Abstract—Digital Image Watermarking is used recently to secure the image by embedding another digital image. It is typically used to identify ownership of the copyright of the signal. Frequency domain transformation methods used widely in Digital Image Compression and Digital Image Watermarking. They reduce the weakness of classics digital image watermarking such as Least Significant Bit (LSB) methods which is more noise-tolerant. Popular transformation method used are Two Dimensional Discrete Cosine Transform (2D DCT), Two Dimensional Discrete Fourier Transforms (2D DFT), and Two Dimensional Discrete Wavelet Transform (2D DWT). This paper will show the comparison result of those three transformation method. The experiments are comparison analysis of image watermark quality using Peak Signal to Noise Ratio (PSNR), color converting, image resizing, image optical scanning and the noise-tolerant of the image watermarked by giving Gaussian noise.

Keywords—Digital Image Watermarking; 2D Discrete Cosine Transform (2D DCT); 2D Discrete Fourier Transform (2D DFT); 2D Discrete Wavelet Transform (2D DWT); Least Significant Bit method (LSB); Digital Signal Processing

I. INTRODUCTION

Digital Image Watermarking is used recently to secure the image by embedding another digital image. Komatsu and Tominaga are the first person using the term Digital Watermarking [1]. It is typically used to identify ownership of the copyright of the signal. The information are embedded in image is called a “digital image watermark”. The information where the watermark is to be embedded is called a “host image” [2,3]. Traditional method for Digital Image Watermarking used Least Significant Bit (LSB). Many researcher proposed the LSB method with some improvement and analysis to create better digital image watermark results [4,5,6]. The method for LSB will be explained in detail in Section 2.

LSB method for digital image watermarking has a weakness which cannot handle simple noise. Image watermarked also will loss the watermark information if some image processing is implemented such as Image Resizing and Image Cropping. Some Frequency Domain Transformations method is implemented to handle such weakness in traditional method. It is also proved that even the image is printed and scanned to return the format in digital, the watermark image can also be extracted smoothly.

Discrete Cosine Transform (DCT) are popular among science and engineering application, from image watermarking, steganography, and lossy compression for audio and image. Cosine function is used rather than sine function due to the critical for compression, fewer cosine functions are needed to approximate the typical signal. Cosine functions also express a particular choice of boundary condition in differential equations. DCT is similar to the Discrete Fourier Transform (DFT), but using only real numbers. DCT are equivalent of DFT of roughly twice the length, operating on real data with even symmetry and in some variants the input or output data are shifted by half a sample.

The remainder of this paper is organized as follows: Section 2 explained the 2D DCT, 2D DFT, 2D DWT and PSNR for analyzing the watermarked image. Section 3 describes our experiment and a technique for image watermarking in frequency domain information. Section 4 presents the experiments results. Conclusion and future work are given in the final section.

II. PROPOSED METHOD

A. Digital Image Watermarking

Digital image watermarking is one of the steganography branches, which is a technic to hide information in a digital media. The purpose is to protect important information [8]. The information inserted in digital image watermarking can be in text, image, or audio format file. There are some criteria to create good image watermarking:

- Imperceptibility: Good Watermark is invisible by human eye. One cannot distinguish well between original and watermarked image.
- Robustness: Good Watermark has to be resisted with file manipulation such as file compression, image noising, color converting, and image resizing.
- Security: Watermarked file can only be detected by the file owner or authorized ones.
• Recovery: Watermarked file must be converted back to original file. Main purpose of watermarking is for copyrighting file owner, which can be used for file authorization.

B. Least Significant Bit Method

Least significant bit (LSB) is very simple and less computation cost compared to the other method of transformations. Figure 1 shows the insertion method in LSB. For every bit starting from MSB of watermark image pixel is inserted to the LSB of some image source pixel. The results will be the addition of 1 if the watermark bit is 1 and same as previous value if the watermark bit is 0. Human eyes will be difficult to distinguish the image source before and after watermarking. However, this method faces some image processing implementations such as Image Resizing and Image Cropping due to the pixel value modification. The PSNR of the LSB 1 bit substitution is 55.8784 [4].

C. 2D Discrete Cosine Transform (2D DCT)

DCT in image processing is first introduced by Ahmed, Natarajan and Rao [7]. DCT is similar to DFT, but using only real numbers. DCT turns over the image edge to make the image transformed into another form of even function. This is one of linear transformations in digital signal processing. 2D DCT is defined as:

\[
F(jk) = a(j)a(k) \sum_{m=0}^{N-1} \sum_{n=0}^{N-1} f(mn) \cos \left( \frac{(2m+1)j\pi}{2N} \right) \cos \left( \frac{(2n+1)k\pi}{2N} \right)
\]

[1]

The corresponding inverse discrete cosine transformation (2D-IDCT) is defined as:

\[
\sum_{m=0}^{N-1} \sum_{n=0}^{N-1} a(j)a(k)F(jk) \cos \left( \frac{(2m+1)j\pi}{2N} \right) \cos \left( \frac{(2n+1)k\pi}{2N} \right)
\]

[2]

The 2D-DCT can not only focusing on transform the main information of original image into the smallest low-frequency component, but also it can cause the image blocking effect being the smallest, which can realize the good compromise between the information centralizing and the computing complication, thus it obtains the wide spreading application.

D. 2D Discrete Fourier Transform (2D DFT)

Consider one N1 x N2 image, f(n1,n2), where we assume that the index range are n1 = -M1,…,M1 and n2 = -M2,…,M2, for mathematical simplicity, and hence N1 = 2M1 + 1 and N2 = 2M2 + 1. Let F(k1,k2) denote the 2D discrete Fourier Transform (2D DFT) of the image. F(k1,k2) are given by

\[
F(k_1, k_2) = \sum_{n_1=-M_1}^{M_1} \sum_{n_2=-M_2}^{M_2} f(n_1, n_2) W_{N_1}^{k_1 n_1} W_{N_2}^{k_2 n_2} = A_F(k_1, k_2)e^{j\theta_F(k_1, k_2)}
\]

[3]

Where \( k_1 = -M_1, \ldots, M_1, \ k_2 = -M_2, \ldots, M_2, \ W_{N_1} = e^{-\frac{2j\pi}{N_1}}, \ W_{N_2} = e^{-\frac{2j\pi}{N_2}}, \) and the operator \( \sum_{n_1=0}^{N_1-1} \sum_{n_2=0}^{N_2-1} \) denotes \( \sum_{n_1=-M_1}^{M_1} \sum_{n_2=-M_2}^{M_2} A_F(k_1, k_2) \) is an amplitude component, and \( e^{j\theta_F(k_1, k_2)} \) is a phase component.

The 2D Inverse Discrete Fourier (2D IDFT) of \( F(k_1, k_2) \) is given by

\[
f(k_1, k_2) = \frac{1}{N_1N_2} \sum_{k_1=0}^{N_1-1} \sum_{k_2=0}^{N_2-1} F(k_1, k_2) W_{N_1}^{-k_1n_1} W_{N_2}^{-k_2n_2}
\]

Where \( \sum_{k_1=-M_1}^{M_1} \sum_{k_2=-M_2}^{M_2} \) denotes \( \sum_{k_1=-M_1}^{M_1} \sum_{k_2=-M_2}^{M_2} \).

E. 2D Discrete Wavelet Transform (2D DWT)

Discrete wavelet transform (DWT) represents an image as a subset of wavelet functions using different locations and scales. It makes some decomposition images. Any decomposition of an image into wavelet involves a pair of waveforms: the high frequencies corresponding to the detailed parts of an image and the low frequencies corresponding to the smooth parts of an image. DWT for an image as a 2-D signal can be derived from a 1-D DWT. According to the characteristic of the DW decomposition, an image can be decomposed to four sub-band images through a 1-level 2-D DWT, as shown in Fig. 2. These four sub-band images in Fig. 4 can be mapped to four sub-band elements representing LL (Approximation), HL (Vertical), LH (Horizontal), and HH (Diagonal) respectively.

\[
\text{Fig. 1. LSB method of Digital Image Watermarking}
\]

\[
\text{Fig. 2. 1-Level Decomposition 2D DWT}
\]
Where: $\varphi(t)$ is the mother wavelet and $\theta(t)$ is the scaling function. $a(L,K)$ is called the approximation coefficient at scale L and $d(j,K)$ is called the detail coefficients at scale j. The approximation and detail coefficients can be expressed as:

$$a(L,K) = \frac{1}{\sqrt{2^L}} \int_{-\infty}^{\infty} f(t)\theta(2^{-L}t-K)dt \quad [5]$$

$$d(j,K) = \frac{1}{\sqrt{2^j}} \int_{-\infty}^{\infty} f(t)\varphi(2^{-j}t-K)dt \quad [6]$$

Based on the choice of the mother wavelet $\varphi(t)$ and scaling function $\theta(t)$, different families of wavelets can be constructed.

**F. Mean Square Error (MSE) and Peak Signal to Noise Ratio (PSNR)**

Peak signal-to-noise ratio (PSNR) is a ratio between maximum possible power of a signal and the power of corrupting noise that affects the fidelity of its representation. PSNR is usually expressed in terms of the logarithmic decibel scale. The signal is an original data, and the noise is the error from watermark system.

PSNR usually defined via the mean squared error (MSE). Given a noise-free m x n image I and noisy approximation K, MSE is defined as:

$$MSE = \frac{1}{MN} \sum_{i=0}^{M-1} \sum_{j=0}^{N-1} (I(i,j) - K(i,j))^2 \quad [7]$$

The PSNR (in dB) is defined as:

$$PSNR = 10 \log_{10} \left( \frac{MAX^2}{MSE} \right)$$

$$= 10 \log_{10} \left( \frac{MAX_I}{MSE} \right)$$

$$= 10 \log_{10}(MAX_I) - 10 \log_{10}(MSE) \quad [8]$$

Where, $MAX_I$ is the maximum possible pixel value of the image. When the pixels are represented using 8 bits per sample, this is 255.

**III. EXPERIMENTS**

Figure below shows the general watermark image steps in frequency domain transforms.

The usage of DCT, DFT, and DWT in image watermarking start by dividing image to 8x8 pixel sub-block. These sub-block will consist of 64 coefficient (1 DC-zero frequency coefficient and 63 AC coefficient in low frequency, middle frequency, and high frequency. Figure 4 shows the DCT frequency division.

**Fig. 3. Watermark image steps in frequency domain transform**

**Fig. 4. DCT Frequency components**

LF represents the low frequency, MF represents middle frequency, and HF represents sub-block highest frequency. In DCT transform, LF can be found in every edge and corner of image sub-block. In DCT and DFT, watermark bit image will be put in LF. In DWT, watermark bit image will be put in LH and HL. Figure 5 shows the diagram block for DCT watermarking process. This diagram block also represents for DFT and DWT.
detransformed using inverse-DCT, inverse-DFT, and inverse-DWT to get Y-component watermarked image.
- Y-component is combined again with Cb-component and Cr-component to get YCbCr watermarked image.
- Last process is YCbCr watermarked converted again to RGB Space to get RGB watermarked.

IV. RESULTS

We use 32x32 binary image resolutions as an image watermark. This image will embed on image with 65536 total pixel amount, since 1 pixel of binary image will embed on 8x8 image sub-block. Figure 5(a) is used as an image watermark and figure 5(b) as an original image.

Table 1 shows the results of embedding image watermark to the LF, MF, and HF of original image.

V. CONCLUSION

Frequency domain transformation methods are used widely in Digital Image Compression and Digital Image Watermarking. It reduces the weakness of classics digital image watermarking such as Least Significant Bit (LSB) methods which is more noise-tolerant. Popular transformation method used are Two Dimensional Discrete Cosine Transform (2D DCT), Two Dimensional Discrete Fourier Transforms (2D DFT), and Two Dimensional Discrete Wavelet Transform (2D DWT). This paper proposed the comparison between those three transformation methods. The experiments are image watermark quality analysis using Mean Square Error (MSE), Peak Signal to Noise Ratio (PSNR), and the noise-tolerant of the image watermarked by giving Gaussian noise in it. The experiments shows result of:

- DCT Transformation embed on High Frequency is the best for image watermarking. It has 40.82 dB PSNR values, as shown in table 1.
- Adding 20% Gaussian noise to the watermarked image, the best Transformation for Gaussian Attack is DCT watermark in Low Frequency. It has 19.36 dB PSNR value, as show in table 2.
- Compressing image using RIOT application for all three transformation, DWT shows the best results as shown in table 3.

Using image contrast manipulation, DCT shows the best results as shown in table 4.
