Abstract—In Intelligent Transport Systems (ITS), Vehicular Ad-hoc Network (VANET) is one of key wireless technologies, which helps in managing road safety, traffic efficiency, fleet, logistics and transportation. The objective of this paper is to give an overview of the implication of different technologies and placement of VANET in transportation and specifically in logistics. We provide researchers with an overview of considered technologies in logistics scenarios and the current projects regarding VANET for safety and non-safety applications. We additionally discuss current and potential domains in logistics in which new applications can improve efficiency by use of new and existing technologies.

Keywords—VANET; IEEE802.11p; Logistics; Vehicular Ad-hoc Network; Transportation; Technology role

I. INTRODUCTION

In project of the European commission (EC) named “Mobility and Transport”, Intelligent Transport Systems (ITS) [1] is one of the transport topics which deals with the traffic management, safety and efficiency among many target transport mode. To get improvement in transportation system, it applies information and communication technologies like computers, electronics, satellites and sensors. These technological possibilities require us to rethink design, implementation and deployment of existing technologies in different transport modes like road, air, water, and rail to provide new services for passengers and freight transport [2]. Therefore, the first goal of ITS is to manage transport systems and the second goal is to render the transport network more safe. In case of the traffic congestion, it aims to reduce both the traffic and also its impact on the environment. Hence, efficiency is the third goal of ITS. To achieve the goal of traffic management, safety, and efficiency, a number of communication technologies are involved in ITS, e.g., ITS-G5 [3], Wi-Fi [4], 3G [5], LTE [6] etc. to create innovative solutions. The linkage between the EC project, ITS and technologies is shown in Figure 1. Several technologies have been deployed to maintain and promote ITS. Logistics companies focus on the flexibility and efficiency to save time and labor cost. Thus, the improvement of the transportation system and communicating interfaces of these companies contributes to achieve the goals [7].

Vehicular Ad-hoc Network is the one of the challenging domains in wireless networks and has unique features. It does not only offer efficient traffic management, logistics and transportation, navigation, and road safety applications, but also regards for online gaming and infotainment applications [8].

Logistics include a number of activities that ensure the timely availability of the right product to the customer and these activities create a bridge between production and consumption [9]. Consequently, it links the production and market locations. Two parameters can have great impact on the distance between production plant to the location market or supplier unit, i.e. availability of the product to deliver, and time efficiency in delivery of it. To get market benefits, delivery of the right product to the right consumer on right time is equally important for all companies. These two requirements have changed the procedure of production and delivery. To cope with this challenge, the sub-system of logistic requires efficiency and automation. Figure 2 shows the logistics process, where each stage has specific requirements with respect to the next level. At each level different technologies are in use to get the required benefits. Regarding raw material, the efficient collection of it can boost the production of the desired product. At the production units, synchronization of production steps autonomously and information management about the product specification according to demand are the important factors. Latest technologies like robotics, WiFi, multi-agent system and others help to increase productivity and improve management systems. Market share increases with the best distribution of product in the market and simple accessibility for the customer. Online technologies play an important role not only for the product advertisement, but also for purchasing.

Each company promotes its product as a best product in the market. A new product progresses through a sequence of stages called product life cycle from introduction to growth, maturity, and decline. The success of the production cycle depends upon type of product, knowledge of production, people and
knowledge of people’s requirements. In order to increase the value of the product, different services are added to the product by converting raw-materials into the customized products. Therefore, the production cycle includes many values into it. For example form-value is added to the product by converting raw-materials into finished product during production and manufacturing, place-value is provided through transportation by moving the finished products to the needed location, and time-value is provided through storage and inventory controls to ensure the availability of the products when needed. Finally, possession-value is added to the product through marketing and sales. In this whole procedure, place and time-values are the key logistics functions.

To meet the challenge of product-delivery from the production-unit to the market, efficiency in transportation is required. Efficiency in terms of time may vary because it depends on the type of product, mode of transport and location of the need [10]–[12]. The development of technology like automobiles, electronic devices, home appliances require different place and time-values than the production of food items. The food-item exhibits a short life span and requires delivery to market when it is fresh. In a competitive market, the latest technologies are used to shorten the process of production, and enhance storage and inventory for the quick distribution, monitoring and possible re-routing. Sourcing from the raw material to the finished products and the respective distribution involves many tiers in the supply chain flow. In practice, supply chain integration is the set screw and also active research area to improve the supply chain performance. Basically, this integration involves two kinds of flows. The first flow involves the physical steps that need to be carried out, while the second flow complements the first flow (logistics) with respective information. Previous studies [13]–[15] addressed these two flows by merging information and logistics. The research studies also showed that with the help of technology transference [16]–[18] and new technologies integration e.g., RFID [19], robotics [20], [21], WiFi and communication technologies [22]–[25] etc., the process of logistics and transportation has become more flexible. The objective of this paper is to pinpoint the advantages of existing technologies and importance of VANET technology in logistics and transportation with respect to the previously mentioned issues, and to discuss use of multiple technologies together to get solution for complex processes. The use of technologies aims to simplify this process by reducing time of product life cycle with value added services and reducing delay while delivering products.

The rest of the paper is organized as follows. Section II gives the state of the art. It reviews the technology role in logistics and transportation, explains different technologies in context of different sub-problems and challenges in the scenario of logistics and transportation, and also discusses VANET current projects in the research area. Section III discusses different scenarios where one or more technologies can add benefits to companies. It also describes applications of different technologies for logistics and transportation. Section IV concludes and explains possible future work.

II. ADVANCED TECHNOLOGIES IN LOGISTICS

The efficient production of customized products and their supply are the key to success for many companies. Failure leads to loss of revenue, decline in level of services, reputation and market share. Recent developments in the market e.g. increase in market competition along number of products with short life cycle and product proliferation, have created a scenario where the customer’s demands are unpredictable. Thus, the ability to appropriately respond to the market has become a major asset for many companies, and a motivation for improving their logistics systems [26].

The last few decades, the business environment has changed due to advances in information technologies in extracting, manufacturing and servicing industries. In addition to these, the positive growth of knowledge industry [27]–[28] has raised productivity by generating more worker autonomy or greater managerial control. This change is particularly visible in the European Union. Many small and medium size companies have logistic management at their high priority to gain competitive benefits [29], [30]. From point of origin to the point of destination, logistics includes planning, implementing, controlling, transportation of goods, services and related information [31]. The reverse logistics system planning [32] is beneficial for home appliances and proposed a mixed integer programming model to determine the optimal configuration. This model used return rates to determine the numbers, storage locations and plants and showed the benefits of sharing facilities in recycling electrical appliances and computers [33]. To obtain an efficient and flexible system start-to-end, different technologies can be used for sub-tasks. Figure 4 divides the logistics tasks and sub-functions. In each sub-function, integration of particular technology offers added values for the efficient execution and best end results. Each technology plays a vital role to solve sub-functions of logistics to earn revenue.
A. Multi-Agent Systems

Logistics and supply chain systems consist of number of sub-system that can communicate with one another autonomously to maximize utility. Considering their complex relationship and decision making processes of these sub-system, a multi-agent system modeling is a suitable approach. It is used for the convenient modeling of these sub-systems to improve efficiency of supply chain, solve dynamic logistic management, food supply chain management, fleet management, mass customisation issues and make profit through e-commerce.

To improve the efficiency of the food supply chain, the authors of introduced an agent technology model and resulting food supply chain includes the new feature of intelligence, which allows to optimize performance of the system. They described two ways for optimization: firstly, they reviewed intelligent agents applications, analyzed and compared the existing technologies, then critically reviewed the integration of agent technology in the supply chain management. Secondly, they explained the multi-agent system and its mechanism of optimization to solve many tasks like inventory issues, bullwhip effect, communication problem or adverse risk sharing. Furthermore, it offers a capability to purchase and sale while in transit. In the authors discussed the convenience of automatic systems for loading and unloading with the increase of the number of parcels. This automation can offer benefits to logistics companies by reducing the cost of labor and consumption of time.

To solve the problem of dynamic logistic process management, a real-time knowledge-based framework has proposed in with the use of RFID-multi-agents. The system is capable of real-time process management which has functionality to identify current process status, perform checking/reasoning, and support to staff members by providing knowledge about the process while handling logistics activity problems. It included an application case study of Eastern Worldwide Company Limited to reveal the performance of operations and resources utilization significantly.

The authors in paper discuss multi-agent system for the case study of e-commerce. Here, for the design of the logistics, delivery of products, their storage and transportation, a third party logistics (3PL) takes responsibility in a supply chain. A 3PL vendor used multi-agent system to build up a private logistics service unit and virtual private logistics subsystem (VPL). By this way, they integrated own logistics business process with the supply chain members. In the supply chain, the logistics and its information flow are seamlessly connected with the financing and trading flows. The 3PL vendor would keep the stability of its own business process while providing customized services to the supply chain members.

The resource allocation problem is usually solved, when system has real time information of all the orders and resources in advance and it does not affect the process of scheduling. On the basis of real time analysis, it is concluded that intelligent applications help to cover mentioned problem in domain of transport system including traffic issues. These intelligent systems include multi-agent simulation platform for traffic modeling, decision support systems for letter transportation, logistics planning, sea freight transportation, vehicle dispatching, scheduling for railway and truck transportation and others.

In the authors defined mass customization as a transition process of individualization of mass-market goods and services which are used to fulfill particular customer needs at an affordable and reasonable price. They discussed the lack of flexibility in conventional enterprise resource planning and supply chain management systems to cope with the new requirements of market. To overcome these drawbacks, multi-agent systems are used to provide suitable means and also presented a solution to handle customization and corresponding information logistics in flexible way and to extend inter-business relations by partial automatic management.

In the authors discussed the cost reduction and complex optimization problem for dispatching and planning scheduling of freight in a highly competitive market with an increasing share for general cargo. To minimize the complexity in such scenario, an autonomous coordination of transport services and planning processes can help. The paper introduced a multi-agent based approach that solved mentioned issues by enabling an autonomous dispatch process in mentioned scenario and also tackled resource allocation problems. Additionally, it supports a human dispatch manager in decision by developing a Decision-Support System (DSS). The responsibility of DSS is to provide proposals for allocations of transport orders to trucks. Table discusses the role of multi-agent systems for the sub-functions of logistics with the proposed solution. Different multi-agent systems are proposed to solve different issues like optimization in the food supply chain, automation problem for loading-unloading, e-commerce solution for customised services, resource allocation problem, mass-customization, information management issue and to reduce cost and complex optimization.

![Fig. 3: Logistics Process with Integration of Technologies](image-url)
B. Robotics

In order to optimize internal material flow, the requirement and demand of industrial robot-technologies is increasing. The use of robotics and other technologies in logistics is common and research institutes (like Massachusetts Institute of Technology, the Bremen Institute of Production and Logistics (BIBA), the Institute of Shipping Economics and Logistics (ISL), London Business School, etc.) are trying to integrate different technologies in logistics. In [20], authors classified robotics-logistics activities in many scenarios such as loading/unloading and palletizing/depalletizing of goods, and discussed possible scenarios for research and development activities. Companies are trying to enhance functionality and flexibility of working in production units by means of robotics.

In [46], the authors discussed introduction of robots in industry. The idea was initially to use it for production of components of industrialized building and modular housing. In earlier Seventeenth century, first robots had been designed for construction and at the end the century, construction site had been developed. In Japan, it had been used to improve quality in prefabrication of modular homes. In addition to it, maintenance and safety robots had been developed for cleaning, inspection and safety. Furthermore, humanoid robots for construction are already tested, but service robots are in planning to build environment in future.

Nowadays, mobile robotics are significantly used not only for commercially and personally, but also for education and research due to offered new application [47]. An autonomous mobile mechatronic system for learning and research has been introduced by company Festo Didactic. This system is named as Robotino [48] and also introduced as standardized platform for education in the area of engineering and information technology. In [49], the authors discussed the impact of Robotino. They argued that this system provides an easy methods for education and also creates enabling environment to the industrially-relevant engineers for practical training.

Autonomous robots contain a software component and perform task-level executions depending upon the instructions for a certain goal. Planning in this case is still an exception rather than the norm because domains are often too dynamic or complex. In [50], authors characterized the RoboCup Logistics League (RCLL) as a medium complex robotics planning domain considering properties, implementation strategies, and planning models and also proposed a RCLL testbed as a benchmark for comparison.

In e-commerce, logistics requires attention to handle problems such as delays in deliveries or wrong deliveries, packages lost while shipping or damaging goods due to improper packing or handling. Automation helps to improve efficiency of storage and retrieval system. Furthermore, it extends their capacities and capabilities through autonomous storage and retrieval system (ASRS). But it has limitation of flexibility due to variant properties of order. In order to get a balance between efficiency, scalability and flexibility, the use of robotics is vital. In [51], the authors discussed the use of mobile robots in industrial developments. These are in being used to achieve robotic picking methods and extended the Product Service System (PSS) where the prime goal is to focus core competencies using a Logistics Automation Service System (LASS) business model.

Table II discusses the problems of loading/unloading, palletizing/depalletizing, construction, education and research methods and training, planning system defects and e-commerce logistics bottle-neck and also lists the possible solution for the mentioned problems using robotics to get economical benefits by reducing labour cost, time and improving efficiency.

C. Online Technologies

In the era of Internet, customers migrated into the online world, therefore Internet marketers use emails to collect and organize data for potential prospects. Email becomes a primary way among many business marketers to connect with customers. With the emerging of e-commerce on the Internet, a new form of marketing has evolved. Online marketers use different strategies to get attention of their customers from online banners to pop ups. Classically, technical marketing focused on the design of product with the specifications and key features, but at the same time designed to appeal to customers with basic information of product. However, it has also grown marketing strategies to encompass any use of modern technology as a marketing tool. Considering a case of a software company, which offers Adobe Systems having worth billions of dollars. A wide range of products are offered by this system. A number of companies rely on it and its potential customers are basically skilled, highly computer literate professionals. The use of this product is a marketing tool for marketers.

The paper [52] addressed the effective use of Information Technology (IT) capabilities and the synchronous online technology in education section. In a teaching, learning and developing environment of an institute, it presented a theoretical model considering key capabilities of IT and synchronous online technology to support the large scale deployment, e.g., Black-board Collaborate. Apart from the education sector,

these online technologies are also used to observe the general online shopping behavior and particular on gender or cultural base behaviour [53] [54]. In competitive business environment where we have a number of providers, the key point in the hand of organizations is to understand the desires and needs of their customers. These online technologies help to analyze the trend of customer behaviour and adopt new policies for their product according to customer need and desire.

D. Wireless Communication Technologies

The article [22] showed the importance of construction supply chain management (CSCM) and how its is helpful. Construction projects are complex and big in size, e.g., high-rised buildings or mega-sized buildings. Usually, on the construction site, there is little storage space, but high demand of construction components and materials. Hence, for the success, efficient and optimized supply chain management is required. In spite of the availability of research and development of radio frequency identification (RFID), the mobile devices are still required to carry to check logistic flow in supply chain process. However, by the use of RFID and Wireless Sensor Networks-based operations, the equipment can become main drive for the whole process and may include movers, trailers, gates, and hoists. Another article [23] discussed the use of Wireless Mesh Network (WMN) for logistics and Wireless Sensor Network (WSN) to control and manage the logistic flow. The enlisted activities are the logistic functions of handling, packaging and distribution.

E. Internet of Things (IoT)

Internet of Things (IoT) is enabling technology and researchers are focusing on enabling the material procurement process improvement of a manufacturer by using it. IoT and Cloud Manufacturing (CM) are linked technologies, are practically inadequate, particularly for a highly service-driven manufacturing execution system. In this system CM supports to respond in capturing the IoT-enabled execution hierarchy dynamically [58]. In the supply chain network, the One Stop Logistic Service Provider (1SLP) is an integrator, which is used to design and implement comprehensive solutions for logistic service by assembling the resources, capabilities, and integrated technologies of supply chain networks. In [59], authors developed the IoT enabled ISLP process to reduce excessive operation times and integrate with the network information. The authors in [60] proposed a novel multilayered vehicular data cloud platform. This platform is designed by using cloud computing and IoT technologies and used for warranty analysis of vehicles in the IoT environment. IoT can provide a good backbone support for ITS, however this area is not mature yet.

The IoT could also contribute significantly in the food and agribusiness industry. In food supply, perishable products have unpredictable supply variations and mean time they require food safety and sustainability. In this scenario IoT are used to solve these issue because it allows for remotely controlling the location, conditions of shipments and products. In [61], authors also developed a reference architecture using IoT for logistic information systems where it supported the provision of affordable tailor-made solutions.

Apart from the production, handling and safety of machinery and material is also important. For material handling, authors in [62] explained material handling system via analysis and performance availability in regard to energy-harvesting, ultra-low-power devices. They also discussed details of the hardware platform including architecture and tested. They paid particular attention to the inBin smart device and energy-harvesting in the mentioned system. For the safety, the authors in [63] developed a monitoring system, particularly focusing for the type of cranes used to hoist heavy loads in the open air environment with the help of IoT. The latter included both hardware unit and software, and applied in engineering.

F. VANET

In case of disaster areas, an important task is to manage the resources via restoring the information flow to help in the recovery process. VANET is a wireless technology that is deployed in such disaster areas to recover the communication link [64] [65]. Communication among vehicles is discussed in [25] and authors presented the concept of car-2-car communication as ‘smart object’ and aimed to increase driving with comfort and safety. This communication should be secure and

confidential [66]. The article [24] discussed its support for applications that notify about route hazards and incidents to both the drivers and logistics coordinators. Apart from the ITS usage, VANET applications includes a number of scenarios, such as information dissemination for safety like emergency alerts, traffic condition, service messages, road jam due to accidents, and collision avoidance. The disseminated information can be used for fleet coordination or rerouting of vehicles [67], but also for advertisements (e.g. disseminate marketing data), multimedia content distribution (e.g. audio, video streaming) [68], [69], [70] and environmental monitoring networks to gather information data (e.g. pollution, traffic monitoring and road pavement defects) [71]. For future services, the expansion of the smart grid represents a unique challenge in terms of the convergence of network platforms. WiFi as VANETs have the potential to become a reliable wireless network platform to support both the requirements of the smart grid and ITS-based services. Logistics companies are required to have flexible and cost efficient system to monitor, control and deliver products on time. The customers are also interested to have hassle free dealing with the logistics companies. In all these cases, multi-hop wireless broadcast is an important component in vehicular networks because network properties allows to exploit this feature. VANET is a good choice to fit in these scenarios due to its unique characteristics, low cost and simple deployment.

In port scenarios, complexity is increasing with the expansion of supply chains. Modern ports require advanced track and trace, security, information sharing and monitoring and VANET has the potential to fulfill these needs of port facilities [72], [73]. In [74], authors discussed the adoption of communication technologies to experience high levels of visibility, control and connectivity across the entire supply chain and examined the feasibility of VANET in a multimodal logistics environment. They recommended architecture to provide mentioned goals, which also assure security while accessing. An other article [75] explained its potential to manage the flow of goods and resources efficiently, particularly within international ports. In [76] authors discussed the key role of Information and Communication Technology (ICT in managing logistics operations and supply chains. Table IV summarizes this discussion along target sub-tasks and solutions provided by the mentioned technology.

III. VANET PROJECTS, APPLICATIONS AND DISCUSSION

Under the European Commission, a wide variety of projects for transportation is currently underway. Intelligent Transport System (ITS) [77] aims to develop road safety and traffic management applications. Secure vehicular communication, passenger comfort and infotainment are also objectives of ITS. To generate novel ideas and development of novel technology, the project “Transport Research and Innovation Portal (TRIP)” [78] considers of transportation aiming to give an overview of research activities at European Union and National level. The European Commission also started a project in for “Transport Research and Innovation in Horizon 2020” [79] to generate ideas for growth of transportation, transport sustainability, seamless mobility and also viewing European Union (EU) as a leader on the globe. Car-2-Car is the project of Car-2-Car Communication Consortium (C2C-CC) [80]. This project aims to contribute to the reduction of deaths in road accidents, reduce traffic congestion, improve efficiency and reduce the impact of the traffic on the environment.

Many projects are also running to develop prototypes of VANET for industry. Car-to-car cooperation [81] is a VANET project running in the Aqua-lab of Northwestern University. This project aims to provide information and entertainment to the passengers and automotive safety, and to reduce the impact of traffic on environment and smooth traffic flow. The project “Innovative Wireless Technologies for Industrial Automation (HiFlecs)” [82] in the University of Bremen, develops innovative wireless technologies for industrial real-time closed-loop applications. In the future industry, the wireless technologies allows to connect machinery and control units wirelessly. There are different challenges for future Industry 4.0 applications like low latency, highly reliability, deterministic, and secure communications. To meet these challenges, HiFlecs develop key technologies for an industrial wireless communication system with new functionality and features for real-time control applications. Intelligent System and Sensors [83] is the project of Auto21 for the development of control and monitoring of vehicle behavior, guidance, navigation, telematics, driving assistance and automation. Another funded project [84] of Auto 21 named “Vehicle Communications And Applications” at the Interlab of University of Sherbrook focuses on the development and testing of cost effective communication infrastructure, design of cooperative control strategies and their integration for vehicular communication applications.“Canadian Association of Road Safety and Professional (CARSP)” [85] is dedicated to enhance road safety by developing safety applications. Last, U.S. department of transportation is dealing with safety application where focused applications are emergency electronic brake lights, blind spot brakes, forward collision warnings, etc. It outlines new ITS Strategic Plan 2015-2019 [86] and provides a framework around with ITS Joint Program Office for research, development, and adoption activities to achieve goals. This plan is built around two key points i.e. priorities-realizing connected vehicle implementation and advancing automation. Furthermore, this plan includes program categories regarding connected

drivers, automotive, emerging capabilities, enterprise data, interoperability and accelerating deployment. Table VII gives the summary of the all presented projects where road safety or automotive safety are key targets. However, some projects are focusing on the monitoring and some projects are working to improve the traffic efficiency with minimal impact on the environment and cost effective communication infrastructure. From the current projects objectives, we conclude that companies are looking for low cost, automotive safety and monitoring solutions to support logistics and general transport applications with high reliability. Table VII summarizes the technologies integrated in logistics and transportation. Each technology aims to solve a problem by using specialized methods, and upon successful implementation and deployment, each system exhibits certain properties. As mentioned in the table, Multi-agent System [29] [87] are used for chain optimization and to create e-market place through centralized and decentralized method. By applying this technique, the system becomes more simple, flexible and harmonized but less coordinated. Online technologies [88] are used to maintain the system information for customers, re-sellers, business partners and to help in the online collaboration with partners, exchange of documents for contracts with customers, suppliers and also negotiation of contracts have become more easy. They provide a centralized and fast information management system, and also introduce e-business opportunities. Therefore, the advanced systems become more simple, flexible and also increase the accessibility and availability of data. Robotics [20] [21] is another technology, which renders the advanced system to be more flexible, efficient and cost effective. Robotics are used for automation of the system using different methodologies like expericism, realism and inductivism. For monitoring the environment, and controlling the process, WSN [22] [23] is applied. This technology allows for automation in information flow and control through environment monitoring, localizing the system, and controlling methods. To improve transportation efficiency, and for controlled and efficient traffic management automation, VANET technology [24] [25] [89] is imposed through communication methods. By using these wireless communication technologies, the transportation can become
more secure, highly reliable and cost effective.

Currently, as mentioned in previous sections, VANET focuses on both safety [90] [91] and non-safety applications [92]. Non-safety applications are used to create commercial opportunities by increasing the number of equipped vehicles with on-board wireless devices. To make journey more pleasant for travelers, comfort and infotainment applications are being design and developed to provide information support and entertainment. Vehicular networks can also be employed to provide connectivity to catastrophe hit areas or remote rural communities lacking a conventional communication infrastructure to provide connectivity. Furthermore, Vehicular applications (for example enhanced route guidance [93] and coordination by logistics providers, optimal scheduling of traffic light, and lane merging assistance by public coordinators) are intended to optimize routes [94], while also providing a reduction of gas emissions and fuel consumption. These applications are even more better when sensors are deployed for monitoring and controlling with VANET technology [95].

In logistics and transportation, many applications can be used like automatic vehicle detection or vehicle parking system for the logistic hot-spots (e.g sea port, warehouses etc.). It can also be used for the efficient traffic management for online delivery of logistics goods from production units to the distributed points or warehouses. Additionally, it allows automatic traffic control, re-routing the traffic in case of the traffic congestion [96] for improving just in time delivery and speed limit enforcement. Figure 4 shows the major four hot-spots of congestion [96] for improving just in time delivery and speed

IV. CONCLUSIONS AND FUTURE WORK

VANET is the one of the enabling technology in ITS that is used for road safety, traffic management and logistics applications. With the objective of the technologies and VANET integration in logistics and transportation, an overview of all technologies with logistics functions have been derived and summarized. Different technologies like multi-agent systems, online technologies, robotics, wireless sensor networks have been used to fast the process of manufacturing and to make the deliveries just in time over the last few years. We highlighted different challenges for each technology to provide flexible and effective solutions in terms of time and cost. We discussed VANET as key technology in logistics and transportation regarding challenges to cope with the mobility and short contact duration, where it is observed that VANET has potential to provide flexible and cost-effective solutions for logistics and transportation. It also has capability to make bridge to interlink hotspots of logistics process. For the deployment of this technology along attractive applications, a number of projects are running. This article also gave an overview of projects focusing respective extensions.
