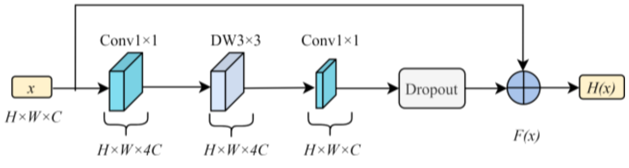

Fig. 4. Residual structure diagram.

The inverted residual structure contains two ordinary convolutions, a DW convolution, a Dropout layer and a jump connection. The input information is first increased by 1×1 size ordinary convolution, then the image size is transformed by DW convolution with a convolution kernel size of 3×3, and finally the number of channels is decreased by 1×1 size ordinary convolution, and the Dropout is used to randomly discard the features to prevent the parameter from relying too much on the training data and the phenomenon of overfitting. Finally, the output of the Dropout layer is added with the result of the jump join to complete the output of the information. The jump connection is mathematically defined as:

$$H(x) = F(x) + x \tag{10}$$

Where $F(\cdot)$ is a function containing convolution, pooling, and modified linear unit operations, x inputs the feature map, and $H(x)$ is the output of the inverted residual structure. The inclusion of jump connections in the inverted residual accelerates the convergence of the network and improves the generalization of the model.

D. E-MHSA Structure

Since MHSA has a strong ability to capture low-frequency signals, which are used to provide global information, the enhanced E-MHSA module is used in this paper for global feature extraction. Compared to the traditional MHSA, E-MHSA incorporates average pooling operation and down-sampling before the computation of the attention mechanism in order to reduce the computational cost and achieve a more efficient and lightweight deployment. As shown in Fig. 5, the E-MHSA module is similar to the Transformer Block in ViT, which first captures the low-frequency signals through E-MHSA with the following formula:

$$\text{E-MHSA}(x) = concat(SA(x_1), SA(x_2), ..., SA(x_h))W^0 \tag{11}$$

Where $x = [x_1, x_2, ..., x_h]$ denotes the division of input feature x into multiple heads in the channel dimension and h is the number of heads divided. In this paper, we take 8 as the number of heads for the attention mechanism. $SA(\cdot)$ is the computational formula for the attention mechanism, and the formula is as follows:

$$SA(x) = Attention(X \cdot W^{Q}, P_s(X \cdot W^{K}), P_s(X \cdot W^{V})) \quad (12)$$

where P_s represents the average pooling operation with step size s.

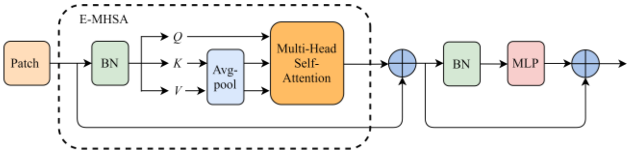

Fig. 5. Structure diagram of E-MHSA.

III. Experiments and Analyses

A. Presentation of Datasets

The experiments were conducted on three public datasets, FV-USM [24], SDUMLA-HMT [25], THU-FVFDT2 [26], and with a self-constructed dataset, FV-SIPL, which were divided in a 2:1 ratio, except for the THU-FVFDT2 dataset, in which the training and test sets were equally divided. The data information is shown in Table I.

TABLE I. Data Information From Four Datasets

Dataset	Total number of categories	Total image count	Total training sets	Total test sets
FV-USM	492	5904	3936	1968
SDUMLA-HMT	636	3816	2544	1272
THU-FVFDT2	610	1220	610	610
FV-SIPL	108	1296	864	432

1) *FV-USM:* The dataset was provided by Universiti Teknologi Malaysia and contained finger vein images from 123 volunteers, with 12 images captured from each of the four fingers of each volunteer. Therefore, the whole dataset covers a total of 492 finger categories and 5904 images. The size of each of these images is 640×480pixels.

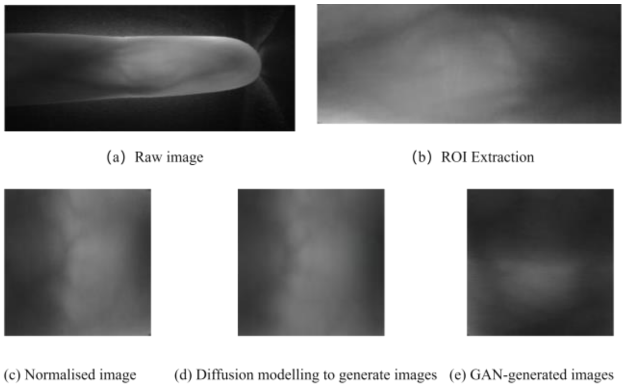
2) *SDUMLA-HMT:* The dataset was provided by Shandong University, which contains finger vein images of 106 volunteers, and 6 images were collected for each index, middle, and ring finger of each volunteer's hands the whole dataset covers a total of 636 finger categories and 3816 images, where each image size is 320×240pixels.

3) *THU-FVFDT2:* The dataset was provided by Tsinghua University and contained finger vein images of 610 volunteers. Finger vein images were collected twice for each volunteer, with a total of 1220 images, each with a size of 200×100pixels.

4) *FV-SIPL:* This dataset was made by the Signal and Information Processing Laboratory of Liaoning University of Engineering and Technology by using infrared finger vein acquisition sensors to collect finger vein images from 27 volunteers. Among them, 12 images were acquired for each of the four fingers of each volunteer, and the whole dataset covered 108 finger categories and 1296 images in total. The size of each image is 176×415 pixels.

B. Image Preprocessing

In order to facilitate the subsequent process of image feature extraction, preprocessing operations are performed on the image. Taking the FV-USM dataset as an example, the main processes are shown in Fig. 6(a) to (d) below.



(a) Raw image
(b) ROI Extraction
(c) Normalised image
(d) Diffusion modelling to generate images
(e) GAN-generated images

Fig. 6. Image preprocessing process.

For the original images in the dataset, first of all, through the ROI extraction operation, to reduce the interference of irrelevant information on the recognition results, and then carry out image normalisation, pass the normalised images into the diffusion model, and set the number of iterations in the training process to be 10000, and the time T to be 1000. the same parameter settings are carried out on the commonly used generative model GAN, and it can be seen through Fig. 6(d) and Fig. 6(e) that the images generated by the diffusion model are clearer and show more similar image features to the original image, so the use of diffusion model is chosen as the data enhancement method in FV-DM.

C. Experimental Environment and Parameter Settings

The experiments were conducted under the Linux operating system using PyTorch1.7 framework, and the graphics card used for training and testing was GeForce RTX 3090. The learning rate was set to 0.001, the batch size was set to 16, and Stochastic Gradient Descent (SGD) was chosen as the optimiser, where the momentum was set to 0.9. The input size of finger veins was uniformly adjusted to 224×224pixels, and the final experimental results were obtained by training iterations 100 times.

D. Evaluation Indicators

In order to evaluate the performance and advantages of the model, metrics such as Accuracy, Equal Error Rate, Average Processing Time for a Single Image, Number of Parameters, and Floating Point Operations (FLOPs) are selected for evaluation. Accuracy rate, as one of the commonly used metrics in finger vein recognition, can reflect the ability of the model to correctly identify different categories of samples in the entire dataset. The formula for accuracy rate is shown in (13):

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (13)$$

Where *TP* denotes the number of correct positive sample predictions, *TN* denotes the number of correct negative sample predictions, *FN* denotes the number of incorrect negative sample predictions, and *FP* denotes the number of incorrect positive sample predictions. In image recognition tasks, the EER value is usually used as an indicator to evaluate the good or bad performance of the model, which is determined by the False Acceptance Rate (FAR) and the False Rejection Rate (FRR). The formulas for FAR and FRR are shown below:

$$FAR = \frac{FP}{FP+TN} \tag{14}$$

$$FRR = \frac{FN}{TP+FN} \tag{15}$$

Wherein the number of samples for incorrect acceptance and incorrect rejection is defined by a predetermined threshold. When the threshold of matching is greater than the preset threshold, it is determined to be incorrectly accepted, and vice versa is determined to be incorrectly rejected. The value when *FRR* and *FAR* are equal is the equal error rate. The equal error rate reflects the overall performance of the recognition method. The smaller the value of equal error rate, the better the performance of the recognition method.

E. Comparison Experiment

In order to verify the effectiveness of the FV-DM method, it is compared with the classical Transformer network models: the VIT-B, Swin-T, Conformer-B, Next-ViT and the lightweight CNN network model EfficientNetV2. The recognition accuracy results of the different methods on the datasets are shown in Table II. The results in the table show that the methods proposed in this paper achieve the best recognition results on all four datasets. Bolding indicates the best results and underlining indicates the second best results. In addition to the accuracy comparison, the average processing time, number of parameters and FLOPs of individual images for the different methods were also compared, as shown in Table III. In terms of the average processing time for a single image, MobileNetV2 is 2.27ms, which is 0.53ms faster than FV-DM, which is due to the MSHA contained in FV-DM. Other than that, FV-DM outperforms the other methods.

TABLE II. RECOGNITION ACCURACY OF DIFFERENT METHODS ON FOUR DATA SETS (UNIT: %)

Method	FV-USM	SDUMLA-HMT	THU-FVFDT2	FV-SIPL
VIT-B[13]	58.67	63.66	59.55	76.28
Swin-T[14]	95.0	93.33	76.01	95.12
Conformer-B[15]	99.0	98.67	96.64	99.33
Next-ViT[27]	98.56	99.0	98.87	99.53
EfficientNetV2[28]	98.10	98.07	97.78	98.20
MobileNetV2[22]	98.12	99.0	98.32	99.0
ResNet101[29]	98.33	98.34	98.21	99.0
FV-DM(Our)	**99.67**	**99.66**	**99.10**	**99.78**

TABLE III. COMPARISON OF EVALUATION INDEX RESULTS OF DIFFERENT METHODS

Method	Time/ms	Parameters/M	FLOPs/G
VIT-B	11.30	103.03	16.88
Swin-T	7.21	28.27	4.37
Conformer-B	7.15	96.63	21.01
Next-ViT	3.52	31.76	5.79
EfficientNetV2	3.49	21.46	2.90
MobileNetV2	**2.27**	3.50	0.33
ResNet101	7.61	44.55	7.84
FV-DM(Our)	2.80	**2.15**	**0.19**

In this paper, four datasets are used to compare different recognition methods, including VIT-B, Swin-T and Conformer-B. The results are shown in Fig. 7.

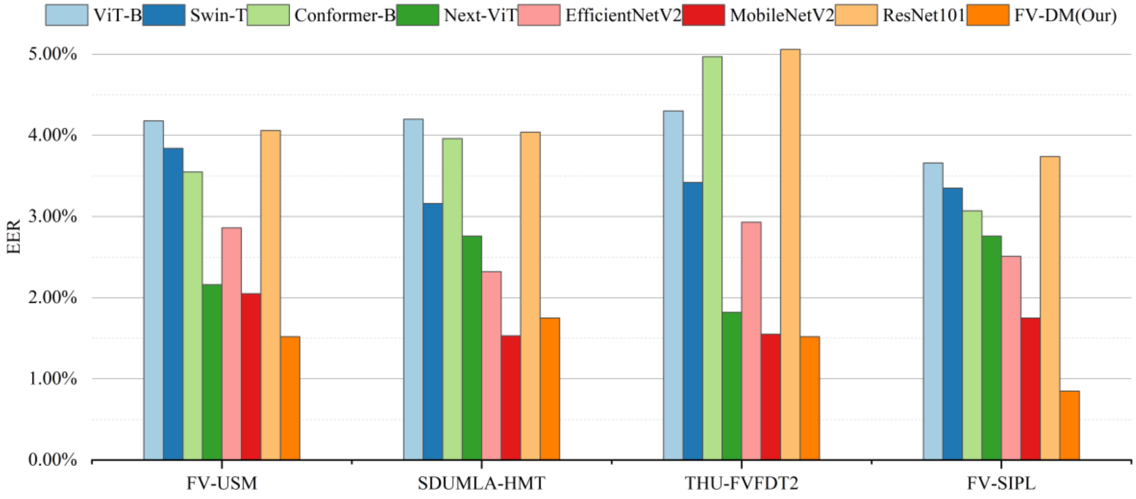


Fig. 7. Comparing the equal error rates of different methods.

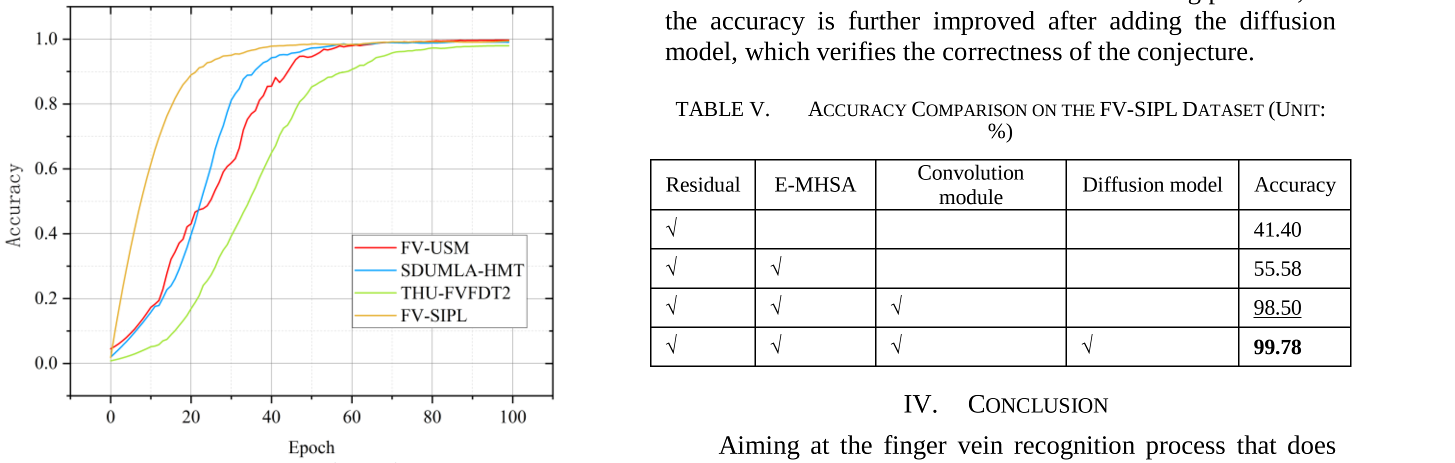
On the SDUMLA-HMT dataset, the equal error rate of FV-DM is slightly higher than that of MobileNetV2, but except for that, FV-DM maintains the lowest equal error rate, which indicates that the FV-DM method has excellent performance in finger vein recognition, and it can be used as an effective recognition method. Compared with other methods, the FV-DM method has higher accuracy and better robustness, so it has a wide range of application prospects in practical applications.

TABLE IV. RECOGNITION ACCURACY OF DIFFERENT METHODS ON PUBLIC DATASETS (UNIT: %)

Method	FV-USM	SDUMLA-HMT	THU-FVFDT2
Merge CNN[30]	96.15	89.99	—
DS-CNN[31]	—	98.00	89.00
Semi-PFVN[32]	94.67	96.61	—
LFVRN_CE[33]	98.58	97.75	—
DGLFV[34]	—	99.25	—
CMrFD[35]	98.33	98.92	—
FVT	**99.73**	97.90	90.66
TFHFT-DPFNN[36]	—	98.00	—
CNNs[37]	97.95	—	—
Coding SchemeA[38]	99.59	95.91	—
FV-GAN	—	—	98.52
Triplet-classifier GAN	99.66	99.53	—
FV-DM(Our)	99.67	**99.66**	**99.10**

FV-DM is compared with novel finger vein models in recent years, and the results are shown in Table IV. Among them, FV-DM obtained the highest recognition accuracy on both public datasets, SDUMLA-HMT and THU-FVFDT2. The recognition accuracy on the FV-USM dataset is lower than that of the FVT method by 0.06%, but it is higher than that of FVT on the SDUMLA-HMT and THU-FVFDT2 datasets by 1.77% and 9.03%, respectively. Therefore, from the overall results, FV-DM recognition results are better.



(a) Recognition accuracy curves for the four datasets.

(b) Loss curves for the four datasets.

Fig. 8. Recognition accuracy and loss curve of FV-DM on four datasets.

By comparing the novel finger vein recognition algorithms in recent years, FV-DM has better performance in terms of recognition accuracy, recognition time, complexity, etc. the recognition accuracy versus test loss curves of FV-DM on the four datasets are shown in Fig. 8.

F. Ablation Experiment

Ablation experiments were conducted in order to better validate the effectiveness of the modules in each part of the network. Under the premise that the rest of the conditions remain unchanged, modules such as Residual, E-MHSA, convolutional module and diffusion model are added to the network sequentially, and the accuracy rate is tested with the FV-SIPL dataset as an example, and the experimental results are shown in Table V. From the table, it can be seen that the accuracy rate increases step by step after the modules are added. Residual and E-MHSA need to be further fused after extracting the local and global features, respectively, to achieve a more comprehensive feature extraction, so the accuracy rate is increased by 42.92% after adding the convolution module compared with the previous one. The introduction of the diffusion model can achieve intra-class enhancement of the data and avoid the overfitting problem, so the accuracy is further improved after adding the diffusion model, which verifies the correctness of the conjecture.

TABLE V. ACCURACY COMPARISON ON THE FV-SIPL DATASET (UNIT: %)

Residual	E-MHSA	Convolution module	Diffusion model	Accuracy
√				41.40
√	√			55.58
√	√	√		98.50
√	√	√	√	**99.78**

IV. CONCLUSION

Aiming at the finger vein recognition process that does not fully consider the global features of the image, is easy to overfit, and has other problems, this paper proposes a two-branch lightweight finger vein recognition method based on the diffusion model. Firstly, the diffusion model is used to generate finger vein images to expand the finger vein dataset. Secondly, a two-branch network composed of a convolutional neural network and improved E-MHSA is used to extract global and local features from the expanded dataset. Then, the extracted global and local features are fused by the convolutional module, and the image features are further extracted. Finally, the recognition results are output, and the effectiveness of the method is verified on multiple datasets at the same time. Experiments show that the method in this paper can improve the recognition performance while keeping the computational cost small. In future work, the application of the diffusion model in finger vein recognition will be explored deeply to seek more possibilities.

Abstract—**Natural Language Processing (NLP) has emerged as a critical technology for understanding and generating human language, with applications including machine translation, sentiment analysis, and, most importantly, question classification. As a subfield of NLP, question classification focuses on determining the type of information being sought, which is an important step for downstream applications such as question answering systems. This study introduces an innovative ensemble approach to question classification that combines the strengths of the Electra, GloVe, and LSTM models. After being tried thoroughly on the well-known TREC dataset, the model shows that combining these different technologies can produce better outcomes. For understanding complex language, Electra uses transformers; GloVe uses global vector representations for word-level meaning; and LSTM models long-term relationships through sequence learning. Our ensemble model is a strong and effective way to solve the hard problem of question classification by mixing these parts in a smart way. The ensemble method works because it got an 80% accuracy score on the test dataset when it was compared to well-known models like BERT, RoBERTa, and DistilBERT.**

***Keywords**—Ensemble learning; long short term memory; transformer models; Electra; GloVe; TREC dataset*

I. INTRODUCTION

There are many areas where machine learning has completely changed how we solve problems. These include healthcare, banking, and natural language processing [1], [2], [3]. It has made it possible for computers to learn from data on their own, making choices, predicting trends, and even finding patterns that are too complicated for humans to understand. NLP is the study of how computers and people use language. With the rise of machine learning, big steps forward have been made in NLP, especially in areas like mood analysis, machine translation, and summary [4], [5], [6], [7]. One of the most important things that natural language processing does is sort questions into groups. In the real world, this job is very important for many things, such as search engines, virtual helpers like Siri or Google Assistant, and customer service bots. Question sorting that is done right can lead to more accurate and useful answers, which improves the service these apps can provide. Think about a medical robot that can correctly classify a health question and give a possibly life-saving answer, or a virtual tourist helper that can tell the difference between questions about food and questions about historical sites. It's not just handy that the good effects happen; they often have big effects [8], [9], [10]. However, the complexity of human language, which includes subtleties in syntax, meaning, and pragmatics, makes it very hard to get very accurate question classification [11], [12]. Support Vector Machines, Random Forests, and other machine learning models have been used for this, but new developments in deep learning and transformer models like BERT, RoBERTa, and ELECTRA have shown that they work even better than expected [13]. These models are very good at understanding the meanings and contexts of words and sentences, which is a key part of question classification [1], [14], [15], [16] and [17]. Here, we show a new method that combines three strong tools: the ELECTRA model for contextual embeddings based on transformers; Global Vectors for Word Representation (GloVe) for creating semantically rich word vectors; and Long Short-Term Memory (LSTM) networks for capturing sequence dependencies. The Text REtrieval Conference (TREC) dataset, which is a common standard for question classification tasks, is used to train and test our ensemble model. The main thing that our work adds is that we combine several different but useful techniques in a way that makes them work better together than current best models at classifying questions.

This study is organized into the following taxonomy: Section II starts by doing a full literature review of earlier work that looked at question categorization and related ensemble methods, Section III shows a full explanation of the method used is given, which includes the ELECTRA model, GloVe embeddings, and LSTM networks, Section IV presents the proposed approach, Section V describes how the experiment was set up, what the results were, and why we came to the conclusions we did, and in Section VI, we talk about the results, the limits, and the opportunities for more study.

II. LITERATURE REVIEW

A. Previous Work

In NLP, question categorization has been a major area of study for twenty years, with many researchers working on it. Over the years, techniques in this area have changed a lot, from simple machine learning methods to the most advanced deep learning models used today. Support Vector Machines (SVM) and other well-known machine learning methods were used in the early stages of this study. For example, Zhang and Lee used SVMs to sort questions [18].

Deep learning methods came out as machine learning got better. These made models more stable. Kalchbrenner et al. were the first to use convolutional neural networks (CNNs) to tag words with questions and put them into groups. After that, scientists studied Recurrent Neural Networks and various types of them, such as Long Short-Term Memory networks. After Zhou et al. used LSTMs well to find the long-term connections in question replies, they came up with some hopeful results [19].

When language models like BERT, RoBERTa, and ELECTRA came out, they were the next big step forward in the field of NLP. A lot of natural language processing jobs, like question classification, were done better by these transformer-based systems. Devlin et al. created BERT and showed that it could record context-rich embeddings [18]. While Liu et al. worked on RoBERTa and Clark et al. worked on ELECTRA, they pushed the limits of efficiency [20], [21].

Individual models have worked well on their own, but group methods have become popular as a way to combine the different strengths of these models. Vaswani et al. suggested a group that combined transformers and LSTMs, which showed a big improvement in performance compared to using just one model [22]. However, ensemble methods that are specifically made for question classification have not been widely used. This points to an interesting area for future study.

The role of word embeddings, especially GloVe, is another part of this changing environment. When Pennington et al. first presented GloVe, it quickly became a mainstay in many NLP tasks, such as question classification [23].

Before they come up with a new type of feature based on question patterns, Nguyen and Le look at lexical, syntactical, and semantic features. The writers came up with a way to choose features that would work for different types of questions. They used the TREC dataset and Support Vector Machines (SVM) for classification to show that their plan worked [24].

Chotirat and Meesad use two datasets—TREC-6 (English) and a Thai speech dataset—to test different machine learning models. The combined CNN-BiLSTM model did better than the other models, according to the findings. These results show that deep learning methods, especially mixed models, can improve the accuracy of question sorting in a lot of languages. The addition of Part-of-Speech tagging was a key factor in this speed boost [25].

The real-world data that Madabushi et al. give show that their system works better. When fine-grained question classification is paired with deep learning models, they show big improvements in how well the answers are chosen. The new taxonomy and object recognition system worked better than earlier models, showing that their way works. These results show how important it is to include question classification in deep learning systems for jobs like answer choice [26].

B. Rationale for the Proposed Approach

Combining Electra, GloVe, and LSTM in a new way, we describe a new ensemble method for question classification, this method was chosen because it can work well with others to help with the complex nature of understanding questions, with its transformer-based structure, Electra is great at handling complex language tasks and fully understanding their context, GloVe adds to this by providing detailed word-level meaning models that describe the complexity of how language is used, and LSTM helps by correctly simulating long-term relationships in text, which is very important for understanding how questions are asked in a certain order. These models work together to get around the problems that separate models like BERT and RoBERTa have, especially when it comes to handling complicated question forms and changing contexts. As you can see from our positive test results, our approach uses the strengths of each model to make question sorting more accurate and faster. This combination not only makes performance measures better, but it also makes it possible to analyze questions in a more detailed and full way, which is a big step forward in natural language processing.

Different modeling strategies have their own pros and cons, and there hasn't been much research on how to combine them into a single model for question classification, our work introduces a new ensemble method that combines ELECTRA, GloVe, and LSTM, the objective is to create a new style for grouping questions into different categories.

III. Background

This section provides a comprehensive overview of the primary components of our ensemble model: the ELECTRA model, GloVe word embeddings, and LSTM networks.

A. ELECTRA

ELECTRA (Efficiently Learning an Encoder that Classifies Token Replacements Accurately) is a transformer-based model developed for natural language processing tasks, proposed by researchers at Google Research in 2020, ELECTRA uses a novel approach to training known as Replaced Token Detection [17].

Traditional transformer models, such as BERT [1], utilize masked language modeling as a pre-training task, where some percentage of the input tokens are masked and the model is trained to predict the original tokens. ELECTRA, on the other hand, introduces a different mechanism. It consists of two parts: a generator and a discriminator. The generator is a small masked language model that suggests replacements for some of the tokens in the input. The discriminator is then tasked with predicting whether each token in the sequence was replaced by the generator or not.

This training mechanism can be described with the following steps:

1) The generator G, a small BERT-like model, is used to replace some tokens in the input sequence.

2) The discriminator D, a larger BERT-like model, then attempts to predict for each position whether it contains the original token or a replacement.

The main advantage of this approach is that it allows for the entire input sequence to be utilized during pre-training, as opposed to just a small masked portion, making the training process more efficient and effective.

B. GloVe

GloVe is an unsupervised learning algorithm developed by the Stanford NLP Group for obtaining vector representations for words. The primary idea behind GloVe is that the co-occurrence statistics of words in a corpus capture a significant amount of semantic information [23]. To construct the GloVe representations, the following steps are carried out:

1) A global word-word co-occurrence matrix is constructed from the corpus, where each element `$X_{ij}$` represents the frequency with which word `i` appears in the context of word `j`.

2) The objective of GloVe is then to learn word vectors such that their dot product equals the logarithm of the words' probability of co-occurrence.

Mathematically, this is represented as:

$$V_i \,.\, V_j = \log(P(i|j)) \qquad (1)$$

where V_i and V_j are the word vectors for words i and j, and P(i|j) is the probability of i appearing in the context of j.

C. LSTM

LSTM networks are a type of recurrent neural network (RNN) architecture [27], specifically designed to address the vanishing gradient problem of traditional RNNs and to better capture dependencies in sequential data [28]. In an LSTM, the hidden state h_t is updated via a series of gating mechanisms:

1) The input gate i_t determines how much of the new input will be stored in the cell state.

2) The forget gate f_t decides the extent to which the previous cell state $c_{(t-1)}$ is maintained.

3) The output gate o_t controls how much of the internal state is exposed to the external network.

The state update equations are as follows:

$$i_t = \sigma(W_{ii}.x_t + b_{ii} + W_{hi}.h_{(t-1)} + b_{hi}) \qquad (2)$$

$$f_t = \sigma(W_{if}.x_t + b_{if} + W_{hf}.h_{(t-1)} + b_{hf}) \qquad (3)$$

$$g_t = \tanh(W_{ig}.x_t + b_{ig} + W_{hg}.h_{(t-1)} +b_{hg}) \qquad (4)$$

$$o_t = \sigma(W_{io}.x_t + b_{io} + W_{ho}.h_{(t-1)} + b_{ho}) \qquad (5)$$

$$c_t = f_t * c_{(t-1)} + i_t * g_t. \qquad (6)$$

$$h_t = o_t * \tanh(c_t). \qquad (7)$$

Here, σ represents the sigmoid function, tanh is the hyperbolic tangent function, * denotes element-wise multiplication, and `.` represents matrix multiplication. The variables W and b are the learnable weights and biases, respectively, of the LSTM.

By employing these gating mechanisms, LSTMs can effectively learn what information to keep or forget over long sequences, making them particularly efficient for tasks involving sequential data.

The combination of ELECTRA, GloVe, and LSTM in our ensemble model aims to leverage the efficient pre-training and high performance of ELECTRA, the rich semantic information encapsulated by GloVe embeddings, and the sequence modeling capabilities of LSTM. This synergistic integration seeks to enhance the performance of question classification tasks by capturing the semantics, context, and sequence information embedded in the questions [29], [30], [31].

IV. Proposed Approach

The proposed approach is designed to amalgamate the capabilities of multiple state-of-the-art language models and embeddings, namely Electra, GloVe, and LSTM, to enhance the classification performance on questions from the TREC dataset. The architecture employs a dual-branch neural network with each branch responsible for processing a different type of embedding—Electra for one and GloVe for the other. Subsequent to this, LSTM layers are applied to the concatenated embeddings, leading to the final classification output.

A. Source of Data

Based on the TREC question classification dataset, which has text-based questions and their related broad terms like "location," "person," etc., the experiment was carried out.

B. Text Standardization

The TensorFlow method tf.strings.lower() was used to change all of the raw text strings to lowercase.

C. Tokenization and Sequence Padding

There were two different tokenization processes for the raw texts: one was made for Electra and the other was made for GloVe. Through padding, a set sequence length of 512 was kept.

D. Architectural Elements: In-Depth Exploration Electra Sub-model: Capturing Contextual Relationships

Electra is the main tool used to find complex and detailed trends in searches. When it comes to Electra, the discriminator is very good at figuring out what a sign means in relation to its surroundings. This is very important for question classification because questions often have clues in the environment that help with classification. For instance, the use of "when" or "what year" could mean a question about time, which Electra is very good at spotting.

E. GloVe Sub-model: Leveraging Global Statistical Information

GloVe is useful because it can gather global statistical features of words based on data about how often they appear together. GloVe, unlike local context, records long-term ties like synonyms or similar ideas, which can be very helpful for finding the right questions. Electra can understand how the words in a question work together in complex ways, but GloVe takes it a step further by understanding the bigger language features of the words used.

F. LSTM Layers: Accounting for Sequential Dependencies

After integration, LSTM networks are used to find the sequence-based relationships in the incoming text. Questions naturally go in a certain order, with "wh" words like "who," "what," and "where" at the beginning and a subject or object at the end. Figuring out this process can often help you figure out what the question is really asking. These gates in LSTMs help them successfully capture long-term relationships, which makes them perfect for this job. The two LSTM layers, which have 256 and 128 units, are set up to add another level of abstraction and pick up more complex models.

G. Classification Layer: Mapping to Categories

The last Dense layer is a classifier that turns the complicated feature representations learned by the layers above into classification choices that can be used. In this case, a softmax activation function is used because the job is classified. There are 6 units in this layer, and each one represents a different type of question in the TREC dataset. The softmax function makes sure that the result can be understood as odds that add up to 1. It's easy to put each question into one of the six broad groups this way.

H. Model Synergy: The Bigger Picture

It is important to note that the architecture is not just a random group of techniques; it is a carefully put together set of techniques that are meant to work around the weaknesses and make the most of the strengths of each part. Electra gathers background, GloVe adds breadth, and LSTMs record how things change over time. These steps work together to make a complete plan for learning how to classify questions.

To put it simply, each design part was carefully chosen and put together in a way that makes a whole model that can change, understand, and do a great job of question classification.

V. EXPERIMENTAL RESULTS

A. Experimental Setup

To thoroughly test how well our suggested ensemble model, Ensemble Electra + GloVe+LSTM, worked, we set up our tests on Google Colab Pro and used its GPU features to make the computations go faster. We put our ensemble model up against Electra and other cutting-edge language models [17], BERT [32], RoBERTa [33], and DistilBERT [34].

B. Mathematical Overview of Models

1) ELECTRA: Electra employs a discriminative training mechanism, where the model learns to distinguish between "real" and "fake" tokens in a sentence. Formally, for a given input X = [x_1, x_2,…, x_n], a generator *G* proposes replacements x_i for masked tokens, and a discriminator *D* estimates the probability P(D(x_i) = 1| X) that each token is real. The objective is to minimize -log(D(x_i)) for real tokens and -log(1 -D($\tilde{x}_i$)) for fake tokens.

2) BERT: BERT uses a masked language model (MLM) for pre-training, where a certain percentage of input tokens are masked. The model aims to predict these masked tokens based on their context. Mathematically, for an input sequence X, the loss L is calculated as -log P(x_i | X_{-i}; θ), where θ are the model parameters.

3) RoBERTa: RoBERTa extends BERT but employs dynamic masking and removes the next-sentence prediction objective. Its objective function remains similar to BERT, focusing on masked token prediction.

4) DistilBERT: DistilBERT is a distilled version of BERT, trained to approximate BERT's output. For each token x_i in the input X, the model aims to minimize the difference between its output O(x_i) and that of BERT B(x_i), typically using the Kullback-Leibler divergence.

C. Evaluation Metrics

We used several metrics to evaluate the performance of each model: Loss, Accuracy, Precision, Recall, and F1 Score.

1) Loss: Represents the error between predicted and actual labels. Lower values are better.

2) Accuracy: Measures the ratio of correctly predicted samples to the total samples.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{8}$$

3) Precision: Indicates the percentage of positive identifications that were actually correct.

$$Precision = \frac{TP}{TP+FP} \tag{9}$$

4) Recall: Shows the percentage of actual positives that were identified correctly.

$$Recall = \frac{TP}{TP+FN} \tag{10}$$

5) F1 Score: Harmonic mean of precision and recall, a balance between the two.

$$F1\,Score = 2 * \frac{Precision*Recall}{Precision*+Recall} \tag{11}$$

Where: TP: True Positive, TN: True Negative, FP: False Positive and FN: False Negative.

D. Results

Our ensemble model, which is a combination of Electra, GloVe, and LSTM, outperformed all other models. The superior performance of our ensemble approach can be attributed to the complementary strengths of the constituent models. Electra, with its discriminator-generator setup, excels at understanding the context of the language. GloVe, on the other hand, captures semantic relationships between words by considering the global word-word co-occurrence statistics. LSTM effectively handles the sequence nature of the language data. Together, they give a complete approach to text classification and lead to great results on the TREC question classification task. This experimental evidence supports our theory that an ensemble of models can significantly improve question classification task performance over standalone models. By leveraging the strengths of each model, we were able to achieve superior results, showing that our proposed ensemble approach works. The results of the experiments are shown in Tables I and II and Fig. 1, 2, 3, 4 and 5.

TABLE I. THE ACCURACY AND MSE OF THE MODELS

Model	*Train Accuracy*	*Test Accuracy*	*Train MSE*	*Test MSE*
Ensemble Electra + GloVe+LSTM	**0.999**	**0.8**	**0.001**	**1.51**

VI. Results and Discussion

All of the comparison data show that the Ensemble Electra + GloVe + LSTM model does better than all of the evaluation factors. This victory isn't just a small step forward; it's a huge step forward from solo ideas.

A. *Generalization and Overfitting*

The ensemble model's ability to transfer from training data to test data is one of the most interesting results. With a training accuracy of 0.999 and a test accuracy of 0.8, the ensemble model shows that it can successfully apply learned patterns to data that it has never seen before. This even result shows that the model does not overfit, which is a common problem in machine learning [35].

B. *Error Analysis*

The ensemble model stays ahead when it comes to Mean Squared Error (MSE). The model's predictions were very close to the real results, with a training MSE of 0.001 and a test MSE of 1.51. Standalone models, like Electra, BERT, and others, have much higher MSE values on both the training and test sets, which means they make more mistakes when making predictions.

C. *Precision, Recall, and F1 Score*

The ensemble model also keeps its high scores in the F1 score, precision, and recall. A high accuracy score means that the ensemble model correctly finds relevant examples on a big scale, and a high recall score means that the model catches most of the relevant events. The F1 score, which is a fair way to measure precision and recall, shows that the model is well-balanced.

D. *Comparative Model Analysis*

Although RoBERTa seems to do better than the other models that work by themselves, it is still not as good as the ensemble model. The ensemble model is the only one that can get Electra's understanding of context, GloVe's semantic depth, and LSTM's sequential reading all at the same time.

E. *Synergistic Strength*

The enormous success of the ensemble model shows that combining parts that are similar to other cutting-edge models can create something new. For the TREC question answering test, it does very well because it knows data very well in both its specific and broad parts. The ensemble model does a great job of categorizing questions, and these results suggest that it could also help with other natural language processing issues.

VII. Conclusion

In conclusion, our results show that an ensemble model with Electra, GloVe, and LSTM does a better job of classifying questions than other models on the TREC dataset. We tested our ensemble method against other advanced models like BERT, RoBERTa, and DistilBERT and found that it regularly did better than them. It achieved high accuracy, precision, recall, F1 score, and lower mean squared error. Electra, GloVe, and LSTM all have properties that work well together in the ensemble model. Combining different models and methods into ensemble methods, which we found, can lead to big performance gains, making them a reliable and effective way to handle difficult tasks like question categorization. Even though these results are positive, we know that there is still room for improvement and adjustment. For instance, different groupings of ensembles and model designs could be looked into, along with more advanced training methods. In the future, researchers may look into how this ensemble method can be used to solve other natural language processing problems besides question classification. Overall, this study adds to the progress being made in natural language processing and lays the groundwork for more research and development of group methods in question categorization and other areas.

VIII. Conflict of Interest

The authors declare that there is no conflict of interest in this paper.

SpanBERT-based Multilayer Fusion Model for Extractive Reading Comprehension

Pu Zhang, Lei He, Deng Xi
School of Computer Science and Technology
Chongqing University of Posts and Telecommunications, Chongqing, P. R. China

***Abstract*—Extractive reading comprehension is a prominent research topic in machine reading comprehension, which aims to predict the correct answer from the given context. Pre-trained models have recently shown considerable effectiveness in this area. However, during the training process, most existing models face the problem of semantic information loss. To address this problem, this paper proposes a model based on the SpanBERT pre-trained model to predict answers using a multi-layer fusion method. Both the outputs of the intermediate layer and the prediction layer of the transformer are fused to perform answer prediction, thereby improving the model's performance. The proposed model achieves F1 scores of 92.54%, 84.02%, 80.86%, 71.32%, and EM scores of 86.27%, 81.25%, 69.10%, 56.42% on the SQuAD1.1, SQuAD2.0, Natural Questions and NewsQA datasets, respectively. Experimental results show that our model outperforms a number of existing models and has excellent performance.**

Keywords—Machine reading comprehension; pre-trained model; transformer

I. Introduction

With the advent of the big data era, getting the right answers from massive amounts of data in a timely and accurate manner has become an urgent task. As one of the most popular natural language processing (NLP) tasks in recent years, machine reading comprehension (MRC) aims to enable machines to learn how to read and understand texts, that is, to find answers to given questions from relevant articles. Extractive reading comprehension, a subtask of MRC, has also made significant progress in recent years, requiring models to extract a continuous passage of text from the given input text as the final answer.

Extractive reading comprehension can overcome the limitations of relying solely on individual words or entities to answer questions. Its task is to use a model to extract an answer from a given passage or paragraph based on a given question. As shown in Fig. 1, given the question "when does season 2 of lethal weapon come out" and the passage "Lethal Weapon is an American buddy cop action comedy ...", the model reads and understands the passage and question, and then extracts a continuous segment "September 26, 2017" from the passage as the answer. The commonly used datasets for extractive reading comprehension include the SQuAD dataset [1], the NewsQA dataset [2], the TriviaQA dataset [3], and so on.

In deep learning-based reading comprehension models, the prediction of answer boundaries relies heavily on information interactions, and scholars have proposed one-way attention models to employ attention mechanisms to enhance the interaction of information between passage and question. For example, Hermann et al. [4] used the one-way attention model as the basis for contextualizing questions, calculating the weight of each word in a passage, and generating a final representation of the passage. However, because one-way attention mechanisms only account for unidirectional attention, resulting in limited interaction between passage and question, researchers later proposed bidirectional attention models. For example, Seo et al. [5] proposed the bidirectional attention model BiDAF, which computes attention between question and passage separately in both directions to enhance information interaction and achieve good results.

In 2018, Google introduced the bidirectional pre-training language model BERT [6]. Since its release, BERT has achieved outstanding results in the field of NLP. Its remarkable performance is attributed to its internal multi-layer transformer structure, and directly using BERT with a simple answer predictor can achieve good performance on the SQuAD dataset [6].

The study by Ganesh et al. [7] showed that different layers of the transformer encoder focus on different semantic information. Ramnath S et al. [8] experimentally demonstrated that the prediction layer of BERT focuses more on contextual understanding and answer prediction, but ignores the interaction between context and question, while the earlier layers of the transformer focus more on the latter. Thus, some semantic information is lost during the learning process.

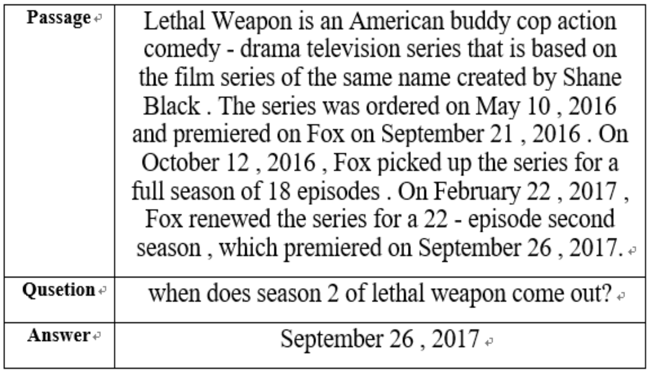
Since BERT was proposed, a number of pre-training models have been successively proposed. Among them, SpanBERT [9] is a representative model. Compared to BERT, SpanBERT [9] is more suitable for extractive tasks. However, it does not take into account the representational information emphasized by intermediate transformer layers, which may affect the final answer extraction in subsequent iterations.

This paper aims to address the potential problem of semantic information loss during learning in SpanBERT by investigating the fusion of semantic information from the intermediate and prediction layers of the transformer. A method is proposed to predict answers using a multi-layer transformer based on the SpanBERT model. The lower layer and the prediction layer of the transformer work together to predict answers. The predicted answer span information from both layers is combined to improve the accuracy of the predicted answers. The contributions of this work are outlined as follows:

1) We propose a model that can address the problem of semantic information loss during the learning process of the pre-trained model SpanBERT. Our model enhances the interaction between the paragraph text and the question by utilizing the SpanBERT model, the representation information emphasized by the intermediate layer and the final prediction layer of the transformer can be fused to improve the performance of the model's answer extraction.

2) A new approach to vector fusion is proposed in this study, which can effectively combine semantic information. An attention mechanism is utilized to fuse the outputs of the intermediate and prediction layers of the transformer, resulting in a new fused vector. This vector can be used to generate a probability distribution vector of the answer span, which is then multiplied by the answer prediction vector to obtain the predicted answer span. Combining the representational information that the final prediction layer and the middle layer focused on will improve the accuracy of the model's answer extraction.

3) We conduct comparison experiments on four datasets, including SQuAD1.1, SQuAD2.0, NaturalQA, and NewsQA, with two evaluation metrics, including F1 score and EM score, experiment results show that the proposed model has excellent performance.



Passage	Lethal Weapon is an American buddy cop action comedy - drama television series that is based on the film series of the same name created by Shane Black . The series was ordered on May 10 , 2016 and premiered on Fox on September 21 , 2016 . On October 12 , 2016 , Fox picked up the series for a full season of 18 episodes . On February 22 , 2017 , Fox renewed the series for a 22 - episode second season , which premiered on September 26 , 2017.
Qusetion	when does season 2 of lethal weapon come out?
Answer	September 26 , 2017

Fig. 1. Example of extractive reading comprehension.

II. Related Work

MRC technology was first developed in the 1970s. In 1977, W.G. Lehnert et al. [10] designed the QUALM system, which used question-answering rules. In the 21st century, researchers integrated machine learning methods into MRC research. However, there were still drawbacks such as weak model generalization and insufficient feature extraction. The development of neural networks provided an opportunity for the advancement of MRC technology. From unidirectional attention mechanisms to bidirectional attention mechanisms, MRC technology has made significant strides and remarkable advancements. In recent years, the bidirectional pre-training language model BERT has achieved superior results in multiple task domains.

Reading comprehension tasks can be categorized as cloze tests, multiple-choice, span extraction, and generative reading comprehension.

Cloze-style tests prompt the machine to select the correct answer from a finite number of alternatives by removing words from the sentence. Representative datasets include CBT [11] and CNN/Daily Mail [4]. Representative models include the Gated Attention Reader [12] and others.

Multiple-choice reading comprehension has a more flexible answer format than cloze tests, as it is not limited to words or entities in context. However, the answers to the questions must still be provided in advance. Representative datasets for this type of task include MCTest [13] and RACE [14], while representative models include DCMN+ [15].

Currently, span extractive reading comprehension is the most popular task in this field, which is more challenging than traditional machine reading comprehension. The goal is to extract a contiguous span from a given text paragraph, which is not selected from a list of options.

Extractive reading comprehension models typically consist of four network architecture components: an embedding module, a feature extraction module, an information interaction module, and an answer prediction module. The embedding module converts each word in the passage and question into a fixed-length vector representation. To achieve this, a classical word vector encoding method such as Word2vec [16] can be used. The feature extraction module is often positioned after the embedding layer to extract context and question features separately. This module typically uses classical deep neural networks, such as recurrent neural networks and convolutional neural networks, to extract contextual information. The information interaction module is responsible for combining the encoded information of the paragraph and the question. It also captures the relationships between the words in the paragraph and the question to obtain their representations. The answer prediction module is located at the end of MRC systems and provides answers to questions based on the primary context.

In the extractive reading comprehension task, two classifiers are typically trained to predict the starting and ending indices of the answer. Common datasets for extractive reading comprehension include SQuAD, NewsQA, TriviaQA, SearchQA [17], and so on. Representative models include SpanBERT, BLANC [18], etc.

Although extractive reading comprehension has made significant advancements, its capabilities remain insufficient. Specifically, confining answers to a specific span within the context is still unrealistic. Generative reading comprehension requires machines to infer, summarize and provide open-ended answers from multiple passages of text. Of the four different types of tasks, generative reading comprehension is the most difficult. NarrativeQA [19] is a dataset that represents generative reading comprehension, and UniLMv2 [20] is a model that represents this type of task.

In addition to the task form, reading comprehension models can be structurally divided into a reading comprehension module and an answer prediction module. The reading comprehension module aims to answer the given questions based on the given passages. It is considered the core part of the model, where the model learns information from the input text passage and question and generates the input text representation. For instance, Seo et al. [5] proposed BiDAF, which uses a bi-directional attention mechanism to improve the interaction between the question and the text passage, resulting in a more effective representation of the input text. BERT, on the other hand, enhances word embedding through multiple layers of transformer. SpanBERT, which is built on top of the BERT architecture, further improves text comprehension in the continuous span extraction task by training with span mask and span boundary objective. In this paper, we use SpanBERT as the foundational architecture of our model.

The answer prediction module is divided into different types of tasks. For the cloze reading comprehension task, the module predicts the probability values of multiple candidate answers based on the text vector information and selects the option with the highest probability as the predicted answer. For the extractive reading comprehension task, the answer is a continuous segment of the given text. The answer prediction module should generate two probability distributions based on the text representation: one for the starting position of the answer and the other for the ending position.

III. Model

Our model utilizes SpanBERT, a pre-trained model with 12 layers of transformer encoder, similar to BERT. The 12th layer is typically used for final answer prediction. However, language is complex and contains not only grammar and semantic information, but also hidden information such as emotion and deduction. Therefore, each layer of the transformer encoder learns different information during the training process. This model addresses the limitation of existing models that ignore other potentially helpful layers for answer prediction, by incorporating them into the prediction process. To improve answer prediction performance, this paper proposes a model that utilizes an information fusion approach. The basic architecture of our model is shown in Fig. 2.

First, both the passage and the question are input into the embedding layer for learning, resulting in the output of each layer of the transformer. Subsequently, the output of the middle layer and the output of the prediction layer are combined to obtain a fusion vector that contains the semantic information from both the middle layer and the prediction layer. Finally, the answer interval information predicted from the fusion vector is further fused with the answer information extracted from the prediction layer to obtain the final answer.

A thorough explanation of our model, including the encoding layer, encoder attention block, answer extraction, loss function, and other components, is given in this section.

A. *Embedding*

Suppose the question sequence is Q=[$q_1, q_2, q_3, \dots, q_m$] and the passage sequence is P=[$p_1, p_2, p_3, \dots, p_n$]. They are separated by a separator when inputting to the model, as shown in the following formula:

$$[\mathrm{CLS}], q_1, q_2, q_3, \dots, q_m, [\mathrm{SEP}], p_1, p_2, p_3, \dots, p_n, [\mathrm{SEP}]\# \quad (1)$$

After inputting the text into SpanBERT, the encoding sequences T_n (n = 1~12) of each layer of the transformer encoder can be obtained through the encoder modules. When n = 12, T_{12} represents the encoding sequence of the SpanBERT prediction layer, and the example of T_n is as follows:

$$T_n = T_{[\mathrm{CLS}]}, T_{q_1}, T_{q_2}, \dots, T_{q_m}, T_{[\mathrm{SEP}]}, T_{p_1}, T_{p_2}, \dots, T_{p_n}, T_{[\mathrm{SEP}]} \quad (2)$$

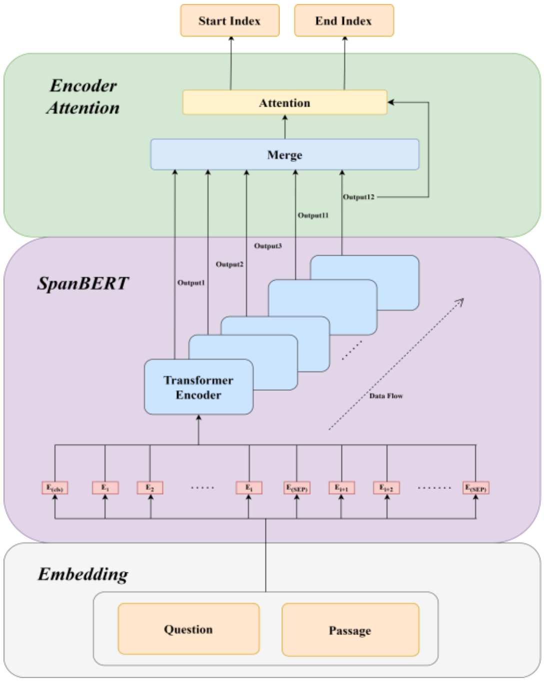


Fig. 2. Model architecture.

B. *Encoder Attention*

The specific steps of information fusion are as follows:

1) Take out the results of the n-th layer and the last layer of the transformer encoder, and the encoding of the question is separately extracted to obtain the encoding information of the question for the two layers, denoted as Q_n and Q_{Last} , respectively.

2) The semantic information is combined between the two layers by means of dot product, and then calculate the weight of each of the two layers through the fully connected layer. The formula is as follows:

$$Q'_n = SUM(Q_n) \quad (3)$$

$$Q'_{Last} = SUM(Q_{Last}) \quad (4)$$

$$E_{Attention} = Q'_n * Q'_{Last} \quad (5)$$

$$w_n, w_{Last} = Linear(E_{Attention}) \quad (6)$$

Q_n and Q_{Last} represent the encoded vectors of the question part in the *n*-th layer and the prediction layer of the transformer encoder. SUM(*) is used to avoid the problem of inconsistent lengths of Q in the input text by stacking the encoding information of Q_n and Q_{Last} according to the word encoding dimension. $E_{Attention}$ represents the fused semantic information. $Linear(*)$ is a linear function. w_n and w_{Last} represent the weights calculated for the *n*-th layer and prediction layer when predicting the answer, respectively.

3) By calculating the weights, we can obtain the fusion vector encoding as follows.

$$T_{merge} = w_n * T_n + w_{Last} * T_{Last} \quad (7)$$

T_n and T_{Last} represent the encoding sequences obtained from the *n*-th layer and the *12*-th layer of the transformer encoder, respectively. T_{merge} represents the fused vector of the word encoding information.

C. Answer-span Prediction

In the previous section, we fused the encoding of the *n*-th layer and the prediction layer to obtain a new fused vector. In this section, we propose a new approach for span prediction to improve the performance of the model. The formula is as follows:

$$pred_s = \frac{\exp(W_a T_{merge} + b_s^a)}{\sum_j \exp(W_a T_{merge_j} + b_s^a)} \quad (8)$$

$$pred_e = \frac{\exp(V_a T_{merge} + b_e^a)}{\sum_j \exp(V_a T_{merge_j} + b_e^a)} \quad (9)$$

T_{merge} represents the fusion vector that fuses the word encoding information from the *n*-th and prediction layers. W_a 、 V_a 、 b_s^a and b_e^a represent the trainable weights and bias parameters. $pred_s$ and $pred_e$ represent the relative probability of each word as the beginning and ending position of the answer.

After obtaining the probability distributions of the answer span, which are represented by the fused vector of $pred_s$ and $pred_e$, the calculation of the guided-layer attention vector can be initiated. The formula is as follows:

$$Attention = pred_s * pred_e \quad (10)$$

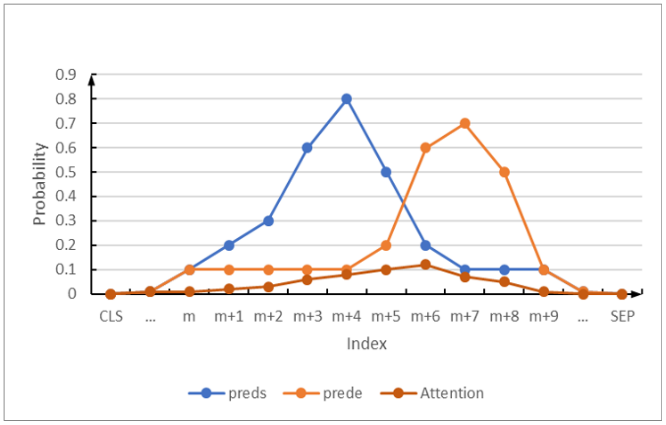

Fig. 3. Distribution of guided-layer attention vector.

The guided-layer vector represents the probability distribution of the predicted answer region. By multiplying $pred_s$ and $pred_e$, as shown in Fig. 3, the predicted probability value of words belonging to the answer span is higher than both ends, and the farther the distance is, the lower the probability value is. That is, the overall distribution of *Attention* is normal. The overall distribution exhibits a normal distribution, which could facilitate the ability to predict answer span for the guided-layer attention vector.

Finally, the answer prediction layer T_{Last} and the probability distribution vector of the answer region are dot-multiplied, and then the final answer prediction is calculated by $softmax(*)$. The calculation formulas are as follows.

$$logits_s, logits_e = Split(T_{Last}) \quad (11)$$

$$Ans_s = logits_s * Attention \quad (12)$$

$$Ans_e = logits_e * Attention \quad (13)$$

$$p_{i=s_a} = \frac{\exp(W_a Ans_{s_i} + b_s^a)}{\sum_j \exp(W_a Ans_{s_j} + b_s^a)} \quad (14)$$

$$p_{i=e_a} = \frac{\exp(V_a Ans_{e_i} + b_e^a)}{\sum_j \exp(V_a Ans_{e_j} + b_e^a)} \quad (15)$$

$Split(*)$ represents the vector splitting operation. $logits_s$ and $logits_e$ are used to predict the start and end indices of context. Ans_s and Ans_e denote answer prediction vectors that have merged the information of the probability distribution vector of answer region. W_a 、 V_a 、 b_s^a and b_e^a represent the trainable weights and bias parameters.

D. Loss Function

The loss function used in our model is the joint cross-entropy loss function, which is based on the negative log probabilities of the true answer's start and end positions in the predicted distribution. The formula is as follows:

$$L_{12} = -\frac{1}{N}\sum_{i=1}^{N}\left[\log\left(P_{y_i^s\,Last}^{start}\right) + \log\left(P_{y_i^e\,Last}^{end}\right)\right] \quad (16)$$

P^{start} and P^{end} are the probability distributions of the start and end positions of the answers predicted by the model. *Last* represents the prediction layer. y_i^s and y_i^e are the start and end positions of the real answer in the *i*-th training sample.

The same answer prediction is done for the fusion vector to obtain the loss function L_n.

$$L_n = -\frac{1}{N}\sum_{i=1}^{N}\left[\log\left(P_{y_i^s\,n}^{start}\right) + \log\left(P_{y_i^e\,n}^{end}\right)\right] \quad (17)$$

We define our final loss function as the weighted sum of the two loss functions:

$$L_{total} = (1-\lambda)L_{12} + \lambda L_n \quad (18)$$

λ is a hyper-parameter moderating the ratio of two loss functions.

IV. Experimental Setup

A. Datasets

To validate the effectiveness of the proposed model, experiments were conducted and analyzed on four datasets: SQuAD1.1, SQuAD2.0 [21], Natural Questions [22] and NewsQA.

The Stanford Question Answering Dataset (SQuAD) is a large-scale English reading comprehension dataset constructed by Stanford University, which has been an indispensable dataset for MRC tasks since its release and has a milestone significance for the development of MRC technology. SQuAD1.1 contains 536 high-quality articles from English Wikipedia, which are divided into natural paragraphs. In addition, there are 107,785 questions and corresponding answers, all of which are manually annotated.

SQuAD 2.0 builds on SQuAD 1.1 by adding unanswerable questions. Dataset creators provide an unanswerable question for each paragraph to interfere with the model's prediction. The training dataset contains 87k answerable and 43k unanswerable questions.

Natural Questions is a dataset of natural language queries. Each example consists of a Google query and a Wikipedia passage, where the answer is a span of the Wikipedia passage. The Natural Questions dataset contains 300,000 natural questions with human annotated answers.

The NewsQA dataset contains examples selected from over 10,000 news articles from CNN, along with 119,633 manually generated question-answer pairs. The answers are snippets of any length from the news article, and the dataset also includes partially unanswerable questions.

B. Evaluation Metrics

F1 is the most widely used evaluation metric in existing extractive reading comprehension models. The Precision value is computed as follows:

$$Precision = \frac{TP}{TP+ FP} \tag{19}$$

TP represents the number of true positive samples and *FP* represents the number of false positive samples. Then the Recall value is then calculated as follows:

$$Recall = \frac{TP}{TP+ FN} \tag{20}$$

FN represents the number of false negative samples. F1 value is calculated from Precision and Recall with the following formula.

$$F1 = 2 * \frac{Precision * Recall}{Precision + Recall} \tag{21}$$

EM (Exact Match) is a common evaluation metric for question answering systems, and it is also one of the main metrics for SQuAD. It measures the percentage of all predictions that exactly match the ground-truth answer. The calculation formula is as follows:

$$EM = \frac{N_{right}}{N_{all}} \tag{22}$$

N_{right} indicates the number of correct predictions and N_{all} represents the number of all predictions.

C. Experimental Setup

The implementation of this model is based on Python and its third-party libraries, with PyTorch serving as the deep learning framework. The hyperparameters λ are set to 0.8 in joint loss functions. The experimental datasets used are SQUAD1.1, SQUAD2.0, NaturalQA, and NewsQA. To facilitate model performance testing and due to limited computing resources, the training batch size is set to 16 for the SQUAD2.0 dataset and 8 for the other three datasets. The learning rate is set to $2*e^{-5}$, and the maximum length of input text is set to 384. The word vector dimension is set to 768, and the number of training epochs is set to 4 on the SQuAD2.0 dataset and 3 on the other three datasets.

D. Baselines

BLANC [18]: To improve the accuracy of the final answer prediction, the model primarily employs a context prediction method. The model first predicts a soft label, then uses this soft label to calculate the context boundary probability, and finally uses the context boundary probability to optimize the final answer boundary prediction.

BERT-base [6]: BERT-base is a pre-trained language representation model that generates a deep bidirectional language representation using a masked language model (MLM). It is regarded as a landmark model in MRC, significantly advancing the field's development.

SpanBERT [9]: This BERT variation is tuned for fragment extraction tasks, resulting in more accurate representations. Two aspects contribute to the optimization. Firstly, it recommends adopting span masking rather than single-word masking for learning at fragments. Second, it trains the masked boundary words representation to anticipate masked fragment information.

ALBERT [23]: Compared to BERT, ALBERT overcomes the difficulties of extensive model parameterization and growing training time. It incorporates three major innovations: factorized embedding parameters, shared parameters across layers, and Sentence Order Prediction (SOP). The SOP creates not only positive examples by establishing the correct order of two consecutive sentences, but also negative examples by reversing their order.

LinkBERT [24]: LinkBERT is a cross-document language modeling training method that takes advantage of document links. In contrast with BERT, this approach has a distinct benefit in that it uses the links between documents to improve language modeling. LinkBERT treats the corpus as a document graph and employs linked documents as supplementary input to the model rather than modeling a single document.

DeBERT-base [25]: The proposed model aims to increase the robustness and effectiveness of the system when dealing with incomplete data. This is achieved by reconstructing hidden embeddings for sentences containing missing words.

OneS [26]: This model is based on the human learning model and introduces a new task of extracting essential knowledge from different knowledge sets for model pre-training.

KALA [27]: To solve the problem of catastrophic forgetting that occurs during adaptive pre-training, this model adjusts the intermediate hidden layer representation of a pre-trained model by incorporating knowledge from multiple domains.

ALBERTbase+V4ES [28]: This model proposes a verification mechanism that divides the machine learning process into two modules: general reading and fine-grained reading. The general reading module involves reading the text and question to obtain a preliminary answer. The fine-grained reading module reads again and generates a final answer.

RoBERTa-base [29]: This model enhances its performance by increasing the number of parameters and training data.

V. Results and Discussion

A. Results

In this section, two evaluation metrics (F1 and EM) are used on four datasets to verify the effectiveness of the proposed model in the paper. The experimental results are shown in Table I, Table II, Table III, and Table IV.

From the experimental results on the SQuAD1.1 dataset, the results in Table I show that the proposed model achieves good performance. The F1 score of our model improved by 0.6% and the EM score improved by 0.84% compared to SpanBERT. Compared to other models such as BERT-base, ALBERT-large, DeBERT-base, OneS and BLANC, the F1 scores are improved by 4.04%, 1.94%, 0.44%, 2.84% and 0.67%, and the EM scores are improved by 5.47%, 2.37%, 0.17%, 3.27% and 0.97%, respectively. In the experimental results of the SQuAD2.0 dataset, as shown in Table II, the F1 score of our model is improved by 0.59% and the EM score is improved by 0.76% compared to SpanBERT. In addition, compared to models such as BERT-base, OneS and ALBERTbase+V4ES, the F1 scores of our model are improved by 3.62%, 3.82% and 0.62%, and the EM scores are improved by 3.65%, 4.15% and 0.95%, respectively.

From the results of the NaturalQA dataset, as shown in Table III, the F1 score of our model is improved by 2.55% and the EM score is improved by 2.50% compared to SpanBERT. Compared to other models such as BERT-base, ALBERT and BLANC, the F1 scores of the model can be improved by 4.47%, 4.97% and 0.82% respectively, and the EM scores can be improved by 4.62%, 5.29% and 0.77%, respectively. From the experimental results of the NewsQA dataset, as shown in Table IV, the F1 score of our model improved from 67.93% of SpanBERT to 71.32%, with an improvement of 3.39%, and the EM score of the model is improved by 3.57%.

All of the above results show that our model has excellent performance.

Overall, our model performs better on the NaturalQA and NewsQA datasets when compared to the SQuAD1.1 and SQuAD2.0 datasets. This is because the SQuAD datasets have a flaw where the questions and answers are very similar, resulting in the front layer of the transformer losing less semantic information during the learning process. On the other hand, the NaturalQA and NewsQA datasets are generated based on real questions and answers, so more semantic information is lost in the front layer transformer during model learning.

B. Effect of Different Layers on Results

There are 12 layers of transformer encoders in SpanBERT, but each layer focuses on different information. During its iterative learning process, some information about the answer in the earlier transformer encoder layers may be forgotten. In this section, F1 and EM are used as evaluation metrics to investigate the effectiveness of each layer in guiding the prediction layer to predict the answer, using SQuAD1.1, SQuAD 2.0, NaturalQA and NewsQA datasets as experimental datasets. The experimental results are shown in Fig. 4.

TABLE I. Results (%) of Experiments on the SQuAD1.1

Models	F1	EM
BERT-base	88.50	80.80
SpanBERT	91.94	85.43
ALBERT-large	90.60	83.90
LinkBERT	90.10	-
DeBERT-base	92.10	86.10
OneS	89.70	83.00
BLANC	91.87	85.30
ALBERTbase+V4ES	91.10	83.40
Our model	**92.54**	**86.27**

TABLE II. Results (%) of Experiments on the SQuAD2.0

Models	F1	EM
BERT-base	80.40	77.60
SpanBERT	83.43	80.49
ALBERT-large	82.30	79.40
DeBERT-base	82.50	79.30
OneS	80.20	77.10
ALBERTbase+V4ES	83.40	80.30
RoBERTa-base	83.70	80.50
Our model	**84.02**	**81.25**

TABLE III. Results (%) of Experiments on the NaturalQA

Models	F1	EM
BERT-base	76.39	64.48
SpanBERT	78.31	66.60
ALBERT-large	75.89	63.81
LinkBERT	78.30	-
BLANC	80.04	68.33
Our model	**80.86**	**69.10**

TABLE IV. Results (%) of Experiments on the NewsQA

Models	F1	EM
BERT-base	65.07	50.11
SpanBERT	67.93	52.85
ALBERT-large	66.02	51.18
LinkBERT	69.30	-
KALA	68.27	54.25
BLANC	70.31	55.52
Our model	**71.32**	**56.42**

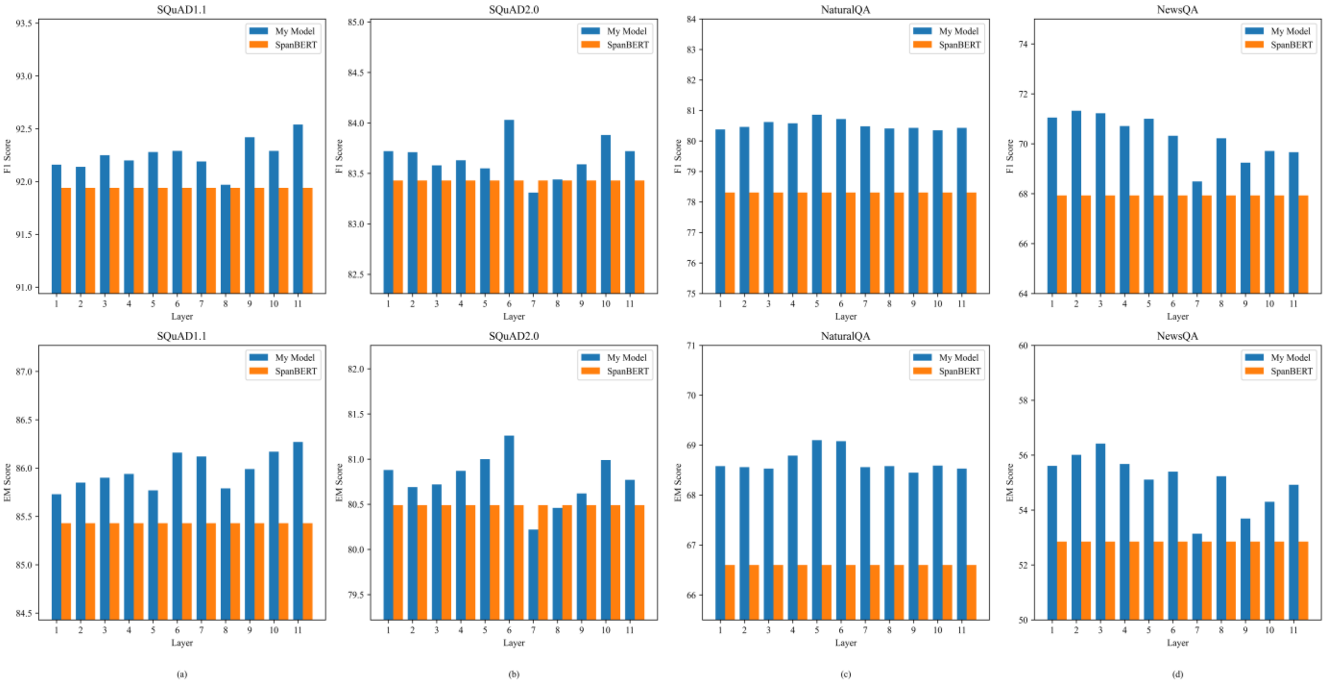

Fig. 4. (a), (b), (c), (d) represent the experimental results (F1/EM score) of different layers of SpanBERT as a guided-layer on SQuAD1.1, SQuAD2.0, NaturalQA, and NewsQA datasets (%), respectively.

From Fig. 4(a), we can see that on the SQuAD1.1 dataset, our model achieves optimal performance when using the output of the 11-th layer of the transformer encoder for fusion vector calculation. Specifically, compared to the SpanBERT model, the F1 score increased by 0.6% to 92.54% and the EM score increased by 0.84% to 86.27%. From Fig. 4(b), it can be observed that when using the prediction layer of the SpanBERT to directly predict the answer, the model achieves 78.31% (F1) and 66.6%(EM) on the NaturalQA dataset. However, when using different intermediate layers of the SpanBERT with the prediction layer to generate a new fused vector through encoder attention, the model achieves an improvement of 2.04% to 2.41% in F1 score and 1.93% to 2.5% in EM score. Among these experiments, the best performance was achieved when using the 5-th layer. This suggests that there is some semantic information loss in the early layers of the SpanBERT encoder during the iterative process. It also demonstrates the effectiveness of the proposed model.

As shown in Fig. 4(c) and Fig. 4(d), experiments on the SQuAD2.0 and NewsQA datasets, it was found that the best performance could be achieved when using the outputs of the 6-th and 2-nd layers of transformer encoder, respectively. Choosing different layers of transformer encoder to conduct experiments on different datasets always resulted in the best performance, indicating that our model is effective, and the 12 layers of transformer encoder in the SpanBERT model have differences in processing semantic information, and each layer focuses on different semantic information.

C. Effects of Hyperparameter λ

In the experiment, a weighted sum of the joint loss function L_{merge} and the loss function L_{12} of the answer prediction layer was used as the total loss function of the model, and a hyperparameter λ was introduced to balance the weight of the two loss values. In this section, we use SQuAD1.1 and NewsQA as experimental datasets, with F1 score and EM score as evaluation metrics, to verify the optimal value of the hyperparameter λ in the joint loss function. The experimental results are shown in Fig. 5.

We set λ to [0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0], and conduct experiments by incorporating λ into the calculation of the joint loss function L_{total}. As λ increases, the accuracy of the model in predicting answers increases. In the experiments on the SQuAD1.1 dataset, the model achieved the best performance when λ was set to 0.8, with an F1 score of 92.54% and an EM score of 86.27%. In the experiments on the NewsQA dataset, the model achieved the best performance when λ was set to 0.7, with an F1 score of 71.35% and an EM score of 56.13%. As λ increases further, the model's performance decreases.

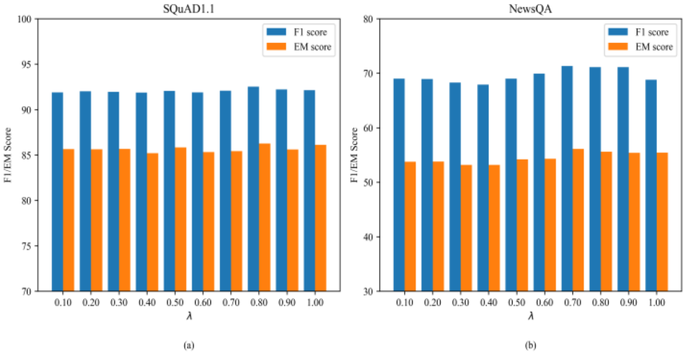

Fig. 5. (a) Results (%) for different values of λ on SQuAD1.1 dataset. (b) Results (%) for different values of λ on NewsQA dataset.

D. Different Pre-trained Models

In the above experiments, we used SpanBERT as a pre-training model to verify the effectiveness of our model. In order to verify the applicability of this method to other pre-trained models, we also conducted comparative experiments by using two pre-trained models including BERT and SpanBERT. The experimental results are shown in Table V and Table VI.

TABLE V. RESULTS WITH DIFFERENT PRE-TRAINED MODELS (SQUAD1.1)

		SQuAD1.1	
		F1	EM
Bert-BASE	BASELINE	88.10	80.49
	+our method	**88.76**	**81.34**
SpanBERT	BASELINE	91.58	84.97
	+our method	**92.54**	**86.27**

TABLE VI. RESULTS WITH DIFFERENT PRE-TRAINED MODELS (NEWSQA)

		NewsQA	
		F1	EM
Bert-BASE	BASELINE	65.07	50.11
	+our method	**66.74**	**51.69**
SpanBERT	BASELINE	67.93	52.85
	+our method	**71.32**	**56.42**

According to Table V, we can see that when using BERT as the pre-training model, our model can improve the model's F1 score by 0.66% to reach 88.76%. The model's EM score can be improved by 0.85% to reach 81.34%. When using SpanBERT as the pre-training model, the model's F1 score can be improved by 0.96% to reach 92.54%, and the model's EM score can be improved by 1.30% to reach 86.27%. From Table VI, on the NewsQA dataset, when using BERT as the pre-training model, our model can improve the model's F1 score and EM score from 65.07% and 50.11% to 66.74% and 51.69%, respectively. Using SpanBERT as the pre-training model, the model's F1 score can be improved by 3.39% to reach 71.32%, and the model's EM score can be improved by 3.57% to reach 56.42%. These results suggest that our method is applicable to other pre-training models.

E. Effects of T_{merge}

In this section, we conduct comparative experiments using just the fusion vector T_{merge} as the prediction layer and evaluate the performance. The experimental results are shown in Table VII and Table VIII.

TABLE VII. RESULTS OF T_{merge} (NATURALQA)

	NaturalQA	
	F1	EM
T_{merge}	78.96	67.21
SpanBERT	78.31	66.60
Our model	**80.86**	**69.10**

TABLE VIII. RESULTS OF T_{merge} (NEWSQA)

	NewsQA	
	F1	EM
T_{merge}	68.54	53.40
SpanBERT	67.93	52.58
Our model	**71.32**	**56.42**

According to the experimental results shown in Table VII, on the NaturalQA dataset, when using the fusion vector T_{merge} as the prediction layer, the model achieved an F1 score of 78.96% and an EM score of 67.21%, which is higher than the pre-trained model SpanBERT's 78.31% and 66.60%. However, there is still a performance gap compared to the experimental results of the proposed model in this paper. Similar experimental results were also verified on the NewsQA dataset. We can see that our model still has the highest performance, which indicates that our model is effective.

VI. CONCLUSION

In this paper, a SpanBERT-based multi-layer fusion extractive reading comprehension model is proposed. By fusing the representational information obtained from the intermediate transformer layer with the representational information obtained from the prediction layer, a new fusion vector is obtained through an encoder attention mechanism. Using the fusion vector, the distribution probability vector of the answer region is then computed and used together with the prediction layer to jointly predict the answer. Finally, answer extraction is performed. We have conducted extensive experiments to demonstrate the effectiveness of our model. Although the comparative experiments have shown the clear performance advantages of our model on the respective datasets, there are still certain problems and room for improvement. Specifically, even though the learning process of the pre-training model no longer suffers from the loss of semantic information, the learning process of our model still relies solely on the input data and does not use external knowledge, whereas people often use external knowledge to improve their understanding of textual data during the reading comprehension process. As a result, future studies can use the incorporation of external knowledge to enhance the semantic data, thereby improving the performance of the model. In the future work, we will also explore other pre-trained models for machine reading comprehension tasks.

***Abstract*—Forecasting crude oil prices hold significant importance in finance, energy, and economics, given its extensive impact on worldwide markets and socio-economic equilibrium. Using Long Short-Term Memory (LSTM) neural networks has exhibited noteworthy achievements in time series forecasting, specifically in predicting crude oil prices. Nevertheless, LSTM models frequently depend on the manual adjustment of hyperparameters, a task that can be laborious and demanding. This study presents a novel methodology incorporating Particle Swarm Optimization (PSO) into LSTM networks to optimize the network architecture and minimize the error. This study employs historical data on crude oil prices to explore and identify optimal hyperparameters autonomously and embedded with the star and ring topology of PSO to address the local and global search capabilities. The findings demonstrate that LSTM+starPSO is superior to LSTM+ringPSO, previous hybrid LSTM-PSO, conventional LSTM networks, and statistical time series methods in its predictive accuracy. LSTM+starPSO model offers a better RMSE of about +0.16% and +22.82% for WTI and BRENT datasets, respectively. The results indicate that the LSTM model, when enhanced with PSO, demonstrates a better proficiency in capturing the patterns and inherent dynamics data changes of crude oil prices. The proposed model offers a dual benefit by alleviating the need for manual hyperparameter tuning and serving as a valuable resource for stakeholders in the energy and financial industries interested in obtaining dependable insights into fluctuations in crude oil prices.**

***Keywords*—Crude oil; deep learning; Particle Swarm Optimization; Long Term-Short Memory; forecasting**

I. INTRODUCTION

As one of the most significant commodities in the world, crude oil is responsible for the energy consumption. It is the foundation for daily items, from plastics to transportation fuels. Considering that fluctuations in crude oil prices significantly influence economies worldwide, price forecasting can help reduce the risks of oil price volatility [1]. Predictive methods in oil and gas operations can boost efficiency, lower costs, and reduce environmental impact from a good forecasting model [2]. Machine learning researchers and developers face challenges when working with large datasets and diverse data types, primarily because of noisy and unclean data [3]. Several pre-processing methods have been developed to address this issue, with specific methods yielding favourable outcomes. Hence, the choice of pre-processing techniques would depend upon the data's characteristics and quality. Typically, benchmark datasets such as ready data do not necessitate extensive pre-processing tasks [4]. However, the most significant challenge is effectively managing substantial quantities, especially the time series data, which requires the development of a more understandable model. The abovementioned difficulties are relevant to the oil and gas data, especially in real-time data monitoring. Further investigation is required to effectively tackle the obstacles and determine the practicability of these methodologies using benchmark and real-life data.

Recently, there has been an increasing preference for incorporating predictive analytics in the oil and gas sector. Machine learning methods and their diverse applications in the oil and gas sector encompass multiple areas, such as pipeline prediction [5], well-log formation [6], and crude oil price forecasting [7].

Due to its effectiveness in predictive analytics, the Long Short-Term Memory (LSTM) model is widely utilized in various oil and gas industry sub-fields and other engineering and finance-related disciplines. Prior studies have examined various methodologies on LSTM, including LSTM with optimization and CNN with LSTM. For instance, CNN and LSTM address two instances of degradation prediction in offshore operation platforms for natural gas treatment plants and seawater injection pumps for oil [8]. Compared to a single LSTM model, the performance of the CNN with the LSTM model is superior, exhibiting a notable enhancement of 15.5% in precision.

Furthermore, the performance of LSTM has also been documented in reputable studies on time series [9], [10]. Yang et al. [9] employed the LSTM model to forecast short-and long-term production events in shale gas wells. The method performed better than the ARIMA, Arps, and Duong methods. In another study, Song et al. [11] used LSTM, a feature extraction and optimization model that incorporates feature engineering and parameter optimization and exhibits the lowest mean absolute error (MAE) value compared to other models such as BPNN, LSTM, and random forest as reported by Dyer et al. [12]

One of the recent challenges in oil and gas is predicting crude oil prices. The demand for crude oil price prediction has increased due to crude oil's complex and highly unpredictable characteristics of crude oil [13]. Several methods were proposed and evaluated using benchmark datasets. For instance, LSTM and Henry gas solubility optimization (CHGSO) technique to estimate crude oil prices using West Texas Intermediate (WTI) and Brent Crude Oil Time Series COTS datasets [14] and Hybrid Wavelet Transform (WT) Bidirectional Long Short-Term Memory Network (BiLSTM)-Attention-CNN. WT-BLAC performs well for WTI data with R2, RMSE, MAPE, and MAE of 0.97, 2.25, 1.18, and 2.63, respectively. Furthermore, it evaluated a similar dataset using ensemble and ANN but with a different range of time series data [15]. The models have acceptable and significant interpretability in time series prediction of crude oil futures prices.

Support vector regression model did another forecasting crude oil prices, which are infamous for being unpredictable and have been fine-tuned using a genetic algorithm [2]. They use a ten-year daily dataset from NASDAQ and key economic input features. A study by Shahbazbegian et al. [10] divided time series into sub-series by the proposed hybrid model, which employs a multifaceted approach to capture distinct characteristics, LSTM is combined with the Markov switching model to forecast volatile and fluctuating sub-series.

After integrating these predictions using a linear combination, a comprehensive estimation of the time series for WTI crude oil prices is generated. The proposed method's respective RMSE and MAPE values are 4.18 and 0.03. Furthermore, He et al. [16] found that a hybrid forecasting model based on multi-modal features for price trends and employing the variational mode decomposition algorithm, extraction of data features with multiple modes, and time series employment of analysis provides acceptable performance. More research on crude oil forecasting solutions is still in demand. LSTM and its variants have great potential to obtain better forecasting results by embedding an appropriate optimization method. This paper focuses on using LSTM embedded with one of the popular computational optimizations, PSO. PSO is chosen due to its ease of implementation, high precision, and fast convergence [17], [18]. The applied forecasting model for oil and gas power transformers obtained an acceptable solution with PSO [19], [20]. Hence, we improve the LSTM by integrating with PSO.

PSO star and ring topology, as well as a new particle representation that could improve the accuracy performance of crude oil forecasting, are embedded. The ring star topology and CHGSO_LSTM method, LSTM, and statistical time series techniques on benchmark crude oil price data compared the experimental results. Benchmark crude oil price data setting is the same as tested for CHGSO_LSTM by [14]. The rest of the paper follows the organization of the section as follows. Section II describes preliminaries on PSO and LSTM. The material and method for the proposed solution are in Section III. The computational results and discussion is mentioned in Section IV and V respectively. Finally, Section VI concludes the paper.

II. Preliminaries

A. Particle Swarm Optimization

In 1995, James Kennedy and Russell Eberhart introduced the PSO algorithm as a powerful population-based optimization technique [17], [18]. PSO has gained popularity among scientists and researchers due to its ease of implementation, high precision, and rapid convergence. The PSO algorithm is renowned for exploring and exploiting the search space effectively, rendering it suitable for various applications [17], [19]. PSO algorithm is a metaheuristic optimization technique that employs a population of particles to iteratively adjust their positions and velocities to find the best solution to a given problem. Before implementing PSO, particle representation must be designed carefully for the proper objective function [20]. The particle representation is an essential element of the PSO design for ensuring the algorithm's efficiency. Particle representation is a mechanism for encoding problem-solving solutions. Its ability to determine the properties of individual particles is used to map feature elements. By assigning an appropriate representation to each particle, PSO could facilitate efficient solutions [20], [21].

PSO can systematically investigate various regions within the search space while leveraging the search process to enhance and optimize a viable solution. The search strategies employed in the PSO algorithm are affected by the parameters, namely the acceleration constants (C_1 and C_2) and the inertia weight, as discussed by Shi and Eberhart [22]. Eq. (1) and Eq. (2) denote the velocity and position formulas adapted from the canonical PSO [18], [22].

$$V_{i(new)} = WV_i + C_1 r_1 (PBest_i - X_i) + C_1 r_2 (Pbest_i - X_i) + C_2 r_2 (Gbest_i - X_i) \qquad (1)$$

$$X_{i(new)}) = X_i + V_{i(new)} \qquad (2)$$

where,

$V_{i(new)}$ = new velocity of the i^{th} particle

V_i = current velocity of the i^{th} particle

X_i = current position of the i^{th} particle

$X_{i(new)}$ = new position of the i^{th} particle

W = inertia weight

C_1 *and* C_2= acceleration coefficient

r_1 and r_2 = random function in the range of $[0, \quad 1]$

$PBest_i$ = position of the personal best of the ith particle

$Gbest_i$ = position of the global best derived from all particles in the swarm

The cognitive component, represented as $C_1 r_1 (PBest_i - X_i)$ encompasses various factors such as the acceleration coefficient, a random function, and the difference between the personal best position, $PBest_i$, and the current position, X_i.

The difference between the previous position, X_i and the personal best position $PBest_i$ can be observed. The social component, $C_2 r_2(Gbest_i - X_i)$, incorporates the acceleration coefficient, a random function, and the disparity between the previous position, X_i, and the global best position, $Gbest_i$. The specific component signifies the historical performance of the particle, which is obtained from the combined version of all particles.

Another PSO strategy is topology. Topology is another PSO technique for exploiting and exploration. Topology controls how particles interact and exchange information, enabling them to jointly explore and seek the best outcome, such as the star, ring, and square. It establishes how information is shared and how interactions take place among particles to find the best solution.

B. Long Term-Short Memory

LSTM can effectively capture long-range dependencies within sequential data [23]. This characteristic renders it highly appropriate for natural language processing, speech recognition, and time series analysis. Due to its feedback connections and capacity to acquire knowledge of long-time features from time series data, the LSTM network demonstrates significant efficacy in processing and predicting sequential data. The ability to capture extensive dependencies in sequential data is a considerable advantage of LSTM in deep learning [23].

LSTM is a deep learning technique demonstrating remarkable efficiency in capturing extensive dependencies within sequential data. LSTM is accomplished by employing memory cells alongside various gating mechanisms, including input, forget, and output gates. The architecture of the LSTM is depicted in Fig. 1. These mechanisms enable the extended short-term memory network to preserve and strategically discard information over duration, thereby facilitating its ability to accurately capture the interdependencies inherent in the dataset.

A neural network model's performance with dense and LSTM units depends on several variables, including the problem's complexity. Increasing the number of dense units in a neural network can enhance the model's ability to discover the patterns and relationships in the data when dealing with complex problems. Similarly, increasing the number of LSTM units would improve its ability to capture long-term dependencies and remember previous information over time. This is especially important in tasks involving sequential data, such as time series analysis.

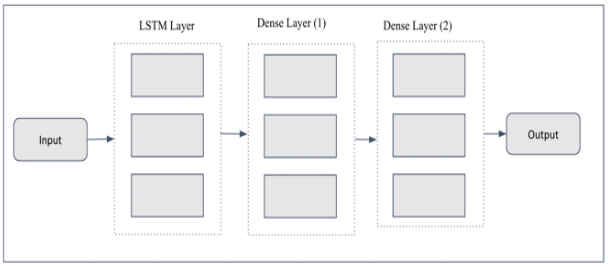

Fig. 1. LSTM architecture.

Furthermore, dense units can transform input data into a higher-dimensional space, increasing the model's ability to separate and classify. However, it is crucial to exercise caution when selecting the appropriate number of dense and LSTM units to prevent the data's overfitting or underfitting. Furthermore, the structure and architecture of the neural network model can influence the effectiveness of dense and LSTM units. Considering the specific problem, it is recommended to experiment with different combinations of dense and LSTM units to find the optimal configuration that yields the best performance and generalization on the given task. The selection and number of dense and LSTM units during the construction of neural network models can impact the performance of the models [24] [25]. The configuration and selection of dense and LSTM units in a neural network model can significantly impact its performance.

III. Materials and Methods

This section elaborates on the description of the materials, data sources, and research methodologies used. The proposed approach captures the steps to see the performance of enhancement of LSTM with PSO models on crude oil forecasting. The approach includes data acquisition, pre-processing, construction of the proposed methods, and evaluation. We propose two variants of the LSTM+PSO model, including the LSTM+starPSO and LSTM+ringPSO models, and compare them with ARIMA, SARIMAX, and LSTM. Fig. 2 demonstrates the overview of the proposed methodology. In addition, we introduced a particle representation or solution mapping for the PSO. Detailed steps are elaborated in the following sub-sections.

A. Data Acquisition

This study uses two different datasets: the WTI Crude Oil dataset [26] and the BRENT Crude Oil dataset [27]. Brent Crude refers to the assemblage of oil extracted from the North Sea's seabed, whereas WTI Crude denotes the amalgamation of oil obtained from land in the United States. WTI and BRENT are widely recognized benchmarks in the oil and gas industry. Specifically, the price of BRENT oil is commonly utilized as a reference point for the light oil market in Africa, Europe, and the Middle East. The datasets used for this study were obtained from the FRED website, a publicly accessible economic data repository owned by the Federal Reserve Bank of St. Louis. The website provides daily frequency data on WTI and BRENT crude oil prices from the early 1990s.

Nevertheless, the scope of this study is limited to the utilization of data solely from the period spanning from January 4, 2000, to April 15, 2021. The WTI dataset comprises 5409 objects, while the BRENT dataset contains 5438 objects. Both datasets share the same features: date, price, open, high, low, volume, and percentage change. A recent finding shows that the same dataset was used as a main part of a study by Altan and Karasu [28], which used two different forecasting methods, PSO+LSTM and CHGSO+LSTM. It was reported that the CHGSO+LSTM approach performed better than the LSTM method. The dataset's narrative was interestingly explored by using other LSTM variants.

B. Data Cleaning

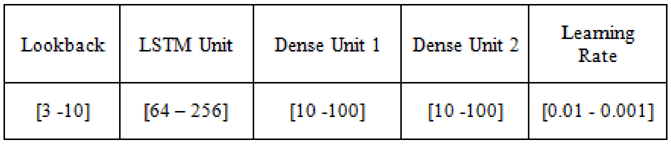
From the data behavior perspective, the two datasets, WTI and BRENT, exhibit no missing values. Therefore, no missing value procedure is imposed. However, the identification of outliers is required. The interquartile range (IQR) method can detect outliers by utilizing the interquartile range Data distribution should be determined in the interquartile range within Q1 and Q3 or between the 25th and 75th percentiles. An outlier is any data point that lies outside a predefined range, typically defined as below the 25th percentile and above the 75th percentile by about 1.5 times. This careful method of outlier discovery and eradication improves the overall data quality and ensures that the dataset is used for subsequent forecasting. Eq. (1) is the IQR formula [29].

$$IQR = Q3 - Q1 \tag{3}$$

where, Q1 is the first quartile, and Q3 is the third quartile.

C. Proposed Method

This section explains an enhancement method of LSTM with PSO in forecasting crude oil. The initial part of the method construction is the identification of particle representation. A new particle representation is proposed to adhere to the LSTM architecture and its parameters. The aim is to find the best position of the particle that can give an optimal or near-optimal solution. It is represented by the particle's item, namely, lookback, LSTM unit, Dense Unit, and learning rate. The representation consists of discrete and continuous values shown in Fig. 3.



Lookback	LSTM Unit	Dense Unit 1	Dense Unit 2	Learning Rate
[3 -10]	[64 – 256]	[10 -100]	[10 -100]	[0.01 - 0.001]

Fig. 3. Particle representation.

The LSTM-PSO algorithm incorporates two distinct topologies: the star and the ring. Consequently, two hybrid methodologies are proposed, specifically LSTM+starPSO and LSTM+ringPSO. Algorithm 1 outlines the procedural steps involved in the implementation of LSTM+starPSO. The LSTM+ringPSO follow similar steps, except Step 9. The algorithm commences by initializing the population of particles or swarm size. It is followed by initializing various parameters, including the number lookback, LSTM unit, dropout, dense unit, and learning rate. The Step 4 involves initializing the inertia weight, w, and acceleration constants C_1 and C_2). Steps 5 and 6 involve the initialization of the minimum value of velocity (Vmin), the maximum value of velocity (Vmax), the minimum position (Pmin), and the maximum value of position (Pmax). The subsequent step involves determining the setting for formulating the objective function and the iteration number, denoted as i. The ninth step involves the uploading of input data. Step 10 involves the implementation of the LSTM+starPSO algorithm, while Step 11 entails the computation of the Pbest and Gbest values for each particle. The updated characteristics of the particle are outlined in Step 14.

Algorithm 1: LSTM+starPSO

```
1   Begin
2   Initialize the number of particles
3   Initiate number lookback, LSTM unit, dropout, dense unit,
    learning rate
4   Declare C1, C2 and W
5   Initialize Vmin, and Vmax
6   Initialize Pmax and Pmin.
7   Set the objective function based on RMSE
8   Set iteration number, i
9   Load datasets
10  Execute LSTM+starPSO
11  Calculate Pbest and Gbest value for each particle
12  Do
13  For each particle
14          Update features of the particle
15          Calculate the new velocity value, $V_{(new)}$
16          Calculate new position, $D_{(new)}$
17          Calculate Pbest $_{(new)}$
18          Calculate Gbest $_{(new)}$
20  While (stopping condition is reached)
21  End
```

The new velocity value for each particle is determined in Step 15 by applying Eq. (1). Eq. (2) is utilized to update the new position, denoted as P(new), in Step 16. Ultimately, Pbest(new) and Gbest(new) values are established by considering the fitness value assigned to the given problem. The iteration process commences at Step 12 and continues until Step 20, during which each particle's current velocity and position are updated. The iteration will continue until it meets the specified stopping condition.

D. Performance Measure

This study has used two essential empirical measurements to evaluate and compare the effectiveness of the LSTM and PSO+LSTM models. The performance metrics, Mean Absolute Percentage Error (MAPE) and Root Mean Squared Error (RMSE) are the cornerstone indicators used to evaluate the precision and dependability of these models. RMSE is a well-known statistical metric that expresses the variance between the predicted values produced by the models and the actual observed values. A lower RMSE value signifies greater accuracy and precision, as the model's predictions closely match the observed data.

Second, by evaluating the relative error as a percentage of the actual values, MAPE provides an insightful perspective on the performance of the models. MAPE averages out the absolute percentage differences between the predicted and actual values. This metric is beneficial for Assessing how well the models can predict values roughly equivalent to the actual data points and approximately proportional to them. A lower MAPE indicates that the models make more accurate predictions with minor relative errors in applications.

IV. Computational Results

A. Parameter Setting

The proposed method encompasses two distinct parameter setting categories: Particle Swarm Optimization (PSO) and Long Short-Term Memory (LSTM). In the Particle Swarm Optimization (PSO) context, a population size for initializing particles is selected from a set of values, namely {10, 20, 30}. The value of the iteration variable, denoted as i, is adjusted to a value of 30. The importance of C1 and C2 remains consistently equal to 2. The lower and upper bounds for the inertia weight are 0.4 and 0.9, respectively. The particle representation set by PSO mapping determines the selection of random values for parameters such as lookback, LSTM unit, dense unit, and learning rate in the context of LSTM. The values are selected randomly during the execution of the program. The lookback parameter is randomly selected from 3 to 10, while the LSTM unit is chosen from 64 to 256. The density unit and learning rate values are specified within the range of [10, 100] and [0.01, 0.01], respectively.

B. Computational Results using LSTM Based on the Number of Lookback

In assessing the impact of lookback on LSTM performance, we conducted experiments using varying lookback values, ranging from 3 to 10, as indicated in Table I. The objective is to determine an appropriate value for the lookback parameter and identify the optimal RMSE and MAPE values. As shown in Table I, the utilization of WTI in LSTM models yields diverse RMSE and MAPE values, indicating variations in performance. Two lookbacks, specifically 5 and 8, stand out due to their comparable RMSE and MAPE results. The root mean square error (RMSE) for Lookback 5 is calculated to be 2.6604, with a MAPE of 4.6256.

On the other hand, Lookback 8 has an RMSE of 2.7761 and a MAPE of 4.2628. Based on the analysis, it is observed that the MAPE of the lookback 8 model is significantly lower than that of the lookback 5 model, with a difference of -0.35. Additionally, the model with RMSE of lookback value equal to 8 is slightly higher than that of lookback equal to 5, with a difference of +0.11. Consequently, the model for lookback equal to 8 is deemed optimal for the WTI dataset. The results obtained on the BRENT dataset indicate a different outcome, highlighting the prominence of a particular lookback value of 7.

C. Comparison Results of Different Methods

The forecasting results on the datasets WTI and BRENT are summarized in Table II and Table III. We incorporate LSTM with starPSO and ringPSO and tabulate the results from the recent finding by [28] and the conventional LSTM and two statistical time series methods, ARIMA and SARIMAX. The best results are highlighted in bold-face type. LSTM+starPSO provides better performance for the two datasets. In Table II, LSTM+starPSO with LSTM units of 212, dense unit of 77, and learning rate of 0.0083, lookback equals to 8 demonstrates the superior performance compared to other methods with RMSE of about 1.7512. We can see from Table III on the BRENT dataset a better forecasting performance offered by LSTM+starPSO, where both RMSE and MAPE are minimized. The performance seems better than CHGSO_LSTM, which reported 1.7540 for WTI and 0.8453 of the RMSE for BRENT. In terms of the number of population, it shows that 20 is acceptable for both datasets. According to the results, although the data is univariate, the statistical models ARIMA and SARIMAX are ineffective compared to LSTM and its variants in forecasting future oil prices.

Every PSO requires an objective function or criterion that the PSO seeks to optimize. In this case, RMSE from the LSTM result is used as the objective function, which PSO tries to minimize the RMSE value. According to our findings, the ideal lookback range and learning rate are [6, 7] and 0.008, respectively. LSTM+starPSO performs relatively similarly to the CHGSO-LSTM model [28] for the WTI and BRENT datasets in RMSE and MAPE. For the WTI dataset, +0.16% and -8.56% are obtained for RMSE and MAPE. A similar trend can be seen with the BRENT dataset, with +22.82% and +18.7% in RMSE and MAPE. On the other hand, LSTM+ringPSO performs slightly lower than LSTM+starPSO, where the result is -3.63% and -13.74% for RMSE and MPE for WTI and +20.7% and +21% for RMSE and MAPE for BRENT. PSO uses the position and velocity update method to find the best RMSE value. LSTM+starPSO outperforms CHGSO-LSTM with RMSE and MAPE with 11% and 5.7% reduction. The same goes for the BRENT dataset, where we see a 39% and 42.8% reduction in RMSE and MAPE, respectively.

TABLE I. COMPUTATIONAL RESULTS USING CONVENTIONAL LSTM BASED ON THE NUMBER OF LOOKBACK

V. DISCUSSION

A. *Effect of LSTM and Dense Units*

In LSTM, dense units can facilitate the transformation of the input data into a higher-dimensional space, increasing the model's ability to separate and classify. On the other hand, the number of dense and LSTM units should be chosen carefully to avoid overfitting or underfitting the data. Therefore, network architecture design, including the composition of dense and LSTM units, is significantly important [30]. It is advisable to experiment with different combinations of dense and LSTM units to find the optimal architecture that yields the best performance of forecasting accuracy. This paper explores using stochastic particle features to determine the most suitable number of dense and LSTM units and the incorporation of dense layers within an LSTM network. Interestingly, the LSTM+starPSO model, which used 212 LSTM units and 77 for dense units on WTI datasets, showed how sufficient dense and LSTM units reduce the overfitting problem and increase forecasting accuracy. In the context of the BRENT dataset, the model architecture consisted of 183 LSTM units and 51 dense units.

B. *Effect of Lookback*

Lookback in time series forecasting establishes how much historical data the LSTM, LSTM+starPSO, and LSTM+ringPSO models should consider when making predictions for the following time step. Depending on several variables, including the data patterns, the effect of lookback on LSTM can be significant. Determining the most effective lookback period is contingent upon the unique attributes of the time series data [31]. More than eight lookback numbers appear required for accurate prediction in the best performance models, which offer little but longer-term dependencies. With such a small number of lookbacks, more is needed.

C. *Effect of Learning Rate*

The role of the learning rate in the LSTM forecasting model is to assist in effective converging and achieving good performance. We represent the particle with the range of learning rate of [0.01, 0.001]. It is randomly chosen within these ranges during the LSTM+starPSO and LSTM+ringPSO execution. The small learning rate value is randomly chosen at about 0.006 to 0.008 for both datasets using LSTM+starPSO, meanwhile about 0.004 to 0.005 when using LSTM+ringPSO. However, the use of a small learning rate value has a significant effect on the forecasting results. It is evident that the choice of a small learning rate in LSTM models for time series forecasting aims to achieve a better convergence and generalization in the exploitation and exploration of the search space [32].

D. *Effect of PSO Topology in LSTM*

Ring topology is a local-based focal point of particles. It attracts particles to the best particle in its corresponding neighborhood. In our experiment, three swarm sizes are used: 10, 20, 30. For instance, each particle has 29 neighborhoods when using a swarm size equal to 30. However, due to the various particle positions in the search space, the nearest particle of each particle considers the local neighborhood involved in the local search. Each particle's local surroundings consist of a fixed number of other particles. It differs from star topology, where all particles within the swarm share information with and are influenced by the particle with the highest performance [33]. Star topology promotes global exploration by encouraging particles to move towards the optimal solution discovered by any swarm member. LSTM with star topology has demonstrated that each particle in the searching space is attracted to the best particle of the swarm. It obtained the best forecasting accuracy performance for WTI and BRENT datasets. The global searching by star topology [34] achieves the objective function of minimizing the RMSE value.

VI. Conclusion

In this study, an enhancement of LSTM incorporated with PSO addresses the challenges of forecasting the daily time series crude oil price data. The proposed method comprises two main steps. At the PSO, particle mapping is designed together with topology to achieve a dynamic LSTM architecture and improve PSO searching capabilities for exploration and exploitation. With this method, more accurate forecasting is obtained. Experimental findings show that compared with the recent CHGSO_LSTM, the suggested LSTM+starPSO offers the most performing methods. It is a better outcome compared to LSTM+ringPSO and conventional methods. However, more experimental work could be conducted by embedding ensembles and executing feature engineering strategy and hyperparameter tuning.

***Abstract*—In recent years, deep learning has garnered widespread attention in graph-structured data. Nevertheless, due to the high cost of collecting labeled graph data, domain adaptation becomes particularly crucial in supervised graph learning tasks. The performance of existing methods may degrade when there are disparities between training and testing data, especially in challenging scenarios such as remote sensing image analysis. In this study, an approach to achieving high-quality domain adaptation without explicit adaptation was explored. The proposed Efficient Lightweight Aggregation Network (ELANet) model addresses domain adaptation challenges in graph-structured data by employing an efficient lightweight architecture and regularization techniques. Through experiments on real datasets, ELANet demonstrated robust domain adaptability and generality, performing exceptionally well in cross-domain settings of remote sensing images. Furthermore, the research indicates that regularization techniques play a crucial role in mitigating the model's sensitivity to domain differences, especially when incorporating a module that adjusts feature weights in response to redefined features. Moreover, the study finds that under the same training and validation set configurations, the model achieves better training outcomes with appropriate data transformation strategies. The achievements of this research extend not only to the agricultural domain but also show promising results in various object detection scenarios, contributing to the advancement of domain adaptation research.**

Keywords*—*Deep learning; neural network; domain adaptation; lightweight; regularization techniques

I. Introduction

Remote sensing technology, as a crucial tool for observing the Earth and its ecosystems, has played an indispensable role in multiple domains [1]. However, due to various factors such as capture devices, time, and location influencing the acquisition process of remote sensing images, there exist differences in remote sensing data across different domains. Consequently, models trained in one domain (source domain) often exhibit decreased performance when applied to another domain (target domain). This challenge is commonly referred to as distributional difference [2].

Indeed, distributional difference has long been a persistent issue in machine learning. A series of studies have demonstrated that as the mismatch between distributions increases, performance noticeably declines [3]. A widely adopted approach to address this issue is Domain Adaptation (DA). Previous research has shown that domain adaptation markedly impacts the accuracy and reliability of processing remote sensing images. To tackle this problem, researchers have explored various methods, such as reannotating a portion of target domain data for model fine-tuning [2], making the data distributions of the source and target domains more similar through feature selection or transformation [4], utilizing adversarial training for domain alignment [5], and employing strategies like self-supervised learning [6] and meta-learning [7]. These approaches have, to some extent, alleviated the problem of distributional differences.

With the rapid development of the third wave of artificial intelligence—deep learning, deep convolutional neural networks (CNNs) are significantly pushing the performance boundaries of computer vision at an incredible pace [8]. The latest advances in Unsupervised Domain Adaptation (UDA) in image processing have been attempted and progressed in various fields. Goel et al. [9] achieved unsupervised domain adaptation by guiding transfer learning and employing the Jensen-Shannon (JS) divergence method. In the remote sensing domain, Elshamli et al. [10] introduced an innovative approach to domain adaptation, incorporating denoising autoencoders and domain adversarial neural networks, especially in the classification of hyperspectral and multispectral images. In the agricultural domain, Zhang et al. [11] narrowed the gap between the source and target domains for agricultural land extraction using Generative Adversarial Networks (GANs). Similarly, Valerio et al. [12] accomplished unsupervised leaf counting, while Marino et al. [13] achieved potato defect classification. In plant disease recognition, Fuentes et al. [14] proposed open-set adaptation and cross-domain adaptation methods to enhance tomato disease recognition using unlabeled data. Additionally, Wu et al. [15] achieved cross-domain recognition of wild plant diseases. In robotics, Magistri et al. [16] introduced Unsupervised Domain Adaptation (UDA) techniques for semantic segmentation, enhancing the adaptability of agricultural robots to better perceive and understand different environments. These collective efforts address challenges associated with domain transfer and variability, contributing to the robustness and adaptability of image processing models for various application domains.

Despite these advancements, it is noteworthy that the visual representations learned by deep CNNs exhibit considerable domain invariance. There is evidence that combining existing CNN representations with a linear classifier can achieve relatively high accuracy [17]. In earlier research, Lu et al. [18] posed a challenging question, namely achieving domain adaptation without explicit adaptation of data distribution. This provided an opportunity to reconsider the problem of cross-domain generalization from a new perspective.

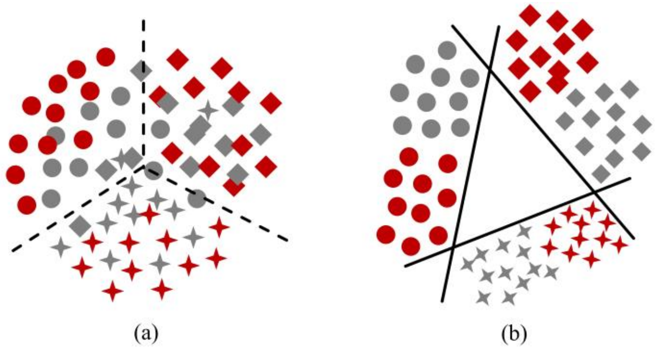

Fig. 1. Two typical scenarios. The target domain is shown in gray and the source domain is shown in red. Different tags indicate different categories.

As Fig. 1 illustrates two typical data distributions, an interesting phenomenon can be observed: samples from different domains but of the same class are close enough, while samples from different classes have a sufficiently large gap. In scenario (a), the distribution difference between the source and target domains is small, but due to confusion among different classes, the final recognition performance is not ideal. In contrast, in scenario (b), despite a marked difference between different domains, samples from different classes are still linearly separable. This suggests that the magnitude of differences between the source and target domains is not a good indicator of the final recognition accuracy. Is the CNN representation powerful enough to eliminate the need for domain adaptation? This study aim to explore a visual model that achieves domain adaptation without the need for explicit adaptation, designed a novel deep convolutional neural network, Efficient Lightweight Aggregation Network (ELANet), which innovatively employs an ELA module for optimizing feature decoding. Experimental results demonstrate the significant optimization of ELANet, showcasing domain adaptability due to the powerful representational capabilities of current CNNs and some carefully designed features. The validation process is based on three datasets: the Global Wheat Head Detection 2021 (GWHD) dataset focusing on wheat [19], and two remote sensing datasets, namely Remote Sensing Object Detection (RSOD) [20] and University of Chinese Academy of Sciences - Aerial Object Detection (UCAS-AOD) [21]. For the remote sensing datasets, the "airplane" category was selected, with RSOD serving as the source domain and UCAS-AOD as the target domain. Extensive experimental results demonstrate the effectiveness of the ELANet method, and some interesting findings are reported.

In summary, the contributions of the research can be summarized as follows:

- ELANet: A visual model with domain adaptation, reporting state-of-the-art performance in cross-domain settings for agricultural and remote sensing scenarios, demonstrating sufficient generality.
- Validation of the effectiveness of regularization techniques: The study proves that utilizing regularization techniques to mitigate domain variance is effective. In particular, incorporating a module that dynamically adjusts feature weights in response to domain redefinition is a more intelligent approach.
- Effective Training Set and Validation Set Configuration: Training under the same configuration for training and validation sets is more effective, provided the existence of data transformation strategies.

II. Methodology

A. ELANet Model Design

The ELANet model is designed based on two components: Encoder and Decoder. The Encoder extracts and downsamples features from input images through a series of convolutional and channel transformation layers, forming feature maps at different resolutions. The Decoder is responsible for the feature extraction task and includes multiple branches. Each branch processes features at different scales through convolutional and channel fusion operations. Multi-scale feature fusion enhances detection performance. Finally, an Adaptive Scale Fusion (ASF) layer is employed to adaptively fuse features, reducing the need for deep downsampling to obtain high-level semantic information [22], as depicted in Fig. 2. The following sections will introduce the global architecture of the ELANet model and its optimizations.

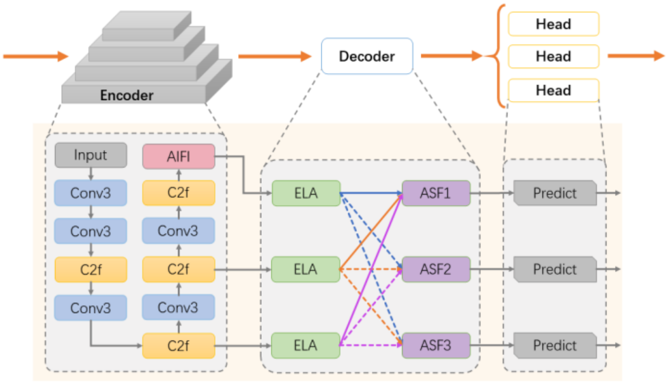

Fig. 2. The architecture of ELANet.

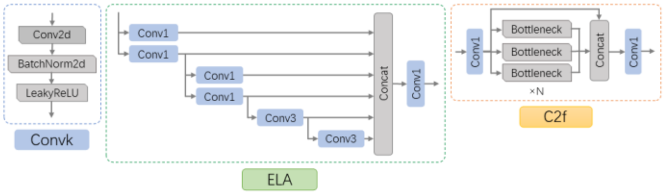

Fig. 3. Details of module design.

B. Encoder

The role of the encoder is to map the input RGB images into feature maps. Specifically, includes five downsampling operations performed by convolutional layers with a stride of 2 and a 3×3 kernel size. In the middle, a C2f module [23] is inserted for feature extraction, generating feature maps at different stages. The sequence of operations can be described as follows: Conv3-Conv3-C2f-Conv3-C2f-Conv3-C2f-Conv3-C2f (In Convk, 'k' represents the size of the convolution kernel). These operations are connected sequentially, with the output of the previous layer serving as the input for the next layer. The initial channel number is 3, corresponding to the RGB image channels, and it increases gradually. It's noteworthy that in the final stage of the Encoder, a Multi-Head Self-Attention module called Attention-based Intra-scale Feature Interaction (AIFI) [24] is employed to handle the highest-level features of the backbone network, as depicted in Fig. 3. The mathematical processes are defined by Eq. (1) and Eq. (2):

$$Q = K = V = Flatten(S_{Last}) \tag{1}$$

$$F_{Last} = Reshape(Attn(Q, K, V)) \tag{2}$$

where, S_{Last} represents the last layer feature map output by the Encoder. Initially, the two-dimensional feature S_{Last} is flattened into a vector, which is then processed by the AIFI module. Subsequently, the output is reshaped back into two dimensions, denoted as F_{Last}, facilitating its transmission to the Decoder for feature analysis.

C. Decoder

The role of the Decoder is to combine and utilize features from the Encoder and decode predictive information. In visual models for processing remote sensing images, the utilization of gradient information is crucial. This process is generally achieved through continuous upsampling to facilitate the fusion of semantic information. Despite being a common approach, there is inevitably a problem of feature information loss or degradation, impacting the fusion effectiveness across non-adjacent levels. To address this issue, this study introduces the ELA module, whose structure is depicted in Fig. 3. Specifically, the ELA module employs two consecutive convolutional operations to capture richer feature representations. Subsequently, by introducing additional gradient flow branches in parallel, incorporates a broader context to enhance abstraction capabilities for targets. The features from the first six layers are concatenated to simultaneously utilize multi-scale information, strengthening the detection capabilities for targets of different sizes. Finally, a 1×1 convolutional layer is applied to reduce the dimensionality of the matrix, thereby alleviating the computational load of the model. With these connection operations, the model gains richer gradient information, achieving higher accuracy and more reasonable latency. Notably, in the ELANet model, a further adaptation is made using Adaptive Spatial Fusion (ASF) proposed by Yang et al. [25], which supports direct interaction between non-adjacent levels for adaptive spatial feature fusion. Through two consecutive convolutional operations, the ELA module adapts well to objects of different scales. The first convolutional operation captures features at a smaller scale, while the second convolutional operation integrates these features within a larger receptive field, making the model more flexible and accurate in detecting objects of different sizes. The design of the Decoder section integrates features from three different levels of the Encoder. ASF allocates different spatial weights to enhance the importance of key levels and reduce the impact of conflicting information from different levels.

Representation learning in convolutional neural networks faces the challenge of strong correlations between adjacent pixels, implying the potential provision of redundant information. To address this issue, there are some carefully designed strategies within each output feature of ASF, utilizing regularization techniques to alleviate domain variance. Specifically, a dropout strategy with a probability of 0.1 and Shuffle Attention (SA) attention strategy [26] during the upsampling and downsampling processes are employed. Since the zeroing of elements after dropout is random, connecting an SA attention strategy for responsive feature weight adjustment is deemed necessary. This necessity will be validated and analyzed in the experiments below. Finally, ELANet merges the decoded feature maps from different stages into the original feature image. Through pixel-level prediction, the regression branch predicts the distance from each anchor point to the four edges of the target bounding box, determining the target's position.

D. Loss Function

In the implementation of the ELANet model, use three loss functions to guide the regression of bounding boxes. The Classification Loss is used to measure the difference between the predicted class and the true class. This process is guided by the cross-entropy loss function, a common binary classification loss function, defined as follows:

$$L_c = -\frac{1}{n}\sum_{i=1}^{n}[y_i \log p_i + (1 - y_i)\log(1 - p_i)] \tag{3}$$

In Eq. (3), let the ground truth be denoted as y, the predicted result as y, and n represents the batch size.

The Regression Loss is composed of Complete Intersection over Union (CIoU) and Distribution Focal Loss (DFL). CIoU is used to guide the model in learning the matching degree of bounding boxes. Specifically, assuming the predicted box and the ground truth box are denoted as b_p and b_g respectively, it is described as follows:

$$L_{CIoU} = IoU - \frac{\rho^2(b_p, b_g)}{c^2} - \alpha v \tag{4}$$

In Eq. (4), IoU represents the Intersection over Union, and $\rho^2(b_p, b_g)$ calculates the Euclidean distance between the center points of the two rectangular boxes. Here, c is the length of the diagonal of the minimum bounding rectangle of the predicted and ground truth boxes, v is used to measure the similarity of aspect ratios, and α is the impact factor of v. Next, dfl optimizes the position of the bounding boxes through smooth L1 loss. For each positive sample i, it is defined as:

$$L_{dfl} = \frac{1}{N_{pos}}\sum_{i=1}^{N_{pos}} Sml(pd_i, gt_i) \times w_i \tag{5}$$

In Eq. (5), N_{pos} represents the number of positive samples, $Sml(pd_i,\ gt_i)$ represents the smooth L1 loss for the ith positive sample, and w$_i$ is the weight associated with the ith sample. Combining Eq. (4) and Eq. (5), the regression loss Lr can be obtained as $L_r = L_{CIoU} + L_{dfl}$.

The final loss for ELANet is defined as the weighted sum of the classification loss and regression loss, i.e., $L_{ELANet} = \alpha L_c + \beta L_r$.

III. Experiment

A. Experimental Details

1) Data preprocessing: The RSOD and UCAS-AOD datasets consist of 446 and 1000 airplane images, respectively, designated as the source domain and target domain. For convenience, this configuration is named RSOD. Beyond that, the GWHD dataset was intentionally set up for cross-domain settings, with 165 wheat spike images in the source domain and 71 in the target domain. In Fig. 4, present the size information for each instance in these two datasets. The RSOD dataset exhibits significant size differences between source and target domain data, while the primary difference in the GWHD dataset originates from variations in the external and internal environments.

2) Training details: The experiments are implemented in PyTorch [27] and accelerated using an NVIDIA RTX 3090 GPU. To improve computational efficiency, the longest side of input images is scaled to 608 pixels, and the other side is scaled proportionally, which also suits the resolution requirements when deploying on low-end edge devices. The Adaptive Moment Estimation (Adam) algorithm [28] was employed as the optimizer with a momentum factor set to 0.937, and the initial learning rate was set to 0.01. Considering convergence speed, perform 150 epochs of optimization on the RSOD dataset and 300 epochs on the GWHD dataset. To ensure the robustness of model training, strategies such as color distortion, random scale transformations, and mosaic data augmentation are employed.

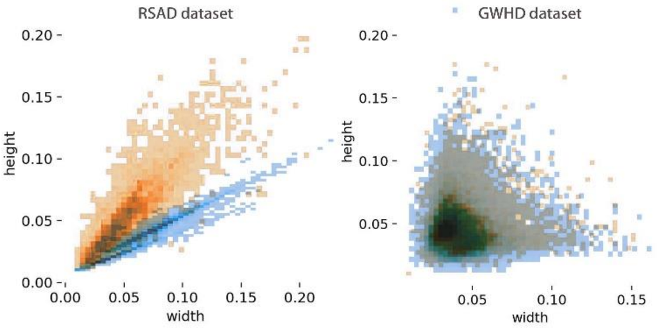

Fig. 4. Instance size information for each dataset.

B. Evaluation Indicators

In the process of establishing a detection model, it is essential to consider both precision and recall. Therefore, this study adopts metrics such as Precision, Recall, mAP@0.5, and mAP@0.5-0.95 to evaluate the model's performance and assess the detection results. The calculation methods for Precision and Recall are as Eq. (6) and Eq. (7):

$$\mathrm{P} = \frac{TP}{TP+FP} \tag{6}$$

$$\mathrm{R} = \frac{TP}{TP+FN} \tag{7}$$

where, P represents precision, and R represents recall. True Positive (TP) is the number of positive samples correctly classified, True Negative (TN) is the number of negative samples correctly classified, False Positive (FP) is the number of negative samples incorrectly classified as positive, and False Negative (FN) is the number of positive samples incorrectly classified as negative.

mAP represents the comprehensive performance at different Intersection over Union (IoU) thresholds, including mAP@0.5 and mAP@0.5-0.95. Here, mAP@0.5 denotes the average mAP when the IoU threshold is 0.5, with a higher value indicating higher detection precision for that category. mAP@0.5-0.95 represents the average mAP at different IoU thresholds (ranging from 0.5 to 0.95 with a step size of 0.05), placing stricter demands on the model's performance. The calculation of mAP is given by Eq. (8):

$$mAP = \frac{1}{n}\sum_{1}^{n} P(R)d(R) \tag{8}$$

where, n is the number of categories. In this experiment, each dataset has only one label, so n=1.

Furthermore, three metrics will be employed in the counting evaluation to assess the consistency between predicted and ground truth values, including Mean Absolute Error (MAE), Root Mean Squared Error (RMSE), and Coefficient of Determination (R^2). Specifically, they are defined by Eq. (9) to Eq. (11):

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|\widehat{y_i} - y_i| \tag{9}$$

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(\widehat{y_i} - y_i)^2} \tag{10}$$

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(\widehat{y_i}-y_i)^2}{\sum_{i=1}^{n}(\overline{y_i}-y_i)^2} \tag{11}$$

In these formulas, the numerator represents the sum of squared differences between the actual values and predicted values, and the denominator represents the sum of squared differences between the actual values and the mean. The result of R^2 falls within the range of [0, 1], indicating the proportion of the squared differences of predicted values to the squared differences of actual values near the mean. This metric can be understood as a measure of how well the model's predictions fit the actual values, with 1 indicating a perfect fit and 0 indicating no linear relationship between actual counts and predicted values.

C. Comparision with other Methods

To validate the effectiveness of ELANet, comparisons with two state-of-the-art methods: the two-stage model Faster R-CNN [29] and the one-stage model YOLOv7-tiny [30], both of which are widely used for visual tasks in images. Table I and Table II present the quantitative results on the two datasets, while Fig. 5 showcases some prediction examples from ELANet.

One notable observation is that, even though both datasets explicitly implement cross-domain settings, the performance on RSOD significantly surpasses that on GWHD. In reality, domain differences in the agricultural domain are extremely complex. The chaotic background makes the visual patterns of plants diverse and misleading, and the changes in plants themselves are also very pronounced. As shown in Fig. 1(a), despite the small distribution difference between the source and target domains, the recognition performance is not ideal due to the confusion of different category samples. As demonstrated in Fig. 5(a), (b), the morphological differences in wheat spikes from different regions and varieties are substantial.

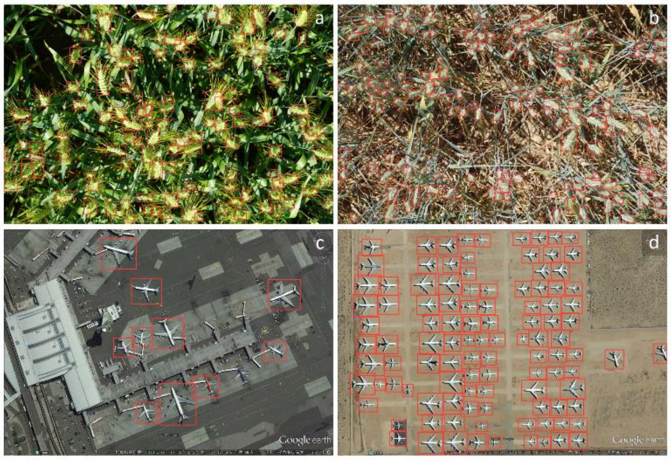

Fig. 5. Part of ELANet's prediction results. (a, b) are from the GWHD dataset, and (c, d) are from the RSOD dataset.

The comparison of object detection methods on the GWHD and RSOD datasets reveals distinct performance characteristics. According to the quantitative results shown in Table I for models on the GWHD dataset, ELANet achieves a precision of 88.7% without the need for adaptation to distribution differences on low-resolution input images. YOLOv7-tiny, while effective in terms of parameters, exhibits moderate precision and recall, with a lower mAP@0.5-0.95 score. Faster R-CNN, with a higher parameter count, shows performance comparable to YOLOv7-tiny but lacks the precision and recall achieved by ELANet, possibly due to information loss resulting from the simplification of their network structures. ELANet achieves optimal performance at the same input size of 608×608, substantially improving precision and average precision.

TABLE I. QUANTITATIVE RESULTS OF GWHD DATASET

Method	P	R	mAP@0.5	mAP@0.5-0.95	Params
YOLOv7-tiny	0.558	0.379	0.387	0.141	11.55M
Faster R-CNN	0.446	0.391	0.343	0.127	42.20M
ELANet	0.882	0.816	0.887	0.501	3.59M

Furthermore, as shown in Table II, the experimental results on the RSOD dataset also demonstrate a similar trend. However, the evaluation gap between the models is smaller in the RSOD dataset experiments. Additionally, it is worth noting that ELANet exhibits a smaller model parameter size, only 3.59M, compared to YOLOv7-tiny and Faster R-CNN with 11.55M and 42.2M, respectively. ELANet achieves significant improvements in both performance and parameter efficiency, indicating that it maintains high performance while being more parameter-efficient, making it well-suited for lightweight tasks without sacrificing efficiency.

TABLE II. QUANTITATIVE RESULTS OF RSOD DATASET

Method	P	R	mAP@0.5	mAP@0.5-0.95	Params
YOLOv7-tiny	0.555	0.821	0.802	0.310	11.55M
Faster R-CNN	0.832	0.751	0.753	0.278	42.20M
ELANet	0.894	0.845	0.861	0.337	3.59M

D. Analysis of Counting Influencing Factors

Due to the dense distribution of targets in both the GWHD and RSOD datasets, evaluating counting performance in this context is meaningful. Particularly in the case of the GWHD wheat head dataset, the model is prone to various natural factors during target detection, such as the influence of lighting, rainy weather, thick fog, etc. What's more, errors may arise from the varying shapes, sizes, and densities of different wheat head varieties. In this experiment, a linear regression plot was employed, along with counting metrics introduced in Section III (B), including Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and the Coefficient of Determination (R^2), to assess counting performance. The diagonal line on the coordinate system represents the ideal state where the model inference results perfectly match the manually counted ground truth. The linear regression plot serves as an effective tool to visually analyze the relationship between model predictions and actual counts, allowing researchers to gain a deeper understanding of the factors influencing counting performance. Additionally, it highlights images with the highest errors, as shown in Fig. 6.

It is evident that the maximum errors are primarily concentrated under varying lighting conditions, where inconsistencies in illumination affect wheat heads in bright and shadowed areas differently. The presence of cluttered foliage further challenges the target detection model. Through experimentation, it was discovered that even human experts find it challenging to discern in such conditions. Despite this, the ELANet model demonstrates good robustness, indicating that the optimized strategies of data augmentation play a positive role in enhancing the adaptability of the model for target detection performance. This also points towards future research directions, specifically addressing how to optimize models for strong interference environments to achieve stability, reliability, and adaptability in complex conditions.

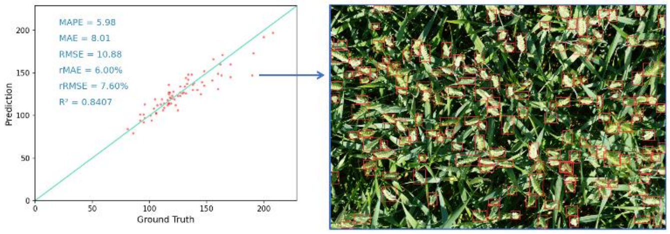

Fig. 6. Linear regression plot and maximum error plot of GWHD dataset count results.

E. Ablation Study

In the RSOD dataset, ELANet's performance is satisfactory. Building upon this, the focus shifted to conducting ablation experiments using Dropout strategy and SA strategy on the GWHD dataset. The experimental results are presented in Table III and compared with two domain adaptation methods. In the table, "Dp" represents the use of the dropout strategy, and "At" represents the application of the SA attention strategy. It can be observed that without employing either strategy, ELANet achieves an accuracy of 0.87. However, using either the dropout strategy or attention strategy alone leads to a performance decrease in the detection task, with reductions of 1.72% and 0.23%, respectively. On the other hand, employing the SA attention strategy after using the dropout strategy proves to be highly effective. The random zeroing of elements after dropout reduces the risk of overfitting, preventing excessive co-adaptation of neurons and maintaining feature diversity. This contributes to improving the model's generalization performance and robustness. The SA attention strategy can re-weight features in response to enhance attention to important regions, adaptively fusing contextual information of different scales.

Another interesting finding is that when the training set and the validation set share the same settings, the model's performance is improved, as shown in Table IV, method A involves separate training and validation sets, while method B uses the same set for training and validation. From a subjective perspective, the model in this situation should not be robust. In reality, data transformation techniques alleviate the impact of this situation, and the performance improvement is attributed, to some extent, to the slightly increased training data.

TABLE III. ELANET USES DROPOUT STRATEGIES FOR ABLATION STUDIES

Dp	At	P	R	mAP@0.5	mAP@0.5-0.95
--	--	0.855	0.810	0.870	0.463
√	--	0.848	0.790	0.855	0.457
--	√	0.850	0.803	0.868	0.472
√	√	0.882	0.816	0.887	0.501

TABLE IV. COMPARISON OF ELANET PERFORMANCE WITH DIFFERENT DATASET SETTINGS

Method	P	R	mAP@0.5	mAP@0.5-0.95
A	0.872	0.779	0.864	0.468
B	0.882	0.816	0.887	0.501

IV. DISCUSSION AND FUTURE WORK

In this study, the challenges of cross-domain object detection were explored, focusing on addressing distribution differences between different datasets. The proposed ELANet model, based on feature extraction and fusion, was introduced. Experimental results indicate that ELANet performs exceptionally well on the RSOD dataset, while its performance on the GWHD dataset is relatively lower. This difference may be attributed to the clearer features in the airplane images of the RSOD dataset, making it easier for the model to learn effective feature representations. In contrast, the complex background and the similarity in color between target objects and the background in the GWHD dataset increase the difficulty of model recognition.

Furthermore, this study compared ELANet's performance on the RSOD and GWHD datasets with other methods, revealing superior performance on both datasets. This suggests that ELANet can better handle cross-domain challenges and improve the accuracy of object detection. Nevertheless, there are still some issues to be addressed. For example, ELANet's performance is influenced by data preprocessing and training details. To further enhance the model's performance, deeper research into data preprocessing and training techniques is needed. Distribution differences have been a long-standing issue in machine learning [31]-[35], and it is hoped that this work will further stimulate researchers' interest in addressing this problem.

In future research, potential improvement avenues can be explored in the following directions:

Adversarial Robustness Learning: Conduct in-depth research to assess ELANet's robustness against adversarial attacks. Strengthening the model's security is crucial for real-world deployment and addressing potential security challenges.

Testing in Complex Environments: Test ELANet's robustness in more complex environmental conditions, especially in scenarios with natural factors such as varying lighting and rainy weather. Consider employing more powerful data augmentation and processing techniques to enhance the model's adaptability to these challenges.

Driving Agricultural Technology Innovation: Expand ELANet's application to more agricultural domains, such as agricultural robots, precision agriculture, and plant disease diagnosis. Through widespread application in agricultural technology, ELANet aims to provide more intelligent and efficient solutions for agricultural production.

V. CONCLUSION

In this study, the focus was on exploring a visual model for domain adaptation without the need for explicit adaptation, particularly addressing the challenge of domain adaptation in supervised graph learning tasks. In this work, the ELANet model was proposed, innovatively introducing the ELA module and integrating it into the feature decoder, successfully achieving high-quality domain adaptation in the remote sensing image domain. The model demonstrated outstanding performance on real datasets. The research indicates that regularization techniques are crucial for mitigating the domain variance between training and testing data, especially when incorporating a module that reweights features in response. Importantly, the use of the ELANet model not only improved accuracy but also enhanced efficiency. In experiments validating the generality and domain adaptation of ELANet, cross-domain settings were employed, demonstrating the model's generality and domain adaptability. Overall, the introduction of ELANet is expected to advance research in domain adaptation, providing an innovative approach to addressing domain adaptation challenges in supervised graph learning tasks.

Improving Brain Tumor MRI Image Classification Prediction based on Fine-tuned MobileNet

Quy Thanh Lu, Triet Minh Nguyen, Huan Le Lam
Information Technology Department, FPT University, Can Tho, Viet Nam

***Abstract*—Brain tumors are a prevalent issue in contemporary society as they impact human health. The location of the tumor in the brain determines the variety of symptoms that may manifest. Some frequent symptoms are cephalalgia, convulsions, visual impairments, nausea, emesis, asthenia, paresthesia, dysphasia, personality alterations, and amnesia. The prognosis for brain cancer differs considerably depending on the cancer type. Nevertheless, brain tumors are amenable to treatment with surgical intervention, chemotherapy, and radiotherapy if the diagnosis is timely. Furthermore, artificial intelligence and machine learning can assist in the detection of brain tumors as they have significant implications for the analysis of Magnetic Resonance Imaging (MRI). To accomplish this objective, automated measurement instruments were proposed based on the processing of MRI. In this study, we employed the latest developments in deep transfer learning and fine-tuning to identify tumors without many complex steps. We gathered data from authentic MRI of 3264 subjects (i.e., 926 glioma tumors, 937 meningioma tumors, 901 pituitary tumors, and 500 normal). With the MobileNet model from the Keras library, we attained the highest validation accuracy, test accuracy, and F1 score in four-class classifications was 97.24%, 97,86%, and 97.85%, respectively. Concerning two-class classification, high accuracy values were obtained for most of the models (i.e., ~100%). These outcomes and other performance indicators demonstrate a strong capability to diagnose brain tumors from conventional MRI. The current research developed a supportive machine learning that can aid doctors in making the accurate diagnosis with less time and mistakes.**

Keywords—Brain tumor; fine-tuning; transfer learning; Magnetic Resonance Imaging (MRI); MobileNet

I. Introduction

The health of people in the modern world is adversely affected by numerous diseases, among which brain tumors are prevalent in various age groups, from adolescents to seniors. Brain tumors are not a helpless disease and there are several treatment options available for patients with this disease. Some of the most common and efficacious methods of treating brain tumors are surgery, chemotherapy, radiation therapy, or a combination of these techniques. Surgery entails excising the tumor or part of it through an operation, while chemotherapy and radiation therapy employ drugs and high-energy rays to eradicate or reduce the tumor cells. The selection of treatment for each patient hinges on multiple factors, such as the type of the tumor, the grade of the tumor, the location of the tumor, the size of the tumor, as well as the age and general health of the patient. By considering these factors, physicians can devise the optimal treatment plan for each patient and enhance their prospects of recovery.

Nevertheless, it is still dangerous if we avoid it. For example, A brain tumor is a grave condition irrespective of its benignity or malignancy. Tumors within the cranium expand and exert pressure on different regions of the brain, impairing their function. A glioma is a tumor that emerges when glial cells proliferate abnormally. Typically, these cells support neurons and facilitate the operation of your central nervous system. Gliomas commonly grow in the brain, but can also emerge in the spinal cord. Gliomas are malignant (cancerous), but some can be very slow-growing. In addition, Meningioma is the most frequent type of primary brain tumor, it is a tumor that develops from the meninges, the protective layers around the brain and spinal cord. Meningiomas occur more often in women and are usually detected at older ages. Moreover, Pituitary tumors are abnormal enlargements that originate in the pituitary gland. Some of these tumors cause the pituitary gland to produce an excess of certain hormones that regulate vital body functions. tumors stimulate the adrenal glands to produce too much cortisol. This causes a condition called Cushing disease. Others can cause the pituitary gland to produce too little of those hormones.

Numerous data gathered in recent years globally indicate the detrimental effects of brain tumors. The CBTRUS Statistical Report states that from 2016 to 2020, 86,030 deaths occurred due to malignant brains. This corresponds to an average annual mortality rate of 4.42 and an average of 17,206 deaths per year [1]. In 2030, 145,650 new cases of brain tumors are projected to be diagnosed in China with 68,730 men and 76,920 women [2]. The 5-year relative survival rate after diagnosis of a malignant brain tumor was 35.7% and for a non-malignant brain tumor was 91.9% [1]. The most frequent malignant brain tumor was glioblastoma with 14.2% of all tumors, and the most common non-malignant tumor was meningioma with 40.8% of all tumors [1]. Glioblastoma was more prevalent in males, and meningioma was more prevalent in females. In children and adolescents aged 0-19 years, the incidence rate of primary tumors was 6.14 out of 100,000 people [3]. An estimated 3,920 new cases of primary childhood brain tumors are expected to be diagnosed in 2023 [4]

Recently, Magnetic Resonance Imaging (MRI) has been considered one of the most efficient methods for identifying the irregular parts of the central nervous system and human brain. Moreover, the early diagnosis of brain tumors is one of the crucial tasks and offers many advantages to patients. Early identification of tumors helps doctors devise suitable treatment plans and helps lower mortality in patients with brain tumors as quickly as possible. There are many methods that clinicians can use to detect brain tumors as Computerized Tomography

(CT) or MRI. However, it would be time-intensive to diagnose using the MRI method. Furthermore, doctors have to prepare and conduct many procedures to finish a standardized process for patients. Therefore, applying the newest advanced techniques in the diagnostic process can spare valuable time for doctors. Moreover, it can provide doctors with a recommendation to improve the diagnostic process and increase the outcomes.

Artificial intelligence is one of the most prominent advanced techniques invented in recent years. Therefore, we decided to use it to assist doctors in diagnosing MRI images. In the field of artificial intelligence, machine learning is related to the development and research of statistical algorithms that can effectively generalize data and syntax. Based on the trained and prepared results, the computer will perform tasks without explicit instructions [5]. Machine learning algorithms have many applications. For example, financial prediction, transportation, education, data structure in health care systems, drug reaction prediction, diabetes research, cyber security, banking and finance, and social media [6].

Our study used transfer learning and fine-tuning, a part of deep learning which is the subset of the machine learning method. That aim enables us to reuse pre-trained models for new tasks and datasets. Moreover, Transfer learning concentrates on transferring general knowledge from one domain to freeze certain layers to preserve general [7]. Fine-tuning adapts the model to a particular allows the pre-trained layers to be updated [8]. We suggest a new method to use the MobileNet model in the Keras library in a Convolutional Neural Network (CNN) which is appropriate for image recognition and processing tasks and it has achieved state-of-the-art outcomes on a wide range of image recognition tasks, such as object classification, object detection, and image segmentation [9]. It is trained using a huge dataset of annotated images. Once trained, a CNN can be utilized to classify new images or extract features for use in other applications such as object detection or image segmentation.

The contributions of this paper are as follows:

- We propose a complete reliable artificial intelligence model that is used for brain tumor classification including glioma, meningioma, and pituitary tumor. Hence, it can create an easy and speedy way for doctors to detect and classification on their medical purpose.
- Our method achieves a high performance (i.e., <97%) of the deep learning models for four-class (glioma, meningioma, pituitary, and normal) and pair-wise classification problems also achieve a high success (i.e., ~100%). As a result. The effectiveness of each model in terms of training and testing times was also evaluated.
- Our collected MRIs of subjects afflicted with brain tumors, as well as healthy ones, as verified by the specialists in the hospital. This dataset is confirmed for the development of automated machine learning and AI algorithms for the detection of brain tumors and can be applied to educating medical students.
- We point out that GradCam can be used effectively for visual explanations. So, highlighting the important regions (i.e., glioma tumor, meningioma tumor, and pituitary tumor) in the image can provide a more intuitive view for physicians

Our research paper comprises four main sections. In the subsequent Section II, we indicate some of the related research that we employed for references. Following the related research section is the methodology Section III, this section elucidates in detail all of the methods utilized in the article. Subsequently, Section IV will refer to the experiments, and how we conduct and evaluate the accuracy of the deep learning model. Lastly, in the final Section V, we summarize our article and examine the essential domains associated with the study.

II. Related Work

Besides the change in environment and population, a lot of diseases have negative effects on human life and one of these is brain tumors. The survey pointed out that 1,323,121 people living with brain and other CNS tumors (malignant and non-malignant) on December 31, 2019 [1]. At that time, a bunch of research on medical and artificial intelligence helped humans in the healing of those sicknesses. Wadhah Ayadi detected brain tumors by suggesting a new CNN that contains various layers such as convolution, Rectified Linear Unit (Relu), and pooling to achieve a best Accuracy is 94.74 [10]. Following Ahmad Saleh, His scholarly investigation endeavors to enhance the proficiency of MRI apparatus in the categorization of cerebral neoplasms and discerning their respective classifications, using AI Algorithms, CNN, and Deep Learning. The MobileNet model is used in this study. The evaluation of the image dataset is conducted utilizing the F1-score metric, yielding a commendable accuracy rate of 97.25% [11].

Machine Learning helped experts and doctors research medical image analysis. This led to, a change in normal examination and treatment to aid medical procedures to avoid a waste of time and money. Hence, typical studies appear more and more such as Wadhah Ayadi. The presented methodology used normalization, dense speeded-up robust features, and histogram of gradient techniques to enhance the quality of MRI and produce a discriminative feature set. The accuracy attained through the implementation of this method is measured at 90.27% [12]. In addition, Muhammad Imran Sharif suggests Densenet201 Pre-Trained Deep Learning Model. The attributes of the trained model are derived from the average pooling layer, elucidating the profound information on each specific tumor type. In addition, He includes two new models Entropy–Kurtosis-based High Feature Values (EKbHFV) and modified genetic algorithm (MGA). Finally, the research paper has achieved an accuracy higher than 95% [13].

Convolutional Neural Network (CNN) is one of the parts of deep learning models commonly used in Computer Vision that help computers understand and interpret images or visual data. It has main contributions to creating intelligent systems with great accuracy. So, it has produced several academic works as S Kumar's research paper. In short, the technical use of the Deep Convolution Neural Network (Deep CNN) for performing the brain tumor classification with Dolphin-SCA as the training algorithm. The database is MRI images given by the BRATS database and SimBRATS, and the suggested model has shown a maximum accuracy of 96.39% [14]. Moreover, Díaz-Pernas applied the method on a publicly available MRI image dataset of 3064 images from 233 patients compared with previously classical segmentation and classification published methods. In this comparative analysis, the proposed method demonstrated exceptional results, achieving an impressively high tumor classification accuracy of 0.973 [15].

Processing medical images by automatic segmentation and classification becoming extremely important around the world [16], [17], especially in the medical field such as diagnostics, growth prediction, and treatment of brain tumors. As a result, a patient can save their life because an early detection of brain tumors that helps to increase their survival rate. Applying machine learning, the brain classification paper from Huong Hoang Luong points out that the K-mean clustering algorithm stratifies the samples into three distinct view angles of MRI, namely, transverse, coronal, and sagittal planes. This strategic classification process was coupled with the integration of a modified Residual Network (ResNet) architecture. Finally, He reached a performance of 96% in the brain tumor classification accuracy [18]. Furthermore, with another k-means algorithm S. Rinesh's innovative approach outperformed conventional methods such as hybrid k-means clustering and parallel k-means clustering, exhibiting superior results with a higher peak signal-to-noise ratio and a reduced mean absolute error value. The proposed model attained an accuracy of 96.47% [19].

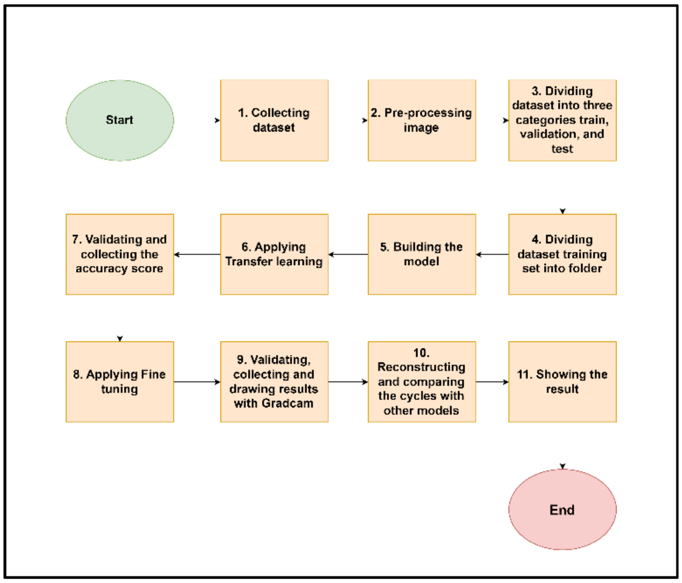
Additionally, we have introduced an automated classification system designed for the intricate challenge of categorizing multiclass brain tumor MRI. This task, inherently more complex and demanding, transcends the relative simplicity of binary classification. The dataset is almost equal to Khan Swatithe's paper uses a pre-trained deep CNN model and introduces a block-wise fine-tuning strategy rooted in transfer learning principles. Notably, this methodology is characterized by its generality, eschewing the need for handcrafted features, and demanding minimal preprocessing. Impressively, the proposed approach attains an average accuracy rate of 94.82% within the context of a five-fold cross-validation framework [20]. Besides, with a straightforward architectural design and the absence of any antecedent region-based segmentation, Nyoman Abiwinanda achieved commendable results, attaining a training accuracy of 98.51% and a peak validation accuracy of 84.19%. Notably, these outcomes stand in favorable comparison to the performance of more intricate region-based segmentation algorithms [21].

In summary, the related work saw notable weaknesses, particularly characterized by low accuracy. Many current models struggle to consistently achieve high precision across diverse datasets, leading to concerns about their robustness and generalizability. Additionally, the lack of a visual explanation such as GradCam for evaluating and comparing models hinders progress. Addressing these limitations is imperative to propel deep learning toward more reliable and universally applicable solutions, ensuring advancements that transcend the current constraints of accuracy and evaluation methodologies.

III. Methodology

A. The Research Implementation Procedure

In this research paper, we propose a method including 11 steps from input to output shown in Fig. 1. The roles of the steps are shown as follows:



Start
1. Collecting dataset
2. Pre-processing image
3. Dividing dataset into three categories train, validation, and test
4. Dividing dataset training set into folder
5. Building the model
6. Applying Transfer learning
7. Validating and collecting the accuracy score
8. Applying Fine tuning
9. Validating, collecting and drawing results with Gradcam
10. Reconstructing and comparing the cycles with other models
11. Showing the result
End

Fig. 1. The implementing procedure flowchart.

1) Collecting dataset: The dataset is collected by Swati Kanchan in B. Tech Dept of CSE from NIT Durgapur. The dataset comprises MRI images, including three types of brain tumors—meningioma, glioma, and pituitary—as well as normal images. This comprehensive collection serves as a valuable resource for medical research and diagnostic advancements.

2) Pre-processing image: This important step requires both resizing and normalization to establish standardized input conditions for machine-learning models. This leads to an increase in the outcome of the results.

3) Dividing the dataset into three categories train validation and test: In total, 3264 images constitute the comprehensive MRI dataset, with random selection for training, validation, and testing phases. The datasets are randomly chosen using an 8-1-1 scale, allocating 8 parts for training, 1 for validation, and 1 for testing, ensuring a balanced distribution for robust model development and evaluation.

4) Dividing the training set into folders: Types of brain tumors (i.e., meningioma, glioma, and pituitary and normal) are divided into many different folders. The biggest include 4 classes (i.e., meningioma, glioma, and pituitary and normal). We want to show the training data more exactly way and use it to compare the biggest folder. Dense, the other folder contains two class classifications includes: meningioma-normal, glioma-normal, and pituitary-normal

5) Building the model: To conduct experiments, we reconstructed the model based on the prototype of the CNN architecture by inheriting its core processing layers and modifying some layers to achieve improved results. As a result, the model creates an excellent result for our training test with Keras's models library.

6) Applying transfer learning: In transfer learning, the model gets trained on a big set of data for a specific job. This dataset could be general or have lots of labeled information. The things the model learns are saved in its weights, especially in the lower layers. These layers gather important features from the input data, making it easier for the model to understand and work with the information.

7) Validating and collecting the accuracy score: After completing the training of the model, we assessed its precision by summarizing the training accuracy derived from the model's predictions. Subsequently, we evaluated the accuracy of the test set using the initially separated testing set."

8) Applying fine tuning: In this procedure, the process of adjusting the hyperparameters of a model to improve its performance on a dataset and using the weights of an already trained model as the starting values for training a new model. Hyperparameters are the parameters that control the learning process and we finish after the model has been trained on a training set, and done when using a validation set.

9) Validating, collecting and drawing results with GradCam: We summary all the metrics like validation accuracy, test accuracy, and F1 score, then. Images used GradCam to represent detected brain tumors in color to more accurately represent the results.

10)Reconstructing and comparing the cycles with other models: When we have results in one model, we rework another model in Keras including MobileNet, Inception V3, VGG16, ResNet50, and EfficientNet B3 to compare the final result

11)Showing the result: After conducting a comparison, results will be presented through tables and graphs to facilitate meaningful comparisons.

B. Pre-processing Image

In the pre-processing pipeline for images, a pivotal step involves both resizing and normalization to establish standardized input conditions for machine learning models. The resizing operation transforms the input image I to a uniform dimension of (new width, new height). As a result, we decided to choose 224 pixels for weight and 224 pixels for height (1) using a chosen interpolation method, as captured by the formula:

$$I_{resize}\left(new_{width}, new_{height}\right) = Resize(I, 244{,}244) \quad (1)$$

This operation (1) is essential for establishing a consistent input size, a prerequisite in various deep-learning applications. Following resizing in equation (2), the subsequent normalization process adjusts pixel values to a range between 0 and 1, facilitating model training and convergence. The normalization is mathematically expressed as:

$$O(x, y) = \frac{I_{resize}(x,y)}{255} \quad (2)$$

In this Eq. 2, $O(x, y)$ signifies the output pixel value at position (x, y) in the preprocessed image. The division by 255 ensures that the pixel values are scaled to fit within the [0, 1] range, aligning with common conventions in image processing.

This dual procedure of resizing to (224, 224) (1) and subsequent normalization not only ensures a standardized size for all images but also provides a consistent pixel value scale (2), thereby enhancing the efficiency and robustness of downstream machine learning tasks.

C. Transfer Learning and Fine Tuning of CNN (MobileNet)

We noticed that transfer learning and fine-tuning of CNN have become pivotal techniques in the realm of computer vision, enabling the effective utilization of pre-trained models on new tasks [22][23][24]. One such exemplary model is MobileNet, a lightweight and efficient architecture design. MobileNet, characterized by depth wise separable convolutions, significantly reduces the computational burden while preserving the model's capacity to capture intricate features in images.

The MobileNet model's architecture is inherently rooted in the principles of convolutional neural networks, with its convolutional layers serving as feature extractors. This architecture excels in tasks demanding real-time performance and resource efficiency. When considering transfer learning, MobileNet offers a valuable starting point. Pre-trained on large-scale image datasets, it possesses a robust understanding of general image features, making it an ideal candidate for various computer vision applications.

The integration of MobileNet into the broader CNN architecture is seamless and complementary such as Fig. 2. The initial layers of a CNN, responsible for low-level feature extraction, can be substituted with the MobileNet backbone. This strategic replacement allows the model to retain its ability to recognize high-level features while benefiting from MobileNet's efficiency in processing low-level features. The resulting hybrid architecture strikes a balance between computational efficiency and task-specific adaptability.

In conclusion, the fusion of transfer learning and fine-tuning within the realm of CNNs, particularly with the utilization of the MobileNet model, represents a powerful approach to solving diverse computer vision challenges. This leads to the final results about validation accuracy, test accuracy, and F1 score increase and reaching a desirable point.

D. Visual Explanation by GradCam

In our paper, we decided to choose a visual explanation by Gradient-weighted Class Activation Mapping (i.e., GradCam), because it stands as a pivotal technique in unraveling the decision-making processes of CNN. It operates by shedding light on crucial regions within an image that heavily influence the model's final prediction, thus enhancing both interpretability and confidence in the outputs.

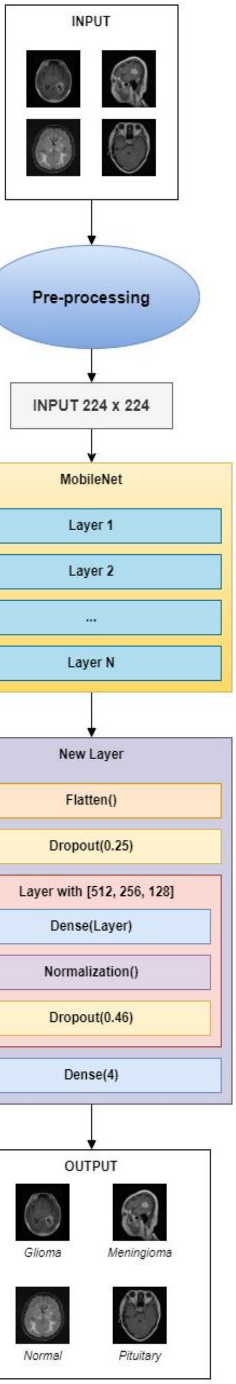


Fig. 2. Procedure of transfer learning and fine-tuning in ours model with custom layers.

In more detail, GradCam relies on the gradient information flowing into the final convolutional layer of a CNN. Let F^k (3) represent the k-th feature map from the last convolutional layer, and w_c^k (3) show the weight of the k-th feature map for the target class 'c.' The GradCam heatmap $L_c^{GradCam}$ (3) is computed as the global average pooling of the positive gradients:

$$L_c^{GradCam} = ReLU(\sum_k w_c^k \cdot F^k) \qquad (3)$$

The ReLU (3) function ensures that only positive contributions are considered, highlighting the regions with a positive influence on the decision for the target class 'c' Fig. 3.

To explain this formula in detail, let's express the weight w_c^k (4) for a specific feature map 'k' as the global average pooling of the gradients:

$$w_c^k = \frac{1}{Z} \sum_{i,j} \frac{\partial y_c}{\partial A_{i,j}^k} \qquad (4)$$

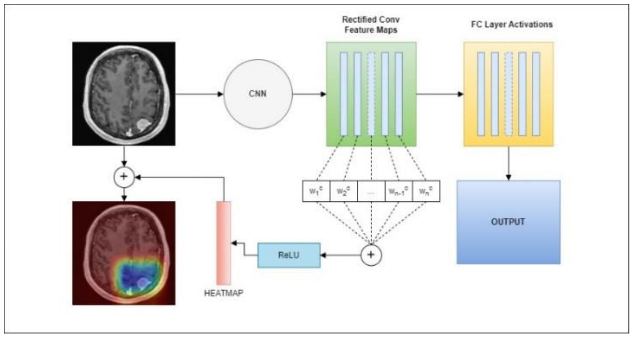

Fig. 3. GradCam functionality.

Because y_c (4) denotes the logit for the target class 'c,' and A_j^k (4) presents the activation of the k-th feature map at position (i, j). The normalization term 'Z' ensures that the weights sum to 1, providing a meaningful contribution measure.

The computation of the gradient $\frac{\partial y_c}{\partial A_j^k}$ (5) involves back-propagating the derivative of the logit with respect to the activation of the k-th feature map at position (i, j). By means of mathematics, this can be expressed as:

$$\frac{\partial y_c}{\partial A_j^k} = \frac{\partial y_c}{\partial F_{i,j}^k} \cdot \frac{\partial F_{i,j}^k}{\partial A_{i,j}^k} \qquad (5)$$

This chain of derivatives involves the gradient of the logit with respect to the activation of the k-th feature map at position (i, j), $\frac{\partial y_c}{\partial F_{i,j}^k}$ (5), and the gradient of the activation at (i, j) with respect to the input activation, $\frac{\partial F_{i,j}^k}{\partial A_{i,j}^k}$ (5).

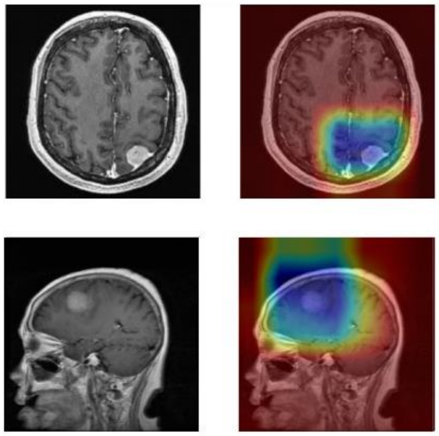

Fig. 4. The final result after applying a visual explanation by GradCam.

By using this GrandCam, our results have the contribution of each feature map to the final decision in Fig. 4, and facilitate future use by professionals and doctors.

IV. Experiments

A. Dataset and Peformance Metrics

The research used a single dataset for both the training, validation, and testing phases in this analysis. The data was taken and augmented by Swati Kanchan in B. Tech Dept of CSE from NIT Durgapur, 3264 images constitute the comprehensive MRI dataset in total including 926 glioma tumors, 937 meningioma tumors, 901 pituitary tumors, and 500 no tumor.

Moreover, the performance of the models was assessed using five metrics: validation accuracy, test accuracy, precision, recall, and F1 score play pivotal roles in assessing the performance and generalization capabilities of a trained model.

Validation accuracy (Val acc) in Eq. 6 represents the model's precision on a separate dataset during training, measuring its ability to learn without overfitting the training data. By means of mathematics, validation accuracy is computed as:

$$Val\ acc = \frac{Total\ Number\ of\ instance\ in\ validation\ set}{Number\ of\ correctly\ predictec\ instrances} \tag{6}$$

Test accuracy (Test acc) in Eq. 7 reflects the model's proficiency in making accurate predictions on previously unseen data, providing insights into its real-world applicability. This metric is calculated by:

$$Test\ acc = \frac{Total\ number\ of\ instances\ in\ test\ set}{Number\ of\ correctly\ predicted\ instances} \tag{7}$$

Recall in Eq. 8, a metric crucial in scenarios where identifying true positives is paramount, is defined as:

$$Recall = \frac{True\ Positives}{True\ Positives + False\ Negatives} \tag{8}$$

Precision in Eq. 9 is a fundamental metric in the evaluation of classification models. Mathematically, precision is defined as the ratio of true positives (instances correctly predicted as positive) to the sum of true positives and false positives (instances incorrectly predicted as positive). The precision formula is given by:

$$Precision = \frac{True\ Positives}{True\ Positives + False\ Positives} \tag{9}$$

The F1 score in Eq. 10, a harmonic mean of precision and recall, is expressed as:

$$F1 = \frac{2 \times Precision \times Recall}{Precision + Recall} \tag{10}$$

B. Scenario 1: The Results of Classifying MRI Images Into Two Classes: Normal or Glioma Tumor

The purpose of the experiments was to evaluate the effectiveness of the pre-trained models, after customization and training, in identifying the correct disease diagnosis of the MRI image. Moreover, these data can help us make easier and more intuitive comparisons across brain tumor categories (four classes or two classes).

Tables I and II show the performance evaluation metrics for classifying MRI images into normal or scoliosis. In transfer learning, the Resnet-50 achieved the highest accuracy (i.e., 100%). After fine-tuning, three models including MobileNet, InceptionV3, and EfficientNetB3 produced results that exceeded expectations (i.e., 100% for three models). In contrast, Resnet-50 showed worse results than the previous experiment.

TABLE I. The Accuracy of Classifying MRI Images Into Two Classes: Glioma Tumor and Normal in Transfer Learning, for Each Deep Learning Model

Model	Transfer learning				
	Val acc	Test acc	Precision	Recall	F1
EfficientNetB3	99.30%	98.60%	98.66%	98.60%	98.61%
ResNet50	100.00%	98.60%	98.60%	98.60%	98.60%
VGG16	99.30%	97.90%	98.02%	97.90%	97.92%
Ours	**99.30%**	**97.90%**	**97.92%**	**97.90%**	**97.91%**
InceptionV3	99.30%	93.01%	93.11%	93.01%	93.04%

TABLE II. The Accuracy of Classifying MRI Images Into Two Classes: Glioma Tumor and Normal in Fine Tuning, for Each Deep Learning Model

Model	Fine tuning				
	Val acc	Test acc	Precision	Recall	F1
EfficientNet B3	100.00%	99.30%	99.31%	99.30 %	99.30%
ResNet50	99.30%	96.50%	96.64%	96.50 %	96.53%
VGG16	99.30%	87.41%	88.33%	87.41 %	86.83%
Ours	**100.00%**	**97.90%**	**97.92%**	**97.90 %**	**97.91%**
InceptionV3	100.00%	98.60%	98.60%	98.60 %	98.60%

Fig. 5 and Fig. 6 show a sample training and validation progress curve showing the loss and accuracy values of ours in fine-tuning. The figure displays a stable learning behavior and appropriate training and validation sets.

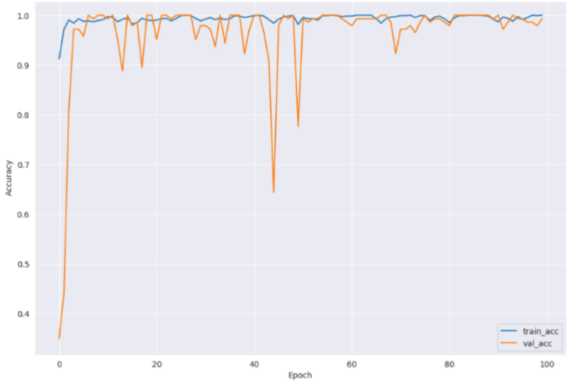

Fig. 5. Training accuracy and validation accuracy in fine-tuning of ours model (Glioma tumors and normal).

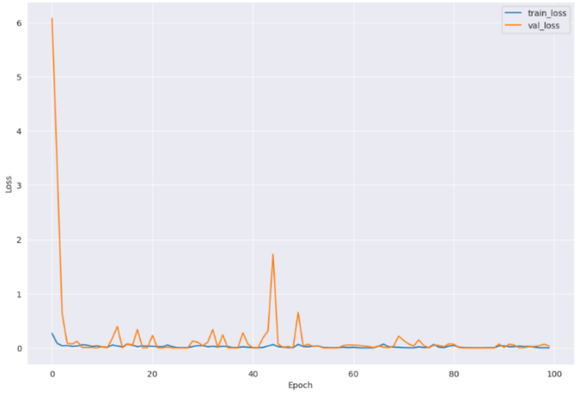

Fig. 6. Training loss in and validation loss in fine-tuning of ours model (Glioma tumors and normal).

Fig. 7 shows the confusion matrix for a sample run of ours model in two classes. In that run, the number of testing images is 143.

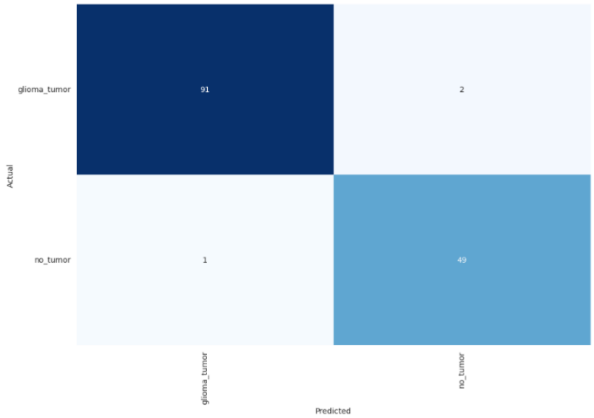

Fig. 7. Confusion matrix in fine tuning for ours model (Glioma tumors and normal).

C. Scenario 2: The Results of Classifying MRI Images Into Two Classes: Normal or Meningioma Tumor

Tables III and IV showed similar results in scenario 2 with the Resnet-50 achieving the biggest accuracy (i.e., 100%) in transfer learning. After fine-tuning, ours achieved extremely impressive results with low test loss and all other aspects reaching 100%.

TABLE III. THE ACCURACY OF CLASSIFYING MRI IMAGES INTO TWO CLASSES: MENINGIOMA TUMOR AND NORMAL IN TRANSFER LEARNING, FOR EACH DEEP LEARNING MODEL

Model	**Transfer learning**				
	Val acc	Test acc	Precision	Recall	F1
EfficientNetB3	99.31%	98.61%	98.64%	98.61%	98.60%
ResNet50	100.00%	96.53%	96.84%	96.53%	96.56%
VGG16	97.92%	97.92%	97.92%	97.92%	97.91%
Ours	**97.22%**	**95.14%**	**95.17%**	**95.14%**	**95.15%**
InceptionV3	95.83%	97.22%	97.43%	97.22%	97.25%

TABLE IV. THE ACCURACY OF CLASSIFYING MRI IMAGES INTO TWO CLASSES: MENINGIOMA TUMOR AND NORMAL IN FINE TUNING, FOR EACH DEEP LEARNING MODEL

Model	**Fine tuning**				
	Val acc	Test acc	Precision	Recall	F1
EfficientNetB3	100.00%	99.31%	99.32%	99.31%	99.31%
ResNet50	100.00%	86.11%	90.08%	86.11%	86.44%
VGG16	99.31%	95.14%	95.17%	95.14%	95.15%
Ours	**100.00%**	**100.00%**	**100.00%**	**100.00%**	**100.00%**
InceptionV3	100.00%	97.22%	97.22%	97.22%	97.22%

In Fig. 8 and Fig. 9, we can see the detail of the training accuracy and training loss about two classes that is pituitary tumors and normal MRI images. This chart can show us the high result of a classification of brain tumors when using ours model.

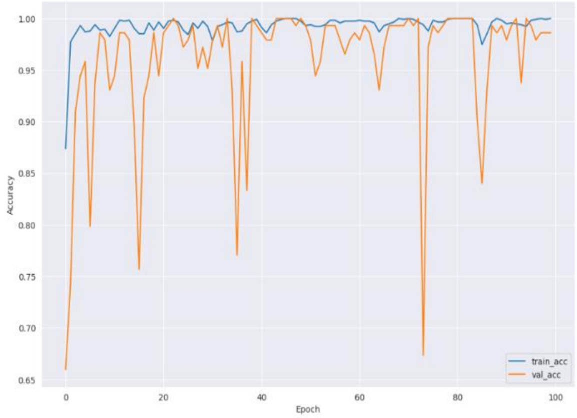

Fig. 8. Training accuracy and validation accuracy in fine-tuning of ours model (Meningioma tumors and normal).

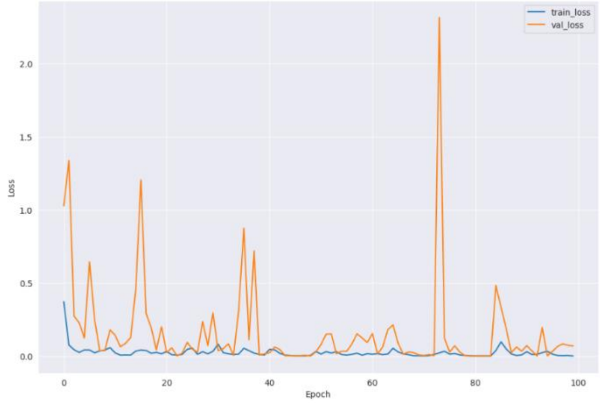

Fig. 9. Training loss in and validation loss in fine-tuning of ours model (Meningioma tumors and normal).

The confusion matrix in Fig. 10 shows that the result of model has a high performance when using it to classify brain tumor.

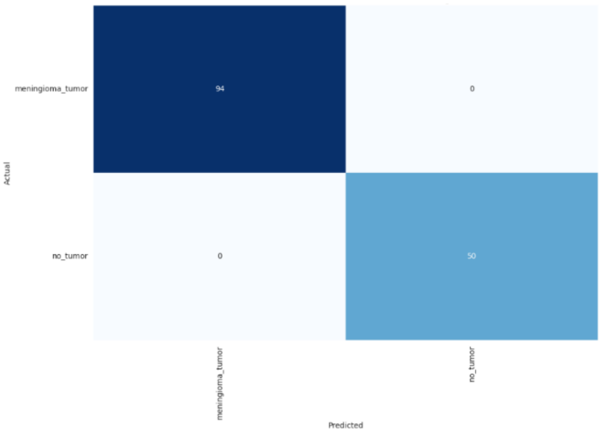

Fig. 10. Confusion matrix in fine tuning for ours model (Meningioma tumors and normal).

D. Scenario 3: The Results of Classifying MRI Images Into Two Classes: Normal or Pituitary Tumor

In scenario 3, Tables V and VI show that ResNet-50 has top results in all aspects (i.e., 100%) while it decreased a litter bit after fine-tuning, other models have a bit of a transformation (i.e., ~99%) when finished two steps.

TABLE V. THE ACCURACY OF CLASSIFYING MRI IMAGES INTO TWO CLASSES: PITUITARY TUMOR AND NORMAL IN TRANSFER LEARNING, FOR EACH DEEP LEARNING MODEL

Model	Transfer learning				
	Val acc	Test acc	Precision	Recall	F1
EfficientNetB3	100.00%	98.58%	98.58%	98.58%	98.57%
ResNet50	100.00%	100.00%	100.00%	100.00%	100.00%
VGG16	94.29%	98.58%	98.58%	98.58%	98.58%
Ours	**100.00%**	**99.29%**	**99.30%**	**99.29%**	**99.29%**
InceptionV3	99.29%	98.58%	98.58%	98.58%	98.58%

TABLE VI. THE ACCURACY OF CLASSIFYING MRI IMAGES INTO TWO CLASSES: PITUITARY TUMOR AND NORMAL IN FINE TUNING, FOR EACH DEEP LEARNING MODEL

Model	Fine tuning				
	Val acc	Test acc	Precision	Recall	F1
EfficientNetB3	100.00%	99.29%	99.30%	99.29%	99.29%
ResNet50	100.00%	99.29%	99.30%	99.29%	99.29%
VGG16	94.29%	35.46%	12.57%	35.46%	18.57%
Ours	**100.00%**	**99.29%**	**99.30%**	**99.29%**	**99.29%**
InceptionV3	100.00%	99.29%	99.30%	99.29%	99.29%

In this experiment, Fig. 11 and Fig. 12 give an explanation of training accuracy and training loss in two classes of normal and pituitary tumors in the 'Ours' model.

Finally, the result confusion matrix is represented in Fig. 13 which shows that the performance of the 'Ours' model is very successful.

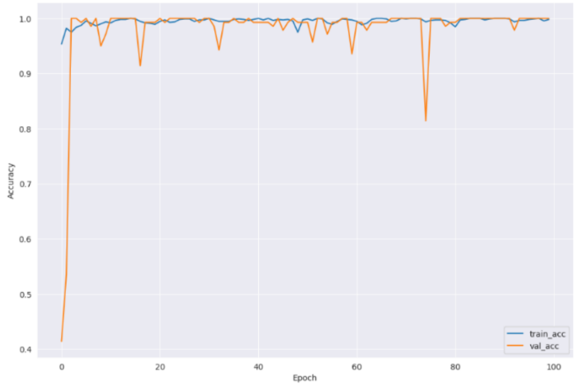

Fig. 11. Training accuracy and validation accuracy in fine-tuning of ours model (Pituitary tumors and normal).

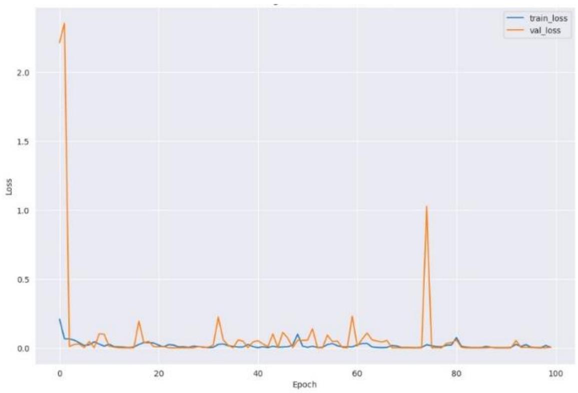

Fig. 12. Training loss in and validation loss in fine-tuning of ours model (Pituitary tumors and normal).

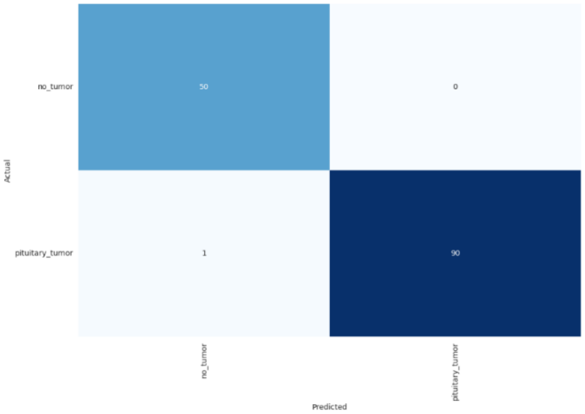

Fig. 13. Confusion matrix in fine tuning for ours model (Pituitary tumors and normal).

E. Scenario 4: The Results of Classifying MRI Images into Four Classes: Normal, Glioma Tumor, Meningioma Tumor, and Pituitary Tumor

Tables VII and VIII show the performance evaluation metrics for classifying MRI images into normal, glioma tumor, meningioma tumor, and pituitary tumor. The ResNet50 achieved the highest accuracy value in transfer learning over the three statistical measures with a validation accuracy of 94,17%, test accuracy of 92.05%, and F1 score of 92.06%. On the other hand, ours model performed the best after fine-tuning with a validation accuracy of 97,24%, test accuracy of 97.86%, and F1 score of 97.86%. The other performance metrics display a consistent and homogenous ability to identify negative as well as positive cases with a similar performance pattern to the accuracy results (i.e., Ours model achieving the best results). The significance of the F1 score lies in its role as an evaluation metric specifically designed for classification problems. An F1 score serves as an indicator of the model's accuracy, emphasizing its ability to achieve both high precision and recall.

TABLE VII. THE ACCURACY OF CLASSIFYING MRI IMAGES INTO FOUR CLASSES: NORMAL, GLIOMA TUMOR, MENINGIOMA TUMOR, AND PITUITARY TUMOR IN TRANSFER LEARNING, FOR EACH DEEP LEARNING MODEL

Model	Transfer learning				
	Val acc	Test acc	Precision	Recall	F1
EfficientNetB3	93.55%	91.13%	91.50%	91.13%	91.16%
ResNet50	94.17%	92.05%	92.18%	92.05%	92.06%
VGG16	86.50%	86.85%	87.09%	86.85%	86.88%
Ours	**89.88%**	**85.93%**	**86.27%**	**85.93%**	**85.89%**
InceptionV3	83.13%	81.65%	81.79%	81.65%	81.69%

TABLE VIII. THE ACCURACY OF CLASSIFYING MRI IMAGES INTO FOUR CLASSES: NORMAL, GLIOMA TUMOR, MENINGIOMA TUMOR, AND PITUITARY TUMOR IN FINE TUNING, FOR EACH DEEP LEARNING MODEL

Model	Fine tuning				
	Val acc	Test acc	Precision	Recall	F1
EfficientNetB3	97.55%	97.55%	97.62%	97.55%	97.55%
ResNet50	97.24%	95.11%	95.20%	95.11%	95.09%
VGG16	65.03%	15.29%	2.34%	15.29%	4.06%
Ours	**97.24%**	**97.86%**	**97.91%**	**97.86%**	**97.86%**
InceptionV3	97.24%	97.55%	97.56%	97.55%	97.55%

In Fig. 14 and Fig. 15 shows the training and validation progress curve for a sample run of the highest-performing model, which gives an indication of the fitting performance of the model and the need for more training. Training accuracy measures a model's performance on the training data, reflecting its ability to learn from the provided examples. Validation accuracy assesses the model's generalization to new, unseen data, helping identify potential overfitting or underfitting issues. Training loss quantifies the disparity between predicted and actual values in the training set, guiding the model to minimize errors during training. Validation loss mirrors this process on a separate dataset, serving as a key indicator of the model's generalization performance.

Fig. 16 shows the 'Ours' sample confusion matrix for four-class classification. This important step makes it possible for us to see a more intuitive comparison of the results achieved. Fig. 17 shows a sample output from the four-class classification process with the visual explanation by GradCam.

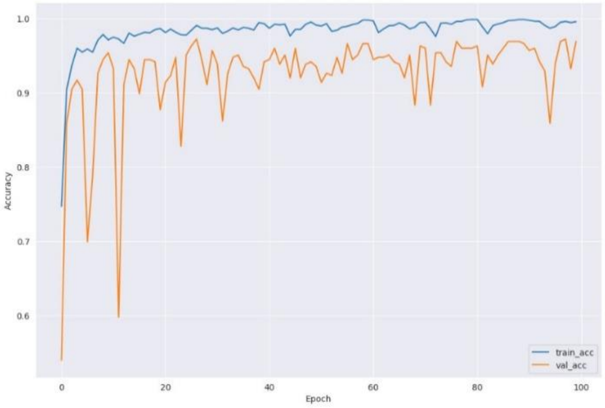

Fig. 14. Training accuracy and validation accuracy in fine-tuning of 'Ours' model (Four classes).

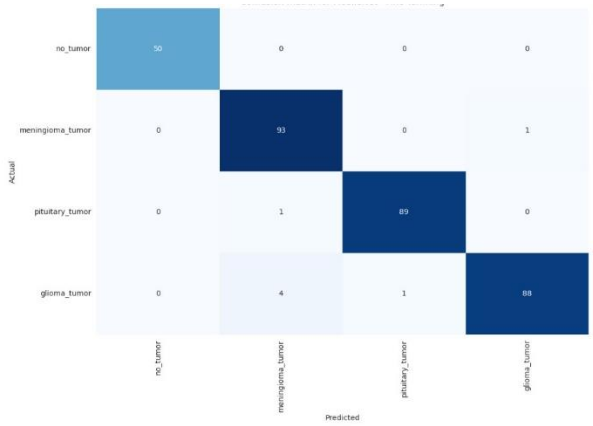

Fig. 16. Confusion matrix in fine tuning for 'Ours' model (Four classes).

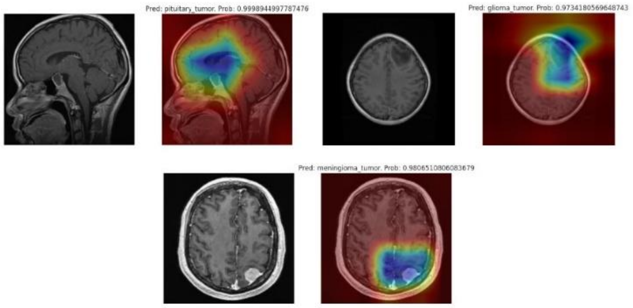
F. *Comparison with others State-of-the-art Methods*

To examine the accuracy of the proposed model that our article has just given out in the previous section, we compare the accuracy score of the proposed model with other CNN architectures, which are VGG16, ResNet-50, ResNet-101and DenseNet201.



Pred: pituitary_tumor. Prob: 0.9998944997787476
Pred: glioma_tumor. Prob: 0.9734180569648743
Pred: meningioma_tumor. Prob: 0.9806510806083679

Fig. 17. Output of four classes classification.

Accuracy, precision, recall, and the F1 score offer many aspects of performance. Accuracy gives overall correctness but may mislead in imbalanced datasets. Precision focuses on the accuracy of positive predictions. Recall assesses the model's ability to capture all relevant positives. The F1 score strikes a balance between precision and recall, making it invaluable for tasks with uneven class distributions. Comparing these metrics involves weighing trade-offs based on task-specific priorities. While accuracy provides a broad overview, precision and recall cater to nuanced aspects, and the F1 score harmonizes their interaction, ensuring a well-informed evaluation of classification models within the constraints of particular objectives. Finally, the result of getting the value of training and accuracy on the test set is illustrated as in Table IX.

TABLE IX. COMPARISON WITH OTHERS STATE-OF-THE-ART METHODS

Ref.	*Proposed*	*Accuracy*

V. CONCLUSION

In our project, we utilized transfer learning, a powerful technique in machine learning, to enhance our model's performance in identifying brain tumors from MRI images. Transfer learning involves leveraging knowledge gained from a pre-trained model on a large dataset for a specific task and applying it to a different, but related, task. In our case, we used the MobileNet model, which was pre-trained on a vast dataset, as a starting point. This allowed our model to inherit knowledge about general image features, enabling it to focus on the intricacies of brain tumor classification.

Fine-tuning played a crucial role in tailoring the pre-trained MobileNet model to our specific medical imaging task. We incorporated dense and dropout layers while adjusting various hyperparameters to optimize the model's performance. The addition of these layers facilitated better feature extraction and prevented overfitting, contributing to the remarkable validation accuracy of 97.24%, test accuracy of 97.86%, and an F1 score of 97.86%.

To provide transparency and insights into our model's decision-making process, we adopted GradCam for visual explanations. This not only aids medical professionals in understanding the model's predictions but also accelerates medical examinations and treatments, making them more efficient and cost-effective.

On the other hand, while our project has shown promising results, certain drawbacks warrant consideration. One significant limitation is the size of the dataset used for training the model. The availability of a relatively small dataset can hinder the model's ability to generalize effectively to diverse and unseen cases. To address the issue of a small dataset, a potential solution involves acquiring and incorporating a more extensive and diverse set of MRI images for training. Collaborating with multiple medical institutions to aggregate data or exploring the use of data augmentation techniques could help augment the dataset, providing the model with a richer understanding of the variations in brain tumor presentations.

Additionally, the current model may face challenges in precisely identifying the boundaries of tumors, potentially leading to false positives or negatives. Furthermore, the reliance on a pre-trained MobileNet model, while beneficial for leveraging general image features, may introduce biases or limitations in capturing subtle nuances unique to medical images. Developing a custom architecture tailored to the intricacies of medical imaging, perhaps through architecture search techniques, could lead to a more specialized and optimized model for brain tumor classification.

In the future, the future trajectory involves refining data preparation, adopting advanced visualization methods, and expanding the dataset. We plan to enhance our model by refining our data preparation techniques, employing advanced visualization methods, and expanding our dataset. By doing so, we aim to further increase the accuracy and robustness of our model, reinforcing its role as a valuable tool in the medical field for the accurate and prompt classification of brain tumors in MRI scans. Our ongoing efforts underscore the significance of artificial intelligence in advancing medical diagnostics and treatment processes.

VI. ACKNOWLEDGMENT

This acknowledgment would be incomplete without expressing our sincere appreciation for Huong Hoang Luong, Hao Van Tran, and Phuc Tan Huynh's encouragement, support, suggestions, and positive influence. I am fortunate to have had the opportunity to collaborate with them, and I am deeply thankful for their contributions. Thank you, for your invaluable guidance and support. Your generosity and commitment have been crucial in bringing this research to fruition.

***Abstract*—Now-a-days, the attacker's favourite is to disrupt a network system. An attacker has the capability to generate various types of DDoS attacks simultaneously, including the Smurf attack, ICMP flood, UDP flood, and TCP SYN flood. This DDoS issue encouraged the design of a classification technique against DDoS attacks that enter a computer network environment. The technique is called Packet Threshold Algorithm (PTA) and is combined with several machine learning to classify incoming packets that have been captured and recorded. Apart from that, the combination of techniques can differentiate between normal packets and DDoS attacks. The performance of all techniques in the research achieved high detection accuracy while mitigating the issue of a high false positive rate. The four techniques focused in this research are PTA-SVM, PTA-NB, PTA-LR and PTA-KNN. Based on the results of detection accuracy and false positive rate for all the techniques involved, it proves the PTA-KNN technique is a more effective technique in the context of detection of incoming packets whether DDoS attacks or normal packets.**

***Keywords*—DDoS; machine learning; accuracy; false positive rate**

I. Introduction

The world now desperately needs an Internet to share resources with other users no matter where they are. It provides many facilities for users to perform daily activities including online games, social media and information search related to teaching and learning. Internet is available 24 hours a day to all users. However, the Internet is often threatened by several network attacks from attackers around the world and this includes DDoS attacks as said by study [1].

When a DDoS attack is launched by an attacker, the computer network or system is inaccessible at that time, even for users who have registered in the system. Typically, attackers apply botnets to perform DDoS attacks to get attacks with incredible speed. It can weaken the target server to serve all requests at that time. According to research [2], DDoS attacks can be categorized into three groups. These categories are volume-based attacks, followed by protocol attacks, and application layer attacks. Volume-based attacks are a category that involves attacks aiming to overwhelm network resources by flooding communication channels with a high volume of traffic. Volume-based attacks often utilize botnets, which are networks of compromised computers controlled by the attacker [3]. By leveraging thousands or millions of infected devices, the attacker generates a massive amount of network traffic, leading to system failures in the targeted infrastructure. The category of protocol attacks focuses on attacking network protocol layers. DDoS protocol attacks often exploit vulnerabilities within the communication protocols used in network infrastructure, such as TCP/IP [4]. Attackers may employ techniques like SYN floods, where they send an overwhelming number of SYN requests to the target server, causing an overload of requests and hindering the server's ability to serve legitimate users. Meanwhile, application layer attacks refer to targeting specific applications or services running on top of the network infrastructure [5]. Application layer DDoS attacks focus on exploiting vulnerabilities within the application's logic or resources it relies on. Attackers can generate various types of DDoS attacks from anywhere. An example of such an attack is the HTTP flood, where attackers overwhelm a web server by sending an abnormally high volume of HTTP requests. This flood of requests leads to a strain on server resources, causing a degradation in performance or even a complete service failure.

There are several types of DDoS attacks that can be generated by attackers from anywhere. These attacks encompass ICMP flood, UDP flood, Ping of Death, Slowloris, Zero-day attack, Smurf, and TCP SYN flood [6]. In order to protect against DDoS attacks, a robust and effective detection strategy is crucial.

The research presents several significant contributions in the following manner:

- In this research, a DDoS attack classification algorithm called the Packet Threshold Algorithm (PTA) was developed to accurately distinguish incoming packets as either normal or malicious. It specifically targets TCP SYN flood, Smurf, UDP flood, Ping of Death, or normal packets. The PTA utilizes a packet threshold mechanism to differentiate and classify incoming traffic.
- To enhance detection capabilities and address the issue of false positives, the PTA was combined with various machine learning techniques, including Support Vector Machine (SVM), K-Nearest Neighbor (KNN), Naïve Bayes (NB), and Logistic Regression (LR). The

objective of this combination was to mitigate the problem of incorrectly classifying DDoS packets as normal packets or vice versa, as experienced in previous techniques.

- In addition to integrating machine learning algorithms with the PTA to enhance the overall performance and accuracy of the detection system, this research also conducted a comprehensive evaluation of the effectiveness of each technique. The results were presented to identify the most efficient approach for detecting malicious packets within a network environment. Furthermore, this study explored potential enhancements and optimizations to further advance the state-of-the-art in DDoS attack detection.

Having a reliable and precise detection strategy is of utmost importance in safeguarding against DDoS attacks. The combined approach of the PTA and machine learning algorithms significantly enhances the system's capability to accurately differentiate and classify incoming packets. By reducing false positives, this strategy provides a more effective defense against DDoS attacks, ensuring the integrity and availability of network resources [7].

The DDoS detection problem is enhanced using machine learning models such as SVM, KNN, Naïve Bayes, and Logistic Regression, which are well-suited for handling classification jobs. Naïve Bayes is strong at probabilistic classification, SVM is good at separating data points, KNN is good at pattern recognition, and Logistic Regression is good for binary classification. By adjusting to a variety of packet behaviors, these models help distinguish between malicious and legitimate packets with accuracy.

There are, nevertheless, certain restrictions. Large datasets may be a problem for SVM and KNN, affecting computing efficiency. The independence between features assumed by Naïve Bayes may not hold true for complex packet dynamics. Non-linear correlations between features may be difficult for logistic regression to handle, which could reduce its accuracy for complex packet classifications. When selecting the best model for DDoS detection, these limitations must be considered.

This paper is divided into several sections. Related work is presented in Section II. Next, in Section III, the methodology is presented, and the evaluation of techniques is described in Section IV, followed by results and discussion in Section V. The final section, Section VI, provides a brief summary of this paper.

II. Related Work

Despite the substantial research efforts dedicated to countering DDoS attacks, the challenge of mitigating them endures. Researchers have introduced various techniques in their attempts to combat the actions of DDoS attackers. Table I provides a summary of the methods proposed by these researchers to address such attacks.

Starting with the first study conducted by study [8], this research addresses the pressing issue of distributed denial-of-service (DDoS) attacks within the context of 5G networks. It emphasizes the predominant focus of previous studies on radio access networks (RAN) and voice service networks, often overlooking the vulnerabilities inherent in core networks (CN). These core network components, including the Access and Mobility Management Function (AMF), Session Management Function (SMF), and User Plane Function (UPF), are pivotal in providing expansive 5G coverage but are susceptible to DDoS attacks. The study introduces a methodology and a threat detection system tailored to counter signalling DDoS attacks specifically targeting 5G standalone CNs. By leveraging fundamental machine learning classifiers and preprocessing techniques such as entropy-based analysis (EBA) and statistics-based analysis (SBA), the research demonstrates the effectiveness of proactive defense strategies against these attacks. Notably, the results underscore the RF classifier as the top performer, achieving an impressive average accuracy of 98.7%.

The second study, led by [9], underscores the critical role of the internet as a fundamental communication tool in contemporary society. In tandem with the internet's indispensability, the frequency and severity of cyber-attacks have escalated, with DDoS attacks ranking among the top five most impactful and costly cyber threats. DDoS attacks disrupt legitimate users' access to network resources, necessitating the development of swift and accurate detection methods to mitigate their considerable damage. The study adopts machine learning classification algorithms, including LR, DT, RF, Ada Boost, Gradient Boost, KNN, and NB to detect DDoS attacks using the CICDDoS2019 dataset, encompassing eleven distinct DDoS attack types characterized by 87 features. The research evaluates classifier performance through various metrics, revealing that AdaBoost and Gradient Boost excel in classification, while LR, KNN, and NB also exhibit strong performance. However, DT and RF classifiers demonstrate less effective classification results.

The third study, conducted by [10], addresses the ongoing challenge of effectively managing DDoS attacks, which pose a significant threat to network security by inundating target networks with malicious traffic from multiple sources. Despite the availability of various conventional methods for detecting DDoS attacks, rapidly identifying these threats using feature selection algorithms remains a formidable task. In this study, a hybrid approach is introduced, incorporating feature selection techniques such as chi-square, Extra Tree, and ANOVA, in conjunction with four machine learning classifiers: FR, DT, KNN, and XGBoost. The primary goal is to enable early detection of DDoS attacks on IoT devices. To validate the proposed methodology, the research employs the CICDDoS2019 dataset, which encompasses a wide range of DDoS attacks, and conducts assessments in a cloud-based environment (Google Colab). The experimental results demonstrate the superior performance of the hybrid methodology, achieving an impressive 82.5% reduction in features and attaining 98.34% accuracy with ANOVA for XGBoost, thereby facilitating the early identification of DDoS attacks on IoT devices.

The fourth study, conducted by study [11], pioneers a comprehensive approach to address pressing security concerns in IoT networks, with a specific focus on the persistent threat posed by DDoS attacks. Their innovative solution involves the integration of SDN with IoT to reinforce security measures and access control. Despite this integration, DDoS attacks continue to pose a formidable challenge. To tackle this issue head-on, the study introduces an advanced machine learning-based security framework. They meticulously craft a controlled testing environment for simulating DDoS attacks, capturing network logs, preprocessing them into a structured dataset, and employing a trio of robust algorithms, namely NB, DT, and SVM for network packet classification. Remarkably, their framework attains impressive accuracy rates, achieving 97.4% for NB, 96.1% for SVM, and an outstanding 98.1% for DT, unequivocally showcasing its effectiveness in mitigating DDoS threats while optimizing resource utilization and proficiently managing network traffic. This pioneering approach holds substantial promise for elevating the security posture of IoT networks.

TABLE I. PAST STUDY MACHINE LEARNING TECHNIQUE

Title of Paper / Year of Published	**Machine Learning DDoS Detection Techniques**			
	SVM	***NB***	***LR***	***KNN***
Machine Learning Based Signalling DDoS Detection System for 5G Stand Alone Core Network (2022)	✓	✓	×	×
Detection of DDoS Attacks Using Machine Learning Classification Algorithms (2022)	×	✓	✓	✓
Analysis of Machine Learning Classifiers for Early Detection of DDoS Attacks on IoT Devices (2022)	×	×	×	✓
Towards a Machine Learning-Based Framework for DDoS Attack Detection in Software-Defined IoT (SD-IoT) Networks (2023)	✓	✓	×	×
Detection of DDoS Attack in IoT Traffic using Ensemble Machine Learning Techniques (2023)	✓	✓	✓	×

In the final study conducted by study [12], the focus is on investigating DDoS attacks within the context of the IoT. The research utilizes machine learning classifiers, including both bagging, and boosting techniques, to categorize attack traffic, making use of the CICDDoS2019 dataset designed to simulate DDoS attacks on the UDP and TCP protocols commonly employed in IoT networks. To tackle data imbalance, the study employs an ensemble sampling approach that combines random under-sampling and ADASYN oversampling. Feature selection is carried out using two methods: the Pearson correlation coefficient and the Extra Tree classifier. The results reveal that RF performs the best with minimal training and prediction time, and Extra Trees for feature selection outperforms the Pearson correlation coefficient method in terms of overall time efficiency for most classifiers. However, it's noteworthy that when using the Pearson correlation coefficient for feature selection, RF remains the optimal choice for attack detection.

After conducting an extensive analysis of prior research in the field of DDoS detection using machine learning methods, it becomes evident that there is a pressing need to improve the process of feature selection in the datasets utilized. It is of paramount importance to minimize the occurrence of false positives in order to achieve a heightened level of detection precision. This revelation underscores the critical importance of carefully selecting relevant and efficient features for incorporation into DDoS detection and classification methodologies. By enhancing feature selection techniques, the potential for generating false positive alerts can be significantly reduced, resulting in outcomes that are more reliable and precise.

III. PROPOSED METHODOLOGY

This section introduces the research methodology, which is organized into four phases as illustrated in Fig. 1, and it outlines various research activities.

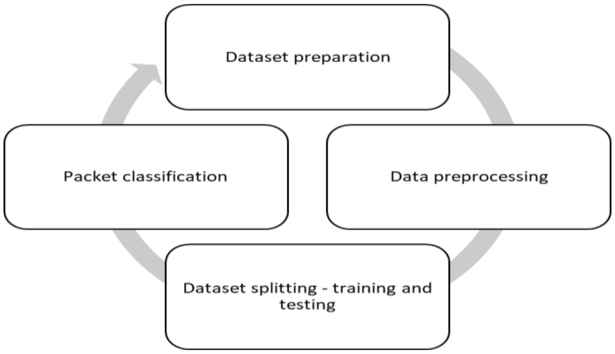

Fig. 1. Methodology of proposed DDoS detection.

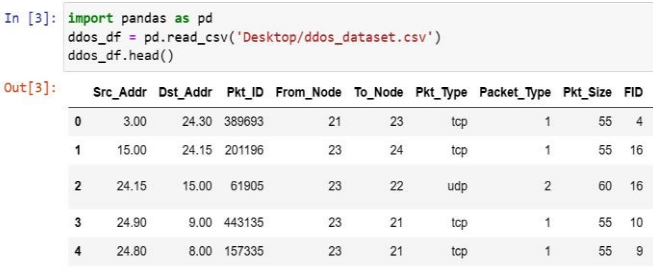
A. Dataset Preparation

A dataset containing several types of DDoS attacks and normal packets is provided in the first phase, as shown in Fig. 2. The dataset is relevant to research activities as it records multiple incoming packets, which are the primary focus.



```
In [3]: import pandas as pd
        ddos_df = pd.read_csv('Desktop/ddos_dataset.csv')
        ddos_df.head()

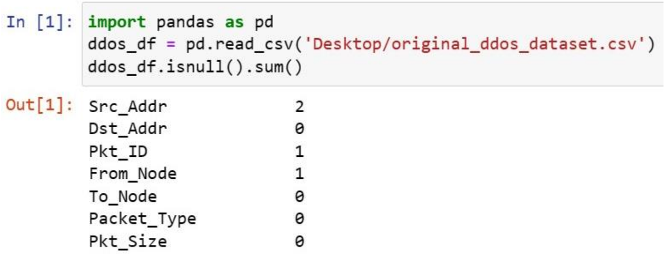
Out[3]:
   Src_Addr  Dst_Addr  Pkt_ID  From_Node  To_Node  Pkt_Type  Packet_Type  Pkt_Size  FID
0      3.00     24.30  389693         21       23       tcp            1        55    4
1     15.00     24.15  201196         23       24       tcp            1        55   16
2     24.15     15.00   61905         23       22       udp            2        60   16
3     24.90      9.00  443135         23       21       tcp            1        55   10
4     24.80      8.00  157335         23       21       tcp            1        55    9
```

Fig. 2. Sample of DDoS dataset.

It includes various features such as source address, destination address, packet type, packet size, and packet class. For instance, the source address refers to the IP address of the sender generating the packet or traffic, while the destination address represents the IP address that receives the packets or traffic.

B. Data Preprocessing

The second research phase is data preprocessing. This phase is crucial in research work as it requires expertise to transform the data into a comprehensible format. Two activities were conducted in this phase: data cleaning and data reduction. Data cleaning is indeed the first activity in the research process, as presented in Fig. 3. This method is called identification of missing values, which is utilized in the research. It indicates that if there is a missing value, the output will show a value 1, 2, and so on. This means that there are missing values or empty cells in the Src_Addrs, Pkt_ID, and From_Node columns in the dataset used.

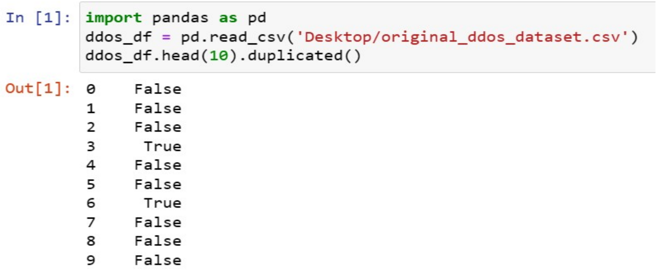


```
In [1]: import pandas as pd
        ddos_df = pd.read_csv('Desktop/original_ddos_dataset.csv')
        ddos_df.isnull().sum()

Out[1]: Src_Addr         2
        Dst_Addr         0
        Pkt_ID           1
        From_Node        1
        To_Node          0
        Packet_Type      0
        Pkt_Size         0
```

Fig. 3. Identification of missing values.

The second activity involves data reduction, reducing the number of data samples by identifying and eliminating duplicate rows in the dataset, as presented in Fig. 4.



```
In [1]: import pandas as pd
        ddos_df = pd.read_csv('Desktop/original_ddos_dataset.csv')
        ddos_df.head(10).duplicated()

Out[1]: 0    False
        1    False
        2    False
        3     True
        4    False
        5    False
        6     True
        7    False
        8    False
        9    False
```

Fig. 4. Identification of duplicate data.

In this case, data duplication occurs in rows 3 and 6, which need removal to generate high-quality data and facilitate analysis. Both activities assist in obtaining complete, consistent, and high-quality data within the dataset.

C. Data Splitting

In the third phase of the research, known as data splitting, further investigation proceeds. The dataset, consisting of a total of 240,000 samples, is partitioned into two distinct sets: the training set and the testing set, as outlined in Table II.

The training set plays a crucial role in assessing the effectiveness of machine learning methods by utilizing data samples from the dataset. On the other hand, the testing set is employed to evaluate these methods. The train and test functions were formed to separate these two sets of data. The dataset was divided according to the data distribution outlined in Table II. For example, the data separation for 80: 20 ratios allocates 80% for the training set and the remaining 20% for the testing set.

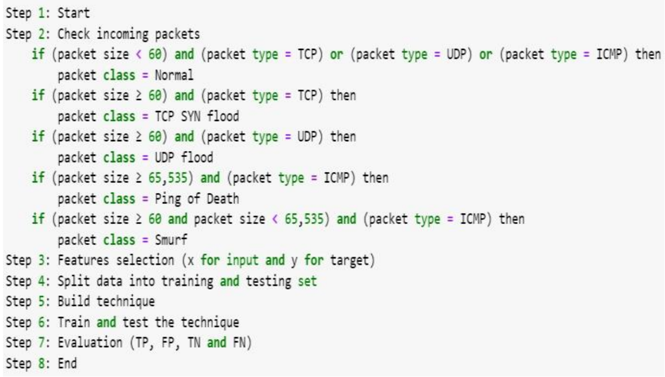
TABLE II. DATA SPLITTING (TRAINING:TESTING)

No.	Data Splitting Training:Testing	No. of Samples	
		Training	Testing
1	50:50	120,000	120,000
2	60:40	144,000	96,000
3	70:30	168,000	72,000
4	80:20	192,000	48,000

D. Packet Classification

Quality data has been selected, and this research continues with the final phase, which is packet classification. In this phase, a technique called Packet Threshold Algorithm (PTA) has been proposed. This PTA is able to identify incoming packets whether normal packets or DDoS attacks. PTA is combined with several machine learning techniques, SVM, KNN, NB and LR. In the research, the functioning of this PTA was analyzed, as shown in Fig. 5. First, the PTA will check incoming packets based on a predefined packet threshold, which involves packet size and packet type received by the server. If the received packet is TCP or UDP or ICMP and a size of less than 60 bytes per second, PTA will issue the incoming packet category is normal packet. If the server receives TCP packets larger than 60 bytes per second, PTA will issue the incoming packet category is TCP SYN flood. Meanwhile, if the server receives a packet size exceeding 60 bytes per second and carries UDP packets, the PTA will issue the incoming packet category is UDP flood. If the type of packet received by the server is an ICMP packet and the size exceeds 65,535 bytes per second, PTA will issue the incoming packet category is Ping of Death. Meanwhile, if the ICMP packet size is less than 65,535 bytes per second but exceeds 60 bytes per second, PTA will issue the incoming packet category is a Smurf attack. The PTA will act to drop all packets received by the server, for which the packet size exceeds 60 bytes per second and the PTA allows packet sizes less than 60 bytes per second to enter the network environment. Finally, PTA is combined with machine learning by involving several phases or activities including features selection, data splitting, construction and evaluation of the techniques involved.

Here is a summary of how PTA determines the category of incoming packets. Firstly, PTA utilizes a predefined packet threshold to evaluate incoming packets. Secondly, PTA examines the packet type and size to determine their respective categories, as described above. Finally, based on the determined category, PTA performs specific actions on the packet: dropping all packets received by the server that exceed 60 bytes per second and allowing packets with sizes less than 60 bytes per second to enter the network. By employing this approach, PTA can accurately classify incoming packets as normal or belonging to various types of DDoS attacks.



```
Step 1: Start
Step 2: Check incoming packets
    if (packet size < 60) and (packet type = TCP) or (packet type = UDP) or (packet type = ICMP) then
        packet class = Normal
    if (packet size ≥ 60) and (packet type = TCP) then
        packet class = TCP SYN flood
    if (packet size ≥ 60) and (packet type = UDP) then
        packet class = UDP flood
    if (packet size ≥ 65,535) and (packet type = ICMP) then
        packet class = Ping of Death
    if (packet size ≥ 60 and packet size < 65,535) and (packet type = ICMP) then
        packet class = Smurf
Step 3: Features selection (x for input and y for target)
Step 4: Split data into training and testing set
Step 5: Build technique
Step 6: Train and test the technique
Step 7: Evaluation (TP, FP, TN and FN)
Step 8: End
```

Fig. 5. Packet Threshold Algorithm (PTA).

IV. Evaluation of Techniques

During the evaluation phase, detection accuracy and false positive rate are employed as metrics to analyze the precise number of packets detected by PTA and the occurrence of erroneous detections. This encompasses cases where normal packets are wrongly identified as DDoS attacks and instances where DDoS attacks are mistakenly classified as normal packets. The calculation of detection accuracy and false positive rate follows a widely accepted standard formula.

$$Accuracy = \frac{TP+TN}{TP+TN+FN+FP} \times 100 \quad (1)$$

$$FPR = \frac{FP}{FP+TN} \times 100 \quad (2)$$

The formula explanation above can be summarized as follows:

- True Positive (TP): Instances where the model correctly detected DDoS attacks when they occurred.
- False Negative (FN): Instances where the model failed to detect DDoS attacks when they were happening.
- False Positive (FP): Instances where the model incorrectly flagged normal traffic as DDoS attacks.
- True Negative (TN): Instances where the model correctly identified normal traffic as not being DDoS attacks.

These four evaluations can be illustrated using the confusion matrix in Table III. The confusion matrix is a crucial tool in machine learning, providing a detailed breakdown of a model's performance by categorizing predictions into TP, FN, FP, and TN. This breakdown helps assess both accuracy and the model's ability to identify positive and negative cases accurately. It is a fundamental instrument for improving classification model effectiveness in various domains, including DDoS attack detection.

TABLE III. Confusion Matrix

		Predicted DDoS	
		DDoS	Normal
Actual DDoS	DDoS	TP	FN
	Normal	FP	TN

V. Result and Discussion

In this section, the experimental results for the various techniques employed are presented. Starting with an evaluation of the effectiveness of the proposed method for DDoS attack detection, followed by a comparative analysis with previously utilized techniques.

A. *Performance Comparison of PTA with Machine Learning Techniques*

This section presents the performance results for four combinations of PTA techniques with machine learning based on data splitting between training and testing sets, as shown in Table III. Upon analyzing the performance of each technique using a 50:50 data splitting, it becomes evident that the PTA-KNN technique attains the highest detection accuracy of 99.86%. It is closely followed by the PTA-SVM technique, which also achieves a detection accuracy of 99.86%. The PTA-LR technique achieves a detection accuracy of 99.12%, whereas the PTA-NB technique reaches a detection accuracy of 98.70%.

Shifting focus to the 60:40 data splitting, the PTA-KNN technique once again emerges as the frontrunner, achieving the highest detection accuracy of 99.86%. Remarkably, the PTA-KNN technique surpasses the detection accuracies achieved by the PTA-SVM, PTA-LR, and PTA-NB techniques, which are 99.66%, 99.17%, and 98.72% respectively. For the 70:30 data splitting, the PTA-KNN technique continues to outperform the other techniques with a detection accuracy of 99.84%. The PTA-SVM, PTA-LR, and PTA-NB techniques achieve respective detection accuracies of 99.65%, 99.16%, and 98.69%. Table IV shows the performance comparison of PTA with machine learning techniques. When considering the 80:20 data splitting, the PTA-KNN technique showcases an impressive detection accuracy of 99.83%, surpassing the PTA-SVM technique that achieves a detection accuracy of 99.63%. Furthermore, the PTA-LR technique demonstrates an impressive detection accuracy of 99.17%, whereas the PTA-NB technique achieves a slightly lower accuracy of 98.68%. Through meticulous examination, it can be deduced that the PTA-KNN technique showcases a remarkable efficacy in identifying incoming packets, regardless of their nature as DDoS attacks or normal packets. Observing the statistical outcomes presented in Fig. 6, which depict the effectiveness of the PTA-KNN technique in the research. This effectiveness stems from its utilization of packet type and size as key criteria. This conclusion is further supported by the exceptional detection accuracies achieved across various data splitting ratios: 99.86% for 50:50, 99.86% for 60:40, 99.84% for 70:30, and 99.83% for 80:20.

TABLE IV. Performance Comparison of PTA with Machine Learning Techniques

Technique	Data Splitting (Training:Testing)	Detection Accuracy	False Positive Rate
PTA-NB	50:50	98.70%	1.10%
	60:40	98.72%	1.08%
	70:30	98.69%	1.10%
	80:20	98.68%	1.08%
PTA-KNN	50:50	99.86%	0.01%
	60:40	99.86%	0.01%
	70:30	99.84%	0.01%
	80:20	99.83%	0.02%
PTA-SVM	50:50	99.66%	0.01%
	60:40	99.66%	0.01%
	70:30	99.65%	0.01%
	80:20	99.63%	0.02%
PTA-LR	50:50	99.12%	0.26%
	60:40	99.17%	0.25%
	70:30	99.16%	0.27%
	80:20	99.17%	0.26%

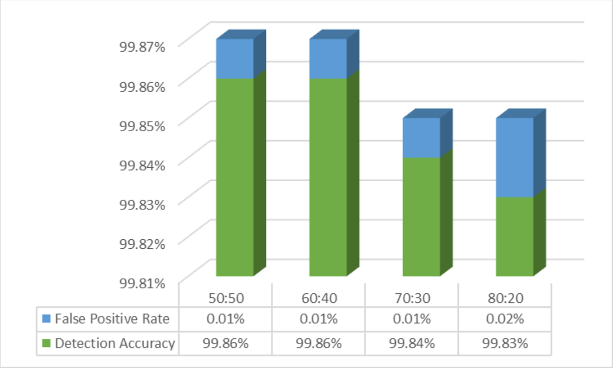


Fig. 6. Statistical outcomes of PTA-KNN technique.

Referring to Table V, it is noteworthy that the detection accuracies presented therein exceed the performance of alternative techniques, thus emphasizing the superiority of the PTA-KNN technique. The detection accuracy percentages for the PTA-KNN technique are determined based on the number of successfully detected incoming packets. For the 50:50 data splitting, 119,827 incoming packets were accurately detected, while 173 packets were misclassified. In the case of the 60:40 data splitting, the PTA-KNN technique successfully identified 95,863 incoming packets as valid, with 137 packets misclassified. Similarly, for the 70:30 data splitting, the technique detected 71,882 incoming packets correctly, but there were 118 misclassified packets. Lastly, for the 80:20 data splitting, the PTA-KNN technique successfully detected 47,920 incoming packets, with 80 packets being misclassified.

TABLE V. DETECTION RESULTS FOR DIFFERENT DATA SPLITTING RATIOS AND PACKET TYPES USING COMBINATION TECHNIQUES

Technique	Data Splitting (Training:Testing)	No. of Incoming Packet Detected				
		Normal	Ping of Death	Smurf	TCP SYN Flood	UDP Flood
PTA-NB	50:50	106,499	354	733	208	10,649
	60:40	85,233	287	591	166	8,495
	70:30	63,943	206	455	128	6,324
	80:20	42,643	133	299	83	4,209
PTA-KNN	50:50	107,165	354	952	229	11,127
	60:40	85,766	287	765	182	8,863
	70:30	64,361	206	581	141	6,593
	80:20	42,914	133	393	88	4,392
PTA-SVM	50:50	107,168	354	731	216	11,123
	60:40	85,769	287	589	173	8,859
	70:30	64,363	206	454	135	6,590
	80:20	42,916	133	298	85	4,389
PTA-LR	50:50	107,168	354	529	212	10,680
	60:40	85,769	287	418	170	8,557
	70:30	64,363	206	321	131	6,376
	80:20	42,916	133	220	84	4,249

B. *Performance Comparison between Proposed DDoS Detection Technique and Previous Techniques*

This section presents a performance comparison between the proposed DDoS detection technique and existing methods, as displayed in Table VI. Within the provided table, which demonstrates performance comparisons in terms of detection accuracy for various techniques across different years of publication, it becomes evident that the highest and lowest accuracies vary significantly among the diverse techniques and algorithms employed. Notably, the proposed technique stands out with the highest overall accuracy of 99.86%, achieved using the KNN algorithm. However, it is essential to emphasize that the lowest accuracy values are somewhat dispersed. For instance, in the case of Park et al., the lowest accuracy values for LR and KNN are denoted as NA, indicating a lack of available data. In contrast, for other techniques, such as Gaur and Kumar, the lowest accuracy is attributed solely to the KNN algorithm, which attains an accuracy of 91.39%.

TABLE VI. PERFORMANCE COMPARISON BETWEEN PROPOSED DDOS DETECTION TECHNIQUE AND PREVIOUS TECHNIQUES

Technique/Year of Published	Performance Comparison in Terms of Detection Accuracy			
	SVM	NB	LR	KNN
Park et al. (2022)	98.76%	87.61%	NA	NA
Dasari and Devarakonda (2022)	NA	99.58%	99.58%	99.55%
Gaur and Kumar (2022)	NA	NA	NA	91.39%
Bhayo et al. (2023)	96.10%	97.40%	NA	NA
Pandey and Mishra (2023)	96.24%	98.23%	89.76%	NA
Proposed Technique (2023)	99.66%	98.72%	99.17%	99.86%

Overall, the proposed technique appears to exhibit the highest accuracy across most algorithms, rendering it a promising approach for detection. Nevertheless, it is crucial to consider other factors, such as computational complexity and practical applicability, when selecting a technique for a specific problem.

VI. CONCLUSION

The team has extensively researched the capabilities of the PTA technique in detecting both DDoS attacks and normal packets. This involves utilizing a predefined packet threshold that considers factors such as packet size and the specific packet types that attackers may generate. By integrating the PTA technique with diverse machine learning approaches, findings reveal that the PTA-KNN technique surpasses PTA-NB, PTA-SVM, and PTA-LR techniques in terms of detection accuracy and false positive rate percentage.

In the research, potential areas for future enhancement have also been identified based on findings. One possible direction for improvement involves exploring adaptive thresholding techniques that dynamically adjust the packet threshold based on network conditions and attack patterns. Additionally, investigating the integration of anomaly detection algorithms and deep learning models could enhance the PTA technique's ability to detect emerging and sophisticated DDoS attacks.

These avenues for future research aim to further enhance the effectiveness and resilience of the PTA technique in combatting evolving cyber threats.

***Abstract*—This study aimed to enhance animal welfare in the context of modern agriculture. The Association Rule analysis method using FP-Growth and Apriori algorithms was employed to identify patterns and factors influencing animal welfare, particularly in the context of live cattle weight loss (shrink) due to stress during transportation. Data obtained from several farms and clinical tests were used to develop insights into the relationship between farming practices, data science, and animal welfare. The research stages included data preprocessing, initial analysis, modeling, evaluation, and interpretation of results, recommendations and implications, and conclusions. The research results indicate that the use of FP-Growth and Apriori algorithms uncovered hidden patterns in the data, resulting in four association rules from FP-Growth and five rules from Apriori. These rules aid in designing recommendations to enhance animal welfare, improve agricultural efficiency, and support sustainability of the cattle sector. Our findings have significant implications in the context of animal welfare and sustainable farm management.**

***Keywords*—Association rule; animal welfare; cattle management; animal product quality; modern agriculture; recommendations; sustainability**

I. Introduction

The issue of tracking and handling pressure in cattle, especially farm animals, for the duration of transportation, has resulted in extensive difficulties for cattle enterprises. The transportation of stay cattle often entails long distances from production facilities to consumption centers, resulting in diverse, demanding situations that need to be addressed. In this context, pressure on farm animals through transportation has been proven to result in sizable weight reduction, which, in turn, impacts the first-rate of meat and promotes charges [1], [2]. Consequently, efforts to reduce and control stress in cattle throughout transportation are essential [3], [4]. One of the factors that can influence the stress levels and weight loss in cattle during transportation is the body temperature condition. This study aims to explore the relationship between body temperature and the body weight of cattle in affecting weight loss due to stress during transportation. The method involves measuring the body temperature of cattle before transportation. Additionally, the body weight of cattle is also measured before and after transportation to calculate the weight difference caused by stress during transportation [5].

Researchers and stakeholders in cattle enterprises have long sought to address this issue. Numerous techniques have been developed, ranging from gazing at animal conduct to measuring physiological and biochemical parameters [6]. However, an essential question arises: are the current techniques adequate and reliable? [7]. In this research, efforts are made to address this question using association techniques. This association method will examine the relationship between the body temperature of cattle and their body weight in influencing weight loss in cattle during transportation.

In this section, we explain the association rules and how they can be used to gain valuable insights into stress in cattle during transport will be provided [8], [9]. Related studies that have successfully employed association rules in various contexts, including traffic pattern comprehension and the detection of unusual events in videos, will be referred to by us [10], [11].

Furthermore, we can discuss the study findings associated with using the Apriori and FP-increase algorithms in determining affiliation guidelines in our dataset, which incorporates temperature statistics, initial weight, and the fee of weight loss of cattle at some point of transportation [12]. These two algorithms are also be compared to assess their effectiveness in generating informative association rules [13].

To provide a broader context, other related research that has employed data mining techniques to address various issues, such as library user behavior analysis and deformation response analysis in landslide hazards, will also be referred to by us [7]. The knowledge gained from these studies offers a broader perspective on the potential use of association rules in the context of stress management in live cattle during transportation in the cattle industry [14].

In conclusion, our findings will be summarized, and further recommendations and implications from this research will be provided to minimize the impact of stress on live cattle during transportation in the cattle industry [4], [15].

II. Related Work

The transportation of stray animals is a critical element in the cattle industry, especially when these animals are destined for slaughter or processing. Previous research has indicated that animal transportation can negatively impact animal welfare [16]–[18]. Animal welfare was assessed via signs that included pressure tiers, weight reduction, and the physical condition of the animals. Several elements have been identified as likely to affect animal welfare throughout transportation. These elements included car density, environmental temperature, travel duration, and animal management. The author in [19] showed that excessive car density can increase the strain degree in animals. Weight loss at some point of transportation is a severe problem that could impact animal productivity and the quality of the resulting meat. Significant weight loss in animals during transport has been documented in several studies [20]–[22]. This may illustrate the stress and soreness experienced by animals during transportation. Governments and global agencies have introduced diverse policies and suggestions to address animal welfare issues at some point of transportation. For instance, the ecu Union has applied strict policies regarding the shipping of live animals [23][24]. However, the implementation and enforcement of these regulations can range across international locations and areas .

While numerous studies have been conducted in the realm of animal transportation, several unaddressed research areas remain. Some investigations may focus on specific animal types or geographic regions, whereas others maintain a broader scope. Furthermore, our understanding of the individual factors within animals that can influence their responses to transportation remains incomplete. In the context of this literature review, our research endeavors to bridge these knowledge gaps by concentrating on live cattle and the variables that affect their well-being and weight loss during transport. This study aimed to provide a comprehensive framework for research within the domain of live animal transportation, elucidating its relevance to our own research. Our findings are correlated with prior research outcomes to facilitate a more profound understanding of this issue and its potential to enhance animal welfare in the cattle transportation sector.

Investigations within the realm of animal transport, specifically concentrating on the interplay between temperature, body weight, and cattle stress, have attracted noteworthy interest. Previous research has extensively explored the nuanced relationships between these factors, offering valuable insights into the difficulties confronted by livestock during transit.

A. *Korelasi Temperature and Stress Correlation*

Previous research has explored the impact of temperature on the stress levels of cattle during transportation. Findings indicate a significant correlation, where increased temperatures often contribute to heightened stress levels [25][5]. These studies utilized various methodologies, including real-time temperature monitoring and observations of stress behavior, to establish robust associations.

The results of these studies suggest that high temperatures can influence the comfort and well-being of cattle during transportation, leading to an increase in stress levels. Furthermore, the research also indicates that cattle experiencing high stress levels during transportation tend to undergo more significant weight loss. Thus, there is a connection between the body temperature of cattle and body weight in influencing weight loss during transportation..

B. *Body Weight Dynamics*

The influence of body weight on cattle stress during transportation has been a focal point in several studies. Researchers have examined how fluctuations in body weight, particularly weight loss, align with increased stress levels. Through comprehensive analysis, these studies aim to unveil patterns and associations contributing to a deeper understanding of stress dynamics during transit. This approach involves measuring the body weight of cattle before and after transportation, along with monitoring their body temperature conditions [6].

The research findings indicate that high temperatures can affect the comfort and well-being of cattle during transportation, leading to an increase in stress levels. Additionally, the study suggests that cattle experiencing high stress levels during transportation tend to undergo more significant weight loss. Therefore, there is a correlation between cattle body temperature and body weight in influencing weight loss during transportation.

III. Research Method

The initial steps in this research process involved data collection, preliminary analysis, and data preprocessing. The data obtained, such as information on body temperature, initial weight of the cattle, and rate of weight loss during transportation, will serve as the primary foundation for advancing this research. Following this, the subsequent phases of our study will involve utilizing association rule algorithms to detect and comprehend the connections among these factors concerning the stress encountered by cattle during transportation. For a summary of the research process, please consult Fig. 1.

Fig. 1. Methodology.

A. *Data Collection*

The primary dataset will encompass details concerning the cattle's initial body temperature, starting weight, and rate of weight loss throughout transportation, sourced from pertinent outlets within the cattle sector. Additionally, information regarding cattle behavior during transit will be documented, encompassing stress indicators like agitation, profuse sweating, or any unusual conduct, as supplementary data for potential future use.

B. Basic Analysis

A descriptive analysis will be conducted on the data to initially comprehend the distribution of pertinent variables. Visual aids like charts, histograms, or scatter plots will be employed to scrutinize data patterns. This was done to provide a better understanding of the data, identify the research significance, determine the most appropriate methods, develop hypotheses and theoretical frameworks, improve planning, avoid data redundancy, and enhance the validity and reliability of the research.

C. Data Preprocessing

The collected data will be analyzed to identify and address missing or invalid data. Temperature, weight, and weight loss rate data were converted into appropriate formats for statistical analysis, including data cleaning, removal of duplicate data, data selection, data transformation, and data encoding if necessary.

D. Implementation of Association Rule Algorithm

Association rule mining is a data-mining technique aimed at discovering implicit association rules from a large amount of transactional data. It is also known as association analysis, which establishes connections between various item combinations within a dataset [26]. This association model was applied to the dataset to identify association rules related to stress in cattle during transportation. This involves configuring parameters, such as support, confidence, and lift ratio. There are two association rule models that we will use: Apriori and the FP-Growth algorithm. The Apriori algorithm is an association rule algorithm commonly used to address issues in data analysis involving transactions or lists of items, such as in retail shopping, online shopping carts, product recommendations, or pattern detection in transactional data. The Apriori algorithm is used to discover association rules connecting items or attributes in transactional datasets. Similar to the Apriori algorithm, FP-Growth is a model algorithm for associations resulting from the development of the Apriori algorithm. The primary use cases for both of these algorithms usually involve solving Market Basket Analysis problems, providing the most suitable product recommendations, and analyzing customer purchase patterns. Additionally, FP-Growth has the capability to handle large datasets, analyze transactional data, and provide recommendations in e-commerce. Here are the required notations to generate an association rule.

To measure the initial probabilities of X and Y, we need an equation called Support, which is as follows [27], [28]:

$$S_{supp}(X \rightarrow Y) = \frac{(|X \cup Y|)}{n} \qquad (1)$$

S_{supp} = Support value

n = total number of transactions.

After obtaining support, the next step is to find the Confidence value, which is a proportion of transactions containing all items in both X and Y compared to transactions containing only items in X [29], The notation for this is as follows:

$$Confidence(X \rightarrow Y) = \frac{(X \cup Y)}{Support(X)} \qquad (2)$$

Lift($X \rightarrow Y$) is a measure used to assess the significance of the association rule $X \rightarrow Y$. Support ($X \cup Y$) reflects how often itemsets X and Y appear together in transactions, whereas Support (X) and Support (Y) are measures of how often each individual itemset appears in transactions.

E. Evaluation and Interpretation of Results

The results from the use of both algorithms will be evaluated to measure their effectiveness in generating informative association rules. Significant association rules were interpreted to understand the relationship between temperature, initial weight, rate of weight loss, and stress in cattle during transportation. Based on the analysis results, this research will also summarize the findings and conclude that association rules can provide valuable insights into the measurement and management of stress in cattle during transportation in the cattle industry.

IV. Result

A. Prepare Dataset

Data collection was carried out through observation. Body temperature data before departure, initial weight, and rate of weight loss during the journey were the primary focus of this study. Fifty data records have been successfully collected from relevant sources in the cattle industry, and for more details, the dataset can be seen in Table I.

TABLE I. DATASET OF PRE-SHIPPING LIVE CATTLE OBSERVATION RESULTS

NO	x1	x2	x3	x4	SUHU AWAL								x13	x14	Shr/kg	%
					x5	x6	x7	x8	x9i	x10	x11	x12				y
1	PO	231	M	4	36	37	36	36	36	36	35	38	36	205	26	11%
2	PO	235	M	4	37	37	37	37	37	37	36	39	37	211	24	10%
3	PO	246	M	5	37	37	37	37	37	37	36	39	37	235	11	4%
4	PO	239	M	5	36	37	36	37	37	37	35	38	36	203	36	15%
5	PO	231	M	4	36	37	37	37	37	37	36	37	37	188	43	19%
….	……	…..	…	….	….	…..	….	….	….	….	….	….	…	…	…	…
….	……	…..	…	….	….	…..	….	….	….	….	….	….	…	…	…	…
49	Bali	151,06	F	4	37	37	40	40	38	39	40	39	39	144	7	5%
50	Bali	143,81	M	4	38	39	40	40	38	39	40	39	39	136	7	5%

The observation results yielded a dataset consisting of 50 data records with 14 independent variables (x) and 1 dependent variable (y). x1 represents the breed of cattle, with two attributes: Peranakan Ongole (PO) and Bali Cattle. x2 represents the initial weight of the cattle, measured either through weighing or estimation based on the chest circumference and body length. x3 indicates the sex of cattle identified through direct observation. Column D represents the age of the cattle. x4–x12 represent temperature measurements taken from various body parts (forehead, orbital, cheek, shoulder, back, thigh, leg, and rectal) using a thermogun for external temperature and a regular thermometer for rectal temperature. x13 represents the average body temperature of the cattle. x14 represents the final weight of the cattle upon reaching their destination. Shr/kg denotes the shrinkage in weight during transportation, measured in kilograms. Column y represents the percentage of weight shrinkage during transportation (Shrink). If observed, we only have 50 data records, a number that indeed appears limited, but obtaining them posed a very challenging task. We utilize this record count as part of algorithm testing, examining how well the algorithm can perform its task with such limited data. Additionally, the limitation in the number of records is turned into a strength in this research.

B. Basic Analysis

Descriptive statistics for the 50 data records indicated that the measurement of live cattle weight before shipment (x2) resulted in a weight range of 125–261 kg, with an average of 195 kg. Age (x3) has a ranged from 3.5 to 4.77 years. The average temperature of the cattle (x13) before shipment range between 35.6°C and 37.4°C. The final weight (x14) has a ranges between 118 kg and 235 kg, with an average of 175.9 kg. The percentage of live cattle weight reduction during transportation (y) ranged from 0% to 27%. We also calculated the correlations for each variable. Table II and Fig. 2 show the results and visualization of the correlation between variables x and y, respectively.

TABLE II. CORRELATION OF EACH VARIABLE WITH THE TARGET VARIABLE

	X2	X4	X5	X6	X7	X8	X9	X10	X11	X12	X13

CP	0,92	0,45	-0,16	-0,17	-0,30	-0,07	0,01	-0,04	-0,22	-0,28	-0,19

[a.] CC (Coeficient Corelation), CP (Coeficient Pearson)

From the initial analysis, it was found that there were some prunings on the variables that had a less significant impact on variable y. These include x1, x3 to x11, x13, and shr/kg. There are several reasons for this pruning, such as data type mismatches for x1 and x3. Additionally, for temperature measurements, discussions with stakeholders and experts led to an agreement to use only rectal temperature, whereas external body temperature measurements were deemed to have invalid calculations. The results of the initial analysis can be seen in Table III.

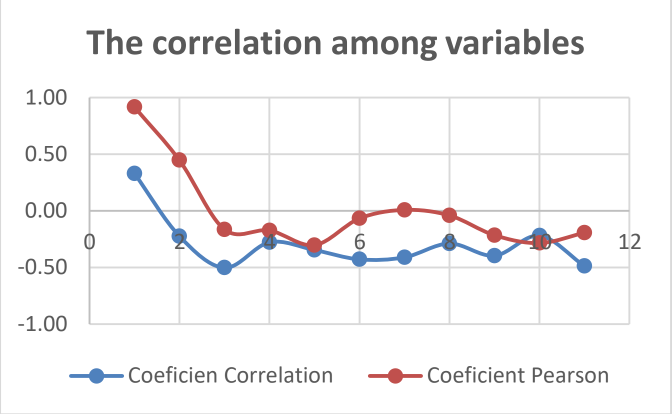

Fig. 2. Illustration of the correlation between each variable x and the label y.

49	151	39	5%
50	144	39	5%

Out of several variables that were pruned, only 2 predictor variables and 1 target variable were retained. This simplifies the subsequent analysis process, as there are not too many influential variables to be calculated.

C. Data Preprocessing Process

In this process, we performed data cleaning. We also found that the data needed to be categorized to facilitate calculations, so we transformed the data into Crisp data. Rectal temperature was divided into three attributes: 1) Low Temperature: < 37.5°C (s_low); 2) Normal Temperature: 37.5°C – 39.5°C (s_normal); 3) High Temperature: > 39.5°C (s_high). The initial weight was divided into five attributes: 1) Very Thin Weight: 125 – 150 kg (w_very_thin); 2) Thin Weight: 151 – 175 kg (w_thin); 3) Medium Weight: 176 – 200 kg (w_medium); 4) Fat Weight: 201 – 225 kg (w_fat); 5) Very Fat Weight: 225 – 262 kg (w_very_fat). The percentage of shrinkage was divided into three attributes: 1) Slight Shrinkage Category: ⩽ 9% (p_slight); 2) Moderate Shrinkage: 10% – 18% (p_moderate); 3) High Shrinkage: > 19% (p_high). The dataset resulting from the data transformation is shown in Table IV.

D. Implementation of the Association Rule Algorithm

Descriptive statistics for the 50 data records indicated that the measurement of live cattle weight before shipment (x2) resulted in a weight range of 125–261 kg, with an average of 195 kg. Age (x3) has a ranged from 3.5 to 4.77 years. The average temperature of the cattle (x13) before shipment range between 35.6°C and 37.4°C. The final weight (x14) has a ranges between 118 kg and 235 kg, with an average of 175.9 kg. The percentage of live cattle weight reduction during transportation (y) ranged from 0% to 27%. We also calculated the correlations for each variable. Table I and Fig. 1 show the results and visualization of the correlation between variables x and y, respectively.

TABLE IV. THE RESULTS OF THE TRANSFORMATION BECOME CRISP DATA

NO	WEIGHT	TEMP	SHRINK
0	w_very_thin	s_normal	p_slight
1	w_very_thin	s_normal	p_moderate
2	w_very_thin	s_normal	p_slight
3	w_very_thin	s_normal	p_slight
....	....	....	....
18	w_medium	s_normal	p_slight
19	w_thin	s_normal	p_moderate
....	....	....	....
48	w_fat	s_normal	p_slight
49	w_fat	s_normal	p_slight

- Apriori Algorithm.

From the analysis conducted, relevant rules for the research were obtained. We set a minimum confidence level of 0.01 with a minimum threshold of 1.0. The results from using the Apriori algorithm produced 84 rules. Subsequently, we selected the most relevant rules from these, resulting in five rules that were most relevant to the actual conditions. The five rules that have been generated are listed in Table V.

TABLE V. APRIORI ALGORITHM ASSOCIATION MODEL

Antecedents	Consequents	Sup	Conf	Lift
weight_b_thin Temp_s_normal	Shrink_p_slight	0,17	0,56	1,19
weight_b_thin; Temp_s_High	Shrink_p_ slight	0,07	1,00	2,14
Temp_s_ normal; weight_b_medium	Shrink_p_moderate	0,07	0,50	1,50
Temp_s_low; weight_b_very_fat	Shrink_p_ moderate	0,03	1,00	3,00
Temp_s_ normal; weight_b_veri_thin	Shrink_p_slight	0,13	0,80	1,71

The results obtained provide an overview that out of the five rules, they are supported by Support values ranging from 0.03 to 0.17, Confidence values from 0.50 to 1.00, and Lift Ratios from 1.19 to 3.00. Therefore, the average confidence values obtained served as the basis for the generated rules, indicating a relatively strong correlation.

- FP-Growth Algorithm.

Similarly to what was done previously with Apriori, we set a minimum confidence of 0.01 with a minimum threshold of 1.0 for the FP-Growth algorithm. The results of using the FP-Growth algorithm yielded 21 rules. We then conducted a selection process for these rules, resulting in the identification of the four most relevant rules in line with the actual conditions. These four rules can be observed in Table VI.

TABLE VI. FP-GROWTH ALGORITHM ASSOCIATION MODEL

Antecedents	Consequents	Sup	Conf	Lift
Temp_s_low	Shrink_p_moderate	0,03	1,00	3,00
weight_w_very_thin'; 'Temp_s_low	Shrink_p_slight	0,03	1,00	3,00
Temp_s_high	Shrink_p_ slight	0,07	1,00	2,14
weight_b_thin; 'Temp_s_high	Shrink_p_ slight	0,07	1,00	2,14

The results obtained indicate that out of the four rules, they are supported by Support values ranging from 0.03 to 0.07, Confidence values of 1.00, and Lift Ratio values ranging from 2.14 to 3.00. Therefore, the average Confidence value obtained serves as a strong basis for the generated rules.

The results of this research offer valuable insights into stress measurement and management in the transportation of live cattle within the cattle industry. The rules derived from the FP-Growth algorithm exhibited an exceptional confidence level of 1.00, signifying their robustness within the dataset and a high level of confidence in their applicability. In contrast, the Apriori algorithm yields rules with varying levels of Support and Confidence ranging from 0.50 to 1.00, highlighting the diversity in confidence levels among these rules. However, the overall self-assurance cost remains splendid, indicating a sturdy correlation with a number of popular policies. Furthermore, FP-growth generates rules with better increase Ratios than Apriori, indicating a higher correlation with a number of the rules it generates in the dataset. Tables VII and VIII show the rules given by the heatmap can further clarify the position of each rule.

TABLE VII. RESULT HEATMAP APRIORI MODEL

Weight Temp	V Thin	Thin	Medium	Fat	Very Fat
Low					
Normal		Slight S = 0,17 C=0,56 L = 1,19	Moderate S = 0,07 C=0,50 L = 1,5	Moderate S = 0,03 C=1,00 L =3,00	Slight S = 0,13 C=0,56 L = 1,71
High		Slight S = 0,07 C=1,00 L = 2,14			

TABLE VIII. RESULT HEATMAP FP-GROWTH MODEL

Weight Temp	Very Thin	Thin	Medium	Fat	Very Fat
Low	Moderate S = 0,03 C=1 L = 3	Moderate S = 0,03 C=1 L = 3	Moderate S = 0,03 C=1 L = 3	Moderate S = 0,03 C=1 L = 3	Moderate S = 0,03 C=1 L = 3
Normal					
High	Slight S = 0,07 C=1 L = 2,14	Slight S = 0,07 C=1 L = 2,14	Slight S = 0,07 C=1 L = 2,14	Slight S = 0,07 C=1 L = 2,14	Slight S = 0,07 C=1 L = 2,14

TABLE IX. RESULT HEATMAP APRIORI MODEL

Confidence	1	0,8	0,6	0,5	0,2
	🟩	🟩	🟩	🟩	🟩

Four rules obtained from FP-Growth will automatically generate 10 rule. This is because rules 1 and 3 provide flexibility for any weight to be given its effect. Table IX shows the description of the heatmap by focusing on its confidence value.

V. CONCLUSIONS

The goal of this study was to determine the effect of temperature and initial weight on the pressure stages and weight reduction in cattle in the context of farm animal enterprises. The data collected and analyses conducted offer crucial insights into the factors affecting cattle well-being during transportation and their practical implications. Influence of Weight and Temperature on Cattle Stress. The evaluation results indicate that pre-transportation weight and temperature measurements significantly influence cattle pressure stages, that is, glaring within the association policies generated by each algorithm, which exhibit a strong correlation between weight and temperature and a lower frame weight (shrinkage) at the stop of transportation. This indicates that preliminary temperature and weight information can function as guidance for stakeholders to provide the maximum appropriate care of their farm animals, in the long run, lowering farm animal strain in the course of transportation. This information has significant practical implications for the cattle industry, allowing farmers to use temperature and weight data as vital indicators in managing cattle stress during transportation. Preventive measures, such as ensuring proper vehicle ventilation and safeguarding against animal welfare threats can assist in stress reduction and minimize detrimental weight loss in cattle.

This paper has certain limitations. Firstly, qualitative data was used to gather information on cattle behavior during transportation, and further analysis may be necessary to gain a deeper understanding of stress-related behavior. Secondly, the research focused solely on temperature as a contributing factor, disregarding other factors like humidity and population density within the transport vehicle, which might also influence cattle stress during transit. While this research serves as a critical foundation exploration of the factors influencing cattle stress during transportation, it is imperative to conduct subsequent studies with broader variables and larger sample sizes to offer a more comprehensive perspective and enhance stress management practices in the cattle industry.

VI. DISCUSSION

In this chapter, we will delve into the acquired research findings and provide additional context regarding their implications, along with offering recommendations for future research. Although this study has provided valuable insights, there are areas that warrant further investigation. Future research in this field should encompass several facets. Firstly, there is a need to collect more comprehensive behavioral data concerning animal behavior during transportation, as this study predominantly relied on qualitative data. Secondly, it is crucial to consider additional variables such as air humidity and population density within the transport vehicle, as they may also exert an influence on cattle stress during journeys. Lastly, conducting advanced research with larger sample sizes and a broader spectrum of variables can provide a more holistic comprehension of the factors contributing to cattle stress during transportation, ultimately contributing to the enhancement of stress management practices within the cattle industry.

ACKNOWLEDGMENT

We wish to convey our deepest appreciation to the Ministry of Agriculture, the Postgraduate Program of the Department of Computer Science at IPB University, the Postgraduate Program of the Department of Animal Nutrition and Feed Technology at IPB University, the Faculty of Computer Science at Universitas Singaperbangsa Karawang, Sapibagus.Com, Valeska Farm Sumbawa in West Nusa Tenggara, and the Ministry of Education and Culture for their generous support, invaluable contributions, and grant funding, which have significantly contributed to this research. Their assistance, provision of resources, data, collaborative efforts, and financial support have played an integral role in enhancing the quality of our research outcomes. We deeply appreciate their unwavering commitment and fruitful collaboration throughout the execution of this research. All of these contributions have helped this research achieve more meaningful and beneficial results.

Abstract—**In the area of video summarization applications, automatic image caption synthesis using deep learning is a promising approach. This methodology utilizes the capabilities of neural networks to autonomously produce detailed textual descriptions for significant frames or instances in a video. Through the examination of visual elements, deep learning models possess the capability to discern and classify objects, scenarios, and actions, hence enabling the generation of coherent and useful captions. This paper presents a novel methodology for generating image captions in the context of video summarizing applications. DenseNet201 architecture is used to extract image features, enabling the effective extraction of comprehensive visual information from keyframes in the videos. In text processing, GloVe embedding, which is pre-trained word vectors that capture semantic associations between words, is employed to efficiently represent textual information. The utilization of these embeddings establishes a fundamental basis for comprehending the contextual variations and semantic significance of words contained within the captions. LSTM models are subsequently utilized to process the GloVe embeddings, facilitating the development of captions that keep coherence, context, and readability. The integration of GloVe embeddings with LSTM models in this study facilitates the effective fusion of visual and textual data, leading to the generation of captions that are both informative and contextually relevant for video summarization. The proposed model significantly enhances the performance by combining the strengths of convolutional neural networks for image analysis and recurrent neural networks for natural language generation. The experimental results demonstrate the effectiveness of the proposed approach in generating informative captions for video summarization, offering a valuable tool for content understanding, retrieval, and recommendation.**

I. INTRODUCTION

Making captions for images is an interesting and useful area of computer vision and natural language processing. The process involves developing algorithms and models that enables machines to provide descriptive and contextually appropriate textual captions for images [24] [25]. This technological advancement serves to connect visual and textual data, so enabling deeper understanding of image content and creating opportunities for diverse applications [1]. The field of image captioning is gaining considerable interest owing to its capacity to boost image accessibility, assist individuals with visual impairments, automate content creation, and enhance image retrieval systems [2]. Especially in video summarization, image caption generation is a potent tool with uses that go beyond individual images. The goal of video summarization is to reduce long videos' main points to more manageable chunks so that viewers may quickly understand the main points without having to watch the full thing. Image caption generation is essential in this situation [3].

The process of video summarization often entails splitting a video into a series of frames, which are effectively separate images. After that, approaches for image captioning are used to these frames, which results in the generation of written descriptions for each frame. There are many ways that image caption creation might be used to the process of video summarization [4]. It may be used in news collection, which provides consumers with the ability to quickly interpret the most important aspects of news broadcasts or events. In educational settings, it can facilitate efficient learning by providing concise summaries of lengthy video lectures. It may be used by content makers to generate appealing video teasers or trailers, and it also has potential applications in surveillance and security, where it might assist analysts in more quickly reviewing video material [5]. The use of image captioning in video summarization not only makes the process of processing material more streamlined, but it also improves searchability and the ability to retrieve certain video portions. This convergence of computer vision and natural language processing puts us one step closer to developing video summarization tools that are more efficient and user-friendly. Due to these challenges, the field of video summarization [6] has seen the emergence of deep learning as a very promising approach. Deep learning, specifically deep neural networks, has an impressive capacity to autonomously acquire complex features and patterns from unprocessed data [27][28]. Furthermore, it can efficiently capture the temporal relationships present in video streams. The process involves the use of sophisticated neural networks and algorithms to examine video streams and identify frames that most effectively depict the information or occurrences inside the film. The frames that have been chosen are often known as "image captures" and function as succinct summaries of the video material [7]. This methodology exhibits a range of realistic implementations, including the retrieval of video material, security and surveillance operations, video search functionalities, and content analysis activities. The primary objective is to discern significant information promptly and effectively inside vast collections of video data. The use of deep learning techniques enhances the efficacy and adaptability of the summarization process, enabling its application across diverse video kinds and areas [8]. It has an intrinsic capability to modify and generalize over a wide range of video genres, making it an attractive option for tackling the complex challenges presented by video summarization.

The objective of this research is to explore the integration of deep learning methodologies with video summarization, specifically emphasizing the production of picture snapshots. It investigates the capabilities of deep learning models in autonomously selecting and constructing cohesive image-based summaries of movies. It presents a valuable tool with wide-ranging applications in many fields such as surveillance, content analysis, and video search. The subsequent parts provide an overview of the most recent deep learning approaches; proceed throughout their benefits for video summarization, and show case studies and experimental findings that demonstrate how well these methods work to solve the problems associated with creating image captures from video streams. The organization of the paper as follows: Section II describes the literature survey and the proposed model is explained in Section III. The simulation results are discussed in Section IV. Finally, Section V concludes the paper.

II. Related Work

Hafiz Burhan Ul Haq et al. [9] proposed a deep learning based system for tailored video summarization. The suggested framework facilitates video summarization based on the Object of Interest (OoI), such as individuals, aircraft, mobile devices, bicycles, and automobiles. Sridevi et al. [10] demonstrated with the use of a deep convolutional neural network in each stream, to create a video summary by extracting the temporal and spatial information from a video. The use of a Two-dimensional Convolutional Neural Network (2D CNN) allows for the exploitation of spatial information, while a Three-dimensional Convolutional Neural Network (3D CNN) is employed to exploit temporal information in order to provide highlight scores for video segments. The fusion of segment ratings from each stream is used to identify highlight portions within the video. Moreover, the resulting highlight representation alone indicates the user's relative degree of interest in a movie. To train the deep convolutional neural network (DCNN) in each stream, a paired deep ranking model is used. The objective is to enhance the highlight score of the highlight segment relative to the non-highlight section via the optimization of the model. The segments that have been acquired are then used in the process of summarizing a video.

Obada Issa et al. [11] illustrated novel methodologies for addressing the issue of key frame extraction in the context of video summarization. The methodology used in the study involves the extraction of feature variables from the bit streams of coded films, which is then followed by an optional stepwise regression process aimed at reducing dimensionality. After extracting the features and reducing their dimensionality, novel frame-level temporal subsampling approaches are used, followed by training and testing using deep learning architectures. The frame-level temporal subsampling approaches rely on the use of cosine similarity and the application of PCA projections on feature vectors. Three distinct learning architectures are constructed by using LSTM networks, 1D-CNN networks, and random forests.

Xu Wang et al. [12] presented a novel deep summarizing network that incorporates auxiliary summarization losses in order to effectively tackle the aforementioned issue. The incorporation of an unsupervised auxiliary summarization loss module using LSTM and a swish activation function is proposed. This module aims to effectively capture long-term dependencies for video summarizing tasks. Furthermore, the proposed module can be seamlessly incorporated into diverse network architectures. The presented model is a novel unsupervised framework for deep reinforcement learning that operates independently of any explicit labels or user interactions. In addition, the suggested model has a low computational burden and may effectively be implemented on mobile devices, hence improving the mobile user experience and alleviating strain on server operations.

Rhevanth et al. [13] presented an effective video summarizing method that extracts essential frames from raw video input and analyzes visual and audio material. Mel-frequency cepstral coefficient (MFCC) extracts information from audio sources, whereas structural similarity index compares frames. Using the preceding two functions removes superfluous video frames. A deep convolution neural network (CNN) model refines the key frames to get a list of potential key frames that summarize the data. Gulraiz Khan et al. [14] suggested a method facilitating users in generating video summaries by using human and object attributes. Cryptographic hashes play a crucial role in the context of blockchain technology. These hashes are derived from condensed video blocks, serving as a means of summarizing the content. Subsequently, these hashes are signed and transferred over the blockchain network. The Cumulus blockchain method is used to safeguard the integrity of the video. The system facilitates distant users in obtaining tamper-proof, condensed video footage of their company locations or other critical properties, which can be accessed on their cellphones. Xiaoning Chen et al. [15] presented a method for video summarization (VS) that leverages the complementary nature of shallow and deep features. The suggested approach involves Multiview feature co-factorization based dictionary selection, which aims to use the shared information from both shallow and deep view features in VS. In order to effectively use the whole visual information of video frames, two view features are employed. Subsequently, the shared information between these two distinct views is extracted using coupled matrix factorization. This retrieved information is then utilized for the purpose of dictionary selection in the context of visual surveillance. Ke Zheng et al. [16] presented a video summarization generation model called DME-VSNet, which utilizes a multi-feature approach to extract various information from the video frames. This study incorporates three key variables: significance score, picture memory strength, and image entropy. In response to the issue of imprecise video shot segmentation, this study presents a video shot segmentation algorithm that utilizes the TransNet network. The system effectively partitions the original video into many shorter shots by identifying shot borders. The suggested model incorporates three specific variables as inputs for this purpose. The video frame score is acquired inside the Multi-Layer Perceptron (MLP) architecture, and subsequently, the key frame is determined based on this score to provide a concise summary of the movie.

Balamurugan et al. [17] illustrated a model for anomalous event detection that combines a hybrid convolution neural network (CNN) with bi-directional long short term memory (Bi-LSTM). The model is designed to have decreased complexity. The proposed model incorporates a convolutional neural network that utilizes a pre-trained model to extract spatio-temporal features from individual frames within a series. These features are subsequently fed into a multi-layer bi-directional long short-term memory network, which is capable of accurately classifying abnormal events in complex surveillance scenes on the road. The fine-grained technique incorporates a hierarchical temporal attention-based LSTM encoder-decoder model to provide an enhanced video summarizing approach that effectively maintains critical information while optimizing storage capacity.

Sah, Ramesh Kumar et al. [18] proposed a framework that utilizes spatial and temporal aspects, including self-attention mechanisms, to select representative content from video sequences. The framework generates temporal proposals and employs supervised learning techniques using manually provided data from individuals or users. Current supervised approaches do not effectively address the temporal interest and its consistency. In addition, achieving temporal consistency requires the ability to anticipate the temporal suggestions of the video segment. The present study approaches the task as temporal action detection, whereby it aims to concurrently forecast the relevance score and placement of the segments. This is achieved by using an anchor-based system that creates anchors of different lengths to effectively identify intriguing ideas.

III. Proposed Methodology

A deep learning-based image caption generator is a framework that automatically generates informative text captions for images. By merging computer vision and natural language processing methodologies, this system is capable of comprehending and articulating the semantic content of an image in a manner that is comprehensible to humans.

A. Image Caption Generator Framework

The image caption generator framework consists of data collection, data presentation, model presentation, and training and validation phases. During the data preprocessing stage, images undergo several operations such as scaling, normalization, and augmentation to ensure uniform dimensions and improved feature representation. Captions/Textual descriptions undergo the process of tokenization, wherein they are segmented into individual units, and subsequently transformed into numerical representations. This conversion is commonly achieved through the utilization of word embedding techniques. The model architecture is implemented using a pre-trained convolutional neural network (CNN), an encoder, which is responsible for processing the image and extracting visual features at a higher level. On the other hand, a decoder, commonly implemented as a recurrent neural network (RNN), utilizes these extracted features to generate textual descriptions. During the training process, the model aims to reduce the disparity between the captions generated by the model and the actual captions by utilizing a loss function, such as cross-entropy. Fig. 1 shows the Image Caption Generator Framework.

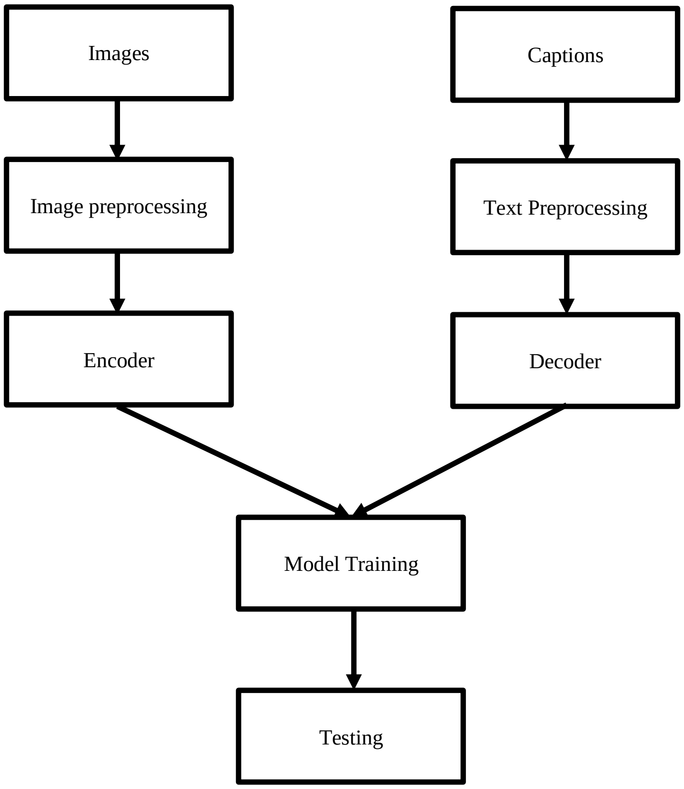

Fig. 1. Image caption generator framework.

1) Image preprocessing: Resizing: To maintain consistency, images in the dataset are frequently scaled to a fixed dimension (such as 224x224). The necessity of performing the resizing phase arises from the fact that deep learning models, particularly convolutional neural networks (CNNs), commonly necessitate input images to possess equal dimensions.

Normalization refers to the process of scaling image pixel values to a predetermined range, commonly denoted as [0, 1] or [-1, 1]. Normalization is a crucial step in data preprocessing that aims to establish a uniform range and mean for the input data. This process plays a significant role in enhancing the training process and facilitating the convergence of the model.

Data augmentation strategies are employed in order to enhance the variety of training data and bolster the resilience of the model. This may encompass various image processing processes such as rotation, cropping, flipping, brightness tweaks, and zooming. Data augmentation is a technique that aids in enhancing the generalization capabilities of a model towards images that have not been previously encountered.

2) Text preprocessing: Tokenization involves the process of breaking down captions, into individual words or sub words. Tokenization refers to the computational procedure of dividing a given text into distinct and meaningful parts, which might include individual words or sub word tokens. This process is commonly accomplished through the utilization of tools such as the Natural Language Toolkit (NLTK) or spaCy. Every token is representative of either a complete word or a fragment of a word.

Vocabulary creation involves extracting the tokens present in the dataset and organizing them into a comprehensive collection. This lexicon encompasses all distinct lexical units or morphological constituents found inside the captions. The size of the vocabulary is governed by the quantity of distinct tokens. Restricting the size of the vocabulary is crucial to maintain computational efficiency during training and inference, as excessively large vocabularies can lead to increased computational costs.

Padding and sequence length issues arise when dealing with captions, as they frequently vary in length. However, neural networks require input sequences of a set length. Consequently, it is possible to add a specific token (such as <PAD>) to sequences in order to achieve consistent length. The determination of a maximum sequence length is also utilized to appropriately truncate or pad sequences. Captions that are lower than the maximum allowable length are extended by adding padding, and captions that exceed the maximum length are shortened by truncation. Word embeddings are frequently employed to transform words into numerical representations. Pre-existing word embeddings, such as Word2Vec, GloVe, and FastText, can be employed to establish a mapping between words and compact vector representations. Embeddings can capture semantic links between words, hence enhancing the model's comprehension of the text. Special tokens, such as "<START>" to denote the initiation of a series and "<END>" to signify its conclusion, are incorporated into the tokenized captions. The utilization of tokens aids the model in acquiring knowledge regarding the appropriate instances to initiate and conclude the process of generating captions during the decoding phase.

Data preprocessing is a crucial step in preparing picture and text data for effective training of deep learning models. The preprocessed data is subsequently utilized to train the image encoder, which is typically a Convolutional Neural Network (CNN), and the text decoder, which is typically a Recurrent Neural Network (RNN) model, in the image captioning framework. The alignment between the data and the model architecture is crucial for effectively training the model and producing coherent image captions.

3) Image encoder: The function of the image encoder is to undertake the processing of the input image and extract significant features from it. Convolutional Neural Networks (CNNs) are frequently employed as image encoders.

a) Pre-trained CNN: A pre-trained (CNN) model, such as VGG, ResNet, or Inception, is employed as backbone for the image encoder. These models have already been trained to extract hierarchical and meaningful visual features from images using data from large-scale image classification tasks like as ImageNet.

b) Feature extraction: To extract features, the input image is processed through the pre-trained CNN. As the input data traverses the many layers of the CNN, distinct characteristics are identified and represented at varying degrees of abstraction. The properties serve to capture and represent relevant information related to the edges, textures, forms, and constituent components of the depicted image.

c) Dense layer: Dense layer or fully connected layer is employed to further transform the feature vector into a feature map that aligns with the desired input size for the text decoder. Embedding of Image Features: The image encoder produces a feature vector as its final output, which serves as a representation of the visual material contained inside the image. The feature vector serves as the initial hidden state for the text decoder. The process of embedding image features into a dense vector is commonly employed to ensure compatibility with the RNN decoder.

4) Text decoder: The text decoder reads the visual features and provides textual captions word by word. Text decoders in natural language processing (NLP) often employ Recurrent Neural Networks (RNNs) or Long Short-Term Memory (LSTM) networks. The following is a comprehensive elucidation of the text decoder:

a) Initial state for the text decoder is derived from the feature vector obtained from the image encoder. This initializes the decoder by utilizing a reference point to generate captions that are derived from the visual characteristics of the image.

b) Embedding layer: The input word tokens or sub word tokens obtained from the preprocessed captions undergo a process of passing via an embedding layer. The process involves the mapping of each word to a dense vector representation, often of a predetermined size. The acquisition of these embeddings takes place during the training process.

c) Recurrent layers: The fundamental component of the text decoder consists of the recurrent layers, specifically the Long Short-Term Memory (LSTM) . The layers receive the embedded word representations as input and iteratively update their hidden states. During each iteration, the decoder generates a prediction for the subsequent word in the caption. The hidden state is modified by using information from both the previously created words and the image features.

d) Output layer: The output layer of the decoder generates a probability distribution across the vocabulary of words at each time step. The generation of this distribution is accomplished by applying a softmax layer on the hidden state. The subsequent word in the caption is selected based on its highest probability. The integration of an image encoder and text decoder inside a sequential framework constitutes the fundamental component of the image captioning model. The objective of training this model is to reduce the disparity between the captions generated by the model and the ground truth captions obtained from the dataset. The model acquires the ability to produce coherent and contextually appropriate captions for a diverse array of images.

B. Proposed Deep Learning Architecture

The CNN-LSTM model that has been presented will be discussed in this section. Fig. 2 illustrates the CNN-LSTM model that has been proposed for use in image captioning. The diagram depicts the various components of the model. The model is made up of several different layers. The CNN layer is used to first extract characteristics from the image. The CNN layer acquires the knowledge necessary to extract features from images, including edges, shapes, and colors, that are crucial to the process of image captioning. After the output of the CNN layer has been formed into a series of vectors, the next layer is the output of the CNN layer. Each vector represents a different part of the image. The sequence of vectors is then passed to the embedding layer. Each vector is inserted into a space with a high dimension by using the embedding layer. This enables the LSTM layer to learn more complex correlations between the vectors. Long-term dependencies in the vector sequence are learned by the LSTM layer. This is crucial for image captioning since a caption should make sense and be in line with the picture's content. The dropout layer receives the LSTM layer's output after that. By removing part of the LSTM layer neurons at random, the dropout layer stops overfitting. The model is compelled to pick up stronger characteristics as a result. Next, the output from the dropout layer is combined with the output from the layer before it. The purpose of doing this is to depict the picture in a more sophisticated way. The model's last layer is a thick layer. The image's caption is produced by the thick layer. The algorithm predicts one word at a time to create the caption. Long Short-Term Memory is an architecture for recurrent neural networks (RNNs)[26] that is meant to manage and analyze sequences of data, such as time series, natural language, and voice. It is abbreviated as LSTM, which is also the name of the corresponding abbreviation. classic RNNs have difficulty collecting long-term dependencies in data, therefore researchers came up with the idea of LSTMs to solve this problem and overcome the limits of classic RNNs. The capacity of LSTMs to successfully acquire and remember information over extended periods is largely responsible for the explosion in popularity of this type of model. The most important innovation of LSTMs is found in their memory cells, which give them the ability to store information and keep it up to date over time. These memory cells are made up of three gates: the input gate, the forget gate, and the output gate. These are the most important gates. The forget gate selects what information is no longer relevant, the input gate regulates what information is stored in the memory cell, and the output gate decides what information is shown to the network's output. These gates are controlled by three gates: the input gate, the forget gate, and the output gate. This architecture not only allows LSTMs to recognize and recall patterns or relationships within sequential data, but it also helps typical RNNs avoid the problem of vanishing gradients, which is a common issue for these types of networks. DenseNet-201 is a convolutional neural network architecture that was devised by Gao Huang, Zhuang Liu, Laurens van der Maaten, and Kilian Q. Weinberger in the year 2016. This model is a modification of the DenseNet-121 architecture, aimed at mitigating the drawbacks commonly observed in conventional deep neural networks like the issue of vanishing gradients and the challenges associated with training very deep networks. Fig. 2 shows the proposed architecture.

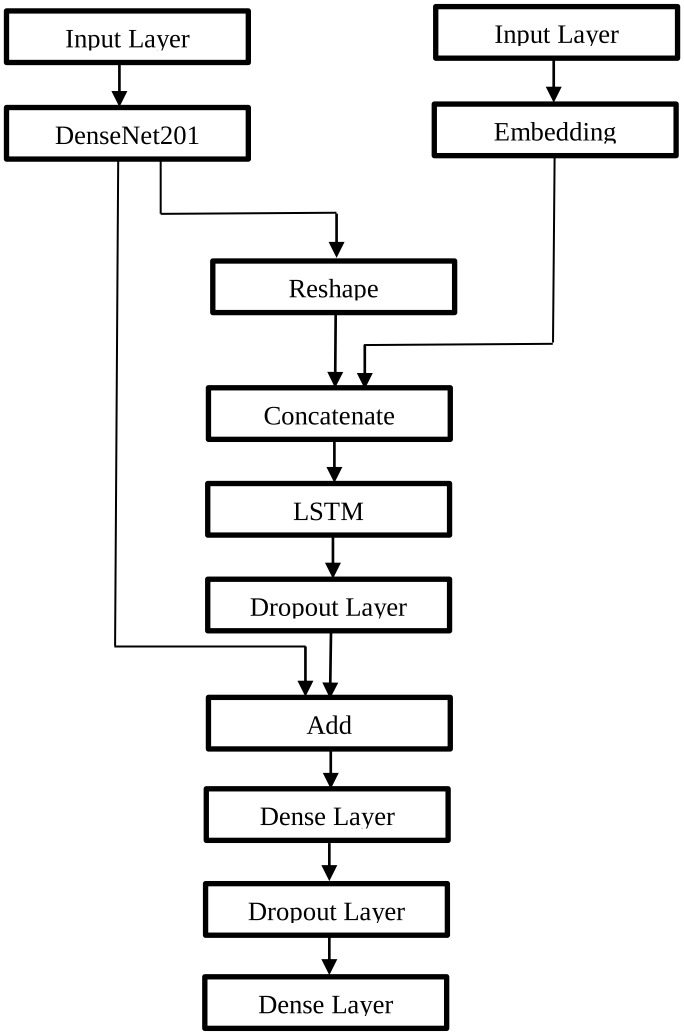

Fig. 2. Proposed model.

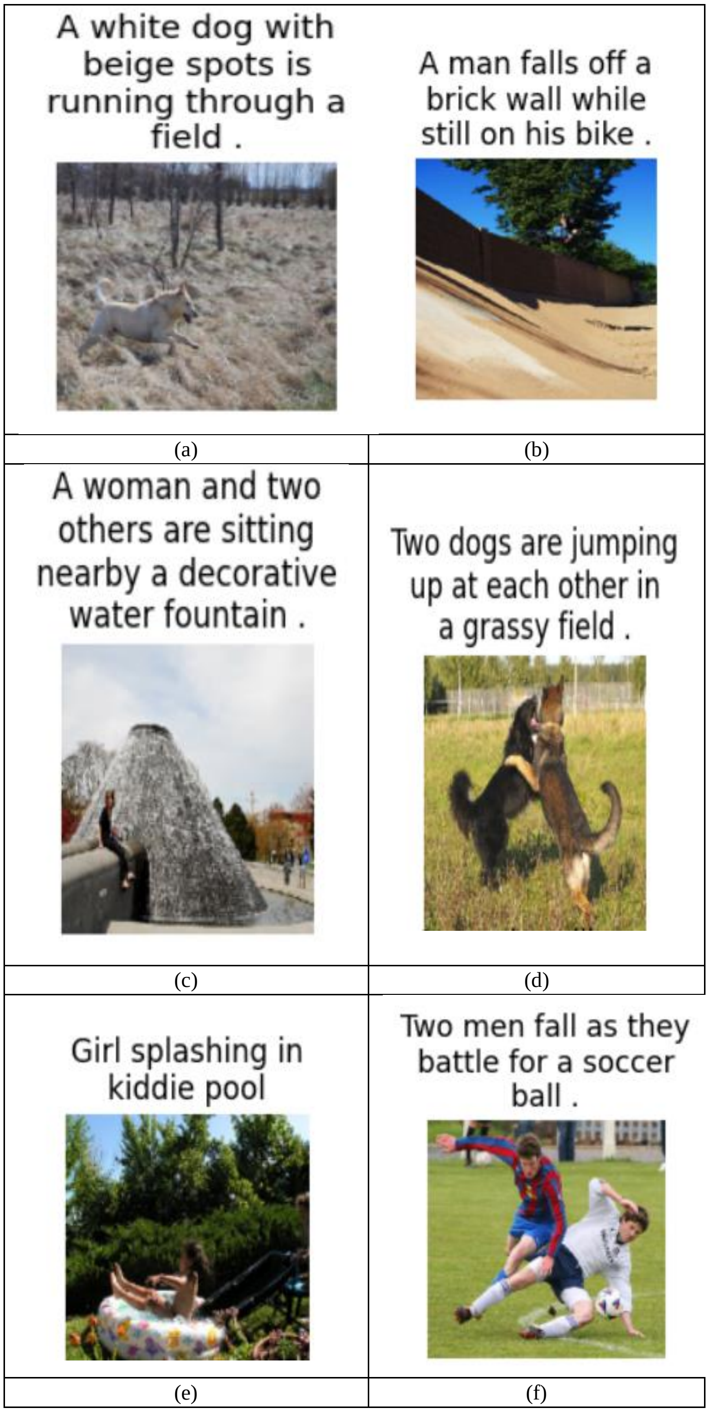
IV. Results and Discussion

This section presents a comprehensive account of the outcomes derived from the simulations carried out utilizing the suggested methodology. The dataset utilized in this research was obtained from Kaggle. The dataset (Flickr 8k) was subjected to processing utilizing the suggested technique. The dataset comprises 8,000 photos, each accompanied by five distinct captions. These captions aim to offer comprehensive descriptions of the prominent things and events depicted in the images. The selection of photographs was derived from six distinct Flickr groups, predominantly devoid of prominent individuals or recognizable landmarks. Fig. 3 shows some sample images and their text captions.

Tokenization is a key approach in the field of natural language processing (NLP) that entails the segmentation of text or language into smaller components known as tokens. The tokens employed in this context generally consist of words, sentences, or even individual characters, depending on the task and the level of detail desired. Tokenization plays a pivotal role as an essential pre-processing step in numerous natural language processing (NLP) applications, facilitating the comprehension and manipulation of human language by computers. In the domain of English language processing, tokenization conventionally entails the division of words by means of spaces or punctuation marks. However, for languages without distinct word delimiters, the process of tokenization may exhibit greater intricacy. The process of tokenization holds significant importance since it facilitates the study of textual data, including many tasks such as text categorization, sentiment analysis, machine translation, and information retrieval. The utilization of algorithms enables the processing of structured and quantified linguistic data, facilitating the extraction of significant insights from textual information, and facilitating effective communication between humans and machines.

The process of image feature extraction in the field of computer vision entails the conversion of unprocessed picture data into a collection of numerical or symbolic descriptors, commonly referred to as features. These features enable more efficient processing and analysis by machine learning algorithms. The process of feature extraction is of utmost importance as it serves to streamline the intricacies associated with visual data, while preserving the vital information required for a multitude of computer vision applications, including but not limited to object recognition, image classification[22], and image retrieval. The techniques employed for feature extraction exhibit a wide range of complexity, encompassing rudimentary approaches such as color histograms and edge detection, as well as sophisticated methods like convolutional neural networks (CNNs) that possess the ability to autonomously acquire pertinent features from images. The collected characteristics play a fundamental role in picture comprehension and facilitate the development of models that possess the ability to identify objects and detect patterns within images. In brief, the process of image feature extraction serves to connect unprocessed visual input with machine learning algorithms, hence enabling the comprehension and examination of images across several domains, including but not limited to autonomous driving and medical imaging.

The notions of training loss and validation loss hold significant importance in the training and evaluation of machine learning models, specifically in the domain of supervised learning tasks like classification and regression. These metrics serve as important indicators for evaluating the performance of the model both during the training process and in subsequent assessments. The training loss is a metric used to evaluate the performance of a machine learning model on the training dataset. Fig. 4. depicts the training and testing loss of the proposed model. The quantification of the inaccuracy or disparity between the predictions made by a model and the actual target values in the training data is referred to as the evaluation of model performance. Throughout the training procedure, the model iteratively modifies its parameters, such as weights and biases, to minimize the loss function. A decrease in training loss signifies that the model is progressively improving its ability to appropriately match the training data. Nevertheless, it is imperative to acknowledge that an excessively low training loss does not guarantee that a model would exhibit strong generalization capabilities when presented with unseen data. Indeed, the phenomenon of obtaining a significantly reduced training loss while exhibiting poor generalization performance serves as an indication of overfitting. Overfitting occurs when a model has efficiently memorized the training dataset yet lacks the ability to accurately predict outcomes for novel, unseen data instances.



A white dog with beige spots is running through a field .
A man falls off a brick wall while still on his bike .
A woman and two others are sitting nearby a decorative water fountain .
Two dogs are jumping up at each other in a grassy field .
Girl splashing in kiddie pool
Two men fall as they battle for a soccer ball .

(a) (b) (c) (d) (e) (f)

Fig. 3. Sample images and captions of flickr 8k dataset.

The validation loss, also known as the test loss, is a metric that evaluates the performance of a model on unseen data, which was not used for training. The validation dataset, which comprises unseen data, serves the purpose of evaluating the model's capacity to generalize, and is separate from the training dataset. The calculation of the validation loss is performed similarly to that of the training loss, where the model's predictions are compared against the actual target values. A low validation loss indicates that the model is effectively generalizing its learned patterns to previously unseen data. The metric functions as a significant determinant of a model's efficacy in forecasting and its capacity to generate precise predictions is when applied to the real-world dataset. The results of the proposed model are depicted in Fig. 5.

Fig. 5. Captions generated by proposed model on sample test images.

The BLEU metric [23], known as Bilingual Evaluation Understudy, is commonly employed to assess the caliber of machine-generated text, particularly within the domain of machine translation. The metric quantifies the degree of similarity between the text generated by the machine and a reference text, yielding a numerical score that assesses the alignment of the machine-generated text with the reference text produced by humans. The BLEU metric is commonly employed in the fields of natural language processing and machine translation for evaluating the effectiveness of language generating models. The BLEU score operates by doing a comparison between the n-grams, which are consecutive sequences of n words or characters, present in the machine-generated text and those found in the reference text. The evaluation metric evaluates the precision, which quantifies the ratio of n-grams in the text generated by the machine that are also present in the reference text. Additionally, it considers brevity, which takes into consideration the length of the generated text in relation to the reference text. The BLEU score is quantified as a numerical value ranging from 0 to 1, where a higher score signifies a stronger correspondence between the generated text and the reference text. The BLEU score obtained by proposed method is 0.6052. The BLEU metric of the proposed model is compared with existing models and corresponding results are reported in Table I. The Table I compares models' image caption generation performance using the BLEU score, a typical criterion for machine-generated text quality. These models establish image descriptions using CNN and LSTM combinations. The findings show different performance levels: VGG16, a common CNN architecture, scored 0.56 in BLEU, whereas DensNet+LSTM scored 0.57. The Conventional CNN+LSTM model scored 0.39. The Proposed CNN+LSTM have the greatest BLEU score of 0.60, showing its capacity to create picture captions that resemble human-generated reference captions.

TABLE I. BLEU COMPARISON RESULTS

S.No	Model	BLEU
1	VGG16 [19]	0.56
2	DensNet+LSTM [20]	0.57
3	Conventional CNN+LSTM [21]	0.39
4	Proposed CNN+LSTM	0.60

V. CONCLUSION

In conclusion, this research has showcased the capabilities of deep learning methodologies in generating image captions for video summarization. By utilizing the DenseNet201 architecture for extracting image features and deploying GloVe LSTM models for text processing, the proposed model has effectively developed a framework that effectively connects visual and textual content, providing a comprehensive solution for applications related to video summarization. The captions provided offer significant contextual information and important perspectives for video content, hence enhancing its accessibility and interpretability. The proposed framework obtained a BLEU score of 0.60. The image caption model built using the Flickr8k dataset with proposed architecture has limitations stemming from the dataset's relatively small size, potentially leading to overfitting and a lack of generalization to diverse images. Access to larger and more diverse datasets, possibly incorporating more specialized datasets for nuanced image understanding, will enhance the model's generalization capabilities.

Evolving Adoption of eLearning Tools and Developing Online Courses: A Practical Case Study from Al-Baha University, Saudi Arabia

Hassan Alghamdi[1], Naif Alzahrani[2]
Department of Computer Information Systems, School of CS and IT, Al-Baha University, Al-Baha, Saudi Arabia[1]
Department of Computer Engineering, School of Engineering, Al-Baha University, Al-Baha, Saudi Arabia[2]

***Abstract*—eLearning or online learning has gained acceptance worldwide, particularly after the Covid-19 pandemic. Although the pandemic has forced the shift towards this learning mode, there is still a continuous need to improve instructors' cognitive and practical competencies to effectively design and deliver online courses. In this paper, a practical case study from Al-Baha University, a Higher Education Institution (HEI) in Saudi Arabia, is presented, showing the development stages of eLearning at the university and how effective utilization of eLearning tools through a structured methodology in a short time, with minimum resources, has helped to improve the teaching and learning experiences for both instructors and students at the university before the pandemic. Various standards and research techniques have been adopted to develop and assess the methodology and its viability of implementation in other higher education institutions. The findings show the methodology's effectiveness and how it helps Al-Baha University smoothly adapt to the online shift at the onset of the pandemic. The methodology is presented to and gained acceptance and recommendation for application in other HEIs in Saudi Arabia from the committee of eLearning and distance education deans in Saudi Universities in March 2023. It also receives the Anthology Middle East award for community engagement in November 2023.**

Keywords—eLearning; ICT competencies; Higher Education Institutions (HEIs); Learning Management System (LMS)

I. Introduction

A commonly accepted definition of eLearning is challenging to find [1], [2], yet it can be described as the utilization of different modes of technological tools for the purpose of education, whether these tools are web-based, web-capable or web-distributed [3]. Online learning is a term commonly used to describe education that occurs only via the web without face-to-face contact [3]. With various eLearning adopted terms and styles, it is broadly accepted among academic institutions and across all educational fields [4], [5].

More recently, due to the Covid-19 pandemic at the end of 2019, educational institutions had to move from conventional learning to digital and online learning as part of the health crisis management [6]. Although eLearning and its tools and practices were widely accepted around the globe before the pandemic, as previously stated, many Higher Education Institutions (HEIs) and faculty members in many countries were not ready for the shift to online teaching once the pandemic occurred [7]. The low level of experience among instructors in adopting new teaching formats and the time constraints to make the shift immediately were affecting the readiness of these institutions [8]. This has led many HEIs to speed up the process of adopting eLearning tools without structured long-term planning [9].

The role of teachers in schools and instructors in HEIs during the pandemic was significant to ensure the continuity of teaching and learning [10]. Recent research shows that instructors in HEIs after the pandemic have appreciated blended and online learning, which allows them to combine the strengths of these teaching styles with the face-to-face style [9]. Jelinska et al. [11] pointed out that teachers with prior experience in dealing with online teaching tools were the best at coping with the challenges faced during the transition of the pandemic and were the most engaging. Similarly, Divjak et al. [12] state that instructors who had prior experiences adopting innovative teaching styles, such as flipped classrooms, before the pandemic had more successful experiences with online teaching implementation during the pandemic. However, instructors' adoption of online tools in HEIs before the pandemic was not pervasive [8]. This has significantly affected their experiences with online teaching during the shift to online mode. The focus should then be on continuous investment and enhancement of Information and Communications Technology (ICT) and eLearning competencies of instructors in HEIs to ensure long-term adoption and adaptation of different teaching and learning styles in HEIs. König et al. [13] emphasize the importance of professional development of digital competencies for teachers to adapt to online teaching. Gameil et al. (2023) [14], in their study findings, pointed out that huge investments must be made to train teachers to improve their instructional designing competencies in terms of cognitive and practical perspectives. They highlighted the issue that employing digital learning platforms after the pandemic requires paying more attention to improving the skills of teachers to cope with the radical changes in the teaching landscape.

Similarly, Svetec et al. [15] state that although instructors in HEIs realize the importance of digitalization support, they are not fully aware of the significant role of digital technologies in enhancing teaching and learning experiences. The enhancement of these experiences and the ability to reach a high level of quality in education are common strategic objectives in HEIs that are sometimes misaligned with available technologies and the actual roles of instructors in these institutions. Jans (2009) [16] also states that teachers and lecturers may have learned and worked with many hardware and software tools; they, however, still require more didactical skills on how to use Learning Management Systems (LMSs) effectively, and longer courses are required to improve their eLearning competencies. According to Jans (2009) [16], eLearning and blended learning tools can only be learned by experimenting with them. Alshammari (2020) [17] also investigated instructors' behavioral intentions to use LMSs in a higher education institution in Saudi Arabia through several factors, such as age, gender, experience, etc., and found a causal relationship between experience and behavioral intention of LMS usage.

This practical case study paper describes a methodology implemented at a higher education institution in Saudi Arabia to elevate the usage of LMS through structured development and delivery of online courses while considering the enhancement of instructors' ICT and eLearning competencies. The methodology is developed following the framework devised by the authors and introduced in the paper [18]. In short, the framework consists of seven iterative stages that assist HEIs in elevating the usage of eLearning technologies by adopting them systematically, ensuring the involvement of related organizational components from alignment and Enterprise Architecture (EA) perspectives.

The following sections in this paper present background information about eLearning in Saudi Arabia in general and at Al-Baha University in particular. Then, the problems that motivate developing the structured approach to elevate the usage of eLearning technologies and develop and deliver online courses are revealed following the framework of Alzahrani et al. (2023) [18]. After that, the approach and its application and findings are described and discussed. Final thoughts and future work are stated by the end of this paper.

A. *eLearning in Saudi Arabia*

One of the fundamental characteristics of the HE system in Saudi Arabia is that it is centralized in terms of control and educational support [19]. This means that the Ministry of Education (MoE) and several specialized quality assurance and assessment centers are responsible for planning, coordinating, and supervising the kingdom's higher education sector. However, in recent years, the HE system has undergone tremendous reforms, unifying all efforts toward achieving Saudi Vision 2030 [20].

During the last two decades, the government of Saudi Arabia has invested enormously in ICT and digital transformation. According to the Digital Government Authority [21], the cumulative investment size in digital transformation in Saudi Arabia from 2022 to 2025 is expected to reach 25 billion USD. These massive investments in digital technologies contribute towards achieving the government's strategic plan "Vision 2030", where Saudi Arabia aims to be a global technology hub. According to published statistics from [21], Saudi Arabia was ranked second worldwide in digital competitiveness by the European Centre, ranked eleventh among the G20 for digital governance by the Japanese WASEDA ranking, and ranked 1st in the ESCWA indicator for the availability of digital services, and 19 agencies were awarded Enterprise Architecture Certification from the Digital Government Authority. Proudly, Al-Baha University was among these agencies. There is no doubt that Saudi Arabia has achieved these numbers regarding digital transformation and digital capabilities since it is the largest ICT market in the Middle East and North Africa (MENA) region [22].

The education sector, in particular, receives the largest segment of the government expenditure [22]. Statistics from the same authority show a 100% digital transformation of teaching and learning activities during the pandemic in schools and HEIs through available platforms of "Madrasti" and LMS. Over 350 million virtual classrooms were created during the pandemic, and similarly, large numbers for other activities, such as homework, discussion boards, online exams, etc., were achieved. All have been achieved through a cooperative approach from involved stakeholders and under direct supervision from the Ministry of Education (MoE) and according to the regulations and standards of the National eLearning Centre (NELC).

Abdulrahim et al. [22] state that research on online learning in Saudi Arabia emphasizes the importance of having a strategic direction for its implementation and ensuring that instructors are trained to design and deliver online teaching effectively. Moreover, course design and technology gaps are among the main limitations that face adopting digital learning in Saudi Arabia [23]. Similarly, Alharbi [24] indicates that although there is a broad acceptance of the usefulness of digital learning in Saudi Arabia, there is a lack of knowledge and skills among students and instructors.

B. *eLearning at Al-Baha University*

Al-Baha University is now 17 years old and was established in late 2006. It has 16 faculties spanning six different geographical areas covering the vast region of Al-Baha province (11,000 square km) southwest of Saudi Arabia. It has a current enrolment of 17748 students, 1536 instructors and 776 employees. The university offers 28 undergraduate programs, 17 master programs, and nine programs for higher diplomas. The number of students is increasing annually from only 13,793 in 2008 to nearly 18000 in 2023.

Colbran et al. (2013) [25] studied the adoption of educational technologies among Saudi universities. They found the lack of IT infrastructure, training, and support, as well as websites and software problems, to be the main inhibitors of the successful adoption of educational technologies in the country. However, Saudi Universities have been transforming dramatically in adopting digital technologies along with the enormous investments and support from the government, especially during the last five to eight years. For example, since 2016, Al-Baha University has undergone tremendous changes in adopting and embracing digital technologies and providing services to its key stakeholders, namely students and instructors. By late 2018, the transformation had extended to reform the utilization of eLearning tools at the university after conducting a gap analysis and being aware of the challenges as described next.

The following sections are arranged in the following manner: First, the issues that drive the development of structured approaches to improve the use of eLearning technologies and the creation and delivery of online courses are discussed. Then, the approach is explained, along with its application and findings. Finally, concluding thoughts and future work are presented.

II. Awareness of the Problem

Following the proposed framework of Alzahrani et al. (2023) [18], it states that being aware of the challenges that face underutilization of eLearning technologies and linking them with the strategic vision and objectives of HEIs are crucial steps towards effective and continuous usage of these technologies by involved stakeholders. It also suggests having an ecosystem to drive eLearning projects to realize strategic goals and assist in attaining them.

Al-Baha University -similar to other public universities in Saudi Arabia- was given a quota of thirty thousand licenses from the Ministry of Education (MoE) to access an LMS in 2012. This number of licenses is renewed every five years through a national agreement initiative to facilitate and spread the adoption of eLearning tools among students and instructors in these universities.

Although the number of students and instructors at Al-Baha University has never reached this number, the MOE was generous in providing more licenses for any expected future growth in the number of users. Surprisingly, the number of active users using the LMS was less than 0.5%, including students and instructors. This number was revealed in the middle of a running semester in December 2018. The number of registered students and instructors was close to 20000, interacting through 6500 study sections. This number was considered a wake-up call for the university and its management to start a new era of adopting and utilizing eLearning tools effectively.

A gap analysis was conducted to examine early adopted approaches that the university has carried out to embrace the adoption of eLearning tools. The outcomes revealed that the university has:

1) *Fifty-five* developed Electronic Courses (eCourses) that were invested in and transformed from conventional courses to eCourses from 2013 to 2015, following instructors' preferences and available content. Some of these developed eCourses are used only once and never used afterward. Others are used two or three times and similarly put on the shelf. This happens due to the absence of development standards and the intensive customizations applied to these eCourses. Like many other universities in the region during the early 2000s, converting traditional courses to eCourses was the mainstream regardless of its drawbacks [26].

2) *Very* limited attempts to adopt eLearning tools with currently available LMS.

3) *High* resistance to change among students and instructors with negative attitudes towards eLearning.

4) *Many* training sessions and workshops were conducted to explain the functionalities and tools of the LMS, but the follow-up was extremely weak, so what has been learned usually goes missing with less practice in place.

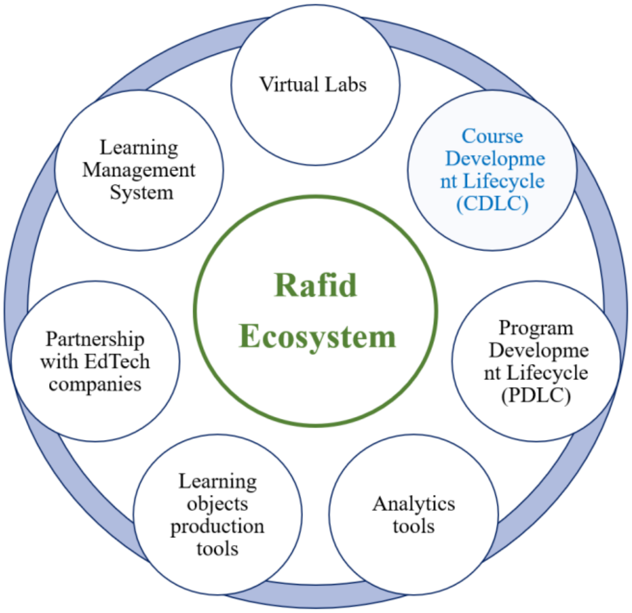
Taking these outcomes into consideration, an eLearning ecosystem named 'Rafid' is created, which consists of a set of components that are linked to the strategic goals of Al-Baha University, aiming to have a holistic transformation and better utilization of eLearning tools at the university.

III. Rafid Ecosystem

"Rafid" is an Arabic word translated as "assistant/ helper/ supporter." It appeared everywhere at Al-Baha University in December 2018 in a ceremony attended and supported by the university's top management. It was a flag of change in students' and instructors' experiences about online teaching and learning. The word Rafid was used to indicate an eLearning ecosystem and change management approach that involves LMS, virtual labs, analytics tools, methodology for developing online courses, etc., that were all made available to assist, help, and support teaching and learning activities at the university (see Fig. 1). The message was clear to the main stakeholders of the university that Rafid ecosystem is found to assist you in your journey of teaching and learning at the university.

One of Rafid's ecosystem components is the Course Development Lifecycle (CDLS), which, in short, is a methodology that takes instructors on a journey of developing and delivering an online course through a structured approach. It was specifically designed to change the mindset of students and instructors towards embracing eLearning tools through teaching and learning processes.

Four stages are defined in the CDLC. These stages are presented in Fig. 2.



Virtual Labs
Course Development Lifecycle (CDLC)
Learning Management System
Rafid Ecosystem
Program Development Lifecycle (PDLC)
Partnership with EdTech companies
Learning objects production tools
Analytics tools

Fig. 1. Rafid ecosystem at Al-Baha university.

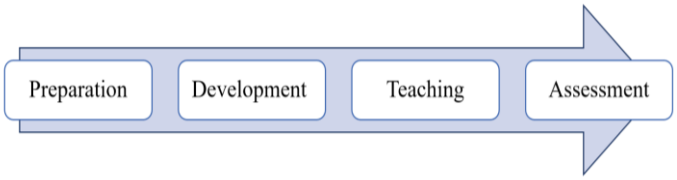


Fig. 2. Course Development Lifecycle (CDLC).

In the first stage, instructors are selected to participate in the process of CDLC based on a nomination process carried out by their faculties according to their ability to allocate 20 hours per week for this project. It was also recommended to nominate instructors who have preliminary ICT competencies such as accessing and browsing the Internet and using some of the main Microsoft Office programs such as Word and PowerPoint to some extent. Once all candidates are nominated, teamwork from the Deanship of eLearning and IT (DeIT), which specializes in course designing and multimedia development, is assigned. Systems and labs are also prepared, the project plan and timeline for course development and delivery are then set, and this stage ends up with a Service Level Agreement (SLA) contract signed by the DeIT from one side and the candidate (i.e., the instructors) from the other side to ensure the commitment of both sides.

In the second stage, participants develop their online courses following best practices and international standards such as Quality Matters (QM) standards for course design. Participants and assigned team members certified in online course design and delivery carry out this stage step-by-step. Assigned team members provide continuous feedback to participants to enhance every aspect of their online courses. This stage focuses on designing and enriching course contents with various resources, creating learning objects, assessment pools, and activities that ensure the engagement and collaboration of students in a standardized and effective learning environment. A master course template (i.e., an online course template structured according to best practices and standards of designing online courses made available for participants on LMS to have hands-on experience while developing their courses step-by-step). In other words, it facilitates developing standardized online courses through what is being learned from the methodology and the assigned certified team member. This course is then made available to students once the development and assessment of fulfilling the requirements are achieved. Several master courses are created and customized according to the nature of the content each faculty delivers at the university.

Once the course is developed, it is revealed to associated students, and the third stage, course delivery, begins. As the name of this stage indicates its objective, the participants deliver their developed online courses to students according to best practices that ensure the instructors' effective, coordinated, and assistant role in delivering online courses.

In the fourth and last stage, an assessment of previous stages is conducted by participants and students. Questionnaires and one-to-one interviews are carried out to find out the strengths and weaknesses of the project and the proposed methodology, more specifically.

Part of the methodology is an online course specifically developed and made available to participants on the LMS to go through the whole experience the students will receive once their online courses are available. This course also helps manage the entire project and lay down the foundations of eLearning and its tools by providing the required materials. Tasks mandatory for participants to complete are also done through assignment tools in the LMS. The project also activates tools such as wikis, discussion boards, groups, virtual classes, etc., where only questions, inquiries, and support needs are accepted and handled through these tools. This is to embrace usability and to show real-life utilization of such tools.

Online (must-attend) workshops provided to participants during the project include forming accurate and measurable learning objectives, designing roadmaps, enhancing and enriching course content with various multimedia content, creating question bank(s), importing and exporting questions, managing tests and assignments and finally delivering effective online courses.

Advanced (optional) online workshops are also offered to participants to expose them to different available techniques and tools that can help them streamline their course design and delivery. Examples of provided workshops include how to use video editing tools and how to build effective presentations through Adobe Suite, Camtasia, Xmind, MindMeister, Microsoft PowerPoint, Prezi, Canva, Kahoot, SurveyMonkey, Mentimeter, Google Docs, and Microsoft OneDrive.

IV. APPLYING CDLC METHODOLOGY

In one academic year, 99 instructors have participated and effectively experienced how to develop and deliver online courses following international standards in the field. This was done during two academic semesters in 2019, starting with 24 instructors and then moving to another 75. Participants were from 15 faculties and across different disciplines.

Upon completing the development and delivery of their online courses, they received recognition and certificates from the university president in a rewarding ceremony. They are then recognized as “Rafid ambassadors” in the change management process. They were passionate about passing the message to other instructors and voluntarily engaged in providing support to others in their free time without hesitation, especially during the Covid-19 pandemic.

Similarly, several students were trained to use LMS effectively as student users. We named them “Rafid Friends” and they also started spreading the message of how easy it is to use LMS and its tools to support the learning process at the university. They then provided help and support to other students whenever needed. These students voluntarily shoot videos of themselves using the system, designing brochures and infographics to spread awareness of the LMS and its tools. All these approaches and techniques were undertaken to change the mindset towards eLearning and its tools among students and instructors at the university.

V. OUTCOMES AND FINDINGS

Ninety-nine instructors who participated in this project were asked and thankfully completed an online open-ended questionnaire and attended a 30-minute online interview each. These research tools were designed to receive feedback from the participants about the following:

1) An overview of the project in general and the level of satisfaction with the components and the defined stages of the developed methodology used in the CDLS project. This also measures the tendency to reengage in the same experiment again and to recommend it to other instructors, how the whole experiment was useful to them, and how it impacted the teaching and learning practices for them and their students. The outcomes are shown in Fig. 3 and measured on a 5-point Likert scale, with five being very satisfied and one very unsatisfied.

2) Participants have learned 46 skills during the project, which enhanced their ICT and eLearning competencies by adopting eLearning tools during the design and delivery processes undertaken throughout the project. The enhancement of ICT and eLearning competencies is not limited to these skills. However, they are drawn from best practices and international standards such as Quality Matters. From the participants ' perspective, the importance of these skills is measured as a percentage, with 100% being very important. Fig. 4 shows the outcomes of this assessment (see Table AI in Appendix A for details of the skills).

3) The ability of participants to implement the learned skills mentioned in the previous point. Participants were asked to provide feedback about the easiness of implementing the defined set of skills. They all agree that they can implement each of the mentioned skills with a percentage close to 100%., except (providing online classes through the LMS to students, recording online classes that are being delivered through LMS and making them available to students, allowing students to communicate through online classes that are created for them, 75%, 70, 60%) accordingly.

4) The ability of participants to teach/support others to carry out similar tasks. Participants confirm that they can teach/help others carry out similar learned skills with a percentage exceeding 95% for each skill.

The findings of the interviews conducted with the participants are illustrated in Table I, which outlines the advantages, disadvantages, and recommendations for improving the project of designing and delivering online courses through a developed approach.

A designed open-ended questionnaire is inserted in the developed ninety-nine courses after obtaining permission from the instructors who deliver them, and students who are registered in these courses are asked to fill out this questionnaire. The questionnaire consists of 40 questions asking students about their new eLearning experience. They were given three options against each question as to whether they agree to a great extent, to some extent, or a little extent. A total of 1800 responses were collected from students, and the outcomes are shown in Fig. 5 (see Table BI in Appendix B for details of the skills).

Students are also allowed to express their attitudes about the eLearning experience they have engaged in throughout the project through three open questions at the end of the questionnaire. Questions are focused on gathering feedback about the positive and negative aspects of the experiment as well as any recommendations for future improvements. Responses in each category exceed 100, but the most repeated answers are illustrated in Table II.

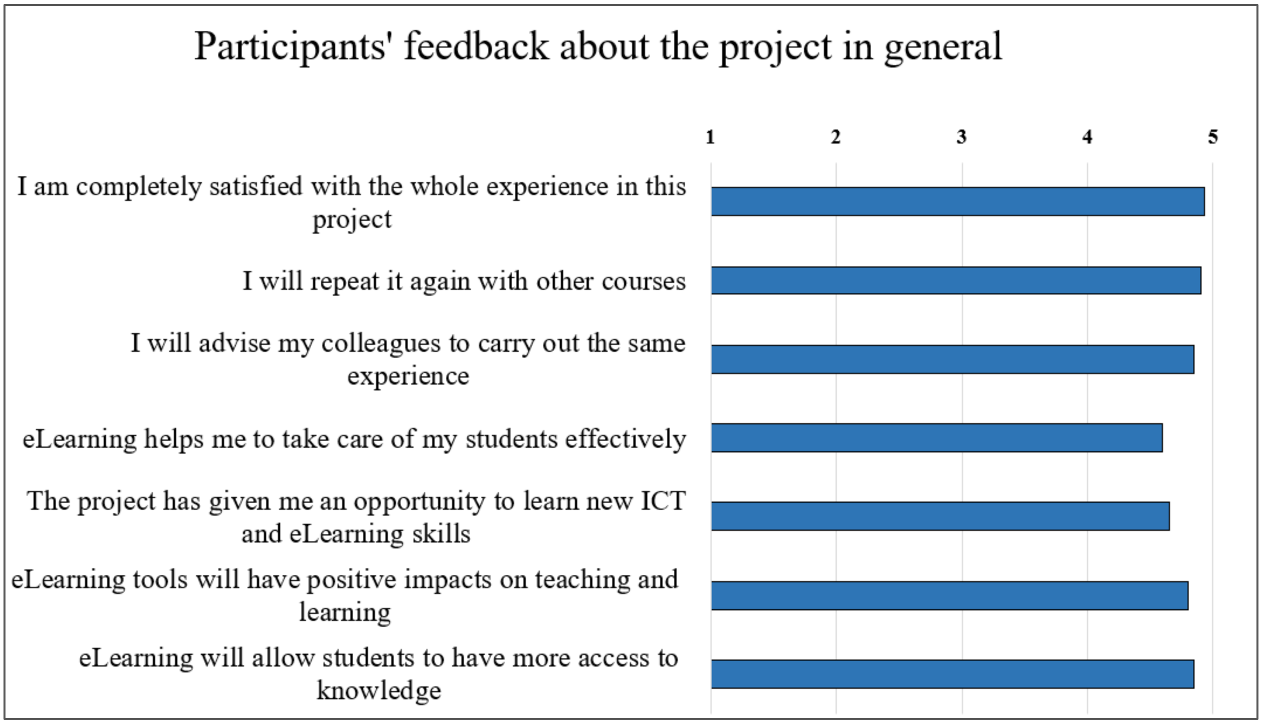

Fig. 3. Feedback about the project in general from ninety-nine participants.

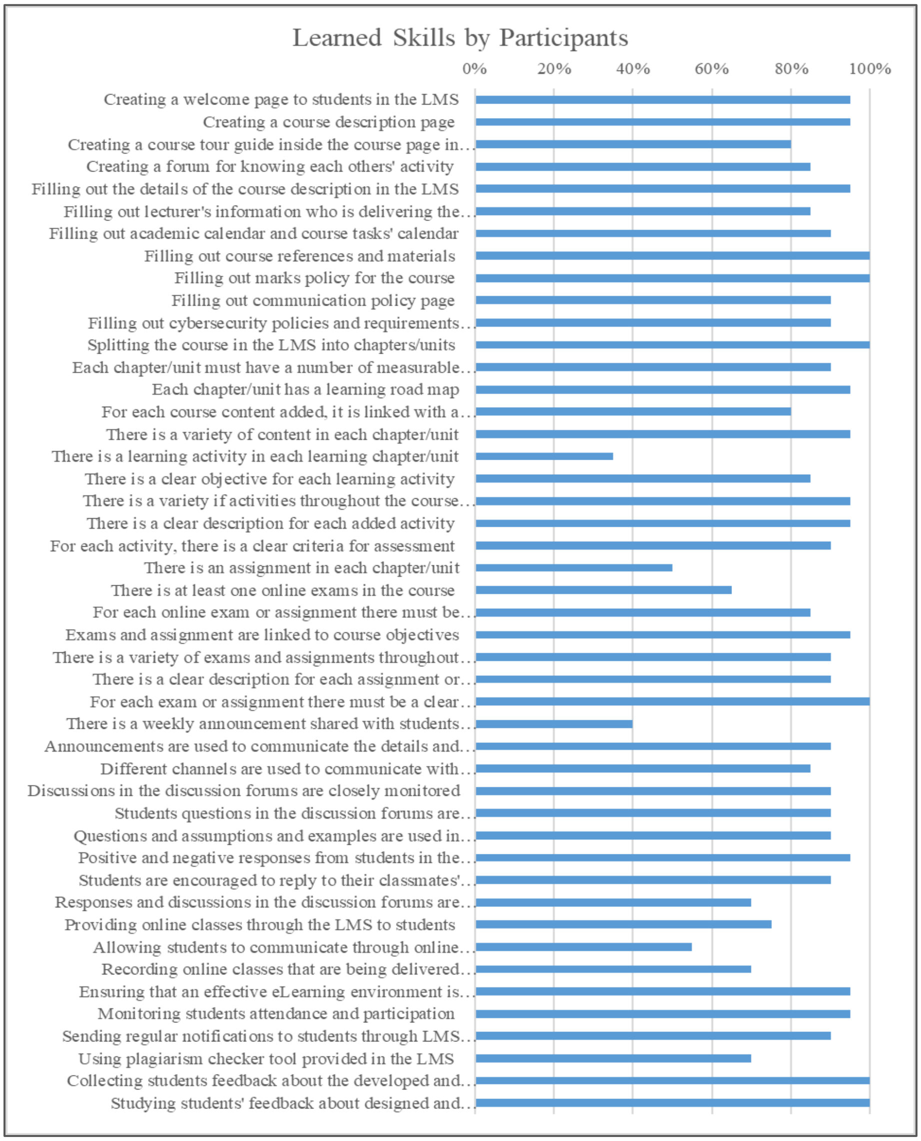

Fig. 4. The importance of each learned skill by participants from their perspective.

TABLE I. ADVANTAGES, DISADVANTAGES, AND RECOMMENDATIONS FOR IMPROVEMENTS FROM PARTICIPANTS

Advantages	Disadvantages
- Clarity of the training course and the flow of steps in each defined phase. - Quick responses and problem-solving from the assigned team members. - Accuracy of follow-up and assessment forms. - Quality of provided training and trainers. - The master course was generally excellent, saving participants time and effort in developing required courses and motivating some participants to continue with the project. - Realizing the benefit of having a road map for each chapter/unit to guide students in the learning flow of the chapter/unit.	- Difficulty engaging in the project and its assignments at the beginning. - Difficulty attending courses and workshops with many assignments while having other administrative roles at the university. - Lack of sufficient labs to conduct online exams on some campuses. - Sometimes, some campuses have Internet and Wi-Fi coverage weaknesses. - There was not sufficient training for students. - Lack of visual content in the training course. - Insufficient time for required assignments. - Sometimes, it was challenging to deal with and modify the content inside the master template in the LMS, especially tables.
Recommendations for improvements	
- Considering the peculiarity of engineering materials. - The project tasks should begin a long time before the semester commences. - A separate e-exam system from LMS should be afforded. - Strengthening the training course with more videos so that it is more of a self-learning course. - Providing participants with a timetable that defines all steps that are required. - There should also be training for students on how effectively they can engage in online learning. - Allow more time for participants to submit the required tasks. - Providing access to virtual experiments and virtual labs in science courses.	

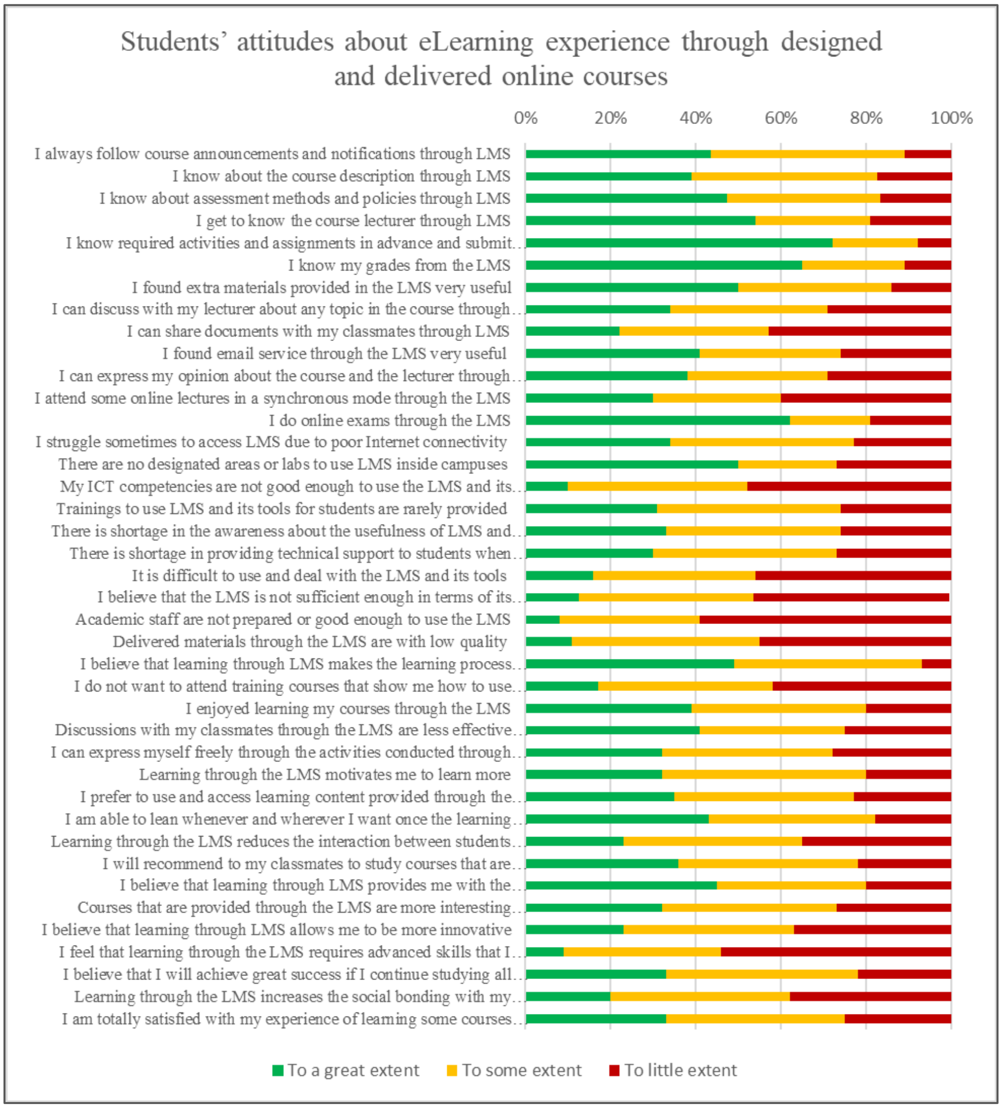

Fig. 5. Students' attitudes about the eLearning experience through designed and delivered online courses.

TABLE II. POSITIVE AND NEGATIVE ASPECTS AND RECOMMENDATIONS FOR IMPROVEMENTS FROM STUDENTS' PERSPECTIVE

<table>
<tr><th>Positive Aspects</th><th>Negative Aspects</th></tr>
<tr><td>- Easy access to course materials at anytime and anywhere.
- Learning has become more flexible.
- Easy access to assessments and grades.
- Ease of communication and interaction with the course lecturer.
- Faster in terms of understanding and accessing information.
- Availability of multiple learning materials that support the main subject of study.
- Learning through the LMS is fun and motivating for students, which increases students' interest in receiving more information.</td><td>- Not all instructors use it.
- The number of activities has increased exponentially.
- Technical problems sometimes occur, such as (poor Internet connectivity).
- Missing assignments and exam submission dates through the LMS due to less familiarity.
- Lack of clarity regarding some assessments, such as (time for submitting assignments, grades, etc.).
- Most online exams are based on objective questions, and there is no opportunity to express answers that the instructors can understand.
- There are no alert notifications in the mobile application that are linked to the LMS.
- Not all functionalities are supported or available in the LMS smartphone application.</td></tr>
<tr><th colspan="2">Recommendations for future improvements</th></tr>
<tr><td colspan="2">- Enhancing the mobile application version of the LMS.
- Forcing all instructors to use it in all courses at the university.
- Provide students with some training, specifically regarding online exams.
- Prepare locations with strong Internet connectivity for students to use the system effectively at the university campus.
- Providing technical support 24/7.
- Provide more training to some instructors to use the LMS effectively with students.</td></tr>
</table>

Different lessons were learned from the feedback of both students and instructors, and new opportunities were opened to enhance the project in general. Still, this project's most valuable outcome was spreading awareness of eLearning and its tools among students and instructors at Al-Baha University. From only 136 active users and 88 active study sections on the LMS in December 2018, the numbers have increased dramatically to reach 3573 users and 2888 study sections, respectively, after one academic year. This growing number of users represents 35% of the total number of users of the system and 44% of study sections that should be active on the LMS system at that time.

We have utilized the feedback received from this project and have transitioned to a higher-level project where we began designing and providing online courses based on an entire study program level. In this project, an agreement is signed with the dean of selected faculties to have a partnership project targeting the development and delivery of an entire program through their instructors and with the help and support of the specialized team from DeIT. This project confirms the importance of having an iterative approach in embracing eLearning technologies in HEIs, which is suggested in the framework of Alzahrani et al. (2023) [18]. Through this extended and enhanced project, 84 online courses were developed with the faculties of CS and IT (department of Computer Science) and the faculty of Business Administration (department of Marketing), 40 and 44 online courses, respectively. This also helped the growth of the number of users of the LMS, reaching 10163 active users and 3620 active study sections, representing 47% of total expected users and 55% of total active study sections at the university at that time. These numbers were reached before the pandemic of Covid-19 occurred, which helped the university enormously to cope with the healthcare restrictions and the compulsory shift to fully online learning. Instructors who have participated in this project and have been trained very well to use eLearning tools have become trainers to support others in effectively using eLearning tools during the pandemic. We have recorded 210 activities performed by 75 trained instructors during the early months of the pandemic. These activities range from providing videos on how to use eLearning tools to reaching a neighbor during the lockdown period and assisting them in setting up an online exam on the LMS.

Besides enhancing the ICT and eLearning competencies of the instructors at the university, which can be utilized to develop more courses, the developed courses are reusable. 6 of the 24 developed courses in the first semester are reused by the instructors who developed them. Seven other developed courses are voluntarily made available and reused by other instructors. In addition, more than 60 virtual classes were delivered by instructors during the first semester of the project, sending a message to other instructors throughout the university that delivering lectures can be done differently outside the university boundaries.

Before this project, male instructors used to travel to female students' campuses to deliver lectures through video conferencing dedicated rooms. These rooms are entirely locked now and have never been used after the pandemic due to the effectiveness of virtual classes through the LMS. During the first semester of this project, it was also the first time official mid and final exams were carried out electronically through the LMS. This has never happened throughout the history of the university.

There was also a significant increase in the use of the university's official emails among students and instructors, along with the implementation of the project. This is because students receive emails about any new announcements from the LMS, and instructors were also advised to use official emails in all correspondence with students. The number of active email users at the university once the project started was only 2032. This number doubled in one semester only, reaching 3880 active email users.

It is important to note that some recent research argues that attending traditional in-person classes leads to better academic performance than taking online courses [27], [28]. Nevertheless, eLearning tools have transformed the education industry by significantly benefiting students and instructors. Adopting these tools has allowed learners to access information anytime, anywhere, and at their own pace. Meanwhile, instructors have been able to deliver interactive and engaging content to their students from the comfort of their homes. Although eLearning has many benefits, we firmly believe that in-person classes supported by advanced eLearning technologies offer the best possible education now and in the future. This is also supported by recent findings of Chen et al. (2023) [29].

VI. Final Remarks

The perception of eLearning among Al-Baha University's students and instructors has been positively transformed through the implementation of this comprehensive project, as evidenced by increasing numbers. This project aims to have an effective holistic alignment of eLearning technologies with the strategic scene of Al-Baha University that seeks to enhance the quality of teaching and learning through ICT adoption. This is supported by the framework the authors suggest in Alzahrani et al. (2023) [18]. Although the quality of online courses delivered does not measure the success of this project, it has changed perceptions towards eLearning among critical stakeholders at the university. With the great support of the university's top management, the project was delivered as planned. However, the quality of delivered online courses is iteratively measured by the end of each project implementation cycle as a long-term plan for course evaluation and enhancement.

This project aims to promote the adoption of eLearning in higher education, with a particular focus on students and instructors, while considering other groups such as employees, senior individuals, and different age groups for future projects. The project discussed and the elaborated case study can benefit academic institutions seeking to engage instructors in onrline course development and delivery processes with minimal costs. All participants in the project at Al-Baha University have shown enthusiasm and a sense of responsibility for enhancing their students' learning and teaching experiences. Some members of Saudi universities' eLearning and distance education deans committee suggest implementing a monetary reward system for project participants to achieve better results, especially after the pandemic.

VII. Future Work

While implementing our CDLC methodology during the Covid-19 pandemic, we observed the unique aspects of course design and delivery in the faculty of medicine. This is expected as the field of medicine requires specific attention due to the application of various teaching methods and the practical nature of the field. As a result, we studied ten different teaching methods and devised an approach for each method to shift it from face-to-face delivery to either blended hybrid or fully online teaching. We will present and discuss our findings in future work.

Acknowledgment

Researchers thank the deanship of scientific research at Al-Baha University, Kingdom of Saudi Arabia, for sponsoring this project in 1442H with a reference number (1442/2). Deep appreciation also goes to the eLearning team at Al-Baha University.

APPENDIX A

TABLE AI. LIST OF LEARNED SKILLS BY PARTICIPANTS

1	Creating a welcome page to students in the LMS
2	Creating a course description page
3	Creating a course tour guide inside the course page in the LMS
4	Creating a forum for knowing each other’s activity
5	Filling out the details of the course description in the LMS
6	Filling out lecturer's information who is delivering the course
7	Filling out academic calendar and course tasks' calendar
8	Filling out course references and materials
9	Filling out marks policy for the course
10	Filling out communication policy page
11	Filling out cyber security policies and requirements requested by cyber security department
12	Splitting the course in the LMS into chapters/units
13	Each chapter/unit must have a number of measurable learning objectives
14	Each chapter/unit has a learning road map
15	For each course content added, it is linked with a chapter/unit objective
16	There is a variety of content in each chapter/unit
17	There is a learning activity in each learning chapter/unit
18	There is a clear objective for each learning activity
19	There is a variety of activities throughout the course chapters/units
20	There is a clear description for each added activity
21	For each activity, there is a clear criteria for assessment
22	There is an assignment in each chapter/unit
23	There is at least one online exam in the course
24	For each online exam or assignment there must be specified objective(s)
25	Exams and assignment are linked to course objectives
26	There is a variety of exams and assignments throughout the course
27	There is a clear description for each assignment or exams included
28	For each exam or assignment there must be a clear criteria for assessment
29	There is a weekly announcement shared with students through LMS
30	Announcements are used to communicate the details and updates about the course
31	Different channels are used to communicate with students such as LMS and emails
32	Discussions in the discussion forums are closely monitored
33	Students’ questions in the discussion forums are answered in acceptable range of time (24hrs max)
34	Questions and assumptions and examples are used in discussion forums
35	Positive and negative responses from students in the discussion forums are monitored
36	Students are encouraged to reply to their classmates' questions in the discussion forums
37	Responses and discussions in the discussion forums are summarized
38	Providing online classes through the LMS to students
39	Allowing students to communicate through online classes that are created for them
40	Recording online classes that are being delivered through LMS and making them available to students
41	Ensuring that an effective eLearning environment is maintained throughout the semester
42	Monitoring students’ attendance and participation
43	Sending regular notifications to students through LMS and emails
44	Using plagiarism checker tool provided in the LMS
45	Collecting students feedback about the developed and delivered course
46	Studying students' feedback about designed and delivered course

APPENDIX B

TABLE BI. STUDENTS' ATTITUDES ABOUT ELEARNING EXPERIENCE THROUGH DESIGNED AND DELIVERED COURSES

1	I always follow course announcements and notifications through LMS
2	I know about the course description through LMS
3	I know about assessment methods and policies through LMS
4	I get to know the course lecturer through LMS
5	I know required activities and assignments in advance and submit them through LMS
6	I know my grades from the LMS
7	I found extra materials provided in the LMS very useful
8	I can discuss with my lecturer about any topic in the course through LMS
9	I can share documents with my classmates through LMS
10	I found email service through the LMS very useful
11	I can express my opinion about the course and the lecturer through questionnaires made available through LMS
12	I attend some online lectures in a synchronous mode through the LMS
13	I do online exams through the LMS
14	I struggle sometimes to access LMS due to poor Internet connectivity
15	There are no designated areas or labs to use LMS inside campuses
16	My ICT competencies are not good enough to use the LMS and its tools
17	Trainings to use LMS and its tools for students are rarely provided
18	There is shortage in the awareness about the usefulness of LMS and its tools
19	There is shortage in providing technical support to students when needed
20	It is difficult to use and deal with the LMS and its tools
21	I believe that the LMS is not sufficient enough in terms of its capabilities
22	Instructors are not prepared or good enough to use the LMS
23	Delivered materials through the LMS are with low quality
24	I believe that learning through LMS makes the learning process much easier
25	I do not want to attend training courses that show me how to use the LMS effectively
26	I enjoyed learning my courses through the LMS
27	Discussions with my classmates through the LMS are less effective and less valuable
28	I can express myself freely through the activities conducted through the LMS
29	Learning through the LMS motivates me to learn more
30	I prefer to use and access learning content provided through the LMS than any other options
31	I am able to lean whenever and wherever I want once the learning content is made available through the LMS
32	Learning through the LMS reduces the interaction between students and lecturers inside classrooms
33	I will recommend to my classmates to study courses that are provided through the LMS
34	I believe that learning through LMS provides me with the opportunity to think critically and reach conclusions
35	Courses that are provided through the LMS are more interesting than other traditionally delivered courses
36	I believe that learning through LMS allows me to be more innovative
37	I feel that learning through the LMS requires advanced skills that I do not have
38	I believe that I will achieve great success if I continue studying all my courses through the LMS
39	Learning through the LMS increases the social bonding with my classmates
40	I am totally satisfied with my experience of learning some courses through the LMS

Implementation of Machine Learning Classification Algorithm Based on Ensemble Learning for Detection of Vegetable Crops Disease

***Abstract*—In India, plant diseases pose a significant threat to food security, requiring precise detection and management protocols to minimize potential damage. Research introduces an innovative ensemble machine learning model for precise disease detection in tomato, potato, and bell pepper crops. Utilizing transfer learning, pre-trained models such as MobileNet and Inception are fine-tuned on a dataset of over 10,403 images of diseased and healthy plant leaves. The models are combined into a diverse ensemble, enhancing the precision and robustness of disease detection. The proposed ensemble models achieve an impressive accuracy rate of 98.95%, demonstrating their superiority over individual models in reducing misclassification and false positives. This advancement in plant disease detection provides valuable support to farmers and agricultural experts by enabling early disease identification and intervention.**

Keywords—DNN; transfer learning; crop; ensemble model; deep stacking and stacking approach; image pre-processing; tomato; bell paper; potato; disease

I. Introduction

In recent years, machine learning techniques have demonstrated significant potential in the field of plant disease detection [1]. This study introduces an innovative ensemble model that surpasses traditional approaches. This novel ensemble model combines several pre-trained models, including MobileNet, Inception, and ResNet, using a comprehensive dataset [2]. The primary objective of the model is to enhance the accuracy and resilience of conventional disease detection methods. This paper offers a thorough examination of the proposed model, elucidating its intricacies, and presents experimental results demonstrating its effectiveness in detecting plant diseases in tomato, bell pepper, and potato crops. In India, tomato, potato, and bell pepper are vital crops that make substantial contributions to the country's agricultural economy. However, these crops are vulnerable to various diseases that pose a significant threat to their yield. Notable tomato diseases in India include Spider mites, specifically the Two-spotted spider mite, Tomato mosaic virus, Target spot, Septoria leaf spot, Tomato Yellow Leaf Curl Virus, Late blight, Leaf Mold, Early blight, and Bacterial spot [3]. In contrast, potato crops are susceptible to fungal diseases like Early blight and Late blight, while bell pepper crops face the threat of bacterial spot disease. These collective diseases lead to substantial decreases in crop yield and quality, resulting in economic hardships for farmers [4]. The Deep Stacking ensemble technique, as depicted in Fig. 1, involves training a set of base models and using their predictions as input for a higher-level advanced model. This advanced model, positioned at a higher level, is trained to merge the predictions derived from the base models, resulting in a final prediction. This approach has demonstrated its ability to enhance the accuracy and resilience of models. Nevertheless, the proposed ensemble model surpasses both of these methodologies in terms of accuracy.

Plant diseases pose a significant menace to global agricultural output and food security. The precise and early detection of plant diseases is of paramount importance for effective disease management and the mitigation of crop losses. This research paper introduces a comprehensive methodology for detecting diseases in three pivotal plant species: potato, tomato, and bell pepper. These crops play vital roles in global food production but are susceptible to a wide range of diseases that can significantly impact yield and quality. The proposed model leverages ensemble learning, deep stacking, and transfer learning, employing well-established convolutional neural network architectures, including MobileNe_v2, ResNet_v2, and Inception_v3 models. Ensemble learning enables the combination of multiple models, harnessing their diverse capabilities to enhance overall detection accuracy and robustness [5]. Deep stacking allows the capture of intricate interactions among the predictions of different models, thereby improving disease classification performance. Transfer learning plays a crucial role in the methodology. By leveraging pre-trained models trained on extensive image datasets like ImageNet, Proposed model can utilize their learned features and representations, which are transferable to various visual recognition tasks. Fine-tuning these models on plant disease dataset enables us to adapt their knowledge specifically to the challenges of disease detection in potato, tomato, and bell pepper plants. The objective of the model is to develop an automated and accurate disease detection system tailored to these specific plant species by harnessing the power of machine learning techniques, particularly ensemble learning and deep stacking. The significance of this work lies in its potential to elevate disease management practices within agriculture. By enabling early disease detection, farmers and agricultural experts can swiftly implement precise treatments and crop protection strategies, thereby minimizing the adverse effects of diseases on both crop yield and quality.

Within this research paper, an elaborate exposition of the employed methodology is provided, encompassing the application of ensemble learning and deep stacking techniques using transfer learning models like MobileNet_v2, ResNet_v2, and Inception_v3. The assessment of performance is discussed, exploring practical implications of the proposed model's disease detection system in real-world agricultural contexts, and shedding light on prospective avenues for future research to enhance the system. Ultimately, this research aims to contribute to the advancement of automated disease detection systems in agriculture, with a specific focus on potato, tomato, and bell pepper plants. By harnessing the power of ensemble learning, deep stacking, and transfer learning, the aim is to improve disease management practices, increase crop productivity, and ensure food security in the face of plant diseases.

II. Related Work

First, Tulshan et al. [1], the authors presented a study on the detection of various plant leaf diseases. They focused on detecting diseases such as Early Blight, Mosaic Virus, Down Mildew, White Fly, and Leaf Miner. The authors achieved a high accuracy of 98.56% with their proposed K-Nearest Neighbors (KNN) model. This model was trained on a dataset consisting of 75 images. Furthermore, they compared the performance of their KNN model with a basic Support Vector Machine (SVM) model, which was trained on a larger dataset of 150 images. The SVM model achieved an accuracy of 97.6%.This research highlights the effectiveness of the KNN model in accurately detecting plant leaf diseases with a relatively smaller training dataset, outperforming the SVM model trained on a larger dataset. Ramesh et al. [6], the authors addressed the issue of detecting and classifying Rice Blast disease. Their approach utilized an Artificial Neural Network (ANN) algorithm. The training phase of their model achieved an accuracy of 99%, while the testing phase yielded a respectable accuracy of 90%.The authors gathered a dataset consisting of 300 images. These images were subjected to preprocessing steps, which involved conversion to the HSV color space and subsequent K-means clustering. It's worth noting that the dataset used in this research was their own, emphasizing the unique contribution of their work in the context of Rice Blast disease detection and classification. Lee et al. [7], conducted research on disease detection in potato leaves, specifically targeting Potato Early Blight and Late Blight. They employed Convolutional Neural Networks (CNN) as their chosen algorithm, achieving an impressive accuracy rate of 99.09% in their experiments. The authors collected and utilized a dataset comprising 2150 images for their research. Furthermore, they conducted a comparative analysis by evaluating CNN against other machine learning algorithms such as Artificial Neural Networks (ANN), Backpropagation Neural Networks (BPNN), K-Nearest Neighbors (KNN), Support Vector Machines (SVM), among others. The results, presented in a table, demonstrated that the CNN model outperformed all other algorithms, yielding the highest accuracy of 99.09%.This survey provides valuable insights into the effectiveness of CNN in the detection of Potato Early Blight and Late Blight diseases in potato leaves, showcasing its superiority over various alternative methods.Asifet.al. [8],the authors explored various Convolutional Neural Network (CNN) architectures, including AlexNet, VggNet, ResNet, LeNet, and a Sequential model, for the detection of diseases on potato leaves. The specific diseases targeted were early blight, late blight, and Septoria blight. Their research achieved an accuracy rate of 97.00% in disease detection. To support this, they used a dataset containing 3000 images and employed a basic CNN approach, which involved image processing techniques and data augmentation to enhance training. It's worth noting that the training process for this model was conducted manually, underscoring the meticulous effort and expertise invested in the research. This study provides valuable insights into the application of various CNN architectures for effective disease detection on potato leaves, showcasing a high level of accuracy in identifying these plant diseases. Tembhurne et al. [9], the authors conducted research on the detection of plant diseases, specifically focusing on early blight and late blight. Their study utilized two deep learning models, namely AlexNet and GoogLeNet, as image classifiers. They evaluated the performance of these models on five key parameters: Accuracy, Precision, Sensitivity, F1 score, and Specificity. To support their research, the authors employed a dataset containing 900 images. The experimental outcomes showcased a remarkable 98.52% accuracy in identifying various plant diseases. Notably, the research was carried out on Kaggle, a widely recognized platform for data science and machine learning competitions and collaborative projects. This investigation offers valuable perspectives on the efficacy of deep learning models such as AlexNet and GoogLeNet in the realm of plant disease detection, highlighting their high accuracy and the use of comprehensive evaluation metrics. Naveen kumar et al. [10], the authors focused on the classification of plant diseases, specifically targeting early blight and late blight. For their research, they employed the InceptionResNetV2 model, achieving a commendable accuracy rate of 95.30%. To support their findings, the authors conducted a comparative analysis with other deep learning architectures, including VGG (16 and 19), ResNet 50, and InceptionV3. Interestingly, their results revealed that InceptionResNetV2 outperformed these models, showcasing a superior accuracy rate of 95.3%.It's worth noting that the dataset used in this research was proprietary, emphasizing the unique contribution of their study in the field of plant leaf disease classification. This research underscores the effectiveness of InceptionResNetV2 as a robust model for accurate and reliable plant disease classification. Kukreja et al. [11], the authors addressed the challenge of potato disease classification, specifically focusing on Potato Early Blight and Late Blight, their approach employed a simple CNN based deep learning model. Through their research, they achieved a notable accuracy rate of 94.77%. The authors not only discussed basic classification results but also provided insights into classification metrics such as F1 score and recall. This study was conducted using a dataset consisting of 900 images and were part of the Plant Village project, emphasizing its contribution to the broader field of plant disease classification. The research highlights the effectiveness of their CNN-based model in accurately classifying potato diseases, particularly Early Blight and Late Blight. Tiwari et al. [12], the authors tackled the challenge of detecting potato leaf diseases, specifically focusing on Potato Early Blight and Late Blight. Their research introduced a novel approach by proposing a VGG19-based model. This model utilized VGG19 as a feature extractor, building upon the CNN architecture. In their experiments, the authors compared the performance of their VGG19-based model with VGG16 and Inception models. The dataset used for their study consisted of 2152 images, and their approach yielded an impressive accuracy rate of 97.80%. This research was conducted as part of the Plant Village project, emphasizing its contribution to the field of plant disease detection. The study underscores the effectiveness of their VGG19-based model in accurately detecting Potato Early Blight and Late Blight in potato leaves. Sinshaw et al. [13], the authors addressed the task of detecting Potato Late Blight disease. They employed three pre-trained CNN models, namely VGG16, VGG19, and InceptionV3, to explore the potential of transfer learning and data augmentation in disease detection. The results of their experiments demonstrated varying levels of accuracy among the three models. InceptionV3 emerged as the top-performing model, achieving an accuracy rate of 94.11%. In comparison, VGG16 achieved an accuracy of 93.2%, and VGG19 achieved 92.9%. These findings indicated that InceptionV3 outperformed VGG16 and VGG19 in detecting Potato Late Blight disease. The authors conducted their research using a dataset comprising 430 images, and it's noteworthy that the dataset was developed in-house, emphasizing the unique contribution of their study. This research highlights the effectiveness of transfer learning and data augmentation techniques, particularly when applied to the InceptionV3 model, in accurately detecting Potato Late Blight disease. Lakshmanarao et al. [14], the authors focused on predicting and classifying plant diseases, particularly within 15 classes encompassing Tomato, Pepper, and Potato. Their research employed ConvNets as the primary methodology. The study produced impressive accuracy rates for disease prediction and classification, with a notable 95% accuracy for Tomato, 98.5% for Bell Pepper, and 98.3% for Potato. To support their findings, the authors worked with a substantial dataset comprising 20,638 images. This research was conducted as part of the Plant Village project, underlining its valuable contribution to the field of plant disease prediction and classification. The study emphasizes the effectiveness of ConvNets in achieving accurate disease identification within the Tomato, Pepper, and Potato plant categories. Karthik et. al. [15], the authors focused on predicting diseases in Tomato and Potato plants and their potential health benefits. Their research utilized a basic CNN approach, involving feature extraction and CNN model generation. This approach yielded a high accuracy rate of 98% in disease prediction for Tomato and Potato plants. The study was conducted as part of the Plant Village project, emphasizing its contribution to the field of plant disease prediction and its potential impact on the health benefits associated with these plants. The research underscores the effectiveness of their CNN-based deep learning techniques in accurately predicting diseases in Tomato and Potato plants.

Crop sustainability and food security pose pressing challenges in agricultural development. The early detection of plant diseases holds paramount importance in addressing these challenges. This study focuses on three crucial plant species: potato, tomato, and bell pepper, which are integral components of the global diet. It addresses the detection of seven different types of diseases. Plant diseases have garnered increasing attention in recent years, posing a significant threat to food security in India and around the world. Detecting these diseases demands expertise, time, and substantial human effort, as it requires proficiency in disease identification. Early disease detection is critical for minimizing damage and increasing crop yields, with far-reaching implications for the global economy. To tackle this issue, a novel ensemble model for plant disease detection is proposed in this research. This model leverages the capabilities of MobileNet, Inception, and ResNet models, which have been pre-trained on extensive image datasets, making them ideal for feature extraction in the proposed framework.

In this research, ensemble learning technique for vegetable leaves disease detection is implemented in the Google Colab environment, which utilizes GPU and TPU. The dataset comprises 10,403 images collected from primary sources and PlantVillage. Diverse image pre-processing methods, encompassing techniques like augmentation, Canny edge detection, noise reduction, and others, are utilized to extract distinctive features from images of plant leaves. Furthermore, implement transfer learning algorithm and then design Ensemble learning Algorithm. Their performance on various evaluation metrics, such as accuracy, f1-score, recall, and precision, is compared. These results are then compared with those obtained from the proposed ensemble model.

While the studies discussed have made significant contributions to plant disease detection, they also exhibit certain limitations that make them less suitable for our problem. For instance, the models proposed by Tulshan et al. [1], Ramesh et al. [6], and Lee et al. [7] were trained on relatively small datasets, which may limit their generalize ability to larger, more diverse datasets. The models used by Asif et al. [8] and Sinshaw et al. [13] demonstrated varying levels of accuracy, indicating a lack of consistency in their performance. Furthermore, the models employed by Naveenkumar et al. [10] and Kukreja et al. [11] were trained on proprietary datasets, which may limit the reproducibility of their results. Our proposed ensemble machine learning model addresses these limitations by leveraging the strengths of multiple pre-trained models and fine-tuning them on our extensive dataset. This approach enhances the precision and robustness of disease detection, making it more suitable for the problem at hand.

III. Proposed Model

The proposed model for this research is an ensemble machine learning model that integrates three deep neural network models: MobileNet, Inception, and ResNet. The choice of these models is motivated by their proven effectiveness in image classification tasks, their ability to handle large datasets, and their robustness to variations in disease presentation. By leveraging transfer learning, these pre-trained models are fine-tuned on our extensive dataset of diseased and healthy plant leaves, allowing them to capture intricate patterns and features specific to each disease. The ensemble approach strategically combines the strengths of individual models, enhancing the precision and robustness of disease detection. This methodology represents a significant advancement in the field of plant disease detection, providing valuable support to farmers and agricultural experts by enabling early disease identification and intervention.

A. Proposed Algorithm

Step 1: First load the acquired data using the imread() method present in CV2:

Step 2: Segment the data into training and testing Sets: from tensorflow.keras.preprocessing.image import ImageDataGenerator

train_datagen = ImageDataGenerator (rescale=1/255,shear_range=0.2, zoom_range=0.2,

horizontal_flip=True, validation_split=0.1)

Step 3: Normalize the data to remove anomalies

Step 4: Perform data augmentation to make the model robust:

To perform edge detection: cv2.Canny(img, 100, 200)

To flip the image: cv2.flip(img, 0)

To blur the image: cv2.blur(img, (20, 20))

For convolution kernel = np.ones((7, 7), np.float3

conv = cv2.filter2D(img, -1, kernel)

Step 5: Implement Transfer learning, with models like MobileNet, Inception, ResNet

feature_extractor_model="https://tfhub.dev/google/imagenet/inception_v3/classification/5"pretrained_model_without_top_layer=hub.KerasLayer(feature_extractor_model,input_shape=(224, 224, 3), trainable=False)

similarly, used mobile net and ResNet models

Step 6: During this process evaluate all the models separately, using a confusion matrix, and compared their results using the respective recall, precision, and f1-scores.

Step 7: Combine the power of all the transfer learning models by using the ensemble learning technique used a deep stack library to combine the above models. Next, two classifiers, namely Random Forest Classifier and Extra Trees Classifier, are specified as estimators for the second-level meta-learner. The meta-learner is the model responsible for amalgamating the predictions generated by the base models. It accepts the outputs or predictions from these base models as inputs and adapts its learning based on them how to best combine them to produce an improved prediction or decision and this is done using random forest.

Step 8: The evaluation measures to proposed model to compare it with the above models.

B. Data Collection

The foundation of the suggested plant disease detection model primarily relied on a dataset containing ten distinct classes. This dataset was derived from both Plant Village and a primary source. To facilitate for both the training and testing phases of the proposed model, a dataset was divided, allocating 80% for training and 20% for testing.

A thorough depiction of the dataset employed in this study is available in Table I.

TABLE I. DETAILS OF DATA SET USED FOR PROPOSED MODEL TRAIN AND TEST PURPOSE

S. No.	**Crop Name**	**Disease**	**Test Image Data Set**	**Train Image Data Set**
1	Pepper bell	Pepper bell Bacterial Spot	201	697
2	Pepper bell	Pepper bell Healthy	297	1034
3	Potato	Potato Late Blight	60	300
4	Potato	Potato Healthy	31	106
5	Potato	Potato Early Blight	60	300
6	Tomato	Tomato Spider Mites	336	1173
7	Tomato	Tomato Bacterial Spot	437	1488
8	Tomato	Tomato Leaf Mold	191	666
9	Tomato	Tomato Septoria Leaf Spot	355	1239
10	Tomato	Tomato Healthy	319	1113

C. Pre-Processing

Data preprocessing is a pivotal phase in machine learning that readies raw data for analysis and model training. It heightens the quality and dependability of machine learning models by eliminating noise, rectifying errors, and converting data into a format that aligns with the model's requirements. In the context of colored images, data preprocessing is even more important due to the complex nature of image data.

- Noise removal: Colored images frequently exhibit noise, which can pose challenges for machine learning models in extracting features and achieving precise predictions. Data preprocessing techniques such as Gaussian blurring and median filtering can be used to remove noise from images, improving the performance of machine learning models.

- Color space conversion involves representing colored images in various color spaces, such as RGB, HSV, and YCbCr. Different color spaces have different properties, and some color spaces may be better suited for a particular machine-learning task than others. Data preprocessing techniques can be used to convert images from one color space to another, making it easier for machine learning models to learn from the data.

- Image resizing: Machine learning models often require images to be a certain size. Data preprocessing techniques can be used to resize images to the correct size, improving the performance of the model.

D. Data Normalization

Effective data normalization is a pivotal step in data preprocessing, significantly improving the accuracy of models for crops image disease detection. This involves both scaling and standardizing the input data. For three-channel (RGB) images, as depicted in Fig. 2, the usual procedure entails calculating mean values for the RGB (Red, Green, and Blue) channels across the entire image dataset, often utilizing list comprehension. Notably, the red channel values demonstrate concentration towards lower values and a slight positive skew. Conversely, the green channel values appear more evenly distributed, featuring a prominent peak around 135, indicating a higher prevalence of green in these images. Lastly, the blue channel values exhibit the highest level of uniformity with minimal skew, but they display notable variation among images.

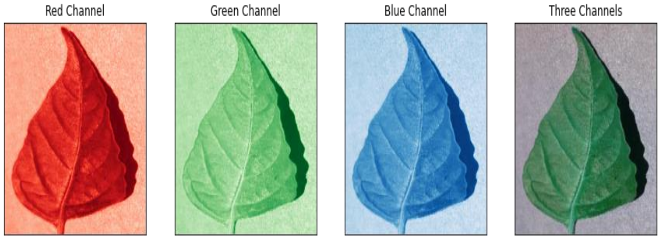

Fig. 2. RGB (Red, Green, and Blue) channels of leaves image.

E. Image Processing

1) First, resize all the images to 224x224 pixels: Using cv2.resize() and creating numpy arrays, these numpy arrays can be employed for exploratory data analysis. When working with three-channel (red, blue, green) images in a dataset, data normalization becomes a crucial step in data pre-processing. To avoid potential issues with unnormalized data, normalization should be performed for each channel separatelyas depicted in Fig. 3. This approach reduces the impact of outliers or extreme values in the data, thereby enhancing the overall model performance.

2) Canny Edge Detection as shown in Fig. 4 is a prominent tool in image pre-processing that helps define the boundary of objects in an image. This efficient technique reduces noise in an image by allowing us to focus on the objects inside the specified boundary [16].

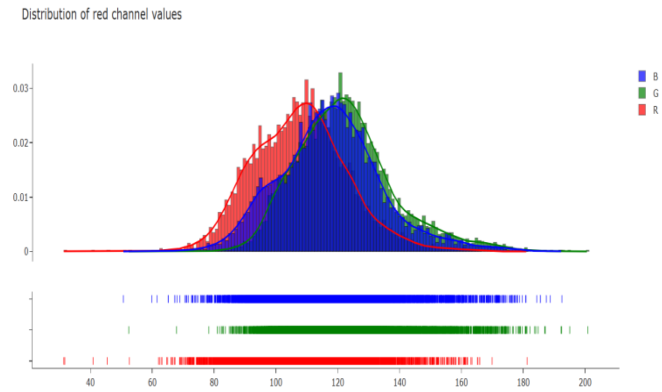

Fig. 3. RGB (Red, Green and Blue) distribution channel value.

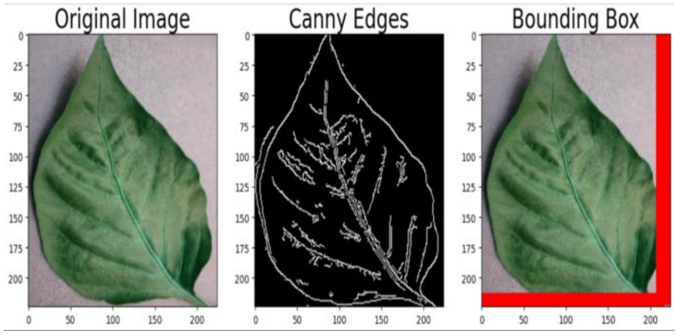

Fig. 4. Canny edge detection image.

3) Further transformations are applied, such as flippingas shown in Fig. 5, which involves reversing the rows and columns to achieve horizontal and vertical flipping. [16].

Image=A_{ijk}

Horizontal flip:$A_{ijk} \rightarrow A_{i(n+1-j)k}$

Vertical flip:$A_{ijk} \rightarrow A_{(m+1-i)jk}$

Although flipping maintains the same structure and features, a more diverse dataset can be created using this augmentation.

4) Convolution is another augmentation technique that performs a basic mathematical operation, in this a 2-D matrix window(kernel) moves across the length and breadth of the images shown in Fig. 6. It can be called a sunshine effect; this helps in building a robust and accurate model.

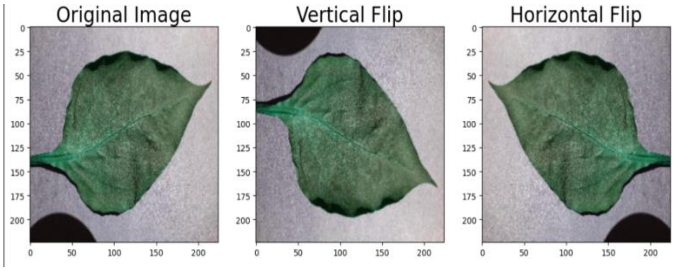

Fig. 5. Flip image.

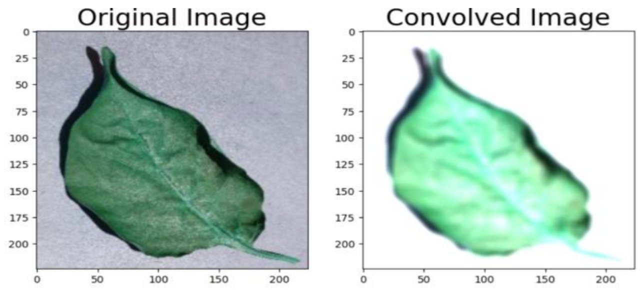

Fig. 6. Convolved image.

F. Proposed Ensemble Model

To create a deep ensemble model using the Dirichlet Ensemble class from the deep stack library, the process begins with the importation of the Keras Member class from deep stack library’s base module. This class is instrumental in creating ensemble members from Keras models. Subsequently, three members are generated for the ensemble, with each one aligned to a fine-tuned pre-trained model. Each member is equipped with its corresponding pre-trained model, and data generators are customized for both the training and validation datasets. This methodology simplifies the generation of ensemble members trained on identical data, sharing a common architecture while having distinct initial weights. Following the successful creation of these ensemble members, the Dirichlet Ensemble class is then employed to establish and train the ensemble model using the train() method.

To accomplish this task, the necessary modules for constructing a stacked ensemble model are imported. These include the StackEnsemble class from the deep stack library and the ensemble module from scikit-learn, which houses the base learners and the stacking classifier.

Specifically, import the following:

- sklearn: The scikit-learn module.
- StackEnsemble: The StackEnsemble class from the deep stack library for creating the stacked ensemble model.
- RandomForestClassifier: A base estimator from the sci-kit-learn ensemble module.
- ExtraTreesClassifier: Another base estimator from the sci-kit-learn ensemble module.
- StackingClassifier: A meta-estimator from the sci-kit-learn ensemble module for stacking the base learners.
- LogisticRegression: A logistic regression classifier for the meta-learner in the stacking classifier.

The mentioned modules and classes can be employed to construct a stacked ensemble model, which consolidates predictions from multiple base learners through a meta-learner. The base estimators encompass a diverse range of machine learning algorithms, including decision trees, support vector machines, and neural networks. In the realm of deep stacking, the base learners frequently consist of deep neural networks trained on the same dataset with varied architectures or hyper parameters.

As illustrated in Fig. 7, the meta-learner serves as a dedicated machine learning algorithm, aiming to learn the optimal combination of predictions from base learners to enhance overall model performance. In the context of deep stacking, the meta-learner often takes the form of a simple linear model, such as logistic regression or a neural network. This meta-learner is fed with predictions from the base learners as input and gains the ability to assign weights, ultimately producing the final prediction.

In the final stage of our ensemble model, a weighted average approach is employed. This approach assigns different weights to the predictions made by each base learner in the ensemble. The weights are determined by the meta-learner based on the performance of each base learner during training. This means that predictions from more accurate base learners are given more importance in the final prediction. The use of a weighted average ensures that our ensemble model leverages the strengths of each individual model, leading to a more robust and accurate prediction.

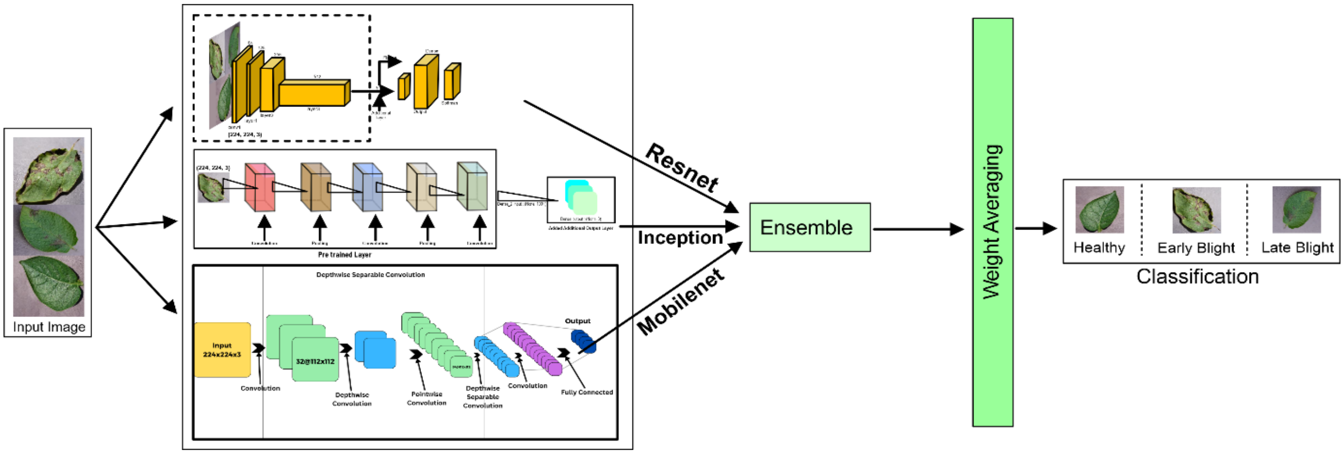

Fig. 7. Proposed model layer weighting average.

G. *Proposed Model Training*

All the member models are being compiled using the compile() function takes several arguments:

- Optimizer: specifies the optimizer algorithm used during training.
- Loss:designates the loss function employed during training, which quantifies the disparity between predicted and actual outcomes.
- Metrics: specifies the evaluation metric(s) that will be used to measure the model's performance during training.

All the member models are being fitted using the fit() function:

- Train generator refers to the input data generator responsible for producing batches of training data
- The batch size defines the quantity of samples utilized per gradient update throughout training, which has been set to 32.
- Validation data is the input data generator that generates batches of validation data.
- Validation steps specify the number of validation steps to evaluate the model after each epoch, which is 2
- Verbose is a flag that controls the level of logging during training. A value of 1 means that progress will be displayed during training.
- The model is trained using 10 epochs.

IV. Results and Discussions

A. *Model Training and Evaluation*

To access the efficacy of the proposed disease detection model in comparison to established counterparts, an evaluation was undertaken on a comprehensive dataset featuring images of diseased plants. This dataset encompassed ten distinct diseases across three plant species: potato, tomato, and bell pepper. The consistent outcomes of these experiments underscore the superior performance of the suggested model in disease detection accuracy when contrasted with other existing models. In direct comparison to individual transfer learning models, the ensemble approach coupled with deep stacking techniques exhibited remarkable performance, achieving higher precision, recall, and F1 scores. This heightened accuracy can be attributed to the synergistic effect of ensemble learning and deep stacking, enabling the model to capture and leverage diverse patterns and features associated with diseases in the targeted plants. Moreover, the proposed model showcased enhanced robustness, resulting in a diminished risk of misclassification and false positives when compared to other models. The effectiveness of the proposed model in early disease identification underscores its potential for real-world applications in supporting farmers and agricultural experts. By facilitating timely interventions and early-stage disease management, the proposed model has the capacity to contribute significantly to improved crop yields, minimized losses, and enhanced food security.

1) MobileNet: Based on Fig. 8, which illustrates Accuracy vs Epoch, it can be inferred that the model performs admirably shortly after 10 epochs. Notably, the accuracy of both Training and Validation sets exhibits minimal disparity, indicating robust model performance. The peak training accuracy stands at 97.4%, while the validation accuracy reaches 96.4%.

Fig. 9 provides insight into loss vs epochs. In this graph, both the training and validation losses undergo a sharp decrease after 10 epochs. The minimum loss values are achieved, with Training at 7.0% and Validation at 9.0%.

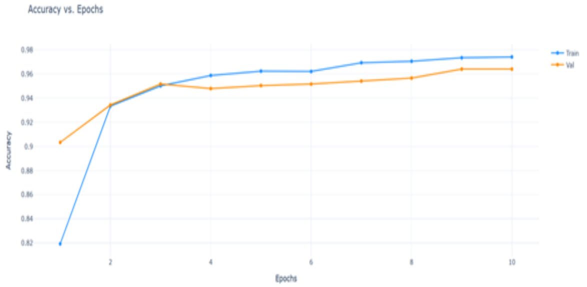

Fig. 8. Accuracy graph of mobilenet model.

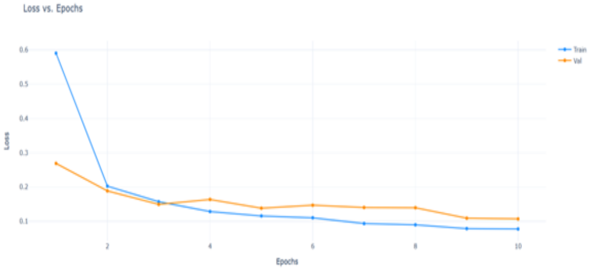

Fig. 9. Loss vs. Epochs mobilenet.

2) Inception: The accuracy vs epochs graph in Fig. 10 the peak training accuracy: 91.03% and validation:90.2% accuracy, with a high jump in accuracy just after 10 epochs loss vs epochs which are shown in Fig. 11 the rapid fall in the losses of training and validation data and with the having losses of 25% and 28% for training and validation respectively.

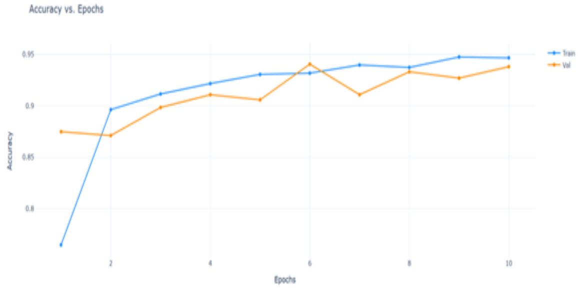

Fig. 10. Accuracy graph of inception model.

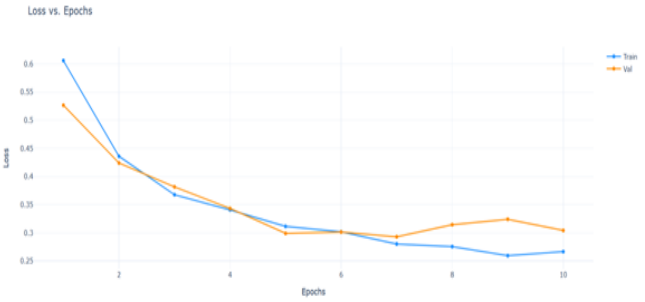

Fig. 11. Loss vs. Epochs of inception model.

3) ResNet: In Fig. 12, the accuracy vs. epochs plot reveals that within the first 2 epochs, there is a substantial increase in accuracy, ultimately reaching 94.66% for training and 94.05% for validation by the 10th epoch.

Fig. 13 displays the losses vs. epochs plot, where it is evident that low losses are achieved after 10 epochs for both Training and Validation. Specifically, Training records a 15.2% loss, while Validation exhibits a 15.3% loss after 10 epochs.

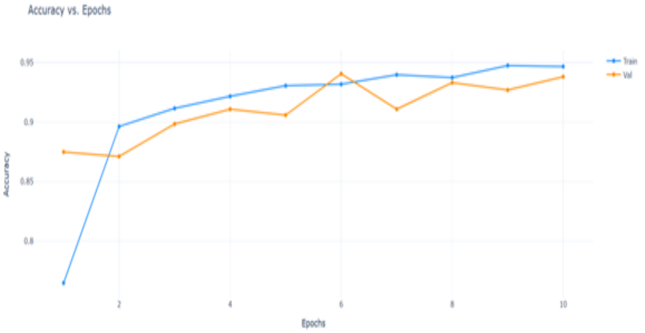

Fig. 12. Accuracy graph of resnet model.

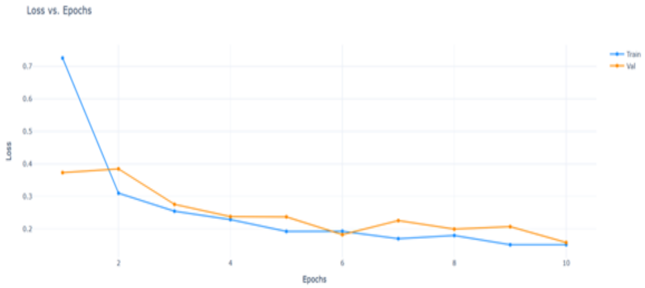

Fig. 13. Resnet Loss vs. Epoch graph of resnet model.

4) Proposed model: In Fig. 14, the accuracy vs. epochs plot illustrates that after 10 epochs, there is a significant increase in accuracy. By the 10th epoch, the accuracy reaches 94.66% for training and 94.05% for validation.

Fig. 15 depicts the plot of losses vs. epochs. As observed, low losses are achieved after 10 epochs for both Training and Validation. Specifically, Training records a 15.2% loss, while Validation exhibits a 15.3% loss after 10 epochs.

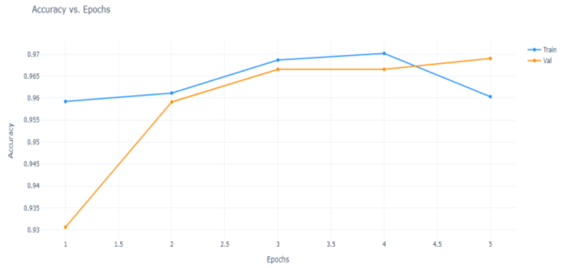

Fig. 14. Accuracy graph of proposed model.

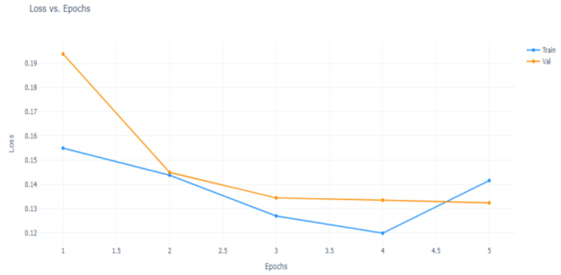

Fig. 15. Loss vs. Epoch graph of proposed model.

B. Performance Analysis

The experiments were carried out using the Keras framework and Tensor Flow-GPU on Google Colab. To gauge the effectiveness of the proposed methodology, various metrics, including accuracy, precision, F-score, recall, and loss, were employed.

Accuracy, encompassing both positive and negative classes, was computed to provide insights into the model's proficiency in categorizing images accurately. Precision, recall, and F-score were utilized to offer additional insights into the model's capacity to accurately predict both positive and negative classes.

1) CNN confusion matrix: In Fig. 16 the confusion matrix there are few classes which have been mispredicted significantly, such as Tomato Spider mites has been predicted Tomato healthy 58 times, therefore impacting the accuracy and precision also there is some mispredictions between the species since pepper bell bacterial spot has been predicted as Tomato Spider mites 16 times and rest there were some misclassifications between the tomato species. The weighted average f1 score was 0.9.

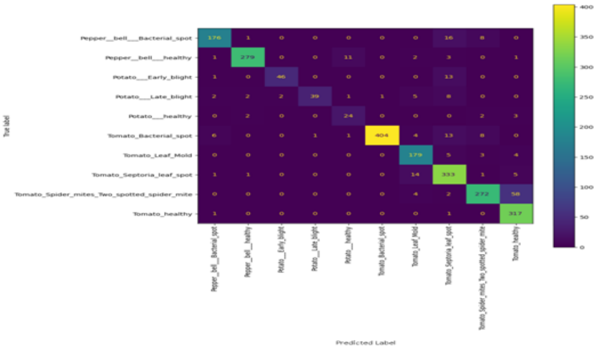

Fig. 16. Confusion matrix representation of the CNN model.

2) Confusion Matrix MobileNet: In Fig. 17 the confusion matrix there are a few classes that have been miss predicted slightly, such as Tomato Septoria Leaf has been predicted Tomato Bacterial Spot 17 times, and pepper bell healthy has been predicted as pepper bell bacterial spot 12 times and rest of misclassifications were less than four times. Therefore, the mispredictions were significantly less than the CNN model indicating higher accuracy and hence its weighted average f1 score was 0.96.

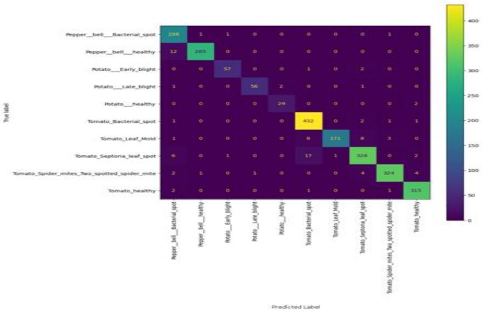

Fig. 17. Confusion matrix representation of the mobilenet model.

3) Confusion matrix inception model: Inception Models in Fig. 18 the confusion matrix some high misclassifications in Tomato Septoria and Tomato Spider mite classes with misclassifications ranging from 3-54 times. And from the above model's confusion matrix it can be inferred that these two classes are most difficult to predict. The inception model has been predicting other classes accurately like the mobile net model but these two classes namely Tomato Septoria and Tomato Spider mite where mispredicted significantly thereby impacting the models weighted average f1 score which comes out to be 0.9.

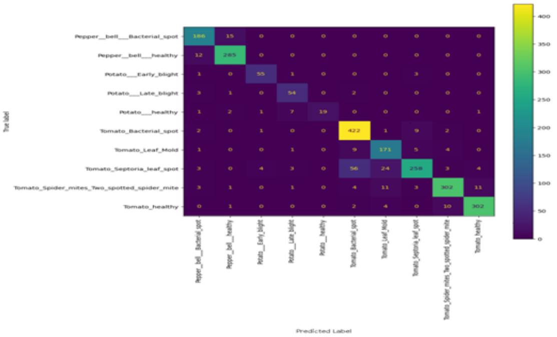

Fig. 18. Confusion matrix representation of the inception model.

4) Confusion matrix resnet model: In Fig. 19 confusion matrix shows some high misclassifications in Tomato Bacterial Spot and Tomato Leaf mold classes, which is different from the above models as they have been misclassifying some other classes and have been classifying these classes correctly. But the rest of the classes are correctly predicted and the mispredictions are less than equal to four times. Therefore, the weighted F1 score is 0.94 of the inception models.

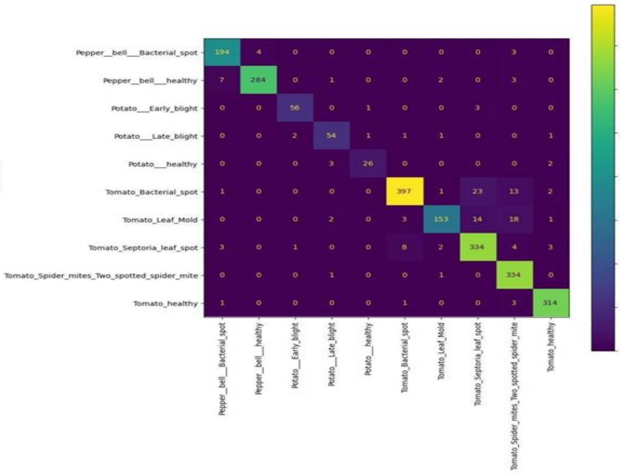

Fig. 19. Confusion matrix representation of the resnet model.

5) Confusion matrix proposed ensemble model: In Fig. 20 the proposed ensemble Model's confusion matrix showed much fewer misclassification than any of the above models. Only two classes Tomato Bacterial spot and Tomato Leaf Mold were wrongly predicted into some other tomato diseased classes and that too only 15 and 12 times respectively, However, apart from these instances, the majority of mispredictions were limited to two or fewer, underscoring the proposed model's superior performance in comparison to the aforementioned models across nearly all classes. The weight average F1 score, precision and recall are 0.97 greater than all the above models, showing its state-of-the-art performance.

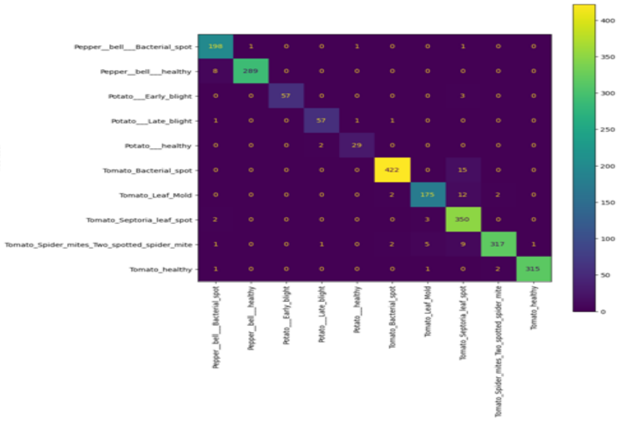

Fig. 20. Confusion matrix representation of the proposed ensemble model.

C. Comparative Analysis of Various Machine Learning Models with Proposed Model

Table II displays the outcomes derived from various models, each utilizing 10,403 images and undergoing 10 epochs for both training and validation. The results suggest that the Stack Ensemble model outperforms other models in terms of accuracy. Fig. 21. Show Comparative analysis of Obtained Results from the MobileNet, Inception, ResNet Models with Proposed Ensemble Model and Fig. 21 shows comparative analysis of proposed work with related Model.

TABLE II. OBTAINED RESULTS FROM THE DIFFERENT TECHNIQUES

Model	Images set	Classes of disease	Epoch	Validation Accuracy
CNN	10,403	10	10	90.05%
MobileNet	10,403	10	10	95.90%
Inception	10,403	10	10	89.91%
ResNet	10,403	10	10	93.80%
Stack Ensemble	10,403	10	10	97.86%
Dirichlet Ensemble	10,403	10	10	97.80%
Proposed Model	10,403	10	10	98.95%

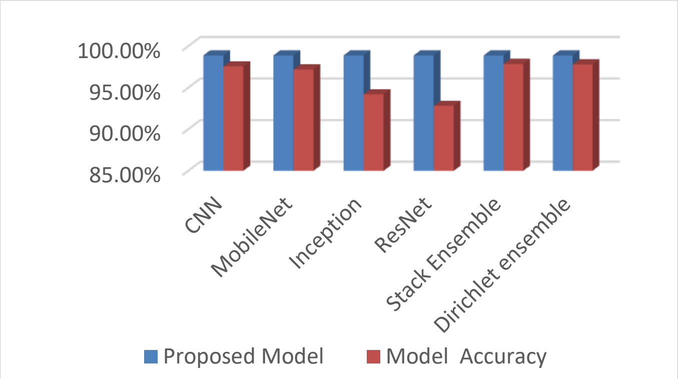

Fig. 21. Comparative analysis of obtained results from the different machine learning models with the proposed model.

V. CONCLUSION

The timely and precise detection and diagnosis of plant health issues play a pivotal role in ensuring global food production. This study offers a comprehensive evaluation of a plant health assessment system specifically designed for potato, tomato, and bell pepper plants. Through extensive experimentation and comparative analysis against existing models, the study emphasizes the exceptional performance of the proposed model in accurately identifying and categorizing plant health issues. The model has undergone training on a dataset containing 10,403 images. By adopting a combined approach that incorporates ensemble learning and deep stacking techniques, the model consistently outperforms individual transfer learning models. The model attains an outstanding accuracy rate of 98.95% in accurately identifying plant diseases. This notable enhancement can be credited to the synergistic collaboration of ensemble learning and deep stacking, enabling the model to discern and capitalize on diverse patterns and features linked to plant health issues in the specific crops. Additionally, the proposed model showcases improved reliability by reducing the risks of misclassification and false positives when compared to alternative models. This increased reliability holds particular significance in real-world applications, where the accurate and timely recognition of plant diseases is of paramount importance for farmers and agricultural specialists. The efficacy showcased by the proposed model in promptly identifying diseases underscores its potential to offer practical solutions for farmers. By enabling timely interventions and the management of diseases in their early stages, the model has the capacity to significantly enhance crop yields, mitigate losses, and contribute to overall food security. This research underscores the substantial benefits of the proposed plant health assessment model and highlights its potential for real-world implementation. The integration of advanced techniques, improved accuracy, and enhanced reliability positions the model as a valuable tool in the field of agriculture, empowering farmers and experts to make well-informed decisions and effectively address plant health concerns.

Revolutionizing Software Project Development: A CNN-LSTM Hybrid Model for Effective Defect Prediction

Selvin Jose G[1], Dr. J Charles[2]
Department of Computer Science, Noorul Islam Centre for Higher Education, Kumaracoil, Tamil Nadu, India[1]
Department of Software Engineering, Noorul Islam Centre for Higher Education, Kumaracoil, Tamil Nadu, India[2]

***Abstract*—Within the domain of software development, the practice of software defect prediction (SDP) holds a central and critical position, significantly contributing to the efficiency and ultimate success of projects. It embodies a proactive approach that harnesses data-driven techniques and analytics to preemptively identify potential defects or vulnerabilities within software systems, thereby enhancing overall quality and reliability while significantly impacting project timelines and resource allocation. The efficiency of software development projects hinges on their ability to adhere to deadlines, budget constraints, and deliver high-quality products. SDP contributes to these objectives through various means. This paper introduces a novel SDP model that harnesses the combined capabilities of Convolutional Neural Networks (CNNs) and Long Short Term Memory (LSTMs) unit. CNNs excel at extracting features from structured data, enabling them to discern patterns and dependencies within code repositories and change histories. LSTMs, conversely, excel in handling sequential data, which is pivotal for capturing the temporal aspects of software development and tracking the evolution of defects over time. The outcomes of the proposed CNN-LSTM hybrid model showcase its superior predictive performance. Simulation results affirm the substantial potential of this model to bolster the efficiency and reliability of software development processes. As technology advances and data-driven methodologies become increasingly prevalent in the software industry, the integration of such hybrid models presents a promising avenue for continually elevating software quality and ensuring the triumph of software projects. In summary, the utilization of this innovative SDP model offers a transformative approach to efficient software development, positioning it as a vital tool for project success and quality assurance.**

Keywords*—Data driven software development; proactive defect identification; software quality; predictive analytics; software defect prediction; artificial intelligence; long short term memory

I. INTRODUCTION

In the modern world, software plays an essential role in every aspect of our daily existence. It includes defense, automobile, healthcare, insurance, finance, banking, telecommunication, government administration sectors. In other words, the normal functionality of these sectors gets affected with the software failure. Technical and managerial issues are the two different issues normally emerge during the software development process. Thirty percent of project failures occur mainly due to technical issues and 70% are management issues [1]. Some of the problems related to managerial issues are insufficient risk management, customer buy-in, limited project resources and inaccurate project structure etc. However, low product delay, high expense, and schedule delay are the issues encountered during software program development. Prior to the analysis of software project risk, an efficient risk mitigation scheme should be developed by the program developer. Based on the accurate management of risk, the success of the project can be determined [2].

SDP is a crucial aspect of modern software development, aimed at improving the effectiveness and efficiency of software projects. In an era where software plays an increasingly pivotal role in our daily lives, organizations strive to deliver high-quality software products while minimizing the time and resources invested in debugging and maintenance. In this context, SDP emerges as an indispensable tool for the modern software development landscape, fostering both agility and the delivery of robust software products. Any fault, error, mistake, in a computer program, or a defect or bug in the software can cause unexpected or inaccurate results which are otherwise called a software defect. In order to enhance software quality, high-risk components must be detected as soon as possible [3].

Software defects can lead to an increase in both the cost and time required for delivering the expected end product. Also identification and rectification of defects is a highly waste of time and a costly software process [4]. One of the persistent challenges within the Software Development Lifecycle (SDLC) has been the ability to predict and identify defects during the initial phases of a project. In the current situation, development of a fault-free software which is highly reliable is a difficult task, as the problems for which software is developed is more complex and the domains that are involved are constantly increasing to constraints such as uncertainty and development processes that are complex [5].

At first, a collection of project data takes place from the software repositories. From the data, factors are calculated. The locations are predicted through models, which have a better potential for the defects contained. Ultimately, using prediction models, various measures are evaluated, such as precision, recall, and explanative power [6].

SDP using Deep Learning (DL) holds immense significance in the realm of software project development. In an era where software systems underpin virtually every aspect of modern life, ensuring their reliability and robustness is paramount. Deep learning methodology, leveraging their capacity to analyzes extensive datasets and detect subtle patterns, present a compelling approach for preemptively recognizing and addressing potential flaws before they escalate into severe problems. By harnessing the power of DL, software development teams can enhance their efficiency, reduce maintenance costs, and deliver higher-quality products to users, ultimately contributing to the successful and sustainable advancement of software projects in an increasingly interconnected world. The major contribution of the proposed work includes:

- Software defect prediction utilizing CNN-LSTM hybrid model.
- To employ CNN in feature extraction from structured data, particularly in code repositories and change histories.
- To employ LSTM in handling sequential data, emphasizing their pivotal role in capturing the temporal aspects of software development and facilitating the tracking of defect evolution over time.

The paper is systematized as follows: Section II offers are view of the existing literature and identifies areas where further research is needed. Section III outlines the methodology in detail. In Section IV, the comprehensive results of the suggested approach are discussed. Finally, in Section V and Section VI, the paper concludes with a discussion and summary respectively.

II. Background

A. Literature Review

Lei Qiao et al. [7] introduced an innovative methodology employing DL approaches for the anticipation of software system defects. This novel approach involves training a DL approach to predict the number of defects in software. Notably, when compared to widely adopted approaches such as Support Vector Regression, Feature-based Support Vector Regression, and Decision Tree Regression, the suggested method demonstrated a substantial enhancement in performance on established datasets. The improvement is notably reflected in a notable reduction in mean square error, ranging from 3% to 13%, and an augmentation in the squared correlation coefficient.

Pan et al. [8] introduced a range of CodeBERT models, specifically designed for SDP. The proposed research involved conducting empirical studies to assess the effectiveness of these approaches in cross-version and cross-project SDP scenarios. The findings demonstrated that leveraging pre-trained CodeBERT models led to enhanced prediction accuracy and time savings. Additionally, incorporating sentence-based and keyword-based prediction approaches further improved the effectiveness of pre-trained neural language frameworks in the context of SDP.

Geanderson Esteves et al. [9], delved into the realm of SDP models, harnessing the power of an efficiently implemented XGBoost variant, known as US-XGBoost. This endeavor generated a multitude of random models, each meticulously assessed for the accuracy and interpretability. The key take away from the findings is that SDP is inherently project-specific. This means that the features constituting the most effective models can significantly differ from one project to another. Hence, comprehending the determinants behind model decisions becomes particularly vital.

Lakshmi Prabha and N. Shivakumar [10] introduced a novel hybrid model that addresses the challenge of classifying massive datasets accurately. The proposed approach combines feature reduction using Principal Component Analysis (PCA) with an overall probability application to minimize data loss during PCA processing. The approach further employed a neural network classification method for program bug detection. The simulation results demonstrated the model's impressive efficiency, achieving an outstanding 98.70 percent Area under the Curve (AUC) accuracy, marking a substantial advancement over existing models.

Hao Wang et al. [11] introduced GH-LSTMs, a novel DL framework for detecting potential code defects within software modules. GH-LSTMs leverage hierarchical LSTM architecture to simultaneously extract semantic and traditional features. A gated merge mechanism was employed to dynamically optimize the fusion of these features. Subsequently, a fully connected layer utilizes the combined features for within-project defect prediction. Remarkably, GH-LSTMs outperform existing methods in terms of F-measure, particularly in non-effort-aware cases.

Bilal Khan et al. [12] presented a comprehensive analysis of seven widely employed Machine Learning (ML) approaches applied to SDP. These approaches encompass SVM, J48, RF, MLP, RBF, HMM, and CDT. The evaluation of these methods utilized various performance metrics, including MAE, RAE, RMSE, RRSE, recall, and accuracy. The findings from the experiments revealed that NB and SVM exhibited superior performance in terms of minimizing MAE and RAE, respectively.

Shuo Feng et al. [13], delved into the robustness of SMOTE-based oversampling methods. This work not only probed the stability of these techniques but also introduced a set of novel and stable SMOTE-based oversampling strategies aimed at enhancing the reliability. These stable techniques minimize the inherent randomness in SMOTE by sequentially selecting defective instances, utilizing a distance-based approach for choosing neighbor instances, and ensuring an evenly distributed interpolation process. The proposed approach supported the findings with both mathematical proofs and empirical investigations across 26 datasets using four common classifiers. The simulation results demonstrated that the effectiveness of stable SMOTE-based oversampling approaches surpasses that of traditional SMOTE-based approaches in terms of stability and effectiveness.

Somya Goyal [14] introduced a pioneering Neighborhood-based Under-Sampling (N-US) algorithm to address the challenge of class imbalance. The study aims to showcase the efficacy of this N-US framework in enhancing accuracy for predicting defective modules. The experimental results revealed that the N-US approach successfully reduces the dataset size by 17.29% and lowers the Imbalance Ratio (IR) by 19.73%. Consequently, it plays a vital role in augmenting classifier performance.

Cong Jin [15] introduced an innovative distance metric learning framework that leverages cost-sensitive learning (CSL) to mitigate the challenges posed by class-imbalanced datasets. This novel method, initially developed to address class imbalance, assigns distinct weights to individual training classes. Subsequently, this CSL-based distance metric learning is integrated into the large margin distribution machine (LDM) to take over the conventional kernel function. Empirical results indicated that these enhancements enable CS-ILDM to exhibit not only excellent predictive performance but also the lowest misprediction cost.

Kun Zhu et al. [16] introduced an innovative feature selection algorithm called EMWS, which optimally chooses a compact set of closely related features tailored to each software project. This approach effectively harnesses the local search capabilities of simulated annealing to augment the relatively weaker exploitation performance of the Whale Optimization Algorithm (WOA) while simultaneously capitalizing on WOA's strong global search abilities to enhance SA's exploration capabilities. A hybrid deep neural network model was also proposed. Empirical results substantiate that EMWS and WSHCKE consistently outperform various methods in various experiments.

Ruba Abu Khurma et al. [17] introduced the Island Model as an enhancement to the Binary Moth Flame Optimization (BMFO) algorithm for addressing the Feature Selection problem in the context of SDP. This innovative approach segments the moth population into multiple islands, facilitating feature sharing among them through migration. This technique serves to bolster solution diversity and govern algorithm convergence. The experiments involved assessing the performance of KNN, NB and SVM classifiers with and without FS, using BMFO-FS, and employing Is BMFO-FS. Notably, across three experiments, the SVM classifier consistently outperformed others, closely followed by the NB classifier.

Shuo Feng et al. [18] introduced a novel oversampling approach known as Complexity-based Oversampling Technique (COSTE). Instead of relying on inter-instance distances, COSTE assesses instance complexity to guide the selection of candidates for generating synthetic instances. The study evaluated COSTE's effectiveness against four other oversampling techniques using various classifiers, including, KNN, MLP, SVM and RF, across 23 imbalanced datasets. Remarkably, the simulation findings consistently demonstrated that COSTE outperformed the other methods across all performance metrics, highlighting its superior performance.

Shiqi Tang et al. [19] introduced TSboostDF, an innovative transfer-learning algorithm designed to address the complex problem of CPDP (Cross-Platform Domain Prediction). TSboostDF effectively combines the BLS sampling method, which considers the sample's weight, with transfer-learning techniques to mitigate the limitations commonly associated with conventional CPDP algorithms. This novel approach has been demonstrated to outperform other CPDP algorithms that rely on transfer-learning methods, highlighting its superior performance in resolving this challenging problem.

Liu Yang et al. [20] introduced an innovative hybrid algorithm that combines the strengths of SSA and PSO. This research involved a comprehensive analysis of the merits and limitations of swarm intelligence algorithms, aiming to devise strategies for enhancement. Notably, the empirical findings demonstrated that the hybrid approach integrating SSA and PSO, as presented in this work, significantly enhances the precision of software reliability model estimation and forecasting. Specifically, the proposed study focused on estimating and predicting software defects using the well-known G-O model. Furthermore, a fitness function was introduced, which is capable of effectively managing the parameter 'b' during initialization by leveraging the maximum likelihood formula.

An algorithm was presented by Nassif et al. [21] that aims to accomplish two significant tasks: learning and prediction. This approach has a high efficiency for other issues, such as software defect prediction, while being widely utilized in information retrieval. In this paper, two common output metrics namely bug density bug count were used as goal variables to compare various models. Additionally, it looked at how eight models with Grid Search optimization were affected by the use of imbalance learning and feature selection. The FPA scores of the bug density results have significantly improved with the usage of imbalance learning; however, the improvement in the bug count results has not been as great. Last but not least, applying feature selection with LTR decreased the bug density metric's FPA score but had no effect on the bug count findings.

B. Research Gap

SDP models offer valuable insights and benefits, but they also come with several limitations. Some of the major limitations of existing SDP models are discussed below. These models heavily rely on historical data, which may be incomplete, inconsistent, or biased. Poor data quality can induce to inaccurate predictions. Software defect datasets often have imbalanced class distributions, with a small number of defective occurrences compared to non-defective ones. This can lead to model bias and lower predictive accuracy. Software systems, tools, and development practices evolve over time. Models trained on historical data may not effectively adapt to new technologies and practices. Creating relevant features from code repositories and other software data is a complex and manual process. Feature engineering can be time-consuming and error-prone. Complex ML models can over fit the training data, making them less generalizable to new projects or software environments. These models identify correlations but not necessarily causation. Identifying the root causes of defects often requires domain expertise and additional analysis. Models may not be transferable to different software domains or projects due to the unique characteristics of each project. Software is continuously evolving, and defects can emerge or be resolved after the training data was collected, making predictions less accurate. Bias in training data and predictions can lead to discrimination or unfair treatment in software development processes. Training and deploying sophisticated ML models can necessitate remarkable computational resources and expertise, which may not be readily available to all development teams. Addressing these limitations requires careful consideration and often a combination of techniques, including data preprocessing, model selection, and ongoing monitoring and validation of the model's performance. Despite these challenges, SDP models have the potential to significantly improve software development processes when appropriately applied and maintained.

III. Materials and Methods

A CNN- LSTM based hybrid DL model is developed and analyzed for SDP for effective software project development. The detailed block schematic of the suggested work is illustrated in Fig. 1. The initial step of the work involves the dataset collection. It is followed by data preprocessing techniques. The preprocessed data is separate into training set and test set. The proposed hybrid model is trained and validated utilizing the training data and test data. Finally, the performance of the SDP model is analyzed.

A. *Dataset Description*

The proposed system utilizes SDP dataset collected from Open ML, an online platform and repository for ML datasets. The dataset contains 31 features of 224 instances. In this paper, the binary classifier is developed to predict software defects based on 31 inputs.

B. *Units Data Preprocesing and Exploratory Data Analysis*

Data preprocessing is a pivotal stage in data analysis, encompassing the tasks of cleansing, restructuring, and organizing raw data to make it appropriate for analysis or ML model training. The quality and efficacy of a learning model are substantially influenced by proper data preprocessing. Key techniques involved in this process include data cleaning, data transformation, handling missing values, addressing duplicate entries, and managing outliers. Among these techniques, the management of missing values stands out as a critical step. It involves handling data points that lack complete or relevant information. Various strategies can be employed for this purpose. One approach is to eliminate rows or columns with an excessive number of missing values, particularly if they do not significantly contribute to the analysis. An alternative method is imputation, which involves filling in the gaps with estimated or calculated values based on the data's distribution. For numerical data, this can involve mean, median, or mode imputation, ensuring that the dataset is more robust and suitable for analysis or modeling.

Exploratory Data Analysis (EDA) serves as a vital initial step in the data analysis process, where data analysts and scientists employ both visual and statistical methods to delve into a dataset. Its primary goal is to unveil patterns, relationships, anomalies, and insights within the data. EDA entails a range of techniques, including data visualization tools such as histograms, scatter plots, and box plots, in combination with summary statistics like mean, median, standard deviation, and more. This multifaceted approach allows for a comprehensive understanding of data distribution, the detection of outliers, an evaluation of data quality, and the development of an intuitive grasp of the dataset's underlying structure. In practice, EDA plays a pivotal role in hypothesis formulation, guiding subsequent analytical processes, and informing decisions related to data preprocessing and modeling strategies. Ultimately, it aids in the discovery of valuable information and concealed patterns within the data. Summary statistics, which provide a concise summary of key dataset characteristics, include measures such as mean, median, mode, standard deviation, variance minimum and maximum values, quartiles including the first, second or median, and third quartiles, and counts or proportions for categorical variables. The summary statistics of SDP dataset is illustrated in Fig. 2.

EDA relies heavily on the strategic use of graphical representations to delve into a dataset. Through the construction of diverse charts, plots, and graphs, including histograms, scatter plots, box plots and heatmaps, it becomes possible to visually examine data distributions, reveal underlying patterns, identify anomalies, and grasp the interplay between variables. The data visualization of counts of classes in the dataset is visualized in Fig. 3.

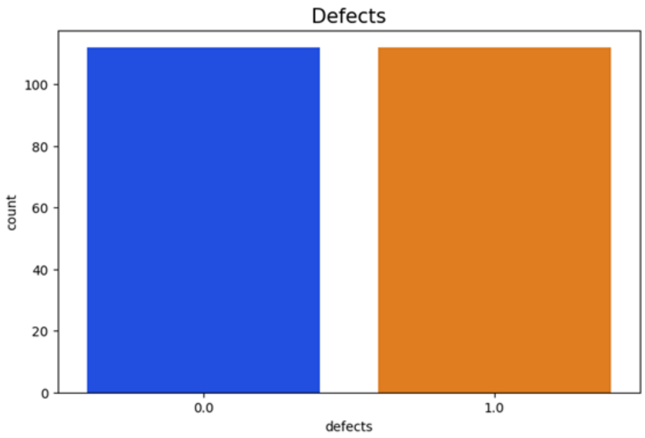

Fig. 3. Data visualization of SDP dataset.

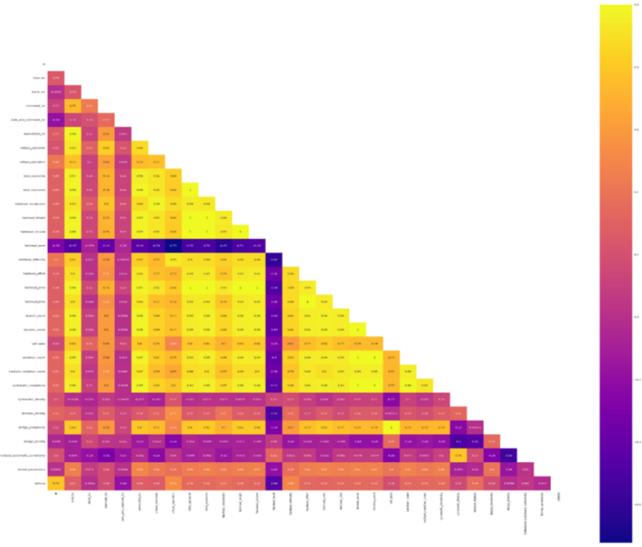

Fig. 4. Heatmap visualization of dataset.

Heatmap visualization serves as a powerful graphical tool for depicting data, representing information within a matrix by employing a range of colors. Its primary utility lies in the effective exploration of complex datasets, as each individual cell in the matrix corresponds to a specific data point, and the color intensity within these cells conveys the underlying data values, often using a color spectrum to illustrate the transition from lower to higher values. Fig. 4 illustrates the heatmap visualization of dataset.

C. SDP Model using CNN-LSTM Hybrid Model

The proposed defect prediction model is a hybrid system that leverages both CNNs and LSTM neural networks. This innovative approach aims to enhance the accuracy of identifying defects within software. CNNs are employed to detect spatial patterns in the code, such as relationships between different code segments, while LSTMs excel at modeling sequential dependencies over time. By amalgamating these two architectural components, the model becomes capable of understanding both localized and global patterns in the code base, enabling it to effectively pinpoint software defects. The approach involves encoding code as input sequences, which are then processed by CNN layers to capture spatial characteristics and subsequently by LSTM layers to capture temporal relationships. The resulting hybrid model offers a more precise and comprehensive defect prediction, which, in turn, supports the development of more dependable software systems.

A CNN is a type of deep ANN that emulates the human visual perception process, making it particularly effective for analyzing visual data [22]. CNNs leverage various multi-layer perceptron algorithms to reduce the need for extensive preprocessing of input data, making them widely adopted in the field of DL. CNNs represent one of the most prevalent neural network architectures, typically comprising millions of interconnected neurons organized into hierarchical layers, as illustrated in Fig. 5.

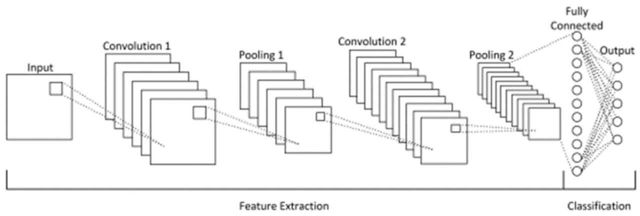

Fig. 5. Basic architecture of CNN.

CNN consist of three fundamental layers: convolutional, pooling, and fully-connected layers. The hidden layers within the convolutional and FC layers play a pivotal role in accessing the network's capacity to learn. The depth of a CNN is defined by the number of layers it comprises, and the deeper these layers are, the more intricate and abstract features they can extract from the input data, especially in the context of high-resolution images [23]. Within the CNN processing pipeline, the neurons in the input layer respond to visual stimuli, initiating the feature extraction process. The major aim of the convolutional layer is to capture these image features and propagate them to the subsequent hidden layers for computation, culminating in the extraction of results from the output layer. Activation functions often act as intermediaries between hidden layers, facilitating the transfer of valuable and essential information to inform the subsequent layers in the network.

The Long Short-Term Memory unit a prominent component of DL belongs to the family of Recurrent Neural Networks (RNNs) [24]. This specialized RNN excels in understanding and capturing intricate order dependencies within sequence prediction tasks. It is specifically designed to manage long-term relationships and tackle challenging problems, particularly those where the input order plays a pivotal role. Over time, numerous variations of Deep RNNs have been devised to combat issues related to vanishing and exploding gradients. Among these, the LSTM network stands out as a unique solution. It achieves its exceptional capabilities by employing distinct activation functions for each of its gates, allowing it to remember essential information from the past while efficiently discarding irrelevant data. Furthermore, LSTM incorporates an internal cell state vector, which serves as a practical representation of the network's retained knowledge from prior inputs. The LSTM unit employs three distinct gates: Forget Gate (f), Input Gate (i) and the Output Gate (o). Fig. 6 illustrates the core structural elements of an LSTM unit.

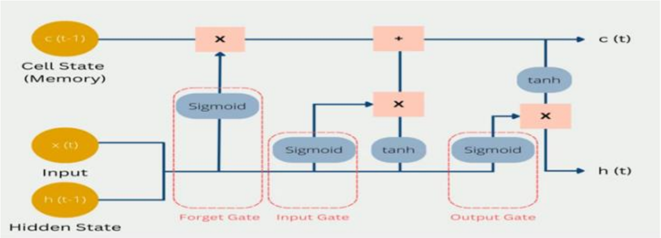

Fig. 6. Basic architecture of LSTM.

In a hybrid CNN-LSTM model, the initial CNN stage operates on the input sequence, effectively pinpointing spatial patterns or local features at each point in time. The resulting CNN layer outputs are subsequently fed into the LSTM component, which is responsible for modeling the temporal dependencies and capturing the sequential patterns within the data. This combined approach enables the model to effectively assimilate both local and global information, making it a robust choice for tasks that entail complex spatial and temporal interactions in sequential data. The architectural representation of the proposed model is visually depicted in Fig. 7.

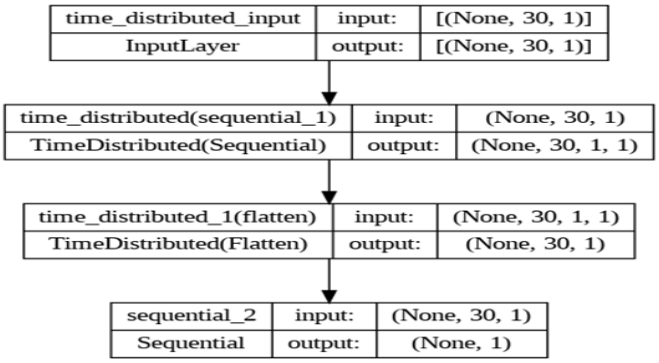

Fig. 7. Proposed model architecture.

The suggested hybrid model begins with a dense layer featuring 100 neurons and a Relu activation function. This is succeeded by two additional dense layers, one with 50 neurons and the other with 25 neurons, both utilizing ReLU activation. The final dense layer has of a single neuron with a sigmoid activation function. Subsequently, an LSTM layer with 64 units is incorporated, followed by the application of a dropout layer with a 0.5 dropout rate to avoid over fitting. This is succeeded by another LSTM layer with 32 units. Finally, the model concludes with a dense layer consists a single neuron and a sigmoid activation function. This hybrid architecture combines a CNN with a recurrent neural network (RNN) using Time Distributed layers. The Time Distributed layers enable the application of feed forward network and flatten operations across each time step of the input sequence, effectively leveraging both spatial and temporal information for sequence-based tasks.

IV. Experimental Analysis

A. Hardware and Software Setup

The proposed system utilizes SDP dataset contains 31 attributes. Google Collaboratory and Microsoft windows 10 are chosen in this research to ensure a stable computing experience. The system is equipped with an Intel Core i7-6850K 3.60 GHz 12- core processor, one NVIDIA Geforce GTX 1080 Ti GPU 2760 4MB. The dataset is split into two sets: training set (70%) and test set (30%). The entire procedure made use of Python and TensorFlow. The 'Adam' optimization function was used in the proposed model. The binary crossentropy is used as the loss function. The training process involved using a batch size of 32 for a total of 750 epochs. Finally, the proposed model predicts software defects as TRUE or FALSE.

B. Result

The effectiveness of the suggested SDP model underwent an assessment using several key performance parameters, including accuracy, precision, recall, F1-score, specificity, and ROC AUC. Accuracy, a statistical measure, was employed to gauge the model's classification performance, representing the percentage of accurately predicted instances out of the entire dataset.

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} \tag{1}$$

Precision is a parameter utilized to find the model's capability to accurately predict positive outcomes. It quantifies the ratio of true positive predictions to all positive predictions, encompassing both accurate positive predictions and false positives.

$$Precision = \frac{(TP)}{(TP+FP)} \tag{2}$$

Recall is a parameter that assesses a model's capacity to efficiently detect all pertinent examples of a specific class in a dataset. It quantifies the ratio of true positive predictions to the total number of actual occurrences belonging to that class.

$$Recall = \frac{(TP)}{(TP+FN)} \tag{3}$$

The F1-Score serves as a metric employed to evaluate how well precision and recall are balanced in binary classification tasks.

$$F1 - Score = 2 * \frac{(Precision*Recall)}{(Precision+Recall)} \tag{4}$$

Specificity refers to the degree of precision or accuracy in targeting a particular characteristic, attribute, or aspect within a given context. The classification report of the proposed SDP model after simulation is tabulated in Table I.

An accuracy plot is a graphical representation that shows how well a model's predictions match the actual outcomes or labels in a dataset. It is a visual tool utilized to assess the effectiveness of a model, with the x-axis usually representing different iterations or epochs of training, and the y-axis indicating the accuracy of the model's predictions. The accuracy plot of the suggested prediction model is visualized in Fig. 8.

TABLE I. PERFORMANCE EVALUATION OF PROPOSED SDP MODEL

Performance Metrics	Obtained Results
Accuracy	95.58 %
Precision	96.66 %
Recall	93.54 %
F1- Score	95.08 %
ROC AUC	0.9542
Specificity	97.29 %
Cohens Kappa	0.9108

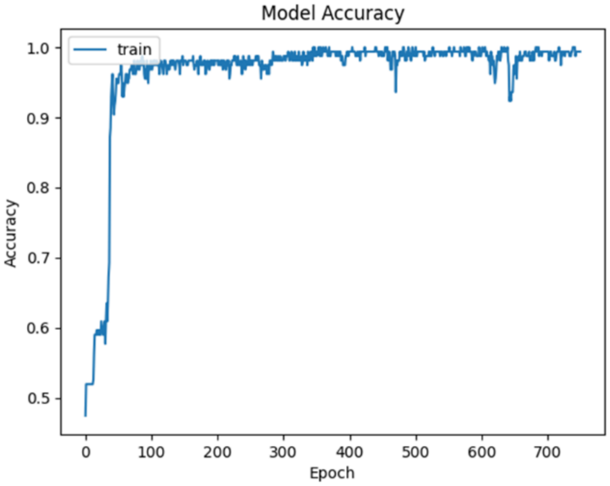

Fig. 8. Accuracy plot of proposed SDP model.

Loss plot typically shows how the loss function, a measure of the error between the predicted and actual values, changes over time as the model learns from the training data. The loss plot is a critical tool for assessing the training process. The loss plot of the proposed SDP model is visualized in Fig. 9.

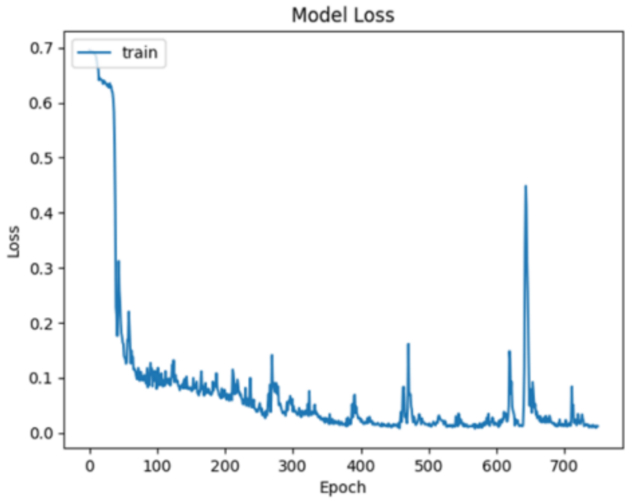

Fig. 9. Loss plot of proposed SDP model.

A confusion matrix is a visual representation of a classification model's performance that helps assess its accuracy and error rates. This grid is structured in such a way that it assigns actual class labels to its rows and predicted class labels to its columns. The cells along the diagonal of the matrix account for the accurate predictions, encompassing both true positives and true negatives. Meanwhile, any discrepancies outside the diagonal signify errors, including false positives and false negatives. The confusion matrix obtained for the proposed SDP model is illustrated in Fig. 10.

The Receiver Operating Characteristic (ROC) curve is a visual tool utilized to assess the effectiveness of models. It provides a graphical representation of how well a model can differentiate between positive and negative classes by depicting the balance between its true positive rate and false positive rate across various threshold settings. When examining a ROC curve, a flawless model would closely follow the upper-left corner of the plot, demonstrating high sensitivity and minimal false positives, whereas random guessing would produce a diagonal line running from the lower-left to the upper-right. The Area Under the ROC Curve (AUC-ROC) serves as a succinct metric summarizing the model's overall performance, with greater values indicating superior discriminatory capabilities. The ROC curve is visualized in Fig. 11. Table II shows the performance comparison of proposed model with existing model.

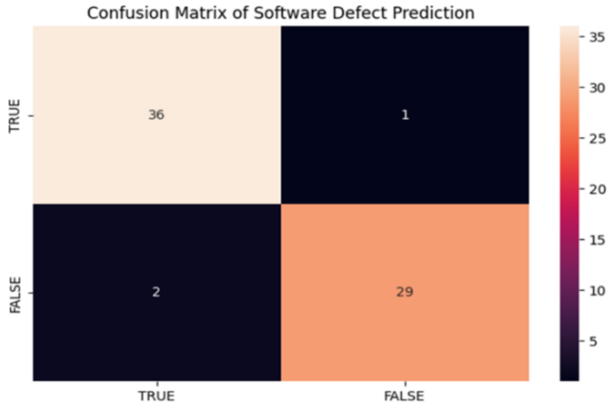

Fig. 10. Confusion matrix of proposed SDP model.

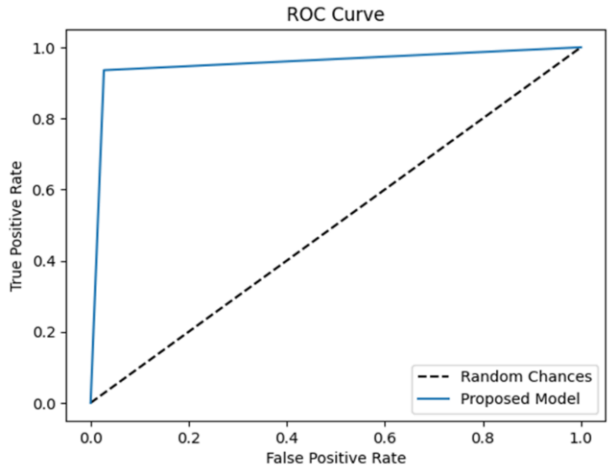

Fig. 11. ROC curve.

TABLE II. PERFORMANCE COMPARISON OF PROPOSED MODEL WITH EXISTING MODELS

Author &Reference	Methodology	Result
12	RF	88.32%

20	Hybrid Particle Swarm Optimization and Sparrow Search Algorithm	88%
Proposed model	**CNN+LSTM**	**95.58%**

V. Discussion

In the realm of software defect prediction, the findings of this study contribute valuable insights into the identification and mitigation of software defects. Through a comprehensive analysis and employing advanced learning algorithms, the study successfully establishes robust models for predicting potential defects in software development. The results reveal key predictors and patterns associated with defect occurrence, shedding light on critical areas that warrant attention during the software development life cycle. Feature extraction from structured data making them adept at identifying patterns and dependencies within code repositories, change histories. On the other hand, are well-suited for handling sequential data, which is crucial in capturing temporal aspects of software development and tracking the evolution of defects over time.

Moreover, the study's exploration of different feature sets and model evaluation techniques enhances the reliability of the proposed defect prediction models. The simulation results demonstrated that the adoption of a CNN-LSTM hybrid model for SDP has the potential to significantly contribute to more efficient and reliable software development processes.

VI. Conclusion

SDP plays a pivotal role in ensuring efficient development in software projects. This approach is proactive in nature, utilizing data-driven methods and analytics to detect possible flaws or weaknesses in software systems prior to the escalation into critical problems. This contributes not only to the improvement of the software's overall quality and dependability but also exerts a substantial influence on project schedules and resource allocation. Efficient software development projects are characterized by their ability to meet deadlines, stay within budget constraints, and deliver a high-quality product. SDP contributes to these goals in several key ways. This paper presented a SDP model utilizing both the benefits of CNN and LSTM. This approach leverages the power of CNN and LSTM to address the challenges associated with identifying and mitigating software defects, ultimately contributing to the improvement of software quality and project timelines. The CNN-LSTM hybrid model combines the strengths of both convolutional and recurrent neural networks. CNNs excel in feature extraction from structured data, making them adept at identifying patterns and dependencies within code repositories and change histories. LSTMs, on the other hand, are well-suited for handling sequential data, which is crucial in capturing temporal aspects of software development and tracking the evolution of defects over time. The proposed prediction model achieved better prediction results. The simulation results demonstrated that the adoption of a CNN-LSTM hybrid model for SDP has the potential to significantly contribute to more efficient and reliable software development processes. As technology continues to advance and data-driven approaches become increasingly prevalent in the software industry, the integration of such models holds promise for continually enhancing software quality and the success of software projects.

US Road Sign Detection and Visibility Estimation using Artificial Intelligence Techniques

Jafar AbuKhait
Dept. of Computer and Communications Engineering, Tafila Technical University, Tafila, Jordan

***Abstract*—This paper presents a fully-automated system for detecting road signs in the United States and assess their visibility during daytime from the perspective of the driver using images captured by an in-vehicle camera. The system deploys YOLOv8 to build a multi-label detection model and then, calculates various readability and detectability factors, including the simplicity of the surroundings, potential obstructions, and the angle at which the road sign is positioned, to determine the overall visibility of the sign. This proposed system can be integrated into Driver Assistance Systems (DAS) to manage the information delivered to drivers, as an excess of information could potentially distract them. Road signs are categorized based on their visibility levels, allowing Driver Assistance Systems to caution drivers about signs that may have lower visibility but are of significant importance. The system comprises four main stages: 1) identifying road signs using YOLOv8; 2) segmenting the surrounding areas; 3) measuring visibility parameters; and 4) determining visibility levels through fuzzy logic inference system. This paper introduces a visibility estimation system for road signs specifically tailored to the United States. Experimental results showcase the system's effectiveness. The visibility levels generated by the proposed system were subjectively compared to decisions made by human experts, revealing a substantial agreement between the two approaches.**

Keywords—Road sign detection; YOLOv8; driver assistance system; fuzzy logic; detectability; visibility estimation

I. Introduction

In recent times, there has been a notable rise in the adoption of Driver Assistance Systems (DAS), primarily driven by the expanding complexity of road networks [1]. These systems are integrated into vehicles to simplify the driving experience and enhance overall driver safety. Road signs serve as a vital source of information for both drivers and these advanced systems, yet their visibility and detectability (the driver's capacity to spot a road sign within a complex or cluttered environment, essentially measuring how effectively the sign stands out) can be compromised in various scenarios. These scenarios can be categorized as either temporary, influenced by factors like lighting and adverse weather conditions, or permanent, resulting from vandalism or improper sign placement [2].

Reduced visibility of road signs significantly diminishes the effectiveness of communication between drivers and these signs. Consequently, DASs can play a crucial role in notifying drivers about warnings in such situations. Road sign detection is a basic step that every DAS system should have. It is noteworthy that an effective Driver Assistance System (DAS) should achieve a balance, avoiding the inundation of drivers with excessive road information. Overloading drivers with information may pose a risk of distraction, as discussed in [3].

Employing computer vision techniques in Driver Assistance Systems (DASs) enables the detection and estimation of road sign visibility. This information can then be used to alert drivers about crucial warnings regarding less visible signs. The implementation of these techniques contributes to enhanced driver safety.

In this work, we propose a fully-automated computer vision system for detecting and assessing the visibility of road signs in the United States in terms of their detectability and readability. Detectability is defined as the driver's capacity to identify and acknowledge the presence of specific road signs within complex or cluttered environments while readability represents the clearness degree of the foreground text on the sign. This proposed system can be integrated into Driver Assistance Systems (DAS) to streamline the information presented to drivers. Furthermore, transportation agencies could leverage this system to assess the placement of road signs across their road networks. The proposed system deploys YOLOv8 in the detection of road signs and estimates their visibility using fuzzy logic after measuring five different visibility parameters.

The proposed system aims to: 1) implement a fully-automated multi-label detection model of United States road signs using YOLOv8 which is the latest YOLOs' detection algorithm; 2) measuring five novel visibility parameters of road signs that describe both sign readability and detectability; 3) evaluate visibility level of road signs to low, medium and high using fuzzy inference system that connects the suggested visibility parameters to the visibility output.

The rest of the article is prepared as follows: Section II provides a background of road sign detection and visibility estimation systems. Section III demonstrates the proposed visibility estimation system. Section IV evaluates the system performance experimentally based on certain metrics. Lastly, Section V elaborates the conclusions.

II. Related Work

Automated estimation systems for assessing the visibility of road signs should integrate Road Sign Detection (RSD) systems. The primary objective of RSD is to pinpoint the location of road sign objects within a scene or within images captured from inside a vehicle. RSD systems can be primarily categorized into two groups: those reliant on color and those based on shape. In the realm of color-based detection, some researchers have utilized RGB color thresholding to segment road sign images, as demonstrated in [4, 5], while others have proposed the use of HSI color space for the same purpose, as indicated in [6].

Conversely, shape-based approaches have also been put forth by various researchers. In study [4], for instance, a Support Vector Machine (SVM) was trained using four vectors representing distances from the border to the bounding box to recognize road sign shapes. Researchers in [7] employed a Distance to Border (DtB) vector to identify the shape of road signs. For detecting Regions of Interest (ROI), a boosted detector cascade was trained using dissociated dipoles, while the recognition of triangular or circular road sign shapes was achieved through the utilization of the Hough transform and radial symmetry, as described in [8]. In study [9], a genetic algorithm was employed, and Haar-like features were deployed in study [6] to detect road sign shapes. Researchers in study [10] employed a set of cascaded geometric detectors, capitalizing on the inherent symmetry of road sign shapes for detection and recognition. In study [11], a speed recognition system has been proposed based on independent component analysis. In research [12], geometric features were deployed in the recognition of speed signs in the United States.

Recently, Convolutional Neural Network (CNN) was deployed with different architectures in detection tasks [13, 14] including road sign detection and recognition. In research [15], mask R-CNN was deployed to detect 200 traffic-sign categories with automatic end-to-end learning. In study [16], the authors analyzed seven architectures for detecting the road signs: YOLO, YOLOv2, YOLOv3, PP-YOLO model and R-CNN, Fast R-CNN, Faster R-CNN. This study implies that YOLOv3 and Faster R-CNN perform comparatively better for road sign detection. In [17], authors proposed a detection model to detect and identify traffic signs based on YOLOv7 and Convolutional Block Attention Module. In study [1], authors proposed a road sign detection and recognition system based onYOLOv5s object detection algorithm.

Several researchers have also proposed methods for estimating road sign visibility from digital images. Researchers in [18] introduced a novel technique for measuring road sign retro-reflectivity using two varied illumination images. In study [3], traffic signals' detectability and discriminability were quantified using in-vehicle images. Researchers in [19] utilized five image features to gauge the visibility of certain sign. For visibility estimation in foggy conditions, authors of study [20] introduced a method utilizing in-vehicle images. Researchers in [21] extracted both local and global features to evaluate a human driver's ability to detect and recognize road sign objects. Lastly, researchers in [22] showcased a novel approach based on SVM learning to estimate road sign saliency. In study [23], tilt angle of road sign was used to assess its condition. In study [24], various detectability features of road signs were measured to estimate the visibility level in cluttered environments.

In research [25], a three-dimensional approach for visibility assessment of highway signs has been proposed. The proposed approach measures sign's visibility, legibility, and readability based on its placement, height, and traffic flow. In [26], a system for classifying horizontal road signs as correct or with poor visibility is proposed. This system deploys YOLOv4-Tiny neural network model for classification and the contrast difference for visibility estimation. In [27], a study authors proposed a camera-based visibility estimation method for a traffic sign. The proposed method integrates both the local features and global features in a driving environment. These features measure sign's positional relationships and the contrast between a traffic sign and its surroundings. In research [28], author proposed an imaging-based system to estimate road sign visibility in a cluttered environment from the driver's perspective in daytime using in-vehicle camera images. The proposed system deploys a geometric sign detector and suggests two visibility parameters which are color difference and environment complexity. In study [29], authors proposed a method that can automatically detect the occlusion and continuously quantitative estimate the visibility of traffic sign. The proposed method deploys road sign orientation and occlusion in evaluating its visibility. In study [30], authors proposed a quantitative visual recognizability evaluation method for traffic signs in large-scale traffic environment. The proposed method evaluates the geometric, occlusion and sight line deviation factors of traffic signs.

In conclusion, the literature demonstrates that the implementation of automated vision-based road signs detection and recognition systems represents a significant advancement in modern transportation networks. In addition, visibility of these road signs is a major concern for both drivers and transportation agencies. The literature shows a lot of shortcomings of current road sign visibility estimation systems which can be concluded as the lack of automation in both the detection and visibility estimation, the deficiency of road sign detection models under different illumination and occlusion conditions, the failure to measure all visibility parameters that represent the road sign readability and detectability, and the need to estimate the road sign visibility to various levels either by a rule-based or machine learning techniques. As artificial intelligence techniques continue to evolve towards greater efficiency, these systems could be improved and automated completely for better safety over transportation networks. Additionally, current road sign visibility estimation systems should deploy powerful detection models that have the capability

III. The Proposed System

The proposed system based on road sign imaging, depicted in Fig. 1, comprises four distinct modules:

1) *Multi-label road sign detection:* In this initial module, the system builds a detection model using YOLOv8 algorithm based on the in-vehicle images to detect and identify three categories of road sign objects (regulatory, warning and stop signs).

2) *Cropping of surrounding regions:* In this module, the system geometrically extracts four adjacent regions around the road sign object. These regions would be used in the next module to calculate some visibility parameters.

3) *Measurement of visibility parameters:* During this module, the system establishes and computes five visibility

parameters which are: 1) readability of sign foreground; 2) color difference between the sign and its four surrounding regions; 3) complexity of surroundings; 4) occlusion; and 5) tilting. These parameters characterize both the readability and detectability of each road sign.

4) Determination of visibility levels: In this module, the system assesses and categorizes the visibility level of each road sign as low, medium, or high using fuzzy logic inference system.

B. Multi-Label Road Sign Detection

In this module, YOLOv8 algorithm is used to detect three different types of US road signs: 1) Regulatory Signs (White Rectangular-shape signs); 2) Warning Signs (Yellow Diamond-shape signs); and 3) Stop Sign (Red Octagonal-shape signs. The multi-label detection model was trained on Google Colab notebook after building an annotated road sign dataset of 664 images. Once the model was trained, it was tested on a separate set of validation images to evaluate its performance.

Fig. 1. Flow diagram of the proposed system.

1) Dataset preparation: Originally, 664 images in which one US road sign is existed, was collected and uploaded to Roboflow. Data analysis operations were achieved such as: pre-processing, resizing, annotation, augmentation and health check. All images were resized to 640x640. The following augmentations were done on these images: Rotation (between -21° and +21°), Saturation (between -20% and +20%), Brightness (between -20% and +20%), Blur (up to 1px), Noise (up to 3% of pixels). A set of 1519 images was achieved splitted as: 1332 for training, 116 for validation, and 71 for testing.

2) Model training and evaluation: The model was trained using YOLOv8. It was evaluated for detecting three classes: Stop signs, Warning signs and Regulatory signs. The number of Epochs used to train the model was 150. The model detection performance was evaluated using mean average precision (mAP), recall and precision.

The output of this module is road sign surrounded by a bounding box as shown in Fig. 2. This detected road sign would be used in the next modules to estimate its visibility.

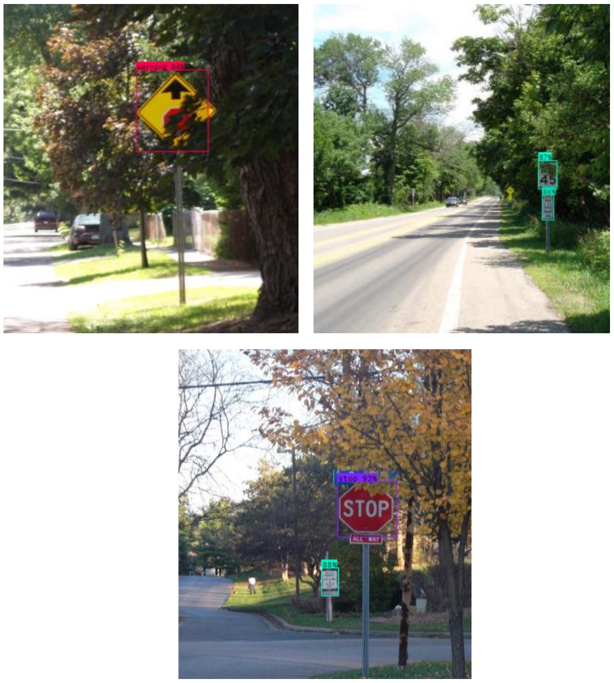

Fig. 2. Examples of detected road signs.

C. Cropping of Surrounding Regions

In the module of the proposed system, road sign visibility is characterized by the driver's capacity to distinguish the sign's location from the surrounding background in a real-life scenario. Various elements in the background might divert the driver's attention away from identifying the road sign's location. To gauge visibility, we assess the road sign's location in relation to its surroundings. For Stop, Warning, and Regulatory signs, we have extracted four adjacent regions from the input image, as illustrated in Fig. 3. This process has been accomplished by mirroring the bounding box in the four directions. For Warning signs, the four regions were obtained after rotating the sign. Each region possesses a symmetrical shape and double the area of the sign region. These four surrounding regions are denoted as R1, R2, R3, and R4, while the sign region is designated as S, as shown in Fig. 3.

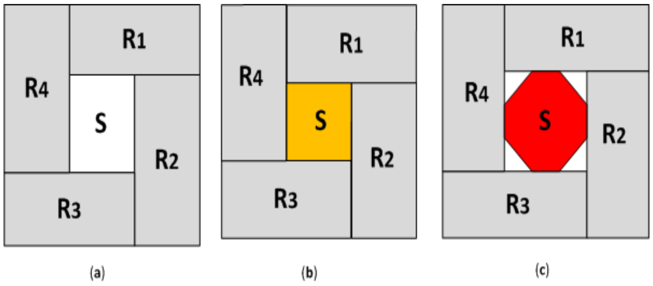

Fig. 3. The four surrounding regions for: a) Regulatory sign; b) Warning sign; c) Stop sign.

D. Measurement of Visibility Parameters

Different detectability and readability parameters of road sign region and surrounding regions are used to determine the visibility level of the road sign. Five parameters are proposed to describe the visibility of road signs: 1) readability of sign foreground; 2) color difference between the sign and the four surrounding regions; 3) complexity of surroundings; 4) sign occlusion; and 5) sign tilting.

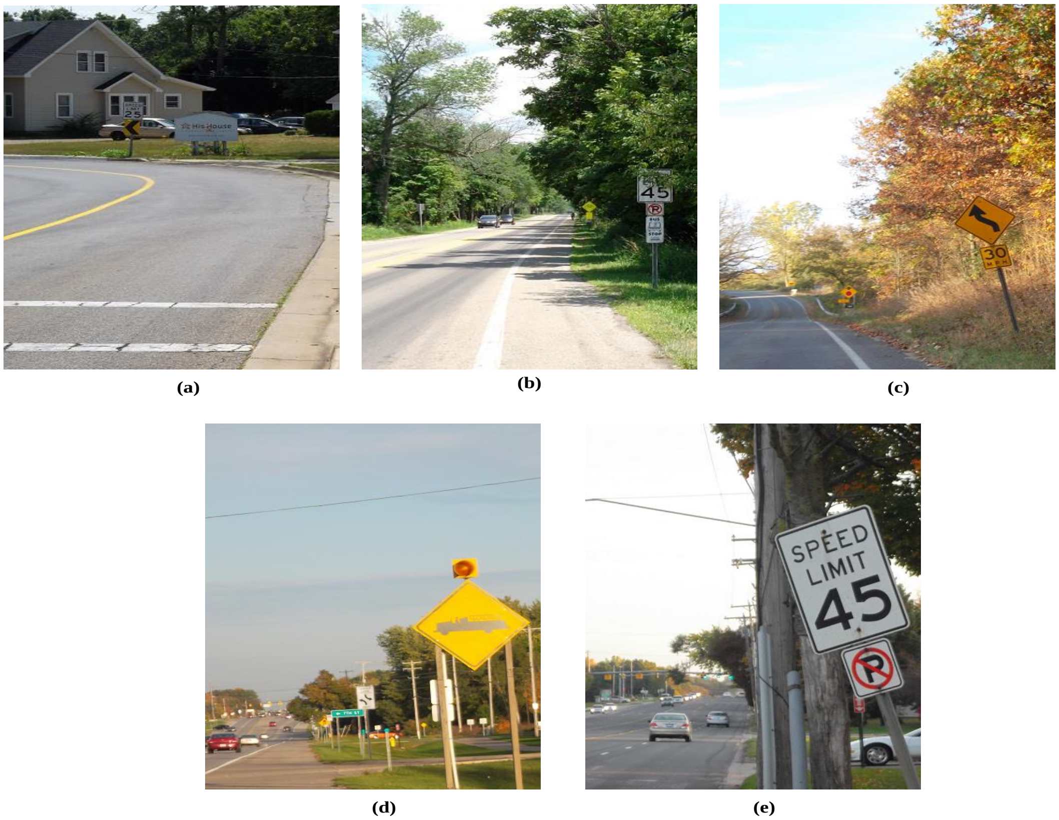
Fig. 4 shows some road signs exhibiting poor visibility based on these parameters. Each parameter is designed as low or high based on ranges that were determined by a human expert.

1) Readability of sign foreground: This parameter measures the clearness degree of the foreground text on the sign. The greater the difference between the foreground and background is better considering the different colors in the three sign classes. This parameter, denoted by R, has been computed on the gray images of the detected signs by subtracting the average gray levels of both foreground and background as:

$$R = G_F - G_B \tag{1}$$

where, G_F is the gray level of the sign foreground (white on Stop signs and black on Warning and Regulatory signs), G_B is the gray level of the sign background (red on Stop signs, yellow on Warning signs and white on Regulatory signs).

A lower color difference between the sign foreground and background (0 - 120) diminishes a driver's ability to read and recognize road signs, whereas a higher color difference (120 - 255) enhances readability probabilities. Therefore, a significant color difference between the sign foreground and background leads to improved road sign visibility.



(a) (b) (c)

(d) (e)

Fig. 4. Examples of low visibility road signs due to: a) Color difference between sign and surroundings, b) Occlusion, c) Complexity of surrounding regions, d) Readability of sign foreground, e) Tilting.

2) Color difference: This parameter measures the clearness degree of the sign with respect to its surrounding regions. The process involves computing the average color of the RGB values for both the road sign and its four surrounding regions. The color disparity between the sign region and each of its four surrounding regions is then quantified as follows:

$$D1 = \sqrt{(\overline{R}_S - \overline{R}_{R1})^2 + (\overline{G}_S - \overline{G}_{R1})^2 + (\overline{B}_S - \overline{B}_{R1})^2} \tag{2}$$

$$D2 = \sqrt{(\overline{R}_S - \overline{R}_{R2})^2 + (\overline{G}_S - \overline{G}_{R2})^2 + (\overline{B}_S - \overline{B}_{R2})^2} \tag{3}$$

$$D3 = \sqrt{(\overline{R}_S - \overline{R}_{R3})^2 + (\overline{G}_S - \overline{G}_{R3})^2 + (\overline{B}_S - \overline{B}_{R3})^2} \tag{4}$$

$$D4 = \sqrt{(\overline{R}_S - \overline{R}_{R4})^2 + (\overline{G}_S - \overline{G}_{R4})^2 + (\overline{B}_S - \overline{B}_{R4})^2} \tag{5}$$

where, ($\overline{R}_S, \overline{G}_S, \overline{B}_S$) are the average RGB colors of the sign region and ($\overline{R}_{Ri}, \overline{G}_{Ri}, \overline{B}_{Ri}$) are the average RGB colors of each surrounding region Ri.

Subsequently, these four disparity values are averaged to derive the overall color difference value, denoted as D. A lower color difference (0 - 120) diminishes a driver's ability to detect road signs, whereas a higher color difference (120 - 255) enhances detection probabilities. Therefore, a significant color difference between the sign region and its adjacent regions leads to improved road sign visibility.

3) Surrounding complexity: This parameter computes the amount of details that exist in the sign surroundings. It involves extracting the edges from all the surrounding areas and calculating the total number of edge pixels. The ratio between the number of edge pixels and the total number of pixels in these surrounding regions is employed to ascertain the shape complexity (C) of the road sign's surroundings, as follows:

$$C = \frac{N_E}{N_T} \tag{6}$$

where, N_E is the number of edge pixels in the surrounding regions and N_T is the total number of pixels in these regions.

A complex environment around the road sign will result in a high complexity parameter value, leading to a reduced level of visibility. The overall complexity level of the surrounding regions of the sign will vary between high (0.2 - 1) and low (0 – 0.2) based on the value of the complexity parameter

4) Occlusion: This parameter quantifies the extent to which the road sign is partially obscured by objects like trees or leaves. It takes into account partial occlusion occurring on the top and right sides of the road sign region while disregarding occlusion on the left and bottom sides. The occlusion parameter (O) is formulated as follows:

$$O = 1 - \frac{A_O}{A_T} \tag{7}$$

where, A_O is the filled area of the apparent sign blob computed as the number of pixels and A_T is the estimated area of road sign region computed as the bounding box area.

The level of occlusion can vary, being classified as either low (0 - 0.15) or high (0.15 - 1) based on the occlusion parameter value. Increased occlusion in the sign region would lead to reduced detectability and visibility of the road sign

5) Tilting: This parameter measures the tilting degree of road sign. The tilting parameter (T) is computed using the regionprops function on Python.

The degree of tilting can be categorized as either low (0 - 15^o) or high (15^o - 90^o), contingent upon the tilting angle value. A pronounced tilt of the road sign would result in reduced detectability and consequently, a low visibility level.

E. Determination of Visibility Levels

Road signs are classified in this module using fuzzy logic in terms of visibility levels to: low, medium, or high. A Fuzzy Inference System (FIS) connecting parameters to the visibility level operates through a series of defined steps to determine the appropriate visibility label based on the input parameters. Considering the parameters calculated in the previous module (Readability, Color Difference, Surrounding Complexity, Occlusion, and Tilting) and their fuzzy sets mapped to visibility levels (Low, Medium, High), here's how the FIS functions:

1) *Input* variables and membership functions

- Parameters like Readability, Color Difference, Surrounding Complexity, Occlusion, and Tilting serve as input variables.
- Each parameter has fuzzy membership functions (e.g., low, high) that describe how input values correspond to these linguistic terms. These membership functions have defined ranges and shapes, such as triangular or Gaussian that assign degrees of membership to each linguistic term based on the input's value within its range. Table I shows the membership functions of the input parameters.

2) *Fuzzy* rules

- Based on expert knowledge or empirical data, fuzzy rules are established to connect the input parameters to the output visibility levels.
- For example, rules might state:
- "If Readability is High AND Occlusion is Low AND Color Difference is Low, THEN Visibility Level is High."

TABLE I. THE MEMBERSHIP FUNCTIONS OF THE FIVE VISIBILITY PARAMETERS

Fuzzy Parameter	Membership Function Type	Parameter Range for Low	Membership Parameters for Low	Parameter Range for High	Membership Parameters for High
Readability	Triangular	0 to 120	a=0, b=60, c=120	120 to 255	a=120, b=180, c=255
Color difference	Triangular	0 to 120	a=0, b=60, c=120	120 to 255	a=120, b=180, c=255
Surrounding complexity	Triangular	0 to 0.2	a=0, b=0.1, c=0.2	0.2 to 1	a=0.2, b=0.4, c=0.6
Occlusion	Gaussian	0 to .15	Mean = 0.075 Standard Deviation = 0.0375	0.15 to 1	Mean = 0.575 Standard Deviation = 0.2125
Tilting	Trapezoidal	0 to 15	a=0, b=5, c=10, d=15	15 to 90	a=15, b=20, c=85, d=90

3) *Inference* engine

- The inference engine evaluates the fuzzy rules based on the current input values.
- It calculates the degree to which each rule contributes to different visibility levels using fuzzy logic operations like AND, OR, and NOT.

- Aggregation methods, such as the Mamdani, combine the rules to determine the degree of support for each visibility level based on the input parameter values.

4) Defuzzification

- Once the inference engine processes the rules and combines their outputs, the defuzzification process aggregates the fuzzy output sets to derive a crisp, actionable output.
- This process converts the fuzzy output into a specific visibility level, such as Low, Medium, or High, based on methods like centroid, mean of maximum (MOM), or weighted average.

5) Output - determining visibility level

- The final step yields a specific visibility level determined by the FIS after processing the input parameters through the defined membership functions and rules.
- This output provides a clear and actionable visibility level based on the linguistic description or numerical range that best fits the input parameter combinations. Table II shows the membership functions of the output variable which is the visibility level.

The Fuzzy Inference System connects the input parameters related to visibility to the appropriate visibility level using fuzzy logic, allowing for a more understanding and decision-making process in scenarios where traditional binary or crisp logic might be insufficient.

The relationship between parameters and visibility levels is determined according to the following fuzzy rules:

1) If Readability is Low AND Occlusion is not high THEN Visibility Level is Low

2) If Occlusion is High THEN Visibility Level is Low

3) If Readability is High AND Occlusion is Low AND Color Difference is Low AND Surrounding Complexity is High AND Tilting is High THEN Visibility Level is Low

4) If Readability is High AND Occlusion is Low AND Color Difference is Low AND Surrounding Complexity is Low AND Tilting is High THEN Visibility Level is Medium

5) If Readability is High AND Occlusion is Low AND Color Difference is Low AND Surrounding Complexity is Low AND Tilting is Low THEN Visibility Level is High

6) If Readability is High AND Occlusion is Low AND Color Difference is Low AND Surrounding Complexity is Low AND Tilting is Low THEN Visibility Level is High

7) If Readability is High AND Occlusion is Low AND Color Difference is High AND Surrounding Complexity is Low AND Tilting is Low THEN Visibility Level is High

8) If Readability is High AND Occlusion is Low AND Color Difference is High AND Surrounding Complexity is High AND Tilting is Low THEN Visibility Level is High

9) If Readability is High AND Occlusion is Low AND Color Difference is High AND Surrounding Complexity is Low AND Tilting is High THEN Visibility Level is High

10)If Readability is High AND Occlusion is Low AND Color Difference is High AND Surrounding Complexity is High AND Tilting is High THEN Visibility Level is Medium

The rules connecting parameters to visibility levels in this fuzzy inference system have varying weights, indicating their significance in determining the visibility level. The lowest weight, at 0.2, is assigned to Rule 1, while Rule 2 holds a weight of 0.7, emphasizing the role of Occlusion in determining visibility. Rules 3 and 4, with weights of 0.8 and 0.9 respectively, highlight the combined impact of Readability, Occlusion, Color Difference, and Surrounding Complexity. Finally, Rules 5 to 10, each with a weight of 1.0, underscore the comprehensive consideration of Readability, Occlusion, Color Difference, Surrounding Complexity, and Tilting in determining the visibility level, demonstrating their paramount importance in decision-making.

TABLE II. THE MEMBERSHIP FUNCTIONS OF THE OUTPUT VARIABLE WHICH IS THE VISIBILITY LEVEL

Visibility Level Fuzzy Output	Membership Function Type	Parameter Range for Low	Membership Parameters for Low	Parameter Range for Medium	Membership Parameters for Medium	Parameter Range for High	Membership Parameters for High
Low	Triangular	0 to 0.33	a=0, b=0.17, c=0.33	0.17 to 0.67	a=0.17, b=0.42, c=0.67	0.33 to 1	a=0.33, b=0.67, c=1
Medium	Triangular	0.17 to 0.67	a=0.17, b=0.42, c=0.67	0.33 to 0.83	a=0.33, b=0.58, c=0.83	0.67 to 0.83	a=0.67, b=0.83, c=0.83
High	Triangular	0.33 to 1	a=0.33, b=0.67, c=1	0.67 to 1	a=0.67, b=0.83, c=1	0.67 to 1	a=0.67, b=0.83, c=1

IV. Experimental Results

The visibility estimation system was tested on images of road signs taken by an in-vehicle camera in the United States. These in-vehicle images were obtained using a SAMSUNG ST65 camera, along with images from the VISAT^{TM} Mobile Mapping System. All images were resized to 640x640 pixels. In this section, we will demonstrate the results of both the detection model and the visibility estimation model.

A. Road Sign Detection Results

In this subsection, we evaluate the performance of the YOLOv8 detection model, which plays a crucial role in automatically identifying the road sign. The evaluation focuses on key metrics such as Accuracy, Precision, and mAP@0.5, providing insights into the model's accuracy and proficiency in object detection. The detection model underwent training for 150 epochs.

Fig. 5 presents a snapshot of quantitative metrics used to gauge the detection model's performance during training, including precision, recall, and mean average precision (mAP@0.5). These metrics shed light on the model's effectiveness in identifying road signs in in-vehicle images. Additionally, it is observed that box loss and class loss are converging.

The detailed breakdown of the model's performance is illustrated in the confusion matrix presented in Fig. 6, outlining true positives (TP), false positives (FP), true negatives (TN), and false negatives (FN) for each object class (e.g., Warning sign, Regulatory sign, Stop sign, and background).

Precision measures the accuracy of true predictions made by the model. It is a crucial metric for object detection, as it assesses the model's ability to correctly identify objects without generating too many false positives. Recall assesses the model's ability to detect all relevant objects, reducing false negatives and ensuring no objects of interest are overlooked. mAP@0.5, a comprehensive metric, combines precision and recall, providing an aggregate evaluation of the model's performance across different object classes and considering precision-recall trade-offs.

The detection model has achieved remarkable results of the three performance metrics where mAP@0.5= 91.5%, Precision= 86.1%, and Recall= 90.5%. It is noticed that the model achieved better results of both Stop and Warning signs while missing some Regulatory signs. This happens because of the high effect of illumination on white signs especially when they are facing the sun.

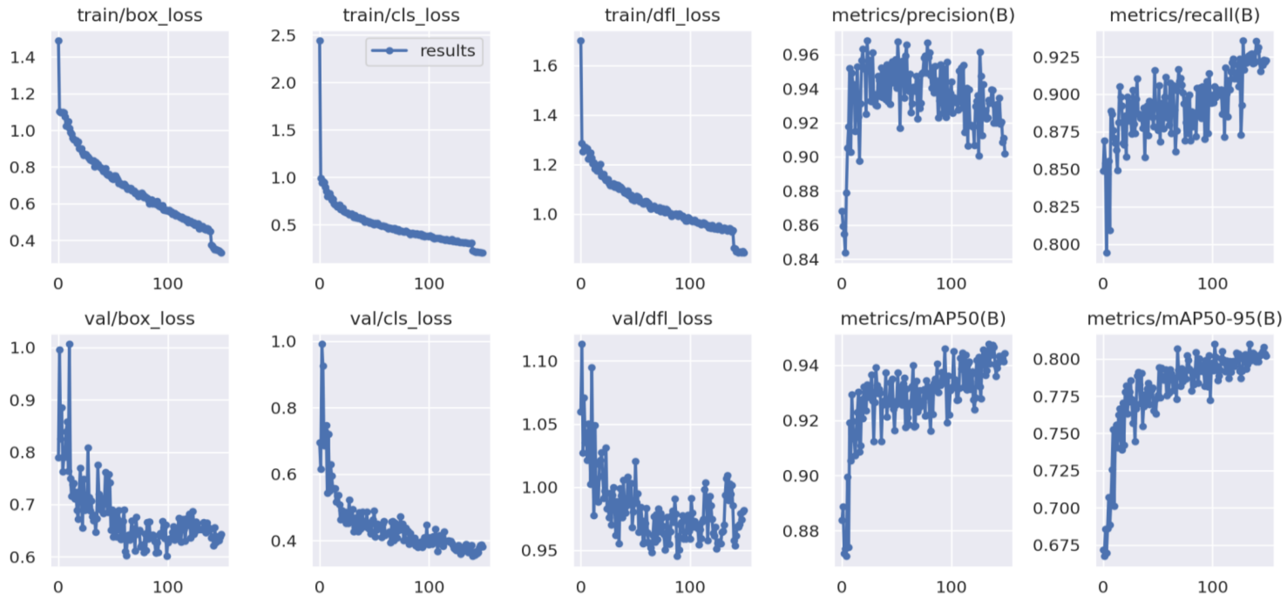


Fig. 5. Performance metrics of the detection model throughout the training process for 150 epochs.

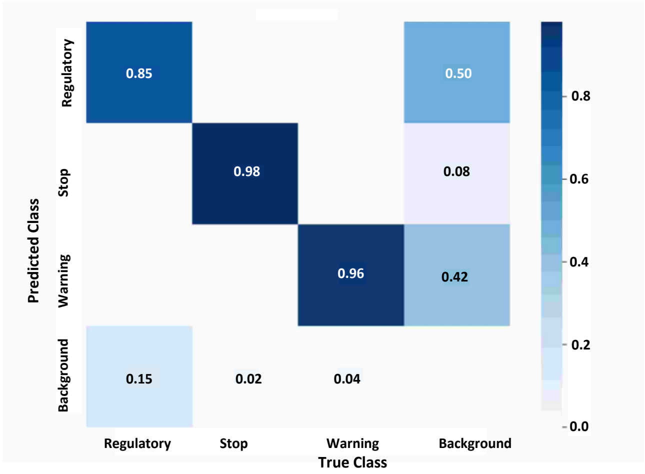

Fig. 6. Confusion matrix of the detection model.

B. Visibility Estimation Results

Testing the fuzzy inference system (FIS) designed for road sign visibility demands a comprehensive procedure, especially when assessing its efficacy with a set of images. The initial step involves sourcing a diverse dataset of road sign images captured in various conditions, encompassing differing lighting, weather scenarios, angles, and distances. This dataset must cover a wide spectrum of potential real-world scenarios to ensure the FIS is tested under varying conditions. Upon gathering the images, preprocessing becomes pivotal. Standardizing the dataset involves resizing images to a uniform dimension, normalizing lighting conditions, and potentially applying filters or enhancements to accentuate visibility features present within the signs. Feature extraction follows, where specific visual features linked to the parameters considered in the FIS - such as readability, color difference, occlusion, surrounding complexity, and tilting - are identified and extracted from the images. This process is crucial to align the image data with the FIS parameters for subsequent analysis.

Integrating the FIS into the testing process involves applying the system to the extracted features from each image. This step aims to predict the visibility level for each sign based on the rules and weights defined within the system. Simultaneously, ground truth labeling becomes essential (assigning visibility labels to the images based on either human judgment or known visibility conditions captured during image acquisition). This establishes a benchmark against which the FIS's predictions can be evaluated. Post-prediction, an evaluation phase ensues where the predicted visibility levels are compared with the ground truth labels using various metrics, such as accuracy, precision and recall. Any discrepancies or misclassifications are carefully analyzed to understand potential shortcomings within the FIS. The procedure allows for iterative refinement. Any observed inconsistencies or errors guide adjustments to the FIS, such as tweaking membership functions, rules, or weights, aiming to enhance its accuracy and reliability.

1) Evaluating the Effectiveness of the Proposed Fuzzy Inference System: In evaluating the effectiveness of the proposed fuzzy inference system for visibility estimation, a distinct approach has been taken. Through a training phase involving 45 in-vehicle images, thresholds for detectability parameters were determined, crucial for classification into high, medium, or low visibility levels. This training set, comprising various road signs and diverse visibility scenarios, was instrumental in setting suitable threshold values, guided by expert decisions. These thresholds, rooted in the training phase, were then applied to a test set consisting of 50 in-vehicle images, including rectangular regulatory, diamond warning and stop signs, mirroring real-world diversity in visibility conditions.

The comparison between the decisions rendered by the proposed system and those of human experts unveils promising results. Out of 50 road signs tested, there was concurrence between the proposed system and expert judgments for 4 signs, representing an impressive 92% accuracy. Notably, even within the 4 instances of discordance, the disagreement usually amounted to merely one visibility level, showcasing a remarkable alignment between the proposed system's estimations and the human expert decisions. Fig. 7 shows examples of the proposed visibility estimation output along with the five visibility parameters and expert decision.

Further analysis revealed a nuanced performance difference in handling yellow and red versus white road signs. The system exhibited a higher proficiency with yellow and red signs owing to the impact of illumination on white color, affecting the accuracy of the color difference detectability parameter.

2) Parametric influence on fuzzy inference system: shaping accuracy and decision dynamics: The effectiveness and accuracy of the outcomes are profoundly influenced by the parameters incorporated within the system. These parameters, such as membership functions, threshold values, and rule weights, play a pivotal role in shaping the decisions and predictions made by the system. Membership functions, serving as the backbone of fuzzy logic, define the degree of membership of an input to a specific linguistic term (like 'low,' or 'high'). Their design profoundly impacts the system's ability to interpret and categorize input data, significantly influencing the resulting output. Threshold values, especially in the context of detectability parameters for road sign visibility estimation, dictate the boundary between different visibility levels. Setting these thresholds involves a delicate balance; they need to be robust enough to delineate distinct visibility categories while remaining adaptable to varying environmental conditions.

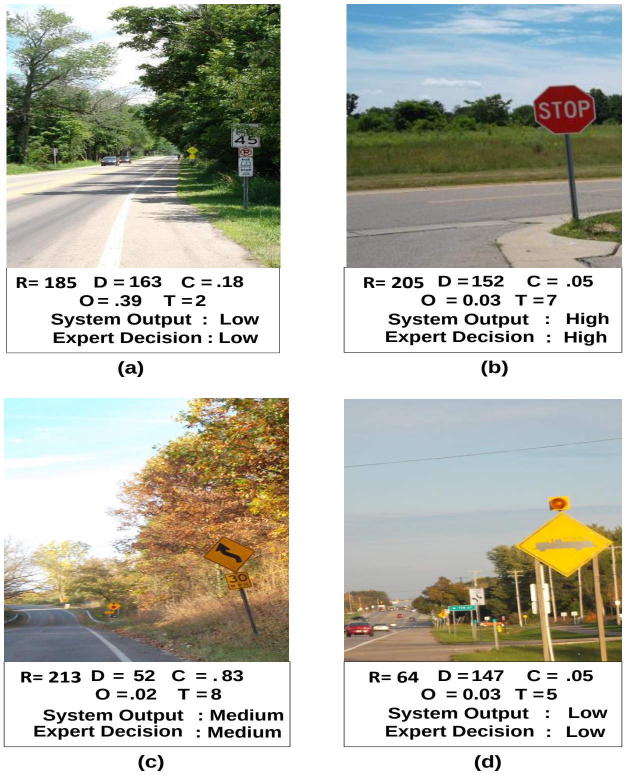

Fig. 7. Visibility estimation outputs of the proposed system for road signs with expert decision: a) Low, b) High, c) Medium, d) Low.

Rule weights hold significance in the determination of the overall decision-making process within the fuzzy system. They assign importance or precedence to different rules, emphasizing the relative significance of specific parameters in contributing to the final output. Properly calibrated weights ensure that more critical parameters exert a more considerable influence on the system's decision. The effect of these parameters on the system's output is intricate and interconnected. Subtle adjustments or alterations in membership function shapes, threshold values, or rule weights can significantly impact the system's performance. Well-tuned parameters often lead to more accurate, reliable, and adaptable outcomes, enhancing the system's robustness across diverse datasets and real-world conditions.

Understanding the influence of these parameters allows for iterative refinement, facilitating continuous improvement in the system's accuracy and adaptability. Through careful calibration and fine-tuning of these parameters, a fuzzy inference system can be optimized to yield more precise and dependable results, making it a valuable tool in addressing complex decision-making tasks where traditional binary logic falls short.

V. Conclusions

In this work, we proposed a fully-automated system to detect road signs in the United States and estimate their visibility from images captured by an in-vehicle camera. Sign visibility is defined as the drivers' capability to perceive road signs on roadways, encompassing both the ability to detect the signs (Detectability) and the ability to read and recognize their contents (Readability).

The proposed system can be deployed in Driver Assistance Systems (DAS) or by transportation agencies. The proposed system has deployed YOLOv8 to build a detection model of three different road sign categories. Then, it measured five visibility parameters which are: readability of sign foreground, color difference between the sign and its surroundings, complexity of surroundings, sign occlusion, and sign tilting. The proposed system classifies road signs to three visibility levels: high, medium, and low. A Fuzzy Inference System (FIS) connecting these parameters to the visibility level operates through a series of defined steps to determine the appropriate visibility label based on the input parameters. The proposed system has achieved outstanding efficiency results with mAP@0.5= 91.5% for the detection model and an accuracy= 92% for the visibility estimation module. The accuracy of the proposed visibility estimation system has been compared with human expert pre-determined decisions.

The proposed system is distinguished by its being fully-automated, the efficiency of detecting road signs under various illumination and occlusion conditions, the ability to classify road signs visibility to multiple levels and the inclusion of both readability and detectability parameters of road signs from the perspective of driver.

In the future, we are planning to include more road sign categories in the visibility estimation system. Additionally, the size of dataset can be increased to improve the precision of the detection model. Hardware implementation can also be implemented based on the proposed computer vision system.

Dual-Branch Grouping Multiscale Residual Embedding U-Net and Cross-Attention Fusion Networks for Hyperspectral Image Classification

Ning Ouyang, Chenyu Huang,' Leping Lin
School of Information and Communication, Guilin University of Electronic Technology, Guilin, China

***Abstract*—Due to the high cost and time-consuming nature of acquiring labelled samples of hyperspectral data, classification of hyperspectral images with a small number of training samples has been an urgent problem. In recent years, U-Net can train the characteristics of high-precision models with a small amount of data, showing its good performance in small samples. To this end, this paper proposes a dual-branch grouping multiscale residual embedding U-Net and cross-attention fusion networks (DGMRU_CAF) for hyperspectral image classification is proposed. The network contains two branches, spatial GMRU and spectral GMRU, which can reduce the interference between the two types of features, spatial and spectral. In this case, each branch introduces U-Net and designs a grouped multiscale residual block (GMR), which can be used in spatial GMRUs to compensate for the loss of feature information caused by spatial features during down-sampling, and in spectral GMRUs to solve the problem of redundancy in spectral dimensions. Considering the effective fusion of spatial and spectral features between the two branches, the spatial-spectral cross-attention fusion (SSCAF) module is designed to enable the interactive fusion of spatial-spectral features. Experimental results on WHU-Hi-HanChuan and Pavia Center datasets shows the superiority of the method proposed in this paper.**

Keywords—U-Net; multiscale; cross-attention; hyperspectral image classification

I. Introduction

Hyperspectral images (HSI) include a wealth of spatial and spectral information [1], which can accurately characterize the physical attributes of features, enhance the ability to discriminate features, and bring great convenience to feature recognition. However, classification of hyperspectral images has its own special problems, such as the redundancy of information in spectral bands [2], the scarcity of training sample data [3], and class imbalance, which bring great challenges to hyperspectral image classification (HSIC).

Traditional HSIC classification methods, such as linear classifier [4], support vector machine [5] and random forest [6], can achieve good classification effect through improvement, but many original traditional methods rely on manual features, and the classification effect is poor when the number of samples is small and the HSI data dimension is high. Therefore, Principal Component Analysis (PCA) has been applied to HSIC by a large number of scholars [7-10]. By compressing the original data to reduce the spectral dimension, the information redundancy between bands and the possible Hughes phenomenon can be avoided, which provides an effective treatment for subsequent feature extraction and enables the network to obtain higher classification accuracy.

With the development of deep learning, the encoder-decoder (U-net) [11] specially designed for biomedical image segmentation has been gradually applied to the field of hyperspectral image classification, which can obtain superior results with less training data. In the absence of datasets, Lin et al. [12] introduced U-Net to solve the problem of complex data capture in practice. Paul et al. [13] combined spectrum partitioning to reduce the redundancy of the spectrum, and then designed U-Net architecture by introducing deep separable convolution to reduce overfitting problems. Besides, due to the clear network structure of U-Net, any customized layer can be easily integrated into the existing network. For example, He et al. [14] embedded the Swin transformer into the classical CNN-based U-Net, which is dedicated to acquiring global contextual information of remote sensing images and obtaining deeper features in the master encoder. Xiao et al. [15] improved the spatial resolution of HSI by fusing spatial features of different scales and depths in the MSI for U-Net.

Moreover, in order to improve the classification performance of hyperspectral images, it has become a major research direction to jointly use spectral and spatial information to design classifiers. The construction of spatial and spectral information through dual branches can make full use of the information. Yang et al. [16] constructed a dual-channel CNN, extracting spectral and spatial information in each channel separately, and then connecting the spatial-spectral features by using cascade, but this simple feature connection cannot capture the complex relationship between the spatial-spectral features. Wang et al. [17] used the grouping strategy and the Long Short-Term Memory (LSTM) model to perceive spectral multi-scale information and obtain spatial context features in spectral finite element and spatial sub-network. Considering the different importance of spectral and spatial components, they used the method of adaptive feature combination for fusion. For effective fusion of spatial-spectral information, Sun et al. [18] designed a weighted self-attention fusion strategy, which combines the output weights of each branch of the previous network with the output weights of self-attention, and obtains efficient fusion on a multi-structured network. Yang et al. [19] used a dual-branch fusion mechanism to promote the exchange of feature information between the two branches through two upstream and downstream modules, so that local fine-grained features could be constructed in more detail and global context information could be better utilized. These works provide new ideas for dual-branch feature extraction and fusion in HSIC.

In general, the method based on U-Net can better learn the representation of the input natural image, which is conducive to the classification of hyperspectral images to obtain high accuracy and obtain satisfactory results, but some small size information will be lost in the process of down-sampling. the design of fusion mechanism under two-branch conditions will also affect the effectiveness of the network. In this context, we propose a dual-branch grouping multiscale residual embedded U-Net and cross-attention fusion network. Among them, the main contributions are as follows:

- A dual-branching grouping multiscale residual embedded U-Net network (DGMRU) is proposed, which combines grouping multiscale residual block (GMR) and U-Net to extract rich global contextual information and deepen the function of feature network extraction.
- The grouping multiscale residual block (GMR) is constructed for digging multiscale information. The multiscale characteristics of this module enable the network to guide the network to focus on various types of samples at different scales, thereby improving the missed detection problem under spatial features and the redundancy problem under spectral features, and improving the effectiveness of feature extraction.
- A spatial-spectral cross-attention fusion module (SSCAF) is designed to cross-fuse the spatial and spectral features generated by the double branch, that is, to fuse the parameters of the other branch into its own branch, increase the interaction of the two branches, and promote the full fusion of the two branches.

The rest of the paper is organized as follows. Section II describes the general framework of the DGMRU_CAF network, GMR and SSCAF, respectively. Section III discusses the dataset, the experimental settings, the experimental results and the discussion. Finally, in Section IV, conclusions are given.

II. Methodology

A. The Overall Framework of DGMRU_CAF

The DGMRU_CAF proposed in this paper is composed of DGMRU, SSCAF and classification network, as shown in Fig. 1. The DGMRU is divided into a spatial GMRU branch which takes the HSI neighbourhood block p_n as input and a spectral GMRU branch which takes the spectral band s_n as input. Each branch extracts corresponding features from the combined paths of U-Net and GMR with different nuclear scales, so as to obtain deeper feature information. In this regard, the designed GMR enhances the model's perception of multiscale spatial and spectral scales by grouping, multiscaling, and residual connection to retain more detailed feature information. Afterwards, in order to jointly utilize spatial and spectral information, the SSCAF module is constructed. Under the guidance of its own features, the module introduces the features of another branch and carries out interactive fusion to generate spatial-spectral features. Finally, in order to obtain the classification results of HSI, the obtained spatial-spectral features are passed through a classification network consisting of a fully connected layer and a softmax activation layer.

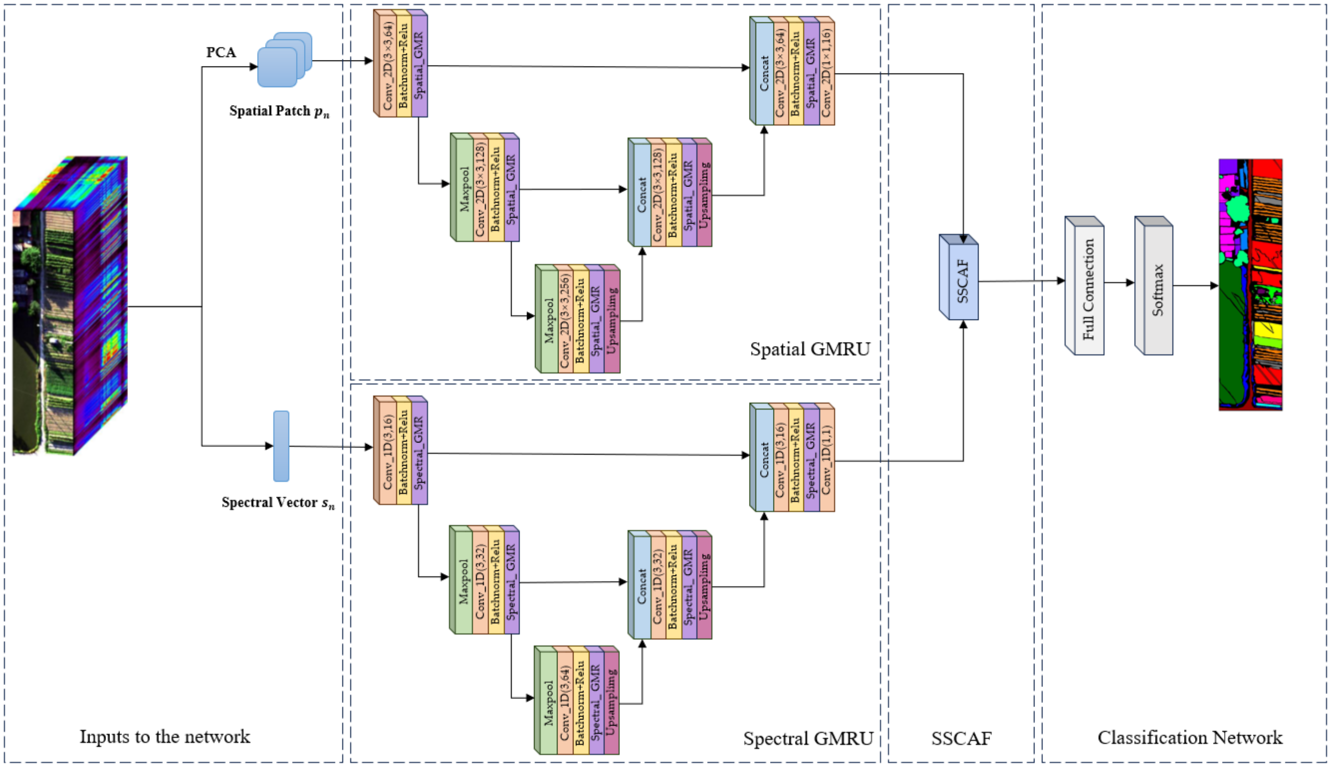

Fig. 1. The overall structure of DGMRU_CAF.

B. The GMR Module

In this paper, a GMR module is proposed to retain more features without increasing parameters. For each branch, spatial GMR and spectral GMR are designed respectively.

1) Spatial GMR: As shown in Fig. 2(a), under the branch of spatial GMRU, for the intermediate features of the input space, spatial GMR uses the grouping module to group its spatial channels in sequence, so that each group of vectors contains different channel information, and each group of spatial vectors is expressed as:

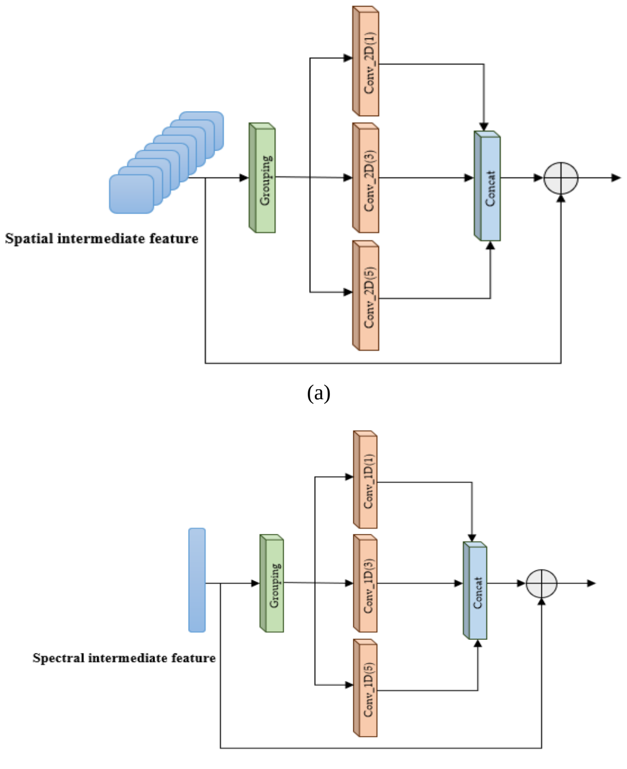
$$c_{spa\_i} = [c_{i\times t}, c_{i\times t+1}, \cdots, c_{i\times t+t}], i = 0, \cdots, g-1 \qquad (1)$$

where, $c_{i\times t}$is the characteristic information corresponding to the channel in the $i \times t$ segment, t represents the number of channels in each group, and g represents the number of groups.

In the process of down-sampling, the features of small-size objects are easy to be weakened and lost, and it is difficult to recover these features by up-sampling, which leads to the misclassification of small-size objects. In order to solve this problem, this paper uses convolution of different sizes for multi-scale feature extraction after grouping to capture local features inherent in space. The convolution output of each group is:

$$s_i = W_i * x_i + b_i \qquad (2)$$

where, x_i is the feature vector of the ith group, W_i is the weight coefficient of the ith group, and b_i is the bias coefficient of the ith group.



(a)

(b)

Fig. 2. The structure of GMR module. (a) Spatial GMR (b) Spectral GMR.

Then, in order to complement the context information of features at different scales, all groups are merged by a cascade method. Finally, the rich low-frequency information is transmitted directly through the residual connection, which speeds up the training of the network. In short, using spatial GMR can extract more representative fine features.

2) Spectral GMR: Hyperspectral images contain a lot of spectral information, but the spectral information is redundant, which is easy to produce Hughes phenomenon and affect the classification results. In order to cope with this problem, and effectively capture the local relevant information of the spectral band. As shown in Fig. 2(b), for the spectral intermediate features, the grouping module of spectral GMR is used to group their spectral dimensions in sequence, so that each group of spectral vectors contains different spectral band information. Among them, the number of spectrum contained in each group and the distance between spectrum are related to the number of divided groups. Each set of spectral vectors is represented as:

$$r_{spe\_i} = [r_{i\times m}, r_{i\times m+1}, \cdots, r_{i\times m+m}], i = 0, \cdots, g-1 \qquad (3)$$

Where, $r_{i\times m}$is the characteristic information of the spectral dimension in the $i \times m$ segment, m represents the number of spectral bands in each group, and g represents the number of groups.

After that, convolution of different scales is used to extract the grouped spectral features, so as to weaken the correlation between spectrums and reduce the redundancy of information. After that, the cascade method is used to merge the output spectral features of each group, which complements the local information of the spectral features of different scales and makes full use of the correlation between the spectral bands. Finally, the original global information is propagated directly by residual connection, which alleviates the problem of gradient degradation. In conclusion, the global and local information of spectra can be fully extracted by spectral GMR.

C. The SSCAF Module

Considering the complementary characteristics between spatial and spectral features, in order to promote the effective fusion of these two types of features, a spatial-spectral cross-attention fusion (SSCAF) module is proposed in this paper. As shown in Fig. 3, the module is a combination of a cross self-attention module, a positional self-attention module (PAM) and a channel self-attention module (CAM). The cross self-attention operation is defined as follows:

$$y_{i,j} = \frac{1}{C(x)} \sum_{\forall i,j} f(f_i, f_j) g(f_i) \qquad (4)$$

The f_i, f_j represent the spatial and spectral feature vectors generated by the two branches, respectively, the function f produces the adaptive weight vector between the two vectors, the function g produces the feature representation of the input individual input vectors, and the normalization factor ss is defined as $C(X) = \sum_{\forall i,j} f(f_i, f_j)$.

To further establish internal connections, PAM and CAM modules are introduced to refine spatial and spectral features. Finally, the feature information is summed and complementarily fused to obtain the final spatial-spectral fusion feature.

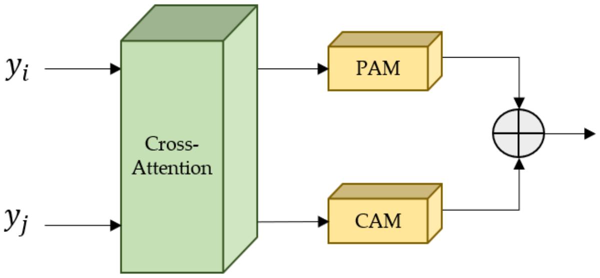


Fig. 3. The structure of SSCAF module.

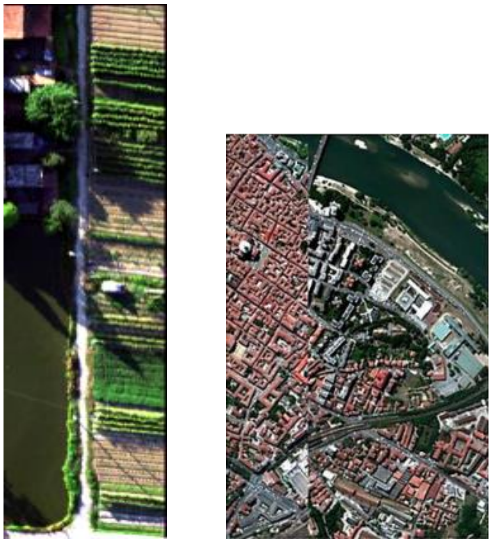
III. Results

A. Dataset and Experimental Setting

In this section, to demonstrate the validity of the proposed method, we conduct a number of experiments on two datasets, which include WHU-Hi-HanChuan (HC) [20],[21] and Pavia Centre (PC). We divided the label samples in different ways for each data set. Table I and Table II provides the specific number of training, test sets and total samples for each class of the two data sets. The false color maps of the two datasets are shown in Fig. 4.



(b)

Fig. 4. False color maps for the two datasets. (a) False color map of HC, (b) False color map of PC.

In the process of training the model, some parameters are set, where the training epoch is set to 200, the batch size is 16, the learning rate is 0.001, the weight decay is 1e-5, and the training is repeated 10 times for all the datasets. In order to prove the superiority of the proposed method, this paper conducts comparative experiments with six advanced methods, namely 2DCNN[22], SSRN[23], A2S2K[24], ASSMN[17], U-Net[11], HyperUnet[13]. The overall accuracy (OA), average accuracy (AA), Kappa coefficient and classification accuracy of single-class are used as the performance evaluation criteria of the model. The higher the each index, the better the classification effect will be.

B. Analysis of Classification Results of Dataset

- Classification Maps and Result of HC Dataset.

The results on the HC dataset are shown in Table III, with the best OA, AA, and Kappa results highlighted in bold. Fig. 5 shows the classification diagram for the different methods.

It can be seen from Table III that our method achieves the best performance, with OA of 96.22%, AA of 96.62%, and Kappa of 95.57%. Compared with other methods, OA, AA, and Kappa are increased by at least 0.8%, 0.76%, and 0.92%. This is because the proposed method has the new idea of combining dual-branch and U-Net, which improves the ability of convolutional feature extraction, so that the method in this paper can achieve the best performance. The grouping multiscale residual block is designed to extract features with different kernel sizes in each group, and reduce the loss of feature information to construct effective feature extraction. The classification results of HSI prove the validity of the method. In addition, it can be seen that the OA of 2DCNN is the lowest, only 78.91%, which is because 2DCNN is trained only on the spatial dimension, ignoring the information between spectrum, and the model performance is poor. Compared with 2DCNN, U-Net constructs U-shaped network structure, improves classification accuracy and performance, and improves 13.38%, 15.84% and 15.3% respectively in the three evaluation criteria. HyperUnet networks, which combine U-Net and grouping ideas, perform poorly on this dataset, possibly because of poor adaptability to large datasets. In addition, it can be observed that the evaluation value of SSRN is comparable to that of U-Net. SSRN extracts spatial-spectral features through the combination of two continuous spectral blocks and spatial blocks. However, the input of the spatial block comes from the spectral block, which leads to the loss of some spatial information in the spectral block, resulting in poor classification accuracy. The OA of A2S2K is better than that of SSRN, increased by 1.69%, which indicates that the introduction of attention mechanism and adaptive methods has a significant impact on the network. Compared with other single-branch algorithms, the dual-branch ASSMN results in better OA values, which indicates that the full use of spatial and spectral feature information can achieve superior classification results, and the effect is much better than that of single spatial or spectral information. Although the effectiveness of the method in this paper is inferior to other algorithms in some categories, the results of these methods are very close to the results of the best classification, so the OA, AA and kappa coefficients of the method in this paper are the highest among these methods.

From the classification diagram shown in Fig. 5, the "salt and pepper" noise is the most severe because spectral information is not included in 2DCNN, while the classification diagram of other networks shows stronger classification ability because spectral information is taken into account. The method proposed in this paper considers the spatial features of different scales and solves the redundancy problem to obtain more small-size objects and feature information. Therefore, for classification maps with more small sizes, the method proposed in this paper is easier to obtain more accurate and cleaner classification maps, and the classification results of various categories correspond to the results in Table III.

OA（%）	78.91	92.61	94.30	92.29	80.75	95.42	**96.22**
AA（%）	78.29	94.11	94.83	94.13	78.22	95.86	**96.62**
Kappa×100	75.70	91.40	93.33	91.00	77.69	94.65	**95.57**

- Classification Maps and Result of PC Dataset

The results on the PC dataset are shown in Table IV, with the best OA, AA, and Kappa results highlighted in bold. Fig. 6 shows the classification diagram for the different methods.

As shown in Table IV, on this PC dataset, all methods, including 2DCNN, achieve decent classification results. Obviously, the AA of both 2DCNN and SSRN are lower than 90%, which is due to poor classification accuracy in some categories, and the classification accuracy of some categories is less than 80%. The values of A2S3K, U-Net and HyperUnet in OA, AA and Kappa all reach more than 90%, but it is still difficult to improve the classification accuracy for some categories. As a two-branch multi-scale network, ASSMN has more stable classification results. Method of this paper is superior, has the best OA, AA and Kappa evaluation values, and achieves the best accuracy for some specific categories, such as Class 4 Self-Blocking Bricks and Class 5 Bitumen, which further proves its validity in terrain classification.

As shown in Fig. 6, our method is smoother and more consistent.

C. Ablation Analysis

In this part, extensive ablation experiments are conducted to demonstrate the validity of the proposed GMR, SSCAF on the two datasets.

The validity analysis of GMR is shown in Table V. It can be seen that without GMR, the values of OA, AA and Kappa of the model are the lowest in the experiment, because it will lead to some small-size samples being ignored in the process of down-sampling. In contrast, the simultaneous presence of GMR modules with two branches can extract spectral and spatial features more effectively, which contributes to the final classification, and its OA, AA, and Kappa can achieve the best results compared with other comparison strategies. Among them, OA increased by 2.6% and 1.51% in the two datasets, respectively, which means the necessity of GMR. In addition, the OA value of "Only Spe-GMR" is higher than that of "Only Spa-GMR", because the HSI contains enough spectral information to extract more useful feature information from it.

The results of SSCAF ablation experiments are shown in Table VI. It can be found that the integration of SSCAF into the two branches of "With GMR" has significantly improved network performance, which means that SSCAF can complement each other with spatial and spectral information to contribute to the final classification decision. Compared with without SSCAF, OA is increased by 4.54% and 3.03%, AA is increased by 3.14% and 3.59%, and Kappa is increased by 5.32 and 3.46, respectively, which fully proves the necessity of the existence of SSCAF.

D. Discussion of Training Times and Testing Times

In order to measure the efficiency of the proposed method, this paper conducted comparative experiments in training and testing time, and the results are shown in Table VII. 2DCNN has the least training time and testing time than other methods, because the simple 2DCNN architecture has fewer training parameters, but the classification accuracy is relatively low. Both U-net and HyperUnet have encoding and decoding path modules, and the addition of more convolutional layers makes the consumption time slightly longer than that of 2DCNN. SSRN and A2S2K use 3D convolution and introduce ResNet, which speeds up convergence and reduces training time. In ASSMN, the combination of dual-branch and multi-scale, together with its strategy of spectrum grouping and spatial grouping, makes the model more complex and requires longer training and testing time. However, the training time and testing time of the method in this paper are average among these comparison methods. The attention mechanism used in the SSCAF module increases the complexity of the proposed network, and the obtained training time and testing time are not the shortest. However, the method proposed in this paper can strike a good balance between accuracy and efficiency, and has certain advantages.

TABLE VII. RUNNING TIME OF DIFFERENT METHODS ON TWO DATASETS

Dataset		2DCNN	SSRN	A2S2K	U-Net	HyperUnet	ASSMN	Proposed
HC	Train(s)	8.96	48.53	63.96	22.54	38.05	192.15	82.46
	Test(s)	42.15	123.80	205.50	61.27	82.04	121.01	138.05
PC	Train(s)	3.11	7.84	11.75	7.45	8.65	54.90	18.88
	Test(s)	9.32	18.74	23.53	34.74	23.30	69.78	73.41

IV. CONCLUSION

In this paper, we propose a dual-branch grouping multiscale residual embedded U-Net and cross-attention fusion network for hyperspectral image classification to improve the classification accuracy in the presence of sparse training samples. The designed DGMRU module is used to extract multiscale context information feature, which is suitable for the case of insufficient HSI samples. Among them, the designed GMR module increases the receptive field without adding parameters, and the feature extraction effect is better than that of the non-existent GMR module, which proves the necessity of this module. In addition, the proposed SSCAF maximizes the utilization of spatial-spectral features by constructing the intrinsic relationship between spatial and spectral features through cross-attention. Compared with other advanced algorithms, the method proposed in this paper has the best experimental results, and in the two data sets, OA increases by 0.8% and 0.47% at least, which is feasible and effective. In the future, we will consider further reducing the complexity of the network model and improving the computational efficiency while maintaining the classification accuracy.

ACKNOWLEDGMENT

The authors thank other laboratories for providing hyperspectral datasets, as well as editors and anonymous reviewers for their comments and suggestions.

***Abstract*—In this study an optimized UNET model is used for FPGA-based inference in the context of brain tumour segmentation using the BraTS dataset. The presented model features reduced depth and fewer filters, tailored to enhance efficiency on FPGA hardware. The implementation leverages High-Level Synthesis for Machine Learning (HLS4ML) to optimize and convert a Keras-based UNET model to Hardware Description Language (HDL) in the Kintex Ultrascale (xcku085-flva1517-3-e) FPGA. Resource strategy, First in First out (FIFO) depth optimization, and precision adjustment were employed to optimize FPGA resource utilization. Resource strategy is demonstrated to be effective, with resource utilization reaching a saturation point at a 1000-reuse factor. Following FIFO optimization, significant reductions are observed, including a 55 percent decrease in Block RAM (BRAM) usage, a 43 percent reduction in Flip-Flops (FF), and a 49 percent reduction in Look-Up Tables (LUT). In C/RTL co-simulation, the proposed FPGA-based UNET model achieves an Intersection over Union (IoU) score of 74 percent, demonstrating comparable segmentation accuracy to the original Keras model. These findings underscore the viability of the optimized UNET model for efficient brain tumour segmentation on FPGA platforms.**

Keywords—UNET; field programmable gate array; high-level synthesis for machine learning; brain tumour segmentation

I. INTRODUCTION

Brain tumours are abnormal growths of cells in or around the brain and can be cancerous or non-cancerous [1]. Mutations in the DNA, radiation exposure and immune system problems are the causes of brain tumours which cause a noticeable mortality and low recovery rates. Early detection of brain tumours is crucial as it increases the possibility of successful treatment [2]. Magnetic resonance imaging (MRI) and computed tomography (CT) are imaging modalities used to diagnose brain tumours, with MRI producing more detailed brain scans [3]. Diagnosis of brain tumours from MRI requires skilled manpower in the medical field [4]. The expertise required for brain tumour diagnosis is insufficient and is susceptible to the human error factor, which has resulted in the implementation of deep learning (DL) to predict tumours to assist doctors [5].

Convolutional Neural Networks (CNN) are the deep DL model that perform better for feature extraction, but they require large datasets for efficient training which is hindrance for applications in medical imaging as large dataset are not easily accessible. Ronnerberger et al. proposes a UNET architecture that requires less image samples for successful model learning [6]. The UNET architecture has a drawback of consuming a lot of resources and computing inefficiency when applied in CPU and GPU [7]. The computational inefficiency of existing tumour prediction methods has become a critical concern in the medical imaging field. In response to this challenge, recent research has focused on areas to apply the UNET model for brain tumour detection in field programmable gate arrays (FPGA's), due to their inherent speed advantage over traditional processors. In a related study [8], the FPGA implementation of CNN was discussed, emphasizing on the necessity of a balanced design that considers resource utilization against performance.

In this work the challenge of balancing computational resource against performance in UNET for brain tumour prediction is addressed by proposing a modified UNET model and a comprehensive optimization of hardware resource utilization during FPGA inference. The modifications methods used in this work are tailored to enhance efficiency and efficacy of the UNET model for brain tumour prediction. The UNET model was optimized by reducing the size of original UNET model and FPGA hardware optimization strategies used entailed resource strategy, FIFO buffer depth optimization and precision.

The rest of this paper is organized as follows: Section II is literature review of relevant theory and related work; Section III describes materials and methods to carry out the work; Section IV is analysis and interpretation of results and discussion and conclusion is given in Section V and Section VI respectively.

II. LITERATURE REVIEW

Brain tumour segmentation is the technique of automatically detecting and labelling malignant brain tissues depending on tumour type [9]. Convolutional Neural Network has been successful in image segmentation applications in deep learning with applications in the medical field. The use of CNN in image segmentation entails deciding on the dataset to train the model; CNN architecture to use; loss function and the back-propagation weight adjustment algorithm.

A. Brain Tumour Dataset

Brain MRI scans is private patient's data which require confidential handling by health practitioners. However with the rise in the use of technology in the medical field, there is a need for the data to be made public and anonymous of patient's identity [10]. International research institutes have made this data available for public use in developing medical imaging solutions such as The Cancer Genome Atlas (TCGA) dataset, BrainWeb dataset and MICCAI Brain Tumour Segmentation (BraTS 2020) Challenge dataset.

1) The Cancer Genome Atlas (TCGA): TCGA has different data such as TCGA Lower Grade Gliomas (LGG) and Glioblastoma Multiforme (GBM) which are basically grades of gliomas standardized by the World Health Organization. LGG are less aggressive while GBM is an exceptionally aggressive kind of brain glioma that develops from astrocytes or their progenitors [11]. In reserach [12], automatic and manual identification of GBM sub-compartments segmentation was performed and results showed that automated segmentation gave the highest area under the curve (AUC) as compared to manual segmentation. The TCGA dataset was created to identify a causal relation between genomic alterations and cancers [13]. TCGA data does not have specific pixel segmentation of tumour regions which will require additional radiologist expert knowledge to label the scans for training a machine learning model [14].

2) BrainWeb: Simulated Brain Database (SBD): The SBD currently has brain MRI data that has been simulated using two anatomical models: normal and multiple sclerosis (MS). T1-weighted (spin-lattice relaxation), T2-weighted (spin-spin relaxation), and PD-weighted (proton-density) sequences were employed to simulate entire three-dimensional data volumes for these models [15]. In study [16], the SBD database was utilized for improving the magnetic resonance imaging (MRI) segmentation using fuzzy C-means method and obtained experimental results that were more stable and accurate when compared to existing methods. SBD was created for computer aided image analysis by providing samples with ground truth. The SBD dataset is simulated for general use in computer-based analysis algorithms which diminishes its appeal when compared to other datasets sourced from actual patients.

3) MICCAI Brain Tumour Segmentation (BraTS 2020) challenge dataset: The BraTS 2020 dataset is made up of clinically obtained pre-operative multimodal MRI images of Glioblastoma (GBM/HGG) and lower grade glioma (LGG) that were collected from multiple institutions [17,18]. It contains a diagnosis that has been verified pathologically and has been divided into training and validation data. The dataset has expert manual segmentations that define the boundaries of the tumour regions, which include enhancing tumour, the peritumoral edema, and the necrotic and non-enhancing tumour core. All the scans of BraTS are in Neuroimaging Informatics Technology Initiative (NIfTIS) file format and they describe native (T1) and post-contrast T1-weighted (T1Gd), T2-weighted (T2), and T2-Fluid Attenuated Inversion Recovery (FLAIR) volumes, and were acquired using various clinical protocols and scanners from numerous institutions. The BraTS dataset has been used in several research with [19] introducing a residual mobile U-Net (RMU-Net) for MRI brain tumour segmentation. The RMU-Net archived dice coefficient scores for WT, TC, and ET on the BraTS 2020 dataset of 91.35%, 88.13%, and 83.26%, respectively, and 91.76%, 91.23%, and 83.19% on the BraTS 2019 dataset, and 90.80%, 86.75%, and 79.36% on the BraTS 2018 dataset.

The BraTS dataset is more versatile than the TCGA as it has manual segmentation that has been done by experts, which is essential for the training of a prediction model. In comparison to the SBD, BraTS dataset is more competitive as it has been sourced from real MRI scans that represents the real life cases as compared to simulated SBD. BraTS dataset is also specialized for segmentation with UNET as it has ground truth that has multiclass labels [20].

B. U-NET

U-NET is a convolutional neural network that was proposed by [6] for biomedical image segmentation applications. It was optimized to archive accurate prediction with few training images, as they are normally few sample images in the medical field. The original model constitutes of a contraction path which records context and expansion path which enables accurate localization. The UNET model is computationally demanding which translates into high resource utilization on hardware. There have been proposed methods to reduce the high resource demand by the UNET.

In study [21] a reduced UNET model architecture for classification of weeds and crops using segmentation was proposed. Reduction of the model was archived by reducing the number of filters per convolution layer. The proposed model in [21] has parameters that are 27% smaller while maintaining accuracy of 95% and an error rate that is 7% lower than the original UNET model. The reduction is however done on the number of filter per layer, and maintains the UNET architecture in terms of layers. In [22], the reduced depth UNET architecture with three down-sampling and two up-sampling sections is proposed, replacing the five down-sampling and four up-sampling sections of the original UNET architecture. Results obtained showed that the approach produced more accurate results [22]. There is gap in the existing work to combine reduction in number of filters and model depth as proposed by [21, 22].

1) Evaluation criteria: In order to evaluate segmentation there are metrics in image processing that can be used for quality assurance. The output image pixels are compared against those of the ground truth to establish the extent of accuracy. Intersection over union (IoU) and dice similarity coefficient (DSC) are the most common used metrics in medical imaging.

a) Intersection over union (Iou): Intersection over union is an evaluation metric that measures the intersection between the predicted mask and the actual mask, also known as the Jaccard index [23]. IoU calculation incorporates two indicators of false positive (FP) and true positive (TP) results. A true positive occurs when the model accurately predicts that a pixel is a component of an object when in fact it is. If the model forecasts a pixel as belonging to an item when in fact it belongs to the background, this is known as a false positive. The intersection of the anticipated segmentation mask and the ground truth mask, when compared to the union of the two masks, is known as the IoU. IoU is particularly useful in multiclass segmentation where there is an imbalance in classes.

$$\text{IoU} = \text{TP} / (\text{TP} + \text{FP} + \text{FN}) \quad (1)$$

where, TP is the number of true positives, FP is the number of false positives, and FN is the number of false negatives.

b) Dice similarity coefficient: The Dice similarity coefficient also termed as Srensen-Dice index or simply the Dice coefficient is a statistical instrument used to determine the similarity of two sets of data [24, 25]. The dice similarity coefficient is both a spatial overlap indicator and a tool for validating reproducibility. The proportion of specific agreement was another name for it. A DSC value ranges from 0 to 1, with 0 indicating no spatial overlap and 1 representing total overlap. DSC examines the agreement between a predicted segmentation and its ground truth at a pixel level.

The equation for the DSC metric is:

$$\text{DSC}=2 * |X \cap Y| / (|X| + |Y|) \quad (2)$$

- Where X and Y are two sets.
- A set with vertical bars on either side denotes the set's cardinality, or the number of elements in that set, e.g. |X| denotes the number of elements in set X.
- ∩ is used to express the intersection of two sets and refers to the items that are shared by both.

2) Model Training Optimization Algorithm

Cost Function

The error between real y and predicted y at its present position is measured by the cost (or loss) function [26]. A loss function can be used to increase the effectiveness of the machine learning model by giving it feedback in order to change the parameters reducing the error, and ultimately locating the local or global minimum. Until the cost function is near to or equal to zero, it iterates repeatedly, moving in the direction of steepest descent. Learning in the model stops at the steepest descent. A cost function determines the average error across the whole training set, whereas a loss function just considers the error of one training sample [27].

Gradient Descent (Gd)

Optimizers update the model in response to the output of the loss function, consequently reducing the loss function. To locate a local minimum or maximum of a given function, gradient descent (GD), an iterative first-order optimization technique, is utilized. This method reduces the cost function and is mostly used as an entry level optimization in machine learning application [28]. Gradient descent however uses a constant learning rate which may need to be tuned manually to reach optimal performance. A higher learning results in faster training which require fewer epochs at the cost of overshooting the minimum. On the contrary a smaller learning rate will result in slower learning which requires more epochs for convergence [29]. The most common optimizers derived from gradient descent are Adaptive Gradient (Adagrad), Adaptive Delta (AdaDelta), Stochastic Gradient Descent (SGD), Adaptive Momentum (Adam), Cyclic Learning Rate (CLR), Adaptive Max Pooling (Adamax), Root Mean Square Propagation (RMS Prop), Nesterov Adaptive Momentum (Nadam), and Nesterov accelerated gradient (NAG) for CNN [30].

Adaptive Moment Estimation Optimizer (Adam Optimizer)

When training neural networks and machine learning models, the gradient descent approach is typically employed for optimization [27].

The Adam optimizer was made for deep neural network training optimization. It can be described as a combination of momentum-based stochastic gradient descent and RMSprop. Adam optimizer delivers computational performance, lower memory usage, and invariant to diagonal rescaling of gradients for applications with huge amounts of data or parameters [31]. Adam optimizer also computes adaptive learning rate, which entails tuning the learning rate during back-propagation, a property which gives it a competitive edge over other gradient descent optimizers. In study [30], ten common GD based optimizer algorithms were compared and analysed, and results obtained showed that Adam optimizer was more competitive with an accuracy of 99.2%.

C. Model Conversion to Hardware Description Language (HDL)

Workflow of implementing neural network in FPGA entails building of model architecture by deciding on the relevant layers and the training of the model using frameworks such as Tensorflow, Keras or Pytorch in high level language such as python and then converts the trained model to hardware description language (HDL). FPGA vendors have high level synthesis tools which synthesize from C++ to HDL. Converting a model in python trained to C++ can be a daunting task. However there are automation tools that bridge between trained models and C++ representations, such as LegUp, DNN Weaver, FINN and HLS4ML among others.

A. Conversion Tools

1) LegUp: LegUp is a high-level synthesis tool that uses C programming to get the system's behavioural description and creates an RTL netlist in Verilog HDL [32]. LegUp is compatible C/C++ language program and gives an output of Verilog HDL. The four major steps in LegUp HLS process are allocation, scheduling, binding, and RTL generation, which run consecutively [33]. LegUp supports Microchip PolarFire FPGA’s.

2) FINN: FINN is an experimental framework developed by Xilinix Research Labs that focuses on the use of deep neural networks on FPGAs. It is designed for Xilinx FPGAS for converting quantized neural networks (QNNs) to HDL. FINN supports Brevitas which is a Pytorch package for neural network quantization that supports post training quantization (PTQ) and quantization aware training (QAT) [34].

3) DNNWeaver: DNNWeaver is an alternate converter for trained model to HDL implementation in FPGA, made at the

Alternative Computing Technologies (ACT) Laboratory, University of California [35]. A synthesizable FPGA accelerator with high efficiency and performance was achieved in [35]. The tool however only supports Caffe model which is a limitation for Tensorflow and Pytorch frameworks applications.

4) HLS4ML: HLS4ML is a tool for machine learning model implementation in FPGA covering both Vivado, Vitis and Quartus HLS backend and C++ inference templates [36]. The tool was developed for the CERN Hadron Collider (LHC), for fast capturing of results from detectors in the LHC. HLS4ML features Keras, Pytorch and ONNX frameworks, models C++ equivalent representations conversion, which can then be transformed to HDL by the backend HLS. Fully connected NN (multilayer perceptron, MLP), Convolutional NN, Recurrent NN (LSTM) and Graph NN (GarNet) are neural network architectures supported by HLS4ML. The support for different backend, frameworks and neural network architectures makes HLS4ML a more suitable tool for FPGA neural network inference.

Neural network implementation consumes a lot of FPGA resources that would be impossible to implement without optimization, which has led research work that incorporates FPGA hardware optimization when using HLS4ML. In study [37], inference of jet substructure model for particle physics in FPGA, archived Flip-flop and BRAM utilization below 4% of budget by employing bit width adjustment. FIFO buffer depth optimization was applied in [38] by recording buffer occupancy during the RTL simulation and then re-running the synthesis with updated FIFO buffer depth reduced resource utilization BRAM by 81%; LUT by 35% and FF by 37%.

III. Method and Materials

A. 2D UNET Architecture

The original UNET has five blocks in the contraction path that entail convolution, ReLU and max-pooling operations. Fig. 1 shows four blocks that perform up-sampling, convolution and ReLU in the expansion path, that are connected to their corresponding layers in contracting path. In this work the UNET architecture was reduced to reduce the resource requirement of the model [39].

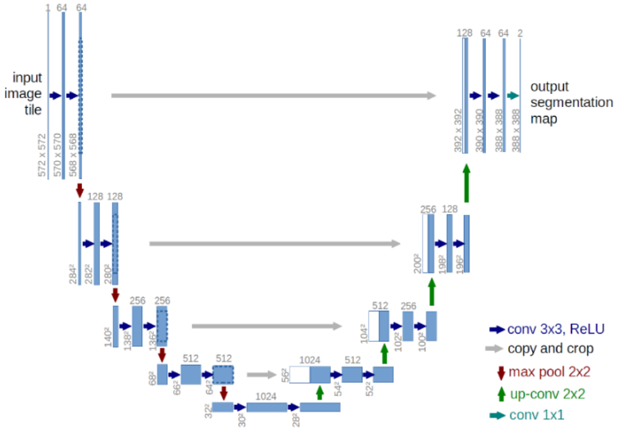

Fig. 1. UNET architecture [39].

B. Reduced UNET Model

The depth of the UNET architecture was reduced and the numbers of filters per layer were reduced. Filter numbers were reduced by 93.8% per layer and only one block of filter was used instead of two per layer. In the contraction path the feature extraction blocks were reduced from five to two consisting of 3*3 convolution kernels, 2*2 max-pooling. For the expansion path feature extraction blocks were reduced to two from four consisting of 2*2 up-sampling and concatenate path from the contracting layer as depicted in Fig. 2. The resulting model reduced model total parameters by 99%. Decreasing the model however comes with a cost of accuracy as the features that the model can capture are reduced. Tensorflow Keras framework was used to train the model.

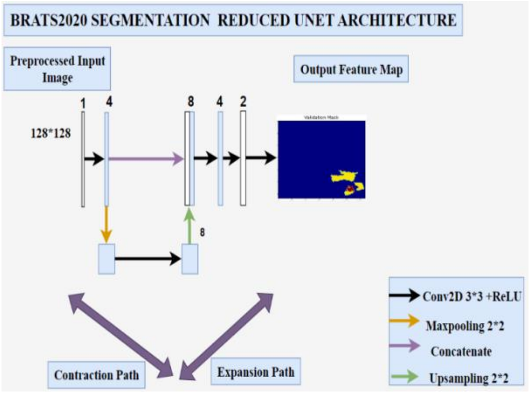

Fig. 2. Reduced UNET architecture.

C. Data Pre-Processing

Data pre-processing entails formatting dataset images to match the input size and features of the UNET model architecture. The BraTS 2020 dataset was used in this work and was pre-processed by resizing, min-max scaling and slicing before being used for training and testing of the model. In order to capture more features T1CE, T2 and FLAIR modalities were used for training.

Resizing

BraTS 2020 dataset consists of 3D MRI images with modalities and segmentation masks marked by experts. The 3D-MRI scans were resized from 240*240*155 to 128*128*128 dimension to reduce the unnecessary background data and for uniformity in the data. Fig 3 shows the resized image with dimensions 128*128 and background cropped out.

1) Min-max scaler: The images were scaled using the min-max scaler for a mean of 0 and max value of 1. Scaling helps to standardize the data for efficient training of the model.

2) Slicing: Since the model was defined for 2D convolution kernels each image was sliced to from 3D to 2D slices for all the modalities and masks. The modalities for each sample were converted to numpy array and combined or stacked into one image which translate to input channels in the model architecture. Fig. 3 is a plot of a 2D slice from the 127 slices obtained per 3D image slicing.

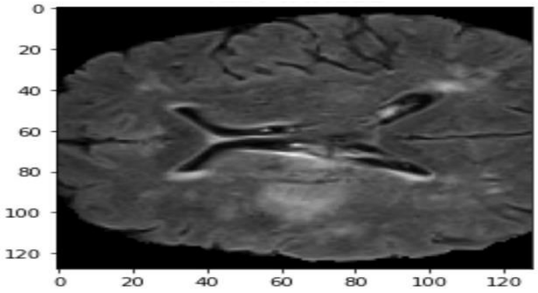

Fig. 3. Pre-processed BraTS 2020 2D slice.

3) Data Generator: A data generator was defined for loading the images and masks during training. The images and masks were loaded as an (X,Y) tuple. In the tuple method the X represents the data which was passed through the model for training and Y is the expected output which was used for calculating the loss against the model output at each iteration.

D. Adam Optimization

Adam optimizer was used during the training to update the weights and learning rate to reach lowest possible loss, through gradient descent method. In order to calculate the loss, dice score coefficient (DSC) was used to compute the total loss which was then back-propagated for updating weights and the learning rate. The optimizer weights were removed from the model after the training since they are not required for inference.

E. Tensorflow Keras Model Conversion to C++ and RTL

HLS4ML was used for converting the trained model to HDL. Adam optimizer Weights added to the model during training was removed before conversion. This reduced the memory footprint of the model as optimizer weights are not required for inference. A script for generating the C++ equivalence of the model was developed. The script describes the optimization category in terms of resource or latency, clock, input/output type (io_type) and backend HLS tool that was used. Fig. 4 illustrates the process flow from model training to FPGA implementation using HLS4ML.

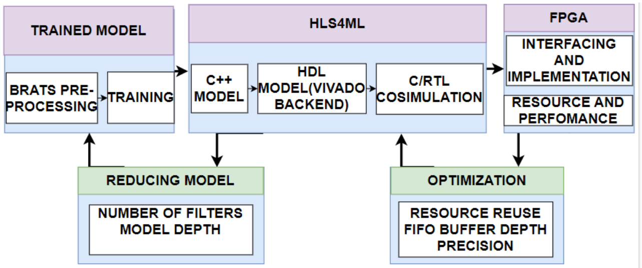

Fig. 4. HLS4ML conversion process.

Conversion to RTL

Table I illustrates the configuration used to convert the reduced model to HDL. The C++ generated representation of the model was obtained from the templates in hls4ml that define CONV2D, MAXPOOL and other layers defined in the model. Vivado HLS supports converting C++ model representation to HDL. In this work the C++ model was converted to Verilog, System-C and VHDL. The main files generated from the conversion are the HDL, data and constraints. HDL files describe various layers of the model; data files contain the weights and biases and the constraint files define the timing and layer interconnections.

TABLE I. REDUCED UNET CONVERSION TO HDL CONFIGURATION

Configuration	Parameter
Backend	Vivado HLS
FPGA	Kintex Ultrascale Part- xcku085-flva1517-3-e
Strategy	Resource (Reuse Factor)
FIFO Depth (Initial)	100_000
Precision	Fixed point arithmetic(ap<>)

F. HDL Optimization

In order to optimize the FPGA resource utilization the precision, resource strategy and FIFO buffer depth optimization techniques were used.

1) Precision: Floating point numbers due to their limitless precision in computation leads to an increased utilization of resources. Arbitrary fixed point type was used in this work which is defined by ‘ap_fixed<a,b>’, where ‘a’ is the total bit width and ‘b’ is the fractional part from the total size of ‘b’. Fixed-point arithmetic is more efficient in reducing resource utilization when compared to floating-point arithmetic.

2) Resource strategy: In multilayer neural networks, each neuron in a layer (consisting of n neurons) produces an output computed by the weighted sum of the output from the previous layer. The weights associated with these connections are represented as a matrix W of size n*m, where m is the number of neurons in the previous layer. Each neuron has a bias that is independent and represented by vector b. The weighted sums and the biases are summed and added non linearity by activation function denoted by f, resulting in the final output of the neuron. This process of weights, biases and activation function is expressed as:

$$y=f(W*\text{previous layer output} + b) \tag{3}$$

The multiplications in neural networks are computed by multipliers in FPGA, which result in high resource utilization if each multiplication was to represent a physical multiplier. Resource strategy was used to optimize the design by reusing of multipliers as demonstrated in Fig. 5.

Multiplier Limit

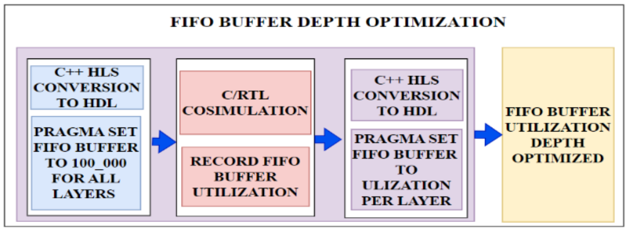
Processing elements are a functional block that preforms specific operations such as multiplication and addition. In the FPGA, operations are efficiently conducted in parallel across multiple PE's, thereby improving computational efficiency. For resource strategy multiplier_limit variable was defined to represent the maximum number of multiplications that can be done in parallel for the available resources. The calculation is based on the number of input values (mult_n_in), the number of output values (mult_n_out) and the reuse factor. A higher reuse factor will mean a lower value of multiplier_limit which translates to actual multipliers used in the FPGA implementation, however the universal time of operation will increase as the multipliers will be shared by a number of operations.

$$\text{Mult\_n\_in} = \text{filt\_height} * \text{filt\_width} * \text{n\_chan} \tag{4}$$

$$\text{Mult\_n\_out} = \text{n\_filt} \tag{5}$$

$$\text{Multiplier\_limit} = \text{DIV\_ROUNDUP}(\text{mult\_n\_in} * \text{mult\_n\_out}, \text{reuse\_factor}) \tag{6}$$

3) First In First Out (FIFO) Buffer Depth Optimization: FIFO buffers store data in between layers. In the initial C++ conversion the size of the buffers is estimated, however the estimated size is above the utilization during simulation. This results in a BRAM and LUT usage that is higher than what the design requires. In FIFO depth optimization method the buffer size for each layer was set to 100_000, which is a value above what is required by the design. The design was then synthesized and during RTL co-simulation the buffer occupation was recorded and used to update the FIFO buffer sizes which translated to a 71% reduction in buffer size. Fig. 6 is an overview of the buffer method capturing of buffer utilization during simulation to the updating of the new buffer size.



FIFO BUFFER DEPTH OPTIMIZATION
C++ HLS CONVERSION TO HDL
PRAGMA SET FIFO BUFFER TO 100_000 FOR ALL LAYERS
C/RTL COSIMULATION

C++ HLS CONVERSION TO HDL
PRAGMA SET FIFO BUFFER TO ULIZATION PER LAYER
FIFO BUFFER UTILIZATION DEPTH OPTIMIZED

Fig. 6. FIFO buffer depth optimization overview.

G. C++ /Register Transfer Level (C/RTL) CO-SIMULATION

C/RTL co-simulation was used to verify the functional preservation of the HDL converted model. The test images were converted to a 1D array and saved as data files with pixel values saved as strings for compatibility with simulator. C/RTL co-simulation was done using test-bench and test data. The comparison of C-Simulation and RTL simulation passed validation and output for inference was a 1D array that was converted to 2D numpy array.

IV. RESULTS

A. Precision

The increase in configured precision for the reduced UNET model during conversion to HDL was directly proportional to the increase in resource utilization as shown in Table II.

TABLE II. INCREASING AP PRECISION INCREASES RESOURCE UTILIZATION FOR THE REDUCED UNET MODEL CONVERSION IN HLS4ML

PRECISION	BRAM_18K	DSP48E	FF	LUT
<16,6>	2118	5	67033	149764
<32,6>	3978	13	97408	188001
<64,6>	7845	65	155388	219201

B. Resource Strategy

Multiplier reuse reduced the resources used as multipliers were shared among operations at the expense of performance. Maximum possible reuse factor is 1152 hence beyond 1500 reuse factor the performance and resource utilization is not affected, as shown by Fig. 7 graph of resource utilization. This is because there is an upper-limit to optimization of resource utilization against performance.

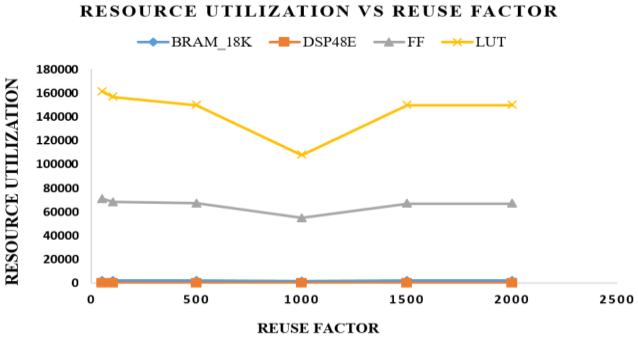

Fig. 7. Increase in reuse factor is directly proportional to resource utilization and reach roofline at 1000 reuse factor.

C. First In First Out (FIFO) Buffer Depth Optimization

New FIFO buffer depth values were inserted in the C++ firmware as pragma directives to guide synthesis. Resource utilization after FIFO optimization showed 54.8% reduction in BRAM's, 29% reduction in FF's and 44% reduction in LUT's. The new FIFO buffer depth was the occupancy increased by value of 1. Table III shows the reduction in resource utilization pre and post buffer size reduction. Table IV illustrates how the buffer size was reduced using pragma directives during synthesis.

TABLE III. FIFO DEPTH OPTIMIZATION REDUCTION IN RESOURCES

Optimization	BRAM_18K	DSP48E	FF	LUT	LATENCY(ms)
No	1634	8	52679	120583	9.8
Yes	739	5	29811	62059	9.8
% Change	-54.8	-37.5	-43.4	-48.5	0

TABLE IV. FIFO BUFFER DEPTH SIMULATION OCCUPANCY RESULTS AND OPTIMIZATION PRAGMAS TO REDUCE BUFFER DEPTH

Layer	Occupancy	New FIFO BUFFER DEPTH	PRAGMA DIRECTIVE
layer20_out_V_data_0_V_U	33348	33349	#pragma HLS STREAM variable=layer20_out depth=33349
layer21_out_V_data_0_V_U	16608	16609	#pragma HLS STREAM variable=layer21_out depth=16609
layer19_cpy2_V_data_0_V_U	819	820	#pragma HLS STREAM variable=layer19_cpy2 depth=820
layer22_out_V_data_0_V_U	134	135	#pragma HLS STREAM variable=layer22_out depth=135
layer23_out_V_data_0_V_U	199	200	#pragma HLS STREAM variable=layer23_out depth=200
layer12_out_V_data_0_V_U	3	4	#pragma HLS STREAM variable=layer12_out depth=4
layer24_out_V_data_0_V_U	37372	37373	#pragma HLS STREAM variable=layer24_out depth=37373
layer25_out_V_data_0_V_U	261	262	#pragma HLS STREAM variable=layer25_out depth=262
layer26_out_V_data_0_V_U	1	2	#pragma HLS STREAM variable=layer26_out depth=2

TABLE V. SHOWING THE REDUCED MODEL COMPARISON WITH EXISTING WORK

Ref	Model	Dataset	Parameters	IoU Score	Accuracy	Execution Time(ms)
UNET MODEL	UNET	BraTS 2020	1.9 M	0.60	0.97	132
[40]Ercüment GÜVENÇ (2023)	FLAIR MR IMAGES WITH U-NET	BraTS 2018	-	0.59	0.99	-
[41]Jwaid (2021)	3D U-Net CNN	BraTS 2017	-	0.69	0.99	-
Proposed	Reduced UNET	BraTS 2020	864	0.74	0.95	38

D. *Reduced Model Result Comparison with Existing Work*

A full UNET model with original architecture was developed to compare with the reduced UNET proposed in this work. Model parameters were reduced from 1.9 million in original 2D-UNET model to 864 in proposed reduced UNET model.

E. *Intellectual Property (IP) Core*

Fig. 8 is the graphical representation of the intellectual property core that was generated from the RTL design. The generate IP core has 3-inputs which correspond to the three input channels in the model architecture and there are four output channels which are aligned to the number of classes for type of tumour and background. IP cores introduce modular design which can then be interfaced with input and output IP cores such as Ethernet.

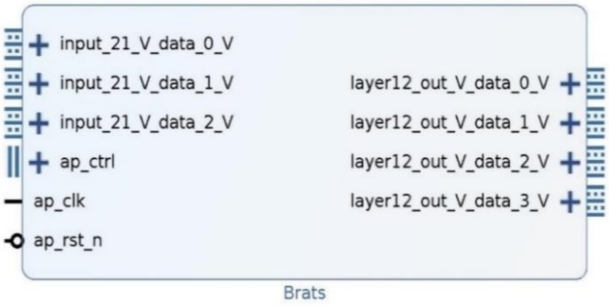

Fig. 8. BraTS 2D UNET tumour segmentation IP core.

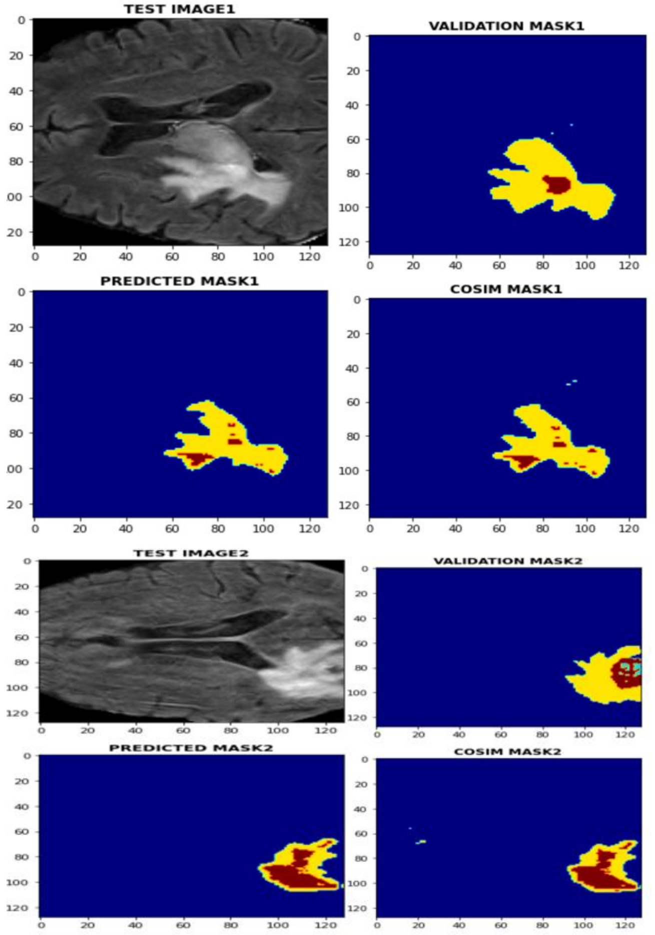
F. *C/RTL Co-simulation Results*

The co-simulation results presented in Fig. 9, visually demonstrate the similarity between prediction output masks of the python model and RTL simulation. Quantitative analysis, computing the IoU score output a comparable value of 74% between the original python model and the RTL simulation, validating the fidelity of the FPGA-based implementation.



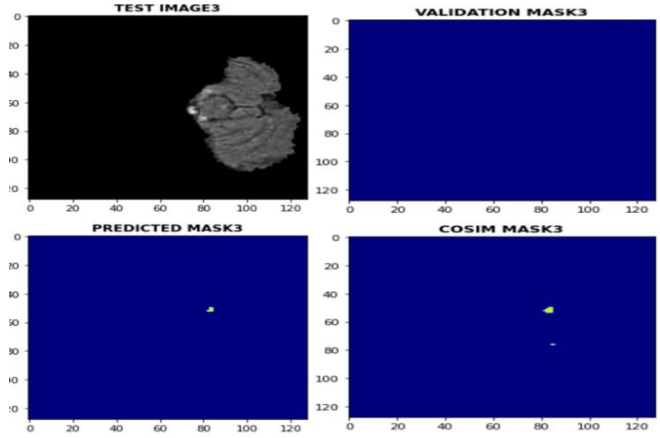


Fig. 9. Reduced UNET python model and C/RTL co-simulation brain tumour prediction masks.

V. Discussion

Table V shows that the proposed model has a higher IoU score over the existing work in [40, 41]. In study [40], only FLAIR images modality which limited the amount of features that can be learned by the model as compared to T1CE, T2 and FLAIR modalities which were used in the proposed model to learn more features from the dataset. The proposed model however has limitations in terms of accurately predicting tumour class. Future work can be focused on improving multiclass prediction of the proposed model.

VI. Conclusion

In this work a reduced UNET model was built and trained in Tensorflow Keras for brain tumour segmentation applications and archived an IoU score of 74%. The reduced model significantly reduced the model parameters by 99% which translates into reduced computational requirements. Converting the reduced model into C++ and HDL equivalent representations using HLS4ML, FPGA resources were used economically while preserving the original model segmentation output mask accuracy. Resource strategy, FIFO buffer depth and precision methods significantly reduced FPGA resource usage. The reduced model segmentation performs well in predicting tumour region, however the tumour classes are still poorly predicted. Further work on choosing the right loss function suitable for unbalanced multi-class segmentation for the reduced model can be done to improve inference accuracy while reducing FPGA resource utilization

Abstract—**The goal of the present research is to better understand the need of accurate and ongoing monitoring in the complicated chronic metabolic disease known as diabetes. With the integration of an intelligent system utilising a hybrid adaptive machine learning classifier, the suggested method presents a novel way to tracking individuals with diabetes. The system uses cutting edge technologies like intelligent tracking and machine learning (ML) to improve the efficacy and accuracy of diabetes patient monitoring. Integrating smart gadgets, sensors, and telephones in key locations to gather full body dimension data that is essential for diabetic health forms the architectural basis. Using a dataset that includes comprehensive data on the patient's characteristics and glucose levels, this investigation looks at sixty-two diabetic patients who were followed up on a daily basis for sixty-seven days. The study presents a hybrid architecture that combines a Convolutional Neural Network (CNN) with a Support Vector Machine (SVM) in order to optimise system performance. To train and optimise the hybrid model, Grey Wolf Optimisation (GWO) is utilised, drawing inspiration from collaborative optimisation in wolf packs. Thorough assessment, utilising standardised performance criteria including recall, F1-Score, accuracy, precision, and the Receiver Operating Characteristic (ROC) Curve, methodically verifies the suggested solution. The results reveal a remarkable 99.6% accuracy rate, which shows a considerable increase throughout training epochs. The CNN-SVM hybrid model achieves a classification accuracy advantage of around 4.15% over traditional techniques such as SVM, Decision Trees, and Sequential Minimal Optimisation. Python software is used to implement the suggested CNN-SVM technique. This research advances e-health systems by presenting a novel framework for effective diabetic patient monitoring that integrates machine learning, intelligent tracking, and optimisation techniques. The results point to a great deal of promise for the proposed method in the field of medicine, especially in the accurate diagnosis and follow-up of diabetic patients, which would provide opportunities for tailored and adaptable patient care.**

Keywords—Diabetes; machine learning; convolutional neural network; support vector machine; grey wolf optimization; e-health systems

I. INTRODUCTION

Over the past few decades, diabetes mellitus, frequently characterized to as diabetes, has become a major worldwide health concern due to its constantly rising predominance. Increased levels of glucose in the blood are a characteristic of this metabolic illness, which is brought on by either inadequate insulin synthesis or an inefficient utilization of insulin by the body. The World Health Organization (WHO) reports, that the rate of diabetes has been rapidly rising globally, making it one of the biggest public health issues of the twenty-first century. Diabetes affects a wide range of individuals worldwide, as evidenced by its epidemiology [1]. With approximately 463 million individuals identified with diabetes as of 2019, developed nations as well as developing ones are struggling with an increase in the number of instances of the disease. If current conditions continue, this number is expected to rise, reaching an astounding 700 million people by 2045. Inactive ways of life, inadequate nutrition, and a growing elderly population are all contributing participants to this trend, which emphasizes the critical requirement for efficient management and preventive actions [2]. Diabetes that goes untreated has serious repercussions that impact several organ systems and cause significant health issues. Long-term effects include renal failure, blindness, neuropathy, and cardiovascular disorders, all of which significantly decrease the standards of life as well as the life expectancies of those who are impacted. Furthermore, the financial impact of diabetes-related medical expenses and lost productivity is significant, creating new difficulties for healthcare systems throughout the world [3].

There are several interrelated causes that lead to the diabetes pandemic. With the introduction of diets excessive in fats that are unhealthy and sugars that are processed and a decrease in physical activity, industrialization and modifications to lifestyles have created an environment that encourages obesity that promotes the development of diabetes. An individual's risk to the illness is influenced by both environmental and genetic variables, which combine to determine the person's susceptibility. Furthermore, the growing incidence of diabetes is made worsened by differences in the availability of healthcare and education, especially for communities with limited resources. Diabetes is becoming more and more common, which has serious consequences for public health and necessitates an all-encompassing strategy [4]. The three main strategies for reducing the rise in diabetes are prevention via health education, lifestyle modifications, as well as early detection. In addition, technological developments including the development of sophisticated monitoring systems have the potential to improve diabetes care while promoting an anticipatory approach to healthcare [5]. To reduce the effects of diabetes and enhance the physical and mental well-being of millions of people globally, the international community needs to collaborate together to address the complex interactions between hereditary, environmental, and lifestyle variables [6].

The complex nature of managing diabetes, characterized by the requirement for continual surveillance and individualized treatment, highlights the necessity for sophisticated monitoring systems. Diabetes, in contrast to many other chronic illnesses, requires close monitoring of blood sugar levels, dietary habits, activity levels, and medication compliance. Diabetes has several facets that impose significant stress on patients and healthcare professionals equally [7]. As a result, there is a strong demand for innovative approaches that may expedite monitoring procedures, give real-time information, and enable faster treatments. Diabetes is a very unique disorder, with changes in medical condition and patient responses to therapy occurring on an individual basis. In order to customize treatment plans to the particular requirements of each patient, sophisticated monitoring systems are now essential [8]. Through the integration of adaptive learning technologies and sophisticated monitoring mechanisms, these systems are able to evaluate large datasets and identify specific trends, offering a more detailed knowledge of a patient's health trajectories. Enhancing therapeutic efficacy, reducing adverse reactions, and ultimately improving patient outcomes are all possible with this customized strategy [9].

Patient-centered care is an innovative approach that prioritizes giving individuals the tools required to take an active role in their own health management. Modern monitoring devices are essential to this change because they provide patients with immediate information on their lifestyle decisions and health parameters. These systems have the potential for motivating patients to follow treatment programs, make educated decisions, and establish up healthy habits by cultivating an environment of ownership and awareness [10]. Furthermore, the incorporation of easy-to-use interfaces and smartphone applications might promote a proactive and cooperative approach to diabetes management by facilitating effortless interaction between patients and medical professionals. By using sophisticated technologies to monitor diabetes proactively, complications may be avoided, and the financial strain of the disease may be reduced. Early intervention can be used to mitigate the frequency of serious illnesses and hospitalizations by promptly detecting abnormalities from normal health indicators [11]. Sophisticated monitoring systems help healthcare systems preserve revenue over the course of time through promoting preventative care and supporting continuous maintenance of health. In order to effectively manage the numerous obstacles presented by this complicated and widespread chronic illness, improved monitoring systems are becoming increasingly necessary as the number of cases of diabetes rises worldwide [12].

Significant progress has been made in the field of diabetes e-health systems, which use technology to improve the treatment of patients and management. These systems usually incorporate a range of technologies to monitor and assist people with diabetes in everyday activities, such as online platforms, wearable technology, and mobile applications. Numerous current systems concentrate on monitoring blood glucose levels, activity levels, and consumption habits in real-time. While wearable technology, such continuous glucose monitors (CGMs), offer a constant supply of physiological information, mobile applications frequently act as a central centre for data gathering and processing [13]. e-Health technologies have made it possible for diabetes patients to take advantage of telehealth services and remote monitoring, eliminating the distance between patients and healthcare professionals in geographically dispersed areas. Regular assessments and treatment plan modifications are made possible through telehealth conversations, which eliminate the need for several visits to the clinic. By facilitating more adaptable and dynamic diabetic treatment, this integration lowers the need for frequent visits to the clinic and increases patient participation.

The incompatibility of various e-health technologies and systems is one of the main disadvantages. Variations in information formats and requirements may prevent the effortless transfer of information between healthcare systems and devices, which could result in evaluations of an individual's health state that are either inaccurate or incomplete. Security and confidentiality of information are major problems in e-health systems because of the sensitive character of health data. Challenges including illegal entry, leaks of information, and insufficient encryption protections caused patient privacy at risk and might undermine users' confidence in these systems. Participation among users and commitment over time to monitoring methods remain issues in regardless of the capacities of e-health systems [14]. The apparent complexities of the systems, unease with wearable technology, or a lack of customized input that aligns with their specific health objectives can all lead to patients detaching from ongoing surveillance. Certain e-health systems could depend on standard algorithms that do not adequately take into consideration the range of diabetes appearances people with the disease can have. An approach that applies to all patients may fail to recognize smaller variations in how each patient reacts to therapy, which could result in undesirable outcomes for certain groups of patients. e-Health systems are effective at collecting physiological data, but they can still do better when it comes to incorporating behavioural data, including how anxiety or other lifestyle factors affect diabetic treatment [15]. Increasing the comprehension of every facet of the patient experience can result in more comprehensive and individualized treatments. Improving interoperability, enhancing privacy and security protocols, boosting user engagement with intuitive interfaces, and fine-tuning algorithms in order to accommodate a range of patient profiles are all necessary to overcome these constraints. The continued development of e-health systems shows possibilities for improving patient outcomes, optimizing diabetic treatment, and expanding the field of electronic health records as technology advances.

The complicated and constantly changing nature of diabetes is the motivating factor driving the integration of intelligent tracking and a hybrid adaptive machine learning classifier in diabetes treatment. Individualized patterns of blood glucose levels, choices regarding lifestyle, and treatment responses are characteristics of diabetes. The complex and changing health trajectories of individuals with diabetes are frequently difficult for traditional, static models to represent. The system attempts to give patients a more comprehensive and individualized approach to diabetes management by combining intelligent tracking, which continually records and customizes to changing patient behaviours, and a hybrid adaptive machine learning classifier, which can learn complicated patterns in large datasets [16]. The traditional standardized method of managing diabetes may not be able to adequately satisfy each patient's specific demands. The device can collect instantaneous information on a patient's activities, eating habits, and physiological reactions because of intelligent tracking systems. This is enhanced by the hybrid adaptive machine learning classifier, which gains knowledge from the recorded information, customizes its model to account for individual differences, and offers individualized recommendations. This combination maximizes the effectiveness of therapies and improves patient outcomes by facilitating the transition towards more individualized and focused treatment techniques.

Continuous monitoring helps significantly in the treatment of diabetes since it makes it possible to identify small variations in health indicators that might signal impending emergencies. Intelligent tracking is integrated to provide an uninterrupted supply of pertinent data, and the hybrid adaptive machine learning classifier is extremely skilled at identifying complex patterns linked to early indicators of health decline. For those with diabetes, this continuous surveillance and early intervention strategy may help avoid complications, lessen the need for emergency interventions, and enhance their general quality of life. The hybrid adaptive machine learning classifier is intended to address the difficulties caused by the intrinsic unpredictability in the initial responses of individuals with diabetes to dietary and medication modifications [17]. Conventional classifiers could have trouble adjusting to these differences, which would result in less than ideal efficiency. Because of its adaptive characteristics, the suggested classifier can adapt over time to the intrinsic variety in diabetes presentations. This flexibility is especially important for patients with chronic conditions like diabetes, whose health can be affected by a wide range of variables. In the area of e-health and diabetes care, the combination of intelligent tracking with a hybrid adaptive machine learning classifier is a newly developed and creative method. While discrete components like machine learning and intelligent tracking have been studied independently, integrating them into a unified framework which functions effectively when combined is a novel contribution. The system's capacity to dynamically adjust to each patient's unique profile, learn from changing information over time, and offer customized suggestions for successful diabetes control essentially makes this system exceptional. This strategy might contribute to the expanding area of customized medicine and raise the standards for digital health interventions for chronic illnesses.

The Key Contribution of the paper is given as follows:

- The research presents a unique hybrid architecture that combines a SVM with a CNN to monitor diabetic patients. By combining the attributes of both models which is SVM's outstanding binary categorization and CNN's feature extraction capabilities, improves diabetes prediction accuracy.
- An intelligent tracking mechanism is utilized to collects detailed body dimension information from diabetes patients using cellphones, sensors, and smart devices. Beyond typical monitoring techniques, this integrated strategy ensures a more comprehensive awareness of the patient's health and contributes to a more individualized approach to treatment.
- The employed Grey Wolf Optimization is based on cooperative optimization observed among wolf packs, to fine-tune the hybrid model. This optimization method improves the efficacy and effectiveness of the model, offering an innovative approach for fine-tuning parameters in machine learning systems that are inspired by nature.
- The suggested approach shows a significant increase in accuracy. CNN-SVM hybrid model exhibits improved classification accuracy when compared to established approaches such as SVM, Decision Trees, and Sequential Minimal Optimization. This indicates the model's potential for dependable diabetic patient monitoring.
- Machine Learning, optimization, and intelligent tracking approaches, contributed to the improvement of e-health systems. This strategy has a lot of potential to improve the accuracy and efficiency of diabetes patient monitoring. Modern technology combined with the enhanced performance of the suggested hybrid model is a significant addition to the field of healthcare informatics.

The rest of the section is organised as shown below. Section II illustrates literature works on e-health Systems. Section III gives the Problem Statement. Section IV covers the proposed technique for Monitoring and Tracking the Patients with Diabetes. Section V illustrates the performance measures and summarises the findings and compares the method's performance to previous techniques. Section VI summarises the conclusion and paves the way for future works.

II. Related Works

Individuals with diabetes who receive continuous medical attention often have a greater standard lifestyle than those who do not. Due to technology improvements, healthcare costs can be reduced by utilizing the Internet of Things. Both the advancement of intelligent devices and a growth in the total amount of software linked to the networks are necessary for addressing the demands of e-health applications. Therefore, the cellular network must be able to accommodate sophisticated medical applications which require outstanding energy consumption in order to accomplish these objectives. The study develops combined voting classifier that utilizes neural networks to effectively forecast patients' diabetes through online monitoring. Internet of Things gadgets is used in the study to track patient cases. IoT devices provide their information for smartphones during evaluating, and those devices transmit the information to the cloud, where categorization is done. The Python tool is used to run the simulation on the gathered observations. The results from the simulation demonstrate that, in comparison to current the most advanced combination models, the suggested strategy provides a higher prediction rate, precision, recall, and f-measure. However, for information to be provided from connected devices to the cloud, the suggested solution depends on the Internet operating without interruptions. Restrictions in internet access might possibly undermine the dependability of the projections by affecting the continuous monitoring capability [18].

Because type 2 diabetes has a significant condition of disease and significantly lowers the patient's standard of existence, using computerized instruments and data technologies to control illness has become common place due to the close connection between healthcare and the worldwide web. The study attempted to determine how well several e-health treatments, varying in length, may help individuals who have type 2 diabetes achieve controlling their glycemic levels. Researchers investigated for randomization managed studies describing various e-health interventions for glycemic management in individuals with type 2 diabetes. Individuals with type 2 diabetes mellitus satisfied the following participation requirements: (1) interventional duration ≥1 month; (2) findings HbA1c (%); and (4) randomization management using e-health based techniques. Cochrane techniques were employed to evaluate potential biases. Researchers performed the Bayesian network a meta-examination using R 4.1.2. The most efficient intervention periods were found to be ≤6 months, according to subgroup evaluations. Individuals with diabetes who have type 2 diabetes can benefit from improved glycemic management through all forms of e-health-based interventions. With an ideal intervention length of ≤6 months, SMS is a high-frequency signal, low-barrier technique that delivers the highest benefit in decreasing HbA1c. The research concepts administration procedures and characteristics of participants may add variability due to the numerous types and timings of e-health treatments included in the inclusion. The variety of approaches may make it more difficult to reach firm judgments on the efficacy of particular therapies [19].

Many of the advances that technology has enabled about for humankind have made even the most difficult things simpler. The development of science and technology has led to the widespread deployment of intelligent machines. Numerous sectors, including health care for the public, medicine, and healthcare, have seen advancements. The monitoring of wellness and various other tasks may now be done effectively, economically, and intelligently thanks to recent advancements in healthcare. This is made feasible in large part by wearables. Despite their compact design, these gadgets are equipped with potent medical sensors that enable the monitoring of users' health problems. As technology and medical science have advanced, wearables have been equipped with an increasing number of sensors for tracking a wide range of activities, such as blood oxygen levels, body temperatures, cardiovascular disease, and activity monitoring systems, among many others. These gadgets allow users to store the outcomes for future usage and can be linked to smartphones. The necessity of wearables in healthcare and their potential to transform medical systems in the future were covered in this study. A case study is given illustrating how wearables may benefit both physicians and patients. Potential applications and research problems are also included in this publication. However, because patient groups vary and wearable devices are different, the report may have difficulty generalizing its results. The general application of the offered findings is limited by the realization that wearable device performance and utilization could differ across various populations, medical conditions, and geographical areas [20].

Globally, an advancing population is one of the biggest healthcare challenges. Due to their increased risk of chronic illnesses, which raise healthcare costs, older individuals demand greater resources from the healthcare system. One of the major developments within healthcare technological advances is the creation and ongoing operation of e-health solutions, which provide patients with mobile services to support and improve their treatment according to monitoring certain physiological information. Healthcare technology has advanced greatly in the previous few decades in terms of size, velocity, accessibility, and connectivity. The fact that individuals are restricted to smart rooms and a bed equipped with monitoring devices is a significant disadvantage of contemporary e-health monitoring systems. Because chronic patients have accessibility, security, and adaptability difficulties, such surveillance is not common. Furthermore, attached to a patient's body health monitoring gadgets provide no evaluations or recommendations. This work presents a multi-agent-based approach to tracking health conditions that aims to enhance the procedure by gathering patient information, reasoning collectively, and suggesting actions to patients as well as physicians in a mobile setting. The paper presents a multi-agent-based system that is assessed using a case study. The findings demonstrate that the suggested approach offers elderly, chronic, and distant patients an effective way to monitor their health. Furthermore, by employing 5G technology, the suggested method works better than the current health system and enables prompt medical services for patients who live far away. However, when the suggested agent-based system is expanded to support enormous user bases or extensive medical networks, its efficacy can encounter difficulties. As the size grows, problems with resource use, communication costs, and system efficiency could become increasingly noticeable [21].

Diabetes is a chronic illness caused by the pancreas' inability to produce enough insulin or to shield the body from non-consumable substances. Diabetes patient health monitoring is a methodical approach that provides us with comprehensive health information on individuals with diabetes. Health observation platforms for diabetic patients are essential for monitoring their state, especially when using Internet of Things connected devices. In simple terms, diabetic patient monitoring platforms may screen individuals with diabetes and save certain health data, such as body temperature, blood pressure, and blood glucose levels. Because predictive analysis may assist diabetic individuals, their relatives, medical professionals, and clinical researchers in making decisions about the patient's medication considering the circumstances of their state, it is necessary for diabetes patients. The study explores future research using Artificial Intelligence algorithms and presents a novel framework for monitoring the health of diabetes patients. However, technological problems and fluctuations may affect the accuracy of the information gathered by IoT devices, such wearables and sensors. The dependability of health information may be impacted by variables such as sensor reliability, measurement, and possible interference with the signal, which might have an effect on the monitoring system's general reliability [22].

In anticipation of the coronavirus disease-19 epidemic, audio-based telemedicine services for consultations and prescription medications were initially implemented in Korea. This study looked at how telehealth services affected health-care usage and drug prescription trends in hypertensive and diabetic individuals. The claims information from the Health Insurance Evaluation and Assessment Services for 2019 to 2021 were utilized. The difference-in-difference technique was utilized to compare the impact of telehealth treatments on the subjects as well as control groups before and following the period of intervention. Individuals in the untreated category employed in-person outpatient treatment, whereas those in the actual category received combined telemedicine and in-person treatments. The study comprised hypertensive individuals and diabetic patients. Telehealth services were linked to a rise in appointments with physicians among hypertensive. Patients with hypertension had a reduction in hospitals and visits to emergency rooms. In addition, policy execution has led to a rise in the medication possession ratio and the percentage of suitable prescriptions among patients with diabetes and high blood pressure. The data indicate a link between telemedicine service implementation and enhanced habits in health care usage and drug prescription, indicating telemedicine's potential utility in chronic illness management. However, the results of the investigation may be unique to the Korean health care system and not immediately relevant to other nations with differing healthcare facilities, laws, and cultural settings. Factors such as regulations, consumer preferences, and healthcare professional practices might differ greatly between nations [23].

The literature review includes a range of subjects related to health monitoring systems, with a special emphasis on the treatment of diabetes patients and the use of technology to deliver healthcare more effectively. The first study uses Internet of Things devices to follow patient cases and offers an integrated voting classifier using neural networks for online diabetes monitoring. Although it shows better prediction rates, accuracy, recall, and F-measure than previous models, it also emphasizes possible limits by pointing out that data transfer to the cloud depends on continuous internet availability. The efficacy of E-Health treatments for glycaemic control in type 2 diabetes is investigated in the second research, which highlights the advantages of brief intervention durations particularly less than six months and the usefulness of SMS in lowering HbA1c levels. In discussing wearables' revolutionary potential in the healthcare industry, the third piece of literature focuses on how intelligently they can monitor a range of health indicators. The study does, however, recognize that demographic heterogeneity and device variety make it difficult to generalize outcomes. The fourth research addresses the healthcare requirements of the aging population by suggesting a multi-agent-based health monitoring system that provides enhanced services and mobility for chronic patients. Finally, the fifth research highlights the use of artificial intelligence algorithms for predictive modelling in the introduction of an Internet of Things-based health monitoring system for patients with diabetes. There are still issues with scalability and data dependability, despite encouraging developments. Together, these studies demonstrate the potential advantages of integrating technology into healthcare, but they also emphasize the necessity of resolving related issues in order to achieve widespread acceptance and effectiveness.

III. Problem Statement

The present techniques used to monitor diabetic patients in electronic health systems frequently encounter issues such imprecise data analysis, restricted flexibility to accommodate different patient profiles, and inadequate real-time tracking capacity. By creating an advanced e-health System with an Integrated Intelligent Tracking Mechanism utilizing a Hybrid adaptive machine learning Classifier—more precisely, the suggested CNN-SVM model—this research seeks to address these problems. Accurate and individualized monitoring has been impeded by the present limitations in conventional approaches, which include their reliance on static thresholds and unsophisticated machine learning algorithms [6]. By combining the advantages of SVM for classification and CNN for feature extraction, the suggested CNN-SVM model outperforms other approaches in terms of robustness and efficiency when handling dynamic, complex patient information.

IV. Proposed Hybrid Adaptive Machine Learning Classifier

The methodology used in the research is an exhaustive approach to creating a sophisticated e-health system for tracking diabetic patients, combining sophisticated surveillance techniques with an integrated adaptable machine learning classifier. The dataset includes information from sixty-seven consecutive days of exams for sixty-two diabetic patients, of which forty-four were male and eighteen were female. Using Min-Max normalization as a preprocessing step, the 13,173 concentrations of glucose information points and five attributes are scaled uniformly. PCA is used in feature extraction to reduce dimensionality and find important factors that influence patient features and fluctuations in glucose levels. The categorization and tracking mechanism, which uses a hybrid convolutional neural network integrated with a support vector machine, is the central component of the suggested system. Seven layers of CNN automatically identify important characteristics, while SVM guarantees robust categorization. The paper presents an innovative Hybrid CNN-SVM framework and demonstrates how SVM's competence in binary categorization and CNN's extraction of characteristics capabilities complement each other. Modelling parameter tuning is done using the Grey Wolf Optimization framework, which takes its information from the cooperative optimization procedure utilized by wolf packs. This optimization, inspired by nature, improves the model's efficiency. Fig. 1 depicts the general architecture of the suggested model.

Performance Evaluation

Fig. 1. Overall structure of the proposed model.

A. Data Collection

The sixty-two diabetic patients (forty-four men and eighteen women) whose medical histories required an average of sixty-seven days of testing were added to the database for this study. There are five characteristics and 13,173 glucose concentration information points in the glucose concentration sets [24].

B. Preprocessing using Min-Max Normalization

Standardized scaling of characteristics was ensured by applying Min-Max normalization throughout the preparation of the dataset. 13,173 glucose concentration information points and five attributes are included in the collection of data. The level of glucose and other features were subjected to Min-Max normalization in order to scale the data within an acceptable range, usually [0, 1]. In order to enable more accurate and efficient modelling of diabetes-related variations and patterns within the information set, normalization is a crucial step in removing scale-related inefficiencies and verifying that each characteristic contributes proportionately to the study.

The research may scale the input information into an appropriate range by using Min-Max normalization, enabling a more rapid and precise evaluation. The relationships between the data sources are preserved without affecting the original information by making effort that all of the variables that are entered are transformed into a similar interval utilizing the normalization approach. The capacity of Min-Max normalization to maintain that connect between information points is one of its main advantages. This demonstrates that following normalization, the information's relative distribution and structure are still maintained. Preserving the fundamental patterns and correlations in the information is essential to accurately manage the elements influencing the projected values. Utilize Eq. (1) to illustrate the Min-Max normalizing method.

$$k = min_{new} + (max_{new} - min_{new}) * \left(\frac{k-min_r}{max_s-min_s}\right) \quad (1)$$

The starting measurement point is represented by $''k''$ in this equation, the requisite values for the standardized data are denoted by min_{new} andmax_{new}, and the maximum and minimum values are indicated by max_r andmin_r, respectively. The speed and effectiveness of Min-Max normalization are its key benefits when handling an extensive amount of information points.

C. Feature Extraction using Principal Component Analysis

An essential first step in evaluating high-dimensional datasets, like the diabetic patient monitoring dataset, is feature extraction. A common method for reducing dimensionality in information includes Principal Component Analysis, which tries to extract the most crucial information from the data being analyzed while removing less significant aspects. PCA can assist in determining the major factors that most influence changes in individual characteristics and glucose levels within the framework of diabetes surveillance.

The main elements, or eigenvectors of the initial information's covariance matrix, are the key idea that supports principal component analysis. Let Z represent the initial information matrix, which has m characteristics and m' observations. Eq. (2) calculates the covariance matrices D.

$$D = \frac{1}{m}(Z - \bar{Z})^T(Z - \bar{Z}) \quad (2)$$

where, the mean-centered matrices is denoted by$\bar{Z}$.

Eq. (3) corresponds to D's eigenvalues λ and eigenvectors w.

$$Dw = \lambda \mathrm{w} \quad (3)$$

The primary elements are represented by these eigenvectors, and the quantity of variation they contain is shown by the associated eigenvalues. The primary elements are obtained in order of importance by categorizing the eigenvectors in decreasing order of eigenvalues.

Choose the highest h eigenvectors that correlate to the h greatest eigenvalues in order to minimize dimensionality. The most significant data in the information is captured by these h main elements. Calculating the initial information Z onto the chosen primary elements yields an updated characteristic matrix X, which is shown in Eq. (4).

$$X = ZW_h \quad (4)$$

And the matrix containing the initial h eigenvectors is denoted by W_h.

PCA makes dimensionality reduction simpler by maintaining the most crucial characteristics that have a substantial impact on the information's variance. As in the case of diabetes patients being monitored with various features and glucose concentration measurements, this reduction is especially useful in situations when the initial data set contains a large number of attributes. Because each principal component of the reduced-dimensional space produced by PCA maintains a mix of initial characteristics, interpretability is improved. Finding appropriate data for diabetes management is made easier by the more intuitively comprehension of patterns and linkages made possible by the information's decreased spatial visualization. PCA can identify the main factors that account for the majority of the variation in patient information when it comes to diabetes. For example, it might identify a variety of behavioural and physical characteristics that are essential to comprehending and tracking the course of the illness. More effective modelling and predictive evaluation may also benefit from the changed information in the reduced space. Comprehensive validation and efficacy assessment are essential to determine the effectiveness of PCA in the diabetic patient monitoring systems. This involves evaluating how well models constructed using the initial information performs in comparison to those developed using the PCA-transformed information, while taking consideration factors including computational effectiveness, interpretability of the models, and categorization accuracy. The evaluation's findings will provide information regarding the value and contribution of PCA to improving the efficiency of the system across all components.

D. Classification and Tracking Mechanism using Hybrid CNN Networks with SVM

Hybrid CNN-SVM integration is used in the suggested Categorization and Tracking procedure, providing a comprehensive method of categorization and tracking. By utilizing two maximum-pooling layers, a pair of convolutional layers, and three layers that are interconnected for obtaining complex patterns from the input information, the combined approach builds on CNNs' advantages for automatic characteristic identification. The array of features is then loaded into an SVM to achieve reliable categorization. The predicted accuracy and flexibility of the model are improved by the collaboration. A thorough and precise categorization and tracking system is ensured by the CNN's automated identification of important characteristics and SVM's skill with high-dimensional spaces and intricate decision limits. The combination of these two effective algorithms operates in conjunction to effectively manage the dataset's complexities, creating a hybrid model that specializes at tasks including patient monitoring and illness prediction. Through exhaustive instruction, validation, and fine-tuning procedures, the efficacy of this hybrid technique is assessed, displaying its capacity as an innovative approach for difficult categorization problems.

1) The CNN model: The first classifier that this study suggests is a seven-layer CNN. The architecture consists of a pair of maximum-pooling layers, a pair of convolution layers, and three fully linked layers. Using a CNN instead of more traditional machine learning techniques has the main advantage that it can track and categorize important features without requiring human intervention. Its higher capacities need less human involvement due to its independence from pre-processing. Indeed, the different stages of convolution, that include a fixed number of filters, are used for autonomously obtaining the maps of attributes. N' is the vectors' dimensions r, $n'$and k represent the vector's indicators, and $s = (s(n'))_{n'}$ is the result of the kernel's convolution of the input data $r = (r(k))_k$As per Eq. (5), the stages of convolution integrate their vector inputs employing different filters. The maximum pooling layer reduces the complexity of networks by collecting the maximum values within a particular filter region. The complete classification is generated by the completely connected layer, which gathers data from the entire characteristic map. It frequently appears in the centre of the output layer.

$$r(n') = \sum_{k=0}^{N'-1} r(k).f(n' - k) \quad (5)$$

The initial layer receives as input a subsection with 500 points. This convolutional layer uses five 1×13 filters with a duration of 1 to convolve the various filters with the five-hundred-point values in accordance with Eq. (5). The result is five characteristic maps. The second layer is a maximal pooling layer with an initial pool size of 2 and a position offset of four. This layer reduces the size of the distinctive maps by combining a 1×2 filtering onto each of the previously created feature maps. As a result, the network must analyse less information and acquire fewer variables. Consequently, a simulation is better able to manage variations in the location of input features. Applying a second layer of convolution with 10 filters that are each 1×9 in size and an advance of only one occurs next. This set of filters is used to extract higher-level features from dimensionally condensed maps of features. The fourth layer, which promotes pooling, carries out the characteristics and responsibilities of the initial layer. There are then three completely connected surfaces totalling 40, 20, and 2 properties. After being flattened, the output from the previous layer was utilized as the initial layer's input. With the exception for the highest layer, which employs the softmax activation function, other layers utilize the Leaky ReLU stimulating function.

Glorot uniform initialization is used for establishing the structure's weights, and backpropagation is employed for updating them over a maximum of sixty-four batches. The simulation is constructed throughout thirty epochs. Consider $\hat{q}_u$ as the estimated probability that the section u has diabetes, as found at the system's output. Eq. (6) shows how the binary cross-entropy function is used to quantify the simulation's loss in detecting the binary problem.

$$\mathcal{L}(q) = \frac{-1}{M} \sum_{u \in \Im_T} y_u . \log(\ \hat{q}_u) + (1 - y_u). \log(1 - \ \hat{q}_u) \quad (6)$$

When M is the total number of these sections, q is the epoch's indicators, and $\Im_T$ is the set of fragment indexes used for developing the system, then M is the greatest number of$\Im_T$. The score that is calculated employing the cross-entropy represents the average deviation among the actual and projected values. The objective is to lower the score, where 0 represents the ideal cross-entropy.

The framework's range of variables can be modified through the use of grid-based searches and trial-and-error techniques. The tuning strategy grid search is used to find the optimal hyperparameter variables. It is a process that traverses over a manually selected subset of the targeted algorithm's hyperparameter space in detail. In this study, grid search is used to adjust the total amount of batches and epochs, and trial and error is used to determine the filter dimensions and durations.

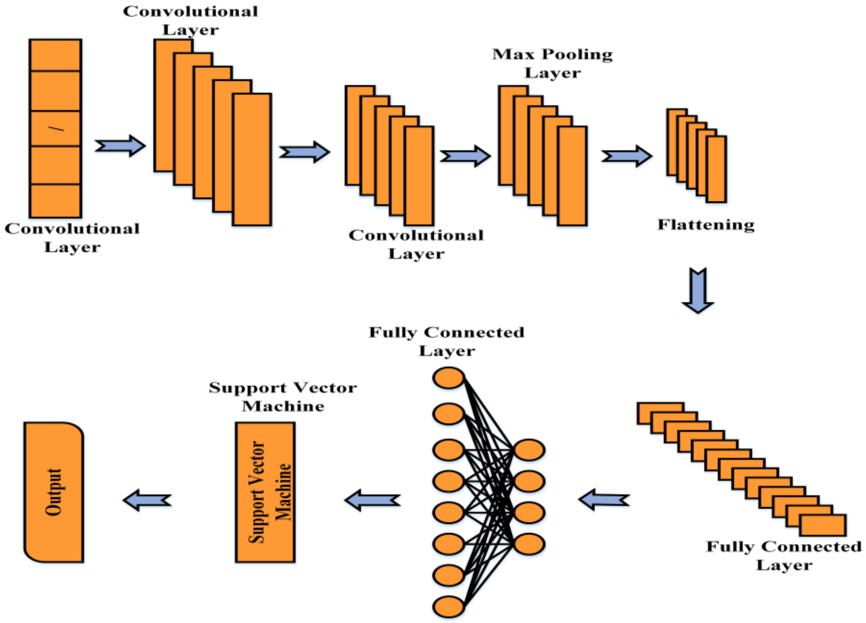

Fig. 2. Structure of the suggested hybrid adaptive deep classifiers.

2) The CNN-SVM model: This section illustrates the recommended network's evolution. Instead of preserving the CNN network's last segment, which is responsible for classification, the study replaces it with an SVM classifier. Fig. 2 depicts the construction of the proposed hybrid CNN-SVM method. Algorithms that combine the outcomes of two or more distinct techniques are referred to as ensemble learning. Diabetes classification, monitoring, and early detection have all benefited from the use of collaborative learning in the field of healthcare. In short, a reduced CNN network is kept to extract attributes, and then the classification is done employing SVM. Consequently, a hybrid CNN-SVM technique is proposed for the diabetes tracking and classification datasets. The best features of CNN and SVM classifiers are combined in the proposed method. The trained CNN uses self-learning algorithms to identify the distinctive maps that are transmitted to the SVM for binary detection. CNN acts similarly to individuals and is particularly adept at remembering invariant local properties. It could extract the most unique information from the initial information. Support vector machines are classification techniques that learn to differentiate between input data's binary labels. Instances are used by a learning algorithm to educate it how to label objects. An SVM is simply a statistical approach that maximizes a particular statistical function with respect to a set of information. It finds a distinct hyperplane that divides information by extending a dataset's margins. The margin is the lowest length, split by a hyperplane, between two pieces of data. The linear SVM technique has been extended to consider non-linear problems by projecting the data onto a higher-dimensional space. This method has proven to be quite successful because of how easily high-dimensional data can be handled and since linear strategies are simple to comprehend. The findings demonstrate that SVM responds well for binary tracking and categorization but inadequately for information with noise. Because of its basic architecture, SVM presents difficulties when learning deep properties. The hybrid CNN-SVM model proposed in this paper replaces the SoftMax layer of CNN with a non-linear SVM functioning as a binary classification algorithm.

E. *Grey Wolf Optimization Framework for Fine-tuning the Parameters*

The novel method for adjusting parameters in this study is the Grey Wolf Optimization framework. GWO imitates the cooperative optimization process that occurs inside a wolf pack and is inspired by the social structure and hunting habits of grey wolves. By distributing the responsibilities of alpha, beta, and delta wolves in the framework of variable optimization, GWO dynamically modifies the stages of exploration and exploitation. While beta wolves investigate the areas within the findings made by alpha wolves, delta wolves concentrate on local research, while alpha wolves take the initiative in global exploration. The convergence towards the ideal values for parameters for the given position is facilitated by the collaborative and hierarchy optimization technique. The fundamental model's parameters are adjusted using the GWO structure, providing that the algorithm is sensitive to the unique features of the dataset as well as optimized for efficiency. By adding GWO, the fine-tuning procedure gains a sophisticated and nature-inspired component that increases the efficacy and efficiency of optimization of parameters for the intended application.

A suggested meta heuristic method is called GWO [25]. The method was influenced by the grey wolf killing strategy and pack structure. Grey wolves have a very hierarchical structure and socialize in packs. The leaders of the wolves, the alphas (α), now make all the decisions. Beta (β) wolves, which belong to the next level, help alpha wolves with their tasks. The final person, Omega (ω), is victimized in this system. A wolf is also known to as a delta (δ) wolf if it does not fall into any of the aforementioned classes. Grey wolves attempt to encompass a food source, assault, and kill, then explore for additional prey in accordance with this well-established structure. Wolves use hunting as a means of enclosing their prey, locating and killing animals, and engaging in conflict with their prey. Grey wolves on a hunting excursion circle their prey according to Eq. (7) and Eq. (8).

$$\vec{L} = \left|\vec{f}\cdot(\overrightarrow{U_z}(m) - \vec{U}(m)\right| \quad (7)$$

$$\vec{U}(m+1) = \overrightarrow{U_z}(m) - \vec{Q}\cdot\vec{L} \quad (8)$$

$\vec{Q}$ and $\vec{L}$ constitute efficient vectors with the subsequent definitions, which are presented in Eq. (9) and Eq. (10). Where $\vec{U}$ represents the location of the wolf in a circular configuration, $\overrightarrow{U_z}$ is the vector position of the prey, and *mis* is the current time.

The wolf's position in a circular arrangement is represented by $\vec{U}$ in Eq. (9) and Eq. (10), while the prey's vectors position is represented by $\overrightarrow{U_z}$ in equations, and the present time is indicated by *m*, and the efficient vectors with matching definitions are $\vec{Q}$ and $\vec{L}$.

$$\vec{Q} = 2\vec{p}\cdot\overrightarrow{d_1} - \vec{p} \quad (9)$$

$$\vec{f} = 2\cdot\overrightarrow{d_2} \quad (10)$$

The elements $\vec{d}$ and$\overrightarrow{d_2}$, where the component *d* is continuously decreasing from 2 to 0, contain random vectors evenly dispersed between 0 and 1. It has been suggested that the *α, β, and δ* wolves understand it easier since the exact spot of the food is never known in advance. Eq. (11), Eq. (12), and Eq. (13) are utilized to find the victim's location based on the locations of the wolves.

$$\vec{L}_\alpha = \left|\vec{f}_1\cdot\vec{U}_\alpha - \vec{U}\right|, \vec{L}_\beta = \left|\vec{f}_2\cdot\vec{U}_\beta - \vec{U}\right|, \vec{L}_\delta = \left|\vec{f}_3\cdot\vec{U}_\delta - \vec{U}\right| \quad (11)$$

$$\vec{U}_1 = \vec{U}_\alpha - \vec{Q}_1\cdot\vec{U}_\alpha, \vec{U}_2 = \vec{U}_\beta - \vec{Q}_2\cdot\vec{L}_\beta, \vec{U}_3 = \vec{U}_\delta - \vec{Q}_3\cdot\vec{L}_\delta \quad (12)$$

$$\vec{U}(m+1) = \frac{\vec{U}_1+\vec{U}_2+\vec{U}_3}{3} \quad (13)$$

The next stage is to follow the victim (exploitation), if the study has an approximate position. The vector $\vec{Q}$ may be used to do this as the circumstance of wolves becomes nearer to the prey's location as *p* in Eq. (11) decreases from 2 to 0. Moreover, by removing the requirement for local averages, variables *f and Q* also contribute to maintaining the method's exploring capabilities. The accessibility of food and the difficulty of foraging may be altered by the variable *f*, but it can also affect a *Q* value larger than one, or $|Q| > 1$, which pushes the wolves to depart from their diet and search it out. Once the method is applied to a group of wolves for a set number of iterations, Eq. (13) will finally display the prey's position or the optimal region on Globe.

V. Results and Discussion

The study uses an exhaustive approach to create an advanced e-health system that combines advanced surveillance techniques with an adaptable machine learning classifier to monitor diabetes patients. The dataset includes information from sixty-two diabetic patients who were examined over the course of sixty-seven days. The 13,173 glucose concentration measurement values and five characteristics are evenly scaled as a preprocessing step using Min-Max normalization. The next step is to extract characteristics using Principal Component Analysis, which reduces dimensionality and identifies important factors impacting patient characteristics and fluctuations in glucose levels. The main component of the suggested system is the tracking and classification mechanism, which makes use of a hybrid convolutional neural network coupled with a support vector machine. Significant characteristics are automatically identified by the seven-layer CNN, and robust classification is ensured by SVM. In order to highlight the complementing advantages of CNN's feature extraction skills and SVM's binary classification, the study presents novel hybrid CNN-SVM architecture. The Grey Wolf Optimization framework is modelled after the cooperative optimization process seen in wolf packs, is used to tune the model's parameters and improve its efficiency.

A. Performance Evaluation

Evaluation indicators are essential for assessing the effectiveness of classification. A calculation of accuracy is the approach that is most commonly utilized for this goal. How well a classifier identifies sample datasets may be used to measure how accurate it is for any given collection of information. Because depending entirely on the accuracy measure will prevent you from making the best assessments conceivable. The researchers also used other parameters to assess the classifier's effectiveness. Measures of accuracy, recall, precision, and F1-score were employed to assess the effectiveness of the proposed method. The definitions of each metric are described as follows

- T_{pos} (True Positive) refers to the amount of information that has been correctly categorized.
- The term $Fpos$ (False Positive) represents the volume of reliable information that was incorrectly categorized.
- False negatives (F_{neg}) are instances where incorrect information has been given an actual classification.
- The categorization of incorrect information values is referred to as T_{neg} (True Negative).

1) Accuracy: The accuracy of the classifier shows how often it makes the correct prediction. Accuracy is defined as the ratio of correct estimations to all other reasonable theories. It is demonstrated by Eq. (14).

$$Accuracy = \frac{T_{pos}+T_{neg}}{T_{pos}+T_{neg}+F_{pos}+F_{neg}} \tag{14}$$

2) Precision: Evaluating a classifier's precision, or degree of accuracy, yields the number of possibilities that are properly identified. Increased reliability leads to fewer false positives, but lower precision results in many more. Precision is defined as the proportion of properly classified cases relative to all occurrences. It is defined by Eq. (15).

$$P = \frac{Tpos}{Tpos+Fpos} \tag{15}$$

3) Recall: Recall determines a categorization's sensitivity, or how much pertinent information it generates. As recollection improves, F_{neg}total amount decreases. The percentage of occurrences that have been accurately classified to all of the expected instances is called recall. This is demonstrable by Eq. (16).

$$R = \frac{Tpos}{Tpos+Fneg} \tag{16}$$

4) F1-Score: Addition of precision and recall yields an association of measurements known as the F-measure, which represents the weighted average of accuracy and recall. It is characterised by Eq. (17).

$$F1 - score = \frac{2\times precision \times recall}{precision\times recall} \tag{17}$$

5) ROC Curve: In deep learning and machine learning, area under the ROC curve, or AUC, is a popular assessment statistic for binary categorization issues. The area under the curve (AOC) is a visual depiction of the receiver operating characteristic (ROC) curve that shows how effective the binary identification technique is. In a binary categorized issue, the classifier determines whether the incoming data is part of a positive or negative partition. The ROC curve displays the $Tpos$ vs. the F_{pos} for different categorization parameters. AOC values range from 0 to 1, with higher numbers denoting more efficiency. An optimum classifier has an AOC of one, whereas a totally randomly assigned classifier has an AOC of 0.5. Since the approach takes into account every conceivable level of detection and offers only one statistic for comparing the effectiveness of various classifiers.

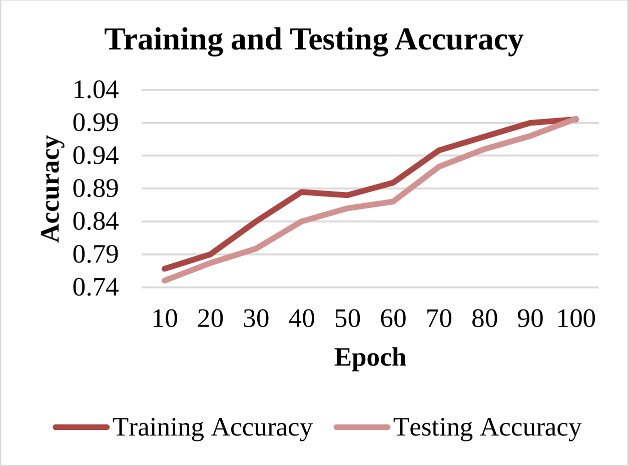

Fig. 3. Training and testing accuracy.

The training and testing accuracy scores at different epochs of the model training procedure are shown in Fig. 3. Training and testing accuracy exhibit a steady rising trend with an increase in training epochs, suggesting that the model is performing better. The model obtains a testing accuracy of 75% and a training accuracy of 76.8% at the beginning of training.

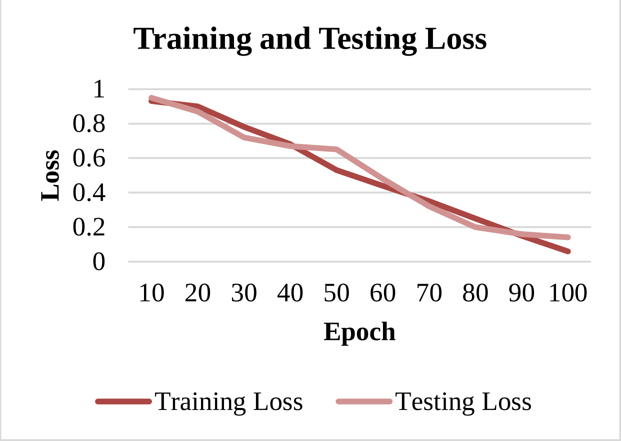

Fig. 4. Training and testing loss.

The training accuracy increases with the number of epochs, reaching at 99% after 90 and 99.6% after 100 epochs. A similar pattern may be found in the associated testing accuracy, which shows how well the model generalizes to new information. The model's ability to learn from and adapt to the dataset is seen by the significant rise in accuracy from 10 to 100 epochs. The final epochs achieve a high degree of accuracy, indicating a resilient and well-trained model. The model is more reliable in correctly predicting patterns associated to diabetes because training and testing accuracy converge at higher epochs, indicating efficient learning without overfitting. The training and testing loss values at various epochs during the algorithm's training procedure are shown in Fig. 4. Lower numbers indicate higher model performance. Loss values show the difference between the expected and actual values. Training and testing loss are both rather high in the early phases of training (at 10 epochs), indicating the model's inadequate ability for precise result prediction. On the other hand, training and testing loss consistently decrease with the number of epochs, indicating enhanced model convergence and accuracy in predictions. The training loss dramatically drops to 0.06 by the 100th epoch, demonstrating that the system effectively eliminates mistakes throughout the learning process from the training set. Additionally, the testing loss drops to 0.14, indicating that the model can generalize even on untested information. The model's capacity for identifying diabetes-related characteristics is supported by the consistent reduction in loss values over epochs, which shows effective learning, and the similarity of testing and training losses, which suggests the model, maintains high accuracy without overfitting.

TABLE I. PROPER AND IMPROPER CATEGORIZED INFORMATION

Methods	SVM [26]	DT [26]	SMO [27]	CNN-SVM
Improper Categorized Data	8.482%	11.030%	13.715%	0.312%
Proper Categorized Data	89.115%	84.541%	79.455%	99.851%

With a focus on data pertaining to diabetes, Table I and Fig. 5 examine how well various categorization techniques performed in terms of accurate and incorrect information categorization. Support Vector Machine (SVM), Decision Trees (DT), Sequential Minimal Optimization (SMO), and the suggested hybrid approach, CNN-SVM, are among the techniques assessed. The rates at which each approach misclassifies information are indicated by the percentages in the Improper Categorized Information. The percentages of incorrectly categorized information for SVM, DT, and SMO are greater (8.482%, 11.030%, and 13.715%, respectively). The CNN-SVM hybrid strategy, on the other hand, performs noticeably better than these techniques, attaining a very low rate of 0.312% in incorrect classification.

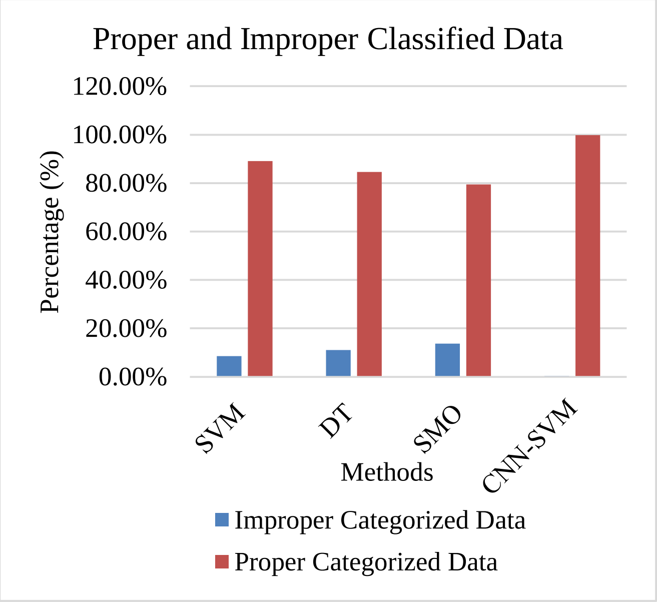

Fig. 5. Proper and improper categorized information.

The Proper Categorized Information, on the other hand, demonstrates how accurately each approach categorizes information pertaining to diabetes. This is where CNN-SVM excels, exceeding SVM, DT, and SMO, with percentages of 89.115%, 84.541%, and 79.455%, respectively, in appropriate categorization with an astounding 99.851% accuracy. The outcomes demonstrate the suggested CNN-SVM hybrid model's improved performance in classifying diabetes-related information with accuracy, indicating its potential as a useful method for patient monitoring and illness prediction.

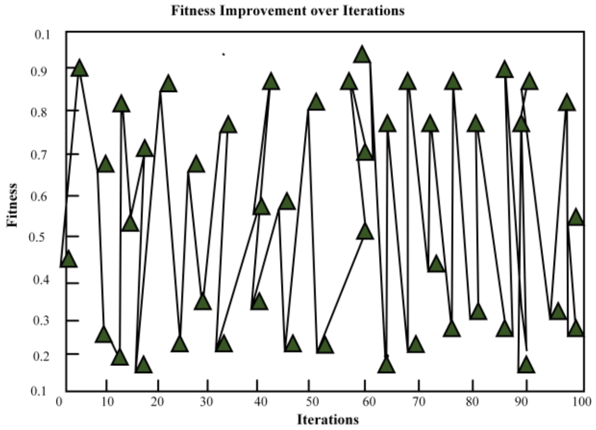

Fig. 6. Fitness improvement over iterations.

The Grey Wolf Optimization algorithm's enhancement in efficiency as iteratively refines the model's parameters is demonstrated in Fig. 6 by the Fitness Improvement over Iterations. The fitness value which indicates the optimization of the objective function increases during the first iterations while the algorithm searches the parameter space. A discernible increase in fitness is shown as the iterations continue on, suggesting that the GWO method is effective in fine-tuning the parameters to get improved placement with the optimization objective. Fitness values show a constant decreasing trend, which indicates that the algorithm is efficient in converging towards the best parameter combinations. The above chart provides a visual demonstration of the GWO algorithm's capacity to dynamically modify parameters to improve the model's efficiency continually. It also demonstrates the algorithm's effectiveness in fine-tuning for optimal outcomes across a number of rounds.

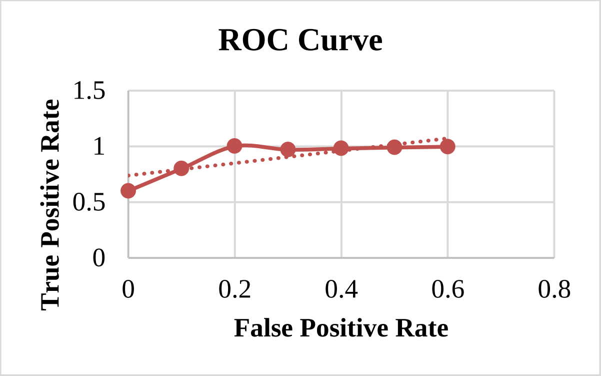

Fig. 7. ROC curve.

Fig. 7 shows a plot of True Positive Rate (Sensitivity) vs. False Positive Rate (1 - Specificity) over several threshold values for a binary categorization model, which represents the Receiver Operating Characteristic (ROC) Curve. The True Positive Rate progressively improves as the discriminating threshold reduces from 0.6 to 0.6 in the given figure of threshold values and associated False Positive Rates, indicating the model's capacity to accurately detect positive events. Additionally, there is an increase in the False Positive Rate, which signifies the occurrences of the model misclassifying negative cases as positive. The relationship between sensitivity and specificity is graphically represented by the ROC Curve, which offers an understanding of the model's overall discriminating strength over a variety of threshold values.

TABLE II. COMPARISON OF ROC OF PROPOSED METHOD WITH OTHER EXISTING APPROACHES

Models	Levels
SVM	0.8148
DT	0.8052
SMO	0.8264
Proposed CNN-SVM	0.8687

Table II presents a comparison of the Receiver Operating Characteristic (ROC) performance metrics for different models, specifically Support Vector Machine (SVM), Decision Tree (DT), Sequential Minimal Optimization (SMO), and the proposed method, a Convolutional Neural Network-Support Vector Machine hybrid (CNN-SVM). The ROC values serve as indicators of the models' ability to discriminate between classes, with higher values suggesting better performance. In this context, the proposed CNN-SVM demonstrates the highest ROC value of 0.8687, indicating superior discriminative capabilities compared to SVM (0.8148), DT (0.8052), and SMO (0.8264). The results suggest that the hybrid approach, combining Convolutional Neural Network and Support Vector Machine, outperforms traditional machine learning models in the specific task or dataset under consideration, emphasizing its potential for enhanced predictive accuracy and classification performance.

The suggested CNN-SVM model's performance metrics for diabetes prediction are compiled in Fig. 8, which displays outstanding outcomes for all major assessment parameters. With an impressive 99.6% accuracy rate, the model demonstrates its ability to accurately categorize occurrences. With a remarkable 99.4% precision rate a measure of the model's accuracy in positive predictions it is clear that there is little chance of false positives. The model's strong sensitivity is further demonstrated by the recall metric, which measures the model's capacity to identify all positive events and is now 99.4%. At a remarkable 99.5%, the F1-Score a balanced metric of accuracy and recall highlights the CNN-SVM model's overall efficacy in diabetes prediction. All of these findings indicate the suggested model's stability and dependability, highlighting its possibilities as an innovative technology for precise and effective diabetic patient monitoring.

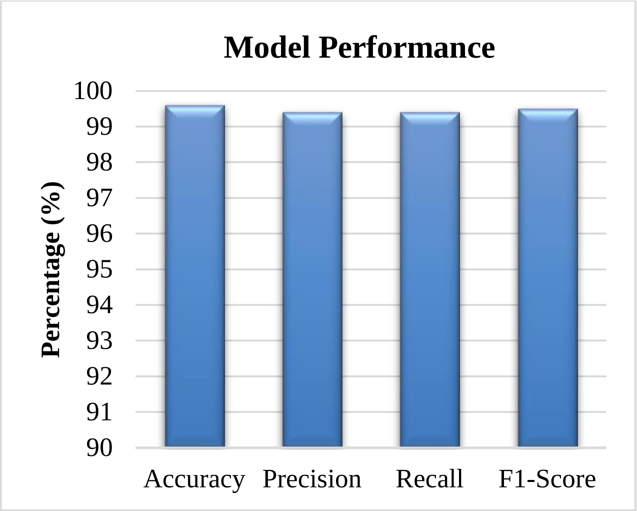

Fig. 8. Model performance.

TABLE III. COMPARISON OF PERFORMANCE METRICS OF PROPOSED METHOD WITH OTHER EXISTING APPROACHES

Models	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
SVM	96.45	95.11	95.15	95.17
DT	95.34	95.23	95.23	95.10
SMO	97.12	96.09	96.10	96.10
Proposed CNN-SVM	99.6	99.4	99.4	99.5

The suggested CNN-SVM model and other methods, such as Support Vector Machine (SVM), Decision Tree (DT), and Sequential Minimal Optimization (SMO), are extensively contrasted using performance metrics in Table II and Fig. 9. With an outstanding 99.6% accuracy rate, the suggested CNN-SVM model performs better than alternative approaches. The suggested model has outstanding performance as seen by its 99.4%, 99.4%, and 99.5% precision, recall, and F1-Score metrics. By contrast, SVM attains competitive precision, recall, and F1-Score values in addition to a high accuracy of 96.45%.

Accuracy ratings of 95.34% and 97.12% for DT and SMO, respectively, also show satisfactory results. However, the suggested CNN-SVM model performs better overall on all assessed parameters, highlighting its effectiveness in tasks involving the prediction and categorization of diabetes. These findings demonstrate the hybrid CNN-SVM approach's potential for innovative healthcare applications, especially when it comes to diabetic patient monitoring.

B. Discussion

By combining a variety of sophisticated surveillance approaches with an adaptive machine learning classifier, the study described here provides a comprehensive method for creating an advanced e-health system for diabetic patient monitoring. The research makes use of a dataset that includes sixty-two diabetic patients who were followed up on for sixty-seven days in a row. The dataset undergone significant preprocessing, which included feature extraction using Principal Component Analysis (PCA) and Min-Max normalization. The fundamental component of the suggested system combines a support vector machine (SVM) with a hybrid convolutional neural network (CNN) for tracking and categorization. Grey Wolf Optimization framework is used to tune model parameters. Accuracy, precision, recall, F1-Score, and the Receiver Operating Characteristic (ROC) Curve are all used in the model's performance evaluation to give a thorough assessment of its prediction competencies. The results show that the model is adaptable in classifying data relevant to diabetes and show a notable improvement in accuracy throughout training epochs, reaching an astonishing 99.6%. The proposed CNN-SVM model has potential for accurate and efficient diabetic patient monitoring by outperforming other conventional methods like SVM [26], DT [26], and SMO [27]. The Fitness Improvement over Iterations graph, which illustrates the study's findings, provides an understanding of how the Grey Wolf Optimization method affects the model's effectiveness. This graph shows how the method refines parameters iteratively, improving fitness values and optimizing the objective function. The model's ability to learn and generalize well is further demonstrated by the continuous decline in loss values during training epochs. The suggested CNN-SVM model is superior to other current techniques in terms of accuracy, precision, recall, and F1-Score, as demonstrated by the comparison shown in Table II and Fig. 9. All of these results point to the possibility of creative healthcare applications using the hybrid CNN-SVM architecture and Grey Wolf Optimization algorithm, especially for accurate diabetes patient prediction and monitoring. The work demonstrates the possibility of combining machine learning and optimization approaches for better healthcare outcomes in addition to adding to the knowledge of diabetes patient monitoring.

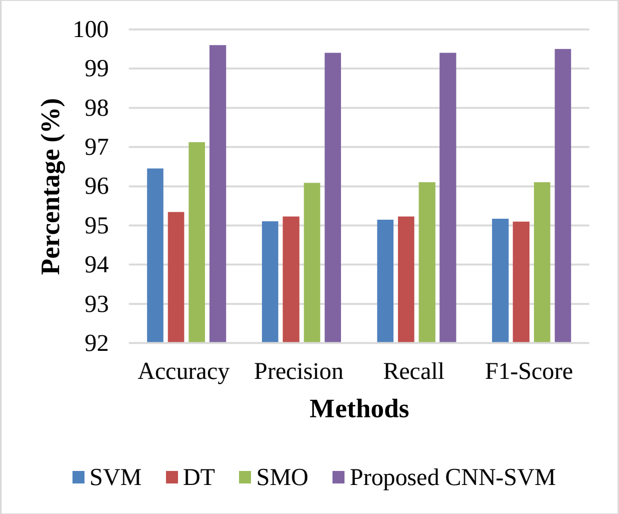

Fig. 9. Comparison of performance metrics of proposed method with other existing approaches.

VI. CONCLUSION AND FUTURE WORKS

In conclusion, this study has showcased an innovative method for monitoring diabetic patients, which has resulted in the creation of a sophisticated computerized health system that combines a sophisticated tracking system with a hybrid adaptive machine learning classifier. The system, which is trained and optimized utilizing the Grey Wolf Optimization technique, takes advantage of the synergies between support vector machines (SVM) and convolutional neural networks (CNN) in hybrid architecture. The comprehensive assessment of conventional performance measures has proven the enhanced accuracy, precision, recall, and F1-Score of the suggested CNN-SVM model, indicating its efficacy in classifying data pertaining to diabetes. Analyses that compare the hybrid model to more conventional techniques like SVM, Decision Trees, and Sequential Minimal Optimization highlight the significant improvement in accuracy that the hybrid model offers. In addition, the study has provided informative visuals which provide an extensive comprehension of the learning dynamics and optimization of the model. These visualizations include fitness increase over iterations, ROC curves, training and testing accuracy graphs, loss curves, and more. The suggested system's resilience and ability to provide accurate and efficient diabetes patient monitoring emphasize its importance in improving e-health applications and creating opportunities for customized and adaptable healthcare solutions. The research makes a significant contribution by presenting a novel framework that combines machine learning, intelligent tracking, and optimization techniques. This framework paves up the opportunity for novel approaches to diabetes care in the e-health era. The generalizability and practicality of the model will be improved in subsequent work by extending the dataset to incorporate more varied demographic information and taking real-world deployment issues into account. Further research into the incorporation of real-time feedback from patient's mechanisms and the possibility of using edge computing to lower monitoring process latency might enhance the responsiveness and user involvement of the suggested e-health system.

Feature Selection Model Development on Near-Infrared Spectroscopy Data

Case Study of Beef Freshness Quality Prediction

***Abstract*—This study aims to develop a feature selection model on Near-Infrared Spectroscopy (NIRS) data. The object used is beef with six quality parameters: color, drip loss, pH, storage time, Total Plate Colony (TPC), and water moisture. The prediction model is a Random Forest Regressor (RFR) with default parameters. The feature selection model is carried out by mapping spectroscopic data into line form. The collection of lines is made into one line by finding the mean value. Next, apply the line simplification method based on angle elimination, starting from the smallest angle to the largest. Each iteration will eliminate one corner, reducing one column of data in the corresponding dataset. Then, the predicted value in the form of R2 will be collected, and the highest value will be considered the best feature selection formation. RFR prediction results with R2 values are as follows: color R2= 0.597, drip loss R2=0.891, pH R2=0.797, storage time R2=0.889, TPC R2=0.721, and water moisture R2=0.540. Meanwhile, after applying the feature selection model, the R2 values for all parameters increased to color R2=0.877, drip loss R2=0.943, pH R2=0.904, storage time R2=0.917, TPC R2=0.951, and water moisture R2=0.893. Based on the results of increasing the R2 value of the six parameters, an average value of increasing prediction accuracy of 17.49% can be taken. So, the feature selection method based on line simplification with an angle elimination system can provide very good results.**

***Keywords*—Beef quality prediction; feature selection; machine learning; Random Forest Regressor**

I. Introduction

People have consumed a lot of meat in the last few decades, and consumption has increased in recent years [1]. Beef is an alternative commodity that is widely consumed to meet the need for protein in many countries [2]. However, meat food products are products that rot quickly, especially under certain conditions, which can accelerate microbial growth [3]. Many cases of consumers getting sick are caused by microbes found in beef that are large in number or above standard [4].

The condition of the meat can change quickly, so a method is needed that can determine the current state of beef quality. One fast method for determining meat quality is to use near-infrared (NIR) technology [5]. NIR spectrometers can predict meat quality parameters, including chemical parameters, technological parameters, quality traits, fatty acids, and many mineral contents [6][7][8].

To speed up and simplify the process of determining meat quality, a portable or handheld NIR device can be built that can be taken anywhere [9][10]. The development of a portable NIR device can be applied in industries that require the process of determining the characteristics of meat products [11][12].

Machine learning can be used as a model to predict meat quality parameters [13]. Machine learning is also able to predict meat quality parameters, including color, tenderness, juiciness, and flavor [14]. The random forest (RF) algorithm works well and produces high accuracy in classifying cattle breeds [15]. Random Forest Regressor (RFR) performs well in predicting pH values in beef in real-time in a beef freshness monitoring system [16].

In this study, we propose a feature selection model on spectroscopic data to increase the accuracy of meat quality predictions. The beef quality parameters in question are color, drip loss, pH, storage time, total plate colony (TCP), and water moisture. The algorithm that will be used is RFR, with algorithm parameters by default. Based on the experimental results, the proposed method is able to increase accuracy in predicting the freshness quality of beef compared to results without using feature selection.

II. Literature Survey

A. Feature Selection

Feature selection involves exploring algorithms designed to decrease the data's dimensionality, thereby enhancing the performance of machine learning. In datasets with N features and M dimensions, the primary goal is to minimize M to M′, where M′ is less than or equal to M [17]. Typically, feature selection often results in improved learning outcomes, such as increased accuracy in learning, reduced computational expenses, and enhanced interpretability of the model.

Recently, experts in fields like computer vision and text mining have introduced numerous feature selection methods. Through both theoretical frameworks and practical experiments, they've demonstrated the effectiveness of their approaches [18]. Feature selection using established line simplification methods such as the Ramer–Douglas–Peucker algorithm and Visvalingam on NIRS data encountered problems in determining epsilon values, making it difficult to produce optimal datasets.

This study will compare the results of prediction accuracy from the proposed feature selection model with the established method from Scikit-Learn, namely SelectFromModel [19]. Comparison of results in the form of accuracy of value prediction on six meat quality parameters using R-squared values (R2) as part of model evaluation both for evaluation of the SelectFromModel feature selection model and for the proposed feature selection model.

B. Random Forest Regressor

Random forests consist of a collection of tree predictors where each tree relies on a randomly sampled vector, independent and identically distributed across all trees within the forest. As the number of trees in the forest increases, the generalization error for forests gradually converges to a limit. This error is influenced by both the effectiveness of the individual trees in the forest and the level of correlation among them [20].

The advantages of feature selection and its relevance to enhancing the effectiveness and interpretability of machine learning algorithms are well-established. In this context, we focus on incorporating feature selection into a Random Forest setup. We propose a method that integrates hypothesis testing with an estimation of the anticipated impact of an irrelevant feature while constructing a Random Forest [21].

The utilization of R^2 in this research for model assessment is due to its superior informativeness and reliability compared to SMAPE, along with its absence of interpretational constraints seen in metrics like MSE, RMSE, MAE, and MAPE[22]. The R2 value range is easy to understand because the value ranges between 0 and 1 and is indicated by a decimal number. The number 0 indicates poor model performance, and one or close to it indicates good model performance. The formula for calculating the R2 value can be seen in Eq. (1) [22].

$$R^2 = 1 - \frac{sum\ squared\ regression\ (SSR)}{total\ sum\ of\ squares\ (SST)} = 1 - \frac{\sum(y_1 - \hat{y}_1)^2}{\sum(y_1 - \bar{y})^2} \quad (1)$$

C. Near-Infrared Spectroscopy

Near-infrared spectroscopy (NIRS) holds a distinct position within the realm of bioscience and its associated fields, differing in characteristics and potential applications from infrared (IR) or Raman spectroscopy. This type of vibrational spectroscopy uncovers molecular details within a sample by detecting absorption bands arising from overtones and combined excitations [23].

The capacity of near-infrared reflectance spectroscopy (NIRS) to differentiate between Normal and DFD (dark, firm, and dry) beef and forecast quality characteristics within 129 Longissimus thoracic (LT) samples derived from three Spanish pure breeds: Asturiana de los Valles (AV; n = 50), Rubia Gallega (RG; n = 37), and Retinta (RE; n = 42). The outcomes obtained using partial least squares-discriminant analysis (PLS-DA) demonstrated successful differentiation between Normal and DFD meat samples from AV and RG (with sensitivity exceeding 93% for both and specificity of 100% and 72%, respectively), whereas results for RE and the overall sample sets were less accurate. Soft independent modeling of class analogies (SIMCA) revealed 100% sensitivity for DFD meat across all sample sets (total, AV, RG, and RE) and over 90% specificity for AV, RG, and RE, but notably lower for the total sample set (19.8%). Utilizing NIRS quantitative models via partial least squares regression (PLSR) allowed dependable prediction of color parameters (CIE L*, a*, b*, hue, chroma). The findings from both qualitative and quantitative analyses hold promise for early decision-making in the meat production process to prevent financial losses and food wastage [24].

Growing apprehensions regarding contaminated meat have spurred the industry to explore novel, non-invasive techniques for swift and precise assessment of meat quality. The primary chromophores in meat (such as myoglobin, oxy-myoglobin, fat, water, and collagen) exhibit similar absorption patterns within the visible to near-infrared (NIR) spectral range. Consequently, variations in the structure and composition of meat can result in proportional disparities in light absorption [25].

III. Material

A. Sample Preparation

This study used fresh beef objects obtained from traditional markets in Bogor City, West Java, Indonesia, and then brought to the laboratory using an ice box, as shown in Fig. 1. The part of the carcass used is tenderloin. The main sample used weighs 1 kg, as shown in Fig. 2.

The next step is to cut it into eight pieces of large samples weighing 17+2 grams and eight pieces of small samples of 3+1 grams, as shown in Fig. 3. All samples were placed on the laboratory table in Petri dishes and supported by wire gauze, as shown in Fig. 4. Large one of samples were used for testing the parameters of color, pH, WHC, water content, and NIR, while small one of samples were used for TPC measurements. The total samples used were eight samples per day and repeated for ten days to obtain 80 samples.

Fig. 1. Sample in the icebox.

Fig. 2. 1 Kg tenderloin.

Fig. 3. Small pieces of sample.

Fig. 4. The samples are placed on a petri dish with a wire mesh base.

B. Data Acquisition

This study uses six beef freshness parameters, where each parameter uses a different tool. The six freshness parameters include color, drip loss, pH, storage time, TPC, and water moisture. The tool used to retrieve color data is Chromameter, as shown in Fig. 5.

The drip loss parameter value is obtained by measuring the weight of the sample between the initial and final times. The measurement interval is one hour with a total time span of seven hours so that eight drip loss data are produced starting from the 0th hour to the 7th hour. The tool for measuring sample weight is a laboratory scale, as shown in Fig. 6.

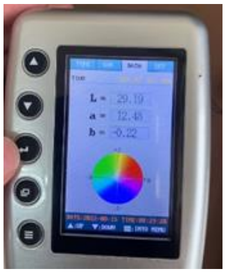

Fig. 5. Measurement results using a chromameter.

Fig. 6. Weight measurement process.

TPC parameter values were obtained from other laboratories and measured professionally by a third party. The samples sent are the same pieces used for measuring other parameters. Examples of samples are shown in Fig. 7.

Fig. 7. Sample for TPC measurement.

Fig. 8. pH measurement process.

The pH value parameter of the sample was measured using an electronic pH meter, as shown in Fig. 8. The storage time parameter value is obtained by simply storing the sample on the table from the 0th hour to the 7th hour with a break every hour. Then, the water moisture value is carried out using the drying or thermogravimetric method in an oven at a temperature of 105 degrees Celsius for 16 hours. Laboratory testing data collection activities were carried out for ten days, resulting in a dataset for 80 data rows, as shown in Table I.

33,92	17,51	1,28	5,46	29,60	3,93	30,50	77,10%
36,46	16,79	0,08	5,55	28,46	3,84	29,41	75,26%
33,29	16,04	3,25	5,50	28,81	4,00	29,82	74,75%
32,47	15,68	4,94	5,55	30,16	3,92	31,19	73,72%
29,50	11,18	3,00	5,50	29,13	3,94	30,19	73,10%
31,62	12,67	3,23	5,48	25,12	3,67	26,16	71,66%
28,29	10,88	5,43	5,59	27,97	3,68	28,97	72,83%

W_0. initial weight; Wt. new weight; ΔW. weight changes; L; lightness; a. red/green value; b. yellow/blue value; Wdish, the weight of the empty dish; Wsample, the weight of the current sample; Wt, weight changes.

C. NIRS Data and Dataset

NIRS data is obtained by scanning samples using a NIRS sensor. The sensor used is the NeoSpectra Development Kit [26] as shown in Fig. 9 and Fig. 10. For the wireless data acquisition process, use a notebook unit equipped with requesting software that is available from the sensor manufacturer as shown in Fig. 11.

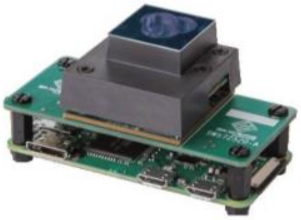

Fig. 9. NeoSpectra development kit.

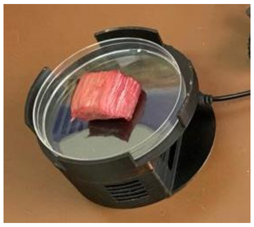

Fig. 10. NeoSpectra development kit with case and sample.

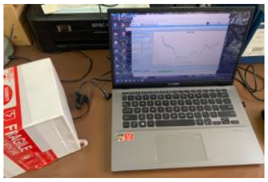

Fig. 11. Acquisition using NeoSpectraKit in progress covered by a box.

Measurement results in a spreadsheet file. The example of the averaged data can be seen in Table II. The original data of NIR Spectroscopy plotted as a graphic can be seen in Fig. 12. The total NIRS data collected is 720 data rows and 136 columns according to wavelength value from the sensor and visualized. as shown in Fig. 12. The wavelength used is between 1346.61 - 2556.24 nanometers (nm).

TABLE II. EXAMPLE OF NIRS DATA

Hour	**Wavelength (nm)**				
	2556.24	***2539.35***	**…**	***1351.35***	***1346.61***
0	2.27	2.37	…	1.41	1.35
1	1.96	2.08	…	1.72	1.95
2	1.78	1.86	…	1.62	1.53
3	2.12	2.22	…	1.89	1.88
4	2.11	2.28	…	1.85	1.77
5	1.71	1.86	…	2.01	2.11
6	2.13	2.30	…	2.86	2.55
7	2.81	2.91	…	3.79	4.01

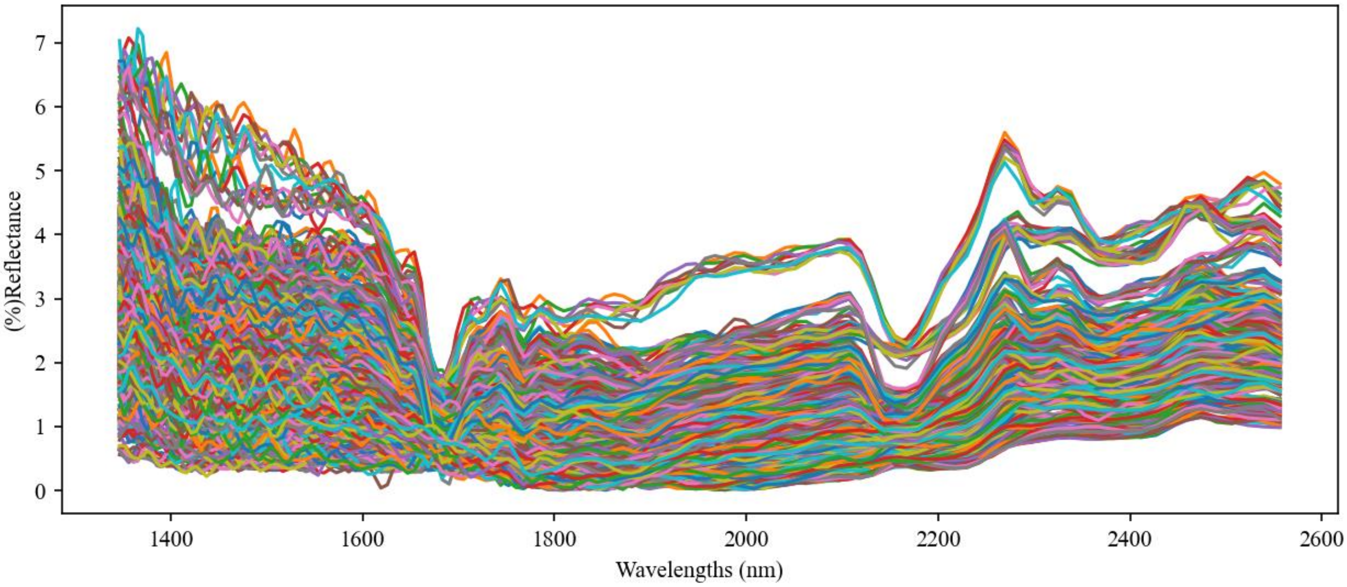

Fig. 12. Plot of original data spectrum.

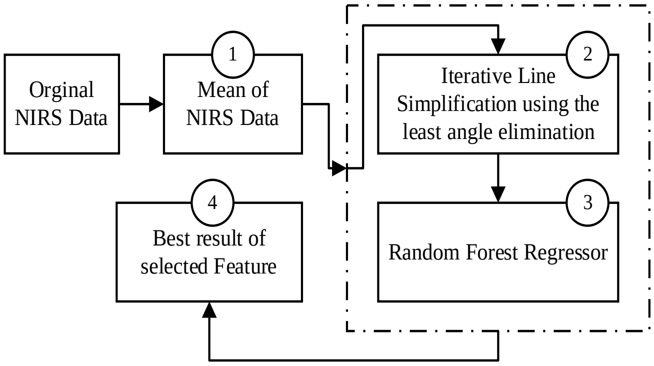
IV. Proposed Feature Selection Model

The proposed feature selection model aims to reduce the amount of data based on columns in the dataset, which by default has 136 columns. This feature selection concept is based on the line simplification model by reducing straight or slightly curved lines. The main stages of the feature selection process can be seen in Fig. 13.



Orginal NIRS Data
1
Mean of NIRS Data
2
Iterative Line Simplification using the least angle elimination
3
Random Forest Regressor
4
Best result of selected Feature

Fig. 13. Flow process of proposed selection feature.

The feature selection process goes through four stages as follows :

A. Mean and Single Data Line

In this process, 1 line is produced, which will represent all spectrum data. as shown in Fig. 14. Then, it is divided into one separate piece represented by one different color, as shown in Fig. 15. Then pair them with adjacent lines. as shown in Fig. 15. Then calculate the angle values of two adjacent lines as illustrated by Fig. 16.

B. Iterative Line Simplification

The process of calculating all angles along a line produces 134 angle values. Then, the angle value data is sorted starting from the smallest value. Each iteration will eliminate one corner with the smallest value. The eliminated corners will correspond to the columns that will be eliminated as well. At this stage. a set of data columns is stored with the storage index in a sequence of iterations. The elimination stages are depicted in the diagram Fig. 17.

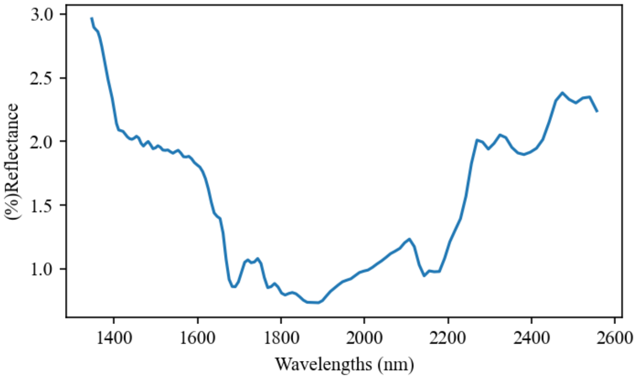


Fig. 14. Mean of all spectrums.

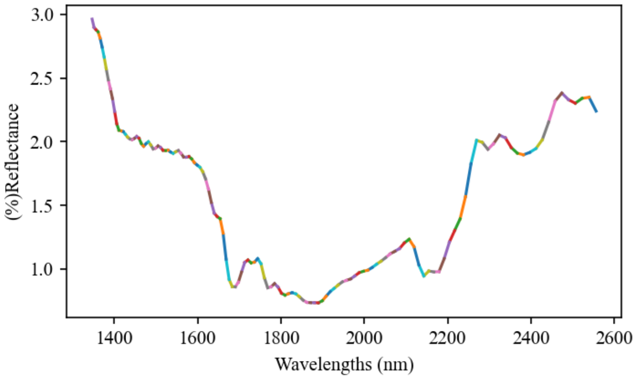

Fig. 15. Separated spectrum into single data line.

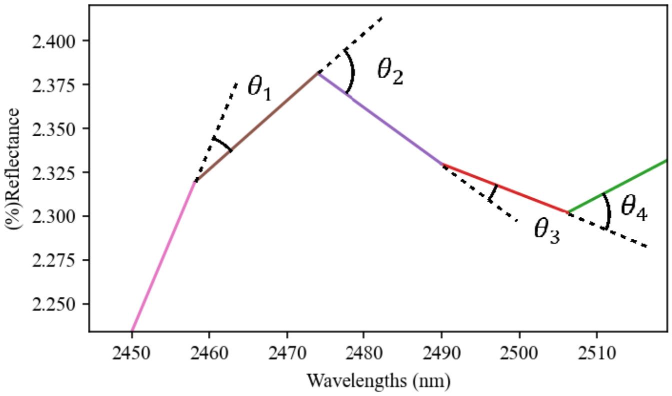

Fig. 16. Illustration of calculating the angle between two adjacent lines.

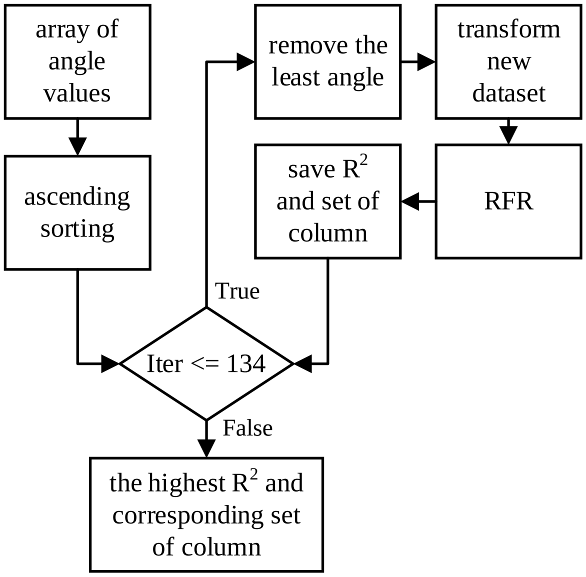

Fig. 17. Iterative angle and column elimination.

C. Random Forest Regressor

Each iteration produces a new dataset with a reduction of 1 column of data. The new dataset will then enter the machine learning process to produce an R^2 value at each iteration. At this stage, the RFR parameters used are the default settings, as shown in Table III. Data splitting for the learning and testing process is 70% to 30%.

TABLE III. DEFAULT PARAMETERS OF RFR [19]

Parameter	Data type	Default value
n_estimators		100
criterion		squared_error
max_depth		None
min_samples_split		2
min_samples_leaf		1
min_weight_fraction_leaf	float	0.0
max_features	int or float	1.0
max_leaf_nodes	int	None
min_impurity_decrease	float	0.0
bootstrap	bool	True
oob_score	bool or callable	False
n_jobs	int	None
random_state	int	None
verbose	int	0
warm_start	bool	False
ccp_alpha	non-negative float	0.0
max_samples	int or float	None
monotonic_cst	array-like of int of shape (n_features	None

The results of R^2 at each iteration will be stored in an array. Then, it will find the highest R^2 value and location in the array to be used as the best column index set.

D. The best result of the selected feature

The final stage is to determine the largest value from the collection of R^2 that has been accommodated in the array. To determine the highest R^2 value in this study, use the numpy library with the numpy.max() command [27]. To find out the iteration position of the highest R^2 value, also use the numpy library with the command numpy.argmax() [28]. This command will display the data index of the highest R^2 value.

To determine the best set of columns is to store the value of R^2 in each iteration. Then, find the highest value of the array to determine the index value. The index value is used to retrieve the set of columns.

V. RESULTS

A. Results from the Original Dataset and the Proposed Model

Of the six meat quality parameters, namely color, drip loss, pH, storage time, TCP, and water moisture, feature selection and machine learning models are applied alternately. Then, we will compare the prediction results using the original dataset with the dataset that has gone through the feature selection stage. The results of the comparison of R^2 values can be seen in IV.

Based on the R^2 value in Table IV, it can be seen that the line simplification-based feature selection model with the corner elimination method has succeeded in increasing the performance of the RFR algorithm in predicting all beef quality parameters. The increase in the R^2 value for all parameters can be said to be satisfactory, with the smallest increase being in the predicted storage time parameter, which is only 0.028.

TABLE IV. R^2 SCORE USING THE ORIGINAL DATASET AND USING FEATURE SELECTION

Beef Quality Parameters	R^2 score		
	Original dataset	*With the proposed feature selection*	*increment*
color	0.597448	0.876992	0.279544
drip loss	0.891545	0.942723	0.051178
pH	0.796903	0.904225	0.107322
storage time	0.889070	0.916581	0.027511
TPC	0.720895	0.951388	0.230493
water moisture	0.539780	0.893200	0.353420

The results were very good, and the highest increase in the R^2 value was in the prediction of the water moisture parameter, namely 0.353. From all the increases in R^2 values, the average value can be taken to be 0.1749 or 17.49%.

B. Results from the Original Dataset and SelectFromModel

As a comparison of performance results in this study, the feature selection model from Scikit-Learn, namely SelectFromModel. was also tested. The experimental results of implementing the SelectFromModel library can be seen in Table V.

TABLE V. R^2 SCORE OF USING ORIGINAL DATASET AND SELECTFROMMODEL

Beef Quality Parameters	R^2 score		
	Original dataset	*SelectFromModel*	*increment*
color	0.597448	0.835490	0.238042
drip loss	0.891545	0.917345	0.025800
pH	0.796903	0.846478	0.049575
storage time	0.889070	0.933890	0.044820
TPC	0.720895	0.928947	0.208052
water moisture	0.539780	0.823419	0.283639

Based on the R^2 value in Table V. it can be seen that feature selection by the SelectFromModel library can also improve the performance of the RFR algorithm. The smallest improvement was in the prediction of the drip loss parameter, namely 0.026, while the biggest improvement was in the prediction of the water moisture parameter, namely 0.2836. With the increase in the R^2 value in the prediction of all parameters, it can be said that feature selection using the SelectFromModel library works very well. Of all the increases in R^2. the average value can be taken to be 0.1417 or 14.17%.

VI. DISCUSSION

A. R^2 Score Comparison between the Proposed Model and SelectFromModel

In this stage. the results of the R^2 values from the proposed feature selection model and the SelectFromModel feature selection model are compared. The comparison results also contain the number of features selected based on their highest R^2 value, which can be seen in Table VI.

TABLE VI. COMPARISON OF R2 SCORES BETWEEN THE PROPOSED MODEL AND SELECTFROMMODEL

Beef Quality Parameters	**Proposed Model**		**SelectFromModel**	
	R^2	***n feature***	***R^2***	***n feature***
color	0.876992	84	0.835490	40
drip loss	0.942723	117	0.917345	20
pH	0.904225	57	0.846478	26
storage time	0.916581	71	0.933890	18
TPC	0.951388	56	0.928947	20
water moisture	0.893200	77	0.823419	31

Based on Table VI. it can be seen that the R^2 values of the proposed feature selection mode are higher than the SelectFromModel results, except for the R^2 value in the storage time parameter prediction. So overall, the average increase in the R^2 value of the proposed model is 17.49% higher than the average R^2 value of SelectFromModel. which produces 14.17%.

B. *Overview of Selected Features*

The result of the feature selection model is a set of features in the form of data columns; in this study, the column names are wavelength values in nanometer (nm) units. The number of features produced by the proposed model and SelectFromModel is definitely less than the number of columns in the original dataset, so this feature selection also leads to a reduction in data dimensionality. For the differences in the number and features selected, a visualization was created for all parameters, which can be seen in Fig. 18 to Fig. 23.

Each color represents one feature selection model. The red color represents the mean of all NIRS data. The green color represents the mean of the data columns selected by the proposed model, while the blue represents the results from the SelectFromModel library.

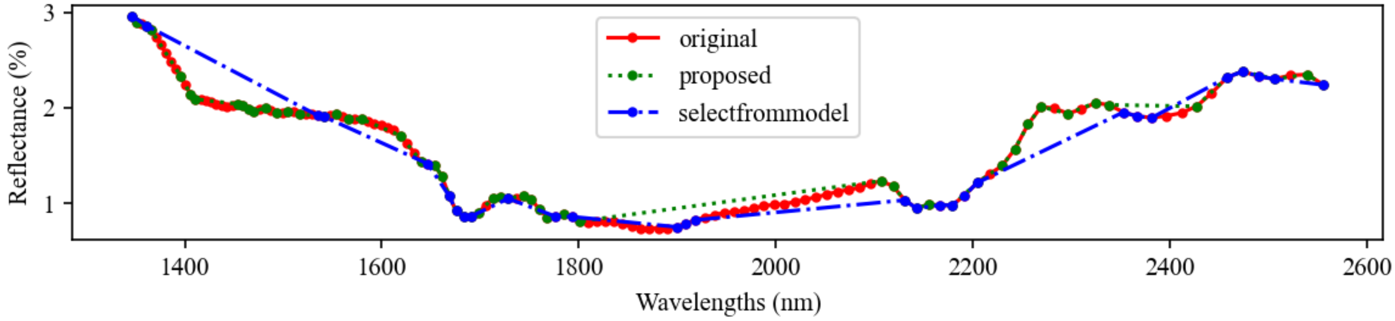

Fig. 20. Spectrums overlay for pH parameter.

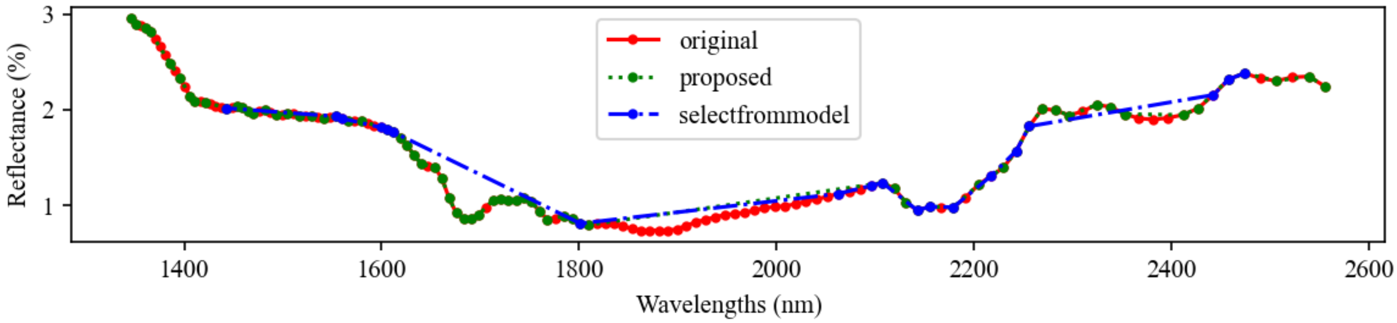

Fig. 21. Spectrums overlay for storage time parameter.

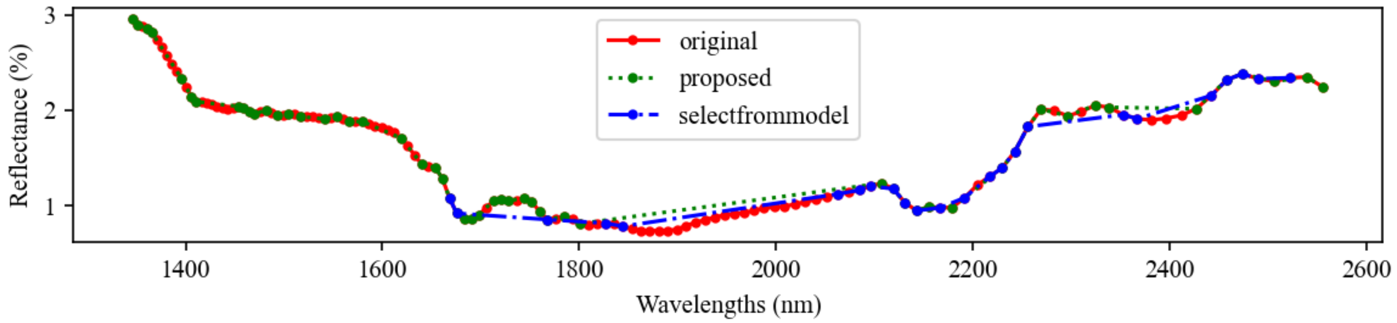

Fig. 22. Spectrums overlay for TPC parameter.

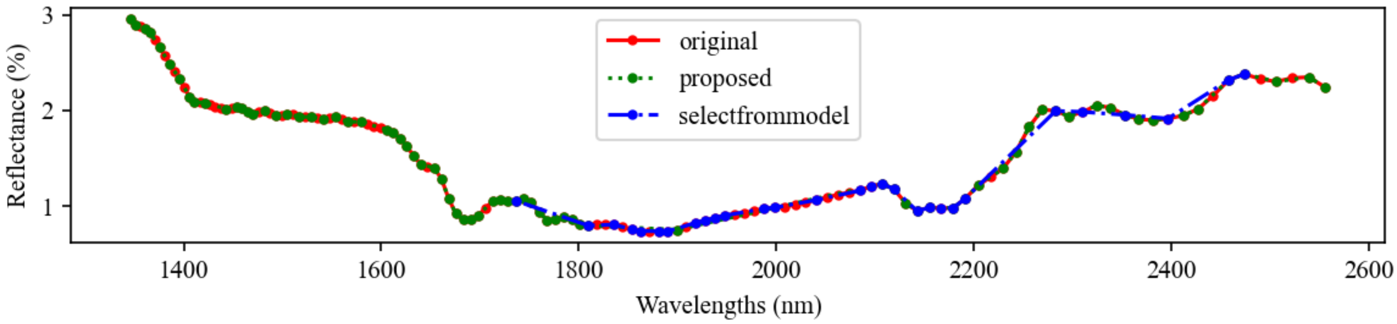

Fig. 23. Spectrums overlay for water moisture parameter.

VII. Conclusion and Future Work

This study has produced a feature selection model based on line simplification by eliminating angles in the average spectrum from beef NIRS data. The result of increasing RFR performance after using the proposed feature selection model is 17.49%. This result is higher than the average increase in R2 value produced by the SelectFromModel library of 14.17%. Apart from being able to increase prediction accuracy, this model can also reduce data dimensions, where fewer data will require a shorter time in the machine learning process.

For further work and development, the proposed feature selection model can be applied to deep learning algorithms. It can also be combined with RFR by applying hyperparameter tuning. The combination with hyperparameter tuning may require a longer time to find the solution set for the highest accuracy. However, RFR with hyperparameter tuning produces better accuracy compared to RFR with default parameters.

Research on Spatial Accessibility Measurement Algorithm for Sanya Tourist Attractions Based on Seasonal Factor Adjustment Analysis

Xiaodong Mao[1]*, Yan Zhuang[2]
School of Tourism and Health Industry, Sanya Institute of Technology, Sanya, Hainan, 572011, China[1]
University of Sanya, Sanya, Hainan, 572011, China[2]

Abstract—**Seasonal factors will lead to changes in tourists' demand for scenic spots in different seasons, which will affect the traffic network and road conditions, and then affect the convenience and efficiency of tourists arriving at scenic spots. Based on the adjustment and analysis of seasonal factors, this study puts forward an algorithm for measuring the spatial accessibility of Sanya tourist attractions. Principal component analysis is used to denoise the data of Sanya tourist attractions in different seasons, and independent component analysis is used to extract the data characteristics of Sanya tourist attractions in different seasons after denoising. On this basis, the spatial accessibility index of Sanya tourist attractions is calculated by combining the spatial information of Sanya tourist attractions and GIS technology, and the spatial accessibility of Sanya tourist attractions is analyzed, and the spatial accessibility measurement model of Sanya tourist attractions is constructed to realize the spatial accessibility measurement of Sanya tourist attractions. The experimental results show that the spatial accessibility measurement method of Sanya tourist attractions is effective, which can effectively improve the accuracy of accessibility measurement and shorten the accessibility measurement time. It aims to help decision makers plan and optimize tourist routes and improve the efficiency and convenience of tourists arriving at their destinations.**

Keywords*—*Seasonal factors; adjustment analysis; Sanya Tourist Attractions; spatial accessibility measure; GIS technology

I. INTRODUCTION

As a famous seaside tourist city in China, Sanya has a unique natural environment and rich tourism resources. With the rapid development of tourism, the spatial accessibility of tourist attractions has become an important factor affecting the development of tourism. However, seasonal factors have a significant impact on the spatial accessibility of tourist attractions [1-3]. Therefore, it is of great practical significance to study the spatial accessibility measurement algorithm of Sanya tourist attractions based on seasonal factor adjustment analysis. Sanya has many famous tourist attractions, such as nansan, Yalong Bay Tropical Paradise Forest Park and Tianya Haijiao. With the development of tourism, the spatial accessibility of tourist attractions has become an important indicator to measure the development level of tourism in a region [4]. Tourist attractions with high spatial accessibility can attract more tourists, create more economic benefits and promote the sustainable development of tourism in Sanya.

Zhou Haitao [5] and others revealed the spatial distribution characteristics of red tourist attractions in Inner Mongolia by means of kernel density and geographical concentration index. Based on the road planning function of Gaode map, the road traffic conditions were obtained in real time, and the spatial accessibility measurement model of red tourist attractions was constructed. The influencing factors of accessibility differences were clarified by using geographical detectors. This method can comprehensively consider the spatial distribution characteristics of scenic spots, traffic network and road traffic conditions, and comprehensively evaluate the accessibility of scenic spots from multiple angles. However, depending on the path planning function and road traffic data provided by Gaode map may have a certain impact on the measurement results. Wang Hao [6] and others, based on the statistical yearbook of Xinjiang road network and the official data of Xinjiang Culture and Tourism Department, analyzed the spatial distribution characteristics of scenic spots of 4A level and above in Xinjiang by using the network analysis method, kernel density analysis method and geographical concentration index of GIS, and analyzed the spatial accessibility from two aspects: scenic accessibility and regional accessibility. This method can accurately calculate the shortest path and time between scenic spots, thus providing more accurate results of scenic accessibility analysis. However, the reliability of the data needs to be verified. Wei Liu [7] and others use the spatial grid method to divide the research scope, count the number of residents in the research scope, and use the API interface of the network map platform to obtain the expected travel time data of residents. On this basis, according to the accessibility model, the fairness of public transport accessibility in Xi 'an is analyzed by using fairness coefficient and Lorenz curve. This method can quickly obtain the calculation results, but the data source is limited. Ma Shuhong [8] and others calculate the travel cost of public transport according to the data planned by real-time routes. Arcgis is used to analyze the accessibility of urban agglomerations, and theil index and fairness coefficient are used to get the difference characteristics of public transport accessibility. The calculation results of accessibility and fairness of this method are accurate and the coverage is limited.

Based on this, this paper puts forward an algorithm for measuring the spatial accessibility of Sanya tourist attractions based on the adjustment and analysis of seasonal factors, aiming at exploring how to better eliminate the influence of seasonal factors, improve tourists' travel experience and promote the sustainable development of Sanya tourism through in-depth research on the spatial accessibility of Sanya tourist attractions. By extracting the data characteristics of Sanya tourist attractions in different seasons, this paper analyzes the spatial accessibility of Sanya tourist attractions, constructs a spatial accessibility measurement model of Sanya tourist attractions, and effectively adjusts and analyzes the spatial accessibility of Sanya tourist attractions due to seasonal factors. This method can effectively measure the spatial accessibility of Sanya tourist attractions, improve the measurement accuracy and shorten the measurement time. By studying the influencing factors of the spatial accessibility of Sanya tourist attractions, it provides scientific basis and decision support for the prosperity and development of Sanya tourism. The research contribution of this paper:

1) Denoising the data of Sanya tourist attractions in different seasons, extracting the data characteristics of Sanya tourist attractions in different seasons, considering the changes in seasonal demand, traffic network, and other factors, assisting decision makers in planning and optimizing tourist routes, improving the efficiency and convenience of tourists arriving at their destinations.

2) Based on the spatial information of Sanya tourist attractions and GIS technology, the spatial accessibility index of Sanya tourist attractions is calculated, so as to evaluate the spatial accessibility of Sanya tourist attractions, provide scientific basis and decision support for the development and planning of Sanya tourism, and make positive contributions to improving tourism efficiency and promoting economic development.

II. Feature Extraction of Sanya Tourist Attractions Data in Different Seasons

Due to the fact that different seasons attract different types of tourists and have an impact on the number of tourists, transportation network, etc. By extracting data features of Sanya tourist attractions in different seasons, it is possible to analyze the changes in demand for Sanya tourist attractions and the operation of transportation and facilities during different seasons. Count the number of tourists to tourist attractions in Sanya during different seasons, understand the characteristics and travel preferences of the tourist group, help formulate more accurate Sanya tourism planning and marketing strategies, conduct seasonal factor adjustment analysis, optimize traffic management and resource allocation, and improve the spatial accessibility of Sanya tourist attractions. Therefore, in order to effectively measure the spatial accessibility of Sanya tourist attractions, first, principal component analysis is used to denoise the data of Sanya tourist attractions in different seasons. Then, independent component analysis is used to extract the features of the denoised data of Sanya tourist attractions in different seasons.

A. Sanya Tourist Attractions Data Noise Reduction in Different Seasons

Based on the principle of constrained optimization, obtain abnormal data of tourist attractions in Sanya in different seasons and flexibly represent them.

The data of tourist attractions in Sanya for different seasons has n dimensions, and each dimension includes a layer d_{rj}, which also has l_r dimension layers. Set the value at position i of the r dimension j layer in the data of Sanya tourist attractions in different seasons to $y_{i_1,i_{2,\dots,}i_{rj}}$. The process of obtaining the expected value $\hat{y}_{i_1,i_{2,\dots,}i_{rj}}$ of Sanya tourist attraction data in different seasons is as follows:

$$\hat{y}_{i_1,i_{2,\dots,}i_{rj}} = y_{i_1,i_{2,\dots,}i_{rj}}\left(\gamma^{G}_{i_{rj}|d_{rj}} \mid G \subset \left\{d_{rj} \mid 1 \le r \le n, 1 \le j \le l_r\right\}\right) \tag{1}$$

In Formula (1), $\gamma_{i_{rj}|d_{rj}}$ is the expected coefficient of Sanya tourist attraction data in different seasons, and G is the constraint condition in Sanya tourist attraction data in different seasons. The abnormal data $s_{i_1,i_2,\cdots,i_{rj}}$ of tourist attractions in Sanya obtained from different seasons is as follows:

$$s_{i_1,i_2,\cdots,i_{rj}} = \frac{\left|y_{i_1,i_{2,\dots,}i_{rj}} - \hat{y}_{i_1,i_{2,\dots,}i_{rj}}\right|}{\sigma_{i_1,i_2,\cdots,i_{rj}}} \tag{2}$$

In Formula (2), $\sigma_{i_1,i_2,\cdots,i_{rj}}$ is the abnormal data index of Sanya tourist attractions in different seasons.

Based on the above calculation results, the abnormal data of Sanya tourist attractions in different seasons will be removed, and then the principal component analysis method [9-11] will be used to denoise the data in Sanya tourist attractions in different seasons. Principal component analysis (PCA) is a commonly used data denoising method, which transforms the original data into a new coordinate system by linear transformation, so that the largest variance appears on the first coordinate axis, the second largest variance appears on the second coordinate axis, and so on. The final principal components are linear combinations of original data changes, and these principal components are sorted according to their variance.

Construct a three-dimensional coordinate system using the component decomposition method in Sanya tourist attractions of different seasons, and the data vectors in Sanya tourist attractions of different seasons in the coordinates are:

$$Z(x) = \left[Z_1(x), Z_2(x), \cdots Z_p(x)\right]^T = S_p(x) + N_p(x) \tag{3}$$

In Formula (3), $S_p(x), N_p(x)$ represents the p -dimensional signal and noise vector of Sanya tourist attraction data in different seasons.

By using the minimum noise separation transformation method, the data from Sanya tourist attractions in different seasons are linearly transformed, and the process is as follows:

$$Y_i(x) = a_i^T Z(x), i = 1, 2, \cdots, p \tag{4}$$

In Formula (4), a_i^T is the transformation coefficient of data from Sanya tourist attractions in different seasons, and $Y_i(x)$ is the transformed data from Sanya tourist attractions in different seasons. Through the above transformation, it can be seen that each band in $Y_i(x)$ exists independently of each other, and the obtained result is the maximum signal-to-noise ratio SNR_{Y_i} of data from Sanya tourist attractions in different seasons. The acquisition process is as follows:

$$SNR_{Y_i} = \frac{\operatorname{var} Y_i(x)\left\{a_i^T S_p(x)\right\} V}{\operatorname{var} Y_i(x)\left\{a_i^T N_p(x)\right\} B} \tag{5}$$

In Formula (5), V, B is the covariance matrix of signal and noise in the data of Sanya tourist attractions in different seasons. Based on the above results, complete the data denoising processing for Sanya tourist attractions in different seasons.

B. *Feature Extraction of Sanya Tourist Attractions Data in Different Seasons*

Independent component analysis (ICA) is a data analysis method applied in signal processing, neural network and other fields. Its core idea is to assume that the observed multidimensional signal is a linear mixture of multiple independent components, each of which has its own statistical distribution. The purpose of ICA is to decompose the mixed signal into independent components through certain linear transformation, so as to realize signal separation and feature extraction. When ICA is used to extract the data features of Sanya tourist attractions in different seasons, it is generally necessary to preprocess the data first, such as using PCA to denoise the data to eliminate the noise and interference information in the data. Then, ICA algorithm is used to linearly transform the preprocessed data to extract the independent components hidden in the data. Using independent component analysis method, extract the features of Sanya tourist attractions data in different seasons after denoising.

Set $Z(x)$ as the original data vector of Sanya tourist attractions in different seasons, and the data vector of Sanya tourist attractions in different seasons after minimum noise separation transformation is $Y(x)$. Retain the first k term in $Y(x)$ and reset the other $p-k$ terms to zero, in order to obtain the dataset of Sanya tourist attractions in different seasons for the first k term of $Y(x)$ and perform minimum noise separation inverse transformation on it. The process is as follows:

$$\begin{cases} Y^{(k)}(x) = \left[Y_1(x), Y_2(x), \cdots, Y_k(x), 0, \cdots, 0\right]^T \\ Q(x) = \left[1Q(x), 2Q(x), \cdots, pQ(x)\right]^T \\ Q_i(x) = SNR_{Y_i} \sum_{t=1}^{p} a_t Y_t \end{cases} \tag{6}$$

In Formula (6), $Y^{(k)}(x)$ is the dataset of Sanya tourist attractions in different seasons obtained from the first k term of $Y(x)$, $Q(x)$ is the dataset of Sanya tourist attractions in different seasons obtained from the minimum noise separation inverse transformation, a_t is the conversion amount during the transformation, and p is a constant. Based on the above calculation results, construct an orthogonal matrix for the dataset of Sanya tourist attractions in different seasons, and the process is as follows:

$$W = Q_i(x) A = \left[1Q(x), 2Q(x), \cdots, pQ(x)\right]^T \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1p} \\ a_{21} & a_{22} & \cdots & a_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ a_{p1} & a_{p2} & \cdots & a_{pp} \end{bmatrix} \tag{7}$$

In Formula (7), A is a singular matrix with zero eigenvalues. Calculate the matrix based on the third-order center distance to obtain the independent component skewness of Sanya tourist attraction data for different seasons. The process is as follows:

$$\det(W) = \det(0)^{\circ} \det(A) = 0 \tag{8}$$

In Formula (8), $\det(A)$ is the independent component kurtosis of the obtained data of Sanya tourist attractions in different seasons. Sort the data of Sanya tourist attractions in different seasons based on the obtained independent component skewness, in order to obtain the characteristics of Sanya tourist attraction data in different seasons.

III. Measurement of Spatial Accessibility of Tourist Attractions in Sanya

The measurement of spatial accessibility of Sanya tourist attractions is based on the data characteristics of Sanya tourist attractions in different seasons, combined with the spatial information of Sanya tourist attractions and GIS technology, to calculate the spatial accessibility index of Sanya tourist attractions, and evaluate the spatial accessibility of Sanya tourist attractions. These results can provide scientific basis for tourism planners in Sanya, helping them understand the changes in spatial accessibility of tourist attractions in Sanya, and carry out reasonable resource development and Sanya tourism route design.

A. Analysis of Spatial Accessibility of Tourist Attractions in Sanya

Assuming SY_m represents the temporal accessibility of the spatial node m of Sanya tourist attractions, it describes the shortest time average value of the spatial node m of Sanya tourist attractions reaching other nodes. The mean temporal accessibility of all nodes is the temporal accessibility SY of the entire Sanya tourist attraction space, and its calculation formula is as follows:

$$\begin{cases} SY_m^s = \det(W) \sum_{m=1, v \neq 1}^{\omega} SY_{mv}^s / (Y_{mv}^s - 1), m \in [1, \omega] \\ SY^s = \sum_{m=1}^{\omega} SY_m^s / Y_{mv}^s \end{cases} \tag{9}$$

In Formula (9), ω represents the number of nodes in the Sanya region, and SY_m^s represents the time accessibility of node m under travel mode s, SY_{mv}^s represents the time barrier between node m and node v in the Sanya tourist attraction space using travel mode s, and SY^s represents the time accessibility corresponding to travel mode s in the study area.

Construct a set of travel modes S, which includes three types of travel modes: car travel, motorcycle travel, and bicycle travel. Assuming Y_{mv}^s is the travel time generated by travel mode s on the designated road section, it can be calculated using Formula (10):

$$Y_{mv}^s = \frac{r_{mv}}{b_{mv}^s} \tag{10}$$

In Formula (10), r_{mv} is the distance between node m and node v in the space of Sanya tourist attractions, and b_{mv}^s is the speed of the existing section r_{mv} under travel mode s.

Assuming that SV_m represents the economic cost distance corresponding to node m in the Sanya tourist attraction space, it describes the minimum average cost of node m to other nodes in the Sanya tourist attraction space. The average time accessibility corresponding to all nodes is the time accessibility SV corresponding to the Sanya tourist attraction space, and its calculation formula is as follows:

$$\begin{cases} SV_m^s = \det(W) \sum_{m=1, v \neq 1}^{\omega} V_{mv}^s / (Y_{mv}^s - 1) \\ SV^s = \sum_{m=1}^{\omega} SV_m^s / Y_{mv}^s \end{cases} \tag{11}$$

In Formula (11), SV_m^s represents the cost accessibility of node m under travel mode s, V_{mv}^s represents the cost of node m using travel mode s to reach node v in the Sanya tourist attraction space, and SV^s represents the cost accessibility of using travel mode s in the study area.

The generalized travel cost usually includes the following types:

1) Parameter comprehensive cost V_{mv}^z:

$$V_{mv}^z = Y_{mv}^s + VOT \times \beta Y_{mv}^s \left(\frac{Y_{mv}^s}{Y_c} \right)^{\chi} \tag{12}$$

In Formula (12), VOT is the unit time cost, β and χ are adjustment coefficients, and Y_c is the time threshold.

2) Parameter time cost V_{mv}^S:

$$V_{mv}^S = VOTY_{mv}^s + VOTY_{mv}^s \beta \left(\frac{Y_{mv}^s}{Y_c} \right)^{\chi} \tag{13}$$

3) Comprehensive cost V_{mv}^{ZH} :

$$V_{mv}^{ZH} = VOTY_{mv}^s + \mathrm{Sin}_{mv}^s \tag{14}$$

In Formula (14), Sin_{mv}^s is the travel cost incurred from node m using travel method s to node v.

4) Travel cost V_{mv}^{CX} :

$$V_{mv}^{CX} = \frac{VOTr_{mv}}{b_{mv}^s} + r_{mv} \omega_{mv}^s \tag{15}$$

In Formula (15), ω_{mv}^s is the fuel consumption generated by using travel mode s on section r_{mv}.

Using the weighted shortest travel time method, calculate the time of the Sanya tourist attraction space at each node to reflect the spatial accessibility of Sanya tourist attractions. The calculation formula is:

$$\begin{cases} A_x = \sum_{y=1}^{\tau} \lambda_y \delta_{xy} / \sum_{y=1}^{\tau} \lambda_y \\ \lambda_y = \sqrt{p_x e_x} \end{cases} \tag{16}$$

In Formula (16), A_x represents the weighted time for the shortest travel in Sanya's tourist attraction space, and δ_{xy} represents the minimum time that should be consumed for the shortest distance in Sanya's tourist attraction space, λ_y

represents the capacity of Sanya's tourist attraction space and the degree of connection with other cities, p_x represents the number of people in Sanya's tourist attraction space, e_x represents the gross economic product of Sanya's tourist attraction space, y represents the location parameter, and τ represents the spatial range of Sanya's tourist attraction. The smaller the A_x value, the higher the spatial accessibility of tourist attractions in Sanya is.

The comprehensive weighted average travel time is used to measure the accessibility of tourist attractions in Sanya, and the calculation formula is:

$$IA_x = \sum A_{xx_i} r_{x_i} \tag{17}$$

In Formula (17), IA_x represents the spatially weighted shortest average travel time of tourist attractions in Sanya, A_{xx_i} represents the shortest average travel time, and r_{x_i} represents the travel weight.

Based on the above calculation formula and the urban spatial gravity model, the shortest spatial time of tourist attractions in Sanya is calculated using the following formula:

$$I_{mn} = IA_x \mu_m \mu_n / d_{mn}^b \tag{18}$$

In Formula (18), I_{mn} represents the spatial interaction force between tourist attractions in Sanya, d_{mn}^b represents the shortest time corresponding to the shortest spatial distance of tourist attractions in Sanya, μ_m and μ_n represent the spatial scale of tourist attractions in Sanya, and b represents the spatial distance friction index of tourist attractions in Sanya.

Using the potential model, calculate the spatial interaction potential J_x of tourist attractions in Sanya, and the calculation formula is:

$$J_x = \sum_{m=1}^{n} I_{mn} + \mu_m \mu_n / d_{mn}^b \tag{19}$$

Traffic impedance is related to factors such as residents' travel modes and transportation environment, and is a physical factor that measures the difficulty of travel. Combining traffic impedance with the spatial road characteristics of Sanya tourist attractions, taking into account both time and cost impedance factors, this paper introduces them into the spatial accessibility analysis of Sanya tourist attractions, and improves the spatial accessibility analysis of Sanya tourist attractions. The function expression is:

$$\xi_i = \frac{(\theta_1 T_i + \theta_2 F_i)}{w_j} J_x \tag{20}$$

In Formula (20), ξ_i represents the traffic resistance value, θ_1 and θ_2 represent the coefficients to be labeled, T_i represents the time resistance value, F_i represents the cost resistance value, and w_j represents the regional importance.

B. *Construction of Spatial Accessibility Measurement Model for Sanya Tourist Attractions*

Based on the analysis of spatial accessibility of tourist attractions in Sanya, a measurement model for spatial accessibility of tourist attractions in Sanya is constructed. According to the time schedule and various data obtained, there are four main types of models for measuring the spatial accessibility of tourist attractions in Sanya, namely physical accessibility evaluation models, comprehensive index models based on residents' spatial preferences for tourist attractions in Sanya, analysis models based on differences in residents' spatial motivations for choosing tourist attractions in Sanya, and analysis models based on temporal and spatial behavior, use these four models to measure the spatial accessibility of tourist attractions in Sanya.

1) Physical accessibility evaluation model: This type of model is often combined with shortest distance, coverage, gravity method, etc. to describe the spatial distribution of transportation vehicles in Sanya's tourist attractions. The most commonly used indicators for evaluating the supply and demand of transportation vehicles are the distance from residents' residential areas to the location of tourist attractions in Sanya, as well as the spatial scale, capacity, and construction quality of tourist attractions in Sanya.

Based on the two evaluation indicators of shortest distance and scale capacity, the calculation formula is:

$$\begin{cases} D_m = \min\limits_{v} d_{mv} \\ C_m = \dfrac{\xi_i \sum S_v}{P_m} \end{cases} \tag{21}$$

In Formula (21), D_m represents the shortest distance from the starting point to the destination, and C_m represents the spatial capacity of tourist attractions in Sanya, d_{mv} represents the geometric centroid distance, $\min$ represents the minimum function value, S_v represents the total area of spatial facilities construction in Sanya tourist attractions, and P_m represents the total population of the city.

Due to the fact that physical evaluation models are more commonly applied to the same transportation vehicle and have certain limitations, the two evaluation indicators of shortest distance and scale capacity have been modified. The shortest distance from residents' residences to the location of Sanya tourist attractions is D_{mm}, and the effective coverage range of

Sanya tourist attractions is C_{vv}. The physical accessibility evaluation model is:

$$R = D_{mm} C_{vv} \xi_i \sum_{d_{mv} < K} E\rho \tag{22}$$

In Formula (22), K represents the effective coverage area, E represents the accessibility difference index for residents to access the spatial facilities of Sanya tourist attractions, and ρ represents the population density of transportation users.

According to geographic information system (GIS) classification [12-13], differences in residents' age, income, and other factors are statistically analyzed. Combined with the distribution of population living space, the degree to which different residential areas are covered by the spatial facilities of Sanya tourist attractions is compared, and an evaluation of the physical accessibility of Sanya tourist attractions is completed.

2) Comprehensive index model Based on residents' spatial preference for Sanya tourist attractions: For residents, each type of Sanya tourist attraction spatial facility has its unique characteristics, which can meet the specific needs of specific subjects. At the same time, residents have various preferences for Sanya tourist attraction spatial facilities. Due to the fact that the audience level of tourist attractions in Sanya depends on multiple reasons, a comprehensive index model (IEI) is established using two indicators: attractiveness and separation to analyze residents' demand and preference for Sanya tourist attractions. The comprehensive index model takes residents' preference for Sanya tourist attractions as a weight coefficient and uses Likert scale scale to represent the spatial preference of Sanya tourist attractions. The expression of the comprehensive index model for Sanya tourist attractions is:

$$F_{ij(k)} = P_k \times W_{j(k)} \times s_{ij}^{-\alpha} \tag{23}$$

In Formula (23), P_k represents the preference coefficient of different residents for the spatial facilities of different Sanya tourist attractions, $W_{j(k)}$ represents the indicator that attracts residents to choose, s represents the measurement value of the spatial separation degree of Sanya tourist attractions, and α represents the spatial separation coefficient of Sanya tourist attractions.

Based on GIS output classification, a visual map with $F_{ij(k)}$ values is obtained to analyze the spatial distribution of tourist attractions in Sanya.

3) Analysis model Based on spatial motivation differences of residents choosing Sanya tourist attractions: This type of analysis model is based on the gravity model and presents the analysis results through GIS and spatial distribution models. Considering the behavioral ability of residents to choose spatial facilities in Sanya tourist attractions and the differences in simulated space, the selection motivation is divided into β_k and α_k. The calculation formula for the analysis model of spatial motivation differences in Sanya tourist attractions is:

$$G_{ij(r)} = \frac{M_{j(r)} \times D_{j(r)}}{\alpha_k \times \beta_k \times T_{kj}} \tag{24}$$

In Formula (24), T_{kj} represents the spatial value of Sanya tourist attractions, r represents the serial number of Sanya tourist attractions spatial facilities, $M_{j(r)}$ represents the scale of Sanya tourist attractions spatial facilities, and $D_{j(r)}$ represents the service range of Sanya tourist attractions spatial facilities.

4) Analysis model based on temporal and spatial behavior: This model mainly analyzes the actual travel schedules of residents and the spatial travel schedules of Sanya tourist attractions, and combines them with spatiotemporal variables to calculate the comprehensive service deprivation coefficient of Sanya tourist attractions. The model considers the matching degree between residents' personal schedules and the spatial schedules of Sanya tourist attractions. Analyze the accessibility of this model from three perspectives:

a) The calculation formula for measuring the spatiotemporal accessibility of tourist attractions in Sanya is:

$$\begin{cases} U_{AB}(z,t_1,t_2) = \max(z,t_1,t_2,f) \\ U_{T_\varepsilon T_\varepsilon}(z,t_1,t_2) = \min(z,f) U_{AB}(z,t_1,t_2) \end{cases} \tag{25}$$

In Formula (25), t_1 and t_2 represent the comprehensive time period, z represents the location of spatial facilities for tourist attractions in Sanya, and f represents the number of spatial facilities for tourist attractions in Sanya during opening hours, $U_{AB}(z,t_1,t_2)$ represents the accessibility ability of residents to reach f in both time and airspace during the comprehensive time period, while $U_{T_\varepsilon T_\varepsilon}(z,t_1,t_2)$ represents the accessibility ability of residents to reach f in the shortest travel time during the comprehensive time period.

b) The calculation formula for measuring the spatiotemporal needs of spatial facilities in tourist attractions in Sanya is:

$$H_t(z,t_1,t_2) = \int_{t_1}^{t_2} N_t(z) dz / a \tag{26}$$

In Formula (26), $N_t(z)$ represents the individual residents' demand for the space of tourist attractions in Sanya, and a represents the demand cycle.

Combining the space accessibility of Sanya tourist attractions with the space requirements of Sanya tourist attractions, the analysis model based on time and space behavior is:

$$\eta(z,t_1,t_2)=\varpi\times\left[U_{T_\varepsilon T_\varepsilon}(z,t_1,t_2)\times H_t(z,t_1,t_2)\right] \tag{27}$$

In Formula (27), ϖ represents the weights of time and spatial indicators.

By calculating the spatiotemporal accessibility of Sanya tourist attractions and the spatiotemporal needs of facilities in the model, combined with temporal and spatial indicators, the results are output through GIS.

In order to facilitate calculation and analysis by unifying various indicators, the range standardization method is used to obtain the calculation formula as follows:

$$\varpi_j=(\varpi'-\min\varpi')/(\max\varpi'-\min\varpi') \tag{28}$$

In Formula (28), ϖ_j represents the standardized values of time-domain and spatial indicators, ϖ' represents the original values of time-domain and spatial indicators, $\max\varpi'$ represent the maximum function, and $\min\varpi'$ represents the minimum function.

Due to the strong objectivity and high numerical accuracy of the entropy method, it can effectively reduce the weight of indicators and be affected by subjective factors. Therefore, using the entropy method [14-15] to determine the weight of each indicator can better reflect the impact of evaluation indicators on the evaluation results. The calculation formula is:

$$\begin{cases} R_j=\varpi'/\sum_{j=1}^{n}\varpi_j \\ e_j=\sum_{j=1}^{n}(R_j\times\ln R_j) \\ g_j=1-e_j \\ W_j=\sum_{j=1}^{n}g_j \end{cases} \tag{29}$$

In Formula (29), R_j represents the proportion of indicators, e_j represents entropy, g_j represents the coefficient of difference, and W_j represents the weight coefficient.

The comprehensive accessibility measurement results of the four models are:

$$Z=\sum_{j=1}^{n}W_j\left[G_{ij(r)}F_{ij(k)}C_{vv}D_{mm}\eta(z,t_1,t_2)\right] \tag{30}$$

Through the above steps, the spatial accessibility measurement of tourist attractions in Sanya can be achieved.

IV. Experimental Analysis

A. Experimental Environment and Data Sources

As a tourist destination in the tropics, Sanya has many natural landscapes, such as beautiful beaches, magnificent mountains and tropical rainforests. These natural landscapes not only attract many tourists, but also become an important feature of Sanya tourism. In order to verify the validity of the spatial accessibility measurement algorithm of Sanya tourist attractions based on seasonal factor adjustment analysis, the experiment is implemented in MATLAB simulation software environment. Taking Coconut Dream Corridor, Yalong Bay, Haitang Bay, Jiajing Island, wuzhizhou Tourist Scenic Area, Fenjiezhou Island and Nanwan Monkey Island as spatial nodes, the data set of Sanya tourist attractions is divided. Through questionnaires, interviews and other means to collect tourists' evaluation of scenic spots, tourism motivation, consumption behavior and other information. Collect relevant data from government departments, tourism websites, scenic spots management offices and other channels, such as the number of tourists, tourism income, ticket sales, etc. Using big data technology, through analyzing data sources such as online search, social media and travel booking websites, we can get information about tourists' attention and preferences to Sanya tourist attractions.

There may be some noises and missing values in the collected tourism data, which need to be preprocessed, including data cleaning, missing value processing, abnormal value processing and so on. For example, removing duplicate data, correcting erroneous data, filling in missing values, etc. Due to the seasonal factors in Sanya, the popularity and demand of scenic spots may be different in different seasons. Summer is the peak of tourism in Sanya, and many beaches and water sports attractions will become more popular. In winter, some hot springs and tropical botanical gardens may be favored by tourists. Therefore, it is necessary to consider the change of seasonal demand when analyzing the data of Sanya tourist attractions. According to the seasonal characteristics of Sanya tourist attractions, the data can be divided into different seasonal segments. Generally speaking, the tourist season in Sanya is mainly concentrated in winter and summer vacations and holidays, and the data can be divided into seasons according to the date. Based on the data collection, preprocessing and seasonal segmentation of Sanya tourist attractions, the accessibility of Sanya tourist attractions at each node is measured by using the spatial calculation method of Sanya tourist attractions.

B. Analysis of the Measurement Effect of Spatial Accessibility of Tourist Attractions in Sanya

Accessibility can reflect the difficulty of interconnecting one region with other regions. In order to verify the effectiveness of the spatial accessibility measurement method for tourist attractions in Sanya, the accessibility of this study is understood as the average travel time from a tourist attraction in a certain administrative region of Sanya City to tourist attractions in other administrative regions. The average travel time s_τ of tourist attraction τ in Sanya is expressed as:

$$s_{\tau} = \sum_{\xi=1,\zeta=1}^{\psi} g_{\xi\zeta} / \psi \tag{31}$$

In Formula (31), ψ is the number of tourist attractions in Sanya, and $g_{\xi\zeta}$ is the travel time from point ξ in the region to point ζ through the shortest route in the transportation network.

Select Coconut Dream Corridor, Yalong Bay, Haitang Bay, Jiajing Island, wuzhizhou Tourist Scenic Area, Fenjiezhou Island and Nanwan Monkey Island as the evaluation index. The smaller the value, the better the spatial accessibility measurement effect of Sanya tourist attractions. The average travel time of tourist attractions in Sanya is shown in Table I.

TABLE I. AVERAGE TRAVEL TIME OF TOURIST ATTRACTIONS IN SANYA

Sanya Tourist Attractions	S_{τ} /min
Coconut Dream Corridor	151.35
Yalong Bay	120.86
Haitang Bay	101.65
Jiajing Island	125.42
Wuzhizhou Tourist Scenic Area	78.24
Fenjiezhou Island	81.24
Nanwan Monkey Island Ecotourism Area	74.43

According to the data in Table I, the average travel time of seven tourist attractions in Sanya is 74.43min-151.35min. Among them, the Nanwan Monkey Island Ecotourism Area, with the shortest average travel time of seven tourist attractions in Sanya, is about 74.43min, and this tourist attraction in Sanya has the best spatial accessibility. Followed by Wuzhizhou tourist Scenic Area, about 78.24min, the average travel time of Sanya tourist attractions is the Coconut Dream Corridor, about 151.35min, and the spatial accessibility of Sanya tourist attractions is the worst. Therefore, the method in this paper can effectively measure the spatial accessibility of Sanya tourist attractions, and has a good effect on measuring the spatial accessibility of Sanya tourist attractions.

C. Precision Analysis of Spatial Accessibility Measurement for Sanya Tourist Attractions

In the process of calculating the spatial accessibility of tourist attractions in Sanya, the Lorentz curve and fairness coefficient are key indicators for judging fairness. Among them, the fairness coefficient is based on the Lorentz curve, and the fairness coefficient value can be calculated based on the area ratio in the Lorentz curve graph. Therefore, the fairness coefficient is used to calculate the fairness level of spatial accessibility of tourist attractions in Sanya. Randomly select 10 time periods as experimental data samples, calculate the fairness coefficients for 10 time periods, and compare the fairness calculation results of the method of reference [7], the method of reference [8], and this article with the actual results. The comparison results of fairness coefficients between different methods are shown in Fig. 1.

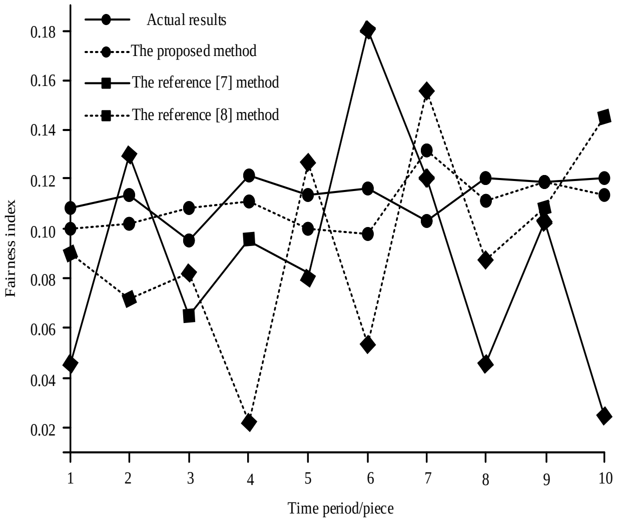

Fig. 1. Comparison results of fairness coefficients of different methods.

According to Fig. 1, the fairness coefficients calculated by different methods in different time periods are different. Comparing the actual results with the methods in this paper, literature [7] and literature [8], we can see that the methods in this paper are in good agreement with the actual results, while the methods in literature [7] and literature [8] are far from the actual results. This shows that the fairness calculation of this method is more accurate and can effectively improve the accuracy of spatial accessibility measurement of Sanya tourist attractions. This is because this method combines the advantages of principal component analysis and independent component analysis, and can consider the characteristics and problems of data more comprehensively. Principal component analysis can reduce the dimension of multivariate to a few principal components and extract the main features of data. Independent component analysis can extract the independent components from the data, further denoising and simplifying the data. By using these two methods comprehensively, the characteristics and problems of data can be considered more comprehensively, thus improving the accuracy of spatial accessibility measurement of tourist attractions.

D. Time Analysis of Spatial Accessibility Measurement for Tourist Attractions in Sanya

On this basis, further validate the spatial accessibility measurement time of Sanya tourist attractions using the method proposed in this paper. Compare the method of reference [7] and the method of reference [8] with the method proposed in this paper, and obtain the spatial accessibility measurement time of Sanya tourist attractions using different methods, as shown in Fig. 2.

According to Fig. 2, with the increase of the number of time periods, the time for measuring the spatial accessibility of Sanya tourist attractions by different methods increases. When the time period reaches 10, the measurement time of the method in reference [7] is 14.7ms, that of the method in reference [8] is 17.6ms, and that of this method is 4.8 ms. Therefore, it takes a short time to measure the spatial accessibility of Sanya tourist attractions by this method. This is because, this method constructs physical accessibility evaluation model, comprehensive index model based on residents' spatial preference for Sanya tourist attractions, analysis model based on residents' spatial motivation differences in choosing Sanya tourist attractions, and analysis model based on time domain and spatial behavior. The physical accessibility evaluation model can transform complex spatial relations into simple distance and time calculations; The comprehensive index model based on residents' spatial preference for Sanya tourist attractions and the analysis model based on residents' spatial motivation differences in choosing Sanya tourist attractions can measure tourists' preferences and choices from different angles, thus avoiding complex spatial optimization algorithms. These models comprehensively consider the influencing factors of the spatial accessibility of Sanya tourist attractions from different angles, including physical accessibility, tourists' preferences, tourists' choices and spatio-temporal behaviors, so as to reduce repeated calculation and invalid calculation, thus saving calculation time.

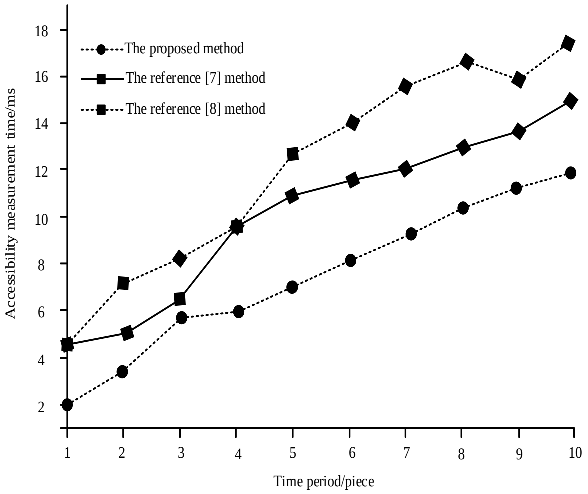

Fig. 2. Measurement time of spatial accessibility of tourist attractions in Sanya using different methods.

V. Discussion

According to the experimental results, the spatial accessibility of Nanwan Monkey Island Ecotourism Area is the best, while the spatial accessibility of Coconut Dream Corridor is the worst. This shows that when planning tourist routes or promoting tourist attractions in Sanya, priority should be given to those scenic spots with good spatial accessibility, such as Nanwan Monkey Island Ecotourism Area and Wuzhizhou Tourist Scenic Area. For scenic spots with poor spatial accessibility, such as Coconut Dream Corridor, more resources need to be put into improvement, such as adding traffic lines and improving the service level of public transportation. The spatial accessibility measurement algorithm of Sanya tourist attractions based on seasonal factor adjustment analysis proposed in this paper has high accuracy and reliability. Therefore, in practical application, this method should be given priority to improve the accuracy and efficiency of spatial accessibility measurement of Sanya tourist attractions. With the increase of the number of time periods, the time for measuring the spatial accessibility of Sanya tourist attractions with different methods increases. This shows that in real-time monitoring or high frequency measurement, we need to pay more attention to computational efficiency and resource consumption. Therefore, in practical application, the appropriate number of time periods should be selected according to the specific situation to balance the calculation efficiency and measurement accuracy.

VI. Conclusion

In this paper, the spatial accessibility measurement algorithm of Sanya tourist attractions based on seasonal factor adjustment analysis is proposed. Through the study of the spatial accessibility of Sanya tourist attractions, this paper puts forward the method of seasonal factor adjustment analysis. By extracting the data characteristics of Sanya tourist attractions in different seasons, combining with the spatial information of Sanya tourist attractions and GIS technology, this paper analyzes the spatial accessibility of Sanya tourist attractions, constructs the spatial accessibility measurement model of Sanya tourist attractions, and realizes the spatial accessibility measurement of Sanya tourist attractions. This method has a good effect of measuring the spatial accessibility of Sanya tourist attractions, which can effectively eliminate the influence of seasonal factors, improve the accuracy of accessibility measurement and shorten the time of accessibility measurement, so as to measure the spatial accessibility of tourist attractions more objectively and accurately. This not only provides a scientific basis for the development of tourism in Sanya, but also helps to improve the tourist experience.

However, there are still some limitations in this study. For example, there may be some deviation when collecting data, and the seasonal influencing factors of some scenic spots may be complicated. Therefore, future research can further expand the data sources and enhance the accuracy of data, and at the same time, deeply study the seasonal influencing factors of different scenic spots, so as to adjust the analysis methods more finely. In addition, we will explore more efficient and accurate measurement algorithms by combining research results in other fields, such as artificial intelligence and machine learning. At the same time, we can further expand the research scope and combine the development of Sanya tourism with environmental protection, cultural inheritance and other related fields to promote the sustainable development of Sanya tourism. Through continuous in-depth study and improvement of seasonal factor adjustment and analysis methods, we hope to provide more valuable scientific basis and decision support for the prosperity and development of Sanya tourism.

Acknowledgment

This research was supported by 2021 Hainan Provincial Social Science Fund Project "Research on the Growth of Hainan Rural Tourism Micro-enterprises from the Perspective of Kinship" (Grant number HNSK（YB）21—13).

***Abstract*—This study conducts a bibliometric analysis of monkeypox research to uncover trends, influential publishers, and key research topics. A dataset of Google Scholar-indexed articles was analyzed using bibliometric methods and tools such as Publish or Perish (PoP), VOSviewer, and Bibliometrix. The study reveals a growing research interest in monkeypox, with a notable increase in publications over the past decade. The Wiley Online Library emerged as the leading publisher, while highly cited articles covered various aspects of the disease. Cluster analysis identified key research topics, including clinical features, zoonotic transmission, and outbreak patterns. Network visualization and bigram analysis showcased relationships between authors, keywords, and publishers, with "monkeypox" being the most frequent keyword. By visualizing topic trends over time, the study identified emerging areas of investigation. The findings contribute to a comprehensive understanding of monkeypox research, aiding in identifying research gaps and guiding future studies. This research highlights the relevance of bibliometric analysis in health and information sciences. By uncovering trends, influential publishers, and key topics in monkeypox research, this study informs prevention, vaccination, and treatment strategies for mitigating the impact of monkeypox on public health.**

***Keywords*—Bibliometrics; monkeypox virus; research trends; publication patterns; research impact**

I. INTRODUCTION

Health problems have become a concern lately, still not recovering from COVID-19, which has haunted humans since 2019 [1]. Now in 2022, the outbreak of the monkeypox virus is a scourge that is quite scary for humans. Monkeypox is a disease of animals that mutate to be able to transmit to humans. Monkeypox is caused by the MPXV virus, which is a member of the genus Orthopoxvirus and the family Poxviridae. This case initially spread from the Democratic Republic of Congo to several parts of the world, such as America, Asia, and Europe. Even the death rate caused by the MPXV virus for unvaccinated cases reaches 10% [2].

With the spread of this virus variant in various parts of the world, more research on this monkeypox virus is to find solutions for prevention [3], vaccination [4], and treatment [5]. The health impact is devastating in terms of health and the economy [6]. Preventive measures are needed to solve this problem. Research needs a method to find things that are being studied a lot and map the topic and author to the geographical location of the researcher. Looking for trending topics by geography, time, etc., is essential.

From the literature search, there are still not many studies regarding the bibliometric analysis of monkeypox cases. This research is significant due to the scarcity of studies focusing on the bibliometric analysis of monkeypox cases. The lack of research in this area highlights the importance of conducting this study to reveal trends and insights related to monkeypox over the years.

Despite the urgency of this matter, there exists a scarcity of studies specifically focusing on bibliometric analysis of monkeypox cases. This research aims to fill this critical gap by employing advanced methodologies, including word cluster analysis, network visualization, overlays, and density using VOSviewer software. Additionally, bigram analysis is utilized to examine the relationships between authors, words, and publishers through Bibliometrix. These information science methods, particularly in bibliometrics, play a pivotal role in analyzing patterns, trends, and relationships within scientific literature. The objective of this study is to comprehensively map the scientific landscape, identify research gaps, and provide a profound understanding of the monkeypox domain through the application of these methodologies to monkeypox research.

II. LITERATURE REVIEW

Bibliometric analysis is a scientific method that integrates mathematical and statistical approaches to analyze and visualize data to determine the structure of topics periodically, develop models, and seek research priorities in a particular field [7]. Bibliometrics research is widely used in the health sector, but according to this paper observation, there have not been many studies involving monkeypox bibliometrics analysis. Publish or Perish (PoP) is software that makes it easy to mine database data from various sources, such as databases indexed by Scopus, Web of Science, Crossref, PubMed, Google Scholar (GS), and others [8]–[10]. In this study mine from the GS-indexed database. GS is a service that makes it easy to collect scientific publications indexed by GS. GS also provides a database that can be used for scientific purposes. Unlike similar services such as Scopus, Web of Science, Pubmed, and others, which require a subscription to access their databases, GS can be used complementary to mine databases indexed by GS [11].

Many publications use this software [12]–[14]. Arias-Chávez et al. [15] using PoP to mine publication data relating to global scientific production on social networks during the Covid-19 pandemic. Postigo-Zumarán et al. [16] used PoP to search for publications on world scientific production on education and COVID-19 between January 2020 to September 2021. Data from the research of both publications came from five databases, namely Scopus, WoS, GS, Microsoft Academic, and Crossref.

VOSviewer can process data in RIS, JSON, and TXT files. Researchers have widely used VOSviewer to visualize literature data, as has been done by Huang, Z. et al. [17], Kirkendall and Krustrup [18], Pagan-Castaño et al. [19] ,and Papatsounis et al. [20]. Bamel et al. [21] examines leading publication trends over a two-decade period (2000-2020), researching the extent and impact of intellectual capital research in the Journal of Intellectual Capital (JIC). Huang, X. et al. [22] investigates related research advances in pharmaceutical science and pharmaceutical education from a bibliometric point of view and aims to provide advice in facilitating the development of pharmaceutical science and pharmacy graduate education [23].

Bibliometrix is open-source software for comprehensive scientific mapping analysis of scientific literature. Mayara et al. [24] build the map the research literature on Biochemistry education, indexed on the Web of Science covering the scientific production, build upon a recent method to simplify some of the key steps of merging datasets when using the R package Bibliometrix to perform bibliometric analyses. Andrea [25] built a new method to simplify some of the key steps of combining data sets when using the Bibliometrics R package to perform bibliometric analysis.

The significance of this research extends beyond the realm of health sciences and biomedical research. It also highlights the relevance of information sciences in investigating and visualizing trends and patterns in health-related research. By leveraging bibliometric analysis, this study demonstrates the applicability of information science methods in analyzing and synthesizing large volumes of scientific literature. This research provides valuable insights into the field of monkeypox, enabling researchers to gain a deeper understanding of the topic and identify areas that require further investigation.

Furthermore, by employing bibliometric analysis, this study contributes to the broader field of information sciences by showcasing the power of these methodologies in uncovering hidden patterns, revealing research trends, and facilitating evidence-based decision-making. Overall, this research is a significant step in bridging the gap between health sciences, biomedical research, and information sciences, highlighting the interdisciplinary nature of scientific inquiry and its potential for meaningful contributions to public health and knowledge management.

III. Methodology

A. Data Collections and Processing

This study relies on a meticulous and systematic approach to collecting and processing article data indexed by Google Scholar (GS). Unlike subscription-based databases like Scopus or Web of Science, GS provides open access to its data, eliminating the need for researchers to subscribe. This open-source nature enhances accessibility and inclusivity in obtaining data for research purposes.

To ensure the reliability and comprehensiveness of the study, we leverage the PoP (Publish or Perish) feature of Google Scholar. PoP is an open-source application that facilitates the collection of journal data not only from GS but also from various reputable sources such as Scopus, Web of Science, PubMed, Crossref, and Semantic Scholar. The data collected is systematically stored in *.ris format, a widely accepted format for bibliographic citation data, enabling seamless processing in subsequent stages of bibliometric analysis.

For data visualization and in-depth analysis, we employ two powerful tools: VOSviewer and Bibliometrix. VOSviewer is instrumental in creating visual maps based on various parameters such as words, authors, and publishers. This visualization is crucial for identifying emerging research topics, discerning gaps in the literature, and determining the novelty of a study [26]–[29].

Bibliometrix, designed as open-source software integrated with the R programming language, plays a pivotal role in conducting comprehensive scientific mapping analysis. It allows the import of data from various databases, including Scopus, Web of Science, PubMed, Crossref, and others [30]–[32].

B. Bibliometrics Analysis

Impact of specific articles: To discern the primary contributors in the field, this paper meticulously compiled data on monkeypox-related articles using the Publish or Perish software, which facilitates a nuanced examination of academic publications.

This research focuses on uncovering trends, influential publishers, and key research topics within the field of monkeypox. Cluster analysis was conducted to identify common themes and interconnections among research studies [33]. Network visualization techniques were employed to visualize relationships between authors, keywords, and publishers [34]. The collected data were analyzed and interpreted to reveal patterns, emerging topics, and prominent contributors within the monkeypox research domain. Insights were drawn from the network visualization, cluster analysis, and keyword co-occurrence analysis to understand the research landscape comprehensively.

IV. Results

A. Annual Publications

From the results of the collection using PoP, 752 articles were collected in that period. The data is saved in *.ris format and extracted with VOSviewer and Bibliometrix. Bibliometric analysis using VOSviewer visualizes a network of frequently occurring topics with an occurrence value of 20 from the title and abstract of the article. From the processing results, it can be from the results of collecting data all the time using PoP from GS, 313 articles entitled monkeypox were obtained. Fig. 1 shows the number of publications from year to year. It can be seen that in the last ten years, the number of publications that have a topic entitled monkeypox has increased. In 2022 the number of publications increased sharply to 144 from only six articles in 2021. The reappearance of monkeypox caused an increase in publication at this time. The highest number of publications on monkeypox topics in 2022 was in 2017, with 12 publications. In 2010 and 2015, there were 11 publications using monkeypox titles.

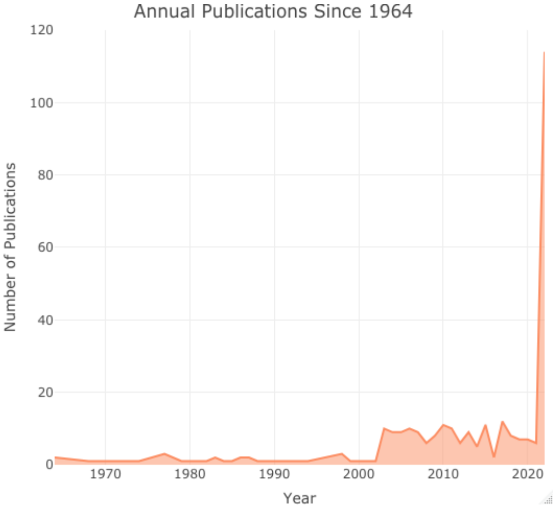

Fig. 1. Distribution of the publications per year.

B. Publications' Patterns

Table I illustrates the leading publishers contributing to the field of monkeypox research, highlighting the number of articles they have published on this specific topic. At the forefront, Wiley Online Library takes the lead with an impressive 26 articles, closely followed by Academic Oxford with 25 articles. The American Society for Microbiology secures the third position, having published 24 articles. Notable contributions are also observed from the National Center for Biotechnology Information (22 articles) and The American Journal of Tropical Medicine and Hygiene (20 articles). Elsevier, a well-established publisher, has contributed significantly with 19 articles, while The BMJ, Europe PMC, and The International Journal of Infectious Diseases have also made substantial contributions with 16, 15, and 10 articles, respectively. PubMed NCBI, a widely used database, also features in the top 10 publishers with 10 articles. Collectively, this comprehensive overview sheds light on the pivotal role these publishers play in disseminating valuable insights and knowledge within the realm of monkeypox research.

Table II enumerates the top 10 articles with the title "Monkeypox," presenting essential details such as citation counts, authors, and publication years. Topping the list is "The detection of monkeypox in humans in the Western Hemisphere" by Reed K.D. et al. (2004), acknowledged with a remarkable 655 citations. Following closely is Likos A.M. et al.'s (2005) "A tale of two clades: monkeypox viruses," recognized with 296 citations, emphasizing the diversity within monkeypox viruses. The third position is secured by Hooper J.W. et al.'s (2004) "Smallpox DNA vaccine protects nonhuman primates against lethal monkeypox," renowned for its findings on the protective potential of a smallpox DNA vaccine with 240 citations. "Poxvirus dilemmas—monkeypox, smallpox, and biologic terrorism" by Breman J.G. et al. (1998) claims the fourth spot with 223 citations, delving into the complexities of poxviruses and their implications in biologic terrorism. Lastly, "Human monkeypox: clinical features of 282 patients" authored by Ježek Z. et al. (1987) completes the top five, boasting 175 citations for its insights into the clinical features of human monkeypox patients. Collectively, these top-cited articles constitute pivotal contributions to the understanding of monkeypox, showcasing their enduring impact on scholarly discourse and research endeavors.

TABLE I. THE TOP 10 PUBLISHERS WHO PUBLISHED ARTICLES WITH THE TOPIC MONKEYPOX

Sources	Publisher	Articles
1	Wiley Online Library	26
2	Academic Oxford	25
3	American Society for Microbiology	24
4	National Center for Biotechnology Information	22
5	The American Journal of Tropical Medicine and Hygiene	20
6	Elsevier	19
7	The BMJ	16
8	Europe PMC	15
9	The International Journal of Infectious Diseases	10
10	PubMed NCBI	10

TABLE II. THE TOP 10 ARTICLES WITH THE TITLE MONKEYPOX

Num.	Title	Citated	Author	Year
1	The detection of monkeypox in humans in the Western Hemisphere	655	Reed K.D. et al. [35]	2004
2	A tale of two clades: monkeypox viruses	296	Likos A.M. et al. [36]	2005
3	Smallpox DNA vaccine protects nonhuman primates against lethal monkeypox	240	Hooper J.W. et al. [37]	2004
4	Poxvirus dilemmas—monkeypox, smallpox, and biologic terrorism	223	Breman J.G. et al. [38]	1998
5	Human monkeypox: clinical features of 282 patients	175	Ježek Z. et al. [39]	1987

C. Topics Cluster

Table III provides a comprehensive overview of topics clusters in the context of monkeypox research. The clustering of topics in the analysis reveals seven distinct thematic clusters prevalent in the literature on monkeypox. In Cluster 1, the focus is on the analysis of human monkeypox cases and outbreaks. The cluster encompasses discussions on clinical features, detection, diagnosis, and patient-related aspects. Geographical references to regions like Congo, Democratic Republic, the United States, and the Western Hemisphere are also prominent, emphasizing the global nature of the disease.

TABLE III. CLUSTERS OF TOPICS IN MONKEYPOX RESEARCH

Cluster	Topics
1	Case, clinical feature, congo, democratic republic, detection, diagnosis, drc, human monkeypox, human monkeypox case, human monkeypox infection, June, may, monkeypox, monkeypox case, outbreak, patient, patient, person, republic, United States, western hemisphere, year, Zaire.
2	Cynomolgus macaque, disease, evaluation, family poxciridae, genus orthopoxvirus, human, infection, macaque, monkeypox virus, monkeypox virus challenge, monkeypox virus infection, mpxv, nonhuman primate, protection, smallpox, smallpox vaccine, treatment, western Africa, zoonotic disease.
3	Comparison, cowpox, differentiation, evidence, mpv, orthopoxvirus, vaccinia, vaccinia virus, varicella zoster virus, variola, variola virus, varv, virus.
4	Animal, central Africa, concern, covid, emergence, first human case, monkeypox disease, Nigeria, spread, west Africa, world.
5	abstract, country, europe pmc, laboratory, lesson, monkeypox outbreak, study, symptom
6	Journal, man, monkeypox infection, mpx, transmission,
7	Africa, Europe, recent outbreak.

Cluster 2 centers around the impact of monkeypox virus on nonhuman primates. Topics within this cluster include disease evaluation, infection in macaques, discussions on smallpox vaccine, and the broader context of zoonotic disease. This cluster delves into the complex interplay between the virus and nonhuman primates, providing valuable insights into potential transmission dynamics. The third cluster involves a comparative analysis of orthopoxviruses, drawing parallels between monkeypox and related viruses such as vaccinia, variola, and cowpox. Discussions within this cluster focus on differentiation, evidence, and the distinct characteristics of these viruses. This comparative perspective contributes to a nuanced understanding of the broader orthopoxvirus family.

In Cluster 4, the analysis shifts towards the ecological impact of monkeypox, specifically in animals. Central Africa and Nigeria are focal points, addressing concerns related to the emergence of monkeypox, its potential connection to COVID, and its spread in West Africa and globally. This cluster underscores the broader implications of the disease within the animal population. The fifth cluster is centered on the study of monkeypox outbreaks and the lessons derived from them. Topics within this cluster include the abstracts of studies, lessons learned, symptoms, and country-specific analyses. This cluster provides valuable insights into the dynamics of monkeypox outbreaks and serves as a resource for understanding and managing future occurrences.

Cluster 6 focuses on journal publications related to monkeypox, highlighting aspects such as infection in humans (man), transmission dynamics, and the role of journals in disseminating information. This cluster sheds light on the dissemination of knowledge within the academic community and the dynamics of information exchange. Lastly, Cluster 7 explores the perspectives on monkeypox in Africa and Europe. This geographical focus includes discussions on recent outbreaks, providing insights into how monkeypox is perceived and managed in these regions. The cluster captures the regional nuances and highlights the importance of considering diverse perspectives in understanding and addressing monkeypox.

D. Relationship Analysis

In Fig. 2 present a detailed analysis of the intricate relationship between authors, abstract content, and publishers using Bibliometrix. The network visualization reveals a rich tapestry consisting of 19 authors, 20 frequently occurring words in the abstracts, and 20 prominent publishers.

Among the 20 words recurrently found in the abstracts, "monkeypox" emerges as the most prevalent, appearing a remarkable 444 times. Other frequently occurring terms include "virus" (22 times), "human" (78 times), "infection" (45 times), "outbreak" (45 times), "disease" (37 times), "smallpox" (29 times), "mpxv" (27 times), "Africa" (25 times), "mpx" (24 times), "variola" (19 times), "zoonotic" (19 times), and "orthopoxvirus" (17 times).

The prevalence of "monkeypox" in abstracts is further underscored by 19 authors consistently incorporating this term in their contributions. Notably, Ii Zuka stands out, utilizing 13 of the identified frequently occurring words a total of 29 times. Following closely are M Saijo, who employs 10 words 25 times, and Ci Hutson, who incorporates 9 words 21 times.

In the realm of publishers, ASM emerges as a leading contributor, publishing articles that prominently feature the identified frequently used words a substantial 151 times. WOL (Wiley Online Library) follows closely with 142 instances, Academic Oxford with 124 instances, NCBI (National Center for Biotechnology Information) with 112 instances, and Elsevier with 89 instances. These findings highlight the pivotal role of these publishers in disseminating research that revolves around the recurrent themes identified in the abstracts, providing key insights into the landscape of monkeypox literature.

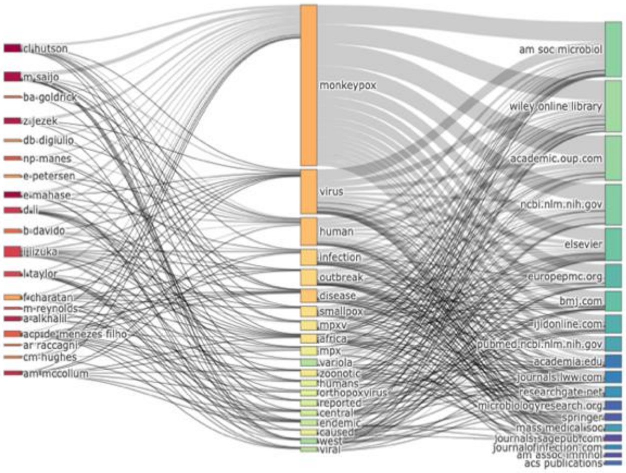

Fig. 2. Sankey diagram relationship between author, abstract, and publisher.

E. Bigram Analysis

To conduct a comprehensive analysis of co-occurring terms within the abstracts of 313 identified articles, this paper employed bigram analysis. Fig. 3 illustrates the noteworthy findings from this analysis. Notably, the phrase "monkeypox virus" emerges as the most frequently occurring bigram, appearing a substantial 117 times, constituting 22% of the total occurrences. Following closely is "human monkeypox," observed in 71 instances, comprising 13% of all identified bigrams.

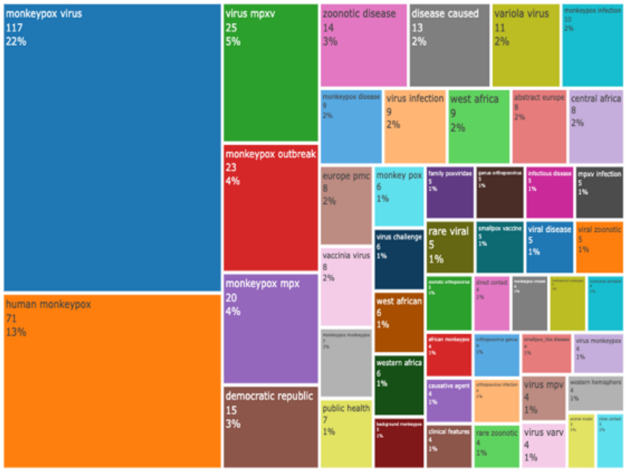

Fig. 3. The most frequent bigrams.

The subsequent five most prevalent bigrams include "virus mpxv" (25 occurrences, 5%), "monkeypox outbreak" (23 occurrences, 4%), "monkeypox mpx" (20 occurrences, 4%), "democratic republic" (15 occurrences, 3%), and "zoonotic disease" (14 occurrences, 3%). This insightful analysis sheds light on the prominent word associations within the abstracts, offering valuable insights into prevalent themes and connections in the realm of monkeypox research.

F. Mapping of Monkeypox Topics

Fig. 4 shows the network of keywords. The red color indicates the topics in cluster 1, the green color represents the members in cluster 2, the blue color represents the terms in cluster 3, and the yellow color represents the topics in cluster 4, the purple color represents the members in cluster 5, the light blue color represents the members in cluster 6, the orange color represents the members in cluster 7. The topic "monkeypox" is the topic that most often appears in cluster 1 with a total number of link strength (TLS) of 874 and occurrence of 214. In cluster 2, "monkeypox virus" became the center of the cluster with a TLS value of 469 and occurrences of 96. The topic "virus" became the center of cluster 3 with a TLS value of 112 and the number of occurrences 24. The topic "animal" is the center of cluster 4 with the number of TLS 65 and the number of occurrences 11. The topic "monkeypox outbreak" is the center of cluster 5 with the number of TLS 106 and the number of occurrences 29. The topic "mpx" is the center of cluster 6 with the number of TLS 136 and the number of occurrences 20. The topic "africa" is the center of cluster 7 with the number of TLS 80 and the number of occurrences 17.

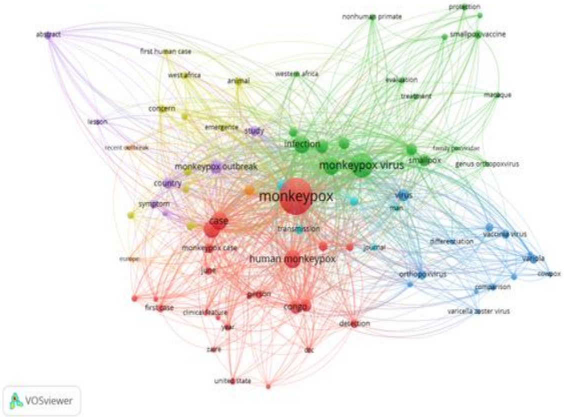

Fig. 4. Network visualization of monkeypox topics.

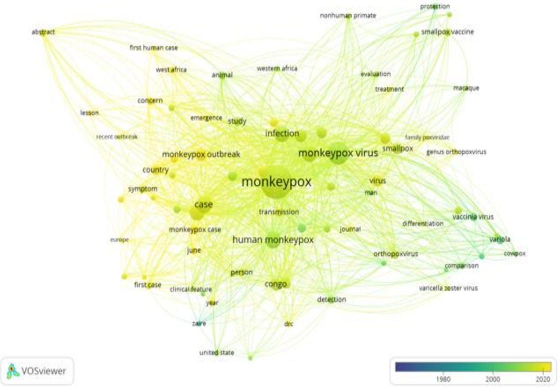

Fig. 5. Overlay visualization of monkeypox topics.

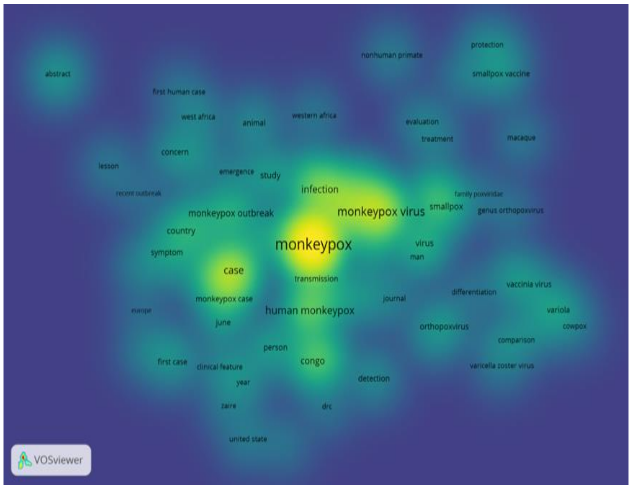

Fig. 6. Density visualization of monkeypox topics.

Fig. 5 maps the trend of the topic network regarding the "monkeypox virus" from 1964 to 2022. Publications using the title "monkeypox" are mapped from 1964 to 2022. The yellow topics are the most recently discussed with the keyword "monkeypox ". Fig. 6 is a density visualization, and this image shows that the lighter the yellow color and the larger the circle size, the stronger the link with the keyword. So the topic "monkeypox virus", "monkeypox virus", "case", “infection”, and “congo” is a general topics with the keywords "monkeypox virus". Meanwhile, if the color fades and shrinks mixed with green, this is not a common topic to discuss. So the topics "europe," "family poxciridae ", and " recent outbreak" become topics that are not very strongly related to topics.

V. Discussions

The results of bibliometric analysis align with existing literature and contribute valuable insights into the publication patterns and trends in monkeypox research. The upward trajectory in annual publications, particularly the significant surge in 2022, corroborates with the findings of Bunge et al., who noted the changing epidemiology of human monkeypox as a potential threat [2]. The correlation between the rise in publications and the resurgence of monkeypox cases emphasizes the dynamic nature of this emerging public health issue, echoing discussions on the evolving landscape of infectious diseases such as COVID-19 [1].

Examining publishers in the field, this study identifies Wiley Online Library (WOL), Academic Oxford, and the American Society for Microbiology (ASM) as key contributors, aligning with the diverse range of publishers identified in various bibliometric analyses [7]. This information provides researchers with valuable insights into where to find relevant studies on monkeypox, similar to the considerations made by researchers in exploring information science publications [8].

The identification of highly cited articles in this study, such as "The Detection of Monkeypox in Humans in the Western Hemisphere" [35], reinforces the importance of foundational research in shaping the discourse within the field, as highlighted by the significance of top-cited articles in various scientific domains [7]. These influential papers serve as crucial references and contribute to the collective knowledge base on monkeypox.

The exploration of topic clusters aligns with the systematic review conducted by Bunge et al., which underscores the importance of understanding various aspects of monkeypox, including clinical features and zoonotic transmission [2]. These findings further emphasize the interconnectedness between different research topics within the field, similar to the identification of trends, patterns, and collaborations in nursing career research through bibliometric analysis [7].

The network visualization and bigram analysis align with the broader literature on bibliometric analyses, showcasing the significance of specific keywords such as "monkeypox" and the role of authors and publishers in contributing to the body of knowledge [11]. Similar network analyses have been conducted in various fields, from nursing career research to the exploration of pharmaceutical science and education [7], [22].

Finally, the visualization of topic trends over time contributes to the understanding of the evolving research interests related to the monkeypox virus. This mirrors the approach taken in other bibliometric analyses, where visualizing trends aids in identifying emerging areas of investigation [19], [29].

VI. Conclusions

In conclusion, this research on the bibliometric analysis of monkeypox provides valuable insights into the trends and patterns of research in the field. The study reveals a significant increase in the number of publications on monkeypox over the last decade, indicating a growing research interest in the disease. The Wiley Online Library, Academic Oxford, and the American Society for Microbiology are identified as the top publishers in this area. The most cited articles on monkeypox cover various aspects of the disease, including detection, virus characterization, vaccination, and clinical features. These highly cited articles serve as foundational research in the field.

The analysis of topic clusters highlights the main themes and areas of focus in monkeypox research, such as clinical features, zoonotic transmission, animal hosts, and outbreak patterns. This information helps researchers identify research gaps and explore interconnected topics within the field. The network visualization and bigram analysis provide insights into the relationships between authors, abstract keywords, and publishers. The word "monkeypox" emerges as the most frequently occurring keyword, emphasizing its central importance in the field. Furthermore, the visualization of topic trends over time demonstrates the evolving research interests related to monkeypox, allowing researchers to identify emerging areas of investigation. Overall, this bibliometric analysis serves as a foundation for future research in monkeypox and provides researchers with valuable information for guiding their studies, identifying research gaps, and contributing to the understanding and managing of the disease.

Healthcare Intrusion Detection using Hybrid Correlation-based Feature Selection-Bat Optimization Algorithm with Convolutional Neural Network

A Hybrid Correlation-based Feature Selection for Intrusion Detection Systems

***Abstract*—Cloud computing is popular among users in various areas such as healthcare, banking, and education due to its low-cost services alongside increased reliability and efficiency. But, security is a significant problem in cloud-based systems due to the cloud services being accessed via the Internet by a variety of users. Therefore, the patient's health information needs to be kept confidential, secure, and accurate. Moreover, any change in actual patient data potentially results in errors during the diagnosis and treatment. In this research, the hybrid Correlation-based Feature Selection-Bat Optimization Algorithm (HCFS-BOA) based on the Convolutional Neural Network (CNN) model is proposed for intrusion detection to secure the entire network in the healthcare system. Initially, the data is obtained from the CIC-IDS2017, NSL-KDD datasets, after which min-max normalization is performed to normalize the acquired data. HCFS-BOA is employed in feature selection to examine the appropriate features that not only have significant correlations with the target variable, but also contribute to the optimal performance of intrusion detection in the healthcare system. Finally, CNN classification is performed to identify and classify intrusion detection accurately and effectively in the healthcare system. The existing methods namely, SafetyMed, Hybrid Intrusion Detection System (HIDS), and Blockchain-orchestrated Deep learning method for Secure Data Transmission in IoT-enabled healthcare systems (BDSDT) are employed to evaluate the efficacy of HCFS-BOA-based CNN. The proposed HCFS-BOA-based CNN achieves a better accuracy of 99.45% when compared with the existing methods: SafetyMed, HIDS, and BDSDT.**

***Keywords*—Convolutional neural network; deep learning; intrusion detection system; healthcare; security**

I. INTRODUCTION

Network Intrusion Detection Systems (NIDSs) identify malicious activities and safeguard the vulnerable services by monitoring network traffic and providing alerts when anomalous events are recognized. Some organizations that are primarily focused on obtaining private user data, establishing the foundation for modern-day detection and protection are attacked by cyber-attackers. Furthermore, the healthcare sector keeps growing, and most hospitals are integrating e-healthcare systems as quickly as feasible to fulfill the needs of their patients. IDS based on cloud networks employ anomaly-based techniques to protect the cloud-based applications [1]. In network security, there are two common detection techniques for NIDS, anomaly-based detection, and signature-based detection [2]. An anomaly-based IDS analyzes the network traffic and correlates it to a created baseline for unknown or known attacks, where a signature-based IDS is allowed to be employed while the attack patterns are established and pre-determined [3, 4]. To address numerous security issues, the cloud utilizes numerous cybersecurity techniques like IDS, Intrusion Prevention Systems (IPS), and firewalls [5]. The centralized processing technique used by cloud computing involves uploading every transaction and processing the end-user service requests based on the transmission bandwidth, capacity of storage, and computer resources [6]. Proactive network security defenses are required to protect essential assets and data because the cloud attack vector has the potential to result in successful security breaches [7].

Network security has always placed a high priority on intrusion detection since it is crucial for identifying anomalous activity on secured internal networks [8]. The network of intermediate, source, and endpoint are used to identify the Distributed Denial-of-Services (DDoS) attacks. The attack's endpoint is easily detected because of the massive volume of network traffic that is generated [9]. A significant number of traditional intrusion detection systems use either a port-based or Deep Packet Inspection (DPI) technique. The port-based technique identifies traffic by using the ports established by the Internet Assigned Numbers Authority (IANA) [10]. Software Defined Network (SDN) is an emerging design that is cost-effective, flexible, adaptable, and controlled, thereby making it more suitable for presently employed complicated applications and bandwidth [11, 12]. SDN's goal is to create a logically centralized hub for internet and networking architects so that they quickly respond to the evolving client demands [13]. Deep learning techniques, especially CNN represent remarkable capacity in automatically extracting features and intricate patterns from complex data, including network traffic [14]. By employing Deep CNN, the IDS efficiently recognizes anomalous behavior and emerging threats in real time [15]. Since cloud services are accessed via the internet by a variety of users, security is a significant concern in cloud-based systems because the health information of patients must be kept confidential, secure, and accurate. Moreover, any change in actual patient data results in errors during the diagnosis and treatment [31-34]. Therefore, the HCFS-BOA based on CNN is proposed in this research, for intrusion detection to secure the entire network in the healthcare system. The main contributions of this research are as follows:

- The proposed HCFS-BOA approach is evaluated on the CIC-IDS2017, NSL-KDD benchmark datasets, and the Min-max normalization technique is employed to normalize the raw data.
- For feature selection, HCFS-BOA is employed to examine the appropriate features that not only have significant correlations with the target variable, but also contribute to the optimal performance of intrusion detection in the healthcare system.
- Finally, CNN is employed for classification to identify and classify intrusion detection accurately and effectively. The efficacy of HCFS-BOA is analyzed based on the performance measures of accuracy, precision, recall, and f1-score.

The rest of the paper is organized as follows: Section II presents the literature survey. The block diagram of the proposed method is discussed in Section III. The results are illustrated in Section IV, while Section V discusses the conclusion of this paper.

II. Literature Survey

Faruqui et al. [16] presented a SafetyMed for Internet of Medical Things (IoMT) IDS by employing hybrid CNN-Long Short-Term Memory (CNN-LSTM). The SafetyMed was the first IDS that included an optimization approach based on the trade-off between Detection Rate (DR) and False Positive Rate (FPR). The SafetyMed enhanced the safety and security of medical devices and patient information. However, the presented SafetyMed method had no defense mechanism against an attack of Adversarial Machine Learning (AML).

Vashishtha et al. [17] implemented a HIDM for cloud-based healthcare systems to detect all kinds of attacks. The hybrid approach was a mixture of a Signature-based Detection Model (SDM) and an Anomaly-based Detection Model (ADM). The datasets of NSL-KDD, CICIDS2017, and UNSW-NB15 were employed to evaluate the efficacy of the HIDM approach. The implemented method had a higher detection rate with the error of Type-I and Type-II for both ADM and SDM. However, combining various detection systems increased the risk of false negatives and false positives.

Kumar et al. [18] introduced a BDSDT for the transmission of secure data in IoT-based healthcare systems. Initially, the architecture of blockchain was created in all IoT devices that were identified and established using a zero-knowledge proof, and then connected to the blockchain network using a smart contract-based ePOW consensus. Then, a bidirectional LSTM was employed using a DL to recognize IDS in the healthcare system. The BDSDT enhanced the privacy and security by combining both DL and blockchain methods. However, BDSDT wasn't effective against web and Bot threat attacks as there were fewer instances of these two classes which led to changes in actual patient data resulting in errors during the diagnosis and treatment.

Halbouni et al. [19] presented a CNN-Long Short-Term Memory (CNN-LSTM) for IDS system. The ability of CNN to extract the spatial features alongside the ability of LSTM to extract the temporal features were the highlights of this model. In order to improve performance, batch normalization and the layers of dropout were created to the presented method. The presented method decreased the false alarm rate and improved the rate of detection. However, CNN-LSTM failed to provide a high detection rate for specific kinds of attacks like web attacks and worms which led to changes in actual patient data resulting in errors during the diagnosis and treatment.

Han et al. [20] presented an Intrusion Detection Hyperparameter Control System (IDHCS) to regulate and train a Deep Neural Network (DNN) extracted feature and the module of k-means clustering in terms of Proximal Policy Optimization (PPO). The most valuable network features were extracted by the DNN under the control of an IDHCS, which also used K-means clustering to detect intrusion. The IDHCS performed effectively for each dataset, as well as the combined dataset. However, to represent a more realistic network environment, a diverse dataset needed to be examined.

Bakro et al. [21] introduced a hybrid feature selection approach that combined filter techniques such as Particle Swarm Optimization (PSO), Chi-Square (CS), and Information Gain (IG). Combining each of these three techniques was a novel method that generated a more reliable process of feature selection by using every technique's strength to increase the possibilities of selecting the most associated features. The introduced method had the benefits of flexibility, time complexity, interpretability, and scalability. But, the feature selection approach was not done properly which resulted in overfitting.

Sudar et al. [22] implemented a Machine Learning (ML) approach based on Decision Tree (DT) and Support Vector Machine (SVM) to detect Distributed Denial of Service (DDoS) attacks. The classification approach was established in the environment of Software Defined Network (SDN). The DT and SVM approaches were deployed to distinguish among malicious and normal traffic data. This approach provided better accuracy and detection rate. Nonetheless, this implemented approach struggled to adapt to evolving attack strategies.

Praveena et al. [23] developed a Deep Reinforcement Learning approach that was optimized by Black Widow Optimization (DRL-BWO) for intrusion detection in Unmannered Aerial Vehicles (UAV). The BWO approach was deployed for parameter optimization of the DRL method which assisted in enhancing the performance of intrusion detection in UAV networks. This approach was fit for the tasks of information extraction in high dimensional space. Nonetheless, the intricate nature of the DRL-BWO approach resulted in minimized interpretability.

Chinnasamy et al. [24] presented a Blockchain DDoS flooding attack with dynamic path detectors. The ML approach was established to identify the attacks which focused on the DDoS assault. The primary essential traits were employed to predict the accurate DDoS attacks by utilizing a different attribute selection approach. Nevertheless, this presented approach led to severe network congestion which hindered the processing of transactions and slowed down the overall system's performance.

Chinnasamy et al. [25] developed an ML approach for effective phishing attack detection. Based on the input features such as Uniform Resource Locator (URL) and Web Traffic, the link was classified as phishing or non-phishing. This approach was determined by retrieving datasets from ML and phishing cases by employing SVM, Random Forest (RF), and Genetic. Nevertheless, ML approaches in phishing detection struggled to maintain pace with constantly evolving phishing tactics which led to potential delays in identifying the new attacks.

Anupriya et al. [26] implemented an ML approach for fraud account detection. To compute buddy similarity criteria, the adjacency network matrix graph was employed and then new features were acquired by utilizing the Principle Component Analysis (PCA). This was employed to equalize the data and transform it into the classifier in the next phase of cross-validation for training and testing the classifier. Nevertheless, due to imbalanced datasets, this approach struggled with evolving the fraud pattern and generated false positives or negatives.

There are some limitations with the existing methods that are mentioned above such as the methods not being effective in detecting attacks which led to changes in actual patient data resulting in errors during the diagnosis and treatment. In order to overcome these issues, the HCFS-BOA-based CNN is proposed for intrusion detection to secure the entire network in the healthcare system.

III. PROPOSED METHODOLOGY

In this research, a hybrid CFS-BOA-based CNN approach is proposed for intrusion detection in healthcare systems using deep learning. It includes datasets, min-max normalization, feature selection using HCFS-BOA, classification using CNN, and performance evaluation. The overview of the proposed method is represented in Fig. 1.

A. Datasets

The proposed HCFS-BOA approach is evaluated on CIC-IDS2017 [27] and NSL-KDD benchmark datasets. The CIC-IDS-2017 dataset includes malicious and normal traffic data that is considered new and does not include an enormous amount of redundant data. It includes eleven new attacks namely, PortScan, Brute Force, DoS, web attacks like SSH, Patator, FTP-Patator, SQL injection, and XSS. It is created by the Canadian Institute for Cybersecurity in 2017, and its 80 features are employed to monitor malicious and benign traffic. The NSL-KDD is an extension of the KDD cup 99 database and contains 41-dimensional vectors with numerical and categorical values. The intrusion attacks in the NSL-KDD database are probe attacks, Remote to a user (R2L), Denial of Service (DoS), and the User to Root attack (U2R). NSL-KDD is an IoT dataset used for model training purposes in healthcare applications.

B. Pre-processing

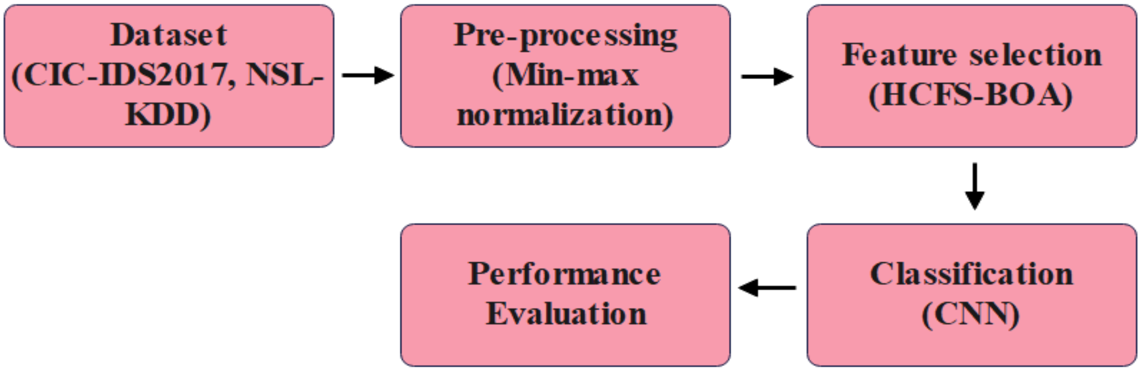
After data collection, the normalizing process is established by rescaling the attributes with a uniform contribution. Typically, the data normalization technique addresses two key problems: the presence of outliers and the presence of dominant features. The various methods for normalizing data based on the measures of statistics are examined. Consider the data with z records and N instances, as expressed numerically in Eq. (1).

$$Data = \{p_{i,n}, q_n | i \in z \; and \; n \in N\} \tag{1}$$

where, q indicates the label of class and p represents the data to be learned via a learning process. The Min-max normalization technique [28] is employed to normalize the raw data, which is one of the various normalization techniques. This approach greatly minimizes the outlier's impact on the data. It scales the obtained data within the range of 0 to 1 which is numerically expressed in Eq. (2).

$$p_{i,n} = \frac{p_{i,n} - min(p_i)}{max(p_i) - min(p_i)}(nMax - nMin) + nMin \tag{2}$$

where, max and min represent the ith attribute's maximum and minimum values. By employing $nMax$ and $nMin$, the acquired data are rescaled by the upper and lower boundaries. This acquired data is then passed as input to the feature selection.



Dataset (CIC-IDS2017, NSL-KDD)

Feature selection (HCFS-BOA)
Classification (CNN)
Performance Evaluation

Fig. 1. Block diagram for the proposed method

C. Feature Selection

After normalizing the acquired data, the hybrid CFS-BOA approach is implemented for feature selection. In CFS-BOA, the features are selected by using a nature-inspired optimization technique to enhance the optimization process. The CFS-BOA's goal is to choose the most useful feature subset for detecting and avoiding security vulnerabilities while minimizing the redundancy and computational complexity. When compared to other optimization algorithms like Ant Colony Optimization (ACO) and Particle Swarm Optimization (PSO), the BOA tunes the optimization process for maximum efficiency for combining with CFS. The HCFS-BOA examines appropriate features that not only have significant correlations with the target variable, but also contribute to its optimal performance of intrusion detection in the healthcare system. This hybrid method has the potential to result in a more efficient and effective IDS that is specific to the unique characteristics of healthcare data and security requirements.

*1) Correlation-based Feature Selection (CFS):*One of the most known filter algorithms is CFS which selects features based on the output of a heuristic (correlation-based) evaluation function. It seeks to choose subsets whose attributes are highly correlated with the class but unassociated with one another. Repetitive features are selected based on their high correlation with at least one other feature, while low-association features are ignored. The function of the CFS feature subset assessment is mathematically expressed in Eq. (3).

$$M_s = \frac{k\overline{r_{cf}}}{\sqrt{k+k(k-1)+\overline{r_{ff}}}} \tag{3}$$

M_s – feature subset's heuristic evaluation for a feature set that includes k features

$\overline{r_{cf}}$ – average degree of connection between the category label and the features

$\overline{r_{ff}}$ – average degree of inter-connection between features

A correlation technique based on the feature subsets is used for the evaluation of CFS. During the procedure, the feature set with the greatest value is determined to decrease the training and testing set size. A larger $\overline{r_{cf}}$ or smaller $\overline{r_{ff}}$ out of the obtained subsets by the approach provides a greater evaluation value.

2) Bat Optimization Algorithm (BOA): BOA is the first algorithm for optimization and computational intelligence, influenced by microbat echolocation behavior. In a d-dimensional search, every bat flies at random with v_i^t velocity, x_i^t location and f_i frequency at t iteration. The current best solution x_* is archived for n bats in a population through an iterative search process.

The procedures for updating the location x_i^t and velocity v_i^t at each time step t are mathematically presented in Eq. (4), Eq. (5) and Eq. (6).

$$f_i = f_{min} + (f_{max} - f_{min})\beta \tag{4}$$

$$v_i^t = v_i^{t-1} + (x_i^{t-1} - x_*)f_i \tag{5}$$

$$x_i^t = x_i^{t-1} + v_i^t \tag{6}$$

where, $\beta \in [0,1]$ is a vector selected at random from a uniform distribution.

Once a solution is chosen from the existing ideal solutions, a new solution for every bat is produced via a local random walk which is numerically expressed in Eq. (7).

$$x_{new} = x_{old} + \varepsilon A' \tag{7}$$

where, ε is a random vector generated from uniform or Gaussian distribution in the range [-1,1].

A' is the average loudness of all bats at a time step.

Furthermore, the rate of pulse emission and loudness are modified as the iterations progress. They are updated using the following Eq. (8) and Eq. (9).

$$A_i^{t+1} = \alpha A_i^t \tag{8}$$

$$r_i^{t+1} = r_i^0(1 - e^{-\gamma t} \tag{9}$$

where, $0 < \alpha < 1$ and $\gamma < 0$ are constant.

3) HCFS-BOA method for feature selection: The significance and correlation of the chosen feature subset are evaluated using the HCFS-BOA-based feature selection method. Correlation-based feature method is used in the HCFS-BOA to create a fitness function and assess the reliability of the reduced feature subset. CFS evaluates the correlation of mean feature class and the average inter-correlation between features for S feature subset with k features, where $S = (s_1, s_2, \dots . s_k)$ using (3). CFS is a classical filter method that selects relevant features based on correlation-based evaluation due to feature redundancy. By storing solutions in a bat's vector, BA is inspired by the echolocation activity of microbats, eliminating redundant features and reducing dimensionality. When a bat moves, it archives the best solution at the time. During the process of iterative search, the population scans for the optimum arrangement by updating and refreshing the position of each bat based on Eq. (4), Eq. (5), and Eq. (6). An ideal intrusion-detection approach has a higher detection rate and a lower false positive rate. Hence, a weighted fitness function is shown in Eq. (10).

$$Maximize\ Fit = w_1 \times DR \times w_2 \times (1 - FPR) \tag{10}$$

where, w_1 and w_2 are the weights for the Detection Rate and False Positive Rate, respectively. A higher fitness Fit means higher intrusion detection performance. In one iteration of the HCFS-BOA, the algorithm chooses a feature subset that depends on its correlation coefficients with the target variable. The bat optimization process involves updating the virtual bat's positions in the search space with each bat representing a potential feature subset. The technique iteratively refines feature selection by adjusting the position of bats and evaluates their performances via correlation-based metrics during both the testing and training phases. Thus, the rescaling acquired data is passed into the feature selection phase which is sufficient for the classification of intrusion detection.

D. Classification

The selected features are classified using the CNN model which produces enormous results in domains such as Natural Language Processing (NLP), image processing, and healthcare diagnosis systems. For recognizing patterns and anomalies in network traffic or system logs, CNN classification is employed to improve intrusion detection in healthcare systems. Using CNN classification for IDS in healthcare helps to protect sensitive patient data, ensure the integrity of healthcare information systems, and avoid security breaches. It is an essential component of healthcare cybersecurity measures to protect electronic health records and vital healthcare infrastructure.

In contrast to Multi-Layer Perceptron (MLP), CNN reduces the number of neurons and parameters, resulting in rapid adaptability and minimal complexity. The CNN model offers an extensive number of clinical classification applications. CNN models are a subset of Feed-Forward Neural Network (FFNN) [29, 30] and Deep Learning models. The convolution operations convention is constant which implies that the filter is independent in function, thereby reducing the amount of parameters. Pooling, convolution, and fully connected layers are the three types of layers used in the CNN method. These layers are required for performing feature extraction, dimensionality reduction, and classification. The filter is slid on the computers through the forward pass of convolution operation, and the input capacity of the activation map that assesses the point-wise result of every score is added to obtain the activation. The sliding filter is employed by linear and convolution operators, being stated as a quick distribution of dot product. Consider w is the kernel function, x is the input, $(x \times w)(a)$ at time t is formulated as in Eq. (11).

$$(x \times w)(a) = \int x(t) w(a-t) da \tag{11}$$

Where, a is R^n for each $n \geq 1$. The parameter t is the discrete which is presented in Eq. (12).

$$(x \times w)(a) = \sum_a x(t) w(t-a) \tag{12}$$

The 2D image I is given as input, K is a 2D kernel, and the convolution is formulated as in Eq. (13).

$$(I \times K)(i,j) = \sum_m \sum_n I(m,n) K(i-m, j-n) \tag{13}$$

In order to improve the non-linearity, two activation functions, ReLU and softmax are utilized. The ReLU is mathematically represented as in Eq. (14).

$$ReLU(x) = max(0,x)\, x \in R \tag{14}$$

The gradient $ReLU(x) = 1$ for $x > 0$ and $ReLU - (x) = 0$ for $x < 0$. The ReLU convergence ability is better than the sigmoid non-linearities. The next layer is softmax, preferable when the result requires including two or more classes which is mathematically formulated as in Eq. (15).

$$softmax(x_i) = \frac{exp(x_i)}{\sum_j exp(x_i)} \tag{15}$$

The pooling layers are applied to the result in a statistic of input, and the structure of output is rescaled without losing the essential information. There are various types of pooling layers, this paper utilizes the highest pooling that individually produces large values in the rectangular neighborhood of individual points (i,j) in 2D information for every input feature correspondingly. The fully connected (FC) layer, which is the last layer with m and n output and input are illustrated further. The parameter of the output layer is stated as a weight matrix $\in M_{m,n}$. Where, m and n are rows and columns, and the bias vector $b \in R^m$. Consider the input vector $x \in R^n$, the fully connected layer output with an activation function f is formulated as in Eq. (16).

$$FC(x) \coloneqq f(Wx = b) \in R^m \tag{16}$$

where, Wx is the matrix product where function f is employed as a component. This fully connected layer is applied for classification difficulties. The FC layer of CNN is commonly involved at the topmost level. The CNN production is compressed and displayed as a single vector.

Table I shows the notation description.

TABLE I. NOTATION DESCRIPTION

Symbol	Description
q	label of class
p	data to be learned via a learning process
min and max	ith attribute minimum and maximum values
M_s	feature subset’s heuristic evaluation for a feature set that includes k features
$\overline{r_{cf}}$	the average degree of connection between the category label and the features
$\overline{r_{ff}}$	average degree of inter-connection between features
v_i^t	velocity
x_i^t	location
f_i	frequency at t iteration
ε	random vector generated from a uniform or Gaussian distribution in the range [-1,1]
A'	average loudness of all bats at time step
w_1 and w_2	weights for the Detection Rate and False Positive Rate
Wx	Matrix product

IV. Experimental Results

In this research, the HCFS-BOA based CNN is simulated using a Python environment with the system configuration of 16GB RAM, Intel core i7 processor, and Windows 10 operating system. The parameters like accuracy, precision, recall, and f1-score are utilized to estimate the performance of the model. The mathematical representation of these parameters is shown Eq. (17) to Eq. (20).

- Accuracy – Accuracy is the proportion of accurate predictions to all input samples and it is calculated using Eq. (10).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{17}$$

- Precision - The precision measures the percentage of actual data records versus expected data records. The performance of the classification model is greater if the precision is higher.

$$Precision = \frac{TP}{TP+FP} \tag{18}$$

- Recall – Recall is calculated as the sum of the true positives and the positive class images.

$$Recall = \frac{TP}{TP+FN} \tag{19}$$

- F1-Score – It is also known as the harmonic mean which seeks a balance between recall and precision.

$$F1 - Score = \frac{2TP}{2TP+FP+FN} \tag{20}$$

A. Quantitative and Qualitative Analysis

This section shows the quantitative and qualitative analysis of the proposed CSF-BOA-based CNN model in terms of precision, accuracy, f1-score, and recall, as presented in Tables II, III and IV. Table II illustrates the performance of feature selection on the CIC-IDS2017 dataset. The performances of ACO, PSO, CFS, and BOA are measured and matched with the proposed HCFS-BOA. Fig. 2 represents a graphical illustration of the feature selection methods. The obtained result shows that the proposed HCFS-BOA algorithm attains an accuracy of 95.98%, precision of 94.23%, recall of 93.62%, and f1-score of 94.96% which is better when compared to the existing optimization algorithms.

Table III illustrates the performance of classification with default features using CIC-IDS2017 dataset. The performance of Support Vector Machine (SVM), Artificial Neural Network (ANN), K-Nearest Neighbor (KNN), and Recurrent Neural Network (RNN) are measured and matched with the proposed HCFS-BOA. Fig. 3 represents the graphical illustration of classification performances. The obtained result shows that the proposed HCFS-BOA algorithm attains an accuracy of 93.68%, precision of 92.92%, recall of 91.69%, and f1-score of 92.73% which is superior when compared to the existing optimization algorithms.

TABLE II. PERFORMANCE OF FEATURE SELECTION USING CIC-IDS2017 DATASET

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
ACO	89.45	85.61	90.12	89.23
PSO	91.82	81.20	88.65	90.14
CFS	94.37	90.47	91.52	92.74
BOA	93.26	92.82	92.76	93.85
HCFS-BOA	95.98	94.23	93.62	94.96

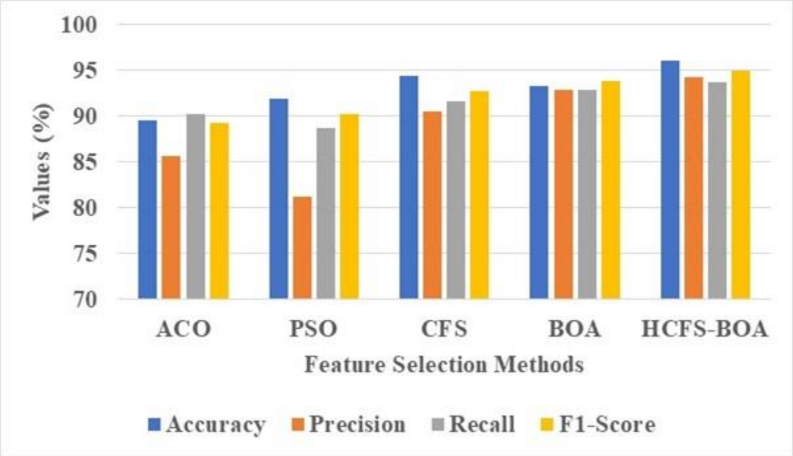

Fig. 2. Graphical representation of feature selection performances.

TABLE III. PERFORMANCE OF CLASSIFICATION WITH DEFAULT FEATURES USING CIC-IDS2017 DATASET

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
SVM	88.21	89.65	89.33	88.37
ANN	86.45	85.37	90.27	89.91
KNN	89.98	88.83	89.24	90.28
RNN	92.47	90.61	90.49	91.96
CNN	93.68	92.92	91.69	92.73

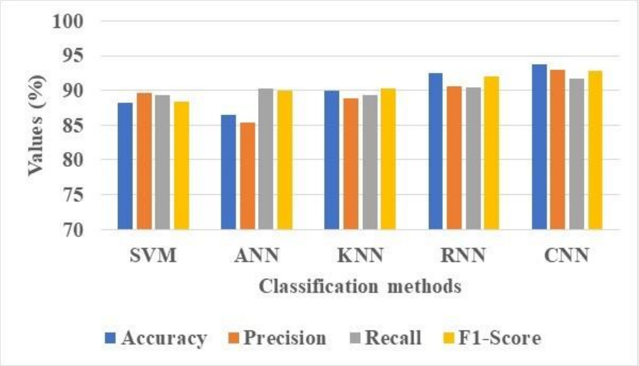

Fig. 3. Graphical representation of classification performances.

Table IV illustrates the classification outcomes with optimized features using CIC-IDS2017 dataset. The performance of SVM, ANN, KNN, and RNN are measured and matched with the optimized feature CNN. Fig. 4 illustrates the graphical representation of classification performances with optimized features. The obtained outcomes prove that the CNN algorithm accomplishes an accuracy of 99.45%, precision of 98.89%, recall of 98.67%, and f1-score of 97.98%, therefore being superior in contrast to the existing optimization algorithms. The ACO, PSO, CFS, and BOA consume 25 seconds, 29 seconds, 31 seconds, and 35 seconds of time, respectively. The time analysis of HCFS-BOA with CNN demands a training time of 20 seconds, being more robust in comparison with other optimization techniques like ACO, PSO, CFS, and BOA on the CIC-IDS2017 dataset. Table V shows the performance of classification with optimized features on the NSL-KDD dataset. Fig. 5 shows that the obtained outcomes of optimized results of the CNN algorithm accomplishes an accuracy of 98.13%, precision of 97.36%, recall of 97.07%, and f1-score of 95.34%, in that way, proving more robust in contrast to the previous optimization algorithms. The ACO, PSO, CFS, and BOA require 22 seconds, 25 seconds, 28 seconds, and 34 seconds of time, respectively. The time analysis of HCFS-BOA with CNN needs a training time of 15 seconds which is lesser than that of the previous optimization techniques like ACO, PSO, CFS, and BOA on the NSL-KDD dataset.

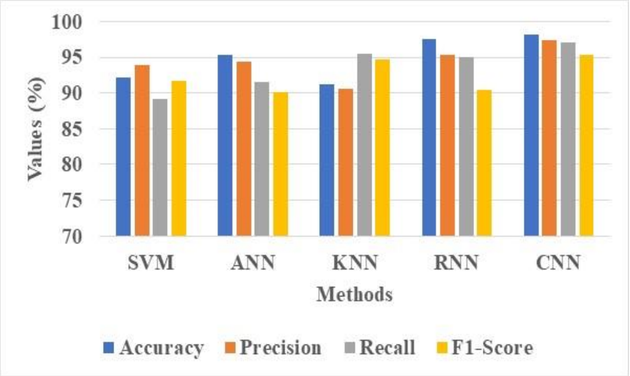

Fig. 5. Graphical representation of optimized feature performances using NSL-KDD.

TABLE IV. PERFORMANCE OF CLASSIFICATION WITH OPTIMIZED FEATURES USING CIC-IDS2017 DATASET

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
SVM	93.54	94.21	92.89	93.96
ANN	97.68	95.86	93.65	94.37
KNN	96.73	91.85	96.73	96.18
RNN	98.66	93.47	97.87	97.25
CNN	99.45	98.89	98.67	97.98

TABLE V. PERFORMANCE OF CLASSIFICATION WITH OPTIMIZED FEATURES USING NSL-KDD DATASET

Methods	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
SVM	92.17	93.95	89.20	91.66
ANN	95.38	94.36	91.51	90.17
KNN	91.20	90.51	95.47	94.68
RNN	97.54	95.34	94.93	90.50
CNN	98.13	97.36	97.07	95.34

B. Comparative Analysis

This section provides the comparative analysis of proposed HCFS-BOA based CNN model on the evaluation metrics: precision, accuracy, f1-score, and recall as shown in Table VI. The previous methods namely, SafetyMed, HIDM, and BDSDT are employed to assess the HCFS-BOA based CNN performance. SafetyMed [16] achieves 97.63% accuracy, 98.47% precision, 97% recall, and 97.73% f1-score. HIDM [17] achieves 85% accuracy and BDSDT [18] achieves 99.04% accuracy, 87.31% precision, 82.89% recall, and 83.2% f1-score. When compared with the existing methods, the proposed HCFS-BOA based CNN achieves higher accuracy of 99.45%, precision of 98.89%, 98.67% of recall, and 97.98% of f1-score.

TABLE VI. COMPARATIVE ANALYSIS WITH EXISTING METHODS

Methods	Dataset	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
SafetyMed [16]	CIC-IDS2017	97.63	98.47	97	97.73
HIDM [17]	CIC-IDS2017	85	N/A	N/A	N/A
BDSDT [18]	CIC-IDS2017	99.04	87.31	82.89	83.2
Proposed HCFS-BOA based CNN	CIC-IDS2017	99.45	98.89	98.67	97.98

C. Validation of Real-Time Applications

The NSL-KDD dataset is commonly deployed for intrusion detection in IoT to ensure reliability and security for healthcare systems. This research uses the NSL-KDD dataset for training and validation purposes on real-time applications in the cloud. The NSL-KDD dataset is split into training, testing, and validation in the ratio of 70:15:15. IDS is created to detect the different types of attacks by evaluating system logs, network traffic, and behavioral patterns. Malware attacks, DoS attacks, Cross-Site Scripting (XSS), etc., are different attacks. These types of attacks are performed when the patient information is blocked or stolen by attackers. Therefore, the NSL-KDD dataset is employed for model training purposes to reduce the attacks in real-time healthcare applications.

D. Discussion

The CIC-IDS-2017 dataset is beneficial for intrusion detection because of its comprehensive representation of realistic traffic network scenarios with different types of attacks and normal activities. It provides a labelled and large-scale dataset that assists the evaluation and enhancement of intrusion detection with enhanced robustness and accuracy. The NSL-KDD dataset is beneficial for intrusion detection as it solves limitations in the original KDD Cup dataset by minimizing redundancy and managing a more balanced distribution of classes. It generates the representation of a more realistic modern traffic network that contains normal behavior and different wider attacks that maximize intrusion detection robustness. By using these two datasets, the proposed approach is analyzed by generic type. Moreover, the advantages of the proposed method and the limitations of existing methods are discussed. The existing methods have some limitations such as the SafetyMed method [16] has no defense mechanism against an attack of AML. Combining various detection systems increases the risk of false negatives and false positives in HIDM [17]. BDSDT [18] isn't effective against web and Bot threats since there are fewer instances of these two attack classes. The proposed HCFS-BOA-based CNN model overcomes the existing models' limitations.

To overcome the problem of AML attack, CFS is used to identify highly informative features for minimizing the risk of adversarial manipulations compared to other algorithms. BOA assists in identifying an optimal subset of features that maximizes detection accuracy and reduces the risk of false positives and false negatives. This is done by focusing on informative features in CFS that assist in enhancing the model's ability to discriminate between various attack classes like web and Bot threat. Combining CFS with BOA enables appropriate features that not only have significant correlations with the target variable but also contribute to the optimal performance of intrusion detection in the healthcare system, in contrast to the other methods. The CNN is deployed to identify and classify intrusion accurately and effectively. New attacks such as web and Bot threat attacks are classified effectively by using CNN. The proposed HCFS-BOA-based CNN achieves a superior accuracy of 99.45% when compared with the existing methods namely, SafetyMed, HIDS, and BDSDT.

V. CONCLUSION

In this research, the HCFS-BOA based on the CNN model is proposed for intrusion detection to secure the entire network in the healthcare system. The proposed method mainly comprises four stages: dataset, min-max normalization, feature selection, and classification. Initially, the data is obtained from the CIC-IDS2017 and NSL-KDD datasets, after which the min-max normalization is performed to normalize the acquired data. For feature selection, HCFS-BOA is employed for optimal performance of intrusion detection in healthcare systems. Finally, the CNN is deployed to identify and classify intrusion accurately and effectively. The proposed HCFS-BOA-based CNN achieves a better accuracy of 99.45% when compared with the existing methods like SafetyMed, HIDS, and BDSDT. In the future, hyperparameter tuning can be applied in feature selection for improving the model's performance.

Context-Aware Transfer Learning Approach to Detect Informative Social Media Content for Disaster Management

Saima Saleem*, Monica Mehrotra
Department of Computer Science, Jamia Millia Islamia, New Delhi, India

Abstract*—In the wake of disasters, timely access to accurate information about on-the-ground situation is crucial for effective disaster response. In this regard, social media (SM) like Twitter have emerged as an invaluable source of real-time user-generated data during such events. However, accurately detecting informative content from large amounts of unstructured user-generated data under such time-sensitive circumstances remains a challenging task. Existing methods predominantly rely on non-contextual language models, which fail to accurately capture the intricate context and linguistic nuances within the disaster-related tweets. While some recent studies have explored context-aware methods, they are based on computationally demanding transformer architectures. To strike a balance between effectiveness and computational efficiency, this study introduces a new context-aware transfer learning approach based on DistilBERT for the accurate detection of disaster related informative content on SM. Our novel approach integrates DistilBERT with a Feed Forward Neural Network (FFNN) and involves multistage finetuning of the model on balanced benchmark real-world disaster datasets. The integration of DistilBERT with an FFNN provides a simple and computationally efficient architecture, while the multistage finetuning facilitates a deeper adaptation of the model to the disaster domain, resulting in improved performance. Our proposed model delivers significant improvements compared to the state-of-the-art (SOTA) methods. This suggests that our model not only addresses the computational challenges but also enhances the contextual understanding, making it a promising advancement for accurate and efficient disaster-related informative content detection on SM platforms.

Keywords*—*Disaster management; twitter; distilBERT; deep learning; multistage finetuning; transfer learning

I. Introduction

According to the “Human cost of disasters 2000-2019” report by the “United Nations Office for Disaster Risk Reduction” (UNDRR)[1], disasters have significantly surged over recent decades. As a result, approximately 1.23 million lives have been lost globally, along with an additional economic loss of 2.97 trillion dollars. To effectively respond and manage such significant ecological disruptions, disaster response organizations increasingly rely on swift and precise human-centric information [1]. In recent years, social media (SM) particularly Twitter, have emerged as invaluable tools for disseminating and obtaining real-time user-generated data during such events [2].

Numerous research works [3-5] have demonstrated that tweets shared on Twitter during disasters often contain informative content, including details about affected people, infrastructure damage, resource needs and availability etc. Such content can be useful for disaster responders in coordinating response efforts, if processed effectively. However, identifying informative content from a substantial volume of irrelevant and noisy tweets during time-critical disaster situations is a challenging task [6]. Moreover, the character limit, uncommon abbreviations, and grammatical mistakes make the detection of informative content even more challenging [7].

Prior research works have explored classical machine learning-based techniques for the automated analysis of SM texts in the context of disasters [8, 9]. However, in recent years, there has been a notable shift towards the application of deep learning (DL) in the analysis of SM text for disaster response [7]. DL has evinced great performance across diverse domains [10-12]. Different DL techniques, including CNN [13, 14], LSTM [15], and Bi-LSTM [16] have been explored for disaster-related tweet classification.

While significant work has been done to analyze SM data related to disasters, the majority of the existing studies rely on traditional non-contextual models within natural language processing (NLP), such as GloVe, Word2Vec (W2V), Bag-of-words (BoW), etc. These models process text sequences in a unidirectional manner, which limits their ability to accurately capture the nuanced context of a tweet sequence. This limitation can lead to inaccurate classification, especially in disaster situations where words like "fire," "flood," and "earthquake" may be used metaphorically. This underscores the need for advanced models capable of understanding the context of disaster-related tweets for the accurate detection of informative content.

In the most recent advancements within NLP, researchers have introduced a spectrum of transfer learning methods and models, notably BERT [17], RoBERTa [18], and DistilBERT [19], among others. These models have demonstrated substantial enhancements across various NLP tasks [20]. They are based on the approach of bidirectional training of transformer-based neural networks to learn the contextual numeric representation of text sequences. This enables them to capture the complete context of a given text sequence, resulting

[1] UNDRR: Human cost of disasters: An overview of the last 20 years 2000-2019. https://www.undrr.org/publication/human-cost-disasters-2000-2019.

in superior performance compared to conventional non-contextual models [21]. However, they often require significant computational resources due to their large size and complexity.

In the context of disaster response, where speed and efficiency are paramount, the DistilBERT transformer emerges as a promising choice among others. It offers significant advantages in terms of computational efficiency due to its smaller size and faster processing. Despite its demonstrated performance and computational efficiency in various real-time applications like fraud detection [22] and network traffic classification [23], the application of DistilBERT to time-critical disaster management applications remain largely unexplored.

This study aims to fill this research gap by harnessing the capabilities of DistilBERT to offer an effective and computationally efficient solution for the specific task of detecting disaster-related informative content on SM. Our novel approach integrates DistilBERT with a Feed Forward Neural Network (FFNN) and employs multistage finetuning of the model on balanced benchmark datasets of real-world disaster data. The integration of DistilBERT with FFNN provides a simple and computationally efficient architecture, while the multistage finetuning enables a deeper adaptation of the model to the disaster domain, leading to demonstrably improved performance. The contributions of this study are outlined below:

- A new context-aware transfer learning approach is proposed that integrates DistilBERT with a FFNN and involves multistage finetuning of the model to adapt it to the disaster domain for enhanced detection of disaster-related informative content.

- Different model variants are designed using DistilBERT and several DL models like CNN, LSTM, and Bi-LSTM to evaluate the proposed model.

- This study addresses the issue of data imbalance, by employing random down sampling technique to balance the distribution of classes. This ensures that the model is not biased towards the majority class, thus providing unbiased results.

- Through comprehensive ablation studies, this study systematically investigates the impact of multistage finetuning, context-aware representation of tweets, and data balancing on the proposed model's performance.

- The proposed model is compared with various state-of-the-art (SOTA) baseline methods including non-contextual and context-aware transformer-based methods.

- The remaining sections of this paper are arranged as follows: The related works are covered in Section II. Section III covers the methodology. Section IV includes the experimental set up. Section V reports the experimental results. Section VI provides a discussion of the results. Lastly, Section VII concludes this study with the future work.

II. Related Work

Over the years, extensive research has been carried out and numerous methods have been proposed to extract disaster-related information useful for humanitarian organizations from SM. We group the existing studies into two categories: non-contextual methods and context-aware methods.

A. Non-contextual Methods

Preliminary studies in this field have mostly employed traditional NLP techniques like BoW along with classical ML algorithms to classify disaster-related SM content. In study [9], the authors presented a system called Tweedr to identify tweets mentioning damage or human fatalities information using a Logistic Regression classifier with BoW features. The authors in [24] extracted situational awareness information from both Hindi and English tweets using lexical and syntactic features with an SVM classifier. In another work [25], the authors employed an SVM classifier along with BoW features to detect tweets related to floods during Manila flooding.

Researchers have also focused on the detection of various information categories present in disaster tweets. In study [26], the authors trained a Naïve Bayes classifier on unigram, bigram, POS, and binary features using the Joplin 2011 tornado disaster dataset to classify tweets into “Caution and advice”, “Fatality”, “Injury”, “Offers of Help”, “Missing” and “General Population Information”. In another work, a system called AIDR [8] has been developed for identifying informative tweets during disasters. This system extracts features based on BoW model from the tweets and then classifies them into user defined categories such as ‘donations,’ ‘damage’ etc.

Additionally, deep neural networks with different word embedding models have been utilized in disaster domain utilizing SM datasets. The authors in study [13, 14] presented CNN-based systems for identifying disaster related SM posts during disasters. They utilized general and domain specific word embedding models for generating features. [15] designed a two-layer LSTM model combined with pretrained GloVe word embeddings for classifying tweet texts of seven different disaster events into informative and not-informative binary categories. In another work [16], the authors employed a Bi-LSTM with pre-trained GloVe embeddings for classifying disaster-related SM textual content.

B. Context-Aware Methods

With advancements in NLP, researchers have begun to employ pretrained transformer-based architectures in disaster domain to enhance the detection of useful disaster-related information from SM. The authors in study [27] finetuned the BERT model for adapting it to the task of identifying informative tweet texts during disasters. In another work [28], the authors provided a RoBERTa based method, an extension of BERT, for identifying disaster related informative tweet texts. They fine-tuned the architecture to adapt the model to the disaster-specific task.

From the aforementioned studies, it is evident that prevailing methods have majorly relied on traditional non-contextual language models for processing disaster-related SM texts. While a limited number of recent studies have explored context-aware transformer-based approaches, they typically employ resource-intensive models. Besides imbalanced datasets have been used, which may result in biased outcomes.

III. Methodology

Detecting disaster-related informative content on SM effectively and efficiently is crucial for effective disaster response. The problem is framed as a binary classification task: given a tweet, detect whether it is an informative or not_informative tweet. An informative tweet offers valuable details such as information about affected individuals, the extent of infrastructure damage, and resource requirements. Conversely, a non-informative tweet lacks crucial information related to humanitarian organizations or victims. We propose a new context-aware transfer learning approach leveraging the computational efficiency of the DistilBERT language model. Our methodology integrates DistilBERT with a FFNN and employs a multistage finetuning process for improved detection performance. We first provide an overview of the DistilBERT language model and subsequently present our proposed model (DistilBERT+FFNN), followed by multistage finetuning process in detail.

A. DistilBERT

DistilBERT is a distilled variant of BERT, an advanced bidirectional pretrained language model based on transformer encoded architecture. It is pretrained on a sizable dataset made up of the Wikipedia and Toronto Book Corpus. The reason for choosing DistilBERT is that it is lightweight than the BERT model in terms of parameters and runs 60% faster than BERT. The description of DistilBERT parameters is shown in Table I.

TABLE I. DistilBERT Parameters

Parameter Name	Value
Number of Layers	6
Hidden States Size	768
Attention Heads	12
Number of Parameters	66 million

DistilBERT comprises six stacked encoders, enabling it to encode the semantic and syntactic information in the tweet sequences as, shown in Fig. 1. The DistilBERT implements a multi-headed self-attention mechanism that captures information from each attention head. This enables the model to look at all the surrounding words in the input tweet sequence, allowing for a better understanding of a word in a particular context.

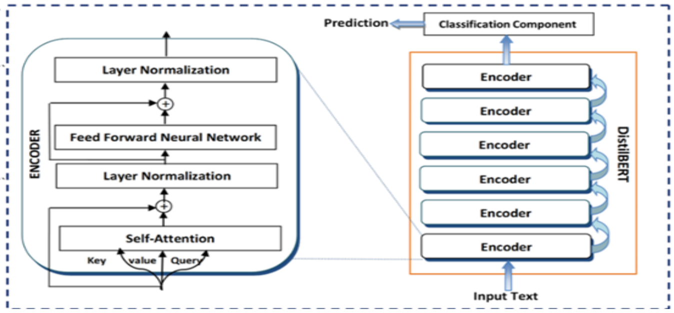

Fig. 1. DistilBERT architecture.

This stands in contrast to other text processing models like W2V and GloVe, which generates context-independent embeddings by processing the text sequence in a unidirectional manner. Thus, it can represent each word with a single vector regardless of contextual variations.

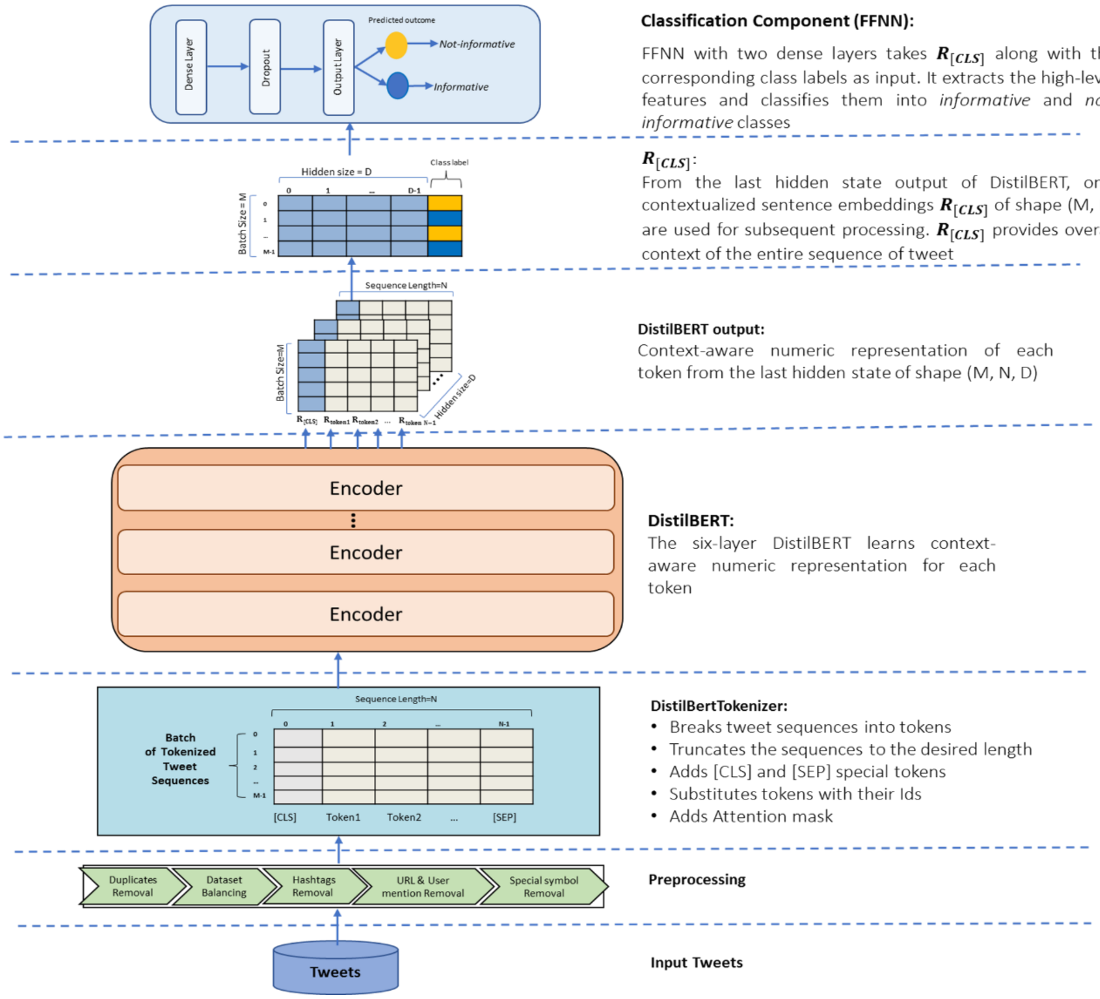
B. Proposed Model

The proposed model is an amalgamation of DistilBERT and an FFNN, leveraging their complementary capabilities to enhance the performance of disaster-related informative content detection task. The DistilBERT is utilized to extract contextual numeric representation of disaster tweet sequences, and the FFNN refines these representations into high-level abstract features for the final prediction. Importantly, FFNN introduces a layer of simplicity to the architecture, ensuring that the model retains its computational efficiency, while maintaining high performance. Fig. 2 illustrates the complete model architecture, showcasing the flow from DistilBERT to FFNN.

To obtain context-aware vector representation of the preprocessed tweets from DistilBERT model, tweets must be transformed into a format understandable by DistilBERT. For this, the tweets are passed to the batch_encode_plus method of DistilBertTokenizer class from the transformers package. It performs the following operations to transform the textual data into an appropriate format:

- Tokenization: Splitting the tweet text sequence into a list of words or sub-words called tokens.
- Padding: Making the length of the tweet sequences equal in case of the unequal sequence lengths.
- Adding special tokens: Adding special tokens such as [CLS], which stand for classification, and [SEP], which stands for separation, to indicate the beginning and the end of each sentence, respectively.
- Encoding: Substituting tokens with their corresponding IDS.
- Adding attention mask: Including an attention mask, a binary array guiding the model on which tokens to focus on it and which to ignore.

For each tweet, the *batch_encode_plus* method returns two sequences (input IDs along with attention mask), which are then input to the DistilBERT. The DistilBERT model outputs hidden states of shape (batch_size, sequence_length, hidden_size), representing the word-level/token-level embedding output of DistilBERT's layers. In this study, the output of the last hidden state is considered as it typically leads to the best empirical results [29]. Moreover, instead of using the word-level/token-level representation, the sentence-level representation of the sequence is used by taking the output for the [CLS] token, denoted as $R_{[CLS]}$. The sentence-level embedding $R_{[CLS]}$ provides the overall context of the entire sequence of tweet text. $R_{[CLS]}$ is a 2D tensor of shape (batch_size, hidden_size), which is passed to the next component of our model i.e., FFNN for predicting whether a tweet is informative or not-informative.



Classification Component (FFNN):

FFNN with two dense layers takes $\boldsymbol{R}_{[CLS]}$ along with the corresponding class labels as input. It extracts the high-level features and classifies them into *informative* and *not-informative* classes

$\boldsymbol{R}_{[CLS]}$:
From the last hidden state output of DistilBERT, only contextualized sentence embeddings $\boldsymbol{R}_{[CLS]}$ of shape (M, D) are used for subsequent processing. $\boldsymbol{R}_{[CLS]}$ provides overall context of the entire sequence of tweet

DistilBERT output:
Context-aware numeric representation of each token from the last hidden state of shape (M, N, D)

DistilBERT:
The six-layer DistilBERT learns context-aware numeric representation for each token

DistilBertTokenizer:
- Breaks tweet sequences into tokens
- Truncates the sequences to the desired length
- Adds [CLS] and [SEP] special tokens
- Substitutes tokens with their Ids
- Adds Attention mask

Preprocessing

Input Tweets

Fig. 2. Proposed model (DistilBERT+FFNN) for the detection of disaster-related informative tweets.

The FFNN is comprised of two dense layers: a hidden layer and an output layer. The hidden layer uses a popular Rectified Linear Unit (ReLU) activation function. The ReLU function is computed as shown in Eq. (1) and Eq. (2):

$$(x) = \max(0, x) \qquad (1)$$

$$f(x) = \begin{cases} 0, & x < 0 \\ x, & x > 0 \end{cases} \qquad (2)$$

It outputs 0 for every value of x < 0 and x itself for all values of x>0. The output of the FFNN is computed as shown in the formula in Eq. (3) and Eq. (4):

$$Z = \sum_{i=0}^{n} W_i \times X_i + B \qquad (3)$$

$$f(z) = f\left(\sum_{i=0}^{n} W_i \times X_i + B\right) \qquad (4)$$

where, f is an activation function (i.e., sigmoid for the output layer), X is the previous layer output, W is the weight matrix, n is the number of inputs from the incoming layer, and B is the bias.

The output of the sigmoid function is always between 0 and 1. The sigmoid activation function is computed in Eq. (5).

$$y' = \frac{1}{1+e^{-z}} \qquad (5)$$

where, y' is the model's predicted value, z is the output generated by the last layer of FFNN as computed in (3). Since, the number of classes is two in our case, Binary Cross Entropy (BCE) loss function is employed which computes how far the model deviates from the correct prediction i.e., error as illustrated in Eq. (6).

$$L_{BCE} = -\frac{1}{N}\sum_{i=1}^{N}\left(y_i \cdot logy'_i + (1-y_i)\cdot\log(1-y'_i)\right) \qquad (6)$$

where N is the training set size, y_i and y_i' is the actual class label and predicted value for the i^{th} sample in the dataset. BCE outputs a loss value that tells how wrong the models' predictions are. The lower the loss value, the higher the model's performance in making accurate predictions.

C. Multistage Finetuning Procedure

This study employs a multistage finetuning approach to finetune the proposed model. In this approach, the proposed model undergoes finetuning in a series of two stages. In the first stage (stage-1), the DistilBERT model is frozen and only the FFNN undergoes finetuning. This allows the FFNN to learn the task-specific knowledge without altering the general knowledge acquired by DistilBERT during pretraining. The model is trained for six epochs using Adam optimizer with a learning rate of 5e-5 and batch-size of 64. During the error back-propagation, the pretrained weights of DistilBERT will remain unchanged; only the FFNN will learn. Once, the weights of FFNN are learned in the subsequent stages (stage-2), the DistilBERT layers are unfrozen, and the entire architecture undergoes further finetuning for six additional epochs. The pretrained DistilBERT weights also get updated during finetuning, implying that the error gets back-propagated through the entire architecture. A lower learning rate is set to prevent significant updates to the gradient. A callback mechanism is used to stop the training process when the model has stopped improving. The DistilBERT attention dropout and DistilBERT dropout are also slightly increased from their default values. This two stage finetuning process allows the model to further adapt to our task and improve overall performance.

IV. Experimental Setup

This section presents the setup for experiments, including datasets used, evaluation metrics, model variants, baseline methods, and training details.

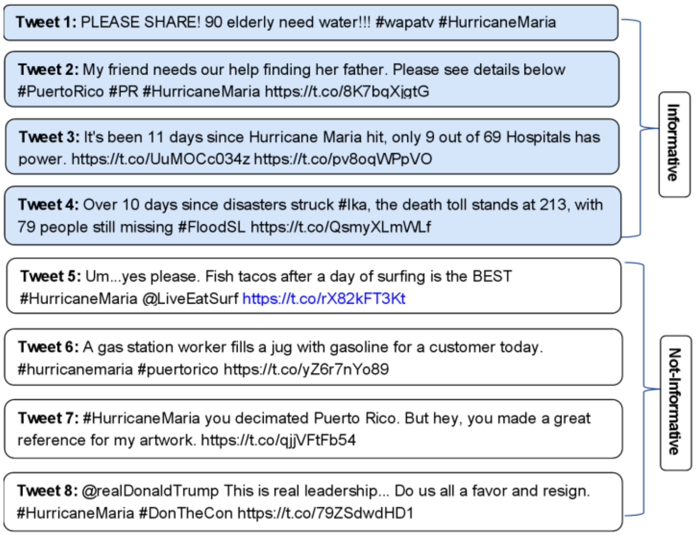
A. Dataset Description and Pre-Processing

The current study evaluates the proposed model on a real-world disaster tweet dataset called CrisisMMD [30]. This dataset encompasses tweets from seven disaster events broadly annotated into informative and not_informative classes. A few examples of informative and not_informative tweets from the CrisisMMD dataset are shown in Fig. 3. An overview of the number of tweets present in each disaster dataset is provided in Table II and the class distribution of each disaster dataset can be seen in Fig. 4.

Before conducting any experiments, the datasets are cleaned by eliminating duplicate tweets, hashtags, URLs, user mentions and various symbols such as “@,” “!”,“#”, “&,” and “%”. As can be observed from Fig. 4, the dataset is imbalanced, to address the class imbalance and ensure equal representation of *informative* and *not_informative* tweets, a balanced sample is obtained using random down-sampling. This simple and effective technique reduces the majority class to match the size of the minority class. Finally, a total count of about 8.6k tweet samples from the CrisisMMD dataset are used for subsequent processing. From each event dataset 70% tweet samples are used for training, 10% are used for validation, and the remaining 20% are used for testing the model’s performance.

TABLE II. CrisisMMD Dataset Details

Disaster event	#Tweets
Hurricane Harvey	4434
Hurricane Maria	4556
Hurricane Irma	4504
Sri Lanka Floods	1022
Iraq-Iran Earthquake	597
Mexico Earthquake	1380
California Wildfires	1588



Tweet 1: PLEASE SHARE! 90 elderly need water!!! #wapatv #HurricaneMaria

Tweet 2: My friend needs our help finding her father. Please see details below #PuertoRico #PR #HurricaneMaria https://t.co/8K7bqXjgtG

Tweet 3: It's been 11 days since Hurricane Maria hit, only 9 out of 69 Hospitals has power. https://t.co/UuMOCc034z https://t.co/pv8oqWPpVO

Tweet 4: Over 10 days since disasters struck #lka, the death toll stands at 213, with 79 people still missing #FloodSL https://t.co/QsmyXLmWLf

Fig. 3. Examples of informative and not_informative tweets from the CrisisMMD dataset.

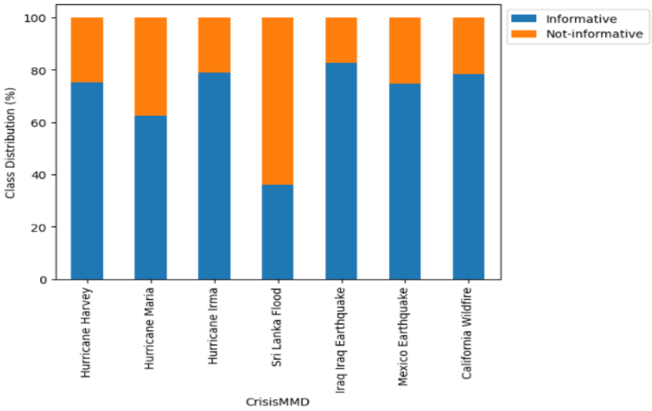

Fig. 4. CrisisMMD class distribution.

B. Evaluation Metrics

To assess our proposed model’s performance, several metrics are used:

1) Precision (P): shows the proportion of correctly predicted informative tweets to the total predicted informative tweets and is equal to:

$$P = \frac{TP}{TP+FP} \quad (7)$$

2) Recall (R): shows the proportion of correctly predicted informative tweets to the total actual informative tweets and is equal to:

$$R = \frac{TP}{TP+FN} \quad (8)$$

3) F1-Score (F1): merges the precision and recall by computing their harmonic mean, as:

$$F1 = 2 \times \frac{P \times R}{P+R} \quad (9)$$

where, TP indicates “True Positive”, which means an informative tweet is correctly predicted as informative. TN indicates “True Negative”, which means a not_informative tweet is correctly predicted as not_informative. FP indicates “False Positive”, which means a not_informative tweet is incorrectly predicted as informative, and FN indicates “False Negative”, which means an informative tweet is incorrectly predicted as not_informative.

C. Model Variants

To evaluate the effectiveness of the proposed model (DistilBERT+FFNN), we design three different model variants. These variants are formed by integrating DistilBERT with various popular DL architectures specifically CNN, LSTM, and Bi-LSTM. The description of each model variant is provided below.

1) DistilBERT+CNN: CNN is combined on top of DistilBERT as a classification component and the input to CNN is a 2-dimensional tensor X obtained from DistilBERT. This tensor undergoes a convolution operation with a filter matrix, generating a new feature map through element-wise multiplication. The resulting feature map is then subjected to a pooling layer, extracting maximum values to form a pooled output. This output is subsequently fed into the output layer, to determine the tweet's class as shown in Eq. (4).

2) DistilBERT+LSTM: An LSTM is used on top of DistilBERT and the input to the LSTM is DistilBERT output. An LSTM comprises recurrently connected memory units. Each unit comprises of a cell state, an input gate, an output gate and a forget gate. The cell state keeps information over arbitrary periods, and the information flow into and out of the cell state is governed by the gates. This allows the model to retain important information. The output from the LSTM layer is fed to an output layer for classification as shown in Eq. (4).

3) DistilBERT+Bi-LSTM: Another variant is designed by using a Bi-LSTM on top of DistilBERT. A Bi-LSTM layer trains two separate LSTM layers of opposite directions (forward and backward) simultaneously on the input generated from DistilBERT and then concatenates the outputs from both layers. This output is fed to a final output dense layer for classifying tweets into informative and not-informative classes as shown in Eq. (4).

D. Baseline Methods

The proposed model is further evaluated by comparing it against the SOTA baseline methods for disaster-related informative content detection. These methods are grouped into two categories: non-contextual methods and context-aware methods. A brief description of each baseline method is provided below:

1) Non-contextual methods:

a) W2V-CNN [13]: The authors in [13] employed a CNN model with filters of different sizes for identifying disaster related SM posts. They used general pretrained W2V embeddings with the CNN model.

b) CW2V-CNN [14]: The authors in [14] used a pretrained crisis embedding model (CW2V) [31] and trained a custom CNN with different filters to identify disaster related SM posts during a disaster.

c) GloVe-LSTM [15]: The authors in [15] used a pretrained GloVe word embeddings of 100 dimension with a 2-layer LSTM model for identifying informative textual content from SM during disasters.

d) GloVe-Bi-LSTM [16]: The authors in [16] used a pretrained GloVe word embeddings of 300 dimension along with a Bi-LSTM neural network for detecting informative textual content from SM during disasters.

2) Context-aware methods:

a) Finetuned-BERT [27]: The authors in [27] finetuned BERT for classifying SM textual posts into *informative* and *not_informative* classes during disasters.

b) Finetuned-RoBERTa [28]: The authors in [28] used a variant of BERT called RoBERTa and finetuned it for identifying informative SM textual posts during disasters.

All of these baseline methods have used the CrisisMMD dataset, with the exception of W2V-CNN [13], CW2V-CNN [14]. For these specific methods, we rely on results computed in [32] on the same CrisisMMD dataset, to facilitate a comprehensive and consistent comparison in this study.

E. Training Details

All the experiments are executed using TensorFlow framework and Google Colab cloud platform with Python programming language. The optimal hyperparameters for the stage-1 and stage-2 of our model finetuning approach are listed in Table III and IV, respectively.

TABLE III. PARAMETERS FOR STAGE-1 OF FINETUNING

Hyperparameter	Value
Learning rate	5e-5
Number of epochs	6
Batch Size	64
Dropout	0.2

TABLE IV. PARAMETERS FOR STAGE-2 OF FINETUNING

Hyperparameter	Value
Learning rate	2e-5
Number of epochs	6
Batch Size	64
DistilBERT Dropout	0.2
DistilBERT Attention Dropout	0.2

V. EXPERIMENTAL RESULTS

In this section, we present a comprehensive evaluation of the performance of the proposed model and its various variants employed in this study. Additionally, a thorough comparison is conducted between the proposed model and SOTA baseline methods. Finally, this section covers detailed ablation studies.

A. Proposed Model vs. Different Model Variants

To demonstrate that the proposed model (DistilBERT+FFNN) is an effective model for the informativeness classification task, it is compared against different model variants, as discussed in Section C. The P, R, and F1 of the proposed model and the model variants on CrisisMMD dataset are reported in Table V, with bold values indicating the best results. As per the table, all the model variants exhibit good performance across seven disasters. The proposed model exhibits the highest P ranging from 73.12 to 96.20, R in the range of 73.11 to 96.04, and F1 in the range of 72.20 to 96.04. These results render the proposed model an effective choice for detecting disaster related informative content.

B. Proposed Model vs. SOTA Baseline Methods

In this subsection, we first present a performance comparison of the proposed model against non-contextual baseline methods. Next, we analyze the comparative performance of the proposed model with respect to context-aware baseline methods.

1) Proposed model vs. non-contextual baseline methods: The comparison of results in terms of F1 of the proposed model against non-contextual methods: W2V-CNN [13], CW2V-CNN [14], GloVe-LSTM [15] and GloVe-Bi-LSTM [16] are reported in Table VI. As per the results, the proposed model consistently outperforms the non-contextual methods across all disasters, with the exception of Hurricane Irma, where GloVe-LSTM [15] outperforms in terms of F1. On average, the proposed model significantly enhances F1, with an improvement ranging from 2.75% to 19.86%.

2) Proposed model vs context-aware baseline methods: The efficacy of the proposed model is further validated through comparisons with recent transformer-based context-aware methods: Finetuned-BERT [27] and Finetuned-RoBERTa [28]. The corresponding results, expressed in terms of F1, are detailed in Table VII. A comprehensive examination of the table reveals that the proposed model outperforms Finetuned-BERT [27] across six out of seven disasters and surpasses Finetuned-RoBERTa [28] on five out of seven disasters from the CrisisMMD dataset. The proposed model exhibits an average F1 improvement of 5.47% over Finetuned-BERT [27] and 1.6% over Finetuned-RoBERTa [28].

C. Ablation Studies

In this subsection, we conduct ablation experiments to investigate the effect of multistage finetuning, context-aware representation of tweets, and data balancing on the proposed model performance.

1) Effect of multistage finetuning: To understand the effect of multistage finetuning on the model performance, we conduct a comparative analysis with a single stage (stage-1) finetuned model, where only the FFNN is finetuned while keeping DistilBERT parameters frozen. The results depicted in Fig. 5 report the F1 achieved with and without multistage finetuning on CrisisMMD dataset. From the results, consistent improvement is observed with multistage finetuning, where the model undergoes a series of two finetuning stages. Specifically, multistage finetuning boosts the performance by 3.89% to 6.85% in terms of F1. This emphasizes the efficacy of multistage finetuning in enhancing the model's ability to capture and adapt to the nuances present in disaster-related tweets, resulting in improved performance.

2) Effect of DistilBERT context-aware tweet representation: To evaluate the impact of context-aware tweet representation derived from DistilBERT on the informativeness classification task, additional experiments are performed, comparing DistilBERT against two non-contextual word embedding models. Experiments are designed where the FFNN classifier uses CW2V [33] and GloVe [34] embedding models.

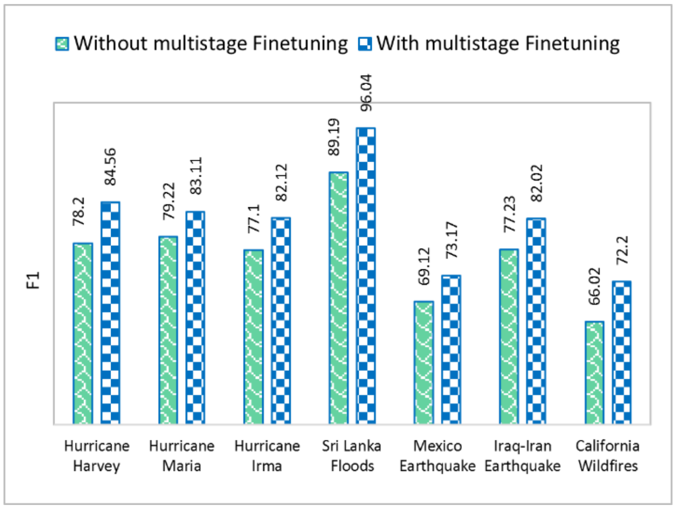

Fig. 5. F1 of the proposed model with and without multistage finetuning.

The CW2V is a 300-dimensional embedding, pretrained using W2V model on disaster related Twitter corpus. GloVe is a pretrained 100-dimensional embedding trained on Wikipedia and web text words. Fig. 6 depicts the F1 of the proposed model and non-contextual models. Our investigation reveals that the context-aware representation generated by DistilBERT model improves the results across all disasters compared to the non-contextual models. Overall, with DistilBERT, a significant improvement in the range of 8.11% to 19.56% compared to GloVe and 9.75% to 21.2% compared to CW2V in F1 is achieved across seven disasters. These results clearly highlight that DistilBERT model captures better contextual information from tweet sequences leading to better detection performance than GloVe and CW2V models.

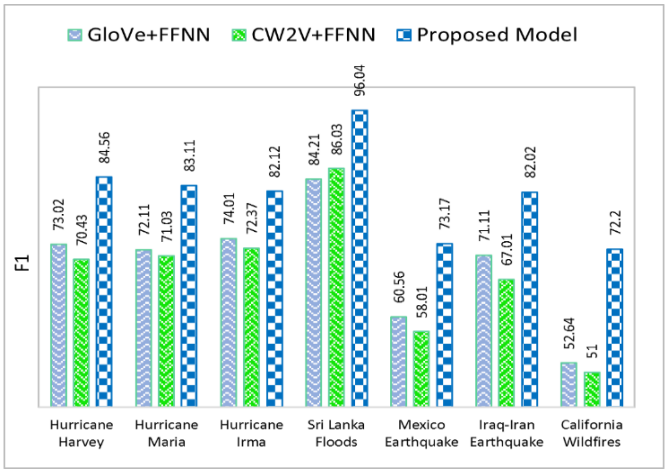

Fig. 6. F1 of the proposed model and non-contextual models.

3) Effect of data balancing: As mentioned earlier, the datasets are imbalanced, and random down sampling is employed to ensure a balanced representation. Table VIII presents a comparative analysis of the proposed model's performance in terms of F1 when trained on imbalanced and balanced dataset. From the table, it can be concluded that the model's performance is notably enhanced, showcasing improved and unbiased results when trained on balanced datasets. On the other hand, training on imbalanced datasets leads the model to disproportionately learn from the majority class, thereby introducing bias towards that class.

TABLE VIII. F1 ANALYSIS OF THE PROPOSED MODEL ON IMBALANCED VS. BALANCED DATASET

Disasters	**Class** **0 (*not_informative*)** **1 (*informative*)**	**Imbalanced**	**Balanced**
Hurricane Harvey	0	61.51	**84.69**
	1	86.24	**84.43**
Hurricane Maria	0	73.89	**82.92**
	1	89.33	**83.30**
Hurricane Irma	0	61.45	**82.03**
	1	80.24	**82.21**
Sri Lanka Floods	0	94.42	**95.59**
	1	71.09	**96.49**
Mexico Earthquake	0	48.80	**73.10**
	1	79.02	**73.24**
Iraq-Iran Earthquake	0	42.87	**82.00**
	1	79.86	**82.04**
California Wildfires	0	36.58	**72.10**
	1	87.45	**72.30**

VI. DISCUSSION

Upon a thorough evaluation of our proposed model on seven real-world disasters from a benchmark CrisisMMD dataset, it stands out as both effective and computationally efficient for the informativeness classification task. In the performance comparison between the proposed model and its variants, it is noteworthy that the integration of CNN, LSTM, and Bi-LSTM DL models with DistilBERT does not enhance the classification performance. Conversely, a simple FFNN proves sufficient for extracting high-level abstract features from the contextualized representations generated from DistilBERT. The results confirm the effectiveness of the proposed model for the informativeness classification task. The outperformance of the proposed model against non-contextual methods based on W2V, CW2V and GloVe models underscores the importance of context-aware representation of tweets in the effective detection of disaster-related informative content. The comparison of the proposed model with SOTA context-aware methods based on BERT and RoBERTa, demonstrates clear advantages of the proposed model in the detection performance. While BERT and RoBERTa are powerful transformer architectures renowned for their contextual understanding, require significant computational resources due to their large size and complexity. The proposed model built on DistilBERT known for its enhanced computational efficiency capitalizes on the efficiency gains through the multi-stage fine-tuning process. The ablation experimental results provide deeper insights, emphasizing the advantages of our multistage finetuning approach for significantly enhancing overall model performance. Additionally, the combination of DistilBERT with an FFNN, and data balancing collectively contributes to the effective and computationally efficient detection of disaster-related informative content on SM. This positions the model as well-suited for time-critical disaster response applications. Nevertheless, one of the limitations of this study is that it considers only English language tweets, while people often communicate in their native language during disasters. So, multilingual transformer-based models are worth investigating to tackle multi-linguality issues.

VII. CONCLUSION AND FUTURE WORK

In the realm of disaster management, this study introduces a novel context-aware transfer learning approach harnessing the computational efficiency of DistilBERT for the detection of disaster-related informative content on SM. Our methodology integrates DistilBERT with an FFNN, providing a simple yet effective architecture. A key feature of our approach involves multistage finetuning of the model on seven real-world disasters, resulting in improved detection performance.

This work contributes to the broader goal of improving the effectiveness and efficiency of disaster response systems using NLP and AI technologies. By developing a specialized model for disaster-related informative content detection, we aim to provide a valuable tool for disaster response organizations to better identify critical information during disasters and provide situational awareness to decision-makers. The model can be implemented in any system for filtering actionable informative content during disasters from irrelevant content, enabling disaster responders to improve their ability to deliver help and make well-informed decisions. Furthermore, the proposed model holds promise for diverse domains such as epidemics and civil unrest monitoring on SM. With domain-specific finetuning, it can be readily adapted to identify informative content during outbreaks, protests, or other volatile situations enabling real-time interventions.

In the future, we plan to extend this work for identifying and categorizing multimodal informative content into distinct humanitarian information categories, including "affected individuals", "infrastructural damage", “help and rescue”, “resource needs” etc. to enable a more targeted and efficient disaster response. Moreover, we recognize the need to explore cross-domain informative content detection, particularly in situations where labeled data for the ongoing disaster might be scarce or unavailable.

Practical Application of AI and Large Language Models in Software Engineering Education

Vasil Kozov[1], Galina Ivanova[2], Desislava Atanasova[3]
Dept. of Informatics, University of Ruse “Angel Kanchev”, Ruse, Bulgaria[1, 3]
Dept of Computer Systems and Technology, University of Ruse “Angel Kanchev”, Ruse, Bulgaria[2]

***Abstract*—Subjects with limited application in the software industry like AI have recently received tremendous boon due to the development and raise of publicity of LLMs. LLM-powered software has a wide array of practical applications that must be taught to Software Engineering students, so that they can be relevant in the field. The speed of technological change is extremely fast, and university curriculums must include those changes. Renewing and creating new methodologies and workshops is a difficult task to complete successfully in such a dynamic environment full of cutting-edge technologies. This paper aims to showcase our approach to using LLM-powered software for AI generated images, like Stable diffusion and code generation tools like ChatGPT in workshops for two relevant subjects – Analysis of Software Requirements and Specifications, as well as Artificial Intelligence. A comparison between the different available LLMs that generate images is made, and the choice between them is explained. Student feedback is shown and a general positive and motivational impact is noted during and after the workshop. A brief introduction that covers the subjects where AI is applied is made. The proposed solutions for several uses of AI in the field of higher education, more specifically software engineering, are presented. Several workshops have been made and included in the curriculum. The results of their application have been noted and an analysis is made. More propositions on further development based on the gained experience, feedback and retrieved data are made. Conclusions are made on the application of AI in higher education and different ways to utilize such tools are presented.**

Keywords—Application of AI-powered software; AI generated images; software engineering; stable diffusion; higher education

I. Introduction

With the release of popular and easy to use text based large language models, Artificial intelligence (AI) chatbots and image generation AI, it has become a necessity to teach students how to properly use them for the correct purposes. A big detriment of using AI by first and second year students is their lack of understanding in the subjects where they are trying to use AI. This sadly leads to less problem-solving thinking and doing actual effort to work on tasks. This in turn leads to less brain development and lack of practical skills. Teaching students how to correctly use such tools to enhance their learning is imperative for developing them into good specialists that may in turn use AI powered software and hardware to their benefit.

The Software Engineering bachelor’s degree was chosen for the inclusion of teaching AI. Based on our experience, the more technically advanced and tech savvy students are more receptive towards the inclusion of new and experimental approaches. This was the main factor in our choice of who to use this approach with. Several subjects were selected, where the methodologies were applied. Workshops and materials to help with training the students were created. In the current report the focus will be on the application of Large Language Models (LLMs) in two subjects - Artificial intelligence (6th semester) and Analyzing system requirements and specifications (5th semester). It will also be discussed how to use LLMs to enhance the subject Introduction to Programming by writing unit tests (while that is still in the testing phase and has only been partially applied), as well as future ideas for the inclusion of image generation AI in Computer Graphics.

In order to apply the tools that contain AI, methodologies have been adapted to suit the needs of the subjects. Two of them will be discussed and the choices that have been made as well as the reasoning behind them will be explained.

II. Application of AI-powered Software

A. Inclusion of AI Assistance in Analyzing Software Requirements and Specifications (ASRS)

At this point in time during their university education, software engineering students have already passed Databases (DBs), Object Oriented Programming (OOP), and some of their Algorithm subjects. They are introduced to the vision on how to lighten their workload using assistive tools powered by AI. ChatGPT is the text generation model that is currently being used, but as new AI chat bots emerge, university staff is testing them and showing students the differences between them.

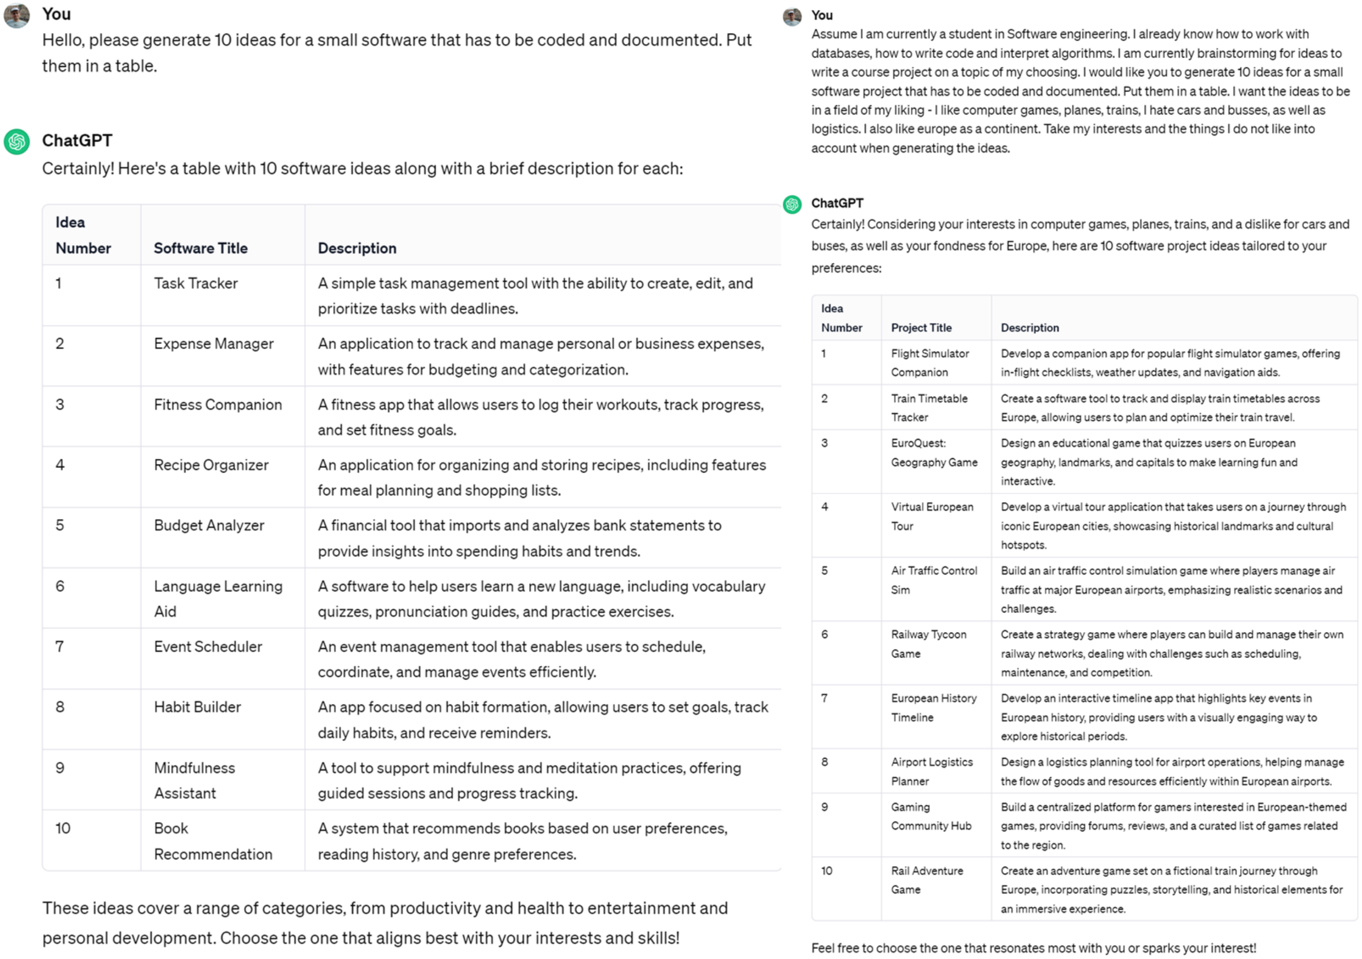
In the subject ASRS, the students are required to submit a project – a software system that they must create and fully document using an iterative process. Our first use of ChatGPT is when we demonstrate its capabilities for idea generation.

As seen on Fig. 1, a description of the problem help is needed with is given on the left, and although it lacks detail, it is a true and valid statement, so the model gives a useful, albeit generic answer. On the right side the LLM is queried using a message that has more details included. It has been decided to include as much relevant information as possible as the specific requirements are narrowed down. A description of the field of study and level of progress in the field is defined – “student in Software engineering”, this can be further expanded by specifying that this is a bachelor’s degree. By noting the current user skillset, the LLM can get software project ideas within the correct scope, omitting unfamiliar technologies. The "course project" part of the message is also a component that will be used to further refine the scope of the ideas, giving them a timeframe. After defining what the LLM is required to do, the specified field is narrowed even further by statements of likes and dislikes. The overall structure of the message on the right helps the LLM print ideas that are more likely to interest the user and are within their means to achieve. The term "prompt engineering" [1] can better help describe this part of the communication with AI. It is highly possible that every person working with LLMs will be required to understand how to express themselves in a meaningful way if they want to be more efficient in the long term. Whether or not that will become a job requirement is speculative, but it is certainly a useful skill to have right now for students.

The logical path in narrowing down the choices that the model must make in its answer looks similar to this hierarchy in this case: field (of study or work) -> constraints (skillset, abilities, requirements) -> environment descriptions (question framework) -> task that has to be completed by the LLM (actual answer format) -> formatting (table, software code, bullet points, queries for other software) -> further requirements (inclusion and exclusion of topics and fields).

It is of course allowed for the students to use their own ideas irrespective of ChatGPT's', and they are encouraged to ask the AI for further fine-tuning – more functional requirements that will help their product become more robust, as well as help them expand their personal vision and make it better. The process is showcased step-by-step in real-time, but a video is prepared in case of service interruption during the demonstration. Outages in the OpenAI services have been less frequent recently, but during the peak hours they still happen, and it is important to have a good backup ready. Creating these videos is like a snapshot in time – it also helps showcase the differences in versions and their progress, as well as the time it takes to answer queries, model differences (3.5 and 4.0), as well as answer consistency. Recording the results has created data points for further research.

A showcase on how the model can play its role is also being created but requires more testing. Researchers have emulated an entire software development team creating and finishing a project [2]. The idea is to showcase how the different roles in a software development process are represented by AI (e.g., "Imagine you are a business analyst working on project 8 - Airport Logistics Planner. What would your workflow be? How would you approach every one of your team members? Please describe your activities using a table."). Current focus is on the fact that users must highly customize their input and requirements gradually if they want to create and document a good and useful product.



You

Hello, please generate 10 ideas for a small software that has to be coded and documented. Put them in a table.

ChatGPT

Certainly! Here's a table with 10 software ideas along with a brief description for each:

Idea Number	Software Title	Description
1	Task Tracker	A simple task management tool with the ability to create, edit, and prioritize tasks with deadlines.
2	Expense Manager	An application to track and manage personal or business expenses, with features for budgeting and categorization.
3	Fitness Companion	A fitness app that allows users to log their workouts, track progress, and set fitness goals.
4	Recipe Organizer	An application for organizing and storing recipes, including features for meal planning and shopping lists.
5	Budget Analyzer	A financial tool that imports and analyzes bank statements to provide insights into spending habits and trends.
6	Language Learning Aid	A software to help users learn a new language, including vocabulary quizzes, pronunciation guides, and practice exercises.
7	Event Scheduler	An event management tool that enables users to schedule, coordinate, and manage events efficiently.
8	Habit Builder	An app focused on habit formation, allowing users to set goals, track daily habits, and receive reminders.
9	Mindfulness Assistant	A tool to support mindfulness and meditation practices, offering guided sessions and progress tracking.
10	Book Recommendation	A system that recommends books based on user preferences, reading history, and genre preferences.

These ideas cover a range of categories, from productivity and health to entertainment and personal development. Choose the one that aligns best with your interests and skills!

You

Assume I am currently a student in Software engineering. I already know how to work with databases, how to write code and interpret algorithms. I am currently brainstorming for ideas to write a course project on a topic of my choosing. I would like you to generate 10 ideas for a small software project that has to be coded and documented. Put them in a table. I want the ideas to be in a field of my liking - I like computer games, planes, trains, I hate cars and busses, as well as logistics. I also like europe as a continent. Take my interests and the things I do not like into account when generating the ideas.

ChatGPT

Certainly! Considering your interests in computer games, planes, trains, and a dislike for cars and buses, as well as your fondness for Europe, here are 10 software project ideas tailored to your preferences:

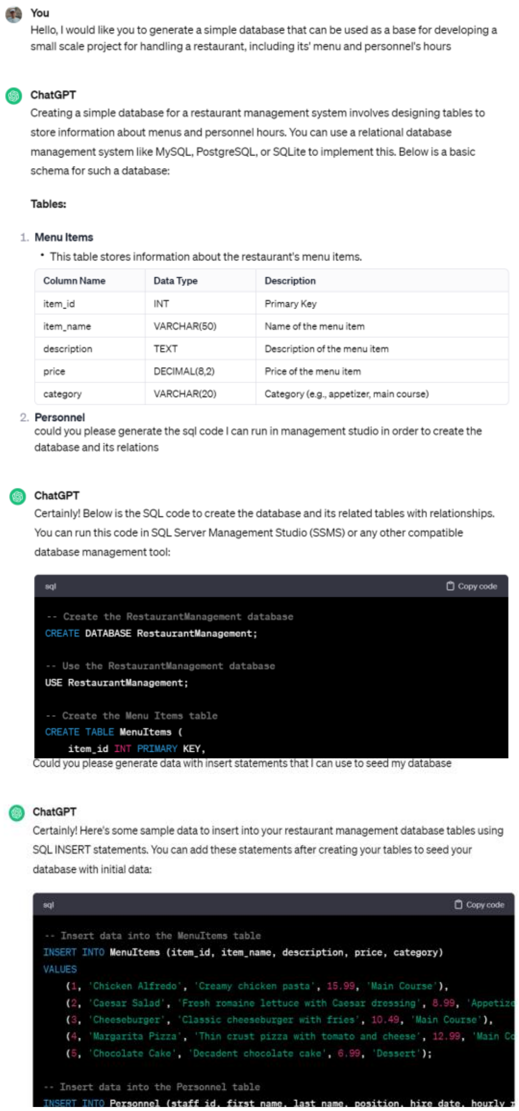
Idea Number	Project Title	Description
1	Flight Simulator Companion	Develop a companion app for popular flight simulator games, offering in-flight checklists, weather updates, and navigation aids.
2	Train Timetable Tracker	Create a software tool to track and display train timetables across Europe, allowing users to plan and optimize their train travel.
3	EuroQuest: Geography Game	Design an educational game that quizzes users on European geography, landmarks, and capitals to make learning fun and interactive.
4	Virtual European Tour	Develop a virtual tour application that takes users on a journey through iconic European cities, showcasing historical landmarks and cultural hotspots.
5	Air Traffic Control Sim	Build an air traffic control simulation game where players manage air traffic at major European airports, emphasizing realistic scenarios and challenges.
6	Railway Tycoon Game	Create a strategy game where players can build and manage their own railway networks, dealing with challenges such as scheduling, maintenance, and competition.
7	European History Timeline	Develop an interactive timeline app that highlights key events in European history, providing users with a visually engaging way to explore historical periods.
8	Airport Logistics Planner	Design a logistics planning tool for airport operations, helping manage the flow of goods and resources efficiently within European airports.
9	Gaming Community Hub	Build a centralized platform for gamers interested in European-themed games, providing forums, reviews, and a curated list of games related to the region.
10	Rail Adventure Game	Create an adventure game set on a fictional train journey through Europe, incorporating puzzles, storytelling, and historical elements for an immersive experience.

Feel free to choose the one that resonates most with you or sparks your interest!

Fig. 1. Comparison between statements for idea generation, showcasing the influence of detailed information to the outcome.

The next step comes when the students have decided on their ideas for each team. At this point they have written most of the requirements, their vision, and they have mostly decided on what technological stack they will use. A showcase on how to create a relational DB that covers their functional requirements is done.

On Fig. 2 the process can be seen – starting with asking for the creation of several versions of the relations in a database and GPT must draw them with tables and connect them. When solutions are iterated several times, the first version of the database is required is completed. At this point SQL statements that will create the DB and its relations are required, specifying the type of software and SQL server they are going to run on. The demonstration currently uses MS SQL server through the Management Studio, but other clients are viable alternatives too – like PostgreSQL or MySQL. The demonstrations do not yet include experimenting with communicating with ChatGPT for NOSQL solutions, due to time constraints, but they are worth looking into.



You
Hello, I would like you to generate a simple database that can be used as a base for developing a small scale project for handling a restaurant, including its' menu and personnel's hours

ChatGPT
Creating a simple database for a restaurant management system involves designing tables to store information about menus and personnel hours. You can use a relational database management system like MySQL, PostgreSQL, or SQLite to implement this. Below is a basic schema for such a database:

Tables:

1. **Menu Items**
   - This table stores information about the restaurant's menu items.

Column Name	Data Type	Description
item_id	INT	Primary Key
item_name	VARCHAR(50)	Name of the menu item
description	TEXT	Description of the menu item
price	DECIMAL(8,2)	Price of the menu item
category	VARCHAR(20)	Category (e.g., appetizer, main course)

2. **Personnel**

could you please generate the sql code I can run in management studio in order to create the database and its relations

ChatGPT
Certainly! Below is the SQL code to create the database and its related tables with relationships. You can run this code in SQL Server Management Studio (SSMS) or any other compatible database management tool:

sql

```sql
-- Create the RestaurantManagement database
CREATE DATABASE RestaurantManagement;

-- Use the RestaurantManagement database
USE RestaurantManagement;

-- Create the Menu Items table
CREATE TABLE MenuItems (
    item_id INT PRIMARY KEY,
```

Could you please generate data with insert statements that I can use to seed my database

ChatGPT
Certainly! Here's some sample data to insert into your restaurant management database tables using SQL INSERT statements. You can add these statements after creating your tables to seed your database with initial data:

sql

```sql
-- Insert data into the MenuItems table
INSERT INTO MenuItems (item_id, item_name, description, price, category)
VALUES
    (1, 'Chicken Alfredo', 'Creamy chicken pasta', 15.99, 'Main Course'),
    (2, 'Caesar Salad', 'Fresh romaine lettuce with Caesar dressing', 8.99, 'Appetize
    (3, 'Cheeseburger', 'Classic cheeseburger with fries', 10.49, 'Main Course'),
    (4, 'Margarita Pizza', 'Thin crust pizza with tomato and cheese', 12.99, 'Main Co
    (5, 'Chocolate Cake', 'Decadent chocolate cake', 6.99, 'Dessert');

-- Insert data into the Personnel table
INSERT INTO Personnel (staff_id, first_name, last_name, position, hire_date, hourly_
```

Fig. 2. Aasking ChatGPT with the creation of a database for a small-scale project.

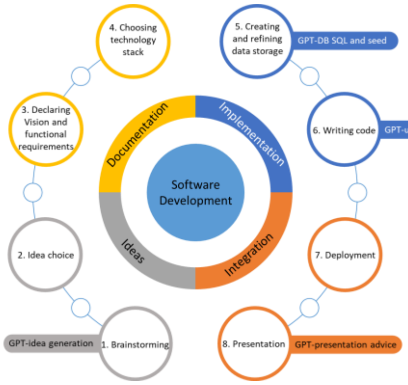


Fig. 3. Inclusion of AI in the software development process in the ASRS subject.

Another important step is showing how to "seed" the database with relevant data. First, a request that simply returns random raw data into several queries is created (see Fig. 3). Afterwards, if necessary, several key points and examples that the message should include in order to get relevant data are defined – for example random data in a special regular expression format is requested. Another option is to give GPT a short list with the example data, or the pattern to which it conforms. GPT can then work with it and iterate on it. This is followed by asking for the insert statements that are used to seed the finished database. There are cases where it has been noticed that there are differences in the format of the required data, as well as problems with relations – the foreign keys are not populated in the corresponding order, which leads to issues. Those issues are easily solvable for students that have passed their database-related subjects and further support the learning experience in working with such tools.

Students are shown how to ask for UI suggestions (mainly HTML and CSS), but as their chosen project tech stacks are different (games, desktop applications, web sites and mobile apps), the use of AI in the development part of the project is concluded here. It is important to note that there are interesting applications for creating unit tests that are mentioned. This part of the subject curriculum is still in development so at this stage students are only shown how to make simple unit tests for C# and how to base them on their functional requirements.

To put the finishing touch to their projects, hints are given on using the roleplaying ChatGPT to help them with their final presentations. A dialogue is shown following a similar structure to: "Hello, you are a business analyst. You are going to present a project on the topic of a flight fleet management software system. Your audience consists of people working in the sector. The project is made using the following technologies: C#, MSSQL, WebSocket, JavaScript and others. What would be your plan to present this project if you only have 15 minutes to talk?". Students are usually very impressed, as most of them are used to using AI tools in other ways.

The use of AI powered software in the different steps of the software development process that is used in the ASRS subject can be seen in Fig. 3. As the focus is on creating requirements, specification and software documentation, it is acceptable to use AI for any of the other steps, as students have already learnt how to complete those by themselves. A strong argument can be made that AI powered chatbots will generate the entire documentation themselves in the near future, but this stage of development is not yet reached. The guiding philosophy is that if students are able to finish a task by themselves and understand it well enough, they should be taught how to automate it at a future point in time.

B. *Inclusion of AI Assistance in the Artificial Intelligence Subject*

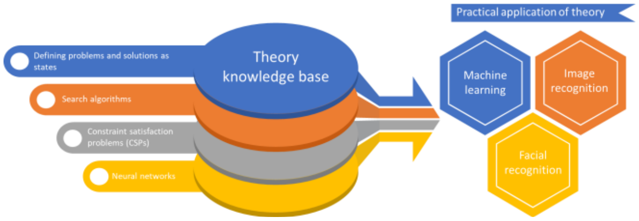
The use of assistive tools with AI in the subject "Artificial Intelligence" is presented in the second half of the semester. Traditionally the first half of the workshop tasks for the students consist of using Python to solve classic AI problems, such as eight queens and different crosswords, while using search and constraint satisfaction algorithms. After the introductory problems are taught, several more advanced topics and workshops are covered. Students are shown neural networks (NNs) - single layered and multilayered. They are tasked with creating several NNs on their own using the Keras library and MNIST data sets. The use of convoluted NNs in various fields such as in finances - predicting financial time series [4], gives the opportunity to teach students the interdisciplinary aspects of software engineering in general. After all, what use is software engineering if there is no field to attach software to? Giving working examples in actual businesses and practical applications gives confidence and generates ideas in our pupils.

In one of the following workshops, instructions on how to use open-source face recognition libraries in Python to detect faces on photos of famous people are included. There are training sets provided that are used to train and validate the model. In the researchers’ experience, doing this workshop takes a significant amount of time – both the process to fulfill all the necessary requirements on each of their personal machines, and then follow the instructions and test the code they have written step by step are time-consuming. After the students have managed to go through all the steps and have created a working piece of software, they are encouraged to train and validate the model using their own set of photos as training sets.

Facial recognition, and image recognition in general, is not a new concept, but it is imperative students are taught how to apply it and use LLM tools on their own product to improve and test it. Students gain more thorough experience on how to modify their software products more efficiently by having access to the ChatGPT terminal, and thus to the entire collective training set using hundreds of billions of parameters that OpenAI have been using and improving.

A simple visual representation of the approach to teaching students in the AI subject is shown in Fig. 4.

The process of preparing additional workshops is constantly undergoing, and some have yet to be completed with students, as the subject is next semester in their curriculum. One workshop includes a comparison in image generation methods for different assisted tools, several of the most popular AI tools are presented - Stable Diffusion, Bing Images, Bard and Dall-E. A sufficiently difficult prompt using weight distribution for each of its parameters is used.



Practical application of theory
Defining problems and solutions as states
Search algorithms
Constraint satisfaction problems (CSPs)
Neural networks
Theory knowledge base
Machine learning
Image recognition
Facial recognition

Fig. 4. Methodology for practical application of theoretical knowledge base in the education of students.

It is worth noting that Bard also hallucinated and tried to say it “drew” an image and responded with a google image search during one of the attempts to make it draw.

Fig. 5, 6, 7 and 8 display some of the collated results that were achieved using the currently most popular available AI-powered models. After multiple attempts, only Bing produced acceptable results, while Bard simply could not create any images itself, and returned googled images in almost all the attempts. The online version of DALL-E could not make images of better resolution and quality than those shown on Fig. 5. It can be said that testing web services in this way is not extensive enough, but when the services are unreliable themselves, produce different results and are in most cases limited, paid or of bad quality, they cannot be reliably used for educational purposes.

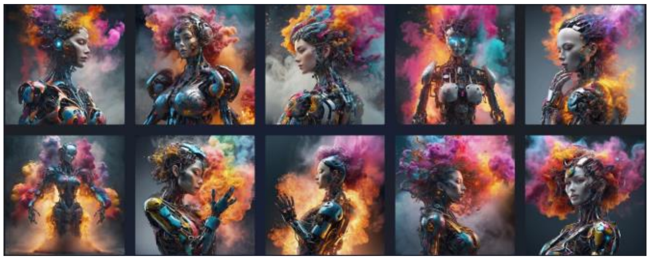


Fig. 5. Using Stable diffusion multiple times using a prompt.

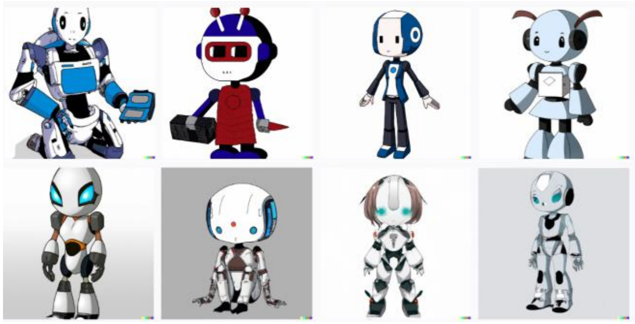

Fig. 6. Dall-E web using a prompt: “please draw a young robot that has a white coat, make the image ultra realistic”.

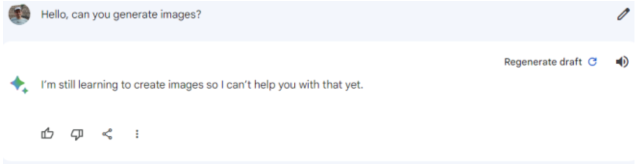
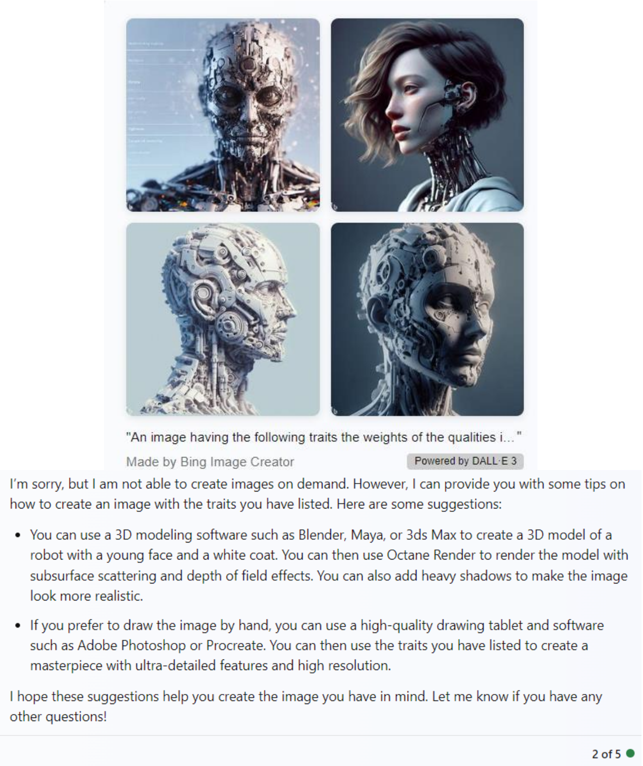


Hello, can you generate images?

I’m still learning to create images so I can’t help you with that yet.

Fig. 7. Bard’s response to drawing prompts.



"An image having the following traits the weights of the qualities i... "

Made by Bing Image Creator

Powered by DALL·E 3

I'm sorry, but I am not able to create images on demand. However, I can provide you with some tips on how to create an image with the traits you have listed. Here are some suggestions:

- You can use a 3D modeling software such as Blender, Maya, or 3ds Max to create a 3D model of a robot with a young face and a white coat. You can then use Octane Render to render the model with subsurface scattering and depth of field effects. You can also add heavy shadows to make the image look more realistic.
- If you prefer to draw the image by hand, you can use a high-quality drawing tablet and software such as Adobe Photoshop or Procreate. You can then use the traits you have listed to create a masterpiece with ultra-detailed features and high resolution.

I hope these suggestions help you create the image you have in mind. Let me know if you have any other questions!

Fig. 8. Bing Images (Dall-E based).

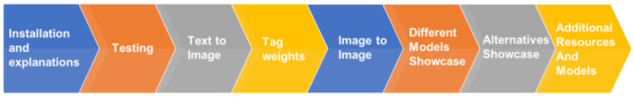
It should be noted that Fig. 6 showcases the result of a very specific prompt with weight distribution that is as follows: “breathtaking, mysterious, fantasy, magical, (female robot:1.5) (creating a machine with hands), surrealism, hyper-realistic, colors and shapes, highly detailed, realism pushed to extreme, fine texture, 8k, ultra-detailed, (vivid swirling smoke, thick smoke:1.4), fluid, fire, cinematic, (intricate details:1.5), (vibrant colors:1.4), flash explosion, (colorful powder explosion), (billowing hair:1.5) "((magical enchantment on hands))" "((creates a machine from hands towards viewer))"”. The LLM allows for incredibly detailed instructions that can be followed, such instructions are unavailable for the other tested tools currently. Fig. 5, 7 and 8 display the limitations of the most popular models. While spectacular results can also be achieved using them, it requires a bigger investment in prompting them, both in terms of time and money (as the paid model tokes are usually limited).

Some advantages and disadvantages are shown in Table I. The best results during the testing were achieved by StableDiffision. All the other services had either service disruptions (Bing, Bard), hallucinations (Bing, Dall-E), required tokens and accounts (Bing, Dall-E), or simply didn’t do as requested (Bing, Bard). The multitude of disadvantages make them unfit to be used in higher education. They are worth looking into further if their future iterations are improved. The currently chosen AI for the future workshops is StableDiffusion. Preliminary testing and scenarios based on the technology are being created and refined.

The methodology that has been adapted for an AI image generation workshop is shown on Fig. 9. It includes stable diffusion and showcases different models and their differences.

TABLE I. COMPARISON BETWEEN THE DIFFERENT AI POWERED IMAGE GENERATION TOOLS

AI	Advantages	Disadvantages	Notes
Bard	Free, on the web. Powered by Google.	Inconsistent behavior – sometimes says it cannot currently generate images; other times returns google image results.	Says it cannot generate images when prompted. After multiple attempts it starts to hallucinate that it can, in fact, generate images. The process itself is erroneous – it returns google image searches instead of generating images.
DALL-E	Free, on the web. Implemented in other software.	Low quality images, uses tokens, results are unsatisfactory.	Has bots in discord that work better than the software itself.
Bing	Free, uses Dall-e.	Only 5 questions. Has memory loss afterwards. Requires Microsoft Edge to work. Sometimes does not work – due to service disruption.	Says that it cannot generate images. Then generates images.
Stable Diffusion	Works offline. Can be downloaded for free. There are various community resources and models available. Active open-source project.	Requires hardware to run. Pre-trained models are at least several gigabytes each. Takes a long time to teach a model if hardware is not powerful enough.	While setting up the software can be difficult, the results are of great quality and require little manipulation before they can be used in production.



Installation and explanations → Testing → Text to Image → Tag weights → Image to Image → Different Models Showcase → Alternatives Showcase → Additional Resources And Models

Fig. 9. Methodology for showcasing AI image generation to software engineering students.

Stable diffusion has an advantage for the current purposes - meaning it can be locally installed for free by anyone, and it doesn't require services or subscriptions. It does have hardware requirements, but they can be satisfied relatively easily for lower image resolutions. There is an enormous number of pre-trained models that are available, as well as learning resources from its community. Several different approaches to combining or altering images after their creation are discussed and prepared for presentation.

C. Introduction to Programming

For many students, the subject is the first time they work with algorithms and needing to understand what they are doing. As it is taught during the first semester, the skill level difference is enormous. Preparing C++ tasks that are relevant and not demotivating is always a challenge everywhere in education [6, 7], some professors have very interesting solutions ways to solve the problem using games [8, 9]. The current established approach is to have automated tests for each small task we give the students, but it is still undecided on whether everyone should be introduced to testing at such an early semester. The benefits of test-driven development (TDD) are unquestionable [10, 11], but it requires a paradigm shift that is based on pre-existing knowledge in programming simple tasks, that many students lack during the first semester. Overloading fledgling software engineers with information is not the goal of the subject. The current idea is to use GPT to automate test creation process for the tasks that are given to the students for each workshop. The unit tests provide a good opportunity to limit test the code of students, but a reasonable way to enable them to access and understand them (as just giving a repository link is difficult for the average first-year student to understand) is not yet found. There are existing frameworks that provide a similar service [12], however they are not fit for this specific purpose.

D. Computer Graphics

There have been discussions on how exactly to integrate tools such as Stable Diffusion and creating applications using technology based on API that works with an AI that is locally deployed, but the complexity of the task is daunting for students at the average skill level during the fifth semester. What has been learned is that there needs to be an in-depth course that helps students familiarize themselves with the usage of image generating software on a deeper level. Software engineers should be able to not only create images – the way they are taught during the Artificial intelligence course, but also understand AI image generating software and how to write code for applications that use the tool themselves. They need to be able to alter the image generating algorithms of the AI models, and create models fit to their projects' needs.

E. Results and Observations

While the Dunning-Kruger effect has an impact on student self-assessment, research has shown that the differences between actual skill (and hence skill improvement) and self-evaluation are within acceptable levels [3]. It can be therefore proposed that students' self-assessment of their own skill improvement is significant enough to warrant noting a positive improvement due to the inclusion of AI in their curriculum subjects. Offloading the burden of menial tasks that can be easily automated leaves ample time for the actual improvement of their own professional interests and creating software products of value. One of the problems that have arisen is how professors evaluate whether the work done has led to improvement in a students' general skills, or just their skill in communicating with AI. That, however, is a complex enough problem to warrant research all by itself.

After questioning the students using a survey, as shown in Fig 10, it has been noticed that there is a good answer distribution among all the questions. It can be concluded that while it is useful, AI powered software needs improvement, and students using it need more experience to use it.

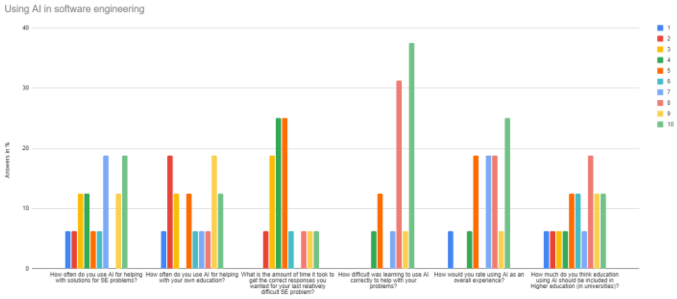


Fig. 10. Methodology for showcasing AI image generation to software engineering students.

What can be said with certainty is that students with the same university background have achieved success in projects that are more complex, more complete, and more in depth than those from previous years. According to the interviews with their teams during their project presentations, AI has certainly played a significant role in "doing the heavy lifting" for most of the teams. The most noticeable improvement is in the lower achieving students – given such powerful tools, they can elevate their skill level to a degree, sufficient for them to be motivated enough to be able to complete a reasonably sized software project. Compared to previous semesters in the same subject - students on the low skill spectrum could not finish as much work in the same amount of time. Elevating the results less skilled learners can achieve is motivating for professors as well. This gives confidence, experience, and motivation to the students, which in turn helps with student retention and an improvement to the system in higher education. Lifting the floor is beneficial to improving educational levels [5].

III. Conclusion

Software engineering students need more exposure to AI tools in higher education. We need to have specialized subjects to help them familiarize themselves with this type of technology. It is imperative that they are not placed in a position where they have to "make do" but have the opportunity to learn how to leverage AI in their projects.

It is important to note that all LLMs often hallucinate, and because of that they are not reliable for checking facts and truth. At this point of their evolution, it is difficult to use them in the same way search engines are trustworthy data sources are used. What they are incredible at though, is giving ideas, workflows, helping with automation and doing the heavy lifting when beginning and polishing projects. This is what we are trying to teach our students, that they must be aware of the strengths and weaknesses of tools that apply AI.

With any emerging nascent technology, there is more testing required in order to make it work better. Familiarizing students with the correct approach to using AI assistive tools - focusing on their strengths and being aware of their weaknesses, is imperative for them to not be in a disadvantageous position in their future careers. As AI grows, everyone not aware of how to take advantage of it will quickly become a less valuable employee for the business. Starting too early is detrimental to brain development and problem-solving skills, but starting late is detrimental to career opportunities and life quality. Communication skills will become even more important in the future but acquiring them will require more effort with the further digitization of communication and the lessening of social relationships people experience.

ACKNOWLEDGMENT

This research is supported by the Bulgarian Ministry of Education and Science under the National Program “Young scientists and Postdoctoral Students – 2.

***Abstract*—Data clustering reduces the number of data objects by grouping similar data objects together. In this process, data are divided into valuable groups (clusters) or expressive without at all previous information. This manuscript represents a different clustering algorithm based on the technique of the adaptive strategy algorithm known as Self-Adaptive Bacterial Foraging Optimization (SABFO). It is a streamlining strategy for bunching issues where a cluster of bacteria forages to converge to definite locations as ultimate group communities by limiting the fitness function. The superiority of this method is assessed on numerous famous benchmark data sets. In this paper, the authors have compared the projected technique with some well-known advanced clustering approaches: the k-means algorithm, the Particle Swarm optimization algorithm, and the Fitness-Based Adaptive Differential Evolution (FBADE) Scheme. An experimental finding demonstrates the usefulness of the projected algorithm as a clustering method that can operate on data sets with different densities, and cluster sizes.**

Keywords—Data clustering; Self-Adaptive Bacterial Foraging Optimization (SABFO); Particle Swarm Optimization (PSO); FBADE scheme; the k-means algorithm and the classical BFO

I. Introduction

A method of analyzing and clustering unlabelled datasets is known as unsupervised machine learning. It is possible to find out the unknown patterns or data groupings using these algorithms without the involvement of human action. In the domain of cross-selling strategies, client segmentation image recognition, etc. The authors can employ the above strategies to find underlying patterns. It also enables us to discover similarities and differences in information. In short, a type of machine learning called unsupervised learning involves training models using unlabelled datasets and allowing them to act upon them without supervision. As opposed to supervised methods, clustering is an unsupervised method that works with datasets that do not have outcomes (target) variables or information about associations among explanations. The clustering algorithm is the key to data analysis and identifying groups (natural clusters). As a result of this process, similar data points are identified and grouped. Clusters make it easier to characterize the attributes of distinct entities. Users can then shift data and analyze certain categories as a result of this. Clustering allows organizations to address distinct client segments based on their attributes and similarities. This aids in profit maximization. If the dataset has too many variables, it can aid in dimensionality reduction. Irrelevant clusters can be detected and deleted from the dataset more easily.

For more than two decades, clustering has taken particular interest among scientists and researchers to apply in versatile domains. Researchers are continuously trying to develop better approaches to clustering.

In order to build knowledge-driven decisions, data mining provides upcoming behaviors that businesses can predict [1]. A clustering technique deals with discovering a structure in an unlabelled collection of data through unsupervised learning [2]. A data cluster is used in order to divide the enormous number of objects into smaller groups, so the objects with similar characteristics are clustered together, and the ones with dissimilar characteristics are in different groups [3]. A cluster is considered too many when it exceeds three, clustering becomes NP-complete, and it is, therefore, challenging to develop a well-organized clustering technique [4]. The clustering problem can be useful for segmenting images [5], clustering documents [6], predicting diseases [7], wireless-related sensors networks [8] analyzing common networks [9], identifying the traffic in the network [10], retrieving information [11], and marketing [12].Partitional clustering is being used in a numbers of real-life applications. It is an algorithm for dividing data objects into small groups based on defined criteria called the distance between them. Data samples are dispersed from one group to another iteratively according to the number of groups determined prior to implementation. To begin, it makes a set of partitions based on a definite measure. Data samples are divided into corresponding groups according to their centres [13]. K-means is the utmost widespread and fashionable algorithm among the partitional clustering algorithms as it is more practical and effective when handling heavy amounts of data. This algorithm's main drawbacks are its sensitivity to the initial cluster centres, inability to find global minima, and convergence to the local optima. Research on the improved BFO algorithm found that the algorithm has some limitations, including a fixed chemotactic step size and feeble bacterial connections.

As a result of the static chemotactic step size, it is problematic to strike the right balance among exploration and exploitation. Secondly, the feeble connection between bacteria shows a poor random city in chemotaxis. As a result of these two drawbacks, the bacteria community will search for a compound multimodal solution set at a local level rather than at a global level when compared to a global convergence.

An approach using self-adaptive BFO (SABFO) is proposed in this paper as one of the novelty of this article. It improves the classical algorithm hypothetically in two ways. By leveraging bacterial search state features, the self-adaptive swimming process overcomes the traditional drawback caused by fixed step sizes. This paper extracts and calculates three vital qualities of the bacterial search state, namely the variety of the population, the number of iterations, and the mean fitness function.

The aim of this manuscript is to propose a new approach to clustering optimization technique, namely SABFO, which will provide performance optimization as the source of data grouping. A new perspective for solving NP-hard clustering problems is provided by Bacterial Foraging Clustering, a global optimization-based technique rather than high speed local search. At the same time, it's a new version of the Bacterial Foraging Optimization technique. In this proposed algorithm there is no need to select the centroid or center required to be chosen in the primary steps.

Further, the proposed algorithm aims to overcome two drawbacks of conventional algorithms:

1) The projected clustering technique achieved a high degree of accuracy as compared with other algorithms.

2) High-dimensional data can be processed resourcefully with the proposed algorithm.

The rest of this manuscript is planned in a subsequent way. In Section II, the literature review is introduced. Section III illustrates the preliminary knowledge of the BFO algorithm and optimization-based clustering. Section IV illustrates fully the entire method of the recommended SABFO-Clustering algorithm. In Section V, the authors present the numerical illustration for the datasets used in this paper. Sections VI and VII summarizes the results and discussion, respectively. Finally, Section VIII shows the manuscript's conclusion and future work.

II. Literature Review

The foraging performance of 18 Escherichia coli in the human being intestinal tract was studied, Passino [14] proposed a bacterium foraging optimization (BFO) algorithm in 2002 for optimizing 17 problems. Despite the 19 BFO algorithm's superiority over several other algorithms, 20 its convergence speed 21 and global search capability need to be improved, because it is extremely simple to fall into local optimal outcomes and convergence is slow.

Different clustering algorithms in recent years have been projected such as segmentation, density based hierarchical, grid-based, and model-based. By using partitioning, the authors can create partitions based on a number of criteria. The pattern belongs to only one cluster when using hard Partitional clustering. Clustering by fuzzy rules extends this notion by allowing patterns to belong to more than one cluster.

During the last few years, the BFO algorithm has often been combined 49 with other algorithms in various fields, Ofosu et al. In 50 [13], the proportional integral and derivative controllers 54 were unable to overcome the difficulties encountered in obtaining optimal PI gains 51 for fuzzy-PI controllers.

An optimal allocation model based on risk has been proposed by Xiong and et al. [15] and a multi-objective optimization57 problem has been solved by merging gradient particle, 58 swarm optimization with bacterial optimization reduces the risks associated with distributed 60 generation and facilitates the advancement of and implementation of distributed generation.

Guo and Zhou [16] employed the trapezoid quadrature formula 65 in combination with the 64 BFO techniques to compute integrals since 64 integrable functions have many primitive functions that aren't elementary. Table I represents the tabular form of literature review with year, Technique and results used by the authors.

III. Preliminaries

A. BFO based Clustering

The process of clustering is a data mining method that involves classifying objects without any prior knowledge (clusters).It is possible to formalize the clustering problem as follows, given a sample data set X=(x_(1,) x_(2 ,)……x_(n)),It is possible to formalize the clustering problem as follows, given a sample data set ,determine a partition of the objects into K clusters which satisfies:

$$\cup_{i=1}^{k} C_i = X; \tag{1}$$

$$C_i \cap C_j \left\{ \neq \emptyset \;,\; i,j = 1,2,\ldots\ldots..k;\;\; i \neq j \right. \tag{2}$$

$$C_i \;\neq \theta \quad i = 1,2,\ldots\ldots..k$$

In the mathematical point of view, cluster C_i can be obtained by:

$$\begin{cases} |C_I = \{x_j | \|x_j - z_i\| \leq \;\|x_j - z_p\|, x_j \;\in X\} \\ q \neq 1, q = 1,2\ldots\ldots\ldots..k \\ z_i \;= \frac{1}{|C_i|} \sum_{C_j \in C_i} x_j \,, i = 1,2,\ldots\ldots..K \end{cases} \tag{3}$$

Where,‖.‖ Signifies the length between of any two data points in the trial set, and z_i =the centre of cluster C_i .

B. The Classical BFO Algorithm

BFO algorithm is enlivened with a movement known as "chemotaxis" showed by bacterial foraging ways of behaving. Motile bacteria like E. coli and salmonella impel themselves by the turn of the flagella. An organic entity swimming or running forward is caused by the flagella turning counterclockwise, while a bacterium that makes a clockwise pivot tumble about with haphazard motion and swims once again. The bacterium can look for nutrients in any direction by switching among "swim" and "tumble" motions. The bacterium begins to swim more often as it gets closer to a nutritional gradient. Bacteria move away from some nourishment to search for further, resulting in tumbling, hence direction changes. Chemotaxis, in its simplest form, involves bacteria swimming and tumbling to reach advanced concentrations of food.

C. Bacterial Foraging Optimization

The three main mechanisms that make up the classical BFO system are chemotaxis, reproduction, and elimination-dispersal. Here are quick summaries of each of these processes:

1) The basic chemotaxis: Chemotaxis for bacteria is the course of the accumulation to nutrient-enriched regions. Bacterial movement designs incorporate both tumbling and swimming. Flips are the unit step lengths that bacteria take when moving in any direction. The extent to which adjustments are necessary determines whether the new position is more attractive than the opposite position. Then, the bacterium will keep up shifting in a more excited propensity for a couple of steps till the limit for variation is not any more shut. The enhanced method will be

$$Q_i\,(\,j+1,k,l) = \;Q_i\,(j,k,l) + \frac{\Delta_i}{\sqrt{\Delta^T\,(i)\Delta_i}}\;C(i)n \tag{4}$$

Here, $Q_i\,(\,j+1,k,l)$symbolize the ith bacterium at the jth chemotactic, kth denotes the reproductive, and lth represented the elimination dispersal steps. $C(i)n$ is denoted as the trend step length of bacteria i in a random direction and Δ lies between −1 and 1 as a random vector.

2) Swarming: The chemotactic behavior of bacteria is not limited to searching for food individually but also includes both gravitation and repulsion between them in the foraging process. A bacteria's attractive information causes it to move to the center of the population, thus fetching the bacteria closer together. Yet, the bacteria's repulsion information keeps them at a distance from each other at the same time.

3) Reproduction: Eventually, bacteria with weak feeding abilities will be removed, while bacteria with robust feeding capabilities evolve to breed offspring to continue the population size. This process follows the usual method of survival of the fittest. The authors proposed a reproduction operation based on simulating this phenomenon. A chemotaxis operator performed by S/2 bacteria eliminated bacteria with poor fitness and let those with higher fitness self-replicate in S-sized populations.

A completed reproduction operation ensures that the offspring inherits the superior characteristics of the parents, and it also results in the protection of the good individuals and the acceleration of the progress towards an optimal global outcome. Fig. 1 represents the basic structure of the Bacteria Foraging Optimization algorithm.

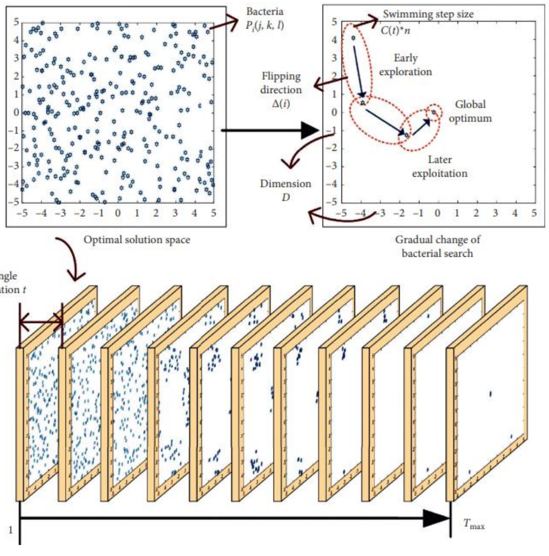

Fig. 1. The basic organization of the Bacteria Foraging Optimization algorithm.

4) Elimination: It is important not to rule out the possibility that unexpected conditions might cause bacteria to die or migrate to a new location during bacterial foraging. It has been proposed to model this phenomenon by simulating elimination-dispersal operations.

IV. Proposed Self-Adaptive BFO (SABFO)

Chemotaxis is a crucial tool in exploring and exploitation of the BFO algorithm during the search for the optimization space. The consequence of chemotaxis depends on the size of the steps and the direction the swimmer flips.

Two improvements are proposed in this paper to get better performance of the BFO algorithm, including extracting and calculating the features of the search state and increasing bacteria's communication. The SABFO algorithm provides a novel BFO algorithm to design dynamic self-adaptive swimming and flipping motions for bacterial cells with these two improvements.

It seems that the method of calculating swimming step size depends on the single swimming step size, C(t), as well as the quantity of chemotaxis, n, as indicated by the above researcher. An algorithm's performance can be adjusted to the ebb and flow state of search based on the size of the swimming steps. At the point when the pursuit state is in the beginning phase, the calculation needs the investigation capacity for worldwide pursuit; then, at that point, in the later stage, the abuse capacity is expected for nearby turn of events.

For various optimization issues, the difference in the BFO search state is likewise unique. In the meantime, on the grounds that the chemotaxis method is nonlinear and it is very complex to such an extent that the progress from the worldwide investigation to the nearby double-dealing can't be essentially depicted and separated by the way of logical conditions.

The proposed paper separates the three components of the BFO in every search state so that the authors can better understand the unique change of the BFO algorithm to the suitable chemotaxis swimming, including iteration, population diversity, and mean fitness. Fig. 2 represents the bacterial population position of BFO Algorithm.

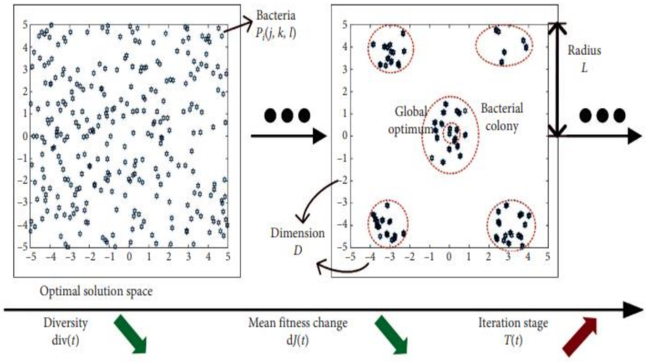

Fig. 2. The bacterial population position of BFO algorithm.

The population diversity of bacteria refers to where it is dispersed. A wider range of bacteria dispersing will increase population diversity, and vice versa. As part of the chemotaxis process of BFO, this manuscript measures the bacterial colony's population diversity.

$$div(t) = \frac{1}{D*S}\; g\sqrt{\sum_{i=1}^{S}\left(\frac{Q_i(j,k,l)-\overline{Q_l(j,k,l)}}{|L|}\right)} \tag{5}$$

Where div (t) is the range between [0, 1], L denotes the solution space's elongated radius. This method measures the distance between the center of each bacterium and the solution space, regardless of the amount or dimension of the bacteria.

The iteration of the BFO algorithm is communicated through a boundary T, which is characterized as an articulation in the reach of [0,1] in equation 6, where t and T_{max} address the record of the current chemotaxis and the most extreme emphasis, separately. Hence, the meaning of parameter T is for the most part suitable to various algorithms regardless of how the parameters, the aspect, with the arrangement space which are programmed into the algorithms:

$$T(t) = \frac{t}{T_{max}} \tag{6}$$

The modification in the mean fitness function is in two chemotaxis processes, where dJ is primarily calculated as one of the essential values for examining the BFO algorithm. To provide a common explanation, the difference in the mean fitness dJ is characterized in the per-unit structure inside [−1,1] as follows:

$$dJ(t) = \frac{J(t)-J(t-1)}{J_{Max}-J_{Min}} \tag{7}$$

Where, J_{Max} andJ_{Min} denotes the maxima and minima of the fitness function, respectively. Fig. 3 shows the flowchart of the proposed algorithm SABFO.

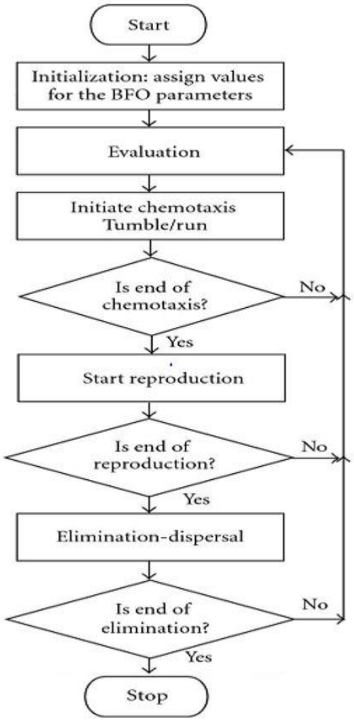

Fig. 3. The flowchart of the proposed algorithm.

So, in this proposed manuscript, the 03 most important variables are the population diversity, the number of iterations and the bacteria's mean fitness value is used as input, which is intended to examine the pursuit status of the algorithm in these manuscripts. As the chemotaxis will be changed as per accompanying with the swim processes are as follows:

$$\begin{cases} n(t+1) = n(t) + dn(t) \\ C(t+1) = C(t) g C_M(t) \end{cases} \tag{8}$$

Where, the 02 output variables are the bacterial swimming movement increases $dn(t)$ [0.01, 1].as well as the bacterial swimming step multiple is C(t) (0, 1).

Another important operation of the BFO algorithm is flipping the bacteria. The direction of chemotaxis is determined by the extremum of each bacterium when swimming. Despite its benefits to the randomness of the search, this method results in a slower search because of blocked information among the bacteria. Therefore, BFO algorithms with suffer from the drawback of tumbling into the local optimum.

In order to resolve the issue, mentioning individuals' data exchange information strategy is used in BFO. So, the BFO algorithm is updated and the flipping variable is given by

$$\Delta_{t+1}(i) = wg\Delta_t(i) + C_1 R_1 \left(P_{local} - P_{N_c}\right) + C_2 R_2 \left(P_{global} - P_{N_c}\right) \tag{9}$$

By adjusting the co-efficient, the chemotaxis process is used in the above-mentioned equation.

Where w, denotes the chemotaxis inertia of the bacteria at a specific distance.

During bacterial chemotaxis, C1 signifies the amount at which each bacterium travels toward its distinct optimal value P_{local}, whereas C2 records the global optimum value P_{global} for all bacteria. For improving the randomness of bacterial flipping and enhancing search ability, R1 and R2 are random the values between 0 and 1. The flowchart of the algorithm is shown in the Fig. 3.

V. Numerical Illustration

In order to compare this proposed approach to Self-Adaptive BFO, five real-life data are Iris [35], Glass [35], breast cancer [35], Wine [35] and Vowel Dataset [35] were used in this proposed paper.

Real- Life Data Sets

- Iris Data: It comprises of three distinct types of iris blossom.
- Glass: The information was examined from six dissimilar kind of glass.
- Breast cancer: It comprises of 9 applicable highlights.
- Wine Data set: It is the outcome of a chemical analysis of wine. This analysis is resolved with the quantities of 13 constituents shown in every one of the three kinds of wine.
- Vowel Dataset: It comprises of 871 Indian Telugu vowel sounds.

The authors have used the following real-life datasets in this proposed paper. Table II represents the data set used in the manuscript.

TABLE II. The Datasets Used

Real-Life Dataset	n	D	K
Iris plants [35]	150	4	3
Glass[35]	214	9	6
Wisconsin breast Cancer data set[35]	683	9	2
Wine[35]	178	13	3
Vowel Dataset[35]	871	3	6

Where, n represents number of data points. D represents number of features and K represents no. of Cluster.

Similarly Table III represents the value of parameter used in the article.

TABLE III. Value of Parameter

Algorithm Name	Parameter Name	Value
FBADE	Population size	10*dim
	Crossover	0.9
	Mutation	0.8
	K_{max}	20
	K_{min}	2
K Mean	Population size	50
	μ_c	8
	μ_m	0.001
	K_{max}	20
	K_{min}	2
PSO	Population size	100
	Inertia Weight	0.72
	C_1, C_2	1.494
	$P_{initial}$	0.75
	$K_{maximum}$	20
	$K_{minimum}$	2
SABFO	Population size (S)	50
	N_C (No. of Chemotactic Steps)	100
	N_S (Length of One swim)	4
	N_{re}(No. of reproduction steps)	4
	N_{ed} (No. of elimination dispersal events)	2
	P_{ed} (Probability of elimination dispersal events)	0.25

VI. Result Analysis

Three performance metrics have been used to compare the SABFO algorithm with other evolutionary algorithms as state-of-the-art clustering techniques:

1) Performance metrics in the CS and DB domains as well as the number of misclassified items for each dataset;

2) Finding the optimal number of clusters; and

3) Computing time.

It is first necessary to measure the fair time of stochastic algorithms like PSO, FBADE, SABFO, and K Mean in order to compare their speed. Meanwhile the algorithms perform a dissimilar amount of work within their inner loops, as well as having different populations, the number of runs or generations cannot be used as a time measurement. Thus the authors choose to calculate computation time based on the number of fitness function evaluations (FEs) rather than the number of generations and iterations. When function complexity increases, counting the FEs is a reliable gauge of runtime complexity because it corresponds strongly with actual processor time.

Generally, two successive runs of four competing algorithms do not match because they are stochastic. As a consequence, the authors conducted 50 independent runs of each algorithm using different seeds. Based on the 40 runs, each result is expressed as a mean and standard deviation. As the various leveled agglomerative calculation utilized here, utilizes no developmental strategy, the amount of function evaluations isn't applicable to this technique. In this algorithm, the authors use the Ward updating equation to efficiently calculate cluster distances given the number of clusters for each problem.

Depending on the clustering validity measure used, any of the four evolutionary clustering algorithms will perform well. A CS measure-based fitness function is used in one set of experiments, while a DB measure-based fitness function is used in the other set of experiments. Four partitional clustering algorithms have been evaluated in terms of CS and DB calculation against the average-link metric based hierarchical method for each dataset.

This algorithm was run in Matlab 2010 under Windows 11 using an Intel Core i5 computer having 3.60 GHz speed and 8 GB of RAM.

The SABFO algorithm continues to offer superior clustering accuracy to each of the other three competitors as shown in Table IV. Tables IV and V represent the first four evolutionary algorithms (using the CS measure), mean classification error and standard deviation over nominal partitions were determined over 40 independent runs.

TABLE IV. 10^6 FUNCTION EVALUATIONS (FES) WITH CLUSTER STRICTNESS (CS)

Name of the Dataset	Algorithm	Avg No. of clusters found	Value of CS calculated	Mean Intra cluster Distance	Mean Inter cluster Distance

Fig. 10 can classify the data set which contain overlapped clusters very efficiently and it also the ability to cluster data sets with high dimension as compared to Fig. 11, 12 and 13.

VII. Discussion

As can be seen in Table IV, the SABFO algorithm continues to offer clustering accuracy that is superior to that of the other three competitors. The first four evolutionary algorithms are shown in Tables IV and V. The mean classification error and standard deviation over nominal partitions were calculated after 40 independent runs using the CS measure.

CS and DB record values were decreased by the SABFO inside a base number of capability assessments in most of cases, as displayed in Tables VI. According to Table VI, SABFO keeps on giving better bunching exactness than the other three contenders. Passages of Genuinely tremendous contrasts among SABFO and its rivals are obvious in Table VI, just for bosom disease, FBADE yield a lower DB esteems than SABFO.

Clustering problems that have several data items, clusters, and overlapping cluster shapes have noticeable performance changes. The clustering accuracy of SABFO is consistently superior to that of its competitors in both Tables IV and V. The FBADE and SABFO methods have two clusters nearly same every time when it's run for the breast cancer dataset, despite having very similar final CS indices. Entries of Statistically significant differences between SABFO and its competitors are evident in Table VI, only for breast cancer, FBADE yield a lower DB value than SABFO.

The results of Tables V and IX indicate that the SABFO produces the fewest misclassified items after clustering. Although all five algorithms demonstrated convincing performance, there were misclassifications in each experiment based on the nominal classification, as expected. In this proposed evolutionary clustering algorithms, the authors found that the fitness values obtained were much better than those obtained from the insignificant classification, which represents that optimization cannot explain through misclassification. As a result, misclassification is caused by underlying expectations in the clustering fitness values (such as clusters' spherical shape), outliers in the dataset, and errors in data collection and nominal solutions. This is indeed not a negative result. Clustering solutions based on statistical criteria and minor classifications can be compared to reveal interesting data points and anomalies. Using a clustering algorithm to pre-analyze data in this way can be very useful.

According to Tables IV and VIII, both the CS and DB indices reached their cut-off values within a minimum number of FE's.

VIII. Conclusion

A SABFO algorithm was proposed in this manuscript to address the fixed step size of the classical BFO algorithm as well as weak correlation among bacteria. Self-adaptive chemotaxis is an adaptation of the self-adaptive swimming technique depends on bacteria's state of search features, combined with enhancement of chemotaxis flipping based on exchange of information.

A comparison of the SABFO algorithm on 05 data sets was conducted by the PSO algorithm, the FBADE algorithm, the K-Mean algorithm and the classical BFO. It was found that SABFO's algorithm is accurate and effective at determining optimal solutions based on the validation results. The SABFO algorithm was also demonstrated to have better exploitation abilities in the future stages and having a more steady search performance.

In brief, the SABFO algorithm has a good stability between exploration and exploitation, which reduces the risks of local convergence. Further it can overwhelm the aforesaid two shortcomings of traditional BFOs.

Additionally, the SABFO algorithm is very stable and performs well when searching. Due to this, SABFO provides an efficient and novel way to accord with complex optimization issues.

In the above table, it appears that all four competitor algorithms terminated with similar accuracy for all the datasets. Based on the proposed algorithm, the CS and DB are found very lowest as per Table IV and VIII. In addition, SABFO successfully found the near-exact number of classes over consecutive iterations (three for iris and Wine data sets).For future researchers, there is a lot of scope to improve the proposed variants that may give much more excellent results on real-world optimization problems.

Traffic Flow Prediction in Urban Networks: Integrating Sequential Neural Network Architectures

Eva Lieskovska, Maros Jakubec, Pavol Kudela
University Science Park, University of Zilina, Zilina, Slovak Republic

***Abstract*—The rapid growth of urban areas has significantly compounded traffic challenges, amplifying concerns about congestion and the need for efficient traffic management. Accurate short-term traffic flow prediction remains important for strategic infrastructure planning within these expanding urban networks. This study explores a Transformer-based model designed for traffic flow prediction, conducting a comprehensive comparison with established models such as Long Short-Term Memory (LSTM), Bidirectional Long Short-Term Memory (BiLSTM), Bidirectional Gated Recurrent Unit (BiGRU), and Time-Delay Neural Network (TDNN). Our approach integrates traditional time series values with derived time-related features, enhancing the model's predictive capabilities. The aim is to effectively capture temporal dependencies within operational data. Despite the effectiveness of existing models, internal complexities persist due to diverse road conditions that influence traffic dynamics. The proposed Transformer model consistently demonstrates competitive performance and offers adaptability when learning from longer time spans. However, the simpler BiLSTM model proved to be the most effective when applied to the utilized data.**

Keywords—Traffic flow; short-term prediction; machine learning; transformer

I. Introduction

Urbanization and the subsequent surge in vehicular traffic pose challenges to the efficiency and sustainability of urban transportation networks. The intricate interplay of dynamic factors, including population growth, urban expansion, and evolving commuter behaviours, necessitates innovative solutions for managing traffic flow. In particular, the advent of advanced predictive models has emerged as a cornerstone in addressing the complexities inherent in urban traffic dynamics [1], [2].

Traffic flow prediction, an important component of intelligent transportation systems, facilitates proactive traffic management, congestion alleviation, and resource optimization. This predictive capability is increasingly crucial in urban planning and policymaking. Precise insights into future traffic patterns empower decision-makers to devise effective strategies for infrastructure development, traffic routing, and overall enhancement of urban mobility. Understanding population behaviours within transport models, especially in relation to mode choice for trips, forms a critical aspect that can influence the precision and application of predictive traffic models [3].

In the domain of traffic flow prediction, the quest for accurate, adaptive, and efficient models has intensified, given the important role of predictive systems in optimizing urban transportation networks. Traditional models, including Long Short-Term Memory (LSTM), Gated Recurrent Unit (GRU), Bidirectional Recurrent models and Convolutional Neural Networks (CNNs) such as Time-Delay Neural Network (TDNN), have significantly contributed to unravelling temporal dependencies within traffic data [4].

The introduction of the Transformer architecture [5], initially developed for Natural Language Processing (NLP) tasks, has paved the way for sequence modelling in various domains. Known for its distinctive attention mechanisms, this architecture revolutionises sequential data processing by employing self-attention mechanisms. This allows for a deeper comprehension of intricate relationships within sequences. The ability to discern temporal correlations has highlighted its potential application in traffic flow prediction models [6]–[8].

In this study, we undertake the task of forecasting future vehicle counts based on historical observations, with a specific focus on univariate traffic flow forecasting. The objective is to harness the capabilities of a transformer, which excels at discerning intricate traffic dynamics. The aim is to analyse how well it can decode complex traffic patterns by capturing time-related nuances and dependencies within the traffic data. Furthermore, we compare the performance of the transformer with the established neural networks for sequence modelling, such as LSTM, Bidirectional Long Short-Term Memory (BiLSTM), Bidirectional Gated Recurrent Unit (BiGRU), and TDNN. The incorporation of temporal features and the evaluation of distinct past observation intervals might yield additional insights for our analysis.

The paper is organized as follows: Section II provides an overview of existing traffic flow prediction models, Section III offers a detailed description of the prediction models, Section IV explains the experimental setup and evaluation methodologies, and Section V presents an analysis and comparative assessment of results. In Section VI, the discussion of the results is presented, and Section VII concludes with remarks that outline implications for future research.

II. Related Works

The evolution of time series prediction has been marked by advancements in data analysis, machine learning, and computational power. Initially, time series prediction relied on statistical (or parametric) methods such as Autoregressive (AR) and Moving Average (MA) models [9], [10]. These models are the building blocks of the Autoregressive Integrated Moving

Average (ARIMA) model [11], which remains a common approach for time series prediction to date. These methods assumed that future values depend linearly on past observations and aimed to capture the underlying trends and patterns.

Another frequently used method is employing Kalman filtering [12], [13]. Due to dynamic traffic conditions and the nonlinear nature of traffic flow, parametric methods may struggle to effectively capture traffic features. As a result, there has been a shift in focus towards non-parametric machine learning methods in the field of traffic flow forecasting [4]. Decision trees, k-nearest neighbour (k-NN) [14], Support Vector Machines, and Neural Networks (NNs) started making their way into the domain. However, challenges remained in handling the temporal dependencies inherent in time series data.

The resurgence of interest in neural networks, particularly Recurrent Neural Networks (RNNs), marked a significant milestone. RNNs, with their ability to capture sequential dependencies, demonstrated improved performance in time series prediction tasks. LSTMs are a type of RNN, which have shown the ability to extract complex correlations in non-linear traffic data and capture long-term dependencies. The study conducted in [15] compares the LSTM architecture with models such as random walk, support vector regression, wavelet neural network, and the stacked autoencoder, emphasizing its favourable outcomes in short-term traffic flow prediction. The hybrid LSTM proposed in [16] optimizes its structure and parameters to adapt to various traffic scenarios. Comparative analysis reveals that the hybrid LSTM model outperformed other typical models (Fuzzy C-Means, Kalman filter and LSTM) in terms of prediction accuracy. This improvement in accuracy was achieved with only a marginal increase in processing time compared to LSTM model.

The performance comparison between LSTM and its simplified counterpart GRU, indicates that GRU outperformed LSTM when the past observation sequences were small [17]. On the other hand, LSTM performed better with more complex datasets and required the use of extended sequences to predict future traffic volume. A comparative analysis with benchmark models proposed in [18], including ARIMA, LSTM, BiLSTM, and GRU, indicates the superior performance of the BiGRU model. The bidirectional model utilizes preceding and succeeding time sequences to extract additional traffic flow information. Notably, deep learning methods, including Bi-GRU, outperformed the traditional ARIMA model in prediction accuracy, particularly during peak periods. However, the BiGRU model exhibited a slight lag in traffic flow prediction.

Recent advances in time series forecasting using Transformer models are gaining traction in the field of traffic forecasting. Known for their prowess in cross-sequence tasks, these models have been refined to predict temporal data, fundamentally transforming conventional methodologies by optimizing computing processes and capturing extensive dependencies. Cai et al. [6] focused on addressing spatio-temporal dependencies in traffic forecasting. Their Traffic Transformer architecture, inspired by the Transformer framework and Graph CNNs, adeptly managed periodicity, and spatial dependencies. It showcased superior performance with real-world traffic datasets. Reza et al. [7] introduced a multi-head attention-based transformer model for traffic flow forecasting. The model demonstrates greater efficiency in capturing prolonged traffic flow patterns compared to recurrent-based models. However, to achieve optimal performance, the proposed transformer required substantial amounts of training data. Existing studies predominantly concentrate on short-term predictions, creating a gap in long-term traffic forecasting research. Tedjopurnomo et al. [8] stress the significance of extending prediction to 24 hours for better congestion planning. To overcome limitations in current recurrent structure-based models for long-term traffic prediction, they introduce a modified Transformer model named TrafFormer, incorporating time and day embedding. Experimental results highlight the superior performance of their proposed model compared to existing hybrid neural network models.

III. Methods

This section delineates the intricacies of sequential neural network architectures—LSTM, BiLSTM, BiGRU, TDNN, and Transformer—applied in the domain of traffic flow prediction models.

A. *Long Short-Term Memory and Bidirectional Long Short-Term Memory*

LSTM, an extension of a Vanilla RNNs, presents a robust architecture aimed at resolving the limitations of conventional RNNs in capturing long-range dependencies. Addressing the vanishing gradient problem inherent in RNNs, LSTM units incorporate a memory cell (c_t) that persists and evolves over time steps.

At each time step, LSTM units navigate through three gates: the forget gate (f_t), input gate (i_t), and output gate (o_t). These gates modulate the flow of information, orchestrating the update and retention of information within the cell state. The LSTM architecture is shown in Fig. 1.

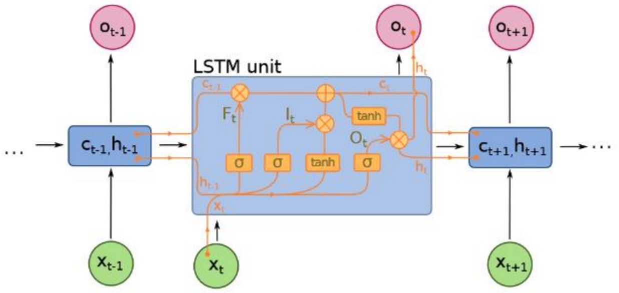

Fig. 1. Graphical visualization of the functioning of the LSTM unit.

Each gate within the LSTM unit serves a distinctive function:

- Forget gate (f_t): This gate regulates the relevance of past information, allowing the LSTM unit to decide the degree of retention or discarding of prior information from the cell state.

- Input Gate (i_t): Responsible for modulating incoming information, the input gate enables the selective update of the cell state based on the present input sequence and the preceding state.
- Output gate (o_t): Governing the flow of information from the cell state to generate the output, this gate ensures the controlled dissemination of relevant information.

In the context of traffic flow prediction models, LSTM networks exhibit remarkable proficiency in capturing and predicting complex traffic dynamics over prolonged periods, owing to their capacity to capture long-term dependencies within sequential traffic data.

BiLSTM extends the capabilities of LSTM by incorporating bidirectional processing, allowing information to flow both forward and backward within the network. BiLSTM units consist of two LSTM layers: one processes the input sequence forward in time, while the other processes the sequence in reverse. Each BiLSTM unit operates with two sets of gates similar to LSTM: forget gates $(\overrightarrow{f_t}, \overleftarrow{f_t})$, input gates $(\overrightarrow{\iota_t}, \overleftarrow{\iota_t})$, and output gates $(\overrightarrow{o_t}, \overleftarrow{o_t})$ for the forward and backward directions, respectively. This dual directionality enables the network to capture dependencies in both past and future contexts simultaneously.

By leveraging information from both past and future contexts, BiLSTM units excel in comprehensively understanding the sequential nature of data. In the domain of traffic flow prediction models, BiLSTM architectures demonstrate enhanced capabilities in capturing complex temporal dependencies, leveraging bidirectional information flow to predict traffic patterns with improved accuracy, especially when dealing with nuanced traffic dynamics influenced by historical and future context [19].

B. Gated Recurrent Unit and Bidirectional Gated Recurrent Unit

GRU presents an alternative architecture to LSTM, designed to capture long-range dependencies in sequential data. GRU units comprise two gates: reset gate (r_t) and an update gate (z_t), effectively regulating the flow of information within the network. The reset gate determines how much of the past information to forget, while the update gate modulates the blending of new input with the previous state. The GRU architecture is shown in Fig. 2.

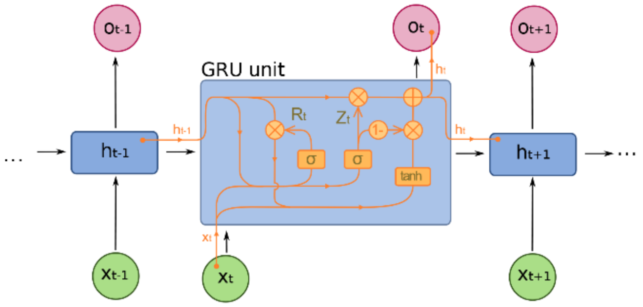

Fig. 2. Graphical visualization of the functioning of the GRU unit.

Unlike LSTM, GRU units do not possess a separate cell state, simplifying the architecture while preserving its capacity to capture temporal dependencies. GRU units are adept at learning from sequential data due to their simplified structure, making them particularly suitable for traffic flow prediction models. Their ability to balance the preservation and update of past information allows for effective modelling of traffic dynamics, enabling the prediction of flow patterns with a focus on essential temporal relationships.

BiGRU extends the GRU architecture to process information bidirectionally. Similar to BiLSTM, BiGRU incorporates two sets of GRU layers that process input sequences in both forward and backward directions. BiGRU units maintain the characteristics of GRU but leverage bidirectional information flow, allowing simultaneous exploration of past and future contexts [20].

In this work, bidirectional RNNs were employed to improve training efficiency by simultaneously processing the input sequence in both forward and backward directions (see Table I). The BiGRU and BiLSTM models comprise two bidirectional recurrent layers, and their outputs are aggregated using global average pooling. For comparison, we also included the classical LSTM model, which comprises three sequential LSTM layers, an aggregating LSTM layer, and densely connected layers.

TABLE I. CONFIGURATION OF RECURRENT MODELS

Layer	LSTM	BiLSTM	BiGRU
1.	LSTM()	Bidirectional(LSTM)	Bidirectional(GRU)
2.	Dropout(0.2)	Dropout(0.2)	Dropout(0.2)
3.	LSTM()	Bidirectional(LSTM)	Bidirectional(GRU)
4.	Dropout(0.2)	Dropout(0.2)	Dropout(0.2)
5.	LSTM()	GlobalAvgPooling()	GlobalAvgPooling()
6.	Dropout(0.2)	Dense()	Dense()
7.	LSTM()	Dense(1)	Dense(1)
8.	Dropout(0.2)		
9.	Dense()		
10.	Dense(1)		

C. Time-Delay Neural Network

TDNN represents a specialized class of feedforward neural networks designed for modelling temporal sequences. These networks utilize fixed-size time windows to capture intricate temporal dependencies embedded within sequential data. Unlike recurrent counterparts such as LSTM or GRU, TDNNs employ distinct convolutional layers, each capturing unique temporal abstractions within the input data.

Operating through convolutional layers that traverse the input sequence, TDNNs adeptly extract features within predefined time windows or delays. These localized features then undergo further processing across subsequent layers, culminating in higher-level representations that encapsulate the temporal intricacies within the data. By focusing on local patterns across diverse time scales, TDNNs excel in capturing short and medium-term dependencies inherent in sequential data. The complete architecture of the TDNN used in our experiments is detailed in Table II.

TABLE II. CONFIGURATION OF TDNN MODEL

Layer	TDNN
1.	TDNNLayer([-2,2])
2.	TDNNLayer([-2,0,2])
3.	TDNNLayer([-3,0,3])
4.	TDNNLayer([0])
5.	TDNNLayer([0])
6.	Flatten()
7.	Dense(32)
8.	Dense(1)

D. Transformer

Transformers have emerged as a paradigm-shifting architecture within neural networks, initially recognized for their success in NLP tasks. Unlike traditional RNNs, Transformers process input data in parallel, disassembling it into smaller tokens embedded within high-dimensional vectors. These vectors are then passed through multiple layers, utilizing a mechanism called self-attention to focus on important input segments. This intrinsic mechanism empowers Transformers to capture long-range dependencies and effectively model the underlying structures of natural language. The utilization of Transformers in traffic flow prediction represents a frontier where their prowess in capturing contextual relationships and long-range dependencies can significantly contribute to the evolution of precise traffic flow prediction models.

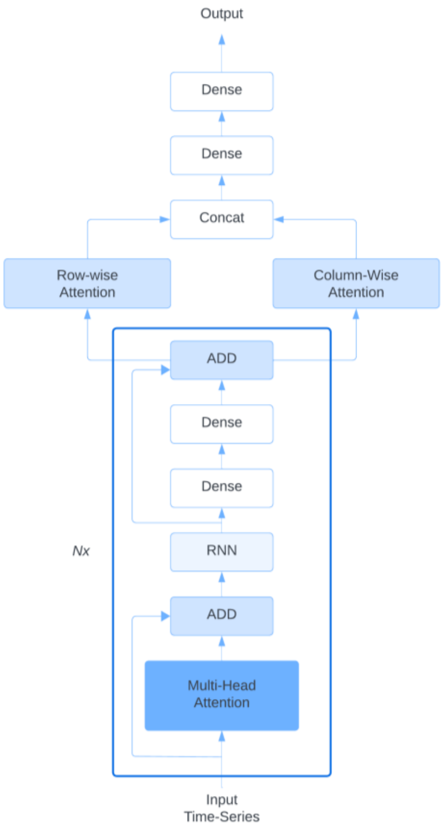

Fig. 3. Transformer architecture.

The Fig. 3 shows the proposed architecture of a single-block Transformer (where *Nx* represents the block ID), consisting of following sub-layers: a multi-head self-attention mechanism, an LSTM layer, and fully connected feed-forward network. In our implementation, we opted for the use of two transformer blocks based on experimental findings. The output of the last Transformer block is aggregated using row-wise and column-wise attention pooling and is then fed to the final dense layers. The model takes as input either the one-dimensional time series or two-dimensional time series × number of features.

IV. EXPERIMENTS

This section provides an overview of the experimental setup, dataset specifics, training strategies, and evaluation metrics crucial for both the development and assessment of the performance of the neural network architectures used in traffic flow prediction.

A. Dataset

The traffic dataset [21] used in this study is publicly available on the Kaggle online platform. This dataset consists of a collection of time series data, recording vehicle counts at hourly intervals across four distinct junctions. The features within this dataset include DateTime, Junction Type, Vehicle Count, and ID. The temporal span of data collection varies, encompassing observations from November 2015 to June 2017 for three junctions and from January 2017 to June 2017 for the remaining junction. Overall, this dataset comprises a total of 48,100 observations, providing insights into the hourly vehicular traffic across multiple junctions. In this study, data from junction number one was selected for experimentation.

Preprocessing techniques, including Z-score normalization and differencing with a one-week window span, were employed to mitigate inherent temporal patterns and trends within the dataset. Normalization addresses the issue of diversity in the value ranges of time series data, which is suboptimal for neural network input. The stationarity of the data was assessed using the Augmented Dickey-Fuller test.

In addition to time series values, we also included derived time-related features such as the month, hour, day of the week, weekend indicator, and lag features representing the values from the previous hour and the same hour on the previous day.

B. Network Setup and Training

The experiments were conducted on a hardware platform, encompassing the environmental parameters listed in Table III.

TABLE III. EXPERIMENTAL SETUP

Parameters	Configuration
CPU	Intel Core i9-12900HX
GPU	nVidia GeForce RTX 3080 Ti
GPU memory size	16GB
RAM	64GB
Operating systems	Win11
Deep learning architecture	Tensorflow 2.10.1

Training of the neural networks—LSTM, BiLSTM, BiGRU, TDNN, and Transformer—entailed parameter tuning. These models were systematically constructed with iterative exploration into diverse epochs, learning rates, batch sizes, and optimizer choices. Furthermore, the Halving Grid Search algorithm was used to narrow down the search for optimal settings through successive halving. The key parameters governing model training are detailed in Table IV.

TABLE IV. KEY PARAMETERS DURING MODEL TRAINING

Parameters	Setup
Epochs	500
Early stopping patience	10
Momentum	0.99
Learning rate	0.001
Weight decay	0.0005
Batch size	128
Optimizer	Adam/Lion

C. Metrics

The evaluation metrics are important in assessing the efficacy of traffic flow prediction models developed using neural networks. While analytical or theoretical validation of these models proves challenging, error metrics play a crucial role in assessing their performance [22].

The evaluation metric used in this work is the Mean Squared Error (MSE) and Mean Absolute Error (MAE). MSE is a common metric employed to measure the average squared difference between the actual and predicted values (1). A higher MSE indicates greater prediction error.

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(y_{ref_i} - y_{pred_i})^2 \qquad (1)$$

where, n denotes the number of values. In this study, the Root Mean Square Error (RMSE) was utilized, which is the square root of MSE. This choice was made because RMSE shares the same scale as the original target variable.

The squaring of deviations in MSE significantly impacts the results, especially for extreme values. MSE exhibits higher sensitivity to these outliers. Conversely, for proximal values, squaring produces even smaller values, indicating their reduced significance rendering MSE less sensitive to nearby values. Therefore, an additional metric was employed to assess the performance of the models.

MAE operates similarly to MSE and represents the average positive deviation between predicted values and reference values. MAE is computed as the average absolute difference between predicted and reference values in Eq. (2) for n instances:

$$MAE = \frac{1}{n}\sum_{i=1}^{n}\left|y_{ref_i} - y_{pred_i}\right| \qquad (2)$$

MAE provides a single value encapsulating all absolute deviations. The MAE metric does not amplify the effect of outliers since it considers absolute differences without squaring.

V. EXPERIMENTAL RESULTS

In this section, we present and analyse the experimental results obtained from applying various time-series forecasting models. The outcomes of the model evaluation are detailed in Table V, encompassing results for five distinct models: LSTM, BiLSTM, BiGRU, TDNN, and Transformer. For each model, performance is assessed across two time intervals—6 hours and 12 hours. Past observations from the last t hours served as input, and predictions for the subsequent time point (t + 1 hour) were generated. Furthermore, two experimental settings were employed: time series modelling using simple sequences, and time series modelling with additional features. During the evaluation phase, we conducted 10 successive model trainings, and the results of the best model are reported.

The results reveal variations in the models' predictive capabilities under different forecasting horizons. In most cases, models that make predictions based on the past 6-hour time interval achieved better results. The Transformer model appears to perform well when forecasting based on longer time spans. The complexity of the proposed Transformer might handle intricate inputs more efficiently.

In general, the inclusion of time features in the learning process resulted in improved error metrics. By integrating temporal information, models acquire the capability to leverage inherent temporal patterns and dependencies within time series data. The best results for each time interval (columns) are highlighted in bold. Among the considered models, BiLSTM, BiGRU, and the proposed Transformer proved to be the most effective, with BiLSTM achieving the highest performance. This outcome can be attributed to the fact that a simpler model is more suitable for a smaller database. While the proposed Transformer model consistently demonstrates competitive performance, particularly evident with MAE values ranging from 0.1695 to 0.1714, it may be better suited for larger datasets. The utilization of pretraining could potentially further enhance its performance.

TABLE V. COMPARISON OF THE EXPERIMENTAL RESULTS

Model	**Metrics**	**Time series**		**Time series × features**	
		6h	12h	6h	12h
LSTM	RMSE MAE	0.2388 0.1720	0.2399 0.1725	0.2365 0.1694	0.2383 0.1703
BiLSTM	RMSE MAE	0.2380 0.1708	0.2392 0.1717	0.2350 0.1688	0.2363 0.1692
BiGRU	RMSE MAE	0.2361 0.1704	0.2398 0.1715	0.2359 0.1692	0.2368 0.1699
TDNN	RMSE MAE	0.2386 0.1720	0.2406 0.1735	0.2388 0.1724	0.2394 0.1727
Transformer	RMSE MAE	0.2385 0.1714	0.2367 0.1711	0.2363 0.1711	0.2376 0.1695

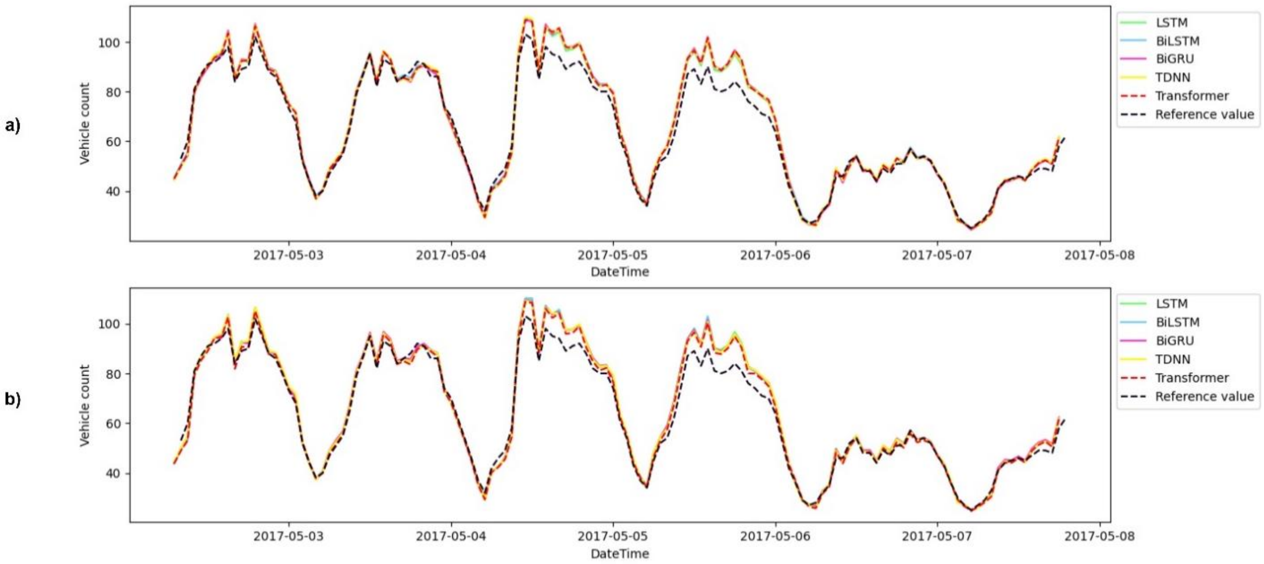

Fig. 4. Five-day prediction comparison across various sequence models: a) simple time series prediction; b) time series prediction with additional features.

VI. Discussion

The evaluation of LSTM, BiLSTM, BiGRU, TDNN, and a modified Transformer over two time intervals (6 hours and 12 hours) and across two experimental settings, including time series modelling with simple sequences and time series modelling with additional features, has provided insights into their predictive capabilities. The effectiveness of models is influenced by the choice of the past time horizon. Notably, most of the models learning from a 6-hour time span demonstrated superior performance compared to those learning from 12 hours. The inherent complexity of the Transformer architecture enables it to effectively capture temporal dependencies, making it particularly well-suited for forecasting based on longer time spans.

The predicted outcomes of all models without the use of time features are visualized in Fig. 4(a). Upon comparison with the addition of time features in Fig. 4(b), subtle improvements in prediction accuracy can be observed. The visualized days start from Tuesday and extend until midday on Sunday. The predicted values closely mimic the real-world values, with one notable exception: the models have learned to anticipate an increase in the number of vehicles on Thursdays and Fridays. Including supplementary information about holidays or non-working days might improve the model's decision-making process, especially in pinpointing the busiest traffic days of the week related to holiday travel.

The prediction outcomes for the proposed Transformer model and the best performing BiLSTM are illustrated in Fig. 5. For a more detailed perspective, only two days are displayed, revealing a distinct decline in the number of vehicles from Friday to Saturday. The incorporation of temporal features (see Fig. 5(b)) to some extent helped align the predicted values more closely with the actual values.

Selecting between BiLSTM and Transformer for time series prediction relies on the characteristics of the data and the available computational resources. While BiLSTM is a type of RNN that can capture temporal dependencies in sequential data, Transformer is a type of attention-based NN that can process sequential data in parallel, resulting in faster training times. The size of a dataset can influence the performance difference between a BiLSTM and a Transformer. The Transformer can be well-suited for transfer learning, particularly when pre-trained on large datasets, making it valuable for tasks involving limited labelled data.

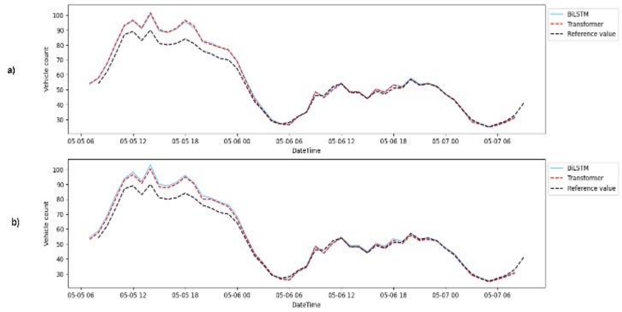

Fig. 5. The prediction outcomes of BiLSTM and Transformer models: a) simple time series prediction; b) time series prediction with additional features.

VII. Conclusion

In this study, we conducted an analysis of various time-series forecasting models, including LSTM, BiLSTM, BiGRU, TDNN, and modified Transformer. The evaluation encompassed two time intervals (6 hours and 12 hours) and two experimental settings: time series modelling using simple sequences and time series modelling with additional features. Our findings indicate variations in the predictive capabilities of the models under different forecasting horizons. Notably, models learning from a 6-hour time interval generally outperformed those learning from 12 hours. The Transformer model demonstrated efficacy in longer time spans, showcasing its ability to handle intricate inputs efficiently due to its inherent complexity.

The integration of time features into the learning process often resulted in improvements in error metrics. This enhancement arises from the models' capacity to leverage temporal patterns within time series data. Among the considered models, BiLSTM, BiGRU, and the proposed Transformer emerged as the most effective, with BiLSTM achieving the highest performance.

In our future work, the potential of transfer learning and improved fine-tuning will be explored. Moreover, evaluating other time series datasets may provide additional insights into the proposed analysis. The findings of this study can contribute to the broader understanding of model selection and optimization in time series forecasting, with implications for both research and practical applications in urban planning and traffic management systems.

Experience Replay Optimization via ESMM for Stable Deep Reinforcement Learning

Richard Sakyi Osei, Daphne Lopez
School of Computer Science Engineering and Information Systems
Vellore Institute of Technology, Vellore, India

***Abstract*—The memorization and reuse of experience, popularly known as experience replay (ER), has improved the performance of off-policy deep reinforcement learning (DRL) algorithms such as deep Q-networks (DQN) and deep deterministic policy gradients (DDPG). Despite its success, ER faces the challenges of noisy transitions, large memory sizes, and unstable returns. Researchers have introduced replay mechanisms focusing on experience selection strategies to address these issues. However, the choice of experience retention strategy has a significant influence on the selection strategy. Experience Replay Optimization (ERO) is a novel reinforcement learning algorithm that uses a deep replay policy for experience selection. However, ERO relies on the naïve first-in-first-out (FIFO) retention strategy, which seeks to manage replay memory by constantly retaining recent experiences irrespective of their relevance to the agent's learning. FIFO sequentially overwrites the oldest experience with a new one when the replay memory is full. To improve the retention strategy of ERO, we propose an experience replay optimization with enhanced sequential memory management (ERO-ESMM). ERO-ESMM uses an improved sequential retention strategy to manage the replay memory efficiently and stabilize the performance of the DRL agent. The efficacy of the ESMM strategy is evaluated together with five additional retention strategies across four distinct OpenAI environments. The experimental results indicate that ESMM performs better than the other five fundamental retention strategies.**

Keywords*—Experience replay; experience replay optimization; experience retention strategy; experience selection strategy; replay memory management

I. Introduction

Deep reinforcement learning (DRL) has emerged as a robust framework for training agents to make intelligent decisions in complex environments [1] in the area of health [2], [3], [4], automobile [5], [6], robotics [7], [8], energy [9], [10], [11] and others. RL algorithms aim to maximize cumulative rewards by allowing an agent to interact with an environment, learning from trial and error. One crucial component of RL is experience replay (ER), which involves reusing past experiences to enhance the learning process. ER has been successful in the RL field since its implementation in the deep Q-network (DQN) algorithm [12] and has undergone numerous improvements by researchers. It has proven to be a valuable technique, facilitating improved sample efficiency, breaking transition correlations, stabilizing learning dynamics, and reducing the cost of training [12], [13], [14], [15]. However, the effectiveness of ER strongly relies on selecting and retaining relevant experiences [16]. Experience sampling involves the sequential or stochastic (random) selection of an experience index (the array index of the stored transitions) to determine the experience to use for training the RL agent. In contrast, experience retention focuses on strategies that can be adopted to determine the experiences to be stored and how these experiences can be managed in the replay buffer to optimize the learning process.

In recent years, various ER strategies have been proposed to address the challenges associated with experience retention. Isele and Cosgan [17] suggests that strategies for sampling experiences can be based on surprise, reward, state-space coverage, global training distribution, and state-action similarities. Similarly, de Bruin et al. [16] identified the full database (Full DB), first-in-first-out (FIFO), temporal difference error (TDE), and exploration as strategies for experience retention. They assert that while the FIFO strategy sequentially replaces old experiences irrespective of their relevance to learning, the exploration strategy stochastically overwrites the least-explored experience. The TDE strategy stochastically overwrites the least surprising experience, while the Resv approach ensures that "observed" experiences have equal retention rights. Moreover, the Full DB strategy uses a large amount of memory to store all experiences and does not require the removal of experiences from the replay memory.

Even with the improvements in ER strategies, they have limitations. The TDE is susceptible to noise, differences in function approximation accuracy, and randomness in the environment [15], [16], [18], [19], [20]. The FIFO strategy is affected by rapid changes in the state distribution, and Resv has premature data distribution convergence and poor coverage of state action over the optimal policy. Exploration takes longer to learn the correct value function, and Full DB promotes the rise of irrelevant experiences in the replay buffer [16]. Hence, there is still ample room for improvement in designing more efficient and effective experience retention strategies.

The proposed experience replay optimization with enhanced sequential memory management (ERO-ESMM) is a novel reinforcement learning algorithm that aims to improve the learning stability of DRL agents. The ERO-ESMM algorithm uses an enhanced sequential memory management (ESMM) strategy to manage the replay memory efficiently and stabilize the agent's performance. Compared to five existing experience retention strategies, the experimental results indicate that ERO-ESMM exhibits superior performance.

In this study, we present an enhanced experience retention strategy for DRL. Our proposed strategy aims to improve the efficiency and effectiveness of experience replay by carefully managing experiences within the replay memory. The primary advancements presented in this study can be outlined as follows:

1) Firstly, we develop three new retention strategies to improve the efficiency and effectiveness of experience replay.

2) Secondly, we investigate the effects of six retention strategies, including the enhanced FIFO, on the ERO-enhanced DDPG algorithm.

3) Finally, we propose an enhanced framework incorporating the highest-performing retention strategy into the ERO framework.

We review existing experience retention strategies in Section III to achieve these objectives. We then present our enhanced retention strategy, outlining its core principles and rationale in Section III. Subsequently, we describe the experimental setup used to evaluate the performance of our approach in Section IV and provide detailed results and analysis. Finally, in Section V, we conclude our study and recommend future work in the field.

II. Related Work

We recognize that sampling and retention strategies are essential to experience replay in reinforcement-learning algorithms. This section briefly overviews the experience replay mechanism and sampling strategy. However, the section focuses on retention strategies, explicitly identifying those that effectively improve the performance of RL algorithms that use experience replays. The section explains the actor-critic method since the study seeks to improve an actor-critic algorithm (DDPG).

A. Experience Replay

With ER, an agent generates experiences using an exploration-exploitation method at specific intervals and stores them in fixed-size replay memory. The agent then samples these experiences uniformly and randomly from the replay buffer into a mini-batch and repeatedly uses them to train the RL algorithm. This random selection prevents high correlation among the sampled experiences.

ER was first introduced by Lin [21] in the early 1990s, but it gained widespread attention when Mnih et al. [12] combined it with a deep convolutional neural network to create a groundbreaking deep Q-network (DQN) algorithm. Since then, ER has become a critical component of RL algorithms, allowing them to use experience effectively and reduce the interactions required with the environment. Before the introduction of ER, algorithms such as Q-learning [20], which relied on a tabular data storage mechanism, could not retain previous state-action values because the current ones of the same state-action pair would overwrite them. This "catastrophic forgetting' [22], [23], [24], [25], [26] behavior leads to slower learning and poor algorithm convergence.

Although many algorithms that implement diverse sampling strategies have been developed, the size and data structure of the replay buffer, mini-batch size, experience retention rate, experience sampling, and retention techniques significantly influence the performance of these algorithms [40]. The selection of the experience index for experience sampling or retention can be sequential or random (uniform or prioritized probability). Sequential index selection is not appropriate for experience sampling because it creates a high correlation among the selected experiences, which subsequently slows down the agent's learning [12], [13], [34], [41]. Table I shows that most cited RL algorithms use a sequential index selection approach to remove experiences from the replay memory.

TABLE I. Some RL Algorithms and their Experience Index Selection Approach for Experience Retention

Algorithm	**Experience Index Selection Approach**		
	Sequential	***Random***	
		Uniform	***Priority***
Deep Q-Network (DQN) [12]	✓

Dueling DQN[28]	✓		
Prioritized Experience Replay (PER) [29]	✓		
Deep Deterministic Policy Gradient (DDPG) [30]	✓		
Twin Delayed Deep Deterministic Policy Gradient (TD3) [18]	✓		
Trust Region Policy Optimisation (TRPO) [31]	✓		
Proximal Policy Optimisation (PPO) [32]	✓		
Episodic Memory Deep Q-Network (EMDQN) [33]	✓		
Advantage Actor-Critic (A2C) + Prioritized Stochastic Memory Management (PSMM) [20], [34]			✓
DQN + Dual Memory Structure (DMS) [12], [35]	✓		✓
DDPG + Experience Replay Optimisation (ERO) [30], [36]	✓		
Combined Experience Replay (CER) [37]	✓		
Attentive Experience Replay (AER) [38]	✓		
Selective Experience Replay (SER) [17]		✓	✓
Prioritized Sequence Experience Replay (PSER) [39]	✓		

The advancements in ER are incorporated in many popular RL algorithms, such as DQN [12], dueling DQN [28], double DQN [27], twin delayed deep deterministic policy gradient (TD3)[18], deep deterministic policy gradient (DDPG) [30], proximal policy optimization (PPO)[32], episodic memory deep Q-Network (EMDQN) [33], and trust region policy optimization (TRPO) [31], still use the naïve ER uniform random sampling strategy. Other algorithms, such as prioritized experience replay (PER) [36], prioritized sequence experience replay (PSER) [37], experience replay optimization (ERO) [38], and attentive experience replay (AER) [39], implement prioritized strategies. Equally, prioritized stochastic memory management (PSMM) [20], combined experience replay (CER) [37], selective experience replay (SER) [17], and episodic memory control (EMC)[40] use experience retention strategies (memory management strategies). In contrast, some replay strategies focus on the structure of the replay memory instead of the content[35], [42], [43]. ERO has proven superior among prioritized selection algorithms, owing to its easy adaptation and generalization to multiple environments [23].

B. Experience Retention Strategies and Algorithms

Experience retention plays a critical role in the success of ER algorithms. We can only select the experiences available in the replay buffer for training. If valuable experiences are maintained in the buffer, there will be a higher probability of sampling a mini-batch full of relevant experience to train the RL agent. In contrast, the worst training could be given to the agent. Therefore, it is imperative to investigate and unearth innovative ways to improve existing retention strategies or, better still, develop new ones.

The naïve approach of randomly selecting buffered experiences uniformly or managing the replay memory with a simple FIFO strategy is simple but less successful than the prioritized approach for managing the replay buffer [16], [29], [44]. Recent enhanced works on experience replay have relied on rule-based strategies that directly prioritize transitions through sampling strategies or indirectly through retention strategies [36]. However, some prioritized strategies incorporate a certain degree of randomness during implementation, using hyperparameters to regulate prioritization. Prioritization relies on features such as the temporal difference error (TDE), reward signal, similarities or diversity of states[18], or a combination of any of these features [20], [36]. A comprehensive study by de Bruin et al. [16] outlines age, exploration, and surprise as the criteria for retaining experiences in the buffer.

Retention depends on the duration for which an experience remains in the buffer. FIFO, Full DB, and Reservoir are strategies that rely on age. Although FIFO uses sequential indexing to remove old experiences without regard for their contribution to learning, Reservoir overwrites experiences in a uniformly random fashion and has limited state-action coverage. The Full DB method accommodates all experiences until the end of the training but may retain irrelevant experiences.

It is worth noting that there are better choices than the exploration criteria when dealing with problems that require minimal interaction with the agent's environment [16]. TDE is an expression of the surprise between the targeted and predicted q-values. Overfitting can occur if not parameterized and regulated [29], [40]. Actor-Critic Method Two major approaches in RL, value-based and policy-based methods, have been widely explored. Value-based methods estimate the value function, while policy-based methods directly optimize the agent's policy [1]. However, each approach has its limitations. Value-based methods tend to suffer from overestimation, the curse of dimensionality, and are often computationally expensive. On the other hand, policy-based methods can be inefficient in exploring the environment and may need help with convergence [13], [18], [45]. To address these challenges, the actor-critic algorithm, a hybrid approach, combines the strengths of value-based and policy-based methods [13], [18], [46]. It consists of two key components: the actor and the critic. The actor represents the policy and selects actions based on the observed states. The critic estimates the value function, providing feedback to the actor by evaluating the chosen actions.

The actor is typically implemented as a parametric model, like a neural network, which maps states to a probability distribution over actions. It explores the environment, collects experiences, and adjusts its policy based on the rewards it receives. The critic, represented by a parametric model, estimates the value function by approximating the expected cumulative reward associated with states or actions. By combining the strengths of both approaches, actor-critic algorithms can achieve faster convergence, more stable learning, and better performance in a wide range of RL problems. This hybrid approach has found successful applications in various domains, including robotics control, game playing, and natural language processing [15], [34].

III. METHODOLOGY

This section briefly introduces ERO and PSMM while paying particular attention to the selection and retention strategies used. It further presents the proposed framework and implemented algorithms.

A. Experience Replay Optimization

ERO is an experience selection method that relies on Reward and TDE for prioritization [36]. Unlike other TDE prioritization sampling strategies that favor experiences with higher TD errors, ERO selects less surprised TDE experiences and uses a novel replay policy network for the prioritization process. A mini-batch of high-priority transitions (transitions with vector 1) was created, and its elements were uniformly sampled to train the agent [23]. After the agent interacts with the environment, the transitions are stored in the replay buffer and subsequently prioritized through a Boolean (0, 1) vectorization process using the replay policy. During training, the replay policy receives feedback from the environment for policy evaluation.

Since the performance of a sampling strategy is highly dependent on the implementing algorithm and the benchmark environment [16], there is the need for a sampling method that can learn and adapt to different algorithms and environments - ERO does rightly so. ERO still uses the FIFO retention strategy despite its novel adapting strategy and superior performance over prioritized sampling methods such as PER [36], [44].

Hence, when the replay memory exceeds its capacity, the oldest transition is sequentially replaced with a new transition, irrespective of its importance in learning. Nonetheless, when relevant transitions are retained and frequently sampled using an intelligent index selection strategy, we are optimistic that the agent's performance and convergence rate will improve [14], [45], [47]. Therefore, there is a need to augment ERO with a memory management mechanism that is better than FIFO[16]. The beauty and novelty of the ERO algorithm depend on its replay policy network, which relies on Eq. (1) to Eq. (4). Table II explains the notations used in the equations, and the replay policy update is presented in Algorithm 1 [36].

$$\lambda = \left\{\phi\left(f_{B_i}\middle|\theta^{\phi}\right)\middle|\ B_i \in B\right\} \in \mathbb{R}^N \tag{1}$$

$$B^s = \{B_i | B_i \in B \wedge I_i = 1\} \quad (2)$$

$$r^r = r^c_\pi - r^c_{\pi'} \quad (3)$$

$$P(I|\phi) = \sum_{j:B_j \in B^{batch}} r^r \nabla\theta^\phi [I_i \log\phi + (1 - I_i)\log(1 - \phi)] \quad (4)$$

where, ϕ denotes the function approximator, B_i is a transition in the replay buffer B. θ^ϕ denotes the parameters of ϕ, f_{B_i} is a feature vector, and N is the number of transitions in a mini-batch. The priority score function is expressed as $\phi\left(f_{B_i}|\theta^\phi\right) \in (0,1)$, where the priority score is represented by Lambda (λ). $I_i \in \{0,1\}$ is the Bernoulli distribution of sample B^s. The replay reward, cumulative reward of the current policy, and cumulative reward of the previous policy are denoted by r^r, r^c_π, and $r^c_{\pi'}$respectively.

Algorithm 1: PolicyUpdate

```
Input:
    Cumulative reward of current policy $r^c_\pi$
    Cumulative reward of previous policy$r^c_{\pi'}$
Output:
    Sample subset $B^s$
Calculate replay reward based on (3)
For (each replay updating step) do
        Randomly sample batch $\{B_i\}$ form B
        Update replay policy based on (4)
End
Sample subset $B^s$ from B using (2)
```

B. Prioritized Stochastic Memory Management

Experience replay selection strategies are often the focus of researchers. However, it is essential to note that a poorly designed retention technique can negatively impact the performance of the learning agent [16], [17], [20]. One proposed method for effective replay memory management is prioritized stochastic memory management (PSMM), which was introduced by Ko and Chang [35]. The PSMM employs a stochastic approach to remove the history with the least TDE or return when the replay memory is full, using the probability computed in Eq. (5).

$$P_{i=} \frac{exp\left(-\rho(\alpha_{actor}R^{(i)}_{norm} + \alpha_{critic}TDE^{(i)}_{norm})\right)}{\sum^c_{i=1} exp\left(-\rho(\alpha_{actor}R^{(i)}_{norm} + \alpha_{critic}TDE^{(i)}_{norm})\right)} \quad (5)$$

The computation of the probability for elimination (P_i) in Kwon and Chang's method involves the utilization of historical information through return and temporal difference error (TDE) metrics [25]. These metrics were normalized to restrict their values from 0 to 1, facilitating unbiased evaluations and promoting stable memory management. The method employs several hyperparameters, such as α_{actor}, α_{critic}, and ρ, which are optimized for improved performance. The α_{actor} and α_{critic} determine the relative weights assigned to the actor and critic components, respectively, whereas ρ represents a probability tuning parameter. This approach ensures the effective utilization of historical data and facilitates the optimization of the method's parameters.

The computations for $R^{(i)}_{norm}$ and $TDE^{(i)}_{norm}$ are shown in Eq. (6) and Eq. (7), respectively.

$$R^{(i)}_{norm} = \begin{cases} \frac{R^i - R_{min}}{R_{max} - R_{min}}, & if\ R_{max} \neq R_{min} \\ 0 & otherwise \end{cases} \quad (6)$$

$$TDE^{(i)}_{norm} = \begin{cases} \frac{TDE^i - TDE_{min}}{TDE_{max} - TDE_{min}}, & if\ TDE_{max} \neq TDE_{min} \\ 0 & otherwise \end{cases} \quad (7)$$

$$P_{i=} \frac{\left(R^{(i)}_{norm}\right)^\alpha}{\sum^c_{i=1}\left(R^{(i)}_{norm}\right)^\alpha} \quad (8)$$

$$P_{i=} \frac{exp\left(-\rho(\alpha_{actor}R^{(i)}_{norm})\right)}{\sum^c_{i=1} exp\left(-\rho(\alpha_{actor}R^{(i)}_{norm})\right)} \quad (9)$$

TABLE II. SYMBOLS AND NOTATIONS USED IN THIS SECTION

Notation	Explanation
ϕ	Function approximator
B	Replay buffer
B_i	A transition in the replay buffer B
θ^ϕ	Parameters of the function approximator
f_{B_i}	Feature vector
λ	Priority score
r^r	Cumulative reward
r^c_π	Cumulative reward of current policy
$r^c_{\pi'}$	Cumulative reward of previous policy
B^s	A specified batch size of sampled transitions
ρ	Probability tuning parameter
α	Parameter for tuning the probability of elimination

C. Proposed Framework

Researchers have recently harnessed and combined various algorithms' strengths to create resilient, stable, and generalized hybrid algorithms. Our proposed framework amalgamates the ERO framework and enhances the FIFO retention strategy.

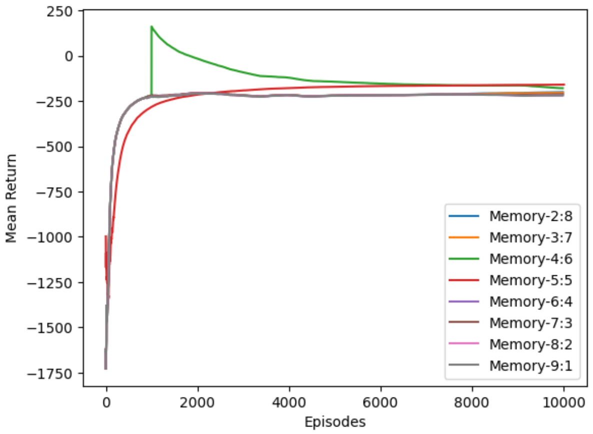

Fig. 1. A preliminary experiment was conducted to identify the optimum experience retention ratio. When the replay memory capacity is reached, the buffered experiences are overwritten using a ratio. A ratio of 2:8 means 20% of the old experiences are sequentially overwritten with new experiences, and 80% are retained. However, for a ratio of 8:2, only 20% of the buffered experiences are retained.

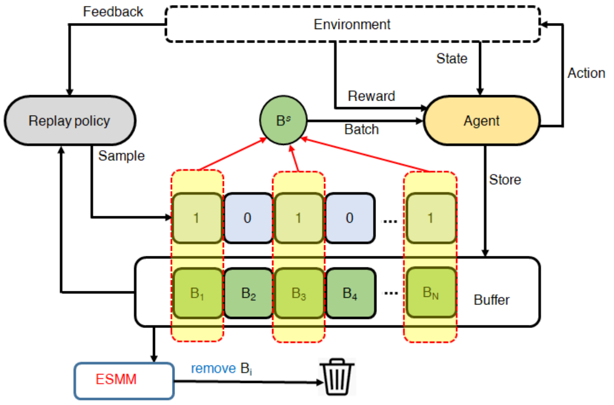

Fig. 2. Proposed Framework: experience replay optimization with enhanced sequential memory management (ERO-ESMM). Transitions from the environment are stored in the replay buffer. Mini-batches from the transitions are vectorized, prioritized by the replay policy, and sampled uniformly at random to train the agent. After training, the replay policy receives feedback for policy evaluation. When the memory is full, ESMM ensures that transitions in the first half of the replay memory are sequentially overwritten with new ones.

The ESMM, PSMM(α), and PSMM(ρ) retention strategies were developed to create the new framework. While PSMM(α) and PSMM(ρ) use Eq. (8) and Eq. (9), respectively, ESMM extends the FIFO retention strategy by sequentially overwriting older transitions in the first half of the memory when the memory is full. The one-half was arrived at after preliminary experiments were conducted using different ratios of the replay buffer for experience retention. Fig. 1, which shows the preliminary experiment results, confirms that an even distribution of old and new experiences in the replay buffer enhances the performance of the RL agent.

The ESMM, PSMM(α), and PSMM(ρ) strategies and FIFO, Full DB, and Resv were further investigated to ascertain their effects on the ERO-enhanced DDPG algorithm. The strategy with the highest mean return, ESMM, was incorporated into the ERO framework to propose an improved framework, an experience replay optimization with enhanced sequential memory management (ERO-ESMM). The proposed framework and its algorithm are shown in Fig. 2 and Algorithm 2, respectively.

Algorithm 2: ERO-ESMM Enhanced DDPG

```
Initialize policy $\pi$, replay policy $\phi$ and buffer B
For (each iteration) do
    For (each time-step t) do
        Select action $a_t$ according to $\pi$ and state $s_t$
        Execute action $a_t$ and observe $s_{t+1}$ and $r_t$
        If (B is full) then
            If (index i+1 == ½ len(B) ) then
                i=0

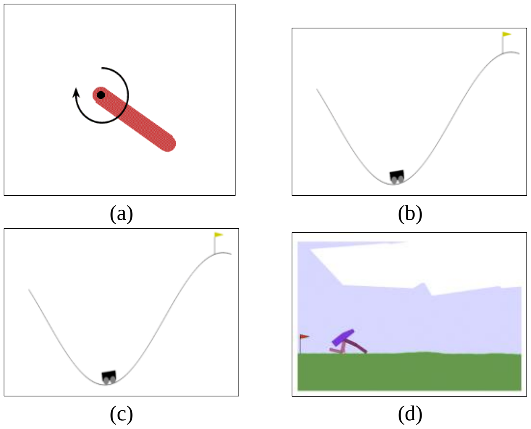
        Update the actor of $\pi$
        Update the target networks
        Update the $\lambda$ for each transition in $\{B_i\}$
    End
End
```

D. Setup of RL Environment

To ascertain the efficiency of the proposed framework, we conducted a series of experiments in the Pendulum-v0, MountainCarContinuous-v0, LunarLandarContinuous-v2, and the BipedalWalker-v3 environments [48] of the OpenAI Gym as a platform for the evaluation and analysis of results. Screenshots of these environments are shown in Fig. 3.



(a) (b)
(c) (d)

Fig. 3. Screenshots of two Classic Control (top row) and two Box2D (down row) environments from the OpenAI Gym. Fig. 3(a) and (b) represent the Pendulum-v0 and MountainCarContinuous-v0 environments, respectively. Fig. 3(c) and (d) represents the LunarLandarContinuous-v2 and the BipedalWalker-v3 environments respectively.

Pendulum-v0 presents a classical inverted pendulum swing-up problem, which demands that the agent persistently swing up the pendulum from an initial arbitrary position until it attains an upright position while its 3-dimensional observation space comprises angle, acceleration, and angular velocity, its action space is continuous, ranging between -2.0 (anti-clockwise torque) and 2.0 (clockwise torque). The agent's rewards depend on its actions and the associated state.

The MountainCarContinuous-v0 environment is another benchmark classical control environment that requires the RL agent to apply actions to a car to reach the top of a hill as quickly as possible. It is an extension of the classic "MountainCar-v0" environment but with continuous action space, making it more suitable for problems requiring continuous control. It consists of a 2-dimensional observation space of the car's position and velocity and a continuous action space between -1.0 and 1.0. The RL agent is negatively rewarded each time an action is taken until the car reaches the top of the hill. Hence, the agent applies continuous efficient actions to overcome the car's inertia and climb the hill.

LunarLanderContinuous-v2 is an extension of the original Box2D discrete action space LunarLander-v2 environment, where the agent controls a lunar lander attempting to land on a designated landing pad on the moon's surface. In contrast to the discrete version, this environment allows the agent to apply a range of continuous actions (a throttle that varies between 0 and 1 and a rotation angle between -1 and 1) instead of selecting from a fixed set of discrete actions. It has an 8-dimensional observation space that includes information about the lander's position, velocity, orientation, angular velocity, whether the legs are touching the ground, and whether the lander has successfully landed. The RL agent receives positive rewards for moving closer to the landing pad and a significant positive reward for landing safely. Negative rewards are given for using fuel, and a slight negative reward is given for each time step.

BipedalWalker-v3 is similarly a Box2D environment where the agent controls a bipedal robot with four legs and must learn to make it walk and navigate through a complex terrain while avoiding obstacles. The challenge lies in learning a coordinated sequence of actions to control the robot's joints and achieve stable and efficient locomotion. This environment is represented by a 24-dimensional observation space, which contains information about the position, velocity, angle, angular velocity, and state of the joints, feet, and lidar sensors. The agent receives positive rewards for progressing forward and avoiding obstacles. However, negative rewards are given for using excessive torque or falling, encouraging the agent to discover stable and effective locomotion strategies.

The suitability of these environments for the DDPG algorithm is attributable to the availability of continuous tasks[30]. Thus, the selection of these environments was motivated by their compatibility with the requirements of the DDPG algorithm and their standard use in previous studies for evaluating RL algorithms [49].

E. Parameter Setting

Because the proposed framework extends the ERO-enhanced DDPG algorithm, the experimental configurations were based on the OpenAI DDPG stable baseline[50], and the hyperparameters for the sampling and retention methods were in line with ERO and PSMM, respectively. However, the memory size and number of time steps were adjusted during implementation.

In Table III, six notations and their explanations are clearly shown to facilitate comprehension of our visualizations. Aside from the Full DB, which has the memory size and number of time steps set to 2 × 106, the other five retention strategies were evaluated with a memory size of 1 × 106 and time steps of 2 × 106. Similar to PSMM[25], we set $\boldsymbol{\rho = 2.0}$, $\boldsymbol{\alpha_{actor} = 0.5}$ and $\boldsymbol{\alpha_{critic}}$= 0.5 when implementing PSMM($\boldsymbol{\rho}$). In the PSMM(α), we rely on an α value 0.6[21]. Other parameters for the evaluation of experiments were done on an Intel(R) Xeon(R) CPU E3-1220 v6 @ 3.00GHz(4CPUs) with 32GB RAM and a Windows Server 2012R2 operating system.

TABLE III. EXPERIENCE RETENTION STRATEGIES EVALUATED IN THE STUDY

Notation	Explanation
FIFO	Sequentially overwrite old experiences with new ones.
ESMM	Replace experiences in the first half of the buffer with new ones.
Full DB	Experiences are not overwritten. The replay memory stores all experiences.
Resv	Experiences are uniformly, at random, overwritten with new ones.
PSMM(α)	Experiences are stochastically overwritten based on (8)
PSMM(ρ)	Experiences are stochastically overwritten based on (9)

IV. RESULTS AND DISCUSSION

This section examines the comparative effectiveness of the retention strategies within each environment. The metric for quantifying the performance of the evaluated strategies is the mean return. The return, also known as cumulative reward or cumulative return, is a measure of the overall success of the RL agent in achieving its goals. It is the summation of rewards received by the agent at each time step from the start of an episode until its termination[1], [51], [52]. The return is typically used to evaluate and compare the performance of different algorithms and policies in a specific reinforcement learning task. The mean return can be derived as follows:

$$G_t = R_{t+1} + R_{t+2} + R_{t+3} + \cdots + R_T \tag{10}$$

$$Mean\ return = \frac{G_t}{number\ of\ episodes} \tag{11}$$

where, G_t is the return, R_{t+1} is the reward at time step *t*, and *T* is the final time-step.

The performance of each retention strategy was evaluated based on the progressive average returns computed using Eq. (11). The results are illustrated in Fig. 4 to Fig. 7.

In the Pendulum environment, as shown in Fig. 4, the ESMM and PSMM(α) strategies exhibit superior performance compared to FIFO, while Full DB and PSMM(ρ) strategies perform worse. The Resv strategy exhibits limited effectiveness as it faces challenges in learning optimal policies to stabilize the pendulum. This struggle is reflected in a mean return of -1061.29.

Regarding the MountainCarContinuous-v0 environment, as indicated in Fig. 5, the ESMM strategy outperforms all other models, including FIFO. The Full DB and Resv strategies show some improvement over FIFO, while PSMM(α) and PSMM(ρ) perform worse with rewards of -6.05 and -6.46, respectively.

In the LunarLanderContinuous-v2 environment, as shown in Fig. 6, the ESMM, PSMM(α), and PSMM(ρ) strategies demonstrate superior performance compared to FIFO. The Full DB model performs worse than FIFO and PSMM(ρ), while the Resv model exhibits the poorest performance.

Likewise, in the BipedalWalker-v3 environment, the ESMM and PSMM(α) models perform better than the FIFO strategy. However, the Full DB and Resv models perform worse than ESMM and PSMM(α), with PSMM(ρ) showing the poorest performance among all models in this environment.

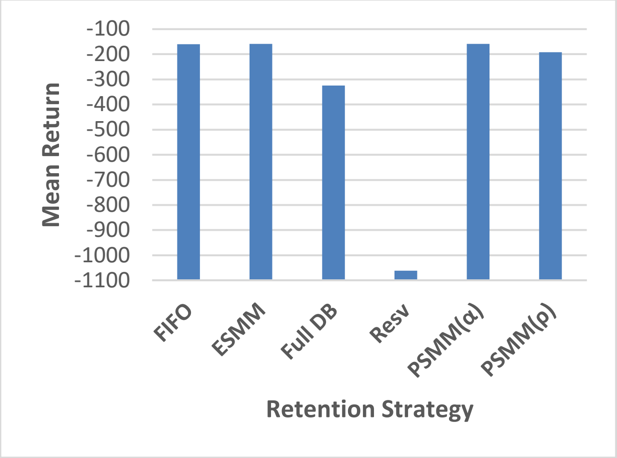


Fig. 4. Performance comparison of the six retention strategies evaluated on the Pendulum-v0 environment.

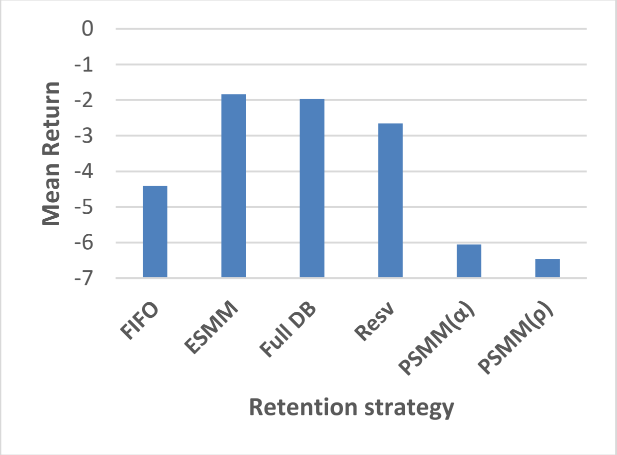

Fig. 5. Performance comparison of the six retention strategies evaluated on the MountainCarContinuous-v0 environment.

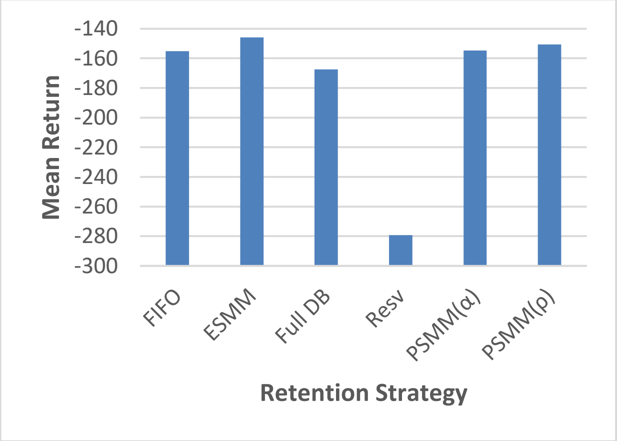

Fig. 6. Performance comparison of the six retention strategies evaluated on the LunarLandarContinuous-v2 environment.

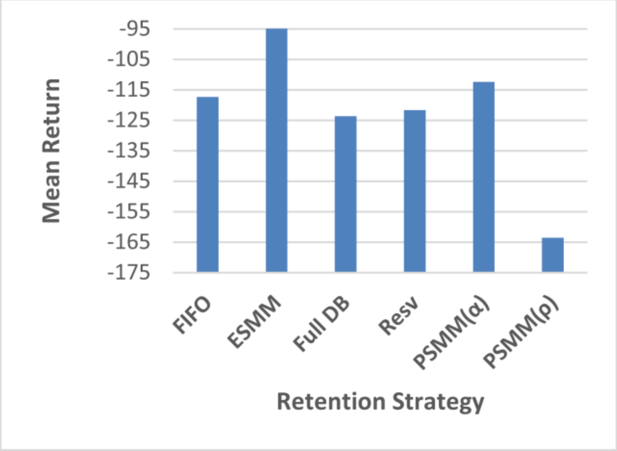

Fig. 7. Performance comparison of the six retention strategies evaluated on the BipedalWalker-v3 environment.

The results indicate significant model performance variation across different OpenAI Gym environments. The ESMM strategy generally exhibits better and more stable performance across the experimented environments, which can be attributed to its fair distribution of experiences in the replay buffer. While the PSMM(α) model performs better in the Pendulum environment, the PSMM(ρ) strategy performs better than other models, except ESMM, in the Lunar Lander Continuous-v2 environment.

Conversely, the Full DB model tends to perform worse in most environments because all experiences are stored, including the worst experiences obtained during the early stages of the RL agent's training. The Resv strategy's performance shows inconsistency across the environments due to its entirely random strategy for identifying the experience to remove when the replay buffer is full.

V. Conclusion

In this study, we developed three new retention strategies to improve the effectiveness of experience replay. These strategies include ESMM, PSMM(α), and PSMM(ρ). The development of these strategies is significant, as they provide new alternatives for managing the memory of an RL agent in a reinforcement learning setting. These strategies addressed specific challenges encountered in experience replay, such as the trade-off between memory usage and retention of relevant experiences.

This study also investigated the effects of six different retention strategies on the ERO-enhanced DDPG algorithm. These strategies include FIFO, Full DB, Resv, PSMM (α), PSMM(ρ), and our proposed method (ESMM). The results of this investigation are significant because they provide insights into the comparative performance of different retention strategies and help identify the most effective strategy. This information can guide the design of more efficient reinforcement learning algorithms.

Finally, we propose an enhanced framework incorporating the highest-performing retention strategy into the ERO framework. This enhanced framework, called experience-replay optimization with enhanced sequential memory management (ERO-ESMM), significantly contributes to reinforcement learning. By integrating the best-performing retention strategy, the framework offers a more optimized approach to experience replay, leading to improved performance in reinforcement-learning tasks.

Overall, the experimental results suggest that developing new retention strategies, combined with their investigation and incorporation into existing frameworks, can significantly improve the performance of reinforcement learning algorithms. These results have implications for future research and demonstrate the importance of exploring new techniques for optimizing reinforcement learning. In the future, we will use a separate neural network to predict the index of the experience to delete from the replay buffer when it exceeds its limit.

Real Time FPGA Implementation of a High Speed for Video Encryption and Decryption System with High Level Synthesis Tools

Ahmed Alhomoud
Department of Computer Sciences, Faculty of Computing and Information Technology,
Northern Border University, Rafha 91911, Saudi Arabia

***Abstract*—The development of communication networks has made information security more important than ever for both transmission and storage. Since the majority of networks involve images, image security is becoming a difficult challenge. In order to provide real-time image encryption and decryption, this study suggests an FPGA implementation of a video cryptosystem that has been well-optimized based on high level synthesis. The MATLAB HDL coder and Vivado Tools from Xilinx are used in the design, implementation, and validation of the algorithm on the Xilinx Zynq FPGA platform. Low resource consumption and pipeline processing are well-suited to the hardware architecture. For real-time applications involving secret picture encryption and decryption, the suggested hardware approach is widely utilized. This study suggests an implementation of the encryption-decryption system that is both very efficient and area-optimized. A unique high-level synthesis (HLS) design technique based on application-specific bit widths for intermediate data nodes was used to realize the proposed implementation. For HLS, MATLAB HDL coder was used to generate register transfer level RTL design. Using Vivado software, the RTL design was implemented on the Xilinx ZedBoard, and its functioning was tested in real time using an input video stream. The results produced are faster and more area- efficient (target FPGA has fewer gates than before) than those of earlier solutions for the same target board.**

I. Introduction

The development of strong, computationally light, and efficient encryption algorithms is therefore necessary to support the ongoing increase in data volume and throughput in Internet of Things applications, as well as video streaming, real-time video processing, mobile transmissions, and other related activities. This is because network security has become. A constant topic for business activities due to the advancements of information technology (IT) applications involving sensitive data [1,2]. For governments, banks, and high-security systems worldwide, the Advanced Encryption Standard (AES) continues to be the recommended encryption standard [3,4]. The last encryption technique is the most often used; it is utilized in 5G systems, WiMAX, Gigabit Ethernet, and Worldwide Interoperability for Microwave Access [5,6,7]. Furthermore, this algorithm can be effectively implemented on both software and hardware platforms; AES software versions give poorer physical security but require fewer resources [8, 9].

However, the increasing need for secure data transmissions at high speeds and volumes while maintaining physical security makes hardware implementation of the AES algorithm imperative [10,11]. The primary challenge with applications utilized in these domains is to ensure real-time system operation [2]. Implementing real-time functionality on a general-purpose computer is often unfeasible due to the inherent limitations of memory, CPU, and peripheral devices. Typically, numerous actions are executed on every pixel in the majority of image processing programs. The sequential execution of these operations by general-purpose processors has detrimental effects on both resource use and performance [2,3]. Nevertheless, FPGAs (Field Programmable Gate Arrays) possess the potential to function in a parallel manner in relation to hardware, setting them apart from conventional CPUs. Operations in FPGAs are partitioned into segments, allowing for concurrent execution of many operations [12,13]. Fig. 1 presents a complete system for real-time image and video processing using an embedded system.

The landscape of smart video encryption is evolving rapidly, demanding sophisticated analysis of live video streams to accurately identify objects, scenes, and critical events. This has led to the integration of advanced analysis mechanisms into the traditional image processing pipelines of modern video cameras [14]. However, the stringent constraints of real-time processing and low power consumption inherent in camera modules limit the complexity and number of operations that can be feasibly implemented [15]. To address this challenge, researchers have focused on a select few pre-processing tasks like motion estimation, image segmentation, and robust video encryption [15].

Recognizing the growing complexity of computer vision systems, designers are increasingly turning to higher-level programming and synthesis tools to expedite the development process and overcome hardware limitations. Two prominent tools in this arena are Simulink Hardware Description Language (HDL) Coder and Xilinx High-Level Synthesis (HLS) [16, 17]. Xilinx HLS stands out for its exceptional suitability for designing large-scale computer vision systems. It boasts the ability to seamlessly integrate pre-existing standard algorithms and offers comprehensive functional verification, ensuring accuracy and efficiency [17]. Additionally, HDL Coder empowers rapid synthesis and verification of diverse image processing methods, ranging from picture statistics gathering and custom filtering to color space conversion [16].

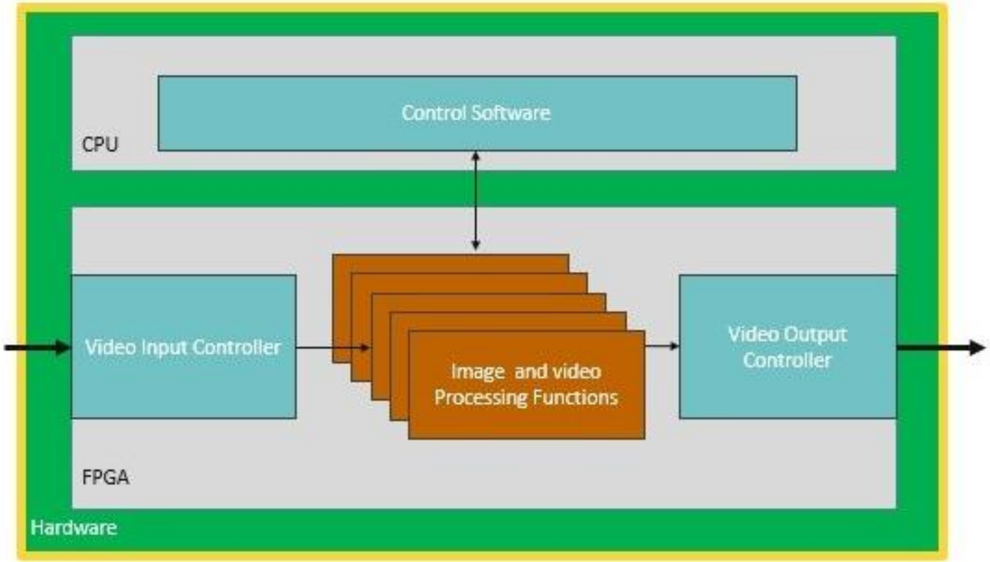

Fig. 1. Embedded real time image and video processing system.

Nevertheless, there is no specific support for picture segmentation tasks in the present toolbox version. To accomplish this, a Simulink model is created that increases this toolbox's capacity and supports this essential feature. While academics have recently proposed a number of advanced methods for image encryption, implement" encryption decryption algorithm" implemented [14, 15] into our proposed hardware in order to minimize the use of logic resources. Moreover, it has been shown that switching from moving averaging to weighted averaging reduces the amount of logic resources needed without sacrificing the accuracy of the results. As a result, the following can be used to summarize the contributions of the completed work: Creation of a synthesizable Simulink model for the AES-based cryptosystem, which isn't yet accessible as an intrinsic block in the Simulink HDL Coder/Vision HDL Coder toolbox (MATLAB R2018b). By substituting the weighted average for the moving average, which necessitates an expensive division operation, logic resource conservation is achieved. In comparison to earlier methods, this work presents a real-time implementation of video encryption and decryption on a Xilinx ZedBoard and shows that it is faster and uses less space on the FPGA. A unique high-level design technique was used to create the design, which synthesizes the design with intermediate signal widths limited by the application (input stimulus). The rest of this essay is structured as follows: An introduction to high- level synthesis is given in Section I. Related work is given in Section II. FPGA High level synthesis is given in Section III. The AES Encryption and Decryption architecture is explained in Section IV. Image and video acceleration is given in Section V. RTL design implementation mentioned in Section VI. Finally Section VII concludes the paper.

II. Related Work

Recently, numerous researchers have undertaken investigations on cryptographic algorithms inside the realm of Internet of Things (IoT). Reference [18] introduced a dynamic pass- word access approach for uniformly storing the key matrix on all nodes. The sender did not need to transmit a basic key, but rather the storage coordinates of the key matrix. The receiver then extracted the key from the matrix based on these coordinates, therefore enhancing the security of key transmission. Reference [19] introduced a Very Large-Scale Integration (VLSI) design that incorporates a 64-bit data path for the lightweight cipher present. This architecture achieves excellent performance, low power consumption, and a compact footprint on FPGA, resulting in a high throughput rate. In order to fulfill the security demands of various application contexts, distinct techniques are necessary for the encryption and decryption system to handle data. Reference [20] developed a customizable encryption system that allowed users to choose their preferred encryption method from a range of options specified in the FPGA configuration file, hence enhancing the flexibility of the system. Reference [21] suggested a hybrid protocol architecture for Short Message Services (SMS) that incorporates AES and Rivest Cipher 4 (RC4) algorithms to enhance the security of smart houses. This solution offered secure communication in the IoT context, ensuring confidentiality and randomness. However, it incurred a certain level of cost in terms of both time and space. Hossain et al. In study [21] author developed a flexible encryption method on the FPGA. Users have the option to choose between the AES, Data Encryption Standard (DES), and 3DES algorithms for encryption, based on their specific needs. This design enhanced system adaptability, but incurred wastage of logic resources. The advent of dynamically reconfigurable technology offered a superior option to achieve a balance between system flexibility and hardware resource usage.

Many studies are devoted to creating specialized hardware accelerators that can be utilized to carry out specific tasks in applications related to image and video processing. To showcase the system's functionality, spatial filters were implemented on the embedded platform Zedboard [22]. The paper examines a recent study on a hardware accelerator for video processing, which was developed on an Altera Cyclone IV FPGA. The accelerator is engineered to possess reduced processing and memory bandwidth demands. The research findings are detailed in citation [23, 24]. Platforms Based Design (PBD) analyzes the Virtex-5 FPGA's performance in real time while processing images and videos by looking for commonalities and differences among different design criteria. To implement an effective architectural solution, the Xilinx ML-507 platform runs a PBD. This system is capable of real-time 60 fps video capturing in VGA resolution [5]. On the Xilinx Zynq7000 System on a Chip (SoC), different designs have been constructed using the Histogram of Oriented Gradients, or HOG, method. These designs can process images with a resolution of 1920 x 1080 pixels and achieve a frame rate of 39.6 frames per second: [6]. The authors demonstrated how to use the OpenCV function on an ARM processor for hardware implementation. The several classifications of hardware accelerated systems that employ Field-Programmable Gate Arrays (FPGAs) for image analysis are concisely listed in reference [2]. FPGAs have the capability to perform concurrent execution of several threads, allowing them to effectively handle a diverse array of applications, including those commonly encountered in the automotive industry. When it comes to driver assistance systems (DA), most researchers have highlighted the improvements in image and video processing [14]. Claus et al. [15] proposed the utilization of dynamic partial reconfiguration (DPR) in driver assistance (DA) systems, employing Multiple Processor System-on-Chip (MPSoC) architecture, to enhance security in various driving situations. The "Autovision" architecture was designed to demonstrate the benefits of DPR by utilizing hardware accelerated engines. Several observations focus on the development of hardware-based real-time lane identification for advanced driving assistance systems. Using the Hough Transform, real-time lane detection is implemented at a clock speed of 100 MHz on the Xilinx Zynq-7000 platform. Thanks to its 480 × 270-pixels resolution, it can run at 130 fps per second. The implementation is performed via the Vivado HLS tool [16]. FPGAs are well-suited for complex video and image processing workloads, such as K-means clustering.

The process of dividing an image into segments and compressing it without any loss of data is referred to as picture segmentation and compressing without loss [17]. Edge detection is an advanced image processing technique mostly used in surveillance systems. The article authored by Kowalczyk et al. [8] examines the practical execution of 4K streaming of videos on Xilinx devices. A high-definition video streaming system utilizing quick prototyping has been developed, employing an FPGA-based edge detection design [9]. The research presents a comparative analysis and investigation into edge recognition filters implemented on Field-Programmable Gate Arrays (FPGAs) for real-time processing of video and images techniques [10]. Babu et al. [11] present a succinct analysis of the various classifications of FPGA architecture and their corresponding applications.

III. FPGA High-Level Synthesis for Image Processing System with Matlab HDL Coder

In this newly created file, highlight all of the contents and import your prepared text file. You are now ready to style your paper; use the scroll down window on the left of the MS Word Formatting toolbar.

Fig. 2 displays the simplified block diagram of the proposed system architecture. The design is suitable for both image and video encryption and decryption, as it allows for the sequential streaming of information for each pixel. However, when it comes to video processing, the method may require a single pixel or several pixels.

The system comprises a range of video processing processes that can be controlled by specific algorithms, resulting in the faster execution of certain filters on the integrated blocks of the Xilinx SoC platform. The output is directly transferred to a video processing component and display component. In addition, the processed output is produced and displayed outside on an HDMI monitor. Xilinx implements various video processing accelerators in the programmable logic (PL) based on the design.

Fig. 2 shows the design schematic for the proposed system. This method is applicable to video and image processing due to the sequential processing of the input pixels. When encrypting and decrypting embedded videos, mega pixels are required. Built on the embedded Xilinx SoC platform blocks, it can run complex algorithms faster thanks to a video block that can be configured with unique algorithms. The video processing block and display component directly accept the output from the video and picture systems [16]. The Xilinx Zynq 7000 platform systems are utilized for the implementation of several FPGA video and image processing accelerators [5,14]. The Advanced Extensible Interface (AXI) in the architecture shown in Fig. 1 connects the processor responsible for transferring the incoming video to the video processing pipeline system. The ARM CPU and the USB camera communicate over interfaces and exchange data. The memory controller contains the frame data. The HDMI display exhibits the method when the video IP core has finished executing it on the frame. The pipeline is being maintained for future versions [10].

The necessity to create intricate DSP systems that call for specialized arithmetic units, such the addition-compare- select unit for the Viterbi decoder, gave rise to the MBD approach for FPGAs. A more refined degree of FPGA-based circuit optimization is needed for these computing units [17]. This degree of optimization is typically linked to conventional digital design systems for processing images and videos. In essence, model-based design describes the real- time interactions that a system will have with the analog environment. The bulk of these apps make use of the widely used Unified Modeling Language (UML). The methods by which these tools establish and describe a system differ. These tools may employ various implementation tactics, some of which may prove to be less effective than others. However, they assure rapid system prototyping, ensuring punctuality. Some factors that affect the choice of a tool are its level of flexibility, its availability as pre-built libraries and blocks, and its general understanding.

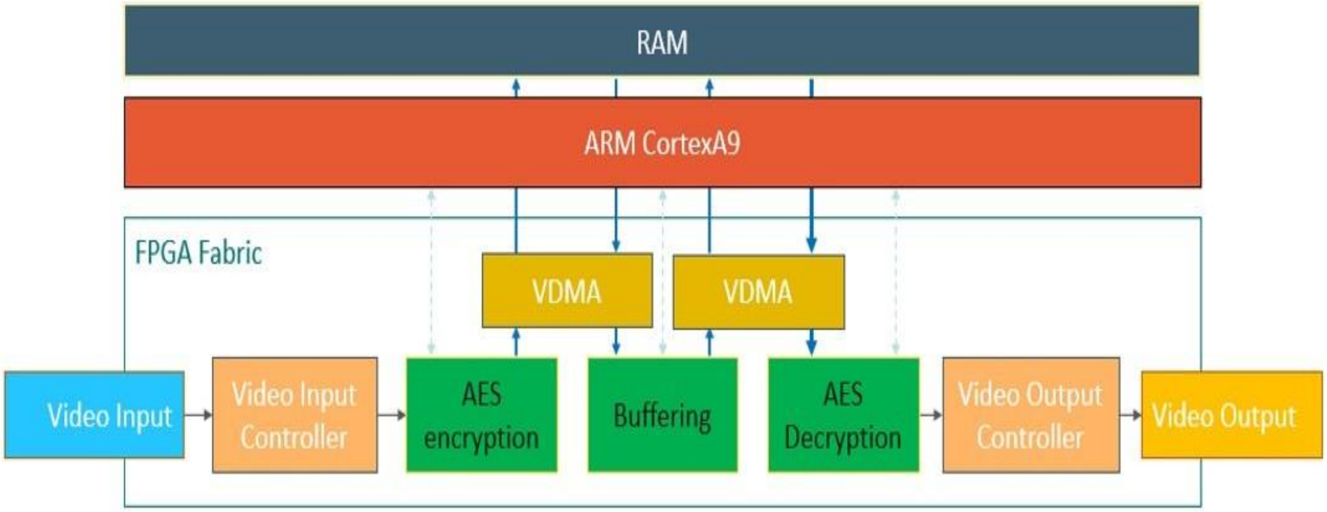

Fig. 2. Crypto-video system on FPGA based on Zynq7000 platform.

Matlab, Simulink Realtime Workshop, Arti-Real Time Studio, and Rhapsody from Ilogix are among the UML-based tools [15]. These instruments are used in the creation of embedded multiprocessor environments. There are two types of tools that facilitate the creation of HDL code for FPGA: block-based tools and C language-based tools that utilize blocks to produce HDL code from block diagrams. Following that, the HDL code is utilized by the hardware of the synthesis tool in order to put the system design into action on the FPGA computer. Synplify DSP, Xilinx System Generator, DSP Builder Altera, and Simulink HDL Coder are some of the tools that are predicated on the Simulink and MATLAB environments. The majority of these tools are based on these environments. These technologies ensure a sophisticated modeling environment for signal processing algorithms. Combining the IP cores from FPGA manufacturers with blocks from the Simulink library results in the creation of HDL code that is singular to the platform in question. The designer benefits from more freedom through the utilization of tools such as Simulink HDL Coder, which seamlessly incorporates MATLAB functions and m-block files. The designer generates a Simulink model and subsequently transforms it into the FPGA environment with these tools.

The second group of MBD tools uses C to construct a system design abstraction. Among these are the Handel-C from Celoxica and the Catapult C from Mentor Graphics. A popular tool for developing embedded systems on FPGA, the Simulink HDL coder is the main engine behind these products [9].

MathWorks introduced its hardware/software workflow for Zynq-7000, with a specific focus on Model-Based Design (MBD), in September 2013, as stated in references [10, 11]. According to the depicted process in Fig. 3, Simulink is utilized with HDL toolkit to create models that may effectively demonstrate a fully dynamic system. These encompass a Simulink model designed for algorithms specifically tailored for the Xilinx Zynq SoC platform. Additionally, it enables the rapid creation of software-hardware implementations for the Zynq platform directly from the algorithm and system architecture.

Fig. 3. Model based design prototyping with MATLAB / HDL coder.

The development of the suggested real-time video processing system is bifurcated into two components: 1) Designing the architecture of a video processing system, and 2) Designing algorithms for video processing. The initial section examines the primary elements that contribute to the video processing system on the Zynq platform, specifically focusing on the AXI4 Interfaces utilized for efficient data transmissions. The subsequent section delves into the strategies and enhancements implemented for constructing video processing algorithms using Vivado HLS [25]. The proposed approach is founded upon the following fundamental principle:

- The utilization of Simulink simulation by system designers and algorithm developers serves two purposes.

The designer's task is building models for an entire system, encompassing communications, image, and video processing components. The second purpose is to enable the division of the model into hardware and software components and achieve a favorable balance for high-level synthesis.

- The Xilinx Zynq 7000 platform can be equipped with high-speed I/O cores and IP cores through the utilization of HDL code generation from HDL coder TM.
- The Zynq Cortex-A9 cores can be programmed using the embedded coder from Simulink, which facilitates quick iteration of embedded software development.
- The ARM processor system and programmable logic with support for Xilinx Zynq 7000 may generate automatic AXI4 interface cores.
- Integration with subsequent processes, such as software compilation, generating the executable for the ARM, and creating bit streams using Xilinx implementation tools like Vivado, allows for a fast prototype process. These jobs can be directly downloaded to Zynq 7000 platform boards.

IV. Fundamentals of the AES-128 Encryption / Decryption Algorithm

Similar to the Data Encryption Standard (DES), the AES algorithm presented in Fig. 4 operates as a block cipher at the bit level. Each block length is set at 128 bits, whereas the key length can be any value between 128 and 256 bits [20]. Every 128-bit data block is divided into 16 bytes, which are then mapped onto a 4 × 4 array called state. Every byte in the state represents a 2 x 8 cardinality Galois Field (GF) element. The algorithm consists of n rounds, or iterations, depending on the length of the key. For a key length of 128 bits, 192 bits, or 256 bits, the number of rounds is 10, 12, or 14. With the exception of the final round, each encryption round consists of the following four operations:

- Substitute Bytes
- Shift Rows
- Mix Columns

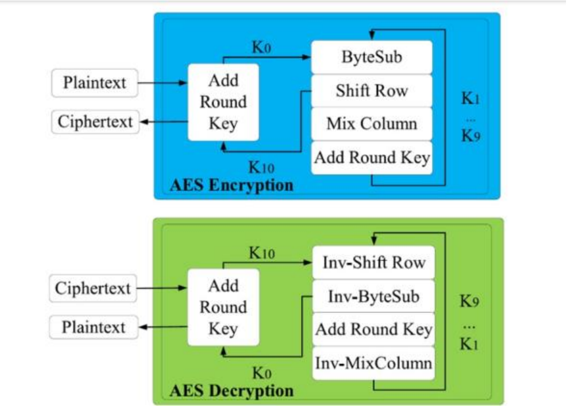

Fig. 4. AES encryption and decryption process.

- Add Round Key

Every operation is executed in turn throughout each round, with the exception of the first Add Round Key; the Mix Columns action is skipped in the last round (see Fig. 5).

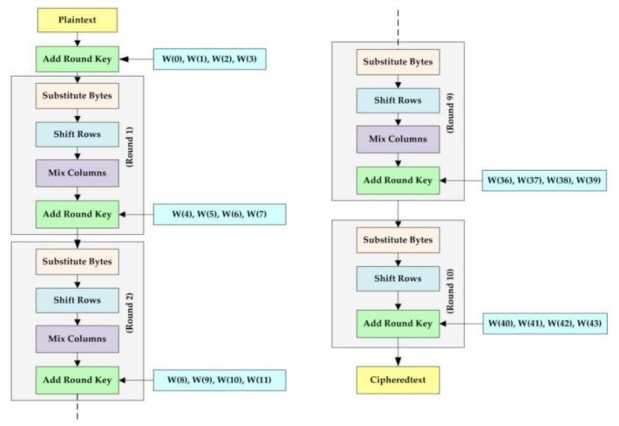

Fig. 5. AES 128 encryption algorithm.

The Substitute Bytes step is a non-linear transformation in which the relationship between the key and the cipher-text is hidden by replacing each byte in the state array with the entry of a fixed 8-bit Substitution Box (Sbox), which is implemented as a lookup table with 2 8 words of 8 bits each. To prevent assaults based on basic algebraic features, the Sbox utilized is constructed from the multiplicative inverse over GF(28) and paired with an invertible geometric transformation, yielding a 16 × 16 bytes table (see Fig. 5). Based on the most and least significant nibbles of the 8-bit input data, the permutation is obtained T The bytes in each row are circularly shifted by a specified offset during the Shift Rows step's operation on the state array's rows. Every byte in the second row is moved one position to the left; similarly, the third and fourth rows are shifted by two and three bytes to the left, respectively. The first row remains unmodified. In the Mix Columns phase, each column of the state array is mixed linearly by treating it as a polynomial over GF(28). Each column is then multiplied, modulo z4 + 1, by a fixed polynomial (c(z) = 03z3 + 01z2 + 01z + 02). The relationship between the plain text and the ciphertext must be concealed using both the Mix Columns and Shift Rows methods.

V. Image and Video Acceleration with High Level Synthesis

The functional diagram of the suggested system design is displayed in Fig. 6. Since the input pixels are processed sequentially, the approach can be used to both image and video processing. Mega pixels are needed in the embedded video processing process. It is constructed from a video block that can be programmed with customized algorithms, speeding up complicated and resource- and time-consuming algorithms on the embedded Xilinx SoC platform blocks. A video processing block and a display component receive the output directly from the video and image systems [16]. The Xilinx Zynq 7000 platform systems are used to implement the several FPGA video and image processing accelerators [5] One MBD tool that makes system modeling, analysis, and simulation possible is Simulink HDL coder. It provides the designer with an organized graphical environment that enables the creation of highly complicated system designs. Moreover, the user of this application can generate adaptable custom blocks using MATLAB functions. utilizing Simulink blocks, the designer can produce bit-precise and synthesizable HDL code from the model by utilizing the Simulink HDL coder. Altera Quartus II, Synplify, and Xilinx Vivado are some of the tools that can be used to synthesis and map the obtained HDL code to the target FPGA board. There are numerous built libraries in the Simulink HDL coder [11]. Adders, multipliers, accumulators, integrators, multi-port switches, lookup tables, etc. are a few examples of these preset libraries.

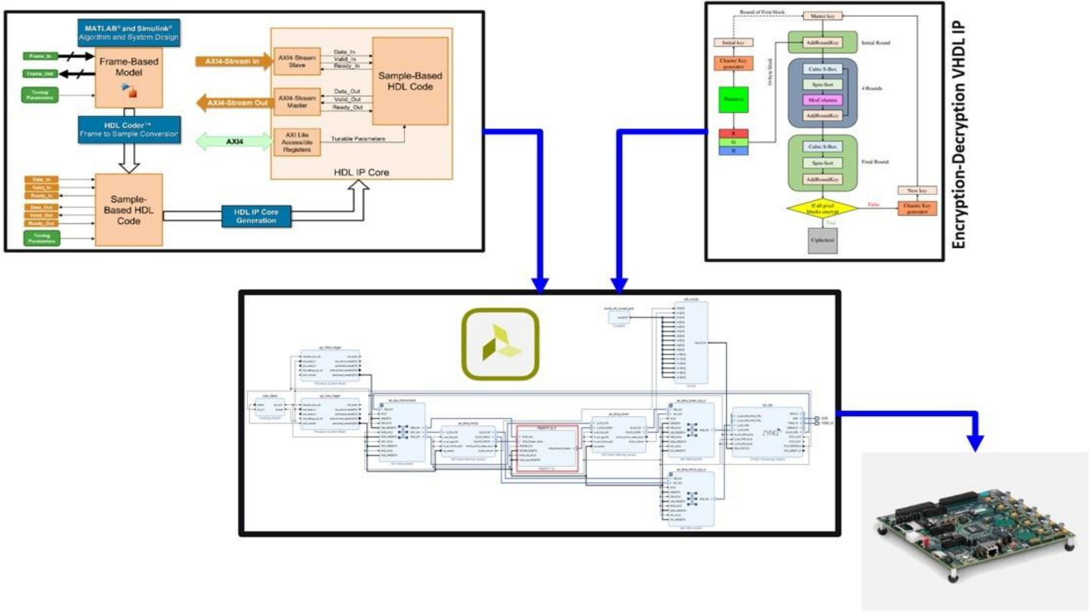

Fig. 6. FPGA crypto system design.

A typical MBD design flow for implementing FPGA-based video and image processing system is shown in Fig. 6. this system is divided on two part,First part is to generate a complete video processing system based on Matlab/HDL Coder . This generated vivado project system is without encryption and decryption IPs.The second part is designing with VHDL language the top level for encryption and decrytion block.After Encryption and decryption IPs simulation and verification. Theese IPs are added to the full complete vivado project for real time video processing.Finally the final combined system for video encryption and decryption is implemented and verified on zynq7000 paltform.

VI. RTL Design Implementation

A. Simulation

To validate the accuracy of the encryptions and decryption implementation, a testbench has been created to compare two distinct ciphertexts generated by this implementation with the expected true ciphertexts provided in reference. The implementation successfully passes the verification process, and a snapshot of the waveform produced from the simulation using the vivado 2017.4 simulator is shown in Fig. 7.

B. Synthesis and FPGA Implementation

In the third and final phase (see Fig. 8), the Simulink HDL Coder transforms the Software-Hardware model of the video processing system into an IP core that is compliant with the AXI4 streaming bus and is in the form of HDL (VHDL) source code. Encryption and decryption IP designed with VHDL language are integrated using Vivado to the full System to generate the RTL video encryption and decryption design as presented in Fig. 8.

In order to confirm the functionality of this IP core in a real-time, practical setting, a Hard- ware–Software co-design (HW–SW) has been directly implemented on a 170MHz Xilinx Zynq-7000 AP SoC XC7Z020- CLG484 FPGA. A Full Vivado project is generated for the HW-SW by the Simulink HDL coder. The Xilinx Vivado tool (version 2017.4), along with all the hardware and software add-ons, can be used to implement this project. Additionally, a single bus connects the Sobel core and the Color transform IP core. The video processing system Vivado project now includes the AES encryption-decryption based on VHDL as an IP. The RTL design for our crypto-video system is shown in Fig. 8.

C. Resource Utilization

The proposed system used the Zynq-7000 SOC to implement the cores of our video processing system. Table I lists the materials that were utilized. BRAM is used to store data values, firmware, and instruction memory.

The architecture of the processor, which includes control signals, internal registers, and mi- crocode, is defined by the consumed LUTs and DFFs. Our suggested system core operates best at about 296MHz with a throughput of 95FPS. The Zynq7000 SOC's resources are impacted by the intricacy of the applied design. The suggested architecture operates with a 1080-1920 frame input resolution. These findings support the Vivado-based reconfigurable SOC platform.Table I provides a breakdown of the resources used by the system, including Block RAM (BRAM) for data storage and Look-Up Tables (LUTs) and Flip-Flops (DFFs) for the processor architecture. This information is crucial for understanding the resource footprint of the design and its feasibility for different Zynq-7020 models.

D. Encryption / Decryption Time Test

Encryption and dcreyption speed is crucial. The timer is implemented to precisely track encryption and decryption cycles, determining the exact number of operations needed for each process. This granular data allows us to optimize performance and ensure efficient data protection.

$$T_{Proc} = N_C \times T_{cycle} = \frac{N_c}{FPGA_{Freq}}$$

where, Nc, the total encryption cycles for the image, is calculated by multiplying the clock cycle duration (Tcycle = 1/FPGAFreq) by the total execution time.

For a 512x512 image, the proposed encryption decryption algorithm required approximately 53.96 million cycles (75ms) and decryption required 54.85 million cycles (80ms). This compares favorably to other solutions in the literature (see Table II).

TABLE I. VIDEO ENCRYTION AND DECRYPTION RESOURCES UTILISATION

Decryption time	0,08
Image preprocessing time	0.035
Total	**0.19**

VII. CONCLUSION

Accurate implementation PPA details can be difficult, if not impossible, to obtain during the algorithm development phase in a normal design flow because doing so means putting a lot of work on the implementation team to complete experimental implementations. Algorithm developers employ imprecise estimations for PPA prediction because of this difficult task. The PPA objectives are frequently not met as a result of algorithm developers' inaccurate estimations. Algorithm developers an quickly obtain precise PPA information using the MATLAB connection with Stratus HLS, which enables measurement- driven algorithm improvement. The solution automates a large portion of the manual process from MATLAB to implementation details with minimal disruption to the current design flow. Additionally, this connection automates the creation of more optimal RTL and micro-architectural exploration, resulting in shorter design deadlines and better PPA. According to preliminary findings, this process will essentially become the norm for creating and executing silicon-targeted algorithms. In this study, the application of typical AES encryption is investigated on a Xilinx ZedBoard equipped with a Zynq- 7000 SoPC. This effort concentrated on the encryption side of AES128; however, it would not be difficult to construct and test the decryption side as well. Xilinx Vivado High Level Synthesis was used to implement the AES after it was first coded in a high-level language. It will be easy to swiftly implement our design and perform changes that significantly raised the AES algorithm’s throughput thanks to the Xilinx HLS tool. Additionally, HLS has the ability to enable thorough examination of a design’s resource utilization in comparison to high-level code placement, as well as hardware testing during the early phases of design.future work will explore expanding the HLS-MATLAB integration to encompass the decryption side of AES as well as investigating its application to a wider range of algorithms across diverse domains. This continued exploration holds immense promise for revolutionizing the way the proposed system is developed and deployed efficiently, high-performance hardware solutions.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deanship of Scientific Research at Northern Border University, Arar, KSA for funding this research work through the project number “NBU-FFR-2024-1092-01”.

A Method to Increase the Analysis Accuracy of Stock Market Valuation: A Case Study of the Nasdaq Index

Haixia Niu*
School of Finance, Henan Finance University; Zhengzhou Henan, 451464, China

***Abstract*—For a significant period, conventional methodologies have been employed to assess fundamental and technical aspects in forecasting and analyzing stock market performance. The precision and availability of stock market predictions have been enhanced by machine learning. Various machine learning methods have been utilized for stock market predictions. A novel, optimized machine-learning approach for financial market analysis is aimed to be introduced by this study. A unique method for improving the accuracy of stock price forecasting by incorporating support vector regression with the slime mould algorithm is presented in the present work. Other optimization algorithms were employed to enhance the prediction accuracy and the convergence speed of the network, which were Biogeography-based optimization and Gray Wolf Optimizer. An assessment of the proposed model's effectiveness in predicting stock prices was conducted through research employing Nasdaq index data extending from January 1, 2015, to June 29, 2023. Substantial improvements in accuracy for the proposed model were indicated by the results compared to other models, with an R-squared value of 0.991, a root mean absolute error of 149.248, a mean absolute percentage error of 0.930, and a mean absolute error of 116.260. Furthermore, not only is the prediction accuracy enhanced by the integration of the proposed model, but the model's adaptability to dynamic market conditions is also increased.**

Keywords—Machine learning; Nasdaq index; support vector regression; gray wolf optimizer; slime mould algorithm

I. Introduction

The stability and safety of the stock market are considered of utmost importance, as it is regarded as a crucial element within national economies [1] [2]. The behaviors and consequences of the stock markets have become a vital area of scholarly investigation owing to the potential risks associated with them [3]. The forecasting of stock price trajectories is deemed a crucial responsibility as it serves the dual purpose of maintaining stability within financial markets by regulators and enabling investors to make informed choices while mitigating potential risks. The utilization of uncertain prediction processes and the subsequent generation of erroneous predictions can potentially lead to significant hazards [4]. Hence, the development of a robust and compelling predictive model is deemed crucial for mitigating potential hazards. The issue of stock market uncertainty is addressed by other theories, while conventional forecasting techniques rely on patterns that exhibit consistent behaviour across time. The aforementioned approach fails to account for the inherent volatility of the stock market, and when combined with the multitude of variables involved, the task of predicting stock values becomes a complex endeavor. Nevertheless, the emergence of machine learning (ML) [5] [6] is being considered. A comprehensive approach that utilizes a variety of algorithms to optimize performance in various situations is demonstrated by the solution offered. This emerging advancement exhibits considerable promise in its capacity to fundamentally transform our methodologies for forecasting stock market trends. The notion that trustworthy information can be discerned and patterns within a given dataset can be identified through machine learning is commonly accepted [7].

The anticipation of stock market trends has been an enduring area of interest for scholars, and machine learning methodologies are progressively assuming a more prominent role in this regard. By conducting a comparative analysis of state-of-the-art machine learning methods using a decade of daily historical data from the top 10 equities on the Casablanca Stock Exchange, our study contributes to this ongoing dialogue. It is worth mentioning that ensemble learning has been utilized in the past for this purpose, as demonstrated by Bilal et al. [8]. These efforts employed various classifiers, including ridge regression, LASSO regression, support-vector machine (SVM), k-nearest neighbors, random forest, and adaptive boosting. SVM, adaptive boosting, random forests, and SVM were discovered to perform exceptionally well in short-term forecasting, demonstrating the effectiveness of ensemble learning across a range of prediction horizons. Expanding upon the aforementioned groundwork, Sonkavde et al. [9] investigated a variety of methodologies including time series analysis, ensemble algorithms, deep learning, and supervised and unsupervised machine learning, in order to address the complexities associated with stock price classification and prediction. Furthermore, a comprehensive analysis of the Nasdaq stock market was presented by Ashfaq et al. [10], who employed a variety of machine learning regressors to forecast the opening prices of specific companies the following day. For the purpose of evaluation, they utilized metrics such as the mean square error and coefficient of determination, thereby enhancing our comprehension of predictive modelling within this particular domain. Agrawal et al. [11] presented a seminal study in which they described an algorithmic approach for predicting the stock market that utilized deep learning and non-linear regression. The researchers' investigation, which utilized a decade's worth of data from the New York Stock Exchange and Tesla Stock Price, demonstrated that their proposed solution outperformed currently available machine learning algorithms. However, in their inability to adapt to the volatile and unpredictable nature of financial markets, these methodologies frequently encountered obstacles. The trade-offs that existed between accuracy and computational efficiency exposed this dilemma.

The advantages and disadvantages of these literatures are presented in the Table I. In order to fill this void, our research presents an enhanced machine-learning methodology that integrates the slime mould algorithm and support vector regression in a synergistic fashion. The objective of this innovative approach is to surmount the limitations identified in prior investigations through the improvement of forecast accuracy and flexibility in the face of market volatility. Our methodology signifies a substantial deviation from traditional approaches, enabling a more intricate examination of intricate market data and surmounting the constraints intrinsic in conventional models. Our objective is to provide a comprehensive resolution to the persistent difficulty of precisely forecasting stock market fluctuations within a dynamic financial environment.

TABLE I. THE ADVANTAGES AND DISADVANTAGES OF THE RELEVANT LITERATURE

Authors	Advantages	Disadvantages
Bilal et al. [8]	Effective for short-term forecasting across a range of prediction horizons.	Lack of adaptability to unpredictable and volatile stock market.
Sonkavde et al. [9]	Addresses complexities of stock price classification and prediction.	Unable to adapt to stock markets that are volatile and unpredictable.
Ashfaq et al. [10]	Enhanced understanding of predictive modeling.	Unableness to adjust to unexpected and chaotic stock markets.
Agrawal et al. [11]	Outperformed existing machine learning algorithms.	Inability to adapt to volatile and unpredictable financial markets.

Linear regression is one of the machine learning models most frequently utilized for forecasting. A valuable statistical technique that can be employed to make predictions about a numerical outcome is provided by linear regression [12]. Artificial neural networks (ANN) [13], Support vector machines (SVM) [13], Decision trees [14], Random Forest [15], Logistic regression [16], Gradient boosting [17], time series forecasting [18], and more. All of these models possess the limitations and advantages that exert a substantial influence on the accuracy of predictions.

The method of research employed in this study is support vector regression (SVR), which is a resilient form of supervised learning. In SVR, an effort is made to minimize both structural risk and empirical risk while also reducing the range of trust in training examples. A significant level of efficacy is demonstrated by the previously mentioned methodology in addressing intricate nonlinear issues, particularly those characterized by a limited sample size. Notable efficacy in addressing intricate nonlinear issues, particularly those characterized by a limited sample size, is demonstrated by the mentioned methodology. A crucial role is played by SVR in mitigating risk and enhancing the overall predictive accuracy of future samples. This, in turn, facilitates the extraction of useful insights and enhances the decision-making process [19]. An in-depth understanding of the principles and advantages of SVR is imperative for achieving ideal outcomes and accomplishments in several fields, such as machine learning, data science, and related domains.

The behavior and performance of a model during training are significantly influenced by a range of hyperparameters. Several factors, such as model complexity, regularization power, and learning rate, among other considerations, are encompassed by the hyperparameters. To optimize the model's efficacy, the careful selection and meticulous refinement of appropriate hyperparameters are imperative. Engaging in this practice has the potential to greatly affect the precision, resilience, and the applicability of the model, enabling it to more effectively align with the dataset on which it is being trained. Hence, the meticulous fine-tuning of the hyperparameters is an essential stage in achieving the utmost performance of the model. Various techniques and algorithms are employed for the optimization of hyperparameters for models, such as grey wolf optimization (GWO) [20] [21], Biogeography-based optimization (BBO) [22], Grasshopper optimization algorithm (GOA) [23], Slime mould algorithm (SMA) [24], Moth flame optimization (MFO) [25], and more. Some of the above optimization techniques are nature-inspired. Three strategies were applied to improve the proposed model's hyperparameters: Biogeography-based optimization, grey wolf optimization, and the Slime mould algorithm.

The GWO algorithm, as proposed by Mirjalili et al. [21], is inspired by the hierarchical structure of leadership and hunting patterns observed in grey wolves. Fundamentally, the grey wolf species are categorized into four distinct groupings, namely alpha, beta, delta, and omega. A methodology known as BBO, proposed by Nazari et al. [26], is utilized. A pioneering methodology called SMA was presented in a study conducted by Chen et al. This methodology is inspired by the behavioural patterns exhibited by slime mould organisms in natural environments. One intriguing attribute of slime mould is its capacity to perceive the olfactory cues associated with the presence of food particles in the surrounding environment. The olfactory perception of food odors in the surrounding environment is a notable characteristic that contributes to the intriguing nature of slime mold. The SMA approach aims to replicate this inherent mechanism to optimize its efficacy in attaining its goals.

In the present study, a comprehensive dataset covering the period from January 2015 to June 2023 was analyzed using many models. To ensure the accuracy and reliability of the produced outputs, thorough training was conducted for the SVR method, taking into account a wide array of input factors. The criteria included several factors such as daily transaction volume, high and low prices, as well as the opening and closing prices. To assess the accuracy of the model's results, a comprehensive testing procedure was conducted, employing the same parameters as those used during the initial phase. The outcome of this intensive training and evaluation procedure yields a model capable of furnishing traders and investors with invaluable market insights, facilitating well-informed decision-making, and ultimately fostering profitable investments. The variable data was acquired from the stock market of the Nasdaq. In order to achieve its objectives, the research employed a methodology comprising multiple analytical stages. The research paper presents a comprehensive examination of the data source and its relevant elements in the subsequent section. The data are analyzed utilizing a variety of methods, including the SMA optimizer, evaluation metrics, and the SVR model. Following the presentation of the analyses' results in the third section, those obtained from alternative methodologies are contrasted. The study concludes with a concise presentation of the results in the concluding section.

II. Methodology

A. Support Vector Regression

A very effective technique utilized in the domain of machine learning, particularly for nonlinear classification. The SVR has become a widely adopted technique among data scientists due to its ability to handle inputs with high dimensions effectively [27] [28]. The SVR, as seen in Fig. 1, has demonstrated remarkable efficacy in resolving classification problems, prompting its extension to tackle challenges associated with regression. Similar to its predecessor, the present improvement, referred to as SVR, demonstrates exceptional proficiency in managing intricate data sets. SVR and its many extensions have emerged as vital tools in the field of machine learning due to their ability to provide a flexible and accurate methodology for addressing regression and classification problems [29].

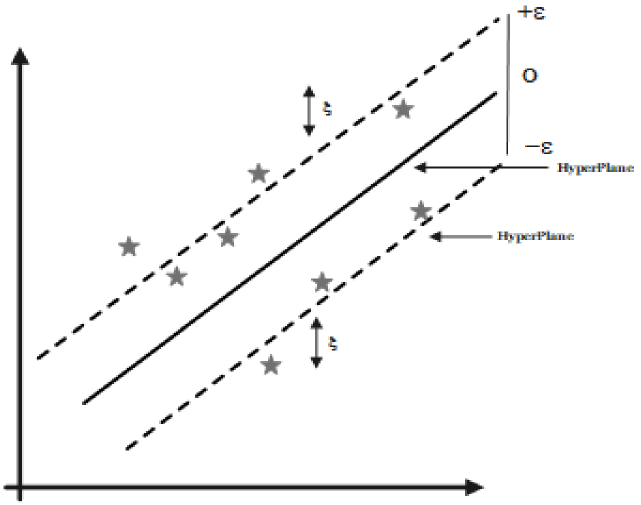

Fig. 1. The diagram of the SVR.

The initial description pertains to a linear function, denoted as f(x), which is characterized by the following mathematical form:

$$f(x) = w \times x + b \tag{1}$$

where, x is the input vector, b is a constant that has to be calculated, and w is the vector holding the parameters. In instances involving nonlinear problems, the data is transformed into a higher-dimensional space by the utilization of a nonlinear kernel.

$$f(x) = w\phi \times (x) + b \tag{2}$$

where, φ(x) is the kernel function.

The utilization of a feature space with larger dimensions can be employed to facilitate the mapping of data, hence enabling the implementation of a linear regression approach. The coefficients w and b can be obtained by minimizing a given function as follows:

$$min \frac{1}{2} \parallel w \parallel^2 + c \sum_{i=1}^{N} (\xi_i + \xi_i^*) \tag{3}$$

The exposure to:

$$\begin{cases} y_i - \langle w, x_i \rangle - b \leq \varepsilon + \xi_i \\ \langle w, x_i \rangle + b - y_i \leq \varepsilon + \xi_i^* \\ \text{with } \xi_i, \xi_i^* \geq 0, i = 1, \ldots..N \end{cases} \tag{4}$$

where, the positive and negative errors are denoted by ξ_i and ξ_i^*, respectively. The constant C>0 is a hyperparameter that enables the adjustment of the trade-off between the permissible error and the flatness of the function $f(x)$.

B. Biogeography-based Optimization

The BBO algorithm operates by simulating the movement of various species, which is determined by the suitability of their respective habitats. This process allows for a comprehensive analysis of the complex relationships between different species and their environments, ultimately leading to more refined and accurate predictions about ecological patterns. In the context of an optimization issue, it might be argued that a solution bears resemblance to a habitat. An optimal approach for addressing population concerns involves the establishment of densely populated habitats that offer superior living circumstances for various species compared to alternative habitats. The environment in which living animals encounter significant challenges is where the least optimal solution within the population is found. Therefore, the superior solutions can attract the inferior solutions due to their shared characteristics. The method of sharing features is accomplished by the utilization of the outlined operators.

Operation of Migration: Migration is a procedure through which a poorer habitat is swapped with a better one based on emigration rates. The quantification of the influx of species in a given area is referred to as the immigration rate. The migration incidence is anticipated to be greater under a more favourable solution compared to a less favourable option.

On the contrary, the quantitative assessment of the number of individuals within a species that depart from their environment is known as the rate of migration. Consequently, the emigration rate is expected to be greater under a suboptimal solution compared to an optimal option. The basic form of BBO has utilized straight paths as shown in Eq. (4).

$$\mu_k = \frac{E \times k}{n} \lambda_k = I \left(1 - \frac{k}{n}\right) \tag{5}$$

$\boldsymbol{\mu_k}$: Migration amount of **k**th habitat.

$\boldsymbol{\lambda_k}$: Migration amount of **k**th habitat.

I: Maximum immigration amount.

E: Maximum emigration rate.

$\boldsymbol{n} =$: Maximum number of species that a habitat can support.

K: Number of species count.

Mutation: Mutation in BBO may be likened to an abrupt alteration in the environmental circumstances experienced by living organisms, such as those caused by natural disasters like earthquakes, volcanic eruptions, or tornadoes. Similarly, the random modifications in the genetic makeup of a species prompt its migration to a new habitat, as the previous habitat becomes unsuitable for its survival.

C. Gray Wolf Optimizer

The GWO is a unique optimization approach that has been developed through the utilization of a meta-heuristic method. The strategy, initially introduced by Mirjalili et al. [18], emulates the social hierarchy and hunting strategies employed by grey wolves. Alpha is often regarded as the most optimum choice, whereas Omega is positioned as the final challenger inside the hierarchical framework of leadership.

Three principal hunting techniques are utilized by the method in order to emulate the behaviours of wolves: The action of following, confining, and assaulting prey. To simulate the locomotion patterns of grey wolves during hunting activities in their natural habitat, the following relate was employed:

$$\vec{D} = \left|\vec{C} \cdot \vec{X}_p(t) - \vec{X}(t)\right|$$

$$\vec{X} \mid (t+1) = \vec{X}_p(t) - \vec{A} \cdot \vec{D} \tag{6}$$

In which, $\boldsymbol{t}$ is the current iteration, $\overrightarrow{\boldsymbol{D}}$ denotes movement, $\overrightarrow{\boldsymbol{X}_{\boldsymbol{p}}}$ denotes prey location, $\overrightarrow{\boldsymbol{A}}$ and $\overrightarrow{\boldsymbol{C}}$ denotes coefficient vectors, and $\overrightarrow{\boldsymbol{X}}$ denotes the grey wolf's position. The coefficient vectors ($\overrightarrow{\boldsymbol{A}}$ and $\overrightarrow{\boldsymbol{C}}$) are constructed using the relationships shown below.

$$\vec{A} = 2\vec{a} \cdot \vec{r}_1 - \vec{a}$$

$$\vec{C} = 2 \cdot \vec{r}_2 \tag{7}$$

The spatial allocation of novel search representatives pertaining to omegas is modified by using data derived from alpha, beta, and delta in the following manner:

$$\vec{D}_a = \left|\vec{C}_1 \cdot \vec{X}_a - \vec{X}\right|, \vec{D}_\beta = \left|\vec{C}_2 \cdot \vec{X}_\beta - \vec{X}\right|, \vec{D}_\delta = \left|\vec{C}_3 \cdot \vec{X}_s - \vec{X}\right| \tag{8}$$

$$\vec{X}_1 = \vec{X}_a - \vec{A}_1 \cdot \vec{D}_u, \vec{X}_2 = \vec{X}_\beta - \vec{A}_2 \cdot \vec{D}_\beta, \vec{X}_3 = \vec{X}_b - \vec{A}_3 \cdot \vec{D}_\delta \tag{9}$$

$$\vec{X}(t+1) = \frac{\vec{X}_1 + \vec{X}_2 + \vec{X}_3}{3} \tag{10}$$

The wolves, denoted by the subscripts $\alpha, \beta,$ and δ , converge to initiate a conclusive assault in order to accomplish the objective successfully. The variable $\vec{\boldsymbol{a}}$ is used in order to replicate the previous assault by altering a value from 2 to 0. On the other hand, the variable a represents a random variable that falls between the range of $-2\vec{a}$ and $2\vec{a}$. Consequently, if $\vec{a}$ is lowered, it will also lead to a decrease in the value of $\vec{A}$. The wolves were compelled to grasp their prey due to the factor tightly $|\vec{A}| < 1$. Grey wolves engage in cooperative hunting strategies by forming packs and exhibiting a hierarchical social structure. These packs are led by an alpha wolf, who guides the group's activities. The pack members disperse to forage for food individually, and then afterwards regroup to launch coordinated attacks. Wolves may separate in search of prey when $|\overrightarrow{\boldsymbol{A}}|$ has a random value greater than unity. The wolf count and generation number are considered to be the two most critical configuration parameters for the GWO algorithm. This means that the total number of objective function evaluations will be equal to the wolf population times the size of the generation or,

$$OFEs = N_W \times N_G \tag{11}$$

D. Slime Mould Algorithm

Li et al. introduced a unique approach called SMA, which draws inspiration from the behaviour of slime mould seen in natural environments [24]. The slime mould, which is represented in Fig. 3, uses its olfactory perception and detects the volatilized scent of nourishment in the air in order to approach its prey. Fig. 2 provides a comprehensive illustration of the general characteristics of SMA.

The behaviour of the slime mould may be mathematically described by the equation that goes as follows:

$$\overrightarrow{X(t+1)} = \begin{cases} \overrightarrow{X_b(t)} + \overrightarrow{v_b} . \left(\vec{W} . \overrightarrow{X_A(t)} - \overrightarrow{X_B(t)}\right) & r < p \\ \overrightarrow{v_c} . \overrightarrow{X(t)} & r \geq p \end{cases} \tag{12}$$

In which, $X_b(t)$ reflects the specific area of the slime mould that now exhibits the greatest level of odour, the variables $X(t)$ and $X(t+1)$ represent the locations of the slime mould in iteration t and $t+1$, respectively. $X_A(t)$ and X_B represent two randomly selected sites of slime mould. The variable v_b varies over time within the range [-a, a], where r is a random number between 0 and 1. The parameter p is specified as ($a = \text{arctanh}(-(\frac{t}{\max\_t}) + 1)$), and v_c is a linearly decreasing parameter ranging from 0 to 1.

$$p = tanh\, |S(i) - DF| \quad i = 1, 2, \ldots, n \tag{13}$$

where, DF denotes the fittest iteration overall, and $S(i)$ denotes the fitness of $\vec{X}$. Following is a definition of the weight W equation:

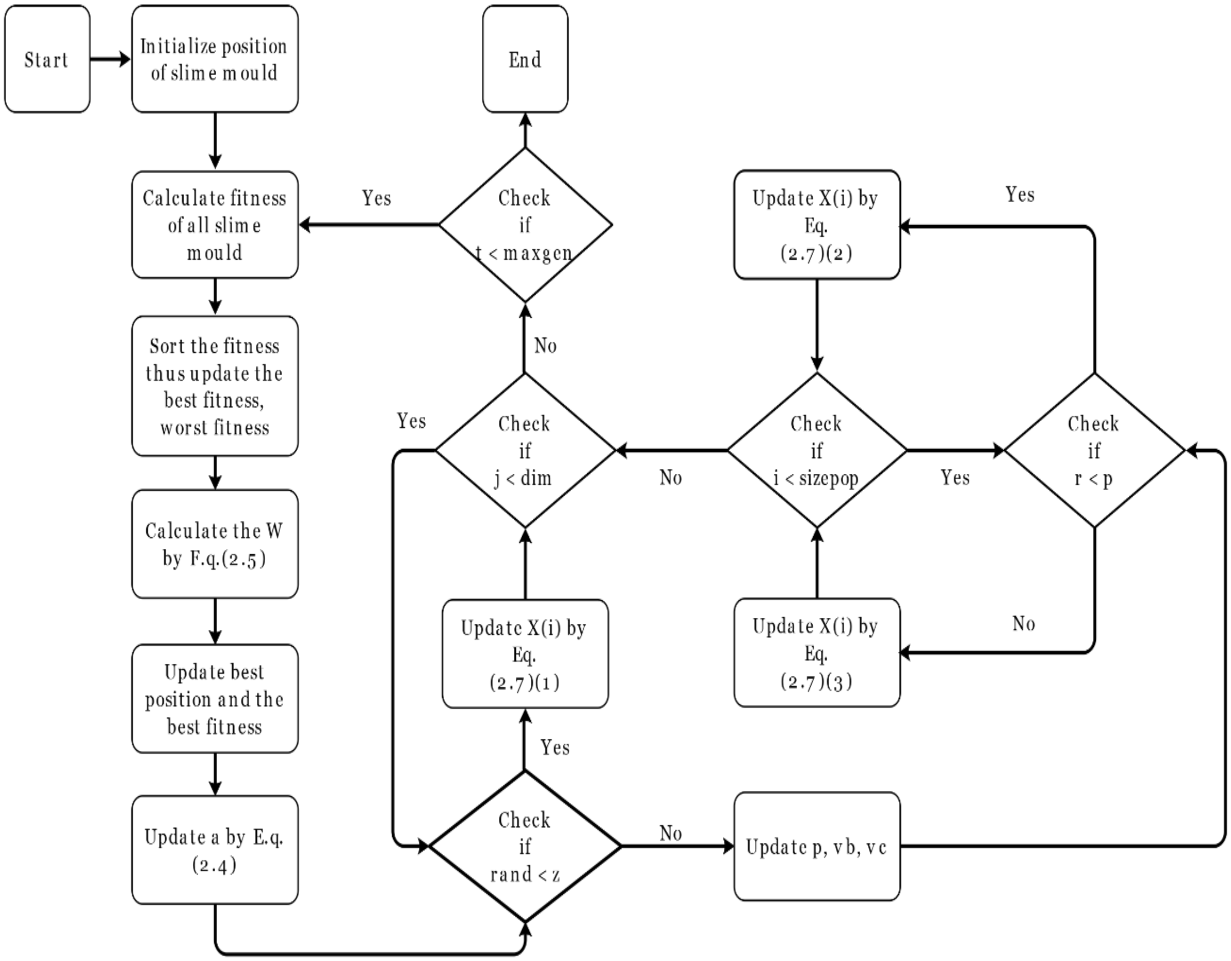
$$\overrightarrow{W(smell\ \imath ndex(l))} =$$

$$\begin{cases} 1 + r.log\left(\frac{bF - S(i)}{bF - wF} + 1\right), condition \\ 1 - r.log\left(\frac{bF - S(i)}{bF - wF} + 1\right), others \end{cases} \tag{14}$$

$$smell\ index = sort(S) \tag{15}$$

The variable $S(i)$ represents the initial half of the population in the given equation. bF for the best fitness, wF for the poorest fitness, and the scent index for the sorted fitness values. By utilizing the formula provided, the spatial coordinates of the slime mould are revised:

$$\overrightarrow{X^*} = \begin{cases} rand(UB - LB) + LB & rand < z \\ \overrightarrow{X_b(t)} + \overrightarrow{v_b} . \left(\vec{W} . \overrightarrow{X_A(t)} - \overrightarrow{X_B(t)}\right) & r < p \\ \overrightarrow{v_c} . \overrightarrow{X(t)} & r \geq p \end{cases} \tag{16}$$



Start
Initialize position of slime mould
Calculate fitness of all slime mould
Sort the fitness thus update the best fitness, worst fitness
Calculate the W by F.q.(2.5)
Update best position and the best fitness
Update a by E.q. (2.4)
End
Check if t < maxgen
Yes
No
Check if j < dim
Yes
Update X(i) by Eq. (2.7)(1)
Check if rand < z
Yes
No
Update p, vb, vc
Check if i < sizepop
No
Yes
Check if r < p
Yes
No
Update X(i) by Eq. (2.7)(2)
Update X(i) by Eq. (2.7)(3)

Fig. 2. The diagram of the Slime mould algorithm.

In this context, the parameter denoted as z is constrained to a range between 0 and 0.1. The terms LB and UB refer to the lower and upper borders of the search interval correspondingly.

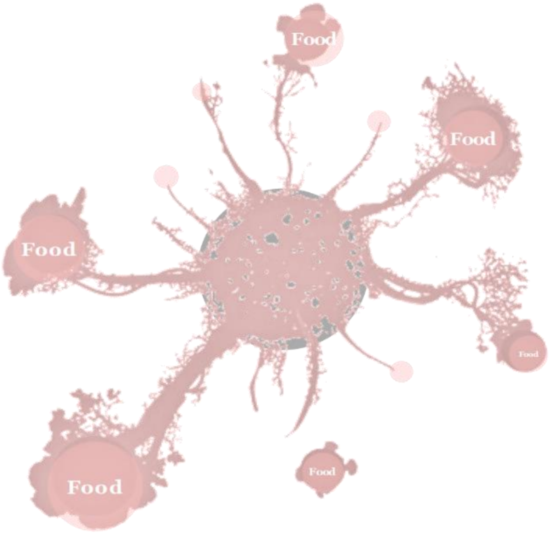


Fig. 3. The illustration of the SMA algorithm.

E. Dataset Collection

In order to conduct a thorough analysis, it is imperative to include trade volume and Open, High, Low, and Close (OHLC) prices during a designated period. Data for this investigation was collected via Yahoo Finance from January 2, 2015, to June 29, 2023. The Nasdaq, which was founded in 1971, is notable for being the inaugural electronic stock exchange in the globe. It distinguishes itself from conventional exchanges by functioning exclusively electronically and utilizing a digital infrastructure that optimizes the trading process. This allows for efficient and rapid transaction processing. In addition to technology firms, the Nasdaq Composite Index comprises companies from consumer services, healthcare, and a variety of other sectors. Due, in part, to its emphasis on emerging sectors and technology, the Nasdaq is a centre for innovative and expanding businesses, given its status as a major participant in international financial markets. Investors routinely track the Nasdaq Composite Index in order to assess the financial well-being of technology and growth firms, as well as to deduce wider economic patterns and investor sentiment.

F. Dataset Description

The process of ensuring the high quality of the raw data is a crucial and fundamental stage in the pursuit of obtaining meaningful insights. The process of data preparation is of utmost importance in attaining this objective. The process encompasses a variety of tasks, such as the elimination of undesirable data, the establishment of standardized formats for widespread applicability, and the arrangement of information in a manner that promotes the retrieval of valuable insights. This has special significance in initiatives that entail substantial quantities of data because data quality takes precedence over mere numerical values. Data preparation activities encompass a range of tasks, such as encoding categorical data, cleaning and organizing data, scaling, standardization, and normalization in accordance with established industry standards. By engaging in these activities, the precision and dependability of the insights derived from the data can be enhanced. To achieve data scaling and normalization, Min-Max scalers were utilized in the project's data pre-processing step. This approach facilitated the removal of inconsistencies, as well as the measurement of null, missing, and unknown values. The methodology was illustrated using the data from the Nasdaq index. The dataset encompasses the timeframe spanning from January 2015 to June 2023 and has undergone several preparatory procedures, such as standardization.

The process of transforming numerical attributes inside a dataset to a specific range, commonly ranging from zero to one, is referred to as feature scaling. This technique is alternatively recognized as Min-Max normalization or data preparation. The objective is to maintain the relative relationships between the values while ensuring that all features are brought to a comparable scale. The consideration of input feature quantity holds particular significance in machine learning algorithms that exhibit sensitivity towards this aspect. The formula for the data normalization procedure is as follows:

$$\text{XScaled } = \frac{(X-Xmin)}{(Xmax-Xmin)} \tag{17}$$

G. Evaluation Metrics

Evaluation metrics are commonly used in the fields of statistics and machine learning to assess the effectiveness of forecasting models quantitatively. They aid in evaluating the predictive accuracy of a model on data that has not yet been observed. The selection of the optimal evaluation metric is contingent upon the particular analytical objectives and the nature of the predictive task at hand. Performance indicators such as R-squared ($\boldsymbol{R^2}$), Root Mean Square Error (RMSE), Mean Absolute Percentage Error (MAPE), Mean Squared Error (MSE), Relative Squared Error (RSE), and Mean Absolute Error (MAE) were utilized in this study to evaluate the prediction accuracy of the developed forecasting models. Below, a compilation of mathematical formulas pertaining to these metrics is provided:

$$\mathrm{R}^2 = 1 - \frac{\sum_{\mathrm{i}=1}^{\mathrm{n}}(\mathrm{y_i}-\hat{\mathrm{y}}_{\mathrm{i}})^2}{\sum_{\mathrm{i}=1}^{\mathrm{n}}(\mathrm{y_i}-\bar{\mathrm{y}})^2} \tag{18}$$

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(y_i-\hat{y}_i)^2}{n}} \tag{19}$$

$$MAPE = \left(\frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i-\hat{y}_i}{y_i}\right|\right) \times 100 \tag{20}$$

$$MAE = \frac{\sum_{i=1}^{n}|y_i-\hat{y}_i|}{n} \tag{21}$$

$$RSE = \frac{\sum_{i=1}^{n}(y_i-\hat{y}_i)}{\sum_{i=1}^{n}(\bar{y}-\hat{y}_i)} \tag{22}$$

$$MSE = \frac{1}{N}\sum_{k=0}^{n}\binom{n}{k}(Fi - Yi)b^2 \tag{23}$$

III. Result and Discussion

A. Statistical Results

Table II displays the statistical characteristics, such as mean, std., min, 25%, 50%, 75%, max, and variance. The central tendency of a data set is quantified by the mean, a statistical term. The calculation involves the sum of all values inside the dataset, followed by the division of the resulting sum by the total count of values. The dispersion or spread of data points relative to the mean is quantified by the standard deviation, a statistical metric. The minimum, minimum value, or minimal observation is the term used for the smallest data point or value in a dataset. It assists in finding the lowest number within a batch of data as well as understanding the range and distribution of the data. The degree to which individual data points in a dataset differ from the average (mean) of the dataset is described by the statistical concept of variance. A low variance denotes that data points are close to the mean, whereas a high variance suggests that data points are dispersed from the mean. Quantiles, specifically the 25th, 50th, and 75th percentiles, play a pivotal role in comprehending the data distribution. As indicated by the 25th percentile (also referred to as the first quartile), 25% of the observed values are situated below this threshold. As an illustration, a 25% percentile of 5776.33 for the opening price indicates that 25% of the dataset's initial prices fall below this threshold. As the 50th percentile, which is also equal to the median, divides the dataset in half, it is a significant indicator. With a median value of 7833.27, the proportion of closing prices that occur either above or below this value is half. The third quartile, or 75th percentile, indicates that 75% of the data are located below this value. A 75% percentile of the close price (1,590.78) indicates that 75% of the closing prices fall below this threshold. These quantiles offer valuable insights regarding the market's overall trend and stability. A significant disparity between the 25th and 75th percentiles, for instance, may suggest that stock prices are more volatile. A comprehension of the distribution of the majority of data points, namely stock prices, can assist analysts and investors in recognising customary price ranges, detecting anomalies, and identifying substantial changes in market trends.

The closing price data is shown in Fig. 4, whereby it has been partitioned into two distinct zones for the purposes of training and testing. This strategy ensures the precision of the data while aiding consumers in acquiring reliable insights.

TABLE II. RESULTS OF THE STATISTICS FOR THE OHCLV MODELS THAT WERE PRESENTED

	Open	High	Low	Volume	Close
mean	8744.356	8805.287	8677.574	3143.8	8745.821

B. *Comparative Analysis*

The algorithms BBO, GWO, and SMA, which were chosen for comparison in this research, are widely acknowledged for their efficacy and efficiency in a range of optimization tasks, including financial market analysis. The selection of these algorithms is based on their established history of success in handling intricate optimization tasks, which is consistent with the aims of our research. Relevant benchmarks, these algorithms have been extensively implemented and cited in prior research for comparable applications. Their widespread usage and recognition within the scientific community signifies their acceptability and validation, thereby furnishing a strong foundation for comparative analysis. The exclusion of other algorithms is warranted due to the fact that our research is primarily concerned with algorithms that have demonstrated exceptional potential in the analysis of financial markets. Furthermore, an excessive number of algorithms may compromise the precision and comprehensibility of the comparative analysis.

In order to accomplish the crucial objective of forecasting the Nasdaq index, an identical dataset was used by each model. In this article, a meticulous analysis and evaluation of the outcomes of each model were conducted to provide a complete and informative comparison of their respective performances. Establishing a comprehensive and equitable comparison requires the clarification of performance indicators used for evaluating the models. By employing a diverse set of significant metrics, as explained in the methodology section, the models were assessed. A comprehensive evaluation of the performance of each model can be conducted by using a variety of indicators, thus facilitating the determination of the model that most effectively meets the established requirements. All the many nuances of how each model performed are displayed in a thorough Table III with the findings.

TABLE III. THE OUTCOMES OF THE MODEL'S EVALUATION CRITERIA AND TIME COMPUTING

Train/Test	Metrics	SVR	BBO-SVR	GWO-SVR	SMA-SVR
TRAIN SET	R^2	0.980	0.985	0.989	0.992
	RMSE	417.512	356.900	303.741	264.583
	MAPE	5.482	4.240	3.028	1.763
	MAE	382.054	329.413	225.660	158.062
	RSE	590.803	505.028	429.810	374.396
	MSE	174316.292	127377.539	92258.490	70004.188
TEST SET	R^2	0.972	0.981	0.988	0.991
	RMSE	265.540	217.667	173.450	149.248
	MAPE	1.666	1.376	1.073	0.930
	MAE	215.186	174.385	134.495	116.260
	RSE	376.411	308.550	245.870	211.564
	MSE	70511.446	47379.041	30084.774	22275.026
Time	Second	0.156	163.85	221.81	139.94

Initially, the obtained outcome was used in the selection process of the SVR model. The decision to develop the SVR model was made after a comprehensive review of the data due to its exceptional performance. Between the commencement of 2015 and the midpoint of 2023, the Nasdaq index data underwent a procedure that included the selection of relevant data and normalization. The collection of important insights will benefit the decision-making process using this detailed technique. The evaluation score for SVR alone is 0.972 in R^2, which, as shown in Table III, has increased due to improvements in the problematic optimizers. The R^2 criteria values for the BBO, GWO, and SMA algorithms are 0.981, 0.988, and 0.991, respectively, indicating the possibility of selecting the optimal course of action. When compared to other optimizers, superior results are produced by the SMA optimizer. The findings of the RMSE model shown in Table III also confirm the superiority of the SMA optimizer. The RMSE values for SVR, BBO-SVR, GWO-SVR, and SMA-SVR are 265.54, 217.667, 17.3450, and 149.248, respectively. Furthermore, the hybrid models outperform the SVR model, suggesting that tweaking the model's hyperparameters can be beneficial for optimization. However compared to SVR, hybrid models require longer running times. The rationale is that while hyperparameters of the SVR are manually set, hybrid-model hyperparameters are optimized via metaheuristic algorithms. A consistent upward trend in all metrics is observed in the training set, progressing from the SVR model to the SMA-SVR model. More precisely, the R^2 value, which indicates the extent to which the independent variables account for the variability of the dependent variable's variance, increases from 0.980 in the SVR model to 0.992 in the SMA-SVR model. This suggests that the SMA-SVR model exhibits superior predictive capability regarding the outcomes. The RMSE, an indicator of prediction error standard deviation, exhibits a substantial reduction from 417.512 in the SVR model to 264.583 in the SMA-SVR model. This pattern is similarly evident in MAPE and MAE, where SMA-SVR exhibits a significant decline in errors, signifying its exceptional precision in prognostication. In addition, the reduction in RSE and MSE provides additional evidence that, among the four models evaluated for the train set, SMA-SVR exhibits the most accurate predictions and the lowest error rates. Similar results are observed when the SMA-SVR model is applied to the test set. The model attains the maximum R^2 value of 0.991, indicating an exceptional capacity for variance prediction. The SMA-SVR model exhibits the lowest values of RMSE, MAPE, and MAE, which further validate its exceptional accuracy and dependability when forecasting on unseen data. The comparatively reduced RSE and MSE values of SMA-SVR, in contrast to the alternative models, provide additional validation for its status as the most precise and dependable model across training and testing scenarios. Fig. 5 shows evaluation of the suggested model’s performance in comparison to other models during training.

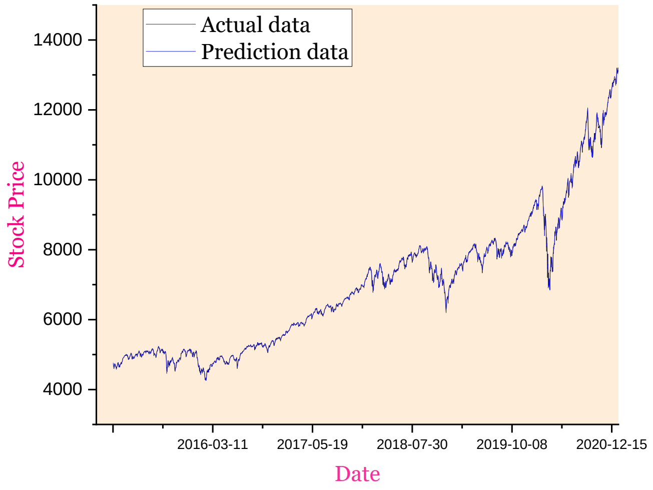

Fig. 5. Evaluation of the suggested model's performance in comparison to other models during training.

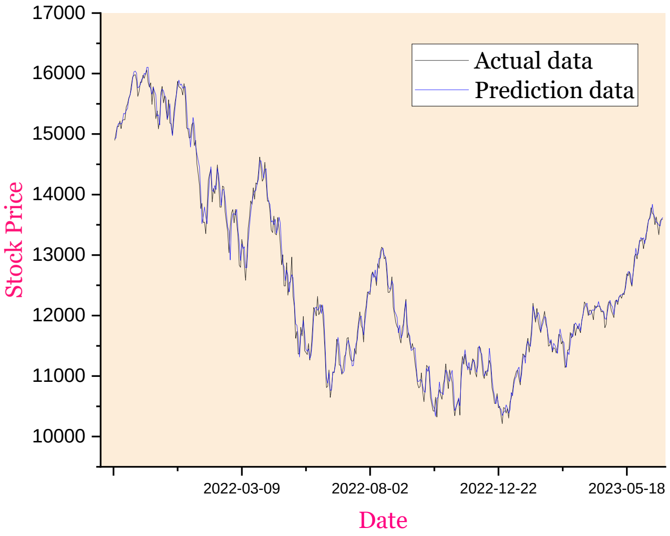

Fig. 6. Evaluation of the suggested model's performance in comparison to other models during testing.

The outcomes of the conducted tests are illustrated in Fig. 7 and Fig. 8, showcasing a robust connection between the model and the empirical data. Among the models tested, the SMA-SVR model exhibited superior performance in comparison to the individual SVR, BBO-SVR, and GWO-SVR models. It is worth mentioning that the utilization of the optimizer approach resulted in a substantial enhancement in the performance of the SVR model. Fig. 6 and Fig. 7 provide a comprehensive examination of the four models, therefore validating the superior performance of the chosen model. These results indicate that the SMA-SVR model is a potential method for precisely forecasting the intended results in the context. These results indicate that the SMA-SVR model is a potential method for precisely forecasting the intended results in the context. The proposed model has the following limitations:

The high R-squared value of 0.991 may potentially signify the occurrence of overfitting in the model. This is the result of an excessive learning load imposed by the training data, which may include noise and outliers, and may consequently hinder the model's performance when applied to novel, unseen data.

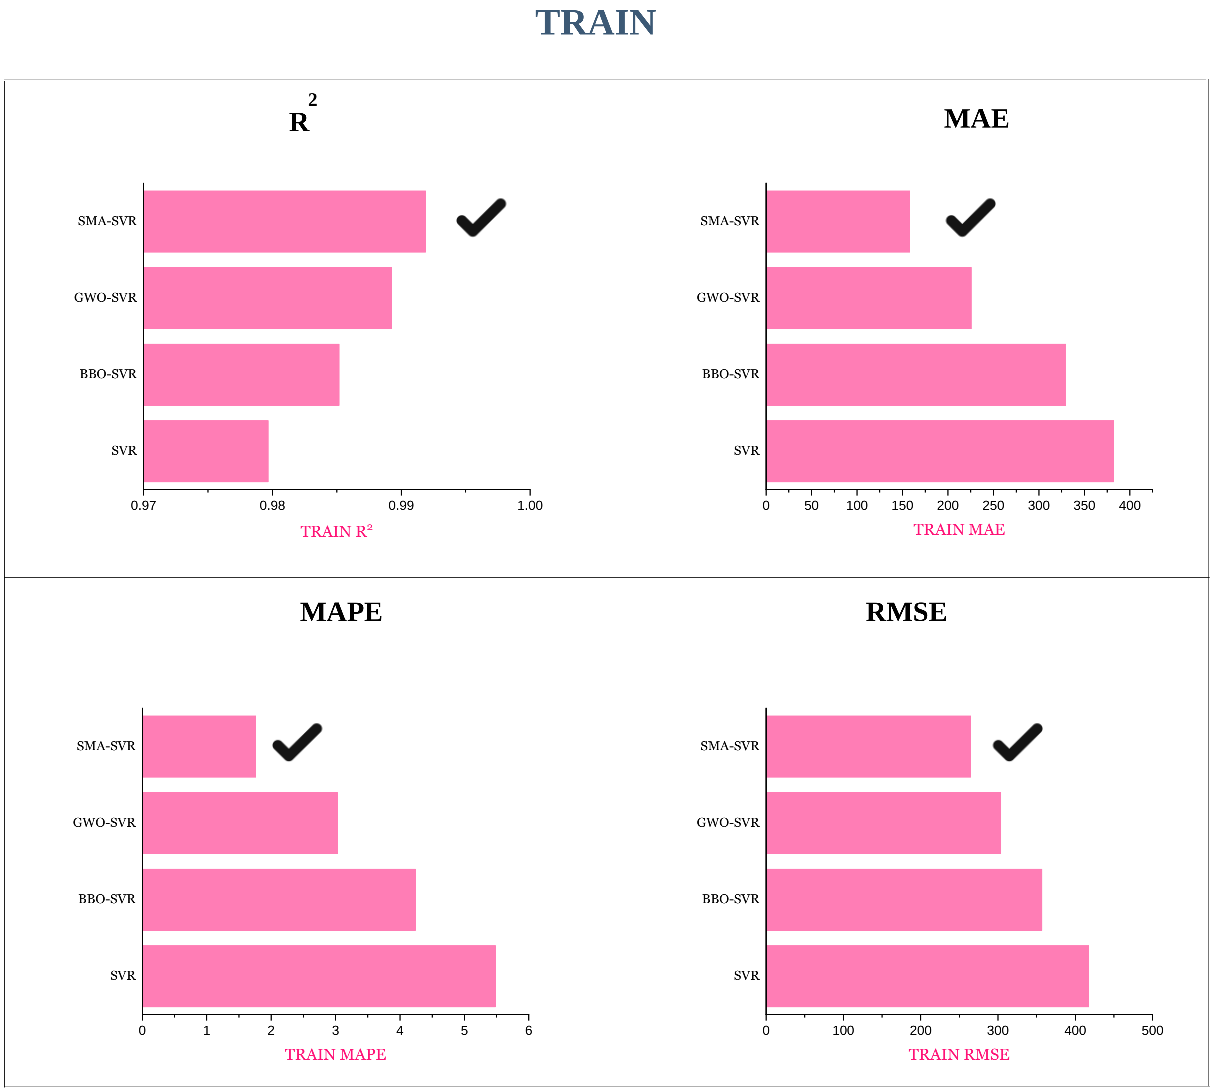

Fig. 7. Evaluation metrics outcomes for the attending models during train.

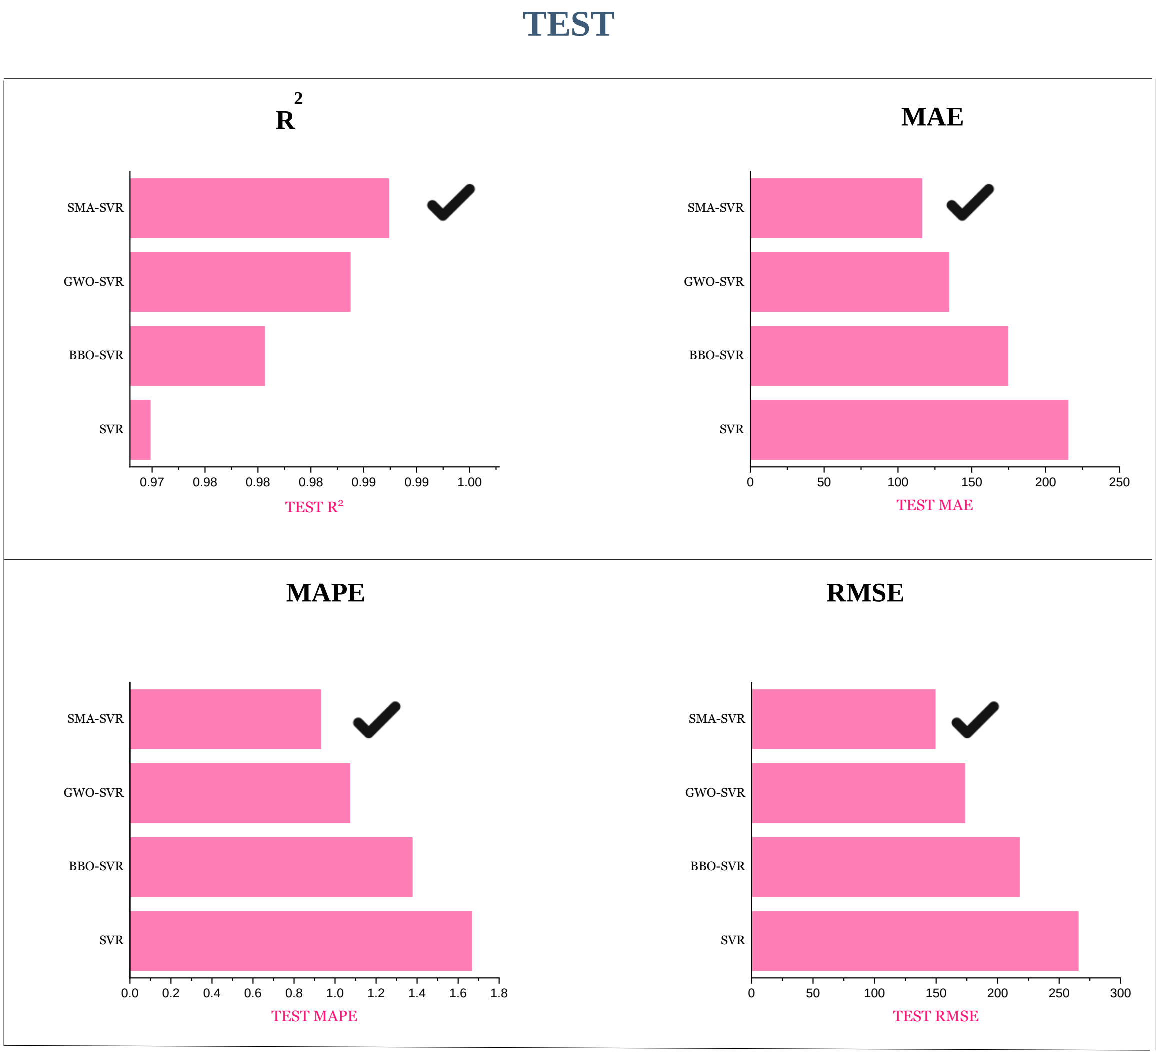

Fig. 8. Evaluation metrics outcomes for the attending models during the test.

The impact of external variables on market volatility: The model may not comprehensively capture the stock market's vulnerability to various elements, including economic indicators, political occurrences, and market sentiment. This constraint serves to underscore the intrinsic indeterminacy of the market.

The effectiveness of the model is widely recognized to be significantly contingent upon the provision of high-quality and exhaustive data. The predictive accuracy may be substantially affected by constraints in the data, including biases or incomplete historical information.

The augmentation of computational demands and complexity is an acknowledged consequence of integrating support vector regression with the slime mould algorithm. Potentially reducing the efficacy of real-time predictions, this could require additional processing time and power.

Market-Specific Variability in Generalizability: It has been noted that the efficacy of the model may differ when applied to various financial instruments or stock markets. This feature highlights the necessity for additional verification and assessment.

It is observed that the performance of the model is highly susceptible to changes in the hyperparameters it is configured with. Potentially inconsistent performance across a variety of datasets may result from the intricacy associated with fine-tuning these parameters.

Restriction on the Study's Scope: The study's concentration on particular algorithms and optimization techniques may have overlooked alternative approaches that have yet to be investigated but could have proven to be more effective.

Concerns Regarding Regulatory Compliance, Transparency, Fairness, and Ethics: The application of sophisticated predictive models in the realm of stock trading gives rise to ethical and regulatory issues. Careful attention should be given to these critical considerations.

Further research could be focused on a number of critical domains in light of the study's findings and methodologies:

Algorithm Improvement: To further enhance the accuracy and adaptability of predictions, further improvements could be made to the integration of support vector regression and the slime mould algorithm through the investigation of additional parameters or alternative configurations.

Conducting comparative analyses with novel or less prevalent optimization algorithms could provide fresh perspectives on fluctuating market conditions by evaluating the performance of the present model.

Analyses of Real-Time Data: The model's practical efficacy and resilience in authentic market situations could be evaluated through its implementation in a real-time trading environment.

Additional Market Segments: To assess the model's adaptability across various market sectors, it might be advantageous to expand its scope to encompass a more extensive array of financial instruments, including bonds, commodities, and cryptocurrencies.

The model's performance in diverse economic and regulatory environments could be better comprehended through cross-market analysis, which involves the application of the model to stock markets in different countries or regions.

Enhancement through Inclusion of Supplementary Data Sources: The predictive accuracy of the model could potentially be improved through the integration of alternative data sources, such as social media trends, news sentiment analysis, or economic indicators.

The potential for enhanced prediction capabilities and the ability to process more intricate data patterns could be investigated through the incorporation of deep learning techniques with the existing model.

The model could be rendered accessible to a wider spectrum of users, including individuals lacking technical expertise, through the development of a user interface that is intuitive and easy to use.

In order to aid investors in comprehending and alleviating potential losses, risk management functionalities might be integrated into the model.

An evaluation of the model's consistency and dependability over prolonged durations could be accomplished through the implementation of a long-term performance analysis.

The examination of the model's reaction to market anomalies or exceptional circumstances, such as unanticipated global events or financial crises, may have valuable implications.

An investigation into the feasibility of attaining a more precise or resilient prediction outcome might involve the implementation of ensemble techniques, wherein the current model is combined with additional predictive models.

Further investigation could be warranted into the ethical and regulatory ramifications associated with the utilization of sophisticated AI for forecasting the stock market, with a specific focus on the principles of trading transparency and fairness.

IV. Conclusion

By employing stock prediction techniques to evaluate asset values and ascertain prevailing market trends, a substantial competitive advantage can be gained by both individual and institutional investors. Informed decisions regarding purchasing, selling, or retaining stocks can be made by investors through the utilization of historical data and advanced algorithms. The implementation of this particular method holds significant importance for investors committed to making prudent investment decisions, as it effectively mitigates risks and increases the likelihood of achieving profitable outcomes. Many predictive algorithms and data sources were employed in this research to evaluate the complex and ever-changing domain of stock prediction. The findings suggest that the accuracy of forecasting might potentially be enhanced through the utilization of a hybrid model or an ensemble technique. Finally, the construction and evaluation of the prediction model underscored the need to use data-driven insights to establish dependable decision-making processes. This highlights the benefits of a data-centric strategy in the modern, rapidly changing business environment, as well as the possible applications of predictive analytics across a wide variety of sectors. The objective of this research was to develop models with enhanced predictive capabilities for stock prices, enabling traders and investors to use these algorithms to make informed decisions on the optimal timing and price for purchasing stocks.

In this study, the following findings were reached:

- First, the data preparation and normalization process were completed, potentially impacting how the prediction model is presented. The chosen model was then prepared to begin its data analysis.
- The best model was selected, findings were analyzed, and hyperparameters were adjusted to increase the model's effectiveness.
- The identification of the most accurate optimization technique as the primary optimizer of the model was achieved through a comparative analysis of the outcomes produced by several optimization algorithms. Among the three optimization algorithms, namely BBO, GWO, and SMA, the SMA technique exhibited the highest performance in terms of the R^2 evaluation criterion, with a result of 0.991, surpassing the results of 0.981 and 0.988 achieved by BBO and GWO, respectively.

Presenting an Optimized Hybrid Model for Stock Price Prediction

Liangchao LIU
College of Economics and Management, Jiaozuo University, Henan Jiaozuo, 454000, China

***Abstract*—In the finance sector, stock price forecasting is deemed crucial for traders and investors. In this study, a detailed comparison and analysis of various machine learning models for stock price forecasting were undertaken. Historical stock data and an array of technical indicators were utilized in these models. The enhancement of the Histogram-Based Gradient Boosting (HGBR) method for predicting the Nasdaq stock index was the focus. Optimization techniques such as genetic algorithm optimization, biologically-based optimization, and the grasshopper optimization algorithm were applied. Among these, the most promising results were shown by the grasshopper optimization method. The optimized HGBR models, namely GA-HGBR, BBO-HGBR, and GOA-HGBR, were found to have achieved significant improvements, with coefficient of determination values of 0.96, 0.98, and 0.99, respectively. These figures underscore the substantial advancement of these models as compared to the baseline HGBR model. Metrics such as Mean Absolute Error, Root Mean Square Error, Mean Absolute Percentage Error, and the Coefficient of Determination were employed to assess the performance of the models.**

Keywords—Stock prediction; machine learning approaches; ensemble learning; grasshopper optimization; histogram-based gradient boosting

I. Introduction

The task of predicting stock prices is undeniably challenging, primarily due to the inherent long-term uncertainties involved [1]. The traditional market hypothesis suggests that stock prices are unpredictable and random, but current technical analysis has revealed that previous records hold valuable information that can assist in predicting future stock values [2]. Furthermore, factors such as political developments, general economic conditions, commodity prices, investor expectations, and other stock market movements can also have a significant impact on the stock market [3]. High market capitalization is utilized to calculate stock group values, and a variety of technical factors can be used to generate statistical data on stock prices [4]. Therefore, it is essential to consider all of these factors when attempting to predict stock prices accurately. Inherent challenges arise when attempting to anticipate stock values because many traditional techniques for doing so rely on stagnant trends.

Furthermore, because there are so many variables at play, forecasting stock values is inherently difficult. The market operates like a voting machine in the near term but more like a weighing machine in the long term, indicating the possibility of forecasting longer-term market changes [5]. Machine learning (ML) is a potent technology that includes a variety of algorithms and has been shown to improve performance in particular case studies considerably. Many people think that ML has the ability to find important information and recognize patterns in datasets [6]. Ensemble models are a machine learning strategy where common algorithms are used to handle a particular problem, in contrast to standard ML approaches, and they have consistently shown higher performance when it comes to time series prediction [7][8][9].

In the field of forecasting, utilizing ensemble approaches has been found to yield more accurate results compared to single models [10]. The reason behind this is that ensembles are able to combine the predictions of multiple models, enabling them to account for potential errors and uncertainties. One of the major challenges in machine learning is overfitting, which occurs when a model performs exceedingly well on training data but fails to generalize to new data. However, ensembles are less prone to overfitting due to their reliance on multiple base models, such as bagging and boosting, which help to mitigate the risk of overfitting [11]. These techniques work by creating multiple models and combining their predictions, thereby reducing the likelihood of a single model overfitting to the training data. Ultimately, the use of ensemble approaches in forecasting can lead to more reliable and accurate predictions [12]. To conduct a comparative analysis of cutting-edge machine learning methods for forecasting stock market returns, ten years of daily historical data pertaining to the top ten equities on the Casablanca Stock Exchange were utilized. When Bilal et al. [13] used an ensemble learning approach was utilized to train six classifiers (ridge regression, LASSO regression, support-vector machine, k-nearest neighbors, random forest, and adaptive boosting) to forecast price directions one day, one week, and one month in advance. In contrast to other models, support vector machines, random forests, and adaptive boosting exhibited superior performance in short-term predictions. Ensemble learning enhanced performance metrics across all prediction horizons by a substantial margin. Sonkavde et al. [14] investigated a range of algorithms to address challenges related to stock price prediction and classification. These algorithms comprised ensemble algorithms, deep learning, supervised and unsupervised machine learning, and time series analysis.

The model presented for forecasting the Nasdaq stock market in this work is a Histogram gradient boosting regressor (HGBR). Nasdaq is one of the major stock exchanges in the United States, particularly associated with technology and internet-based businesses, and renowned for its electronic trading platform. The HGBR is a machine-learning approach that addresses regression-related issues by combining the principles of gradient boosting with histogram-based feature splitting. It is an adaptation of the popular Gradient Boosting Machine (GBM) technique [15]. Regression and classification are the two primary subtypes of gradient boosting, a machine-learning approach for prediction. This paradigm is intended to manage complicated and substantial difficulties as opposed to simple and small ones, in contrast to previous techniques. The gradient-boosting technique known as HGBR was created expressly to overcome regression issues. This technique is renowned for its quickness and capacity to hasten decision-tree learning. By discretizing the input variables, HGBR does this by splitting extra trees into several values [16].

Providing precise forecasts is the primary goal of prediction models. To achieve this, optimizing these models can significantly improve their accuracy, especially in sectors where even a minor increase in accuracy can have a substantial impact, such as healthcare, banking, and manufacturing [17]. Different methods and models are provided to optimize the HGBR. Some of them, like Moth flame optimization [18], Biogeography-based optimization [19] and gray wolf optimization [20], are inspired by nature. The optimization methods used to optimize for the model of this paper are genetic algorithm, biogeography-based optimization and grey wolf optimization.

The genetic algorithm is a computational optimization technique that draws inspiration from natural selection and evolution. This powerful tool is widely employed to solve or estimate a wide variety of optimization and search problems, ranging from engineering and finance to biology and physics [21]. By mimicking the process of natural selection, genetic algorithms are able to efficiently navigate complex search spaces and identify optimal solutions for a wide range of problems. In essence, this approach is based on the idea that the fittest solutions are more likely to survive and reproduce, leading to a gradual improvement in the overall quality of the solution over time [22]. Overall, the genetic algorithm is a versatile and powerful tool that has revolutionized the field of optimization and has enabled researchers and practitioners to tackle some of the most challenging problems of our time [23]. Another optimization method in this paper is biogeography-based optimization is a method of optimization that takes its cues from nature. Biogeography is the study of how organisms spread and adapt through time in various habitats [19]. BBO is used to solve numerous optimization problems in a variety of disciplines, including engineering, biology, economics, and data science. Biogeography is the scientific study of the geographical distribution of living organisms. The 1960s saw the discovery and development of the fundamental mathematical equations regulating the spread of organisms [24]. The GWO algorithm [20] is an innovative solution that finds its inspiration in the social hierarchy and hunting habits of grey wolves in the wild. This nature-inspired optimization technique has gained popularity in the fields of computational intelligence and machine learning due to its effectiveness in solving complex search and optimization problems [25]. By mimicking the social behavior of grey wolves, the GWO algorithm proves to be an efficient and effective way to tackle real-world optimization challenges. Its unique approach provides a fresh perspective on the problem-solving process, allowing for a more comprehensive and dynamic method of finding solutions [26]. This paper makes a substantial contribution to the current research on predicting stock prices by thoroughly examining and analyzing several machine-learning algorithms. The application of optimization techniques, like genetic algorithm optimization, biologically-based optimization, and the grasshopper optimization algorithm, adds a layer of depth to the inquiry. The focus on improving the Histogram-Based Gradient Boosting technique for forecasting the Nasdaq stock index is remarkable. This study underscores the pragmatic significance for investors, emphasizing the cruciality of utilizing historical data and sophisticated algorithms to guide investment choices. The proposal to utilize ensemble techniques or hybrid models is in line with the progressive nature of stock prediction, recognizing the intricate and dynamic character of the market. The recognition of the grasshopper optimization algorithm as the most efficient optimizer contradicts current beliefs and offers a nuanced viewpoint on optimization methods in predicting stock prices. To summarize, this study enhances previous research by improving and perfecting the HGBR method, demonstrating the efficacy of particular optimization techniques, and providing practical guidance for investors in the ever-changing field of stock prediction.

According to the reviewed literatures, the main research gaps and novelties of the paper can be stated as follows.

A. *Research Gaps*

The field of stock price prediction, especially for the Nasdaq stock index, has long faced difficulties because of the complex interplay between contributing factors and the stock's intrinsic unpredictability. Due to their dependence on stagnant trends and inadequate analysis of the numerous factors influencing the stock market, traditional tactics frequently fail. The intricacy of this problem is exacerbated by the tendency of many machine learning models to overfit, which causes them to perform incredibly well on training data but poorly on new, untested data. Moreover, ensemble approaches are often underutilized in current models, despite the fact that they have been demonstrated to provide improved time series prediction accuracy by combining several predictions and reducing errors and uncertainties. Furthermore, although a number of optimization strategies, including Moth flame, Biogeography-based, and Gray Wolf optimization, have been studied in the literature, there is a dearth of thorough evaluation and comparison of these strategies, especially when it comes to using them to optimize the Histogram-Based Gradient Boosting (HGBR) method for stock price forecast-making.

B. *Novelties of the Work*

Using the powerful Histogram-Based Gradient Boosting Regressor (HGBR) in conjunction with cutting-edge optimization methods like genetic algorithms, biologically-based optimization, and most notably, the grasshopper optimization algorithm, this study presents an optimized hybrid model for the prediction of Nasdaq stock prices. The creation of the GA-HGBR, BBO-HGBR, and GOA-HGBR models is the result of a thorough comparison and empirical examination of various optimization techniques, which is where the innovation lies. These models have amazing coefficients of determination values and show significant improvements over the baseline HGBR model. The exceptional efficacy of the grasshopper optimization method is revealed in this study, which is innovative in its application to stock price prediction. Furthermore, the huge dataset that was obtained from Yahoo Finance and the Nasdaq Stock Exchange and included a wide range of factors over a long period of time offers a distinctive and reliable basis for the predictive analysis. By lowering the chance of overfitting, this study not only fills in the holes in the current predictive models but also offers fresh perspectives on how well ensemble and nature-inspired optimization strategies might improve stock price predictions.

Lastly, the paper's structure is broken down into multiple sections, each of which focuses on a different aspect of the in-depth investigation that was done:

In Section II, the research methodology is the main topic of discussion in this section. It includes the explanation of the data that was utilized, the specifics of the model that was used, the optimization strategies that were used, and the evaluation criteria. The purpose of Section III is to present the study's result and discussion. Finally, Section IV concludes the paper.

II. Methodology

A. Data Description

This data was acquired from the Yahoo Finance Website to compile a complete historical dataset of publicly listed firms. A broad spectrum of valuable data, encompassing daily stock prices and trading volumes, was made available by this source. Five important variables—Open, High, Low, Close prices, and Trading Volume—were the main focus of the analysis in this work in order to train and test our model. To comprehend the dynamics of the stock market, these factors are essential. The opening price of a stock or other financial instrument is the price at which it is traded at the start of the trading day. It establishes the foundation for every trading day. The stock price may fluctuate and reach its highest point, referred to as the High price, during the trading day. This represents the day's peak demand or valuation. On the other hand, the price can potentially fall to what is known as the Low price—its lowest point of the day. This represents the lowest demand or valuation. The closing price is the last trading price at the conclusion of the day. It is frequently used as a benchmark for the day's performance of the stock. Additionally, trading volume is the total number of shares, contracts, or financial instruments that are exchanged in a given trading day. Elevated volumes may suggest heightened attention or involvement in a specific stock. Additionally, this dataset was supplemented with data collected directly from the Nasdaq Stock Exchange, ensuring its comprehensiveness. Access to supplementary trade metrics and market indicators was granted by this esteemed financial data source, enhancing our understanding of market dynamics. The dataset, which spans a significant timeframe from January 2015 to June 2023, includes various market conditions, including periods of stability and volatility, owing to its wide temporal range. Given its diverse array of data points that can be harnessed to construct a comprehensive industry portrait, it can be claimed that this dataset was ideally suited for robust model training and evaluation.

Nasdaq, a preeminent global stock exchange established in 1971, Nasdaq has come to represent innovation, technology, and sophisticated financial markets. Its inception aimed to modernize and streamline the stock trading process, introducing revolutionary changes to the conventional open-outcry system [27].

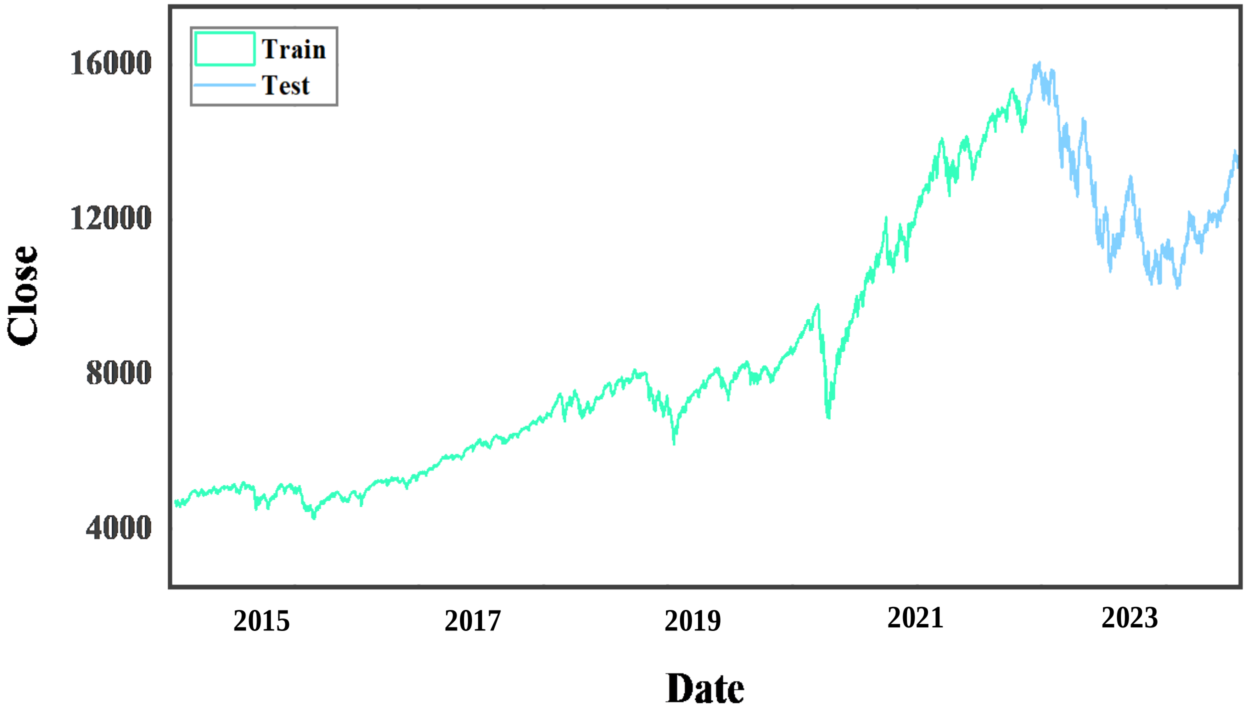

Fig. 1. Data division into training and testing.

The training and testing portions of the produced dataset are separated, as illustrated in Fig. 1. Data analysis and machine learning both start with the division of data into training and test sets. You may evaluate the results of the model and generalization skills using this technique.

B. Description of the Applied Model

1) Histogram-based gradient boosting: HGBR represents a subtype of Gradient Boosting Regressor that accelerates the computation of the gradients and Hessians of the loss function by using histograms [28]. The algorithm starts by fitting a regressor to the training data, and then it fits other regressors to the residual errors of the first ones [15]. Weak learners are weighted together to form the final algorithm. The algorithm's main goal is to reduce the loss function:

$$\mathrm{L} = \sum_{i=1}^{N} (y_i - \hat{y}_i)^2 \tag{1}$$

The approach fits a weak learner $h_t(x)$ to the residual errors of the prior regressors at each iteration. The decision tree used by the weak learner divides the data into bins according to the values of the input characteristics. The approach then directly determines, rather than estimating, the gradients and Hessians of the loss function using the histogram data. Then, using precise gradients and Hessians, the weight of the learner is determined. Understanding categorical characteristics and values that are missing organically by generating new bins for each category or missing value is one benefit of histogram gradient boosting. The ultimate model is a weighted average of each weak learner separately:

$$\hat{y}(x) = \sum_{t=1}^{T} \alpha_t h_t(x) \tag{2}$$

where, α_t is the learner's weight for the t-th weak learner.

C. Obtained Optimization Method

When it comes to developing a reliable machine learning model, one of the most critical factors is optimizing the hyperparameters correctly. This can significantly impact the accuracy, precision, and recall of the model, which in turn can have a significant impact on the quality of the decisions and forecasts that it produces [29]. By taking the time to fine-tune the hyperparameters, developers can ensure that their model performs optimally and is better equipped to handle real-world scenarios [30].

1) Genetic algorithm: GA is an algorithm used for solving optimization and search issues that replicates the process of natural selection. Its basic principle is to repeatedly apply genetic operators like selection, crossover (recombination), and mutation on a population of candidate solutions or individuals to produce new individuals. The fitness function, which gauges the caliber of the solution, is then used to assess the new people. Until a workable solution is identified, this procedure is repeated over several generations [22].

a) GA consists of three key elements [31]: Each person is represented by a chromosome, which is a string of numbers or letters. The exact issue being handled determines the encoding. Evaluation of the fitness function is used to gauge each person's contribution to the quality of the solution. The fitness feature was created with the current issue in mind. Using evolutionary operators, new individuals can be produced from existing ones. Selection, crossover, and mutation are the three most often utilized operators. To choose the most fertile people, selection is utilized. Chromosomes from two people can be combined through a process called crossover to create a third person. The mutation is utilized to induce minor, random alterations in an individual's chromosomes. It's essential to remember that GA is a heuristic optimization technique; it cannot be relied upon to discover the best overall solution, but it can offer a good one at a reasonable computing cost. However, for large-scale issues, it could be computationally demanding and time-consuming, particularly if the dataset is sizable and the training procedure is drawn out [32].

2) Biological-based optimization: BBO, a natural-inspired optimization approach, is based on the concepts of biogeography, a scientific field that investigates how species are dispersed across time in varied ecosystems. BBO is used to handle optimization difficulties in various fields, including engineering, biology, economics, and data science. Biogeography is the study of how biological organisms are distributed geographically. The discovery and development of mathematical equations that control how organisms disperse occurred in the 1960s [24]. The concept of Biogeography-Based Optimization has caught the attention of an engineer who believes that nature can teach us valuable lessons. This algorithmic approach was developed based on the principles of biogeography, which include the birth of new species, species migration between islands, and the extinction of species. Back in 2008, Dan Simon introduced this flexible and metaheuristic strategy. It uses a mathematical framework to explain how animals move across habitats, seeking refuge from unfavorable conditions and gravitating towards more hospitable ones. The Habitat Appropriateness Index is a helpful tool for evaluating and recording the suitability of different habitats. It relies solely on the objective function of the optimization problem. One of the most esteemed evolutionary algorithms is biogeography-based optimization. This algorithm systematically enhances the best solutions by optimizing a function based on a specific quality or fitness function [33].

3) Grasshopper optimization algorithm: The Grasshopper Optimization Algorithm, a popular metaheuristic algorithm, draws inspiration from nature. Finding the finest solutions that produce the biggest potential outcome is the key objective, and randomization is used to prevent being caught in local optima. The method has shown to be very effective and efficient in optimization thanks to its speedy convergence and impressive exploration abilities. GOA has performed better in test problems than a variety of other approaches, proving its excellence and promise in practical applications. GOA is also adaptable, balancing exploitation and exploration to ensure the optimal result is reached. This unique characteristic makes GOA an excellent choice for research applications. The overall cycle of the GOA optimizer is shown in Fig. 2.

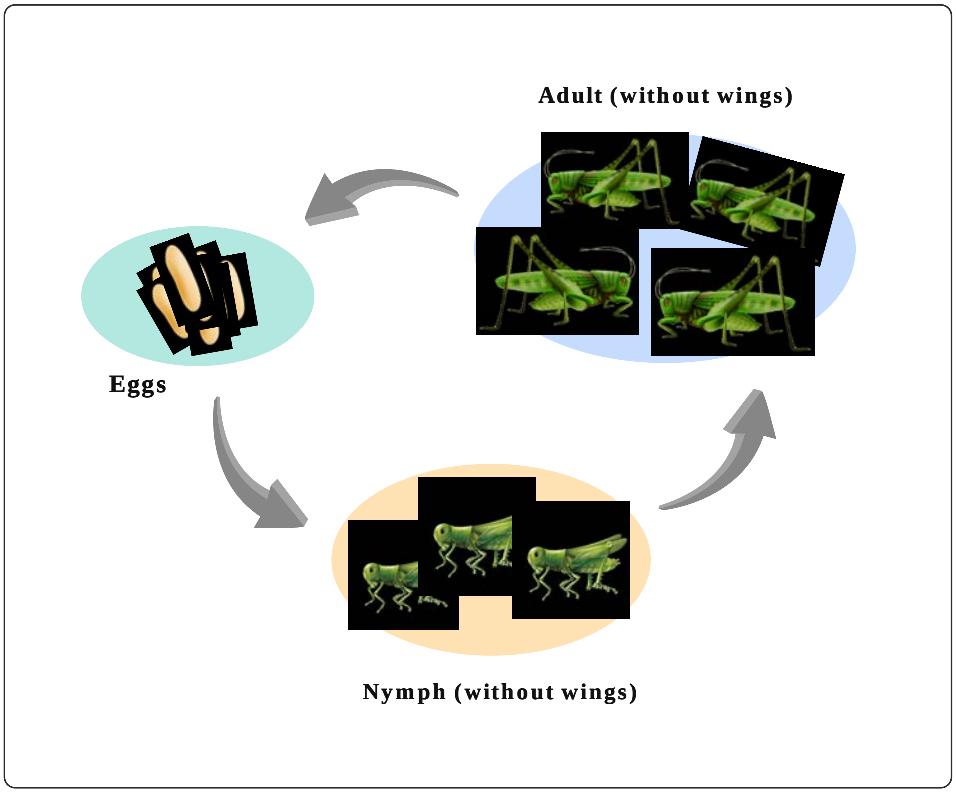

Fig. 2. Comprehensive cycle of GOA.

Suggested GOA, a Swarm Intelligence algorithm. [34] proposed GOA. Each grasshopper's position in the swarm, which is patterned after the behavior of grasshoppers, which regularly form swarms, represents a potential solution. The position of the ith grasshopper is indicated by the following equation:

$$X_i = S_i + G_i + A_i \tag{3}$$

where, S_i is for social interaction, G_i stands for gravity and A_i stands for wind advection.

The following equation, with the gravity element removed and the direction of the wind considered to be toward the target, states the equation adjusted for N grasshopper optimization:

$$X_i^d = c\left(\sum_{\substack{j=1 \\ j\neq i}}^{N} \frac{ub_d - lb_d}{2} s\left(\left|x_j^d - x_i^d\right|\right) \frac{x_j - x_i}{d_{ij}}\right) + \widehat{T_d} \tag{4}$$

The symbol d_{ij} represents the separation among the ith and jth grasshoppers, while the function s represents the strength of the social forces, where l stands for the attractiveness scale and f for the level of attraction, all of which are calculated using the equations below:

$$\begin{aligned} d_{ij} &= \left|d_j - d_i\right| \\ s(r) &= f e^{\frac{-r}{T}} - e^{-r} \end{aligned} \tag{5}$$

The coefficient c, which decreases the comfort zone proportionately to iterations, is found using the equation.

$$c = c_{max} - l\frac{c_{max} - c_{min}}{L} \tag{6}$$

where, l is the current iteration, C_{max} denotes the maximum value, C_{min} denotes the minimum value, and L denotes the maximum number of iterations. How the GOA optimizer works from the beginning to the end of the process is shown in Fig. 3.

D. Evaluation Criteria

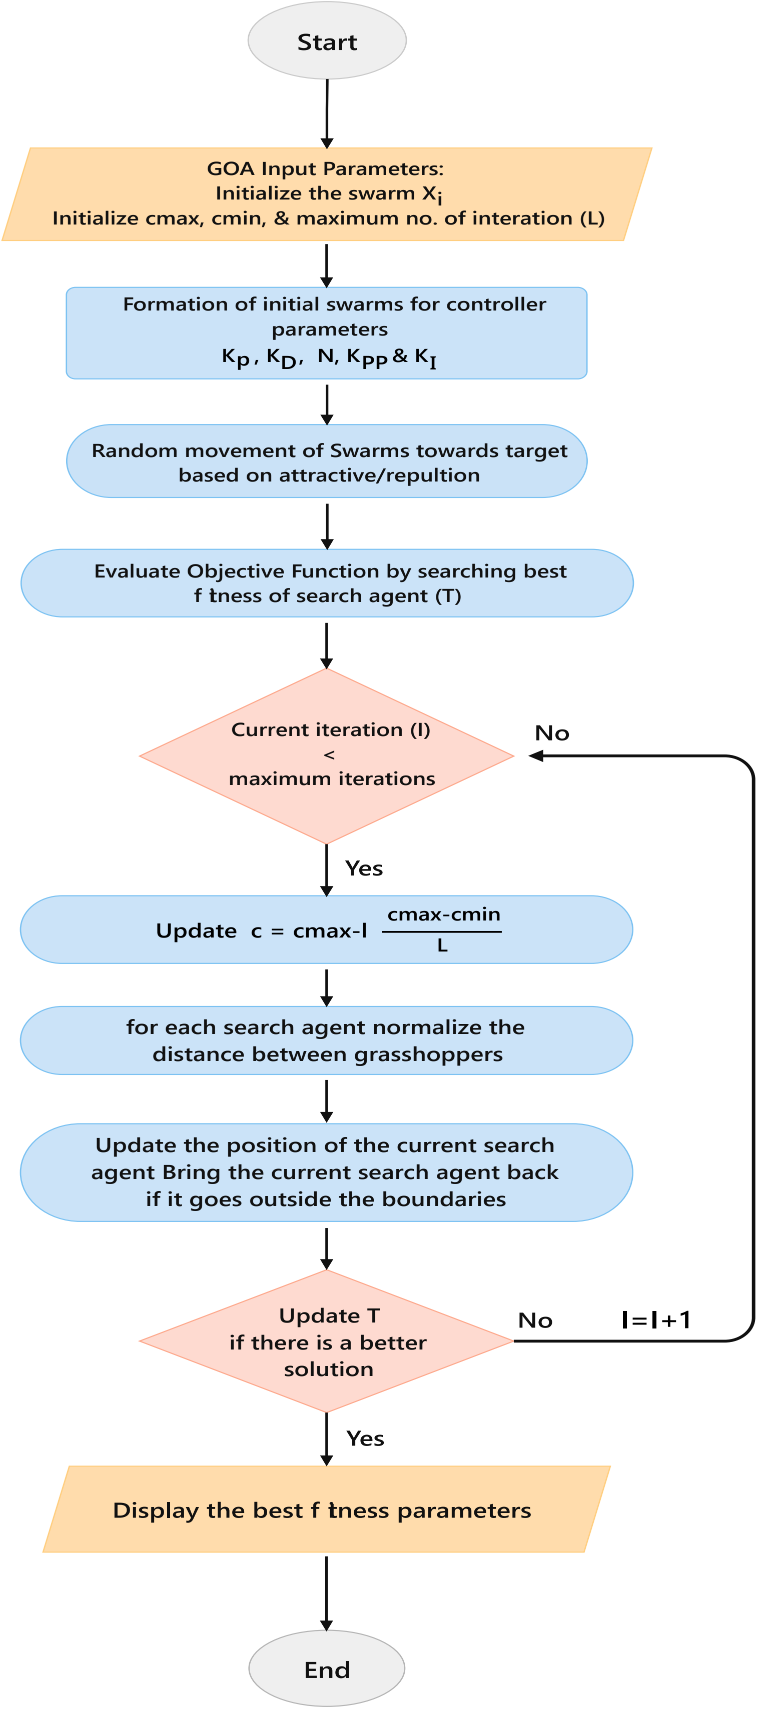
In statistics and machine learning, evaluation metrics are the chosen quantitative measurements for assessing the efficacy of prediction models. They assist in determining a model's ability to produce precise predictions on as-yet-unobserved data. The kind of prediction problem and the specific analytic goals determine the optimum assessment metric. Performance metrics, including $RMSE$, MAE, $MAPE$, and R^2 were employed in this study's predictive measures to assess the constructed forecasting models' predictive accuracy. A collection of mathematical formulas for these measurements is provided below:

$$RMSE = \sqrt{\frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{n}} \tag{7}$$

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\left|\frac{y_i - \hat{y}_i}{y_i}\right| \tag{8}$$

$$MAE = \frac{\sum_{i=1}^{n}|y_i - \hat{y}_i|}{n} \tag{9}$$

$$R^2 = 1 - \frac{\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}{\sum_{i=1}^{n}(y_i - \bar{y})^2} \tag{10}$$



Start
GOA Input Parameters:
Initialize the swarm X_i
Initialize cmax, cmin, & maximum no. of interation (L)
Formation of initial swarms for controller parameters
K_P, K_D, N, K_{PP} & K_I
Random movement of Swarms towards target based on attractive/repultion
Evaluate Objective Function by searching best fitness of search agent (T)
Current iteration (l) < maximum iterations
No
Yes
Update c = cmax-l (cmax-cmin)/L
for each search agent normalize the distance between grasshoppers
Update the position of the current search agent Bring the current search agent back if it goes outside the boundaries
Update T if there is a better solution
No
l=l+1
Yes
Display the best fitness parameters
End

Fig. 3. Flowchart of the main optimization method.

III. Result and Discussion

A. Data Statistical Results

Table I presents the statistical results of these data points, offering insights into their distribution and variability. The table indicates the count, mean, standard deviation, minimum, 25th percentile, 75th percentile, and maximum values for each variable. The count for all variables stands uniformly at 2,137, ensuring a consistent dataset for analysis. The mean values provide an average level of each variable, with the mean Close price at 8,745.821, suggesting an overall higher closing trend in the dataset. The standard deviation, particularly high in the case of High and Low prices (3,362.163 and 3,298.311 respectively), indicates significant variability and potential volatility in the market. The minimum and maximum values highlight the range of the dataset, with a notable range in the High price (from 4,293.22 to 16,212.23). The 25th and 75th percentiles reveal the distribution's skewness, where a noticeable difference is seen in the volume, and indicating periods of both low and high trading activity.

B. Comparative Analysis

The efficacy of the models given was evaluated using a variety of standard metrics including MAE, $MAPE$, R^2, and $RMSE$. These metrics provide a thorough analysis of the forecast accuracy of the models. The performance indicators for four models, HGBR, GA-HGBR, BBO-HGBR, and GOA-HGBR, are summarized in Table II. Utilizing historical stock price information for a Nasdaq stock market index, covering from January 2015 to June 2023, these models were created and assessed.

Based on the results shown in Table II, it is clear that the GOA-HGBR model performs better than the other models in terms of predicting accuracy. The model's ability to accurately represent the complex temporal patterns and correlations contained in stock price data is demonstrated by its impressively low values for MAE, $MAPE$, and $RMSE$. These findings imply that the GOA-HGBR model may be a trustworthy resource for identifying potential market trends and making wise investment choices.

TABLE I. Data Statistical Results

count	2137	2137	2137	2137	2137
mean	8744.356	8805.287	8677.574	3143.8	8745.821
Std.	3332.744	3362.163	3298.311	1551.37	3332.058
Min	4218.81	4293.22	4209.76	706.88	4266.84
25%	5776.33	5821.95	5769.39	1908.94	5793.83
75%	11573.14	11699.63	11476.66	4416.84	11590.78
max	16120.92	16212.23	16017.23	11621.19	16057.44

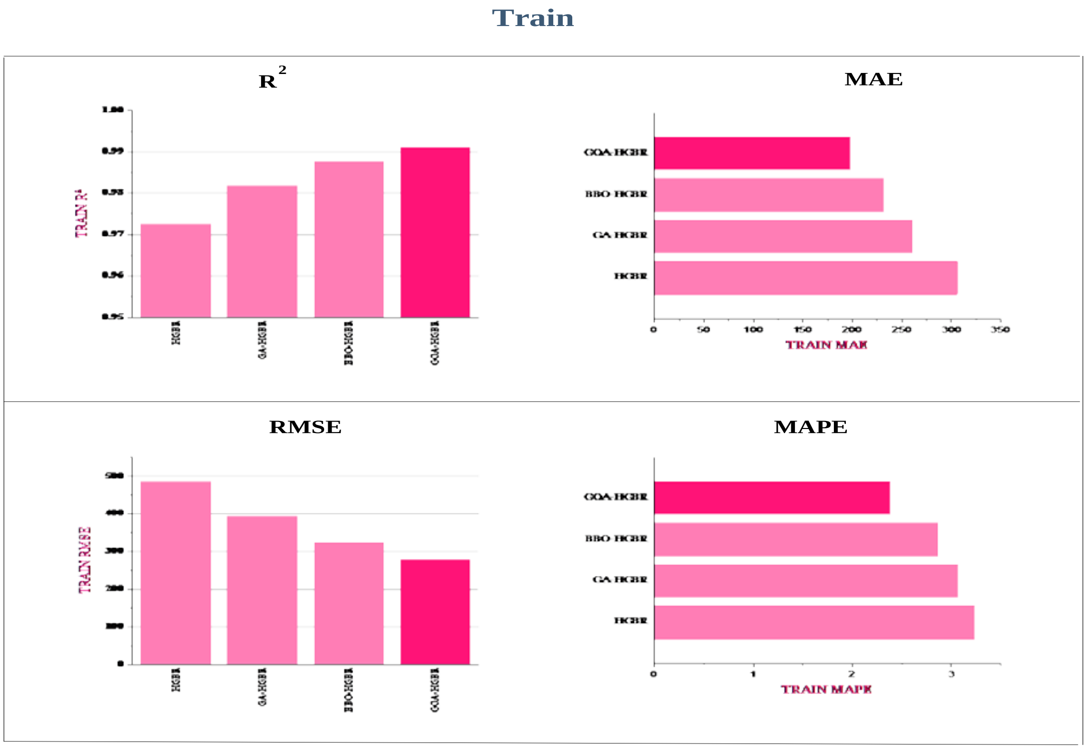


Fig. 4. The results of the evaluation criteria of the developed models during training.

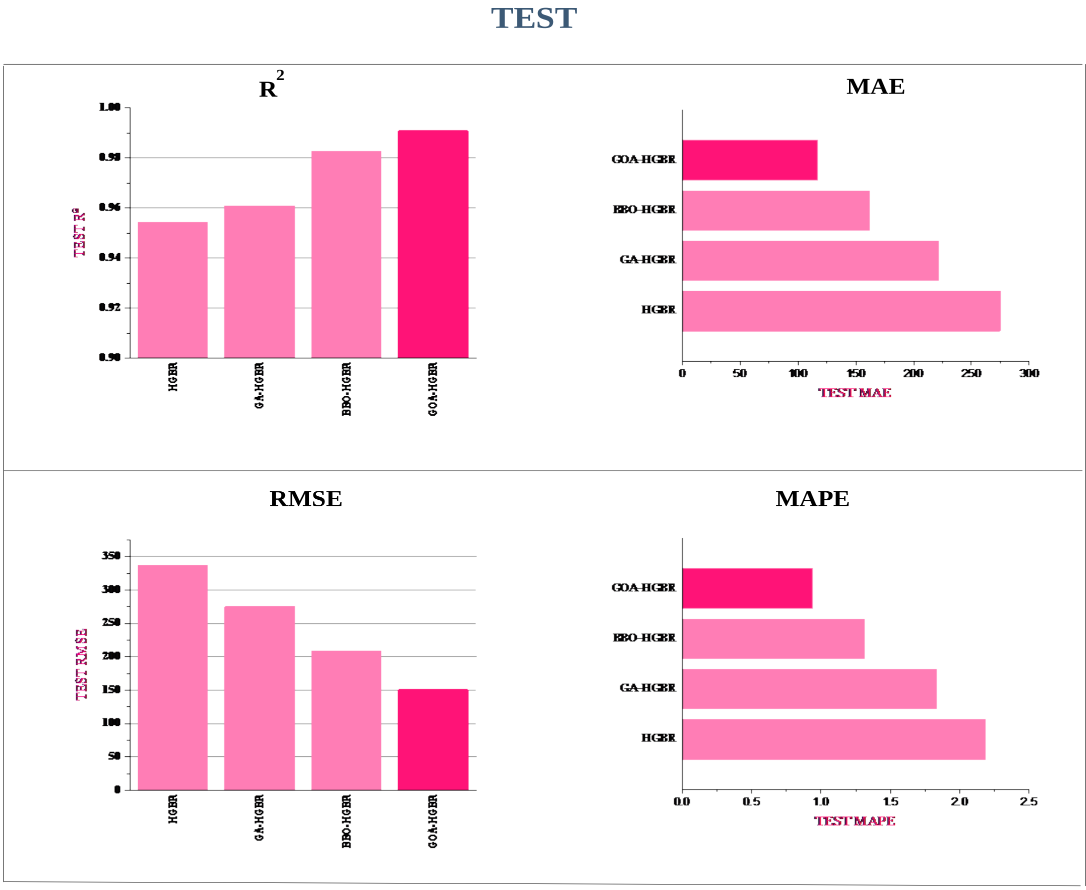

Fig. 5. The results of the evaluation criteria of the developed models during testing.

TABLE II. THE RESULTS OF MODEL PERFORMANCE CRITERIA FOR THE NASDAQ INDEX

MODEL / Metrics	TRAIN SET				TEST SET			
	RMSE	*MAPE*	*MAE*	*R^2*	*RMSE*	*MAPE*	*MAE*	*R^2*
HGBR	485.22	3.23	305.86	0.9726	337.05	2.18	274.83	0.9543
GA-HGBR	394.17	3.06	259.86	0.9819	275.18	1.83	221.78	0.9609
BBO-HGBR	324.99	2.86	231.27	0.9877	208.27	1.31	162.18	0.9825
GOA-HGBR	278.33	2.38	197.58	0.9910	150.97	0.94	117.44	0.9908

When the performance of the four models in Table II is compared, it can be observed that the GOA technique, followed by BBO and GA, produced the best results for optimizing the hyperparameters of the model that is being presented. The baseline HGBR model, although demonstrating robust prediction ability, acts as the standard for assessing the effectiveness of hybridization. The test set demonstrates an RMSE of 337.05 and an R^2 of 0.9543, providing a solid basis for evaluating the hybrid models. The incorporation of the genetic algorithm in the hybrid model results in significant enhancements. The GA-HGBR model demonstrates a decrease in the RMSE to 275.18, the MAPE to 1.83, and the MAE to 221.78 in the test set. The increase in R^2 (0.9609) indicates a higher level of accuracy in fitting the data, implying that the genetic algorithm successfully optimizes the hyperparameters to improve prediction accuracy. The integration of BBO into the hybrid model showcases additional enhancement. Significantly, BBO-HGBR demonstrates superior performance in the test set, as evidenced by its lower RMSE (208.27), MAPE (1.31), and MAE (162.18), indicating an enhanced capacity to accurately capture stock price patterns. The R^2 value of 0.9825 confirms the effectiveness of BBO in optimizing the model for enhanced accuracy in forecasting. The outcomes of the GA-HGBR, BBO-HGBR, and GOA-HGBR findings as 0.96, 0.98, and 0.99, respectively, demonstrate the improvement in the model outcomes. The evaluation results of the developed models are shown in Fig. 4 and Fig. 5, and as it is evident in the figures, it can be seen that GOA-HGRB has the best results for all evaluation criteria. The outcomes demonstrate that the prediction result has been enhanced by the optimized model. For the R^2 evaluation criterion, the GOA-HGBR model, which is optimized using the GOA technique, has a result of 0.99. This result demonstrates that optimization has a beneficial impact on predicting when compared to the HGBR model, which is not optimized. Without using the optimization approach, the HGBR was 0.95.

The comparison of the developed models is illustrated in Fig. 6 and Fig. 7. The principal objective of this research endeavor was to assess the efficacy of the GOA-HGBR model in predicting NIKKEI 225 closing prices between 2013 and 2022. The comprehensive findings of this investigation are detailed in Table III, which offers an abundance of information regarding the accuracy and effectiveness of the model across various indices. With a R^2 value of 0.9870 for the NIIKEI 225 data set, the GOA-HGBR model exhibited superior performance compared to other models that were comparable to the NASDQE index data set. The results suggest that the GOA-HGBR model could potentially be a valuable instrument for forecasting the forthcoming values of the aforementioned indices. Financial analysts and investors may utilize this information to aid in the formation of well-informed investment decisions. In its entirety, this research offers substantial contributions to the existing body of knowledge regarding stock price forecasting and underscores the potential of the GOA-HGBR model in predicting forthcoming financial market trends.

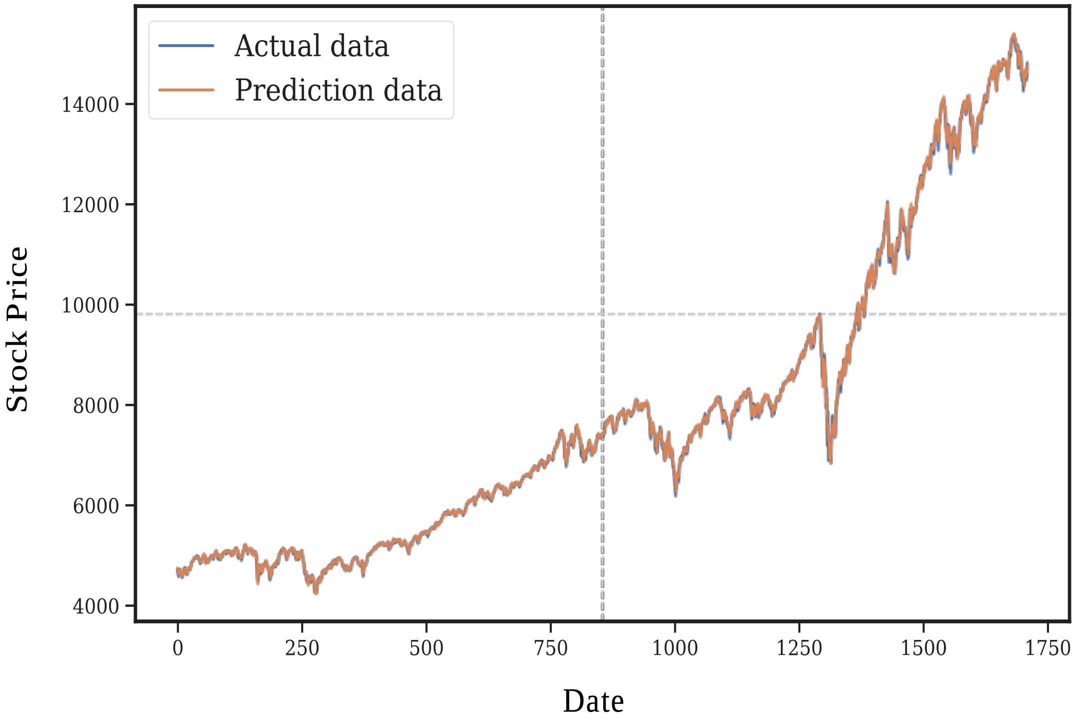

Fig. 6. Fit diagram of GOA-HGBR with other developed models during training.

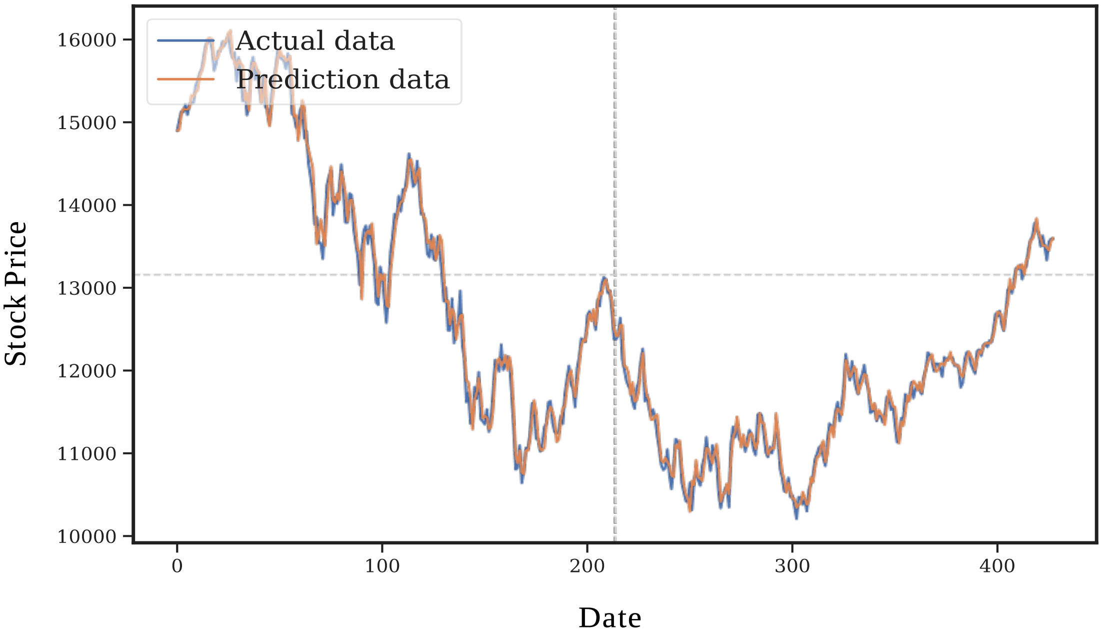

Fig. 7. Fit diagram of GOA-HGBR with other developed models during testing.

TABLE III. THE RESULTS OF MODEL PERFORMANCE CRITERIA FOR THE NIKKEI 225 INDEX

MODEL / Metrics	TRAIN SET				TEST SET			
	RMSE	MAPE	MAE	R^2	RMSE	MAPE	MAE	R^2
HGBR	359.5165	2.7144	288.0514	0.9783	185.5216	1.4299	145.5727	0.9688
GA-HGBR	335.9287	2.4682	260.1081	0.9821	175.7187	1.4188	135.3647	0.9712
BBO-HGBR	270.3312	2.1711	206.9693	0.9842	143.3115	1.4113	121.7996	0.9737
GOA-HGBR	247.8360	2.0554	186.8910	0.9873	121.9168	1.3252	98.1423	0.9870

In conclusion, the study and its findings warrant the following observations regarding future research and limitations:

- One of the model's limitations is its significant dependence on historical stock data. Particularly in the volatile and unpredictable stock market, past performance is not always indicative of future results. Consequently, this may present a constraint.
- The computational demands of sophisticated algorithms such as GA-HGBR, BBO-HGBR, and GOA-HGBR may restrict their practicality in real-time trading situations that require prompt decision-making.
- Without substantial recalibration and testing, these models may not generalize well to other stock indices or markets, despite their impressive performance for the Nasdaq stock index.
- Genetic algorithm, biologically-based optimization, and grasshopper optimization algorithm comprise the bulk of the study's attention. Alternative optimization techniques might potentially produce outcomes that are superior in quality or efficiency.

Further investigations may be warranted to examine the extent to which these models can be applied to diverse financial instruments and stock markets, thereby evaluating their adaptability and resilience.

Future Insights:

- A substantial progression would be the development of a framework for real-time data analysis and prediction, which would enable investors and traders to formulate decisions in accordance with the most up-to-date market conditions.
- Further examination of hybrid models, which amalgamate the merits of distinct algorithms, may result in the development of forecasting tools that are more precise and dependable.
- Incorporating deep learning methodologies, which have demonstrated potential in numerous predictive modeling contexts, into stock price forecasting experiments may yield novel insights and enhancements.
- Subsequent research endeavors may center on enhancing the models' capacity to navigate the frequent abrupt occurrences and market volatility that characterize the financial industry.
- By integrating these sophisticated models into user-friendly applications or platforms, they could be rendered more accessible to a wider spectrum of investors and speculators.

IV. CONCLUSION

The best course of action for investors to take, whether to buy, sell, or hold onto stocks, can be determined by using historical data and advanced algorithms. This approach is essential for investors who are committed to making intelligent investment decisions since it lowers risks and increases the likelihood of achieving profitable results. The complex and dynamic world of stock prediction was examined in this study using a variety of predictive algorithms and data sources. These findings suggest that an ensemble technique or a hybrid model may be able to anticipate more correctly. Last but not least, the creation and evaluation of the prediction model illustrated the need for data-driven insights in order to provide trustworthy conclusions. This shows the benefits of a data-centric approach in the modern, quickly changing business environment, as well as the possible applications of predictive analytics across a wide variety of sectors. In order for interested traders and investors to utilize these algorithms to buy on the correct day and at the appropriate price, this study set out to create models that could more accurately predict stock prices.

- The study's findings both support and question previous research. Utilizing a range of metrics, including Mean Absolute Error, Root Mean Square Error, Mean Absolute Percentage Error, and the Coefficient of Determination, allows for a thorough evaluation of the model's performance. The optimized hybrid genetic algorithm-based regression models, specifically GA-HGBR, BBO-HGBR, and GOA-HGBR, demonstrate substantial enhancements, achieving a coefficient of determination value of 0.9908. This not only confirms the significance of machine learning models in predicting stock prices but also undermines conventional approaches by showcasing their superior prediction powers.
- Deciding on the best model, examining the outcomes, and then modifying its hyperparameters to enhance the performance of the previously provided model.
- To further validate the efficacy of the GOA-HGBR, these algorithms were applied to and contrasted with the NIKKEI 225 index data sets.

- By contrasting the outcomes of several optimizers, the most effective optimization has been determined as the main optimizer of the model. The GOA technique yields the best results when compared to GA, BBO, and GOA, whose R^2 assessment criterion scores are 0.96, 0.98, and 0.99, respectively.

***Abstract*—With the rapid development of electric vehicles, their charging strategies significantly impact the overall power grid. Solving the spatiotemporal scheduling problem of vehicle charging has become a hot research topic. This paper focuses on recommending suitable charging stations for electric vehicles and proposes a scalable accelerated intelligent charging strategy recommendation algorithm based on Deep Q-Networks (DQN). The strategy recommendation problem is formulated as a Markov decision process, where the continuous sequence of regional charging requests within a time slice is fed into the DQN network as the input state, enabling optimal charging strategy recommendations for each electric vehicle. The algorithm aims to maintain regional load balance while minimizing user waiting time. To enhance the algorithm's applicability, a scalable, accelerated charging strategy framework is further proposed, which incorporates information filtering and shared experience pool mechanisms to adapt to different expansion scenarios and expedite strategy iterations in new scenarios. Simulation results demonstrate that the proposed DQN-based strategy recommendation algorithm outperforms the shortest path-first strategy, and the scalable, accelerated charging strategy framework achieves a 64.3% improvement in iteration speed in new scenarios, which helps to reduce the cloud server load and saves overheads.**

Keywords—Scalable acceleration; smart charging; Deep Q-network; Markov decision

I. Introduction

In recent years, the global energy structure has slowly transitioned towards low-carbon resources, with low-carbon energy gradually gaining a higher share in the power sector. China has also announced its efforts to achieve carbon neutrality by 2060, which will stimulate the development of the renewable energy industry in the country. According to the Renewable Energy Market Report 2023 published by the International Energy Agency, the global installed capacity of renewable energy saw an increase of over 50% in 2023 compared to the previous year, marking the most significant annual increment since 1999. By the end of 2023, the number of new energy vehicles in China reached 20.41 million, with 6.278 million charging piles available, resulting in an electric vehicle (EV) to charging pile ratio of approximately 3.3:1. The rapid growth of electric vehicles has led to an explosive demand for charging infrastructure, presenting both new challenges and opportunities for the power grid. In addition, in the face of a vast domestic user group, the existing charging stations in cities are gradually overburdened due to their sparse and uneven distribution, resulting in a severe mismatch between the current rate of new charging piles in China and the growth rate of new EV sales, and an urgent need for construction. This brings new challenges and opportunities for the intelligent charging strategy for electric vehicles.

Existing research has mainly focused on two aspects: energy storage scheduling at charging stations [1-4] and recommendation of charging strategies for electric vehicles [5-8]. Energy storage scheduling involves storing electrical energy generated by photovoltaic power generation [9-11] and managing cross-temporal energy dispatch to allocate electricity across different charging scenarios, mitigating sustained load pressure on the power grid [12]. In reference [13], a cross-temporal scheduling model integrating photovoltaic power and energy storage systems was constructed. It stored electricity during periods of low power consumption and released it during peak periods to meet changing demands. However, such cross-temporal energy scheduling algorithms rely on accurate energy usage prediction and suffer from limited energy storage efficiency and high costs. Regarding the research on the recommendation of charging strategies for electric vehicles, reference [14] developed a data-driven framework for energy prediction and utilized dynamic programming algorithms to seek optimal charging strategies. However, data-driven approaches become increasingly ineffective as the volume of data grows. Reference [15] proposes a strategy for the localization and route planning of public charging infrastructure for logistics companies based on a two-tier scheme. A two-tier genetic algorithm is used to derive the optimal routing and charging plan, and a simulated annealing descent algorithm is used to select charging station locations. The proposed method is tested and compared with a meta-heuristic approach using a benchmark instance with charging stations. Reference [16] proposes a nonlinear integer programming model with multiple objectives, including minimizing the average daily acquisition and charging costs of the electric bus routes, minimizing the time cost of waiting for charging of the electric buses and maximizing the charging revenues of the electric buses to synergistically realize the vehicle types allowed to be charged in each time window, the daily service journeys and charging journeys allocated to each electric bus. Subsequently, an algorithm was developed to solve the formulated optimization model by combining enumeration with branching and pricing to solve the nonlinear problem. Reference [17] explored ordered charging strategies for electric vehicles using Monte Carlo algorithms, but the probabilistic nature of Monte Carlo algorithms introduces uncertainties in accurately assessing the quality of strategies. Reference [18] proposed a decision framework for charging and repositioning agent-based Shared Autonomous Electric Vehicles (SAEVs) fleets, which adjusts charging before expected demand, spatially and temporally dispersing the demand to reduce peak loads on the power grid and minimizes anticipated costs for operators. However, this framework does not consider the temporal evolution of SAEV demand and Electric Vehicle Charging Station (EVCS) supply or the cost of electricity, as its objective function only seeks to minimize response time rather than balancing charging frequency and response time.

The recommendation of charging strategies for electric vehicles is essentially a temporal scheduling problem [19], but numerous uncertain factors complicate the problem. With the rapid development of reinforcement learning, Markov decision models are well suited for charging strategy recommendations. In reference [20], a novel Markov decision process was constructed, dividing all connected electric vehicles into groups at each time step based on their charging priorities. Reinforcement learning agents were then employed to determine the charging proportions for each group of vehicles during each time interval. However, the arrival time and battery level of each electric vehicle at the charging station must be known to allocate it to a priority group. In reference [21], a graph reinforcement learning-based representation method integrates multi-dimensional information from charging stations, traffic nodes, and grid buses into a graph using feature projections. Graph convolution of coupled system states can then be implemented to facilitate environment perception. In reference [22], a novel multi-agent mean-field hierarchical reinforcement learning (MFHRL) framework was proposed to provide proactive charging and relocation advice for electric taxi drivers, maximizing the long-term cumulative rewards of their orders. The framework employed hierarchical reinforcement learning, with the manager setting goals that inherently guide the decision-making of workers, who receive rewards for following these goals. The integration of each level in the two hierarchies with mean-field approximation was carried out to incorporate the mutual influence of agents in decision-making, enabling finer temporal resolution at short intervals. In reference [23], an incentive demand response model was proposed, analyzing user behavior through reinforcement learning and subsequently guiding users to select periods with sufficient power supply. However, this approach only addresses the temporal scheduling problem, while the spatial scheduling problem remains unresolved. In reference [24], a multi-agent spatiotemporal reinforcement learning approach was introduced, altering the charging decision of electric vehicles by simulating future competitive environments using a delayed access policy. Reference [25] employed neural networks as function approximators to model user demands, training a central agent to develop charging plans for electric vehicles. None of these spatio-temporal scheduling strategies discusses the variability of the actual environment.

Considering that China is in a period of development of charging infrastructure construction, the number of charging stations in the region is increasing, and the expandability of the scheduling strategy in the actual operation process is particularly important. Existing recommendation studies seldom consider the stability of the electric power system and the load balance while adapting to the changing environment, resulting in the charging recommendation strategy having a high maintenance and upgrading cost, and the strategy's practicality is poor.

The main contributions of this paper are mainly as follows:

1) To address the spatiotemporal scheduling issues in traditional electric vehicle charging strategies, a smart charging strategy recommendation algorithm based on Deep Q Network (DQN) is proposed. In this approach, the charging requests within a time slot are treated as a continuous sequence of charging request states and fed into the DQN network to generate optimal charging strategy recommendations for each electric vehicle.

2) To enhance the applicability of the proposed algorithm, an expandable and accelerated regional charging strategy recommendation algorithm framework is introduced. This framework utilizes a shared experience pool strategy to store strategy experiences from different regions. When a new region is added, the framework prioritizes training using experiences stored in the shared experience pool. At the same time, new experiences are stored in the experience pool of the new region. This significantly reduces the training iteration time of the model. Additionally, leveraging the experiences in the shared experience pool allows the model to converge faster and better fit the charging patterns of new regions.

The overall structure of this paper is as follows. Section II provides an introduction to the smart charging strategy recommendation model for electric vehicles based on Deep Q Network (DQN). In Section III, an expandable and accelerated regional charging strategy recommendation algorithm network framework is proposed. Section IV discusses the simulation results of the algorithm. Finally, Section V presents the conclusions and future directions for further work.

II. Smart Charging Strategy Recommendation Algorithm for Electric Vehicles based on DQN

A. Basic DQN Concepts

Deep Reinforcement Learning (DRL) [26] is a combination of Deep Learning (DL)[27] and Reinforcement Learning (RL)[28], which retains the ability of RL to solve policy problems. It involves the continuous interaction between an individual agent and an unknown environment, where the agent takes relevant control actions to maximize its future rewards. In theory, the value function can compute the reward value for any state and action, using methods such as Q-learning [29]. The Q-learning approach stores the state-action pairs and their corresponding rewards in a table, and when the state transitions to an environment corresponding to a table entry, the action's reward value is obtained through table lookup. However, when there are a large number of states and actions, the computation or query time for the value or lookup function significantly increases.

The key difference between DQN and RL lies in the use of neural networks to approximate the agent's value function. Specifically, the state, s, is used as input to the neural network, and the output is the value Q(s, a) and its corresponding action, a. The Greedy(s, a) function is then combined with Qmax(Q, a) to select the best value action while maintaining a certain level of exploration. DQN calculates the current action value in a manner similar to Q-learning, using the difference between it and the output of the value neural network as the loss value. This loss value is then passed into the loss function for iterative learning. During the iterative learning process, the insertion of memories from the experience pool facilitates mixed learning, resulting in a more efficient update of the neural network.

$$\boldsymbol{y_t} = \begin{cases} \boldsymbol{R_t} \text{ \#\#}\boldsymbol{end} \\ \boldsymbol{R_t + \gamma max_{a_{t-1}} Q_{t-1}(s_{t-1}, a_{t-1})} \quad \text{\#}\boldsymbol{not\ end}\text{\#\#\#\#\#\#\# \#\#\#\#\#\#\#\#\#} \end{cases} \quad (1)$$

$$\boldsymbol{L_\theta = E\big(y_t - Q_t(s_t, a_t, \theta)\big)^2} \quad (2)$$

Eq. (1) and Eq. (2) represent the target value, y_t and the reward value, R_t_trespectively, at time step t. The learning discount rate is denoted as γ, and $Q_{t-1}(s_{t-1}, a_{t-1})$ represents the value network value at time step $t-1$. L_θ corresponds to the value of the loss function.

B. A DQN-based Recommendation Model for Smart Charging Strategies for Electric Vehicles

This study primarily focuses on providing charging strategy recommendations for electric vehicles (EVs) at public charging stations. As illustrated in Fig. 1, EVs with charging demands within a designated area send their charging requests to a central processor. They also transmit their specific vehicle information, including current battery level and location, to the central processor. The central processor collects all the charging requests from EVs within the same time period in the area, forming a temporal sequence of charging requests. This sequence serves as the input to the Deep Q-Network (DQN) for generating optimal charging strategy recommendations for all EVs within a time slice. Considering the timeliness of charging strategy recommendations, the study employs time slicing by dividing each minute into 60 time slices, with each time slice representing 1 second. Within a time slice, the processor composes timing input vectors from the states of all requests combined with the load conditions of the charging station and charging pile information, etc., and makes the correct strategy decision for the EV through a deep reinforcement learning model to guide the EV to complete the charging, which satisfies the need to maintain the load of the regional power grid while shortening the user's waiting time.

The recommendation of charging strategies for electric vehicles (EVs) can be viewed as a Markov decision process, which involves coordinating the interaction between EVs and the regional charging environment. The goal is to guide each EV to make informed decisions regarding charging strategies while minimizing user waiting time and the load on the regional power grid. However, treating each individual EV as the main agent does not satisfy the continuity of the state space in the Markov decision process. Therefore, a time slicing approach is adopted, where all charging requests from EVs within a time slice in the region are sorted based on their submission time, forming a continuous state space for the regional charging requests. As shown in Fig. 2 and described by Eq. (3) and Eq. (4), when the agent C_1 submits request q_1, its current location state $Qarea$, state of charge $Qsoc$, and the location information of each charging station Larea are combined to form the overall state s_{q_1}. Subsequently, the state transitions from $s_{q_1}$to s_{q_2}as the vehicle C_2 request is processed. The collection of all request states s_{q_m} within the time slice t_1 forms the aggregate state s_{t_n}, which serves as the input to the DQN network for training in a single episode.

$$\boldsymbol{s_{q_m} = (Qarea_{q_m}, Qsoc_{q_m}, Larea_{q_m})} \quad (3)$$

$$\boldsymbol{s_{t_n} = \{s_{q_1}, s_{q_2}, \ldots, s_{q_m}\}} \quad (4)$$

The DQN action space employed in this study corresponds to the selection of charging stations, where EVs continuously make decisions on charging stations within a time slice, and the action space is the same for all requests. As shown in Fig. 3, the action space corresponds to different discrete charging stations. The agent can choose from the following four actions: 1、Charging station 1, 2、Charging station 2, 3、 Charging station 3, and 4、Charging station 4. These charging stations are randomly distributed, and their initial charging states are also randomized. The agent is trained in various stochastic environments to cope with challenges in real-world settings.

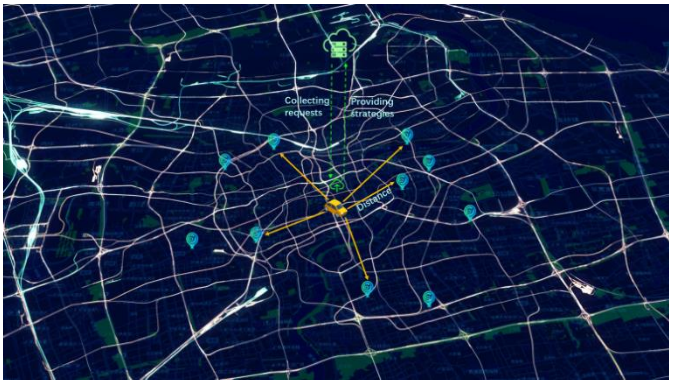

Fig. 1. Scenario of the use of DQN-based recommendation model for smart charging strategy for electric vehicles.

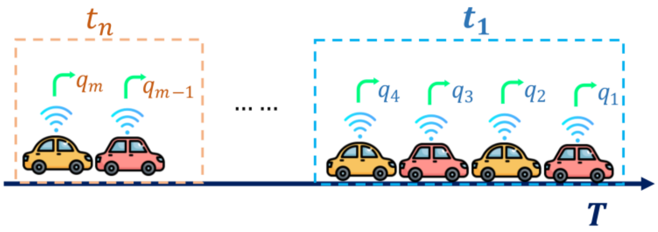

Fig. 2. Time slice model diagram.

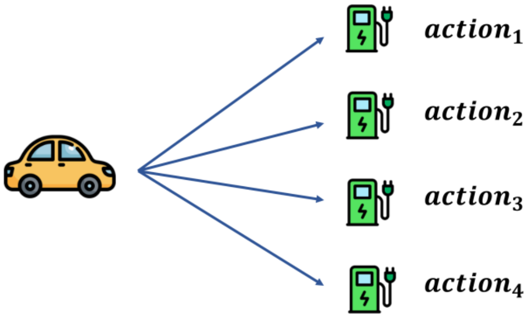

Fig. 3. Action space diagram.

Rewards provide direct or delayed feedback to the agent's decisions, enabling the agent to continually update its decisions to maximize the rewards. Rewards quantify higher-level objectives in multi-agent reinforcement learning. Specifically, in the context of electric vehicle charging strategies, the reward is set as a composite reward to expedite the training iteration of the intelligent agent. Upon making a decision regarding the request q_t, the intelligent agent receives the reward functions $r_{dis}(s_{q_m}, a_{q_m})$, $r_{wait}(s_{q_m}, a_{q_m})$, and $r_{load}(s_{q_m}, a_{q_m})$as defined in Eq. (5) and Eq. (6), respectively:

$$\begin{cases} r_{dis}(s_{q_m}, a_{q_m}) = \begin{cases} -\frac{dis_{range}}{dis_{min}} & dis_{range} + dis_{min} < mile_{min} \\ -dis_{range} & dis_{range} + dis_{min} > mile_{min} \end{cases} \\ r_{wait}(s_{q_m}, a_{q_m}) = -t_{wait} \\ r_{load}(s_{q_m}, a_{q_m}) = \begin{cases} \sum_{n_{charge}}^{i} \frac{1}{n_{rest}} \\ \sum_{n_{charge}}^{i} \frac{1}{n_{wait}} \end{cases} \end{cases} \tag{5}$$

$$R_t(sli_t, a_t) = \partial r_{dis}(sli_t, a_t) + \beta r_{wait}(sli_t, a_t) + \delta r_{load}(sli_t, a_t) \tag{6}$$

The variables in the equation are defined as follows: dis_{min} represents the shortest distance to the charging station, dis_{error} denotes the difference between the selected station and the shortest station in terms of distance. $mile_{min}$ represents the minimum remaining mileage of the vehicle based on its current condition. t_{wait} represents the charging waiting time. n_{charge} corresponds to the sequence number of the charging station. n_{rest} and n_{wait} respectively indicate the number of available charging piles at the currently selected station and the number of vehicles queuing for charging. s_{nc} represents the current charging status of the station, which collectively determines the overall load of the region. Finally, ∂, β, and δ are discount factors.

Observation value: To give the central processor a better grasp of the global information, an observation value is set for each intelligent body. They are set as shown in Eq. (7).

$$obs_m = \{Qarea_{q_m}, fpile_{q_m}, load_{q_m}\} \tag{7}$$

In the equation, s_m represents the state set composed of the position status and battery status of all electric vehicles within the current region. f_m denotes the number of available charging piles in the region, while l_m represents the total load of the region.

C. Reinforcing the Learning Process

The recommended smart charging strategy for electric vehicles based on DQN is illustrated in Fig. 4. The process begins by initializing the experience replay buffer, neural network parameters, and the initial state denoted as s in the DRL model. Subsequently, the states of all electric vehicles within the region are collected to form a state set. The charging policy network and the charging value network are separately utilized to obtain the actual reward r, value network reward r', next state s', and action a. These parameters are then stored in the experience replay buffer. At irregular intervals, parameters are randomly sampled from the experience replay buffer and added to the EV state set for training. Following this, the value network reward r' and the actual reward r are input into the loss function to train the charging value network. The EV state s is updated to s' and the EV state set is updated iteratively until the current training round is completed. Finally, the next LSTM model predicts the EV state, and this process continues until the training is completed, resulting in the output of the trained charging value network model.

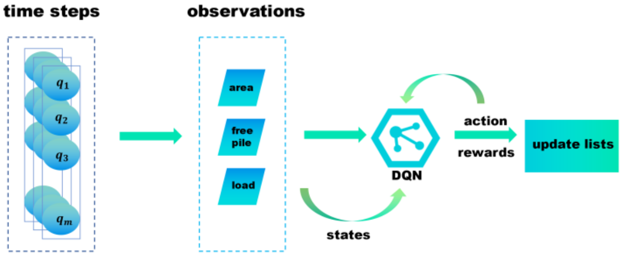

Fig. 4. Diagram of recommended smart charging strategies for electric vehicles.

III. An Algorithmic Framework for Recommending Regional Charging Strategies with Scalable Acceleration

A. Framework Background

Currently, electric vehicles are undergoing an incredible and rapid development, leading to a continuous increase in charging demand. To alleviate the pressure on charging load, many regions have started constructing new charging stations. However, existing charging strategies [30-32] have not addressed their scalability. Adding a new charging area and starting the training of charging recommendation strategies from scratch undoubtedly incurs additional costs. Therefore, this paper proposes a scalable and accelerated framework for regional charging strategy recommendation algorithm.

B. Framework Scenario Analysis

The individual charging station information within a single region is presented in Fig. 5 and Fig. 6, including the operational status, available quantity of charging piles, and specific locations of the charging stations. Initially, the information filtering layer is employed to select the information from the n closest charging stations to the charging-requesting vehicle, forming a new tuple of charging station information features with a length of n. The specific value of n will be described in detail in the experimental section. Subsequently, the new tuple of features is input into the DQN network for training, ultimately providing policy recommendations. The initial input states, decisions, rewards, and other parameters for each policy recommendation are stored in the network's own experience replay buffer and the shared experience pool of the extended framework. During the training of policy recommendation across multiple regions, when updating the policy value network, random sampling from the shared experience pool is incorporated to achieve experience sharing. This facilitates accelerated training when new regions join the shared experience pool, effectively avoiding the issue of random recommendations due to insufficient initial experience pool capacity. Furthermore, the self-experience replay buffer is continually improved during the training process. Once its capacity is full and construction is completed, the framework utilizes its own experience replay buffer. Next, the applicability of this framework will be discussed based on three extended scenarios [33].

Scenario 1: Addition of new charging piles within the region. The purpose of this algorithm is to recommend the optimal charging station. Within the algorithm environment, there is a queue of information regarding available charging piles at the charging stations. When new charging piles are added to a charging station, it simply increases the count of available charging piles, without affecting the functionality of the algorithm.

Scenario 2: Addition of new charging stations within the region. The first layer of the proposed recommendation algorithm framework filters the information of all charging stations within the region. It retains a tuple of information features with a length of n ensuring that the input dimension of the DQN network remains consistent. This, in turn, guarantees consistency in the action space dimension of the DQN network. Specifically, when a vehicle makes a request, the DQN network takes a filtered queue of n nearest charging station information as input and ultimately provides policy recommendations among these n charging stations for the vehicle.

Scenario 3: Addition of a new charging area. The shared experience pool within the proposed recommendation algorithm framework is designed to address this scenario. The new region can directly utilize the shared experience pool to accelerate training, continuously accumulate and improve its own experience replay buffer, and eventually develop its specific charging strategy.

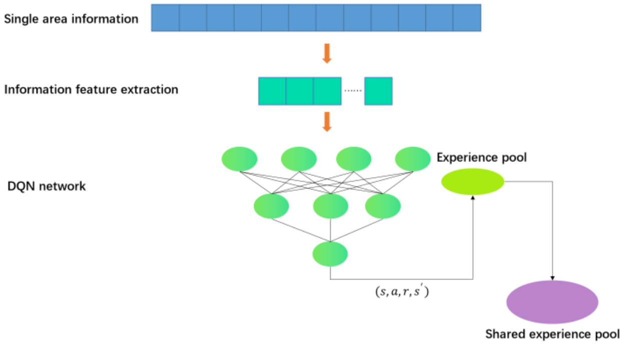

Fig. 5. Framework of the scalable regional charging policy recommendation algorithm.

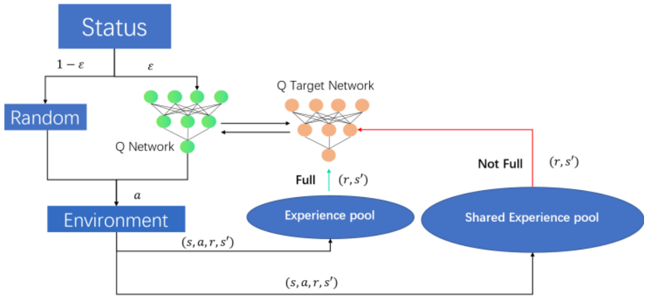

Fig. 6. Flow chart of the shared experience pool.

IV. Algorithm Analysis

A. DQN-based Algorithm for Recommending Smart Charging Strategies for Electric Vehicles

1) Experiment description: This experiment primarily simulates the decision-making behavior of electric vehicles in a region regarding public charging stations. The region is set to a size of 2000*2000 grids, and at the beginning of each experimental round, the coordinates of the charging stations within the region, as well as the positions and coordinates of the charging requests within the region, are randomly initialized. The coordinates are used to simulate real-world latitude and longitude.

In this experiment, a comparison will be made between the DQN-based intelligent charging strategy recommendation algorithm and the nearest distance-first strategy in terms of specific performance metrics such as average charging waiting time and average regional load. The experiment involves storing the location information of the region's charging stations on a server and simulating the application scenarios of the scalable regional charging strategy recommendation algorithm framework through local-server interactions.

2) Parameter setting: To validate the proposed algorithm, the following experiments were conducted in the simulation environment as shown in Table I. In this algorithm, the batch size of 32 was selected for each training iteration. The learning rate lr of the DQN network was set to 0.01, the exploration-exploitation trade-off rate ε was set to 0.9, and the discount factor γ for the policy was set to 0.9. The experience replay buffer size was set to 100,000, and the target network was updated every 100 iterations .

TABLE I. SIMULATION ENVIRONMENT CONFIGURATION TABLE

Configuration of experiment	Specific Parameters
CPU	Intel Core i7-11700K@ 5.0GHz
GPU	NVIDIA GeForce GTX 1660 Super
Memory	16GB
Operating system	Windows10
Programming environment	python3.7、pytorch 1.10.2+cu102
Reinforcement learning environment	gym0.10.5

3) Analysis of results: After 5000 iterations of training, as shown in Fig. 7, where the first 1000 iterations were used for the experience replay buffer population, the reward values for the DQN-based intelligent charging strategy recommendation algorithm converged to approximately -3.5. To demonstrate the performance of the proposed algorithm, we will now discuss the simulation results in detail. Fig. 8(a) presents the load situation of the charging strategy recommendation algorithm based on DQN, while Fig. 8(b) shows the load situation for the nearest distance-first strategy. It can be observed that with the increase in time steps, our proposed algorithm exhibits some fluctuations. However, it shows an overall decreasing trend, significantly different from the nearest distance-first strategy. Based on calculations, the average load per step for the DQN-based charging strategy recommendation algorithm is 1.14, while for the nearest distance-first strategy, it is 1.20, resulting in an improvement of approximately 5.0%.

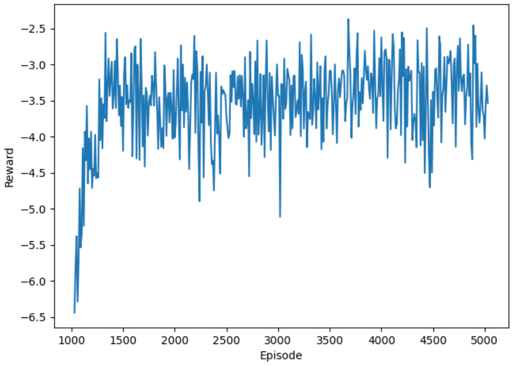

Fig. 7. Iteration diagram of the DQN-based charging policy recommendation algorithm model.

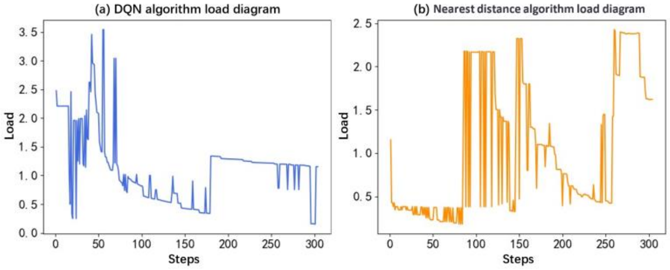

Fig. 8. DQN based intelligent charging strategy recommendation algorithm for electric vehicles and the nearest distance recommended load comparison diagram.

In terms of waiting time, as shown in Fig. 9, where Fig. 9(a) represents the DQN-based electric vehicle charging strategy recommendation algorithm's ability to make correct recommendations for immediate use when all charging stations in the area are initially vacant and to reasonably schedule charging plans even when all charging stations are under load in the latter part. In contrast, Fig. 9(b) depicts the nearest distance-first strategy, which fails to make optimal charging plan arrangements from the beginning. Based on calculations, the average waiting time per step for the DQN-based charging strategy recommendation algorithm is 1.75 ms, while for the nearest distance-first strategy, it is 1.91 ms, resulting in an improvement of approximately 8.37%. It can be observed that the DQN-based charging strategy recommendation algorithm proposed in this paper not only maintains balanced area loads but also significantly reduces users' waiting time, which helps alleviate user anxiety and enhances the user experience.

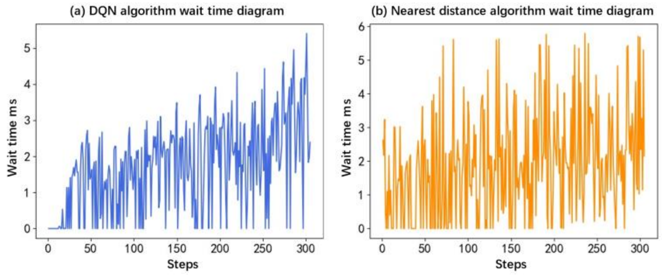

Fig. 9. DQN based intelligent charging strategy recommendation algorithm for electric vehicles and the nearest distance recommended waiting time comparison diagram.

In addition to waiting time, the distance to the recommended charging station is also a criterion for measuring the algorithm's accuracy. Fig. 10(a) and 10(b) below represent the DQN-based electric vehicle charging strategy recommendation algorithm and the nearest distance recommendation algorithm, respectively. From the figures, it can be observed that the DQN-based recommendation algorithm is primarily consistent with the nearest distance recommendation algorithm. Out of 300 testing steps, the DQN-based recommendation algorithm recommended the nearest distance priority in 121 cases. In contrast, in the remaining 179 cases, it selected other charging stations to minimize total time.

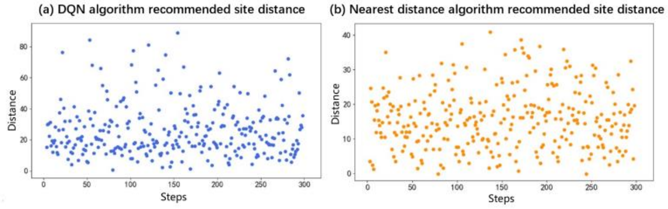

Fig. 10. DQN based intelligent charging strategy recommendation algorithm for electric vehicles and the nearest distance recommendation algorithm recommended site distance comparison diagram.

In terms of enablement, the experiments tested the DQN-based scalable EV smart charging policy recommendation algorithm model size of 1.21M with an average delay of 923ms, which has a strong real-time performance and can be applied to practical scenarios.

B. *Scalable Acceleration Algorithm for Electric Vehicle Charging Strategy Recommendation*

1) Experiment description: This experiment mainly simulates the expansion charging scenario in the region, the iteration speed of the model will be verified separately, and the expandability in different scenarios.

2) Parameter setting: The experimental parameters of the network part of this experiment are consistent with the DQN strategy algorithm above, i.e. the number of samples selected for one training session is 32, the learning rate lr is 0.01, the greed rate ε is 0.9, the discount rate γ is 0.9, the experience pool size is set to 100000, and the target network following frequency is 100. The total experience pool size in the algorithm is set to 10,000,000 and the following frequency is 10,000.

3) Analysis of results: To cope with increasingly complex charging scenarios, the proposed scalable and accelerated electric vehicle charging strategy recommendation algorithm in this paper filters the charging station information within a single region through an information filtering layer. It forms a new charging station information feature tuple of length n, as illustrated in Fig. 11. In order to observe the impact of n on the waiting time in the recommendation algorithm, we conducted the following experiments, and the average waiting time was minimized when n was set to 9.

To validate the feasibility of the algorithm, this study conducted simulation experiments on the following scenarios based on practical application scenarios: Scenario 1: Adding new charging poles to charging stations within a region; Scenario 2: Adding new charging stations within a region; Scenario 3: Adding new charging regions; Scenario 4: Complex real-world scenarios. In Scenario 4, the number of experimental subjects in Scenario 3 was doubled. Specific parameters are shown in Table II.

Fig. 12 presents a comparison of the average waiting time for each scenario. Fig. 12(a) shows the original waiting time graph obtained from Experiment IV (A), while Fig. 12(b), Fig. 12(c), and Fig. 12(d) correspond to Scenario 1, Scenario 2, and Scenario 3, respectively. In Scenario 1, adding new charging poles within the region provides the algorithm with more choices, resulting in a significant decrease in the average waiting time to 0.59 ms. In Scenario 2, adding new charging stations slightly reduces the average waiting time to 0.96 ms. In Scenario 3, expanding the charging region results in a decreased average waiting time of 1.69 ms, representing improvements of 66.3%, 45.1%, and 3.4%, respectively. Thus, it can be concluded that the proposed scalable and accelerated electric vehicle charging scheduling recommendation algorithm remains applicable in complex scenarios, and its performance improves as the complexity of the scenarios increases.

In terms of the load aspect, as shown in Fig. 13, Fig. 13(a) represents the original load graph, Fig. 13(b) represents the load graph for Scenario 1 with an average load reduction of 0.8, Fig. 13(c) represents the load graph for Scenario 2 with an average load reduction of 0.84, and Fig. 13(d) represents the load graph for Scenario 3 with an average load reduction of 1.12. These reductions correspond to 29.8%, 26.3%, and 1.75% improvements, respectively. The average algorithm latency for each scenario is 889 ms, 893 ms, and 897 ms, representing reductions of 3.7%, 3.2%, and 2.8%, respectively. In conclusion, the proposed scalable and accelerated electric vehicle charging scheduling recommendation algorithm in this chapter reduces user waiting time while ensuring the stability of the regional load in complex scenarios. This contributes to better revenue generation for operators.

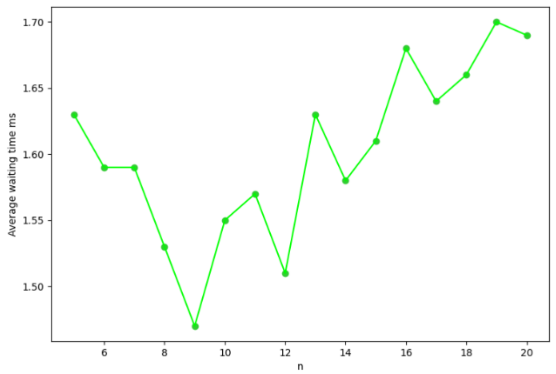

Fig. 11. Graph of results for feature tuple length n.

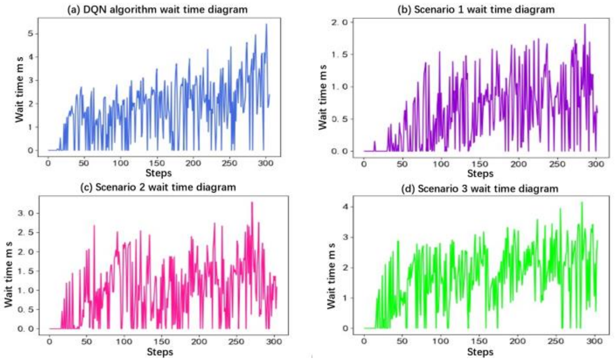

Fig. 12. Comparison of the average waiting time in each scenario.

TABLE II. COMPARISON TABLE OF SCENE PARAMETERS

Scene Name	The original scene	Scenario 1	Scenario 2	Scenario 3	Scenario 4
Size of grid	2000*2000	2000*2000	2000*2000	2000*2000	6000*6000
Number of requests per unit time	300	300	300	300	300
Number of charging stations	20	20	40	20	40
Number of charging piles per charging station	20	40	20	20	40

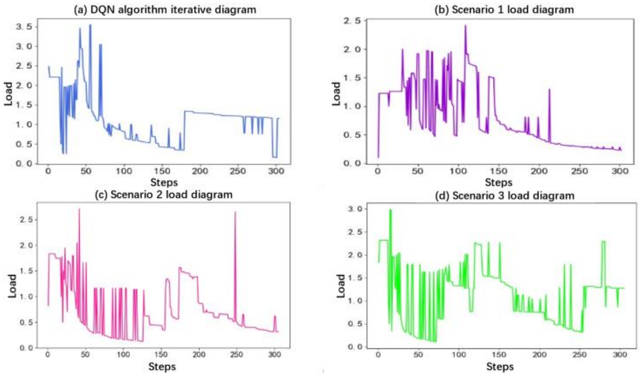

Fig. 13. Load comparison diagram of each scenario.

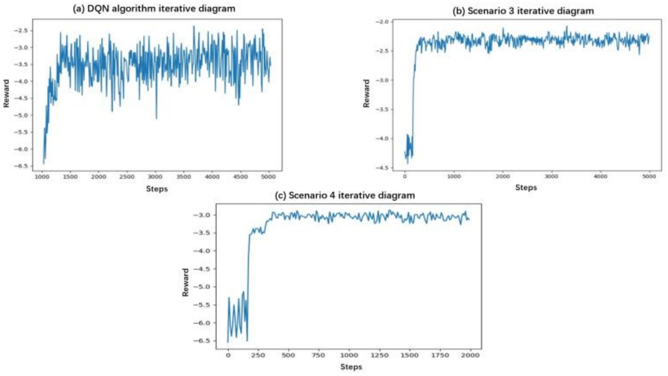

Fig. 14. Comparison diagram of training iteration speed of each scene.

To validate the applicability of the proposed algorithm in real-world complex scenarios, we introduced increased complexity to the scenario parameters, and the results are shown in Fig. 14. Fig. 14(a) depicts the iteration graph of the charging strategy recommendation algorithm based on DQN, which converges after approximately 1400 iterations due to the need for experience pool storage. Fig. 14(b) represents the iteration graph for Scenario 3, while Fig. 14(c) corresponds to the iteration graph for Scenario 4. It is evident that compared to the DQN-based charging strategy recommendation algorithm, expanding the new region in training, as proposed in this study, using the shared experience pool approach eliminates the time required for storing the experience pool. Moreover, the experiences generated by the shared experience pool, compared to those randomly selected by DQN for action generation, are more practical and accelerate the fitting of model parameters, resulting in faster model iterations. In particular, the iteration speed is improved by 64.3% (500 iterations) and 67.8% (450 iterations) for Scenario 3 and Scenario 4, respectively. This significantly reduces the load on the cloud server and saves costs. Regarding waiting time, as shown in Fig. 15, Scenario 4, with the addition of more charging stations and charging piles and an expanded map area, offers users more choices, leading to a decrease in average waiting time compared to Scenario 3, reaching 0.51ms. Complex scenarios often accompany increased model execution time. However, in the simulated experiments of this algorithm in Scenario 4, the average algorithm latency remained relatively unchanged at 901ms, as mentioned earlier. The results demonstrate that as the complexity of the application scenarios increases, this algorithm can further accelerate the model iteration speed, reduce average waiting time for users, and maintain a consistent algorithm latency, showcasing its high applicability.

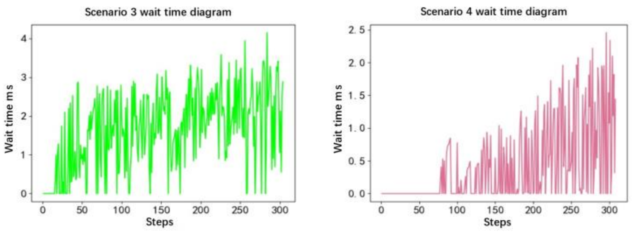

Fig. 15. Scenario 3 and Scenario 4 Waiting time comparison.

V. Conclusion

This paper presents an intelligent electric vehicle (EV) charging strategy recommendation algorithm based on Deep Q-Network (DQN). The algorithm utilizes Markov modeling of user-requested charging events to formulate reasonable charging plans and effectively addresses the spatial scheduling issues in traditional EV charging strategies. Considering the rapid development of charging infrastructure construction in China, we propose a scalable and accelerated regional charging strategy recommendation algorithm framework. This framework not only adapts to increasingly complex and evolving charging scenarios but also maintains a consistent algorithm latency, further accelerating the iteration of the algorithm model. Experimental results show that the algorithm can improve the efficiency of charging strategy recommendation, charging waiting time, and charging demand response speed. In contrast, the expandable and accelerated charging strategy framework improves the iterative speed by 64.3% in new scenarios, which reduces the cloud server load and saves overheads. In future work, we will further refine the hardware implementation of the algorithm to realize a more efficient, precise, and practical charging strategy recommendation algorithm. This will provide superior, efficient, and convenient charging services for EVs, positively contributing to the development of innovative urban transportation.

ACKNOWLEDGMENT

This research was partly funded by the National Natural Science Foundation of China (No. 62362017, No. 62341117).

Department of Information Technology-CCS, MSU-Iligan Institute of Technology, Iligan City, Philippines[1]
MSU-Iligan Institute of Technology, Iligan City, Philippines[2, 3, 4]

***Abstract*—This project introduces a web and mobile application that integrates Geographic Information Systems (GIS) to identify pharmacies with available prescription drugs, addressing the expanding role of Information and Communication Technology (ICT) in healthcare. The primary objective is to offer the general public an easy-to-use platform that locates the closest pharmacy having the searched drugs or medicines. Adopting the Rapid Application Development methodology ensures continuous engagement with stakeholders, allowing developers to closely align the application with user requirements. Essential elements of the web platform include chat functionality, inventory management, pharmacy oversight, and the display of medication listings. General users may check medication lists, search pharmacies, find pharmacy locations and the best routes, search for specific medications, access comprehensive medication information, and more with the mobile application. Fifty respondents, comprising five pharmacists and forty-five general users, expressed overall satisfaction with the system's functionality, emphasizing its ease of use and straightforward navigation across most features. This project not only amplifies the importance of ICT in the healthcare industry, but it also shows how technology can be successfully integrated to improve accessibility and expedite healthcare procedures for both the general public and professionals.**

***Keywords*—ICT in health; mobile application; web application; GIS; pharmacy mapping**

I. Introduction

Access to necessary medical care, especially prescription medication, is an essential aspect of public health, yet it is still a major problem in the Philippines. People seeking necessary medications face a complicated web of difficulties due to the convergence of factors like escalating medicine costs, insufficient delivery methods, and limited accessibility. As stipulated in international human rights agreements, the World Health Organization (WHO) states that guaranteeing access to necessary medications is a crucial part of the right to health [1].

But in the case of the Philippines, the difficulty in obtaining prescription drugs is made worse by the lack of reliable ICT (information and communication technology) tools that can help people find prescribed medication. Prescription medicine accessibility in the Philippines is impeded by a number of variables, such as geographic differences, financial limitations, and a disjointed healthcare system. The lack of a centralized, dependable system that makes it simple for people to find out whether their prescription medications are available at different pharmacies and medical facilities increases these difficulties. Clinical services offered by pharmacists positively impact disease management, contributing to the broader spectrum of healthcare [2] [3]. The role of pharmacies, often the initial point of contact for patients, is pivotal in diminishing health disparities and strategically influencing patient health [4] [5] The lack of efficient ICT tools complicates the problem of pharmaceutical accessibility in a nation where the healthcare sector faces logistical and infrastructural limitations. Even if the Philippines has achieved progress in the field of healthcare, the lack of digital tools to find pharmacies offering the necessary medications makes it difficult to make the most use of the resources that are available.

Global Positioning System (GPS) and Geographic Information System (GIS) technologies play essential roles to the transformation of healthcare systems, particularly when it comes to medication location. By combining GIS and GPS, a potent toolkit can be developed for improving medication accessibility, resolving distribution issues, and improving public health outcomes [6] [7].

II. Related Literatures

A. Global Perspectives on Healthcare Accessibility

Access to Prescription medication in particular is a global issue with multiple factors to consider. In order to ensure every individual worldwide has access to necessary medical care without facing financial hardship; the World Health Organization (WHO) emphasizes the significance of Universal Health Coverage (UHC) [1]. Studies like the in [8], which examined the costs, accessibility, and availability of medications in 36 developing and middle-income nations and revealed structural and economic factors affecting pharmaceutical access, nevertheless, continue to show the persistence of worldwide inequities. Information technology is becoming a transformational force in the field of global health. The World Bank's "World Development Report 2021" notes how information technology, such as telemedicine and electronic health records, is enhancing access to and the quality of healthcare provided worldwide [9].

Tools for information and communication technology (ICT) have become vital for improving medicine delivery networks throughout the world. e-Prescribing platforms, digital health apps, and mobile health apps all help to provide better patient access and effective prescription medication management [10]. Due to ongoing difficulties in pharmaceutical supply chains, organizations such as in [11] and [12] have launched the Access to Medicine Index, an assessment of pharmaceutical firms' global efforts to improve ethics and accessibility. The significance of inclusivity and innovation in tackling global healthcare accessible concerns is emphasized by collaborative worldwide efforts, patient-centric methods, and strategic collaborations [13].

B. Factors Affecting Medication Accessibility in the Philippines

Medication accessibility in the Philippines has various problems influenced by the country's socioeconomic structure, healthcare system, and geographic dispersion. Affordability is a major concern, especially considering the wide economic gaps among the people. The Philippines has a mix of public and private healthcare services, and medicine out-of-pocket costs can be a burden for a lot of people, particularly those without appropriate insurance coverage [14]. High drug costs add to financial hurdles, influencing treatment adherence and may compromise health results.

The decentralization of the Philippines healthcare system and the geographic dispersal of healthcare institutions offer challenges to pharmaceutical accessibility, particularly in rural or isolated locations. In these areas, limited access to pharmacies and healthcare practitioners might result in increased travel costs and drug outages, adding to health inequities [15]. The government's initiatives to address these concerns, such as the passage of the Universal Healthcare Law, seek to enhance access to vital medications by reducing financial risk and extending healthcare coverage [16]. However, obstacles remain in ensuring that such policies are implemented effectively.

Disruptions in pharmaceutical delivery, for example, might have an influence on drug supply in the Philippines. The country has faced medicine shortages, impacting the population's access to some prescriptions [17]. Pharmaceutical accessibility in the Philippines is also influenced by regulatory constraints such as demanding licensing processes and limits on specific treatments. Understanding and addressing these characteristics is critical for devising tailored treatments to increase drug availability and adherence, especially given the country's unique healthcare system. Future research and policy initiatives should continue to investigate approaches to improve pharmaceutical accessibility while taking into account the distinct challenges and potential of the Philippine healthcare system.

Finally, healthcare delivery technologies such as telemedicine and digital health solutions have the potential to improve pharmaceutical accessibility by offering alternate channels for prescription distribution and monitoring [18]. Integrating these technologies into healthcare systems can increase convenience and accessibility, particularly for people with mobility issues or who live in rural places.

C. Role of ICT in Pharmaceutical Services

The use of ICT in pharmaceutical supply chain management has substantially increased the distribution process's reliability and transparency. ICT also makes inventory management, order processing, and demand forecasting easier, ensuring that pharmaceutical items are accessible when and where they are required, resulting in a more dependable and responsive supply network. ICT-enabled pharmacy information systems and electronic health records (EHRs) have transformed patient care and drug administration. Telepharmacy services, a subset of ICT in pharmaceutical services, have been recognized, particularly in rural or disadvantaged regions, through offering patients with prescription consultations and professional guidance without the need to visit a physical pharmacy [19].

In the Philippines, Information and Communication Technology (ICT), specifically Geographic Information System (GIS) applications, are establishing themselves as a valuable tool for addressing difficulties linked to pharmaceutical supply and monitoring within the healthcare system. GIS technology proves essential for mapping and visualizing the geographical distribution of healthcare institutions, pharmacies, and pharmaceutical supply chains. This assists in identifying overlooked regions and improving the distribution of healthcare resources across the archipelago to promote more equal access to medications [20]. Furthermore, GIS applications serve to track and monitor drug availability by providing real-time data on the condition of pharmaceutical supplies in various locations, assisting in the management of shortages and improving overall supply chain management.

Integrating GIS into pharmacy information systems has the potential to transform pharmaceutical monitoring and prescription administration. GIS enables pharmacy geospatial mapping, allowing healthcare professionals to analyze the accessibility of pharmaceutical services and identify locations with drug distribution shortages [21]. This data is useful in establishing targeted actions to enhance medicine availability, particularly in rural or isolated areas. The use of GIS in pharmacy information systems can help improve medication adherence monitoring by providing insights into patient demographics and their proximity to healthcare institutions.

While incorporating ICT such as GIS into pharmaceutical services has significant advantages, problems such as data security, interoperability, and providing fair access to digital healthcare solutions must be carefully considered. To realize the potential of ICT in pharmaceutical services, ongoing research and deliberate implementation efforts are required, ensuring that technological innovations contribute favorably to the overall quality, safety, and accessibility of pharmaceutical care.

III. Methodology

This study adopts the Rapid Application Development (RAD) approach, a methodological framework designed to address the drawbacks inherent in total system development methods [22]. The RAD model emphasizes on flexibility and adaptability facilitating the swift and cost-effective development of high-quality systems that can easily meet changing user needs. The method comprises four main phases: requirement planning, iterative development, system prototyping, and the throwaway prototype as shown in Fig. 1.

Central to this process is the initial development of the alpha version, where subsequent user testing and feedback inform the refinement of subsequent versions. This iterative process establishes a clear and linear understanding of the project's scope, enabling the development team to develop systems with extensive functionality within timelines [22].

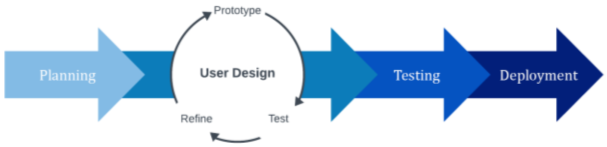

Fig. 1. Rapid application development.

A. Planning

A web application and a mobile application are the two separate application models that are integrated into the system's architecture based on the requirements set by stakeholders. Every model has a different set of features and is designed to meet the needs of particular user groups based on discussions. While the mobile application is meant for general users and offers a user-friendly interface for a wider audience, the web application has been tailored for pharmacists to use, catering to their unique demands such as the management and inventory of medical drugs. The inherent features of mobile applications frequently contribute to their being considered as more adaptive which is more preferred by general users. Research on user-centric design concepts highlights how mobile app development must be customized to users' demands and touch interfaces and smaller screens [23]. Usability and responsiveness are often given first priority in these apps, which makes them ideal for mobile use. Furthermore, mobile applications can be easily integrated with device-specific functionality, such as cameras and GPS, to provide enhanced user experiences.

B. User Design

The system comprises two integral components: the frontend and the backend as shown in Fig. 2. Together, these parts function collectively to provide an effective and logical experience.

The frontend, or user interface, is in the forefront and allows users to interact with the system. When users initiate requests, the frontend actively collects input data, creating a bridge between the user and the system. This input data is then encapsulated into JavaScript Object Notation (JSON), a lightweight data interchange format, preparing it to communicate with the backend.

The backend, which functions as the system's engine, receives the JSON data that has been processed. In this case, the complex task of processing the received request is handled by the backend, which makes use of a number of well-defined system logics to guarantee correct and effective handling. This covers tasks such as running algorithms, querying databases, and managing the system's general operation.

To ensure consistency in data transmission, the backend encodes the response into JSON format after processing is complete. The frontend receives this response, which presents the results of the user's request. The JSON respond to is then decoded by the frontend and formatted such that it can be readily read and understood by the user.

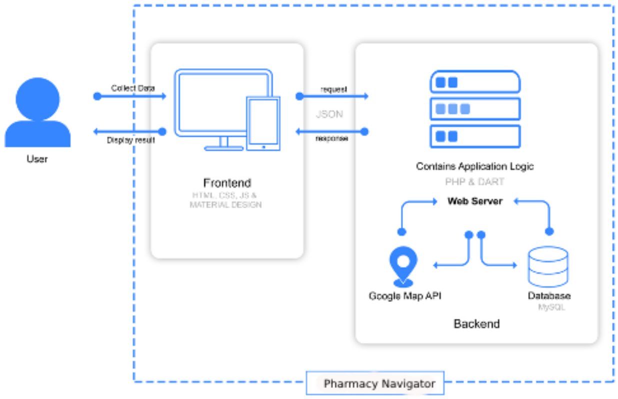

Fig. 2. Pharmacy navigator architectural framework.

On the other hand, after three iteration and frequent consultations from stakeholders, two of whom were pharmacist, five general users, and two developers, features which are distinct and common to both applications are shown in Table I.

TABLE I. LIST OF FEATURES, DISTINCT AND COMMON TO THE MOBILE AND WEB APPLICATION

Application Model	*Features*
Web Application	The software is intended for use by pharmacists and their staff. It includes a thorough list of all the prescription medications that the pharmacy has on hand. A specialized component of the system is designed to manage the stock of pharmaceutical drugs that are available. This section offers a simplified interface to facilitate effective inventory management.
	Geographic information systems are incorporated into both models, which improves their functionality by offering location-based information like the closest pharmacy having the needed prescription medication. Chat system is also incorporated to allow users to communicate with the pharmacy or the client vice versa.
Mobile Application	The application is exclusively designed for patients or general users. It incorporates a search feature that enables users to check the availability of specific pharmaceutical medicines. Upon initiating a search, the system provides information on the nearest pharmacy where the desired pharmaceutical drug is available.

The system has been purposefully developed to meet the user requirements collected during the Rapid Planning Phase, translating these requirements into an effective system design. Table II and Table III provided below present a list of the functional requirements distinct for web and mobile applications respectively.

TABLE II. LIST OF FUNCTIONALITY AVAILABLE FOR THE WEB APPLICATION

Web Application	
Functions	***Actions***
User Registration	The system is expected to prompt an error message for unsuccessful registration and confirmation message if successfully registered.
Login/Logout	The system has a validation process for registered users. If either or both of the username or password are/is invalid, the system is expected to prompt an error message. The system will allow the entry of the user in the system of username and password are verified. The system is expected to allow the user to logout from the system
Display List of Medicines	The system is expected to display all medicines stored in the pharmacy. The system is expected to display the medicine searched by the user
Manage Inventory	The system will prompt a response message when updating, adding, and deleting inventory
Manage Pharmacy Information	The system allows the management of information and is expected to prompt a response message for every action performed.
Chat System	The system is capable of sending and receiving messages

TABLE III. LIST OF FUNCTIONALITY AVAILABLE FOR THE MOBILE APPLICATION

Mobile Application	
Functions	***Actions***
View List of Pharmacies	The system is expected to show the list of pharmacies available in the database.
Search Pharmacy	The system is expected to display the information of the pharmacy, based on the information provided to the system.
Get Pharmacy's Location	This allows the user to get information of the pharmacy selected by tapping or navigating within the map.
Get Pharmacy's Shortest Route	The system is expected to show the shortest route leading to the selected pharmacy having the prescribed medicine.
Search Medicine	The system is expected to display the drug(s) information based on the search item.
Display Medicine	The system is expected to display all stored medicine in the database.
Chat System	The system is capable of sending and receiving messages

C. Testing

For the usability test of the mobile application, the study targeted random participants aged eighteen (18) and above who met at least one of the following criteria: (a) residing in Iligan City, (b) having studied in Iligan City, or (c) currently enrolled in a school in Iligan City.

This research study includes the voluntary participation of respondents with basic understanding of pharmaceuticals and be able to perform activities such as naming, classification, and categorization of pharmaceutical goods. Participants are not required to live or study in Iligan City.

Demographic information was collected as part of the questionnaire. To uphold ethical standards, letters of consent were provided to participating respondents. A total of forty-five respondents have tested the mobile application while there were only five pharmacists for the web application.

The tests were conducted online, utilizing the "Play Store" for the mobile application (for general users) and a URL for the web application (pharmacist/staff role). The main goals of the alpha test, which is the initial assessment stage, were to get relevant user feedback and validate that the developers had successfully complied with the user system requirements.

To begin the testing procedure, participants were given a Google Form with instructions and tasks. This method allowed for "freestyle" testing, allowing participants to explore the application in their own way. The given activities were designed to determine if the application efficiently meets the research questions and preserves the integrity of its functionality, especially in the context of the mobile application and web application. A survey was given after the task. This survey was essential in determining how well the application met the users' expectations and requirements. It examined a number of issues, such as overall application satisfaction, interface design, and user experience. A five-level Likert scale was employed for rating each question.

A key part of the survey was obtaining qualitative input from users. It was encouraged for participants to share thoughts and recommendations, especially with reference to areas where changes or enhancements could improve their experience. Users were encouraged to provide their opinions on possible improvements by answering questions like "Is there anything else you would like us to improve or change?" in order to gather insights that might not be addressed by initial activities.

IV. RESULTS AND DISCUSSION

The design, functionality, and user interfaces of the desktop and mobile applications are assessed and compared in this section. Aiming to improve stakeholders' engagement and satisfaction, developers designed at incorporating all of their requirements in the digital interfaces and functionalities.

Incorporating participants' feedback from the alpha testing is enhanced in the beta testing phase, which is the final stage of assessing the mobile application in the research study. Coherence with the parameters and constraints of the research is certain through this method. During the alpha testing, the researchers identified human errors, which prompted a series of UI/UX re-engineering for the program.

A. Mobile Application

This mobile application is intended for patients or general users, and it was developed to a user-friendly search option that lets people locate whether certain prescription medications are available. The following are the features of the mobile application.

1) View list of pharmacies, search pharmacy and get pharmacy's location: This functionality enables users to navigate, tap, and untap specific pharmacy using the participant's geo-coordinates, facilitating interaction with the application map. A persistent bottom sheet emerges on the bottom left, displaying the pharmacy's name and a "view" button that directs the user to the pharmacy's dedicated page.

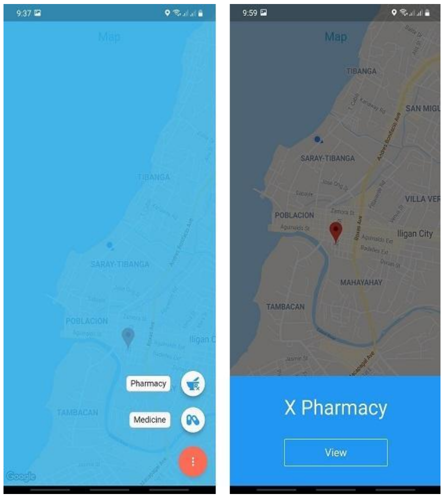

Fig. 3. Screenshot of the get pharmacy’s location feature in the alpha test.

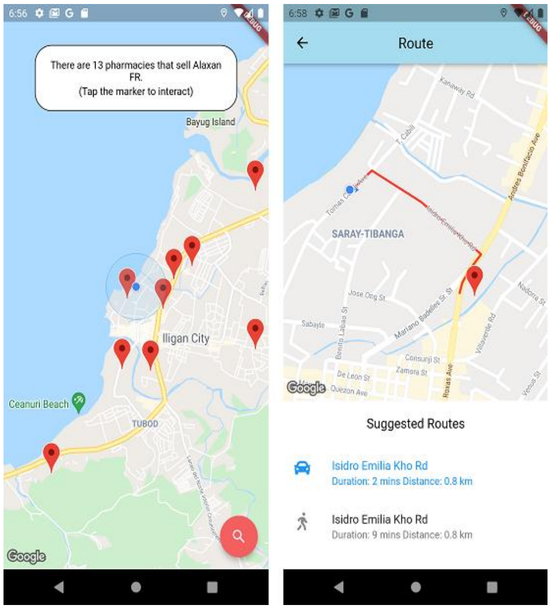
The challenge with this interface as shown in Fig. 3 during the alpha test was the number of underlying pages, which could be minimized for a clearly defined functionality. As a result, it becomes diverted by the multitude of page elements and deviates from its primary goal of locating a pharmacy.



There are 13 pharmacies that sell Alaxan FR.

Route

Suggested Routes

Isidro Emilia Kho Rd
Duration: 2 mins Distance: 0.8 km

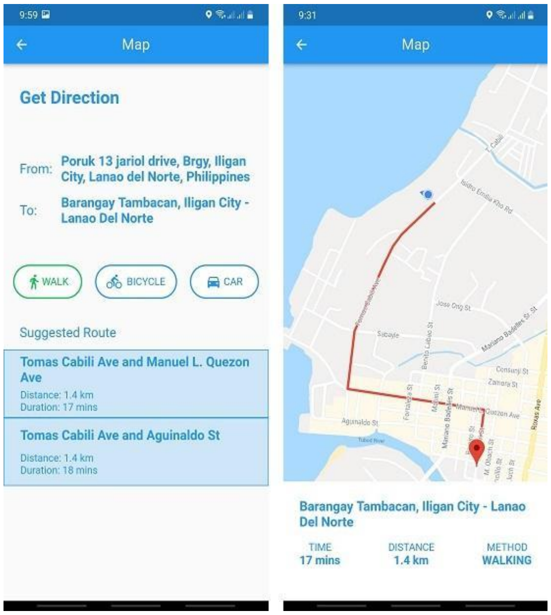
Isidro Emilia Kho Rd
Duration: 9 mins Distance: 0.8 km

Fig. 4. Screenshot of the get pharmacy’s location feature in the beta test.

Fig. 4 displays an improved iteration of the Get Pharmacy's Location Feature, incorporating feedback obtained during the alpha test. In this version, the search function is exclusively in the persistent bottom sheet, minimizes pages and buttons. Upon conducting a search for a specific medicine, the system displays all pharmacies offering the desired drug, allowing users to tap on a location/pharmacy to access detailed information. Each pharmacy's location is displayed, allowing users to make informed decisions based on proximity and convenience. The objective is to provide a user-friendly interface that promotes ease of use and accessibility.

2) Get pharmacy’s shortest route: An essential component of the application's testing phase, this functionality uses the Google Map API in order to guide visitors from their starting place to the selected pharmacy. Based on the user's starting location and preferred method of transportation (walking, cycling, or driving), participants assess how well the program performs in providing directions. Walking is chosen as the default method to consider the means of transportation by the majority of users. Furthermore, the feature provides users with several route possibilities, enabling them to select the most appropriate direction. In order to enhance the entire process of decision-making, this user-centric approach also includes crucial information like arrival time, distance, and route means.

Similar with the Get Pharmacy location, the alpha test result pointed out that this feature loses efficiency because it takes up numerous pages rather than being contained to one, making it difficult to use as shown in Fig. 5.



Map

Get Direction

From: Poruk 13 jariol drive, Brgy, Iligan City, Lanao del Norte, Philippines

To: Barangay Tambacan, Iligan City - Lanao Del Norte

WALK BICYCLE CAR

Suggested Route

Tomas Cabili Ave and Manuel L. Quezon Ave
Distance: 1.4 km
Duration: 17 mins

Tomas Cabili Ave and Aguinaldo St
Distance: 1.4 km
Duration: 18 mins

Map

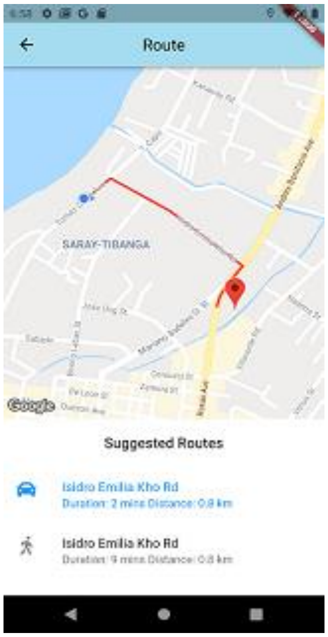
Barangay Tambacan, Iligan City - Lanao Del Norte

TIME	DISTANCE	METHOD
17 mins	1.4 km	WALKING

Fig. 5. Screenshot of the get pharmacy’s shortest route in the alpha test.

With the influence from Google Maps for navigation, showed that a single page approach was more practical and user-friendly which is shown in Fig. 6. In addition to being in line with this preference, combining the two pages into one, improves interaction and simplifies the functionality for users.

3) Search medicine and display medicine: This tool makes it simple for consumers to search for a specific medication. It executes a case-insensitive search algorithm by interpreting the user's input and taking into account both the brand and generic names of medications. A list of medications that match the keyword entered appears as the result, making the search process simpler and user-friendly.



Suggested Routes

Isidro Emilia Kho Rd
Duration: 2 mins Distance: 0.8 km

Isidro Emilia Kho Rd
Duration: 9 mins Distance: 0.8 km

Fig. 6. Screenshot of the get pharmacy's shortest route in the beta test.

The researchers discovered that one issue with the previous version of the feature was that it displayed extraneous information and was not engaging enough as shown in Fig. 7. Instead of needing to present the results on another page, smart predictions will appear below the search box and, when clicked, will divert to another website.

B. Web Application

The web application's core functionalities; Registration, Login, Medicine Display, Inventory Update, and Pharmacy Management, performed as expected during usability testing, aligning with the positive ratings provided by respondents. While the overall functionality met expectations, constructive feedback from one participant emphasized the need for enhancement in the UI/UX design. This feedback emphasizes the need of refining the user interface's perceived plainness and lack of vitality.

Despite the feedback, the Pharmacy Management tool was a significant feature. This module is excellent for developing trust in both the general public and pharmacy management. The pharmacy must register the pertinent data in the Register Pharmacy feature, as depicted in Fig. 9 to keep track of important pharmacy information. It works by including a pharmacy log, which carefully documents every activity taken by a certain pharmacy. This thorough documentation process maintains transparency and prevents pharmaceutical brands from being swapped. As a result, this feature adds greatly to the pharmacy's operational integrity.

The Display Medicine functionality, shown in Fig. 10, which allows the system to display every medication stocked in the pharmacy, is strength of the program. Notably, one respondent suggested that the presentation be improved by including the medication expiration dates for tracking. In addition, another respondent recommended changing the "Availability" label to "Stock" for consistency. This recommendation would include existing pharmaceutical information such as Generic Name, Brand Name, Dosage, Form, and Price, as well as real-time stock levels. The refinement intends to provide management a picture of the pharmacy's inventory, supporting informed decision-making and effective pharmaceutical resource management.

One of the distinguished features of the system is the incorporation of a messaging system that allows users to communicate directly with any pharmacy's representative, enabling responsive and customized engagement environment. The feature was designed to serve as a dynamic link for users for inquiries, seek information, or address any concerns. As the system develop from the alpha test phase to the more polished beta version, the focus of development shifts to the complexities of its user interface. This shift is more than just a standard upgrade; it is a concerted attempt to improve the user experience. The refining process is extremely responsive to user feedback, ensuring that the system not only meets the different demands of its user base, but also delivers an intuitive platform.

C. For Both System

Fig. 11 shows the interface of the chat system incorporated into the system. Users can navigate questions about dose, possible side effects, and other options through interactions, which promotes a more informed and decision-making process. To put it simply, the integration of this chat system simplifies communication while also providing people with a useful tool for getting precise and customized information on their medical needs and health.

D. Testing and Evaluation

A majority found the implementation of the Google Map API, with the utilization of geo coordinates, to be successful in its early stages. A substantial 37 respondents, as shown in Fig. 12 were extremely satisfied with the functionality of the Search and Locate Pharmacy. It is clear that the majority of respondents thought the feature was useful and functional, despite the fact that one and five respondents, respectively, expressed a modest satisfaction and neutrality with the feature. The majority of participants' overall favorable response highlights the usefulness of the Search and Locate Pharmacy capability, demonstrating that it satisfied their needs and expectations.

Forty-four respondents were satisfied with the functionality of the "View Available Medicine/Drug" feature as shown in Fig. 13. One of the comments emphasized how simple it was to locate particular medications, indicating that the search medicine feature answers the needs of most users. This feedback means how well the functionality works to give consumers a practical and easy-to-use experience when looking through the medications that are accessible.

A word cloud of comments received during the alpha testing stage is shown in Fig. 14. Respondents generally expressed satisfaction for the application's overall convenience, ease of use, and user-friendliness. Users responded positively to the application's design and use, highlighting its simple navigation and easy operations. A subset of feedback highlighted concerns related to the redundancy of pages and experience (UI/UX) during testing. In response, the research team proactively addressed these issues, focusing on the refinement of redundant pages through a comprehensive re-engineering process.

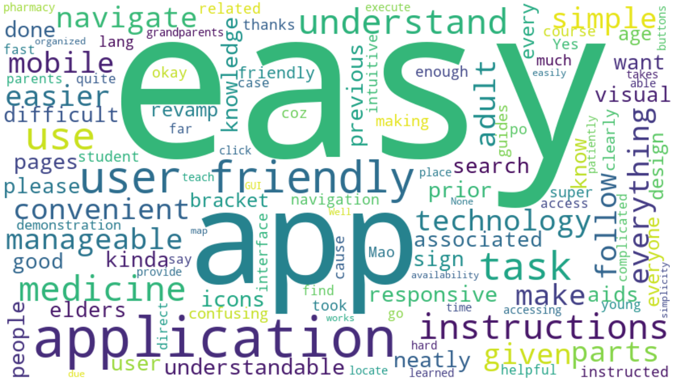

Fig. 14. Word cloud of the application during the alpha test.

The word cloud in Fig. 15 depicts the input gathered throughout the beta testing stage. Remarkably, more users acknowledged the application as an improved version over the alpha test. The redesign prioritized resolving issues brought up in previous testing, making the experience more efficient and user-friendly. In particular, unnecessary pages and intricate content were improved for more basic versions, in line with user expectations for a more refined application.

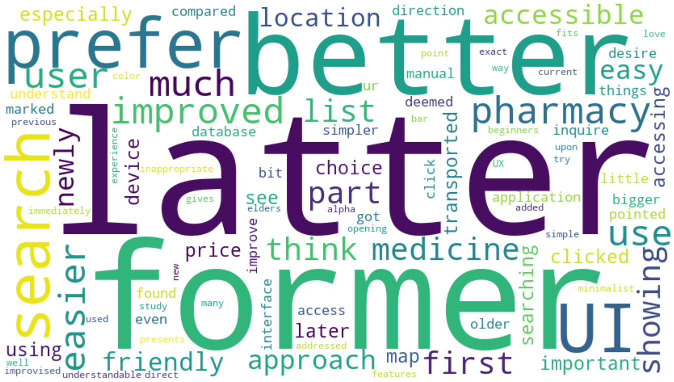

Fig. 15. Word cloud of the application during the beta test.

In addition to verifying the changes made, the beta testing stage reaffirmed at improving the application in response to user feedback. The purpose is to make sure that the application satisfies the needs and preferences of a wide range of users by optimizing the user experience and improving the way information is presented.

V. Conclusion

In conclusion, the development and implementation of the web and mobile application integrating Geographical Information System (GIS) for locating prescribed medicine have been driven to enhance medication accessibility, distribution challenges, and improve public health outcomes [24] [25]. The adoption of the Rapid Application Development (RAD) methodology, having continuous engagement with stakeholders aims to meet user needs and requirements in efficiently locating prescribed medicines from nearby pharmacies. The mobile application, equipped with features such as viewing medicine lists, searching pharmacies, obtaining pharmacy locations and shortest routes, searching for specific medicines, displaying medicine details, and incorporating a chat system, serves as a user-friendly platform designed for the general public in managing their healthcare needs in terms of searching prescribed medicine. Simultaneously, the web system offers features like displaying medicine lists, managing inventory, overseeing pharmacy information, and integrating a chat system to cater to a wider range of user needs. The positive feedback received during both the alpha and beta testing phases further validates the success of the application's functionalities. Respondents consistently reported that the features were easy to use, easy to navigate, and aligned with their needs. This user-centric approach, with the set of features, positions the integrated web and mobile application as a valuable resource in locating medicines, and contributing to the overall improvement of public health outcomes.

***Abstract*—In order to furnish diverse resource requirements in cloud computing, numerous resources are integrated into a data centre. How to deliver resources in a timely and accurate manner to meet user expectations is a significant concern. However, the resource demands of users fluctuate greatly and frequently change regularly. It's possible that the resource provision won't happen on time. Furthermore, because some physical resources are shut down to save energy, there may occasionally not be enough of them to meet user requests. Therefore, it's critical to offer resource provision proactively to ensure positive user involvement using cloud computing. To enable resource provision in advance, it is essential to accurately estimate future resource demands. Using machine learning techniques, we offer a unique approach in this study that tries to identify key features, accelerating the forecast of cloud resource consumption. Finding the classification method with the greatest fit and maximum classification accuracy is crucial when predicting cloud resource consumption. The attribute selection method is used to decrease the dataset. The categorization process is then given the reduced data. The hybrid attribute selection method used in the investigation, which combines the bio-inspired algorithm genetic algorithm, the pulse-coupled neural network, and the particle swarm optimization algorithm, improves classification accuracy. The accuracy of prediction employing this technique is examined using a variety of performance criteria. When it comes to predicting the demand for cloud resources, the experimental results show that the suggested machine learning method performs more effectively than traditional machine learning models.**

***Keywords*—Cloud computing; resource demand; machine learning; cloud resource demand prediction; bio-inspired algorithm**

I. Introduction

With the benefits of characteristic features like resource pool and a pay-as-you-go paradigm, cloud computing has found widespread use in a variety of industries. Infrastructure as a Service (IaaS) is a brand-new cloud service paradigm which offers clients virtual machines as resources (VMs). Accurate and timely allocation of VMs to client tasks in IaaS service model is a major concern. Some cloud providers continue to offer VMs statically, which results in increased operational cost for customers and reduced resource usage for cloud providers. A better alternative is to create VMs dynamically in response to the current resource demands.

However, resource demands fluctuate significantly at times and change continuously throughout time. Users can quickly apply for numerous VMs, for instance. This causes these VMs to take a very lengthy time to create. Due to some of the physical resources being shut down to save energy, even those that are currently in operation may not be enough to meet user requests. For this reason, developing a proactive resource provision is essential to guaranteeing that customers get a positive cloud computing experience. In response to anticipated resource demands, proactive resource provision might offer resources in advance. However, if overestimated, this can be a resource waster.

It goes without saying that if the resource demand is estimated to be less than the actual requirements, user demand of the resources are not met. Therefore, the main challenge is to effectively forecast future resource demands to reduce overestimation and underestimation. An overview of the challenges and approaches for forecasting usage of resources in cloud computing can be found in the study [1]. To prevent resource over-provisioning, Chen et al. [2] developed a forecast method exclusively for burst workload. To eliminate bursts and sounds, this technique employs the Fast Fourier Transform (FFT) algorithm, which increases prediction accuracy. A cloud workload prediction model is put out by Roy et al. [3]. This model predicts future workload using autoregressive moving average method of the second order (ARMA) and then uses a performance model of the average app response time to forecast resource requirements.

Using ensemble models, two self-adaptive resource demand prediction techniques are proposed [4, 5]. In order to increase prediction accuracy, Xu et al. [6] propose the GFSS-ANFIS/SARIMA prediction model, which integrates Seasonal Autoregressive Integrated Moving Average Model (ARIMA) and Generalized Fuzzy Soft Sets with Adaptive Neuro Fuzzy Inference System. Data mining and statistical techniques are used in Verma et al. [7] resource prediction framework for multi-tenant service clouds to forecast resource demands in order to minimize resources and provisioning time. To obtain precise performance forecasts in hybrid clouds, Imai et al. [8] suggest a model which has workload-tailored elastic compute unit (WECU) as a computing power unit. Brown's quadratic exponential smoothing approach is used by Mi et al. [9] to forecast activities ahead and adjust resources as needed in a data center.

The resource prediction method used by Minarolli et al. [10] incorporates the cross relation of asset utilization among VMs that are part of the same application. Bankole et al. [11] proposed three performance prediction models that employ neural networks (NN), linear regression (LR), and support vector regression (SVR) methods independently. The experimental findings demonstrate that SVR is the favored model, outperforming other models in terms of prediction accuracy. Similar to this, certain machine learning techniques, such as the multi-layer perceptron (MLP) [12], Support vector regression (SVR) [12], deep belief network (DBN) [13], and artificial neural network (ANN) [14], are used to forecast resource utilizations. There are two categories of prediction. The former involves statistical methods and the latter employs machine learning techniques. Even though machine learning methods can produce predictions with a higher degree of accuracy, it requires setting up the training model and extracting the features from a humungous amount of data. Though sampling data might occasionally change greatly and be insufficient as inputs for machine learning techniques. The prediction accuracy of statistical methods is often poor for non-stationary and non-linear data.

One such well-known metaheuristic method based on swarm-intelligence is particle swarm optimization (PSO), which has demonstrated its superiority in resolving a variety of real-world optimization issues from fluid mechanics, wireless sensor networks, engineering, applied sciences and academia [15]. Despite its success in locating competitive solutions, the PSO still has trouble sustaining strong exploration and is susceptible to becoming stuck in local optima, which leads to an insufficient exploration-exploitation tradeoff [16]. These flaws have an impact on the subsequent quality of the scheduling solution. Additionally, the "No Free Lunch Theorem (NFL)" [17] establishes the impossibility of finding a single metaheuristic algorithm capable of efficiently solving all optimization issues. These facts serve as powerful impetuses for the current research project, which proposes a hybrid PSO-based scheduling solution to get over the constraints of regular PSO by combining it with genetic algorithm (GA) and pulse coupled neural networks (PCNN).

The remainder of the paper is organized as below. Section II includes an overview of prior studies in the same field. The methodology, system workflow, feature extraction, and demand prediction employed in the proposed approach are covered in Section III. Section IV includes the performance analysis of the proposed hybrid solution. Section V provides a conclusion, marking the end of the paper.

II. Related Work

To solve cloud based scheduling (CBS) difficulties, current research uses heuristics and metaheuristics, such as shortest job first (SJF), First come first served (FCFS), Max-min, Min-min, Minimum completion time (MCT), Minimum execution time (MET), and Suffrage [18]. Heuristics offer problem-specific solutions and are apt for solving minor problems. In contrast, ensemble methods (MHs), are simple, iterative, adaptable, highly speculative, algorithms that direct a subordinated heuristic through smart mechanism [19]. For complicated and larger scheduling issues, metaheuristics-based scheduling solutions have outperformed problem-specific heuristics [20]. However, MHs typically have a few flaws, such as premature convergence, getting stuck in neighboring best value, an absence diversity, and imbalance among the examination and development stages of the energy spectrum [21]. If these flaws are applied to work scheduling issues, the results can be undesirable.

The research has also advocated the use of combination heuristics to address the drawbacks of solo metaheuristics [22]. Several whale optimization algorithms (WOA)-based scheduling approaches have already been put out for scheduling bag-of tasks (BoT) applications to get results that are almost optimal and are motivated by the humpback whales' hunting method. These solutions include those that employ conventional, customized, and fusion of WOA techniques [23]. A standard WOA, Gaussian model, and opposition-based learning (OBL) approaches are combined and used in a cloud scheduling solution called GCWOAS2 [24] to provide effective task-resource couples. One more current study paper [23] proposes a combination metaheuristic approach dubbed OWPSO to address the shortcomings of the original WOA by combining OBL and PSO algorithms. The authors of [25] proposed random double adaptive WOA (RDWOA) employing the Bee optimization algorithm techniques for arranging cloud workloads to decrease implementation cost and time.

The increase and decrease operators might be augmented to the typical WOA to enhance search efficiency, according to authors in [26], who also proposed utilizing two advanced optimization algorithms. In study [27], authors proposed an Improved WOA for Cloud task scheduling (IWC) algorithm that makes use of the local weight method to enhance neighboring explore effectiveness and prevent the basic WOA's early convergence. WOA and harmony search algorithm (HS) were hybridized to create WHOA by the authors of [28] in order to reduce execution costs and energy usage. The WOA-based cloud task scheduling solution, which simultaneously optimizes makepan and energy usage, was proposed by Sharma and Garg [29]. To schedule BoT applications over clouds, the whale-Scheduler technique was recommended, yielding the best makespan and execution cost [30]. There have been many different GA-based scheduling approaches proposed in the past, including the basic GA method [31], improved GA strategies employing modified mutation as well as crossover procedures, and fusion of GA results that combine classic GA among additional methodologies [32].

Numerous studies have greatly improved scheduling efficiency over cutting-edge heuristics by using basic variants of SOS and particular improvements to Symbiotic Organism Search (SOS) algorithms utilizing chaotic sequences with dissent learning [33]. To overcome CBS concerns and achieve different QoS objectives, researchers have suggested conventional ant colony optimization (ACO) as well as other altered ACO-based optimization techniques [34]. In numerous researches, classic PSO algorithms, modified PSO variations, and hybrid PSO variants have all been applied to handle CBS situations in order to achieve a variety of objectives, including minimizing computation time and complexity and addressing load balance challenges [35]. An adjustable inertia weighting method is suggested for the CBS problem to tradeoff between exploration and exploitation [36]. For maintaining population variety and enhancing solution quality, Chen and Long [37] proposed a fusion of optimization approach integrating PSO and ACO algorithms. A bi-objective PSO scheduler was used by the developers of [38] to improve system performance and lower execution costs. A multi-objective PSO strategy is used in two deadline-constrained scheduling techniques to enhance QoS metrics values [39].

A non - linear and non PSO was employed by the authors of Ref. [40] to lessen the time for scheduling the workload. Several strategies for workload allocation in a cloud have been suggested, using both a standard Cuckoo Search (CS) implementation [41] as well as modifications to the CS's basic structure and the incorporation of additional metaheuristics. Chhabra et al. proposed a fusion of CS method in [42] to enhance the exploration potential of standard CS and to achieve more appropriate scheduling than current generation heuristics. This metheuristic merged CS and DE algorithms. a solid metaheuristic in the form. GWO has been employed in the past to create almost ideal scheduling solutions to improve various QoS metrics. To optimize both makespan and energy, for instance, a MO-GWO technique was recommended [43]. Modified GWO is formulated in [44] with alterations on the fitness function to consider makespan and cost. In [45], mean GWO is studied to achieve better performance tackling scheduling concerns. It results in lower makespan and reduced energy usage.

Elaziz et al. in [46] integrated the DE algorithm's effective local searching feature and Moth search (MS) method for better scheduling solution. The Bacterial Foraging Optimization (BFO)-based scheduling strategy has been recommended by Milan et al. [47] to optimize extent of imbalance, idle time, and overall execution time. The study in [48] proposes a novel approach to cloud computing scheduling problem solution: Water Pressure Change Optimization (WPCO). The phenomena of water density changing as pressure is increased due to changes in the physical properties of water serves as the inspiration for the novel WPCO technology. WPCO provides the best solution quality in comparison to the standard metaheuristics. According to the authors of [49], a scheduling strategy based on social group optimization algorithm (SGO) is proposed for a diverse cloud environment that can be used to resolve CBS issues with the highest possible throughput and the shortest possible makespan.

Inadequate exploration and utilization process balancing, slow convergence, a failure to focus on schedule order optimization, a lack of products developed using standard workloads, a lack of numerical solutions to tune metaheuristic variables, and concurrent performance and energy consumption optimization are common problems or limitations of the current research studies based on metaheuristic approach for scheduling BoT applications over cloud systems. These flaws leave a lot of room for developing new metaheuristics or refining already-existing ones to increase the CBS problem's efficiency.

III. Proposed Approach

Fig. 1 depicts the planned work's entire organizational structure. It consists of two phases namely training and using the constructed model for prediction. The major goal of the training phase is to learn about the cloud resource requirements and how to predict resource demand from provided data sets. As a result, it is referred to as the training phase. At this point, a method called attribute selection is used to cut down on the amount of data that was collected. The correlating attributes are identified when the data set's dimensions are reduced. These characteristics are crucial for forecasting cloud resource consumption.

Training Phase

Fig. 1. Organizational structure of the proposed approach.

The steps of training and prediction are the same. The similar procedure was performed throughout prediction for the test data. Finally, the anticipated outcomes will be attained. In the following section, each procedure is thoroughly explained. The following list of modules contains the working stages of the planned work.

1) Attribute Selection using PCGPSONN.
2) Correlation feature extraction.
3) Cloud Resource Demand Prediction using SVM.

A. Attribute Selection using PCGPSONN

Only the unique Pulse Coupled Genetic Particle Swarm Optimization Neural Network (PCGPSONN) is used to determine the cloud resource database's most crucial properties. The attributes must be carefully chosen for an accurate demand prediction of cloud resources. Low accuracy, prediction inaccuracy, or failure might result from the incorrect selection of these attributes. If the feature selection initial selection was incorrect, the approach will never reach the global minimum and more runs will only take the algorithm to a local minimum. The best position for each particle, Pg, as determined by the Genetic Particle Swarm Optimization (GPSO) algorithm, is searched for in this work using the Pulse Coupled Neural Network (PCNN) algorithm.

In GPSO method, the GA operators and the PSO update mechanism typically operate with the same population throughout initialization step. Uniformly distributed random numbers should be used to create the initial population of all its members. Therefore, the attribute selection process must go through more iterations because of this random distribution's sluggish convergence. However, in our suggested method, GPCNN solutions are used to allocate the PSO's initial population. GPCNN and PSO split the entire number of iterations evenly. GPCNN runs the first half of the iterations, and the answers are provided as the PSO's initial population. PSO is in charge of the final iterations. Thus, the issue of delayed convergence is resolved, and the attribute selection process requires fewer iterations.

Additionally, the hybrid approach we suggest should include local and worldwide search. Then, for each particle, generate the best position Pg, and the attribute selection method is then given these best positions Pg to further refine the search process. Consequently, our hybrid strategy performs better than this approach. The PCGPSONN algorithm is displayed below.

Algorithm of PCGPSONN:

Input:

- Attributes (X) and their values.
- Population Size (pop_size): Number of individuals in the population.
- Max Generations (max_gen): Maximum number of generations.
- Crossover Probability (crossover_prob): Probability of crossover occurring.
- Mutation Probability (mutation_prob): Probability of mutation occurring.
- Particle Swarm Size (swarm_size): Number of particles in the swarm.
- Inertia Weight (inertia_wt): Weight for the inertia term in PSO.
- C1 and C2 (c1, c2): Constants for the cognitive and social components in PSO.

Output:

- Best Attribute (S): The best solution found.
- Fitness Value (W): The fitness value corresponding to the best solution.

1. Initialize Population:
    - Generate an initial population of solutions (pop_size) randomly.
2. Loop through Generations:
    - Repeat for a specified number of generations (max_gen) or until a convergence criterion is met.

    2.1 Evaluate Fitness:

    - Evaluate the fitness W of each solution X in the population.

    2.2 Genetic Algorithm Steps:

    - Select solutions S1 for crossover based on their fitness.
    - Perform crossover with a certain probability (crossover_prob).
    - Mutate selected solutions with a certain probability (mutation_prob).

    2.3 Particle Swarm Optimization (PSO) Steps:

    - Initialize a particle swarm (swarm_size) with positions and velocities.
    - Evaluate the fitness W of each particle X.
    - Update particle positions and velocities based on PSO equations.
    - Track the global best position S2 found by the swarm.

    2.4 Combine Genetic and PSO Steps:

    - Replace the worst solutions S1 in the population with the best particles from the swarm S2.

    2.5 Update Population:

    - Create a new population for the next generation by combining the modified population and the PSO swarm.
3. Return Best Solution:
    - Return the best solution S found in the final population.
4. Execute PCNN:

- Execute PCNN with W and S

PCNN algorithm

Alpha_F = 0.1 Decay term for feeding

Alpha_L = 1.0 Decay term for linking

Alpha_T = 1.0 Decay term for threshold

V_F = 0.5 Magnitude scaling term for feeding

V_L = 0.2 Magnitude scaling term for linking

V_T = 20.0 Magnitude scaling term for linking

Beta = 0.1 Linking strength

Num = 100 The number of iterations

W= [0.5 1 0.5;1 0 1;0.5 1 0.5] Initial values for W

M = [0.5 1 0.5;1 0 1;0.5 1 0.5] Initial values for M

F = zeros(size(S)) Initial values for F

L = F Initial values for L

Y = F Initial values for Y

U = F Initial values for U

T = Ones(size(S)) Initial values for T

S = im2double(S) Normalizing to lie within [0,1]

for n = 1:Num

F = exp(_Alpha_F) *F + V_F*conv2(Y,W) + S Update the feeding input

L = exp(_Alpha_L) * L + V_L*conv2(Y,M) Update the linking input

U = F_ *(1 + Beta*L) Compute the internal activation

Y = double(UiT) Update the output

T = exp(_Alpha_T) *T + V_T*Y Update the threshold input

End

The genetic algorithm's fitness value is W in this case and S is the best quality of genetic algorithms. The proposed approach chooses seven of the 11 attributes that are present in the cloud resource dataset. Table I provides a description of the complete attributes. Table II provides descriptions of the chosen features.

Based on the values of the attribute weights, PCGPSONN chooses the attribute. Instead of using binary presentation, a population of 200 clients used real-valued representation since the parameter coefficients were expressed using real-valued numbers rather than just 0 and 1. Seven separate attribute weight sets totaling 28 qualities made up each individual. The beginning population's members were chosen using machine learning techniques and expert-set weights. More precisely specified is the initial population. The PCGPSONN used a uniform crossover with discrete recombination for offspring creation and a roulette-wheel selection for parent selection. 80.0% of the time was spent on the crossover, and each gene's crossover points were selected separately and arbitrarily. The gene underwent mutation with a likelihood of 1.0% and was uniformly carried out by selecting a random value at random from the range and setting it as the new value at the present place. Additionally, elitism was employed during runs to preserve the greatest person among the population. The weight set that performed the best during evolution was something we did not want to lose. If the total population was higher than 21 at the culmination of the generation, a strategy for survivor screening was used. Those with the lowest categorization accuracy were removed from the population after the individuals were graded according to their accuracy. After 20 generations, the PCGPSONN algorithm concluded, or sooner if the best classification accuracy remained constant during a period of 10 iterations. Additionally, the examination came to an end if every member of the population were the same. The proposed PCGPSONN approach is contrasted with the GPSO and GPCNN approaches to demonstrate its efficacy. Tables III and IV display the GPSO and GPCNN results, respectively.

The selected attribute list of GPSO is shown in Table III. In GPSO approach first genetic algorithm is completed to get the fitness values of all attributes and then it is given to the PSO approach to complete the attribute selection process.

TABLE I. FEATURES OF CLOUD RESOURCE DATASET

S.No	Feature name
1	Timestamp
2	Disk read throughput
3	Disk write throughput
4	Network transmitted throughput
5	Provisioned capacity for CPU
6	Use of CPU [MHZ]
7	Use of CPU [%]
8	Provisioned Memory capacity [KB]
9	Memory consumed [KB]
10	Network received throughput [KB/s]
11	CPU cores

TABLE II. SELECTED FEATURES BY PCGPSONN

S.No	Feature name
1	Provisioned capacity for CPU
2	Use of CPU [MHZ]
3	Use of CPU [%]
4	Provisioned Memory capacity [KB]
5	Memory consumed [KB]
6	Network received throughput [KB/s]
7	CPU cores

TABLE III. SELECTED ATTRIBUTES BY GPSO

S.No	Feature name
1	Disk read throughput
2	Disk write throughput
3	Network transmitted throughput
4	Provisioned capacity for CPU
5	Use of CPU [MHZ]
6	Use of CPU [%]
7	Memory capacity provisioned [KB]
8	Memory usage [KB]
9	Network received throughput [KB/s]
10	CPU cores

Table IV displays the GPCNN's chosen attribute list. When using the GPCNN strategy, all attributes' fitness values are first obtained using a genetic algorithm, and they are then given to the PCNN approach for double threshold operation during the attribute selection phase.

TABLE IV. SELECTED ATTRIBUTES BY GPCNN

S.No	Feature name
1	Disk read throughput
2	Disk write throughput
3	CPU capacity provisioned
4	Use of CPU [MHZ]
5	Use of CPU [%]
6	Memory capacity provisioned [KB]
7	Memory usage [KB]
8	Network received throughput [KB/s]
9	CPU cores

B. Correlation Feature Extraction

The degree to which two or more variables vary together is shown by a statistical metric known as correlation. It describes, in layman's terms, how much one variable changes in reaction to a slight variation in another. In accordance with the direction of the change, it might have positive, negative, or zero values. An independent attribute's strong significance in affecting the output is shown by a high correlation value between it and a dependent attribute. Finding the connection between the dependent and all of the independent variables in a multiple regression setup with numerous parameters is required to produce a more accurate and useful model. It is important to always keep in mind that additional characteristics do not necessarily translate into greater accuracy. Irrelevant characteristics would add unnecessary noise to our model and the accuracy could fall.

The Pearson r correlation method used in this study can be used to identify correlation between two attributes. The Pearson r correlation is the most often used correlation statistic to assess the degree of relationship between two linearly related characteristics. It is possible to determine the Pearson correlation between any two qualities, x, and y using:

$$r_{xy} = \frac{n\Sigma x_i y_i - \Sigma x_i y_i}{\sqrt{n\sum x_i^2 - (\Sigma x_i)^2}\sqrt{n\sum y_i^2 - (\Sigma y_i)^2}} \tag{1}$$

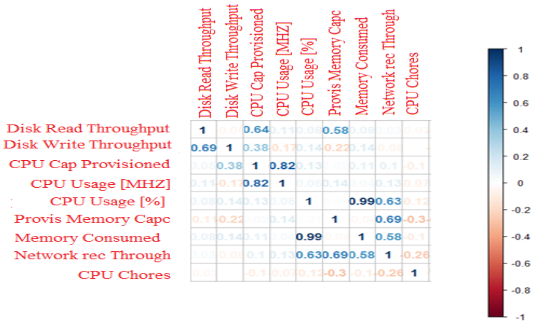

Fig. 2. Correlation Feature extracted values using Pearson correlation method.

Pearson correlation coefficient, often denoted as r, that calculate the Pearson correlation coefficients between each selected attributes which are derived from section 3.1 and the target variable (cloud resource demand). Using Pearson correlation coefficient, the extracted correlation feature table is shown in Fig. 2. In the Fig. 2, the Pearson correlation ranges from -1 to 1, where:

- r=1 indicates a perfect positive linear relationship.
- r=−1 indicates a perfect negative linear relationship.
- r=0 indicates no linear relationship.

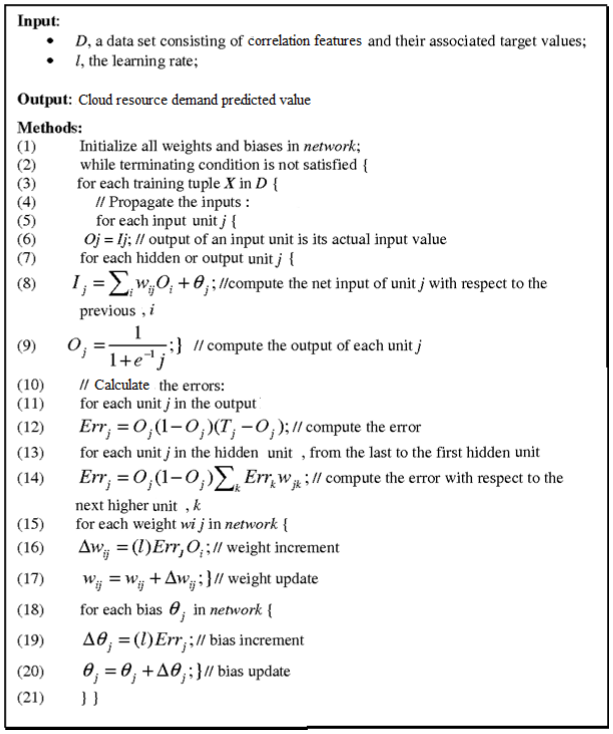
These extracted correlation feature values are given into the SVM to predict the cloud resource demand.

C. Cloud Resource Demand Prediction using SVM

The equations are an exception to the prescribed specifications of this template. You will need to determine w Regression analysis and classification are two applications of support vector machines, commonly referred to as support vector networks or SVMs, which are supervised learning models in machine learning. They examine data and identify patterns. Provided a set of training examples that have been labelled as falling into one of two categories, an SVM training process builds a model that places new examples into either group. The model is now a non-probabilistic binary linear classifier as a result of this. The objective of an SVM model is to generate as big of a gap as possible between the instances of the different categories by mapping the examples as points in space. Next, by mapping them into the same region and identifying which side of the gap they fall into, new instances are projected to fit into a particular category. SVMs can perform non-linear classification as well as linear classification by implicitly translating their inputs into feature spaces with many dimensions, a method known as the "kernel trick."

The primary objective of SVM in cloud resource demand prediction is to find a hyperplane that best separates data points belonging to different classes. The hyperplane is chosen to maximize the margin, which is the distance between the hyperplane and the nearest data points from each class, known as support vectors. The hyperplane serves as the decision boundary that separates data points into different classes. The margin in SVM is the distance between the hyperplane and the nearest data points from each class (support vectors). SVM aims to maximize this margin. Support vectors are the data points that lie closest to the decision boundary. They play a crucial role in defining the optimal hyperplane. Train an SVM model in this work, using correlation features as input and cloud resource prediction value as the target variable. Use the trained SVM model to predict cloud resource prediction value for new, unseen data.

The work flow of SVM for cloud resource prediction is shown in Fig. 3.



```
Input:
  • D, a data set consisting of correlation features and their associated target values;
  • l, the learning rate;

Output: Cloud resource demand predicted value

Methods:
Initialize all weights and biases in network;
while terminating condition is not satisfied {
  for each training tuple X in D {
    // Propagate the inputs :
    for each input unit j {
      Oj = Ij; // output of an input unit is its actual input value
    for each hidden or output unit j {
      $I_j = \sum_i w_{ij} O_i + \theta_j$; //compute the net input of unit j with respect to the previous , i
      $O_j = \frac{1}{1+e^{-I}j}$;} // compute the output of each unit j
    // Calculate the errors:
    for each unit j in the output
      $Err_j = O_j(1-O_j)(T_j - O_j)$; // compute the error
    for each unit j in the hidden unit , from the last to the first hidden unit
      $Err_j = O_j(1-O_j)\sum_k Err_k w_{jk}$; // compute the error with respect to the next higher unit , k
    for each weight wi j in network {
      $\Delta w_{ij} = (l) Err_j O_i$; // weight increment
      $w_{ij} = w_{ij} + \Delta w_{ij}$; }// weight update
    for each bias $\theta_j$ in network {
      $\Delta\theta_j = (l) Err_j$; // bias increment
      $\theta_j = \theta_j + \Delta\theta_j$; }// bias update
  } }
```

Fig. 3. SVM algorithm.

IV. Results

The dataset used for designing and developing the cloud resource demand prediction using SVM comprises information on resource utilization over a period of one month. In total, there were 123 million observed instances involving 1250 machines. The dataset which is used in this work is Real-time dataset named GoCJ. The GoCJ datasets used in our work is the publicly available dataset collected from https://data.mendeley.com/datasets/b7bp6xhrcd/1. The new proposed approach is implemented in Matlab.

A. *Examination Parameters*

A wide range of assessment criteria are available to assess the prediction algorithms' performance. This work considers the following elements.

Detection Accuracy is:

$$\frac{True\ Positive(TP)+True\ Negative(TN)}{TP+False\ Positive(FP)+TN+False\ Negative(FN)} \tag{2}$$

Error Rate is:

$$\frac{No\ of\ Datas\ of\ falsely\ labeled\ texts}{Total\ No\ of\ texts} \tag{3}$$

Precision rate:

$$\frac{TP}{TP+FP} \tag{4}$$

Recall rate:

$$\frac{TP}{TP+FP} \tag{5}$$

B. *Performance Analysis*

Using the performance measures indicated above, the classifier system's performance is analyzed and contrasted with that of other techniques. The tables and graphs below demonstrate this.

1) Experiment No #1: Newly Developed Attribute Selection Approach Evaluation with Accuracy.

We will evaluate the impact of every attribute selection strategy used in the work in this research. Eq. (2) to Eq. (5) are used to evaluate the effectiveness of this cloud resource demand prediction technique. A great attribute selection strategy is preferred to have a high value of Eq. (2). The PCGPSONN accuracy analysis is listed in Table V.

As is evident from Table V, the PCGPSONN has an accuracy of 96.29. The accuracy of attribute selection is shown in Fig. 4.

TABLE V. NEWLY DEVELOPED ATTRIBUTE SELECTION APPROACH EVALUATION WITH ACCURACY

GPSO	GPCNN	PCGPSONN
93.14	94.23	96.29

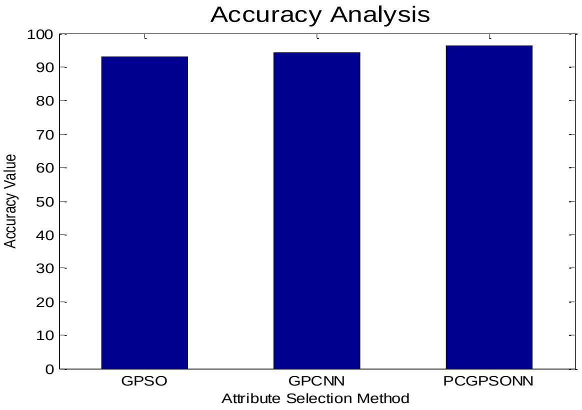


Fig. 4. Accuracy of feature selection strategies.

2) Experiment No #2: Newly Developed Attribute Selection Approach Evaluation with Precision Rate.

Precision tells the proportion of instances that the models predicted as positive and were actually positive out of all the instances it predicted as positive. A high precision indicates that when the model predicts a positive outcome, it is likely to be correct. The PCGPSONN Precision rate analysis is listed in Table VI.

TABLE VI. NEWLY DEVELOPED ATTRIBUTE SELECTION APPROACH EVALUATION WITH PRECISION RATE

GPSO	GPCNN	PCGPSONN
90.21	91.35	93.10

As is evident from Table VI, the PCGPSONN has Precision rate of 93.1, which is better than other approaches. As a result, the PCGPSONN classifier is thought to be the best for choosing attributes. The Precision rate of attribute selection is shown in Fig. 5.

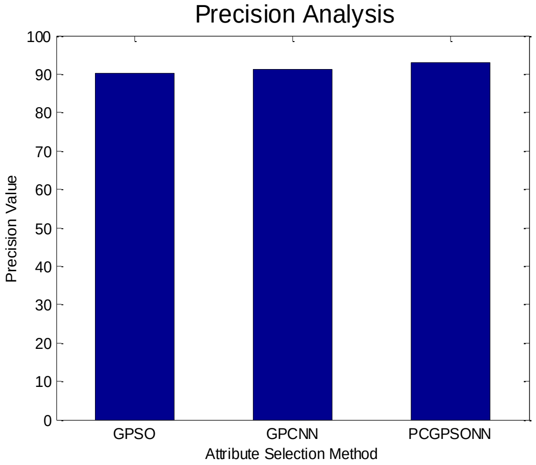

Fig. 5. Precision rate of attribute selection strategies.

3) Experiment No #3: Newly Developed Attribute Selection Approach Evaluation with Recall Rate.

Recall depicts the proportion of actual positive instances that were correctly predicted by the model out of all the actual positive instances. A good attribute selection strategy is preferred to have a high value of Eq. (4). The PCGPSONN Recall rate analysis is listed in Table VII.

TABLE VII. NEWLY DEVELOPED ATTRIBUTE SELECTION APPROACH EVALUATION WITH RECALL RATE

GPSO	GPCNN	PCGPSONN
90.11	91.35	92.85

As is evident from Table VII, the PCGPSONN has Recall rate of 93, which is better than other approaches. The Recall rate of attribute selection is shown in Fig. 6.

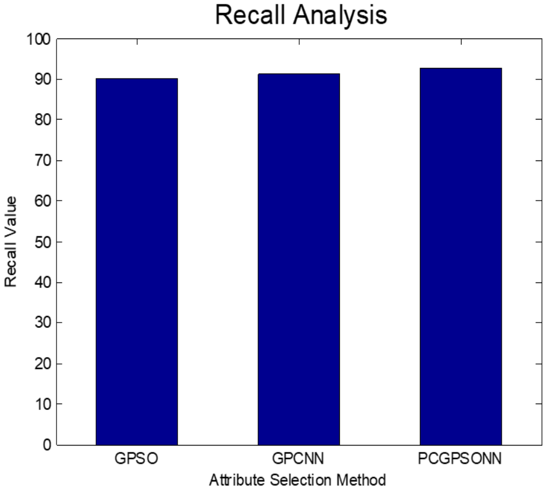

Fig. 6. Recall rate of attribute selection strategies.

As can be seen from the accompanying figure, the PCGPSONN's Recall Rate is better than other methods. Therefore, the PCGPSONN is the best for choosing attributes.

4) Experiment No #4: Newly Developed Attribute Selection Approach Evaluation with Error Rate.

Error rate, in the context of machine learning, is a metric that represents the proportion of incorrectly classified instances in a model's predictions. It is the complement of accuracy. The PCGPSONN error rate analysis is listed in Table VIII.

TABLE VIII. NEWLY DEVELOPED ATTRIBUTE SELECTION APPROACH EVALUATION WITH ERROR RATE

GPSO	GPCNN	PCGPSONN
6.86	5.77	0.03703704

As is evident from Table VIII, the PCGPSONN has an error rate of 0.037. The error rate of attribute selection is shown in Fig. 7.

As can be seen from the associated figure, the PCGPSONN's error rate is lower than other methods. Therefore, the PCGPSONN is the best for choosing attributes.

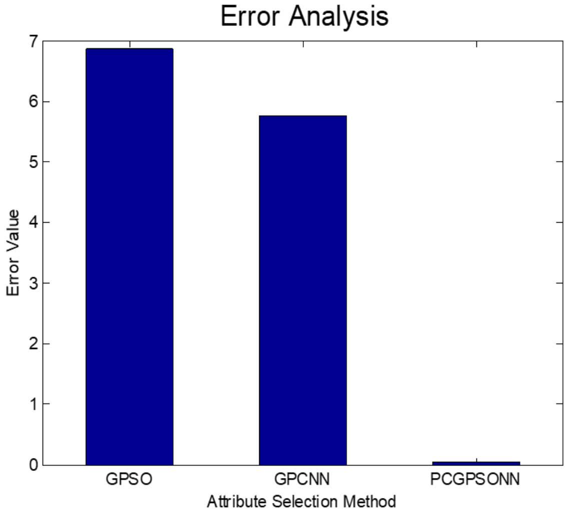

Fig. 7. Error rate of feature selection strategies.

V. CONCLUSION

Demands on cloud resources can be sudden, intense, and volatile. The reactive resource providing approach may result in sluggish or insufficient resource delivery. Thus, to guarantee resource availability, it is imperative to predict resource demands. To process the raw data and produce a fresh and original prediction for Cloud resource demands, machine learning techniques were applied in this study. We were able to develop a more accurate model for cloud resource demand prediction in this study by effectively using a feature selection method based on data mining methodology. PCGPSONN showed to be quite accurate at predicting the demand for Cloud resource. The future direction of this research can be carried out with several machine learning approaches to enhance prediction techniques. Additionally, novel feature selection techniques can be used to develop a deeper comprehension of critical traits and enhance predictions of cloud resource consumption.

Spatial Display Model of Oil Painting Art Based on Digital Vision Design

QiongYang[*], Zixuan Yue
School of Architecture Engineering, Xuzhou College of Industrial Technology, Xuzhou, 221000, China

***Abstract*—Oil painting, owing to its unique expressive approach, holds infinite charm in classical artistic creation, yet introduces complexities in terms of manual maintenance. In pursuit of digital spatial visualization of oil painting art, this study employs a stereo matching algorithm and Efficient large-scale stereo matching, focusing on aspects like disparity maps and pixel contrasts. Furthermore, enhancements in the algorithm involve the incorporation of the cross-arms strategy for image registration and the selection of auxiliary point sets to optimize the handling of image features. Results indicate that the proposed model, evaluated on the Middlebury dataset, achieves high accuracy, recall rates, and F1 scores, measuring 97.2%, 95.0%, and 97.5% respectively, surpassing the DecStereo algorithm by 3.4%, 8.2%, and 5.7%. When tested on the Photo2monet oil painting dataset, the proposed model achieves peak signal-to-noise ratio and average structural similarity index values of 16.781 and 0.833 respectively. This suggests that the proposed model excels in digital visual representation of oil paintings, exhibiting higher image precision, stronger stereo matching capabilities, and superior spatial display performance.**

Keywords—Oil painting; spatial visualization; Stereo matching; Spatial display; ELAS

I. Introduction

Oil painting is an art form that combines lines and colors, showcasing significant changes in color during creation, primarily reliant on the movement and intensity control of painting tools, employing layered pigment transitions to portray various color combinations [1]. Although colors may change during the creation of an oil painting, it essentially relies on precise control of the painting tools and changes in the layers of pigment to show different color effects. In recent years, with the development of technology, especially advances in digital visual design, the way oil painting art is displayed and created is undergoing a revolutionary change. Three-dimensional visualization methods demonstrate image content from multiple angles through 3D scanning and associated nodal information. Techniques and artistic styles hold pivotal positions in contemporary oil painting creation [2]. However, limitations in traditional oil painting methods and tools lead to susceptibility to damage or color fading, even with strict protective measures. Stereo matching technology, a critical component of stereo vision systems, has garnered increased attention and research among scholars [3]. This method rectifies positional differences between left and right images after epipolar line correction, determining matching cost values based on disparities among image points. As it utilizes partial window regions for computation, it boasts higher computational efficiency and suitability for parallel processing, especially in scenarios demanding high real-time performance [4]. Yet, due to its reliance on partial image windows, it yields numerous false matches, diminishing accuracy in disparity determination. Three-dimensional solid matching methods eschew cost aggregation, exclusively computing matching costs, disparities, and undergoing post-processing. Overall, employing holistic visual perception methods that consider individual pixel points across the entire image constructs an energy function to optimize disparity estimation for the whole image, thereby enhancing matching accuracy and overall visual effect [5]. Presently, scholars worldwide focus on enhancing image processing accuracy and real-time performance. However, no method adequately balances disparity and matching speed, where high-precision algorithms often sacrifice computational speed. This research focuses on developing a new type of spatial matching model for oil painting art images by applying stereo matching technology and three-dimensional visualization construction methods to enhance the presentation skills and styles of modern oil paintings. Traditional oil painting creation and display are limited by physical media and tools, and are prone to problems such as damage or color loss. In addition traditional methods often fail to provide an interactive and immersive art experience. Therefore, the research is dedicated to overcoming these limitations by utilizing digital technology to accurately capture and analyze the oil brush paths as well as the key frames of the paintings through 3D visualization techniques, so as to preserve and enhance the style and realism in the creation of contemporary oil paintings. In view of this, the stereo matching technique and 3D entity matching method used in this study can efficiently deal with the parallax problem in images and improve the matching accuracy. The use of this technique not only improves the accuracy and real-time of image processing, but also makes the digital presentation of art works more realistic and dynamic. A spatial matching model for oil painting art images based on a fast and effective stereo matching algorithm is developed. The model not only preserves the style and realism of contemporary oil painting, but also enhances the audience's participation and the expressiveness of the artwork. In addition, the research has innovatively transformed the way of displaying and appreciating oil painting art by integrating advanced technologies such as image processing, virtual reality and interaction design, which has brought a long-term impact on the art field. A spatial matching model for oil painting art images based on a fast and effective stereo matching algorithm is studied and developed. The model not only preserves the style and realism in the creation of contemporary oil paintings, but also enhances the audience's participation and the expressiveness of the artwork. In addition, by integrating advanced technologies such as image processing, virtual reality and interaction design, the research has innovatively transformed the way of displaying and appreciating oil paintings, which has brought a long-term impact on the art field.

The research is mainly divided into four sections: Section II involves a literature review related to digital visual design and art design; Section III focuses on the construction of an oil painting spatial display model based on image stereo matching algorithms; Section III analyzes the performance results and application outcomes of the image stereo matching algorithm; discussion and conclusion is given in Section V and VI respectively.

II. Related Works

Numerous scholars have conducted diverse research in the field of digital visual design. Logeshwaran et al. proposed a segmentation-based visual processing algorithm aimed at enhancing resolution and clarity to some extent through multi-visual enhanced pixels [6]. Parker and others studied the impact of digital technology on artwork design, illustrating how new technologies positively and negatively affect work resources based on various factors [7]. Peng and colleagues considered visibility analysis as an important research area in visual landscape research and developed a new computational algorithm for complex environments that can analyze views from multiple angles [8]. Johnson et al. constructed a pseudo-image-based color mapping table, optimized 3D scanning meshes for data visualization, and synthesized textures from pseudo-images. Additionally, there is an interactive rendering engine with custom algorithms and interfaces that can showcase various new visual styles to depict points, lines, surfaces, and volumetric data [9]. Ye et al. proposed a feasible method to quantitatively measure perception-based street visual quality and developed a Java-based program to automatically collect experienced urban designers' preferences for representative sample images. The results indicated that the evaluation model has satisfactory accuracy and provides insights into the perception-based visual quality and detailed mapping of various key elements in streets, offering accurate design guidance to aid more effective street renovations [10]. Chen et al. achieved a paradigm shift in perceptive environments by capturing local pixel-level intensity changes and generating asynchronous event streams. From standard computer vision to event-based neural morphological vision, advanced technologies in autonomous vehicle visual sensing systems have been developed [11]. Ren et al. systematically discussed the history and current status of optical lighting, image acquisition, image processing, and image analysis in the field of visual detection. The latest advances in machine vision-based industrial defect detection were introduced, emphasizing the increasing importance of deep learning in the further development of visual detection [12].

In the realm of digital research in art, particularly in the digitization of oil paintings, Castellano G and others have outlined some of the most relevant deep learning methods for pattern extraction and recognition in visual arts, especially in painting and sketching. The ongoing advancements in deep learning and computer vision, coupled with the ever-expanding collections of digitally visualized artworks, present new opportunities for computer science researchers [13]. Sandoval and colleagues introduced a novel two-stage image classification method aimed at enhancing the accuracy of style classification. Experiments conducted on three standard art classification datasets indicated a significant improvement over existing baseline techniques [14]. Scholar Mao W conducted research and analysis on oil painting art education videos using machine learning combined with virtual reality computing. Through the application of virtual reality technology in teaching practices, the study analyzed the effectiveness of teaching methods, allowing students to immerse themselves in art appreciation activities, embrace multiculturalism, experience learning, and enhance aesthetic qualities [15]. Mills and others investigated users' creative digital designs, including a popular 3D virtual painting program. The analysis focused on how students convey the same story in written, oral, and virtual painting modes, tracking key themes in students' virtual experiences [16]. Scholar Kent examined the works of McNeill and Hamill, emphasizing the importance of conducting abstract experiments in virtual reality as a creative medium [17]. Scholar van der Veen M approached the intersection of two visual modes from an augmented reality perspective. In this approach, the real environment is sensed by machines, magnified, scanned, located, and linked to a 3D model [18]. Scholar Doyle provided a historical overview of virtual reality, analyzed major works in the first wave, and discussed the application of virtual reality in contemporary practices through the concept of emotional engagement [19]. Ren Shihong et al. proposed a web-based VPL, JSPatcher, in order to address the problem of multimedia presentation or content generation.The tool allows users to build audio graphs using the Web Audio API and to graphically design and run digital signal processor algorithms using domain-specific audio processing languages. Experimental results show that the tool can be used with other JavaScript language built-ins, Web APIs, etc. to create interactive programs and artworks that can be shared online [20]. Nicole Johnson-Glauch et al. in order to explore how students can utilize representational features, proposed a synthesis of the results of two previous studies Method. The results suggest that visual representations have an impact on students' ability to access and use domain knowledge. Students may confuse concepts represented by similar features and not use concepts without salient features, and statics students are more coordinated in switching representations. These findings provide a generic domain pathway for redesigning the notation and representation of engineering concepts and suggest future research directions [21].

In summary, scholars have primarily focused their attention on environmental perception or programming methods in the digital visualization of images. There is a limited application of these approaches in the direction of oil painting. The integration of artworks and computer vision is often approached through theoretical analysis with a lesser emphasis on incorporating machine vision algorithms. In light of this, the current study aims to design a spatial display model for oil painting art based on an improved image stereo matching algorithm.

III. Oil Painting Art Spatial Display Model Based on Improved Stereo Matching Algorithm

To achieve the three-dimensional spatial display of oil painting art, this study, from the perspective of image stereo matching, constructs a method of digital visualization for oil paintings based on a fast and efficient stereo matching algorithm. The goal is to realize the modern intelligent preservation of traditional hand-painted oil paintings.

A. *Stereo Matching Algorithm for Oil Painting Images Based on PatchMatchStereo-ELAS*

PatchMatch Stereo This is an image matching algorithm used in stereo vision. The core idea of PatchMatch is to find the best match between images using random search. This method finds correspondences between images by quickly and randomly guessing the matching points and iteratively improving them. PatchMatch Stereo is used to compute parallax maps between images captured by two cameras, which is very important for reconstructing the three-dimensional structure of a scene. Efficient Large-Scale Stereo Matching (ELAS) algorithm is an efficient stereo matching method mainly used to compute the depth information of large-scale scenes. It employs a dense method that utilizes geometric constraints between pixels to improve the matching process, thus improving the computational efficiency and matching accuracy. Drawing inspiration from the PatchMatch approach, it employs various propagation techniques such as random initialization, spatial propagation, viewpoint propagation, temporal propagation, and surface optimization to obtain sub-pixel disparity values [22]. However, this method requires the initialization of unit normal vectors and disparity values for each pixel in an oil painting image. A challenge arises as the chosen initial values often deviate significantly from the actual data, making it difficult to find a surface that best fits the real data during the iterative algorithm, resulting in prolonged computation times. In this study, an efficient large-scale stereo matching algorithm (ELAS) is proposed to acquire initial information for oil painting images and 3D labels, thus circumventing the issue of arbitrary initial values in traditional three-dimensional image processing. Fig. 1 illustrates the process of the Patch Match Stereo-ELAS algorithm.

The PatchMatchStereo algorithm initially initializes the disparity map and surface normals for each pixel in oil painting images and then iteratively propagates the disparity map and surface normals. This process incurs a substantial computational cost. On the other hand, ELAS divides the problem into multiple disparity surfaces to obtain robust matching support points. While it enables rapid computation of the disparity map, its performance on low-dimensional measurement images is often inferior to high-resolution images. To address this, the proposed approach first utilizes the ELAS method to obtain robust support points and disparity values. Subsequently, the original disparity values and the constructed parameters of the disparity surface are input into the PatchMatchStereo algorithm. This joint algorithm utilizes support points as vertices within the smaller texture range of oil painting images, enhancing the disparity effect. Eq. (1) represents the calculation of pixel disparity values.

$$d_p = a_{f_p} p_u + b_{f_p} p_v + c_{f_p} \tag{1}$$

In Eq. (1), d_p represents the disparity value, a_{f_p}, b_{f_p}, c_{f_p} represent disparity parameters, and p represents a pixel. With the aid of equation 1, the problem of estimating disparity can be transformed into the estimation of the disparity plane, i.e., determining how to satisfy the optimization conditions of the disparity surface for each pixel. Eq. (2) illustrates the relationship between the three parameters of the disparity plane and the plane's normal vector.

$$\begin{cases} a_{f_p} = -n_x / n_z \\ b_{f_p} = -n_y / n_z \\ c_{f_p} = -\left(n_x * p_u + n_y * p_v + n_z * d_p\right) / n_z \end{cases} \tag{2}$$

In Eq. (2), n_x, n_y, and n_z represent the coordinate values in the xyz directions. Equation 3 is the expression for computing the matching cost.

$$m(p,f) = \sum_{q \in W_p} w(p,q) \beta\left(q, q - \left(a_f q_u + b_f q_v + c_f\right)\right) \tag{3}$$

In Eq. (3), $m(p,f)$ represents the cost value, f represents the disparity plane, W_p represents the specified square matching window, and $w(p,q)$ represents the adaptive weight. Eq. (4) is the expression for calculating the adaptive weight.

$$w(p,q) = e^{-\left\|I_p - I_q\right\| / \gamma} \tag{4}$$

Fig. 1. Process diagram of patchmatchstereo ELAS algorithm.

In Eq. (4), γ represents a custom parameter, and $\left\|I_p - I_q\right\|$ represents the L1 distance of the RGB colors of pixels p and q. If the color difference between two adjacent pixels is large, then these two points are less likely to lie on the same plane, hence $w(p,q)$ is smaller. The Census transformation compares the grayscale values of the central pixel in a given window with the grayscale values of adjacent pixels. The size relationship is set to 0 and 1, expressing the grayscale information of the central pixel as a binary bit sequence of 0s and 1s. By comparing the bits, the Hamming distance is calculated. Fig. 2 illustrates the Census transformation.

115	110	101
106	142	138

1	1	0
1	*	0
0	1	1

Fig. 2. Schematic diagram of census transformation.

Census transformation effectively considers the differences between points in the window and the central point, reducing the adverse effects of changes in lighting conditions. It is robust in regions of oil painting images with low noise and weak texture. In this process, the study will use both color and grayscale information in the image, combining them with Census transformation for image matching. Eq. (5) represents the improved matching cost expression.

$$\beta(q,q') = \frac{(1-\alpha)}{1+\varepsilon}\left(\left\|G_q - G_{q'}\right\| + \varepsilon * \left\|Cen_q - Cen_{q'}\right\|\right) + \alpha \min\left(\left\|\nabla I_q - \nabla I_{q'}\right\|, \tau_{grad}\right) \quad (5)$$

In Eq. (5), $\left\|G_q - G_{q'}\right\|$ represents the absolute difference in grayscale values between pixels q and q', $\left\|Cen_q - Cen_{q'}\right\|$ is the Hamming distance of their Census values, ε is a custom scalar parameter for adjusting the ratio of feature grayscale size to Census transformation, and $\left\|\nabla I_q - \nabla I_{q'}\right\|$ represents the absolute difference in gradients between q and q'. α is a custom scalar parameter for balancing the color and gradient proportions of each pixel. Fig. 3 shows the spatial propagation schematic of the PMS-ELAS algorithm.

The PMS-ELAS algorithm utilizes the prior disparity information obtained from ELAS to enhance the positioning accuracy in weak texture areas and the local optimization ability in weak or non-textured regions. It iteratively goes through two phases: spatial expansion and view propagation, involving odd and even iterations in both upward and downward directions. This approach can be applied to multiple images and reduces the disparity regions in PMS, thereby improving computational speed and potentially eliminating the need for plane optimization.

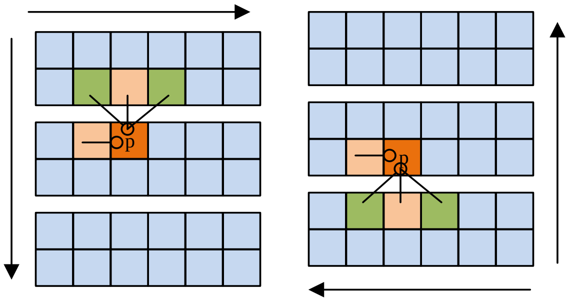

Fig. 3. Schematic diagram of spatial propagation of PMS-ELAS algorithm.

B. ELAS Algorithm Improved by Cross-Arm

The ELAS algorithm utilizes pixel counts with high confidence levels to form a triangular disparity plane, followed by rapid interpolation on the triangular surface. This method not only reduces computational speed but also swiftly calculates disparities in high-resolution images. However, mismatches in support points can introduce errors in constructing the disparity search distance, increasing the disparity values between points on the disparity surface. Consequently, this diminishes the disparity after interpolation and maximum a posteriori probability estimation on the same plane. Moreover, since the feature points extracted from oil paintings are often distributed in texture-rich and rapidly changing areas, ELAS-derived support points are mostly located at borders and areas with drastic changes. Robust support points are scarce for weakly textured or non-textured regions. To address these issues, research is proposed to enhance the accuracy and efficiency of support point localization and improve the accuracy of disparity estimation using an ELAS algorithm based on cross-arm enhancement. Fig. 4 illustrates the schematic diagram of the improved ELAS framework.

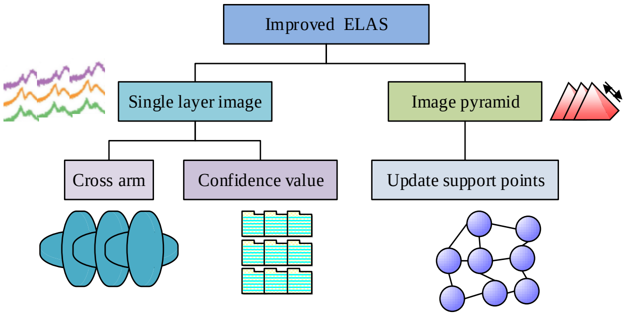

Fig. 4. Schematic diagram of improving the ELAS framework.

Considering the relationship between a single oil painting image and hierarchical images, the disparity calculation for each hierarchical image is based on support point selection and matching costs. Cross-arm structures are employed for image registration and auxiliary point set selection. By matching hierarchical images, confidence values for each level are obtained, enabling layered processing of images. Sampling is primarily conducted in a pyramid-like fashion, and based on confidence values, support point sets for high-resolution images are updated, simultaneously reducing the search range for each hierarchical image. Using a 3D Sobel operator on both left and right images, the grayscale gradients in the X and Y directions are employed for grayscale estimation in the left and right images. Feature descriptors for the images are constructed by selecting appropriate gradient values in the vicinity of each pixel among 32 points and computing corresponding matching costs. Let $\left(u_n,v_n\right)$ be the pixel coordinates, $d\left(u_n,v_n\right)$D be the disparity of the pixel, and $f\left(u_n,v_n\right)$ be the 32-dimensional feature vector in the region, including gradients in the horizontal and vertical directions for each pixel. Fig. 5 illustrates the selection method for auxiliary points.

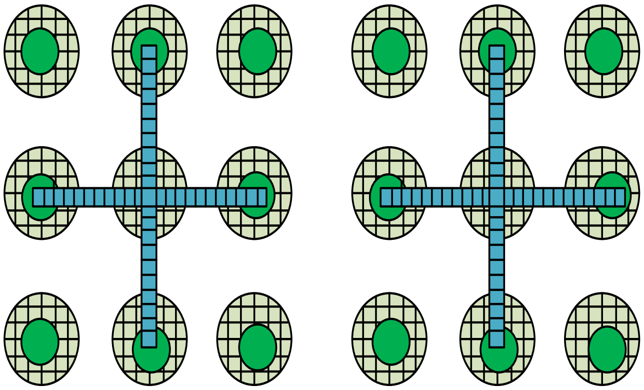

Fig. 5. Selection method of auxiliary points.

The local matching algorithm utilizes a larger window width, resulting in higher image quality and reduced noise. However, it tends to lose texture details and boundary features in the image while also leading to increased time complexity and decreased efficiency. On the other hand, a smaller window can capture more texture details and edge information, providing faster operation and effectively extracting image features to enhance algorithm execution efficiency. By jointly processing multiple feature vectors of multiple points, referred to as auxiliary points, and selecting these auxiliary points strategically, multiple small windows in different regions can be merged into larger windows, leveraging their respective advantages. This improves the overall accuracy of image registration while minimizing the image size for efficient computation, emphasizing local features to enhance computational efficiency. The proposed cross-shaped structure extends the arms to increase the selection window for auxiliary points, reducing dual inconsistencies. Establishing a window involves determining the arm lengths in the upward, downward, leftward, and rightward directions from the central pixel, with the stretch length determined based on the pixel differences. Stretching occurs in a specific direction until a significant color difference is encountered, and there is a maximum arm length limit. The cross arms maximize the perception range of the recognition window and efficiently detect boundaries. Eq. (6) represents the mathematical expression for confidence calculation.

$$cf^{s}_{(u,v)} = 1 - \frac{\min_{d} E\left(u,v,d\right)}{\min_{d \neq D(u,z)} E\left(u,v,d\right)} \tag{6}$$

In Eq. (6), $E\left(u,v,d\right)$ represents the matching cost value of pixel $\left(u,v\right)$ at disparity d. $D\left(u,v\right)$ represents the disparity when the minimum cost value is found in the disparity search area. Confidence is constrained to the range [0,1]. The ratio between the minimum and second-minimum cost values reflects confidence. Fig. 6 illustrates the schematic diagram of image pyramid upsampling.

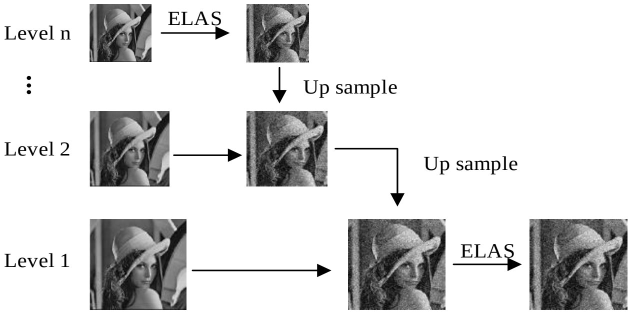

Fig. 6. Schematic diagram of image pyramid upsampling.

In local stereo matching, effective local information around the central pixel improves matching accuracy. For smaller texture areas, increasing the cross configuration expands alignment coverage, captures more image features, and enhances feature characterization accuracy. However, using a larger window width increases computational complexity and noise. Therefore, a method combining image pyramids and confidence is proposed for multi-scale fusion of support point sets. Downsampling two stereo image pairs yields a higher spatial resolution image pair, from which support points and corresponding disparity and confidence at different levels are obtained. If the disparity values of pixels satisfy left-right consistency conditions, their confidence values increase by a constant △cf. In high-resolution images, a deep downsample of the disparity and confidence maps is performed to obtain the disparity map and confidence of the high-resolution image. Upsampling is then used to obtain a higher confidence support point set when searching for support points.

IV. Analysis of the Utility of the Oil Painting Artistic Space Display Model Based on Improved Stereo Vision Matching Algorithm

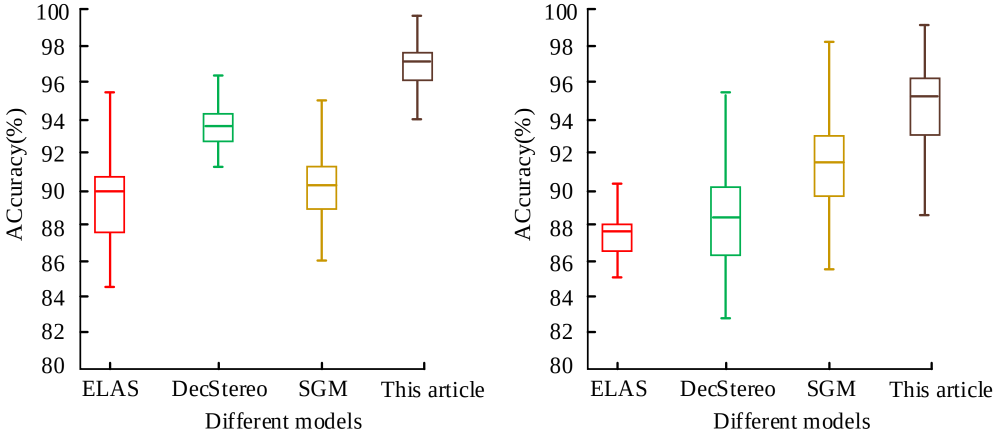
To validate the performance of the stereo matching based on the improved ELAS algorithm on image datasets and evaluate its capability in stereo matching spatial imaging applications, this study selected the Middlebury dataset, KITTI dataset, and Photo2monet oil painting style dataset as experimental samples. Diverse image quality evaluation metrics were employed for data analysis, resulting in comparative results for different image recognition algorithms.

A. Performance Analysis of the Improved Stereo Vision Matching Algorithm

The study utilized the Middlebury dataset and KITTI dataset as experimental samples for the visual matching algorithm. The Middlebury dataset comprises 33 pairs of static stereo images in indoor settings, with a maximum resolution of up to 6 million pixels and a maximum disparity range from 200 to 800. The KITTI dataset is used for stereo matching and includes 389 pairs of grayscale stereo images, consisting of 194 training data pairs and 195 testing data pairs. The compared algorithms include the ELAS algorithm, DecStereo algorithm, and Semi-global Matching (SGM). Evaluation metrics include accuracy, recall, and F1 score. Fig. 7 shows the accuracy results.

From Fig. 7(a), it is evident that the proposed model achieved the highest accuracy on the Middlebury dataset, reaching 97.2%. In comparison, the accuracy values of the ELAS algorithm, DecStereo algorithm, and SGM algorithm are all below 96%, with values of 90.0%, 93.8%, and 90.2%, respectively. Therefore, the proposed model improved accuracy on this dataset by 7.2%, 3.4%, and 7.0%. From Fig. 7(a), On the KITTI dataset, the proposed model achieved the highest accuracy of 95.3%. In contrast, the accuracy values of the ELAS algorithm, DecStereo algorithm, and SGM algorithm are all below 92%, with values of 87.8%, 88.5%, and 91.6%, respectively. Consequently, the proposed model improved accuracy on this dataset by 7.5%, 6.9%, and 3.7%. Fig. 8 presents the recall results.

From Fig. 8, it can be observed that on the Middlebury dataset, the recall curve of the proposed model shows a progressively increasing trend, reaching a convergence value of 95.0% at 50 iterations. In contrast, the recall curves of the ELAS algorithm, DecStereo algorithm, and SGM algorithm exhibit significant fluctuations with a decreasing trend during iterations, and their final convergence values are 85.2%, 86.8%, and 88.6%, respectively. Therefore, the proposed model outperforms them by 9.8%, 8.2%, and 6.4%, respectively. On the KITTI dataset, the recall curve of the proposed model exhibits a stepwise linear increasing trend, reaching a convergence value of 96.8% at 50 iterations. Comparatively, the final convergence values of the ELAS algorithm and SGM algorithm are 87.5% and 90.3%, respectively. The DecStereo algorithm did not achieve a convergence value. Consequently, the proposed model surpasses them by 9.3% and 6.5%. Fig. 9 illustrates the F1 score results.



(a) Middlebury dataset

(b) KITTI dataset

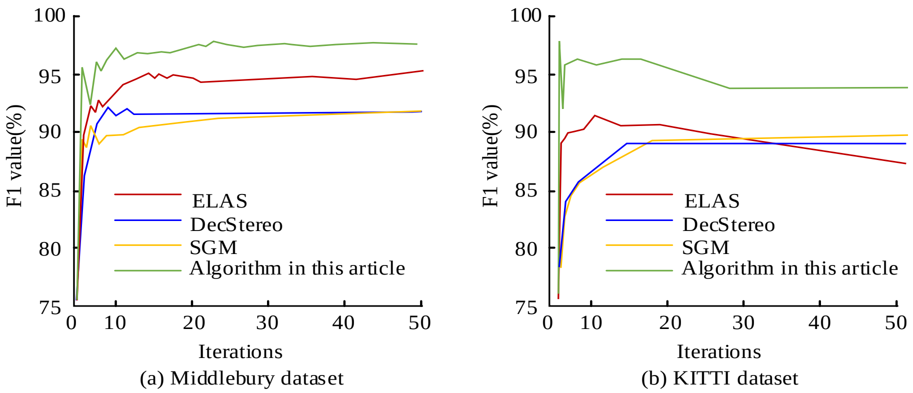
Fig. 8. Recall rate result chart.



(a) Middlebury dataset (b) KITTI dataset

Fig. 9. F1 value result graph.

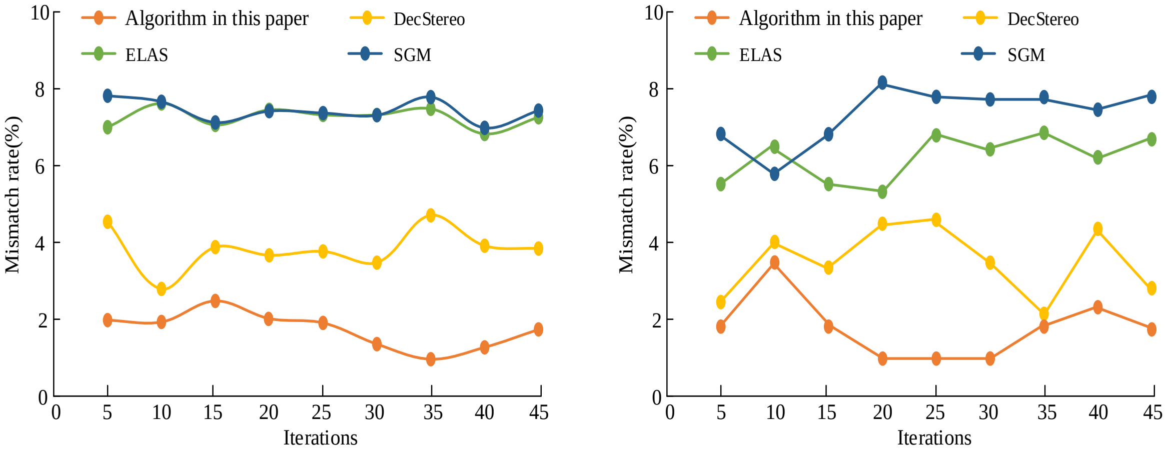
For the Middlebury dataset, the F1 score curves of the proposed model and the comparative models show fluctuating yet gradually increasing trends. At 50 iterations, the convergence values of the proposed model, ELAS algorithm, DecStereo algorithm, and SGM algorithm are 97.5%, 95.0%, 91.8%, and 91.8%, respectively. Hence, the proposed model outperforms them by 2.5%, 5.7%, and 5.7%. Concerning the KITTI dataset, only the proposed model, DecStereo algorithm, and SGM algorithm achieved convergence values, which are 94.2%, 89.8%, and 89.6%, respectively. Therefore, the proposed algorithm surpasses them by 4.4% and 4.6%, while the ELAS algorithm did not achieve a convergence value.

B. *Analysis of the Application Effect of a Spatial Matching Display Model for Oil Painting Art*

The study employed the Photo2monet oil painting style dataset for experimentation, with a training-to-testing set ratio of 3:1. All dataset images were RGB color images of size 256×256. The evaluation metrics chosen for the study included the mismatch rate, average absolute error, Peak Signal to Noise Ratio (PSNR), and Structural Similarity (SSIM). ELAS algorithm, DecStereo algorithm, and SGM algorithm were selected as comparative algorithms. Fig. 10 illustrates the mismatch rate results.

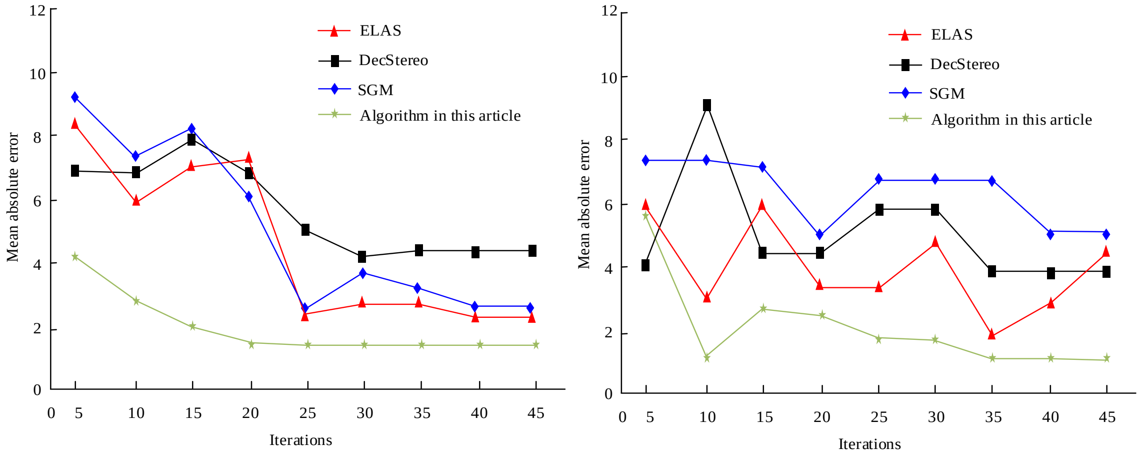
From Fig. 10, it is evident that, in both the training and testing sets, the proposed model consistently achieved the lowest mismatch rates, with curves showing variations around a horizontal value of 2. The lowest and highest mismatch rates for the training set were 1.0% and 2.5%, respectively. For the testing set, the corresponding values were 0.9% and 3.6%. In contrast, the ELAS and SGM algorithms exhibited mismatch rates above 5% in both training and testing phases, while the DecStereo algorithm fluctuated around 3.5%. The proposed algorithm reduced the fluctuation level by 1.4%. Fig. 11 presents the average absolute error results.

From Fig. 11(a) shows that during the training phase, the proposed model exhibited a smooth descent followed by horizontal convergence, starting to converge at 20 iterations, with a final average absolute error convergence value of 1.78%. In contrast, the average absolute error curves for ELAS, DecStereo, and SGM algorithms in the training dataset displayed significant fluctuations before 25 iterations, with final convergence values of 2.40%, 4.35%, and 2.80%, respectively. Hence, the proposed model reduced the error by 0.62%, 2.57%, and 1.02%. In the testing phase, From Fig. 11(a), the proposed model achieved a convergence value of 1.68%, while the DecStereo and SGM algorithms had corresponding values of 3.96% and 4.62%, indicating reductions of 2.28% and 2.94%, respectively. Table I summarizes the image quality assessment results.



(a) Training set (b) Testing set

Fig. 10. Mismatch rate.



(a) Training set

(b) Testing set

TABLE I. IMAGE QUALITY EVALUATION RESULTS

Oil Painting Dataset	Evaluating indicator	ELAS	DecStereo	SGM	Model in this article
Training set	PSNR	11.214	14.65	16.781	18.429
	SSIM	0.346	0.801	0.726	0.888
Testing set	PSNR	9.464	15.564	12.927	16.525
	SSIM	0.301	0.833	0.622	0.846

From Table I, it can be observed that the model proposed by the research institute achieved the highest values in image quality evaluation metrics, both in the training and testing sets. Specifically, the PSNR (Peak Signal-to-Noise Ratio) and SSIM (Structural Similarity Index) metrics for the training set were 18.429 and 0.888, respectively, while for the testing set, these metrics were 16.525 and 0.846. In comparison, the highest values for the PSNR and SSIM metrics of the contrast models ELAS, DecStereo, and the SGM algorithm were 16.781 and 0.833, indicating an improvement of 1.648 and 0.042 by the proposed model.

V. DISCUSSION

In the field of contemporary art, oil painting, as an ancient and classic art form, has been widely appreciated and studied. However, with the rapid development of digital technology, traditional oil painting art is facing new challenges and opportunities. When comparing the accuracy of the system model, it is found that the accuracy of the algorithmic model used in the research can reach the highest value in the dataset Middlebury, in which for the accuracy of other algorithmic models the accuracy of the research using the algorithmic model is higher, and it can get a better ability to test the data, which indicates that the research using the model of the current construction can achieve better data processing ability on the dataset. At the same time on the KITTI dataset, the accuracy rate of the research use method is also the highest value, which at the same time shows that the research use method in the two datasets to get the best accuracy rate, the research use method for the different datasets have less impact on the accuracy rate of all can get a relatively good accuracy rate. In comparing the recall of different algorithmic models, the recall curve of the research proposed model shows an increasing trend, while the recall of the research used model is higher. This indicates that the current research use algorithmic model is able to maintain a relatively smooth curve change in the recall test, and has a better data test correctness rate compared to other algorithmic models. When comparing the F1 values of different algorithmic models, the F1 values of the research use model can reach 97.5% and 94.2%, comparing with the other algorithmic models higher F1 values, which indicates that the research use model performs better indicators in different data sets, and it can achieve a better processing effect for the processing of oil painting image art. When comparing the change of the false matching rate of the test set and training set of different algorithm models, the research and use method is at the lowest value of the false matching rate index, and the curves show a straight line around the level value of 2. Meanwhile, the change of the false matching rate of the research and use model is higher than that of the other algorithm models, which is due to the fact that the research and use method can achieve better stability in the training and testing. When comparing the convergence of the algorithmic models, the convergence curve of the research use model shows a smooth decline and then a horizontal convergence trend, and starts to converge when the number of iterations is 20, and the final average absolute error convergence value is 1.78%, then it will show that the research use method has better convergence, and it is easier for convergence to take place, which has a better performance for the testing and analyzing of the data. In comparing the quality assessment of the research use method, the research use method is able to achieve better indicator values, which indicates that the research use method is able to get better data testing results either in the training or testing set.

In summary, the research using method can perform well in the comparison of different data indexes, which indicates that the data model constructed by the current research can complete and achieve better data analysis and testing in the optimization of image data processing, and the method has better performance, which has a good guiding value for the subsequent research in this direction.

VI. Conclusion

The enduring artistic value of oil paintings has attracted attention in the context of integrating it with the trends of digital modernization. To achieve virtual creation of oil paintings in a three-dimensional visual presentation, this study, The research successfully integrates the artistic value of oil painting with digital modernization technology, and realizes the virtual presentation of oil painting art in three-dimensional visual space through the improved stereo matching model of ELAS algorithm. Meanwhile, the algorithm model algorithm is improved from the level of parallax map and pixel contrast in order to optimize the processing of image features, especially in the cross-crossing arm strategy image alignment and the selection of auxiliary point sets are improved and innovated. This research adopts the stereo matching technology and three-dimensional entity matching method, which not only improves the accuracy and real-time of image processing, but also makes the digital presentation of artworks more realistic and dynamic. Meanwhile, the research also developed a fast and effective stereo matching algorithm for the spatial matching model of oil painting art images, which retains the style and realism in the creation of oil paintings, and enhances the audience's participation and the expressive power of the artwork. The results indicate that, for the KITTI dataset, the proposed model achieved accuracy, recall, and F1 values of 95.3%, 96.8%, and 94.2%, respectively, surpassing the SGM algorithm by 3.7%, 6.5%, and 4.6%. For the Photo2monet oil painting style dataset, the proposed model exhibited the lowest error matching rate, with fluctuations around 2% during both training and testing phases, while the error matching rate for the DecStereo algorithm fluctuated around 3.5%. In terms of the mean absolute error metric, the proposed model achieved a convergence value of 1.68% in the final testing phase, representing a reduction of 2.28% and 2.94% compared to the DecStereo and SGM algorithms, respectively. Therefore, these findings suggest that the proposed spatial stereo matching model has a distinct advantage in the digital presentation of oil painting art, preserving the realism and artistic style of oil paintings. This study has achieved a lot of results, but there are some problems with the use of data in the study, such as the use of a small dataset, for this reason more and larger datasets will be included in subsequent studies to be analyzed.

Research on Neural Network-based Automatic Music Multi-Instrument Classification Approach

Ribin Guo
Shanxi College of Applied Science and Technology, Taiyuan, Shanxi 030062, China

***Abstract*—The automatic classification of multi-instruments plays a crucial role in providing services for music retrieval and recommendation. This paper focuses on automatic multi-instrument classification. Firstly, instrument features were analyzed, and Mel-frequency cepstral coefficient (MFCC) and perceptual linear predictive coefficient (PLPC) were extracted from instrument signals. Features were selected using the entropy weight method. The optimal initial weight threshold of a back-propagation neural network (BPNN) was obtained by utilizing the sparrow search algorithm (SSA), achieving a SSA-BPNN classifier. Experiments were conducted using the IRMAS dataset. The results demonstrated that the combination of MFCC and PLPC selected through the entropy weight method achieved the best performance in automatic multi-instrument classification. The method yielded high P value, recall rate, and F1 value, 0.72, 0.71, and 0.71, respectively. Moreover, it outperformed other algorithms such as support vector machine and XGBoost. These results confirm the reliability of the automatic multi-instrument classification method proposed in this paper, making it suitable for practical applications.**

Keywords*—Neural network; musical instrument; automatic classification; auditory feature; sparrow search algorithm

I. INTRODUCTION

Music serves as a medium for conveying emotions [1]. With the continuous progress and popularization of computer technology, an increasing amount of music information circulates and spreads on the internet, offering users a more convenient means to enjoy music. In order to enhance the user experience further, music information retrieval (MIR) has gradually emerged as a crucial area of research [2]. Through MIR, users can efficiently discover their preferred music. MIR research includes the identification and classification of musical instruments, genres, and styles [3]. Automatic classification of musical instruments refers to the use of intelligent algorithms to automatically classify different musical instruments through processing their signals. In multi-instrument automatic classification, different instrument signals can easily interfere with each other, resulting in a decrease in classification effectiveness.

Neural networks are a type of machine learning that possess strong self-learning capabilities, enabling them to derive useful conclusions from a series of complex and seemingly unrelated data. They have wide applications in fields such as speech recognition, image processing, and automation control, where they demonstrate certain advantages in handling complex data. Therefore, in order to further improve the accuracy of multi-instrument automatic classification, this study focuses on researching neural networks.

Based on the analysis of musical instrument signals, this article selected back-propagation neural network (BPNN) as the main algorithm. In order to further improve its performance, the sparrow search algorithm (SSA) was used to optimize BPNN. Finally, the performance of the proposed method was verified on the IRMAS dataset.

The main contribution of this article lies in providing a more accurate method for automatic classification of multiple musical instruments, which also offers some new references for music signal classification and even speech signal classification. This is conducive to promoting the further application of neural network algorithms in the field of music research.

II. LITERATURE REVIEW

With the continuous development of machine learning and other technologies, an increasing number of algorithms have been applied in MIR research.

In terms of music popularity prediction, Martin-Gutierrez et al. [4] introduced a deep learning architecture called HitMusicNet for predicting the popularity of music recordings. The experimental results demonstrated its superior predictive capabilities compared to existing techniques. Voetter et al. [5] presented two novel datasets to predict song popularity based on the data from AcousticBrainz, Billboard Hot 100, the Million Song dataset, and last.fm. They verified the usability of the designed dataset by performing experiments on different models.

In terms of singer recognition, Rajesh and Nalini [6] conducted experiments to validate the effectiveness of their approach in singer recognition, which involved the integration of MFCC with chroma DCT-reduced pitch features. Kooshan et al. [7] developed a singer recognition system by integrating deep learning and feedforward neural networks. They utilized long short-term memory (LSTM) to identify vocal frames within music segments, followed by the application of another LSTM for singer identification. Experimental validation confirmed the superior performance of this approach compared to existing methods.

In terms of music recommendation, Feng et al. [8] proposed to model and combine melody, chord, and rhythm features and utilized a multilayer perceptron for music recommendation. The experimental results indicated a 3.52% improvement over the best baseline. Elbir et al. [9] developed an innovative deep neural network that utilizes the acoustic attributes of music to classify genres and provide music recommendations.

In the domain of instrument recognition and classification, Chatterjee et al. [10] proposed employing a convolutional siamese networks along with its residual variation to identify instruments based on scalograms derived from audio recordings. They conducted experiments using two publicly accessible datasets to validate their approach. Wise et al. [11] developed an attention-enhanced convolutional neural network specifically designed for accurately classifying a wide range of 19 orchestral instruments, and they substantiated the effectiveness of this technique through experimental evaluations.

III. Instrument Feature Extraction

Different musical instruments emit distinct vibration frequencies, which, in turn, yield different sounds. Timbre represents the subjective, natural perception of these vibrations by humans. To achieve the automatic classification of various musical instruments, it is essential to extract features that reflect the timbral characteristics of the musical instrument sound signal. Currently, in the realm of speech signal recognition, a predominant reliance on time-domain and frequency-domain features is observed. These feature types are relatively straightforward and easy to analysis. However, they fall short in adequately characterizing timbre, resulting in suboptimal classification performance. This paper primarily focuses on the analysis of two categories of features derived from the human auditory system for musical instrument feature extraction.

MFCC is a feature obtained by simulating the auditory characteristics of the human ear [12], which has a good performance in speech recognition [13]. It is extracted in the following way.

1) Pre-emphasis, frame-by-frame, and windowing operations are performed on the original instrument audio signal to get pre-processed signal $\mathrm{x_i(m)}$.

2) A fast Fourier transform (FFT) is performed on $x_i(m)$, and

$$X(i,t) = FFT[x_i(m)] \tag{1}$$

is obtained.

3) The energy spectrum is calculated:

$$E(i,t) = [x_i(m)]^2. \tag{2}$$

4) A filtering operation is performed on $E(i,t)$. The spectrum energy is obtained through a group of triangular filters:

$$S(i,m) = \sum_{t-0}^{N-1} E(i,t) H_m(t), \tag{3}$$

where, $H_m(t)$ represents the transfer function of the triangular filter.

5) The final MFCC is obtained by discrete cosine transform (DCT):

$$X(i) = \sqrt{\frac{2}{M}} \sum_{m=0}^{M-1} lg[S(i,m)] \cos\left[\frac{\pi(2m-1)}{2M}\right], \tag{4}$$

where, M is the filter order.

PLPC is also a feature that mimics the auditory characteristics of the human ear [14] and is extracted as follows:

1) FFT is also performed on $x_i(m)$ to convert it to the frequency domain to obtain $X(i,t)$. $E(i,t)$ is calculated.

2) $E(i,t)$ is converted to the Bark domain:

$$\varphi(f) = 6 \ln\left\{\frac{f}{600} + \left[\left(\frac{f}{600}\right)^2 + 1\right]^{0.5}\right\}, \tag{5}$$

where, φ is the value of the signal frequency in the Bark domain and f is the angular frequency.

3) The critical bands in the Bark domain are considered as a group of filters, and the function of each filter is:

$$\varphi(Z - Z_0(k)) = \begin{cases} 0, Z - Z_0(k) < -1.3 \\ 10^{Z - Z_0(k) + 0.5}, -1.3 \le Z - Z_0(k) \le -0.5 \\ 1, -0.5 < Z - Z_0(k) < 0.5 \\ 10^{-2.5(Z - Z_0(k) - 0.5)}, 0.5 \le Z - Z_0(k) \le 2.5 \\ 0, 2.5 < Z - Z_0(k) \end{cases}. \tag{6}$$

The output of each critical band is obtained:

$$\theta(k) = \sum_{Z - Z_0(k) = -1.3}^{2.5} E(\varphi - \varphi_i)\, \varphi(Z - Z_0(k)). \tag{7}$$

4) Equal loudness curve pre-emphasis is carried out on $\theta(k)$:

$$\Gamma(k) = D[f_0(k)]\theta(k), \tag{8}$$

where, $f_0(k)$ corresponds to central frequency $Z_0(k)$ of each filter, $Z_0(k)$ refers to the equal loudness curve,

$$D[f_0(k)] = \frac{16\pi^4 f_0^4(k)(4\pi^2 f_0^2(k) + 5.68\times10^7)}{(4\pi^2 f_0^2(k) + 6.3\times10^6)^2 \times (4\pi^2 f_0^2(k) + 3.8\times10^8)}. \tag{9}$$

5) Finally, the simulation of human ear hearing is realized by converting from intensity to loudness:

$$\Psi(k) = \Gamma(k)^{0.33}. \tag{10}$$

In the context of speech recognition tasks, MFCC is usually set as 13 dimensions along with their corresponding first-order and second-order difference coefficients, resulting in a total of 39 dimensions. Additionally, PLPC usually employs 24 filters to yield 24 dimensions. If both the 39-dimensional MFCC and the 24-dimensional PLPC features are utilized for automatic multi-instrument classification, the cumulative dimensionality reaches 63 dimensions. To mitigate the potential complexity and computational load associated with this higher dimensionality, this paper uses an entropy weight method [15] to optimize these features.

Information entropy is related to the probability of an event occurring. When it is applied to feature optimization, the greater the information entropy, the more disordered the distribution of that feature value is. For a $T_n \times T_m$ original feature set, it is assumed that the feature vector corresponding to the t_m-th feature item is Z_{t_m}, the process of feature optimization is presented in Fig. 1.

Feature item weight > threshold?
No
Discard
Yes
Retain

Fig. 1. The feature optimization process based on entropy weight method.

The specific calculation process is as follows:

1) Standardized eigenvalue:

$$Z'_{t_n,t_m} = \frac{z_{t_n,t_m} - min(z_{t_m})}{max(z_{t_m}) - min(z_{t_m})}. \tag{11}$$

2) The information entropy is calculated:

$$E(t_m) = -\sum_{t_n=1}^{T_n} p_x(t_n, t_m) \ln p_x(t_n, t_m), \tag{12}$$

where, $p_x(t_n, t_m)$ refers to the percentage of different eigenvalues in the corresponding term, $p_x(t_n, t_m) = \frac{X'(t_n,t_m)}{P_z(t_m)}$, $P_z(t_m) = \sum_{t_n=1}^{T_n} X'(t_n, t_m)$.

3) The feature term weight is calculated:

$$W_{t_m} = \frac{1-E(t_m)}{T_m - \sum_{t_m=1}^{T_m} E(t_m)}. \tag{13}$$

4) A threshold is set, and feature items with weights greater than the threshold are retained as subsequent features used for automatic multi-instrument classification.

IV. Automatic Classification Method Based on Neural Networks

Back-propagation neural network (BPNN) has excellent performance and is most widely used in automatic classification tasks [16]. Therefore, in this paper, BPNN is chosen as a classifier for automatic classification of multi-instrument. A simple BPNN structure is presented in Fig. 2.

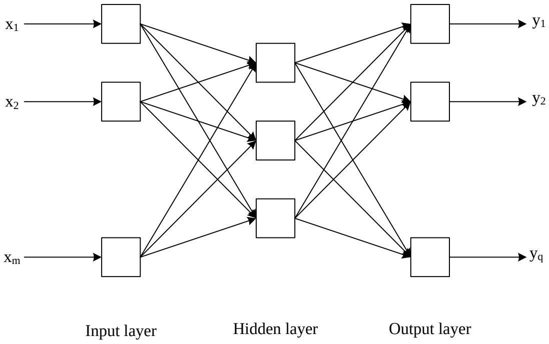

Fig. 2. The BPNN structure.

It is hypothesized that the number of nodes in the input layer, hidden layer, and output layer of BPNN is $m - p - q$. The output of the hidden layer during training can be written as:

$$h_j = f\left(\sum_{i=1}^{m} w_{ij}^{h} i_i - b_j\right). \tag{14}$$

The output of the output layer can be written as:

$$o_k = f\left(\sum_{j=1}^{p} w_{jk}^{o} h_j - b_k\right). \tag{15}$$

where, w and b denote the weight and threshold of each layer.

The global error function can be written as:

$$E = \frac{1}{2}\sum_{k=1}^{q} (y_k - o_k)^2, \tag{16}$$

where, y_k is the desired output. The BPNN continuously corrects the weight threshold according to the error until the error meets the requirements. However, the performance of BPNN is easily affected by the initial weight threshold, so it can be tempting to become trapped in the local optimum. In order to solve this problem, this paper uses the sparrow search algorithm (SSA) [17] to optimize the BPNN.

SSA is a sparrow-inspired algorithm that utilizes the foraging behavior of sparrows, which exhibits excellent global optimization performance and is used to calculate the optimal initial weight thresholds for BPNN. During the foraging process, some sparrows are responsible for finding the foraging area and direction, the rest of the sparrows feed, and some sparrows will sound an alarm when danger is detected. The population is categorized into discoverers, followers, and alerts, and their positions are updated as follows.

1) Discoverer:

$$X_{i,j}^{t+1} = \begin{cases} X_{i,j}^{t} \cdot exp\left(-\frac{i}{\alpha \cdot t_{max}}\right), R < A_{ST} \\ X_{i,j}^{t} + QL, R \geq A_{ST} \end{cases}, \tag{17}$$

where, α is a random number in [0,1], R is an alert value in (0,1], and A_{ST} is the threshold at which the shift occurs, Q is a random number obeying a normal distribution, L is a $1 \times d$ matrix, $R < A_{ST}$ means that the area is dangerous and the finder needs to move to a safe area, and $R \geq A_{ST}$ means that the area is safe and sparrows can look for food.

3) Follower:

$$X_{i,j}^{t+1} = \begin{cases} Q \cdot exp\left(\frac{X_{worst}^{t} - X_{i,j}^{t}}{i^2}\right), i > \frac{n}{2} \\ X_b^{t+1} + \left|X_{i,j}^{t} - X_b^{t+1}\right| \cdot A^{+} \cdot L, i \leq \frac{n}{2} \end{cases}, \quad (18)$$

where, X_{worst} is the worst position of the individual, X_b is the best position of the discoverer, $A^{+} = A^T(AA^T)^{-1}$, A is a $1 \times d$ matrix, randomly assigned as -1 or 1.

4) Watcher:

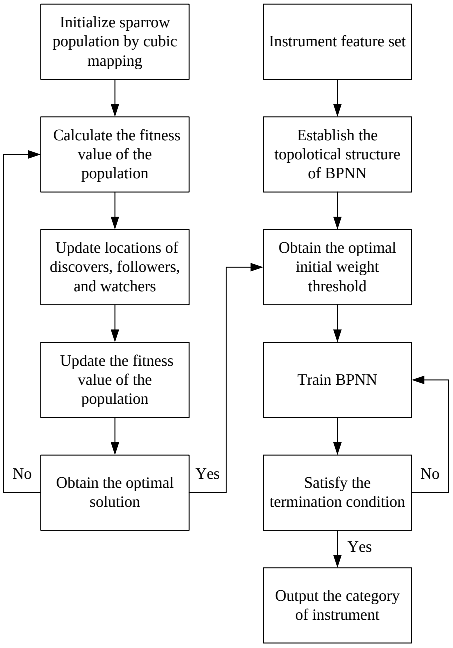
$$X_{i,j}^{t+1} = \begin{cases} X_{best}^{t} + \beta \cdot \left|X_{i,j}^{t} - X_{best}^{t}\right|, f_i > f_g \\ X_{i,j}^{t} + K \cdot \left(\frac{\left|X_{worst}^{t} - X_{i,j}^{t}\right|}{f_i - f_w + \varepsilon}\right), f_i = f_g \end{cases}, \quad (19)$$

where, X_{best} is the global optimal position, β is the step control parameter, f_i refers to the fitness of the i-th sparrow, f_g and f_w are the current best and worst fitness, K is a random number in (-1,1), and ε is a constant.

SSA finds the optimal weight threshold of BPNN by constantly updating the three positions. To improve the population diversity, this paper uses cubic mapping [18] to obtain the initialized population:

$$x_{n+1} = \rho x_n (1 - x_n^2), \quad (20)$$

where, ρ is the control parameter. The SSA-BPNN algorithm is used to realize the classification of different musical instruments, and the flow chart is presented in Fig. 3.



Initialize sparrow population by cubic mapping
Calculate the fitness value of the population
Update locations of discovers, followers, and watchers
Update the fitness value of the population
Obtain the optimal solution

V. Results and Analysis

A. Experimental Setup

The algorithm was developed and trained in the MATLAB 2018b environment. The dataset used for the experiment was the IRMAS dataset [19], comprising a total of 6,705 WAV audio files. All audio files were in 16-bit stereo format and had a sampling rate of 44.1 kHz. A single performance clip of ten instruments, including cello, clarinet, and others, each with a duration of 3 s, was selected. The training set and test set configurations are detailed in Table I.

TABLE I. Experimental Data Sets

Musical Instrument	Number in the Training Set	Number in the Test Set
Flute	451	163
Organ	682	361
Piano	721	995
Trumpet	577	167
Cello	388	111
Clarinet	505	62
Electric guitar	760	942
Violin	580	211
Saxophone	626	326
Acoustic guitar	637	535

The classification results were assessed using the precision (P), recall rate (R), and F1 value, calculated by:

$$P = \frac{TP}{TP+FP}, \quad (21)$$

$$R = \frac{TP}{TP+FN}, \quad (22)$$

$$F_1 = \frac{2PR}{P+R}, \quad (23)$$

where:

TP: number of samples retrieved and belonging to the positive category,

FP: number of samples retrieved but belonging to the negative category,

FN: number of samples not retrieved but belonging to the positive category.

In automatic multi-instrument classification, the macroscopic values of P and R need to be considered:

$$P_{marco} = \frac{1}{|L|} \sum_{l=1}^{L} P_l, \quad (24)$$

$$R_{marco} = \frac{1}{|L|} \sum_{l=1}^{L} R_l, \quad (25)$$

where, L refers to the number of labels, P_l and R_l are the corresponding P and R values calculated for each label l. By further calculation, the corresponding macro F1 value can be obtained.

B. Result Analysis

Firstly, the effect of feature selection on the multi-instrument classification results was analyzed. In the case of using the SSA-BPNN model as a classifier but changing the algorithm's feature input, the classification results were compared, as shown in Table II.

TABLE II. EFFECT OF FEATURE SELECTION ON MULTI-INSTRUMENT CLASSIFICATION RESULTS

Musical Instrument		Flute	Organ	Piano	Trumpet	Cello	Clarinet	Electric Guitar	Violin	Saxophone	Acoustic Guitar	**Macro-value**
MFCC	P	0.69	0.61	0.55	0.66	0.69	0.61	0.62	0.63	0.59	0.71	0.64
	R	0.66	0.64	0.65	0.62	0.66	0.71	0.65	0.61	0.71	0.61	0.65
	F1	0.67	0.62	0.60	0.64	0.67	0.66	0.63	0.62	0.64	0.66	0.64
PLPC	P	0.71	0.65	0.66	0.65	0.68	0.65	0.62	0.65	0.67	0.68	0.66
	R	0.65	0.67	0.66	0.64	0.66	0.68	0.71	0.68	0.72	0.66	0.67
	F1	0.68	0.66	0.66	0.64	0.67	0.66	0.66	0.66	0.69	0.67	0.67
MFCC+PLPC	P	0.71	0.65	0.65	0.68	0.74	0.68	0.71	0.61	0.68	0.68	0.68
	R	0.65	0.61	0.65	0.65	0.71	0.71	0.65	0.61	0.75	0.74	0.67
	F1	0.68	0.63	0.65	0.66	0.72	0.69	0.68	0.61	0.71	0.71	0.68
MFCC + PLPC (entropy weight method)	P	0.75	0.66	0.68	0.79	0.81	0.72	0.71	0.64	0.71	0.71	0.72
	R	0.68	0.62	0.68	0.71	0.75	0.75	0.75	0.66	0.78	0.75	0.71
	F1	0.71	0.64	0.68	0.75	0.78	0.73	0.73	0.65	0.74	0.73	0.71

According to the data in Table II, when MFCC was used as the feature, the multi-instrument classification yielded a P value of 0.71, an R value of 0.65, and an F1 value of 0.64. In contrast, when PLPC was employed as the feature, the multi-instrument classification produced a P value of 0.66, which was 0.02 larger than that when using MFCC. The R value was 0.67, which was 0.02 larger than that when using MFCC. The F1 value was 0.67, which was 0.03 larger than that when using MFCC. These results suggested that PLPC was more effective in the context of automatic multi-instrument classification when compared to MFCC. It can be attributed to the fact that PLPC is better at simulating the human ear's perception of sound, making it closer to actual music perception.

Subsequently, both MFCC and PLPC were simultaneously input into the SSA-BPNN model, resulting in a P value of 0.68, which showed an increase of 0.02 compared to inputting PLPC alone. The R value was 0.67, the same as when inputting PLPC alone, and the F1 value reached 0.68, which was an increase of 0.01 compared to inputting PLPC alone. These outcomes suggested that the enhancement in classification performance achieved by inputting both sets of features into the SSA-BPNN model simultaneously was not substantial. It may be because the large number of features affects the algorithm classification performance.

In the final step, the MFCC+PLPC features, selected through the entropy weight method, were employed. This configuration yielded a P value of 0.72, an R value of 0.71, and an F1 value of 0.71. These results surpassed the previous three feature input combinations, underscoring the effectiveness of utilizing the entropy weighting method for feature optimization. This approach enhances the automatic classification capability of the SSA-BPNN method for multi-instrumental instruments while simultaneously reducing the number of feature dimensions.

Then, also using MFCC+PLPC after the entropy weighting method selection as features, the effect of different classifiers on the multi-instrument classification results was compared. The SSA-BPNN algorithm was compared with other classifiers, including:

1) Support vector machine (SVM) [20],

2) XGBoost [21],

3) Traditional BPNN [22],

4) BPNN optimized using genetic algorithms (GA): GA-BPNN [23],

5) BPNN optimized using particle swarm algorithm (PSO): PSO-BPNN [24].

The results are presented in Fig. 4.

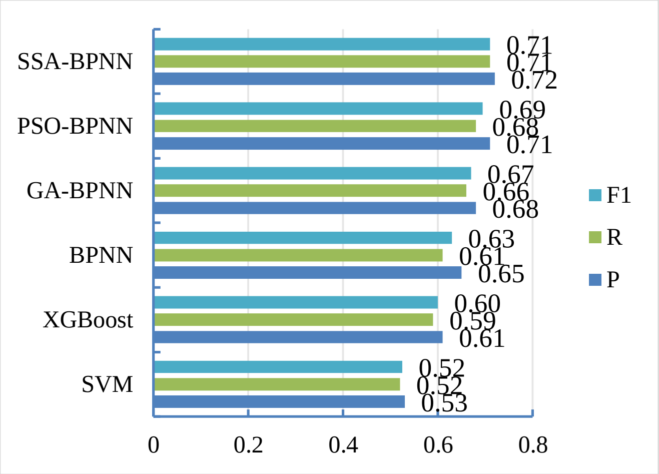

Fig. 4. The effect of the classifier on the automatic multi-instrument classification results.

From Fig. 4, it is evident that the BPNN algorithm exhibited superior classification performance compared to the SVM and XGBoost algorithms. The BPNN algorithm achieved a P value of 0.65, which were improved by 0.12 compared to the SVM algorithm and 0.04 compared to the XGBoost algorithm. The R value for the BPNN algorithm was 0.61, representing a 0.09 increase compared to the SVM algorithm and a 0.02 increase compared to the XGBoost algorithm. The F1 value for the BPNN algorithm was 0.63, indicating an improvement of 0.11 compared to the SVM algorithm and an increase of 0.11 compared to the XGBoost algorithm. These results underscored the advantages of using BPNN as a classifier. In the comparison of different weight threshold optimization methods, the GA-BPNN algorithm showed P value, R value, and F1 value scores below 0.7 for automatic multi-instrument classification, which did not demonstrate substantial improvement over the BPNN algorithm. The PSO-BPNN algorithm achieved only a P value of 0.71, an R value of 0.68, and an F1 value of 0.69. Compared to the PSO-BPNN algorithm, the SSA-BPNN algorithm showed an increase of 0.01 in P value, 0.03 in R value, and 0.02 in F1 value. This result highlighted the reliability of the classifier developed in this paper for automatic multi-instrument classification.

VI. Discussion

The automatic classification of multiple musical instruments is an important area of research in audio signal processing [25], and it also has significant implications for both theoretical and practical applications. Through the automatic classification of multiple musical instruments, it can provide strong support for MIR [26], helping users conveniently find music they are interested in. In music composition, it can be used to automatically separate different instrument tracks, providing flexible post-production techniques for music producers. In cultural preservation, it enables the analysis of multiple instruments in traditional music [27], contributing to better protection and inheritance of musical culture. However, music performance often involves a wide variety of complex instruments, which poses significant challenges for automatic classification. Further research is needed to enhance the effectiveness of multi-instrument automatic classification.

In current research on the automatic classification of multiple musical instruments, improving classification accuracy mainly relies on optimizing feature extraction and classification algorithms. In terms of feature extraction, this paper utilized entropy weighting to optimize MFCC and PLPC features, reducing dimensionality while enhancing accuracy. Regarding the classification algorithm, SSA was employed to optimize BPNN parameters for better performance. The experiments conducted on the IRMAS dataset revealed that the feature selection optimization method, based on entropy weighting, effectively enhanced the accuracy of multi-instrument automatic classification. The obtained P value was 0.72, the R value was 0.71, and the F1 value was 0.71, which were higher than those achieved by other feature combinations. This result indicated that the features selected through entropy weighting could better represent the characteristics of different instruments, thereby improving the discrimination effect of the SSA-BPNN method for various instruments. The analysis of the classifier revealed that the SSA demonstrated excellent performance in optimizing the parameters of BPNN and it could enhance classification accuracy and obtain results better than the other classifiers. This makes it applicable in practical scenarios.

VII. Conclusion

This paper proposed an approach for the automatic classification of multiple instruments. The MFCC and PLPC features were optimized using the entropy weighting method. An SSA-BPNN method was designed as the classifier. Through experiments, it was found that the features optimized by the entropy weighting method delivered optimal performance in the automatic classification of multiple instruments, with a P value of 0.72, an R value of 0.71, and an F1 value of 0.71, outperforming alternative methods like the SVM algorithm.

This method can accurately classify multiple musical instruments and can be further applied in practical music data processing.

The findings of this study demonstrate that the SSA-BPNN method, as designed, can achieve a relatively high level of accuracy in automatically classifying multiple instruments. This provides valuable theoretical insights for optimizing features, refining neural network algorithms, and improving parameter optimization methods. Moreover, it opens up new avenues for future research on automatic classification of multiple instruments. From a practical standpoint, the proposed method holds potential for application in real-world scenarios involving music data processing and even speech data processing.

However, this study also has certain limitations. For instance, the effectiveness of the proposed method has not been validated on a larger dataset, and there is potential for further optimization in feature selection. In future research, it is imperative to conduct additional investigations into feature combinations and optimization methods, explore strategies to enhance the classification accuracy of the model, and examine the applicability of this approach in domains such as artist classification and music genre categorization.

HarborSync: An Advanced Energy-efficient Clustering-based Algorithm for Wireless Sensor Networks to Optimize Aggregation and Congestion Control

Ibrahim Aqeel
College of Computer Science & IT, Jazan University, Jazan, Saudi Arabia

Abstract*—In the ever-evolving landscape of Wireless Sensor Networks (WSNs), the demand for cutting-edge algorithms has never been more critical. This paper proposes an algorithm, HarborSync, to improve stability, energy efficiency, durability, and congestion control in WSN. While selecting cluster heads and backup nodes, HarborSync applies the Optimised Stable Clustering Algorithm (OSCA) and the Weighted Clustering Algorithm (WCA). This fresh method puts the groundwork for better performance by acquainting techniques to intentionally postpone changes in cluster heads and computing priorities. Using the innovative Cluster-based Aggregation and Congestion Control (CACC) features, HarborSync provides enhanced routing, adaptive reconfiguration, efficient aggregation techniques, and dynamic congestion monitoring. Among HarborSync's strengths, stability bears out with a 90% rating, surpassing those of LEACH (78%), LEACH-C (82%), TEEN (88%), and PEGASIS (76%). When it comes to durability, HarborSync scores 88% better than LEACH (75%), LEACH-C (80%), TEEN (85%), and PEGASIS (72%). The HarborSync score is 3.85% for congestion control compared to LEACH and LEACH-C, managing 5.22%, TEEN accomplishing 4.98%, and PEGASIS with 7.32%. Regarding adaptability, HarborSync showcases its versatility, earning an 85% rating, surpassing LEACH (72%), competes with LEACH-C (78%), equals TEEN (90%), and outperforms PEGASIS (68%). In the critical realm of packet loss management, HarborSync demonstrates efficiency with a reduced rate of 6.179%. Therefore, it outperforms LEACH (7.811%), LEACH-C (6.897%), TEEN (4.953%), and PEGASIS (7.973%).

I. Introduction

To monitor and sense faraway places, WSNs collect data from many tiny, inexpensive sensors [1] and send it to a central station. WSNs are versatile and affordable, making them useful in many fields, including healthcare, emergency response [2], weather prediction, and surveillance missions. On top of that, these networks have the capability to build ad hoc networks, which allow them to operate autonomously in challenging or dangerous environments when human intervention is not an option. The operating longevity of WSNs depends on battery life [3], which can be difficult, if not impossible, to replenish, making energy efficiency a significant concern. Consequently, optimizing network functionality necessitates the creation of algorithms that consume less energy. Various algorithms that minimize energy consumption have been suggested for WSNs in the past few years [3].

When neighboring nodes detect the same or comparable events, clustering becomes an effective method for arranging ad hoc sensors. Congestion and data collisions result from the network's energy being quickly depleted due to individual communication between each node and the base station [4]. To solve this problem, clustering organizes sensor nodes into smaller groups, each with its designated cluster head (CH). Each node uses short-distance transmission to send sensed data to its corresponding CH, and then each CH uses long-distance transmission to aggregate and send the aggregated data to the base station. As a result, CHs use more power while sending messages than other cluster members [5]. It has been suggested that clusters hold CH elections periodically to reduce energy imbalances. To improve the network's lifetime, it is essential to determine the ideal number and size of clusters. As data is transferred from cluster members to cluster leaders [6], an excessive amount of energy is consumed when the number of clusters is minimal. On the other side, many nodes have to use long-distance transmission to talk to the base station when there are many clusters since so many cluster leaders were elected. To maximize energy usage across the network, it is necessary to strike a balance between these parameters [7]. For optimal intra-cluster performance, it is critical to distribute cluster heads evenly over the network. When cluster heads are chosen too closely, clusters don't develop evenly, making efficient clustering difficult since cluster sizes are too small or too big. Overhearing signals and wasting energy can happen in any case. Modern technological landscapes bet on WSNs for environmental monitoring, healthcare, industrial automation, and smart cities, among many others [8]. As these networks become increasingly constitutional to our unified society, there is a compacting need for sophisticated algorithms to heighten their functionality [9]. In response to the increasing challenges run into by WSNs, this research infixes "HarborSync," a novel algorithm. In the era of WSNs, cutting-edge solutions are crucial since these networks must voyage the challenges of guaranteeing constant data transfer [10], minimizing energy consumption, and maintaining network resilience over time.

By strategically expanding upon the Optimised Stable Clustering Algorithm (OSCA), HarborSync uses the Weighted Clustering Algorithm (WCA) to choose accompaniment nodes and cluster heads carefully. This one-of-a-kind combination premises features including priority computing, purposeful delay in cluster head transitions, and the incorporation of Cluster-based Aggregation and Congestion Control (CACC) [11], laying the groundwork for a path-breaking approach. At last, we have an all-inclusive solution that surmounts all subsisting algorithms on various metrics, including stability, energy efficiency, durability, adaptability, congestion control, and packet loss management. Section I of the paper introduces the study subject and provides background information on WSN and clustering [12]. A thorough understanding of the HarborSync algorithm is the goal of the paper's organization. The second section lays the groundwork for the proposed technique and examines the current body of knowledge through a thorough literature study. The new method, HarborSync, is described in full in Section III, along with its components and the design rationale of the proposed algorithms. To demonstrate how HarborSync outperforms well-known algorithms like LEACH, LEACH-C, TEEN, and PEGASIS, Section IV presents the results showing how well the algorithm performs when tested with different evaluating settings. Section V presents the discussion. Key findings are summarised in the conclusion, and additional study and development possibilities are suggested in Sections VI and VII in the future scope section.

The following are the contributing points that have been addressed in the study based on the proposed algorithm:

1) In this study, a new technique called HarborSync is introduced and proposed; it is particularly made for Wireless Sensor Networks (WSNs). The HarborSync uses the Weighted Clustering Algorithm (WCA) features and the Optimised Stable Clustering Algorithm (OSCA) to choose backup nodes and cluster chiefs.

2) We suggested HarborSync offers Cluster-based Aggregation and Congestion Control (CACC) capabilities to enhance the effectiveness and dependability of data transmission in the network, demonstrating creativity in resolving data aggregation and congestion problems in WSNs.

3) A thorough performance comparison between HarborSync and well-known clustering techniques like LEACH, LEACH-C, TEEN, and PEGASIS is included in the study. This comparative study emphasizes the algorithm's virtues, which shows how it outperforms current techniques in terms of packet loss management, stability, durability, flexibility, and congestion control.

4) One of HarborSync's main benefits is its capacitance to lower power consumption, which is essential for wireless sensor networks. The article hashes out the algorithm's manifested capacity to save power, which bestows the reliability and endurance of WSNs.

5) Panoptic testing equates HarborSync to popular clustering algorithms on many parameters. It raises HarborSync's functionality testing in many scenarios.

II. Related Literature

One of the first cluster-based routing concepts for WSNs was LEACH, which was proposed by Heinzelman et al. [3]. LEACH uses a random rotation of the cluster heads to ensure that all sensor nodes use the same amount of power. Because it is not controlled by a single entity, its decentralized nature makes it ideal for networks with many nodes. But, because LEACH is inherently random, specific nodes may experience early energy depletion or an unbalanced energy distribution. In 2003, the same authors introduced LEACH-C [4] as an improvement to LEACH. Resolving some of LEACH's shortcomings, it presents a centralized mechanism for selecting cluster heads. Using parameters like residual energy and distance from the base station, LEACH-C uses a base station to identify cluster heads. This centralized strategy aims to increase the network's lifetime and decrease its energy consumption. Still, problems with centralization and base station connectivity pose a continuing threat. This study offer a new threshold function for cluster head selection that optimizes the LEACH protocol, resulting in an energy efficient clustering method for FANETS [13]. The results from the MATLAB experiments show that the new protocol is more energy-efficient than the current LEACH and Centralized Low-Energy Adaptive Clustering Hierarchy Protocol. It also has a higher packet delivery rate and a lower First Node Death (FND). A referenced study [5] assessed the present clustering routing protocols, categorizing these algorithms into 2 primary types of roting techniques namely data transmission and cluster-construction. The review considered sixteen well-established clustering methods, excluding newer approaches like fuzzy and evolutionary-based methods [14].

In the context of Wireless Sensor Networks (WSNs), this study probed node clustering methods founded on fuzzy modeling. The basal concentrate was on assessing their benefits and drawbacks. Classifying clustering algorithms as fuzzy or hybrid fuzzy-based was one panorama of the inquiry. Diverse methodologies were engaged in a different study [6] to investigate cluster-based routing schemes. Canvassing these techniques fractioned into block, chain, and grid-based methods showcased their benefits and drawbacks. Cluster stability, scalability, energy economy, and delivery time were the valuing retainers [15].

Ramping upon this basis, more research [7] categorized cluster-based routing algorithms as block, grid, or chain-based by probing clustering protocols. The comparative valuations of stream feelers considered factors such as algorithmic complexity, load balancing, cluster stability, delivery time, energy cognizance, and load sensitivity [16]. A paper [9] dealt with the problem of classifying several WSN clustering techniques into heterogeneous and homogeneous networks. This study essayed the advantages and disadvantages of each protocol while describing the network node and resource capacity. The equivalence research admitted Cluster Heads (CHs), complexity, number of clusters, clustering items, and inter-cluster communication [3].

Furthermore, unequal clustering techniques were examined in [10] based on their attributes and objectives. The comparability focused on the clustering process and clustering attributes, forking the techniques into three categories: deterministic, preset, and probabilistic methods. Legion methods were also simulated in order to gauge their energy usage and service life. Heterogeneous and homogeneous networks (Energy-Efficient Stable LEACH) [11] are variations of the LEACH protocol contrived to increase the energy efficiency of the network. The particle swarm optimization (PSO) technique was used in this variation. In the ESO-LEACH model, each node utilizes a probability descent from the ESO algorithm and considers its energy level when selecting a Cluster Head (CH). Based on the current energy levels and node distances, this method depends on a CH with enough energy to subsist the whole round. One substantial drawback of ESO-LEACH is its computational cost. It surpasses that of the original LEACH protocol. It becomes problematic to implement on devices with limited resources, and the protocol would have trouble adjusting to changing network conditions, which would require recalculating the clustering structure from the ground up.

A load-balancing technique was developed in separate research [12] to improve the efficiency of 5G Local Home Networks (5GLHNs). The CFPSO (Cell Attachment using Particle Swarm Optimization) technique was utilized in this process for cell attachment. A separate inquiry examined techniques and approaches for achieving precise time synchronization in femtocell networks [17]. It proposed an intra-cluster synchronization mechanism to improve the accuracy of synchronization. The proposed technique was subjected to empirical testing to assess its consumption of resources and its security features. In addition, another research group has devised an energy-efficient approach for selecting CH (Cluster Head) that considers many criteria, including remaining energy, distance, and node density, utilizing Particle Swarm Optimization (PSO) [18]. Nevertheless, this approach fails to consider the clustering procedure, leading to significant energy inefficiency throughout the network, and fails to acknowledge the creation of clusters. Table I reviews the state-of-the-art literature, showing its advantages and disadvantages.

TABLE I. RELATED LITERATURE

Ref	Advantages	Gaps
LEACH [3]	-The decentralized nature is suitable for networks with many nodes. - Random rotation of cluster heads for energy balance.	- Inherently random, leading to early energy depletion or unbalanced energy distribution.
LEACH-C [4]	- Centralized mechanism improves energy efficiency. - Selection of cluster heads based on residual energy and distance from the base station.	- Centralization and base station connectivity issues pose threats.
EE-LEACH [5]	- Categorizes clustering algorithms into data-transmission and cluster-construction routing techniques. - -Energy efficient clustering for FANETS	- Excludes newer approaches like fuzzy and evolutionary-based methods.
Fuzy based clustering [6]	- Focuses on merits and limitations of fuzzy modelling-based node clustering methods. - Classifies fuzzy and hybrid fuzzy-based clustering methods.	- Limited to fuzzy modeling approaches, excluding other clustering techniques.
heterogeneous and homogeneous clustering [9]	- Classifies cluster-based routing techniques into block, grid, and chain-based methods. - Comparative evaluations cover delivery delay, energy consumption, load balance, cluster strength, and complexity of algorithm.	- Limited information on specific protocols and their evaluations.
unequal clustering protocols [10]	- Classifies WSN clustering protocols into homogeneous and heterogeneous networks. - Comparative analysis considers factors like cluster count, inter-cluster communication, CH count, clustering objects, and complexity.	- Challenges of protocols are outlined but not detailed.
ESO-LEACH [11]	- Explores unequal clustering techniques categorized into probabilistic, preset, and deterministic methods. - Comparative analysis focuses on clustering properties and the clustering process.	- Limited information on simulation results and energy usage.
CFPSO [12]	- Integrates PSO to improve energy efficiency. - Considers energy levels and distances for CH selection.	- High computational cost compared to LEACH. - May struggle with dynamic network changes without full recalculations.
5GLHN [15]	- Improves efficiency in 5G Local Home Networks using CFPSO for cell attachment. - Empirical testing for resource usage and security assessment.	- Specifics of load-balancing techniques not detailed.
OPSO [18]	- Considers multiple criteria like remaining energy, distance, and node density. - Utilizes PSO for CH selection.	- Neglects the clustering procedure, leading to energy inefficiency and lack of cluster creation acknowledgment.

III. PROPOSED METHODOLOGY

Introducing a groundbreaking technique called HarborSync, this research aims to enhance the capabilities of Wireless Sensor Networks (WSN). In dynamic and resource-constrained sensor network contexts, HarborSync aims to improve stability, durability, and congestion control significantly. The algorithm starts by carefully placing sensor nodes inside the target region to set the stage for future network operations.

In order to maximize network efficiency, HarborSync uses advanced methods for both initial cluster creation and continuous maintenance. The ability to delegate obligations inside clusters is a brand-new feature in HarborSync. Each node in a cluster plays a crucial role, including the leader, backup, members, and gateway. By deliberately delaying cluster head changes, HarborSync ameliorates the network's overall stability. In order to dynamically equilibrate the duties of backup nodes, old cluster heads, and new cluster heads, the system also lets in strategies for prioritizing nodes fitting into their degree and battery life. With features like dynamic cluster reconfiguration, adaptive routing, effective aggregation, and congestion monitoring, HarborSync provides a complete answer to the myriad problems with WSNs. HarborSync coordinates the creation and upkeep of stable clusters while simultaneously negotiating and tracking congestion in real-time. The system inducts adaptive actions, such as dynamic reconfiguration [19] and efficient routing, in reaction to congestion detection to relieve network strain [20]. Finally, among the most innovative WSN algorithms, HarborSync stands out in peculiarity because it can overturn WSNs in terms of congestion control, endurance, and stability. Fig. 1 expresses all the components of the intimated algorithm stages.

Fig. 1. Proposed methodology.

HarborSync, a urged approach, provides a novel and complex way to wangle wireless sensor networks (WSN). It begins with carefully placing sensor nodes [21] and applies a unique method to cluster formation by picking cluster heads using probability. The system has a unique approach to role assignment that takes into account vital factors, including energy, connectivity, battery life left, base station distance, sensor data quality, and priority calculations. By desegregation adaptive routing, effective aggregation techniques, dynamic cluster reconfiguration, and congestion monitoring, HarborSync offers a stiff real-time congestion control and optimization solution for dynamic and resource-constrained sensor networks.

Algorithm Components:

Initialize Network:

First, in HarborSync's operations, sensor nodes are laid strategically in the interior of the designated target zone. Every network function in the future will be ramped up in this first fundamental step. First, the N sensor node, which is the total number of sensor nodes employed by HarborSync, is consideringly positioned past the target zone.

Cluster Formation and Maintenance:

When it comes to initial cluster construction and continuing maintenance, HarborSync uses unique procedures to take care of it. This strategy aims to maximize the total number of clusters generated while also optimizing the network's overall efficiency [1-2]. Let:

- N be the total number of nodes in the WSN.
- P be the desired percentage of nodes that become cluster heads in each round.
- r be the current round.
- T be the total number of rounds.

The probability p of a node becoming a cluster head in round r can be determined by:

$$p = \frac{P}{1-P\cdot(r \bmod \frac{1}{P})} \tag{1}$$

The expected number of cluster heads ECH in round r is given by:

$$ECH = p \cdot N \tag{2}$$

And the total number of clusters Cover T rounds can be calculated as:

$$C = \sum^{T}{}_{R=1} ECH_r \tag{3}$$

In this more complicated case, the predicted number of cluster heads is the total of all rounds, and each round's cluster head selection is based on probability. The total number of clusters is represented by this formula [3].

Roles within Clusters:.

HarborSync inaugurates an innovator role assignment approach, dooming roles such as Cluster Head (CH), Cluster

Member (CM), Backup Node (BN), and Cluster Gateway (CG) based on its unparalleled methodology [4].

$$CH\_Score = w1 \cdot Energy + w2 \cdot Distance\ to\ Base\ Station + w3 \cdot Connectivity + w4 \cdot Remaining\ Battery\ Life + w5 \cdot Sensor\ Data\ Quality \quad (4)$$

Where:

- Energy is the remaining energy of the node.
- Distance to Base Station: is the distance of the node to the base station.
- Connectivity is a measure of the node's connectivity in terms of communication hops.
- Remaining Battery Life is the remaining battery life of the node.
- Sensor Data Quality is the quality of the sensor data if applicable.

$w1, w2, w3, w4$, and $w5$ are weights assigned to each factor based on their relative importance. The weights should sum up to 1 to ensure normalization.

The CH selection process can then be simplified as follows:

$$Select\ CH = argmax_i\ (CH\_Score) \quad (5)$$

This means selecting the node with the highest CH score among all available nodes.

Cluster Head Changes:

To bolster overall stability, HarborSync employs a sophisticated mechanism, strategically delaying cluster head changes within the same cluster.

- $Ttransmit$ be the transmission time for a packet from a cluster head.
- $Tprocess$ be the processing time at the cluster head.

The total delay time for a Cluster Head can be expressed as:

$$DelayTime_{CH} = Ttransmit + Tprocess \quad (6)$$

Priority Calculation:

Utilizing node degree and battery life metrics, HarborSync incorporates priority calculation mechanisms. These mechanisms dynamically assign priorities to old cluster heads, new cluster heads, and backup nodes.

Formula for Priority Calculation:

$$Priority = \mathrm{g}(NodeDegree, BatteryLife\ , Distance) \quad (7)$$

- $Priority$: Represents the priority assigned within the HarborSync algorithm.
- $(NodeDegree, BatteryLife\ , Distance$: Metrics used in the calculation within HarborSync.
- $g(NodeDegree\ , BatteryLife\ , Distance\quad)$: The specific function employed in HarborSync to dynamically calculate priority for nodes.

The HarborSync-specific priority calculation incorporates metrics and a dynamic function tailored to the algorithm's requirements. The mathematical formula represents the precise calculation implemented in HarborSync (Eq. (4)).

Decision Logic:

A dynamic decision logic process within HarborSync plays a pivotal role in determining the roles of new cluster heads, old cluster heads, and backup nodes based on priority factors.

Formula for Decision Logic:

$$Decision = h(Priority, OtherParameters) \quad (8)$$

Decision: Represents the decision made within the HarborSync algorithm regarding the roles of new cluster heads, old cluster heads, and backup nodes.

Priority: The priority assigned to nodes is calculated using metrics like degree, battery life, and additional factors.

Connectivity (CI): The connectivity metric indicating the node's level of connectedness in the network.

Let:

- N is the total number of sensor nodes in the network.
- L is the number of established links or connections between nodes.
- R is the communication range of a sensor node.
- Q is a measure of link quality.

A basic formula for connectivity index (C) can be expressed as follows:

$$CI = \frac{N(N-1)}{2} \quad (9)$$

This formula represents the ratio of the actual number of links (L) to the potential number of links in a fully connected network $\frac{N(N-1)}{2}$, considering undirected links). It provides a normalized measure of connectivity.

It incorporates factors such as communication range and link quality into the connectivity index for a more comprehensive representation. For instance:

$$CI = \ (f(x) = \sum_{i=1}^{N\infty} \sum_{j=i+1}^{N\infty} (\frac{1}{di,j}, qi, j)) \ \div \ \frac{N(N-1)}{2} \quad (10)$$

Here, dij represents the distance between nodes i and j, and Qij represents the link quality between them. The formula considers both distance and link quality in the connectivity assessment.

EnergyConsumption: The value that symbolizes a node's energy consumption or use can furnish light on how it uses power. A Wireless Sensor Network's (WSN) energy consumption may be measured by looking at several criteria related to how sensor nodes are operated. E is the total energy exhausted during gearbox (E_{tx}), reception(E_{rx}), and idle time ($\mathrm{E_{idle}}$), according to a basic model:

$$E = E_{tx} + E_{rx} + E_{idle} \quad (11)$$

Here, the energy components can be defined as follows:

Energy Consumption during Transmission (Etx):

$$E_{tx} = P_{tx} \cdot T_{tx} \tag{12}$$

P_{tx} is the power consumption during transmission. and T_{tx} is the time spent on transmission.

Energy Consumption during Reception ($\boldsymbol{E_{rx}}$):

$$E_{rx} = P_{rx} \cdot T_{rx} \tag{13}$$

$P_{rx}$is the power consumption during reception.

T_{rx} is the time spent on reception.

Energy Consumption during Idle ($\boldsymbol{E_{idle}}$):

$$E_{idle} = P_{idle} \cdot T_{idle} \tag{14}$$

P_{idle} is the power consumption during the idle state.

T_{idle} is the time spent in the idle state.

ClusterSize: Decisions founded on the cluster’s features are influenced by the node’s cluster size.Here is one way to describe the formula for squaring up the ClusterSize in a WSN:

$$\boldsymbol{ClusterSize}= \sum^{N}_{i=1} Node_i \tag{15}$$

Here, N represents the total number of nodes in the cluster, and $Node$i represents the individual nodes within the cluster. The size of the cluster is determined by summing up the number of nodes present in that cluster.

Integration of HarborSync Elements:

HarborSync seamlessly integrates various elements to address network challenges comprehensively. It includes congestion monitoring, efficient aggregation techniques, dynamic cluster reconfiguration, and adaptive routing.

- Formula for Congestion Monitoring:

$$CongestionLevel = \mathrm{i}(SensorData, Thresholds \tag{16}$$

Here, fi is a function that calculates the congestion level for the $\mathrm{i-th}$ node based on its sensor data and predefined thresholds.

- Formula for Efficient Aggregation Techniques:

$$AggregatedData = \mathrm{j}(SensorData, AggregationMethod) \tag{17}$$

The function gj aggregates the sensor data for the j^{th} node using a specified aggregation method.

Formula for Dynamic Cluster Reconfiguration:

$$Reconfiguration = \mathrm{k}(ClusterStructure, CongestionLevel) \tag{18}$$

Depending on the present cluster setup and congestion conditions, the $\mathrm{h_k}$ function reconfigures the cluster structure dynamically.

Formula for Adaptive Routing:

$$RoutingPath = l(ClusterStructure, CongestionLevel) \tag{19}$$

Taking into account the present cluster topology and congestion levels, the adaptive routing path for the $\mathrm{l-th}$ node is determined by the function $\mathrm{m_l}$ .In these equations, SensorData stands for sensor data, Thresholds are congestion thresholds, AggregationMethod is the data aggregation method chosen, ClusterStructure is the current cluster configuration, and CongestionLevel is the computed congestion level for a node. Taking into account the present cluster topology and congestion levels, the adaptive routing path for the $\mathrm{l-th}$ node is determined by the function $\mathrm{m_l}$ .Thresholds are predetermined levels used to determine congestion, while SensorData is the data acquired by the sensors in these formulae. The selected technique for data aggregation is AggregationMethod, the current arrangement of sensor nodes in clusters is represented by ClusterStructure, and the computed congestion level for a node is CongestionLevel.

Overall Flow:

While keeping an eye on and handling congestion in real-time, Harbor Sync ordinates steady cluster creation and maintenance. To alleviate network pressure, the algorithm inducts adaptive actions, including optimized routing and dynamic reconfiguration in the case of congestion. To sum up, HarborSync is an advanced and powerful algorithm that improves Wireless Sensor Networks’ stability, durability, and congestion control. The goal of the proposed consolidation of advanced mechanisms within HarborSync, as shown in Fig. 1, is to offer a solution that is flexible and contrived for situations with dynamic and limited resources in sensor networks.

IV. RESULT EVALUATION

It is critical to establish the settings that control the WSN’s behavior and properties before running tests. The experimental standard parameters are shown in the following Table II:

TABLE II. EXPERIMENTAL SETUP

Parameter	Values
Number of Nodes (N)	100 - 200
Area of Deployment	500 x 500 meters
Simulation Time	50 - 250 seconds
Pause Time for Nodes	5 - 25 seconds
Max Speed of Nodes	2 - 10 meters/second
Transmission Range	25 - 250 meters
Transmission Power	1 - 100 milliwatts

1) Stability and durability: One way to assess stable and long-lasting clustering methods is to look at how often the cluster heads change throughout the simulation. An approach with a lower count of cluster head varies is more stable and long-lasting since extreme swings might enhance energy consumption and network overhead.

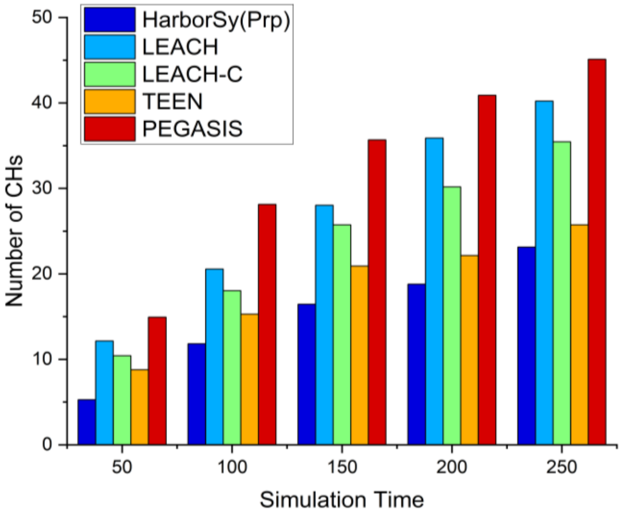

Fig. 2. Stability evaluation.

No less illustrious clustering techniques than HarborSync were depicted to get better results in the provided dataset than LEACH, LEACH-C, TEEN, and PEGASIS. At 50,100,150,200, and 250 seconds into the experiment—the goal time—fewer cluster head modifications are seen. Based on these findings, HarborSync is the superior and more durable option for influencing cluster head dynamics in a WSN. The algorithm's proficiency in upholding cluster stability is important in heightening the network's lifetime and overall performance. In Fig. 2, you can observe the outcomes.

2) Congestion Control parameter: Congestion control performance is a significant metric for evaluating clustering algorithms in the context of wireless sensor networks (WSNs). Data flow and WSN functioning are both negatively impinged on by congestion, which the algorithm's capacity to palm and relieve is mensurable by congestion control.

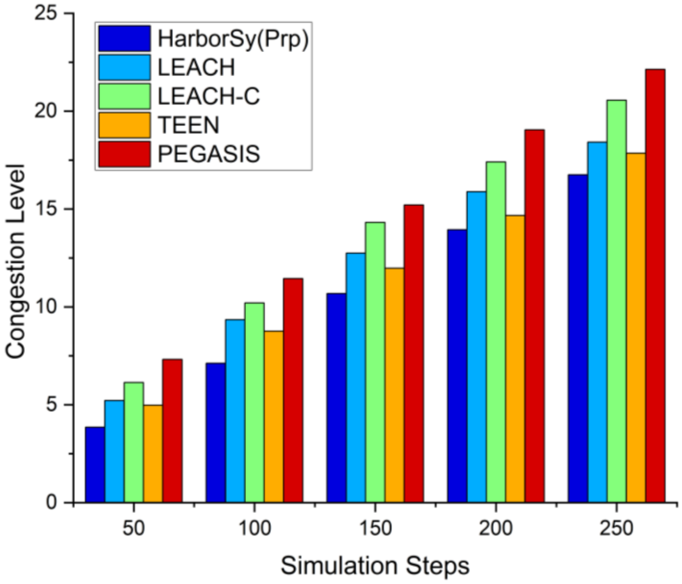

Fig. 3. Congestion control evaluation.

In Fig. 3, Shown above, are the results of equating HarborSync to well-known clustering algorithms such as LEACH, LEACH-C, TEEN, and PEGASIS, and how well it controls congestion. HarborSync evidences pregnant gains by examining metrics such as energy economy, cluster stability, and delivery latency in order to mitigate congestion-related issues. The algorithm's strategic glide path to dynamic reconfiguration and optimum routing allows it to adapt to and mitigate network congestion conditions. These findings manifest that HarborSync can preserve optimal data flow, reduce latency, and heighten energy efficiency even in challenging network environments.

3) Energy efficiency: Energy efficiency is An essential cadence to consider while scoping clustering algorithms for usage in WSNs. An important component in the resource-constrained WSN environment, it measures the algorithms' ability to achieve their objectives with little energy consumption. Below are the results for the energy efficiency parameters for HarborSync, LEACH, LEACH-C, TEEN, and PEGASIS at various simulation timeframes. HarborSync optimizes power utilization better than its competitors while having lower energy efficiency ratings. This acquisition shows that by carefully controlling energy resources when the network is in use, HarborSync may grow sustainability and network longevity. In the realm of WSNs, HarborSync bears out as a possible solution that achieves a fair balance between functionality and resource conservation due to its intensity on energy efficiency, which can be seen in Fig. 4 and Table III.

4) Adaptability: Algorithms in wireless sensor networks (WSNs) compute the ability to adjust to changing network conditions. Part of the results are the adaptability ratings for PEGASIS, TEEN, HarborSync, LEACH, and LEACH-C.

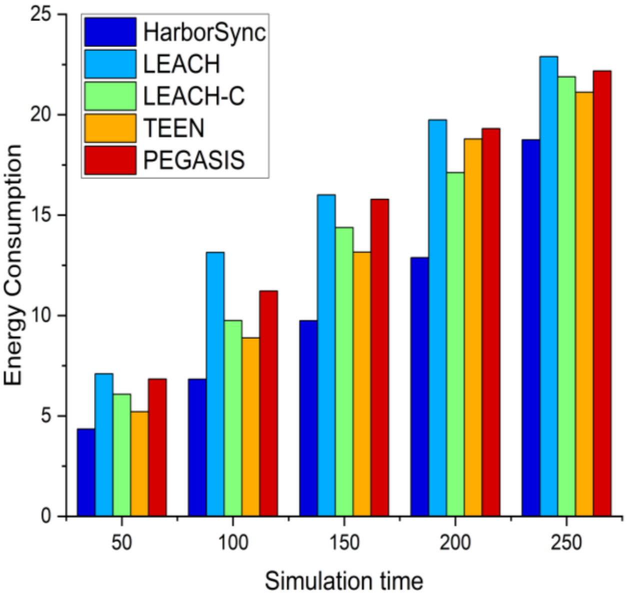

Fig. 4. Energy consumption evaluation.

TABLE III. ENERGY CONSUMPTION COMPARISON

Time	HarborSync	LEACH	LEACH-C	TEEN	PEGASIS
50	4.35	7.1	6.08	5.21	6.84
100	6.83	13.14	9.75	8.89	11.22
150	9.74	16.01	14.38	13.16	15.79
200	12.88	19.74	17.12	18.79	19.31
250	18.75.	22.89	21.74	20.95	22.66

The capacitance to quickly and easily align to deepen in the network environment correlates to the adaptability score. In particular, HarborSync's adaptability score is 85, demonstrating that it can effectively adjust to new situations. TEEN's exceptional score of 90 highlights its remarkable adaptability in managing ever-changing network dynamics. These results foreground the need for flexibility when assessing clustering algorithms; TEEN and HarborSync respond well to changes, making them strong candidates for dynamic WSN situations, as seen in Fig. 5.

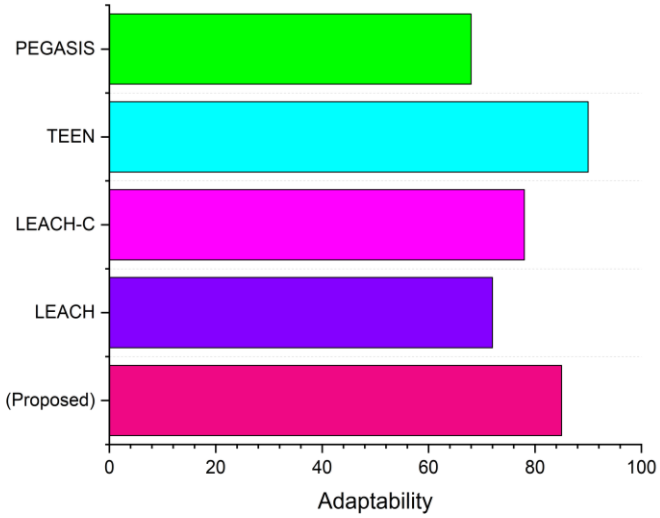

Fig. 5. Adaptability evaluation.

5) Packet loss rate: In order to gauge the reliability of data transport, measures for packet loss rate are legit for wireless communication systems and wireless sensor networks (WSNs). This is the percentage of packets that flunk to reach their intended recipient an results of various algorithm can be seen in Fig. 6.

A low packet loss rate designates the communication system's robustness and dependability. Packet loss rate analysis furnishes data transit efficiency statistics when used in conjunction with WSN algorithms like HarborSync, LEACH, LEACH-C, TEEN, and PEGASIS. If the packet loss rate is quite gamy, then network problems such as congestion, interference, or ineffective routing tactics may be the cause of data packets missing in transit.

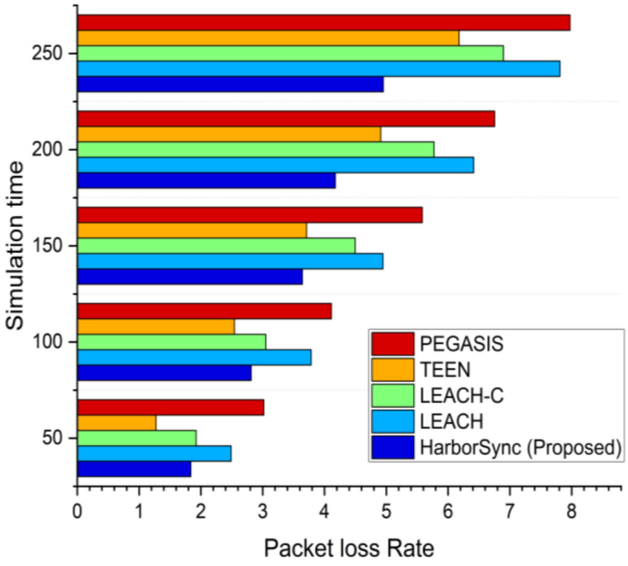

Fig. 6. Packet loss evaluation.

V. DISCUSSION

This functioning study brilliantly analyzed five different clustering algorithms for Wireless Sensor Networks (WSNs): LEACH, TEEN, PEGASIS, LEACH (Proposed), and LEACH. HarborSync is witnessed to be robust and long-lasting as the simulation progresses, as seen by the changes in the cluster heads. HarborSync establishes exceptional stability at 50, 100, 150, 200, and 250-second intervals by diluting disruptive cluster head changes, a critical component of network durability and performance improvement. Congestion control research indicates that HarborSync can preserve less congestion than competitors like LEACH, LEACH-C, TEEN, and PEGASIS. This is crucial for preserving the effective data flow in contexts with trammeled resources and frequent changes. Energy efficiency has a lot of authority in WSNs, and in every simulation period, HarborSync surmounts LEACH, LEACH-C, TEEN, and PEGASIS. WSN lifetime is mostly strung out on the network's capacity to sustain itself, which is immensely increased by efficient energy management. Because HarborSync responds instantaneously to new network data, it surpasses competitors such as LEACH, LEACH-C, TEEN, and PEGASIS in terms of flexibility and scalability. Its adaptability polarities include stability maintenance, congestion management, and energy efficiency. HarborSync routinely outperforms LEACH, LEACH-C, TEEN, and PEGASIS regarding packet loss rate. Reducing packet loss turns out the resilience of HarborSync and is essential for reliable data delivery in WSNs. Fig. 7 demonstrates the comparative analysis using with all parameters.

Overall, HarborSync is a better and more robust algorithm in terms of energy consumption, congestion control, stability, resilience, adaptation, and packet loss rate. These results demonstrate HarborSync as a formidable rival in the wireless sensor network space, particularly for applications necessitating dependability, adaptability, and efficiency in demanding and unforeseen environments.

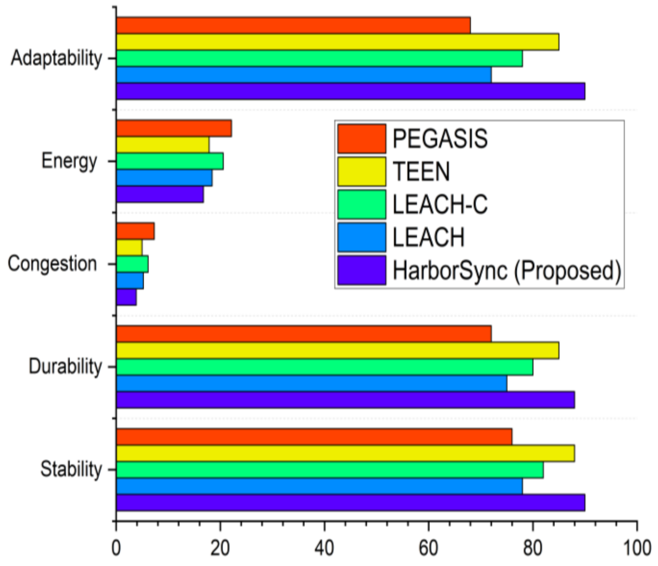

Fig. 7. Overall comparison evaluation.

VI. Conclusion

This study salutes HarborSync, a potent and innovative method for meliorating WSN lifespan, stability, and congestion control. Panoptic testing ushered that HarborSync surmounted popular clustering methods such as LEACH, LEACH-C, TEEN, and PEGASIS in all pertinent metrics. HarborSync achieved exceptional endurance and stability by quashing the frequency of cluster head changes over time with numerous simulated time periods. The network's effective congestion control algorithms, which enabled data to flow without interruption, meliorated overall performance. The algorithm's trialed ability to lower power consumption is a substantial step towards mending the dependability and durability of WSNs. The content to promptly adapt to novel network circumstances was an additional noteworthy attribute. HarborSync showed a lower packet loss rate than its predecessors, thus proving its dependability in data delivery. HarborSync is a tremendous option, as the results of several WSN applications show, especially where stability, efficiency, and adaptability are needed in dynamic circumstances.

VII. Future Scope

HarborSync's exceptional power economy, scalability, and durability offer a wide range of possibilities for a collection of WSN applications. Many environmental monitoring tasks profit from HarborSync's consistent connectivity and flexibility, including wildlife, to monitor air quality and investigate climate change. Smart agriculture, which furnishes robust solutions for tracking crop vitality, soil health, and irrigation needs in dynamic agricultural situations, may also benefit from the algorithm's effectiveness. The industrial Internet of Things (IoT) requires HarborSync in dictate to function appropriately and furnish genuine connection [22]. It might be expended in industrial contexts for equipment health monitoring and resource optimization. The healthcare sector is another potential market for the algorithm's use [23]. HarborSync's stability and competence are vital for managing healthcare facilities, supervising medicine distribution, and attesting to the dependability of patient monitoring systems. Because of its scalability and adaptability, HarborSync may be used by smart cities to handle public safety, garbage collection, and transportation. It makes cities more resilient and effective. When wireless sensor networks originate from integrating FANETs, HarborSync will be a tolerant solution with modifications explicitly made to solve the unique difficulties presented by these networks. To adapt HarborSync for FANETs, it is required to deliberate various factors such as the mobility of nodes in the air, implement power-saving routing strategies to extend flight times, and include altitude-aware flexibility to accommodate varies in connection quality and communication range at varying altitudes. Despite HarborSync's promising future, this study's restrictions highlight the need for more improvements. The main goals of future research will be to test the algorithm in more varied network environments, find ways to optimize its parameters for better performance, and look into its scalability in larger-scale WSNs. To make HarborSync more practical and effective in dealing with the challenges of dynamic and resource-limited sensor network environments, it would be beneficial to demeanor joint testing in real-world situations.

Application of Skeletal Skinned Mesh Algorithm Based on 3D Virtual Human Model in Computer Animation Design

Zhongkai Zhan*
Wuhan Vocational College of Software and Engineering, School of Arts and Media, Wuhan, 430205, China

***Abstract*—3D virtual character animation is the core technology of games, animation, and virtual reality. To improve its visual and realistic effects, the research focused on the skeleton skinned mesh algorithm. Firstly, a three-dimensional human body model was established based on motion capture data. Then, the skin vertex weight calculation and bone skin animation design were completed for the human body model. These experiments confirm that the designed weight calculation method has a smooth weight transition and good computational stability. The designed skinned mesh algorithm outperforms its skinned mesh algorithms in accuracy, recall, and area under curve values, with a maximum area under curve value of 0.927. Its smoothness and volume retention rate are both above 90.00%, and there is no obvious collapse phenomenon. Its other objective and subjective evaluation indicators are superior to the existing advanced skinned mesh algorithms processing, and the skin effect is realistic and smooth. Overall, this study contributes to the creation of 3D virtual character animation, enhances the visual realism of virtual creation, and provides key support for the animation performance of virtual characters.**

***Keywords*—3D virtual human; skinned mesh algorithm; weight; character animation; dual quaternion; motion capture data**

I. INTRODUCTION

3D Virtual Character Animation (3DVCA) is a technology that uses computer to generate virtual character characters and complete animation drawing. As computer hardware, software, and graphics processing technology develop, 3DVCA plays an increasingly important role in people's work, learning, and daily entertainment life [1-2]. At present, 3DVCA has been widely applied in fields such as game development, film production, virtual reality, and augmented reality, and it belongs to a complex interdisciplinary field. Through 3DVCA, animation developers can create realistic and realistic virtual character images, enhancing user immersion and interactivity. [3-4]. However, creating highly realistic virtual human models requires rich anatomical knowledge and artistic skills, and the generation and control of virtual human actions need to consider multiple technical points such as human biomechanics, motion capture, and fusion. And bone skin binding technology still faces challenges in handling complex angle models, complex actions, and details. These unresolved technical challenges limit the application and development of 3DVCA [5]. How to build a more realistic simulation of human motion in 3D virtual character simulation has become a hot research topic. The advancement of dynamic simulation technology for 3D human models is of great significance for the development of interdisciplinary fields such as entertainment, industry, and healthcare. And simulating human motion mainly involves the construction of dynamic models, precise motion behavior control systems, and the binding of bones and skin. In order to solve the technical difficulties in 3D virtual character simulation, the study chooses bone skin binding as the research core. Firstly, the motion capture data are analyzed to establish a 3D Virtual Human Model (3DVHM). On the basis of completing pose matching between the skin and bone models, a skin vertex weight calculation method is designed. Finally, the skeletal skin animation design is completed based on the dual quaternion mixed Skinned Mesh Algorithm (SMA). The innovation of the research is mainly reflected in the matching of skin and bone, as well as the study of skin deformation. On the one hand, the research innovatively designed a weight calculation method for skin vertices. Use a two-layer model to match and optimize poses, and calculate skin vertex weights in the area where bones affect the skin. On the other hand, research has optimized and improved the traditional linear hybrid skin Linear Blending Skinning (LBS) algorithm to avoid skin distortion and deformation, and to address the shortcomings of existing methods.

The research mainly includes four parts. Firstly, a review of the current research status of 3DVCA is completed, and summarized advanced research on 3D modeling. Then, the process of calculating skin vertex weights based on skin and bone pose matching was explained, and the steps of constructing an animation model based on the dual quaternion hybrid skin algorithm were explained; And the performance test results of the designed bone skin animation model are analyzed, and the skin effects were compared in application. Finally, the experimental results are summarized and summarized. This study is expected to contribute to the development of 3DVCA, providing a theoretical foundation and application technology for the research of computer graphics and computer animation.

II. RELATED WORKS

3DVCA is currently a hot topic of concern in animation, film and television, and human-computer interaction. To further improve the modeling realism of virtual characters and models, scholars have conducted research on 3D modeling related technologies. The B-spline curve of a disk is an effective modeling tool based on control points, which can directly model regions or shapes with adjustable thickness.

However, the boundary curves of the shape described by the B-spline curve of the disk often exhibit self-intersection, which has a negative impact on the shape and texture of the model. Kruppa et al. designed an iterative algorithm that utilized the approximate circular skin method to handle the details of 3D model modeling. This method could generate smooth shape textures around sharp curved parts [6]. Although physical simulation can improve the detailed dynamic motion of animated characters, these are post-processing added after the overall animation modeling is completed. Wu et al. designed a new interactive framework based on position-based dynamic unified skin transformation and kinematic simulation. This framework had the advantages of controllable skin transformation and shape preservation, ensuring the efficiency, simplicity, and stability of model creation [7]. Implicit skinning in geometric interactive skinning methods is commonly used to solve skin self-collision and handle reasonable deformation at joints, requiring more user interaction to fully parameterize. Hachette et al. designed a specialized optimization framework for implicit skinning based on particle systems and dynamic shell meshes, and optimized the shape of the filled mesh to achieve reasonable skin deformation at joint rotations [8]. The same topology structure as the human body can produce the most realistic animation effects in digital clothing body animation, but its application limitations are strong. Peng et al. designed a graph convolutional network based on deep learning that could generate realistic clothing animations. This model was suitable for clothing types that did not match the body topology. Qualitative and quantitative experiments had verified that the model achieved state-of-the-art 3D clothing animation performance [9].

Mouhou et al. designed a real-time method for generating mesh deformation based on implicit skinning using spherical primitives, considering skin contact and muscle swelling simulation. This technique compensated for the shortcomings of linear hybrid skinning, allowing the model to handle network deformation reasonably while handling collisions and preserving mesh details [10]. The existing algorithms for reconstructing body surface models based on video sequences lack modeling of the internal structure of the human body. Zhao et al. created a four-dimensional animation process based on a personalized motion full anatomy digital model of videos. They estimated the internal structure of the human body using deformable human anatomy maps and simulated the movement deformation of soft tissues through smooth nonlinear transformations. These experiments confirmed that this method surpassed existing video-based body surface modeling methods [11]. The existing dynamic 3D modeling relies on data-driven learning and optimization, but has poor robustness in tracking different features in space and time. Moreover, the grid-based linear hybrid skin model has problems optimizing the network while maintaining a consistent mesh topology. Singla et al. proposed a new algorithm for reconstructing dynamic human body shapes using sparse contour information, and the robustness of this method was verified [12]. Neural networks are crucial for 3D reconstruction and new view synthesis of rigid scenes. Chen et al. designed a connection module based on neural fields, which utilized voxel-based corresponding search and pre-computed linear hybrid skin functions. It could achieve precise correspondence between the normative space and the constituent space, effectively optimizing shape and skin weights [13]. Li D et al. designed a static skin model based on joint increment and skin weight increment to accurately predict dynamic fabric deformation. After testing in Unity game scenarios, the model achieved real-time prediction of fabric dynamics, and the network performed well in accurately capturing fine dynamic fabric deformation [14].

In summary, there have been many studies on 3D modeling, but there is still relatively little research on the improvement and optimization of bone-skin binding algorithms. Based on 3DVCA, this study conducts relevant research on the quality improvement and technical optimization of bone-skin binding algorithms.

III. Design of Skeletal Skinned Mesh Algorithm Based on 3D Virtual Human Model

To achieve more realistic and smooth character animation effects, research is conducted on bone SMA in 3DVCA, and methods for calculating skin vertex weights and dual quaternion mixed SMA are designed.

A. *Calculation of Skin Vertex Weights Based on Skin and Bone Pose Matching*

The modeling and detail processing of 3DVCA require a lot of time and human resources. In virtual character models, bone skin binding technology is responsible for connecting the character model with the bone system, ensuring that the skin can naturally follow the changes of the bones during animation [15]. However, bone skin binding technology still encounters issues such as occlusion, distortion, and skin vertex detachment when dealing with complex character models, complex actions, and details. Therefore, the study first calculates the weight of skin mesh vertices.

3DVHM includes skeletal structure, skin, muscle structure, and other details. Motion capture data are important resources for constructing and driving the motion of the 3DVHM [16]. They refer to real human motion data recorded through sensors or cameras, including joint positions, motion trajectories, and postures of the human body. Common motion capture data formats include ASF/AMC, BVH, C3D, etc. The study used ASF/AMC format to drive the 3DVHM. ASF contains skeleton information, defining the initial state of motion, while AMC is a motion data file. The separation of skeleton and motion information facilitates their matching [17]. Eq. (1) is the motion data frame in AMC format. In Eq. (1), f_i represents motion data. r_i^j represents the rotation information of the bone segment j in frame i. $t_{i,x}^0, t_{i,y}^0, t_{i,z}^0$ represent the translation components of the root node in the world coordinate system.

$$\begin{cases} f_i = \left\langle t_i^0, r_i^0, r_i^1, r_i^2, \ldots, r_i^n \right\rangle \\ t_i^0 = \left(t_{i,x}^0, t_{i,y}^0, t_{i,z}^0 \right) \\ r_i^j = \left(t_{i,x}^j, t_{i,y}^j, t_{i,z}^j \right) \end{cases} \tag{1}$$

The study uses a skin-bone two-layer model to construct a human bone model, numbers and names the root nodes in the ASF file, and defines the hierarchical relationship between different joint points. Bones are formed between joint points, and the end joint points store the length and direction information of the bones. The root node and joint points contain 6 and 2 degrees of freedom information, respectively, to ultimately obtain a human skeleton with physical and activity characteristics. On this basis, the study uses the 3D modeling software 3D Max to complete the 3D human body modeling, and uses the Open GL function library to draw a polygonal mesh model to obtain modeling effect map.

To drive the human skin mesh model, it is necessary to establish a connection between the skin mesh and the joints or bones, that is, to calculate the weight of the influence of bones near the skin on the skin vertices. Maya software is used to establish a skin bone model that matches the skin model, and posture matching is performed with the motion bone model constructed from ASF files. The bone node information in the skin bone model is exported, and its joint node information is consistent with the definition of the bone model in the ASF file. The initial posture matching first calculates the bone length and completes the matching of limb length. Then, the angle information between different bones is corresponded one-to-one, and the joint direction information of the skin bone model is assigned to the moving bone model.

Usually, Maya software uses the nearest distance algorithm to calculate the range of action of bones on the skin. But it only considers the distance between bone and skin vertices, ignoring the hierarchical relationship of joints will increase the estimation error of the range of action. Therefore, the study extends a certain size of bone bounding boxes along the direction of the bone and perpendicular to the bone, and uses AABB bounding boxes to divide the bone model into different regions. Based on the bone bounding boxes, the impact of the bone on the skin is determined. Fig. 1 shows the skeleton bounding box.

The specific calculation of bounding boxes generally includes data pre-processing, determining expansion direction, and expanding bounding boxes. Firstly, based on the local coordinates of the joint points and bone information, the global coordinates of the joint points are obtained. The joint point coordinates of the bone are P_i and P_{i+1}, respectively. The projection lengths of bones on different coordinate axes are represented as $x_{i+1}-x_i$, $y_{i+1}-y_i$, and $z_{i+1}-z_i$, respectively. The direction with the greatest change in length is approximately the bone's direction. The expansion coefficient of the bounding box is determined based on the human body structure. The bounding boxes of adjacent bones should intersect at a common joint point, and the expansion coefficient at the intersection is one-fifth of bone's length. The thickness of the bounding box at the bone cross-section is the thickness from the bone to the skin. However, considering the differences in bone and skin thickness in various parts of the human body, the cross-sectional expansion coefficient was set to one-third of the bone length. Fig. 2 shows the bounding box extension area.

The bone bounding box is defined as B_i. The criterion for determining whether the skin vertex $v_i\left(x_v, y_v, z_v\right)$ is in the bounding box is represented by Eq. (2).

$$\begin{cases} x_{\min}-\frac{1}{3}length \le x_v \le x_{\max}+\frac{1}{3}length \\ y_{\min}-\frac{1}{3}length \le y_v \le y_{\max}+\frac{1}{3}length \\ z_{\min}-\frac{1}{3}length \le z_v \le z_{\max}+\frac{1}{3}length \end{cases} \tag{2}$$

Fig. 3 shows the calculation principle of skin vertices. When the skin vertex is a non-joint vertex, the weight size is related to the distance between the joint and the skin vertex, and the joint weight is calculated using the linear gradient method. When the skin vertex is a vertex at a joint, it will be affected by three joints.

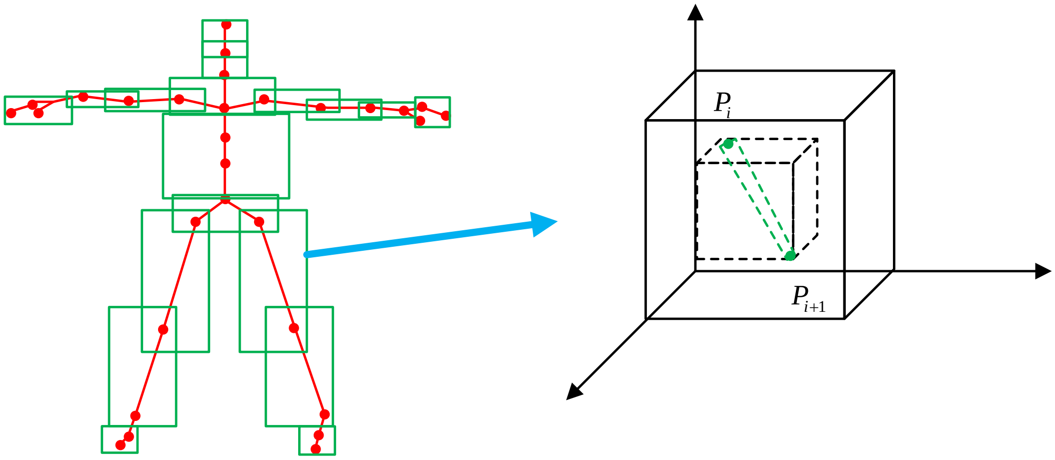

Fig. 1. Schematic diagram of the skeleton bounding box.

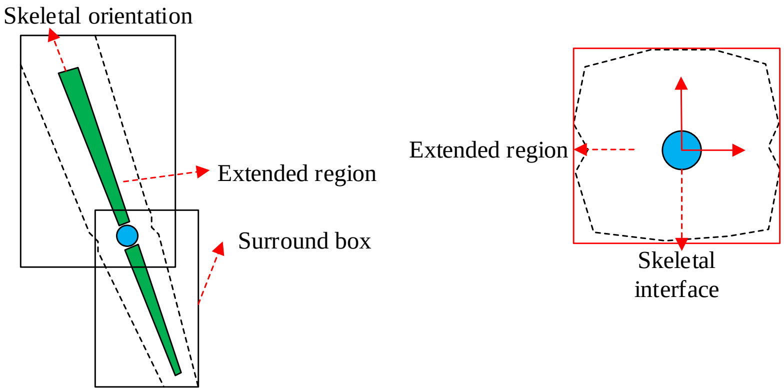

Fig. 2. Schematic diagram of the bounding box extension area.

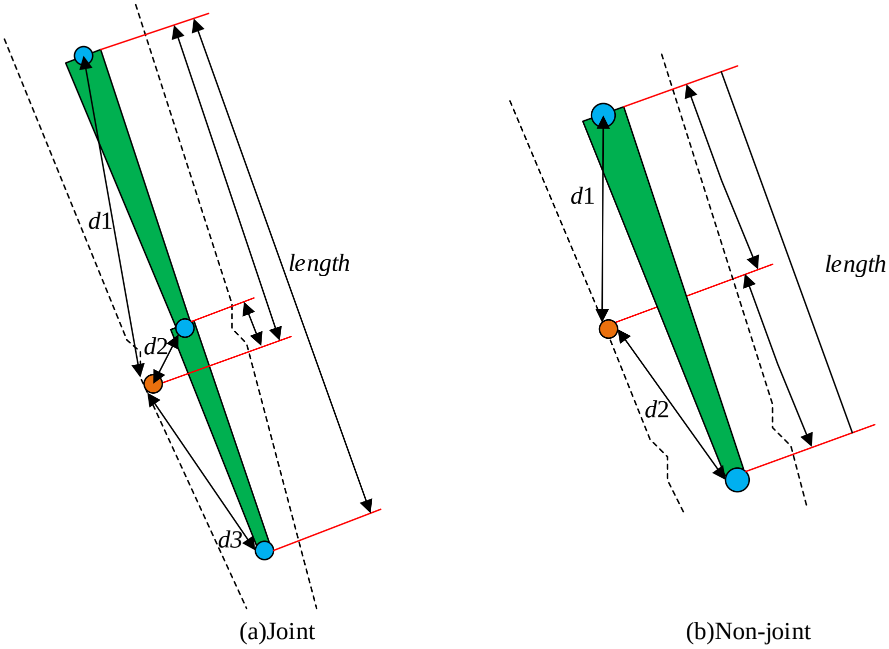

Fig. 3. Calculation principle of skin apex.

If the skin vertices are non-joint vertices, the weight calculation is represented by Eq. (3). w_a and w_b respectively represent the weights of the joint points at both ends of the skeleton within the bounding box. D_1 and D_2 respectively represent the projection of the distance from the skin vertex to the joint points at both ends in the bone direction.

$$\begin{cases} \frac{w_a}{w_b} = \frac{D_2}{D_1} \\ w_a = \frac{D_2}{D_1 + D_2} \\ w_b = \frac{D_1}{D_1 + D_2} \end{cases} \tag{3}$$

If the skin vertex is a vertex at the joint, the weight calculation is represented by Eq. (4). w_a, w_b, w_c are the joint weights.

$$\begin{cases} w_a : w_b : w_c = \frac{1}{D_1} : \frac{1}{D_2} : \frac{1}{D_3} \\ w_a = \frac{D_2 D_3}{D_1 D_2 + D_2 D_3 + D_1 D_3} \\ w_b = \frac{D_1 D_3}{D_1 D_2 + D_2 D_3 + D_1 D_3} \\ w_c = \frac{D_1 D_2}{D_1 D_2 + D_2 D_3 + D_1 D_3} \end{cases} \tag{4}$$

B. Animation Model Design Based on Dual Quaternion Hybrid Skinned Mesh Algorithm

Skin deformation is the process of transforming the skin of one object onto another object, commonly used in applications such as character animation, model fusion, and deformation [18]. It is very important in 3DVCA and plays a crucial role in achieving realistic and smooth character animation effects. SMA is an important algorithm in skin deformation technology. It associates the skeletal system of the 3D human model with the skin mesh, updates the position of the skin mesh vertices in the world coordinate system, and enables the character's skin to naturally follow the movement changes of the bones during animation [19]. The performance of SMA is related to the deformation and transformation of animated characters, determines the adjustment of model details and quality, and directly affects the efficiency and performance of rendering. The selection of SMA is very important.

Homogeneous coordinates and matrix forms are used to describe the coordinate changes in three-dimensional space. The homogeneous coordinate change is represented by Eq. (5). (x,y,z) is the original coordinate. $(x^{'},y^{'},z^{'})$ is a homogeneous coordinate. h means the scaling factor.

$$(x,y,z) \Rightarrow \begin{cases} x = x^{'}/h \\ y = y^{'}/h \\ z = z^{'}/h \end{cases} \tag{5}$$

The skin vertex undergoes translation or rotation transformation, and the transformed skin vertex $v^{'}$ is represented by Eq. (6). M, T, and R are skin vertex change, translation transformation, and rotation transformation matrices, respectively. The rotation matrix can be decomposed into the rotational changes of a point around three coordinate axes.

$$\begin{cases} v^{'} = \mathrm{M} \cdot v \\ \mathrm{M} = \mathrm{T} \cdot \mathrm{R} \end{cases} \tag{6}$$

The motion of the designed 3D virtual is based on the global coordinate system, and the basic position of the model is determined by the root nodes and joint points of the skeleton. The motion of the joint points is defined relative to the position of the parent node, and these two affect each other. So the base coordinate system and local coordinate system in Fig. 4 are introduced to describe this bone model. The base coordinate system refers to the coordinate system established with the sacral joint point as the origin in the initial pose of a three-dimensional virtual human. The local coordinate system is the rotational information defined relative to the global coordinate system.

The change in the coordinate line of any joint point is represented by Eq. (7). φ, α, and β are the angles at which a node rotates around z,x,y axes. G_i represents the rotation offset matrix of the related node relative to the parent node in the world coordinate system.

$$G_i = R_i^z(\varphi) \cdot R_i^x(\alpha) \cdot R_i^y(\beta) \cdot T_i \cdot \left[R_i^z(\varphi)\right]^{-1} \cdot \left[R_i^x(\alpha)\right]^{-1} \cdot \left[R_i^y(\beta)\right]^{-1} \tag{7}$$

The global change matrix M_i is represented by Eq. (8). $f(i)$ is the parent node number of the joint point. F means a set of all node numbers. G_0 represents the global affine transformation matrix of the root node, $G_0 = R_0 \cdot T_0 \cdot R_0^{-1}$.

$$M_i = G_0 \cdot \ldots \cdot G_{f(i)} \cdot G_i = \prod_{k=0,k\in F}^{i} G_k \tag{8}$$

SMA uses transformation matrices to bind skin and bones, and the calculation of LBS is represented by Eq. (9). $v^{'}$ and v_0 are the positions of skin vertices after and before the transformation, respectively. n represents the number of bones that affect the current skin. D_i means the global affine transformation matrix from the local coordinates of the skeleton to the global coordinates in the initial state of the model, and its calculation is similar to M_i.

$$v^{'} = \sum_{i=1}^{n} w_i M_i D_i^{-1} v_0 \tag{9}$$

The transformation process from skin vertices in the global coordinate system to the local coordinate system in the initial state is the inverse transformation of Eq. (9). After transformation, AMC data are used for motion transformation to complete skin deformation. The deformation calculation is consistent with Eq. (8), and the values of the rotation offset matrix are analyzed and read based on AMC data. Fig. 5 shows the working mechanism of the entire LBS.

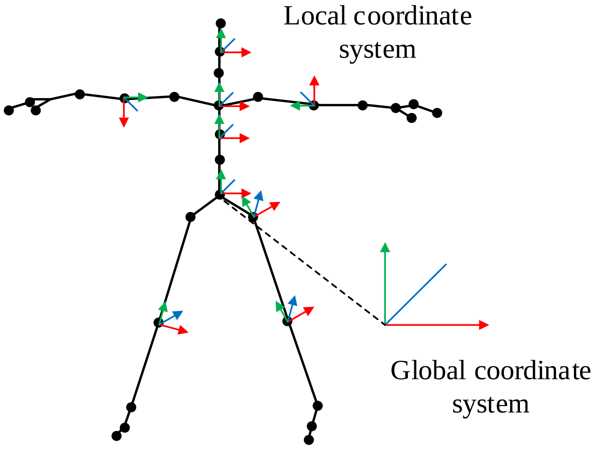

Fig. 4. Global coordinate system and local coordinate representation.

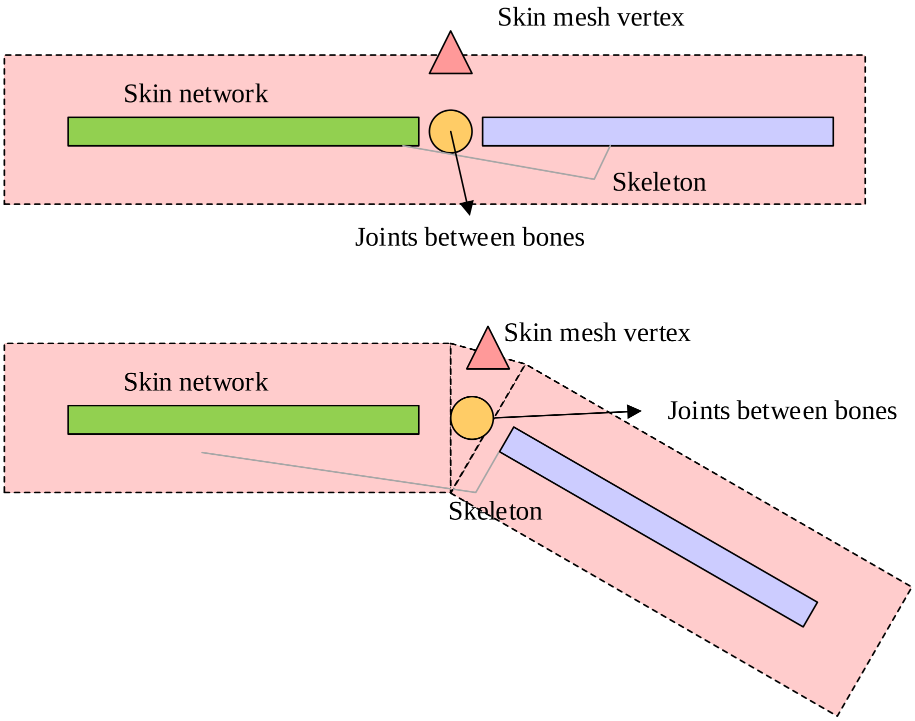

Fig. 5. Schematic diagram of skin deformation.

LBS is widely used in skin deformation calculation, but there are still significant application defects in LBS. LBS calculates bone influence weights through linear interpolation. When vertices are affected by multiple bones or overlap with multiple bones, it is easy to cause volume scaling or cross deformation problems [20]. Therefore, the study improves on the basis of LBS and designs a dual quaternion hybrid SMA using dual quaternions. The dual quaternion $\overset{\$}{q}$ consists of pairs of even numbers and quaternions, the two expressions for even numbers are given in Eq. (10). One way of expressing this can be understood as a quaternion in which all elements of the formula are pairs of even numbers, and the other expression can be understood as a quaternion in which all elements are pairs of even numbers. $w,\overset{\$}{x},\overset{\$}{y},\overset{\$}{z}$ are even numbers. q,q_{ε} are quaternions, representing the real and dual parts respectively, the real part contains the rotation information. ε means dual units. i,j,k are orthogonal unit vectors.

$$\begin{cases}\overset{\$}{q}=w+i\overset{\$}{x}+j\overset{\$}{y}+k\overset{\$}{z}\\ \overset{\$}{q}=q+\varepsilon q_{\varepsilon}\end{cases} \tag{10}$$

The unit dual quaternion of the three-dimensional space vector $\vec{r}=\left(r_0,r_1,r_2\right)$ is represented by Eq. (11). When $q_{\varepsilon}=0$, $\overset{\$}{q}\overset{\$}{r}\overline{\overset{\$}{q}}^{*}$ means the rotational transformation of the rigid body. $\overset{\$}{q}^{*}$ and $\overline{\overset{\$}{q}}$ are conjugate and dual conjugate of dual quaternions, respectively.

$$\hat{r}=1+\varepsilon\left(r_0 i+r_1 j+r_2 k\right) \tag{11}$$

The unit dual quaternion of the translation transformation vector $\vec{t}=\left(t_0,t_1,t_2\right)$ of a rigid body is represented by Eq. (12). $\overset{\$}{t}\overset{\$}{r}\overline{\overset{\$}{t}}^{*}$ is the translation transformation of a rigid body.

$$\hat{t}=1+\frac{\varepsilon}{2}\left(t_0 i+t_1 j+t_2 k\right) \tag{12}$$

The process of a rigid body rotating first and then translating in three-dimensional space is represented by Eq. (13), which means that the dual quaternion $\hat{t}q$ can achieve the process of rotating first and then translating.

$$\hat{t}\left(q\hat{v}\overline{q^{*}}\right)\overline{\hat{t}}^{*}=\left(\hat{t}q\right)\hat{v}\overline{\left(\hat{t}q\right)}^{*} \tag{13}$$

The transformation matrix in LBS is converted into a dual quaternion, and the translation information in the matrix is defined as $\overset{'}{a}=\left(a_{14},a_{24},a_{34}\right)$. The transformation between the translation matrix and the unit dual quaternion is represented by Eq. (14).

$$\left(a_{14},a_{24},a_{34}\right)=\left(t_0,t_1,t_2\right) \tag{14}$$

The coordinate of the skin vertex position $p^{'}$ after linear mixing of dual quaternions is represented by Eq. (15). p is the position coordinate of the current skin mesh vertex. w_i is the weight. Eq. (15) represents the process of mixing and unitizing the global transformation matrix according to the weight values after transforming it into dyadic quaternions.

$$p' = \frac{\sum_{i=1}^{n} w_i \hat{q}_i}{\left\| \sum_{i=1}^{n} w_i \hat{q}_i \right\|} p \tag{15}$$

Through this change, LBS converts the linear transformation of the global transformation matrix $E_i = M_i D_i^{-1}$ into linear mixing of dual quaternions. The mixing of dual quaternions was completed based on the weight size. The mixed dual quaternions are unitized and then transformed into a transformation matrix, which are multiplied by the coordinates of the skin vertices to update the skin vertices. Fig. 6 shows the workflow of the entire dual quaternion mixed SMA.

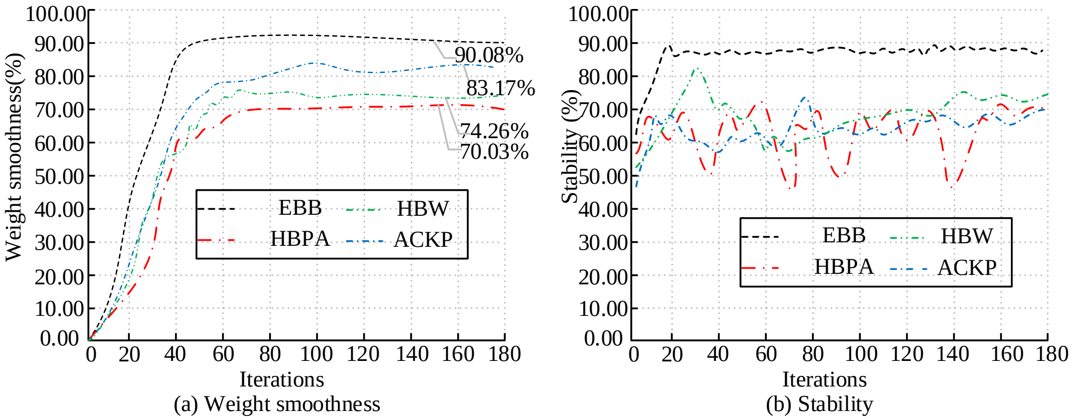
IV. Performance Testing and Application Analysis of Computer Skeletal Skinned Mesh Algorithm Animation Design

To verify the application effect of the bone SMA designed in the design of 3DVHMs, relevant performance tests and effect evaluation experiments were designed, and the results were analyzed and discussed.

A. Performance Testing of Weight Calculation Method Based on Posture Matching and Dual Quaternion Hybrid Skinned Mesh Algorithm

Experimental Environment Setting: The experiment was conducted on an operating system running on Windows 7, i7 CPU, GTX1060 GPU, and 16GB of memory. All algorithm models were implemented using C++and Python programming. Firstly, the designed posture matching-based Extended Bounding Box (EBB) weight calculation method were compared with other weight calculation methods for skin vertices, including Heat Balance Principle Algorithm (HBPA), Approximation Calculation of Skeletal Projection (ACKP), and Hand brush weight (HBW). Weight smoothness and stability were selected as the evaluation indicators for testing. Fig. 7 shows the experimental results. The EBB-based weight calculation method, which corresponded to the pose of the sports skeleton and skin skeleton models, performed well in the smoothness of skin surface weight. After 180 iterations, its weight smoothness finally stabilized at 90.08%, which was significantly better than other methods and 20.05 percentage points higher than HBPA of 70.03%. Meanwhile, this method had better stability in weight calculation and lower error rates for different models.

To conduct performance testing on SMA, a program was written using C++ language in the VC++6.0 software to implement the required algorithms for testing. The designed Dual Quaternion Blending Skinning (DQBS) was compared with Spherical Hybrid Skinning Deformation Algorithm (SHSD), Skinning Algorithm Based on Position-Based Dynamics (SA-PBD), and traditional linear hybrid SMA. 1686 sets of 3D virtual character models created by the design and modeling team of a certain animation development company were selected as the test dataset, which was divided into a training set and a testing set in a 7:3 ratio.



(a) Weight smoothness

(b) Stability

Fig. 7. Comparison of weight smoothness and stability of different weight calculation methods.

Comparing the precision and recall of four SMA algorithms, Fig. 8 shows the PR curves of different algorithms. PR is a curve drawn with precision as the vertical axis and recall as the horizontal axis. When the precision of the designed DQBS was 80% and 90%, the corresponding recall was 75.89% and 85.98%, respectively. In contrast, when the precision was 90, the recall of SHSD, SA-PBD, and LBS was 61.98%, 57.74%, and 50.16%, respectively. The precision and recall of SHSD, SA-PBD, and LBS were significantly lower than those of the study design method.

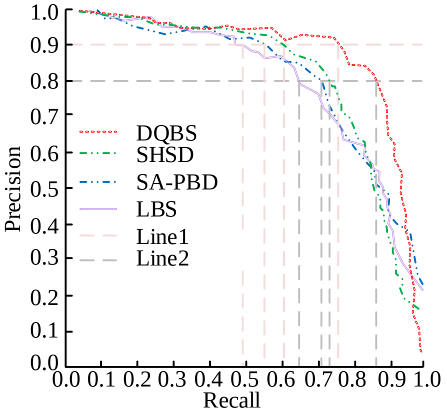


Fig. 8. Comparison of accuracy and recall rates of different skin algorithms.

The Receiver Operating Characteristic (ROC) curve is selected to evaluate different SMAs, and Fig. 9 shows the results. AUC is the area below ROC, used to measure the stability of model performance and overall effectiveness. Different SMAs had different AUC values, and the designed DQBS had the highest AUC, reaching 0.927. SA-PBD had the smallest AUC, only 0.634. Overall, the designed SMA performs better.

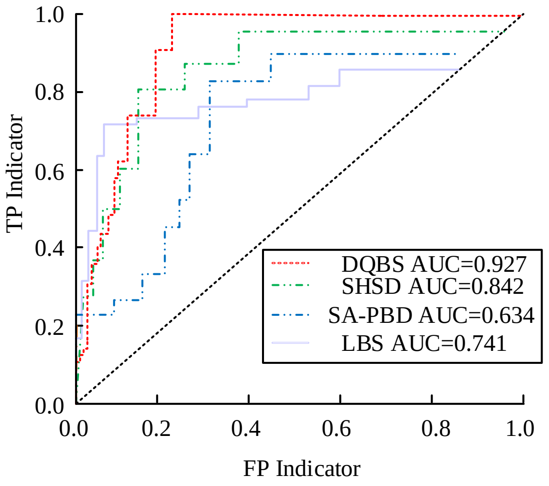

Fig. 9. Comparison of ROC curves for different skin algorithms.

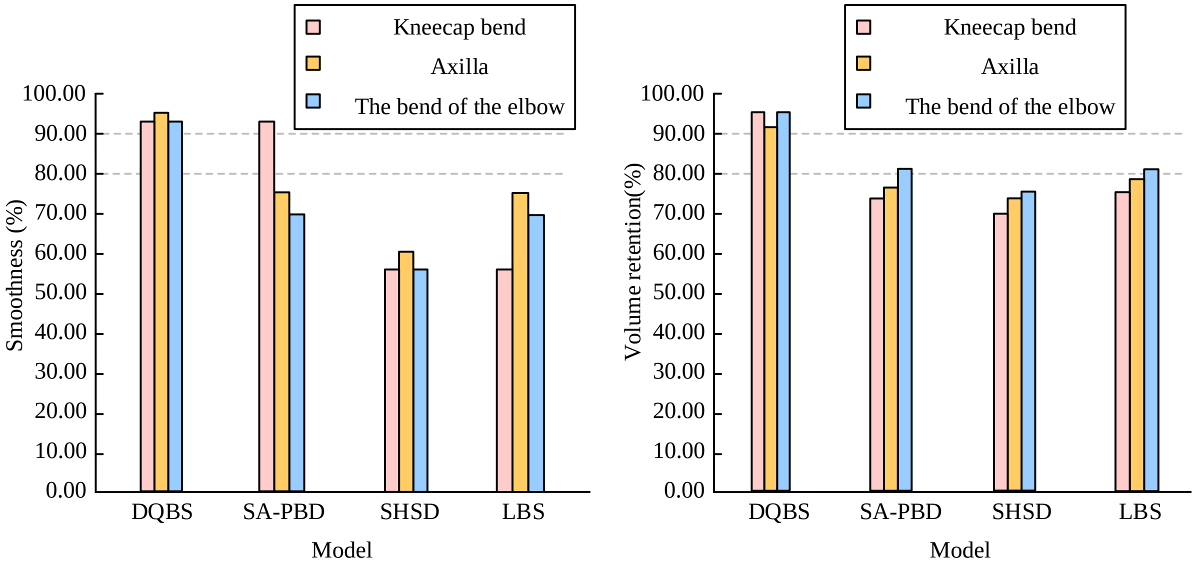
B. Evaluation of Skinned Effects for 3d Virtual Human Based on Dual Quaternion Hybrid Skin

The simulation system for skin animation uses Visual Studio 2010 as the development platform and motion capture data ASF/AMC files designed and developed by Acclaim Games. The skin effects of SMA with inherent defects were compared, and the knee bone bending, armpit bending, and elbow bending with larger joint rotation were selected. From an objective evaluation perspective, smoothness and volume retention rate were selected as evaluation indicators for effect comparison. Fig. 10 shows the experimental results. After 50 iterations, the smoothness and volume retention of the SMA in three different parts were all above 90.00%. The designed model did not show obvious collapse, and the volume loss of the model was relatively small.



(a) Smoothness

(b) Volume retention

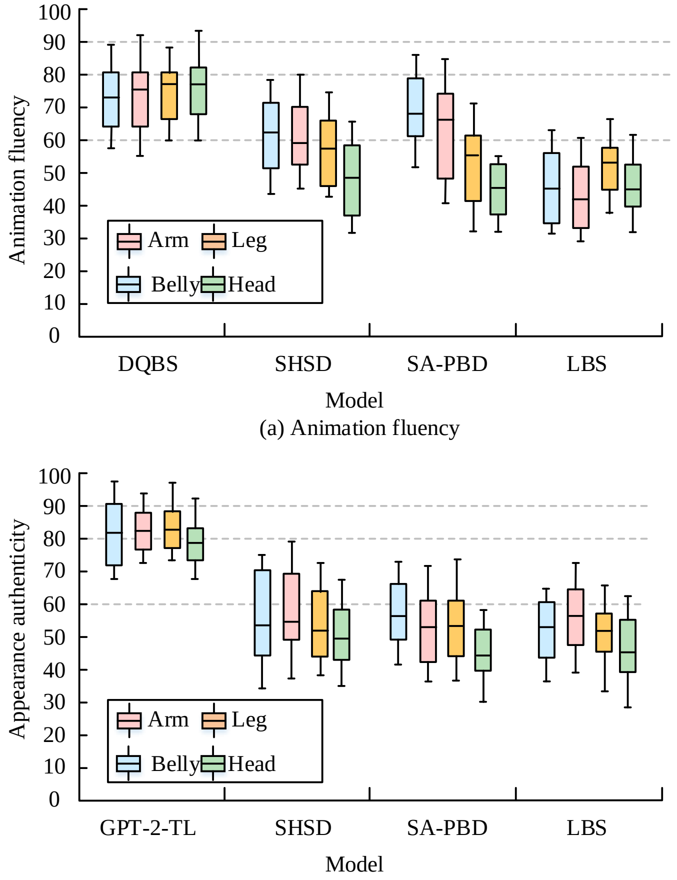
Fig. 10. Comparison of smoothness and volume retention of different skinning algorithms.

The study selected objective and subjective evaluation indicators, including model generation time, bone generation time, skin time, memory usage, stability, texture preservation ability, usability, and scalability. Table I shows the statistical results. The calculation time of DBQS was short, and the skinning time was only 0.49S. Its entire weight allocation, vertex transformation, and interpolation processes were calculated at a fast speed, and the memory usage was only 1247K, indicating good performance. In addition, the stability and texture retention ability of DBQS reached 90.63% and 80.68%, respectively, significantly higher than other SMAs. The subjective evaluation indicators had obvious advantages in usability and scalability, both exceeding 85%.

Finally, animation fluency and appearance realism were selected to rate the 3DVHM. A total of 30 users were gathered to evaluate the generation models of different SMAs from the perspectives of arms, legs, abdomen, and head. Fig. 11 shows the experimental results. Authenticity is the evaluation of whether the final effect of a model is realistic and whether it can provide users with an immersive feeling. Fluency is the evaluation of whether the animation effect is smooth and natural, especially in complex deformations and actions, whether it can maintain good continuity and fluency. In Fig. 11, the fluency and authenticity scores of DBQS were relatively high in different parts, with median scores ranging from 70 to 80. Its overall effect is good.

TABLE I. COMPARISON OF SUBJECTIVE AND OBJECTIVE EVALUATION OF DIFFERENT SKIN ALGORITHMS

Evaluating indicator	DBQS	SA-PBD	SHSD	LBS
Model generation time	13.35S	15.19S	12.73S	18.25S
Bone formation time	1.20S	1.32S	1.29S	1.41S
Skin time	0.49S	0.52S	0.74S	0.96S
Internal memory	1247K	2871K	3217K	4126K
Stability	90.63%	63.45%	73.01%	72.35%
Texture retention	80.68%	68.97%	76.17%	62.06%
Expandability	94.73%	72.01%	69.39%	84.14%
Ease of use	86.21%	74.58%	66.37%	77.69%



(a) Animation fluency

(b) Appearance authenticity

V. CONCLUSION

The 3D virtual human skeleton skin animation technology is the key to 3DVCA creation. To achieve more realistic 3D virtual human animation effects and achieve precise bone skin deformation, a skin vertex weight calculation and hybrid SMA for virtual characters were studied and designed. These experiments confirm that the designed EBB-based weight calculation algorithm performs well in weight smoothness and stability, with the highest smoothness reaching 90.08%, which is 20.05 percentage points higher than the lowest value. After 50 iterations, the designed SMA has higher smoothness and volume retention in different parts, and there is no obvious collapse phenomenon and the volume loss rate is relatively small. The calculation time of DBQS is short, the skinning time is only 0.49S, and the memory usage is only 1247K. Its stability and texture retention ability reaches 90.63% and 80.68%, respectively. Its subjective evaluation indicators have obvious advantages in usability and scalability. DBQS has high scores for fluency and authenticity in four different parts, with median scores ranging from 70 to 80. Its overall effect is more realistic. The designed SMA has obvious advantages in the application of 3D virtual human animation design. The skin of virtual characters can naturally follow the movement changes of bones during animation. This is a more realistic presentation of character animation, which is the technical key to improving animation realism, smoothness, and rendering efficiency. However, research has adopted a double-layer structure to model virtual humans, and future research can adopt more accurate skeleton extraction algorithms. The study did not involve changes in the muscles of the characters, nor did it simulate facial expressions and expressions, which can be a focus of future research work.

VI. SYMBOL INDEX

All conforming explanations in the text are shown in Table II.

TABLE II. INTERPRETATION OF SYMBOLS USED IN THE STUDY

Notation	Interpretations
3DVCA	3D Virtual Character Animation
3DVHM	3D Virtual Human Model
SMA	Skinned Mesh Algorithm
EBB	Extended Bounding Box
HBPA	Heat Balance Principle Algorithm
HBW	Hand brush weight
DQBS	Dual Quaternion Blending Skinning
SA-PBD	Skinning Algorithm Based on Position-Based Dynamics
SHSD	Spherical Hybrid Skinning Deformation Algorithm
ROC	Receiver Operating Characteristic
LBS	Linear Blending Skinning

Abstract*—In this innovative exploration, "Applying Computer Vision Techniques in STEM-Education Self-Study," the research delves into the transformative intersection of advanced computer vision (CV) technologies and self-directed learning within Science, Technology, Engineering, and Mathematics (STEM) education. Challenging traditional educational paradigms, this study posits that sophisticated CV algorithms, when judiciously integrated with modern educational frameworks, can profoundly augment the efficacy of self-study models for students navigating the increasingly intricate STEM curricula. By leveraging state-of-the-art facial recognition, object detection, and pattern analysis, the study underscores how CV can monitor, analyze, and thereby enhance students' engagement and interaction with digital content, a pioneering stride that addresses the prevalent disconnect between static study materials and the dynamic nature of learner engagement. Furthermore, the research illuminates the critical role of CV in generating personalized study roadmaps, effectively responding to individual learner's behavioral patterns and cognitive absorption rhythms, identified through meticulous analysis of captured visual data, thereby transcending the one-size-fits-all educational approach. Through rigorous qualitative and quantitative research methods, the paper offers groundbreaking insights into students' study habits, proclivities, and the nuanced obstacles they face, facilitating the creation of responsive, adaptive, and deeply personalized learning experiences. Conclusively, this research serves as a clarion call to educators, technologists, and policy-makers, emphatically demonstrating that the thoughtful application of computer vision techniques not only catalyzes a more engaging self-study landscape but also holds the latent potential to revolutionize the holistic STEM education ecosystem.

I. INTRODUCTION

In the rapidly evolving educational landscape, traditional teaching methodologies are incessantly being re-evaluated and challenged, particularly in Science, Technology, Engineering, and Mathematics (STEM) disciplines. The advent of digital technology has reshaped pedagogical strategies, heralding new approaches like self-directed learning, which has gained prominence for fostering students' autonomy and responsibility in the learning process [1]. However, maximizing the efficacy of self-study in STEM education requires addressing intrinsic complexities and diverse student engagement methodologies [2]. This research aims to bridge this gap by harnessing computer vision (CV) techniques, offering a transformative perspective on enhancing self-study's effectiveness in STEM education.

STEM fields, inherently multifaceted and dynamic, demand educational approaches that not only convey complex concepts but also adapt to individual cognitive styles and paces [3]. Traditional self-study, while offering flexibility, often falls short of this adaptability, leading to learner frustration and sub-optimal learning outcomes [4]. Computer vision's potential in education, particularly in monitoring and responding to student engagement and facilitating personalized learning trajectories, remains largely underexplored [5].

Computer vision, a field that grants computers a high-level understanding of digital images and videos, is traditionally aligned with applications in security, surveillance, and detection [6-7]. However, its implications extend profoundly into educational realms. Through detailed visual data analysis, CV holds the promise of decoding student engagement patterns, providing educators with nuanced insights into the often imperceptible aspects of self-study behaviors that either catalyze or hinder learning. This research pivots around the innovative application of CV in capturing and analyzing these intricate behavioral nuances, thereby guiding the development of more responsive and adaptive self-directed learning models.

Integrating CV into education, especially within STEM, poses unique challenges and opportunities. The precision required in STEM subjects translates to the necessity for educational resources to adapt in real-time to students' understanding, ensuring concepts are neither misinterpreted nor oversimplified [8]. By employing CV techniques, such as facial recognition and object detection, it becomes feasible to analyze students' interaction with educational content, thereby tailoring materials and study paths that resonate with individual learning approaches, an advancement far beyond the capabilities of traditional educational software [9].

Moreover, the role of CV in tracking and analyzing engagement brings a new dimension to educators' understanding of student performance. Conventional assessment methods offer only summative feedback, often neglecting the formative aspects of a learner's journey [10]. Through continuous and non-intrusive monitoring, CV provides a wealth of formative feedback, empowering educators to make informed, timely interventions and students to gain awareness of their learning habits.

Significantly, the ethical considerations of utilizing CV in education are paramount, entailing careful navigation. Privacy concerns, data security, and the consent of the involved parties are crucial factors that educators and technologists must prioritize. Establishing robust ethical protocols and transparent operational guidelines ensures the responsible use of CV in educational settings, safeguarding participants' fundamental rights while harnessing technology's benefits [11].

In light of the above, this study ventures into an interdisciplinary examination of how CV can revolutionize self-study within STEM education. It builds on existing literature that outlines the theoretical frameworks of self-directed learning and delves into empirical evidence supporting the integration of advanced technologies in education [12]. By establishing a symbiotic relationship between CV technology and educational pedagogy, this research underscores a forward-thinking approach to cultivating STEM competencies, proposing a model that respects individual cognitive differences and celebrates personalized educational journeys.

Through this paper, we invite educators, technologists, and policy-makers to envision a future where technology and education converge to offer enriched, student-centric learning experiences. By navigating the technical, pedagogical, and ethical terrains of this integration, we aim to construct a comprehensive understanding that could fundamentally transform the way STEM education perceives and leverages self-study.

II. Related Works

The synthesis of technology and education, especially in self-directed STEM learning, has instigated a plethora of research, with various studies corroborating the transformative potential of integrating advanced technological frameworks, such as computer vision (CV), into educational models. These scholarly pursuits, encompassing a diverse range of insights and findings, lay the groundwork for understanding the trajectory and implications of utilizing CV in self-regulated learning environments.

Starting with the broader impacts of technology in education, studies have indicated a paradigm shift in instructional strategies, emphasizing the need for more learner-centric approaches facilitated by technology [13]. In the context of STEM education, researchers have highlighted the necessity for innovative methods that cater to enhancing students' critical thinking and problem-solving skills, proposing that digital technologies can bridge the gap between theoretical knowledge and practical application [14].

The concept of adaptive learning, pivotal to this discussion, leverages technology to tailor educational experiences to individual needs. One study [15] provide insights into adaptive learning systems' role in promoting cognitive growth, arguing that these systems accommodate diverse learners' profiles, thereby fostering a more inclusive learning environment. However, the challenge remains in effectively tracking and interpreting individual learner interactions and responses in real-time, a gap that computer vision promises to address [16].

Computer vision’s foray into educational strategies marks a relatively new venture. Its application has been predominantly explored in surveillance, recognition systems, and user interaction tracking in various sectors [17]. Within educational research, studies have often circumscribed their focus to online learning environments, utilizing simple CV techniques for user log-in and basic interaction [18]. However, more nuanced applications of CV, such as emotion recognition, behavioral analysis, and engagement tracking, are emerging themes in contemporary literature [19].

Next study [20] delve into the potential of CV in recognizing and interpreting human emotions, an aspect crucial for personalizing learning experiences. They argue that emotional states play a significant role in learning efficiency, with certain emotional conditions favoring the absorption and retention of new information. Incorporating CV into educational platforms could thus allow for real-time adaptation based on learners' emotional cues, providing immediate feedback or altering content presentation to enhance learning efficacy [21].

Furthering the discourse on personalized learning, researchers have explored data-driven approaches. For example, [22] highlights the importance of learning analytics in understanding students' learning processes. They discuss how data obtained from students' digital footprints on learning platforms can inform more personalized and effective teaching strategies. This data-centric approach aligns with the capabilities of CV in capturing and analyzing extensive datasets of learner interactions and behaviors [23].

In the realm of self-directed learning, especially in online and digital contexts, maintaining student engagement and motivation is paramount. Studies by Chen, Lambert, and Guidry [24] underscore the challenge educators face in keeping students engaged with digital platforms. CV's potential to monitor visual cues and physical responses presents unprecedented opportunities for understanding and enhancing student engagement on a much finer, more personalized scale [25].

The integration of CV in education also extends to practical skill-based learning in STEM. For instance, research on laboratory learning indicates that CV can significantly enhance remote laboratory experiences, a critical component of STEM education. Gravier, Fayolle, Bayard, Ates, and Lardon [26] have explored these prospects, emphasizing that CV can facilitate more interactive and hands-on experiences in a virtual environment.

Despite the promising advancements, the literature consistently echoes the ethical implications of employing CV in educational settings. Privacy concerns, particularly with facial recognition and behavioral tracking, are prevalent [27]. Next research [28] stresses the need for robust privacy protection frameworks, emphasizing informed consent, data security, and transparency in how monitoring technologies are used in education. These considerations are crucial in ensuring the ethical integrity of integrating any form of surveillance or tracking technology into learning environments.

Conclusively, the body of work surrounding the integration of computer vision in education outlines a landscape ripe with potential yet requires careful navigation concerning ethical, technical, and pedagogical constraints. This research contributes to this ongoing scholarly dialogue, contextualizing the application of CV within the specific challenges and opportunities presented by self-directed STEM education [29-32]. Through an interdisciplinary lens, this study seeks to build upon the foundations laid by existing literature [33-37], proposing an innovative convergence of CV technology and educational pedagogy to enhance the quality and effectiveness of self-study in STEM disciplines.

III. Materials and Methods

In order to investigate the central research query, several "STEM Workshops: Python and Raspberry Pi Practical Activity" were organized as a precursor to the main experimental procedure. These preliminary sessions were instrumental in gathering the necessary data for the creation and subsequent validation of the RASEDS, directly contributing to the resolution of the initial research query. Once the efficacy of RASEDS was confirmed, the data derived from the system were harnessed to develop a predictive model for student performance in STEM subjects. Subsequently, this predictive mechanism was designed to suggest customizable learning resources, tailored to forecasted performance trends. Our research adopted a quasi-experimental design to ascertain whether introducing personalized educational resources, recommended through RASEDS, could significantly improve student involvement and confidence in STEM-related tasks, thereby providing comprehensive answers to the second and third research inquiries. The sequence of research activities is graphically represented in Fig. 1.

To meticulously record the nuances of each learner's practical engagement, we strategically installed cameras to film their hands-on interaction with the educational materials, a critical component for the RASEDS's engagement detection mechanism. Care was taken in choosing camera perspectives that would clearly record the learners' hands and the instructional tools they used. Mindful of the ethical considerations when filming individuals, especially those underage, we established rigorous measures to secure informed consent from all attendees or their legal guardians (for those younger than 18. This measure was pivotal in maintaining ethical standards concerning the visual content that included identifiable participant imagery.

In the aftermath of these sessions, we collected 4,515 photographs. These were methodically divided into primary and secondary datasets, following an 80:20 split. Consequently, we allocated 3,612 photographs for initial training purposes and reserved 903 as a subsequent test collection. These images are integral to the training phase of the YOLOR model, representing a significant stride towards achieving our research's overarching goals.

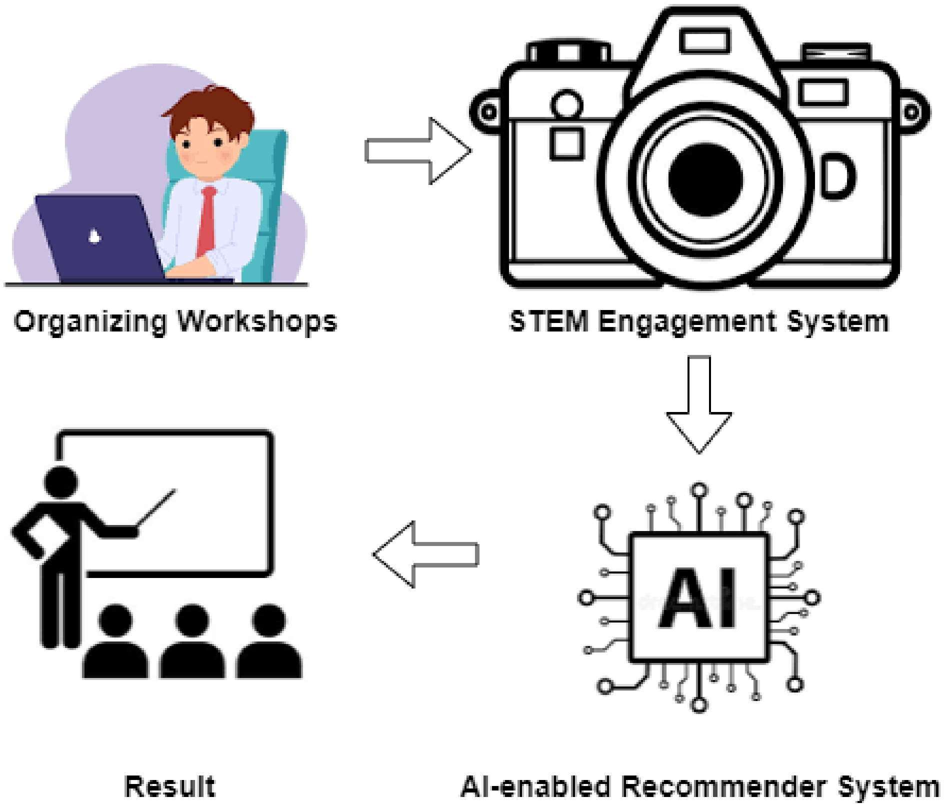

Fig. 1. Flowchart of the proposed system.

Following the workshop's end, the participants showcased their STEM initiatives, firmly rooted in the Internet of Things (IoT) sphere. Utilizing the insights gained about sensors and coding principles throughout the workshop, the students embarked on devising creative approaches to tangible issues through the application of IoT. Their ventures spanned various concepts, from intelligent domestic setups and energy-saving configurations to automated methods promoting greener lifestyles and operational spaces.

Upon the conclusion of the project presentations, each was subjected to a thorough analysis conducted by two connoisseurs within the STEM domain. The assessment protocol was grounded in the principles specified by the Creative Product Analysis Matrix (CPAM) approach, involving three broad categories and nine evaluative markers, elaborately itemized in Table I. This technique of appraisal, validated in its efficacy by Besemer in 1998, guaranteed an exhaustive and precise examination of the students' endeavors.

TABLE I. DIALOG TESTS IN CLASSROOM

Scale	Indicator
Novelty	Original
	Amazing
Resolution	Valuable
	Useful
	Understandable
Synthesis	Organic
	Elegant
	Good

Evaluation was carried out utilizing a five-point Likert scale, enabling a detailed interpretation of each project's merits and areas for improvement. The consistency of scoring between the two experts was confirmed, with a correlation coefficient marking between 0.68 and 0.84. This high degree of concordance underscored the substantial agreement in their assessments, bolstering the integrity of the evaluation phase. Such a metric reinforced the consistency and trustworthiness of the ratings given, laying a dependable groundwork for the authentic data essential for substantiating the predictive model of STEM learning outcomes.

In response to the intricate and ever-evolving facets of STEM activity-based learning, we pioneered a system known as the Real-time Automated STEM Engagement Detection System. This system is designed to autonomously and instantaneously gauge students' engagement levels. At its core, RASEDS utilizes cutting-edge object detection, particularly the YOLOR method, to pinpoint the presence of students' hands and all associated educational materials engaged during the tasks. This interaction between the students' hands and the educational tools is documented, reflecting direct insights into the students' immediate actions. These consequential behaviors are then aligned with the parameters set by the ICAP framework, serving as a robust metric for evaluating student engagement throughout STEM-centric tasks.

This study engages with the SHAP (SHapley Additive exPlanations) methodology, an advanced technique within the realm of interpretable artificial intelligence, to critically analyze the contributory features inherent in the academic performance prediction model. Concurrently, an intriguing observation emerges from the C1 cohort, exhibiting a marginal enhancement in predictive accuracy relative to the established baseline, which is preliminarily set at 50%. This nuanced increment, albeit minimal, signals a critical inference: the interactive dynamics encapsulated within the online classroom environment exert a relatively insubstantial influence on the academic trajectories associated with non-STEM coursework. This revelation underscores the necessity for a differential pedagogical approach, potentially customized to the distinct educational exigencies of STEM and non-STEM curricula.

IV. EXPERIMENTAL RESULTS

A. Evaluation of Emotional Expression of Students

We implemented a quasi-experimental approach to investigate the impact of using RASEDS for recommending adaptive learning materials in STEM education, particularly in enhancing student engagement and self-confidence. This experiment was integrated into the 'Networks Embedded System and Application' course, spanning two academic terms. While students undertook the course independently, collaboration and dialogue were encouraged during the project development phase. Emphasizing IoT and AI, the course required students to leverage their understanding of both software and hardware to devise solutions for real-world challenges, thereby resonating with the fundamental tenets of STEM education (see Fig. 2).

The experimental phase of the study was meticulously structured and spanned duration of seven weeks. This phase was critically segmented into two distinct assessment periods, wherein participants from diverse groups were engaged in comprehensive evaluations. The primary objective of these assessments was to ascertain and quantify two fundamental dimensions: the degree of participant involvement and the perception of personal competence.

At the outset of the experimental phase, in the first week, an initial assessment was conducted. This preliminary evaluation served as a baseline measurement, establishing the initial state of participant engagement and their self-assessed competence. This was crucial for providing a reference point against which any subsequent changes could be measured. The initial assessment was designed to be comprehensive, ensuring that all relevant aspects of involvement and personal competence were adequately captured.

As the program progressed, participants continued their engagement in the designed activities and interventions. This progression was systematically documented and is visually represented in Fig. 3 of the study. The figure illustrates the temporal flow of the program, marking key milestones and the transition from the initial to the final stages.

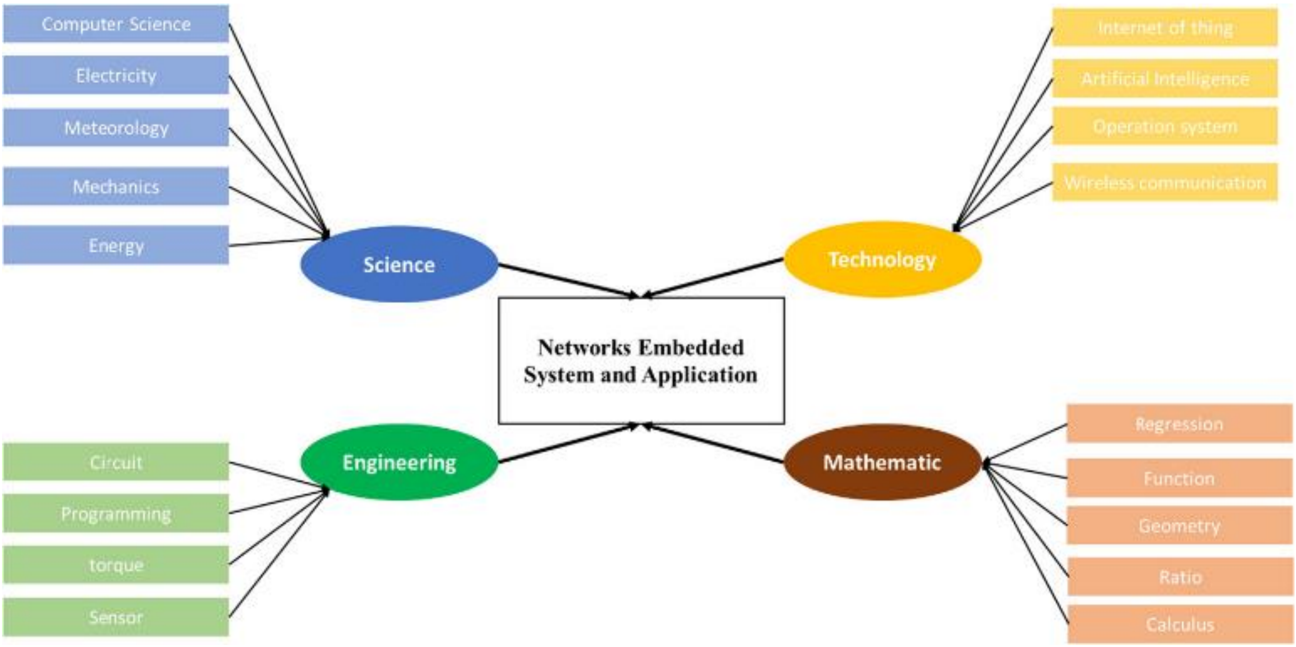

Fig. 2. STEM education process in Application

Presenting and Sharing Findings in the Classroom
Post-test and Questionnaire
Week 7

Fig. 3. Pretest and posttest engagements of self-efficacy.

In the concluding phase of the program, during the fifth week, a final assessment was conducted. This assessment mirrored the initial one in structure but aimed to capture the evolved state of participant involvement and competence. The comparison between the initial and final assessments was pivotal in determining the effectiveness of the program. It enabled the researchers to quantify the changes in the levels of involvement and personal competence, attributing these changes to the interventions and activities experienced by the participants.

In summary, the experimental phase, with its well-defined and strategically placed assessments, provided a robust framework for evaluating the impact of the program on participant involvement and personal competence. The assessments, anchored at the beginning and end of the program, offered critical insights into the developmental trajectory of the participants, as detailed in Fig. 3.

The outcomes derived from the confusion matrix, presented in Fig. 4, enable the computation of precision, recall, and F1 score for each category of engagement as detected by RASEDS. In the realm of machine learning model evaluation, a confusion matrix serves as a pivotal tool, offering nuanced insights into the classification prowess of a model across various categories [38]. The presented matrix delineates the performance of a classifier in segregating data into five distinct classes: Interactive, Constructive, Active, Passive, and Other. The matrix's structure, with rows representing actual classes and columns depicting predicted classes, provides a comprehensive view of both the model's accuracy and its errors in classification.

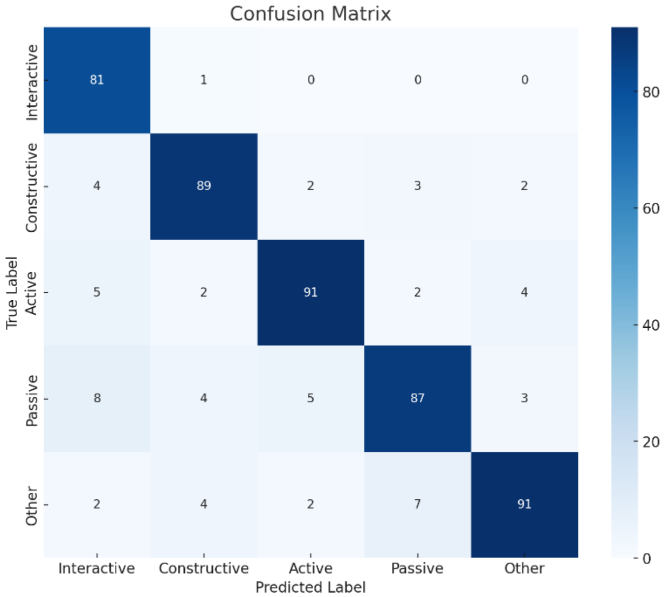

Fig. 4. Experimental results.

A closer inspection of the matrix reveals intricate details about the model's performance. For the 'Interactive' class, there is a prominent diagonal element of 81, indicative of a high rate of correct predictions. However, there is a noticeable misclassification with the 'Passive' and 'Constructive' categories, as evidenced by the presence of 8 and 4 instances, respectively, in these columns. This pattern suggests a certain level of ambiguity or overlap in the defining characteristics of these classes as interpreted by the model.

The 'Constructive' class exhibits impressive prediction accuracy, with 89 instances correctly classified. Nonetheless, there are marginal confusions with the 'Interactive', 'Active', and 'Passive' classes, albeit to a lesser extent than observed in the 'Interactive' class. This points to a generally robust model performances in this category, with room for improvement in differentiating finer nuances between certain classes.

For the 'Active' and 'Passive' classes, the model demonstrates commendable predictive accuracy, as indicated by 91 and 87 correct predictions, respectively. Misclassifications in these categories are relatively lower, suggesting that the model effectively captures the distinct features of these classes. The 'Other' category, with a high correct prediction count of 91, confirms the model's capacity to accurately identify instances that do not conform to the primary classes.

In sum, the confusion matrix provides an invaluable quantitative assessment of the model's classification abilities, highlighting areas of strength and pinpointing aspects that warrant further refinement [39]. Through this detailed analysis, researchers can gain a profound understanding of the model's behavior across varied classifications, guiding targeted improvements in its predictive accuracy.

Intricately woven into this analysis are six pivotal variables, each derived from a comprehensive aggregation of the absolute values of corresponding interactive or emotional metrics within a specific interactive phase. For instance, the variable 'summary_interaction' is computed by summing the absolute SHAP values of various interactive categories during the summary stage, represented formulaically as: summary_interaction = |ics| + |ims| + |ios| + |ccs| + |cms| + |cos|. Analogously, 'summary_emotion' encapsulates the emotional undertones of the summary phase, calculated as: summary_emotion = |ips| + |cps| + |ins| + |cns|.

V. Discussion

In this study, a comprehensive literature review was conducted, focusing on the application of machine learning and computer vision techniques across various domains, as cited in references [40-42]. These techniques have been noted for their diverse utility, ranging from healthcare to educational applications. Building on this foundation, the current study specifically applies machine learning and computer vision methods within the realm of STEM education, aiming to explore and expand the educational potential of these innovative technologies.

In the context of STEM education, the integration of computer vision and machine learning (ML) offers transformative potential [43-45]. This research paper has explored how these technologies can be leveraged to enhance self-study methodologies in STEM subjects, with a focus on personalized learning, engagement, and improved learning outcomes.

Personalization of Learning: One of the most significant contributions of ML in STEM education is the ability to tailor educational content to individual students' needs. By analyzing student performance and learning behaviors, ML algorithms can adaptively modify the curriculum, presenting topics in a manner that aligns with each student's unique learning style and pace. This personalization is crucial in self-study environments, where learners often lack the direct guidance of an instructor.

Enhanced Engagement through Computer Vision: The application of computer vision in educational tools has been shown to increase student engagement. By incorporating interactive visual elements and real-time feedback systems, computer vision can make abstract STEM concepts more tangible and comprehensible. This visual interactivity is particularly effective in self-study scenarios, keeping students motivated and engaged in the absence of traditional classroom dynamics.

Data-Driven Insights: ML algorithms provide valuable insights into student learning patterns, identifying areas of difficulty and success. This data can inform the design of future educational content, ensuring that it addresses common challenges and reinforces key concepts. In self-study, these insights become crucial for students to monitor their progress and for educators to understand the efficacy of the learning material.

Overcoming Challenges: Despite the advantages, the integration of computer vision and ML in STEM education is not without challenges. Concerns regarding data privacy, the digital divide, and the need for robust and unbiased algorithms are paramount. Ensuring that these technologies are accessible and equitable for all students, regardless of background or resources, is essential for their successful implementation in educational settings.

Future Directions: Looking forward, the continued development and refinement of ML and computer vision technologies promise even greater advancements in STEM education. The potential integration of augmented reality (AR) and virtual reality (VR) technologies, combined with ML-driven personalized learning paths, could revolutionize the way STEM subjects are taught and learned. Additionally, the ongoing improvement of algorithmic transparency and fairness will be crucial in ensuring that these technologies serve all students effectively.

In conclusion, the application of computer vision and machine learning in STEM-education self-study represents a significant step forward in educational technology. These tools offer the potential for highly personalized, engaging, and effective learning experiences. However, careful attention must be paid to the challenges and ethical considerations that come with the implementation of such advanced technologies. As the field progresses, continuous evaluation and adaptation will be necessary to fully realize the benefits of these innovations in STEM education.

VI. Conclusion

This study's journey into the realms of advanced technology's application within educational settings, particularly through the Real-time Automated STEM Engagement Detection System (RASEDS), unveils new horizons in STEM-related pedagogies. The evidence presented underscores the potential of such innovative intersections between technology and education, where systems like RASEDS are not mere analytical tools but catalysts for transformative educational experiences. The ability of RASEDS to discern engagement levels accurately heralds a future where learning can be genuinely individualized, responding in real-time to students' engagement fluctuations. Moreover, the observed enhancement in self-efficacy among learners signals a profound impact on learners' psychological resources, potentially influencing their academic trajectories and career paths in STEM fields.

However, the journey does not conclude here. While the findings affirm the positive trajectories, they also cast light on the complexities and multi-dimensional challenges within technology-integrated education. Future research needs to navigate these sophisticated dynamics, including the nuanced understanding of engagement and self-efficacy, ethical considerations surrounding data security, and the psychological safety of learners. Furthermore, pedagogical strategies must evolve in tandem with these technological advancements, ensuring that human-centric learning remains at the core of educational endeavors. As we stand on the brink of this new era, the responsibility is collective—educators, technologists, policymakers, and researchers must collaborate to ensure these innovations are harnessed responsibly, ethically, and with the holistic development of learners in mind.

Automated Fruit Sorting in Smart Agriculture System: Analysis of Deep Learning-based Algorithms

Cheng Liu[1], Shengxiao Niu[2]*
College of Digital Business, Jiangsu Vocational Institute of Commerce, Nanjing 210000, Jiangsu, China[1]
Handan Polytechnic College, Handan 056000, Hebei, China[2]

***Abstract*—Automated fruit sorting plays a crucial role in smart agriculture, enabling efficient and accurate classification of fruits based on various quality parameters. Traditionally, rule-based and machine-learning methods have been employed for fruit sorting, but in recent years, deep learning-based approaches have gained significant attention. This paper investigates deep learning methods for fruit sorting and justifies their prevalence in the field. Therefore, it is necessary to address these limitations and improve the effectiveness of CNN-based fruit sorting methods. This research paper presents a comprehensive analysis of CNN-based methods, highlighting their strengths and limitations. This analysis aims to contribute to advancing automated fruit sorting in smart agriculture and provide insights for future research and development in deep learning-based fruit sorting techniques.**

Keywords—Smart agriculture; automated fruit sorting; deep learning; Convolutional Neural Network (CNN); analysis

I. Introduction

Automated fruit sorting has emerged as a promising technology in the field of smart agriculture, revolutionizing the way fruits are cultivated, harvested, and processed [1, 2]. These technologies integrate advanced sensing, data analytics, and automation techniques to improve productivity, efficiency, and quality in fruit production and processing [3, 4]. Automated fruit sorting plays a vital role in the post-harvest stage, ensuring accurate and efficient classification of fruits based on various quality parameters such as size, color, shape, and ripeness [5]. One of the key components of automated fruit sorting systems is video-based fruit sorting [6], which utilizes computer vision and image processing techniques to analyze visual information and make real-time applications [7, 8].

Video-based fruit sorting has gained significant attention due to its non-destructive nature, high-speed operation, and ability to handle a large volume of fruits [9, 10]. This approach involves capturing video footage of fruits from multiple angles and utilizing computer vision algorithms to extract relevant features for classification. By analyzing the visual characteristics of fruits, video-based sorting systems can accurately classify them into different categories, ensuring consistent quality and reducing manual labor.

In recent years, there have been remarkable advancements in video-based fruit sorting systems driven by the rapid progress in computer vision, machine learning, and deep learning techniques [10, 11]. These technologies have enabled the development of more sophisticated and efficient algorithms for fruit classification, leading to improved accuracy and speed in sorting operations [12, 13]. Deep learning, in particular, has shown great potential in fruit sorting applications, leveraging its ability to learn discriminative features from large-scale data automatically.
