A seven-tuple  $A = \langle d, req^{ins}, \alpha, t^{ept}, t^{max}, P^{max}, P^{low} \rangle$  is used to describe a task where,  $d$  denotes the size of input data,  $req^{ins}$  denotes the Million Instructions (MIs) required.  $\alpha$  is a 0-1 variable that describes the type of tasks. When  $\alpha$  is 0, the type of the task is DT, and when  $\alpha$  is 1, the type of the task is DS. We assume a task has an expected delay  $t^{ept}$  and a tolerable maximum latency  $t^{max}$ .  $P^{low}$  and  $P^{max}$  represent the minimum and maximum price a user is willing to pay for a task, respectively.

For a DT task, if it can be completed within the expected time, marked as  $t^{ept}$ , the user will be satisfied and willing to pay in full, marked as  $P^{max}$ . If  $t^{ept}$  is exceeded, but the deadline, marked as  $t^{max}$ , is not exceeded, the willing fee of the user will gradually decrease, and eventually reach a balance value, marked as  $P^{low}$ , between the CLP and the user. Thus, for a DT task, the relationship between the delay  $t$  and the user's quotation  $Q(t)$  can be shown in (1).

$$Q(t) = \begin{cases} P^{max}, & t < T^{ept} \\ k_{dt} \cdot (T^{max} - t) + P^{low}, & T^{ept} \leq t \leq T^{max} \\ P^{low}, & t > T^{max} \end{cases} \quad (1)$$

Where,  $k_{dt}$  is determined by (2).

$$k_{dt} = \frac{P^{max} - P^{min}}{T^{max} - T^{ept}} \quad (2)$$

For DS tasks, users will be willing to pay in full if they can be completed within the expected time. If the delay exceeds the user's expectation, the user's willingness to pay will decrease sharply. If the delay exceeds the deadline, the user will be unwilling to pay, or only willing to pay at a very low price. We chose the latter, meaning that when the deadline is exceeded, the user will be willing to offer only a very low price, which is usually close to or even lower than the CLP cost. We design (3) to describe the relationship between the delay  $t$  of a DS task and the user's quotation  $Q(t)$ .

$$Q(t) = \begin{cases} P^{max}, & t < T^{ept} \\ P^{max}((1 - \alpha(t - T^{ept}))^\beta), & T^{ept} \leq t \leq T^{max} \\ P^{low}, & t > T^{max} \end{cases} \quad (3)$$

Where,  $\alpha$  and  $\beta$  are adjustable parameters, and their values should ensure that the curve described by (3) is continuous on the interval  $[T^{ept}, T^{max}]$ .  $\alpha$  indicates the delay sensitivity of the user. The larger the  $\alpha$ , the higher is the sensitivity.  $\beta$  reflects the descent gradient of user willingness. The larger the  $\beta$ , the larger is the gradient.

Fig. 2(a) and Fig. 2(b) depict the curves of delay versus quotation for DT and DS tasks, respectively.

### C. Delay Model

When the FCLM of a CLP receives a task, the FCLM may schedule it to the local cloudlet, or to the federated cloudlet, or to the cloud. In general, the amount of data output after the task execution is much smaller than the amount of data input before the task execution. Similar to [23] and [24], the transmission time required for the output information of a task to be returned to the user is not considered. Meanwhile, the queuing delay is

negligible when the federated resources are sufficient to handle user tasks.

1) *Local cloudlet*: When a task is scheduled to the local cloudlet, its delay can be divided into two parts. The first part includes transmission delay and propagation delay, denoted as  $t_{cl}^1$ , which can be determined by (4).

$$t_{cl}^1 = \frac{d}{R} + \frac{D_{cl}}{S^P} \quad (4)$$

Where  $d$  is the amount of data to be transmitted,  $R$  is the data transmission rate,  $D_{cl}$  is the distance of the selected local cloudlet from the user, and  $S^P$  is the propagation rate. Assume that the value of  $S^P$  is the same for all channels and the value of  $R$  is the same for all devices.

The second part is the time required for the task execution on the selected cloudlet, denoted as  $t_{cl}^2$ , which is determined by (5).

$$t_{cl}^2 = \frac{req^{ins}}{CPU_{proc} \cdot N_{cpu}} \quad (5)$$

Where  $req^{ins}$  is the MIs required to execute the task,  $CPU_{proc}$  is the Million Instructions per Second (MIPs) for the CPU provided by the selected cloudlet, and  $N_{cpu}$  is the number of CPUs configured by the selected cloudlet.

Thus, the total delay, denoted as  $t_{cl}^{total}$ , for a task scheduled to a local cloudlet can be calculated by (6).

$$(6)$$

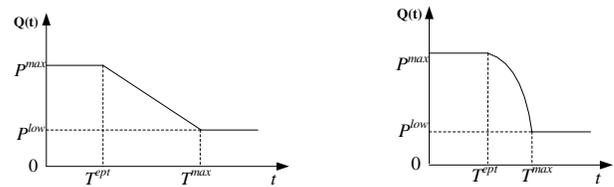

2) *Remote cloud*. When a task is scheduled to the remote cloud, its delay calculation is very similar to that when it is scheduled to a local cloudlet. However, since the user is usually far away from the cloud, the delay of the task will be huge.

The total delay, denoted as  $t_c^{total}$ , for a task scheduled to the remote cloud can be calculated by (6).

$$t_c^{total} = t_c^1 + t_c^2 = \frac{d}{R} + \frac{D_c}{S^P} + \frac{req^{ins}}{CPU_{proc} \cdot N_{cpu}} \quad (7)$$

Where,  $D_c$  is the distance of the cloud from the user,  $CPU_{proc}$  is the MIPs for the CPU provided by the cloud, and  $N_{cpu}$  is the number of CPUs configured by the cloud.

3) *Federated cloudlet*. If a task is assigned to the federated cloudlet, its delay includes the following parts: authentication delay between alliances, task offloading delay from user to FCLM, task offloading delay from FCLM to the selected cloudlet, and task execution delay.

(a) For DT task. (b) For DS task.

Fig. 2. Curves of Delay Versus Quotation.

When a task is transferred from the FCLM receiving it to the FCLM of a federation, some authentication information often needs to be exchanged between FCLMs, so as to introduce authentication delay, marked as  $t_{fed}^1$ , which is considered to be a constant.

To avoid CLP user information being detected by the federated CLP, tasks are delivered first to the FCLM that receives them and then to the selected Cloudlet. The delay of offloading the task from the user to the FCLM, denoted as  $t_{fed}^2$ , can be calculated by (8).

$$t_{fed}^2 = \frac{d}{R} + \frac{D_1}{SP} \quad (8)$$

Where  $D_1$  represents the distance between the user and the FCLM associated with it.

The delay of offloading tasks from FCLM to the selected cloudlet is denoted as  $t_{fed}^3$ , which can be calculated by (9).

$$t_{fed}^3 = \frac{d}{R} + \frac{D_2}{SP} \quad (9)$$

Here,  $D_2$  represents the distance between the FCLM associated with the user and the selected cloudlet.

The execution delay of the task, denoted as  $t_{fed}^4$ , can be determined by (10).

$$t_{fed}^4 = \frac{req^{ins}}{CPU_{proc} \cdot N_{cpu}} \quad (10)$$

Where,  $CPU_{proc}$  is the MIPS for the CPU provided by the selected cloudlet, and  $N_{cpu}$  is the number of CPUs configured by the selected cloudlet.  $CPU_{proc}$  and  $N_{cpu}$  in (5), (7) and (10) are not symbolically distinguished. In fact, they correspond to different computing resources and take different values.

Thus, the total delay, denoted as  $t_{fed}^{total}$ , can be calculated by (11).

$$t_{fed}^{total} = t_{fed}^1 + t_{fed}^2 + t_{fed}^3 + t_{fed}^4 \quad (11)$$

#### D. CLP Resource Pricing Model

When a CLP needs to rent the cloudlet resources of another CLP, the leasing price of the resources needs to be determined. The consistent pricing strategy is adopted, and the leasing price of resources is considered to be related to the user's quotation, resource cost and resource utilization of CLP.

Assuming that the user quotation of task  $A$  is  $Quote_A$ , the cost of resources needed to execute  $A$  is  $Cost_A$ , and the total cloudlet resources and residual resources owned by some CLP are  $Total_{CLP}$  and  $Res_{CLP}$  respectively, then the cost of CLP renting the resources required by task  $A$ , denoted as  $Rent_A^{CLP}$ , can be determined by (12).

$$Rent_A^{CLP} = Cost^A + \frac{Total_{CLP} - Res_{CLP}}{Total_{CLP}} (Quote_A - Cost^A) \quad (12)$$

The intuition of (12) is as follows: the rental price of resources should be higher than that of the cost. The net profit between rental price and cost should be positively correlated with the profit of the lease and the resource utilization of the lessor accordingly. The willingness of renting resource is

growth with the user's quoted price, and as the increasing of the resource utilization, the tenant willingness of renting is decreasing.

When a task is executed on the cloud, its profit is the difference between the user's quote and the cost of the cloud resource. When executed on the local cloudlet, its profit is the difference between the user's quote and the local cloudlet resource cost. When executed on the federated cloudlet, its profit is the difference between the user's quote and the rental resource price.

#### IV. PROPOSED ALGORITHM

Based on the distributed processing idea and greedy strategy, for each CLP, when its FCLM receives a task, we design a Delay-aware and Profit-maximizing Task Migration (DPTM) algorithm to schedule the task. DPTM tries to maximize the profit of CLP while guaranteeing the user delay according to the task type. It first determines the type of tasks. For DS tasks, a scheduling algorithm called Task Migration for DS (TMDS) is proposed. For the DT task, an algorithm called Task Migration for DT (TMDT) is proposed.

##### A. TMDS Algorithm

For DS task, the goal is to minimize delay on the basis of ensuring profit. For this purpose, locally arrived DS tasks are divided into High Delay Sensitive (HDS) and Low Delay Sensitive (LDS) tasks according to their delay requirements. For a HDS task, local scheduling is preferred. If it cannot be scheduled locally, it is processed as an LDS task. For a LDS task, if the cloud has the highest profit and can guarantee the delay, the cloud is regarded as the best scheduling. Otherwise, on the premise of ensuring profit, the cloudlet with the minimum delay should be sought.

The TMDS algorithm for scheduling DS tasks is shown in Algorithm 1. In Algorithm 1,  $Avg_k$  records the average  $t^{ept}$  of the last  $k$  DS tasks,  $t^{ept}(A)$  and  $t^{max}(A)$  represent the  $t^{ept}$  and  $t^{max}$  of task  $A$  respectively,  $t_{cl}^{total}(VM)$  represents the delay of  $A$  when executed on the  $VM$  of a cloudlet,  $p_{cl}(VM)$  represents the profit when  $A$  is executed on the  $VM$  of a cloudlet, and  $p_c(A)$  represents the profit when  $A$  is executed on the cloud. A task is identified as HDS when its  $t^{ept}$  is less than  $Avg_k$ . In this case, firstly, the  $VM$  that can execute  $A$  and delay less than  $t^{max}(A)$  are searched on the local cloudlet. Otherwise, find all  $VM$ s that can execute  $A$  with latency less than  $t^{max}(A)$  and schedule  $A$  to the one with the least latency. If no suitable  $VM$  is found after the above two steps,  $A$  will be treated as an LDS type.

For a task  $A$  identified as a LDS, the latency and profit of  $A$  when executed on the cloud are calculated, denoted as  $t_c^{total}(A)$  and  $p_c(A)$ , respectively. If  $t_c^{total}(A)$  is less than  $t^{max}(A)$  and  $p_c(A)$  is greater than 0, the  $VM$  with executable  $A$ , delay less than  $t^{max}(A)$ , and profit greater than  $p_c(A)$  is sought on the cloudlets of all CLPs. If one or more  $VM$ s can be found, the  $VM$  with the minimum latency is selected for  $A$ . Otherwise,  $A$  is scheduled to the cloud.

If  $t_c^{total}(A)$  is not less than  $t^{max}(A)$  or  $p_c(A)$  is not greater than 0, the  $VM$  that can execute  $A$  and the profit is greater than 0 is searched on the cloudlets of all CLPs, and the one with

minimum delay is the best for A. Otherwise, A will be abandoned.

In Algorithm 1, a maximum of three scheduling attempts is required on each VM for a task. If  $n$  is used to represent the number of VMs, the time complexity of algorithm 1 is  $O(n)$ , that is, algorithm 1 has linear time complexity.

Calculate  $t_c^{total}(A)$  using (7) and  $p_c(A)$ ;  
If ( $t_c^{total}(A) < t^{max}(A) \&\& p_c(A) > 0$ ) {  
    For each VM in all cloudlets {  
        Calculate  $t_{cl}^{total}(VM)$  using (6) or (12);  
        If ( $t_{cl}^{total}(VM) < t^{max}(A) \&\& p_{cl}(VM) > p_c(A)$ )  
            add  $\langle VM, p_{cl}(VM) \rangle$  to  $VM\_T$ ;  
    }  
    If ( $VM\_T$  is not null)  
        return VM with minimum delay in  $VM\_T$ ;  
    else  
        return VM in cloud;  
}  
For each VM in all cloudlets {  
    Calculate  $t_{cl}^{total}(VM)$  using (6) or (12);  
    If ( $p_{cl}(VM) > 0$ )  
        add  $\langle VM, t_{cl}^{total}(VM) \rangle$  to  $VM\_T$ ;  
}  
If ( $VM\_T$  is not null)  
    return VM with minimum delay in  $VM\_T$ ;  
else  
    return null;

---

**B. TMDT Algorithm**

For the DT task, the goal is to minimize the delay while pursuing the maximum profit. Considering that the delay of a task executed on the local cloudlet is usually less than that on the federated cloudlet or the cloud, in order to save the local cloudlet as much as possible for scheduling DS tasks, DT tasks can only be scheduled to the federated cloudlets with the lower quotation or the cloud. The criterion is profit maximization.

The TMDT algorithm is used to schedule tasks of type DT, as shown in Algorithm 2. For a task A, the profit executed on the cloud, denoted as  $p_c(A)$ , is firstly calculated. If  $p_c(A)$  is greater than 0, the VM that can execute A and have higher profit than  $p_c(A)$  is found on all the federated cloudlets, and A is scheduled to the one with the maximum profit. If no such VM can be found, A is scheduled to the cloud. If  $p_c(A)$  is not greater than 0, the VM that can execute A and have higher profit than 0 is found on all the federated cloudlets. If such VMs exist, the

one that can make the maximum profit is the best choice. Otherwise, scheduling A is abandoned.

Algorithm 2 traverses all VMs at most two times, so its time complexity is  $O(n)$ .

---

**Algorithm 2** TMDT

---

**Input:** task A with type of DT  
**Output:** VM is arranged for A  
Set  $VM\_P \langle VM, Profit \rangle = \emptyset$ ;  
Calculate  $p_c(A)$ ;  
If ( $p_c(A) > 0$ ) {  
    For each VM in federated cloudlets  
        If ( $p_{cl}(VM) > p_c(A)$ )  
            add  $\langle VM, p_{cl}(VM) \rangle$  to  $VM\_P$ ;  
    If ( $VM\_P$  is not null)  
        Return VM with maximum profit in  $VM\_P$ ;  
    Else  
        Return VM in cloud;  
}  
Else {  
    For each VM in federated cloudlets  
        If ( $p_{cl}(VM) > 0$ )  
            add  $\langle VM, p_{cl}(VM) \rangle$  to  $VM\_P$ ;  
    If ( $VM\_P$  is not null)  
        Return VM with maximum profit in  $VM\_P$ ;  
    Else  
        Return null;  
}

---

## V. RESULTS AND DISCUSSION

### A. Simulation Parameters Setting

We considered the cloudlet federation scenario composed by three individual CLPs and a remote cloud. Each CLP deploys four servers within its managed area as its cloudlet. Each cloudlet server has 20-30 VMs, while the cloud has 2000 VMs. Referring to Amazon, two types of VMs are supported. One with four Virtual CPUs (vCPU) and 16GB of memory, priced at \$0.424, serves DT tasks; the other has two vCPUs and 8GB of memory, priced at \$0.212, serves DS tasks. The processing speed of a vCPU is 20000MIPS. The task type is randomly selected. The influence of distance between servers in a cloudlet is not considered. Other parameters are set as shown in Table I.

### B. Comparison with the Baseline Algorithm

In order to verify the effect of the proposed method in terms of time delay and profit, the proposed method is compared and analyzed with DATM and CATM proposed in literature [25]. DATM is a delay-aware task migration algorithm that migrates tasks to the cloudlet that minimizes the latency of task execution. And CATM is a cost-aware task migration algorithm that migrates tasks to the cloudlet that minimizes the cost of task execution. Considering the obvious difference in delay expectation between DS and DT tasks, statistics are carried out for DS and DT tasks respectively when comparing the delay.

Fig. 3 and Fig. 4 compare the average delay of DPTM, DATM and CATM with the number of tasks. Here, Fig. 3 counts all DS tasks, while Fig. 4 counts all DT tasks.

TABLE I. PARAMETER SETTINGS

Parameter	Definition	Value
$D_{cl}$	Distance of user to local cloudlet	10-50m
$D_c$	Distance of user to the cloud	1-10km
$D_{fctm}$	Distance between FCLMs	200-500m
$S^p$	Propagation speed	$3 \times 10^8$ m/s
$R$	Data transmission rate	3Mbps
$t^{ept}$	Expected delay of DS task	50-100ms
	Expected delay of DT task	200-400ms
$req^{ins}$	DS task size	1000-2000MI
	DT task size	500-1000MI]
$P^{low}$	Minimum quotation for DS task	\$2
	Minimum quotation for DT task	\$1
$P^{max}$	Maximum quotation for DS task	\$3
	Maximum quotation for DT task	\$2
$d$	Size of input data for task	0.1-2MB
$k_{dt}$	The parameter in (1)	0.6
$\beta$	The parameters in (3)	3

Fig. 3 shows that for DS tasks, DPTM achieves better average delay than DATM, while DATM outperforms CATM. Although DATM is optimized for delay, it does not distinguish between DS and DT tasks. DPTM tries to reserve local cloudlet resources for DS tasks. Therefore, for DS tasks, DPTM obtains a better average delay than DATM.

For the DT task, the results in Fig. 4 show that DPTM achieves better average latency than CATM, but not as good as DATM. DPTM gives priority to DS tasks in terms of latency, thus, for DT tasks, it is not surprising that its average latency is lower than DATM. For CATP, it aims at minimizing task migration cost and does not focus on delay. Although DPTM mainly optimizes the profit for DT tasks, the profit is negatively correlated with the delay, so it optimizes the delay to a certain extent.

Fig. 5 compares the profit with the number of tasks. From Fig. 5, it can be observed that DPTM achieves the best profit, followed by CATM and DATM. The quotation of the task is related to the time delay, while the lease price is related to the resource utilization and the quotation. Therefore, the profit of the task is related to both the time delay and the resource utilization. For CATM, although it aims to minimize the migration cost, the profit decreases due to the high average delay. For DATM, the latency is relatively small, which can increase profits. However, in order to pursue low latency, tasks are preferentially scheduled to the local cloudlet, resulting in high resource utilization of the cloudlet, which pushes up the task quotation and reduces the profit.

In general, DPTM achieves better profit because it treats DT and DS tasks differently and differentiates the relationship between the quotation and the delay of these two types of tasks. For DS tasks, DPTM also achieves better average delay.

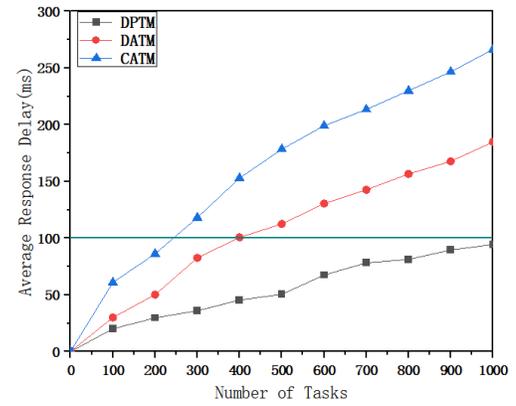

Fig. 3. Average Delay of DS Tasks.

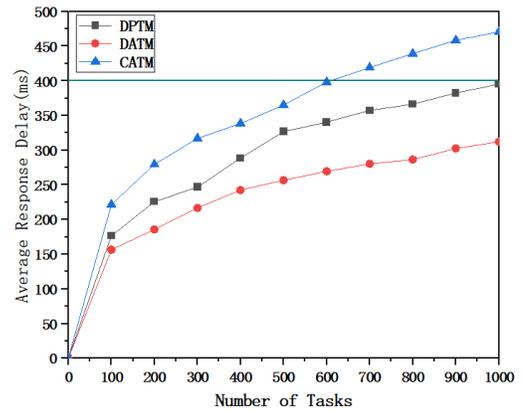

Fig. 4. Average Delay of DT Tasks.

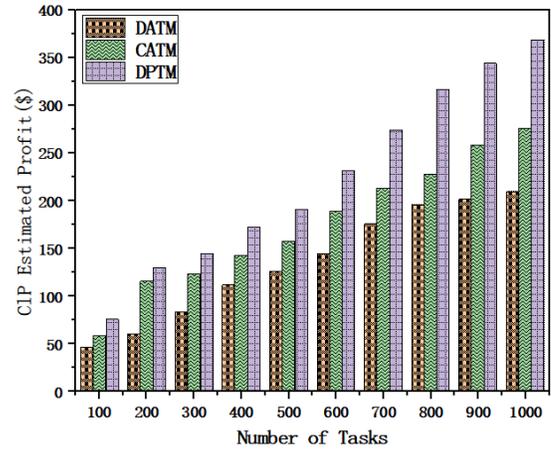

Fig. 5. Average Profit of Tasks.

### C. The Necessity of the Federation

To verify the necessity of considering federation, the federation scenario is compared with the non-federation scenario where cloudlet resources cannot be shared between different CLPs.

Fig. 6 compares the average latency of the two scenarios. Where, Fed-DPTM-DS and Fed-DPTM-DT represent the average delay of all DS and DT tasks in the federated scenario, respectively. NonFed-DPTM-DS and NonFed-DPTM-DT indicate the average latency of all DS and DT tasks in the non-

federated scenario, respectively. From Fig. 6, it can be found that the average delay of DS and DT tasks are both significantly reduced when considering federation. This is because in the federation scenario, different CLPs share cloudlet resources, which can reduce the impact of the difference in the number of tasks and the uneven distribution of cloudlet resources among CLPs. For DT tasks, the decrease effect of average delay is more obvious, because DPTM preferentially migrates DT tasks to the federated cloudlet. However, without considering federation, tasks tend to be migrated only to the cloud, resulting in higher latency.

As can be seen from Fig. 7, considering federation can improve profits, and the more tasks there are, the more obvious the improvement effect will be. On the one hand, DPTH is specifically designed for the federation scenario. On the other hand, CLP federation supports cloudlet resources sharing, which reduces the average delay and reduces the probability of tasks being scheduled to the cloud or rejected.

Fig. 8 compares the ratio of the number of rejected tasks to the total number of tasks in the two scenarios. As can be seen from Fig. 8, no matter which scenario, with the increase of the number of tasks, the situation that the task is rejected for scheduling occurs, and the proportion of rejected increases with the increase of the number of tasks. However, compared with the non-federation scenario, the proportion of tasks rejected for scheduling is much lower in the federation scenario.

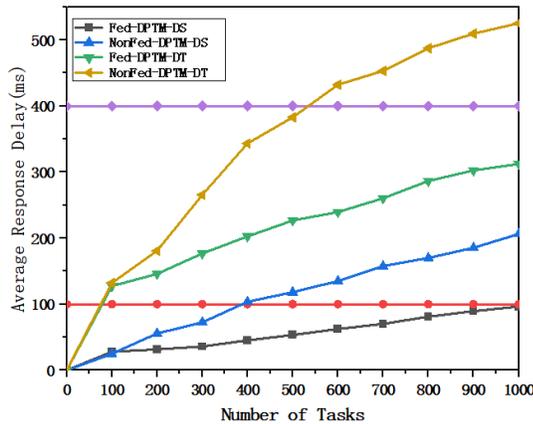

Fig. 6. Profits for the Two Scenarios.

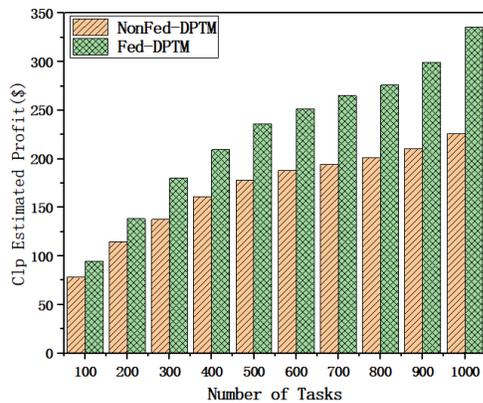

Fig. 7. Average Profit of Tasks.

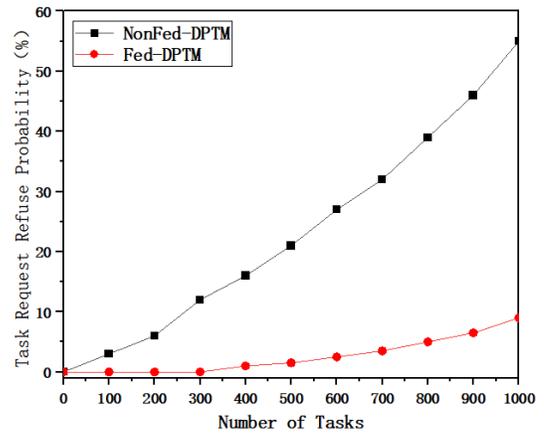

Fig. 8. Refuse Probability of Tasks.

In general, considering the federation scenario, the average delay can be reduced, profits can be increased, and the probability of task rejection can be reduced.

#### D. Impact of Authentication Delay

During resource sharing, some authentication information may need to be exchanged between CLPs, which may lead to authentication delay. Fig. 9 and Fig. 10 analyze the influence of authentication delay on the average delay of DS and DT tasks, respectively. For DS tasks, the results in Fig. 9 show that when the number of tasks is small (no more than 100), the authentication delay has almost no effect on the average delay, because almost all DS tasks are scheduled to the local cloudlet. However, when the number of tasks is large, the average delay of DS tasks increases with the increase of authentication delay, because more and more tasks have to be scheduled to the federated cloudlet.

As shown in Fig. 10, the average delay of DT tasks increases with the increase of authentication delay, even if the number of tasks is small, because DT tasks are preferentially deployed on the federated cloudlet. Different from DS tasks, authentication delay is not sensitive to the number of DT tasks.

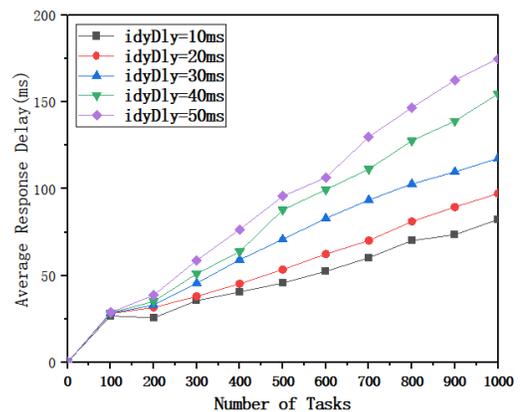

Fig. 9. Impact of Authentication Delay to DS Tasks' Delay.

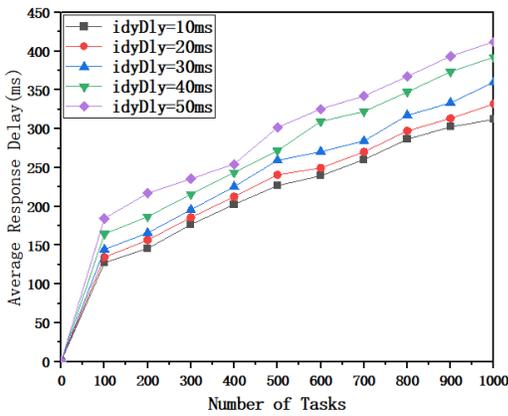

Fig. 10. Impact of Authentication Delay to DT Tasks' Delay.

Fig. 11 analyzes the impact of authentication delay on profit. Fig. 11 shows that the profit decreases as the authentication delay increases. And the longer the delay, the faster the profit decreases. This is because for a DT task, when the delay exceeds the threshold, the quotation is linearly reduced. And for DS tasks, the quotation is exponentially reduced when the delay exceeds the threshold.

In a word, the authentication delay can affect the task delay and profit, so the authentication delay should be minimized.

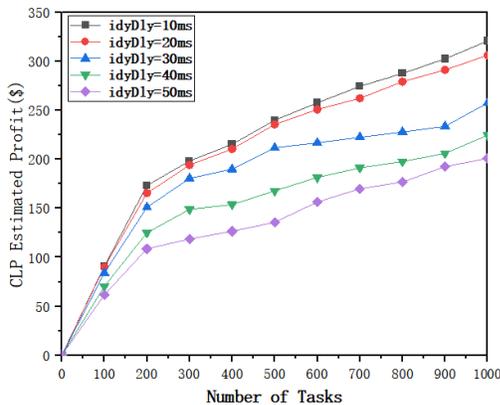

Fig. 11. Impact of Authentication Delay to Profit.

### E. Discussion

CLP can share resources with each other in the form of alliances, to solve the problem of resource limitation and the high cost of resource expansion and benefit from the heterogeneity of resource prices provided by different CLPs in alliances. CLP has more options for task migration, resulting in higher benefits. As far as we know, most of the existing studies consider horizontal edge federation or cloud federation, and there are few researches on task migration for the cloudlet federation. Meanwhile, few types of research on task migration for the cloudlet federation combine the powerful computing power of cloud center. For this reason, because of the shortcomings of existing research, this paper considers a cloudlet federation scenario integrating CLP and cloud center computing resources. At the same time, the cost of CLP and task processing delay are considered in the process of task migration, and the authentication delay is considered in the delay calculation.

As shown in Fig. 5 and Fig. 6, the DPTM algorithm proposed in this study balances the needs of users and CLP. The algorithm outperforms the baseline approach in terms of latency and profits of CLP and helps to satisfy more requests. Initially, DPTM divides tasks according to their delay sensitivity. Next, DPTM takes the delay minimization as the optimization goal in the DS task migration and ensures the task delay requirement in the DT task migration. However, the specific calculation process of authentication delay between different CLP resources during task migration and the factors that may affect the authentication delay need to be explored next. At the same time, some users may move during task migration, which is another factor to be considered.

## VI. CONCLUSIONS AND FUTURE WORK

Cloudlet federation can effectively reduce the deployment and management cost of cloudlet by sharing resources among CLPs. However, the differences in the number of users and resources among CLPs bring new challenges to task migration. When studying the task migration strategy for the cloudlet federation, two types of tasks, DS and DT, are considered, and the relationship functions between user quotation and delay of these two types of tasks are designed. A task migration algorithm, called DPTM, which takes into account both delay and profit, is proposed. The DPTM algorithm consists of two sub-algorithms: TMDS and TMDT. The former is used to schedule DS tasks with delay as the main optimization objective. The latter is used to schedule DT tasks with profit as the primary optimization objective. Simulation results demonstrate the effectiveness of the proposed method.

In the future, we plan to design a centralized task migration strategy. In addition, the secure access problem when resources are shared between different CLPs is further discussed. Meanwhile, we intend to design a more intelligent task scheduling algorithm based on Artificial Intelligence (AI).

# Collaborative Ontology Construction Framework: An Attempt to Rationalize Effective Knowledge Dissemination

Kaneeka Vidanage<sup>1</sup>, Noor Maizura Mohamad Noor<sup>2</sup>, Rosmayati Mohamad<sup>3</sup>, Zuriana Abu Bakar<sup>4</sup>  
Faculty of Ocean Engineering Technology & Informatics, Universiti Malaysia Terengganu<sup>1, 2, 3, 4</sup>  
OREL IT – Research and Development Unit, Sri Lanka<sup>1</sup>

**Abstract**—Ontologies are domain rich conceptualizations, which can be utilized for effective knowledge dissemination strategies. Knowledge dissemination plays a vital role in any industry. In this research, novel framework is designed and experimented for the collaborative ontology construction. With the iterative and incremental involvement of the domain specialists and ontologists rational process has been discussed and planned for the collaborative ontology construction. Additionally, existing shortcomings associated with the current ontology construction methodologies and frameworks also have been rigorously reviewed to identify the shortcomings. Henceforth the responses received from the domain specialists and ontologists, along with the gaps located from the literatures have been utilized as the backbone in designing this novel framework. Designed ontology increments have the potential of effective knowledge distribution once it's coupled with technologies like chatbots. In this research, proposed framework has been deployed in three different domains and three different ontology increments have been created for each domain. Consequently, their efficacy have been tested with the involvement of domain specific stakeholders. Overall results have yielded an 82% of acceptance from the stakeholders.

**Keywords**—Collaborative; domain-specialists; framework; methodology; ontologies

## I. INTRODUCTION

Knowledge is the fuel which drives current economies. Therefore, effective mechanisms on knowledge diffusion are very critical. This research discusses about construction of knowledge enriched ontologies for effective knowledge dissemination. Ontologies are human understandable and machine-readable cognitive conceptualizations associated with a specific domain [1]. Once an ontology is constructed with accurate domain associated conceptualizations, it could be utilized as a centralized resource for effective knowledge dissemination [2]. For an instance, if an ontology is constructed on the domain of COVID-19 pandemic, a chatbot can be coupled with it to ensure engaging knowledge distribution to educate varied populations. Nevertheless, capturing the expert human insights and construction of the ontology can be identified as a challenging yet very critical necessity to be accomplished precisely [3]. Because there are no fully automated mechanisms that exist so far for the ontology construction, hence it's a complex philosophical task, which can only be handled effectively by humans [4].

This research emphasizes on a specialized framework for precise ontology construction amidst collaborative involvements. Because, deriving expert knowledge from humans with multivariate specialties and concisely evolving it to a level of cognitively enriched ontology is not an easy task [3-4]. However, the use case of knowledge distribution via a chatbot becomes operational only if the ontology creation is successful and accurate. Therefore, a systematic approach to efficiently gather knowledge from heterogeneous human experts for the purpose of collaborative ontology development can be characterized as a research gap that needs to be filled.

This research proposes “Collaborativity” framework to fulfill the aforementioned requirement. This novel framework comprises of separately defined dedicated modules to foresee numerous critical aspects associated with collaborative ontology construction. Governing module, operational module, traceability module and opinion aggregation module are such modules residing inside this framework. Those modules collaboratively communicate to streamline the opinion acquisition, process enforcement and decision logging for the enhanced traceability.

Opinion aggregation module utilizes a voting strategy to adequately represent the collaborative participation of all the involved stakeholders. All these strategies will eliminate the black boxes associated with the entire procedure and improve the clarity and the transparency of the entire workflow. Collaborative ontology engineering is the latest trend associated with the ontology construction. Though there are several collaborative ontology construction methodologies available, almost all of them have severe shortcomings. Those aspects will be discussed in detailed during the literature review section. In such setting, this novel framework can be identified as a significant contribution to the domain of collaborative ontology engineering.

## II. LITERATURE REVIEW

Ontology construction is a complex process. It's impossible to create an effective ontology from a one shot [5]. This makes, ontology construction procedures iterative and incremental [6]. Another important aspect to consider is the role separation of ontologists and domain specialists. Ontologists are the semantic tech specialists, who create and evolve the ontology as per the specifications and knowledge provided by the domain specialists [7]. Majority of the existing methodologies and

frameworks have not properly distinguished between the roles of ontologists and domain specialists. This leads to operational confusions amidst the ontology construction process. Below Tables 1 to 3 contain a comprehensive review on the deficiencies associated with second, third generation methodologies and frameworks respectively.

As reviewed above, though there are numerous methodologies and frameworks for the ontology construction, almost all of them have multiple weaknesses such as:-

- 1) Ambiguous workflows – This leads to operational glitches of the involved stakeholders.
- 2) Explicit instructions are not provided – Allows excessive freedom to the stakeholders to act as they wish. This tarnishes the process consistency.

3) Role duality issues – Roles of the ontologists and domain specialists are not clearly defined. This leads to lots of operational confusions, during the working of the methodology/framework.

4) Poor logging of the operational decisions. This hinders lateral audits.

5) Absence of a mechanism to handle the collaborative communication flows occur between domain specialists and ontologists.

6) Irrespective of ontology construction being a cognitively enriched mental task; only engineering aspects are considered, ignoring the associated cognitive gravity.

TABLE I. SECOND GENERATION METHODOLOGY REVIEW

Significant second-generation Methodologies	Key deficiencies located on collaborative accomplishments
Methontology [8]	Lack of a clearly defined workflow causes many uncertainties such as; poorly organized activities, and issues with post-audit inspections. Additionally, there is no enough documentation of collaborative decisions made. The responsibilities of the domain experts and ontologists are not regulated.
TOVE [9]	The obligations of the domain specialists and ontologists are not specified. This casts doubt on the parties' ability to maintain interoperability and consensus causing operational glitches
IDEF5 [10]	The procedures for verifying ontology increments are not well-structured. In a group setting, how do you decide whether to move on to the next increment or repeat the same increment again? How does ideology collaboration between domain specialists and ontologists take place? Similarly, there are several process ambiguities.
Enterprise Model [11]	Very abstract and high-level. It is impossible to assess operational success due to a lack of standardized operating procedures (SOPs).
OTKM [12]	Roles of the ontologists and domain specialists are not clearly defined.

TABLE II. THIRD GENERATION METHODOLOGY REVIEW

Significant third-generation methodologies	Key deficiencies located on collaborative accomplishments
Diligent [13]	Users are given an overabundance of control. As a result, the controlled operational flows have been jeopardized.
SMOD [14]	Explicit work procedures are not defined. This allows excessive freedom for the stakeholders, jeopardizing process consistency.
Neon [15]	Many uncertainties, such as poorly coordinated operations and problems with post-audit inspections, are brought on by a lack of a clearly defined workflow. Decisions are not sufficiently documented, as well. There are no rules governing the duties of domain experts and ontologists.
Upon-Lite [16]	Explicit work procedures are not defined. This allows excessive freedom for the stakeholders.
AMOD [17]	The transition process of ontology increments is absent. Several hidden black boxes trigger; great deal of ambiguity.
CO <sub>4</sub> [18]	Poor processors. The roles of ontologists and domain specialists are not well defined.
(KA) <sub>2</sub> [19]	Poor processors. The roles of ontologists and domain specialists are not well defined.

TABLE III. FRAMEWORK REVIEW

Framework	Key deficiencies located on collaborative accomplishments
Semiotic [20]	Excessive ambiguity. No structured workflow for transparency and traceability.
RapidOWL [21]	Too lenient, which could jeopardizes the process consistency
Generic Ontology Development Framework [22]	Poor processors. The roles of ontologists and domain specialists are not well defined.
Platform Independent Ontology Development Framework [23]	Explicit work procedures are not defined. This allows excessive freedom for the stakeholders, jeopardizing process consistency.
Industry Relevant Ontology Development Framework [24]	Poor processors. The roles of ontologists and domain specialists are not well defined.
Systemology [25]	Poor processors. The roles of ontologists and domain specialists are not well defined.

The literature review conducted above clearly reveals the shortcomings associated with the existing methodologies and frameworks available for the ontology construction. Therefore, it can be justified as a research gap which requires to be addressed.

### III. METHODOLOGY

As the outcome of this research, it suggests a novel framework capable of addressing aforementioned deficiencies. The overall research methodology followed for the construction and evaluation of this framework can be depicted in form of a process diagram as depicted in Fig. 1.

This framework is named as “Collaborativity”, hence its main goal is to collaborate all viewpoints of the stakeholders in a methodical manner and trigger the ontology increment construction. The flow of this framework was developed through several trial-and-error tests with domain specialists, as well as it equips with remedies to the inadequacies found in existing approaches and frameworks discussed in the literature review section.

“Collaborativity” framework comprises of mainly four modules with designated responsibilities. Operational module comprises of a stepwise orchestration on the ontology increment construction. Each important insights generated during the operational module’s steps are logged within the respective tracker sheets structures, belonging into the traceability module. This ensures transparency and assists in latter auditing requirements of the collaborative opinions of the involved stakeholders.

Governing module is mainly responsible for handling the cognitive perspectives and the workflow of the involved stakeholders. As a result of the fact that ontology development is a complicated cognitive process that involves several stakeholders from various domains, a methodical pipeline is required to efficiently handle the collaborative interactions and workflows that occur in the group environment.

The pipeline introduced inside the governing module is defined with the name “Synchronized Action Plan Meet.” This is a time-boxed workflow, governing numerous cognitive and process specific tasks associated with the respective operational module’s phase. This process enforcement has been identified as very vital. Unless it could lead to biases and numerous opinion conflicts among the involved stakeholders. Therefore, governing module plays a vital role in addressing process consistency perspectives. The entire operation inside this framework is governed via pool of ontologists, who are designated with multiple roles as convener, timekeeper and documenter.

Opinion aggregation module is responsible in governing the phase-specific transitions inside the operational module. Fig. 2 depicts the operational workflow of the opinion aggregation module.

Governing module’s “Synchronized Action Plan Meet” process will be applied across all phases of the operational module. Henceforth, all stakeholder’s vote is inquired on the completed phase. If the vote percentage exceed more than 80% of the involved participants, a collaborative decision is taken

for the transition to the next phase of the ontology increment construction. If the majority vote of the stakeholder’s do not exceed 80%, same phases is examined for shortcomings and reiterated with the suggested modifications. This way it ensures, transparency and collaborative participation of the stakeholders for the decisions reached in the forward movement of the ontology increment construction. This idea is enforced by the Power of 80% rule, which is strongly enforced in clinical trials associated with humanoid subjects.

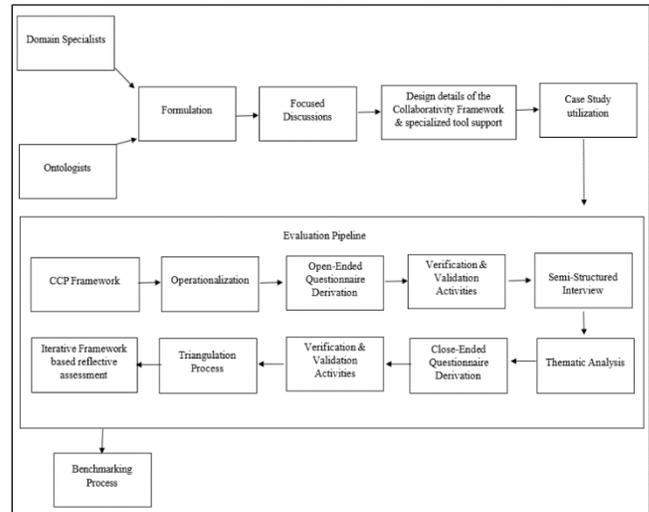

Fig. 1. Research Methodology Flow.

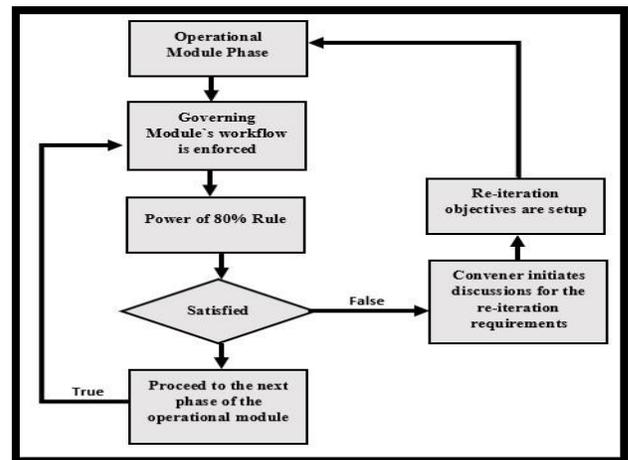

Fig. 2. Opinion Aggregation Module’s Workflow.

Fig. 3 denotes the roles of the governing module, operational module and opinion aggregation modules in conjunction.

Fig. 4 denotes the fixation of all four modules inside the Collaborativity Framework. Fig 4, denotes synchronized action plan meet workflows belonging inside the governing module, mapping between the operational and traceability module as well as the process enforcement of the opinion aggregation module.

It’s significant to emphasize, that each operational module’s step is executed as per the workflow enforced by the governing

module (i.e. synchronized action plan meet phase I and II). Subsequently, transition from one operational module step to the next is controlled by the process enforced via the opinion aggregation module. All collaborative decisions emerged during the stakeholder interactions are logged inside the traceability module's tracker worksheets.

Once the framework's structure is finalized, subsequently, it's decided to apply the framework for three case studies to assess its operational efficacy in order to fulfil this requirement.

COVID-19, Criminal Law and Aquaculture domains were selected. Henceforth, "Collaborativity" framework was applied, and three different ontology increments were created. Henceforth, those were coupled with chatbots and with the involvement of the respective domain specialists' responses derived via the chatbots were reviewed as well as the structures of the constructed ontology increments.

Evaluation pipeline depicted in Fig. 1 was utilized for the assessment of the "Collaborativity Framework." CCP framework [26] and operationalization [27] procedures were utilized in combination to compile applicable sets of questionnaires. Once the basic versions of the questionnaires were compiled, those were validated and verified for their reliability and accuracy.

Henceforth, controlled interview sessions with the respective domain specialists of the three fields were conducted using the compiled questionnaires and responses were recorded.

Consequently, the logged qualitative responses of the stakeholders were reviewed and analyzed using thematic analysis. Outcome of the thematic analysis was utilized to

determine the most significant topics associated with the insights derived from the stakeholder's interviews. Eventually, targeting the significant topics emerged from the qualitative interview responses, series of close ended questions were created again using the CCP and the operationalization procedures [26-27].

Combinations of the quantitative and qualitative questionnaires utilized for the experiment is as depicted in Fig. 5.

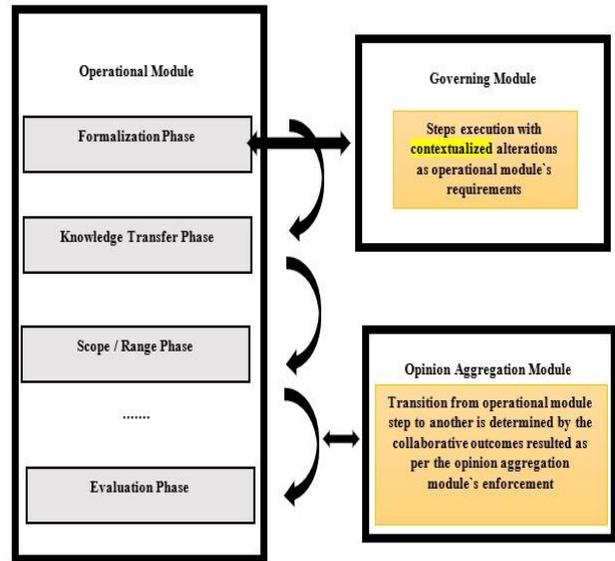

Fig. 3. Combinatory Roles of the Modules.

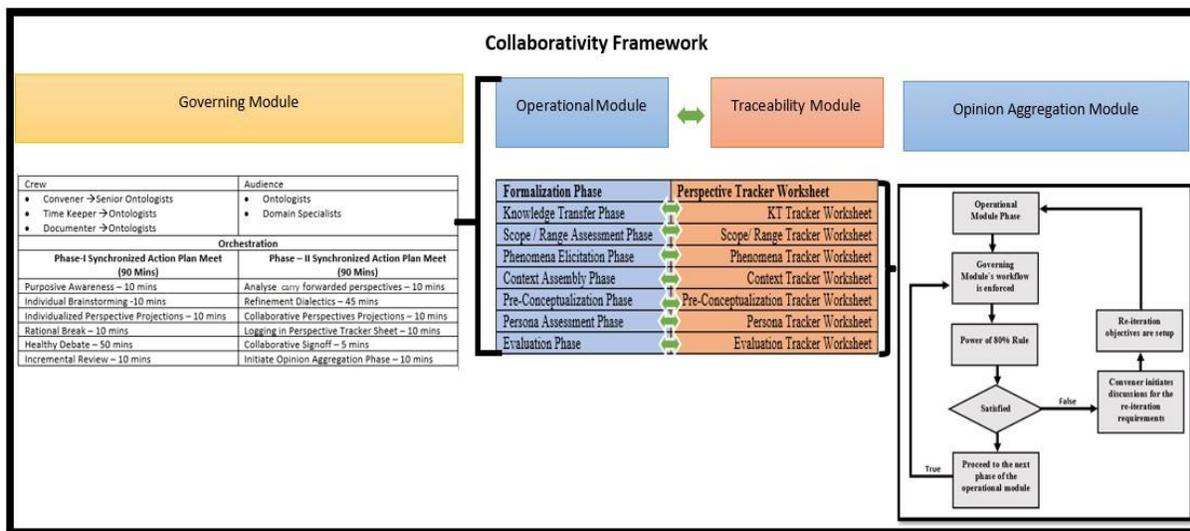

Fig. 4. Collaborativity Framework.

Qualitative Questionnaire	1. What observations have you made about existing frameworks applications on collaborative ontology construction? Please elaborate
	2. What observations have you made about the collaborativity framework's role in collaborative ontology construction? Please elaborate
	3. What do you expect from a novel framework for collaborative ontology construction?
	4. Does this framework ensure collaborative insight? Please explain
	5. Does this framework ensure collaborative consensus? Please explain
	6. Does this framework ensure collaborative goals related to ontology increment construction? Please explain
Quantitative Questionnaire	1. How satisfied are you with the framework's collaborative insight enforcement?
	2. How satisfied are you with the collaborative consensus enforcement of the framework?
	3. How effective are the governing, operational, and opinion aggregation modules in controlling the framework's flow?
	4. How would you rate the overall operation of the framework?
	5. How effective are the "Action plan meets" for communication synchronization and framework's target-oriented execution?
	6. How useful is the Dialectics step for communication synchronization?
	7. How useful is the Opinion assessment heuristic for collaborative communication synchronizations?
	8. How would you rate the overall communication synchronization enforced by this framework?

Fig. 5. Questionnaire Sets.

Reponses for the qualitative questions were retrieved via controlled interview sessions conducted. A special response grid depicted in Fig. 6 was used to record the responses for the quantitative questions.

10	20	30	40	50	60	70	80	90	100
Very poor	Fairly OK-Major revisions			Good & Acceptable- Few minor revisions				Exceptional	

Fig. 6. Quantitative Response Grid.

#### IV. RESULTS AND DISCUSSION

Significant themes emerged out from the thematic analysis of the interview responses have been logged in Table IV.

Consequently, quantitative close-ended questions were formulated covering the themes emerged from the thematic analysis. Responses of qualitative feedback has been logged in Table V.

Henceforth, Cronbach analysis was performed to assess the reliability of the responses provided and the outcomes for the domains have been logged in the Table VI.

According to Cronbach reliability tests of the user responses, a Cronbach Alpha value ranging in between 0.65 – 0.95 is accepted as a reliable distribution [28]. Therefore, Cronbach reliability test confirms the reliability of the stakeholders` responses yielded, covering all three domains and the ontologists. Table VI denotes the reliability test distribution results.

Additionally, an ANOVA test also has been conducted to reveal the significance of the user responses and to confirm there are no significant statistical anomalies [29]. Table VII denotes the outcomes of the ANOVA test conducted.

As depicted in Table VII, P-value (i.e., 0.23) for the test conducted in greater than the standard alpha value of 0.05 [29]. Hence, it confirms, that the population has responded to the questionnaire without any outliers causing no statistically significant anomalies.

TABLE IV. THEMES REVEALED FROM THE THEMATIC ANALYSIS OF INTERVIEW RESPONSES

Qualitative themes emerged from the controlled interview session conducted on Collaborative Framework	Collaborative Goals
	Transparency of Operations
	Process Enforcement
	User Friendliness

TABLE V. RESPONSE SCORES OF THE CLOSE-ENDED QUESTIONNAIRE

Question Cluster	Domain	Averaged Response Scores
Collaborativity Framework	Law	88%
	COVID-19	85%
	Aquaculture	82%

TABLE VI. CRONBACH ALPHA RELIABILITY TEST SCORES

Domain/Segment	Cronbach Alpha Value
Criminal Law	0.736
COVID-19	0.713
Aquaculture	0.728
Ontologists	0.702

TABLE VII. ANOVA SIGNIFICANCE TEST

ANOVA						
Source of Variation	SS	df	MS	F	P-value	F crit
Between Groups	167.458333		55.8194444	1.5690379	0.22806	3.09839
	3	3	4	3	8	1
Within Groups	711.5	0	35.575			
	878.958333	2				
Total	3	3				

Subsequently, a benchmark test has been conducted to assess the uniqueness associated with the Collaborativity framework. Eight existing and latest methodologies and frameworks have been utilized for this comparative assessment. Results associated with the benchmark test has been logged in the Fig. 7.

Finally, Iterative framework [30] has been utilized to triangulate and amalgamate all the experimental tests conducted against the research's expectation. Iterative Framework is an established research framework utilized to consolidate multiple test experiments against the research's expectations [30]. Table VIII denotes the application of the Iterative Framework for this research study.

Feature Index	Researched Framework: Collaborativity	Existing Methodologies & Frameworks							
		Systemology	Diligent	SMOD	NeOn	U-pon-Lite	AMOD	RapidOWL	Se

TABLE VIII. APPLICATION OF THE ITERATIVE FRAMEWORK

Iterative Framework's questions		Mapping Evidence
1. What are the data telling me?	•	Four important themes have been yielded from the thematic analysis conducted
	•	Averaged quantitative response score for all three domains: -85%
	•	Averaged Cronbach Alpha Reliability Score: - 0.72
	•	ANOVA Significance Score: -0.23
2. What do you want to know?	•	Overall effectiveness of the newly designed Collaborativity framework for ontology constructions in collaborative atmospheres.
3. Is there a dialectical relationship between 1 & 2	•	Yes. Mapping Evidences of Question 1, reflects the Question 2 , perspectives have been satisfied in a consolidated fashion.

### V. CONCLUSION

This research paper discusses about the application of a newly designed framework for effective ontology increment construction on the collaborative group atmospheres. Efficacy of this framework has been tested using case study mechanism. Three independent case studies have been conducted on three different domains. Three separate ontology increments have been compiled and they were tested by the structure and practical applications. For the practical utilization test, the

created ontology increments have been linked with chatbots and validity of the responses provided were assessed by the subject specialists.

COVID-19, ontology increment was tested by general physicians, based on the validity of the responses provided. Criminal Law increment and Aquaculture increment was tested by the respective experts in the fields. Once, these prototypes got evolved to the level of products, they can be effectively utilized to educate and disseminate knowledge on medical students, law students and zoology students. This practical application could immensely reduce the workloads of the university lectures, without penalizing the user experience of the students as well. Currently, the prototype version has yielded up to 82% of user acceptance.

This research contributes a novel ontology construction framework, addressing the deficiencies of the existing methodologies and frameworks. Additionally, its use cases are very valuable to all the fields where knowledge dissemination plays a vital aspect. In future, it's expected to boost the power of this framework via integration computerized tool support as well.

Laboratory of Computer Sciences, faculty of sciences Ibn Tofail University, Kenitra, Morocco

**Abstract**—Sentiment analysis has become more and more requested by companies to improve their services. However, the main contribution of this paper is to present the results of the study which consists in proposing a combined model of sentiment analysis that is able to find the binary polarity of the analyzed text. The proposed model is based on a Bidirectional-Long Short-Term Memory recurrent neural network and the TextBlob model which computes both the polarity and the subjectivity of the input text. These two models are combined in a classification model that implements each of the Logistic Regression, k-Nearest Neighbors, Random Forest, Support Vector Machine, K-means and Naive Bayes algorithms. The training and test data come from the Twitter Airlines Sentiment data set. Experimental results show that the proposed system gives better performance metrics (accuracy and F1 score) than those found with the BiLSTM and TextBlob models used separately. The obtained results well serve organizations, companies and brands to get useful information that helps them to understand a customer's opinion of a particular product or service.

**Keywords**—Sentiment analysis; textblob; long short term memory; logistic regression; k-nearest neighbors; random forest; support vector machine; k-means; naive bayes

## I. INTRODUCTION

Sentiment analysis is a technique that focuses on the evaluation of emotions, attitudes and opinions. Today, organizations, companies and brands use this technique to obtain useful information that helps them to understand a customer's opinion of a particular product or service. For this purpose, several models of sentiment analysis, which is a field of artificial intelligence, in particular natural language processing, have emerged. In this sense, given the importance of texts coming from Twitter, several studies have been focused on this topic, among these studies, we can cite the analysis of subjectivity [1], the detection of events [2], the evaluation of online reputation [3], the identification of trends on social networks [4]. Sentiments are essentially labeled according to the polarity of the text, i.e., whether the message has a positive, negative or neutral connotation. The determination of polarity can be done at different levels, namely the document [5], the sentence [6], the word [7] or the attribute [8]. In a previous study, Chiny et al. [9] proposed a hybrid sentiment analysis model based on three input models; the LSTM model, the TF-IDF word weighting model and the pre-trained model based on the VADER lexicon. These three models are combined using a classifier that returns the binary

sentiment experienced in the input text. The proposed architecture is characterized by the small amount of data required for training. In addition, the model is characterized by its ability to transfer the knowledge already acquired to process a different dataset than the one that provided the training data. However, in a text, the semantics of a given word does not only depend on the words preceding it, but also on the following words. For this reason, we thought of implementing the BiLSTM model which evolves in both directions rather than the LSTM model which considers the current word and the previous words only as a temporal sequence. Therefore, the aim of this research paper is to propose a hybrid sentiment analysis system by combining two input modules. The first model is based on the use of BiLSTM networks. In the second model, a Textblob sentiment analyser is used to evaluate the subjectivity and polarity of texts. Subjectivity and polarity are features of a linear regression model that returns a single sentiment score. Both models were trained on the US Airlines Sentiments twitter dataset. Each model returns scores of positivity or negativity from the text to be analyzed. Then, these two (input) models are combined into a binary classification model in which the Logistic Regression, k-Nearest Neighbors, Random Forest, Support Vector Machine, K-means and Naive Bayes models are implemented.

After implementing the proposed architecture, we wish to have performance metrics (i.e., accuracy and F1 score) superior to the metrics calculated for the two modules (BiLSTM and TextBlob) separately. The main contribution of this paper is to have a more advantageous performance than the model proposed in the study by Chiny et al. [9]. This improvement will allow organizations, companies and brands to have more relevant and meaningful information that will help them to understand and analyze customer opinions about a product or service provided.

## II. RELATED WORK

### A. Bidirectional Long Short Term Memory

Processing sequential data and natural language (NLP) leads to several major problems related to the nature of the data. To solve these problems, the authors of [10] used recurrent neural networks (RNN), which are artificial neural networks that use hidden states to model the behavior of dynamic systems.

According to [11], a BiLSTM (Bidirectional Long Short-Term Memory) network is a recurrent neural network that processes data in two different ways. The use of this network is particularly requested in the field of natural language processing. Indeed, the meaning of a word in a sentence may depend on the preceding and following words. Therefore, in this kind of cases, it is desirable to go through the sentence in both directions to get the right meaning. The BiLSTM offers this particularity which makes it different from LSTM networks.

The bi-directional nature of BiLSTM has given it great potential to be at the heart of many works related to natural language processing. For example, Zhou et al. [12] applied a two-way LSTM with 2D max pooling to the Stanford Sentiment Treebank (STS) database; each vector is represented by a 2D matrix. In addition, to find optimal performance, Shen et al. [13] proposed a new design combining the CNN and BiLSTM models. They found that this combination achieved an accuracy of 89.7%. This result is better than that of each of the models individually. In another study, Yoon et al. [14] proposed a CNN-BiLSTM architecture for document-level emotion prediction using multi-channel integration with CNN. The model worked on different datasets and achieved average performance from 51.97% to 70.08%.

Wu Xing et al. [15] used long-term memory (LSTM) to automatically generate poems based on the author's style. In [16], Felix et al. studied bidirectional long-term memory networks (BLSTMs) and i-vectors to model the author's speech. They also used i-vectors to model the longer term acoustic context. Also, in [17], Nowak et al. (2017) compared the LSTM model and the BLSTM model in the emotion classification of Amazon's book review dataset. The results obtained by the authors show that the BLSTM model is more accurate than the LSTM model in this task.

Seneewong Na Ayutthaya and Pasupa (2018) attempted to merge the BLSTM and CNN deep learning models to examine word sequences and discover local text characteristics [18]. The results showed that the combination of deep learning models improved the accuracy of sentiment analysis. Furthermore, deep bi-directional LSTMs (DBLSTMs) have recently been shown to provide performance for solving many problems, such as text analysis. These problems include sentiment classification [19], speech recognition [20], semantic labelling [21] and large-scale acoustic modeling [22]. BLSTM networks have proven useful in discovering character input patterns for processing a wide variety of natural languages.

In the literature, different deep learning algorithms have been applied to process different types of data. The researchers used complex neural networks (CNNs) to process computer vision subjects and analyze text to infer a local structure, while using long-term memory (LSTM) and bidirectional LSTM (BLSTM) for sequential data processing and different language models [23,24,25].

To analyze the sentiment trend of Chinese texts. Gan et al. [26] used a joint multi-channel dilated evolutionary architecture of a convolutional neural network and a

bidirectional long-term memory model (CNN-BiLSTM) with an attention mechanism.

In [27], Wang et al. used a bidirectional short-term memory network enhanced by emotion semantics (BiLSTM) with the multi-headed attention mechanism model (EBIL).

The work of Batbaatar et al. [28] aimed to propose a new neural network architecture, called SENN (Semantic-Emotion Neural Network), which can use both semantic/syntactic and emotional information by adopting pre-trained word representations.

### B. Subjectivity and Polarity

Sentiment analysis, also known as opinion research, is aimed at understanding how a reader could interpret a person's subjectivity and translate it into an algorithm capable of performing this task automatically. According to the authors' studies [29, 30], the polarity of a sentiment is a quantified measure on the scale of values corresponding to a positive or negative assessment of emotional significance. From this quantification, we can test the polarity of the subjective text by the classification of sentiment. Indeed, if we have a review about a product, the sentiment analysis system must determine whether the emotion expressed in that review has a positive or negative connotation. In general, the polarity of the text can be positive, negative and sometimes neutral to identify a lack of feeling in a text.

According to [31], studies on polarity analysis are subdivided into two approaches: a lexical approach (also known as a knowledge-based approach) and a machine learning-based approach. The first approach uses dictionaries, such as LIWC (Language Inquiry and Word Count) [32] and Senti Word Net [33]. Generally, a dictionary consists of words and the corresponding classification value. Indeed, in a dictionary, we can find the word "pleasure" with a value +1 which signifies that this word has a positive polarity or, conversely, it can contain the word "hate" with the value -1 representing a negative polarity. According to the authors [32] and [33], adding the values of all the words in the text gives the resulting polarity. The result of the summation (positive or negative) determines the global polarity of the text. On the other hand, the second approach, is based on the use of classification algorithms, such as Naïve Bayes (NB), Maximum entropy (ME) and Support Vector Machines (SVM). These algorithms have been tested by the authors [34, 35, 36, 37] to perform text classification; the obtained results are promising. Polarity determination can be measured at the levels: document [48], sentence [39], word [40] or attribute [41]. The document level treats the whole document as the basic unit. The sentence level draws and determines the sentiment of each sentence in the text. At the word level, each word in the text is analyzed and classified. The attribute level identifies and extracts the attributes of an entity (e.g., product, person, company) in the text and determines the sentiment for each attribute [42].

Subjectivity aims at determining whether a text is subjective (opinion, emotions, evaluations, beliefs or speculations) or simply a fact, while the classification of feelings aims at determining the proper value of this

subjectivity [43]. Subjectivity detection prevents sentiment ranking from considering only texts that are relevant or potentially misleading. In addition, it reduces the size of the set of labels that can be assigned to a text, i.e., it must first be checked whether the text is objective or subjective, and those that are considered as such are subjected to a new classification process that will determine the polarity. In addition, sentiment analysis may involve identifying the target entity, i.e., the subject of the text to which the sentiment is addressed, and identifying the person or organization expressing the opinion [44]. There are texts in which the polarity is not as noticeable, as in mixed experiences, i.e. when there are both positive and negative remarks, which is different from a neutral text that is purely factual.

Among the most commonly used feedback mechanisms in Twitter data analysis is sentiment analysis, which provides insight into the sentiment expressed in messages [45]. This feeling is essentially labelled according to the polarity of the text, i.e. whether the message has a positive, negative or neutral connotation. For companies, this measure provides insight into the public's and market's opinion of themselves.

In [46], the authors found that machine learning techniques applied to sentiment analysis perform better than those obtained by random selection (50%) or by human classification (between 58% and 64%). To generate a classification model, this approach needs a dataset for training.

Pak et al. [47] discuss ways to collect tweets to exploit them in sentiment analysis. They employ a specific lexicon of emotions to reduce the manual tagging of tweets for the classification of feelings. Emotions are classified into two types, happy representing a positive sample and sad for a negative sample.

Among the works that used learning techniques for the classification of feelings, Pang et al. [48] employed Naïve Bayes algorithms, logistic regression and the support vector machine. In this work, the authors used film reviews to classify the polarity of sentiments. But, opinions are considered neutral when there is no opinion in the text or the opinion falls between the two polarities.

### III. PROPOSED SENTIMENT ANALYSIS ARCHITECTURE MODEL

The purpose of this research is to propose and test the validity of a new model of sentiment analysis (Fig. 1) composed of two input models. In the first model we used the BiLSTM algorithm, the validation of this model is tested on a corpus of US Airlines twitter sentiments. In the second model, we have exploited the TextBlob sentiment analyzer in the goal to evaluate the subjectivity and polarity of natural language texts. The subjectivity analysis attempts to estimate how subjective or objective the text is, while the polarity analysis determines whether the feeling in the text is positive or negative. The two outputs of the TextBlob model that represent the subjectivity and polarity scores are coupled with a multiple regression model to estimate the weights associated with each of these two features in the category of texts in our

study (short microblogging texts such as those from Twitter). After, the binary sentiment of the input text will be provided by a classifier that uses the scores already calculated by the BiLSTM and TextBlob models.

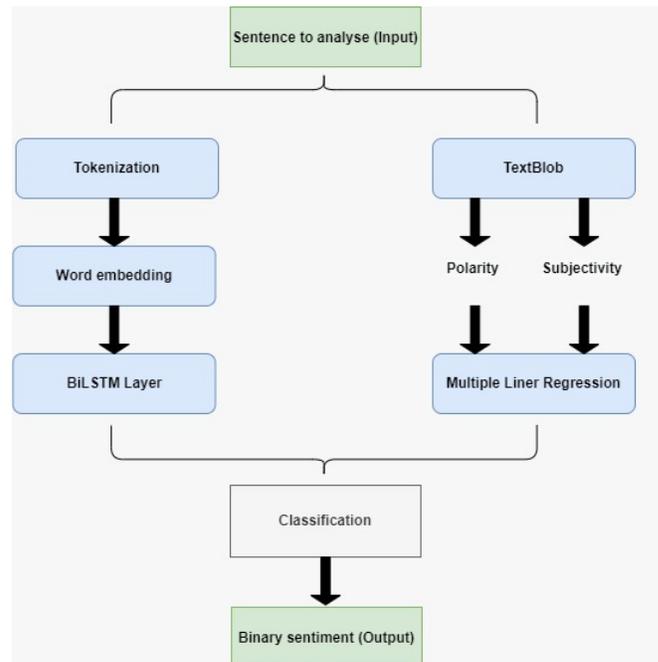

Fig. 1. Proposed BiLSTM and TextBlob based Combined Sentiment Analysis Model.

#### A. LSTM Bidirectional

The bidirectional LSTM algorithm (BiLSTM) is a recurrent neural network. This algorithm finds its major application in natural language processing. It has the advantage that the input flows in both directions: forward and reverse direction. BiLSTM is a very efficient algorithm for modeling sequential dependencies between words and sentences in both directions of the sequence.

To use the BiLSTM algorithm in the text to be analyzed, we need to do cleaning and filtering, followed by tokenization and then word embedding.

#### B. TextBlob

The TextBlob sentiment analyzer is a Python library for processing text data. It makes it possible to recognize the subjectivity and polarity expressed in natural language texts. Polarity analysis determines whether a subjective text is positive or negative in a range between [-1, 1], -1 indicating negative feelings and +1 positive feelings.

#### C. Cleaning and Filtering

To analyze the tweets reliably and correctly by our proposed system, we performed preprocessing on the dataset. The purpose of this preprocessing is to ensure that the tweets will be prepared in a formal language format that will be interpreted by the machine. Subsequently, we chose a dataset of 14,427 unique texts for the training and testing of our model.

#### D. Tokenisation

Tokenization is a technique used to transform text into single words (unigram) (individual tokens) or combinations of successive words (n-gram). In our model, we have divided the texts into a series of individual tokens in order to use the Glove model. We have defined the sequence length that is equal to the number of time steps for the BiLSTM layer.

#### E. Word Embedding

Word embedding is a technique based on the linguistic theory founded by Zelling Harris. It is in great demand in the classification of documents [49] because it uses machine learning algorithms to represent textual data (words or sentences of a text) by vectors of real numbers. In our research, this representation facilitates and improves the performance of automatic language processing methods (or Natural Language Processing) and more particularly it simplifies the processing of Sentiment Analysis.

To describe the words of our text by a numerical vector, there are several algorithms including Word2Vec and GloVe. We used the algorithm GloVe (Global Vectors for Word Representation) [50]. This choice is dictated by the nature of our proposed system. We used the calculated 100-dimensional GloVe integrations of 400,000 words.

#### F. BiLSTMLayer

When defining the BiLSTM layer, we tested several parameters and kept the ones that gave good results. The number of hidden units is set at 256 and the rmsprop optimizer is used, which compares favorably with other adaptive learning algorithms. The Table I summarizes all the hyper parameters of the chosen model.

#### G. Training and Evaluation of the Model {BiLSTMetTextBlob}

To train and evaluate our proposed system, we chose to use the US Airlines Twitter dataset [51]. This database is exemplary on the binary classification of text. It contains 14449 unique texts. We have selected 7000 reviews in the train and 2000 in the test series of our BiLSTM and TextBlob models.

The TextBlob model allows the calculation of polarity and subjectivity scores separately. We therefore used these two scores as features of a linear regression model to calculate an overall sentiment score. The two input models (BiLSTM, TextBlob) are then combined into a binary classification model.

#### H. Model de Classification

To improve and increase the performance of predictions on the sentiment conveyed by the input text, we propose a hybrid system consisting of two sentiment analysis models with a classification model. For this, we chose the BiLSTM model in the first place. This model is characterized by its ability to adapt to sequential data processing. In the second step, and to recognize the subjectivity and polarity expressed in the texts, we worked with the TextBlob sentiment analyzer.

TABLE I. HYPER-PARAMETERS OF THE BiLSTM MODEL

Hyper-parameter	value
Bath_size	128
Epochs	2
Outout embedding dimension	100
BiLstm layer internalunits	256
Optimizer	Rmsprop
Loss	Categorical_crossentropy

With this proposal, we aim to have a good accuracy and a good F1 score that will be provided by our system compared to the BiLSM and TextBlob models applied separately on the same data.

To have a general binary prediction (positive or negative) of the sentiment of the input text, the two inputs of our classifier (Fig. 1) are linked directly to the outputs of the BiLSTM and TextBlob models. It should be mentioned that the values of the entries of the classifier are continuous in an interval of [0,1].

We randomly chose 7000 reviews from our dataset. These data are different from the training set and test set data used for the BiLSTM and TextBlob models. To have the predictions calculated by the BiLSTM and TextBlob models, we provided this data as input to our global system. Subsequently, the output of the results are divided into two datasets, 75% for the train set and 25% for the test set of our binary classification model. In this work, we used six classifier algorithms namely: Logistic Regression (LR), k Nearest Neighbors (k-NN), Random Forest (RF), Support Vector Machine (SVM), K-Means and Naive Bayes (NB).

Table II summarizes the chosen hyper parameters that were subsequently applied to our classification models. These hyper parameters are experimentally retained; we have taken those that have given the best possible evaluations for our dataset.

TABLE II. HYPERMETERS APPLIED TO ALGORITHMS IMPLEMENTED IN CLASSIFICATION MODELS

Algorithme	hyperparameter	Value
Logistic Regression	Inverse of regularization	1
K Nearest Neighbors	strength Number of neighbors	13
Random Forest	-Number of in the forest	18
	-Maximum depth of the tree	2
Support vector Machine	Kernel type	rbf
Naïve Bayes	Function	Gaussin
K-Means	n_clusters	3

IV. RESULTS

A. Evaluation of our Proposed Model

To demonstrate the performance improvement brought by the proposed architecture, we trained the whole model with the same set of tests that allowed us to evaluate separately the BiLSTM and TextBlob. Fig. 2 shows the implementation of six different algorithms in the Classifier model.

TABLE III. PERFORMANCE METRICS DISPLAYED BY THE TWO INPUT MODELS ON THE TWITTER US AIRLINES SENTIMENTS

Model	Recal	F1	Accuracy
Bilstm	0.37	0.49	0.85
TextBlob	0.36	0.37	0.87

Table III shows that after training the BiLSTM model, its evaluation on the test data gave an accuracy score of 0.85 and an F1 score of 0.49 and with TextBlob we obtained an accuracy score of 0.87 and an F1 score of 0.34.

Table IV summarizes the performance obtained. These results are obtained after training and evaluating our model which consists of six classification algorithms.

TABLE IV. THE PERFORMANCE MEASURES OF OUR MODULE OBTAINED BY THE IMPLEMENTATION OF THE SIX CLASSIFICATION ALGORITHMS

Algorithme	Recal	F1	Accuracy
Logistic Regression	0.75	0.72	0.89
K Nearest Neighbors	0.80	0.68	0.87
K-Means	0.84	0.73	0.89
Random Forest	0.71	0.71	0.89
Naïve Bayes	0.88	0.64	0.82
Support vector Machine	0.72	0.71	0.89

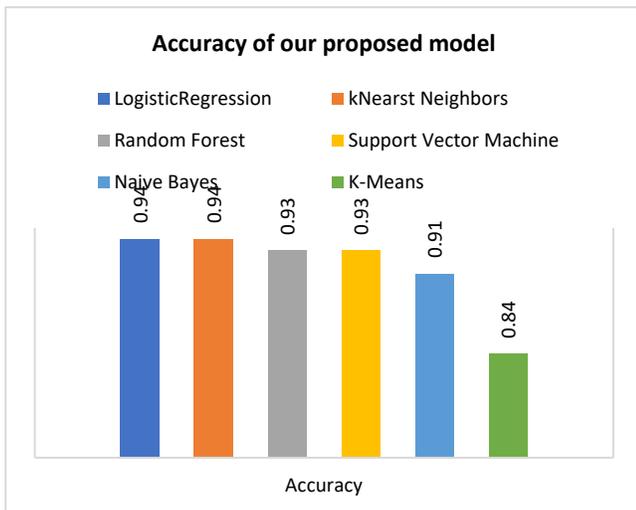

Fig. 2. Accuracy of our Proposed Model.

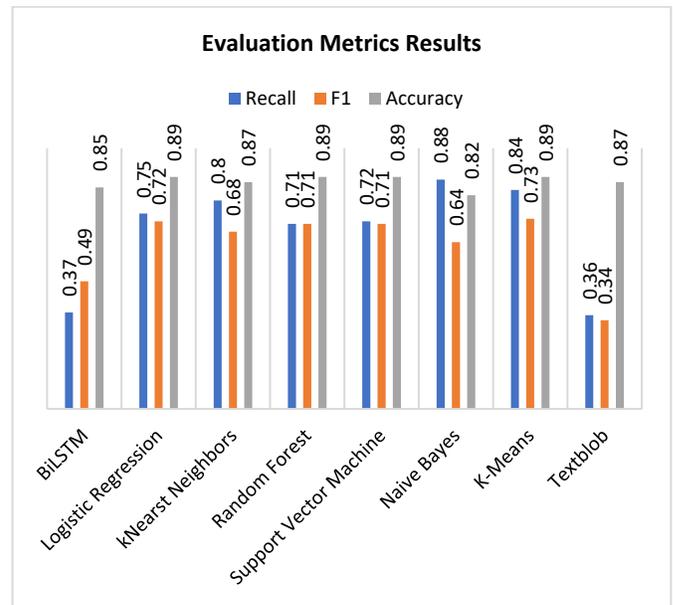

Fig. 3. Evaluation Metrics Results.

Fig. 3 shows the evaluation scores obtained with our model. We obtained six scores which depend on the classification algorithm used. The experimental results showed that the scores of our system are better than those obtained with the two models BiLSTM and TextBlob used separately. We note that the accuracy obtained with the BiLSTM (0.85) and TextBlob (0.87) models perform slightly better than the naive base algorithm (0.82).

Remarkably, it can be seen that the other classifiers Support Vector Mchine, Logistic Regression, Random Forest and K-Means gave a significantly higher accuracy (0.89) compared to the accuracy obtained with the two BiLSTM and TextBlob models. It can also be seen that the logistic regression model also provides a better F1 score (0.72) which is 23% higher than the BiLSTM F1 score (0.49) and 38% higher than the TextBlob F1 score (0.34).

With the exception of the results obtained by the Naive Bayes algorithm, it can be stated that our proposal improves the accuracy and F1 score results provided by the BiLSTM and TextBlob models used individually.

V. DISCUSSION

The experimental results obtained validate the usefulness of our proposed system. They also show the new performances in terms of accuracy and F1 score. Our proposed system, allowed us to have a 4% higher accuracy score and a 24% higher F1 score using the k-Means algorithm. It can be said that the use of BiLSTM and TextBlob input models will be effective in studies interested in sentiment analysis provided that they are hybridized with regression algorithms.

Moreover, most of the proposed models obtained better performances in terms of accuracy and F1 score (K-means, Logistic Regression, svm, Random Forest, K-nn respectively), except for the Naive-Baise model which obtained a slightly lower score in terms of accuracy (0.82) compared to the BiLSTM and Text Blob input models which have an accuracy

score of 0.85 and 0.87 respectively. The main reason could be that the Naive Bayes Classifier algorithm assumes the independence of the variables: This is a strong assumption and is violated in most real cases. Harry Zhang's publication [52] provides an explanation for this counter intuitive performance.

## VI. CONCLUSION

Sentiment analysis of tweets remains an important technique to take advantage of the opinions and trends of the public around several events, in order to classify them according to polarity. However, categorizing the polarity of Twitter messages remains a difficult task for a number of reasons, including the speed at which messages are generated, the large number of messages generated on a particular topic, the short duration of those messages, and the familiarity of messages. To overcome these problems, this paper introduced a hybrid sentiment analysis model based on a BiTSM network and TextBlob. The TextBlob model allows the polarity and subjectivity scores to be calculated separately. We therefore used these two scores as features of a linear regression model to calculate an overall sentiment score. The two input models (BiLstm,TextBlob) are then combined into a binary classification model. For the attainment of this, we have implemented the following algorithms: Logistic Regression, k-Nearest Neighbors, Random Forest, Support Vector Machine, K-means and Naive Bayes. Then, both models were trained on a limited amount of data from the twitter US airlines data set.

The results of our experiments showed that the proposed hybrid system shows better performance in terms of accuracy and F1 score, compared to the input models considered in this study (BiLstm and TextBlob). This is mainly due to the different mechanisms implemented in each model. The mutualization of these mechanisms via our hybrid architecture was able to increase the performance demonstrated by the calculated metrics.

It should be noted that due to its bidirectional nature, the implementation of BiLSTM neural networks generates an overhead in terms of computational power and consequently, on the processing time, in this case with respect to long texts. For this reason, we recommend the use of the model proposed in this study to capture feelings in short texts such as tweets.

**Abstract**—This paper evaluates timber defect classification performance across four various Local Binary Patterns (LBP). The light and heavy timber used in the study are Rubberwood, KSK, Merbau, and Meranti, and eight natural timber defects involved; bark pocket, blue stain, borer holes, brown stain, knot, rot, split, and wane. A series of LBP feature sets were created by employing the Basic LBP, Rotation Invariant LBP, Uniform LBP, and Rotation Invariant Uniform LBP in a phase of feature extraction procedures. Several common classifiers were used to further separate the timber defect classes, which are Artificial Neural Network (ANN), J48 Decision Tree (J48), and K-Nearest Neighbor (KNN). Uniform LBP with ANN classifier provides the best performance at 63.4%, superior to all other LBP types. Features from Merbau provide the greatest F-measure when comparing the performance of the ANN classifier with Uniform LBP across timber fault classes and clean wood, surpassing other feature sets.

**Keywords**—Automated visual inspection; local binary pattern; timber defect classification; texture feature; feature extraction

## I. INTRODUCTION

Malaysia is known for its biological diversity concerning forests and marine environments, making it a megadiverse country. Since 2017, the timber sector has substantially influenced the gross domestic product (GDP). It contributed around RM 759 million to the total foreign investment. It is expected to expand by 65 per cent (RM 491.7 million), augmented by the domestic investment of around RM 267.3 million (35 per cent) annually by 2020 [1]. The amount and distribution of naturally occurring timber flaws have worried timber experts; hence, an appropriate detection method is a crucial examination procedure in the timber industry of Malaysia [2-3].

However, due to its susceptibility and the possibility of human mistakes, manual visual defect evaluation is not only acknowledged as being inaccurate in the timber industry but is also physically demanding. Acute headaches and eye fatigue are connected to strenuous labour [3-5]. The results of the detecting procedure have a significant impact on the quality of timber products [6]. Overlooked or defective products could negatively influence the industry, jeopardizing safety and causing revenue loss due to the inability to address failure or liability claims. As a result, product quality control is critical to prevent manufacturing mistakes and defects before products reach the shipping stage.

The Automated Visual Inspection (AVI) method includes automated image capture, enhancement, segmentation, feature extraction, and categorization. AVI is a completely automated extraction and categorization procedure that would enhance the inspection process and lower labour expenditures [7-9].

This research aims to classify timber faults using a pattern recognition technique contributing to AVI, emphasizing the feature extraction stage. Several studies have used Local Binary Pattern (LBP) to detect timber flaws [10]. LBP can accurately recognize and detect timber defects [11-14]. The technique was considered superior for feature extraction to other techniques based on the research [15].

LBP is still an area of active research in different domains. More recently, extended the methods using LBP to extract features from new finger vein images to improve the recognition performance system [16], spatiotemporal data fusion for producing time-series satellite images for real-world applications [17], and new blood cell classification using a hybrid learning model based on blood cell image identification [18].

Similar work has also been pursued, which utilizes the multiple feature fusion method for video emotion recognition [19]. Each keyframe belonging to real-world video sequences is processed to extract features using Uniform LBP and the scale-invariant feature identification. Conceptually similar work was performed that used LBP for extracting seven types of wheat texture features in East Azerbaijan Province to accelerate the seed supply for cultivation in seed supply centres [20].

The recent literature proposes several techniques related to LBP. Recent work used pseudo-visual search and the histogram of oriented gradients (HOG)-LBP feature fusion for intelligent vehicle detection in severe weather [21]. In addition, to completing local quartet patterns, a new version of LBP plays a crucial role in fabric textile quality-control systems [22]. Moreover, edge-aware filtering and improved LBP (EF-ALBP) is a robust edge extraction method for medical images having redundant noise, blurred details, and low contrast [23].

This study aims to recognize the general challenges concerning the automated visual inspection of timber. The focus was on the feature extraction approach and evaluating the timber defect classification performance across LBP variants. Firstly, we focused on constructing rotation-invariant uniform

feature representation of timber defects based on statistical texture features using a variation of LBP (Rotation Invariant Uniform LBP, Rotation Invariant LBP, Uniform LBP, and Basic LBP). The timber defect images dataset, labelled and validated by industry experts [3], was used here. The dataset represented several species of Malaysian hardwood, namely Rubberwood, KSK, Meranti and Merbau. Sixteen feature sets were produced and tested in the next phase. Subsequently, we evaluated timber defect class discrimination based on sixteen proposed texture feature sets using classification accuracy measures. The performance of the suggested feature set was confirmed by evaluating classification accuracy metrics with the help of common classifiers (ANN, KNN, and J48).

Finally, we compared the performance of the proposed feature sets across timber defects. Due to the superior performance of the ANN classifier in earlier studies compared to other classifiers, we chose to use it. We also used Uniform LBP because of its high classification accuracy than other LBP types. Extensive analysis revealed that all timber species displayed respectable classification accuracy, demonstrating the value of the suggested criteria in class distinction. The discriminating performance of the suggested feature sets across all classes highlighted the possibility of defect detection applications for future research, even though the study focused on identifying defects over clean wood.

## II. MATERIALS AND METHODS

### A. Approach Overview

This study used the timber defect dataset from the UTeM database [3]. Nine different types of timber defects, including clear wood as shown in Table I, were extracted from 3600 timber defect images (900 samples for each timber species, 100 samples for each timber defect) on several timber species. The dataset for timber defects includes 630 training pictures of clean wood and eight types of natural timber defects. Specimens of light timber, such as Rubberwood, while Meranti, KSK, and Merbau from heavy timbers are from several secondary timber product industries in Melaka, Malaysia, were used to augment the timber defect dataset. Sample collection was limited by the availability of the timber species based on end-products manufactured by the factories commonly used by different timber industries in Malaysia [3].

Ungraded, dressed, dried, and dirt-free sawn timbers used in rough milling were considered for this study. The collected timber samples had a 45-70 mm width, 100-150 mm length, and 18-22 mm thickness. The eight natural timber defects are wane, split, rot, knot, brown stain, borer holes, blue stain and bark pocket. Table II depicts the details of the timber defect image settings used for this research.

Fig. 1 illustrates extracting the statistical texture features based on LBP variants. First, timber defect images were converted to greyscale (tone-independent). Then, (1) is used for parameter setting: radius and the sampling point. All steps are to derive the rotation-invariant uniform formulation based on LBP variations. The LBP was performed by applying pixel labelling using an LBP thresholding formulation. The formulation uses a single parameter setting; sampling point,  $sp=8$  and radius,  $R=1$ . Then, extracting statistical texture

features from an LBP variation for the four timber species. In phase one, sixteen feature sets have been produced and calculated using (1) to (9).

### B. Feature Extraction

1) *Basic local binary pattern: basic lbp produces 256 values.* The LBP code for each basic LBP pixel must be determined. The pixel is labelled using decimal numbers by encoding the local structure around each pixel. For example, by deducting the value of the centre pixel, each pixel in a  $3 \times 3$  neighbourhood is compared to its eight neighbours; if the result is positive, value 1 is used. In contrast, negative results generate 0. The process outputs 8-bit integers by arranging each bit clockwise, starting from the top-left to obtain eight different binary patterns. The mathematical expression of the LBP is specified in (1).

$$LBP_{p,R}(x_c, y_c) = \sum_{i=0}^{p-1} s(g_i - g_c) 2^i \quad (1)$$

TABLE I. TIMBER DEFECT CLASSES [3]

	
Knot	Split
	
Blue Stain	Brown Stain
	
Bark Pocket	Borer holes
	
Rot	Wane

TABLE II. TIMBER DEFECT IMAGE SETTINGS [3]

<b>Sensor used</b>	Optical sensor
<b>Optical imaging device</b>	Area scan cameras
<b>Image setting</b>	1024 by 768 pixels (300dpi) 24-bit depth and 256 intensity levels for the red, green and blue channel
<b>Sub-image setting</b>	60 x 60 pixels

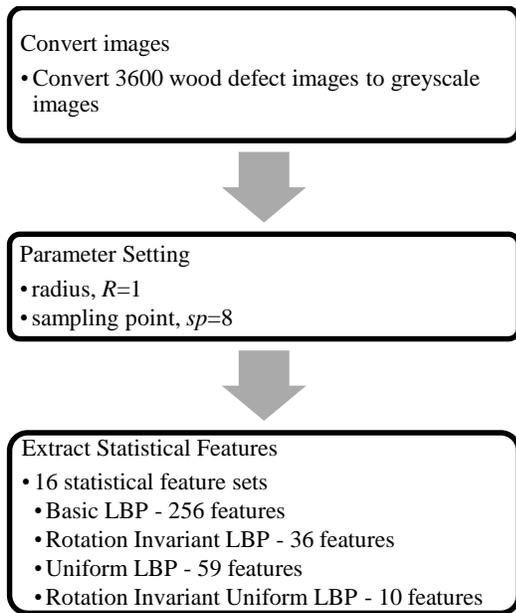

Fig. 1. Process of Extracting Statistical Texture Features based on LBP Variants.

The notation (P, R) designates P sampling points on a circle of radius R;  $(x_c, y_c)$  designates the centre of a pixel,  $g_c$  represents the grey value of the centre pixel; and  $g_i$  ( $i=0,1,\dots,P-1$ ) designates the grey value of the P sampling points next to it. Signed differences  $g_i - g_c$  are interpreted as P-bit binary numbers, producing  $2^i$  distinct values. The thresholding function  $s(x)$  is defined in (2):

$$s(x) = \begin{cases} 1 & \text{if } x \geq 0 \\ 0 & \text{if } x < 0 \end{cases} \quad (2)$$

2) *Rotation invariant local binary pattern*: Rotation invariant LBP is used to analyze and compute the value of the rotated picture [24]. The  $g_i$  grey values along the perimeter of the circle around  $g_c$  vary when the image is rotated. The binary pattern rotates in a clockwise direction, resulting in various LBP values. As a result, the lowest value of the binary pattern generated from the direction of maximal rotation is chosen for computation. Similarly, for cluster-like patterns, the rotation invariant LBP with the lowest value of the circular bitwise clockwise direction of the x bit sequence by  $i$  steps or the  $ROR(x, i)$  can thus be recognize as:

$$LBP_{P,R}^i = \min\{ROR(LBP_{P,R}, i) \mid i = 0, 1, \dots, P - 1\} \quad (3)$$

Rotation invariant LBP can generate 36 different patterns.

3) *Uniform local binary pattern*: Since circular rotation bit patterns with 0-1 or 1-0 transitions are used to determine the LBP uniformity [25], uniformity can be identified from the two transitions comprising a single binary pattern. On the other hand, if the transitions exceed this count, i.e., if the binary pattern comprises more than two transitions, it does not belong to the uniform LBP category. Uniform LBP can be seen in patterns  $00000000_2$  (0 transition) and  $00001000_2$  (2

transitions) and each uniform pattern has a separate output label. Transition count calculation can be obtained using (4):

$$U(LBP_{P,R}) = |s(g_{P-1} - g_c) - s(g_0 - g_c)| + \sum_{i=1}^{P-1} |s(g_i - g_c) - s(g_{i-1} - g_c)| \quad (4)$$

There are  $P(P - 1) + 3$  different P-bit output labels; eight sampling points produce 59 labels, where 58 are uniform and 1 is non-uniform.

4) *Rotation invariant uniform local binary pattern*: The superscript  $riu^2$ , which donates the maximum uniform value of two, is used by the rotation-invariant uniform patterns, as stated in (5). By definition,  $P + 1$  occurs in a circular symmetric neighbour set of P pixels in uniform binary patterns. The above equation determined 27 non-uniform patterns and 9 uniform patterns. The mapping of 8-bit binary numbers from  $LBP_8$  to  $LBP_8^{riu^2}$  comprises 10 unique outputs than a 256-element lookup table:

$$LBP_{P,R}^{riu^2} = \begin{cases} \sum_{i=0}^{P-1} s(g_i - g_c) & \text{if } U(LBP_{P,R}) \leq 2 \\ P + 1 & \text{otherwise,} \end{cases} \quad (5)$$

### C. Evaluation of Detection Performance

1) *Precision, recall, f-measure, and classification accuracy*: Precision and recall are conventional and appropriate assessment metrics to evaluate the performance of content-based image retrieval. Precision and recall are calculated using positive and negative system replies for every query. [26]. In this study, clear wood images accounted for a significant part of the dataset than timber defect samples. It is typical in the secondary timber industry.

Equation (6) shows precision is the ratio of actual timber defects to the total number of detected ones. Precision, sometimes referred to as positive predictive value, results from the retrieval system's true positive and false positive images. A recall is the ratio of the total number of real defects in the timber to the total number of actual defects in timber, as defined in (7). The recall is a function of the true-positive and false-negative images in the retrieval system [27]. The F-Measure in each class is a composite measure of precision and recall, as shown in (8).

$$\begin{aligned} \text{precision}, P &= \frac{\text{number of true defects}}{\text{number of defects detected}} \\ &= \frac{\text{true defects}}{\text{true defects} + \text{false defects}} \end{aligned} \quad (6)$$

$$\begin{aligned} \text{recall}, R &= \frac{\text{number of true defects}}{\text{number of actual defects}} \\ &= \frac{\text{true defects}}{\text{true defects} + \text{false clear wood}} \end{aligned} \quad (7)$$

$$F - \text{Measure}, F = 2 \frac{PR}{P+R} \quad (8)$$

The experiment aims to improve experiment accuracy, typically measured using classification accuracy [28]. Classification algorithms are assessed using classification accuracy [29], as defined in (9).

$$\text{Classification Accuracy (\%)} = \frac{\text{Number of correct classification}}{\text{Total number of samples}} \cdot 100\% \quad (9)$$

### III. RESULTS AND DISCUSSION

#### A. Classification Performance across LBP Variants

For a more in-depth understanding of the applicability of various characteristics across each LBP variation, the best classification performance is compared to other classifiers for that version. Table III shows the F-measure for each feature set. By integrating precision and recall values, the F-measure benchmark evaluates picture segmentation and classification accuracy. Comparing the ANN classifier to the KNN and J48 classifiers produces good results.

Fig. 2 shows the mean or average percentage classification accuracy of the standard classifier across all LBP variants. Basic LBP has a 48.42% classification accuracy, while Rotation Invariant LBP is 48.7% accurate. Moreover, Uniform LBP has 56.8% accuracy values, while Rotation Invariant Uniform LBP has 52% accuracy values.

#### B. Classification Performance across Timber Defects

The ANN classifier delivered the best classification performance, as we previously concluded. Performance assessment continues by evaluating the ANN classifier and Uniform LBP across timber defect classes and clear wood. Since Basic, Rotation Invariant, and Rotation Invariant Uniform LBP datasets previously showed low classification performance, we will now look at the classification details of a well-performed Uniform LBP dataset only.

Fig. 3 illustrates the F-measure calculation for timber defect classes. Bark pocket, split, and borer hole classes show the lowest F-measure across all classes, achieving less than 0.63 F-value. Meanwhile, the top three F-measures across timber defect classes are wane, clear wood, and rot. The attributes of the Rubberwood dataset are the most effective in classifying

rot, wane, and brown stain. In contrast, the split was best ranked for the KSK dataset.

TABLE III. CLASSIFIERS COMPARISON WITH F-MEASURE OF LBP VARIANTS

Class	F-measure	Classifier
Basic LBP	0.553	ANN
	0.487	KNN
	0.413	J48
Rotation Invariant LBP	0.515	ANN
	0.502	KNN
	0.444	J48
Uniform LBP	0.634	ANN
	0.629	KNN
	0.441	J48
Rotation Invariant Uniform LBP	0.527	ANN
	0.536	KNN
	0.497	J48

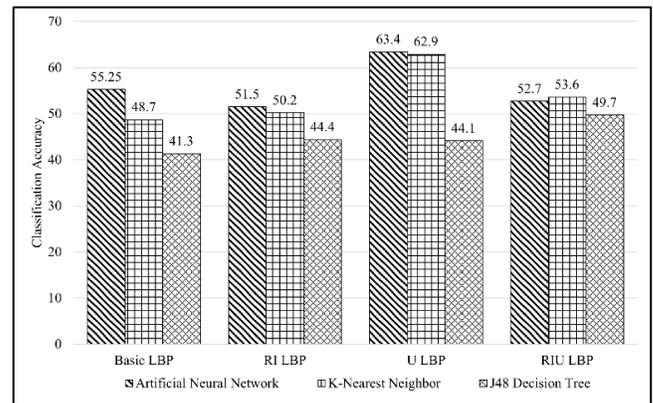

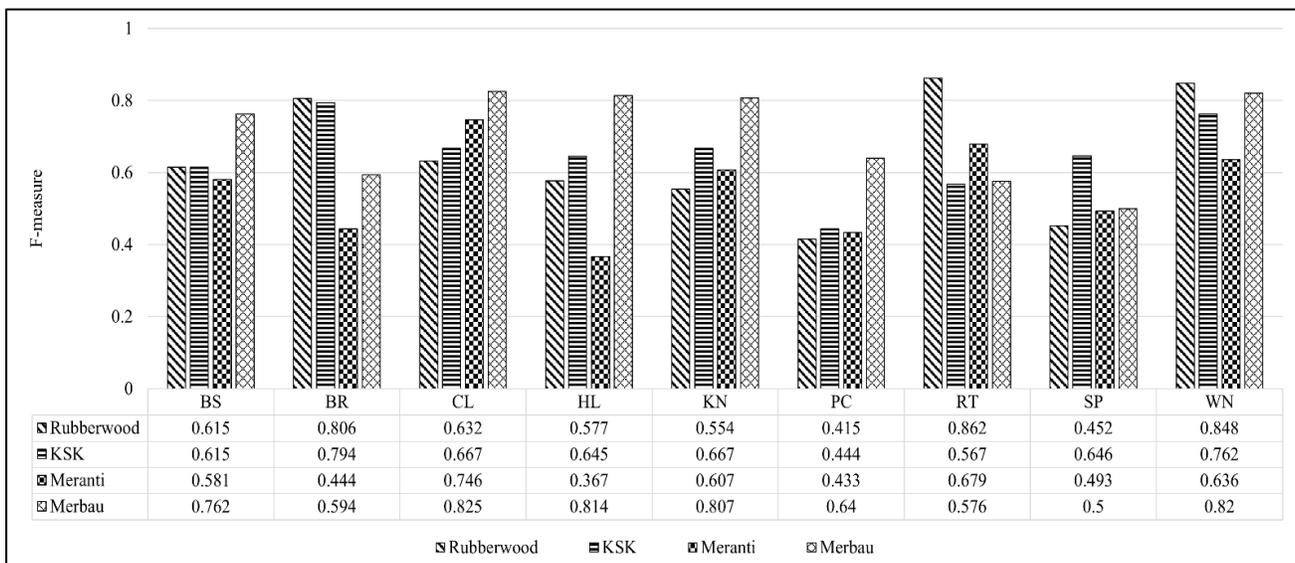

Fig. 2. The Mean or Average Percentage Classification Accuracy of the Standard Classifier Across all LBP Variants (RI LBP = Rotation Invariant LBP, U LBP = Uniform LBP, RIU LBP = Rotation Invariant Uniform LBP).

(BS-Blue Stain, BR-Brown Stain, CL-Clear Wood, HL-Borer Holes, KN-Knot, PC-Bark Pocket, RT-Rot, SP-Split, WN-Wane)

Fig. 3. F-measure for Each Timber Defect Class, Including Clear Wood, Calculated using ANN Classifier and Uniform LBP.

Similarly, the characteristics of Merbau were the best in classifying blue stain, clear wood, borer holes, knot, and bark pocket. Merbau features provide the best F-measure when considering generalised differences among timber defect classes, beating other feature sets.

#### IV. CONCLUSION

The paper presented the evaluation of timber defect classification performance across LBP variants. The experiment highlights the average percentage classification accuracy for all LBP variants. Comparing all LBP types, uniform LBP with ANN classifier offers the greatest performance at 63.4%. By analyzing the performance of the ANN classifier with Uniform LBP across timber defect classes and clear wood, features from Merbau species give the best F-measure, outperforming other feature sets from other timber species. In line with the findings of this paper, it demonstrates that Merbau-derived traits were most effective for classifying blue stains, clear wood, borer holes, knots, and bark pockets. Moreover, brown stain, split, wane and rot show the lowest F-measure. In this research, statistical texture based on variations of LBP to represent wood surface characteristics was employed. Other texture feature extraction techniques could be explored to further improve the feature representation and for better discrimination capabilities between wood defects and clear wood. Other researchers working on certain timber defect classes focusing on applications will find this discovery useful.

**Abstract**—The modern internet era has several advantages and disadvantages, including the advent of immoral Internet conduct in addition to better, quicker, and increased working capacity in less time. Even though the area of study on unethical Internet activity has advanced, systematic literature reviews from a comprehensive perspective on unethical Internet behaviour among university students are still lacking. As a result, this systematic literature will provide theoretical foundation that address the following research questions: RQ1-How are unethical Internet behaviours among university students classified; RQ2-What are the various theoretical lenses that are used in unethical Internet behaviour research; RQ3-What demographic and risk factors are involved in unethical Internet behaviour research; and RQ4-What are the challenges and research opportunities for unethical Internet behaviour research within university settings? To respond to a formulated set of research questions, a total of 64 publications that were published between 2010 and 2020 underwent a systematic review. The study illustrates how university students' unethical Internet activity is categorised. This study offers a comprehensive grasp of the factors that affect unethical Internet behaviour and an overview of the theories that have been utilised to explain and forecast unethical Internet behaviours in this sector. This study discusses literature gaps for future research to contribute to human ethical behavioural studies.

**Keywords**—Systematic literature review; unethical Internet behavior; university student; Internet; ethics

## I. INTRODUCTION

The academic environment has made extensive use of the Internet as a component of the processes and instruments of learning in both internal and external classroom contexts. However, according to Baum in [1], its usage was motivated by a lack of ethical awareness and education and a lack of regulations governing its use for teaching, learning, and research. Irresponsible exploitation of this essential resource poses a significant threat to the technological community and society. Following the definition set by Jones (1991), ethical behaviours can be defined as legal behaviours that are morally acceptable in the society in which they occur, and unethical behaviours is defined as unlawful actions that are not morally acceptable [2]. Based on definition set by Adenisa in [3], unethical behavior deviates from what is regarded ethically

correct or appropriate for a person, a profession, or an industry. On the other side, ethical action entails doing the right thing, and unethical behavior entails doing the opposite. Ethics in the context of the Internet refers to how people interact with technology and the potential outcomes of those interactions [4]. The Internet can give rise to a plethora of new types of abnormal conduct, some of which are radically new, and others are technologically updated versions of longstanding ethical implications. The Internet Activities Board (IAB) code of ethics is outlined in an RFC document. RFC 1087, Ethics and the Internet, was issued in 1987 to offer a policy for Internet-related ethical behaviour [5]. Based on the IAB, the following actions would constitute unethical behaviour if they were committed intentionally [5]:

- 1) Attempts to access Internet resources without authorization.
- 2) Disrupts the Internet's intended usage.
- 3) Wasting resources (people, capacity, and computers).
- 4) Destroys the integrity of computer-based information by such acts.
- 5) Interferes with consumers' privacy.

Ming et al. (2015) conducted a systematic literature review (SLR) on computer ethical issues. The article presents the review methodology employed, the subject under consideration, and the key findings [6]. The SLR extracted forty studies that focused mainly on software piracy, computer piracy, the PAPA (Privacy, Accuracy, Property, and Accessibility) framework, and other general concerns. The main difference of this SLR is that the SLR conducted by [6] focuses on categories of computer ethics among students and professionals, whereas our SLR concentrate on the categorisation of unethical Internet behaviours in high education settings as well as the demographic and risk factors related to each of the categories.

In 2017, Vossen et al. conducted an SLR to identify descriptors for unprofessional behaviours among medical students. The SLR is intended to investigate, analyse, organize and report the findings of research on the unprofessional behaviour of medical students as observed by stakeholders or acknowledged by students themselves [7]. The literature review focuses on qualitative research to develop themes and

summary descriptors for unprofessional behaviours. On contrary, our SLR focus on unethical behaviour in the cyber environment.

Finally, Costa et al. (2021) did an SLR which focused on the methodology for the scientific production of netiquette research, such as country, date, objectives, methodological design, key factors, sample information, and measurement methods [8]. Their meta-analysis reveals the need to change the theoretical framework and evaluate empirical hypotheses whose samples are supported by participants such as students and others. However, our SLR is centralised on the outcome of unethical Internet behaviour research.

To our best knowledge, not many systematic literature reviews have been conducted on unethical Internet behaviour. This paper presents the results of a systematic literature review (SLR) by categorising the data into a taxonomy that can be used to comprehend the current state of the art of unethical Internet behaviour in higher education. Therefore, the contributions of this SLR are as follows:

- 1) The classification of unethical Internet behaviours. Additionally, based on the literature on unethical Internet behaviours, this review provides an appropriate definition for each category.
- 2) The presentation of theories that have been utilised in previous research on unethical Internet behaviours.
- 3) The identification of demographic and risk factors that are associated with unethical Internet behaviours
- 4) The investigation on the challenges and research opportunities for unethical Internet behaviour in high education settings.

## II. REVIEW METHOD

### A. Introduction

This section describes the approach for conducting a systematic review of Internet behaviour among Malaysian university students. Literature reviews are a kind of secondary research that helps form primary research results [9], [10] explicit methodology. The Cochrane Collaboration stated that a systematic review attempts to assemble all evidence that meets pre-specified eligibility criteria to address a specific research question [11]. It employs specific, systematic processes that are carefully chosen to avoid bias, resulting in accurate data from which conclusions and judgments may be taken. Kitchenham and Charters (2007) defined a systematic review as a process of discovering, analysing, and interpreting all available studies that are relevant to a specific research question [10].

The review methodology in this paper is based on the standards set by Kitchenham and Charters (2007). According to Kitchenham and Charters (2007), a systematic review of the literature is divided into three phases: planning, conducting, and reporting. The preparation phase of systematic reviews begins with establishing a protocol that will govern the review's conduct. A review protocol details the procedures that will be followed to conduct a systematic review.

A pre-defined protocol is essential to eliminate the risk of researcher bias [3]. The review protocol is based on Khan et al. (2003) five-step process for performing a systematic review, as shown in Fig. 1.

### B. Framing Research Questions for the Review

The PICO (population, intervention, control, and outcome) format is a well-known technique for structuring a research question. Petticrew and Roberts (2008); and Kitchenham and Charters (2007) suggest using the PICO format with an additional element: Context. This element refers to the setting in which the intervention is administered or to the participants in the study [10], [12].

Table I shows the research questions' Population, Intervention, Comparison, Outcomes, and Context (PICOC) structure. This systematic literature review included all empirical studies investigating unethical Internet behavior within a higher education setting, regardless of whether the setting has formal or non-formal cyberethics awareness activities. Therefore, this review did not include any specific comparison in the PICOC structure.

In general, the primary purpose of this systematic literature review is to obtain knowledge on the evidence of Internet ethics issues and awareness among university students. Therefore, in order to have this knowledge in the current investigation, the defined the following research questions (RQ):

RQ1 What are the categorizations of unethical Internet behaviour among university students?

RQ2 What are the different theoretical lenses that are used in unethical Internet behaviour research?

RQ3 Which demographic and risk factors are involved in unethical Internet behaviour research?

RQ4 What are the challenges and research opportunities for the unethical Internet behavior research within university setting?

### C. Identifying Relevant Works

After identifying the research questions, the subsequent step is to specify the search strategy and search string. The search process's main objective is to discover relevant articles that discuss unethical Internet behaviour in higher education settings. The search strategy included an automated search of digital libraries via a search string constructed from the PICOC structure in Table I.

TABLE I. SUMMARY OF PICOC FOR THIS STUDY

Population	Undergraduate students
Intervention	Awareness in cyberethics
Comparison	None
Outcome	Unethical Internet behaviour
Context	Any empirical studies on unethical Internet behavior within a higher education setting

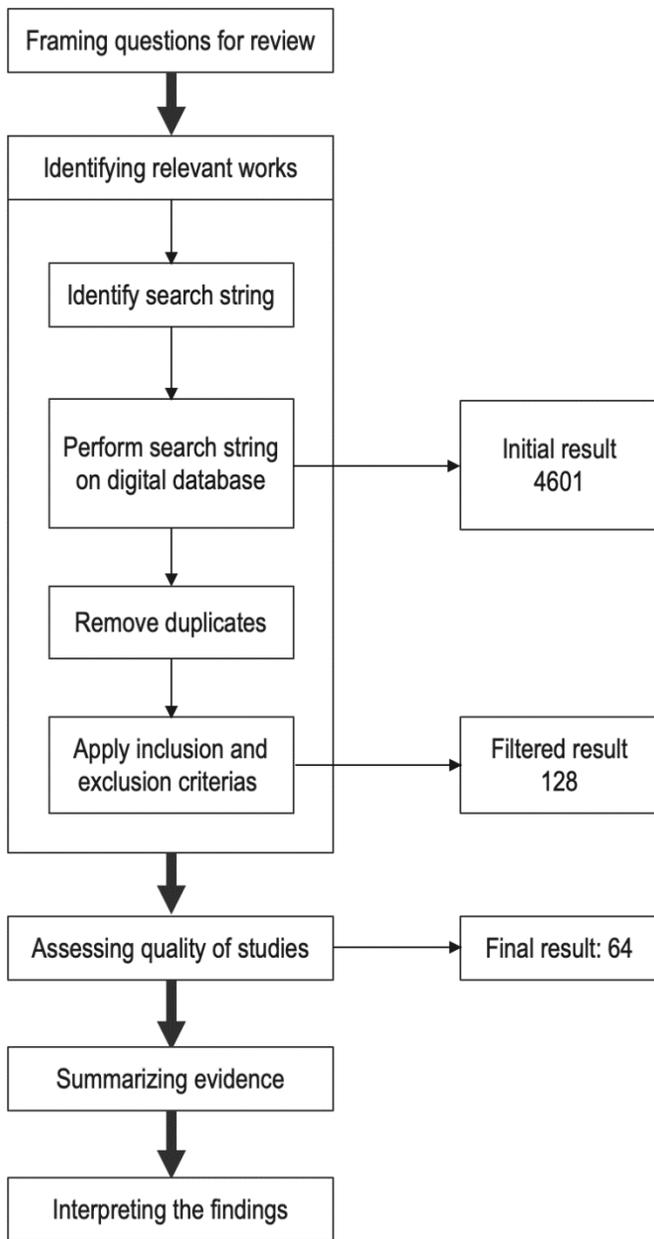

Fig. 1. Systematic Literature Review Methodology for this Study.

1) *Identify search string*: Various keywords have been established with the intent of specifying database search strings and inclusion and exclusion criteria. The search strings were defined by considering the question items' synonyms and other spellings and connecting them with "and" and "or." Following the PICOC structure, the most relevant and applicable terms were selected for the study area. As a result, the following search terms were chosen: "undergraduate", "awareness", "unethical Internet". To examine the inclusion of the review's findings, the outcomes of the initial examination were used as a pilot and passed several phases before specifying the query. Since some of the investigations in the review were not obtained by the first query, the query string was modified and included some more keywords. The

keywords that were added to the search string are as follows: "university student", "university", "Internet ethics", "cyber", "computer", "ethics", "problematic Internet". The whole search phrase used to do the literature search was as follows:

(Undergraduate OR "university student" OR university) AND {[awareness AND (ethic\* OR "internet ethics")] OR ("unethical internet" OR "problematic internet" OR "internet ethics")}

2) *Identifying the sources and selection of studies*: The title and abstract of each publication were examined for keywords to get as many relevant articles as feasible. A total of ten digital databases were used in the primary search process: ACM Digital Library, Dimensions, EBSCOhost, Emerald, IEEEExplore, ISI Web of Science, Sage Full Text Collections, Science-Direct, Scopus and SpringerLink.

A systematic literature search was conducted on chosen databases using the search phrase provided above; yielding 4651 studies as a result of the initial search (refer to Table II). In the next step, all remaining articles' inclusion and exclusion criteria were applied before any duplicate papers were removed.

Inclusion criteria:

- Articles from year 2010 - 2020
- Articles must be published in a journal or a conference proceeding
- Articles published must be in university setting
- Articles must be within the area/domain of computer science, engineering, social engineering, social sciences, education, and information science.

Exclusion criteria:

- Articles related to law, policy, and regulations
- Articles related to psychological domain
- Articles related to internet ethics subject and training.

TABLE II. THE RESULTS OF THE SELECTION PROCESS

Online Databases	Initial Results	Selected Studies
ACM Digital Library	452	-
Dimensions.ai	50	20
EBSCOhost	1789	-
Emerald	20	-
IEEEExplore	238	4
ISI Web of Science	42	1
Sage Full Text Collections	22	-
Science-Direct	804	10
Scopus	739	5
SpringerLink	495	24
<b>TOTAL</b>	<b>4651</b>	<b>64</b>

The complete texts and abstracts of the selected articles were evaluated to guarantee that only publications that had been thoroughly investigated were included in the study at the same time. For each selected article, a set of criteria is used to evaluate its quality and determine the relevance of the results and interpretations from the main study. As shown in Fig. 1, the filtered result yielded 128 articles after the initial results were filtered according to inclusion and exclusion criteria, and duplicate articles were removed.

3) Quality Assessment: In accordance with the methodology [10], [13] suggested, this paragraph describes the quality assessment procedure used to determine the quality of each item chosen. The quality of each article included in this research is critical to ensure that high-quality SLR studies on unethical Internet behaviour are made accessible and to avoid bias in terms of the quality of previously published studies. A set of quality checklists is used for each selected article to evaluate its quality. The checklists also determine the relevance of the results and interpretations from the main study. When developing the quality checklist for the review, some of the questions presented in the literature were reused [10], [12], [14].

TABLE III. QUALITY ASSESSMENT CHECKLIST

ASSESSMENT	DETAILS
Was the article refereed?	-
Were the aim of the study clearly stated?	-
Were data collections carried out very well?	Quantitative: The paper explain the questionnaire design procedure (mention the source of existing scale or explaining design procedure for new questionnaire). Qualitative: The paper explain the design of data collection tool (structured/unstructured question for interview or focus group, observation, diary, journal).
	Sampling: The paper mention the number of respondents/participant.
	Duration (Longitudal study/ Qualitative study): The paper mention the recruitment or data collection time frame. For example: 3 weeks, from January to March
Were the approach to and formulation of the analysis well conveyed?	Quantitative: Minimum of descriptive statistics (mean or median) Qualitative: Include participant's quotation or excerpt from data collection tools.
Were the findings credible?	The paper must be methodologically explained.
	The paper must provide assessment validity Quantitative: If the questionnaire is newly developed (not from existing scale), the paper must include validity test (content validity or expert review/construct validity), EFA(Exploratory Factor Analysis), CFA (confirmatory factor analysis) Qualitative: Provide triangulation/expert validation

From the filtered results (refer to Fig. 1, each of these studies was screened according to the quality assessment checklist (refer to Table III). Full articles were utilised when titles and abstracts were insufficient to determine a paper's relevance. The scoring method for the quality assessment was either good, fair, bad, or unknown (i.e. no information was supplied). Anawar oversaw the quality assessment process. Each of the researchers assessed articles from at least two databases. Eventually, 64 articles were chosen as the final study for the systematic survey (refer to Table II).

### III. RESULTS AND DISCUSSION

#### A. Introduction

The search results are generated using the search strings supplied in Section II. The present SLR synthesised a total of 64 main studies (refer to Appendix A: List of the Included Studies). This number was determined following a thorough assessment of the publications included in the current investigation. Notably, the writers focused on research that matched the criteria for inclusion outlined in Section II. The distribution of selected studies according to the digital libraries is shown in Fig. 2. Fig. 3 shows the distribution of all studies from 2010 to 2020.

#### B. RQ1 - Categorization of Unethical Internet Behavior

For the first research question, the context of the studies specifically focus on certain behaviors was identified in Table IV.

The SLR identified 11 papers studied in cyberbullying, seven articles on cyberslacking, and only one evidence was found in online trolling, catfish, risky online posting and cyber dating abuse.

Cyber slacking is defined as using the Internet and digital technology during scheduled class time for non-class related purposes [15]. Cyber slacking can be divided into in-class (slacking during class) and out-of-class (outside of class) [S1], [16]. From Table IV, seven papers discussed cyberslacking; five studies focus on in-class cyberslacking [S1], [S3], [S5]–[S7] and three studies on out-of-class cyberslacking [S2], [S4], [S7].

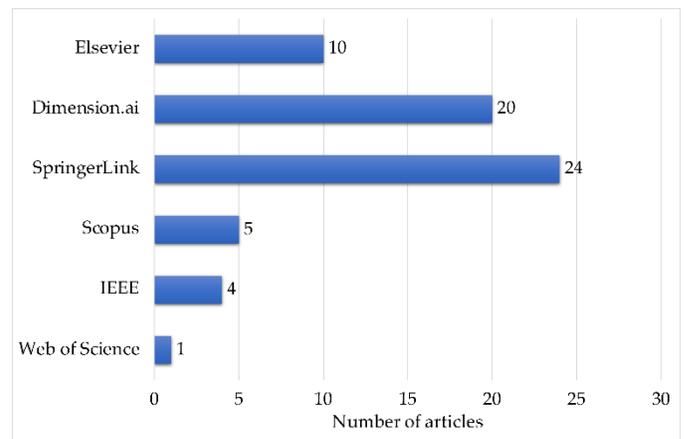

Fig. 2. Number of Publications based on Databases.

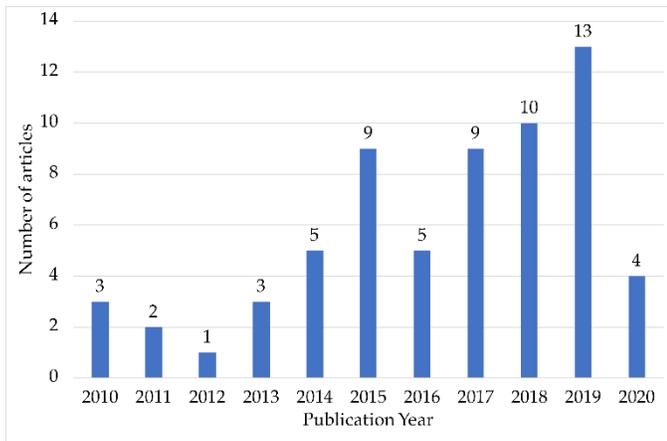

Fig. 3. Distribution of Studies based on Year of Publication.

TABLE IV. TYPE OF UNETHICAL INTERNET BEHAVIOUR STUDIES CONDUCTED FOR STUDENTS IN HIGHER EDUCATION SETTINGS

Unethical Internet Behaviour	Sources	Total Studies
Cyberslacking	[S1], [S2], [S3], [S4], [S5], [S6], [S7]	7
Cyberbullying	[S8], [S9], [S10], [S11], [S12], [S13], [S14], [S15], [S16], [S17], [S18]	11
Risky Online Posting	[S19]	1
Cyber Dating Abuse	[S20]	1
Online Trolling	[S21]	1
Catfish	[S22]	1
Digital Piracy	[S23], [S24], [S25], [S26], [S27], [S28], [S29], [S30], [S31], [S32]	9
Plagiarism	[S27], [S30], [S33], [S34], [S35], [S36], [S37], [S38], [S39], [S40], [S41], [S31], [S32], [S42], [S43], [S44], [S45], [S46], [S47], [S48], [S49], [S50], [S51], [S52], [S53], [S54], [S55]	24
Fabrication	[S37], [S40], [S31], [S42], [S44], [S46], [S56], [S55]	8
Cheating	[S34], [S35], [S37], [S39], [S40], [S31], [S32], [S42], [S57], [S43], [S44], [S46], [S58], [S49], [S51], [S56], [S52], [S59], [S55]	18
Collusion	[S34], [S35], [S39], [S40], [S31], [S42], [S44], [S46], [S49], [S56], [S55]	11
Online Sexual Activity (OSA)	[S60], [S61], [S62], [S63]	4
Online Gambling	[S64]	1

Cyberbullying refers to the use of electronic forms by a group or individuals to act aggressively, repeatedly and over time against a victim(s) who cannot easily defend him or herself or themselves [17] [S10]. Whereas, Charmaraman et al. (2018) defined it as “the use of information and communications technology to intimidate, harass, victimize, or bully an individual or a group of individuals” [18] [S18].

Online trolling is defined as “an action of using Internet by a user using a deceptive identity of sincerely wishing to be part of the group in question, including professing, or conveying pseudo-sincere intentions, but whose real

intention(s) conflict for the purposes of their own amusement” [19] [S21].

Catfish is a malevolent form of online dating deception which involves the creation of a false internet identity to scam, blackmail, or con those they meet in online communities or chat rooms without the intention of meeting in person [S22].

Risky online posting is an activity in which a user discloses inappropriate, personal and unfavourable information by posting personal photos or media clips or sharing personal comments on social media [S19].

Cyber dating abuse is a form of dating violence through technology either by sharing private information on the social media platforms and insulting or threatening using these platforms, but also includes behaviours that intrude on the victim’s privacy or the act of monitoring the victims (e.g. having access to social media or using their partner’s password without permission) [S20].

Trolling, cyberbullying and cyberstalking are similar in the way that the Internet is used to cause harm and distress [S21]. Cyberdating abuse is similar to cyberbullying in that the activities conducted are aggressive and harmful to the victim. Whereas catfish and risky online posting are similar to cyber dating abuse as it involves online relationships. Thus the category cyber abuse is coined from this type of unethical Internet behaviour.

The widespread nature of corruption and financial scandals has directed attention to the ethical decision-making process and the influence of higher education in developing the leaders of tomorrow. Although the university is a place for educators and students to pursue knowledge ethically, academic dishonesty has been widespread in higher education [20]. Kibler (1993) defined academic dishonesty as “forms of cheating and plagiarism that involve students giving or receiving unauthorised assistance in an academic exercise or receiving credit for work that is not their own” [21]. Pavela (1978) identifies four primary types of academic dishonesty behaviour as (i) Cheating: “intentionally using or attempting to use unauthorised materials, information, or study aids in any academic exercise. The term academic exercise includes all forms of work submitted for credit or hours”; (ii) Fabrication: “intentional and unauthorised falsification or invention of any information or citation in an academic exercise”; (iii) Facilitating Academic Dishonesty: “intentionally or knowingly helping or attempting to help another to violate a provision of the institutional code of academic integrity”; and lastly, (iv) Plagiarism: “deliberate adoption or reproduction of ideas or words or statements of another person as one’s own without acknowledgement” [22]. Molnar and Kletke (2012) broadly define cheating as any violation of that definition that goes against a university’s academic integrity policy that includes cheating with or without the use of the Internet, plagiarism and digital piracy [S31]. However, Cho and Hwang (2019) and Molnar (2015) used academic ethics violations and academic dishonesty to refer to plagiarism, cheating and copyright [S32], [S37]. Technology development has facilitated pirating or paying for digital products, making plagiarism interrelated to intellectual property, copyright and authorship [23]. In the context of the

digital era in university, cheating, plagiarism, and digital piracy have been reported as academic dishonesty [24]. Thus, we used academic dishonesty to group these types of unethical behaviours. In this paper, digital piracy is defined as “an unauthorised reproduction, use, or diffusion of a copyrighted digital product” [25]. From the evidence in Table IV, 30 papers have discussed plagiarism which is 24 studies, 18 studies on cheating, eight studies on fabrication, 11 on collusion and nine studies on digital piracy.

Online Sexual Activity (OSA) is defined as “the use of the Internet (via text, audio, video, and graphic files) for any activity that involves human sexuality” [26]. At the same time, Online Gambling refers to “all forms of gambling (including wagering) via the phones and wireless devices” [27]. OSA and online gambling are categorised under Unethical Internet Access as these activities are considered immoral [28] and harmful [29]. The evidence found in the SLR shows four studies in OSA and one study in online gambling (refer to Table IV).

Although cybercrime is part of unethical internet behaviour, no evidence was found in higher education setting. The unethical Internet behaviours presented in Table IV can be categorised into four main categories: cyber abuse, academic dishonesty, unethical website access and cyberslacking, as shown Table V.

Fig. 4 and Fig. 5 present the distribution of the sources for each of unethical Internet behaviours categories. Referring to Fig. 4 and Fig. 5, among the categories, source of evidence from academic dishonesty forms the predominant number of papers accounting for 58 per cent of all 64 papers, followed by cyber abuse produced 23 per cent. Cyberslacking contributed 11 per cent of sources, while the source of evidence from unethical website access constituted 8 per cent.

C. RQ2 - Different Theoretical Lenses that are used in Unethical Internet Behaviour Research

A variety of theories were used to analyse unethical internet behaviour. Researchers have employed integrated theories in certain studies, but in others, they have used a single theory and added new constructs from other models. Table VI shows theories used in unethical internet behaviour research. Different theories were used for each category of unethical internet behaviour research.

Academic dishonesty research is largely influenced by the Theory of Reasoned Action (TRA) and the Theory of Planned Behavior (TPB). TRA and TPB are the most widely accepted academic dishonesty research hypotheses. TRA and TPB have served as a foundation for study in several domains, including the prediction of human behaviour. Specifically, TPB is an expansion of the TRA, which is often used to identify solutions for behavioural change. These hypotheses assert that behavioural purpose is frequently unobservable and the best indication of behaviour as a surrogate for probable behaviour [30], [31]. According to the TPB, academic dishonesty is caused by the opportunity and purpose to engage in dishonest behaviour. Therefore, attempts to prevent academic dishonesty should consider environmental and behavioural factors.

TABLE V. CATEGORISATION OF UNETHICAL INTERNET BEHAVIOURS

Categories	Unethical Internet Behaviours
Cyberslacking (CS) - 7 papers	In-class Cyberslacking
	Out-of-class Cyberslacking
Cyber Abuse (CA) - 15 papers	Cyberbullying
	Risky Online Posting
	Cyber Dating Abuse
	Online Trolling
	Catfish
Academic Dishonesty (AD) - 37 papers	Digital Piracy
	Plagiarism
	Cheating
	Fabrication
	Collusion
Unethical Internet Access (UIA) - 5 papers	Online Sexual Activity
	Online Gambling

TABLE VI. THEORIES USED IN UNETHICAL INTERNET BEHAVIOUR RESEARCH

No.	Theory	Total Studies	Sources
1.	Theory of Reason Action /Theory of Planned Behaviour	CS (1 paper) AD (19 papers)	[S5] [S23], [S25], [S26], [S27], [S28], [S29], [S33], [S34], [S37], [S38], [S39], [S40], [S32], [S57], [S43], [S46], [S48], [S54], [S55]
2.	User and Gratification	CS (2 papers)	[S2], [S4]
3.	Zimbardo Time Perspective	CS (1 paper)	[S1]
4.	Theories of Meta- Attention	CS (1 paper)	[S7]
5.	Sensation Seeking Theory	UIA (1 paper)	[S61]
6.	Big Five Personality	AD (2 papers) CA (5 papers)	[S41], [S57] [S8], [S11], [S13], [S15], [S21]
7.	Ethical Decision Making	AD (1 paper)	[S25]
8.	Cognitive Moral Development	AD (3 papers)	[S25], [S29], [S38]
9.	Self-Perception Theory	AD (8 papers)	[S26], [S28], [S30], [S38], [S39], [S40], [S51], [S56]
10.	ICT Literacy Self-efficacy	AD (2 papers)	[S36], [S38]
11.	General Aggression Model	CA (10 papers)	[S8], [S9], [S11], [S12], [S13], [S14], [S15], [S20], [S17], [S21]
12.	Lifestyle Exposure Theory	CA (1 papers)	[S13]
13.	Social Media Engagement Theory	CA (1 papers)	[S21]
14.	Attachment Theory	CA (1 papers)	[S22]

Most cyber abuse researchers employed the General Aggregation Model (GAM) in their studies. GAM is a comprehensive and integrated paradigm for studying aggression that considers the role of social, cognitive, psychological, developmental, and biological factors in the emergence of violent behaviour [32]. GAM has been utilised in several abusive behaviour scenarios, including media violence impacts, interpersonal violence, intergroup violence, and pain effects [33]. The dominance of GAM in cyber abuse research on unethical online behaviour is largely because these theories define characteristics associated with cyberbullying, cyber trolling, cyber dating abuse, cyber harassment, and cyber victimisation, all of which are abusive and aggressive behaviours.

User and Gratification Theory (UGT) is frequently discussed in relation to cyberslacking. Blumler and Katz initially presented UGT in order to comprehend why individuals utilise particular sorts of media, what demands they have when utilising them, and what satisfactions they derive from doing so [34]. Individuals employ a particular technology or medium to satisfy their desires or requirements, as determined by UGT. Doty et al. (2020) and Grieve (2017) utilized UGT in their research and discovered that certain factors, such as social connectivity, technological engagement, social interaction, and incentives, led to cyberslacking among students [35], [36].

The Sensation Seeking Theory (SST) was then applied to the category of unethical Internet access. SST is "a characteristic characterised by the pursuit of varied, unique, complicated, and intense feelings and experiences, as well as

the readiness to assume physical, social, legal, and financial risks for such experiences" [37]. Sensation seeking has arisen as an explanation for several behaviours, including sex, computer and video game activity, gambling, and others [38]. Several sensation-seeking variables, including sensitivity to boredom and disinhibition, were discovered to be precursors to online sexual behaviour when this theory was applied to unethical Internet use [39].

According to these findings, several theories dominate the categories of unethical online behaviour. Each category's dominant theory suggests that it is an area that is still in flux. Exploring alternative ideas may yield fresh insights for a deeper comprehension of unethical online behavior research.

#### D. RQ3 - Demographic and Risk Factors Involved in Unethical Internet behaviour Research

The aim of this section is to present and discuss the demographic and risk factors extracted from the papers listed in Table IV. Demographic factors are used to determine the characteristics of an individual or a population [40]. Among the most often employed demographic characteristics are race, age, income, marital status, and educational attainment [40]. Table VII lists the demographic factors that were investigated in the 64 papers of this literature survey. A risk factor can be defined as a characteristic, condition, or behaviour that makes a person more vulnerable to an event or occurrence [41]. In the context of this survey, risk factor is factors believed to influence the student engagement of unethical internet behaviour in higher education settings. Altogether, 39 factors were identified by a total of 64 studies which investigated how these factors correlated with student engagement of unethical

internet behaviour. Table VIII lists the predictive factors, studies that analyse the factor which gave significant, no significant or mixed effect.

1) *Demographic factors*: According to Table VII, gender and academic performance factors have a profound influence on unethical behaviour in the category of academic dishonesty. From Table VII, 22 studies found that students with high academic achievement exhibit more ethical behaviour than those with low academic performance. Table VII also shows that ten studies reported that gender factor significantly affects AD behaviour.

Among papers that reported gender factor has a significant effect on academic dishonesty in higher education context, [S31], [S40], [S42], reported that male students were more likely than female students to participate in academic dishonesty behaviour. Whereas study in [S58] showed that more female students witnessed cheating in examinations than the male students, and in [S49], more male students admitted to engaging in AD behaviour than female students. A study in [S36] reported that gender does not have a significant effect on AD behaviour; however, students in higher income groups have more tendencies to be involved in AD behaviours.

Among all the demographic factors indicated in Table VII, only the gender factor has a noticeable effect on cyber abuse behaviours. Nine studies [S8], [S9], [S13]-[S16], [S20]-[S22], reported that male students were substantially more likely to engage in cyberbullying than their female counterparts. A study done by [S15] showed that gender was a significant predictor of cyberbullying behaviour, where male students perpetrated cyberbullying more frequently than female students. In the same study, females had higher scores on empathy and more substantial nonverbal skill proficiency. Research in [S16] revealed that males are much more prone to group bullying than females. Research in [S21] and [S22] showed that males were over two times as likely to engage in trolling and catfishing, respectively, than females.

Studies by [S8] and [S9] showed that cyberbullying was more prevalent among those who used the Internet weekly than those who used it less often or moderately. In [S12], the authors studied students' experiences with traditional bullying and cyber-teasing and the role that sociodemographic factors may have in preventing or contributing to these forms of violence. The study also discovered that the majority of cyber-teasing victims also reported being victims of traditional bullying (and vice versa). Traditional bullying victimisation was more prevalent among males than females, and cyberbullying was more prevalent among female students than male students. Students who experienced traditional bullying were more likely to have financial difficulties, family conflicts, and a history of cannabis use.

2) *Risk factors*: Table VIII shows that attitude, intention and controllability were the three most commonly investigated factors in unethical internet behaviour studies. In terms of attitude, 15 articles on academic dishonesty (AD) and one study on cyberslacking (CS) reported that the students' attitudes would influence the student engagement in unethical

Internet behaviour [S5], [S25], [S26], [S28], [S29], [S34], [S38], [S32], [S57], [S43], [S44], [S46], [S48], [S51], [S54], [S55]. At the same time, AD studies by [S27], [S33], [S37], [S39], [S40], reported that attitude has no significant effect. Nine AD studies regarded intention will influence the student engagement in unethical Internet behaviour [S23], [S25], [S27], [S28], [S38], [S48], [S50], [S54], [S55], while two AD studies reported that intention [S40], [S44] has no significant effect on the student engagement. Controllability factors are a group of factors such as Perceived Behavior Control (PBC), self-efficacy, self-control, self-regulation, and self-monitoring. Reportedly, eight AD, one CS, one Cyber abuse (CA) and one unethical internet access (UIA) found that these factors influence the student engagement in unethical Internet behaviour [S5], [S19], [S29], [S39], [S57], [S48], [S50], [S59], [S54], [S55], while Uzun et al. [S38] claimed that self-efficacy has no significant effect.

Concerning self-perception and self-concept factors, six out of 11 studies found that self-perception is an AD factor. Self-perception has significantly influenced student involvement in unethical Internet behaviour [S26], [S28], [S30], [S38], [S39], [S51], and one study by CA found that negative self-concept factor also has a significant influence on student engagement [S14]. However, four AD studies by [S27], [S40], [S48], [S56] claim that self-perception does not have a significant effect.

Behaviour frequency is a group of cyber-bullying, dating abuse, trolling, cyber-victimisation, dating victimisation, or trolling victimisation frequency. Seven out of nine studies in cyber-abuse ascertained that unethical behaviour frequency is a significant factor [S8], [S9], [S11], [S13], [S15], [S20], [S17]. However, two CA studies claim that behaviour frequency is considered as insignificant [S14] [S21].

The nine studies that investigated the effect of characteristics of subject-course produced contradictory findings [S30], [S36], [S31], [S43], [S44], [S47], [S49], [S56], [S52]: six studies reported that the characteristics of subject-course plays essential roles in influencing the student engagement in unethical Internet behaviour. [S36] and [S44] claimed that the characteristics of the subject-course did not influence student involvement. The study by [S56] suggests that different characteristics of subject-course have a different effect on student engagement.

Five AD studies and one CS study out of eight studies analysed that perceived prosecution risk able to influence the student engagement in unethical Internet behaviour [S27], [S40], [S48], [S56], [S52], contrary to the AD studies by [S25] and [S33]. Five AD studies [S29], [S39], [S48], [S54], [S55] and one CS study [S5] out of eight studies reported that norms are a significant factor in student engagement in unethical Internet behaviour. In contrast, the study by [S38] and [S20] of AD and CA respectively claimed that norms are insignificant.

Two studies that investigated the effect of Big Five Personalities on student involvement in unethical Internet behaviours show mixed findings [S41], [S57]. Wilks et al.

[S41] found that conscientiousness and agreeableness behaviours while other factors do not significantly affect student involvement in unethical Internet

TABLE VII. LIST OF DEMOGRAPHIC FACTORS INVESTIGATED IN UNETHICAL INTERNET BEHAVIOUR STUDIES

No.	Demographic Factor	Total Studies	Significant Effect (SE*)	No Significant Effect (NSE)
1.	Age	CS (1 paper) CA (1 paper) AD (13 papers)	[S4] - [S43], [S56], [S58]	- [S8] [S23], [S24], [S34], [S37], [S46], [S48], [S51], [S59], [S54], [S55]
2.	Gender	CS (1 paper) CA (9 papers) AD (30 papers) UIA (3 papers)	[S3] [S8], [S9], [S13], [S14], [S15], [S16], [S20], [S21], [S22] [S35], [S37], [S40], [S31], [S32], [S46], [S47], [S58], [S49], [S51] [S60], [S62], [S63]	- - [S23], [S24], [S30], [S34], [S42], [S43], [S48], [S59], [S54], [S55] -
3.	Ethnic group/Culture	CA (1 paper) AD (6 papers) UIA (1 paper)	[S18] [S25] [S34], [S44] [S64]	- [S42], [S48], [S55] -
4.	Income/Social class	CA (1 paper) AD (7 papers)	[S12] [S36], [S58], [S59]	- [S34], [S37], [S32], [S48]
5.	Education Level	CA (1 paper) AD (10 papers)	[S12] [S53]	- [S24], [S35], [S32], [S47], [S58], [S49], [S51], [S56], [S54]
6.	Marital Status	AD (2 papers)	-	[S24], [S55]
7.	Academic Performance	CA (1 paper) AD (22 papers) UIA (1 paper)	- [S27], [S30], [S34], [S35], [S36], [S37], [S40], [S42], [S44], [S45], [S46], [S47], [S58], [S49], [S50], [S51], [S52], [S53], [S55]	[S11] [S33], [S43], [S56] -
8.	Internet Service Availability	CS (2 paper) AD (5 papers)	[S8], [S9] [S25], [S27], [S36], [S31]	- [S28]

\*SE comprised of Positive Significant Effect and Negative Significant Effect

AD = Academic Dishonesty; CS = Cyberslacking; CA = Cyber Abuse; UIA = Unethical Internet Access effect while others reported a contradictory result. Neuroticism is reported as significant by [S8], [S13], [S15], while other is not.

However, Day et al. [S43] reported that conscientiousness has a positive influence compared to openness, while neuroticism does not significantly affect student engagement in AD. Interestingly, five CA studies show mixed findings [S8], [S11], [S13], [S15], [S21]. All studies found that conscientiousness has a significant effect while openness to experience does not have a significant effect. Only [S8], [S13], [S21], found that agreeableness has a significant effect, while the other find reported that it is not significant. Whereas [S8], [S11], [S15] found that extraversion has a significant

Psychopathology symptoms are a group of factors that include depression, hostility, anxiety, somatization, shyness, and ostracism that were studied in whole or partly. Four CA studies [S9], [S11], [S13], [S17], and one UIA study [S61] found that these factors have a significant effect, while two CA studies [S8], [S14] have a mixed effect.

Experience is factors that involve students' past engagement in unethical behaviour, either as a victim, perpetrator or witness. Students' experience in using tools to conduct the behaviour is also included in this group. Three AD studies [S34], [S44], [S51], and three CA studies [S11], [S12], [S21], found that past experience is a significant factor. Villora et al. [S20] reported that control abuse has a significant effect while direct abuse is not significant showing a mixed effect in this CA study.

Five out of six studies in academic dishonesty investigated that ethics has a significant effect on student engagement in unethical Internet behaviour [S23], [S32], [S30], [S35], [S37], whereas [S33] claimed it is not. Although Akbulut and Dönmez [S26] and Baetz et al. [S51] reported that social desirability does not have a significant effect, however, Riquez et al. [S33], Akbulut et al. [S3] and Rasmussen et al. [S62] refute this finding.

Five studies explored the aspect of morality and provided different effects [S25], [S29], [S30], [S38], [S49]. Most studies yield that morality has a significant effect in influencing student engagement in unethical Internet behaviour [S29], [S38], [S30]. Lin et al. [S25] claimed that morality does not significantly influence student involvement in unethical Internet behaviour. Ampuni et al. [S49] find that a mix of moral integrity and moral disengagement significantly affects student engagement while other aspects do not.

Two out of four CA studies [S10], [S11] reported that internet usage type has a significant effect, while [S8] refuted this claim. Interestingly, one CS study [S2] and one CA study [S13] have a mixed effect. In terms of individual perceived pressure, three AD studies [S43], [S47], [S52], and one UIA study [S61] agreed that it is one of the significant factors that influence student involvement in unethical Internet behaviour. Two studies researched the effect of perceived benefit effectiveness on student behaviour, but reportedly it has no significant effect [S25], [S42].

Empathizing-systemizing is a group of factors such as empathy, cognitive empathy, affective empathy, emotional reactivity and social skills. Cognitive and affective empathy is a significant factor found by [S14] but not by [S8] and [S21]. The only study by [S8] reported that emotional reactivity and social skills significantly affect student behaviour, which has a mixed effect on these factors. Two CA studies agreed that impulsivity has a significant effect on student behaviour [S14], [S19], while one CS study reported a mixed effect [S6]. Attentional impulsiveness is significant, while motor impulsiveness is not.

Regarding sensation-seeking factors, one CA study [S9], and one UIA study [S61] showed mixed effects. A study in [S9] shows that boredom susceptibility, disinhibition, and experience seeking has significant effect while adventure seeking is not. While in [S61], only disinhibition has a significant effect while boredom susceptibility and total sensation seeking have no significant effect.

Another significant factor is loneliness, researched by Kokkinos et al. [S8] and [S13] in CA studies. Other studies, such as Thongmak [S23], reported that idolatry significantly

affects student engagement in unethical Internet behaviour, while Lin et al. [S25] refuted this claim. Attachment is a significant factor by [S22] but not significant in the study by [S8].

Few academic dishonesty studies have investigated novelty seeking, music quality, Constructivist Practices in the Learning Environment (CPL) and perceived cost. Lin et al. [S25] reported that novelty seeking and music quality positively impact the intention of unethical Internet behaviour. A study by Alt [S59] shows that students were less inclined toward academic cheating in constructivist pedagogical practices in the learning environment. Thongmak [S23] reported that perceived cost is not a significant factor in AD studies.

Cyberslacking studies by Rana et al. [S5] and Wu [S7] have investigated that escapism and attention significantly affect cyberslacking behaviour, respectively. On the other hand, Labar et al. [S1] reported factors that have mixed effects on cyberslacking behaviour. The time perspective of past negative and future orientation is significant factors in cyberslacking behaviour. While the time perspective of present fatalistic and present hedonistic are not significant.

On the subject of cyber abuse studies, Kokkinos et al. [S9] claimed that interpersonal sensitivity, psychopathic traits and anxiety determine unethical behaviour. Furthermore, Kowalski et al. [S11] argued that disabilities and self-esteem are also significant factors in the CA study. Additionally, body image dissatisfaction is found to be significant by Balta et al. [S17]. Nevertheless, only social support is found not to be significant by Howard et al. [S21]. Lastly, Kircaburun and Tosunta [S15] showed a mixed effect on biological clock factors: the evening type's chronotype and sleeping quality had a significant effect, while the morning type and the neither morning nor evening type were not significant.

#### *E. RQ4 - Challenges and Research Opportunities for the Unethical Internet Behaviour Research within University Setting*

This section aims to address Research Question 4, highlighting some challenges and problems regarding unethical behaviour in a university setting. The presented issues are categorised according to the type of unethical internet behaviour, namely academic dishonesty and cyber abuse, to facilitate the extraction of important challenges that emerged from the reviewed works. Note that this study does not find research area challenges presented by the studies under unethical Internet access and cyberslacking categories. The mapping of challenges in unethical behaviour among university students is summarised in Table IX.

Challenges in addressing academic dishonesty have been discussed in many pieces of literature. Under academic dishonesty, the most widely cited issues are organisational related, followed by awareness problems, cost of software and tools problems, and government enforcement problems. The inflated cost to acquire digital products [S23], [S28], [S30], such as software and digital academic materials, may drive student intention for piracy. Therefore, challenges in keeping these digital products affordable through an effective pricing

model [S23] need to be addressed to reduce digital piracy problems among university students. Additionally, universities must promote awareness of academic integrity among the students and lecturers. On the students' side, there is a lack of

student awareness of digital piracy to be regarded as ethically problematic, as cited in [S26]. Similarly, lecturers lack understanding of what constitutes academically dishonest behaviour [S33], [S35].

TABLE IX. CHALLENGES IN UNETHICAL BEHAVIOUR AMONG UNIVERSITY STUDENTS

Unethical Behaviour	Categories of Challenges	List of Challenges	Total Studies	Sources
Academic Dishonesty	Cost of digital products	1. High costs of digital products that drives piracy behaviour.	2	[S23], [S28]
		2. High costs to manage and update plagiarism checker/detection tools.	1	[S30]
	Awareness	1. Lack of student' s awareness on digital piracy to be regarded as an ethically problematic.	11	[S25], [S26], [S27], [S28], [S30], [S37], [S38], [S41], [S31], [S32], [S57]
		2. Lack of lecturer' s understanding of what constitutes an academically dishonest behaviour.	2	[S33], [S35]
	Organisational	1. Lack of campus Honor Code (acknowledgment by student) as policing initiatives.	3	[S33], [S38], [S54]
		2. Lack of affirmative and systematic punishment	7	[S33], [S31], [S57], [S48], [S52], [S53], [S55]
		3. Lack of anti-plagiarism policy and practice	5	[S33], [S31], [S45], [S56], [S55]
		4. Lack of formalized pedagogy and training that address academic integrity.	13	[S30], [S33], [S37], [S32], [S57], [S43], [S45], [S47], [S48], [S52], [S59], [S54], [S55]
		5. Organizational Culture/ Environmental factors	7	[S28], [S33], [S57], [S43], [S45], [S47], [S55]
	Laws and regulations	1. Lack of law enforcement	1	[S25]
Cyber Abuse	Awareness	1. Lack of awareness among lecturer/ counselor	4	[S8], [S9], [S14], [S19]
		2. Lack of privacy awareness among student	1	[S21]
	Organisational	1. Lack of student support and intervention	6	[S8], [S9], [S11], [S16], [S20], [S22]
		2. Lack of reporting avenue	1	[S8]
		3. Lack of collaboration	2	[S8], [S12]
		4. Lack of formalized pedagogy and awareness program that address cyberabuse.	7	[S8], [S12], [S13], [S14], [S16], [S20], [S17]

There is an abundance of discussion in the literature that cites organisational-related issues in academic dishonesty. The most cited issues are the lack of formalised pedagogy and training that address academic integrity. Authors in [S45] highlighted the importance of the higher learning institution effectively communicating their expectations about learning and integrity to the students. The lack of awareness among students and lecturers regarding academic integrity practice is often attributed to a lack of pedagogical training in teaching academic writing. Ongoing skill development among lecturers in the technical aspect [S45], time management and organisational skill [S57], and academic writing [S45] should be supported by the faculty. The lack of anti-plagiarism policy and practice [S55], [S56], campus "Honor Code" [S33], [S38], [S54], and ineffective punishment [S48], [S52], [S53] challenges must be tackled to reduce breaches of academic integrity. In addition, addressing organisational culture issues [S43], [S57] is especially important to shape and define university's academic integrity's practices. Finally, the lack of law enforcement at the national level [S25] may also contribute to university students' digital plagiarism behaviour.

#### IV. CONCLUSION

This study provides a systematic literature review of the literature on the current state of unethical Internet behaviour in higher education published in prominent academic journals

from 2010 to 2020. It defines each category based on the research on unethical Internet behaviours; the presentation of theories used in earlier research on unethical Internet behaviour; the discovery of demographic and risk factors linked to unethical Internet behaviour; and finally, the analysis of the issues and research possibilities posed by unethical Internet behaviour in higher education institutions. The findings of this survey from 64 research articles are presented in a taxonomy that can be utilised to comprehend the current state of unethical Internet behaviour in higher education. Regarding the present study's limitations, which occur in research based on a systematic review, there is a possibility of information loss as a result of the searching strategy used in this study. Although the authors strived to create comprehensive keyword and key string listings, it is plausible that some synonyms were overlooked. In constructing the SLR, insufficiency in synthesising keywords and key strings can influence search results. The fact that this analysis is restricted to English language journals and conference publications leaves room for the potential of other pertinent writings that were left out. This limitation may also cause zero evidence of articles discussing cybercrime or hacking, as discussed in RQ1.

Furthermore, this SLR exclude studies on unethical Internet behaviours that are closely related to any type of addiction or disorder that have been defined in The Diagnostic

and Statistical Manual of Mental Disorders, Fifth Edition, Text Revision (DSM-5-TR). The main reason for this exclusion is that the current authors do not have the expertise to analyse such studies. This exclusion may make it more likely that more pertinent articles will be overlooked.

#### ACKNOWLEDGMENT

This research was supported by the Universiti Teknologi Malaysia (UTM) Collaborative Research Grant National (CRG 47.2) under Grant R.K130000.7356.4B471 and Universiti Teknikal Malaysia Melaka (UTeM) Short Term Grant (PJP) with project number PJP/2019/FTMKCACT/CRG/S01705.

**Abstract**—The era of Industrial Revolution 4.0 has brought the debate of teachers' willingness to use information technology in teaching Arabic. Thus, new technologies have emerged with a positive effect on teaching, such as augmented reality technology applied in the education system, especially in teaching. However, there is still limited research with regards to teaching in a foreign language. Therefore, the present study discusses the readiness of teachers from the aspect of knowledge and their attitude towards the use of augmented reality technology in the teaching of Arabic in Malaysia. The study was carried out using quantitative methodology with the use of survey questionnaire that is distributed to 36 Arabic language teachers as respondents. The usage of questionnaires as a research instrument forms the basis for data collection to identify respondents' level of readiness. Afterwards, data analysis was carried out using the Statistical Package for the Social Science version 26 (SPSS). The results of the study show that the level of readiness of the teachers in terms of their attitude towards the use of augmented reality technology in the teaching of Arabic in Malaysia is at a moderate level. Nevertheless, teachers' attitudes and knowledge are still found to be at a low level, especially for veteran teachers who have no experience in information technology to influence their enthusiasm towards the use of technology in their teaching. The implication of the current study is hoped to be useful and beneficial as a guide to stakeholders who are responsible for ensuring the process of teaching and learning Arabic which is based on augmented reality technology can be implemented in a meaningful way, thereby improving the performance of students in mastering the Arabic language.

**Keywords**—Attitude; teachers; augmented reality; Arabic language; primary school

## I. INTRODUCTION

Contemporarily, augmented reality technology has its own advantages and importance in line with the development of various rapidly growing and sophisticated technologies. The augmented reality technology is an application that is often used in developed countries' educational system as a teaching and learning process of the 21st century. With the availability of technology and evidence of its use in most developed countries, it proves that the teaching and learning process in any school or institution in developing countries, especially Malaysia requires an urgent attention in order to keep up with

the current fast changing world order in technological advancement. This is because, the use of technology can apply a culture of innovation among teachers, in addition to encouraging teachers or lecturers to be more creative in teaching which allows teaching and learning to be more interactive that will eventually help raise the quality of education in Malaysia [1].

For a teacher, there are many steps or efforts that need to be known and mastered including knowledge, skills, approaches, attitudes, methods, and the best techniques to make the teaching process interesting. Preliminary research [2] has found that there are a number of learning processes that have the potential to affect the excellence and interest among students during teaching process. Information technology is one that has significant ability to increase student's understanding, thus requires the knowledge and preparation of teachers to make augmented reality technology an educational tool. Active learning is a process that involves the combination of the students and teachers' participation [3]. For example, the teacher provides freedom to the students so that they are able to learn in a more enjoyable atmosphere and this will create interest in the students as well as make the teaching process more effective and fun.

Based on this, the study [4] identified that teaching Arabic is not separated from the influence and role of information technology. This is because research carried out on modules and Arabic language learning techniques have shown the need for the usage of information and communication technology, particularly at primary level. In [5] and [6], there is a common view on the influence of information and communication technology that can attract students to learn Arabic. This statement is also supported by Muhammad Nazir's view in his study which emphasized the function of multimedia Arabic language games which are seen to be able to have a good impact in understanding the Quran [7].

As such, study [8] identified that teachers are the most accurate and responsible individual to implement this transformation in their teaching. This includes integrating technological advances in the teaching of Arabic. Quality teachers have a level of readiness that covers the aspects of knowledge, including attitudes towards the use of technology

and are able to link their knowledge with more effective teaching methods [9]. Next, study [10] found that 21st century education requires teachers to produce students who are creative, critical, and innovative. Therefore, teachers must first be prepared to master and equip themselves with the latest pedagogical knowledge in accordance with the development progress of the Industrial Revolution 4.0 (4IR) so that teaching can be carried out to meet the 21st century learning standards outlined by the Malaysian Ministry of Education while also being able to attract student's interest and motivation in learning, as teacher is the main factor or role model who will contribute to the success of progress in a modern education system on par with other developed countries.

Therefore, the use of augmented reality technology that combines virtual objects into the real world so that users can interact with virtual objects in real time becomes eminent to be applied in the education system of Malaysia, especially in the teaching of Arabic language [11]. The existence of user-friendly augmented reality applications can help teachers integrate virtual and improve the quality of their teaching and learning process to a more realistic experience [12,13]. A study related to the analysis of the use of applications based on augmented reality technology found that in order to make a better learning, student and teachers need a convenient atmosphere in addition to making learning and teaching more interesting to increase students' interest in learning [14]. As can be seen from the development of technology in the national education system, augmented reality technology is a new and sophisticated form of technology that has yet to be fully explored by researchers. Therefore, it is necessary for the current study to focus on the development of augmented reality technology usage in the national education system in line with the 21st century learning standards outlined by the Malaysian Ministry of Education.

## II. PROBLEM STATEMENT

Malaysia is now a developing country with an economic condition that is very competitive among developing countries. This has led to the presence of 4IR which emphasizes the construction of virtual reality technology without much use of human energy, which has an impact on various aspects of life. In order to face the challenges of 4IR in the era of national education, especially in the teaching and learning of the Arabic language, it is necessary to get out of the comfort zone.

Arabic language subject requires teaching and learning methods that emphasize practice or practicality based on information technology in line with the development of 4IR. This is due to the fact that Arabic language teachers in primary or secondary schools face problem with students' attitude that are easily bored and then feel that learning Arabic language in the classroom setting is not interesting. This unfavorable condition gets more critical when the conventional way of learning produces many students who are weak in the command of the Arabic language which at later stage causes a decline in Arabic language achievement at the primary and secondary school levels in Malaysia. However, as at current, the national education policy strongly emphasizes the aspect of systematic learning which is expected to change

the direction of learning and teaching in Arabic. Therefore, it is opined that teaching methods that have a combination of practicality and usage of information technology can have a more positive effect in teaching Arabic language [2].

In recent time, teachers' problems in teaching Arabic language are often debated. Many past studies have discussed the issues faced by teachers in delivering Arabic lessons to school students in Malaysia. According to [15], there are various problems faced by Arabic language teachers in Malaysia during lessons' delivery. Among the problems often faced by the teachers are ability, pedagogy, motivation, teaching aids, environment, and lack of exposure related to information technology.

Other researchers found that the level of teachers' readiness for information technology platforms is still at a less than satisfactory level. This has been supported through the study [16] who found that 39 percent of teachers in Malaysian schools have a weak level of knowledge about the use of computers and smartphones in their teaching method and the integration of learning process by using such gadgets. As such, it is opined that more problems will arise if teachers are not interested in mastering knowledge and skills of information technology.

The result of the foregoing shows that there are many studies that have identified problems associated with Arabic language teachers, testing teaching models based on information technology, the methods of teachers who teach Arabic and connection with the use of information technology among others. Nevertheless, the booming era of 4IR also requires and encourages researchers to focus their studies on teaching and learning methods for Arabic subjects that are more practical, such as the use of augmented reality technology as there are still limited researchers in Malaysia compared to other countries. Therefore, the present study aims to identify teachers' readiness from the aspect of attitude towards the use of augmented reality technology in the teaching of Arabic language in Malaysia.

## III. AUGMENTED REALITY TECHNOLOGY

### A. Concept and Definition

The development of digital technology has led to the dire need of augmented reality technology. According to [17], the concept of augmented reality technology was first introduced by Ivan Sutherland in 1965. However, in the early 1990s, the term augmented reality began to be used by [18], who developed an augmented reality technology system as a tool to train employees at Boeing Corporation USA to understand and operate the wiring of the aircraft.

Thereafter, study [19] introduced the reality-virtuality as a continuum taxonomy that identifies the relationship between the real environment and virtual reality technology or virtual reality. Based on the taxonomy, the virtual environment refers to a virtual reality technology environment that features all objects virtually. Augmented reality technology is located near the real world where it is expanded with virtual objects produced by computers [17].

This technology has the ability to keep users connected to the real world while interacting with virtual and physical objects [20]. Previous researchers stated that augmented reality technology can be defined as a behavior between human and computers, acting as an additional virtual object to the real environment through display of video cameras or other computers gadget in real time [21].

Study [22] stated that augmented reality is a variation of virtual environments or virtual reality environments commonly known as virtual reality. This is a system or application that is able to create a view in the real world by inserting virtual objects produced by computers including objects in 3-dimensional form into the real environment in real time [22].

There are distinct differences between augmented reality technology and virtual reality technology. The later refers to a situation where the goal is to fully immerse the user in a synthetic environment while earlier is a situation where the goal is to complete the user's perception or view of the real world through the addition of virtual objects. The virtual environment completely replaces the real world, while with augmented reality technology users see the real environment, which is the merging of the virtual with the real [17].

Research [23] studied the concept of augmented reality technology and found that there are generally three types of augmented reality methods which are based on marker-based augmented reality technology; (i) Marker-Based Augmented Reality technology, (ii) Markerless Augmented Reality technology, and (iii) GPS Based Tracking. According to [24], marker-based augmented reality technology requires certain markers or labels to register the position of an object that will be displayed in the real environment. Whereas, in the Markerless Augmented Reality method, users do not need to use markers to show digital elements [25]. Also, markerless technology that is growing through android devices can make augmented reality technology more interesting and can be used anytime and anywhere [26].

Nevertheless, the concept of augmented reality technology that uses GPS Based Tracking is the most widely used method nowadays. It is often developed in various mobile phone applications, such as IOS and Android. This technique accesses the GPS and the compass in the mobile device usually takes data from the GPS while the compass shows the desired direction in real time [27].

#### B. Related Works

Globally, augmented reality technology is used to increase the level of proficiency in Arabic language, especially in Malaysia. A study related to 3D Arabic Augmented Reality (3D BAAR) and focused on the ability to improve Arabic language proficiency among students conducted by [4]. The objective of that research was to test Arabic reading and speaking skills among Year 4 students at a school in the Johor Bahru district through 3D BAAR application that uses augmented reality technology. The results of the study showed a positive effect of the application in improving Arabic reading and speaking skills among the Year 4 students. The majority of students show that they are very satisfied with the

use of applications based on augmented reality technology in their learning. The researchers stated that the students were very interested in the multimedia elements found in the application and displayed through the smartphone screen. Such application allows the students to learn to recognize and pronounce Arabic words with the correct pronunciation. The researchers concluded that the mastery of the Arabic language, such as the ability to speak and read the Arabic language can be improved with the availability of technology based on augmented reality.

Apart from that, the testing of effectiveness of augmented reality applications in basic Arabic language education had been carried out. According to [28], an application has been developed using a Mobile Augmented Reality (MAR) approach specifically for use in teaching basic Arabic language. This application uses the ADDIE (Analyze, Design, Develop, Implement, and Evaluate) technique in terms of design, implementation, testing phase and others. The advantage of the application involves two teaching modules developed by researchers, namely the teaching module and a set of practice questions. The results of the study found that the students showed so much interest in using it, as they stated that the application is interesting, very useful, and easy to use. They are also very satisfied due to the opportunity to learn Arabic words quickly.

Another study by [29] titled "The Application of Augmented Reality Technology in Arabic Language Learning Media: Durus Al-Lughah Volume 1" stated that an application related to augmented reality technology was developed for learning Arabic language at Universitas Darussalam Gontor (UNIDA). The application uses the Android platform and is developed in software, such as Blender 3D, Corel Draw, and Unity 3D. The application is useful for people who use mobile phone with a minimum specification of android version OS 4.0 Jellybean, screen size 4 inches, RAM 512 MB, free memory space (phone memory) with a minimum 200 MB and rear camera 13 MP. The results of the study showed that the application developed is very interesting for learning Durus Al Lughah because it has a very good design, operation, display method, and information structure. However, some aspects still need to be improved from time to time so that the appearance of the application can attract the attention of students to use it in learning Arabic language.

#### IV. METHODOLOGY

The present study purpose is to determine Malaysian teachers' perspectives and attitude to use augmented reality technology in teaching Arabic language. This study was carried out across 14 states comprising several schools in different locations of Malaysia. The respondents include 36 teachers who are chosen through basic random sampling procedure. The teachers selected to participate in this research are Arabic language teachers who teach at the participating schools.

Additionally, a survey questionnaire containing demographic information and teachers' preparedness was employed in this investigation across several stages. The first stage involves collecting respondents' information by determining variances in respondents' levels of preparation

depending on gender, age, education level, teaching experience, type of option, location of the school where they serve, and experience with various information technologies (IT). The second section is a construct designed to assess teachers' attitudes on the usage of augmented reality technology in the classroom in Malaysia.

Conversely, in order to measure the teachers' attitude in using augmented reality technology, four levels of the Likert scale were employed, namely, 4 (Strongly agree), 3 (Agree), 2 (Disagree), and 1 (Strongly Disagree). A high score will give an impression of a positive level of readiness towards a certain criterion and vice versa. Furthermore, in order to obtain data regarding the constructs found through literature and expert studies, questionnaires were delivered to respondents via Google Forms. Thereafter, the data were then examined using descriptive statistics like frequency, percentage, mean, and standard deviation in the Statistical Package for the Social Sciences (SPSS) version 26 software.

## V. ANALYSIS FINDINGS

### A. Respondent Demographics

The respondents involved in the present study are Arabic language teachers from schools throughout Malaysia, in which 36 people represent the total number of Arabic language teachers of the population sample. Table I below shows the demographics of the study, which is divided into 7 questions, such as personal background i.e., gender, age, education level, teaching experience, type of option, experience using information technology, and the name of the school where they serve.

Based on Table I, a total of 31 people (86.1%) are female teachers who teach Arabic subjects, and the remaining 5 people (13.9%) are male teachers. The total number of respondents for this study is 36 people. The findings show that from all the respondents of the study, the number of female Arabic teachers from the sample is more than the total number of their male Arabic teachers' counterparts.

In terms of the distribution of respondents age, it can be seen that the largest number of teachers are between the age of 30 to 39 years and between the age of 40 to 49 years, representing 11 people each with a percentage of 30.6%. This is followed by teachers who are within the age of 20 to 29 years, representing a total of 9 people (25.0%), while the least number of teachers are from the age group of 50 to 59 years, representing a total of 5 people (13.9%). This finding explains that the teachers who teach Arabic language subjects in Malaysia are young, in which the majority are between the age of 20 and 39 years with a percentage of 55.6%. This further explains that the strength possessed by Arabic language teachers is from the aspect of human resources, in which the majority of them are adults. This age group teachers are also easier to accept and make changes to their teaching practices. This group is highly motivated and exposed to many of the latest elements in education, especially creative and innovative teaching that are capable of bringing a positive reform to the country's education.

Meanwhile, the demographics of the study sample also show that the majority of teachers who teach Arabic language

have their highest education at the bachelor's degree level, representing a total of 17 people (47.2%). This is followed by the Malaysian Higher Certificate of Religion (STAM) and Malaysian Higher Certificate of Education (STPM), which are 9 people (25%). The total numbers of the Malaysian Certificate of Education (SPM) are as many as 7 people (19.4%). Meanwhile, at the master's degree and Diploma level, there is one person (2.8%) each who has the qualification. Lastly, there seem to be no teachers who teach Arabic language subject with a Doctor of Philosophy (PhD) degree. This confirms the findings of previous studies that stated the number of Arabic language teachers who hold master's and PhD degree are not much in schools compared to teachers who hold bachelor's degree or diploma.

Regarding the aspect of teachers' teaching experience, it was found that respondents who have taught between 5 and 15 years surpass the others with a total of 7 people (47.2%) followed by more than 15 years with a total of 11 people (30.6%). Only 8 people (22.2%) have less than 5 years of teaching experience. This finding explains that the majority of teachers who teach Arabic language in Malaysia have more than 5 years of teaching experience with a percentage of 77.8%. This can be seen that the Arabic language teachers in this study consist of experienced teachers who are able to implement the teaching and learning process effectively.

On the other hand, the majority of respondents are teachers of Al-Quran and Fardhu Ain (KAFA) which represent the type of teacher option that teaches Arabic which are 24 people (66.7%), followed by Islamic Education Teachers (GPI) which are 8 people (22.2%), while only 4 people (11.1%) are Arabic Language Teachers (GBA). This finding shows that there is no religious teacher who teaches Arabic language.

Referring to the aspect of experience using information technology, the majority of respondents have less than 5 years of experience deploying information technology, with a total of 22 people (61.1%) while 14 people (38.9%) have more than 5 years of experience employing information technology. In general, it was found that not all Arabic language teachers are literate in information technology, especially the group of teachers who are categorized as veteran teachers. They struggle to surf the internet and apply various systems and applications that are beginning to be used in the country's education system.

Finally, Table I shows that the majority of respondents serve at Sekolah Kebangsaan Penambang, totalling 13 people (36.1%), followed by respondents from Sekolah Kebangsaan Kedai Buloh 2, which is 5 people (13.9%). Respondents from Sekolah Kebangsaan Che Latif and Sekolah Kebangsaan Pulau Kundor have the same number of 4 people each (11.1%), followed by Sekolah Kebangsaan Pasir Gudang 3 which are 2 people (5.6%). Also, only one respondent (2.8%) is from Sekolah Kebangsaan Bukit Kuchai, including Sekolah Kebangsaan Bandar Seri Alam, Sekolah Kebangsaan Setiawangsa, Sekolah Kebangsaan Convent Jalan Peel, Sekolah Kebangsaan Seafield 3, Sekolah Kebangsaan Taman Desa 2, Sekolah Kebangsaan Salak South and Sekolah Kebangsaan Chicha Menyabong, all represent the least participating respondents.

TABLE I. DEMOGRAPHIC OF RESPONDENTS

Variable	Item	Frequency	Percentage
Gender	Male	5	13.9
	Female	31	86.1
Age	20 to 29 years old	9	25.0
	30 to 39 years old	11	30.6
	40 to 49 years old	11	30.6
	50 to 59 years old	5	13.9
Educational status	SMU/SMA	1	2.8
	SPM	7	19.4

### B. Teachers' Attitudes Towards the use of Augmented Reality Technology in Teaching Arabic in Malaysia

This study has used descriptive statistical analysis referred to as descriptive statistics to describe the characteristics of a variable by using indicators of mean, standard deviation, frequency, percentage, and then draw conclusions based on numerical data [30]. For the data obtained from the questionnaire, the present study has used the interpretation value of the mean score level outlined by [31] which is 1.0 to

2.4 indicating a low-level interpretation, while the mean score between 2.5 and 3.4 shows medium level and 3.5 to 5.0 is at a high level.

Table II shows the distribution of frequency, percentage, mean, standard deviation, and mean interpretation based on descending order to identify the level of readiness from the aspect of teachers' attitude towards the use of augmented reality technology in teaching Arabic language subject in Malaysia. The overall mean of all items for teachers' attitudes towards the use of augmented reality technology in teaching

Arabic language subject in Malaysia is 3.36 which is at a simple level of interpretation. This explains that the majority of teachers who teach Arabic language at the school level are at a moderate level in terms of the teacher's attitude towards the use of this technology and they are able to use it effectively in the teaching as well as learning process of Arabic language. This finding shows that all 8 statements presented are at a moderate level of interpretation. The mean range is between 3.28 and 3.44.

Additionally, Table II explains that the two highest mean scores have the same value for the level of readiness from the aspect of teachers' attitudes towards the use of augmented reality technology in the teaching of Arabic in Malaysia, which is a statement that refers to augmented reality technology capable of increasing students' interest in learning the language Arabic (Mean = 3.44, SP = 0.65) and the statement referring to augmented reality technology is able to attract students' attention to focus on a topic being taught (Mean = 3.44, SP = 0.56).

The findings of the study show that 19 teachers (52.8%) strongly agree, 14 teachers (38.9%) agree, and 3 teachers (8%) choose to disagree that augmented reality technology can increase students' interest in learning Arabic language. In addition, a total of 17 teachers (47.2%) strongly agree, 18 teachers (50%) agree and only one teacher (2.8%) chooses to disagree that augmented reality technology is able to attract students' attention to focus on a topic being taught.

Meanwhile, two items in the questions were used to respond to the current study, namely the statement referring to augmented reality technology makes it easier for teachers to deliver teaching information faster and augmented reality technology is very effective in helping to improve the quality of teaching and learning Arabic subjects in Malaysia,

recording the mean score and value of the same standard deviation (Mean = 3.44, SP = 0.56). The two statements also recorded the same frequency and percentage, in which a total of 16 teachers (44.4%) choose strongly agree, 18 teachers (50%) agree and only 2 teachers (5.6%) choose to disagree.

Referring to the statement of augmented reality technology, the percentage of students' proficiency in Arabic language recorded the third lowest mean score (Mean = 3.36, SP = 0.54), showing an increased number with a frequency of agree and strongly agree of 35 people (97.2%), disagree and strongly 1 person disagreed (2.8%). This is followed by the statement that augmented reality technology is a new teaching material around the world of education (Mean = 3.31, SP = 0.62) with a frequency of agree and strongly agree of 33 people (91.7%), disagree and strongly disagree of 3 people (8.3%).

Meanwhile, Table II shows that 2 items out of 8 items related to the level of readiness from the aspect of teachers' attitudes towards the use of augmented reality technology in the teaching of Arabic language in Malaysia, both recorded the same mean score and are the lowest among the statements presented. The statement that refers to augmented reality technology is very suitable to be applied in the teaching of Arabic language in Malaysia (Mean = 3.28, SP = 0.57). A total of 12 teachers (33.3%) chooses strongly agree, 22 teachers (61.1%) agree, and 2 teachers (5.6%) choose to disagree. Meanwhile, for the statement that refers to augmented reality technology is a sophisticated teaching material to be used in Malaysia when teaching Arabic (Min = 3.28, SP = 0.66), the results show a total of 13 teachers (36.1%) strongly agree, 21 teachers (58.3%) agree, and 1 teacher (2.8%) chooses to disagree. However, there is also one teacher (2.8%) who chooses to strongly disagree with the statement.

TABLE II. FREQUENCY, PERCENTAGE, MEAN, STANDARD DEVIATION AND INTERPRETATION OF TEACHERS' ATTITUDES TOWARDS THE USE OF AUGMENTED REALITY TECHNOLOGY IN TEACHING ARABIC LANGUAGE IN MALAYSIA

Statement	Frequency				Mean	SD	Interpretation
	SD	D	A	SA			
Augmented reality technology is able to increase student interest to learn the Arabic language.	0 0%	3 8.3%	14 38.9%	19 52.8%	3.44	0.65	Moderate
Augmented reality technology is capable to draw students' attention to focus on a topic that taught.	0 0%	1 2.8%	18 50%	17 47.2%	3.44	0.56	Moderate
Augmented reality technology make it easier for teachers to deliver teaching information faster.	0 0%	2 5.6%	18 50%	16 44.4%	3.39	0.60	Moderate
Augmented reality technology is very effective to help improve the quality of P&P in Arabic subject in Malaysia	0 0%	2 5.6%	18 50%	16 44.4%	3.39	0.60	Moderate
Augmented reality technology is able to increase the percentage of students' proficiency in Arabic.	0 0%	1 2.8%	21 58.3%	14 38.9%	3.36	0.54	Moderate
Augmented reality technology is a new teaching material in the world of education.	0 0%	3 8.3%	19 52.8%	14 38.9%	3.31	0.62	Moderate
Augmented reality technology is very suitable to be applied in teaching Arabic in Malaysia.	0 0%	2 5.6%	22 61.1%	12 33.3%	3.28	0.57	Moderate
Augmented reality technology is a sophisticated teaching material to use in teaching Arabic language in Malaysia.	1 2.8%	1 2.8%	21 58.3%	13 36.1%	3.28	0.66	Moderate
<b>Overall mean</b>					<b>3.36</b>		<b>Moderate</b>

Overall, the findings explain that teachers who teach Arabic language in Malaysia have a moderate level of attitude towards the use of augmented reality technology. On average, the respondents are positive and open to accepting the use of augmented reality technology in the teaching of Arabic language at school and believe that augmented reality technology is able to enhance the teaching and learning process of Arabic language by combining elements of technology and knowledge. This indirectly means that they will master the creativity of teaching, especially in the aspects of motivation and environment when implementing the teaching process using augmented reality technology.

## VI. DISCUSSION

### A. *Augmented Reality Technology is a New and Advanced Teaching Material in the World of Education*

According to [32], augmented reality technology is a technology that has been discovered for the past 40 years, which has sophisticated and interesting attributes or characteristics that are able to accommodate deficiencies that are not found in existing teaching media and traditional teaching systems. which has long been practiced in Malaysia. This technology is capable of becoming a new teaching material to be used in the world of education in Malaysia. Augmented reality technology has new and advanced features, such as allowing users to interact in real time with 3D virtual objects as if holding real objects [11,33,34]. It can be said that augmented reality technology is an advanced technology that brings virtual imagination to the real world by mixing the virtual environment with the physical environment instantly [35].

According to the study [36], augmented reality technology can encourage students, especially children to use different and creative new learning approaches. Students can learn independently by using their own style and able to train themselves to act efficiently as well as learn personally. This clearly shows that augmented reality technology is capable of creating new teaching and learning methods that are more interesting, dynamic, interactive, contextual, easy to understand, and be interpreted due to the two-way transfer of information. Therefore, it is not surprising that the finding of this study shows a positive effect on teachers' attitudes towards the use of augmented reality technology in the teaching of Arabic language in Malaysia.

### B. *Augmented Reality Technology is Able to Increase Students' Interest in Learning Arabic*

The findings of the study show that the majority of teachers who teach Arabic language have a good opinion that augmented reality technology is effective and able to stimulate interest in learning Arabic language. The effect of using augmented reality technology applications in language learning has also been proven by [37] who used an augmented reality application named Letters Alive! It not only increases the percentage of students' reading proficiency but also in the ability to form sentences correctly. This is in line with the opinion of [38], who stated that the visual effect and user interaction in real time on an object can improve the memory and cognitive process of students in visualization.

Similarly, [39] found that augmented reality technology has advantages, such as being able to attract the attention and stimulate the interest of students, especially children in the learning process because it facilitates the understanding of learning content, maintains long-term memory, and user-friendly. It clearly shows that augmented reality technology provides benefits in the learning of students at the primary level.

Teaching aids used by teachers are referred to as platforms to ease the teachers in providing students clear understanding during teaching. This finding is supported by the study of [40], where the use of teaching aids, such as augmented reality technology has a positive impact in improving students' understanding of a subject.

According to [41], students will increase their interest in learning because of the advantages of augmented reality technology that combines the virtual world with the potential to increase students' imagination in relation to the real world [42]. As such, it is able to mobilize students' creativity in learning, especially in Arabic language. This then allows students' concentration to increase along with their interest in the technology [34].

### C. *Augmented Reality Technology is Able to Attract Students' Attention to Focus on a Topic being Taught*

Findings show that the augmented reality technology application is not only able to attract the attention of teachers involved in the study but also prove that the augmented reality technology is able to attract the attention of students to focus on a topic being taught and the students' curiosity in the lessons being studied [11,29]. This statement is supported by the study [33] who found that students, especially children are very interested in using mobile phones in order to learn something new which is often used by them in their daily lives. Therefore, study [33] chose new software which is the use of augmented reality technology in learning words in English where preschool children can use mobile phones in learning as independent learning in line with PAK21.

Study [43] also supported that technology which applies interesting teaching aids and has gamification elements in teaching can increase students' focus and interest. Through this method, the teacher will be able to increase the interest and curiosity of the students towards his/her teaching. This is because, students who get motivation from the teacher will usually be more interested which in turn helps the process of achieving learning objectives.

### D. *Augmented Reality Technology makes it Easier for Teachers to Deliver Teaching Information Faster*

The findings of the present study also show that teachers have a positive attitude towards augmented reality technology because not only it helps teachers in carrying out interesting teaching process, but also delivers the teaching information faster [11]. According to [44] augmented reality technology can help teachers to bring learning experiences outside the classroom to students that are previously impossible. Therefore, with augmented reality technology, teaching information can be done quickly. For example, teachers are able to bring the atmosphere of a visit to the zoo without

having to visit the zoo as the augmented reality technology will take the student to a virtual world with the atmosphere of being in the zoo to see animals. Hence, it is proven that using augmented reality technology in learning would help the students to understand something quickly [45,11]. Besides that, the development tools for AR environments have seen significant change over the past ten years, and currently there are many options. However, it is challenging to create an AR educational environment and to develop content in a simple and efficient approach because all these solutions still demand a high level of technical knowledge or a lot of time to generate [50, 51].

*E. Augmented Reality Technology is Very Effective in Helping to Improve the Quality of Arabic Subject Teaching and Learning in Malaysia*

Findings show that the teachers involved in the present study agree that the use of augmented reality technology is very effective and able to increase the quality of teaching Arabic language. This finding is supported by [24] who stated that most students consider augmented reality technology as an effective learning tool, which can help them understand the concepts learned and ultimately improve the quality of education as well as students' performance. Study [21] stated similar scenario with study [24], arguing that students who use augmented reality technology as a learning aid have shown higher academic performance compared to the use of traditional methods. Furthermore, this believe is supported by the study [25], which described augmented reality technology as interesting and effective to education. It can encourage students to explore learning content from different perspectives. Other than that, study [24] believed that the use of augmented reality technology in the world of education is able to improve the quality of teaching and improve the quality of student learning activities, especially teaching and learning of Arabic language subjects in Malaysia.

Based on a study by [41], the use of augmented reality technology as a teaching method is the latest trend capable of changing the learning landscape from traditional methods to the use of the latest elements, such as animation, simulation, and video. If the use of augmented reality technology is expanded, it will create a fresher, more interactive, and effective teaching as well as learning system. Indirectly, its use can improve the quality of national education [46].

*F. Augmented Reality Technology is Able to Increase the Percentage of Students' Proficiency in Arabic*

The majority of Arabic language teachers in the present study describe a positive attitude towards the use of augmented reality technology because they believe the technology can improve students' Arabic language. This believe is supported by the study [34] which stated that augmented reality technology can also be used to help visualize abstract concepts to understand the structure of a teaching model that can improve students' understanding of lessons. Also, study [47] stated that augmented reality technology creates an immersive experience by expanding the virtual environment so that students can visualize the content of learning, gain a better understanding, and view on a specific learning topic or subject.

According to [48], the use of technology-based teaching aids will produce students who behave positively, such as studying diligently and making efforts by showing a deep interest in mastering Arabic language subjects. This will be a platform for students' excellent mastery of the subject. A positive attitude will produce encouraging results for their performance.

*G. Augmented Reality Technology is Very Suitable to be Applied in Teaching Arabic Language in Malaysia*

Findings show that the teachers involved in the present study agree that augmented reality technology is very suitable to be applied in Malaysian education. This is supported by study [33], who stated that augmented reality technology is suitable for preschool children in learning English words. Having the technology according to that study would enable preschool children to learn new words in English through practicing self-learning without the guidance of a preschool teacher.

Similarly, study [49] stated that augmented reality technology is suitable for practice in coloring activities. This is because augmented reality technology can increase the level of creative thinking among preschool children. Preschool teachers in Malaysia can refer to the teaching and learning plan developed to plan coloring activities with the help of augmented reality technology. Augmented reality technology application software developers can also build applications with special features to develop creative thinking among preschoolers.

## VII. CONCLUSION

Overall, the present study shows that Arabic teachers' level of readiness from the aspect of attitude towards the use of augmented reality technology in teaching Arabic language in primary school in Malaysia is at a moderate level. However, if there is a low and negative attitude as well as knowledge of teachers, especially for veteran teachers who have no experience in information technology. This will affect their enthusiasm and willingness to practice the method of using augmented reality technology in teaching in the era of the technology, thereby undermining the effectiveness of the technology in the Malaysian education system.

Therefore, the drafters of the Arabic language curriculum at primary and secondary school level under the supervision of the Malaysian Ministry of Education are expected to be able to use the findings of the current study as a guide in designing the use of augmented reality technology in the teaching of Arabic language curriculum. This is because the implementation of augmented reality technology usage in education system requires readiness from all involved parties while considering various aspects. Apart from that, it also requires commitment from the authority in providing training, seminars, and workshops to ensure that the vision and mission of national education is achieved. Besides that, the present study would be helpful to increase the level of teachers' readiness from the aspect of knowledge and attitude to implement teaching using techniques as well as methods that are effective with the use of technology based in regard to 4IR.

Thus, this study's findings are very significant because they can be used to determine the level of readiness in terms of teacher knowledge of the use of augmented reality technology in teaching Arabic in Malaysia. The Ministry of Education Malaysia, through its division School management, can use this study as a starting point to design and plan programs, trainings, seminars, and other activities for teachers. However, this study has some limitations, one of which is that it only included responses from Arabic language teachers employed by Malaysia's Ministry of Education. Therefore, it is suggested that future research be expanded to include private schools in Malaysia or compared to other countries.

College of Computing and informatics, Universiti Tenaga Nasional, Selangor, Malaysia<sup>2</sup>

BIOCORE Research Group, Faculty of Information & Communication Technology, Al-Farahidi University, Baghdad, Iraq<sup>3</sup>

**Abstract**—The manual technique that might use for shrinking vessels blood in the retinal fundus images has significant limitations, such as the high rate of time consumption and the possibility of human error, precisely appear with the sophisticated structure of the blood receptacle and a hung amount of the retinal fundus photograph that needs to be anatomic. Moreover, the automatic proposed algorithm that will utilize shrinking and explore helpful clinical characteristics from retinal fundus photographs in order to lead the eye caregiver to early diagnosis for various retinal disorders and therapy evaluations. A precise, quick, and fully-automatic algorithm for shrinking blood receptacles and clinical characteristics measuring technique for internal retinal pictures is suggested in order to increase the diagnostic accuracy and reduce the ophthalmologist's burden. The proposed algorithm's main pipeline consists of two fundamental stages: picture shrinkage and medical feature elicitation. Many exhaustive practices were conducted to evaluate the efficacy of the sophisticated fully-automated shrinkage system in figuring out retinal blood receptacles using the DRIVE and HRF datasets of exceedingly demanding fundus images. Initially, the accuracy of the created algorithm was tested based on its ability to accurately recognize the retinal structure of blood receptacles. In these attempts, several quantitative performance measures precisely five were computed to validate the efficacy of the exact algorithm, including accuracy (Acc.), sensitivity (Sen.), specificity (Spe.), positive prediction value (PPV), and negative prediction value (NPV). When contrast with modern receptacles shrinking approaches on the DRIVE dataset, the produced results have enormously improved by obtaining accuracy, sensitivity, specificity, positive predictive value, and negative predictive value of 98.78%, 98.32%, 97.23%, and 90. Based on five quantitative performance indicators, the HRF dataset led to the following results: 98.76%, 98.87%, 99.17%, 96.88%, and 100%.

## I. INTRODUCTION

Direct ophthalmoscope, or manual examination of the internal photograph by a professional, is being replaced by a computer-attribution diagnosis of retinal internal images. Furthermore, the computer-attribution diagnosis of retinal internal pictures is as accurate as a direct ophthalmoscope and

requires less processing and analysis time. Retinal fundus pictures are commonly used to diagnose many eye-related illnesses that lead to vision loss, for instance, diabetic retinopathy in addition to macular degeneration [1]. The extraction of retinal blood vessels from fundus pictures is one of the essential processes in detecting diabetic retinopathy. Even though numerous segmentation approaches have been proposed, segmentation of the retinal vascular network and picture quality remains difficult. Noise (typically owing to uneven lighting) and narrow vessels are now critical obstacles in retinal vascular segmentation. Additionally, most of the proposed segmentation algorithms optimize the preprocessing and blood receptacle segmentation subjects for each dataset separately. As a result, these algorithms can typically reach a high rate of accuracy for the optimized dataset, but their accuracy will be lowered when applied to different datasets. Although most vessel segmentation methods include pretreatment procedures to improve vessel appearance, other plans skip the preprocessing steps and jump straight to the segmentation stage [2].

Blood receptacle segmentation is an essential required step to do the quantitative investigation of retinal photographs, where a set of critically beneficial clinical features such as the tortuosity, length, density, and thickness, of the blood vessel can be extracted from the segmented vascular tree. Furthermore, the segmented vascular tree has also been used in several medical applications, including retinal image mosaic structure, temporary and/or multi-modal image registration, optic disc identification, biometric identification, and fovea localization. Many segmentation approaches nowadays use machine learning ideas in conjunction with traditional techniques to improve segmentation accuracy by providing a statistical analysis of data to enhance segmentation algorithms [3]. Based on the usage of labeled training data, these machine learning principles can be divided into unsupervised and supervised approaches. In a supervised technique, a human operator labels and select a class for every single pixel in the internal picture, such as vessel and non-vessel. A classifier is trained using the tags supplied to the input. A sequence of characteristics vectors is formed from the data being processed (pixel-wise characteristics in picture segmentation defects). Similar samples are grouped into various classes using predetermined characteristics vectors

\*Corresponding Author.

that are distinguished without any labels in an unsupervised technique. This accumulating is dependent on several assumptions about the input dataset structure, namely that there are two kinds of classes of the input dataset with identical characteristics vectors (blood receptacle and not blood receptacle). Depending on the situation, this matching metric might be sophisticated or specified by a basic metric like pixel contrasts [4].

The analysis of the blood receptacle tree in internal images with precision and accuracy can provide several essential aspects for diagnosing various retinal disorders. However, when utilized as the first step which is represented by preprocessing for higher-level picture detection, retinal blood vessel segmentation might significantly impact other applications. For instance, reliable blood vessel tree detection might be employed in recording time series internal images, finding the optical disc or over, recognizing the retinal blood receptacle fiber layer, and biometric identification. There is a substantial amount of work on this topic due to the applications wide range and the fact that shrinkage of retinal blood receptacles is one of the critical jobs in retinal picture processing [5].

To increase diagnosis precision and reduce ophthalmologists' burden, an accurate, quick, and totally automatic blood receptacle shrinking and clinical characteristics measuring algorithm for retinal internal pictures is presented. The proposed algorithm's main pipeline consists of two critical stages: picture segmentation and clinical feature extraction. In the segmentation stage, a fully automated segmentation method called a morphological filtering algorithm addressed by MFA is used to find blood receptacles in retinal photographs.

In the morphological filtering algorithm, an efficient and reliable image pre-processing procedure is applied to preserve the vessel's structure and eliminate the noise level using the Anisotropic Diffusion (AD) filtering and Gaussian filtering, respectively. This is followed by removing all undesired objects (e.g., small vessel segments) in the enhanced image by applying morphological operations. Finally, all the retinal blood vessels are detected by utilizing an efficient edge algorithm based on efficient filter which is an improved Canny edge detector. Finally, the output segmented images produced from the proposed segmentation algorithm is fused to produce the final segmented image. In the post-processing step, a novel blood vessel linking procedure is proposed to correctly join the discontinuous blood vessels produced in the segmented picture resulting from the fusing stage. In the clinical features extraction stage, several helpful clinical characteristics are computed, for instance the tortuosity, thickness, density, and length of the blood vessel, which are efficiently used in the early diagnosis of several cardiovascular and ophthalmologic diseases. In this stage, an efficient and accurate algorithm for computing the blood vessel thickness is proposed. The main contributions list can be summarized as follows:

- An accurate, quick, and fully-automated blood vessels shrinkage and clinical characteristics assessment

algorithm is suggested to improve diagnosis precision and reduce ophthalmologists' burden.

- Fully-automated segmentation algorithm is proposed and named as a morphological filtering algorithm to accurately detect the blood vessels in the retinal images.
- A novel blood vessel linking procedure is proposed to correctly join the discontinuous blood vessels produced in the segmented image resulting from the previous step.
- This research considers as a second stage from our main goal by developing a fully automated and real-time retinal blood vessels hybrid segmentation and clinical features extraction model in fundus images and for the first stage represented by trainable filter algorithm that already completed successfully.[6].
- The rest zone of this study is consist of Section II which presented a related works on Blood receptacles shrinking and medical feature measuring algorithm for internal pictures of the retina Section III outlines the major processes of the proposed morphological filtering algorithm, which consists of three primary stages: image preprocessing, morphological operations, and vessel recognition. Several comprehensive tests were undertaken to evaluate the performance and accuracy of the newly created fully-automated shrinkage system for analyzing retinal blood receptacles through utilizing two difficult internal binary photograph datasets, as described in Section IV in addition to Section V discusses the outcome results and future work as a final topic.

## II. RELATED WORK

The shrink in the retinal internal image is considered as a first stage concerned with identifying the several diseases that related to the eyes. In general, blood receptacles look like a structure tree. Morphological characteristics includes width, length plus to branching of the eye, and others play an enormous part in detecting and treating various of eyes diseases, according to work published by [5] Classification of microaneurysms and non-macro aneurysms is a concern using morphological filters algorithm to detect diabetic retinopathy in retinal vessels images by utilizing the evaluation matrix such as accuracy, sensitivity, and specificity. In addition, the study did the experiments using the IDRiD dataset with an average result of 80.85%. Thus, its notice some limitations in their proposed methods summarized by resolution point need to be more enhancement. They have used only one dataset in the whole of the experiments. According to S. Annand et al. [7] they are working on Optic disc analysis in retinal blood vessels in the fundus using contourlet sub-bands, superimposed edges with morphological filling through several kinds of datasets, including DRIVE, STARE, MESSIDOR, etc. E-aphtha, DiaretDb1. Moreover, the utilized dataset highlights the accuracy channel that registers 97.15% output result even though the outcome is high. Still, there are some points it needs to be enhance, such as the datasets that are used with significant numbers of users lead to have the

configuration complexity that might happen between the various datasets and the proposed methods. Another work by [8], the study proposed the domain of Retinal Vessel Segmentation in Diabetic Retinopathy Using a Morphological Top Approach in medical Images by implementing two types of data: HAGIS and HRF, which succeed by achieving 95.12%, 94.37%, respectively. Several disorders may be impacted by a particular segmentation procedure, resulting in limits because there are numerous types of diseases, for instance glaucoma, age macular degeneration, hypertension, that concenter harmful and significantly affect the patient's health.

In [9], the work on the execution analysis of auto-detection of diabetic retinopathy utilizing the proposed operation algorithms with the same concept of evaluation matric but with a deferent dataset named by DIARETDB1 to achieve a 98.68% percentage. At some point, the computational timing is quite long, based on several observations. Another study by [10], its introduced analyses of retinal blood receptacle from eyes scope images through utilize morphological method implemented through DRIVE, HRF dataset to extract the Acc., Sen., and Spe. with the exact result of the accuracy is 0.9541,0.9478 respectively. Therefore, there are some misclassified structures, such as vessels giving poor segmentation output. Also, U. Ozkaya et al. [11] presented the efficiency of retinal blood receptacle shrink utilizing morphological operations using DRIVE dataset to achieve 95.61% with some limitations of the proposed methods that do not diagnose critical diseases such as hypertension and diabetic retinopathy. Charu Bhardwaj et al. [12] focusing on the execution analysis of retinal characteristics for diabetic retinopathy characterization and diagnoses by using DRIVE, STARE to extract the evaluation matric category that is divided into three types starting by accuracy and end with specifically to highlight the accuracy average result 95.50%, 94.80% respectively. However, it needs to be more accurate to positively match the manual segmentation results. In this paper, we emphasize the morphological filter algorithm that was modified using a very powerful and common dataset, DRIVE and HRF, for accurate, quick, and full-automatic blood receptacle shrink and clinical characteristics. A measurement approach for retinal internal pictures is presented to enhance or develop diagnostic quality and reduce ophthalmologists' effort.

### III. PROPOSED AUTOMATIC BLOOD VESSELS SEGMENTATION AND CLINICAL FEATURE MEASUREMENT ALGORITHM

The quantitative investigation of retinal images is widely utilized for rapid detection, observation, and treatment assessment of cardiovascular and ophthalmologic diseases, for instance, macular degeneration, eyes diabetes, glaucoma, hypertension, arterio-sclerosis, vein occlusion, and choroidal neovascularization. Among these mentioned diseases, diabetic retinopathy and macular degeneration are considered the two main reasons for blindness. Blood receptacle shrink is an essential stage required for the quantitative investigation of retinal photographs, where a set of critically beneficial medical characteristics for instance the density, tortuosity, length, and thickness, of the blood vessel, can be extracted

from the segmented vascular tree. Furthermore, the segmented vascular tree has also been used in several medical applications, including retinal image mosaic structure, temporary and/or multi-modal image registration, optic disc identification, biometric identification, and fovea localization. Accordingly, it is hypothesized that an autonomous method for segmenting and extracting valuable clinical information from retinal blood vessels will aid ophthalmologists and eye specialists in the early diagnosis of various retinal illnesses and the evaluation of treatment options. Fig. 1 shows the projected blood vessel segmentation and clinical features measurement.

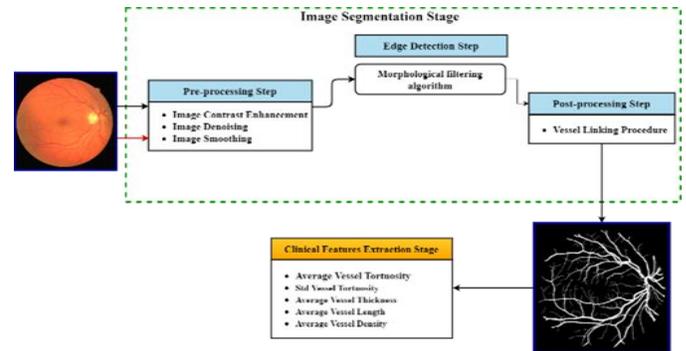

Fig. 1. Diagram of the Proposed Blood Receptacles Shrink and Clinical Features Measurement Algorithm.

#### A. The Morphological Filter Algorithm

As we presented in Fig. 2 the main steps of the morphological filtering algorithm, which is composed of three main stages, including the image pre-processing stage, the morphological operations stage, and the vessels detection stage. In the image pre-processing step, the AD filtering and Gaussian filtering are applied on top of the extracted green channel of the retinal image to enhance edges' structures and eliminate the noise in the retinal fundus image, respectively. Then, a set of morphological operations are applied on top of the enhanced image produced from the previous stage to discard the background and all the unwanted objects (e.g., small vessel segments). Finally, the retinal blood vessels are detected by utilizing an efficient edge detection algorithm based on edge detector filter addressed by an improved Canny edge detector. The main steps of the selected filter are explained in detail in the next sub-sections.

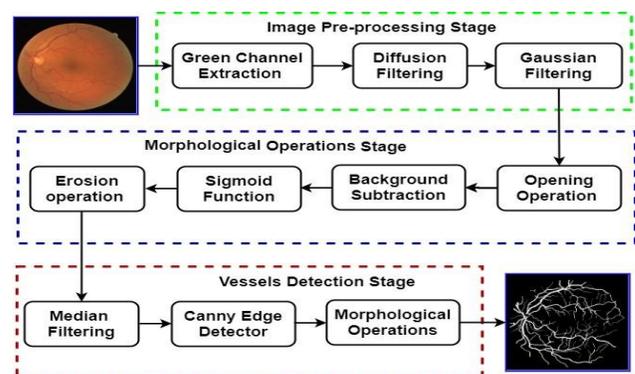

Fig. 2. The Fundamental Stages of the Proposed Morphological Filtering Algorithm for Detecting the Retinal Blood Vessels.

1) *Image pre-processing stage*: In this stage, the crucial aim is to improve the non-uniform illumination, controlling the contrast of the retinal picture and de-creasing the background noise. The main steps of the proposed image pre-processing can be summarized as follows:

- a) Extracting the best channel which is the green from the colored retinal internal photograph.
- b) Correcting the non-uniform illumination and enhancing the visibility of the edges' tree structures in the retinal internal picture by using AD filter.
- c) Applying the 2D Gaussian filter to smooth the retinal image and eliminate the background noise.

Despite of the human observer can efficiently identify the blood vessel structures using the full-color image, however, processing the three channels of the input image can increase the computational complexity of the proposed algorithm where a long time will be required to deliver the final segmented image. Thus, the proposed morphological filtering algorithm starts with extracting the green channel of the input picture because it gives a better distinction between the background layer and the retinal blood receptacle than other channels, as shown in Fig. 3.

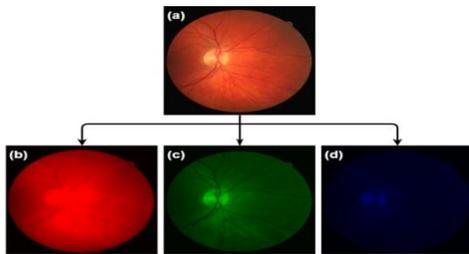

Fig. 3. The Three Channels of the Coloured Retinal Image: (a) Main Picture, (b) Red Conduit Picture, (c) Green Conduit Picture, and (d) Blue Conduit Picture.

In most cases, the retinal images have some background pixels with intensity values similar to the lighter pixels of the retinal blood vessels. These pixels can significantly degrade the outcome of the proposed segmentation algorithm. Therefore, the AD filter [13] was used to the green conduit of the retinal picture after rescaling it to the range of [0, 1], to correct the non-uniform illumination and enhance edges' structures in the retinal picture, as presented in Fig. 3(b). The AD filter can be represented as follows:

$$I_{i,j}^{t+1} = I_{i,j}^t + \lambda [c_N \cdot \nabla_N I + c_S \cdot \nabla_S I + c_E \cdot \nabla_E I + c_W \cdot \nabla_W I]_{i,j}^t \quad (1)$$

Here,  $I$  refer to the retinal image,  $0 \leq \lambda \leq 1/4$ , The  $(c)$  parameter represents the conduction coefficients which is updated every iteration as a brightness gradient function,  $(t)$  represents the iteration index, and  $(\nabla)$  refers to the nearest neighbour variances in all the directions N, S, E, and W, as bellows:

$$\nabla_N I_{i,j} = I_{i-1,j} - I_{i,j}$$

$$\nabla_S I_{i,j} = I_{i+1,j} - I_{i,j}$$

$$\nabla_E I_{i,j} = I_{i,j+1} - I_{i,j}$$

$$\nabla_W I_{i,j} = I_{i,j-1} - I_{i,j} \quad (2)$$

In this work, these values of the  $\lambda$  and  $t$  parameters are set to 0.20 and 5, respectively. This was followed by applying the 2D Gaussian filter to assure the smoothness in the retinal internal picture in addition to eliminating the background noise, as presented in Fig. 3(c). The 2D Gaussian filter is distinguished by a non-uniform low-pass filter, whose 2D filter coefficients are computed as follows:

$$G(x, y) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y^2}{2\sigma^2}} \quad (3)$$

Here, the  $(x, y)$  refers to the filter center, and  $\sigma$  refers to (SD) Standard Deviation of the Gaussian filter.

2) *Morphological operation stage*: Typically, morphological operations can be employed to accurately extract the image's components, which are proven to be extremely helpful for interpreting and representing the different shapes that exist inside the input image rather than pixels' intensities, such as borders, skeletons, and convex hulls [14]. The morphological operations are considered powerful tools that can be efficiently employed in solving several tasks in image processing. Dilation, erosion, opening, closing, bottom-hat, and top-hat transformation are the fundamental morphological operations that can be utilized to segment, manipulate and adjust the objects shown in the input image depending on their structure [15]. In general, these morphological operations were only applied to the binary images, and then they were extended to process the grey-scale images as well. The primary aim of this stage is to define the vessels' structure precisely by eliminating the defects, such as various kinds of noise that can influence the blood vessels' structure and produce more visible structures of the blood vessels. The main stages in the selected morphological operations stage are implemented sequentially as follows:

- a) Applying the opening operation with a disk structure element of 3 pixels.
- b) A background subtraction procedure was implemented to split the foreground objects from the image's background.
- c) A sigmoid function was employed to decrease the effect of the non-uniform illumination of the retinal pictures.
- d) Improving the appearance of the retinal blood receptacles by applying the erosion process.

In this stage, two different morphological operations were applied, namely the opening and erosion operations. The morphological operations were further employed in other steps of the proposed blood vessel segmentation algorithm to exclude the unwanted features (e.g., small vessel parts) without changing the main structure of the blood vessel. Usually, the morphological operations take two different parameters, including the picture that needs to be processed. The shape in addition to size of the tree structure element plays a significant role in detecting a feature representation of a given size and shape in the input image. Thus, the size and shape of the structuring element are selected according to the demand and purpose of the adopted application. The erosion

and dilation operations are the essential morphological operations utilized to lessen and boost the objects in the image, respectively. The erosion and dilation operations are defined as follows.

$$f \ominus B = \min_{u,v} (f_{(x+u,y+v)} - B_{(u,v)}) \quad (4)$$

$$f \oplus B = \max_{u,v} (f_{(x-u,y-v)} + B_{(u,v)}) \quad (5)$$

where  $(f)$  represents a greyscale image  $B$  refers to the structuring element.  $f \ominus B$  and  $f \oplus B$  represent erosion and dilation, respectively. Morphological opening operation is applied to delete undesired precise structures in the input picture by implementing an erosion procedure followed by a dilation process. In contrast, a morphological closing operation is applied to fill or merge some structures in the input picture by implementing the dilation procedure followed by the erosion process. The morphological opening and closing operations can be defined as follows:

$$foB = (f \ominus B) \oplus B \quad (6)$$

$$f \bullet B = (f \oplus B) \ominus B \quad (7)$$

In this stage, several kinds of experiments were conducted to select the methods of applied in this stage using retinal fundus images with various levels of noise and lighting conditions. The main aim here is to improve the structure of blood vessels without missing essential characteristics in the retinal picture. In the current stage, the opening operation was applied to the enhanced image produced from the prior stage by employing an optic disk element of 3 pixels. Then, a subtraction procedure for the background layer was implemented to split the foreground objects from the image's background and identify the retinal blood vessels accurately. Next, a simple image contrast enhancement process using a sigmoid function [16] is implemented as follows:

$$g(x, y) = \frac{1}{1 + e^{(c \cdot (Th - f(x,y)))}} \quad (8)$$

Where  $f$  and  $g$  of  $(x,y)$  is the input and the enhanced photograph. Herein, the contrast parameter  $(c)$ , and the Threshold parameter  $(Th)$ , are empirically chosen to be 4 and 0.5, respectively. The main advantage of this step is to decrease the impact of the non-uniform illumination by narrowing in addition to extending the values range of the bright and dark pixels in the retinal photograph, sequentially. Finally, the erosion process was also applied by employing a structural element of 2-pixels to improve the appearance of the retinal blood vessels, as presented in Fig. 3(d). Undesired segments of one-pixel size were excluded.

3) *Vessel's detection stage*: The vessels detection procedure was applied to preserve beneficial structural details of the blood vessels' borders and to carefully discard the unwanted objects. As depicted in Fig. 4, the fundamental steps of the selected vessels detection process might be outlined as follows:

a) Eliminating the noise level produced from the morphological operations stage by applying the median filter.

b) An improved Canny edge detector was employed to accurately identify the blood vessels.

c) A refinement vessel's structure procedure based on applying a set of morphological operations was implemented to maintain the actual thickness of the detected blood vessels and to eliminate unwanted objects in the segmented image.

Initially, the median filter was applied to eliminate the noise produced from the morphological operations stage that can significantly influence the precision of the blood vessels detection in the later steps. The median approach is a non-linear method that is utilized to eliminate the noise from a given image to enhance the outcomes of subsequent processing (e.g., the edge detection process in an image). The median filter is very widely applied in addressing several image processing problems due to its ability in preserving the edges and removing noise. In this work, a media filter of size  $(5 \times 5)$  pixels.

The blood vessels were then identified by using an improved Canny edge detector. First, the Gaussian filter was applied to further decrease the noise level in the picture. This was followed by calculating the gradient magnitude along with its vectors for each pixel of the enhanced image. An algorithm of non-maxima suppression was later implemented by utilizing the gradient magnitude and direction to be recognized and assigned as a border pixel by employing the thresholding approach. The main stimulus for applying the improved Canny edges detector is to accomplish some beneficial characteristics, including reducing the possibility of duplicated responses to a singular edge; reducing the likelihood of neglected edges; reducing the distance computed between the pixels of the identified edges and the original edges. These four characteristics might conceder as a critical role in solving the problems of detecting retinal blood receptacles precisely. The main steps of applying the improved Canny edges detector can be summarized as follows:

1) *Smooth Image*: Reducing the noise and smoothing the retinal image by applying the Gaussian filter. Suppose  $G(x, y)$  represents the Gaussian filter as revealed in Eq. (9) and  $I(x, y)$  represents the retinal image. Then the smoothed image can be obtained by convoluting  $I$  with  $G$  of  $(x, y)$  as follows:

$$S(x, y) = G(x, y) \otimes I(x, y) \quad (9)$$

2) *Gradient Magnitude*: Computing the gradient magnitude of the smoothed image  $S(x, y)$  is utilized to compute the variation value of  $(G_x)$  and  $(G_y)$ , sequentially, same as below:

$$G_x(x, y) \approx [S(x, y + 1) - S(x, y) + S(x + 1, y + 1) - S(x + 1, y)]/2 \quad (10)$$

$$G_y(x, y) \approx [S(x, y) - S(x + 1, y) + S(x, y + 1) - S(x + 1, y + 1)]/2 \quad (11)$$

From Eq. (10) and (11), the gradient magnitude and its direction are computed, respectively, as in Eq. (12) and (13):

$$G(x, y) = \sqrt{G_x^2(x, y) + G_y^2(x, y)} \quad (12)$$

$$\theta(x, y) = \tan^{-1} \left( \frac{G_y^2(x, y)}{G_x^2(x, y)} \right) \quad (13)$$

3) Non-maxima Suppression Algorithm: The computed gradient magnitude usually includes extended ridges nearby the local maximum. Thus, the non-maxima suppression algorithm was applied to thin these extended ridges. A gradient vector (di) composed of four discrete directions (e.g., horizontal, vertical, 45° and - 45°) is computed for each pixel (x, y) of the normal edge. Then the closest direction to  $\theta(x, y)$  is defined from these four directions. If the value of gradient magnitude  $G(x, y)$  was lower than the vectors (di), then the non-maxima algorithm is equal to zero (suppression); else,  $N(x, y) = G(x, y)$ .

4) Hysteresis Thresholding Algorithm: This algorithm is applied to detect and connect the pixels of the actual edges.

In most cases, thresholding the input image can produce several false detected edges. To decrease the rate of false detected edges, a thresholding algorithm can be applied using two different threshold values, named the low threshold (TL) and the high threshold (TH). It defines the non-maxima approach NH (x, y) after hysteresis thresholding N (x, y) using the high threshold (TH) and defines the non-maxima approach NL (x, y) after the method of thresholding using the low threshold (TL). Obviously, the NH (x, y) has the stronger edge representations compared with the NL (x, y) which contains the weaker edge representations.

After the improved Canny edge detector has applied, a refinement vessel's structure procedure was implemented to maintain the actual thickness of the detected blood vessels and to eliminate some unwanted objects in the segmented image. This refinement procedure starts by applying the dilation process by employing two line-formed structural elements of three pixels with angles between 90° and 0°, sequentially. Then, the erosion process was implemented by employing a structural element of one pixel to sharpen the edges of the defined blood vessels. Finally, all the objects of an overall area of fewer than 100 pixels were discarded from the final segmented image, as shown in Fig. 4(e).

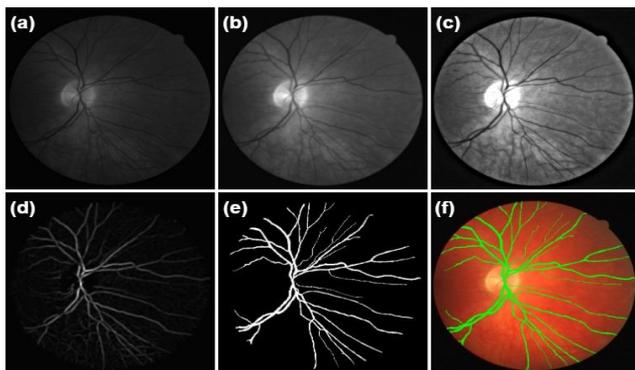

Fig. 4. The Proposed Morphological Filtering Algorithm Outputs: (a) Normalized Green Conduit, (b) AD Output, (c) Gaussian Filtering Output, (d) The Output of the Morphological Operations Stage, (e) The Final Output of the Edge Detection Stage, (f) The Overlapped Automated Segmented Image with the Original Retinal Image.

### B. Post-Processing Stage

Once, the segmented retinal image is obtained from the morphological, the output is used to produce the final segmented image. Then, a novel blood vessel linking procedure was proposed to correctly join the discontinuous blood vessels produced in the segmented image resulting from the previous step. These discontinuous blood vessels are presented in the eventual segmented picture due to poor visibility of the specific portions of blood vessels or the noise presented in the retinal image. The accuracy of the extract clinical characteristics, for instance, the thickness, length, density, and tortuosity of the blood vessel can significantly be affected by the appearance of the discontinuous blood vessels. Thus, a new process was selected in this study to correctly join the discontinuous blood vessels in the final segmented photograph. The proposed blood vessel linking procedure was implemented as follows:

1) Producing the skeleton blood vessels structure of the final retinal segmented image, and then identifying the vessels' end-points.

2) Defining a possible highest distance between the endings of each two segments of a disconnected blood vessel. Then a circular-shaped structure element of radius = (highest distance)/2 was placed at the end of each blood vessel. If the ends of the two blood vessels were approaching each other, then the placed structural elements were overlapped, as displayed in Fig. 5(c).

3) Finally, the thinning process was applied to the whole image. Hence, a line of one pixel wide will be left by the thinned structural elements to link the two endings of the vessel. While, the separated ends are recovered to their initial structure, as displayed in Fig. 5(d).

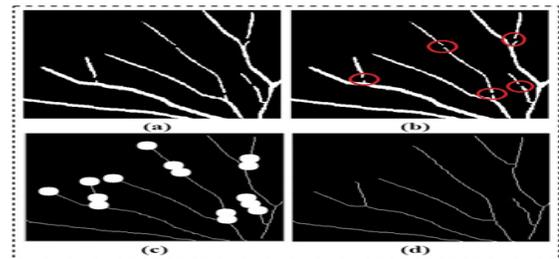

Fig. 5. The Proposed Blood Vessel Linking Procedure: (a) The Segmented Blood Vessel Structures, (b) The Disconnected Blood Vessels Marked in the Red Circles, (c) The Binary Circular-shaped Structural Elements are Drawn at the Ends of each Blood Vessel Segment, and (d) The Resulting Image with Linked Blood Vessels.

### C. Clinical Feature Extraction Stage

The abnormalities in the retinal blood vessel structures, including the morphologic modifications in vessel tortuosity, shape, thickness, and length might be connected to the existence of cardiovascular and eye diseases. Therefore, the automatic quantitative analysis process of abnormalities in blood vessel structures can be extremely useful to help ophthalmologists and eye specialists in the early diagnosis of different retinopathies diseases, describe their severity level, and treatment assessments. One of the main aims of this work is to develop an automated morphologic description procedure

to analyze the whole blood vessel network in the retinal image. The clinical features extraction stage computes a set of useful clinical features from the automatically detected retinal blood receptacle in an accurate path. In the current stage, a number of morphological clinical features associated with the healthiness of the retinal blood receptacles are extracted as follows:

1) *Vessel's length*: The length of the retinal blood vessel was computed for each vessel's segment by firstly taking the vessel's skeleton structure, and then the distance between sequential pixels in the blood vessel segment is summed as in Eq. (14).

$$Vessel\ Length = \sum_{i=1}^{N-1} \sqrt{(x_{i-1} - x_i)^2 + (y_{i-1} - y_i)^2} \quad (14)$$

Here, (N) refers to the number of sequential pixels produced from the blood vessel skeleton part, with  $(x_i, y_i)$  refers to the pixel's coordinates in the blood vessel part.

2) *Vessel density*: The retinal blood vessels density was calculated by dividing the sum of all the pixels in the blood receptacles by overall area of the whole retinal image as shown in Eq. (15):

$$Vessel\ Density = \frac{\sum The\ vessel\ pixels}{ImageArea\ (mm^2)} \quad (15)$$

3) *Vessel tortuosity*: The tortuosity coefficient of the blood vessel is interpreted as a degree of twists presented in the blood receptacle course, as shown in Fig. 6. Some studies have proved that the vessel tortuosity coefficient can be linked with the average fundus blood pressure, however, no significant increase was observed until the critical blood pressure level is reached [17, 18]. Herein, the mean tortuosity coefficient of the whole retinal blood vessel network was computed. First, the skeleton structure of the blood vessels was produced. This was followed by defining the branch points of the blood vessels to divide the length of Blood Vessel Segment (BVS) into (b) branches as in Eq. (16):

$$BVS = s_1 + s_2 + \dots + s_b \quad (16)$$

Then, the tortuosity coefficient index for the (BVS) was then computed as follows:

$$TC(BVS) = \sum_{n=1}^b \frac{s_{length}(n)}{s_{straight}(n)} \quad (17)$$

Fig. 6. An Example of Severe Retinal Blood Vessel Tortuosity is a Patient with Severe Non-proliferative (NPDR) Disease [19].

where  $s_{length}$  refers to the length of the vessel branch, and it was estimated by Eq. (14).  $s_{straight}$  is the straight distance between the endings point and was estimated as follows?

$$s_{straight} = \sqrt{(x_N - x_1)^2 + (y_N - y_1)^2} \quad (18)$$

Here, (N) refers to the specific number of essential subjects captured from the sub branch of the blood vessels. While  $(x, y)$  refers to the pixel's coordinates in each branch of the blood vessels. Finally, the mean tortuosity coefficient of the entire blood vessels network was acquired by calculating the mean tortuosity values obtained of each blood vessel.

4) *Vessel thickness*: The blood vessel thickness is referred to as the average width of the retinal blood vessels. In this PhD thesis, a new procedure for computing the retinal blood vessel thickness is developed. Fig. 7 presents the outcome results of the enhanced thickness procedure. The primary steps of the developed procedure after identifying each blood vessel were implemented as below:

a) Distance transformation was computed from the photograph of detected retinal blood vessels, where all background pixels in the transformed image become white, while the object pixels become black. This transform calculates the Euclidean distance for each black pixel in the segmented image to the nearest non-zero pixel. In the developed procedure, the distance transform was implemented on the inverse of the binary image of the detected retinal blood vessels. Thus, for each pixel of the detected blood vessel, the Euclidean distance of that specific pixel or subject to the nearest border pixels of the blood vessel was computed.

b) After applying the distance transforms, the blood vessel pixels that have the greatest distance values in the distance transform will be located in the middle of the blood vessel segment. The distance values that represent the halfway edge in between the blood vessel segment were obtained with some leniency of the largest distance values because of the floating-point computation.

c) Eventually, the overall average of accumulated distance values defines the half-width of the blood vessel. Consequently, the blood vessel thickness (width) was measured by multiplying the outcome reached by two.

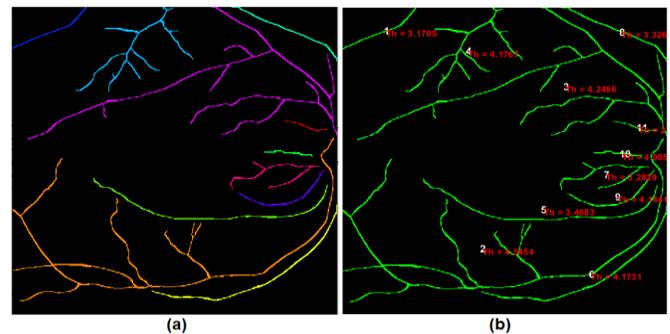

Fig. 7. The Output of the Developed Thickness Procedure: (a) Coloured Labeled Retinal Blood Vessels and (b) Image Map for the Retinal Blood Vessels along with their Indexes and Average Thickness Values.

#### IV. EXPERIMENTAL RESULT AND DISCUSSION

In the current research, the accuracy of the developed segmentation approach for recognizing retinal blood vessels was tested using two very difficult fundus image datasets, DRIVE [20] and High-Resolution Fundus (HRF) [21]. These datasets were used to test the method.

Firstly, the main details of the applied retinal image datasets in current experiments are present. Secondly, the evaluation procedure of the fully-automated shrinkage algorithm is given along with their combination and compared their performance among (GT) which represents the ground truth pictures. Finally, the execution of the developed algorithms is compared with the modern approaches.

##### A. Dataset Precise Description

The execution of the selected blood vessel segmentation algorithms has been tested using two established publicly available datasets of retinal fundus images (DRIVE and HRF). These two datasets have gained special popularity due to they provide the associated GT images, in which the blood vessel is manually detected by different expert observers. Thus, they enable the possibility of comparing the results obtained against the provided GT images to check the reliability and quality of the selected algorithm. The main aim of these two datasets is to establish and encourage comparative studies on developing an automated algorithm for retinal blood receptacles in the fundus pictures.

1) *DRIVE dataset [20]*: The DRIVE is consisting of 40 colored retinal pictures split into testing and training sets, each one consisting of 20 pictures. A Mask picture that represents the view field (FOV) of the retina area is supplied for each image together with the corresponding GT image. The blood receptacle in the retinal pictures of the training set was manually segmented by one expert. In this work, the training set was used to figure out the elements of the selected segmentation algorithms. On the other hand, the blood vessels in the testing set images were manually segmented by two other experts. The real execution of the proposed receptacle algorithm was assessed using the testing category. DRIVE database contains retinal images captured from several causes of diabetes up to 400 subjects the record starts with age 25 until 90 years old in the Netherlands. Then, 40 images were randomly chosen, 33 images without diabetic retinopathy registered causes and 7th of the images marked in early diabetic retinopathy. Retinal pictures were captured utilizing a Canon machine with a precise model CR5 non-mydratric 3CCD camera with an angle of 45° as a field of view. All the images were saved in a specific size which is (768 × 584). As an instance of retinal internal photographs from DRIVE dataset responding manually gold standard images are shown in Fig. 8.

2) *HRF dataset [21]*: The HRF dataset has 45 pictures taken by three different groups, such as healthy people, people with diabetic retinopathy, and people with glaucoma.

3) *Each group has 15 pictures* utilizing a mydratric fundus camera with precise model CANON CF-60UVi with

angle 60° as field of view. All the images were saved in JPEG format with 24-bits coloured image. Binary field of view mask pictures of the provided dataset in order to perform the analysis only in the region surrounded by the dark background [see Fig. 9(b)]. In this dataset, the tree of blood vessels was manually traced by several experts in the domain of retinal picture interpretation. For instance, retinal internal pictures from HRF dataset images are shown in Fig. 9.

##### B. Blood Vessel Segmentation Evaluation

In the binary classification task, every single pixel in the input picture is identified as a blood receptacle by the proposed algorithm. In addition to classified as a blood receptacle in the GT image is computed as a (TP) true positive. Moreover, every single pixel is identified as a blood receptacle in the final segmented picture, yet not in the to the ground truth picture is computed as a (FP) false positive. In the evaluation of the retinal vessel segmentation, the average values of five quantitative performance measures were computed to experiment the quality of the selected algorithms, including the Acc., Sen., Spe., PPV, and NPV. These five quantitative measures are computed as follows:

$$Accuracy (Acc.) = \frac{TP+TN}{TP+FN+TN+FP} \quad (19)$$

$$Sensitivity (Sen.) = \frac{TP}{TP+FN} \quad (20)$$

$$Specificity (Spe.) = \frac{TN}{TN+FP} \quad (21)$$

$$Positive Predictive Value (PPV) = \frac{TP}{TP+FP} \quad (22)$$

$$Negative Predictive Value (NPV) = \frac{TN}{TN+FN} \quad (23)$$

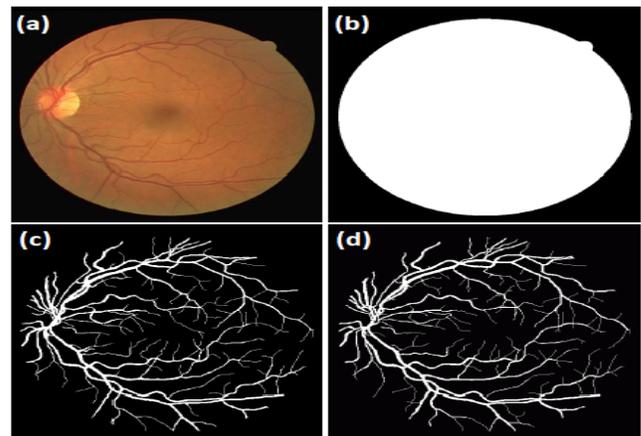

Fig. 8. Image Example from the DRIVE Dataset: (a) The Main Picture, (b) FOV-mask Picture, (c) The Manually Segmented Picture of the First Expert, and (d) Manually Segmented Picture of the Second Expert.

Fig. 9. Image Example from the HRF Dataset: (a) The Main Photograph, (b) FOV-mask Photograph, and (c) The Manually Segmented Photograph of Expert.

Here, the FN, FP, TN, and TP are referring to False Negatives, False Positives, True Negatives, and True Positives sequentially. Acc. measurement is referring to the average of the total amount of correctly identified pixels among to the number of pixels that located in the field of view mask picture. Sen. relates to the selected algorithm’s ability to recognise the blood receptacle pixels accurately. Spe. is the capacity of the suggested method to recognise non-vessel pixels accurately.

The positive prediction value is referring to the pixels’ average correctly classified as vessel pixels. Finally, the negative prediction value is the pixels average to correctly identified as non-blood receptacle pixels (e.g., background).

C. 4.3. Results on Drive Dataset

Firstly, the execution of the selected algorithm for detecting the retinal blood receptacle was checked out based on the DRIVE dataset. Using training group pictures, several executions were done in field to choose the best value for a group of parameters in order to maximize the segmentation quality of the proposed algorithms. For instance, using the proposed morphological filtering algorithm, the ( $\lambda$ ) and ( $t$ ) parameters values are determined to 0.20 and 5, respectively. The 2D Gaussian filter size was set to ( $7 \times 7$ ) pixels, values of the low threshold (TL) and the high threshold (TH) were set to 25 and 40, respectively. Then, the segmentation accuracy was computed to select the best value of the parameter ( $t$ ). So, 121 tests were done where the parameter ( $t$ ) was changed each time by 0.1.

As shown in Fig. 10, the best value of the parameter ( $t$ ) was set to 0.5. In the evaluation stage, five performance evaluation metrics were computed using the testing images along with the two provided human observers as the GT images.

The adopted five evaluation metrics using the proposed morphological filtering algorithm are shown in Table IV. Using the two provided human observers as the GT images in the DRIVE dataset the proposed morphological filtering algorithm has managed to achieve an overall average Acc. of 98.06%, Sen. of 97.995%, Spe. of 97.775%, PPV of 90.07%, and NPV of 94.725%. Form Table I, although the proposed morphological filtering algorithm has obtained a higher Spe. of 98.32% using the 1st human observer compared to Spe. of 97.23% using the 2nd human observer, better results were obtained using the letter in terms of other evaluation metrics. Then, the proposed blood vessel linking procedure was applied to correctly join the discontinuous blood vessels produced in the segmented retinal image resulting from the previous step. In this work, to validate the advantage of applying the proposed blood vessel linking procedure, the adopted five evaluation metrics were computed with and without the applying the proposed blood vessel linking procedure. An example of the output segmentation results on the DRVIE dataset is shown in Fig. 11.

In this work, On the images that come from DRIVE group dataset, the execution of the suggested algorithms was compared with modern methods for separating blood vessels.

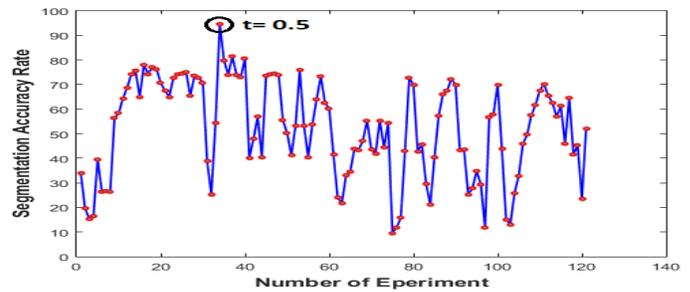

Fig. 10. The Segmentation Accuracy Obtained during 121 Experiments to Fine the Best Value of the Parameter ( $t$ ) in the using the Proposed Morphological Algorithm.

TABLE I. THE AVERAGE VALUES OF FIVE QUANTITATIVE PERFORMANCE MEASURES USING THE PROPOSED MORPHOLOGICAL FILTERING ALGORITHM ON DRIVE DATASET

Measurements	1st Observer	2nd Observer	Average
Acc.	97.34	98.78	98.06
Sen.	97.67	98.32	97.995
Spe.	98.32	97.23	97.775
PPV	89.92	90.22	90.07
NPV	93.89	95.56	94.725

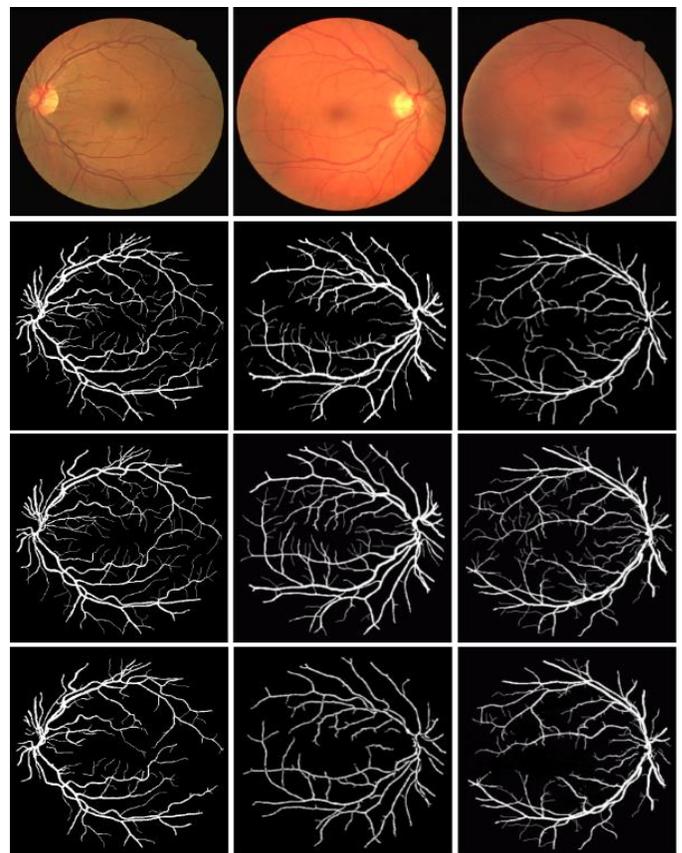

Fig. 11. The Output Segmentation Results in the DRVIE Dataset: The main Picture, The 1<sup>st</sup> Human Observer Picture, The 2<sup>nd</sup> Human Observer, and The Output Segmented Picture of the Proposed Morphological Algorithm.

Herein, the results obtained on the 2nd human observer have been considered for comparison purposes. It has been noted that most previously published approaches in the literature are reporting the values of Acc., Sen., and Spe. Thus, the overall average of these three metrics along with the PPV and NPV values have been computed with GT images (2nd human observer) and listed in Table II. Although, Li and his team, [22], Jin, [23], Hassan, [24], Dasgupta and Singh [26], Tamim, [30], and Yang, [28] have achieved a higher Spe. and NPV value compared with the proposed morphological filtering algorithm, they achieved inferior results on the other metrics.

D. 4.4 Result of HRF Dataset

The execution of the selected vessels segmentation algorithm has been assessed using HRF dataset using the same parameters configuration described in Section II.2. Initially, the adopted five evaluation metrics have been calculated to the selected vessel shrink algorithms utilizing the GT pictures provided in the HRF dataset, as shown in Table III. It has been noted that a comparable performance has been achieved with the proposed morphological filtering where a PPV of 96.88% and NPV of 100% have been obtained using the proposed morphological filtering algorithm. An example of the output segmentation results for the HRF dataset group is presented in Fig. 12.

The execution of the selected blood vessel segmentation algorithms has also been compared with the modern approaches to the HRF group, as given in Table IV. It has been observed that some existing approaches have achieved slightly higher segmentation accuracy compared with the proposed algorithms. For instance, Kishorea and Ananthamoorthy [29] have reached an Acc. of 99.6% compared to an Acc. of 98.76% and 98.78 using the proposed morphological filtering algorithm. However, the work presented in [32] has obtained inferior results in terms of other

evaluation metrics, for instance, Sensitivity, Specificity, positive prediction value, and negative predictive value which were compared with the proposed morphological filtering algorithm. On the other hand, Chalakkal et al. [35] have achieved a slightly better Spe. value of 100% compared with a Spe. value of 99.17%, 99.35%, and 99.78%, using the morphological filtering algorithm, respectively. However, they got inferior results on the other evaluation metric (e.g., Acc. and Sen.). Finally, one can see the best Sen. value of 98.87%, 99.12%, and 99.89% has been obtained using the morphological filtering algorithm, respectively, the outcome results compared with the modern approaches to HRF dataset.

E. 4.5. Clinical Feature Evaluation

In this section, a medical valuation process was conducted to accurately evaluate the efficiency in addition to the reliability of the proposed algorithms in terms of extracting helpful medical features. These clinical features include the tortuosity, length, density, and thickness of the blood vessel, which are efficiently used to detect several ophthalmological diseases. In the conducted experiments, the automated estimations of the four clinical features were calculated by utilizing the definition of the clinical feature on GT pictures in the adopted datasets.

Initially, the automated estimation of the clinical features from the DRIVE dataset using the 1st human observer was computed by the proposed algorithms and directly compared with the reference values generated from the GT images of the 1st human observer. The overall average (AV.), Standard Deviation (STD), Maximum (Max), and Minimum (Min) of each clinical feature on manual in addition to automated generated pictures. Moreover, (Diff) represents the Difference and (Diff %) represents the percentage difference between both of them which are presented in Table V. The overall average of (Diff%) between the manual shrinkage method and automated using the proposed morphological filtering algorithm was less than 19%, 16.5%, 10%, and 18% for the tortuosity, thickness, length, and density, respectively.

TABLE V. EXECUTION COMPARISON WAS CONDUCTED BETWEEN THE MANUAL SHRINKAGE METHOD AND AUTOMATED ESTIMATIONS OF FOUR CLINICAL FEATURES UTILIZING THE 1ST HUMAN OBSERVER OF DRIVE DATASET

Using the 1st human observer of DRIVE dataset, Pearson correlation plots were also adopted to further confirm the clinical reliability and usefulness of the proposed blood vessel segmentation algorithms as effective tools to provide a precise and automated estimation of the vessel's clinical features. As shown in Fig. 13, the proposed morphological filtering algorithm has managed to achieve (r) representing Pearson's correlation and (p) representing coefficient of: ( $r = 0.86$ ,  $p < 0.0001$ ) for vessel tortuosity, ( $r = 0.86$ ,  $p < 0.0001$ ) for vessel thickness, ( $r = 0.79$ ,  $p < 0.0001$ ) for vessel length, and ( $r = 0.91$ ,  $p < 0.0001$ ) for vessel density.

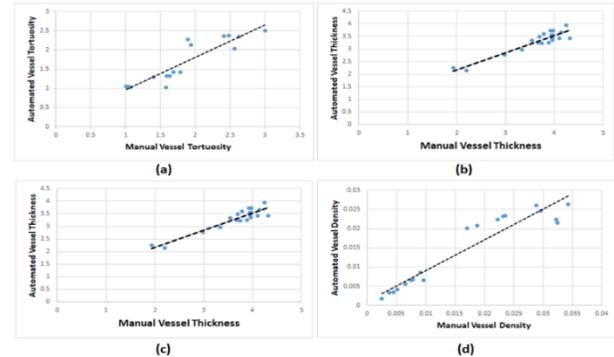

Fig. 13. Correlation Plots between Manual using the 1st Human Observer and Automated Clinical Estimations for the DRIVE Dataset using the Proposed Morphological Filtering Algorithm: (a) Tortuosity, (b) Thickness, (c) Length, and (d) Density. The Same Clinical Evaluation was Carried Out to Get the Automated Estimation of the Clinical Features from the DRIVE Dataset using the 2nd Human Observer.

Fig. 14 and Table VI presents the selected morphological filtering has managed to achieve (R) and (P) with the scale of : ( $r = 0.94$ ,  $p < 0.0001$ ) for vessel tortuosity, ( $r = 0.86$ ,  $p < 0.0001$ ) for vessel thickness, ( $r = 0.89$ ,  $p < 0.0001$ ) for vessel length, and ( $r = 0.76$ ,  $p < 0.0001$ ) for vessel density.

The evaluation process is an important task to validate the proposed algorithm and has been used in many studies, such as [29-32]. Further evaluation was performed on HRF Dataset which contains 40 GT images to assess the performance of the selected blood vessel shrinking algorithms. As shown in Table VII, the overall Min, AV, Max, and STD of every clinical feature for the automated and manual pictures were computed along with the Diff and Diff % between them. The average Diff% between manual and automated estimations calculated

using the proposed morphological filtering algorithm was 4.485% v 2.560%, 12.584% v 12.59%, 3.632% v 2.484%, and 10.087% v 5.529% for the tortuosity, thickness, length, and density, respectively. Correlation plots between manual and automated clinical estimations for the HRF dataset using the proposed morphological filtering algorithm are presented in Fig. 15.

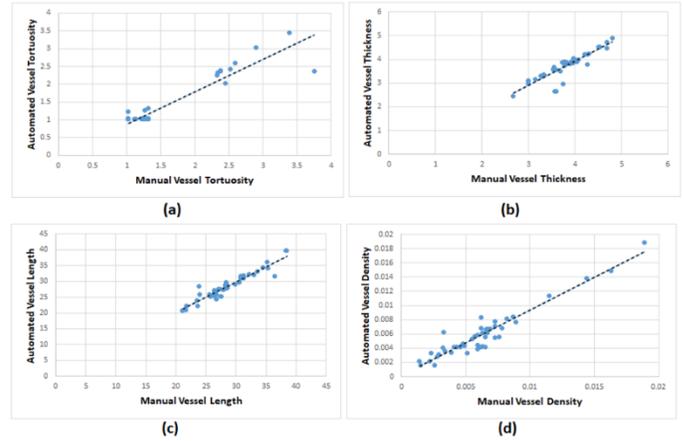

Fig. 15. Correlation Plots between Manual and Automated Clinical Estimations for the HRF Dataset using the Proposed Morphological Filtering Algorithm: (a) Tortuosity, (b) Thickness, (c) Length, and (d) Density.

## V. CONCLUSION

In this study, a precise, quick, and fully-automatic blood vessel shrinking in addition to the clinical feature measuring system for retinal fundus images is presented. The proposed morphology has two main steps: separating the blood vessels and pulling out the clinical features. In the blood vessels segmentation stage, a fully-automated segmentation algorithm was proposed and named as a morphological filtering algorithm to classify the blood receptacles in the retinal internal pictures. The algorithm has its own image enhancement procedure which is addressed by pre-processing stage in order to figure out the problems of blurring, variation levels of the light, and poor contrast of the retinal internal picture, plus to promote the early diagnosis of several eye pathologies. Several exhaustive experiments were purely conducted to evaluate the efficacy of the developed fully-automated shrinking algorithm in classified retinal blood receptacles using the DRIVE and HRF datasets of exceedingly demanding fundus images. Initially, the accuracy of the created algorithm was tested based on its ability to accurately recognize retinal blood receptacles. Five quantitative performance measures were computed to validate the efficacy of the selected algorithm, including the accuracy, sensitivity, specificity, positive predictive value, and negative predictive value of 98.78%, 98.32%, 97.23%, 90.22% and 95.56%. According to the HRF dataset results are based on five quantitative performance measures 98.76%, 98.87%, 99.17%, 96.88%, and 100% respectively. Then, the efficiency and reliability of the proposed algorithm in terms of extracting useful and helpful clinical features were also evaluated by conducting a set of extensive experiments. Statistically notable correlations between the manual and automated estimations of the adopted four clinical features have been obtained using the proposed algorithm on both datasets (DRIVE and HRF).

# Detection of Cyber-Physical Attacks using Physical Model with Nonparametric EWMA Detector

Joko Supriyadi, Jazi Eko Istiyanto, Agfianto Eko Putra

Department of Computer Science and Electronics, Universitas Gadjah Mada, Yogyakarta, Indonesia

**Abstract**—Industrial Control System (ICS) can suffer of cyber-physical attacks resulting in accident, damage, or financial loss. The attacks can be detected in both in physical space or cyberspace of the ICS. The detection in physical space can be based on physical models of the system. To model the physical system this study uses a data-driven modeling approach as an alternative of the analytic one. This study models the system using the dynamic mode decomposition method with control (DMDc) assuming a full state measurement. The attack detector used in some researches with predictive physical models is the cumulative sum (CUSUM), which only applies to normally distribute residual data. To detect any cyber-physical attack, this research uses a nonparametric exponentially weighted moving average (EWMA) detector. This study uses a data set from a testbed of Secure Water Treatment (SWaT). The approach used in this study was successful in detecting 8 out of 10 attacks on the first SWaT subsystem. This study demonstrates that DMDc used in this study results a better goodness of fit and the nonparametric EWMA can be used as an alternative as detector when residual data do not follow a normal distribution.

**Keywords**—Industrial control systems; cyber-physical attacks; physical model; dynamic mode decomposition method with control (DMDc); nonparametric exponentially weighted moving average (EWMA)

## I. INTRODUCTION

Industrial Control System (ICS) is automation system used to control and monitor industrial functionality. It can be found in the industrial sectors and critical infrastructures, such as nuclear and thermal plants, water treatment facilities, power generation, heavy industries, and distribution systems [1].

ICS has four levels to conduct its functionalities [2]. On the field level, it has sensors and actuators. On the control level, it has a programmable logic controller (PLC). It has a human-machine interface (HMI), and on the enterprise level, it has an information technology (IT) system. The second and third levels with their cyber components conduct computation to control physical space. With this trait, ICS is an example of cyber-physical systems.

As a cyber-physical system, ICS carries the risk of cyberattacks aimed to disrupt the physical processes. A cyber-physical attack is an attack via cyberspace that targets the physical system of the ICS. Examples of such attacks are Stuxnet which attacked Iran's uranium enrichment facilities, and Black Energy 3 which struck several power transmission substations in Ukraine [3]. These attacks can have some adverse effects on factory safety or financial loss.

To detect cyber-physical attacks on ICS, researchers develop intrusion detection systems (IDS). There are three IDS categories for ICS [4], protocol analysis-based, traffic mining-based, and control process analysis-based. The former two categories are conducted in cyberspace. The third category is conducted on physical space and includes process data analysis-based, control command analysis-based, and physical model-based techniques [4].

This study is in the field of detection in physical space using a physical model, i.e. the third category in [4]. The work in [5] identify that most of researches in this field do not use input-output approach in modelling physical behavior and most use the simulation data. This research proposes to use dynamic mode decomposition method with control (DMDc) as a system identification with input-output method. It will be applied to a real data from a testbed not at simulation data.

To detect the anomalies, some researches use cumulative sum (CUSUM) that has an assumption that the distribution is normal. In this research we propose to use nonparametric exponentially weighted moving average to cover all distribution condition.

The significant contributions of this work are:

- We anticipate a full state measurement condition of physical systems. To model it, we use DMDc as a kind of a system identification approach.
- We use EWMA detector as an alternative for CUSUM detector to cover a non-normal distribution of residual.

The rest of the paper is organized as follows. In section 2 related works are presented. It posits our research in the field of detection of cyber-physical in physical space of ICS. Section 3 presents the research methods of this study. It covers the DMDc method and EWMA detector. In section 4 the results of the experiment are presented and discussed.

## II. RELATED WORKS

According to Urbina *et al.* [5], there are two ways to model physical systems. The first is to develop a physical equation model that connects all the physical parameters to determine the system's dynamics. The second is to create a model based on observation through a technique known as system identification. Most researchers use the first approach, and only a few uses the second.

Researchers in [16] use input-output model developed from physical equation for a water treatment system. Their research leverages connectivity of two subsystems to detect

any cyber physical attack to upstream with behavior of the downstream of the system. Their experiment is launched directly to a real system and their procedure was conducted at the real time.

Our study is focused on the use of system identification and not model the system using physical equation. There are two options in system identification, output only model and input-output model. Researchers in [5] used both approaches to model a physical system. The system is a simulator of frequency control in the power grid. After comparing both models, researchers in [5] concludes that the input-output model has a potential in detection and motivates future researchers to use it to model physical systems. To detect any cyber-physical attacks, there is a need to model the physical model from measurement data in the form of input-output model.

Researchers in [6] used the system identification method to model a physical system with the input-output model. They used a method in a group of subspace models. They used EPANET, a software that can customize a water distribution system simulator as the physical system.

Other researchers [7] conduct modelling with subspace system identification with input-output model with CUSUM detector, bad data detector, and noiseprint. To detect the anomaly, they used CUSUM detector with false positive target around 5%.

Usually, the system identification approach used in [5,9] do not assume that the system being modeled is in full measurement. But nowadays, with the affordability of measurement cost, the system status can be measured in full. Unlike the studies, our study proposes using dynamic mode decomposition with control (DMDc) to model the physical system, assuming a complete system measurement.

The author in [5] used simulations as physical systems to be modeled. But there is a problem with simulations; although the physical model is detailed but the simulation is not in a real situation. Unlike theirs, our study uses a data set from Secure Water Treatment (SWaT), a physical system testbed that mimics a real water treatment system.

Some researchers use the same data set to propose their method to detect cyber-physical attacks. One of them [8] uses a graphical model-based approach that will be compared with our work.

Based on the physical model, cyber-physical attacks can be detected by monitoring an anomaly in the systems. The monitoring systems get inputs from sensors and command controls and then identify any anomalies [6]. Some researchers use CUSUM detector or bad data detector [5, 6, 7, 9, 16]. But the use of both as detector applies only to data with a normal distribution. Because not all conditions meet the normal distribution, our study proposes to use a nonparametric exponentially weighted moving average (EWMA) detector that does not depend on data distribution.

### III. RESEARCH METHOD

In this section, we will explain the methods we used in our research. It includes details of DMDc, nonparametric EWMA, and a brief explanation of steps to apply the methods.

#### A. Physical System Modelling

A discrete state-space model will be used to represent the ICS control system. This model is used because it is generally more compatible with discrete digital controls. For discrete-time systems, the time may be referred as an integer index  $k=0, 1, 2, \dots$ . In the system, the state as a set of variables from the system can be estimated based on the previous state. Given a linear system has several states, inputs, and output, respectively. The equation of the system can be modeled as shown in (1) and (2).

$$x_{k+1}=Ax_k +Bu_k \quad (1)$$

$$y_{k+1}=Cx_k \quad (2)$$

In (1) and (2),  $x_k \in \mathbb{R}^n$  is the state of the system at time  $k$ ,  $u_k \in \mathbb{R}^l$  is the input, and  $y_k \in \mathbb{R}^q$  is the output with  $n$ ,  $l$ , and  $q$  as number of states, inputs, and outputs respectively. Meanwhile,  $A$  is a dynamic matrix,  $B$  is the control matrix, and  $C$  is the discrete-time sensor matrix. State vector  $x$  from the system can be estimated from sensor measurement  $y$ . There is a condition called full state measurement if all components of the state vector can be measured.

The system can be modeled with a system identification approach, namely by using measurement data to obtain the desired model. In this study, the dynamic mode decomposition (DMD) method [10] is used, assuming that measurements are made of all states of the system (full-state measurement).

Initially, DMD was developed for systems that do not have input, for example, control input. By taking into account control input, DMD method developed to be DMD with control (DMDc). Both DMD and DMDc methods initially were developed for large dimension systems with a dimension reduction. The next exposition will explain DMDc method based on [10] but without dimension reduction steps.

DMDc analyses the relationship between measurement vectors at  $k+1$  ( $x_{k+1}$ ) with the measurement at  $k$  ( $x_k$ ) and control input at  $k$  ( $u_{k+1}$ ). The three data are assumed to be approximately by linear operators  $A$  and  $B$  relates as shown in (3).

$$x_{k+1} \approx Ax_k +Bu_k \quad (3)$$

where  $x_k \in \mathbb{R}^n$ ,  $u_k \in \mathbb{R}^l$ ,  $A \in \mathbb{R}^{n \times n}$ , and  $B \in \mathbb{R}^{n \times l}$  with  $n$  and  $l$  are number of sensors and actuators respectively. DMDc tries to find the solution for operators  $A$  and  $B$ .

If there are  $m$  measurements for  $n$  sensors in vector  $x$  we can create a matrix  $X$  with dimension  $n \times m$ ,  $X \in \mathbb{R}^{n \times m}$ . We can create matrix  $Y$  and  $Z$  from matrix  $X$ , where  $Y$  is matrix  $X$  without its first column, while  $Z$  is matrix  $X$  without its last column. The relationship of matrix  $Y$  and  $Z$  with matrix  $A$  can be described with (4).

$$Y \approx AZ \quad (4)$$

Accordingly, from control vector  $u$ , we can create a matrix  $\Gamma \in \mathbb{R}^{l \times (m-1)}$  contains the  $l^{st}$  data to  $m-1^{th}$  data for  $l$  actuators. So (4) can be rewritten to be (5).

$$Y \approx AZ + B\Gamma \quad (5)$$

A concatenation method can be used to assign matrix  $G = [A \ B]$  and matrix  $\Omega = \begin{bmatrix} Z \\ \Gamma \end{bmatrix}$  to solve the (5). Thus, (5) changes to be (6) as follows.

$$Y \approx G\Omega \quad (6)$$

Then  $Y$  and  $\Omega$  is stated as eigen decomposition of the matrix  $G$  as shown in (7).

$$G \approx Y \Omega^\dagger \quad (7)$$

Where  $\dagger$  means Moore-Penrose pseudoinverse. The accurate and efficient method to find the pseudoinverse is singular value decomposition (SVD), as shown in (8).

$$\Omega = U\Sigma V^* \quad (8)$$

where  $U \in \mathbb{R}^{n \times n}$ ,  $\Sigma \in \mathbb{R}^{(n \times m) - 1}$  and  $V^* \in \mathbb{R}^{(n \times m) - 1}$ .

Using the SVD of  $Y$ , the matrix  $G$  can be approximated with (9).

$$G \approx \bar{G} = YV\Sigma^{-1}U^* \quad (9)$$

where  $\bar{G}$  is an approximation of the matrix  $G$ . From the matrix  $\bar{G}$ , the approximation of matrix  $A$  and  $B$  can be obtained by breaking operator  $U$  into two separate components given by (10)

$$[A, B] \approx [\bar{A}, \bar{B}] = [YV\Sigma^{-1}U_1^*, YV\Sigma^{-1}U_2^*] \quad (10)$$

where  $U_1 \in \mathbb{R}^{n \times n}$ ,  $U_2 \in \mathbb{R}^{l \times n}$ , and  $[U^*] = [U_1^* \ U_2^*]$ . From (10), the dynamic systems can be constructed to be (11) as follows.

$$x_{k+1} = \bar{A}x_k + \bar{B}u_k \quad (11)$$

Equation (11) is the model we use to mimic the behavior of the physical system.

### B. Residual and Non Parametric EWMA

Cyber-physical attacks on industrial control systems have a potential to change sensor readings behavior. Therefore, the difference between the estimates obtained from the model and the sensor readings can be monitored. The behavior of to the difference can be used to indicate if any attack to the system. The difference is called the residual  $r_k$ , namely the difference between measurement at  $k$ ,  $x_k$ , and the estimation  $\hat{x}_k$  as shown in (12).

$$r_k = x_k - \hat{x}_k \quad (12)$$

The value of estimation  $\hat{x}_k$  is determined by (11); thus, (12) can be expressed as (13) as follows.

$$r_k = x_k - (Ax_{k-1} + Bu_{k-1}) \quad (13)$$

The sensors of the system can be more than one, so with  $i = \{1, \dots, n\}$ ,  $r_{k,i}$  is residual of sensor  $i$  at measurement  $k$ . Murguia *et al.* [9] used individual sensor residual to monitor cyber-physical attacks by making them input for CUSUM

detector and bad data detector. The two detectors implicitly assume that the residual follows a normal distribution.

In this study we use a nonparametric Exponentially Weighted Moving Average (EWMA) as the residual does not follow a normal distribution. This approach is generally used to statistically monitor a product's quality or process [11, 12]. The next description will explain the approach as describe in [12].

Given  $X_k$  is the individual measurement from the continuously monitored distribution with median  $\theta$ ,  $SN$  as statistic sign can be provided by (14).

$$SN_k = \text{sign}(X_k - \theta) \quad (14)$$

where:

$$\text{sign}(x) = \begin{cases} 1 & \text{if } x > 0 \\ 0 & \text{if } x = 0 \\ -1 & \text{if } x < 0 \end{cases} \quad (15)$$

The plotting statistic ( $Z_k$ ) of the nonparametric EWMA as a sequentially accumulating the sign statistic  $SN_1, SN_2, SN_3, \dots$  defined by equation (16).

$$Z_k = \lambda SN_k + (1 - \lambda) Z_{k-1} \quad (16)$$

where  $\lambda$  is a weighting that has a value from 0 to 1, and  $Z_0 = 0$ .

Two controls can be used for the value of  $Z$ , upper control limit (UCL) and lower control limit (LCL), that can reach its steady-state after a long time. They can be determined by using (17).

$$\begin{aligned} UCL &= L \sqrt{\frac{\lambda}{2 - \lambda}} \\ CL &= 0 \\ LCL &= -L \sqrt{\frac{\lambda}{2 - \lambda}} \end{aligned} \quad (17)$$

In (17) CL is the central line valued as 0. The values can be used to determine if the system is under control or not.

The choosing of parameters  $L$  and  $\lambda$  is conducted to get the targeted average run length (ARL), namely the number of average measurements before the detector detects an anomaly from a normal condition. Graham [11] has calculated the value of pair parameter  $L$  and  $\lambda$  for nonparametric EWMA with the Markov method until  $ARL = 500$ .

We need to calculate the alarming rate that gives us the number of  $Z_k$  values calculated by (16) exceed UCL or LCL for a while. Then we set  $Z_k = 0$  if  $Z_{k-1} \geq UCL$  or  $Z_{k-1} \leq LCL$ .

### C. Detection Parameter

We assume there is difference behavior between an attack condition with the normal one. In this research we use comparison of false alarm rate (FAR) or false positive rate (FPR) value between both conditions.

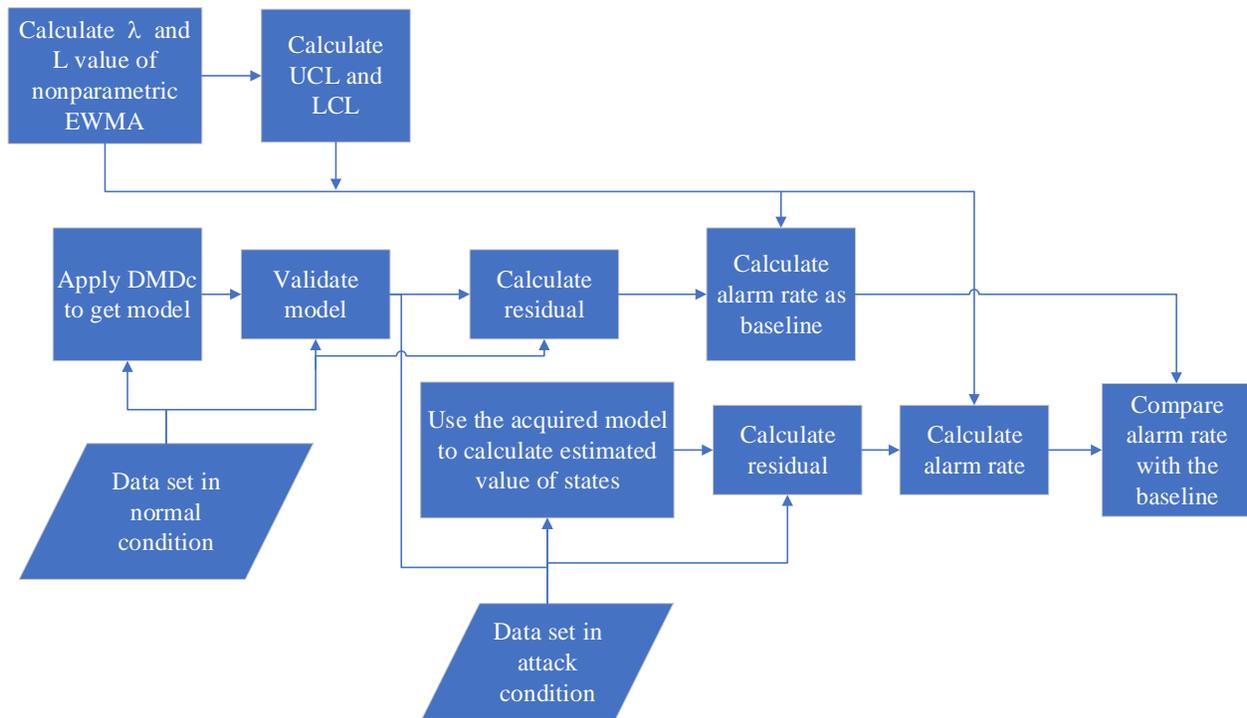

Fig. 1. Flow Chart of Detection System Set up.

The value of FPR is targeted in normal condition and considered as alarm rate of the system or components. Using the value as the baseline we judge a condition is under attack if FPR of a component is significantly more than its normal condition. With its procedure, security operator monitoring the system can detect any potential attack if the alarm rises significantly than the baseline.

#### D. Research Steps

Before using DMDc to model the physical system, we calculate  $L$  and  $\lambda$  values for specified ARL, for example,  $ARL=500$  if we expect to get one false alarm per 500 measurements. The values were then used to calculate the value of UCL and LCL.

Parallel with previous steps; the physical system is modeled using DMDc method with the input of the normal condition data. Then the acquired model is validated by calculating its goodness of fit. If the value is satisfying, we calculate residuals as differences between model estimation and measurement. Based on the value of the residual,  $L$ ,  $\lambda$ , UCL, and LCL, we calculate the value of  $Z_k$ . The alarm rate baseline is calculated based on the number of  $Z_k$  values that exceed UCL or LCL.

The next step is to use the model to detect cyber-physical attacks. The following procedure will be applied for every attack separately. With the acquired model from the previous steps, residuals' value is obtained by applying DMDc method on the data set in attack condition. Like previous steps in normal conditions, the value of alarm rate can be obtained using a parametric EWMA method.

To judge if the concerned attack is detected, we compare the alarm rate baseline's value of the alarming rate. We believe

that alarm is detected if the alarming rate is ten or more from the baseline. Fig. 1 shows the flowchart of the research steps.

#### IV. RESULT AND DISCUSSION

In this section, we will discuss our research results based on steps explain in the previous section.

##### A. Physical Modelling

This study uses the data set collected from a testbed that simulates Secure Water Treatment (SWaT) [13,14]. SWaT is a testbed in a full-scale replica water treatment facility consisting of several subsystem stages. A data set containing network data and process data is generated [13] recorded every second. The data set consists of two parts:

- 1) Data set of the system in a normal state without attack,
- 2) The data set of the system under attack condition.

The SWaT system has six subsystems, as described in [13], from subsystem P1 to P6. For this research, we use the first subsystem, P1 only, namely the subsystem that takes raw water and stores it in a reservoir. This subsystem has several main components [13], namely an MV-101 valve that drains water from the source into the storage tank T.101, whose water level is measured by the sensor LIT-101. Meanwhile, a flow meter FIT-101 is used to measure the source's flow rate into the tank. A pump P-101 is used to drain water from the reservoir to the next subsystem. Also, this subsystem has a pump P-102 as a backup for the pump P-101. Fig. 2 [13] shows the components and piping of the subsystem P-1. Thus, there are two sensors and three actuators in subsystem P1 as shown in Table I.

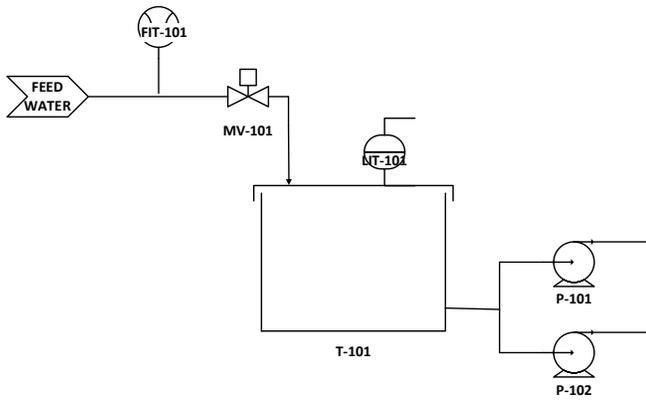

Fig. 2. Subsystem P1 of SWaT [13].

TABLE I. COMPONENTS OF THE SUBSYSTEM P1

Component	Type	Units
Flow rate FIT-101	Sensor	m <sup>3</sup> /h
Level meter LIT-101	Sensor	mm
Valve MV-101	Actuator	On/off
Pump P-101	Actuator	On/off
Pump P-102	Actuator	On/off

We use DMDc to model the subsystem P1 in the form of the discrete linear model provided by (11). From (11), the vector  $x$  contains subsystem P1 as a dynamic variable following the dynamics of water supply and demand for raw water. Thus, the vector  $x$  includes the measurement of the LIT-101 sensor. Meanwhile, the vector  $u$  in (11) contains the input into the subsystem. Among these inputs is the water supply, whose debit is measured using the FIT-101 sensor. Another information model for subsystem P1 is the pump P-101 pump and its pump P-102 as a backup.

The two pumps are modeled because the two pumps can be turned on alternately. The MV-101 valve is not modeled as it is redundant to the FIT-101. When the MV-101 valve is turned on, water flows with the discharge measured by the FIT-101 sensor. Thus, in (11), subsystem P1 can be modeled in its discrete form with (18).

$$[LIT - 101_{k+1}] = \bar{A} [LIT - 101_k] + \bar{B} \begin{bmatrix} FIT - 101_k \\ P - 101_k \\ P - 102_k \end{bmatrix} \quad (18)$$

In this subsystem modeling, matrix  $\bar{A}$  and  $\bar{B}$  are matrices that will be sought with the DMDc method by using a dataset in normal conditions without attack as input. Data set for normal conditions without attack contains measurement results of sensors and actuator conditions that are monitored every second. There are 494999 pieces of datum for each sensor and actuator. The first 3.5 hours of data are not used to let the system achieves a steady-state condition. The remainder is divided into two, 70% data for modeling and 30% data for testing.

Start from (5), the matrix  $Y$  is obtained as sensor measurement data from the 2<sup>nd</sup> to  $m^{th}$  measurement, the matrix

$Z$  the sensor measurement data from the 1<sup>st</sup> to  $m-1^{th}$  measurement, and the matrix  $\Gamma$  as the actuator data from the 1<sup>st</sup> to  $m-1^{th}$  measurement. Furthermore, by following the procedure as described in (6) to (10), the values of a matrix  $\bar{A}$  and  $\bar{B}$  in (18) is obtained as follows.

$$\bar{A} = [1.000]$$

$$\bar{B} = [0.195 \quad -0.461 \quad 0.392]$$

With the values of the matrix  $\bar{A}$  and  $\bar{B}$ , the value of the inflow of water from the source and the water level at  $k + 1$  can be estimated based on the measurement value at time  $k$ . The comparison of the level value of water in the tank measured by the LIT-101 sensor with the model's estimation results is shown in Fig. 3.

The estimation results are then compared with the actual measurement value to determine the model's level of suitability (goodness of fit) with the measurement results. Based on calculations using data for testing (30% of the overall data), the goodness of fit of the sensor LIT-101 is 99.7%. The value of goodness of fit is better than result in [6] that use another method of system identification. They use simulation data from EPANET, software to simulate a water system. With their method they achieve goodness of fit of 70%.

The value of goodness of fit shows a good agreement between model and measurement. Since the data set to test the model is independent of the training data set, it can be concluded that the model is not overfitted to the training data.

Meanwhile, Fig. 4 shows the error fluctuation in the form of the difference between the measurement results and the model estimation results. The error fluctuation is calculated with (13) as a residual that will be used to monitor the anomalies of subsystem P1.

### B. Nonparametric EWMA

The residual as the difference between the estimation results from the model and the measurement at each time  $k$  resulted has a non-normal distribution. Therefore, the use of the CUSUM detector cannot be legitimized, and thus the nonparametric EWMA detector as described previously is used in this study.

The EWMA detector has a parameter  $\lambda$  and  $L$  as shown in (16) and (17). For this study we choose  $ARL_0=500$ . For this ARL value we choose a low value of  $\lambda$  ( $\lambda=0.01$ ) to get a smooth change of  $Z_k$  sequences. For this value  $\lambda$ , Graham [11] get value of  $L = 1.990$  as his calculation with Markov method.

With the value of  $L$  and  $\lambda$ , we calculate the control limits for UCL and LCL for a normal condition of their residual value of sensor LIT-101 with (17). The acquired values for UCL and LCL are 0.141067 and -0.141067 respectively.

With the acquired value of the parameters, the value of  $Z$  is sequentially calculated by (14). The value of  $Z_k$  fluctuates between the value of UCL and LCL as shown in Fig. 5. When it hits one of them the next value will be set to zero and the sequence starts again.

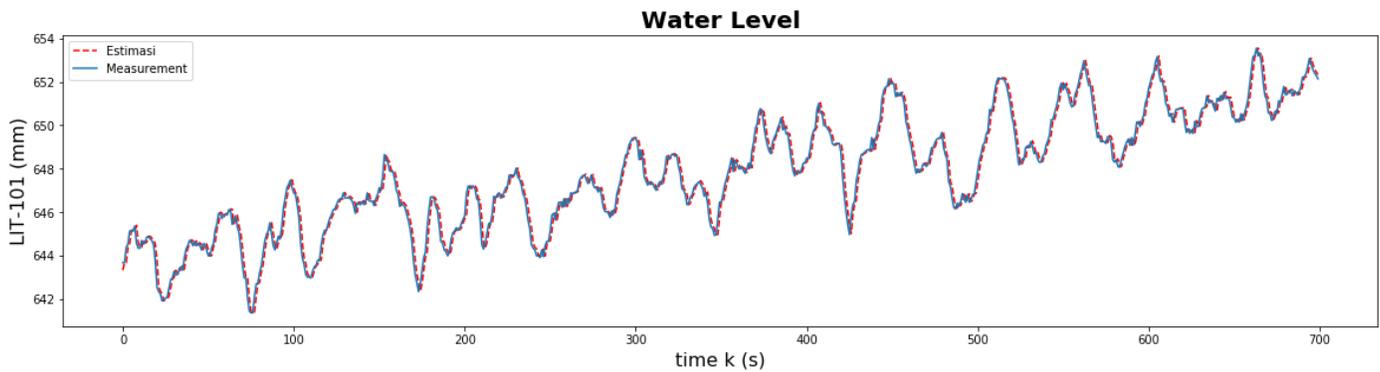

Fig. 3. The Dynamics of the Water Level from Measurement and Estimation.

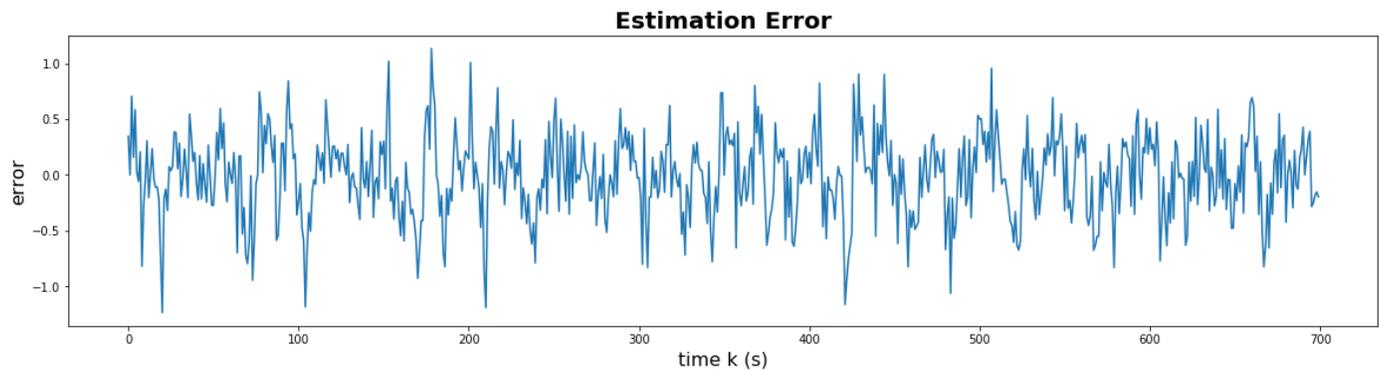

Fig. 4. Error Fluctuation of the Estimation of Water Level.

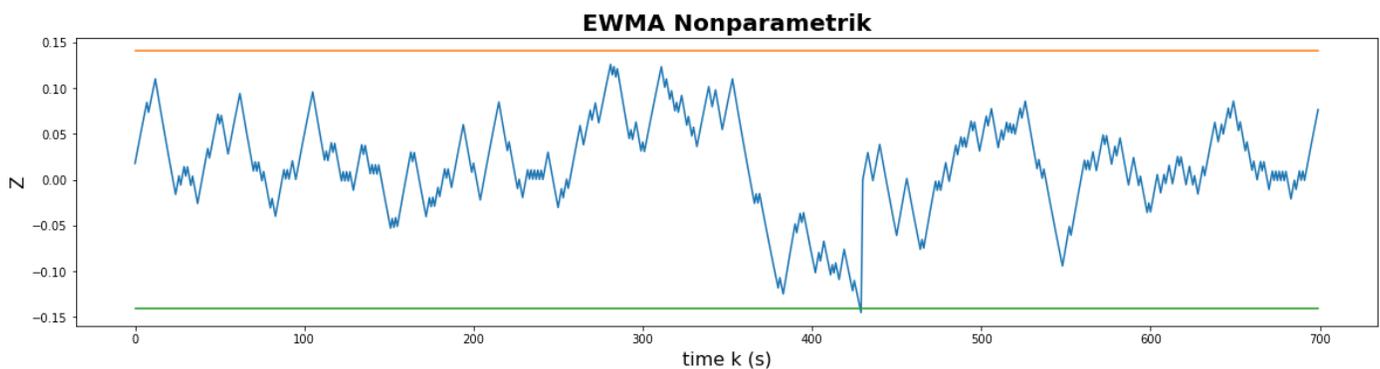

Fig. 5. The Fluctuation of Value Z with UCL and LCL as the Control.

The  $Z_k$  value passes UCL and LCL with a ratio of 1 in 489 data (alarm rate equals 0.00204). In other words, about 2.2% deviations from the ARL calculation theoretically using the Markov method of  $ARL_0=500$  as the target. From the perspective of detection, the ratio is an expected false alarm rate in a normal condition. We use the value of the ratio as the baseline where the alarm rate of attack conditions will be compared, as we will explain in the next subsection.

The benefit of using nonparametric EWMA than CUSUM as in [5, 6, 9] is there is no need to assume the distribution of residual  $r$  as normal. As shown in the next subsection, this approach can be used to detect the cyber-physical attack as other detector.

### C. Detection of Cyber-physical Attacks

To test the proposed detection design, we also use data set in [14] that contains sensors and actuators data from the SWAT under attack conditions. The attacks result in the data set use attack and attacker models developed by Adepu and Mathur [15]. The attacker model relates to the attacker's intention with the systems' components, properties, and performance.

The attack model captures the space of potential attacks aimed at achieving a specific set of goals. For example, an attack has a plan to make a tank overflow. The attack needs to consider some points of the system involved, for example, pumps or valves. A suitable procedure to launch the attack consists of identifying the tag in the programmable logic controller (PLC) that should be manipulated and a step to

compromise the link between PLC and supervisory control and data acquisition (SCADA) a step to conduct the manipulation of the tag.

There were 41 attack scenarios launched to the SWaT testbed, but only 36 attacks had physical impacts and were recorded in the data set. From the 36 attacks, there were 10 attacks involving the subsystem P1 in the data set as shown in Table II. All of the attack scenarios were launched to subsystem P1 only, but scenario 26 launched to subsystem P1 together with subsystem P3.

The system model and the nonparametric EWMA detector obtained from the previous section are used to detect cyber-physical attacks based on the data set [12]. The model is used to estimate the LIT-101 sensor reading value at time  $k + 1$  with the time  $k$ . The estimation result is compared with the sensor reading value, which produces a residual value  $r_k$ . Then the residual value is used to detect an attack with an indication if the  $Z_k$  value exceeds the UCL or LCL values.

The  $Z_k$  value is calculated using (16) and (17) for each attack as described in Table II. As an illustration, Fig. 6 show the behavior of  $Z_k$  when subsystem P1 is under attack number 2 condition. Differ from the normal condition as shown in Fig. 5 that show a random behavior, the value of  $Z_k$  in attack no 2 as shown in Fig. 6 is systematically pushed to hit its lower threshold LCL. The change of behavior is an indication that the system is not in normal condition and the cyber-physical attack is a probable cause. As explained in the previous subsection, the baseline of false alarm rate (FAR) or False Positive Rate (FPR) for sensor LIT-101 calculated in normal conditions based on the normal condition dataset is 0.0020 (0.2%). To judge if any attacks can be detected, we compare the alarming rate in any attack conditions with the baseline.

TABLE II. DESCRIPTION OF ATTACKS SCENARIO

No.	Attack Number	Description of the attack	Duration (s)
1	1	Open MV-101	940
2	2	Turn on P-102	1407
3	3	Increase LIT-101 by 1 mm per second	383
4	21	Keep MV-101 on continuously; Value of LIT-101 set as 700 mm	701
5	26	P-101 is turned on continuously; a set value of LIT-301 as 801 mm	1445
6	30	Turn P-101 on continuously; Turn MV-101 on continuously; Set value LIT 101 as 700 mmP-101	1171
7	33	Set LIT-101to above H	444
8	34	Turn P-101off	101
9	35	Turn P-101off; keep P-102 off	481
10	36	Set LIT-101 less than LL	474

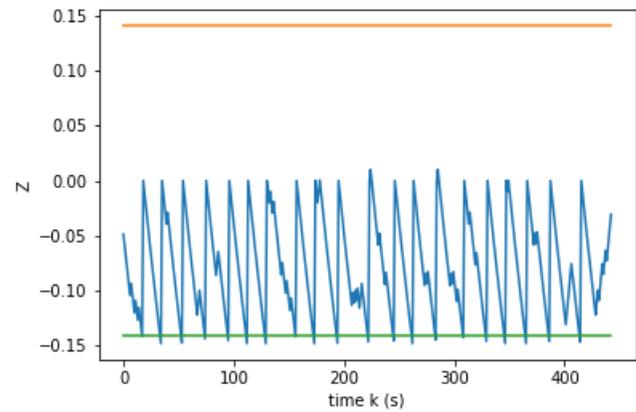

Fig. 6. The Fluctuation of Value  $Z_k$  when System is under Attack no.2 Condition.

TABLE III. ALARM RATE FOR ATTACKS INVOLVING SUBSYSTEM P1

No.	Attack Number	Alarm rate (compared to baseline)	Judgment	Detection in [8]
1	1	0.0021 (1.40)	Not detected	Detected
2	2	0.0452 (22.09)	Detected	Detected
3	3	0.0470 (22.99)	Detected	Not detected
4	21	0.0585 (28.62)	Detected	Detected
5	26	0.0505 (24.72)	Detected	Detected
6	30	0.0564 (27.58)	Detected	Detected
7	33	0.0495 (24.24)	Detected	Detected
8	34	0.0297 (14.53)	Detected	Detected
9	35	0.0 (0)	Not detected	Detected
10	36	0.0570 (27.89)	Detected	Detected

We choose if the alarm rate is more than 1 order (multiply by 10) compared to the baseline rate of 0.0020. The choice is based on consideration that person operate and monitor the security system can detect the anomaly in 1 order. Based on this procedure, 8 from 10 attacks can be detected, as shown in Table III. The alarm rates for detected attacks as shown in Table III are 14 to 28 times greater than the baseline of 0.0020.

The results show that our approach can detect all attacks involve sensors as targets (Scenario 3, 21, 26, 30, 33, and 36). This success can be understood because our approach monitors the value of water level. Thus, the discrepancy between sensor reading and model estimation can increase or decrease the  $Z$  value systematically.

The other four attacks (scenarios 1, 2, 34, 35) involve actuators only. It is just two (scenarios 2 and 34) of the four attacks that can be detected. Attack scenario 1 opens valve MV-101 when it should be close. The attack cannot be

detected because the level sensor will respond normally with raw water flow. The other three attacks involve one or both pumps. The three attacks cannot be interpreted easily because of a long normal condition pump P-102 as a backup was never turned on.

It is to be noted that the attacks duration is vary from around 1 to 3 times ARL as shown in Table I, except the attack no. 34 is only 100 seconds. Because of the random nature of the residual  $r$ , it can be understood that the alarm rate of attack no. 35 is zero. But for the other attacks that our set up can detect them their short durations does not affect the detectability.

As a matter of comparison, Table III contains the research results [8] that used the same SWaT data set but with a different approach. The research uses a novel graphical model-based approach for anomaly detection. From the table, it can be concluded that their system is better than ours to detect attacks on actuators. But their system cannot detect scenario three that ours can detect. The scenario can be under the radar of detection because it increases the reading of the sensor gradually. Based on the consideration our approach has a promising result to be leveraged to detect stealthy attacks.

## V. CONCLUSION

In this study, the physical modeling is successfully carried out using the DMDC method with a goodness of fit of 99.7%. It shows that the model has a good agreement with the measurement. The high value of goodness of fit gives the model a potential to be used to detect any anomaly caused by cyber-attack deviating the sensor measurement or actuator signal.

The difference between the model's predictions and the actual sensor measurement results is monitored with a nonparametric EWMA detector to detect anomalies resulting from cyber-physical attacks. From 10 attacks conducted to the subsystem, 8 of them can be detected using method used in this research. Compared with the baseline in normal condition, the alarm rates of detected attacks are 14 to 28 times greater. It shows that this method is successful in detecting most attacks, especially on sensors.

As observed in [5] there is a lack of use of input-output models in security field. Besides that, most of researches in security using physical-model use physical equation and not many researches use data-driven method. The other lack is use of real data or data drawn from testbeds, and mostly use simulation data. Our research fills the lacks by using DMDC as input-output model and it is a kind of system identification using data to model the physical behavior of system. Our research also uses the data collected from a test bed.

When we start our research, we plan to use CUSUM as the detector to detect anomalies as proposed in [5, 6, 9]. But we find that in our research the distribution of residual is not normal. Then the nonparametric EWMA is used to detect the anomalies. This research show that DMDC as a system identification combined with EWMA as detector can be used to detect cyber-physical attacks.

In future, this research can be continued by utilizing the interrelationships between subsystems. In this case, attacks on the upstream subsystems may be detected by the downstream subsystems. With the approach the detection probability may be increased because of the double detection, in the subsystem itself and in its downstream. Differ from [16] we use system identification method with DMDC instead of physical equation.

**Abstract**—The Iris recognition technique is currently the most efficient biometric identification system and is a common system on the practical front. Though most of the commercial systems use the patented Daugman's algorithm, which mainly uses wavelet-based features, research is still active in identifying novel features that can provide personal identification. Here the first novel proposal of using ordinal pattern measure based on nonlinear time series analysis is put forth to characterize the unique pattern of the iris of individuals and thereby perform personal identification. Dispersion Entropy is a nonlinear time-series analysis method highly efficient in the characterization of the complexity of any data series with proven effectiveness in the characterization of model system dynamics as well as real-world data series. The results show that dispersion entropy can be used to identify iris images of specific individuals. The efficiency of this method is evaluated by computing correlation and RMSE between dispersion entropy values of normalized iris image rubber sheet data. The experimental results on the popular IRIS database- CASIA v1- demonstrate that the proposed method can effectively perform differential identification of iris images from different individuals. The results specifically indicate that the density of information along the angular direction of iris images which falls along the rows of rubber sheet data. This can be efficiently utilized with the method or ordinal pattern characterization and proves to be having promising potential for being incorporated into biometrics personal identification systems.

**Keywords**—Dispersion entropy; iris recognition; rubber-sheet data; ordinal patterns; correlation

## I. INTRODUCTION

In the past few decades, Iris recognition system has gained the status of the most reliable biometric authentication system. The highly unique pattern for every individual iris has a wealth of texture detail which makes this system extremely outstanding compared to other physiological biometric features like face, palm print, and even fingerprint features. Iris pattern-based Personal Identification system gained popularity because of this texture patterns long-term stability with respect to aging and other physiological changes. Iris is defined as the colored muscular diaphragm located behind the cornea of the eye. It surrounds the pupil sharing a common center with it and controls its size to adjust the amount of light entering through it. It has been scientifically and genetically proven that the microstructure of the iris region of an individual is extremely unique and distinct with respect to

characteristics like shape, size, and shading, thereby sufficient enough to establish a person's identity [1].

Texture analysis in two-dimensional images is generally carried out using methods like Gray Level Co-occurrence matrix and texture entropy [2]. Recently, new approaches based on the quantification of image irregularity using nonlinear measures have proven to be efficient in the characterization of fine details of two-dimensional images [3]. Successful applications of such methods in the characterization and analysis of small fine textural details of images in various technological as well as biomedical fields have been reported in the literature [4]. Efficient characterization of the iris patterns is an ever-demanding research topic due to the fact that its success and failure will lead to extremely sensitive outcomes related to national and international security and related contexts, as well as the reliability of general commercial applications. An application of an efficient nonlinear method of dispersion entropy for iris image characterization and personal identification is proposed in this work. Nonlinear methods-based image processing is a very recent proposal, and only a few reports are available in the literature. These proposals are mainly based on two-dimensional extensions of measures like sample entropy [5], distribution entropy [6], and dispersion entropy [7]. Among these measures, dispersion entropy is focused on overcoming the drawbacks of all its predecessors. It is proven to be extremely efficient in the characterization of one-dimensional as well as multi-dimensional signals, including images [8][9].

Complexity analysis of the dynamical system, as well as real-world systems and signals using the nonlinear time-series analysis method, has gained extreme popularity among the research community and has successfully marked its own place in potential real-world application [10]. The entropy concept can be used to measure the complexity of signals and, thereby, their related system. High complexity is represented using high entropy values, whereas lower entropy values indicate more regularity of a time series [11]. Earlier methods like approximate entropy, sample entropy, permutation entropy, and distribution entropy were reported to be successful in the characterization of the complexity of short time series from various real-world systems [12]. Later research on these measures revealed shortcomings of these measures related to amplitude and noise ratios. Dispersion entropy was later proposed as a fast and powerful approach,

\*Corresponding Author.

together with successfully overcoming the drawbacks of the above-mentioned measures. The two-dimensional extension of all these measures, including dispersion entropy, has been reported for the characterization of image texture. When applied to image texture characterization, a high value of entropy indicates that the pixel values have high variance, whereas a low entropy value means the pixel values are relatively uniform. Among these measures, dispersion entropy is proven to be a fast and efficient method for the characterization of both small and large-scale image texture [13].

Considering the efficiency of dispersion entropy of both one and two-dimensional in the characterization of fine-scale irregularities, among all such analysis measures, it is proposed to apply this measure for the characterization of the texture feature of the iris image. Also, the peculiarity in the spread of patterns along the radial directions in iris images is of special concern while applying any measures for iris texture characterization. To the best of the current knowledge, this is the first proposal of applying nonlinear measures of time series analysis for the purpose of feature extraction for iris recognition application since the proposal of using fractal dimension for iris classification. However, it is noteworthy that fractal measures are based on conventional nonlinear time-series analysis methods, which are sensitive to noise and short data length [14].

Taking into consideration this peculiarity of iris images, it is proposed the use of one-dimensional dispersion entropy along the radial as well as angular directions to extract the wealth of information embedded in these images [15]. Further, the efficiency of the proposed method in personal identification is evaluated on the freely available dataset CASIA v1 [16].

The texture information contained in the iris images can be efficiently extracted by using the most appropriate methodology of image characterization. The wealth of information contained in iris texture can be efficiently extracted in the form of entropy values calculated based on dispersion entropy. In general, for image analysis, bi-dimensional extensions of the various ordinal pattern entropy measures are found to be useful, of which two-dimensional dispersion entropy (DispEn<sub>2D</sub>) is reported to be comparatively more efficient. However, in iris images, local details spread is distributed in the radial direction, which corresponds to the columns of the rubber sheet images [17]. Correspondingly the information density will be higher along the angular directions of the corresponding rows of the normalized rubber sheet images [18]. In the information theory field, image predictability and regularity are evaluated using the recently developed two-dimensional sample entropy (SampEn<sub>2D</sub>). Though it is efficient in its function, some limitations hold it back. The major limitations: 1) for small images, SampEn<sub>2D</sub> values are undefined; and 2) for real-world applications, SampEn<sub>2D</sub> is computationally expensive. These limitations can be overcome by two-dimensional dispersion entropy (DispEn<sub>2D</sub>) measure.

Section II of this paper elaborates the related works and the materials and methods and database descriptions

illustrated in Section III. It is then presented the novel methodology for iris recognition by using the computation of Non-linear texture feature extraction. Section IV gives an overview of the experimental analysis and the obtained results of this proposed methodology. The conclusion of this methodology is narrated in Section V.

## II. RELATED WORKS

Iris pattern-based personal identification was first proposed in 1987 by Flom and Safir, which further gained substantial research interest in the following years [19]. Further, in 1993, Daugman laid a strong foundation for an iris recognition algorithm based on statistical independence evaluated in terms of the phase-dependent feature of the variation in pixel intensity of the iris image. Applying the Gabor filter and Hamming Distance for the integrodifferential operator, a matching parameter was considered the door-opening for the iris recognition process [20]. For feature matching, many researchers have used Hamming Distance, Euclidean Distance, Weighted Euclidean Distance etc. [21]. Daugman's approach is still considered the most common technique applied to several personal identification and authentication systems till date.

The enormous literature on iris recognition systems can generally be classified into three groups based on the following feature identification technique: 1) Phase analysis, 2) Zero crossing, and 3) Texture analysis. The phase analysis approach follows the Daugman's methodology and related modifications, whereas the zero-crossing approach depends on methods like wavelet features [22]. Image texture-based methodology is a relatively recent approach proposed by Li Ma [23]. Further several other methodologies like Gray Level Co-occurrence Matrix (GLCM) [24] include Auto Correlation Function (ACF), Local Binary Pattern [25], Histogram Pattern [26], Haar wavelet [27], Contourlet [28] and Texture code [29] have been identified for iris recognition purpose. To measure the consistency of the iris image of the same eye, two dimensional correlation filters were used by Kumar et.al. [30].

## III. MATERIALS AND METHODS

### A. Dataset used

The proposed method is evaluated on a publicly available database which is captured with the help of a CASIA close-up iris camera. The database has 108 individuals, with seven images per individual. Out of the seven images of a single person, the first three images are in session 1, and the remaining four are acquired in session 2. A total of 756 images are available. The images are in JPG format.

### B. Image Pre-processing

Iris recognition systems mainly involve the following steps: 1) Iris image capturing, 2) Pre-processing, Iris Localization, and Segmentation, followed by 3) feature normalization of the segmented iris region. In the iris localization step, the inner and outer boundaries of the iris portion are identified based on the Hough transform, which involves the Integro-differential operator and is segmented, as shown in Fig. 1(a). Further, the famous Daugman's algorithm is applied to convert the image from a cartesian coordinate

system to a pseudo-polar system. Thus, using the Daugman's algorithm, the circular-shaped Iris region is converted to a rectangular block of a specific size, as shown in Fig. 1(b). For the images investigated here, this Rubber sheet normalization generated images of size 240 x 20 pixels, which hold an immense amount of unique information about each individual [31].

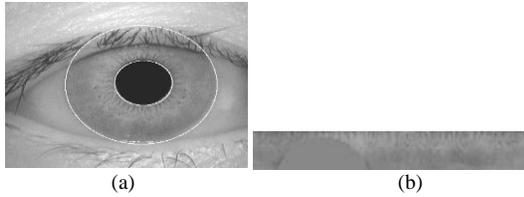

Fig. 1. (a). Segmented Iris, (b). Iris Rubber Sheet Model.

### C. Dispersion Entropy

Dispersion entropy is a metric that can be used to evaluate the irregularities of any given time series. The method is economical in terms of computational cost and has proven to be very efficient in characterizing the complexity or orderliness of various real-world time series data [32]. Dispersion entropy is an ordinal pattern-based entropy measure proposed for overcoming the limitations of earlier methods like permutation entropy [33]. Ordinal pattern-based entropic measures are generally evaluated based on the probability distribution of the different possible states of a system estimated from the distribution of its dynamical variables. Sample Entropy can be considered to be the first proposal characterizing uncertainty in system dynamics based on dynamical variables using such probability distribution [34], and has been applied to both signal and image characterization. Though the method was proved to be efficient for such application, in-depth analysis revealed that, certain limitations of Sample Entropy is with respect to signal length. Later research provided better methods like Permutation Entropy which could overcome several limitations of Sample Entropy, but it was again found to fail at certain instances, regarding amplitude differences within a signal [35]. Dispersion Entropy effectively extracts the specific patterns in the ordinal positions of elements in any signal or time series.

For any given time series of 'N' number of elements,  $N \times = x_1, x_2, x_3, \dots, x_N$ . Multiscale Dispersion Entropy is calculated on coarse-grained versions of the same as follows:

1) The elements  $x_1$  to  $x_N$  of the time series are divided into non-overlapping segments of length ' $\tau$ '. The average of each segment of length ' $\tau$ ' is calculated, thereby generating a coarse-grained version of the same time series.  $x_{ki}(\tau) = 1/\tau$ . In general, for any time series analysis, a range of scale factors 1 to n are chosen. Thus, for a given time series  $X = \{x_1$  to  $x_N\}$ , 'n' different coarse-grained versions are obtained, corresponding to each of the scale factors 1 to 'n'. Further dispersion entropy is calculated, for each of the coarse-grained time series [36].

2) The element of each of the coarse-grained series is mapped to different classes 'c' using linear or nonlinear mapping approaches. Normal Cumulative Distribution

Function (NCDF) is the most generally used function for this purpose. NCDF generates a new series  $y = \{y_1, y_2, \dots, y_N\}$ .

3) The new time series y is embedded similar to the approach of Taken's embedding theorem. Thus generating short sequences or embedding vectors Z.

$$z_i^{m,c} = \{z_i^c, z_{i+d}^c, \dots, z_{i+(m-1)d}^c\}$$

Each short sequence is further mapped to a dispersion pattern

$$\pi_{v_0 v_1 \dots v_{m-1}}$$

where

$$z_i^c = v_0, z_{i+d}^c = v_1, \dots, z_{i+(m-1)d}^c = v_{m-1}$$

As every element in any of the coarse-grained series is now represented by integers from 1 to c, according to its class, the number of possible dispersion patterns that can be assigned to each time series  $z_i^{m,c}$  is equal to  $c^m$ , where 'm' is the number of elements in that coarse-grained series.

4) For each coarse-grained series, the relative frequency of each of the possible dispersion pattern is calculated as follows.  $p(\pi_{v_0 v_1 \dots v_{m-1}})$

$$= \frac{\text{Number}\{i | i \leq N - (m-1)d, z_i^{m,c} \text{ has type } \pi_{v_0 v_1 \dots v_{m-1}}\}}{N - (m-1)d}$$

Finally, dispersion entropy for each coarse-grained series is defined according to Shannon's information theorem  $DE(x, m, c, d)$ .

$$= - \sum_{\pi=1}^{c^m} p(\pi_{v_0 v_1 \dots v_{m-1}}) \cdot \ln(p(\pi_{v_0 v_1 \dots v_{m-1}}))$$

An extension of  $DispEn_{1D}$  is then applied, which is named as  $DispEn_{2D}$  to verify the effectiveness of this methodology [37]. The result of both  $DispEn_{1D}$  and  $DispEn_{2D}$  is illustrated in the following section.

### D. Iris Feature Extractions

For extracting the texture information, Dispersion Entropy values of order '4' and delay '1' is computed for every row and column of the rubber sheet matrix corresponding to each iris image of the dataset. The dispersion entropy file size of an image is only 12KB. The size of the images in the dataset is in the range of 70KB to 95KB, whereas its Rubber sheet matrix ranges from 33KB to 44KB. Therefore it is recommended to use this dispersion entropy matrix, which can then be modified to make it a code and stored for further iris matching.

For every image of a given subject, the dispersion entropy of order '4' and delay '1' is calculated for the Rubber sheet matrix of images of the size of 20 rows and 240 columns. Considering each of these rows as  $\emptyset$ , 1-D series dispersion entropy values computed for every row and column of the Rubber sheet matrix of the image. Thus Dispersion Entropy matrix of rows contains 20 values. Similarly, for columns, each column will be represented by one dispersion entropy value, and hence a total of 240 dispersion entropy values will be obtained for columns also. These values can be stored as

the representational feature for use in further recognition processes.

The efficiency of the DispEn<sub>2D</sub> is verified with real and synthetic datasets in the following sections. DispEn<sub>2D</sub> is an extension of DispEn<sub>1D</sub>.

### E. Iris Feature Matching

Further investigation focused on the match between the iris entropy features of different images of the same person as well as the mismatch between different persons. If this entropy value matches the images of the same person and differs widely between the images of two subjects, then it can be used as an identification feature. The feature-matching process is depicted in Fig. 2. This is carried out as follows. For an iris, Rubber sheet of 20 rows and 240 columns, 20 dispersion entropy values for rows and 240 dispersion entropy values for columns were obtained. The correlation between dispersion entropy sets of every image pair is calculated for images of the same person as well as a different person.

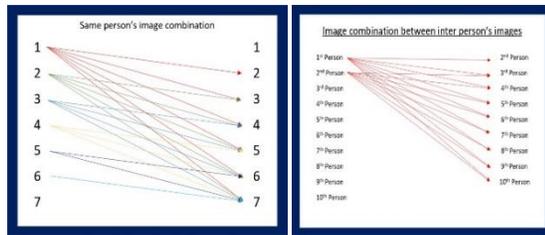

Fig. 2. Feature Matching Process.

In this work, investigation was carried out to find out the effectiveness of this method in the personal identification and classification of iris images. For this purpose, the iris matching between the images of a person and matching between two different persons were evaluated using correlation values between row-wise and column-wise dispersion entropy. From the two separate plots, it is evident that it should be widely different from the same image of a person with another person's image.

Correlation values are calculated between the dispersion entropies of images of the same subjects and that between different subjects to evaluate the efficiency of dispersion entropy in performing personal identification. These values are calculated for every image pair within the seven images of each subject. The average correlation value for all combinations is used as a measure of match between the dispersion entropies of two images of the same eye of a single subject, represented as CORR<sub>same..</sub>. Similarly, these values are calculated for every image pair among all images between each pair of subject combinations. The average values of these measures are calculated for all image combinations for a given subject for all other subjects in the database represented as CORR<sub>diff.</sub>. This is performed for the rows and columns separately.

## IV. RESULT ANALYSIS AND DISCUSSION

Considering the peculiar nature of pattern spread in iris images, it was hypothesized that one-dimensional dispersion entropy along rows and columns of iris rubber sheets would provide a specific advantage in texture characterization. To

test the hypothesis, investigation was done for verifying the differences in values of these measures for the datasets given in section III. The efficiency of the proposed method of feature representation using investigated in terms of DispEn<sub>2D</sub> as well as DispEn<sub>1D</sub> along rows and columns for iris recognition purposes is evaluated separately. Subsets of images from the Kylberg dataset and CASIA v1 are chosen for initial screening of the performance of the two measures in the characterization of general texture images and iris images, as well as in representing the uniqueness of iris patterns of individuals.

Four groups of images, such as blanket1, ceiling1, canvas1, and floor1, were used to analyze the textural information. Four sample images from the Kylberg dataset [38] are shown in Fig. 3, and two images of four different persons taken from CASIA v1 are shown in Fig. 4. Table I below shows the DispEn<sub>1D</sub> for four scale factor values and DispEn<sub>2D</sub> values of the four texture image samples. Similarly, Table II and Table III show mean values of the DispEn<sub>1D</sub> for four scale factor values and DispEn<sub>2D</sub> values of Iris columns and rows, respectively.

Table IV gives the mean correlation and RMSE values between  $DispEn_{1D}$  of rows of iris rubber sheets of iris images of every subject in the sample dataset of texture image represented as  $DispEn_{1D\_Row_{same}}$ . Similarly, Table V gives the mean  $DispEn_{1D\_Row_{diff}}$  values of correlation between rows of iris rubber sheets of every image of each of the subjects with every image of all of the other subjects in the sample data taken from CASIA v1. In the same way, mean correlation and RMSE values between  $DispEn_{1D}$  of columns of iris rubber sheets of iris images of the same subject as well as different subjects, are listed in Table VI and Table VII. Table VIII and Table IX show the mean correlation and RMSE values between  $DispEn_{2D}$  between the same subject images as well as between images of different subjects represented as  $DispEn_{2D\_same}$  and  $DispEn_{2D\_diff}$ .

From these values, it can be observed that the correlation values between iris images of the same subject for both rows as well as columns are very high values, all of which fall above 0.95, indicating high similarity, whereas the same values between images of different subjects are all below 0.6. In the case of RMSE, between images of the same subjects are all less than 0.4 and between different subjects is above 0.6. The difference in these values for cases of same subject's images and for images of different subjects is very promising. In the case of  $DispEn_{2D}$  the values of correlation and RMSE for images of same subject and those between different subjects in not as widely separated as observed in the case of  $DispEn_{1D}$  in both cases of rows and columns. These results indicate the suitability of  $DispEn_{1D}$  for personal identification. Further, the efficiency of one-dimensional dispersion entropy for iris biometric identification is explored in the following section, in which its rows and columns features are separately verified.

#### A. Iris Recognition Analysis using $DispEn_{1D}$

The proposed method of dispersion entropy is applied to iris images of 108 subjects from the CASIA v1 dataset. The dataset contains iris images of 108 subjects; wherein seven images correspond to a single subject. The efficiency of dispersion entropy in characterizing the unique texture of an individual's iris, thereby performing personal identification, is evaluated in terms of correlation, as explained in Section II.

Fig. 5(a-d) depicts the mean values of dispersion entropies of all the images corresponding to each of the subjects along rows, and Fig. 6(a-d) shows the corresponding values for columns. The values of dispersion entropy for the columns fall within the range of 1.8 - 2.8 for scale factor 1 and within the range of 1.5 – 2 for scale factor 2. In the case of rows, the values range between 3 and 4 in both cases of scale factors of 1 and 2. Higher values of dispersion entropy indicate more randomness in pixel intensity values within rows of the Rubber sheet images. It is also noteworthy that in the case of row-wise dispersion entropy, the values are almost in the same range for both instances of scale factors of 1 and 2.

Further investigations on the efficiency of the dispersion entropy feature in characterizing the uniqueness of iris image pattern of an individual and thereby performing personal identification are carried out using a measure of the correlation between different images of the same eye of each of the subjects and between images of eyes of different subjects. Fig. 7(a) to 7(d) show the mean correlation values between row-wise dispersion entropy values of all images of each subject, with its own images represented in green and mean values of correlations between images of each subject with that of all other subjects represented in red. It can be clearly observed that the correlation values between the dispersion entropy of rows of different subjects are lower than between images of the same subject, and these values do not cross over into each other, even in the case of higher scale factors.

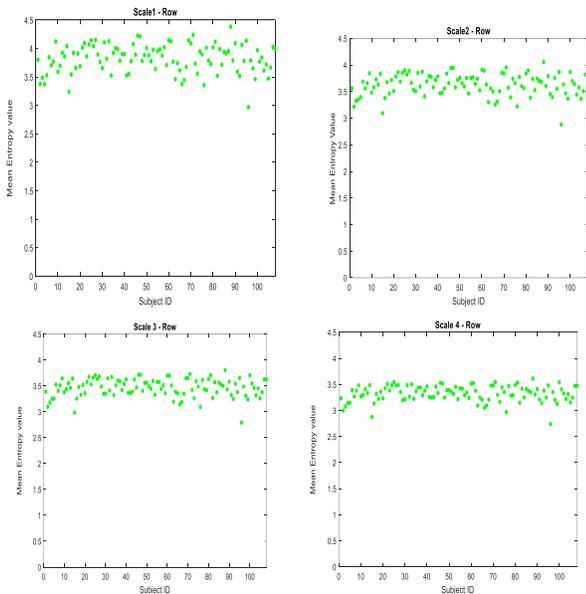

Fig. 5. MVDE Plot, Fig. 5(a) – 5(d). Mean Value Plot for the Row-scale1, Row-scale2, Row-scale3, Row-scale4.

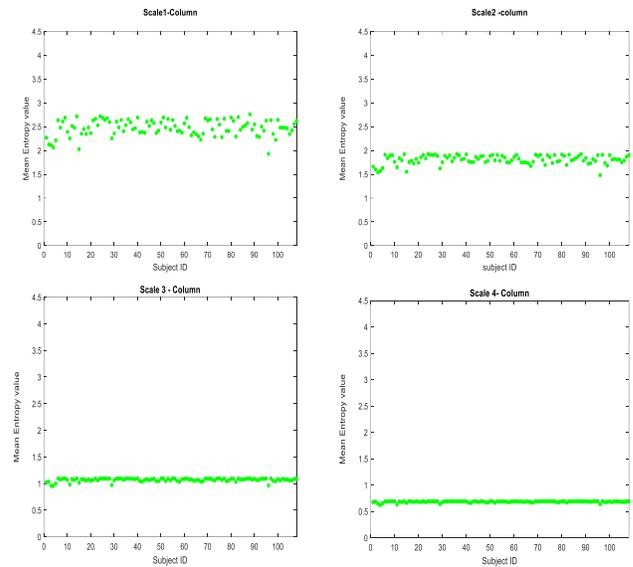

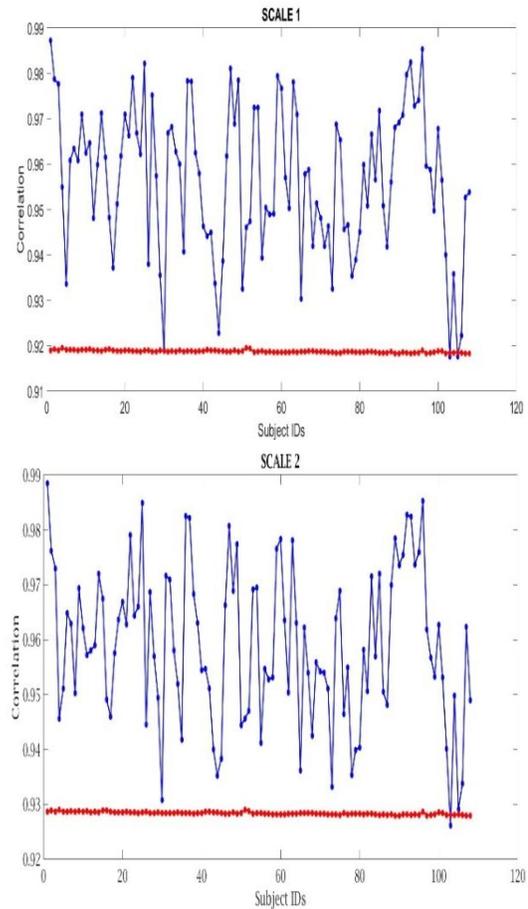

Fig. 6. MVDE Plot, Fig. 6(a) – 6(d). Mean Value Plot for the Column-scale1, Column-scale2, Column-scale3, and Column-scale4.

### 1) Correlation-row

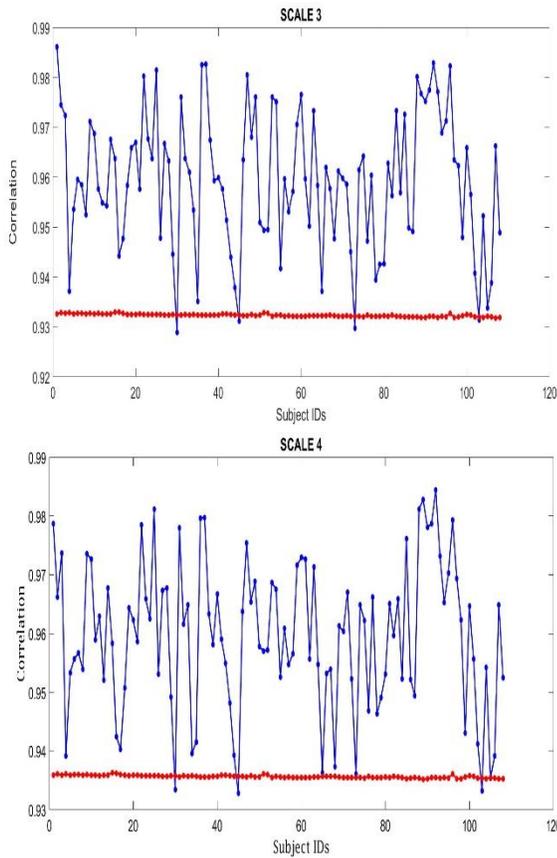

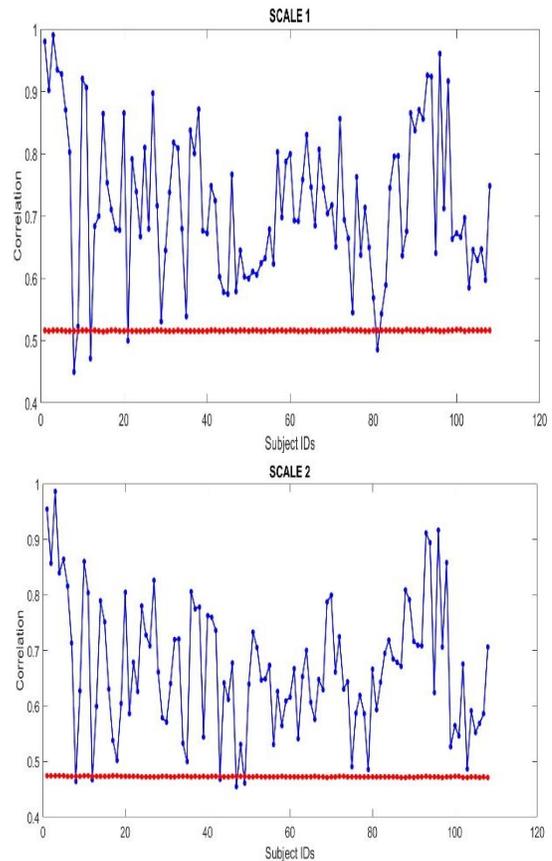

Fig. 7. Correlation Plot for Row Values. 7a. Scatter Plot of Scale 1, 7b. Scatter Plot of Scale 2, 7c: Scatter Plot of Scale 3, 7d. Scatter Plot of Scale 4.

Though it was observed that the dispersion entropy values themselves get reduced with higher scale factors indicating decreased pattern, this however is not drastically hindering the efficiency of this feature in differentiating the images of different subjects. This is especially interesting because the correlation values are around 0.9 for all cases of varying subject correlations, and it is getting slightly increased with an increase in the scale factor. This can be viewed as a consequence of the decrease in dispersion entropy value as a result of the averaging of more and more neighboring pixel intensities with increasing scale factors. In the case of correlation values for the same subject images, the values range between 0.92 – 0.99, indicating very high similarity.

A very encouraging finding in these figures is that the correlation value of the same subject images never crosses below those of different subject values. Though the variation of these values of correlation for the whole dataset of 108 subjects is higher than the variation observed for correlation of different subject images, a majority of these values fall around 0.95 – 0.98. The overall results indicate that the correlation will never be higher than 0.92 or 0.925 for any case of images of different subjects. This is a very strong factor to recommend this feature for the purpose of personal identification, as the chances of wrongly identifying images of different people to be the same are very low.

Fig. 8(a) to 8(d) show the mean correlation values between column-wise dispersion entropy values of all images of each subject, with its own images represented in green and mean values of correlations between images of each subject with that of all other subjects represented in red. The figures indicate that the values of correlation values for images of different subjects fall around the range of 0.5-0.8, which is much low compared to that observed for row-wise dispersion entropy. However, the values of the same subject images show wide variation, with values falling between 0.5 and 1, with a majority of values falling between 0.6 and 0.8. It is noteworthy that though there is not much cross-over of the same subject image correlation into the range of correlation values of different subject images in the cases of scale factors 1 and 2, the different subject image correlation values increase and cross over into the same subject correlation value range in the cases of scale factors of 3 and 4. The better stability of results in the row-wise analysis is in good agreement with the observations and recommendations, which stated that information is more independent along the angular direction [39]. The different rows correspond to different circles, and the pixels along each row represent angular direction. The present results indicate that ordinal pattern-based Dispersion entropy is very efficient in extracting the maximum utility of the statistical independence between the pixel intensity values along the angular direction in each circle.

## 2) Correlation-column

### B. Performance Evaluation Measures

The effectiveness of this proposed work is verified using the performance measures such as False Acceptance Rate (FAR), False Rejection Rate (FRR), False Positive Rate (FPR), Specificity, Sensitivity and Equal Error Rate (EER). Following equations are used to formulate the performance evaluation measures

$$\text{False Acceptance Rate (FAR)} = \text{FP} / (\text{FP} + \text{TN})$$

$$\text{False Rejection Rate (FRR)} = \text{FN} / (\text{FN} + \text{TP})$$

$$\text{Equal Error Rate (EER)} = (\text{FAR} + \text{FRR}) / 2$$

$$\text{Precision} = \text{TP} / (\text{TP} + \text{FP})$$

$$\text{Recall} = \text{TP} / (\text{TP} + \text{FN})$$

$$\text{Sensitivity} = \text{TP} / (\text{TP} + \text{FN})$$

$$\text{Specificity} = \text{TN} / (\text{TN} + \text{FP})$$

Where TP and TN represent true positive and true negative, FP and FN represent false positive and false negative. For row values, if the threshold value of scale 1 is set for 0.92 then the FRR is zero, which indicates that no person will be falsely rejected. The threshold can be selected based on the dataset which is used. The Specificity and Sensitivity value shows that this system gives accurate True Negative Rate and True Positive Rate. The results are shown in Table X and Table XI for rows and columns, respectively. By examining the values of the threshold, it can be clearly understood that the row values gives better results than column values. Lower the EER higher the accuracy of the biometric system.

TABLE I. PERFORMANCE EVALUATION OF ROW\_DISPEN<sub>ID</sub>

## V. CONCLUSION

A new method for iris recognition is a nonlinear time series analysis based on Dispersion entropy proposed in this work. Dispersion entropy is estimated based on the complexity of ordinal patterns of elements in a time series. The method is tested on the standard CASIA v1 dataset. The rows and columns of normalized iris images are considered one-dimensional time series, and the corresponding dispersion entropy values are calculated. Correlation between mean dispersion entropy values is calculated to evaluate how efficiently two images of the same subjects can be identified as well as how well two images of different subjects can be differentiated. This is carried out for the dispersion entropy of rows and columns separately. High correlation and values are obtained between different images of the same individual, whereas low correlation values are obtained between images of different subjects. The results of the row-wise analysis demonstrated much higher performance than the column-wise analysis. The results indicate that the dispersion entropy values of one-dimensional series of pixel intensities along rows of normalized iris images are very efficient in characterizing the uniqueness of the iris texture of individuals. The results also point towards the extreme possibility of utilizing the capabilities of nonlinear analysis for iris recognition purposes. These results prove the potential of nonlinear analysis-based texture entropy to be further developed into a tool that can provide a group of features to constitute a feature vector based on ordinal pattern measures of iris image texture for personal identification. This methodology has to be evaluated with other datasets. Also, it is considered the future scope of this work. In addition, similar nonlinear entropy measures can be used to build a feature vector so that the proposed novel approach can be developed.

**Abstract**—Cloud computing would be an easy method to obtain services, resources and applications from any location on the internet. In the future of data generation, it is an unavoidable conclusion. Despite its many attractive properties, the cloud is vulnerable to a variety of attacks. One such well-known attack that emphasizes the availability of amenities is the Distributed Denial of Service (DDoS). A DDoS assault overwhelms the server with massive quantities of regular or intermittent traffic. It compromises with the cloud servers' services and makes it harder to reply to legitimate users of the cloud. A monitoring system with correct resource scaling approach should be created to regulate and monitor the DDoS assault. The network is overwhelmed with excessive traffic of significant resource usage requests during the attack, resulting in the denial of needed services to genuine users. In this research, a unique way to the analyze resources used by the cloud users, lowering of the resources consumed is done when the network is overburdened with excessive traffic, and the dynamic cloud load balancing algorithm DCLB (Dynamic Cloud Load Balancing) is used to balance the overhead towards the server. The core premise is to monitor traffic using the fuzzy logic approach, which employs different traffic parameters in conjunction with various built in measured to recognize the DDoS attack traffic in the network. Finally, the proposed method shows a 93% of average detection rate when compared to the existing model. This method is a unique attempt to comprehend the importance of DDoS mitigation techniques as well as good resource management during an attack and analysis of the.

**Keywords**—DDoS attack; resource scaling; DCLB; fuzzy logic; traffic parameters

## I. INTRODUCTION

Cloud computing threats are becoming more prevalent regularly, with attack channels and patterns changing. It provides a wide range of services with considerable benefits for corporate organizations, businesses, and individuals transitioning to this environment. Despite its numerous benefits, security is typically the decisive factor for businesses when determining if cloud infrastructure is the best solution for their users. According to the assault report in [1], the most prominent attack is the DDoS attack among the abundance of attacks affecting the great majority of organizations globally. DDoS attacks have fully-fledged in admiration in recent years because of the simplicity with which they may be deployed. DDoS attacks have increased in recent years because of the

ease with which they may be launched. According to [2], the scale of a DDoS attack, which was just 8 Gbps in 2004, has already surpassed 800 Gbps in 2016. Among the plentiful recent attacks [3], a few significant assaults have expanded a lot of courtesy in the scholarly community [4]. "Lizard Squad attacked", has affected the Microsoft and Sony cloud-based gaming services, knocking them offline on Christmas Day in 2015. "Rackspace", is a cloud service provider, which was affected by a massive distributed denial of service (DDoS) attack against its services.

Another exceptional assault scenario was for the Amazon EC2 cloud servers to be exposed to yet another incredible DDoS attack. These assaults caused major downtime, commercial losses, and other enduring and short-term effects on the victims' businesses. According to "Verisign iDefense Security Intelligence Services" [4], the cloud and SaaS (Software as a Service) industries have been the most targets of DDoS attacks in recent quarters. The contribution to the paper is listed below:

- 1) A thorough understanding of DDoS attacks is offered for the reader to gain correct insight and comprehension.
- 2) A monitoring system to identify DDoS attacks in traffic.
- 3) An effective Load balancing mechanism for smooth conduction of the cloud services.

As a consequence, the DDoS detection and prevention system [5] is an essential element in the overall growth of an organization's statement since it explains the rules and methods for providing security. The academic community has focused on identifying several forms of DDoS attacks in the cloud, such as ICMP, HTTP, and TCP protocol flooding [6]. Our key discovery is associated with resource scaling, which may become less effective if the conflict in the network is developed during the attack. The following is the objective of this research:

- 1) Research the DDoS attack and its impact on the cloud server.
- 2) To create a hybrid approach for mitigating DDoS attacks using DCLB and FUZZY logic.
- 3) To monitor and assess the algorithm's effectiveness in mitigating DDoS attacks.

This paper is mainly focused on the mitigation of DDoS attacks and reducing resources utilization. The framework used for the mitigation process of a DDoS attack contains a monitoring system and a load balancing method.

The research paper is constructed as follows. Section II depicts a study of DDoS attacks and the various methodologies employed. Section III of the study then discusses methodology and terminology. Section IV describes in detail the technique and algorithm used for network monitoring and load balancing. Section V presents the experimental data, and Section VI covers the discussion. Section VII brings the work to a conclusion.

## II. RELATED WORK

Wahab et al. [7] developed a two-pronged strategy that enables the hypervisor to create believable confidence in the virtual machine. In this case, the suggested system employs the Game solution guide hypervisor approach to identify the ideal detection as well as load balancing.

Liang et al., [8] provided detailed research on machine learning algorithms utilized for DDoS attack detection. The ML approaches detected the class imbalance problem, but the results reveal that a single method cannot overwhelm the DDoS assault, hence enhancements to the ML-based strategies are necessary.

Kousar et al. [9] presented a novel mechanism by combining the statistics and machine learning models. To identify the DDoS attempt, the work was implemented in the Apache Spark Framework. In addition, the approach detects the attack using the NSL-KDD cup methodology as the benchmark dataset.

Alsirhani et al. [10] proposed a DDoS detection framework based on the "Gradient Boosting Classification Algorithm (GBT)" and the Apache Spark engine. The traffic volume (dataset) and feature space assist in the creation of a depth decision tree to identify the assault.

Cloud-Traceback technology (CTB) was created to detect and also to mitigate the DDoS assaults in cloud computing by identifying the origin of HTTP and XML-based attacks, Chonka et al. [11]. It also introduces the use of backpropagation in conjunction with a cloud defender, which filters out malicious traffic.

Guo et al. [12] suggested a resource allocation approach for cloud data centers called "dynamic resource allocation" to protect the resources against DDoS attacks. This article made use of idle cloud resources and avoided them by employing quick filtering algorithms.

Bikram et al. [13] identify the features of a DDoS assault and propose a system called a "Snort-based Intrusion Detection System (IDS) tool" for DDoS detection. It also describes a system that would alert the network administrator of every attack on any imaginable resource, as well as the sort of attack. It also temporarily suspends the attacker for the network administrator to devise a backup strategy. The proposed method mitigates the impact of DDoS attacks by

detecting them early and altering many parameters that make it simpler to diagnose the problem.

Sathya et al., [14] suggested a new framework entitled "Anti-DDoS" that detects high-rate DDoS assaults. This method uses the "graphical Turing test" and "Authentication model" to prevent the cloud from the attacked. It also uses the count hop filtering technique for detecting the attack, the traffic was controlled using a control list.

Liu et al., [15] proposed a strategy that uses the BIRTH algorithm to detect aberrant traffic flows by employing frequency domain information from the network flow's autocorrelation sequence as a clustering feature.

Sahi et al., [16] demonstrated a methodology for detecting the flooding of DDoS attacks by combining data flow and using a list to blacklist to identify the source IP of attack packets.

Barde et al., [17] A "deception detection" approach were proposed for detecting high-rate DDoS attack traffic in the cloud computing domain.

Navaz et al., [18] provide multi-level detection methodologies for camouflaged small traffic DDoS assaults and employ entropy-based algorithms in combination with anomaly detection systems. The researchers have presented a detection algorithm for flooded DDoS attacks and random DDoS attacks, The method gives acceptable results for DDoS attacks with heavy traffic in a cloud environment, the time required to complete the operation is exceedingly slow. The results in the cloud environment are slower, and the approaches rarely examine the real system that is subjected to a variety of attacks.

Zheng et al., [19] suggested a DDoS attack mitigation architecture that helps to detect and responds to attacks quickly. Furthermore, the author argued that SDN network technology helped in the prevention of DDoS assaults.

Saravanan et al. [20] provided an approach for recognizing and mitigating DDoS attack impact assaults. It employs three screening checks to protect the server against assaults, as well as several limitations to identify the attacks. To repel the attack, it employs two queues.

Scaling the VM's capacity is a critical step in estimating the overall number of requests processed in a particular period. The duration of time necessary to perform the request impacts the number of resources consumed. The scale inside-out strategy enhances capacity while simultaneously scaling internal applications to minimize resource use. Somani et al. [21] pioneered this concept.

This work focuses on DDoS attacks that are primarily aimed at detecting bandwidth and connection flooding. Karan et al., [22] generate a solution by integrating the OpenStack firewall with raw socket programming for monitoring network traffic.

## III. DESIGN AND ASSUMPTIONS

In the section, the overall proposed model system design is shown. Each cloud user (CU) will access the cloud resources

effectively. The problem faced by the legitimate user (normal user) is the delay that occurs when the user requests the cloud for particular resources.

As the cloud works on-demand policy [24], the cloud system should be more efficient to provide the resource on time as user requests them. The delay in the network occurs due to some unwanted request that will be placed in the network by the assault(attacker). The attacker floods the network with the unwanted request so that the legitimate user will be halted from the requested resource, such attacks are known as DDoS attack.

So, it is necessary to launch an effective mitigation mechanism to prevent the system from this type of attack. As discussed in the ‘related work’ section, there are a lot of mechanisms to detect the DDoS attack but the challenge faced is to identify the attacker and to make the system work properly by removing the unwanted request and regulating the relationship between the and cloud user (balancing the workload).

As shown in Fig. 1, the overall architecture is divided into two main parts: verification and detection process and service access in cloud computing. In verification and detection process is again subdivided into two, one is VV model (Virtualization & Verification) and the other is LB model (Load Balancing). Each cloud user is owned by a virtual machine to access the cloud resources.

The request will be monitored by the virtualization and verification model (VV model) based on the analysis detect made of the request characteristic; the VV model is consist of 4 phases of the procedure and each phases process help to the DDoS attack. In each phase different value is computed based on the request characteristics. The computed value is compared with some predefined threshold value by using the concept of fuzzy logic [23].

The VV process applies various analyzing strategies to the incoming request such as in & out statistics, checking the protocol, number of requests coming, and packet analysis. The result obtained from the VV model detects the DDoS attack and forwards the results to the LB model.

In the LB model, the request load is balanced by using a dynamic cloud load balancing algorithm (DCLB), it applies a vertical scaling mechanism on resource allocation to mitigate the attack after the detection process. Usually, each cloud user which owns the virtual machine is allocated a sufficient number of resources such as P, D, M, and NT (processor, disk, memory, and network throughput).

The number of connections at a particular time many varies, so the idea is to scale down the resources when the attack is detected in the network. When the attack is detected in the cloud system the resources are minimized and the virtual machine which provides the same request or random request will be halted for some time, so that the legitimate user will be able to access the system efficiently.

A. Notation and Assumptions

Let  $CC = \{cc_1, cc_2, \dots, \dots, \dots, cc_n\}$  be the finite set of cloud users in the cloud at a particular time. The cloud user (CC) accesses the cloud through the virtual machines. Each CC is owned by a unique virtual machine  $VM_i = \{VM_1, VM_2, \dots, \dots, \dots, VM_n\}$ . Each virtual machine  $VM_i$  uses some set of resources  $\langle P_i, D_i, M_i, NT_i \rangle$  which is represented in vector form.

Along with the cloud user, there is a malicious user known as an attacker which is denoted as  $AT_i$  which accesses the cloud as the normal cloud user and captures “n” virtual machine to perform a DDoS attack.

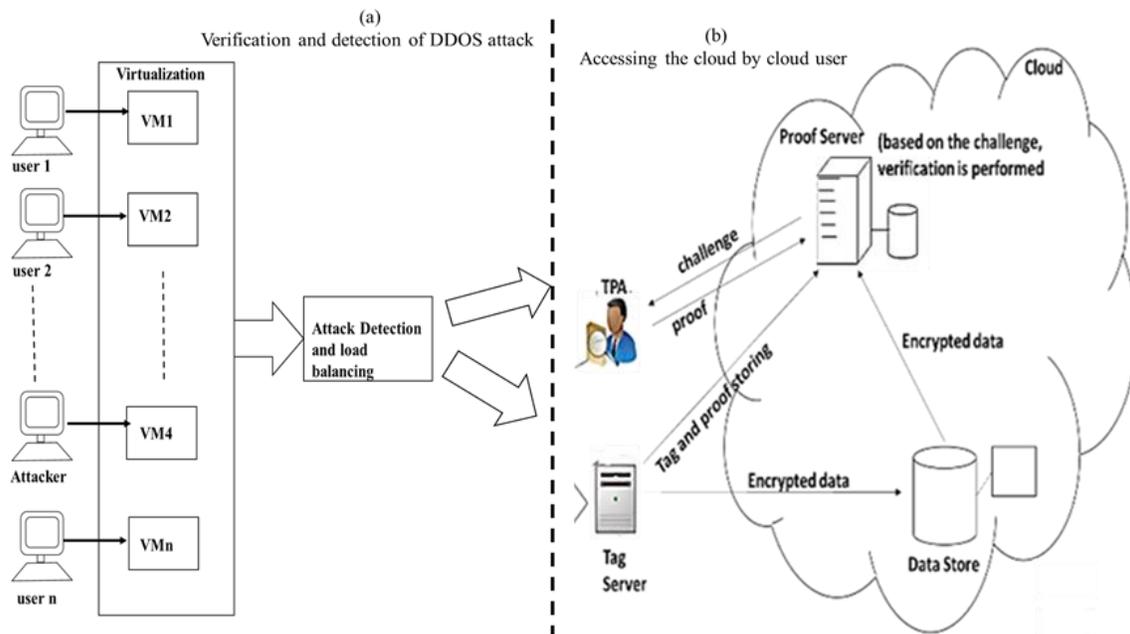

Fig. 1. Overall Proposed System Architecture.

In this proposed system, the request can come from the same source or different sources, so it has been examined that the arrival of several requests from the same source  $R_{ss}$  and requests from different resources  $R_{ds}$  is less than or equal to the maximum request  $R_{max}$  at a particular time.

Also in this system, the number of the incoming packets and the outgoing packet is calculated as  $n_{rin}$  and  $n_{rout}$ . In the network, there are different protocols from which we can send the request to the cloud such as TCP, UDP, ICMP, etc. In this paradigm, calculating the entropy of protocols that play a substantial role in attack detection,  $E_p$ , is critical. In addition, when it comes to protocols, the duration of an IP packet flow is a critical parameter to examine to detect an assault. The flow calculation is denoted as  $L_{ipflow}$  in which the average is calculated for all packets from each client virtual machine.

The VV model's output (analysis report) is sent to the LB model, which predicts the manifestation of a DDoS assault, the load balancer checks the result and will reduce the resources allocation by scaling down the Resource Utilization Factor  $RUF_{nor}$  to a threshold value which is allocated based on analyzing the intensity of the traffic in the network as  $RUF_{att}$ . When  $RUF_{att}$  is set instead of releasing the complete resource at a time it will release one by one so that the resource is not affected and legitimate users can also access the resource without any delay.

Virtualization cloud Definition 1: A cloud system consists of a set of cloud users  $CC = \{cc_1, cc_2, \dots, \dots, cc_n\}$  owing a set of virtual machines  $VM_i = \{VM_1, VM_2, \dots, \dots, VM_n\}$ . to access a set of resources, provide by the cloud system.

Each virtual machine owned by the user will have a unique session ID  $S_{id}$ , so that it will be easy to identify which the virtual machine is loading the network with heavy traffic. The VV model analysis the traffic and remove the same request coming from the single session of the same virtual machine. Notations used in the proposed system are given below in Table I.

TABLE I. NOTATION USED IN THE PROPOSED SYSTEM

Notation	Description
$CC_i$	A finite set of cloud users
$VM_i$	A finite set of Virtual Machine owned by the cloud user
$P_i$	Processor usage
$D_i$	Disk usage
$M_i$	Memory Utilization
$NT_i$	Network Throughput access
$AT_i$	Represent the attacker from the set of user
$R_{ss}$	The request coming from the same source
$R_{ds}$	The Request coming from a different source
$R_{max}$	A limited number of requests from the source
$n_{rin}$	Number of the incoming request
$n_{out}$	Number of outgoing response
$E_p$	entropy calculation of different protocol
$L_{ipflow}$	length of ip packet flow
$RUF_{nor}$	Normal resource utilization
$RUF_{att}$	The threshold value is set when an attack occur.
$S_{id}$	Unique session ID for each user in their owned virtual machine

#### IV. IMPLEMENTATION OF THE PROPOSED

The overall architecture is of the integrated cloud load balancing algorithm and fuzzy logic (i.e. incorporating different parameters of requests coming from the cloud user) along with the dynamic scaling of resources. The proposed model is divided into two models: VV (Virtualization & Verification) model and LB (Load Balancing) model. These two models are used to spot (detect) and mitigate the attack and help to reduce the access to resources and some other services also.

##### A. VV Model

In this proposed model, each request coming from the user and the attacker has initially undergone to VV model in which the virtual machine details and request verification is done. The VV model verifies the incoming request that comes from each virtual machine. It also gather the unique session id  $S_{id}$  of each request.

The DDoS attack is attained by utilizing a flooding attack in which the request is following the same pattern concerning the protocol also (Fig. 2). The VV model is subdivided into 3 phases: RAI (Request arrival Inspection), PI (Protocol Inspection), and IPI (IP flow inspection).

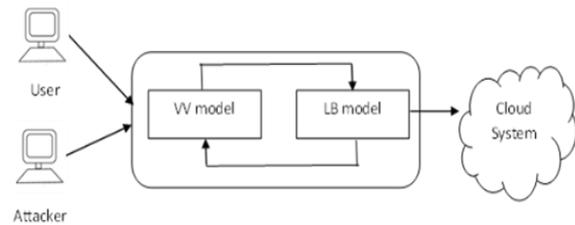

Fig. 2. Overall Implementation Design.

1) RAI: The RAI is the process in which the request arrival is analyzed. Each request comes to the system in the form of a special packet with header fields. The header field help to identify the source and destination address. To identify the chances of a DDoS attack, the source address is considered the critical factor. Here, the packet used is a 32-bit IP packet along with a unique session ID of 4 bits (Fig. 3).

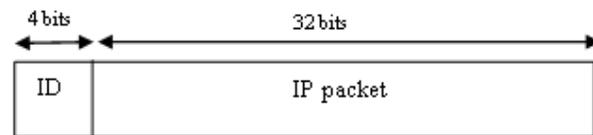

Fig. 3. Packet used for the Accessing the cloud System.

The unique session id is first extracted from each packet. An attack is feasible if the number of requests from the same source consistently exceeds the maximum limit in a certain period. (i.e.,  $R_{ss} > R_{max}$ ). If the number of requests comes from a different source at a particular time and exceeds the maximum limit then there is a chance of an attack to occur (i.e.,  $R_{ds} > R_{max}$ ) Next, we calculate the ratio of the  $R_{ss}$  and  $R_{ds}$  which are the main parameter to consider in detecting DDoS attacks. The proportion of incoming and outgoing requests over some timestamp is calculated based on the eq (1),

$$R_{io} = \frac{R_{ss}}{R_{ds}} \quad (1)$$

Usually, the propagation should be constant if the traffic is normal. So here if the  $R_{io}$  exceeds the threshold value ( $i.e \geq 1$ ) thus it indicates the event of an attack. It will be balanced if the ratio is less than 1.

2) *PI*: Essentially, if  $\langle TCP, UDP, ICMP \rangle \Rightarrow \langle T, U, I \rangle$  packets are employed then, the DDoS attack will be successful [21]. A DDoS attack is indicated by the ratio of these protocols. The formula for calculating the ratio of different methods is displayed in eq (2).

$$R_T, R_U, R_I = \frac{\sum P_T}{\sum Packet\_IP}, \frac{\sum P_U}{\sum Packet\_IP}, \frac{\sum P_I}{\sum Packet\_IP} \quad (2)$$

Then the entropy [25], is calculated for the above-computed value as shown below in eq (3),

$$E_p = \sum_{i \in T, U, I} -P_i \log_2 P_i \quad (3)$$

3) *IPI*: As the arrival and protocol inspection likewise, another significant criterion is the IP Packet flow in the network. Counting the number of packets that fulfill the same criterion yields the average duration of an IP flow. The requirements include the source and destination addresses, as well as the port number and protocol utilized. A packet with the same source and destination might arrive with a different protocol. As a result, the length of the IP flow is computed using Equation (4).

$$L_{ipflow} = avg \left( \frac{\sum ip\_packets}{\sum ip\_flow} \right) \quad (4)$$

The typical IP flow length is usually between 5 and 10. If the value is close to one, it means an attacking packet was discovered. Here when the attack is detected then the *Attflag* flag is set to one. Which indicates the load balance of the attack occurrences? The entire operation and algorithm utilized for the VV model are detailed below, and a graphical depiction of the method is depicted in Fig. 4.

---

#### Algorithm of VV model

---

##### Input :

The ip address of the packet,  
initial set threshold values

$R_{max}$

##### Output:

Attack Detection or accepting the packet

##### Procedure VV():

1. Retrieve the session id from the request  $S_{id_i}$

Analysis():

i. if  $n_{rin} > 100$  then

halt the all the request from the same session ID  $S_{id_i}$

ii. else

1. Compute the  $R_{ss}$  and  $R_{ds}$

2. Calculate the ratio of incoming and outgoing packets

3. If  $R_{ss} < R_{max}$  &&  $R_{ds} < R_{max}$  &&  $R_{io} \leq 1$   
goto step 4

4. else

mark the incoming packet as an attack packet set the  $att_{flag} = 1$ , and move on to the load balancing process.

5. Calculate  $R_T, R_U, R_I = \frac{\sum P_T}{\sum Packet\_IP}, \frac{\sum P_U}{\sum Packet\_IP}, \frac{\sum P_I}{\sum Packet\_IP}$

6. Compute the entropy

for ( $i \in \langle TCP, UDP, ICMP \rangle$ )

{

$$E_p = \sum -P_i \log_2 P_i$$

}

7. If  $E_p \neq 0$  && deviation  $(R_T, R_U, R_I)!$  low  
goto step 7

8. else

mark the incoming packet as an attack packet set the  $att_{flag} = 1$ , and move on to the load balancing process.

9. Calculate IP flow average length  $L_{ipflow} = avg \left( \frac{\sum ip\_packets}{\sum ip\_flow} \right)$

10. Calculate the entropy value

for ( $i \in \langle TCP, UDP, ICMP \rangle$ )

{

$$E_{ipflow} = \sum -P_i \log_2 P_i$$

}

11. If  $5 < L_{ipflow} < 10$  &&  $2 < E_{ipflow} < 4$

Accept the packet and forward it to the LB module

12. else

mark the incoming packet as an attack packet, set the  $att_{flag} = 1$ , and move on to the load balancing process.

---

$$R_{io} = \frac{R_{ss}}{R_{ds}}$$

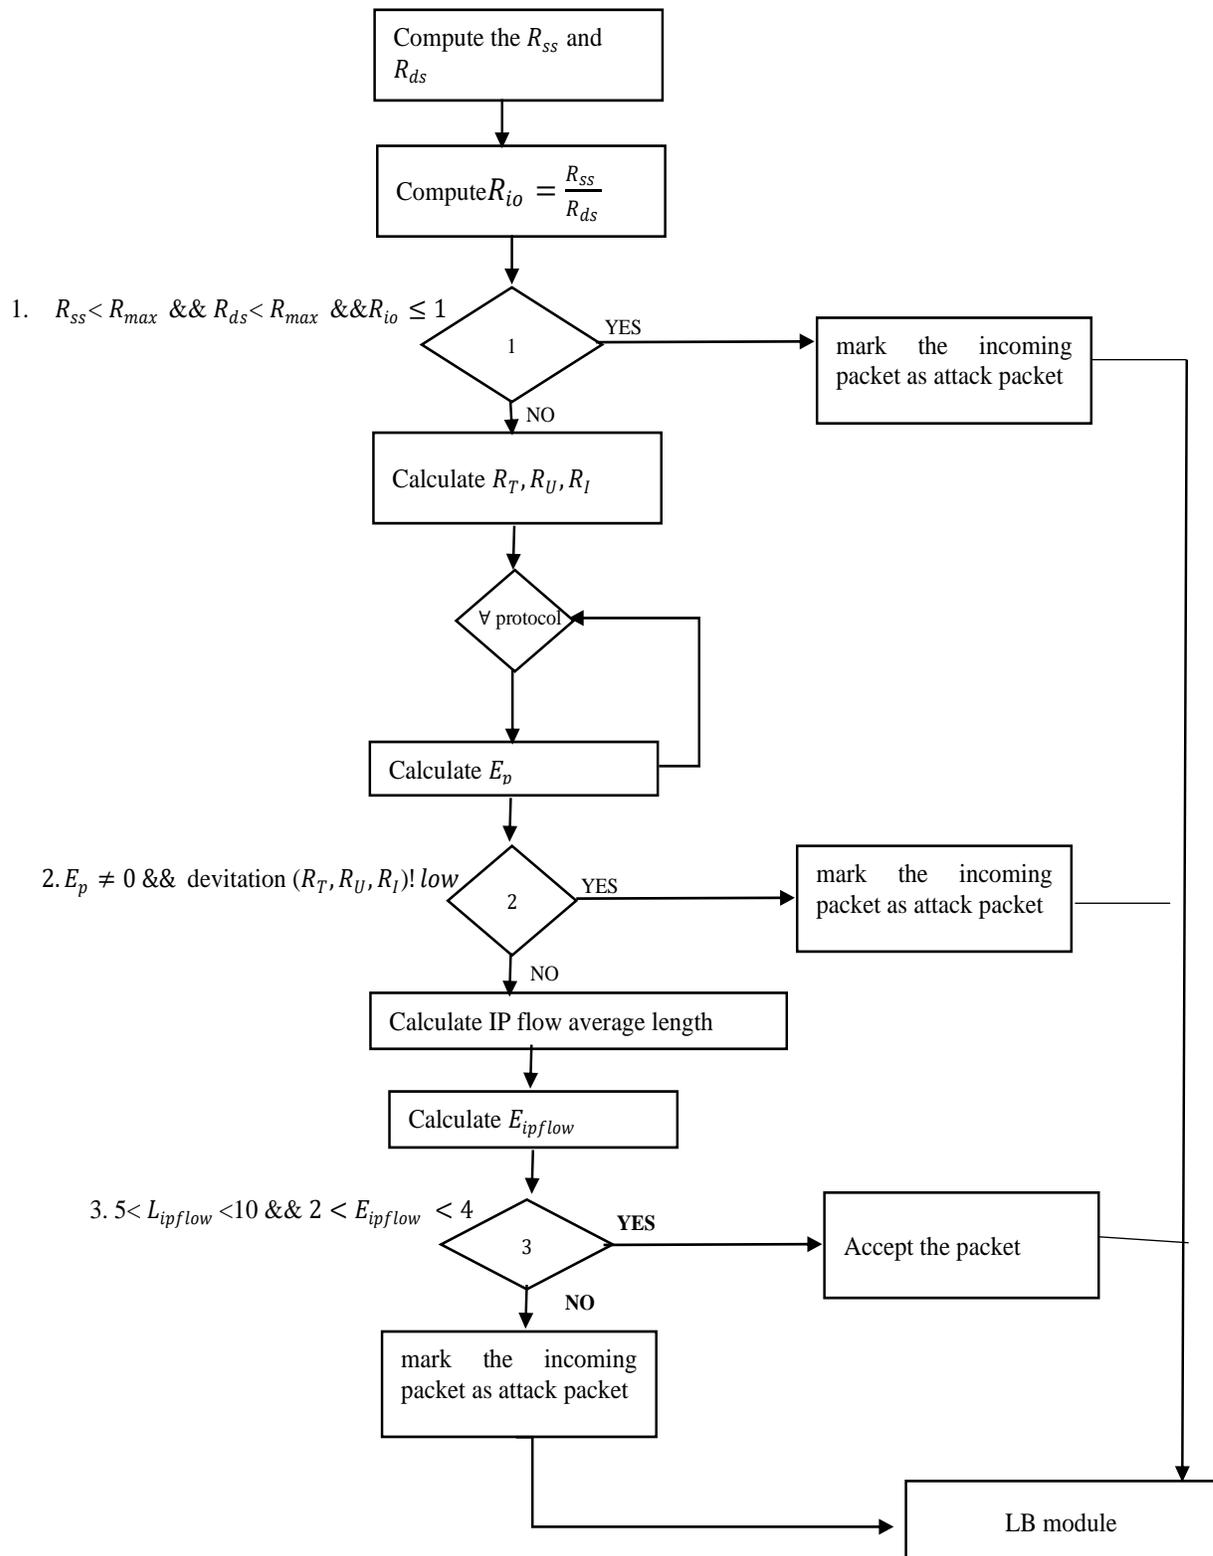

Fig. 4. Flow Chart of VV Model.

### B. LB Model

After the VV model, the flow goes to the LB model, in which the resources are balanced based on whether the attack occur or not. The result from the VV model is forwarded to

LB however it is using the MAX-MIN load balancing technique. Initially the services from the cloud will be allocated with favorable resources, if the analysis report shows an occurrence of a DDoS attack, then the MAX-MIN load

balancing is implemented. In these techniques each request will be provided with the initial resources  $RUF_{nor}$  as the occurrence of the DDoS attack is detected in the VV model the resource allocation is minimized to  $RUF_{Att}$ .  $RUF_{Att}$  is a Resource utilization factor that has a threshold value set, when the attack occurred is detected. But here, this proposed system it is dealing with the dynamic nature. The value of  $RUF_{Att}$  will varies based on the intensity of the attack, that is, the resources that are suspended will be released one at a time rather than all at once. Minimizing resources during an assault and returning to normal once the attack has ended will boost the virtual machine's capacity. When there is a high volume of traffic, the initial requests are processed, and subsequent requests are retransmitted. This implies that just the index page is displayed to the user, and all subsequent requests are queued or retransmitted. Assaulters who have released a huge volume of traffic will not wait for the provider to respond. As a result, completing the original request may minimize resource use and enhance virtual machine capacity.

Algorithm of LB model

**Input :**

Analysis report from the VV model  
 $Att_{flag}$  value

**Output:**

Minimize  
and maximize the resource usage

**Procedure LB():**

1. Allocate the resource to the requested services
  - a. Compute  $RUF_{nor} = \frac{VM_{CAPACITY}}{n_{maxreq}}$
  - b. Set the resource factor  $RF = RUF_{nor}$
2. do
  - a. Call the VV() procedure periodically.
  - b. If  $Att_{flag} == 1$ 
    - i. Compute  $RUF_{att} = 1/2(RUF_{nor})$
    - ii. Reduce the  $RF = RUF_{att}$
  - c. Else
    - i. Set the resource factor  $RF = RUF_{nor}$
3. Continue the process for all requests.

The procedure of LB Model help us to maintain the resources and keep the system throughput same for all the cloud user CU (Fig. 5). The VV model identifies the high-rate traffic, and set the  $Att_{flag}$  to 1 other wise the  $Att_{flag}$  will be 0 indicate that the traffic is normal.

In the LB model the  $RUF_{nor}$  (Resource Utilization Factor) is calculated for the normal traffic of the cloud user CU. This  $RUF_{nor}$  will be allocated to the requested user and when the attack is detected, the resource allocated to the CU user will be 50% of  $RUF_{nor}$  ( $RUF_{att} = 1/2(RUF_{nor})$ ). So that it helps to maintain the equivalency among the cloud user. All users can access the server and server can process the user request.

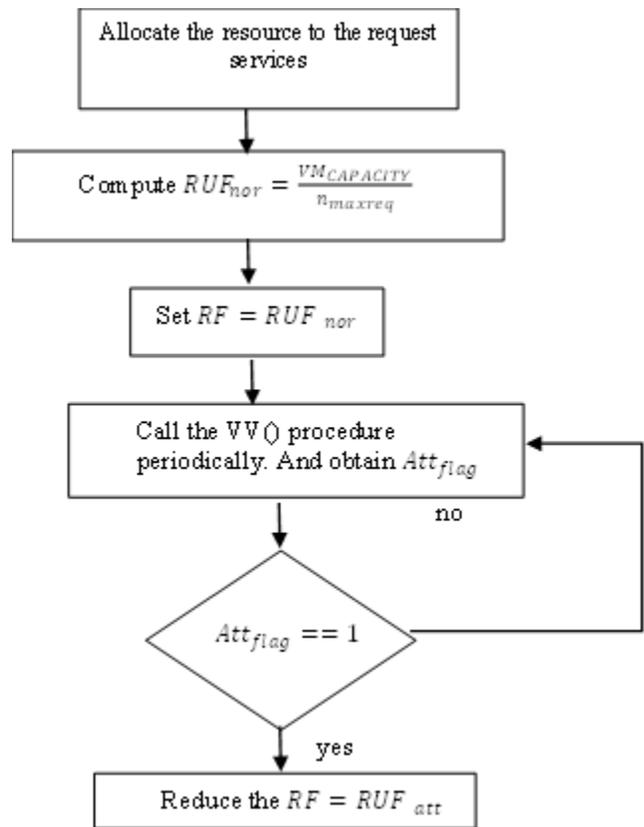

Fig. 5. Working of LB Model.

V. EXPERIMENTAL AND RESULT ANALYSIS

The experiment is carried out by establishing 50 requests to test the availability of cloud service to the requested user even in the event of an attack (including user and attacker requests). At the same timestamp, this request is launched towards the cloud side. The cloud simulator tool is used to mimic the operation of the proposed system and to analyze the system's results. The cloud service taken is the storage of doubled encrypted files and access of the double encrypted file.

A. Computation Cost

The above specified methodology contains operations such as multiplication, division, addition, subtraction and comparison operation with the time  $t_m, t_d, t_a, t_s$  and  $t_c$ . The time taken for the entropy calculation, IP address comparison etc. as calculated for the two phases: The complexity cost of the VV model when compared with the SIO and ANTI-DDoS model is  $2nt_d + (n + 1)t_s + nt_c$  and for the load balancing the cost is  $n(t_d + t_c) + \alpha_d$ , where  $\alpha_d$  is the delay taken to reduce the resource scale from the normal to minimum when attack is detected. The below Table II show the complexity cost of proposed system with the SIO and ANTI-DDoS schemes.

The proposed model is compared with the SIO and ANTIDDOS model, in which the load balancing is the main factor in the above 3 schemes.

TABLE II. COMPUTATIONAL COST

Complexity Cost	Schemes		
	SIO	ANTI-DDOS	Proposed model
Verification Cost	$(n^2 + 1)t_d + 2nt_m$	$n^3t_d + (n + 1)^2t_s + 4nt_c$	$2nt_d + (n + 1)t_s + nt_c$
Load balancing Cost	$nt_d + n^3t_c - (n + 1)^2\alpha_d$	$n(t_d + t_c) + n^2t_s - \alpha_d$	$n(t_d + t_c) + \alpha_d$
Detection cost	$(n + 1)(t_d + n^2t_c)$	$nt_d + n^2t_c$	$(n + 1)t_c$

The load balancing process complexity in SIO model is  $nt_d + n^3t_c - (n + 1)^2\alpha_d$  and for ANTIDDOS model is  $n(t_d + t_c) + n^2t_s - \alpha_d$ , here the complexity is high than the proposed model because in SIO the delay for the resource balancing takes  $O(\log n^2 + 1)$  and for the ANTIDDOS model the delay for the resource balancing takes  $O(n^2)$ . All delay is overwhelm in the proposed model in which the load balancing process complexity is  $(t_d + t_c) + \alpha_d$ , the delay for the resource balancing is  $O(1)$ .

Also while comparing the verification cost of SIO and ANNTIDDOS model shows a  $O((n + 1)^2)$  and  $O((n - 1)^2)$  but the proposed system shows a complexity of  $O(2n + 1)$ . In the detection process the cost is  $O(n + 1)$  for the prosed system which is very less complex that the other two schemes.

**B. Result Analysis**

It is also seen on the TPA side, where auditing requests are tracked. The cloud server processor is an Intel Xeon CPU with 8GB RAM and a 1TB hard disc. The traffic rate is considered to be between 10 and 500 requests per second and does not exceed 500. To analyze the performance, input files of varied sizes are employed. The system's performance is evaluated using three metrics: attack detection time, Rate of Reporting. The above system is contrasted with the AntiDDoS framework [10] and the Scale in-out model [17]. The experiment was carried out by varying the number of DDoS attacks recorded on the deployed cloud server. The detection rate and false-negative rate for a variety of DDoS assaults were compared for the existing methodologies and the proposed model. Table II displays the results. The system's performance is evaluated by comparing the service provided by the cloud during normal and outage periods. The obtained result is shown below in Table III which is compared with existing methods also.

The above table shows the service time of each request without the resource scale down. When the attack occurred in the system the victim server (cloud server) will process the request, the Table IV shows the proposed model taking less time to process the request than the other two.

Table V shows the service time of each request without the resource scale down. When the attack occurred in the system the victim server (cloud server) will process the request, the Table III shows below describe the proposed model taking less time to process the request than the other two. Tables II and III show that the new system works faster than the previous technique. The average value from each table is calculated and it is observed that the proposed system's average value is less than the earlier methodologies. The proposed approach has a detection rate of 93 percent on

average. As a result, the suggested technique outperforms the other current methods in terms of detection rate. Also, the proposed system service the request at a high rate than the others, the average service time of the request is 41.3s at the normal rate and 76s during the attack period (see Fig. 6 to 8).

TABLE III. PERFORMANCE COMPARISON OF ATTACK DETECTION

Resources request	SIO	ANTI-DDOS	Proposed model

## VI. DISCUSSION

This paper proposed a new model IDCLB-FL using the integration of Dynamic Load balancing (Min-Max load balancing is used) with Fuzzy Logic. The cloud user CU provide request to the cloud server, the cloud server provide the resources required for the user as their demand. The problem discussed in this paper is the high rate Ddos atack which provide a huge running traffic request along with the legitimate user request. To detect the normal legitimate user

request and unwanted attacker request, a proposed model was designed with 2 phase of detection process. The 2 phase of the model is VV model and LB model, one phase is used to deytected the DDoS traffic and other phases are to balance the load of each request. The feature considered in the VV procedure is:

1) The first feature of In and out requestion ratio is calculated as the  $R_{ss}, R_{ds}, R_{io}$  value to compare withe condition  $R_{ss} < R_{max} \ \&\& \ R_{ds} < R_{max} \ \&\& \ R_{io} \leq 1$  and based on the analysis, it set the  $Att_{flag}$  as 1 or 0.

2) Other feature used in VV procedure is the Entropy calculation of each request based on the protocol used by the traffic request as  $E_p \neq 0 \ \&\& \ deviation \ (R_T, R_U, R_I) \ low$  and based on the analysis, it set the  $Att_{flag}$  as 1 or 0.

3) The last feature is IP flow along with the entropy value calculated as,  $5 < L_{ipflow} < 10 \ \&\& \ 2 < E_{ipflow} < 4$  and based on the analysis, it set the  $Att_{flag}$  as 1 or 0.

4) As the value is of  $Att_{flag}$  is set to 1 or 0, the LB model is processed and if  $Att_{flag}$  value is 1 then the resource is reduce to be 50% of  $RUF_{nor}$  ( $RUF_{att} = 1/2(RUF_{nor})$ ).

5) If  $Att_{flag}$  value is 1 then the resource is provided as  $RUF_{nor}$ .

## C. Limitation of the Proposed Model

The proposed model was test by providing 50 test requests with normal and abnormal traffic pattern. The limitation faced by the system is the time, when detection and verification process take 76s for the 50 requests, but if the number of requests increase the time also increases. Second limitation of the proposed model is that, it is not able to detect the low-rate DDoS attack occurs along with the normal traffic. Third limitation is that, the entropy calculation of each request should lie between the range of 0 and -1, but some time, some normal request also shows the entropy value in this range itself and set the flag as 1 i.e. attack request. So, the proposed model shows a fatal rate of 0.2%.

## VII. CONCLUSION AND FUTURE SCOPE

The cloud server's primary priority is protecting the cloud from numerous threats and vulnerabilities. A distributed denial of service attack is the most frequent vulnerability, which prohibits legitimate users from accessing resources. The analytical report received from the preceding experiment demonstrates an effective methodology for mitigating DDoS attacks. This solution provides an efficient framework for verifying each request and securing cloud server services and resources from being manipulated by an attacker. The proposed model is a combination of verification and load balancing, with the concept of fuzzy logic, which helps to detect the attack easily than the others with an average accuracy of 93%. The model effectively removes the high traffic (request) from a single session id and also verifies the other request by some criteria discussed in the implementation session.

The future work will focus on offering an improved method for identifying low-rate DDoS assaults, which are a concern in cloud systems. Also the improved method should reduce the fatal rate from 0.2% to 0%.

**Abstract**—Brain tumor is a fatal disease and one of the major causes of rising death rates in adults. Predicting methylation of the O6-Methylguanine-DNA Methyltransferase (MGMT) gene status utilizing Magnetic resonance imaging (MRI) imaging is highly important since it is a predictor of brain tumor responses to chemotherapy, which reduces the number of needed surgeries. Deep Learning (DL) approaches became powerful in extracting meaningful relationships and making accurate predictions. DL-based models require a large database and accessing or transferring patient data to train the model. Federated machine learning has recently gained popularity, as it offers practical solutions for data privacy, centralized computation, and high computing power. This study aims to investigate the feasibility of federated learning (FL) by developing a FL-based approach to predict MGMT promoter methylation status using the BraTS2021 dataset for the four sequence types, (Fluid Attenuated Inversion Recovery (FLAIR), T1-weighted (T1w), T1-weighted Gadolinium Post Contrast (T1wCE/T1Gd), and T2-weighted (T2w)) MRI images. The FL model compared to the DL-based and the experimental results show that even with imbalanced and heterogeneous datasets, the FL approach reached the training model to 99.99% of the model quality achieved with centralized data after 300 communication rounds between 10 institutions using OpenFl framework and the improved EfficientNet-B3 neural network architecture.

**Keywords**—Federated Learning (FL); BraTS2021; Data Privacy; O6-Methylguanine-DNA Methyltransferase (MGMT); OpenFl; EfficientNet-B3; brain tumors; Deep Learning (DL)

## I. INTRODUCTION

Brain tumors are a grave problem that threatens human life and leads to death if not diagnosed and treated early. Especially, Glioblastoma (GBM) and astrocytic glioma with molecular features of GBM (WHO Grade 4 astrocytoma). The glioblastoma multiform tumor is a highly malignant brain tumor. Most of these brain tumors occur in adults, and they are characterized by a wide range of symptoms. It has a poor prognosis with a median survival of about ten months in most cases [1]. Recently been discovered that, the presence of a specific genetic sequence in the tumor known as MGMT (O6-methylguanine-DNA methyltransferase) promoter methylation during GBM patient's chemotherapy is a significant and independent predictive factor of favorable survival in glioblastoma patients undergoing the treatment.

MGMT is a protein that repairs damage to the DNA of human body cells. The chemotherapy drugs cause damage to

tumor cells. Thus, the more MGMT protein the tumor produces, the less effective the chemotherapy drug is expected to be, as the protein will repair the damage to the tumor. The detection of MGMT requires the performance of a biopsy (removing tissue from the tumor and analyzing it) and can take several weeks depending on the results and the types of treatments initially implemented, subsequent surgery may be necessary [2]. The development of an efficient method of detection utilizing medical imaging (i.e., MRI, radio genomics) could potentially minimize the number of surgeries.

Deep learning (DL) based applications have shown promising results in this area but to cover all medical questions that can be applied to a vast patient population and ensure high and accurate performance, DL-based applications rely on large, diverse datasets from different health institutions [3]. This is particularly challenging due to the natural sensitivity of healthcare informatics, legal and cultural challenges. Each health institution (e.g., hospital, clinic, lab, etc.) is often resistant to sharing patient data. Moreover, the available data in a single institution is not adequate for the training due to the low incidence rate of brain tumor pathologies and limited patient numbers. These limitations raise the need to seek alternative approaches [4-6].

A recent surge in popularity has been witnessed by federated learning, a paradigm that offers great promise for learning with fragmented, sensitive data. By allowing training a global model through a central server while keeping the data in local institutions where they originated, rather than aggregating data from different places altogether or using the traditional discovery and replication approach, a shared global model can be trained [7-9]. The main idea is moving computations to data, where a globally shared model is brought to where the data is.

## II. MOTIVATION AND CONTRIBUTION

In this study, a set of contributions are achieved using the proposed study:

- 1) Development of an improved EfficientNetB3 model relying on the combination of convolution neural network (CNN) and Recurrent neural network (RNN) architectures.
- 2) Four types of Scans are used in this study, while other related work depended on only one or two scans.
- 3) Two approaches are applied based on classical and federated learning.

4) The federated learning showed the ability to deal with data privacy, diversity, real time continuous learning, and hardware efficiency.

### III. RELATED WORK

Recently, machine learning and deep learning techniques have been used to predict MGMT status, and it achieved satisfactory results. Korfiatis et al. in 2017 trained three residual deep neural network architectures, ResNet18, ResNet34, and ResNet50 in order to predict MGMT methylation status based on MRI scans with T2 and T1 weighted post-contrast images obtained from Mayo Clinic. [10]. in another work by Yogananda et al., 2021, Based on 3D-Dense-UNets, they developed a T2WI-only network (MGMT-net) to detect MGMT methylation status and segment tumors. Using MRI scans from The Cancer Imaging Archive (TCIA) and The Cancer Genome Atlas (TCGA) datasets [11]. The deep-learning approach developed by Chen et al., 2022 for MGMT promoter methylation using MRI scans of 111 patients was based on ResNet18 with fivefold cross-validation. Four sequences were analyzed for radiomics features for two regions of interest (the whole tumor area and the tumor core area), including T1 weighted images (T1WI), T2 weighted images (T2WI), apparent diffusion coefficient maps (ADC), and T1 contrast-enhanced images (T1CE) [12].

Despite the efficiency of the mentioned works but all of them depended on the classical way of learning, That Lacked patient privacy protection. Even removing metadata such as names or dates of birth is insufficient to protect privacy because it is possible to reconstruct a patient's face from MRI data. This sensitivity of healthcare informatics directed the researchers toward using federated learning in the healthcare applications such as federated medical imaging, federated remote health monitoring, and federated EHRs management applications [13, 14]. Due to the novelty of the approach, there are a few articles on Brain tumor diagnosis using federated learning, and almost all of these articles focus on brain tumor segmentation only.

The first use of federated learning in a multi-institutional collaboration was presented by Sheller et al. in 2019, allowing deep learning modeling without sharing patient data. They used the Brats dataset and achieved 99% of the model performance with a data-sharing model. They compared federated learning with two alternative collaborative learning methods, Cyclic Institutional Incremental Learning (CIIL) and Institutional Incremental Learning (IIL). The comparison shows that these two methods failed to match the performance of federated learning. Even though CIIL may seem like a simpler option, full validation should be carried out periodically, such as at the end of a cycle, which will help in selecting a good model. The validation process would need the same synchronization and aggregation steps as FL and would even add communication costs over FL. in addition, a large number of institutions with small amounts of data do not scale well with IIL and CIIL [15].

Using a deep neural network, Li et al. applied federated learning for the segmentation of brain tumors using the BraTS dataset as a part of the NVIDIA Clara Train SDK. They

studied various practical aspects of the federated model sharing with an emphasis on preserving patient data privacy. While a strong differential privacy guarantee. The experimental results show that the FL training was done at twice the number of epochs in the data centralized training to reach the same result [16].

An FL-based cross-site modeling platform has been proposed by Guo et al. in 2021 for the reconstruction of MRI images collected from a variety of institutions with different scanners and acquisition protocols. The experiments were conducted on a variety of datasets with promising results. Hidden features were aligned with hidden features extracted from various sub-sites [17]. Table I summarizes the effective methods for predicting the MGMT methylation status based on the Classical and the recent federated learning approaches for brain tumor diagnosis.

### IV. MATERIALS AND METHODS

#### A. Training Model

The training model is based on an improved EfficientNet-B3 architecture relying on RNN layers. The EfficientNet-B3 was released by Google in 2019. It is a convolutional neural network architecture and scaling technique that uses the compound coefficient technique to uniformly scale depth, width, and resolution in a simple and efficient manner. Which make it is better at analyzing images than the existing Artificial intelligence models such as ResNet, inception and DenseNet [18]. The EfficientNet-B3 is a part of the EfficientNet family, which ranges from B0 to B7. B3 was selected among this family because it offers a good compromise between computational resources and accuracy. The compound scaling method uniformly scales each

dimension with a certain fixed set of scaling coefficients. Instead of randomly scaling up width, depth, or resolution. Equation (1) show how it is achieved mathematically.

Fig. 1 illustrate the architecture of the proposed model. The fully connected features extracted from the EfficientNetB3 are input to a proposed RNN architecture based on a long short term memory (LSTM) layers. The fully connected layer output is input to a sequence input layer, 2 LSTM layers, 2 dropout layers, 1 fully connected layer, and a Softmax layer.

$$S.t. \alpha \cdot \beta^2 \cdot \gamma^2 \approx 2 \quad (1)$$

$$\alpha \geq 1, \beta \geq 1, \gamma \geq 1$$

compound coefficient:  $\phi$

depth:  $d = \alpha^\phi$

width:  $w = \beta^\phi$

resolution:  $r = \gamma^\phi$

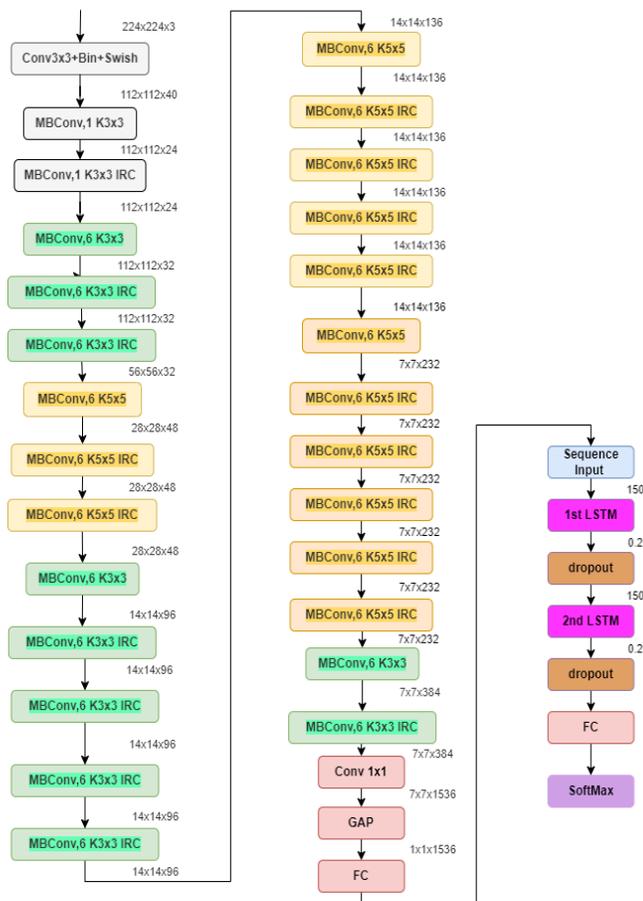

Fig. 1. The Improved EfficientNet-B3 Model Architecture.

The training process carried out on four distinct models based on the scan type FLAIR, T1w, T1wCE, and T2w respectively. Each model calculates a probability that the model belongs to class 0 (no presence of MGMT) or class 1 (present presence of MGMT).

Algorithm 1 shows how the final score per patient is obtained. Although the training model works on each scan

type separately, each scan type has the same pre-processing and training steps. All the resulted predictions are aggregated to finally predict the MGMT value of each patient. The results of the prediction are aggregated together for each patient in order to get the most confident result reached out of all predictions. The aggregation process is applied by obtaining the mean of the four types of scans for each patient individually. Moreover, the maximum and the minimum are also calculated. Then, the difference between the mean and the maximum, and also the variance between the mean and the minimum is compared. Finally, the nearest difference to the mean is the optimal value (maximum or minimum).

**Algorithm 1** Predicting MGMT Value

**Start**

Predicted\_MGMT\_Value: List

**For each scan type** ['flair', 't1w', 't1wce', 't2w']:

T\_df, V\_df, ← training and validation sets data frames

Ts\_df ← testing set data frame

T\_g, V\_g, Ts\_g ← Augmentation (T\_df, V\_df, Ts\_df)

Best\_model ← train\_model (MRI, T\_g, V\_g, E=20)

Ts\_pred ← best\_model.Prediction (Ts\_g)

Ts\_df [Pred\_y] ← Ts\_pred

M\_pred ← Ts\_pred.mean ()

Ts\_pred\_agg ← Aggregate the predictions results on

all MRI types for each patient

**For each patient\_id:**

Ts\_pred\_agg ← Max (Ts\_df [Pred\_y])

**If** Max (Ts\_df [Pred\_y]) – M\_pred > M\_pred – Min (Ts\_df [Pred\_y])

**Else if** Min (Ts\_df [Pred\_y])

**End if**

**End**

Predicted\_MGMT\_Value ← Ts\_pred\_agg

**End**

**End**

Data augmentation is performed on the images and the type of augmentation applied was based on geometric techniques. The augmentation step aims to balance the number of images in each class before training. The model takes the whole training and validation data (Original and augmented) as an input. The epochs of the model are defined with 20 (E=20), whereas the number of iterations for each epoch is equal to 58. This forms a total of 1160 iterations for the entire model.

**B. Federated Learning**

To preserve patient data privacy, we need to eliminate the existence of a centralized dataset to prevent data movement and share it with others. On the other hand, the single medical site has its data only, which is a bit amount of data and insufficient to train the model. Federated learning (FL) is a data-private collaborative learning approach that enables multiple health institutions to parallel train a machine learning model at the same time using their own data [19].

The general architecture of federated learning consists of four main components. Fig. 2 illustrates the architecture of the federated learning approach. The training model learned using the local dataset and sends the results to the central server (Aggregator), the server sends these results to the global

model to learn from it. After that, the global model sends back the updated results to all the local models. The whole training process is done through several communication rounds between the aggregator and the collaborators.

- **Aggregator:** is the responsible for the aggregation process, receives updates and results from each local model, and feeds them with the updates.
- **Collaborator(s):** represent the medical institutions.
- **Local Model:** learn from the local data.
- **Global Model:** learn from the local model gradients.

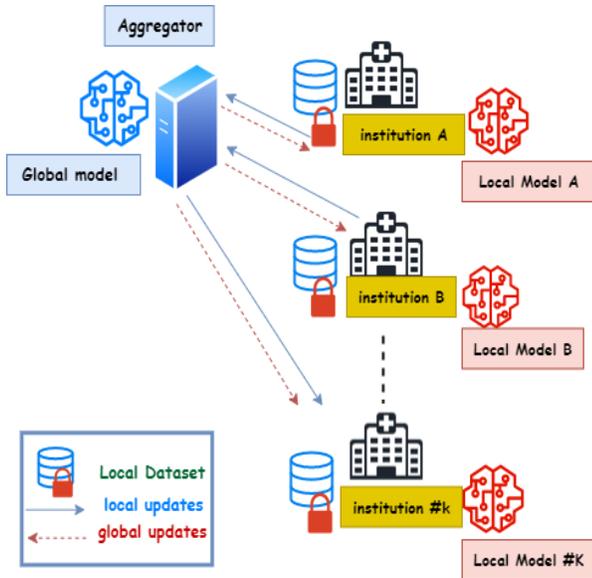

Fig. 2. The Architecture of the Federated Learning Approach – Hospitals Represents the Medical Institution.

In this way, FL enables connecting data from different institutions while not requiring any movement of patient data. Furthermore, FL solves insufficient data volume problem in a single institution.

## V. EXPERIMENTAL RESULTS

### A. Experimental Setup

1) *BraTS Dataset:* collaboration with the MICCAI Society (the Medical Image Computing and Computer-Assisted Intervention Society), the Radiological Society of North America (RSNA) provided a massive dataset of MRI scans from patients diagnosed with gliomas (BraTS2021) [20]. These scans were obtained from various institutions under standard clinical conditions, and various imaging equipment and protocols were used to produce a heterogeneous image quality reflecting the diverse clinical practices at different institutions. Four different sequence types of images are collected for each patient (Fluid Attenuated Inversion Recovery (FLAIR), T1-weighted (T1w), T1-weighted Gadolinium Post Contrast (T1wCE/T1Gd), and T2-weighted (T2w)). A total of 585 scans were collected for the training set and 87 scans were collected for the testing are sorted by the

patient ID. A binary label is used to describe the methylation status of the MGMT promoter (0: unmethylated, 1: methylated). Fig. 3 shows four types of scans for two patients with various MGMT\_value.

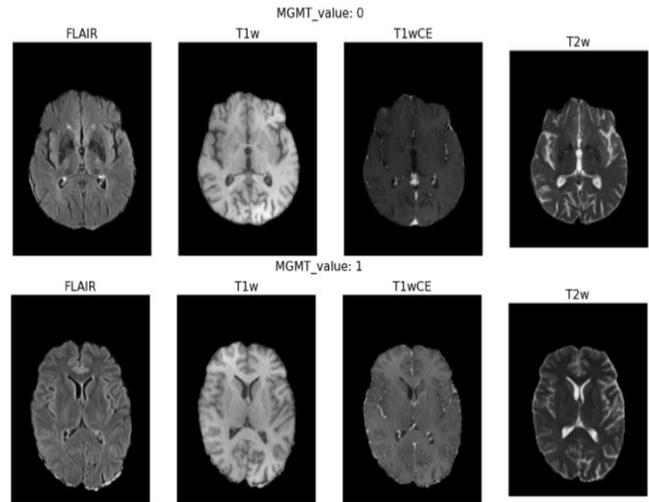

Fig. 3. Sample from the Dataset Includes Two Patients with two different MGMT\_Value.

2) *Data Pre-Processing:* This dataset is presented in DICOM (Digital Imaging and Communications in Medicine) format, which is extremely complex and inefficient for image processing and analysis. DICOM has the drawback that a single volume is stored as a series of 2D slices. The FLAIR sequence of patient #00014 is 74 slices as shown in Fig. 4, while the FLAIR sequence of patient #00000 contains 400 slices, making it extremely challenging to analyze.

To facilitate the data handling, the DICOM sequences were converted to the NIfTi (Neuroimaging Informatics Technology Initiative) format.

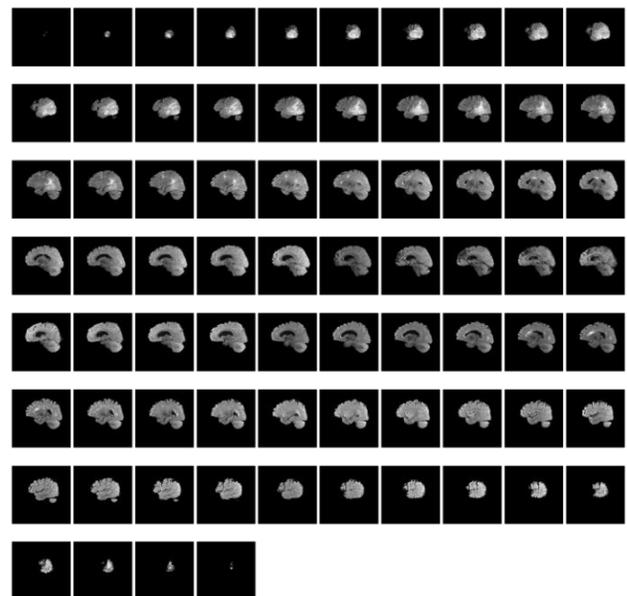

Fig. 4. The FLAIR Sequence of Patient with ID #00014.

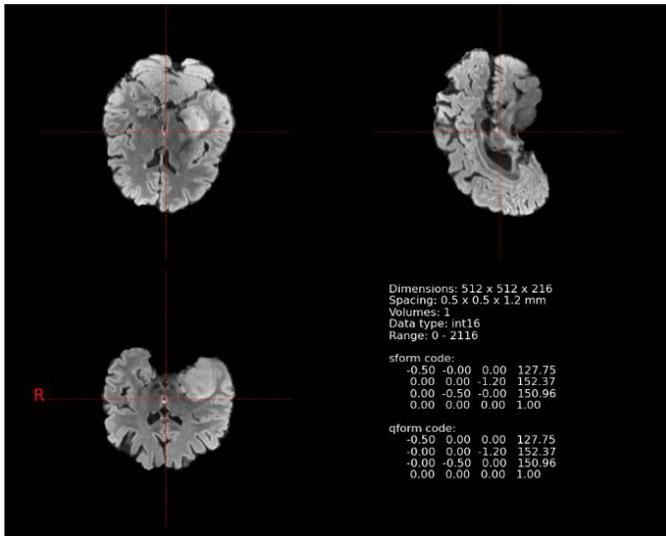

Fig. 5. FLAIR Sequence of Patient 00014 after converting it to the nii Format.

Fig. 5 shows the FLAIR sequence of patient #00014 that was displayed before in Fig. 5 after converting it to NIfTi format. The generated NIfTi file has 512 x 512 x 216 dimensions in x, y, and z. In both x and y dimensions, the spacing between slices is 0.5 mm, and in z dimensions, it is 1.2 mm.

In each NIfTi file, the header file contains sform and qform code matrices, which are always related to the input image. These code matrixes are appropriately remapped when padding, cropping, or applying affine spatial transformations. Whenever the sform is set in processing operations that deal with a single image, it is transformed in the same manner as qform. These matrices displayed in detail with Fig. 6.

Some simple preprocessing transformations applied to the NIfTi files. They normalized, resized and rotated to be easier in loading and processing Fig. 7 displays the nii file for the same patient after applying those preprocessing steps. After resizing the NIfTi files, they have x, y, and z dimensions of 128 x 128 x 64, with a spacing value of 1.0 millimeters between slices. After normalization, the range is reduced from 0-2116 to -1.0-1.0. Furthermore, sform and qform code matrix values have been changed.

3) *Data partitioning*: The host of the provided dataset has confirmed that these three cases have some issues in the training dataset. For the two patients with ID #00109 and #00709, the FLAIR sequences are blank, and for the patient with ID #00123, the TW1 sequence is blank. As a result, 582 patient’s cases were successfully trained. We shared the two training and testing datasets with 10 collaborators, corresponding to the 10 institutions that exist in real life. The resulting patient counts for each of the institutions, which we will refer to as collaborators (C) 1–10 are given randomly with high variations. A local validation set, consisting of 10% of training data of each institution, is also held out as a validation set. The actual numbers of patients at each institution in the training, validation, and testing datasets illustrated in Table II.

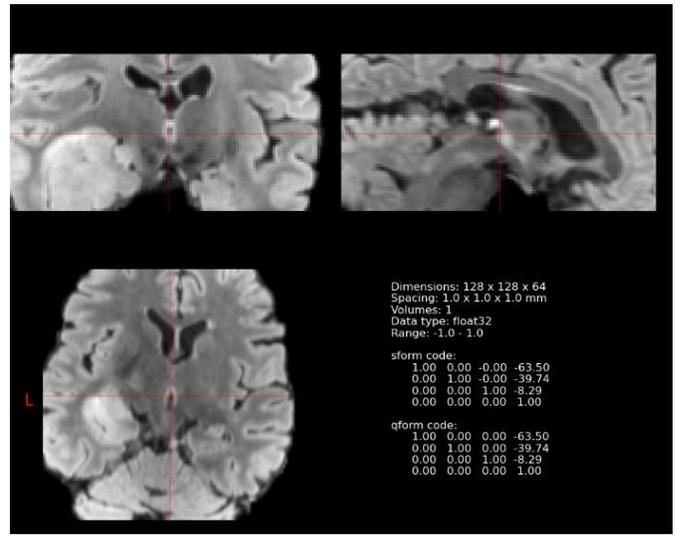

Fig. 6. The FLAIR Sequence of Patient 00014 after the Normalization Process.

TABLE II. PATIENTS DISTRIBUTION FOR EACH COLLABORATOR

Collaborator #Number	Number of Patients		
	Training	Validation	Testing
C1	72	8	10
C2	63	7	9
C3	67	8	9
C4	54	6	8
C5	31	4	8
C6	58	7	8
C7	45	5	9
C8	36	4	8
C9	32	4	8
C10	63	7	10

The data partitioning process followed the Horizontal partitioning (sharding) strategy which partitioned the dataset into multiple different datasets. The partitions all share the same features but have entirely different patients. Similarly, each partition has its own set of data.

4) *Work flow*: Federated Learning projects require a trusted execution environment to support the development process and facilitate the implementation of all necessary features in a secure manner. OpenFL is an open-source Python 3 framework for federated learning developed by Intel Labs in collaboration with the Internet of Things Group. Through a plugin mechanism, ML models and neural network training frameworks such as Tensor Flow and PyTorch can be used to train models. Communication between participants is secured by certificates [21].

OpenFL can be used to establish and run experiments with federations in two different ways: via Director-based workflows and Aggregator-based workflows. Fig. 7 illustrates the Aggregator-based workflow in OpenFL framework, which

is the chosen workflow in the conducted experiment. The federation runs between the aggregator node which owns the learning model and an arbitrary number of collaborators. This workflow is based on creating a workspace at the aggregator node and sending this workspace to each collaborator individually.

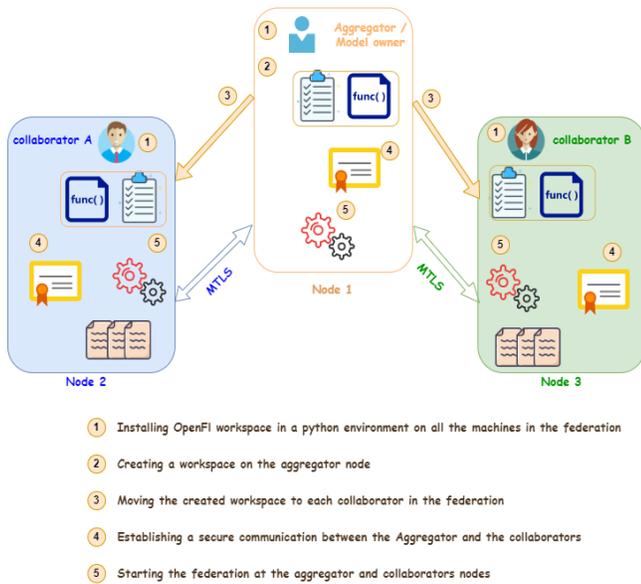

Fig. 7. The Architecture of the Aggregator-based Workflow.

This workspace consists of the plan and the learning model. The plan is a YAML file where the experiment settings are defined and is used to modify the workspace to the needed requirements such as the address of the aggregator, the global model that will be sent to collaborators, the number of federation rounds, and the encryption for network connections. Other parameters describing the model training process can be included as well.

To establish the connection, all participants must provide a valid public key infrastructure certificate signed by a trusted certificate authority (CA). OpenFL uses mutually authenticated transport layer security (TLS) connections. It is possible to create a certificate authority and generate X.509 certificates with OpenFL, but it is intended only for non-production testing. Once the connection is established, the federation starts with the aggregator and the collaborators.

### B. Practical Considerations

1) *Training parameters:* Several parameters are adjusted to the EfficientNetB3 architecture to achieve high accuracy performance. The first parameter is the optimizer, and it is selected to be adaptive moment estimation (Adam). The second parameter is the learning rate, and it is set to 0.001. The third parameter is the number of epochs of the model, and it is defined with 20, whereas the number of iterations for each epoch is equal to 58. In order to prevent overfitting, batch normalization is added and a 40% dropout is added before each fully connected layer. A sigmoid activation function is used on the last layer to resolve the two-class classification problem. A binary-crossentropy function is used for the cost

function to solve the two-class classification problem. Also, some parameters are adjusted to the proposed RNN architecture. The number of neurons of each LSTM layer is 150, and the dropout layer has a probability value of 0.2.

2) *Plan parameters:* The experiment conducted with 10 collaborators represent the 10 institutions and lasted for 300 communication rounds to achieve the same results. OpenFL framework supports four aggregation algorithms in this experiment the FedOpt algorithm is used with the Adam optimizer.

### C. Experimental Results

We conducted two experiments the first, followed the classical way of learning, the training model use a centralized dataset to predict the MGMT value. In the second, we use the same data set and the same Learning model but with the federated learning approach. The main goal is to show that the developed FL-based model can perform the same as the DL-based model in addition to persevering the patient's privacy, preventing data transferring and aggregation from data owners, and using less computational power, which makes it better for healthcare applications. The two developed model were evaluated according to the performance of the model and the resulting values of the MGMT promoter methylation.

1) *Model performance:* To test the performance of the machine learning model, 10% of the dataset has been allocated for testing the model and it achieved accuracy with a score 96.21% and with 3.783 loss.

The following line charts Fig. 8 illustrate the classical model performance over the twenty epochs for each scan type. a and b represent the training accuracy and Loss of the four scan types and each scan type is colored by a specific color. The first two scan types are colored in yellow and black for Flair and T1w respectively, while the last two scan types are colored in red and blue for T1wce and T2w, respectively. The validation accuracy and loss represented in c and d, respectively.

The Federated learning model was also tested on 10% of the dataset and achieved an accuracy of 96.713% and a loss of 3.287. Fig. 9 shows the performance of the same previous model but as the global model in the FL experiment in terms of training and validation. a and c manifest the validation and training accuracy curve in the yellow and blue colors over 300 rounds and b and c manifest the validation and training loss.

2) *Predicted MGMT\_value:* The presence of the MGMT protein is the main desired results of the proposed approach and the most important factor to measure the effectiveness of Federated Learning approach. The results of the two models are shown In Table III and Table IV. Using both federated and classical learning respectively. Each table consists of three columns. The first column represents the records of the patients, while the second column describes the patient ID and it was provided with the dataset, whereas the last column presents the predicted MGMT value. The predicted MGMT value for each patient in the two models are the same, which ensures the efficiencies of the federated

model to work as the classical one and produce the same results.

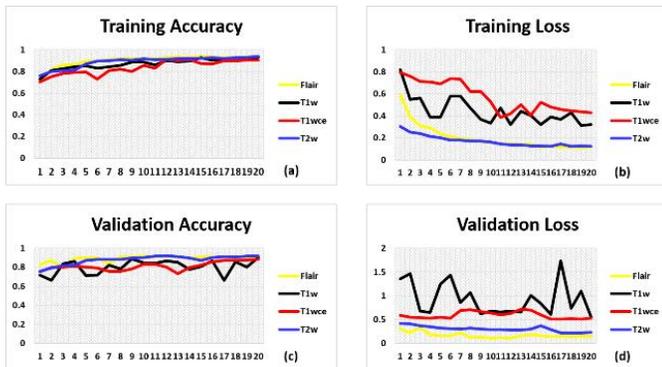

Fig. 8. (a) and (b) Represent the Training Accuracy and Loss for Four Scan Types and (c) and (d) Illustrates the Validation Accuracy and Loss for the Same MRI Scan Types.

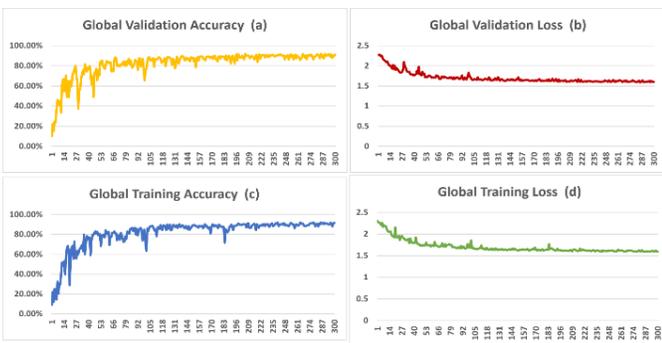

Fig. 9. (a and c) Represent the Global Accuracy Curves on the Training and Validation Data (b and d) Represent the Loss Obtain from the Training and Validation Data.

TABLE III. RESULTS OF THE FEDERATED LEARNING MODEL

Federated Learning Results		
Record	BraTS21ID	MGMT_value
0	1	0.6135
1	13	0.4693
2	15	0.4871
3	27	0.6152
4	37	0.4731
----	-----	-----
80	826	0.5684
81	829	0.5231
82	833	0.4285
83	997	0.5021
84	1006	0.5481

Several trials were applied using different values for the round number. The trials started from 10 rounds till reached 500, and at 300 rounds the performance of the federated and the classical learning was approximately identical. The MGMT values from both models show a 99.99% similarity degree.

TABLE IV. RESULTS OF THE CLASSICAL LEARNING MODEL

Federated Learning Results		
Record	BraTS21ID	MGMT_value
0	1	0.6135
1	13	0.4693
2	15	0.4871
3	27	0.6152
4	37	0.4732
----	-----	-----
80	826	0.5684
81	829	0.5231
82	833	0.4285
83	997	0.5021
84	1006	0.5481

A sample of 87 patients was used in the experiment for testing and obtaining their MGMT values. Fig. 10(a) and (b) visualize the probability distribution of the patients using federated and classical learning respectively. Each class in federated learning is exactly equal in the number of patients to its corresponding class in classical learning.

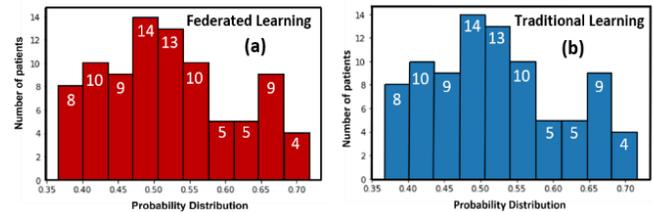

Fig. 10. (a) MGMT Probability Distribution using Federated Learning (b) MGMT Probability Distribution using Classical Learning.

## VI. DISCUSSION

The study proposed a methodology based on an improved efficientNetB3 model for the predicating the MGMT promoter methylation of GBM brain tumor with the aim of measuring the response of the tumor to the chemotherapy. At the beginning the data were obtained from the BraTS2021 dataset entirely. The next step is converting the images from the DICOM to NIFTI format. The reason for this conversion is to enhance the performance and it can be easy and simple in the processing. Then, the images in the NIFTI format are normalized to be ready for feature extraction using the improved efficientNetB3. The features are extracted using the improved efficientNetB3 based on the combination of the CNN and RNN architectures. The entire methodology ran using two different approaches. The first approach is based on classical or conventional learning, while the second approach relies on the federated learning. The illustrated results in Table III, Table IV and Fig. 10, show that the proposed federated model architecture using the OpenFl framework and the BraTS2021 dataset through 300 communication rounds between the aggregator and 10 collaborators managed to surpass the limitation of the classic training model in the following points:

1) *Data privacy*: Each one of the ten collaborators participates in the training process while, keeping its data private, only sharing results and its model gradients.

2) *Data diversity*: Federated learning facilitates training the machine learning model with various and diverse datasets from different institutions, eliminating the need for a centralized data center while making the local data of each collaborator sufficient for the training process as the local training model utilizes its local data and the gradients of the other collaborators.

3) *Real-time continual learning*: Continual learning is done by using client data instead of aggregated data to improve models.

4) *Hardware efficiency*: Since federated learning models operate without a central server, less complex hardware is needed.

## VII. CONCLUSION AND FUTURE WORK

Our study explores various practical aspects of the federated model sharing with an emphasis on protecting the privacy of patient data in order to predict the MGMT promoter value of brain tumors. We demonstrate how clinical institutions can train their models without sharing their data by using federated learning. Our FL experiments shows that even with imbalanced datasets, such as the BraTS institutional distribution the FL approach among 10 institutions reached the training model to 99.99% of the model quality achieved with centralized data.

Incorporating such an FL system into a clinical setting for multi-institutional collaboration, which produces computer-aided analytics and assistive diagnostics, is expected to contribute to precision medicine at a catalytic level. Integrating knowledge from another institution into the trained models would be particularly beneficial since patient data wouldn't have to be shared, thereby removing concerns about privacy and data ownership. As a result, the final accuracy achieved a value of 96% on both classical and federated learning. This proves that the federated learning is more efficient in all terms as an environment than the classical learning.

We are striving to improve the performance of the FL model to achieve the results with a smaller number of communication rounds and reduce time consumption in addition to increasing the number of collaborated institutions and exploring different workflows using swarm intelligence.

**Abstract**—At present, most people prefer using different online sources for reading news. These sources can easily spread fake news for several malicious reasons. Detecting this unreliable news is an important task in the Natural Language Processing (NLP) field. Many governments and technology companies are engaged in this research field to prevent the manipulation of public opinion and spare people and society the huge damage that can result from the spreading of misleading information on online social media. In this paper, we present a new deep learning method to detect fake news based on a combination of different word embedding techniques and a hybrid Convolutional Neural Network (CNN) and Bidirectional Long Short-Term Memory (BILSTM) model. We trained the classification model on the unbiased dataset WELFake. The best method was a combination of a pre-trained Word2Vec CBOW model and a Word2Vec Skip-Word model with a CNN on BILSTM layers, yielding an accuracy of up to 97%.

**Keywords**—Deep learning (DL); Bidirectional Long Short-Term Memory (BILSTM); Convolutional Neural Network (CNN); Natural Language Processing (NLP); fake news

## I. INTRODUCTION

Nowadays, social media has become an integral part of people's lives [1]. It's a fertile ground for connecting people, creating and sharing information, and staying up to date on trending events [2]. However, these advantages, it's become more difficult for many people to find the difference between confirmed facts and low-quality information with purposefully false data, commonly known as fake news [3]. The increased prevalence of fake news is a worrying phenomenon that has the ability to influence individuals' decisions, opinions and that may lead to severe influence on both people and society [4]. Consequently, an increasing number of researchers are focusing their efforts on identifying dubious information and fake news on online social media platforms and trying to develop effective and automatic systems for detecting online fake news using Artificial Intelligence (AI) techniques.

AI techniques have been successfully used in recent years to solve different prediction and classification problems in large range of research fields [5]–[15].

Specifically, the use of either classic machine learning methods or deep learning techniques in the fake news

detection [16] have showed an encouraging results. Traditional machine learning approaches are ineffective for dealing with complicated real-world situations like Natural Language Processing (NLP) tasks and text classification [17], [18]. When compared to Machine Learning (ML) techniques, Deep Learning (DL) has shown significant improvements over time [19]. Furthermore, multiple preprocessing and feature engineering techniques are required for traditional ML algorithms. On the other hand, DL approaches may be able to automatically find useful features in content [20].

In this paper, we present a novel approach to detect fake news based on news content with concatenation of word embedding vectors, and a hybrid approach that combines Convolutional Neural Network (CNN) and Bidirectional Long Short-Term Memory (BILSTM). The main contributions of this study are:

- Proposing a novel CNN-BILSTM hybrid approach and extensive experiments are provided to perform the proposed classifier.
- Using concatenation of word embedding technique Word2Vec (CBOW), Word2Vec (Skip-Gram) and Glove.

The rest of this paper is organized as follows: In Section II some important related works are cited. The mathematical problem formulation and the proposed fake news detection system architecture are described in Section III. The used methods of detection and classification are explained in Section IV. Results and discussion are given in Section V. Finally, Section VI concluded this paper.

## II. RELATED WORKS

In recent years, many researchers have attempted to create a system for identifying the fake news [21]–[28]. In [29], the authors achieved an accuracy of 92%. The authors used a Term Frequency and Inverse Document Frequency (TF-IDF) features-based approach to detect fake news, and only machine learning traditional classification techniques. The study compared six different supervised classifiers, K-Nearest Neighbor (KNN), Linear Support Vector Machine (LSVM), Logistic Regression (LR), Decision Tree (DT), Support

Vector Machine (SVM), and Stochastic Gradient Descent (SGD). The SVM classifier achieved the highest accuracy.

To detect emerging rumors of breaking news, the authors in [30] proposed an approach based on word embedding using Word2Vec and trains a recurrent neural network LSTM. The accuracy achieved was 79.5%. However, the model still requires more improvement. In another study [31], the authors proposed a hybrid method based on an LSTM-CNN model for the classification of tweets into rumors and non-rumors (fake vs genuine). The proposed method achieved an accuracy of 82%.

In [32], the authors used a hybrid method that combines BiLSTM with different CNN architectures to detect rumors. They use various pre-trained embedded layers. The best accuracy of the model was 86.12%. The authors of [33] used a hybrid method that combined CNN, LSTM, and BiLSTM to develop different models to detect fake news based on the relationship between article headline and article body. The best accuracy of the proposed models was achieved at 71.2%.

The authors in [34] proposed a novel approach based on word embedding over linguistic features by merging linguistic features with word embedding vectors, then using voting classification approach. The best accuracy achieved was 96.73%. In [35], the authors used linguistic features (stylo-metric, semantic, and syntactic, ...). Moreover, for classification they use voting method based on traditional machine learning algorithms. The best accuracy achieved was 96.36%.

### III. PROPOSED FAKE NEWS DETECTION SYSTEM ARCHITECTURE

#### A. Problem Formulation

In this paper, we introduce the problem of fake news detection as shown in Fig. 1.

Given a news content from a corpus of news titles, the objective is to determine if this text content is a fake news. We can formulate this task like a binary classification problem:

Let  $T_i = \{w_1; w_2 \dots w_L\}$  be a sequence of words (tokens) of length  $L$  of textual content  $T_i$ . Given  $T_i$  as an input, the first goal is to represent this sequence of words as a sequence of meaningful vectors  $E_{v_i} = \{u_1; u_2 \dots u_L\}$  with  $u_i \in \mathbb{R}^D$ , the second objective is to train a hybrid CNN-RNN model to classify  $E_{v_i}$  as a fake news or real news by giving a label from the set  $Y = \{0 : \text{for fake news} ; 1 : \text{for real news}\}$ .

#### B. Proposed Approach

We proposed a four-step framework to detect fake news based on news content. The structure of the proposed system is shown in Fig. 2.

In the first step, we start by applying a series of preprocessing operations on the input data. Among these preprocessing operations, reducing noise, deleting unnecessary repetitions, removing punctuation and alphanumeric characters [36].

Indeed, the preprocessing step is a critical stage in every NLP task. Before we provide the data to the DL model, we

cleaned the raw text by removing punctuation. In this step, we used predefined function in python and regular expression to replace all punctuation with empty string. Moreover, we tried to remove all alphanumeric characters such as hashtags and URLs. For every article, we convert all uppercase characters to lowercase. Finally, we split the cleaned article into vectors of words called tokens.

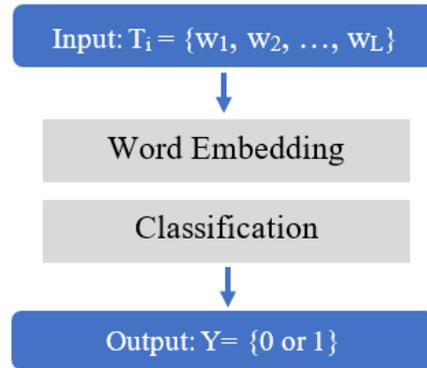

Fig. 1. Formulation of the Proposed Approach of Detection Fake News.

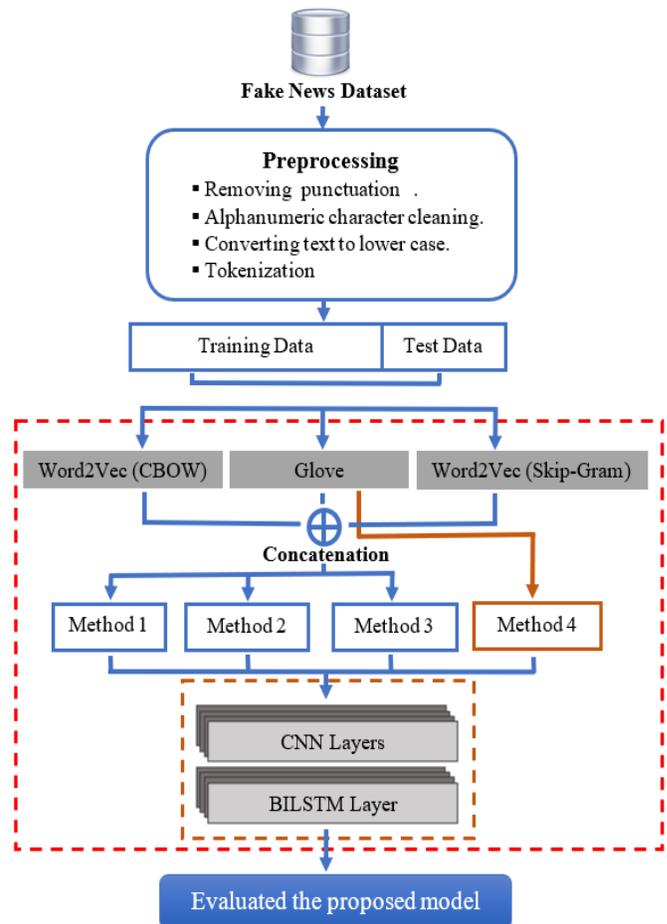

Fig. 2. The Flowchart of the Proposed Approach using CNN-BiLSTM Classifier.

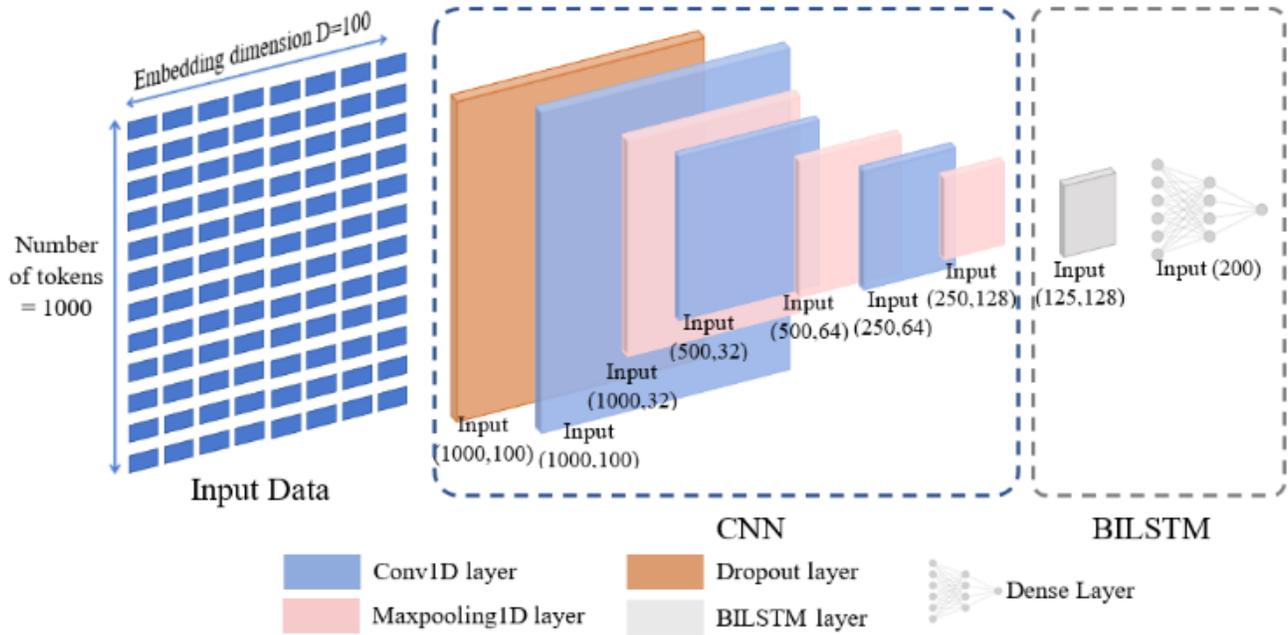

Fig. 3. The Architecture of the Proposed CNN-BILSTM Model

In the next step, the preprocessed input data was converted into word embedding vectors based on the concatenation of two word-embedding techniques. To study the influence of word embedding combination techniques on the proposed model, we proposed four methods to representing words. In method 1, we concatenate the obtained word representation vector using the Word2Vec (CBOW) and the Word2Vec (Skip-Gram) techniques. Method 2 was based on the concatenation of Glove and Word2Vec (Skip-Gram) vectors. In method 3, we concatenate the obtained word representation vector using the Glove and Word2Vec (CBOW) techniques. Method 4 (Baseline) used the Glove word embedding technique. For each method, we provide the obtained vectors to the proposed hybrid CNN-BILSTM network. Then, we conducted four different experiments to study the effect of concatenation. The next step was training the hybrid model. The objective of using CNN layers in this model architecture was to extract fake news features. While, the objective of using BILSTM was to capture the dependencies in the data. The fourth step is to evaluate and compare the application of the four methods on the model.

In Fig. 3, we illustrate CNN-BILSTM architecture used to train the model. From this architecture, we have the convolutional layer that plays a vital role in CNN architecture. It is comprised of a set of convolutional filters [37]. The input data is convolved with these filters to generate the output feature maps [38]. Moreover, the pooling layer is used to sub-sampling and reducing the feature maps dimension with preserving the majority of dominant information. The pooling layer applies statistical methods, such as max pooling, average pooling [39]. The BILSTM Layer. Finally, the Dense Layer consists to connect each unit (neuron) to all neurons of the previous layer and next layer. This layer is activated by an activation function and it is commonly utilized as the CNN classifier [40], [41]. To overcome the overfitting problem, we

used regularization technique based on dropout layers by dropping randomly a number of previous layer outputs during training. This technique is efficient for improving the performance of neural networks especially in vision, speech recognition, document classification tasks [42].

#### IV. MATERIALS AND METHODS

##### A. Dataset Description

In this study we use WELFake dataset from [34]. It is one of the largest available datasets that contains 72134 news articles with 37106 fake and 35028 real news. These datasets respect the standards and rules of creating unbiased fake news datasets [43] which in summary are: 1) All articles of dataset should be labeled by experts. 2) Fake news should be collected from different sources. 3) Obtain real news from credible journalism organizations. 4) Collect articles from a variety of news categories in order to create a diverse collection of credible news. The WELFake dataset contains two features (title, content). In addition, all articles are labeled as follow: 0 for fake news and 1 for real news.

As shown in Table I, the dataset was divided into two parts: The training dataset contains 57229 articles, which represents 80% of the global data. Moreover, the testing and validation dataset represent 20% with 14308 articles.

To have a clear view on the dataset, Fig. 4 illustrates the Word Cloud representation for each class.

TABLE I. NUMBER OF USED FAKE AND REAL NEWS ARTICLES

Label	Train	Validation and Test
Real	29207	7302
Fake	28022	7006
Total	57229	14308

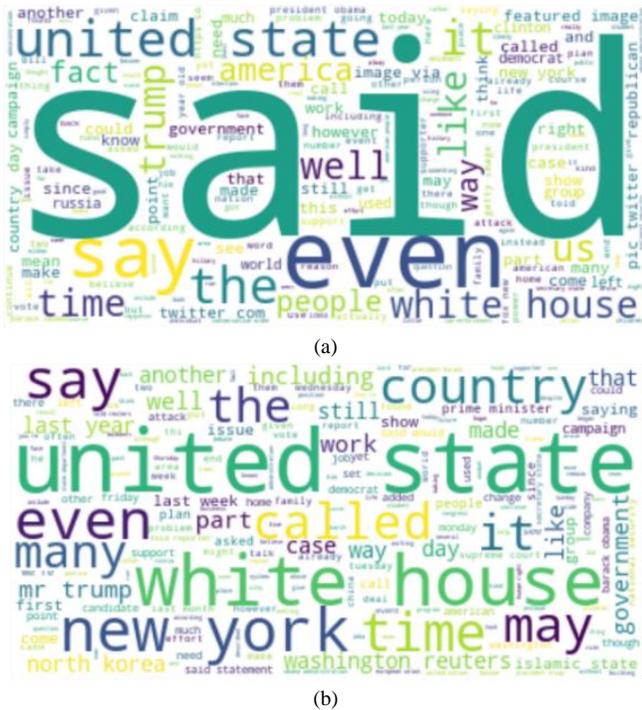

Fig. 4. Word cloud Representations of Dataset: (a) for Real News, (b) for Fake News.

**B. Word Representation**

Word Embedding (WE) is the representation technique of words that converts words to numerical vectors in  $\mathbb{R}^D$ , whose relative similarities correlate with semantic similarity [44]. Several pretrained word-embedding presentations exist for direct use. The most popular word embedding techniques are:

1) *Word2vec*: Word2vec is a well-known word embedding algorithm that has two main variants: Skip-Gram and CBOW, both of them are trained by using a neural prediction-based model [45], Skip-Gram predicts the surrounding words (context-words) from the target word [46]. Given a sequence of training words  $w_1, w_2, w_3, \dots, w_L$ , Skip-Gram models are trained by maximizing the average log probability:

$$\frac{1}{L} \sum_{t=1}^L \sum_{\substack{j=-c \\ j \neq 0}}^{j=c} \log p(w_{t+j}|w_t) \tag{1}$$

Where  $c$  is the size of the training context, and  $\{w_{-c}, \dots, w_c\}$  is the word context of the target word  $w_t$ . In contrast of Skip-Gram, the objective of Continuous Bag-of-Words Model (CBOW) is to predict a word given its context, CBOW models are trained by maximizing the average log probability:

$$\frac{1}{L} \sum_{t=1}^L \log p(w_t|w_{t-c}, \dots, w_{t-1}, w_{t+1}, \dots, w_{t+c}) \tag{2}$$

2) *Glove*: Glove is a model that produces a word vector space with meaningful substructure, a weighted least squares model trained on global co-occurrence counts of words and therefore making effective use of statistics [47]. The Glove model is trained by minimizing the loss function

$$\sum_{i=1}^L \sum_{j=1}^L f(X_{ij})(v_i^T u_j + b_i + c_j - \log X_{ij})^2 \tag{3}$$

Where  $v_i \in \mathbb{R}^D$  is the vector representation of the word  $w_i$ ,  $X_{ij}$  is a weighted count of times word  $w_j$  occurs in the context of word  $w_i$ ,  $u_j$  is separate context word vectors, Parameters  $c_j$  and  $b_i$  represent the bias terms for  $u_j$  and  $v_i$ , and  $f$  is the weighting function defined as follow:

$$f(x) = \min((x/x_{\max})^\alpha; 1) \tag{4}$$

There are different embedding vector sizes with  $D=50$ ,  $D=100$ ,  $D=200$ , and  $D=300$  dimensions. In this paper we choose the pretrained Glove model that trained on one billion words dataset with a dictionary of 400 thousand tokens and  $D=50$ .

**C. Deep Learning Methods**

1) *Convolutional neural network*: Convolutional Neural Network (CNN) is a sub-class of deep neural networks. It is particularly used for multimedia content classification tasks such as images and texts, and for time series analysis. One of the main advantages of CNN is recognizing significant features without human intervention [1] that means the ability to solve problems that not contain features which are spatially or temporally dependent. The CNN is inspired from Multi-Layer Perceptron (MLP). Every traditional CNN model includes an input and output layers, and a combination of hidden layers to extract discriminative features [48].

2) *LSTM*: Long short-term memory (LSTM) is an improved version of recurrent layers applied to learn order dependence in time series and sequence data. LSTMs are similar to RNNs, except that the hidden layer is updated using purpose-built memory cells in order to extract dependencies in the data [49]. Fig. 5 illustrates a LSTM memory cell structure.

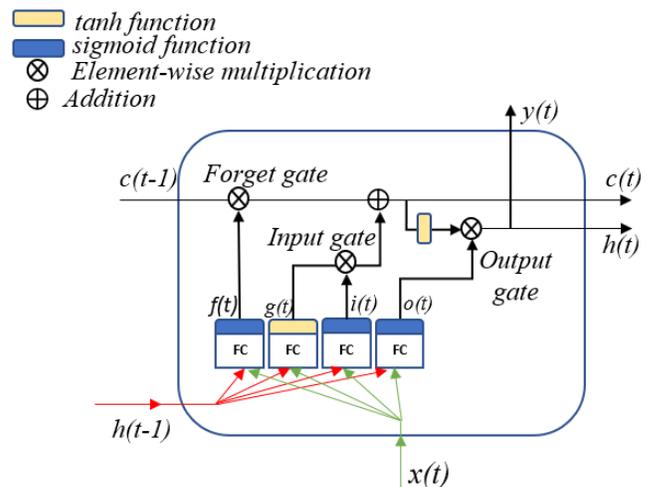

Fig. 5. Single LSTM Memory Cell.

LSTM cell is composed of three gates: input gate, forget gate and output gate. The functions of gates are defined as follow:

$$f_{(t)} = \sigma(W_{x_f}^T x_{(t)} + W_{h_f}^T h_{(t-1)} + b_f) \quad (5)$$

$$i_{(t)} = \sigma(W_{x_i}^T x_{(t)} + W_{h_i}^T h_{(t-1)} + b_i) \quad (6)$$

$$g_{(t)} = \tanh(W_{x_g}^T x_{(t)} + W_{h_g}^T h_{(t-1)} + b_g) \quad (7)$$

$$c_{(t)} = f_{(t)} \otimes c_{(t-1)} + i_{(t)} \otimes g_{(t)} \quad (8)$$

$$y_{(t)} = h_t = o_{(t)} \otimes \tanh(c_{(t)}) \quad (9)$$

$$o_{(t)} = \sigma(W_{x_o}^T x_{(t)} + W_{h_o}^T h_{(t-1)} + b_o) \quad (10)$$

Where, and  $W_x$  and  $W_h$  are the weight matrices and  $b$  is the bias.

3) *BILSTM*: The BILSTM neural network is an advanced version of LSTM. The BILSTM architecture contains LSTM units that function in both directions to integrate left and right context information. Bi-directional network consists of two parallel layers: The forward layer and backward layer extract representation of the left and right context. The outputs of these two layers are then concatenated to produce a complete representation of an element of the input sequence [50]. Fig. 6 illustrates the BILSTM network architecture.

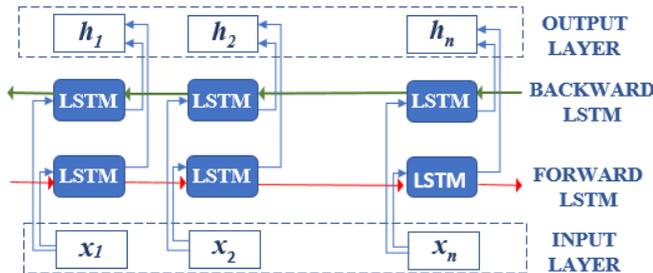

Fig. 6. Simple BILSTM Network Architecture.

## V. RESULTS AND DISCUSSION

### A. Experimental Setup and Optimal Algorithms Configuration

In this section, we present the experiment and evaluation results on fake news detection. The experimental models are implemented inside an open cloud environment Google Colab

that provides a Tesla K80 GPU with 12GB of GDDR5 VRAM. Python 3.7 and different libraries like TensorFlow and Scikit-learn are used to build the models. In order to find the optimum hyper-parameters of the proposed model, the experiments were conducted with grid search. Table II shows the optimal parameters setting of the model architecture.

### B. Evaluation Metrics

We use four metrics to evaluate the results based on the number of True Positives (TP), True Negatives (TN), False Positives (FP) and False Negatives (FN) in the binary classification:

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+TN+FN} \quad (11)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (12)$$

$$F_1 \text{ score} = \frac{2 * (\text{precision} * \text{recall})}{\text{precision} + \text{recall}} \quad (13)$$

$$\text{Precision} = \frac{TP}{TP+FP} \quad (14)$$

### C. Training Results

Fig. 7 shows the variation of accuracy and loss metrics across epochs. On training, the improvement in term of accuracy and loss of the three models is linear until the 10th epoch. After that, the training performance begins to stabilize and the improvement becomes slow. On the opposite, the validation performance increase with unstable manner.

TABLE II. PARAMETERS SETTINGS OF THE BILSTM-CNN CLASSIFIER

Parameter	Value
Vocabulary size	20 000
Input vector	1000
Word Embedded size	100
Number of convolutional layers	3
Number of filters	128
Filter size	3,5,7
Dropout rate	0,2
Activation function	Sigmoid
Number of epochs	15
Optimization	Adam

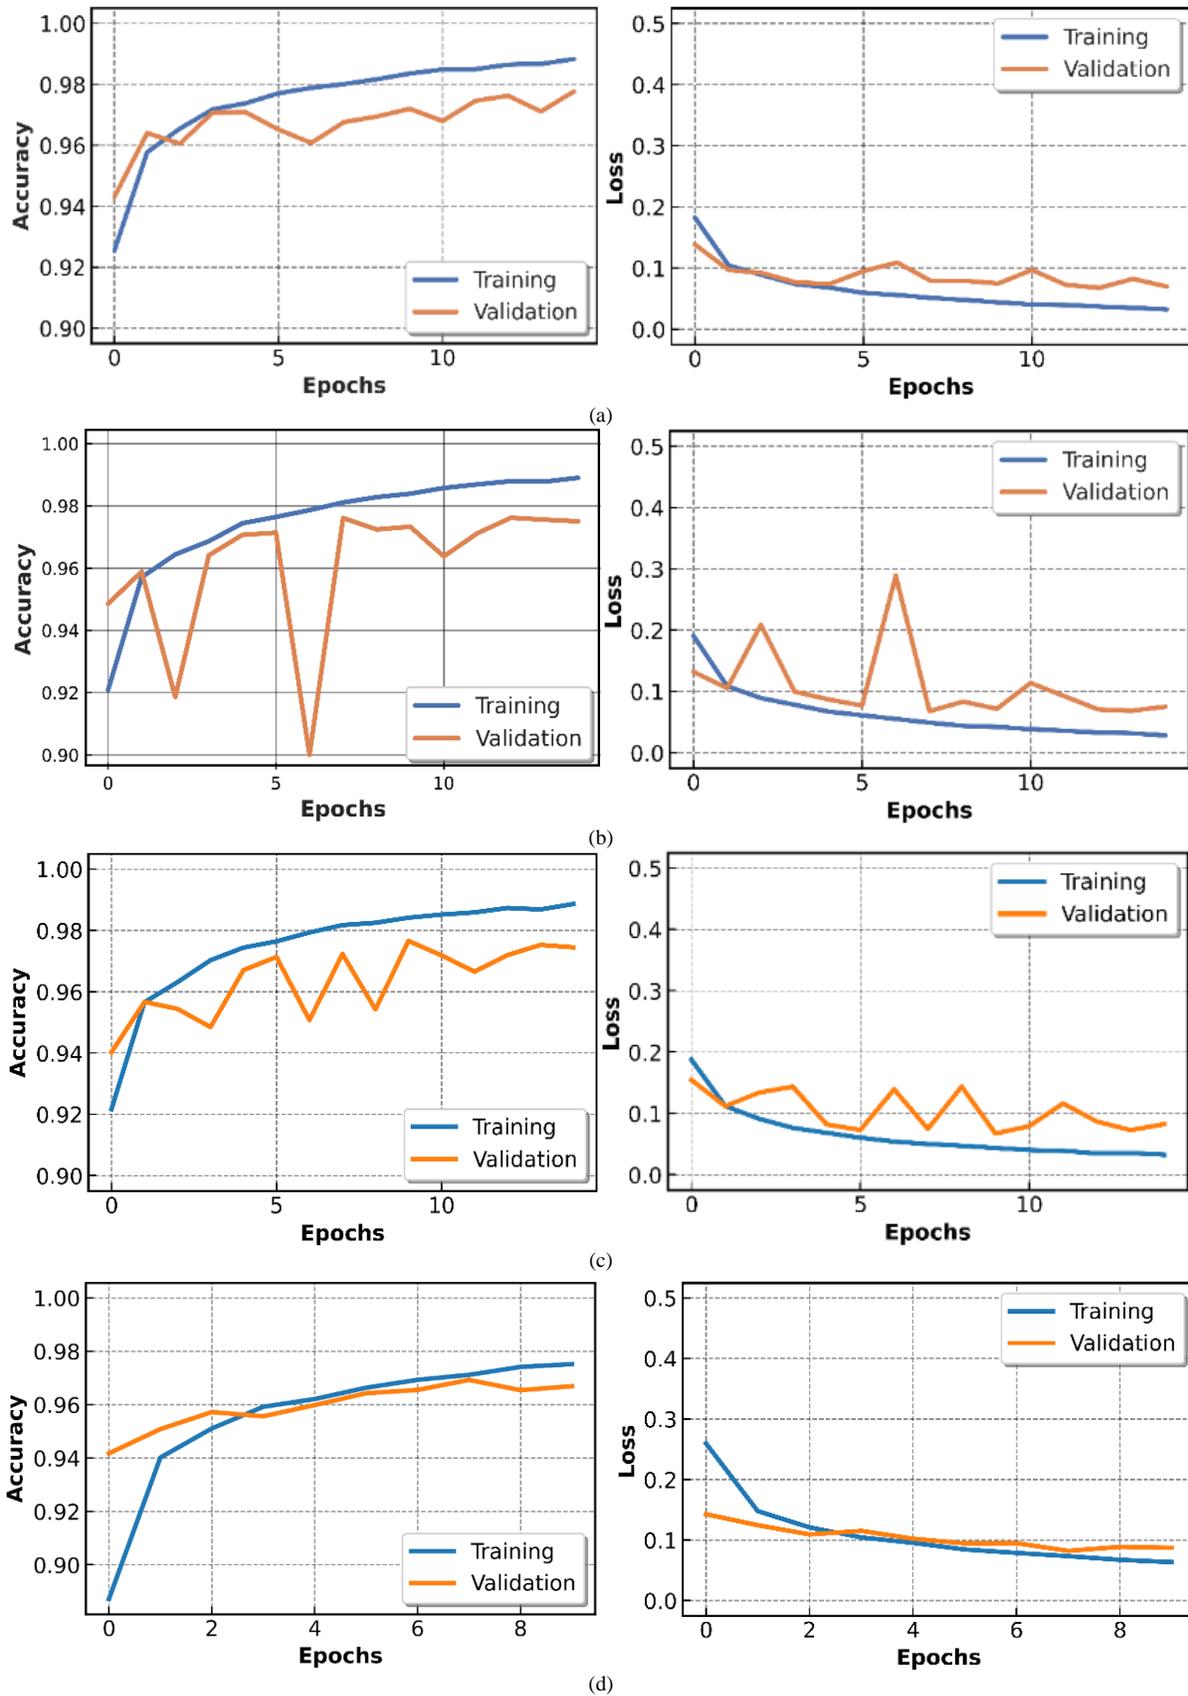

Fig. 7. Accuracy and Loss Curves Obtained by Training and Validating of Proposed Models. (a) Method 1, (b) Method 2, (c) Method 3 and (d) Method 4 (Baseline).

### D. Testing Results

Training a CNN models provides a prediction-ready model with the appropriate weights that corresponds to the task being performed. As indicated in Table III, a comparative result in terms of accuracy, recall, F1-score and precision of the model variants. We can clearly observe that the combined word embedded techniques reached an improvement when compared to baseline method.

Among all methods, the method 1 provided the best result in terms of accuracy (97.74%) and precision (97.74%). While, the method 4 based on one-word embedding technique is the lowest in term of accuracy, F1-score and Precision. The method 1 shows better performance in the detection of fake news. The confusion matrix of the proposed model is shown in Fig. 8. We found 3472 news was predicted as fake and was actually fake news. In addition, 66 news was predicted as fake was actually real. On the other hand, 3520 real news were predicted as real and was actually real. Moreover, 96 was predicted as real and was actually fake.

To investigate these findings, a ROC curve illustrating the sensitivity vs specificity (or False Positive Rate versus True Positive Rate) of a diagnostic test might be employed. This shape of the curve enables us to compare several models depending on the value of the AUC variable. This number indicates the total area under the ROC curve between two dimensions. This article depicts the ROC curve for each model considered in this investigation. Fig. 9 depicts a scatterplot of the False Positive Rate (TPR) vs the True Positive Rate (TNR) for the proposed CNN-BILSTM model using word embedding Method 1.

TABLE III. MODELS PERFORMANCE WITH DIFFERENT COMBINATION OF WORD EMBEDDING TECHNIQUES

	Accuracy	Recall	F1-score	Precision
Method 1	<b>97.74%</b>	97.35%	97.75%	<b>98.16%</b>
Method 2	97.71%	98.59%	97.75%	96.93%
Method 3	97.46%	96.99%	97.47%	97.96%
Method 4 (Baseline)	96.56%	97.54%	96.63%	95.74%

### E. Discussion

In this study, we proposed a hybrid deep learning model to detect fake news based on news content. we used WELFake dataset which is one of the biggest databases accessible and comprises 72134 news, of which 37106 are fraudulent and 35028 are authentic. These datasets adhere to the principles and guidelines of developing impartial fake news. The WELFake dataset includes two characteristics (title, content). Additionally, each article is categorized as follows: zero for false news and one for genuine news. In the first step, we started by applying a series of preprocessing operations on the input data. These operations include reducing noise, deleting unnecessary repetitions, removing punctuation and alphanumeric characters. The preprocessed input data was converted into word embedding vectors based on the concatenation of two word-embedding techniques.

In proposed system architecture, we presented four approaches to represent words in order to examine the effect of word embedding combination strategies on proposed model. In approach 1, the acquired word representation vector is concatenated using Word2Vec (CBOW) and Word2Vec (Skip-Gram). The second method was based on the union of the Glove and Word2Vec (Skip-Gram) vectors. The acquired word representation vector is concatenated using the Glove and Word2Vec (CBOW) approaches in method 3. Method 4 (Baseline) used the Glove approach for word embedding. We submit the acquired vectors for each approach to the suggested hybrid CNN-BILSTM network. For each method, we provided the obtained vectors to the proposed CNN-BILSTM network. The objective of using CNN layers in model architecture was to extract fake news features. Then, we provided the acquired vectors for each approach to the suggested CNN-BILSTM network. The goal of using CNN layers into the model architecture was to extract elements of fake news. The experiments concluded that the combination of two-word embedding vectors offers a benefit and it increases the accuracy of the proposed model when compared to using one-word embedding technique. Table III and Fig. 11 show that the combination of Word2Vec (CBOW) and the Word2Vec (Skip-Gram) gives the best results in term of accuracy and precision when compared to the other possible combinations.

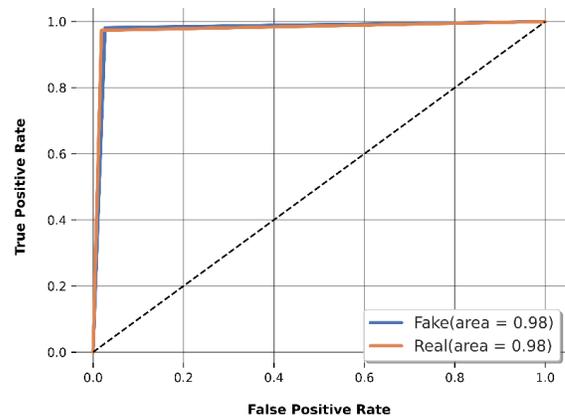

Fig. 9. The ROC Curves of Method 1.

Overall, the results of the experiment indicate that all models attained exceptional precision with a low loss rate. In addition, these findings demonstrate that the incorporation of a hybrid model based on the feature descriptor approach improves prediction performance relative to other models in the literature.

In Table IV, we compare the performance of the proposed model to that of some similar research examined in the present paper.

The Fig. 10 shows the improvement of the proposed method 1 compared to the traditional machine learning methods. The accuracy of the proposed model achieved 97.74%, while DT, RF, LR and SVM achieved a maximum accuracy only up to 93.51%, 94.37%, 95.42% and 97.09%, respectively.

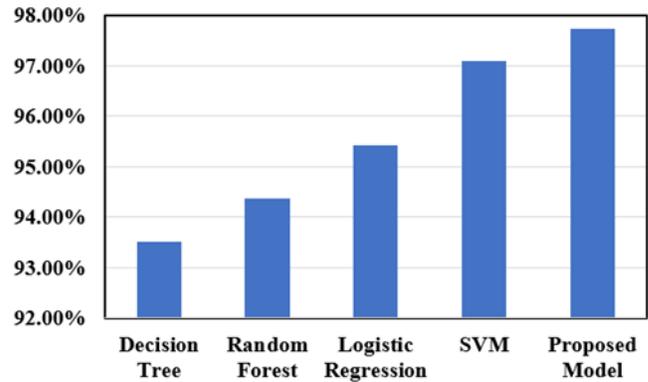

Fig. 10. Accuracy Comparison of Proposed Model with Traditional Machine Learning Algorithms.

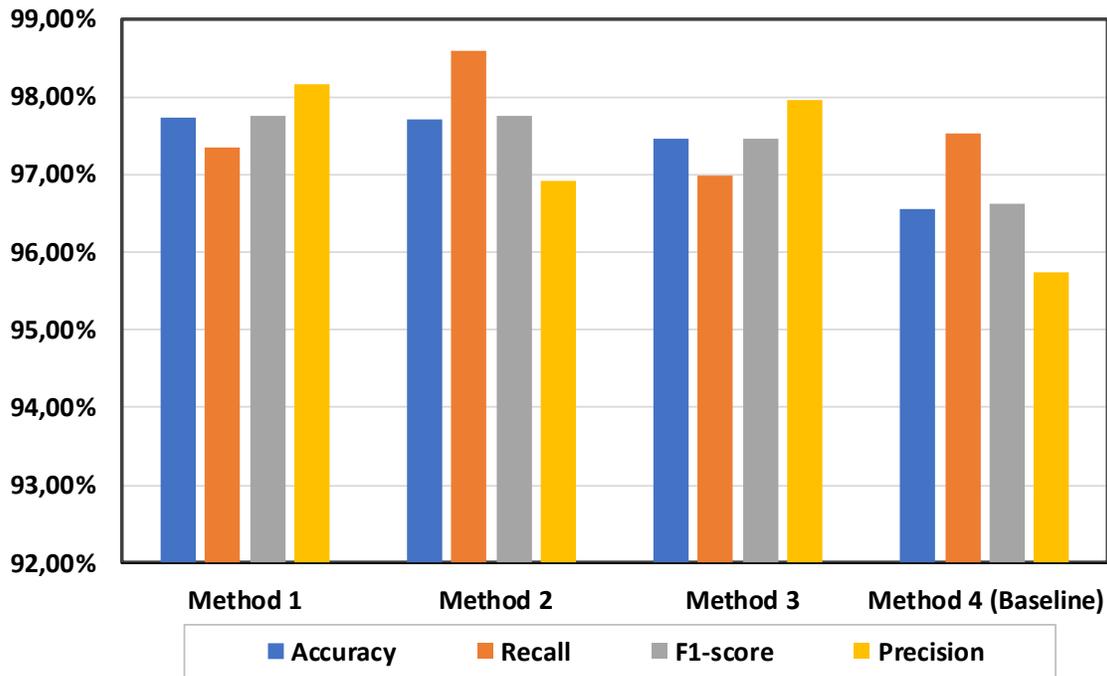

Fig. 11. Summarize of All the Experimental Findings Provided in this Research.

TABLE IV. ACCURACY COMPARISON OF PROPOSED MODEL WITH RELATED WORKS

Authors	Dataset	Feature Representation	Classification Algorithm	Accuracy
[29]	Their own dataset of 25200 articles from Reuters and Kaggle	TF-IDF	KNN, SVM, LR, LSVM, DT	92%
[30]	PHEME	WORD2VEC	LSTM	79.5%
[31]	PHEME	WORD2VEC	Hybrid LSTM-CNN	82%
[32]	PHEME	WORD2VEC-GLOVE-FASTTEXT	Hybrid BILSTM-CNN	86.12%
[33]	FNC-1	GLOVE	Hybrid LSTM/ BILSTM -CNN	71.2%
[35]	ISOT	Linguistic features (stylo-metric, semantic, and syntactic...)	Voting classifier based on traditional machine learning algorithms	96.36%
[34]	WELFake dataset	Combine linguistic feature with Word embedding	Voting classifier based on SVM , DT , NB, Bagging, AdaBoost, KNN	96.73%
<b>Proposed method</b>	<b>WELFake dataset</b>	<b>Combine linguistic feature with Word embedding</b>	<b>CNN-BILSTM</b>	<b>97.74%</b>

## VI. CONCLUSION AND PERSPECTIVES

In this paper, we presented a new approach to detect fake news using the unbiased dataset WELFake. The main objective of this research was obtaining a good result and improving the performance of the proposed fake news detection system. In this study. The first task of this approach was representing words to meaningful numerical vectors using combination of different word embedding techniques. The second task was training the proposed hybrid model based on CNN and BILSTM architectures. The obtained results show an improvement in terms of accuracy and precision when compared to traditional machine learning algorithms and related work results. The simple concatenation of the different pre-trained embedding models increases the dimension of embedded vectors. Moreover, that leads to a high computational complexity. To solve this problem in future works, we propose to reduce the dimension of concatenated vectors with preserving characteristics of the original data using features engineering techniques such as features selection and dimensions reduction.

**Abstract**—An improved model based on YOLOv5s is proposed for the problem that the YOLOv5 network model does not have high localization accuracy when detecting and identifying obstacles at different distances and sizes from the blind, which in turn leads to low accuracy in measuring distances. There are two main core ideas: firstly, a feature scale and a corresponding prediction head are added to YOLOv5 to improve the detection accuracy of small objects on blind paths. Secondly, SK attention mechanism is introduced in the feature fusion part. It can adaptively adjust the perceptual field for feature maps of different scales and more accurately extract objects of different distances and sizes on the blind path, which can improve the accuracy of detection and the accuracy of subsequent distance measurement. It was experimentally demonstrated that the improved YOLOv5 model improved the mAP by 6.29% compared to the original YOLOv5 model based on a small difference in time consumption. And for each category of AP values, the improvement ranged from 2.13% to 8.19%, respectively. The average accuracy of the measured distance from the obstacle at 1.5m to 3.5m from the camera is 98.20%. This shows that the improved YOLOv5 algorithm has good real-time performance and accuracy.

**Keywords**—Binocular ranging; object detection; attention mechanism

## I. INTRODUCTION

Blind corridors are one of the main guides for blind people to walk around. However, they are occupied by obstacles in almost every city. This causes inconvenience to the blind. Therefore, accurate identification and distance measurement of obstacles on blind paths is essential for the blind to travel safely.

In life and industrial scenarios, commonly used distance measurement methods include infrared distance measurement, stereo vision distance measurement, laser distance measurement and ultrasonic distance measurement. Among them, stereo vision distance measurement is a technology that allows computers to simulate human visual system to achieve distance measurement. The principle of the traditional stereo vision-based binocular ranging method is to use two cameras to acquire left and right images from the same viewpoint [1]. Then a stereo matching algorithm is used to find out the parallax. Finally, the distance from the target object to the camera is obtained by constructing similar triangles through the camera imaging principle. Stereo matching technology is an important part of binocular distance measurement. Before matching, it first extracts image features.

The mainstream stereo matching algorithms are GC (graph cuts) algorithm based on global feature matching [2], SGBM (semi-global block matching) algorithm based on semi-global feature matching [3], and SIFT(scale-invariant feature transform) algorithm [4], SURF(speeded up robust features) algorithm [5] and ORB(Oriented FAST and Rotated BRIEF) algorithm [6] based on local feature matching, etc. GC, SGBM algorithm can construct parallax images with high accuracy. However, the matching speed is slow, it is difficult to meet the requirements of high real-time, and the parallax image information is relatively simple. SIFT, SURF and ORB are three feature matching algorithms. Generally, feature points are used to match the left and right images from the same viewpoint, and then the distance is calculated according to the disparity of the feature points. The feature points that can be matched together are often those whose gray values change significantly and have similar trends. However, this often leads to the problem of mismatch, and the disadvantage of time-consuming detection of all feature points of the whole map (including uninterested areas).

The matching algorithms introduced above are always unsatisfactory in terms of speed or accuracy. Therefore, this paper uses a deep learning based method to detect the target from the left and right images of the binocular camera, and obtains parallax after getting the position information of the target. Finally, the distance from the target object to the camera is obtained by the binocular ranging principle.

In this research, the purpose is to improve the performance of target detection in blind channel images to solve the above problems. In addition, the speed of detection poses a great challenge to detection algorithm, because blind channel obstacle ranging is often real-time. The You Only Look Once (YOLO) neural network [7] is one-stage target detection algorithm that improves detection speed by making the target classification and localization set a one-level regression problem. YOLOv5 is the fifth version of YOLO, and its target detection performance is better than the first four versions, which is the most widely used version.

Although YOLOv5 can achieve multi-target detection quickly and accurately, it is difficult to apply directly to one specific image for target detection. Therefore, this paper proposes an improved model based on YOLOv5s for the detection and recognition of blind roadway pictures taken by binocular cameras. First of all, for the problem that the depth feature map after YOLOv5 feature fusion causes the loss of small object feature information due to excessive down-sampling, an up-sampling operation is added in the Neck part

\*Corresponding Author.

to get a new feature scale for feature fusion with the shallow features of the Backbone network. And a corresponding prediction head is added in the head to improve the detection accuracy of small objects on blind corridors. Secondly, the SK attention mechanism is introduced after the last four feature fusions, which can adaptively adjust the sensing domain for the four different scales of feature maps. Thus, objects of different distances and sizes on the blind path can be extracted more accurately. The accurate recognition of blind obstacle and the accurate measurement of distance are achieved.

Author contributions can be summarized as follows:

- A new feature scale fusion layer is added in YOLOv5, which fuses shallow features in the network to maximize the retention of feature information and avoid the loss of small object features in the deep network.
- The attention mechanism Selective Kernel Networks (SKNet) is added to the feature fusion part in YOLOv5. It can adaptively adjust the perception field for feature maps of different scales, and it has different effects for objects of different distances and sizes on the blind path, so as to extract the target information more accurately.
- Mean Average Precision (mAP) of 0.843 is achieved with the model proposed in this paper on a homemade blind pathway dataset with complex objects. The improved YOLOv 5 model is used to detect and recognize binocular blind road pictures. After obtaining the position information of the same obstacle in the two pictures, the distance of the obstacle is obtained by using the principle of binocular ranging. At the obstacle distance from 1.5 m to 3.5 m from the camera, the average accuracy of measuring distance can reach 98.20%. It's very accurate.

The main part of this paper consists of five parts. Section I is the introduction, which introduces the background and significance of blind distance measurement for obstacle, as well as the research method of this paper and the reasons for adopting this method. Section II is the related work, which introduces the related research about target detection. Section III is the core part of the paper, which introduces the improved model of this paper, and how and why it was improved. In Section IV, the model proposed in the Section III was tested, and the experimental results and analysis were given. Section V is a summary of the overall research methods of this paper and the outlook for the future.

## II. RELATED WORK

### A. Traditional Object Detection Algorithm

The traditional target detection algorithm [8] can be roughly divided into three steps: region selection, feature extraction and target classification. Region selection refers to first locating the target location. Then the images or image sequences are traversed by sliding windows of different scales and aspect ratios. Finally, all possible positions containing the detected target are framed by an exhaustive strategy. Feature extraction refers to the extraction of visual features of the

target candidate regions. For example, SIFT (Scale Invariant Feature Transformation), HOG (Gradient Direction Histogram) [9], Haar [10] and LBP (Local Binary Pattern) [11] and other feature extraction operators are used for feature extraction. Object classification refers to the classification of the target by using the classifier through the extracted features. The commonly used classifiers are DPM (Deformed Part Model) [12], Adaboost [13], SVM (Support Vector Machine) [14] and so on.

Although traditional object detection methods have achieved certain results in the field of detection, they also have drawbacks. The high time complexity and many redundant windows in the region selection stage by sliding window selection candidate region strategy lead to the performance degradation of subsequent feature extraction and classification. Due to the object's own factors and environmental factors, the manual feature design method is poor in robustness, versatility and detection accuracy [15]. Traditional target detection methods have been difficult to meet people's pursuit of high performance.

### B. Deep Learning based Object Detection Algorithms

In 2012, AlexNet [16] based on deep Convolutional Neural Network (CNN) won the ImageNet image recognition competition with a significant advantage. Since then, deep learning has been receiving widespread attention. Object detection is also gradually entered the era of deep learning.

The mainstream object detection algorithms [17] based on deep learning are classified into one-stage object detection algorithms and two-stage object detection algorithms according to whether exist a candidate frame generation stage. The two-stage target detection algorithm first extracts candidate frames for image targets, and then classifies the detection results based on the candidate frames. The representative algorithms have R-CNN [18], Fast R-CNN [19], Faster R-CNN [20] and R-FCN [21], etc. Single-stage target detection algorithms do not generate candidate frames and compute the detection results directly on the image. The classical single-stage target detection algorithms have SSD [22], Retina-Net [23] and YOLO series.

The YOLO algorithm was proposed by Redmon et al. in 2016, and there have been seven generations of iterations so far. YOLOv1 [7] is the first object detection algorithm based on regression analysis. It directly divides the image into regions and predicts the bounding box and probability of each region simultaneously. Its detection speed has been greatly increased. However, the detection accuracy is low, especially for small objects. YOLOv2 [24] built a new backbone network Darknet-19 on top of v1. Darknet-19 has fewer convolution layers, and its performance is higher. YOLOv2 maintains the advantage of fast inference while significantly improving prediction accuracy. However, the backbone network of YOLOv 2 is deeper and the recall rate of small target detection is low. And it is poor for dense group target detection. The underlying network of YOLOv3 [25] is Darknet-53, which borrows the residual structure of ResNet [26] for multiscale prediction. YOLOv3 has obviously improved the overall detection accuracy, detection accuracy for small objects, the inference speed and so on. YOLOv4 [27]

uses CSPDarkNet53 [28] instead of DarkNet53 and SPP+PAN instead of FPN. The computation is further reduced and the detection accuracy is improved. In June 2020, Jocher proposed YOLOv5 [29]. Compared with YOLOv1~YOLOv4, YOLOv5 has small size and short inference time, and is suitable for edge devices with limited computational and storage resources. YOLOv5 contains 4 models, in descending order according to model depth and feature map width, YOLOv5s, YOLOv5m, YOLOv5l, and YOLOv5x. Among them, YOLOv5s was iterated to version 6.1 in March 2022.

### III. BLIND OBSTACLE RECOGNITION BASED ON IMPROVED YOLOV5

#### A. Improved YOLOV5

The network model in this paper is improved based on YOLOv5s version 6.1. The improved part is shown in Fig. 1 at the red box line. Firstly, one up-sampling and one down-sampling operation were added in each Neck part. The up-sampling operation is continued after the second up-sampling to obtain a new feature scale for feature fusion with the shallow features of the Backbone network, and a corresponding prediction head is added to the head. The aim is to improve the detection accuracy of small objects on blind paths. Secondly, the SK attention mechanism is introduced after the last four feature fusions, which can adaptively adjust the perceptual field for the four different scales of feature maps. Thus, the objects of different distances and sizes on the blind corridor can be extracted more accurately.

#### B. Improved Multi-scale Feature Detection

The YOLOv5 network uses three resolutions of the output feature maps to detect objects of different sizes. When a blind person walks on a blind path, there are inevitably smaller obstacles on the road, so a feature scale to focus on smaller targets and a prediction head accordingly are added, as shown

in the Head section in Fig. 1. After the second up-sampling in the Neck part, the up-sampling operation is continued to obtain a feature map with a resolution of 160×160. This feature map is feature fused with the shallow high-resolution feature layer obtained in the backbone network after the first C3 structure. The obtained high-resolution feature information makes the added prediction head more sensitive to small objects.

Fig. 2 shows the prediction part of the model with four different scales of feature layers, and the grid-based prediction is performed on these four feature layers in turn. The prediction results of each feature layer are the center adjustment parameters  $t_x$  and  $t_y$ , the width and height adjustment parameters  $t_w$  and  $t_h$ , and the confidence score of the prior frame, respectively. The center  $(x, y)$  and width and height  $(w, h)$  of the predicted frame are obtained based on the first four adjustment parameters. Based on the ground truth of the object, the network establishes the loss between the predicted and true values and calculates the loss for each feature layer.

Through the feedback of the loss, the model gradually optimizes the performance and completes the training. The loss of each feature layer is calculated in the same way and is obtained by calculating the sum of the bounding box regression loss, category loss and confidence loss. As shown in (1).

$$\text{Loss} = \lambda_1 L_{cls} + \lambda_2 L_{obj} + \lambda_3 L_{ciou} \quad (1)$$

In equation (1), the rectangular box loss ( $L_{ciou}$ ) is obtained using CIoU loss [30], and the classification loss ( $L_{cls}$ ) and confidence loss ( $L_{obj}$ ) are calculated by BCE (Binary Cross Entropy) loss.  $\lambda_1$ ,  $\lambda_2$  and  $\lambda_3$  are balance coefficients.

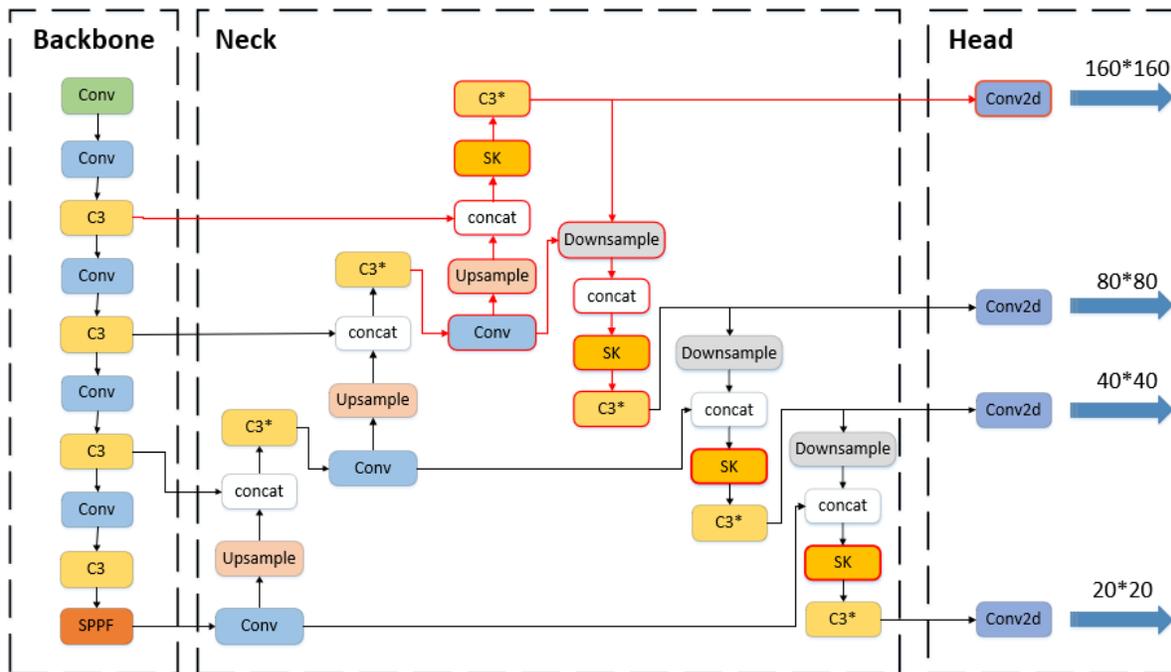

Fig. 1. Improved YOLOv5 Network Model.

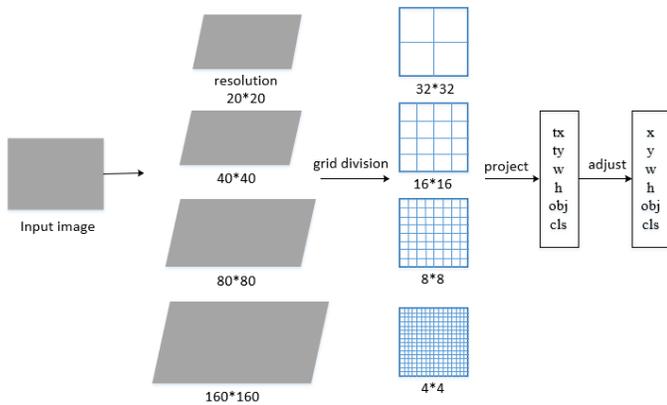

Fig. 2. Improved Model Prediction Section.

### C. The SK Attention Mechanism Introduced

The size of the receptive fields of neurons in the visual cortex of the brain is adjusted according to the stimulus when people with normal vision look at objects of different distances and sizes. SKNet (Selective Kernel Networks) [31] is a kind of network with a similar function that adaptively adjusts the size of the receptive fields according to the multi-scales of the input information, so as to extract objects of different sizes and distances more accurately. Since the obstacles on the blind path are different in sizes and the distances, we added the SK attention mechanism to the four feature maps of different resolution sizes obtained after feature fusion in the Neck network. As shown in the Neck part in Fig. 2.

The structure of SKNet is shown in Fig. 3, it is composed of Split, Fuse, and Select. The part of Split obtains two feature maps  $U1$  and  $U2$  by convolution kernels of  $3 \times 3$  and  $5 \times 5$  respectively for the original feature map. Then the feature map  $U$  is obtained after the addition operation. The Fuse stage is to calculate each convolutional kernel weight.  $S$  is obtained using global average pooling ( $F_{gp}$ ) for  $U$  with dimensionality  $C \times 1$ , and compact features  $Z$  is generated by fully connected layer ( $F_{fc}$ ) with dimensionality compressed to be  $d \times 1$ . As in (2-4).

$$F_{gp}(U) = \frac{1}{W \times H} \sum_{i=1}^H \sum_{j=1}^W U(i, j) \quad (2)$$

$$s = F_{gp}(U) \quad (3)$$

$$z = F_{fc}(s) = \delta(BN(Ws)) \quad (4)$$

In (2),  $W$  and  $H$  are the width and height of the vector  $U$ , respectively.  $i$  and  $j$  are the  $i$ -th row and  $j$ -th column of  $U$ , respectively. In (4),  $\delta$  is the ReLU activation function and  $BN$  denotes the batch normalization operation.

The Select part reclassifies the feature  $Z$  into two feature vectors  $a$  and  $b$ , which are the weights of the two convolution kernels, by a softmax operation (5).

$$a_c = \frac{e^{A_c^z}}{e^{A_c^z} + e^{B_c^z}}, \quad b_c = \frac{e^{B_c^z}}{e^{A_c^z} + e^{B_c^z}} \quad (5)$$

In equation (5),  $A_c, B_c$  are the  $c$ th row data of  $A$  and  $B$ .  $a_c, b_c$  are the  $c$ th elements of  $a, b$  respectively.

The final output feature map  $V$  is obtained by weighting the previous  $U1, U2$  by the two weight matrices  $a$  and  $b$ . The following (6).

$$V_c = a_c \cdot U1_c + b_c \cdot U2_c, \quad a_c + b_c = 1 \quad (6)$$

where  $V = [V1, V2, \dots, VC]$ ,  $Vc$  dimension is  $H \times W$ . Since the function values of  $a_c$  and  $b_c$  add up to 1, it is possible to set the weights for the feature maps in the branches.

Since the SKNet attention mechanism uses different convolutional kernel weights for different images, adding the SKNet network to the network to adaptively adjust the perceptual field for our four different resolution feature maps, which will have different effects for objects of different distances and sizes and improve the accuracy of detection.

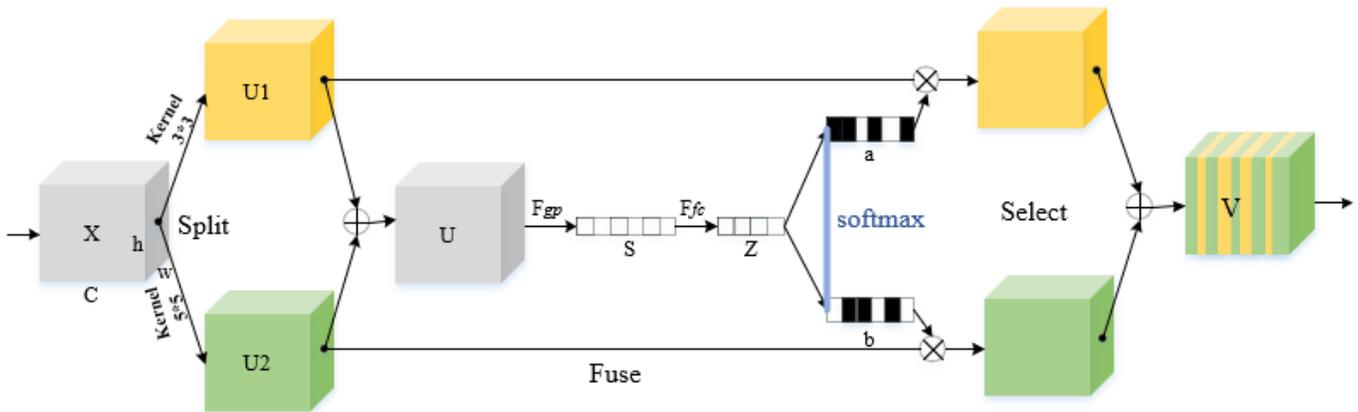

Fig. 3. SKNet Network Structure.

#### IV. EXPERIMENT AND ANALYSIS

##### A. Experimental Data

Since there is no authoritative dataset for blind roadway images, this research dataset consists of two main parts. One part is to use some images from The PASCAL Visual Object Classes Challenge 2007/2012 (VOC07+12) dataset, mainly selected images containing people, cats, dogs, and common vehicles. The other part is a manual field photography of the blind road surface and a browser search for keywords such as "blind road occupied" and "blind road obstruction" to get a web page with search results and download images. These two parts were filtered and aggregated to create a total dataset of 1245 images, each with a resolution between 1280×720 and 333×333. Some of the samples are shown in Fig. 4.

The dataset uses the PASCAL VOC format, and the targets in the images are selected by manual annotation of the frames. Eight types of common obstacles were selected as recognition objects, namely, people, bicycles, cars, motorcycles, cats, dogs, fire hydrants, and manhole covers. In addition, the dataset was randomly divided into training set, test set, and validation set according to the ratio of 6:2:2, where there were 747 images in the training set, 253 images in the test set, and 245 images in the validation set.

##### B. Model Training

Experimental environment configuration: The hardware environment is Intel(R) Core(TM) i7-6500 CPU with 2.50 GHz and 8 GB memory. The software environment is Windows 10 operating system, Python 3.6.15 development language, and PyTorch 1.2.0 deep learning framework.

Training parameters: For model training, the model is initialized using a pre-trained weight file on the COCO dataset, and the model input image size is 640×640. The training period is 100. Batch size is set to 16. The initial learning rate is 0.01. The minimum learning rate is 0.0001. The SGD optimizer is used for optimization. The momentum parameter is 0.937. The decay coefficient of the weights is 0.0005. The learning rate decreases by "cos". And the weights are saved every 10 epochs.

##### C. Performance Comparison Experiment

The improved network model predicts the images, and the results are shown in Fig. 5 and Fig. 6. Fig. 5 shows the image to be predicted, and Fig. 6 shows the prediction results. From the prediction results, it can be seen that the figure contains some objects that can be basically predicted accurately both in the strong light of day and in the weak light of street light at night. The rectangular box position accurately frames the outer edge of the target. For the partly obscured objects in the target and some small objects at a distance can also be accurately detected.

To validate the performance of the proposed improved YOLOv5 network model, it is evaluated with homemade dataset. Precision, Recall, F1 Score and mean average precision (mAP) are used as evaluation metrics to assess the effectiveness of model training and prediction. The evaluation results are shown in Table I. From Table I, the Recall value, Precision value, and F1 score corresponding to each category

of the improved YOLOv5s network model at Confidence of 0.5 are shown. The performance experiments were also compared with the original YOLOv5s network, the YOLO-FIRI network proposed in literature 32 [32] under homemade dataset. The accuracy and average elapsed time comparison results are shown in Table II.

The mAP values of the three algorithms and the AP values for each category can be seen in Table II. With Recall as the horizontal coordinate and Precision as the vertical coordinate, the curve plotted is the PR curve. The AP value is the area under the PR curve, which represents the average accuracy of a single category. It is used to measure how good the model is on a single category. The mAP is obtained by averaging the AP values of all categories, and is used to measure the goodness of the model in all categories. In terms of accuracy, this paper proposed YOLOv5s model improves the mAP by 6.29% compared to the original YOLOv5 model, and for each category of AP values, the improvement ranges from 2.13% to 8.19%, respectively. Compared to the YOLO-FIRI network, the mAP improved by 2.36%, and the AP values for each category ranged from 1.28% to 4.31%, respectively. This indicates that the improved network has better detection accuracy. The AP values for the three smaller object categories of cats, dogs and fire hydrants are 76.31%, 77.84% and 86.43%, which are 4.11%, 8.19% and 3.96% better than the original YOLOv5s model. This indicates that the improved YOLOv5 network model is more accurate in detecting small objects. In terms of inference time, the average time consumed by the improved model for each image is 12ms, which is not much different from the original YOLOv5s time consumed. Compared to the YOLO-FIRI model, the average elapsed time per image is 2ms faster. This shows that the improved model has a faster inference speed.

AS a whole, the improved YOLOv5s model has better accuracy compared to the original model for a single category versus all categories with comparable time consumption. This shows that the improved algorithm in this paper has good real-time performance and accuracy.

#### D. Distance Measurement Experiment

To verify the performance of the algorithm in ranging in this paper, this research used binocular cameras to capture pictures of obstacles at 1.5m, 2.0m, 2.5m, 3.0m and 3.5m at the same location. The binocular camera is calibrated with a known focal length of 2.13mm, a baseline length of 60.4mm, and an image element size of 3μm.

The prediction was performed after stereo correction of the left and right images at different distances (as shown in Fig. 7). The same nearest obstacle in the two pictures was screened by the center longitudinal coordinates of the outer rectangular box of the obstacle. And then the distance was obtained according to the difference of their center transverse coordinates using the principle of binocular ranging [33], as in (7-8). The experimental results are shown in Table III.

$$Z = \frac{fB}{d} \quad (7)$$

$$d = x_l - x_r = d_x (u_l - u_r) \quad (8)$$

In (8),  $u_l$ ,  $u_r$  are the central pixel horizontal coordinates of the same object rectangular box on the left and right images.  $d_l$ ,  $d_r$  are the central physical horizontal coordinates of the same object rectangular box on the left and right images.  $d_x$  is the image element size.

Fig. 7. Graph of Prediction Results for different Distances.

TABLE III. DISTANCE MEASUREMENT RESULTS

Actual distance /m	obstacle on the left/pixel	obstacle on the right /pixel	Parallax /pixel	Measuring distance /m	Accuracy /%
1.5	(475.5,159)	(447.5,158)	28	1.532	97.87
2.0	(542,228)	(521,226)	21	2.042	97.90
2.5	(721,255)	(705,255.5)	16	2.523	99.08
3.0	(790.5,209.5)	(776,208.5)	14.5	2.958	98.60
3.5	(716.5,246)	(704,246)	12.5	3.431	98.03

As can be seen from the data in Table III, the parallax, distance measurement results and accuracy of the nearest obstacle in the figure at a distance of 1.5m to 3.5m from the binocular camera. The measured distances obtained from parallax calculations were 1.532m, 2.042m, 2.523m, 2.958m, and 3.431m at actual distances from 1.5 m to 3.5m, respectively. The accuracy of the measured distance is above 97.87%, and the average accuracy is 98.20%. The accuracy at 2.0m and 2.5m reached 99.08% and 98.60%, respectively. The error was the smallest at the obstacle distance camera at 2.5 m, and the measured distance was the most accurate. This shows that the improved YOLOv5s algorithm has good accuracy and robustness in predicting the recognition of objects at different distances.

## V. CONCLUSION

This paper proposes an improved model based on YOLOv5s for blind roadway picture detection. Firstly, a feature scale and corresponding prediction head are added in YOLOv5 to improve the detection accuracy of small objects on blind path. Secondly, SK attention mechanism is introduced in the feature fusion part to adaptively adjust the perceptual field for feature maps of different scales to more accurately extract objects of different distances and sizes on blind path. Finally, the improved network model is used to detect the left and right maps of the binocular camera, and the exact distance of the blind obstacle from the camera is obtained by the binocular ranging principle. The experimental results show that the improved YOLOv5s algorithm can achieve the accurate recognition of blind obstacle and the accurate distance measurement.

In the future, this research will achieve accurate blind path identification. Combining blind path identification with blind obstacle ranging proposed in this paper can form a complete navigation system for the blind. This will be of great help for blind person to travel.

## ACKNOWLEDGMENT

This work was supported by the Key Scientific Research Project of Henan Universities. The project is entitled "Research on Stereo Vision Based Ranging Technology for Blind Navigation System". The project number is 22B510018.

# Classification Method for Power Load Data of New Energy Grid based on Improved OTSU Algorithm

Xun Ma\*, Kai Liu, Anlei Liu, Xuchao Jia, Yong Wang

Marketing Service Center, State Grid Hebei Electric Power Co., Ltd., Hebei, China

**Abstract**—The classification method for power load data of new energy grid based on improved OTSU algorithm is studied to improve the classification accuracy of power load data. According to the idea of two-dimensional visualization of time series, GAF (Geographical Adaptive Fidelity) method is used to transform the current data of power load in new energy grid into two-dimensional image of power load in new energy grid. The intra class dispersion is introduced, and the improved OTSU algorithm is used to segment the foreground and background of the two-dimensional image according to the pixel gray value of the two-dimensional image and the one-dimensional inter class variance corresponding to the pixel neighborhood gray value. The two-dimensional foreground image of power load is taken as the input sample of convolution neural network. The convolution neural network extracts the features of the two-dimensional foreground image of power load through convolution layer. According to the extracted features, the classification results of power load data of new energy grid are output through three steps: nonlinear processing, pooling processing and full connection layer classification. The experimental results show that this method can accurately classify the power load data of new energy grid, and the classification accuracy is higher than 97%.

**Keywords**—Improved OTSU algorithm; new energy grid; power load; classification method

## I. INTRODUCTION

The classification of power load data of new energy grid helps power selling companies accurately grasp the power consumption characteristics of users, introduce a reasonable demand response mechanism and formulate scientific marketing strategies, which is of great significance for peak shaving and valley filling, optimizing power consumption curve, improving power quality and so on [1]. Improving terminal efficiency and guiding users to use electricity reasonably is one of the important contents of power demand side management. To realize this demand side management, it is necessary to timely understand the power consumption of household users and realize the interaction between supply and use. DSM (Demand Side Management) is a means to guide power consumers to adopt a reasonable way of using electricity [2] and achieve energy conservation and emission reduction. Smart grid utilizes advanced technology to dispatch demand side resources and improve the participation rate of power consumers, so as to realize the two-way interaction between information and power. Power consumers can respond to DSM strategy only when they understand their own power consumption mode [3]. For household power users, only electricity meters provide information for both suppliers and users, while the current smart electricity meters only have the

function of time-sharing pricing, which provides limited information. Therefore, in order to enhance the demand response of power users and optimize the power consumption mode [4], it is necessary to effectively monitor the household load and then measure it by classification. The current smart meter has neither time-sharing measurement nor load classification measurement [5], and can not provide power consumption details to power management departments and users, so it is very necessary to classify the power load data of new energy grid.

Image segmentation is an important step in the process of image analysis. Its goal is to divide the regions of interest in the image. Among many image segmentation methods, threshold segmentation technology is a widely used method in image segmentation [6]. Its basic principle is to calculate the segmentation threshold based on the image gray histogram, and then segment the image according to the threshold. OTSU algorithm is a commonly used algorithm in threshold segmentation. It selects the threshold by maximizing the variance between classes [7]. This method has the characteristics of easy to understand principle, considerable segmentation effect and stable algorithm. However, one-dimensional OTSU algorithm can not deal with more complex images. When segmenting images with too small gray difference between the background and the pixels in the target area, false segmentation will occur. Since the OTSU algorithm was proposed, it has attracted widespread attention of researchers. OTSU algorithm mainly lies in its simple principle, efficient calculation, wide application range and good segmentation effect [8]. OTSU algorithm is an image segmentation method without real-time supervision, without parameter regulation and automatic optimization. Based on the one-dimensional histogram, the threshold is selected by maximizing the variance between classes. Although OTSU algorithm has a good segmentation effect, it is prone to false segmentation when the gray value of the image background and the pixel points in the target area are not much different [9]. The segmentation result of one-dimensional OTSU algorithm is not accurate, but it has been reasonably improved in two-dimensional OTSU algorithm. The expression form of two-dimensional OTSU algorithm is good anti-interference ability, but its calculation process is too complex and requires a lot of running time to process it.

### A. Related Work

At present, many researchers have studied power load. J. J. Hu et al. applied data mining algorithm to power load forecasting [10], and verified that this method can effectively predict power load through simulation tests; H. Bakhtiari et al.

\*Corresponding Author.

Used Markov chain Monte Carlo simulation method [11] to simulate the uncertain random load in the operation of independent microgrid of renewable energy. Although the above two methods can realize the function of power load and uncertain random load prediction, they do not specifically classify the power load of users, so their applicability is poor.

In view of the problems of the above two methods, to further improve the classification accuracy of power load data, the classification method of power load data of new energy grid based on improved OTSU algorithm is studied, and the OTSU algorithm is used to segment the two-dimensional visual image of power load data transformation of new energy grid, so as to obtain the classification results of power load data of new energy grid. The experiment shows that the contribution of this method is that it can accurately classify the power load data of new energy grid, and has high applicability. The specific process schematic diagram of the method used in this paper is shown in Fig. 1.

## II. MATERIALS AND METHODS

### A. Sequence Visualization of Power Load Data of New Energy Grid

The power load data of new energy grid can be visually displayed through the current monitoring data, and the current can be regarded as a one-dimensional sequence related to time in essence. According to the idea of two-dimensional visualization of time series [12], GAF method is introduced into the power consumption field of new energy grid to build a two-dimensional visualization image for the power load data of new

energy grid. Assuming that  $X = \{x_1, x_2, \dots, x_n\}$  is a sequence containing  $n$  sampling values of non-active components of current, the steps to convert it into a two-dimensional visual GAF diagram of power load of new energy grid are as follows:

1) The elements in  $X$  is normalized to the interval  $[-1, 1]$ , that is:

$$\tilde{x}_i = \frac{(x_i - \max X) + (x_i - \min X)}{\max X - \min X} \quad (1)$$

2) The current sequence after standardization is encoded in polar coordinates, namely:

$$\begin{cases} \Psi_i = \arccos \tilde{x}_i & \tilde{x}_i \in [-1, 1] \\ r = t_i, & t_i - i - 1 \end{cases} \quad (2)$$

Where:  $\tilde{x}_i$  is the non-active component of the load current of  $x_i$  in new energy grid after standardization;  $\Psi_i$  is the arccosine of the encoded sample value;  $r$  is the radius after timestamp coding;  $t_i$  is the sampling timestamp corresponding to  $x_i$ .

Since  $\tilde{x}_i \in [-1, 1]$  after standardization, the definition domain of the inverse cosine function is  $[-1, 1]$ , so  $\Psi_i \in [0, \pi]$ .

When the current sequence of the power load of the new energy grid is given, each sampling point has and only has a unique mapping result in the polar coordinate system [13], that is, the bijection relationship.

3) After completing the polar coordinate transformation of the current sequence of the standardized new energy grid power load, the GAF method is used to convert the current sequence of the one-dimensional new energy grid power load into an  $n$ -order matrix, and the values of the elements in the matrix are mapped to the blue-red color range, making the matrix a two-dimensional image with color and texture distribution [14].

GAF method has two definition methods, namely, Gramian Angular Summation Field (GASF) and Gramian Angular

Difference Field (GADF), and the corresponding matrices  $A_s$  and  $A_D$  are respectively:

$$A_s = \begin{bmatrix} \cos(2\Psi_1) & \cos(\Psi_1 + \Psi_2) & \cdots & \cos(\Psi_1 + \Psi_n) \\ \cos(\Psi_2 + \Psi_1) & \cos(2\Psi_2) & \cdots & \cos(\Psi_2 + \Psi_n) \\ \vdots & \vdots & \ddots & \vdots \\ \cos(\Psi_n + \Psi_1) & \cos(\Psi_n + \Psi_2) & \cdots & \cos(2\Psi_n) \end{bmatrix} \quad (3)$$

$$A_D = \begin{bmatrix} 0 & \sin(\Psi_1 - \Psi_2) & \cdots & \sin(\Psi_1 - \Psi_n) \\ \sin(\Psi_2 - \Psi_1) & 0 & \cdots & \sin(\Psi_2 - \Psi_n) \\ \vdots & \vdots & \ddots & \vdots \\ \sin(\Psi_n - \Psi_1) & \sin(\Psi_n - \Psi_2) & \cdots & 0 \end{bmatrix} \quad (4)$$

GAF method is evolved from Gram matrix. Polar coordinate system is used to represent time series instead of Cartesian rectangular coordinate system. Trigonometric function is used to refine the implicit current difference information between each two sampling points in the sequence to expand the amount of data, so as to improve the dimension of the sequence. Compared with the one-dimensional sequence of the current of the power load in the new energy grid, the two-dimensional image of the current sequence of the power load in the new energy grid significantly improves the identification of the power load. Polar coordinate coding of current sequence has the following advantages: polar coordinate transformation meets the double shooting condition, and the sampling point of current sequence of each new energy grid load has and only has a unique mapping result in the polar coordinate system, ensuring the uniqueness of the coding process; After the polar coordinate transformation, the time from the upper left corner to the lower right corner of the matrix element increases continuously; Compared with the rectangular coordinate system, the polar coordinate system retains the current magnitude relationship and time information of the new energy grid load between the sampling points. Through the above process, the power load data of new energy grid is transformed into a two-dimensional image of time series.

### B. Two-dimensional Image Segmentation of Power Load in New Energy Grid based on Improved OTSU Algorithm

1) Image segmentation method based on OTSU: The gray level  $G=1, 2, \dots, L$  of the two-dimensional image of the power load in the new energy grid is set, and  $f_i$  is used to represent the total number of pixels contained in the gray level  $i$ . The total number of pixels in the two-dimensional image of the power load of the new energy grid is  $N$ ,  $N = f_1 + f_2 + \dots + f_i = \sum_{i=1}^l f_i$ .  $P_i$  is used to indicate the occurrence frequency of  $i$ , a gray-scale pixel,  $P_i = f_i / N$ , then  $P_i > 0$ ,  $\sum_{i=1}^l P_i = 1$ . A threshold  $t$  is selected to divide all pixels of the two-dimensional image of the power load in the

new energy grid into two parts,  $C_0$  and  $C_1$ ,  $C_0 = \{1, 2, \dots, t\}$ ,  $C_1 = \{t+1, t+2, \dots, L\}$ . The probability distributions of these two types are as follows:

$$\omega_0 = P_r(C_0) = \sum_{i=1}^t P_i = \omega(t) \quad (5)$$

$$\omega_1 = P_r(C_1) = \sum_{i=t+1}^l P_i = 1 - \omega(t) \quad (6)$$

The two types of gray mean values in the two-dimensional image of the power load in the new energy grid are respectively:

$$u_0 = \sum_{i=1}^t i \times P_r(i / C_0) = \sum_{i=1}^t \frac{iP_i}{\omega_0} \quad (7)$$

$$u_1 = \sum_{i=t+1}^l i \times P_r(i / C_1) = \frac{u_r - u(t)}{1 - \omega(t)} \quad (8)$$

$$u_r = u(L) = \sum_{i=1}^l iP_i, \quad u(t) = \sum_{i=1}^t iP_i,$$

Then

$$\omega(t) = \sum_{i=1}^t P_i$$

For any  $t$ , the following formula is satisfied:

$$\omega_0 + \omega_1 = 1 \quad (9)$$

$$\omega_0 u_0 + \omega_1 u_1 = u_r \quad (10)$$

The evaluation function is introduced to judge the advantages and disadvantages of the threshold in OTSU algorithm:

$\lambda = \frac{\sigma_B^2}{\sigma_w^2}$ ,  $k = \frac{\sigma_r^2}{\sigma_w^2}$ ,  $\eta = \frac{\sigma_B^2}{\sigma_r^2}$ .  $\sigma_B^2$ ,  $\sigma_w^2$  and  $\sigma_r^2$  are inter class variance, intra class variance and overall variance respectively. The three decision functions are maximized, and the objective function becomes the selection of the optimal threshold  $t$ .

Since  $\sigma_r^2 = \sigma_B^2 + \sigma_w^2$ , the following relationship is satisfied:

$$k = \frac{1}{1 - \eta} \quad (11)$$

$$\eta = \frac{\lambda}{\lambda + 1} \quad (12)$$

It can be seen from the above formula that the monotonicity of the three decision functions is the same [15]. Since  $\sigma_r^2$  is a known constant and has nothing to do with the value of  $t$ ,  $\eta$

$$\eta(t) = \frac{\sigma_B^2(t)}{\sigma_r^2}, \text{ so } \sigma_B^2$$

is the simplest of the three functions, can be used as a judgment function for the performance of two-dimensional image segmentation of power load in new energy grid:

$$\sigma_B^2(t) = \frac{[u_r \omega(t) - u(t) \omega(t)]^2}{\omega(t)[1 - \omega(t)]} \quad (13)$$

Where,  $u_r = u(L) = \sum_{i=1}^L ip_i$ ,  $u(t) = \omega(t) = \sum_{i=1}^t ip_i$

The optimal threshold  $t^*$  of two-dimensional image segmentation of power load in new energy grid is:

$$\sigma_B^2(t^*) = \max_{1 \leq t \leq L} \{ \sigma_B^2(t) \} \quad (14)$$

2) *Two-dimensional OTSU algorithm with improved threshold selection algorithm:* Aiming at the high computational complexity of two-dimensional OTSU algorithm, an improved OTSU algorithm is proposed. This algorithm divides the traditional two-dimensional algorithm into two one-dimensional OTSU algorithms: a threshold is obtained from the one-dimensional histogram based on the gray value of the two-dimensional image of the new energy grid's power load, and its purpose is to extract the target; A threshold value [16] is obtained from the one-dimensional histogram based on the neighborhood average gray value of the two-dimensional image of the new energy grid's power load, and its purpose is to filter out noise. The two thresholds obtained by these two one-dimensional OTSU algorithms are used to replace the thresholds of the original two-dimensional OTSU algorithm. This improved algorithm not only considers the gray information of the two-dimensional image of the new energy grid's power load itself, but also considers the information of its neighborhood pixels, so that the algorithm has good denoising ability. From

the frequency  $f_{ij}$  of  $(i, j)$  in the two-dimensional image histogram of the new energy grid's power load, the frequency

$q_i = \sum_{j=0}^{L-1} f_{ij}$  of the pixel gray value  $i$  in the two-dimensional image of the power load of the new energy grid and the

frequency  $r_j = \sum_{i=0}^{L-1} P_{ij}$  of the neighborhood gray value  $j$  are

derived. By analogy, the probability distribution  $P_{ij}$  can be used to obtain the one-dimensional histogram distribution of the pixel

gray value  $i$  and the neighborhood gray value  $j$  of the two-dimensional image of the new energy grid's power load, and

$$U_i = \sum_{j=0}^{L-1} P_{ij}, \quad V_i = \sum_{i=0}^{L-1} P_{ij}$$

their probabilities are , respectively.,

In two-dimensional OTSU algorithm, edge points and noise points account for a small number [17], that is, the probability corresponding to the noise and edge part can be approximately

$$\sum_{i=s+1}^{L-1} \sum_{j=0}^t P_{ij} = 0, \quad \sum_{i=0}^s \sum_{j=t+1}^{L-1} P_{ij} = 0$$

0, that is, . It can get the

expression of the proportion  $\omega_0$  and  $\omega_b$  of the target and background in the one-dimensional histogram corresponding to the pixel gray value  $i$  of the two-dimensional image of the new energy grid's power load as follows:

$$\omega_0 = \sum_{i=0}^s \sum_{j=0}^s P_{ij} + \sum_{i=0}^s \sum_{j=t+1}^{L-1} P_{ij} = \sum_{i=0}^s U_i \quad (15)$$

$$\omega_b = \sum_{i=s+1}^{L-1} U_i \quad (16)$$

The mean vectors corresponding to the two categories are:

$$\mu_{oi} = \sum_{i=0}^s iU_i / \omega_0 \quad (17)$$

$$\mu_{bi} = \sum_{i=s+1}^{L-1} iU_i / \omega_b \quad (18)$$

The overall mean vector of the improved OTSU algorithm is:

$$\mu_i = \sum_{i=0}^{L-1} \sum_{j=0}^{L-1} iP_{ij} = \sum_{i=0}^{L-1} iU_i \quad (19)$$

From the above formulas, it can be deduced that the one-dimensional interclass variance corresponding to the pixel gray value  $i$  of the two-dimensional image of the new energy grid's power load is:

$$\sigma_{B_i}(s) = (\omega_0 + \omega_b)(\mu_{oi} - \mu_i)^2 + (\mu_{bi} - \mu_i)^2 \quad (20)$$

Similarly, it can be obtained that the one-dimensional interclass variance corresponding to the neighborhood gray value  $v$  of the two-dimensional image of the new energy grid's power load is:

$$\sigma_{B_j}(t) = (\omega_0 + \omega_b)(\mu_{oj} - \mu_j)^2 + (\mu_{bj} - \mu_j)^2 \quad (21)$$

Where:  $\omega_0$  and  $\omega_b$  represent the proportion of target and background respectively, and  $\mu_{oj}$ ,  $\mu_{bj}$  and  $\mu_j$  represent the average vector and overall mean vector of the two categories respectively.

According to the principle of one-dimensional Otsu algorithm, the optimal threshold  $s^*$ ,  $t^*$  should meet:

$$\sigma_{B_i}(s^*) = \max_{0 \leq s \leq L-1} \{\sigma_{B_i}(s), \sigma_{B_j}(t^*)\} = \max_{0 \leq t \leq L-1} \{\sigma_{B_j}(t)\} \quad (22)$$

Although the threshold segmentation method for the traditional OTSU algorithm considers the variance between the foreground class and the background class [18], it does not consider the discreteness within the class, so it can not more comprehensively reflect the quality of classification and achieve more accurate segmentation. By introducing the intra class dispersion, the segmentation result of the two-dimensional image of the new energy grid's power load not only achieves the maximum variance between classes, but also better realizes the intra class consistency. The classification discrete measure corresponding to the pixel gray value of the two-dimensional image of the new energy grid's power load is defined as:

$$\tau_{di} = (\omega_0 + \omega_b) \sum_{i=0}^s |\mu_{oi} - iU_i / \omega_0| + \sum_{i=s+1}^{L-1} |\mu_{bi} - iU_i / \omega_b| \quad (23)$$

Based on the above formula, a new threshold recognition function expression is constructed as follows:

$$\xi_i = \omega_0 (1 - \omega_0) \times \sigma_{B_i} / \tau_{di} \quad (24)$$

Similarly, the threshold recognition function  $\xi_j$  is also constructed for the one-dimensional histogram composed of the average value of neighborhood gray.

In order to optimize the segmentation effect of two-dimensional image of power load in new energy grid and minimize the dispersion within the class, it is necessary to calculate the maximum value of  $\xi_i$  and  $\xi_j$ , that is, to calculate the minimum value of  $\tau_{di}$  and  $\tau_{dj}$ . In order to quickly and effectively determine the two-dimensional image segmentation threshold of the power load of the new energy grid, the solution of  $\xi_i$  and  $\xi_j$  is taken as the fitness function, and the genetic algorithm is used to automatically obtain the appropriate threshold vector, so as to realize the two-dimensional threshold segmentation for the two-dimensional image of the power load of the new energy grid.

### C. Classification of Power Load Data of New Energy Grid based on Convolutional Neural Network

Compared with the traditional neural network, convolutional neural network has a special structure. The weight structure can reduce the complexity of the classification model and reduce the amount of calculation of the algorithm. Convolutional neural network is often used in image

classification. Images can be directly used as the input of classification model. The extracted three-dimensional feature signals make the classification accuracy of convolutional neural network higher. Convolution neural network is used to classify the load data of new energy grid. Convolution neural network is divided into four parts: convolution, nonlinear processing, pooling and full connection layer classification.

1) *Convolution layer*: In convolution neural network, the main purpose of the first step convolution is to extract its feature matrix from an input image, and extract image features through the graphic signal of the input data, so as to maintain the spatial relationship between pixels. The convolution kernel size  $G(s, t)$  used for convolution is  $A \times B$ , and the weight of convolution kernel function directly affects the effect of the final recognition result. The larger the weight is, the stronger the force is.  $C(i, j)$  is the characteristic matrix, which is the convolution matrix obtained by convoluting the two-dimensional image of the power load of the original new energy grid with the convolution kernel  $G$ . The operation expression is as follows:

$$\begin{aligned} C(i, j) &= f(x, y) \times G(s, t) \\ &= \sum_{x=1}^a \sum_{y=1}^b G(s, t) \times f(i+x-1, t+y-1) \end{aligned} \quad (25)$$

Where, the value range of  $s$  and  $t$  is  $1 \leq i \leq M - A + 1$ ,  $1 \leq j \leq N - B + 1$ .

It is obvious from formula (25) that the convolution neural network algorithm is to use the convolution kernel matrix to filter the original signal image, extract the features of the corresponding positions, and finally obtain a new feature image. One of the most important features of convolution neural network operation is the operation through convolution layer. Multiple convolution checks are used to extract features from the two-dimensional image of power load of new energy grid [19], forming multiple new feature matrices.

It is very important to extract characteristic signals and establish convolution kernel function of characteristic matrix in the convolution process of two-dimensional image of power load in new energy grid. The number of convolution kernels is an important parameter. The extracted number corresponds to the convolution kernel function used in the convolution operation. Different convolution kernel functions are used to convolute the two-dimensional image of the power load of the new energy grid to map different features. The number of convolution kernels corresponds to the number of types of features selected for convolution. The magnitude of the convolution kernel matrix sliding in the image is also an important parameter. When the step is 1, we only move one pixel at a time. When the step is 2, the sliding filter processes two pixels at a time. The larger the step is, the longer the sliding span is, and the smaller the characteristic matrix is generated at the same time. The value of convolution kernel matrix is also

an important parameter. Different convolution kernels map different characteristic matrices. The value in the convolution kernel matrix is needed to control, that is, control the output range of the characteristic matrix.

2) *Nonlinear processing*: After convolution processing of convolution neural network, the second step of nonlinear transformation is required. Its purpose is to process the target in the two-dimensional image of power load of new energy grid by using nonlinear function. The sigmoid function is used for nonlinear processing of the two-dimensional image of the new energy grid's power load, and the expression is as follows:

$$f(x) = \frac{1}{1 + e^{-x}} \quad (26)$$

Nonlinear processing can further purify and sample the data, optimize the data type, and facilitate the subsequent sampling calculation. Nonlinear processing further processes the signal and replaces all negative pixel values to zero during feature mapping. The purpose of nonlinear processing is that most real-world data are not smooth and ideal. It is hoped that through further processing of signal data, convolutional neural network can recognize signals more accurately and reliably.

3) *Pooling processing*: Pooling can also be called subsampling or subsampling. Its purpose is to reduce the dimension of each feature map and retain the most important information. Pool processing can be: maximum value, average value, adjacent and so on. In the process of pooling, a feature window  $a \times b$  is defined, and the secondary feature extraction of the first step feature matrix is carried out through the pooling window. Through pooling, we can gradually reduce the size of the input space, make the input dimension smaller and easier to calculate, and retain the important characteristics of the network, so that the small transformation, distortion and translation in the two-dimensional foreground image of the segmented power load of the new energy grid remain unchanged.

4) *Full connection layer classification*: Each pixel of the characteristic matrix in the two-dimensional image of all new energy grid power loads after pooled sampling is arranged in turn to form a feature vector. The feature vector forms a full connection with the output layer as a full connection layer. The full connection layer is the last step of the convolutional neural network, which is used for the output of the whole neural network. In the full connection layer, a classifier is usually trained for the convolutional neural network [20]. Generally speaking, the full connection layer adopts the traditional multi-layer classifier, such as softmax or support vector machine. The purpose of full connection layer is to use the characteristics of data to achieve the classification purpose of input and output through training. The full connection layer is located in the classification link of convolutional neural network structure.

In the process of convolution neural network classifying the power load data of new energy grid, the first step is to select the test set and sample set, and select the foreground image of the two-dimensional image of new energy grid's power load

obtained after segmentation as the input sample of convolution neural network. After determining the test sample and training sample, the classification process is as follows:

1) Initialize the weight matrix and bias parameters of convolutional neural network.

2) Select a sample from the training samples, input the selected samples into the network, and obtain the corresponding actual output value.

3) Calculate the error between actual data input and ideal output.

4) Carry out back propagation and adjust the parameters.

5) Input the remaining training samples into the network in turn until all training samples are input, and complete an iteration.

6) Input the test samples into the trained sample model, and use the classifier to obtain the accuracy of classification.

The convolution neural network is used to classify the segmented two-dimensional image of the power load of the new energy grid, and the classification results of the power load data of the new energy grid are output.

### III. RESULTS

In order to verify the classification effectiveness of the classification method for power load data of new energy grid based on the improved OTSU algorithm, the method in this paper is applied to the new energy grid's power consumption management of a power enterprise. The power enterprise uses current sensors to collect the current changes of different smart meters, as shown in Table I.

According to the current changes of smart meters in the new energy grid collected by the current sensor in Table 1, the GAF method is used to build a two-dimensional visual image of the time series of power load data in the new energy grid, as shown in Fig. 2.

According to the experimental results in Fig. 2, the current data related to load data in the new energy grid can be effectively converted into two-dimensional visual images by using the method in this paper, and the two-dimensional visual images can be used to visually display the load changes in the new energy grid. In this paper, the improved OTSU algorithm is used to segment the two-dimensional visual image of time series. The segmentation results of the two-dimensional visual image of the new energy grid's power load data are shown in Fig. 3.

According to the segmentation results of the new energy grid's electricity load image in Fig. 3, the accurate segmentation of the two-dimensional visual image of the new energy grid's electricity load can be achieved by using the method in this paper, and the two-dimensional visual image can be divided into the target foreground area and the background area by image segmentation. The experimental results in Fig. 3 show that the method in this paper has a high image segmentation effect, and the edge of the segmented image is clear, which can effectively display the target information contained in the image.

TABLE I. CURRENT CHANGE ACQUISITION RESULTS

Fig. 3. Image Segmentation Results.

The method in this paper is used to classify the load data managed by a smart meter in the new energy grid to verify the effectiveness of this method. According to the segmented electricity load image of new energy grid, the classification results of electricity load data of new energy grid using this method are shown in Table II.

According to the experimental results in Table II, the improved OTSU algorithm can be used to classify the power load data of new energy grid with high classification accuracy. The experimental results in Table II verify that the method in this paper has high classification effectiveness of power load

data of new energy grid. This method can accurately classify the power load data of the new energy grid, which is helpful for the dispatching management decision-makers of the new energy grid to make the dispatching and management decisions of the new energy grid according to the classification results of the power load data of the new energy grid.

The method in this paper is used to classify the power load data in the new energy grid. The operating power changes of each power load are shown in Table III.

According to the experimental results in Table III, there are obvious differences in the power of different power loads in the new energy grid. The method in this paper can effectively classify the load data of the new energy grid, and accurately analyze the load data of the new energy grid through the power changes of different load types.

Statistics adopts the method in this paper to classify the power load data of new energy grid. For the classification accuracy of different types of load data, the classification performance of this method is verified by the classification accuracy of load data. The statistical results are shown in Fig. 4.

TABLE II. CLASSIFICATION RESULTS OF ELECTRICITY LOAD DATA OF NEW ENERGY GRID

Time	Classification result	Is the classification correct
8:05	Turn on the rice cooker	Yes
8:13	Turn off the rice cooker	Yes
8:25	Turn on the TV	Yes
18:16	Turn on the refrigerator	Yes
18:32	Turn off the tv	Yes
19:25	Turn on the rice cooker	Yes
19:35	Turn off the rice cooker	Yes
19:51	Turn off the refrigerator	Yes
20:18	Turn on energy-saving lamps	Yes
20:23	Turn off the hair dryer	Yes

TABLE III. CHANGES IN OPERATING POWER OF ELECTRICAL LOAD

Electric load type	Max power/W	Minimum power/W	Average power/W
refrigerator	185.6	134.4	148.5
TV set	285.4	234.5	257.6
electric fan	135.5	126.5	129.4
hair dryer	1820.4	1685.4	1710.5
kettle	1864.5	1812.5	1835.7
air conditioner	1358.6	1205.7	1285.4
washing machine	280.6	250.4	265.8
Micro-wave oven	750.4	658.6	716.5
induction cooker	4050.4	3895.8	3925.4
computer	330.5	290.4	315.6

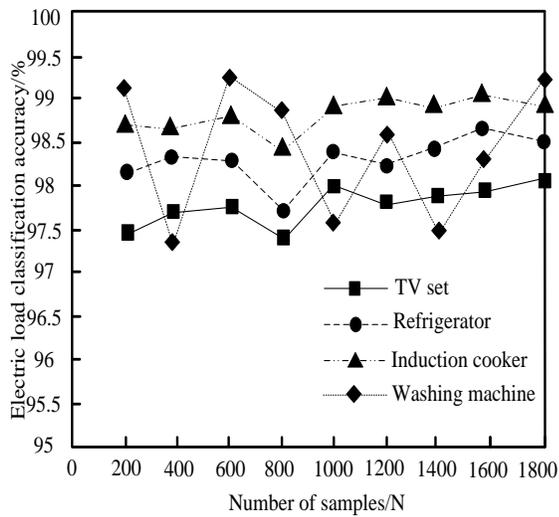

Fig. 4. Load Data Classification Accuracy.

According to the experimental results in Fig. 4, the classification accuracy of different types of power load data using the method in this paper is higher than 97%. The experimental results verify that this method has high classification effectiveness of power load data of new energy grid. For different types of load data, this method can achieve accurate classification. It is verified that the method in this paper has high efficiency of load data classification, and can be applied to the practical application of power load data classification in new energy grid.

The classification calculation time of this method is counted for different types of load data. The statistical results are shown in Fig. 5.

As shown in Fig. 5, the classification time of the present method is less than 50ms, indicating that the method has high load data classification efficiency and is suitable for the practical application of power grid load data classification.

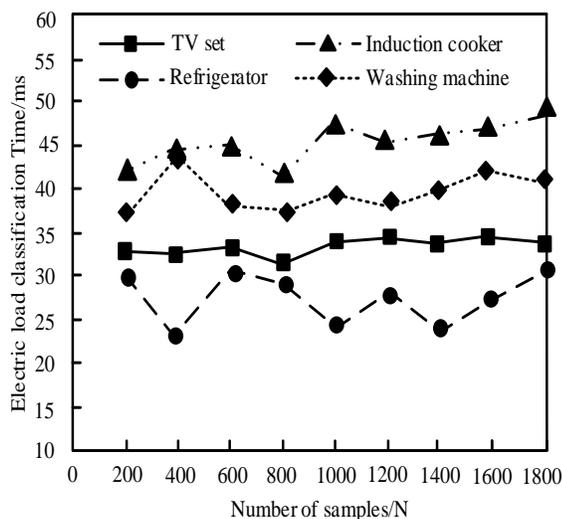

Fig. 5. Classification Time.

#### IV. DISCUSSION

This paper studies the classification method for power load data of new energy grid based on improved OTSU algorithm, and verifies that this method can accurately classify the data of new energy grid through experiments. The energy problem has always been a problem perplexed by mankind. With the development of the times, the energy crisis and greenhouse effect have become increasingly serious. How to effectively improve energy efficiency and reduce polluting gas emissions has become a high concern and attention of all sectors of society. The new energy grid has become the main trend of the development of the power field. The working state and energy consumption of each power load in the new energy grid can be obtained by classifying the power load data of the new energy grid. According to the comprehensive information such as energy consumption information, time-of-use electricity price and electric energy measurement, effective energy-saving measures can be obtained, reasonable energy-saving plans can be formulated, and targeted power loads can be purchased.

The significance of power load data classification of new energy grid is specifically shown in:

1) In the planning of power system, medium and long-term load forecasting is the basis of power system development planning and fuel planning, while short-term load forecasting is the premise of making daily power generation plan and determining the operation mode of power system. The classification of power load data of new energy grid only through the installation of monitoring equipment at the user's power entrance to understand the power consumption, operation status and operation time of the load, and in-depth understanding of the energy consumption and detailed power consumption information of each load. The fine-grained power consumption information is helpful to obtain the characteristics and power consumption modes of different load types, and more accurately predict the spatial density distribution map of load at various spatial scales and time scales, to improve the accuracy and reliability of load forecasting which greatly improves the scientificity of power system planning and the real-time, safe and economic operation of the power grid.

2) The classification method for power load data of new energy grid can obtain the specific power consumption information of each power load, carefully consider the time-varying characteristics of load operation, provide the possibility for load modeling and dynamic management of load model parameters, improve the operation accuracy of load model in the process of power system simulation, and reduce the economic loss of error caused by load model.

3) The classification of power load data of new energy grid can enable power companies to obtain detailed power consumption information such as the type, working state, power consumption time and energy consumption of different loads, and can help power companies formulate electricity prices and power demand side management more scientifically and provide corresponding incentive policies. At the same time, the working state information of power load can help power companies verify whether users make timely and accurate response to grid

demand according to the relevant demand of power demand side management, such as load shedding during peak hours of grid operation. At the same time, the power supply company can carry out user expansion business according to the power consumption information. For example, the power supply company can formulate a detailed power consumption plan for users and obtain corresponding remuneration.

4) The classification of power load data of new energy grid to obtain the detailed power consumption information of users can greatly improve the visualization of power system, especially for the fault state and abnormal operation state of power grid load, which is conducive to the detection, quasi positioning, self-healing reconstruction and rapid restoration of power supply and other functions of power system distribution network's outage fault.

5) The classification of power load data of new energy grid can obtain the working state, power consumption time and energy consumption of each power load in real time, such as whether the electric kettle is in the heating state, whether the LCD TV is in the working state, and whether the refrigerator is in the fault state.

6) Residential users adjust and optimize their power consumption behavior according to the detailed power consumption information of the power load, so as to achieve the purpose of saving electricity and reducing electricity expenses, such as changing the use time of the power load, avoiding the peak electricity price, or adjusting the operating parameters of the power load, so as to reduce unnecessary power waste.

7) According to the detailed power consumption information, users can quickly and accurately obtain whether the power load is in fault and which equipment is high-efficiency equipment, and use energy-saving power loads as much as possible. For example, if the refrigerator is monitored to be in the operation state of maximum power all the time, rather than the intermittent operation state, the refrigerator is in the fault state; Or if it is judged that the air conditioner consumes too much power, it can be considered to replace the energy-saving air conditioner, which is conducive to saving electricity expenses. At the same time, the detailed electricity consumption information of residents' various loads provides a regulation basis for smart home and household electricity automation.

8) In the research, the challenge encountered in this paper is to use the image segmentation for classification data, which is prone to noise interference and affects the classification accuracy. Therefore, this paper uses the one-dimensional classification threshold to filter out the noise and obtain accurate results.

9) The importance of all quantities in the relationship lies in that this paper uses the average vector and the overall average value corresponding to the gray value of the neighborhood of the new energy grid load two-dimensional image to calculate the one-dimensional inter class variance, find the best gray threshold, and perform more accurate segmentation. By introducing intra class dispersion, the load two-dimensional image segmentation results reach the maximum variance within

the class, and the classification results are optimized; The convolution kernel matrix is used to filter the original signal image, extract image features, and nonlinear process the load two-dimensional image, which improves the accuracy and efficiency of classification.

## V. CONCLUSION

With the growing maturity of smart grid and the gradual enhancement of users' awareness of energy conservation, the demand for household electricity transparency on the power demand side is also more urgent. Therefore, in this paper, the classification method for power load data of new energy grid based on the improved OTSU algorithm is studied, to display the collected power load data of new energy grid in the form of two-dimensional images, segment the two-dimensional image of power load data of new energy grid using the improved OTSU algorithm, and use the segmented two-dimensional image to realize the effective classification of new energy grid's power load data. The classification of power load data of new energy grid can optimize the power consumption mode of users and improve the participation of power consumers in demand side management. Due to the limited conditions, the present method has some shortcomings and only study the data classification, and future studies can optimize the user power consumption pattern using the classification results.

# Study on the Technical Characteristics of Badminton Players in Different Stages through Video Analysis

Jin Qiu

Chongqing Institute of Engineering  
Chongqing 400900, China

**Abstract**—Through video analysis, Tai Tzu Ying, an excellent athlete, and badminton player A from Chongqing Institute of Engineering, were studied in this paper. The videos of the two athletes were organized and recorded, and the use of techniques in different stages were compared. The results found that Tai Tzu Ying's serve technique was flexible, with few errors, while Play A's serve technique was single and had many errors; in terms of serve receive, Tai Tzu Ying was more aggressive, mainly using rush shot and spinning net shot, while A mainly used techniques of spinning net shot and lift shot. The comparison of techniques in front, middle and back courts showed that Tai Tzu Ying's playing style was more aggressive, while A's playing style was more conservative. This paper compared the two athletes to understand the technical characteristics of excellent athletes and gave some suggestions for the training of school badminton players.

## I. INTRODUCTION

Badminton is a small-scale ball sport [1]. With the continuous development of sports, badminton has also been widely loved by people [2], continuously popularized [3], and become an important project in the Olympic Games [4]. With the progress and development of the international badminton world, badminton game system has been reformed [5], the badminton technology has also been continuously innovated and changed, the level of athletes has been improved, and the situation of the badminton world has become more complex. With the development of men's technology, women's singles play and technology have also changed, becoming more comprehensive, faster, and more competitive. Research on badminton has also become more extensive and deeper.

Most of the comparisons of technical characteristics of badminton focus on the world's best athletes, and there is a lack of comparisons between excellent athletes and ordinary athletes. The comparison between excellent athletes and ordinary athletes is of great significance to help ordinary athletes better understand the differences between themselves and excellent athletes, learn, and improve. Therefore, in order to further understand the gap between excellent athletes and ordinary athletes, the technical characteristics of excellent athletes and ordinary athletes were studied in this paper. Chinese Taipei player Tai Tzu Ying is ranked No. 1 in the World Badminton Federation and is a very good player with a well-rounded playing style. This paper compared the technical characteristics of Tai Tzu Ying and an average college athlete through video analysis to better understand the gap between them.

## II. LITERATURE REVIEW

At present, research on badminton involves sports injuries [6], neurocognition [7], muscle structure [8], and biomechanics [9], but most studies focus on sports training [10], i.e., how to strengthen skill levels. Ardiantoro et al. [11] used the top Indonesian badminton player Jonathan Christie as a model and analyzed the tactical approach of the player using a frequent pattern (FP) growth algorithm to help the coach to improve the performance of the player. Zhou et al. [12] built a model of the score rate and technical movements of badminton in international tournaments with computers based on the probability theory and quantitatively compared the differences in scoring rates in international tournaments, thus providing a basis for improving training. Huang et al. [13] studied the optimization of training patterns for badminton players using the Apriori algorithm, providing a new idea for studying badminton technical movement rules. Pérez-Turpin et al. [14] conducted a study on men's singles and double outdoor badminton matches, recorded 20 men's single matches using a video camera, and compared the use percentage of different techniques using the Dartfish video analysis package.

## III. RESEARCH SUBJECTS AND METHODS

### A. Research Subjects

Tai Tzu Ying: An excellent female badminton singles player who holds the racket with her right hand and currently ranks No.1 in the world.

Play A: A badminton player from Chongqing Institute of Engineering who holds the racket with her right hand.

### B. Research Methodology

1) *Literature method*: We collected and read a large amount of literature on badminton and its technical features through search resources such as the library of Chongqing Engineering College, China National Knowledge Infrastructure (CNKI), Duxiu Academic Web, and Google to understand the current research status and trends.

2) *Video analysis method*: The video data of 20 matches that Tai Tzu Ying participated in between 2016 and 2019 were obtained from the Internet sports video software such as Tencent Sports and Migu Sports, as shown in Fig. 1. The videos of 20 amateur badminton matches that Play A participated in between 2016 and 2019 were obtained from the school for comparison, as shown in Fig. 2. The videos were played by slow playback

and analyzed by pausing frame by frame confirm and record the type of technique and the landing point.

3) *Comparison method:* The excellent athlete Tai Tzu Ying was compared with the ordinary player A to compare the differences in their technical characteristics in different stages, analyze their characteristics in playing style, and provide data support for research.

4) *Data analysis method:* After analyzing the video, the data were organized, processed, and analyzed in Excel to motivate the use of different techniques in front, middle and back courts. The usage rate of every technique was calculated. The graphs were drawn in Excel to present the comparison between Tai Tzu Ying and ordinary athlete A and understand their difference.

Fig. 2. Screenshots of Play A's Video.

#### IV. RESEARCH RESULTS

##### A. Analysis of the Technical Characteristics of Serve and Receive

A successful serve can gain the initiative of a match and put pressure on the opponent. At the same time, a serve can force the opponent to use the technique expected by the server to return the shuttle; therefore, the study of the serve technique is important for the study of points scored and lost. A comparison of the technical characteristics of the two players when serving is shown in Table I and Fig. 3.

It was seen from Table I and Fig. 3 that Tai Tzu Ying mainly used the forehand clear and forehand low serve, with usage rates of 51.2% and 27.1%, and seldom used the flick serve, with the usage rate of around 3%, and the number of serve errors was 87, accounting for 9.2%; player A mainly used the technique of forehand low serve, for 572 times, with the usage rate of 76.9%, about 50% higher than Tai Tzu Ying, and the rest of several techniques were seldom used, with the usage rates below 5%, and she also made many errors, for 103 times, accounting for 13.8%, 4.6% higher than Tai Tzu Ying.

The forehand clear makes the shuttle hang in the air for a long time, which is good for players to adjust position and make

adequate preparation for the next shot, while the forehand low serve can limit the opponent's ability to attack from the back court. In comparison, Tai Tzu Ying's serve was more flexible, with the forehand clear as the main technique, supplemented by the forehand low serve, which is more conducive to mastering the initiative of the match, while Player A's serve was single and had more errors, showing insufficient advantages in serve.

TABLE I. COMPARISON OF TECHNICAL CHARACTERISTICS OF SERVE

Technique	Tai Tzu Ying		Player A	
	Number of uses	Usage rate	Number of uses	Usage rate
Forehand low serve	257	27.1%	572	76.9%
Forehand flick serve	30	3.2%	17	2.3%
Forehand clear	486	51.2%	22	3.0%
Backhand flick serve	32	3.4%	12	1.6%
Backhand net shot	57	6.0%	18	2.4%
Errors	87	9.2%	103	13.8%

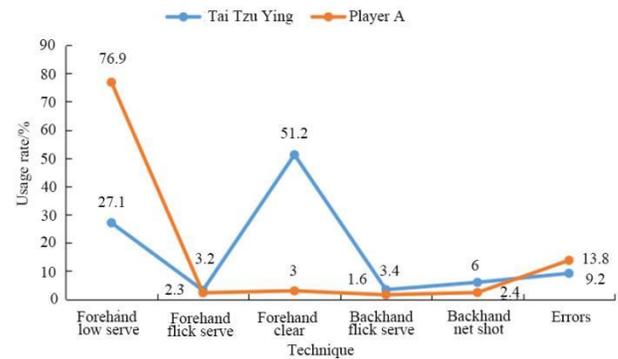

Fig. 3. Comparison of usage Rate between different Serve Techniques.

The comparison of the technical characteristics of serve showed that attention should be paid to the training of students' serve technique to improve the quality of students' forehand serve and students' awareness of serve, and matches could be simulated to strengthen students' anticipation ability to make them fully consider the way of opponent's return and the way of handling the third shot.

A comparison of the technical characteristics of the receiving serve is shown in Table II and Fig. 4.

It was seen from Table II and Fig. 4 that Tai Tzu Ying and player A had a large difference in the technique of returning the front-court serve and had a small difference in the technique of returning the back-court serve. Tai Tzu Ying used push and spinning net shots frequently to return the front-court serve, with usage rates of 45.25 and 33.4%, and mainly used smash to return the back-court serve, with a usage rate of 49.9%, supplemented by clear and lift shot, with usage rates of 28.4% and 21.7%. Player A used net and lift shots to return the front-court serve, with usage rates of 41.4% and 39.4%. The usage rate of push shot of player A was significantly lower than Tai Tzu Ying, and her usage rate of lift shot was significantly higher

than Tai Tzu Ying. The similarity between Tai Tzu Ying and player A was that the usage rate of rush shots was the lowest. In the aspects of returning the back-court serve, player A mainly used the smash and clear techniques, with usage rates of 50.2% and 27.5%, and used the drop shot with the lowest probability, 22.3%.

TABLE II. COMPARISON OF TECHNICAL CHARACTERISTICS OF RECEIVING SERVE

		Tai Tzu Ying		Player A	
		Number of uses	Usage rate	Number of uses	Usage rate
Return of the front-court serve	Push shot	142	45.2%	11	4.4%
	Spinning net shot	105	33.4%	103	41.4%
	Crosscourt shot	47	15.0%	32	12.9%
	Lift shot	13	4.1%	98	39.4%
	Rush shot	7	2.2%	5	2.0%
Return of the back-court serve	Smash	234	49.9%	221	50.2%
	Clear	133	28.4%	121	27.5%
	Drop shot	102	21.7%	98	22.3%

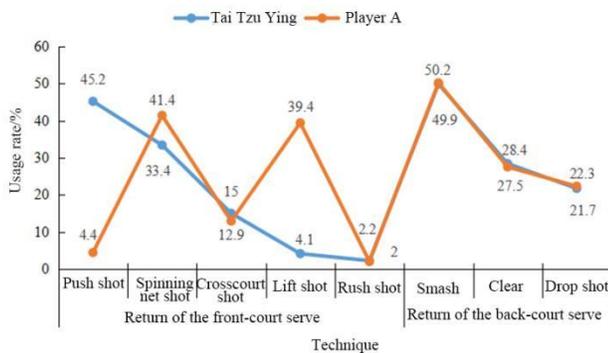

Fig. 4. Comparison of usage Rate between Serve Receive Techniques.

The video analysis found that Tai Tzu Ying changed the route frequently and was offensive when receiving the service, with the main purpose of consuming the opponent’s physical strength. Techniques such as push and spinning net shots are good for limiting the opponent’s attack. Smash is featured by fast attack, tricky landing point, and difficult return. Clear can suppress the opponent at the baseline, which is good for her to seize the initiative. The comparison of the technical characteristics of receiving the serve demonstrated that the player could create good conditions for the subsequent attack by taking the initiative through smash and high shots.

**B. Analysis of Technical Characteristics of the Front-court Shot**

With the advancement of badminton technology, the net technique has also received more and more attention. Although it is relatively difficult to score through net shots, players can create more opportunities to score through the control of the front court. The comparison of the technical characteristics of the front-court shot is shown in Table III and Fig. 5.

TABLE III. COMPARISON OF TECHNICAL CHARACTERISTICS OF THE FRONT-COURT SHOT

Used technology	Tai Tzu Ying		Player A	
	Number of uses	Usage rate	Number of uses	Usage rate
Lift shot	507	31.7%	464	28.5%
Spinning net shot	453	28.4%	327	20.1%
Push shot	267	16.7%	202	12.4%
Cross-court shot	211	13.2%	315	19.3%
Rush shot	157	9.8%	321	19.7%

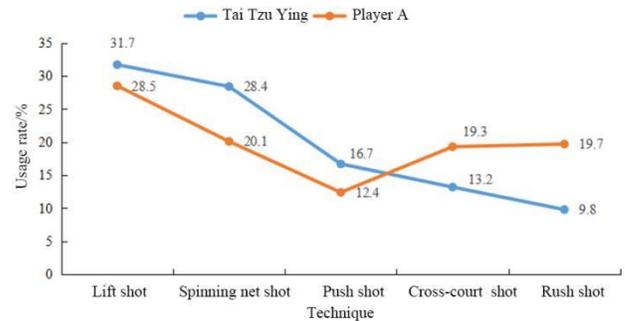

Fig. 5. Comparison of usage Rate between Front-court Shots.

It was seen from Table III and Fig. 5 that Tai Tzu Ying used lift shots most frequently in the front court, with a usage rate of 31.7%, followed by spinning net shots (28.4%). Player A also had a high usage rate of lift shots, but at the same time, the usage rates of other techniques were even, among which the usage rates of cross-court and rush shots were higher than Tai Tzu Ying. The usage rate of cross-court shots of player A was 19.3%, 6.1% higher than Tai Tzu Ying; her usage rate of rush shots was 19.7%, 9.9% higher than Tai Tzu Ying.

Lift shots can mobilize the opponent by opening the distance and running, and spinning net shots can dominate the attack. Tai Tzu Ying forced the opponent to lift the shuttle through net control to increase the chance of attack. Player A opened the distance with the opponent by lift shots and other techniques and also got rid of the opponent’s net control by cross-court and rush shots. The comparison of the technical characteristics of the front-court shots suggested that athletes should strengthen the training of techniques such as lift and net shots and learn to use different techniques to return according to the hitting position, so as to effectively mobilize the opponent.

**C. Analysis of Technical Characteristics of the Middle-court Shot**

Compared with front-court and back-court shots, the middle-court technique is used relatively less frequently, usually to defend against the attack in passive situations; however, the middle-court technique is also important. Block in the middle court is mainly to return the opponent’s aggressive ball to the opponent’s net. Drive is aggressive and defensive. Lift shots are mainly used for defending. The number of times the technique was used by both players is

shown in Table IV. A comparison of the usage rate is shown in Fig. 6.

It was seen from Table IV and Fig. 6 that Tai Tzu Ying used the technique of block most frequently, 925 times (63.6%), followed by drive (20.2%) and lift (16.2%) when she was in the middle of the court. Player A used blocks most frequently, but the usage rate (58.6%) was 5% lower than Tai Tzu Ying, but its usage rate of lift shots (22.2%) was 6% higher than Tai Tzu Ying.

Both players mainly used the block technique in the middle court, accounting for more than half of all the techniques, but there were still some differences. Tai Tzu Ying was defensive in the middle court, avoiding the opponent's clear by blocks. She also frequently used blocks to get rid of the passive situation. Player A attacked through the combination of block and drive, hindering the opponent's return to gain the initiative. Through the analysis of the excellent player, it was seen that the training of the block technique should be paid attention to in the daily training to avoid being passive in the game.

**D. Analysis of the Technical Characteristics of the Back-court Shot**

The back court of badminton is the main scoring place. The main techniques used in the back court are clear, drop shot, and smash. Clear is slow and makes the ball hang in the air for a long time, which is helpful to get rid of the passive state and prepare for the next shot. A high shot can also control the opponent in the back court, which can be used to restrain players who are poor in attacking in the back court. Smash is fast and is an effective active scoring technique. A drop shot is a way to mobilize the opponent, which can disrupt the opponent's rhythm and then score on the follow-up smash. The comparison of the technical characteristics of the two players in the back court is shown in Table V and Fig. 7.

TABLE IV. COMPARISON OF THE NUMBER OF TIMES THE MIDDLE-COURT TECHNIQUE WAS USED

Used technology	Tai Tzu Ying	Player A
Block	925	876
Drive	294	286
Lift	235	332

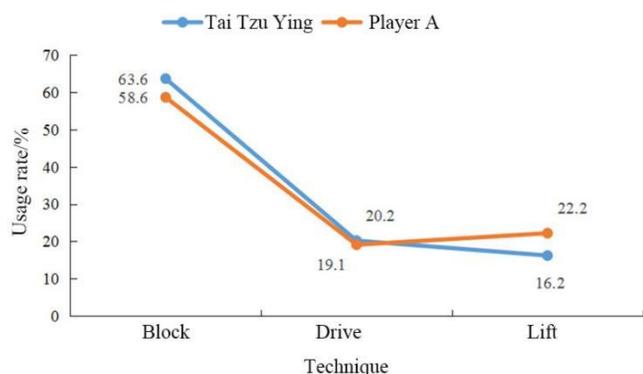

Fig. 6. Comparison of usages Rates of Middle-court Techniques.

TABLE V. COMPARISON OF TECHNICAL CHARACTERISTICS OF THE BACK-COURT SHOT

Used technology		Tai Tzu Ying		Player A	
		Number of uses	Usage rate	Number of uses	Usage rate
Clear	Offensive clear	633	22.78%	721	27.5%
	Defensive clear	253	9.10%	336	12.8%
Drop shot	Slice	698	25.12%	712	27.2%
	Drop spike	305	10.98%	318	12.1%
Smash	Cut smash	78	2.81%	52	2.0%
	Spot smash	231	8.31%	168	6.4%
	Heavy smash	581	20.91%	312	11.9%

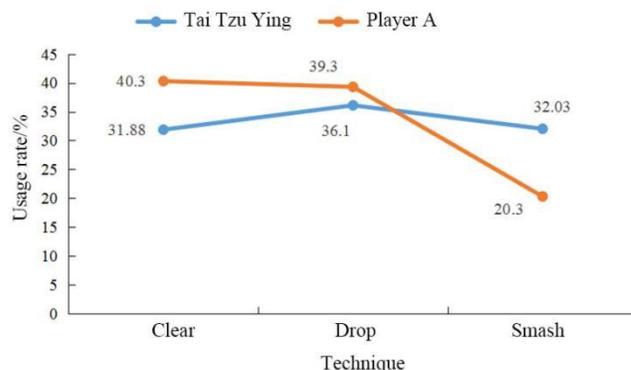

Fig. 7. Comparison of the usage Rate between High Shot, Drop Shot, and Smash.

It was seen from Table V and Fig. 7 that Tai Tzu Ying used the drop shot most frequently in the back court, followed by smash and clear, but the overall differences were not significant, about 30%, indicating that she used the back-court techniques with similar frequencies, while Player A was more likely to use clear and drop shots. The usage rate of clear of player A was 40.3%, close to two fifths; her usage rate of drop was 39.3%, also close to two fifths; her usage rate of smash was 20.3 %, 11.73% lower than Tai Tzu Ying. The difference of the usage rate of smash was the largest difference between Tai Tzu Ying and player A in the usage of back-court techniques.

Offensive clear is more aggressive than defensive clear. Tai Tzu Ying used offensive clear more frequently. Offensive clear is used to speed up the rhythm of the back court to find out the opponent's weakness. Defensive clear is usually used for passive defense. In the use of drop shots, the usage rate of the slice was higher. Tai Tzu Ying consumed the opponent's energy with a lot of slices to make him passively defend in most cases. In the use of smash, Tai Tzu Ying used heavy smash most frequently, which is the most aggressive, followed by spot smash. Overall, Tai Tzu Ying used an aggressive style in the back court. Compared to Tai Tzu Ying, Player A used techniques of drop shots and clears more frequently to mobilize

the opponent; her playing style was defensive and used the technique of smash less frequently. The comparison of the technical characteristics in the back court showed that smash, clear, and drop shots were important techniques, especially clear. To enhance the quality of smash, sports training should strengthen students' strength quality and physical stability.

## V. DISCUSSION

With the development of science and technology, video analysis methods have also been well applied in the field of sports. Videos can be processed to find the technical characteristics of athletes to help improve the training efficiency of athletes [15]. Those methods have mature applications in various sports, such as basketball and soccer [16] and have excellent performance in athlete detection and classification, athlete or ball tracking and trajectory prediction, team strategy identification, and sports classification [17].

This paper compared the technical characteristics of two badminton players through the method of video analysis. In the current research on badminton and video analysis, Chen et al. [18] investigated badminton trajectories and stroke types and applied video analysis methods to real-time analysis of badminton matches. Liu et al. [19] designed an end-to-end system for racket motion analysis to improve performance in court identification, 2D trajectory estimation, and hitting recognition. Lin et al. [20] achieved tracking and trajectory prediction of moving objects after segmenting video images. Their method can predict badminton serve trajectories accurately. Ongvises et al. [21] recorded the drop shot in badminton with high-speed video and found that the impact velocity of the racket was proportional to the velocity of the badminton when it left the racket. Most of the comparisons of technical characteristics focus on the comparison between the world's best athletes to provide reference for the development of international competition and to improve the competitive level of the best athletes. There are few analyses between excellent athletes and ordinary athletes; therefore, this paper compared the technical characteristics of Tai Tzu Ying, a world excellent badminton player, with an ordinary college student. The results of the video analysis showed significant differences between the two players in the usage of front-, middle-, and back-court techniques. In general, compared to player A, Tai Tzu Ying has the following technical characteristics.

1) She has a stronger sense of active offense, will fully move the opponent's position, and is good at creating offensive opportunities to score.

2) She has a stronger sense of occupying the net in the front court and is more proactive in receiving and serving to wait for opportunities to attack.

3) She counterattacks in the midfield usually through her defensive skills to turn passive into proactive and realize the integration of attack and defense.

4) She used clear, drop, and smash shots in the back court to disrupt the opponent's judgment and take the initiative.

With the help of video analysis and data analysis, the research results of this paper intuitively show the differences in technical characteristics between the excellent athlete and ordinary athlete, which provides a good reference for better

understanding the advantages of excellent athletes and the shortcomings of ordinary athletes to guide athletes and narrow the gap between ordinary athletes and the world's best athletes. This work contributes to the improvement of the competitive level of badminton players.

## VI. CONCLUSION

This paper compared and analyzed the technical characteristics of Tai Tzu Ying and a school badminton player through video analysis. It was found that there were some differences between the two players in the use of different techniques. In general, Tai Tzu Ying used lift shots and spinning net shots frequently in the front court, used block frequently in the middle court, and used drop and smash frequently in the back court, which was more flexible and aggressive. The comparison of the technical characteristics between the two players in this paper provides some suggestions for the training of school badminton players through analyzing the difference between excellent athletes and ordinary athletes in technical characteristics, so that they can learn the characteristics of the excellent athletes to improve their technical level. This paper also verified the reliability of video analysis technology in the sports field. In future research, this method can be applied to other sports to help athletes improve their technical ability more effectively. However, this paper also has some shortcomings. The research sample was relatively single, so the study of technical characteristics was relatively limited. In future research, more in-depth work is needed to further understand the differences between outstanding and ordinary athletes.

# Deep Architecture based on DenseNet-121 Model for Weather Image Recognition

Saleh A. Albelwi

Department of Computer Science, Faculty of Computing and Information Technology  
Industrial Innovation and Robotics Center, University of Tabuk  
Tabuk, Saudi Arabia

**Abstract**—Weather conditions have a significant effect on humans' daily lives and production, ranging from clothing choices to travel, outdoor sports, and solar energy systems. Recent advances in computer vision based on deep learning methods have shown notable progress in both scene awareness and image processing problems. These results have highlighted network depth as a critical factor, as deeper networks achieve better outcomes. This paper proposes a deep learning model based on DenseNet-121 to effectively recognize weather conditions from images. DenseNet performs significantly better than previous models; it also uses less processing power and memory to further increase its efficiency. Since this field currently lacks adequate labeled images for training in weather image recognition, transfer learning and data augmentation techniques were applied. Using the ImageNet dataset, these techniques fine-tuned pre-trained models to speed up training and achieve better end results. Because DenseNet-121 requires sufficient data and is architecturally complex, the expansion of data via geometric augmentation—such as rotation, translation, flipping, and scaling—was critical in decreasing overfitting and increasing the effectiveness of fine-tuning. These experiments were conducted on the RFS dataset, and the results demonstrate both the efficiency and advantages of the proposed method, which achieved an accuracy rate of 95.9%.

**Keywords**—Weather recognition; DenseNet-121; deep learning; data augmentation; transfer learning

## I. INTRODUCTION

Weather conditions have a significant effect on humans' daily lives and production [1], ranging from clothing choices to travel, outdoor sports, and solar energy systems. The growth of the intelligent transportation field has further prompted the development of a system that can automatically detect weather conditions [2]. Previously, traditional weather classification systems relied on human observation, but these methods are prone to error and are also time consuming. Current weather recognition systems depend on hardware equipment such as sensors [3], but the number of sensors, as well as their upkeep, necessitates both installation and regular maintenance, which can be expensive. This is especially so considering the impact of the weather on the sensors themselves—as the sensors weather various conditions, their accuracy may decrease, which may lead them to report erroneous weather conditions [4].

Recent advances in computer vision have shown notable progress in both scene awareness and image processing problems. One such study utilized multiple techniques to classify, segment, and localize pixels within urban images [5].

Research such as this has led to advances in intelligent vision systems, which can accurately recognize weather conditions using colored images. Due to these advances, as well as the presence of security cameras, computer vision systems are well-suited for automatic weather detection. Machine learning-based methods such as support vector machine (SVM), random forest, k-NN, and neural networks have since been proposed for weather condition recognition. They extract features from images, including saturation, contrast, noise, etc. The drawback is that these systems utilize multifaceted feature engineering as well as manual extraction, both of which increase their complexity and decrease their generalizability [6, 7].

Deep learning models such as AlexNet [8], VGG [9], Inception [10], and ResNet [11] have recently obtained outstanding performances in numerous computer vision applications, including image recognition, object detection, and semantic segmentation [12]. Deep learning models can obtain detailed data from weather images, which makes them more beneficial than classical machine learning methods. This is because deep learning techniques such as convolutional neural networks (CNNs) and ResNet have the capability to extract rich, abstract, and semantic information. For weather recognition in particular, they obtain better information than other techniques. Deep learning is, therefore, a more advanced machine learning method, one that can solve complicated problems that often stump traditional methods [13].

To further improve performance, researchers have constructed deeper and deeper CNNs, as the additional layers improve optimization. For example, AlexNet (the winner of ILSVRC2012) consists of eight layers, including five convolutional layers and three fully connected layers, VGG19 consists of 16 convolutional layers and three fully connected layers. Inception (the winner of ILSVRC2014) is composed of 21 convolutional layers and a single fully connected layer. Though these additional layers improve optimization, they increasingly expose CNNs to the critical issue of vanishing gradients. Several approaches have been proposed to address this, such as ReLU activation [14], batch normalization [15], and powerful weight initialization [13]. A second problem also arose, in that not all deep CNNs could be easily optimized. This has been addressed through two methods: the first is highway networks [16], which allow 2D-CNNs to connect via a memory device, thus training highway networks through gradient descent. The second is ResNets (the winner of ILSVRC2015), which simplified the former technique using a skip connection device, allowing deeper layers to receive data. The latter is

more efficient than the former. DenseNet architecture further improved upon this by connecting all layers with the CNN, thereby improving data flow [17].

This paper proposes a system based on a DenseNet-121 deep learning model to classify weather conditions from images. DenseNet has achieved excellent performance, while also utilizing less memory and processing power than other state-of-the-art techniques. The proposed system can be utilized in the monitoring of traffic conditions, intelligent transit systems, and auxiliary driving features in automobiles, among others. The main advantage of DenseNet-121 is that it addresses vanishing gradients, which has multiple positive effects: one, it lessens the training burden of deep learning models; two, it allows for the reuse of features; and three, it lowers parameter use as compared to other popular deep learning models. The largest challenge in implementing this model was the lack of a labelled training dataset, and so two techniques were implemented: transfer learning and data augmentation. The former uses an ImageNet [18] dataset to pretrain the model, which decreases training time. The latter prevents overfitting, and also improves fine-tuning, by increasing the size of the training set based on image geometric transformations such as rotation, translation, flipping, and scaling. Overall, the proposed system is efficient, effective, and responsive, which allows it to make the best possible decisions even in poor weather conditions. The contributions of this paper are as follows:

- This paper presents a deep learning-based method using DenseNet-121 to effectively classify weather conditions from images in real time. The results have shown importance of model depth, as deeper models offer better results.
- To train the DenseNet-121 model, the proposed model needed large amounts of data. To circumvent the difficulty of obtaining additional weather images, this paper applied transfer learning and geometric image data augmentation techniques to reduce convergence time and increase performance.

The remainder of the paper is organized as follows: Section II provides the recent related works. Section III describes the model in detail. Section IV presents and discusses the experimental results. Finally, the conclusions and future works are presented in Section V.

## II. RELATED WORKS

Early weather classification methods often extracted powerful features, a process that needed elaborate, hand-crafted features. Other methods utilized machine learning algorithms for classification, such as support vector machine (SVM), random forest, and K-NN. For example, Roser and Moosmann [6] proposed a method to define regions of interest. They employed a color histogram to extract the feature space, which was then passed into SVM to classify the weather images. The research in [19] concatenated the features extracted from a gradient amplitude histogram, the HSV color space, and road information. The extracted features were then fed into an AdaBoost algorithm to assign the image its weather label. Lagorio et al. [20] designed a statistical model based on a

mixture of Gaussians to identify weather conditions from images. This mixture can identify both spatial and temporal changes, which assists the model in identifying the weather input. The downside of this method is that it cannot capture all weather events; it can only be implemented in particular conditions. Shen and Tan [21] built a weather condition detector, which can identify, for example, cloudy versus sunny weather using light illumination. In general, the methods that utilized hand-crafted weather features did not recognize weather conditions accurately.

Recently, improvements in the fields of deep learning and CNNs have been applied to weather recognition tasks. New research has utilized deep learning algorithms for classifying weather from images. For instance, Xiao et al. [22] presented a MetaCNN for classifying weather phenomena. MetaCNN is a modified version of the VGG16 [9] model. In MetaCNN, the authors replaced the fully connected layers in VGG16 with a single, global, average pooling layer. The final output was a softmax that estimated the probability distribution for each weather class label. The authors introduced a new dataset called the weather phenomenon database (WEAPD) that consists of 6,877 images for 11 different weather classes. Other researchers, such as Huang and Chang [23], employed a self-organizing map (SOM) to automatically classify weather images based on six variables at five different weather stations in Taiwan. Xia et al. [24] modified ResNet-50 to ResNet-15 to classify weather images, where the convolutional layers extracted the weather features that would be fed into the softmax function for classification. Guerra et al. [4] proposed a framework to classify weather as rain, fog, or snow using super-pixel masks that enhanced the input image. Then, the features were extracted using a pre-trained CNN and passed into an SVM for classification. Zhao et al. [1] developed a CNN-RRN model for multi-class weather on a single image, where the CNN was exploited to extract features. Next, the channel-wise attention model chose the most discriminative features; the convolutional LSTM was then used to estimate the weather class label. These deep learning methods of weather recognition are generally superior to traditional methods, but the limitations are as follows: one, these methods utilize large datasets, and two, they require a high-end GPU for training, making them computationally expensive.

Due to the great performance of DenseNet architecture, it has been used in diverse areas, including disease diagnosis, in the detection of Alzheimer's disease using an MRI [25], COVID-19 from chest images [26], and plant diseases [27].

Depth is an important consideration in improving the findings of deep learning models. Because of this, the proposed model is based on DenseNet-121, which has dense connections and thereby increases accuracy. These connections are advantageous because they utilize feature reuse to remain compact; use feed-forward networks; lower the number of parameters needed; increase feature propagation; and encourage feature generation, all of which increase accuracy and speed.

## III. PROPOSED MODEL

The workflow of the proposed system is shown in Fig. 1. First, the pretrained DenseNet-121 model was loaded. This

model was trained on ImageNet for weight initialization. The last layer was removed and replaced with a softmax with three neurons, where each neuron predicts the weather condition class (rain, fog, or snow). Then the model was re-trained and fine-tuned with the RFS dataset. In the testing phase, this trained model was efficiently used to estimate weather conditions.

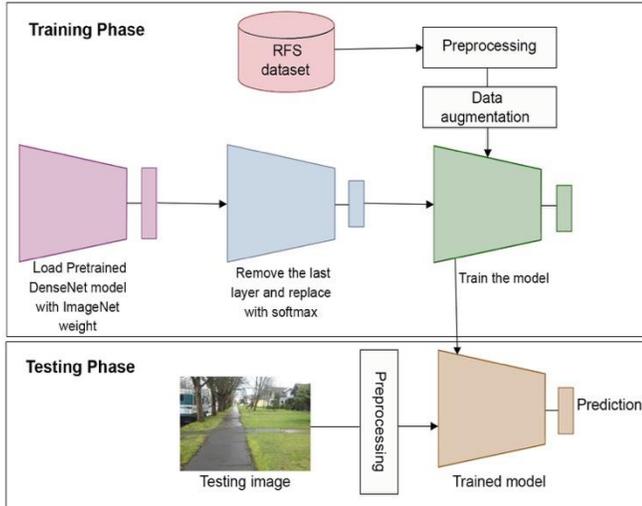

Fig. 1. The Workflow of the Proposed System.

### A. Model Architecture

This paper utilized a Dense Convolutional Network (DenseNet) [28] comprised of 121 layers to classify weather images. DenseNet is a special kind of CNN that was originally proposed by Huang et al. It achieved state-of-the-art results on several image classification datasets, such as Cifar-10 and SVHN. In a DenseNet architecture, layers are connected with dense blocks, meaning that each layer utilizes inputs from all previous layers in order to create a feature map that will send data to all of the following layers. Therefore, the  $l^{th}$ -layer receives all previous features maps  $(x_0, x_1, \dots, x_{l-1})$  as inputs:

$$x_l = H_l([x_0, x_1, \dots, x_{l-1}]) \quad (1)$$

Here,  $[x_0, x_1, \dots, x_{l-1}]$  represents the concatenation of all previous feature maps of  $l^{th}$ - layer.  $x_l$  is the output of the  $l^{th}$  layer, and  $H_l$  represents  $l^{th}$  layer, which is a composition function consisting of three successive operations including batch normalization, a ReLU activation function, and convolution. DenseNet is similar to methods such as ResNet, but the latter combines previous layers with future layers while DenseNet concatenates layers instead. DenseNet approaches the problem of vanishing gradients by reusing features which also reduces the number of parameters. As shown in Fig. 2, DenseNet-121 utilizes four dense blocks. Between each block is a transition layer that utilizes down-sampling on the feature maps to create a  $1 \times 1$  convolution as well as a  $2 \times 2$  average pooling layer. The dense blocks comprise multiple convolutional layers, which are connected in series and serve as cross-layer connections between distant layers. To increase non-linearity, DenseNet-121 utilizes a ReLU activation

function to increase non-linearity. The proposed ReLU activation is defined as follows:

$$ReLU(x) = \max(0, x) \quad (2)$$

The last layer is a fully connected layer with a softmax function that predicts the probability of a weather image class.

The softmax is defined by the following equation:

$$sm(z)_i = \frac{e^{z_i}}{\sum_{j=1}^C e^{z_j}} \quad \text{for } i = 1, \dots, C \quad (3)$$

Here,  $z = (z_1, \dots, z_C) \in \mathbb{R}^C$ .  $z$  is the input vector, and the exponential is implemented for each value  $z_i$ . Note that the sum of output vector  $sm(z)$  is equal to 1. A summary of the DenseNet-121 model layers is presented in Table I.

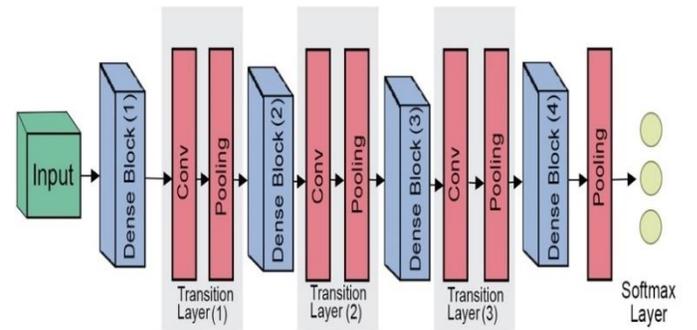

Fig. 2. The DenseNet-121 Architecture, which Consists of Four Dense Block Layers and Three Transition Layers.

TABLE I. LAYERS DETAILS OF DENSENET-121. THE DENSENET-121 HAS 6, 12, 24, 16 LAYERS IN FOUR DENSE BLOCKS

Layers	Output size	DenseNet-121
Convolution	$112 \times 112$	$7 \times 7$ conv, stride 2
Pooling	$56 \times 56$	$3 \times 3$ max pool, stride 2
Dense Block (1)	$56 \times 56$	$\begin{bmatrix} 1 \times 1 \text{ conv} \\ 3 \times 3 \text{ conv} \end{bmatrix} \times 6$
Transition layer (1)	$56 \times 56$	$1 \times 1 \text{ conv}$
	$28 \times 28$	$2 \times 2$ average pool, stride 2
Dense Block (2)	$28 \times 28$	$\begin{bmatrix} 1 \times 1 \text{ conv} \\ 3 \times 3 \text{ conv} \end{bmatrix} \times 12$
Transition layer (2)	$28 \times 28$	$1 \times 1 \text{ conv}$
	$14 \times 14$	$2 \times 2$ average pool, stride 2
Dense Block (3)	$14 \times 14$	$\begin{bmatrix} 1 \times 1 \text{ conv} \\ 3 \times 3 \text{ conv} \end{bmatrix} \times 24$
Transition layer (3)	$14 \times 14$	$1 \times 1 \text{ conv}$
	$7 \times 7$	$2 \times 2$ average pool, stride 2
Dense Block (4)	$7 \times 7$	$\begin{bmatrix} 1 \times 1 \text{ conv} \\ 3 \times 3 \text{ conv} \end{bmatrix} \times 16$
Classification layer	$1 \times 1$	$7 \times 7$ global average pool
		Softmax layer

### B. Transfer Learning

The deep DenseNet-121 model requires a large training set to increase its accuracy rate, but collecting labelled weather images is difficult. Transfer learning (TL) has been proposed as a common technique to address this limitation. The TL strategy pre-trains a model on a large, labelled dataset and then transfers the gained knowledge (learned weights) to other related tasks within the same architecture design. It treats the model as a starting point in the target task's training, which avoids the process of training the model from scratch with random weight initializations. Once TL is complete, the last layer must be altered to the number of required classes and then fine-tuned on the target dataset of interest. Recent research has demonstrated that TL improves performance rates compared to training a model from scratch on a small dataset. In addition, TL enhances generalization, reduces both overfitting training time, and decreases the labeled data required. Recently, TL has been applied widely in computer vision and natural language processing applications [29].

This research used a DenseNet-121 model pre-trained on the ImageNet dataset, which is composed of 1.2 million colored images in 1000 categories; therefore, the initialization of DenseNet-121 weights came from the pre-trained model. The output layer was removed and replaced with another layer containing three neurons, each matching up to a weather class label. A softmax function was applied in the final layer of the proposed model to predict the probability of each class as the output. Finally, the model was trained and fine-tuned across all layers on the RDF weather dataset.

### C. Image Data Augmentation

Another way to deal with a limited training set is image data augmentation. This technique alters the images in the existing training set. This leads to an increase in the number of examples, and therefore the diversity, in the training set. Another advantage to data augmentation is the reduction of overfitting. Data augmentation can be divided into two main classes: geometric and color transformations. Geometric augmentation affects only the location of the pixels (e.g., flipping, shifting, cropping, and resizing) as illustrated in Fig. 3. In contrast, color augmentation modifies the values of the image pixels (e.g., blurring and color distortion). Since the color of weather images plays a critical role in recognizing the weather, this paper only applied geometric augmentation to increase the training set while keeping the image pixel values. The geometric augmentation was performed as follows:

- Rotation was performed by rotating the image between 0 and 360 degrees randomly. This research rotated the images randomly in range from 0 to 45.
- Flipping flipped the image across the x and/or y axis.
- Translation moved the image horizontally or vertically (or both). Width translation and height translation were ranges (as a fraction of the total width or height) within which images were randomly translated vertically or horizontally.
- Cropping removed part of the image.
- Scaling increased or decreased the size of the image.

Fig. 3. Different Methods of Data Augmentation Including Rotation, Flipping, Translation, and Cropping and Resizing.

## IV. EXPERIMENTAL RESULTS AND DISCUSSION

### A. Dataset

In this work, we used the Rain Fog Snow (RFS) weather dataset. This is an open source dataset that was proposed by [2] to support computer vision and deep learning applications in classifying weather via images. The images are collected from different locations with different environmental settings. Each class contains 1100 images. Fig. 4 shows a sample of the RFS dataset for each weather class. This dataset is particularly effective for this research because it contains quality images, various environments, and targeted labels. All images were resized to  $224 \times 224 \times 3$  for suitable input into our DenseNet-121 model. We randomly selected 800 images for training and 300 for testing for each class.

### B. Pre-processing

Image pre-processing is significant in deep learning models. Min-max normalization is one of the common techniques used to rescale and transform original image pixels into an appropriate size, typically a range between 0 and 1. This removes biases by eliminating differences in magnitude. As a result, this normalization accelerates training and enhances the model's performance. In this paper, we normalized the image pixels in a range from 0 to 1 using the following equation:

$$x' = \frac{x - \min(x)}{\max(x) - \min(x)} \quad (4)$$

where  $x$  is the original pixel value,  $x'$  is the new value, and  $\min(x)$  and  $\max(x)$  represent the minimum and maximum pixel values of the image, respectively.

Fig. 4. A Sample of RFS Dataset for each Class. Each Column Represents One Class.

### C. Training Setting and Model Implementation

The proposed system was implemented in Python. DenseNet-121, and other deep learning models, were developed using the PyTorch framework. The experiments were then performed using Google Colab Pro to access a faster GPU. Adam [29] optimizer was also used to optimize the weights and biases of the DenseNet-121 with a learning rate of 0.001 and a momentum set to 0.9. The batch size was set to 64 and the number of epochs to 100. The formula for updating weights based on Adam optimizer is defined as follows:

$$\theta_{t+1} = \theta_t + \Delta\theta_t \quad (5)$$

where

$$v_t = \beta_1 * v_{t-1} - (1 - \beta_1) * g_t \quad (6)$$

$$s_t = \beta_2 * s_{t-1} - (1 - \beta_2) * g_t^2 \quad (7)$$

$$\Delta\theta_t = -\lambda \frac{v_t}{\sqrt{s_t + \epsilon}} * g_t \quad (8)$$

Here,  $\lambda$  indicates the initial learning rate,  $g_t$  is the gradient with respect to  $\theta_t$  at time  $t$ .  $v_t$  represents the first moment estimate,  $s_t$  is the second moment, and  $\beta_1$  and  $\beta_2$  are hyperparameters. The values of  $\beta_1$  and  $\beta_2$  are set to 0.9 and 0.99, respectively. To minimize the loss function, the proposed model utilized a backpropagation algorithm. This research employed categorical cross-entropy as the loss function, defined as follows:

$$\mathcal{L}(\theta) = -\frac{1}{n} \sum_{i=1}^n \sum_{j=1}^C y_{i,j} \log(\hat{y}_{i,j}) \quad (9)$$

where  $y$  is the correct output,  $\hat{y}$  is the predicted output,  $n$  represents the number of training samples, and  $C$  is the number of classes ( $C = 3$ ).  $L_2$  regularization was implemented to alleviate overfitting with a weight decay value of  $10^{-4}$ . Data augmentation was implemented using Transforms from the Torchvision library. It contains multiple transforms, which allowed for different types of augmentation on the images. The proposed model was initialized with weights that were pre-trained on ImageNet dataset. Doing this allowed this research to leverage the pretrained model. Then, the model was customized to weather recognition by training and finetuning it on the weather dataset.

### D. Results and Discussion

To gauge the efficacy of the proposed system for labelling weather conditions from images using DenseNet-121, the proposed system was compared to deep learning models that obtained state-of-the-art results in a variety of computer vision tasks. These models include AlexNet [8], VGG16 [9], Inception [10], and ResNet-18 [11]. To evaluate the performance of the model, this research used accuracy to measure performance. The accuracy of the testing set was computed as follows:

$$Acc = \frac{\text{Number of correct predictions}}{\text{Total number of testing examples}} \quad (10)$$

To compute this, the proposed DenseNet-121 model was trained on the FRS training set. Once this was completed, this research tested the proposed model and received, as an output, the classification results, which were one of three weather conditions: fog, rain, or snow. The accuracy of this model's

recognition was then tested on over 900 test images. The results are shown in Table II and Fig. 5. The proposed model obtained the best average accuracy 1, with a rate of 95.6%, followed by ResNet-18, AlexNet, VGG16, and Inception, respectively. DenseNet-121 had an accuracy at least 2% higher than the other deep learning models.

The results also show the accuracy of each category for each deep learning model. Among them, the proposed model achieved an accuracy rate on foggy images of 97.55%, 93.55% on rainy images, and 96.98% on snowy images. This means that the proposed DenseNet-121 model achieved superior results on classifying weather conditions from all three image types.

This research also studied the effect of TL for training a model versus training one from scratch with random weights. To do this, this paper evaluated the performance of the proposed DenseNet-121, trained with initial weights set to the pre-trained model from ImageNet dataset, as compared to a second DenseNet-121 model that was trained from scratch with random weights at initialization. Table III displays the results. By utilizing weight initialization, the pre-trained model achieved an accuracy of 95.9% as compared to 91.3% for the model trained from scratch. Performing TL allows the necessary features to be extracted from ImageNet; by doing this, the data is used more efficiently and thereby the proposed model is trained to identify weather conditions more easily. A DenseNet-121 model with random weight initialization obtained accuracy rate of about 59% after the first iteration (see Fig. 6 (a)), while DenseNet-121 based on transfer learning obtained an accuracy rate of 85% after the first iteration. As shown in Fig. 6, the proposed TL model converged in fewer iterations than the model that started with random weights, in respect to loss and accuracy rate. This decreased the computation time.

TABLE II. ACCURACY COMPARISONS OF THE PROPOSED METHOD WITH DIFFERENT DEEP LEARNING MODELS

Model	Foggy (%)	Rainy (%)	Snowy (%)	Avg. Accuracy (%)
VGG16 [9]	93.81	93.54	92.56	93.2
Inception [10]	88.89	89.00	93.40	90.3
AlexNet [8]	92.43	92.64	95.53	93.5
ResNet-18 [11]	92.47	90.79	94.30	93.7
DenseNet-121 (proposed model)	97.55	93.55	96.98	95.9

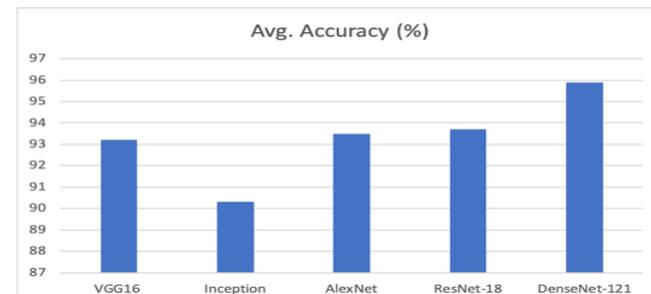

Fig. 5. Comparison of Average Accuracy for different Models.

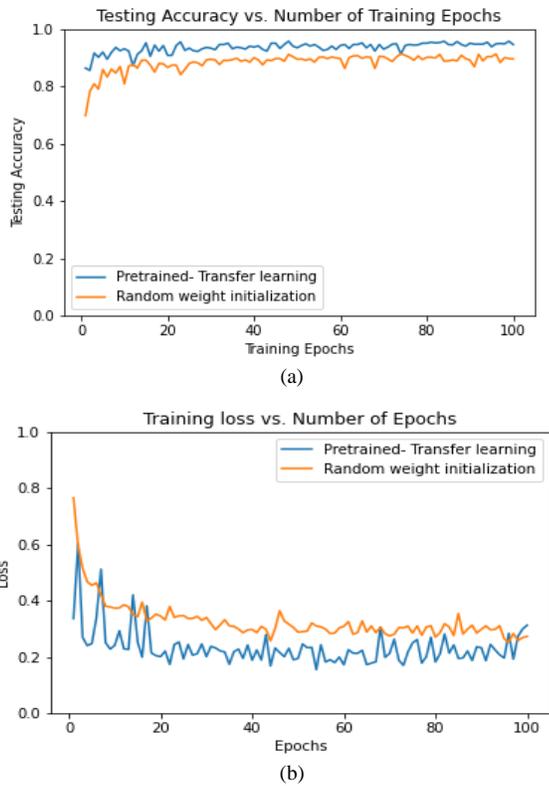

Fig. 6. (a) The Testing Accuracy Achieved from the DenseNet-121 Models Trained from Scratch and with TL. (b) The Loss Values Obtained for the DenseNet-121 Models Trained from Scratch and TL.

TABLE III. COMPARISON OF ACCURACY RATE OF DENSENET-121 BASED ON WEIGHT INITIALIZATION APPROACH

Weight Initialization Approach	Accuracy (%)
Random weight initialization	91.3
Pretained from ImageNet	<b>95.7</b>

Deep learning models require massive amounts of training to achieve high accuracy. The training examples are augmented by rotation, flipping, and shifting, and the accuracy has been, therefore, improved. In addition, pre-training DenseNet-121 with a large dataset such as ImageNet further improved the performance, and the model learned faster than the one trained from scratch. Data augmentation plays a significant role in reducing overfitting in particular when the training set is small.

These results suggest that the performance of the proposed model outperformed previous research and state-of-the-art techniques. Continued hardware and software advances will enable researcher to build deeper neural networks, which have higher representation power than shallower ones. These results demonstrated the importance of network depth, as networks with more layers achieved better outcomes. One of DenseNet's advantages is its increased flow of information and gradients, which improves training time. Each layer can access both the loss function and the original input, creating a deep supervision that trains deep architectures. In addition, feature propagation allows for the repetition, and efficient use, of features. It also reduces the parameters needed and, therefore, reduces the calculations needed, all of which is an advantage because

DenseNet layers are narrow. They may have only 12 filters per layer, and may add only a small set of feature maps to the network's collective knowledge; it is the final classifier that uses all the feature maps to make a decision. This paper's results and analysis show that the proposed model classifies weather conditions accurately by utilizing DenseNet features effectively. Furthermore, the proposed model also works well in real-time environments, which is another advantage.

## V. CONCLUSIONS AND FUTURE WORKS

Weather conditions have a significant impact on daily activities. Deep learning models have shown promising results in numerous computer vision and image analysis tasks. Recent research has demonstrated that CNNs can be deeper, and also more accurate and efficient, if there are shorter connections between the inputs and outputs. To test these hypotheses, this paper employed DenseNet-121 to recognize weather conditions from images. The results demonstrated that the proposed system, based on a DenseNet-121 model with transfer learning and data augmentation, maximized the accuracy rate with a small number of training examples. This paper also implemented and evaluated popular deep learning methods for recognizing weather conditions from images.

Future works will focus on simplifying the DenseNet-121 architecture to fit with edge devices while keeping the same performance. In addition, future research should apply self-supervised learning to utilize an unlabelled training set in pre-training, so that the proposed model can learn discriminative features.

# Research on Improved Shallow Neural Network Big Data Processing Model based on Gaussian Function

Lifang Fu

Faculty of Science

Henan University of Animal Husbandry and Economy  
Zhengzhou, 450044, China

**Abstract**—The application of the current new generation communication technology is gradually diversified, and the global Internet users are increasing, leading some large enterprises to increasingly rely on faster and more efficient big data processing technology. In order to solve the shortcomings of the current big data processing algorithms, such as slow computing speed, computing accuracy to be improved, and poor online real-time learning ability, this research combines incremental learning and sliding window ideas to design two improved radial basis function (RBF) neural network algorithms with Gaussian function as the kernel function. The Duffing equation example and the data of "Top 100 single products for Taobao search glasses sales" were used to verify the performance of the design algorithm. The experimental results of Duffing equation example show that when the total sample is 100000, the mean square errors of IOL, SWOL, SVM and ResNet50 algorithms are  $1.86e-07$ ,  $1.59e-07$ ,  $3.37e-07$  and  $2.67e-07$  respectively. The experimental results of the data set of "Top 100 SKUs for Taobao Search Glasses Sales" show that when the number of samples in the test set is 800, the root mean square errors of IOL, SWOL, SVM and ResNet50 algorithms are 0.0060, 0.0056, 0.0069 and 0.0073 respectively. This shows that the RBF online learning algorithm designed in this study, which integrates sliding windows, has a stronger comprehensive ability to process big data, and has certain application value for improving the accuracy of online data based commodity recommendation in e-commerce and other industries.

**Keywords**—Gaussian function; RBF; big data processing; incremental learning; sliding window

## I. INTRODUCTION

With the popularization of cloud computing, the Internet of Things and other technologies, a large number of industries began to explosively appear massive data, and the types of data also increased significantly, which began to show more and more characteristics of big data [1]. However, although the large data set has a large amount of data and low value density, it is still of great analysis and calculation value to discuss it as a whole, and some key information that is conducive to improving the business competitiveness of enterprises or the level of government services can be mined from the huge data [2-3]. However, it puts forward higher requirements for the processing speed and precision of the algorithm. At the same time, under the big data environment, there is another kind of more application demand, that is, the analysis model is updated regularly and in real time according to the updated data, so that the algorithm can meet the requirements of real-time update with the input data [4]. Traditional offline algorithms can not meet the needs of big data application scenarios for data mining,

and the processing accuracy and speed of mainstream online learning algorithms used in the market are still poor. Therefore, it is necessary to design data analysis algorithms that more closely match big data application scenarios, which is also the main motivation for this study. The expected result is that the improved neural network algorithm designed in this research can improve the efficiency and accuracy of big data processing.

## II. RELATED WORKS

Experts in the fields of Internet of Things, e-commerce, communication and information have carried out a large number of researches involving various aspects for the rapid analysis and mining of big data. Valerio et al. found that processing online social big data fused with multimedia data sources is highly complex, so the research team evaluated two current state-of-the-art big data processing architectures, namely Lambda and Kappa, the discussion results show that for the investigated problem, Lambda outperforms the Kappa architecture [5]. The Habeeb research team believes that network anomaly detection is the key to Internet security. However, the survey results show that the existing methods for detecting network anomalies are not effective enough. The reason is that the devices connected to the network accumulate a large amount of data, which greatly increases the difficulty of algorithm detection. Therefore, the author first explains the current main methods of real-time big data processing, anomaly detection machine learning algorithms, and then reviews big data processing techniques. Finally, the research challenges of real-time big data processing in anomaly detection are discussed [6]. Zhang et al. proposed a near-computation-enhanced big data processing architecture that can better handle big data and its corresponding applications. The structure consists of near-edge computing and far-edge computing units. Simulation and experimental results show that the task assignment and architecture proposed by the author have certain effectiveness [7]. Lwin designed an extended program toolkit that can assist GIS to process meteorological and geographic big data in view of the weak ability of processing big data in current geographic information systems. The test results show that the toolkit can effectively improve geographic the speed and precision with which information systems process big data [8]. Cigna F et al. found that with the increase of satellite tasks and the increase of task complexity, the big data processing method of communication system is more and more difficult to meet the needs of use, so they designed an improved satellite big data combining deep learning algorithm and online learning idea. The simulation experiment results

show that the model can shorten the time-consuming system processing satellite big data and improve the processing accuracy [9]. Muhammad et al. found that as the amount of data collected during manufacturing increases, monitoring systems are becoming an important factor in management decisions. Therefore, the researchers propose a real-time monitoring system that combines IoT sensors, big data processing, and hybrid predictive models. The results show that IoT-based sensors and the proposed big data processing system are sufficient to effectively monitor the manufacturing process. Furthermore, the proposed hybrid prediction model has better fault prediction accuracy than other models when sensor data is input [10]. Wang et al. believe that with the increasing global requirements for public safety governance, various surveillance sensors installed and used provide a large amount of data for public safety decision makers and managers, and traditional data mining algorithms cannot well summarize these large data. The data value contained in the data, so the author designed a big data mining algorithm that mixes simulated annealing algorithm and RBF neural network. The experimental results show that the algorithm compared with the neural network and machine learning algorithm can better mine the abstract high-dimensional features in the data, and improve the accuracy of the analysis results [11].

To sum up, experts designed a variety of improved algorithms or improved hardware systems to solve the problem of low efficiency of big data processing in communication, industrial production and other fields, and achieved various research results. However, most of the algorithms they designed are complex, difficult to train and time-consuming, and few of them can realize the function of real-time algorithm updating based on new samples. Most importantly, the solutions proposed in these studies are often only for a certain sub field of big data processing, with poor universality. In view of these shortcomings, this research attempts to use a relatively simple RBF neural network to build a processing algorithm for various types of big data in e-commerce, Internet of Things and other industries that can realize online learning.

### III. DESIGN OF IMPROVED RBF BIG DATA PROCESSING ALGORITHM BASED ON GAUSSIAN FUNCTION

#### A. Construction of RBF Algorithm Integrating Gaussian Function and Incremental Learning

After the training data scale increases significantly, the algorithm training time will also increase. If the training time does not change significantly, the computer needs to have stronger computing power [12-13]. In addition, if there are sample types that do not exist before in the increased samples, the algorithm trained to a certain extent cannot adapt to this change well. According to the traditional solution, the model should be retrained at this time. However, the re-learning process needs to retain most of the data left before, which will put forward higher requirements for database data storage [14]. Therefore, the incremental learning method can be used to solve such problems, because the original data is not necessary for the training of the incremental learning algorithm, so that it is less affected by the data size and requires more data storage capacity. It is more suitable for processing continuous large-scale real-time data [15].

The algorithm used in this study is built on the basis of RBF neural network. The RBF neural network is a neural network used to simulate the signal reception and processing between neurons in the human brain, so as to convert the linearly inseparable data in low-latitude space into linearly separable data in high-latitude space, and then cooperate with the combination of data layers to classify and regress the data. The typical structure of the network is shown in Fig. 1.

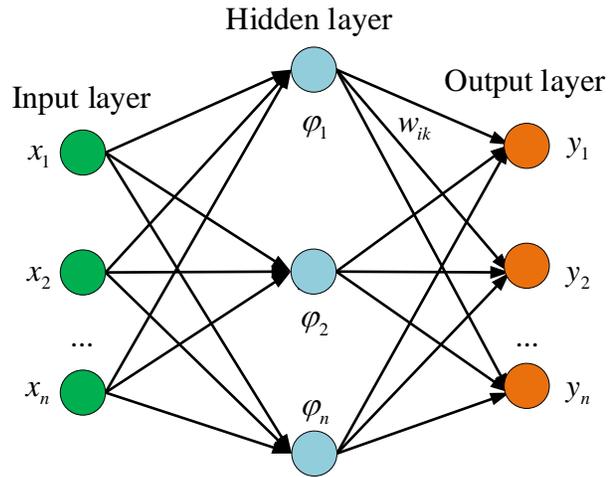

Fig. 1. Typical Structure of RBF Neural Network.

RBF neural network has the advantages of simple structure, fast training speed, good local optimality of algorithm output solution, and high approximation accuracy [16]. The RBF neural network consists of three structures: input layer, hidden layer, and output layer. It is a feedforward neural network and has the performance of approximating complex nonlinear functions. This ability is mainly provided by the hidden layer [17-18]. The hidden layer in the RBF neural network plays a linking role in the whole network. It is not only used to process the input vector using the specified basis function mapping, but also responsible for adjusting the weights to obtain the abstract integrated data of the output.

The following is a detailed discussion of incremental online learning and an analysis of the way it is incorporated into RBF neural networks. When a large data set is given,  $u$  one sample is selected as the initial training set, and one sample is added during the incremental learning model construction process  $L$  (taking into account the application scenario of this research, the  $L$  value is 1), and the online model The input data matrix is constructed recursively, that is, the matrix of the previous stage is the calculation basis of the adjacent matrix, and the algorithm will continue to construct the data matrix until the samples are added, which is the core idea of incremental learning [19]. To achieve incremental learning, the following three conditions need to be met at the same time. First, the model must be able to learn data features that are different from the previous samples. That is to say, if the samples in the input data set  $(x_j, y_j)$  have already appeared in the previous model training stage However, when it reappears in the application scene, it will be treated as a new instance of the old class. Finally, when there is a sample in the application scenario that the model has

never seen during training  $(x_m, y_m)$ , it will be treated as a new category. Secondly, during incremental learning, only new data and categories that have not appeared in the application scenario are  $(x_k, y_k)$  used as training sets [20]. In general, incremental learning mainly has the following three implementations. The first is to filter the most informative samples, the second is to use a combination of multiple trained models to form an integrated model, and the third is to adjust the model indicators and parameters.

It can be seen from the above content that the sample set in incremental learning is in an increasing state, that is, with  $t$  the increase of running time, the sample set  $\{X_i, Y_i\}_{i=1}^{t-1}$ , or  $\{(x_i, y_i)\}$  a fixed new  $L=1$  sample will be added each time, if  $x(t)=[x_1, x_2, \dots, x_t]$ ,  $y(t)=[y_1, y_2, \dots, y_t]^T$ , and  $x_i \in R^n$ , are assumed  $y_i \in R$ . Then the RBF matrix whose kernel function used in this study is a Gaussian function can be expressed in the form of Equation (1).

$$A = \begin{bmatrix} \phi(\|x_1 - x_1\|) & \phi(\|x_1 - x_2\|) & \dots & \phi(\|x_1 - x_t\|) \\ \phi(\|x_2 - x_1\|) & \phi(\|x_2 - x_2\|) & \dots & \phi(\|x_2 - x_t\|) \\ \dots & \dots & \dots & \dots \\ \phi(\|x_t - x_1\|) & \phi(\|x_t - x_2\|) & \dots & \phi(\|x_t - x_t\|) \end{bmatrix}_{t \times t} \quad (1)$$

where  $\phi()$  is the Gaussian kernel function, the radial basis function can be expressed by formula (1),

$$f(x) = \sum_{i=1}^t \beta_i \phi(\|x - x_i\|) \quad (2)$$

However, when using the RBF algorithm based on the Gaussian kernel function to build a big data processing model, it is also necessary to satisfy  $f(x_i) = F(x_i)$  or  $F = A \cdot \beta$ , where  $A$  is the radial basis kernel function,  $F = [F(1), F(2), \dots, F(t)]^T$ , when the function  $A$  is a positive definite function or the sample points of formula (2) do not coincide, there is formula (3).

$$\hat{\beta} = A^{-1} \times F \quad (3)$$

It can be seen from formula (3) that  $\hat{\beta}$  the inverse function of the radial basis kernel function needs to be calculated first, but when the  $A$  dimension is high, the calculation of the inverse matrix consumes a large amount of calculation, so the block matrix technique is used to calculate  $A^{-1}$ . It can  $A_{t+1}$  be obtained by  $A_t$  recursion, and the calculation formula between the two is deduced below. Observing  $A_{t+1}$  the  $A_t$  elemental composition of and, it is found that the former can be written in the form of formula (4).

$$A_{t+1} = \begin{bmatrix} A_t & H(t) \\ H(t)^T & f(t) \end{bmatrix} \quad (4)$$

In formula (4),  $H(t) = [\phi(\|x_{t+1} - x_1\|), \dots, \phi(\|x_{t+1} - x_t\|)]^T$ ,  $f(t) = \phi(\|x_{t+1} - x_{t+1}\|)$ . Now define a block matrix

$B = \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix}$ . And when  $B^{-1}$  both  $B_{11}^{-1}$  exist, there is the relationship of formula (5),

$$B^{-1} = \begin{bmatrix} B_{11}^{-1} & B_{12} \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} B_{11}^{-1} & B_{12} \\ -E & 0 \end{bmatrix} \cdot (B_{22} - B_{21} \cdot B_{11}^{-1} \cdot B_{12})^{-1} \cdot \begin{bmatrix} B_{21} \cdot B_{11}^{-1} - E \end{bmatrix} \quad (5)$$

In Equation (5),  $B_{11}$ ,  $B_{12}$ , are respectively a symmetric matrix and a column vector  $I$ , and  $B_{21}$ ,  $B_{22}$  is  $I^T$  a non-zero scalar vector  $q$ ,  $A = B_{22} - B_{21} \cdot B_{11}^{-1} \cdot B_{12}$  and if, Equation (5) can be simplified to Equation (6),

$$B^{-1} = \begin{bmatrix} B_{11}^{-1} & 0 \\ 0 & 0 \end{bmatrix} + R \cdot R^T \cdot Z \quad (6)$$

In formula (6)  $R = [I^T \cdot B_{11}^{-1} - E]$ ,  $Z = (q - I^T \cdot B_{11}^{-1} \cdot I)^{-1}$ , can be obtained by using the block matrix inversion method  $A_{t+1}^{-1}$ , see formula (7).

$$A_{t+1}^{-1} = \begin{bmatrix} A_t^{-1} & 0 \\ 0 & 0 \end{bmatrix} + r_1(t+1)r_1(t+1)^T Z_1(t+1) \quad (7)$$

In formula (7)  $r_1(t+1) = [H(t)^T \cdot A_t^{-1} \cdot -E]^T$ , it can be seen from the  $Z_1(t+1) = [f(t) - H(t)^T \cdot A_t^{-1} \cdot H(t)]^{-1}$  observation of formula (7) that it  $A_{t+1}^{-1}$  can be obtained by  $A_t^{-1}$  calculation, and when it  $t$  is small, it  $A_t^{-1}$  can be directly obtained. According to the above two points, the large matrix inversion operation process can be effectively avoided, thereby improving the overall calculation efficiency of the algorithm. According to the above design content, an improved RBF neural network algorithm based on the fusion of Gaussian kernel function and incremental learning can be constructed, and the training process is shown in Fig. 2.

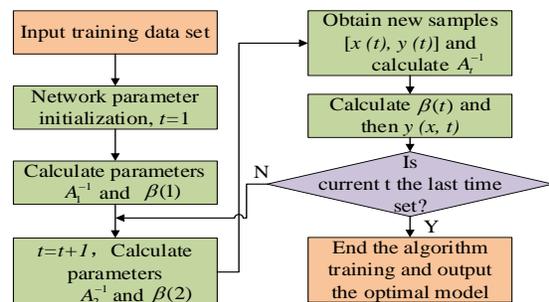

Fig. 2. The Training Flow Chart of the Improved RBF Neural Network Algorithm based on Gaussian Kernel Function and Incremental Learning.

### B. Design of Improved RBF Algorithm Combined with Windowed Online Learning Ideas

The improved RBF algorithm based on incremental learning designed in the above content has significant advantages when dealing with static big data, which can simplify the training process and greatly reduce the training time of the algorithm. However, when using this algorithm to deal with another form of big data, that is, dynamic streaming big data that cannot be collected at one time, because dynamic streaming big data is real-time, volatile, bursty, disordered, and infinite. The improved RBF algorithm based on incremental learning previously designed is used to deal with static big data and dynamic big data, and the computing performance is obviously limited, so another processing algorithm needs to be designed for this data form. This research decided to build a windowed learning model by combining radial basis functions and sliding fixed-length windows on the basis of the improved algorithm of incremental learning RBF.

The windowed online learning algorithm is an online learning algorithm based on a sliding window. In this algorithm, new samples can only be added to the window after deleting an old sample, and the total length of the window remains stable. At the same time, in the process of dynamically updating the data set, the data newly added to the algorithm is processed, and the online processing of streaming dynamic big data is realized. Windowed online learning has the following advantages. First, the historical data used by the training algorithm does not need to be stored in a special technology, which can reduce computer memory consumption. Secondly, this type of algorithm can efficiently use the previously trained data while processing the new data, reasonably reduce the processing time of the new data, and reduce the time length of the algorithm. At the same time, in the windowed online learning algorithm, since the training samples are continuously updated and the historical training results are retained to a certain extent, the accuracy of the algorithm can be continuously improved. The last point, which is also the main reason for this research to choose this technology to improve the RBF network, is that the windowed online learning algorithm can update the window by overlapping online, which ensures that no matter how many samples are added, the single training time of the algorithm remains unchanged, so as to improve the training efficiency and effectively solve the processing problem of streaming dynamic big data.

The fixed-length sliding window strategy is adopted here, that is, each time a new sample is input in the algorithm, an old sample will be deleted at the same time, so as to maintain the total number of samples in each training. Assuming that the sample  $T = \{x_i, y_i\}_{i=t}^{i=t+m+1}$  will be updated with time  $t$ , the sample set can be expressed as  $\{x(t), y(t)\}$ ,  $x_i$ ,  $x(t)$  are the features of the variable sample,  $t$  the feature vector of the input sample set at the time,  $y_i$ ,  $y(t)$  respectively represent the label of the variable sample, the input sample set at the  $t$  time The label vector, and  $x(t) = \{x_t, x_{t+1}, \dots, x_{t+m+1}\}$ ,  $y(t) = \{y_t, y_{t+1}, \dots, y_{t+m+1}\}^T$ ,  $x_t \in R^n$ , and  $y_t \in R$ ,  $m$  are the window lengths (4 after adjusting the algorithm parameters

many times in this study).  $t$  At the moment, the Gaussian kernel function of the RBF radial basis function is in the  $A_t$  form of an  $m$  order square matrix, and its internal elements can be obtained by analogy with formula (1), which will not be repeated here  $A_t$ .

$$A_t = \begin{Bmatrix} h(t) & H(t)^T \\ H(t) & w(t) \end{Bmatrix} \quad (8)$$

Among them  $h(t) = \phi(\|x_t - x_t\|)$ ,  $H(t) = [\phi(\|x_{t+1} - x_t\|), \dots, \phi(\|x_{t+m-1} - x_t\|)]^T$ , and the  $w(t)$  calculation method is shown in formula (9).

$$w(t) = \begin{bmatrix} \phi(\|x_{t+1} - x_{t+1}\|) & \dots & \phi(\|x_{t+1} - x_{t+m-1}\|) \\ \dots & \dots & \dots \\ \phi(\|x_{t+m-1} - x_{t+1}\|) & \dots & \phi(\|x_{t+m-1} - x_{t+m-1}\|) \end{bmatrix}_{(m-1) \times (m-1)} \quad (9)$$

Since  $H(t)$ ,  $h(t)$ ,  $w(t)$  represent  $m-1$  a column vector of dimensions, a scalar that is not 0, and  $m-1$  a square matrix of dimensions, respectively. At the  $t+1$  moment, new samples  $(x_{t+1}, y_{t+1})$  are added to the training set, and  $(x_{t+1}, y_{t+1})$  samples are deleted from the training set at the same time, which  $A_{t+1}$  can be calculated according to formula (10).

$$A_{t+1} = \begin{bmatrix} w(t) & V(t+1) \\ V(t+1)^T & f(t+1) \end{bmatrix} \quad (10)$$

In formula (10)  $V(t+1) = [\phi(\|x_{t+m} - x_{t+1}\|), \dots, \phi(\|x_{t+m} - x_{t+m-1}\|)]^T$ ,  $f(t+1) = \phi(\|x_{t+m} - x_{t+m}\|)$ . Therefore, the block matrix calculation method can be used to obtain  $A_t^{-1}$ ,  $A_{t+1}^{-1}$ , and the former calculation method is shown in formula (11)

$$A_t^{-1} = \begin{bmatrix} 0 & 0 \\ 0 & w(t) \end{bmatrix} + R(t) \cdot R(t)^T \cdot Z(t) \quad (11)$$

In formula (11)  $R(t) = [H(t) \cdot w(t)^{-1} - E]^T$ ,  $Z(t) = 1 / [h(t) - H(t)^T \cdot w(t)^{-1} \cdot H(t)]$ , can be described by formula (12) in the same  $A_{t+1}^{-1}$  way.

$$A_{t+1}^{-1} = \begin{bmatrix} w(t)^{-1} & 0 \\ 0 & 0 \end{bmatrix} + R(t+1) \cdot R(t+1)^T \cdot Z(t+1) \quad (12)$$

In formula (12)  $R(t+1) = [V(t+1)^T \cdot w(t)^{-1} - E]^T$ ,  $Z(t+1) = 1 / [f(t+1) - V(t+1)^T \cdot w(t)^{-1} \cdot V(t+1)]$ .  $h(t) \in R$ ,  $H(t) \in R^{m-1}$  is composed of kernel function elements and vectors that delete samples during the sliding window movement, and  $f(t+1) \in R$ ,  $V(t+1) \in R^{m-1}$ . Observing

formula (12), we can see that if we want to calculate it  $A_{t+1}^{-1}$ , we need to find it first  $w(t)^{-1}$ , and formula (13) can be deduced according to formula (11).

$$A_t^{-1} = \begin{bmatrix} 0 & 0 \\ 0 & w(t)^{-1} \end{bmatrix} + \begin{bmatrix} \frac{1}{Z(t)} & \frac{-H(t)^T w(t)^{-1}}{Z(t)} \\ \frac{-w(t)^{-1} \cdot H(t)}{Z(t)} & \frac{w(t)^{-1} \cdot H(t) \cdot H(t)^T \cdot w(t)^{-1}}{Z(t)} \end{bmatrix} \quad (13)$$

When it  $A_t^{-1}$  is known, it can be obtained by its (1,1) position element, and then  $\frac{1}{Z(t)}$  the row vector can be obtained  $Q_1$  by using the first row element  $A_t^{-1}$ . The calculation method is shown in formula (14).

$$Q_1 = \frac{-H(t)^T w(t)^{-1}}{Z(t)} \quad (14)$$

Then use  $w(t)$  the first column vector element to calculate the column vector  $Q_2$ , and the calculation method is shown in formula (15).

$$Q_2 = \frac{-w(t)^{-1} \cdot H(t)}{Z(t)} \quad (15)$$

Finally, combining equations (14) and (15), we can obtain

$$\begin{aligned} Q_3 &= \frac{w(t)^{-1} \cdot H(t) \cdot H(t)^T \cdot w(t)^{-1}}{Z(t)} \\ &= Q_1(t) \cdot Q_2(t) \cdot Z(t) \end{aligned} \quad (16)$$

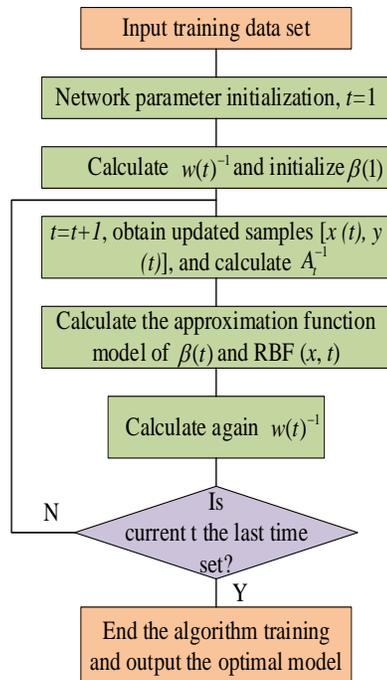

Fig. 3. The Training Flow Chart of the Improved RBF Neural Network Algorithm based on Sliding Window.

From the above content, it can be seen that the  $w(t)^{-1}$  numerical value is equivalent to  $\phi(t)^{-1}$  the matrix subtraction after removing the first row and the first column  $Q_3(t)$ , and then combining the formula (10) and formula (12), it can be obtained, that is, the  $A_{t+1}^{-1}$  design of the recursive method from  $A_t^{-1}$  to to is formed.  $A_{t+1}^{-1}$ . So far, the improved RBF online learning neural network algorithm based on sliding window is designed, and its calculation flow is shown in Fig. 3.

#### IV. IMPROVE THE PERFORMANCE VERIFICATION OF RBF ALGORITHM

##### A. Algorithm Performance Verification Experimental Design and Data Set Processing

This research plans to design two verification experiments. One is to use the Duffing equation example, which is widely used to verify the training effect of deep learning algorithms, to train and compare the performance of each algorithm. In this study, the parameters in the Duffing equation were set as  $p_1 = -1.1$ ,  $p_2 = 0.4$ ,  $\Delta t = 0.01$ ,  $w = 1.7$  and  $q = 1.5$ , respectively, and the experimental plans of 1000, 3000, 5000, 10000, and 100,000 samples generated by the Duffing equation were set respectively. In order to avoid the influence of errors caused by random factors, each experimental scheme was repeated 10 times. In the experiment, the super parameter acquisition method of each algorithm is to use dichotomy to repeatedly run 10 times within the range of conventional parameter adjustment, and the parameter of the best run result is the final parameter. The second experiment scenario is a typical application scenario of big data mining algorithms, namely the Taobao online store sales forecast experiment. The data in the experiment is the data of “Taobao Search Glasses Sales Top 100 Single Items” provided by a domestic data supplier. The purpose of the experiment is to input this data into the algorithm to predict the sales volume of the glass single product in the store. A total of 5,500 sample data of Taobao e-commerce research and sales TOP100 single products were obtained, which contained a total of 18 variables. Except for the two characteristics of “commercial name” and “credit”, which cannot be numerically processed, the others are numerical characteristics, which are respectively praised. rate, complaint rate only in 30 days, return rate in the past 30 days, sales volume in the past 30 days, original price, discount, postage, sales price, collection volume, days on the shelf, main credit ratio, customer evaluation, seller service points, goods Average refund speed, shipping score, description score. It is necessary to convert the “credit” feature that affects the prediction result in the data set. The value of this feature includes “other”, “blue crown”, “gold crown”, “diamond”, “heart”, and “Tmall”. Each equivalence contains several different secondary classifications. Statistics show that items with different credit ratings correspond to different frequencies of appearance, which means that there is a certain relationship between credit ratings and product sales. Therefore, the credit rating is assigned with reference to Taobao’s credit regulations. The single product credit rating, frequency of occurrence, and numerical ranking results are shown in Table I.

TABLE I. THE STATISTICS OF THE “CREDIT” VARIABLE OF THE TOP100 SINGLE PRODUCT DATA SET OF TAOBAO SEARCH GLASSES SALES

Grade 1 and 2 credit rating	The number of occurrences	Numerical mapping	Grade 1 and 2 credit rating	The number of occurrences	Numerical mapping
Tmall	1125	Twenty-one	1 gold	152	8
1 heart	11	17	2 gold	20	6
2 hearts	15	16	3 gold	33	7
3 hearts	40	18	4 gold	46	9
4 hearts	46	20	1 blue	319	10
5 hearts	45	19	2 blue	289	1
1 drill	144	12	3 blue	346	2
2 drills	168	11	4 blue	184	3
3 drills	249	13	5 blue	122	5
4 drills	417	15	other	5	4
5 drills	272	14	/	/	/

In order to improve the model training effect, the data set also needs to be processed by data dimensionality reduction. In order to compare the performance and application value of the algorithm, this study chose Support Vector Machine (SVM) and ResNet50 to build a comparative analysis model.

*B. Analysis of Validation Experiment Results*

After the calculation of all experimental schemes under the two experiments is completed, the experimental data are counted. The following first analyzes the performance test experiment based on the Duffing equation example. Under the premise of five sample sizes, the statistical results of the mean square error of each algorithm are shown in Table II.

In order to verify whether there is a significant difference in the calculation results of each algorithm under each total experimental scheme, an F test was performed, and the significance level of the difference was set to 0.05. Note that

IOL and SWOL in Table II represent the improved RBF algorithm based on incremental learning and the modified RBF algorithm incorporating sliding windows designed in this study, respectively. It can be seen from Table II that the root mean square error data P values of the output test set of each group of algorithms under various experimental schemes are all less than the significance level of 0.05, and the difference is considered significant. Specifically, under the experimental schemes of various sample numbers, the mean square error of the SVM model is the largest, followed by the ResNet50 model. The mean square error of the test set of the IOL and SWOL algorithms designed in this research is relatively small, and the mean square error of the SWOL algorithm is relatively small. minimum. For example, when the total sample is 100000, the mean square errors of the IOL, SWOL, SVM, and ResNet50 algorithms are 1.86e-07, 1.59e-07, 3.37e-07, and 2.67e-07, respectively. Then analyze the training time of each algorithm, and the statistical results are shown in Table III.

TABLE II. MEAN SQUARE ERROR STATISTICS OF EACH ALGORITHM ON THE DUFFING EQUATION EXAMPLE SAMPLE TEST SET

Algorithm	Total samples 1000; test set: training set = 300:700	Total samples 3000; test set: training set = 900:2100	Total samples 5000; test set: training set = 1500:3500	Total samples 10000; test set: training set = 3000:7000	Total samples 100000; test set: training set=30000:70000
IOL	3.25e-04	4.36e-06	5.64e-07	3.28e-07	1.86e-07
SWOL	3.06e-04	4.12e-06	5.38e-07	3.02e-07	1.59e-07
SVM	4.57e-04	5.98e-06	6.74e-07	5.35e-07	3.37e-07
ResNet50	3.59e-04	4.41e-06	5.92e-07	4.81e-07	2.67e-07
F value	1.651	1.548	2.154	5.833	9.645
P value	0.034	0.039	0.022	0.007	0.003

TABLE III. STATISTICS ON THE TRAINING TIME OF EACH ALGORITHM ON THE DUFFING EQUATION EXAMPLE SAMPLE (UNIT: SECOND)

Algorithm	Total samples 1000; test set: training set = 300:700	Total samples 3000; test set: training set = 900:2100	Total samples 5000; test set: training set = 1500:3500	Total samples 10000; test set: training set = 3000:7000	Total samples 100000; test set: training set=30000:70000
IOL	3.2	73.8	389.4	3564.4	3.79e+06
SWOL	1.9	30.5	175.2	1442.0	1.48e+06
SVM	5.9	86.2	833.6	7957.9	8.25e+06
ResNet50	4.2	74.2	759.1	6553.1	6.73e+06
F value	1.954	2.694	2.545	2.844	3.177
P value	0.031	0.021	0.020	0.016	0.013

The numbers in the cells of Table III represent the average model training time of the corresponding algorithm under the corresponding experimental scheme. It can be seen from Table III that the P values of the training time data of each group of algorithms under each experimental scheme are all less than the significance level of 0.05, and the difference is considered to be different. significant. Specifically, under the experimental schemes of various sample numbers, the training time of the SVM model is the largest, followed by the ResNet50 model. The training time of the IOL and SWOL algorithms in this study is relatively small, and the training time of the SWOL algorithm is the smallest. For example, when the total number of samples is 100,000, the training time of the IOL, SWOL, SVM, and ResNet50 algorithms are 3.79e+06, 1.48e+06, 8.25e+06, and 6.73e+06, respectively. The following is an analysis of the performance of each algorithm in the second experiment. First, the change of the loss function value of each algorithm during the training process is counted, as shown in Fig. 4.

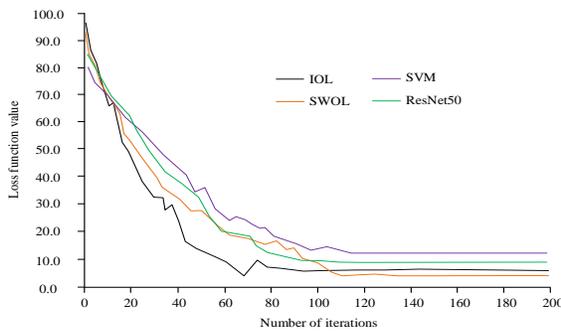

Fig. 4. Changes in the Loss Function Value of Each Algorithm during the Training Process of the e-commerce Dataset.

Observing Fig. 4, it can be seen that with the increase of the number of iterations, the calculation time of each algorithm shows an overall decreasing law, and finally converges. From the point of view of convergence speed, the IOL algorithm has the fastest convergence speed, and the algorithm training is roughly completed around the 85th time, while the SVM algorithm has the slowest convergence speed, which roughly completes the convergence around 117 times. After convergence, the loss function of the SWOL algorithm is the smallest, which is 4.2. The calculation time-consuming situation of various algorithms is counted, as shown in Fig. 5.

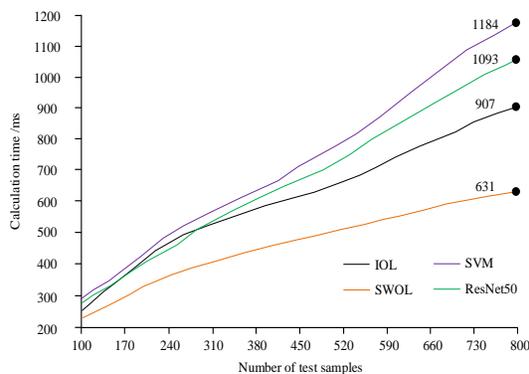

Fig. 5. The Calculation Time Change of Each Algorithm in the e-commerce Data Test Set.

Observing Fig. 5, it can be seen that with the increase of the number of test samples, the time consumption of each algorithm to process the test samples shows an overall increasing trend, but the overall calculation time of the SVM algorithm is the largest, and the overall calculation time of the SWOL algorithm is the smallest. When the number of samples in the test set is 800, the training time of the IOL, SWOL, SVM, and ResNet50 algorithms are 1184ms, 1093ms, 907ms, and 631ms, respectively. The processing performance of the algorithm is analyzed again, and the root mean square error variation of each algorithm on the test set is shown in Fig. 6.

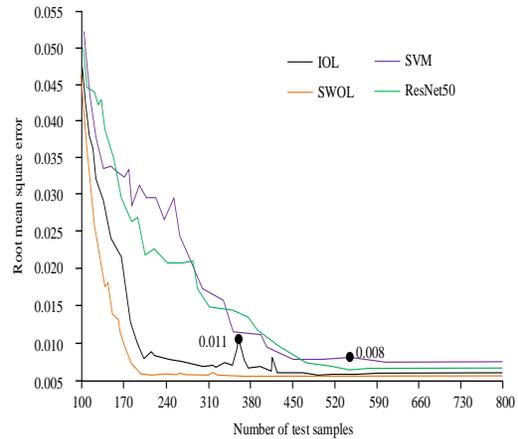

Fig. 6. Variation of the Root Mean Square Error of Each Algorithm in the e-commerce Data Test Set.

Observing Fig. 6, we can see that the root mean square error performance of the IOL and SWOL algorithms designed in this study is better under different test set samples, but the stability of the former is slightly worse than that of the latter, when the number of iterations is about 362 times, the root mean square error of the IOL algorithm has a large rebound. When there are 800 training samples, the root mean square errors of the IOL, SWOL, SVM, and ResNet50 algorithms are 0.0060, 0.0056, 0.0069, and 0.0073, respectively. In order to ensure the reliability of the research results, the change of the mean absolute error of each algorithm on the test set is finally analyzed, as shown in Fig. 7.

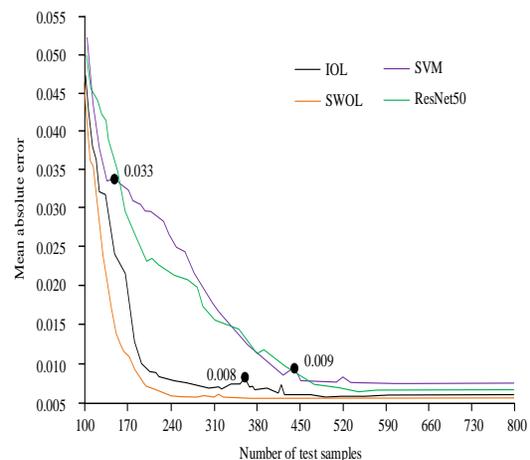

Fig. 7. Absolute Error Variation of Each Algorithm in the e-commerce Data Test Set.

Observing Fig. 7, it can be seen that the overall change of the mean absolute error of each algorithm with the increase of the number of test samples is basically the same as that of the root mean square error, but the variation range of the mean absolute error of each algorithm is reduced, especially the IOL and SWOL algorithms. However, there are still some data rebound phenomena in IOL. For example, when the number of training samples is about 360, the average absolute error of the IOL algorithm briefly rises to 0.008.

Finally, in order to further verify the application effect of the algorithm proposed in this study, 20 online sales store owners were selected from China and invited to use the customer in store consumption prediction system based on this algorithm and other comparison algorithms. The input data of this system are the customer's stay time in the store, the length and content of communication with customer service, the number of page clicks and the number of comparisons of similar products. The mean square error of the prediction results and the satisfaction of the shopkeepers (five point evaluation, the higher the score, the more satisfied) are used as indicators to measure the application effect of the algorithm. Since the data obtained from the experimental results are few and simple, the experimental results are described and analyzed in text. The experimental results show that the mean square error of the prediction results of the customer's in store consumption prediction system based on the IOL, SWOL, SVM and ResNet50 algorithms is 42.7 ¥, 29.6 ¥, 52.3 ¥ and 44.5 ¥ respectively, and the average of the shopkeeper satisfaction scores obtained are 3.85, 4.16, 4.03 and 3.61 respectively. It can be seen that the system designed based on this study has the most accurate consumption prediction and the highest user satisfaction.

## V. CONCLUSION

With the increase in the scale of Internet data, the use of big data technology to deal with huge data needs in e-commerce, Internet of Things and other industries is increasing. This research attempts to use the incremental learning idea to construct an improved RBF neural network, and combines the sliding window technology to design another improved RBF neural network. Using a variety of algorithms to predict the results of the Duffing equation example, the results show that when the total sample is 100,000, the mean square errors of the IOL, SWOL, SVM, and ResNet50 algorithms are  $1.86e-07$ ,  $1.59e-07$ , and  $3.37e-07$ , respectively.  $-07$ ,  $2.67e-07$ , the training time is  $3.79e+06$ ,  $1.48e+06$ ,  $8.25e+06$ ,  $6.73e+06$ , respectively. The simulation experiment results of each algorithm in the "Taobao Search Glasses Sales TOP100 Single Product" data set show that when the number of samples in the test set is 800, the training time of the IOL, SWOL, SVM, and ResNet50 algorithms are 1184ms, 1093ms, 907ms, and 907ms, respectively. 631ms, the root mean square error is 0.0060, 0.0056, 0.0069, 0.0073 respectively. The two experimental results show that the two improved RBF algorithms designed in this study have faster training speed and higher data processing accuracy, and the improved RBF algorithm based on sliding window has the fastest speed in processing big data among the comparison algorithms.

**Abstract**—Rapid technological advancement has altered the demands of user experience (UX) in product design. However, research has shown that there is a gap and paucity of conceptual and practical models in this research field that may serve as guidelines for the design of immersive technologies such as augmented reality (AR) applications. Identifying the variables and components that influence the enhancement of AR design is critical for creating a great UX. The literature indicated that emotion is the primary driver of the UX. Therefore, this study proposed a conceptual design model for AR mobile application that incorporates user interface, interaction, and content design elements while taking their emotions into consideration in order to improve the UX. The focus of this study is to evaluate the proposed conceptual design model of augmented reality mobile application design (ARMAD) through expert reviews. Feedbacks from the expert reviewers are compiled and illustrated in order to refine the initial ARMAD model. The findings showed that majority of the expert reviewers agreed that the conceptual design model is suitable to be used as guideline in designing AR applications that enhances the UX through emotional elicitation. Accordingly, ARMAD model has been refined according to the feedback and suggestions from the expert reviewers. This model will provide researchers and practitioners insight into the essence of AR design that influence the user experience.

**Keywords**—Augmented reality; conceptual design model; emotional UX; Kansei Engineering; mobile application; user experience

## I. INTRODUCTION

Augmented reality (AR) has received increased attention over the last few years and has shaped a new way people interact with technologies. With the advent of smartphones, mobile augmented reality (MAR) has brought new opportunities and experiences, leading to MAR's exponential growth in recent years, with 1.1 billion AR users in 2022 [1]. The report also showed that around 83.1 million individuals will use AR application at least once in a month [1]. The emergence of AR technology has significantly improved the usability and experience of smartphone users. MAR has increased the accessibility to products and services in various sectors including retail [2]–[4], transportation [5]–[7], tourism [8], [9], games [10], [11], health [12], [13], and education [14]–[16].

The advancement in this AR immersive technology has altered the way people interact with devices and information, hence provide new opportunities for investigating how to design in immersive environments. To leverage AR in improving the user experience (UX), the AR application must be meticulously designed to captivate the user's attention and satisfaction. Based on the literatures, there is a clear need for research that considers the user emotions in AR design to enhance UX [17]–[19] since user demand has expanded beyond functionality to also include emotional satisfaction [20]. Similarly, [21] argued that application design should address the whole UX rather than the concept of usability alone. However, the user may experience various design challenges when using such immersive technologies [22], [23]. As AR technology becomes more prevalent, the requirement to grasp the intricacies of MAR interface design to satisfy its users grows [24]. To deliver a positive UX design, designers must address the user challenges by comprehending the factor and components of AR design.

Although the usage of this persuasive technology is on the rise, there is a scarcity of conceptual and practical models to serve as a guide when designing AR applications for UX. Most of the existing models focused only on the AR application development [25], [26], games development [27], [28], or AR for learning [29]. Although there exist models on AR UX, their emphasis has been on overall system development [30] and researching user acceptability on AR applications [31], rather than investigating the relationship between AR design components, emotions, and UX. Therefore, what are the significant components for designing an emotional UX for AR mobile application? This study aims to find out the answer to this question by obtaining and incorporating expert opinions. For that purpose, this study proposed a conceptual model for augmented reality mobile application design (ARMAD) through a combination of user interface (UI), interaction and content design components to better understand the influence of those components on the user's emotional experience. The main concern of the expert validation is to verify the following research questions (RQ):

RQ1) What are the significant components that are required in designing the AR mobile application?

RQ2) Does the design components able to elicit the user's emotion?

\*Corresponding Author.

This study employed *Kansei Engineering* (KE) [32]; a widely used method for emotional design research [33]. KE suggested using specimens to identify the relationship between emotion and product design [34]. Therefore, in this study, the specimens were provided to the expert reviewers throughout the validation procedure so that they could experience the AR product samples and evaluate whether the specimens could elicit their emotions. This study is motivated by the advanced technological research and trends in UX and AR. Since the past literatures demonstrated that UX is a phenomenon that contributes to the success of technological products [35]–[37], therefore investigating the potential of emotional UX in the field of AR technology is warranted.

## II. RELATED WORKS

### A. Emotional user Experience Design

The landscape of UX demand has significantly changed as a result of rapid advancements in information technology. UX is a field in which emotions play a significant role [21], [38]. According to [39], UX design is concerned with the emotional state of the user during, before, and after using a particular technological product. This emotional experience influences the user's proclivity to remain involved with the product in the future. UX design is the practice of designing products with users in mind in order to provide meaningful, relevant, and engaging experiences to the intended users. UX is crucial in technological product design because it has the ability to enhance the user's satisfaction and loyalty [17], [19]. The most crucial factor in deciding how successful a product is how widely it is accepted and adopted by its users [40]. While the user acceptance is often influenced by their user experience, therefore a user's perception and emotions of a product also rely on the quality of their interaction with the product. Unfortunately, the human factor is often disregarded in most product development, as argued by [41], [42]. This is also supported by [43], who advocated for early user involvement in the product design phase. [44] argued that it is extremely important to comprehend how a user feels about the design's aesthetics and other visual elements. In line with this, [19] also argued that incorporating the user's emotions into the design leads in a more satisfying and engaging experience for the user. But how can the user's emotions be incorporated into the product's design? There is a popular method in emotional design research known as *Kansei Engineering* that may address human affect by translating their emotions into design components [34]. KE often entails evaluating product samples or specimens to identify how the design components influence the user's emotional experiences.

### B. User Experience in the Augmented Reality Context

AR is a technology that substantially enhances the UX by superimposing audio or visual content [45]–[47]. In another word, AR enables mobile devices to create engaging user experiences by layering digital contents on physical environments [48], [49]. This way, AR application may captivate the user's attention through its immersive environment. It has been argued by [50] that not only it is able to improve the UX, but AR has also elevated the user interface

(UI) to a new level. According to [50], AR is capable of facilitating emotionally engaging experiences. Nevertheless, [51] argued that without careful design, AR application might result in user dissatisfaction and confusion, besides being difficult to comprehend and adapt. As reported by [51], the AR UI that is supplemented with unnecessary information has confused the users and has caused them to have problems to understand the features. This is also supported by [52] who conducted a study on graphical user interface, which found that some of the users have reported funny or negative feelings when using the AR mobile applications, and the design may give users confusion with the unsuitable visual cues displayed on the mobile screen. The limited screen size of a mobile devices also plays a role in triggering user negative emotions, if the screen is cluttered or improperly designed [31], [47]. Hence, [51], [52] has suggested to use proper and only necessary visual design elements in AR design. Therefore, there is a need to explore the possible design components for the AR-based mobile application design that can foster positive emotions and user experience.

Although the literatures asserted that AR mobile applications are capable of delivering a new level of interaction via their virtual UI [47], [50], however there is a lack of models that emphasize on AR mobile application design for the UX. The summary of the existing AR models is presented in Table I.

As depicted in Table I, most of the existing models focused on the overall AR product development [25], [26], [53], [58], user engagement [28], AR learning [29], [55], [56], games development [27], [28], [57], and user acceptance or adoption of the MAR applications [31], [40]. However, none of these models put an emphasis on the AR design components that may elicit a positive emotional UX, thus need further research [59], [60]. Therefore, it is important to have a model that explores the user emotions and investigate how they are influenced by AR design elements in order to design a positive AR user experience.

### C. The Importance of Expert Review in Model Development

An expert is someone who can provide a professional and useful opinion based on their knowledge, experience, and reputation in their field of expertise [61]. In research, field experts are the valuable source of information in providing empirical input and judgment in evaluation [62]. Expert opinion is valuable in reviewing a certain model and framework, or when verifying a phrase, method, or approach in research, because in order to acquire relevant and concrete results, a research needs to obtain necessary feedback from the expert knowledge [61]. According to the literature, model validation can be performed by reviewing and enlisting experts in evaluating the suitability and completeness of all variables or components involved, and should be pertinent to the research objective [63]. The procedure of expert review is conducted to ensure that the model is acceptable and that each of its component is pertinent to the research [64]. Therefore, in this study, experts play a significant role in reviewing and verifying the model's suitability for the research at hand.

TABLE I. EXISTING AUGMENTED REALITY APPLICATION MODELS

Source	Model Context	Aspects Discussed	Research Focus
[30]	Conceptual model for AR application design and development for user experience	Design and Implementation of User Experience Model for AR Systems	AR Application development
[26]	Conceptual model for M-learning application development	Enriching learning in architectural classroom with MAR	
[53]	Conceptual model for AR application development (hardware, software) with enjoyable aspect	MAR for cultural heritage towards enjoyable informal learning

### III. METHODOLOGY

#### A. Description of the Proposed Model (ARMAD)

In this section, the proposed model is described in detail. The model is a conceptual design model for AR mobile application. A conceptual design model is a representation of a system that illustrates its components' interdependencies [65]. It serves as a base prior to the product design and requires understanding with design concepts in their entirety [66]. Examining the conceptual design model may provide insight into how well the variables are related in light of the research objective [65]. The purpose of this model is to identify the design components that are able to elicit the user's emotion. As a reflection of the two research questions stated in Section I, the formation of this conceptual design model

attempts to achieve two research objectives; 1) To identify the significant components required in designing an AR mobile application, and 2) To determine whether the design components can evoke the emotions of the user. The expert review procedure was designed to ensure that the ARMAD model was constructed in accordance with the study's objectives. Therefore, the expert review process will focus on these two main concerns of the model.

Generally, the proposed conceptual design model for AR mobile application consists of five main components which are user interface design, interaction design, content design, context of the system, as well as emotion. The method used to construct the ARMAD model is based on [67]. The model is presented in Fig. 1 and each of the model's component is further elaborated below.

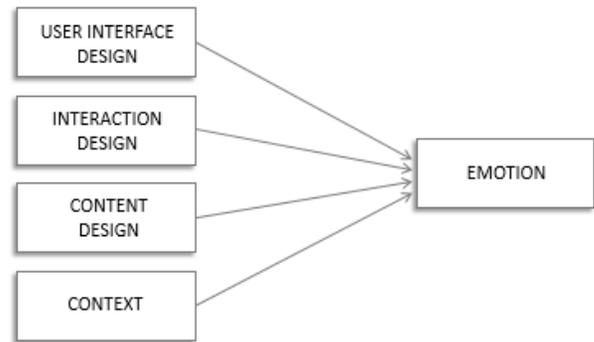

Fig. 1. The Initial Conceptual Model of Augmented Reality Mobile Application Design

The following Table II presents the components of the ARMAD model. Their descriptions are provided in order to explain why each of the components is relevant to this study.

TABLE II. THE MODEL COMPONENTS OF AUGMENTED REALITY MOBILE APPLICATION DESIGN

Components	Description of Significance	Source
User interface	An application's interface is the first station where the user will land on a system. The user interface (UI) will serve as the user's point of contact with the system, allowing them to view, access, or manipulate the information or visual elements on the screen.	[30], [48], [68], [69]
Interaction	To increase individual's involvement with the system so that person in the virtual world may engage naturally and feel in control. By providing users with timely feedback and the means to manipulate the visual elements, the system can provide a realistic simulation to the users.	[21], [30], [70]–[72]
Content	The virtual content is intended to aid users in adapting to their new surroundings and engaging with the system's activities in an immersive environment.	[73]–[76]
Context	The environment in which AR technology being designed will function or be incorporated.	[77]–[79]
Emotion	The perceptions and feelings that develop in the mind of a person as a result of that person's unique set of experiences.	[80]–[82]

**B. Procedures for Expert Review**

Evaluation strategies based on expert review have proven to be very effective [64]. Therefore, in this study, an expert review procedure was conducted in two main phases to validate the proposed model. As illustrated in Fig. 2, several steps were carried out in order to achieve the review objective; 1) to finalize the list of expert reviewers and 2) to acquire the experts' review findings.

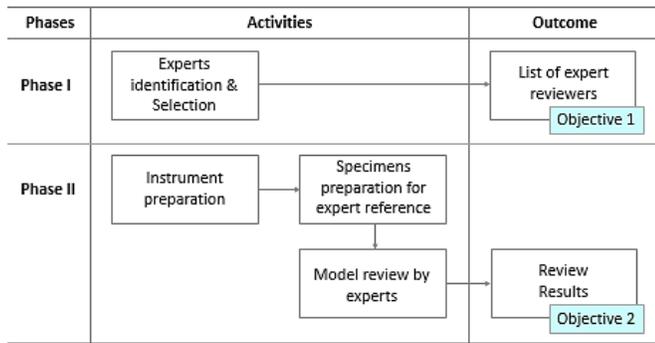

Fig. 2. Phases Involved in Expert Review Procedure

**C. Phase I – Experts Identification and Selection**

The objective of the first phase is to finalize the list of expert reviewers. According to [63], expert selection is very important in the validation process. This entailed identifying the requirements for expert reviewers, which were set in accordance with the following criteria:

- 1) Possess at least five years of work experience in the relevant fields of this study.
- 2) Have at least practical, teaching, or research experience pertaining to UX design, augmented reality, mobile application design, or Human Computer Interaction (HCI).

All of the selected experts have more than five years of experience in their respective disciplines and have expertise in the relevant domains of UI/UX design, mobile application design, AR, or HCI. According to [83], the ideal number of involvement should be three to five experts in the process of gathering knowledge or making recommendations. Therefore, five experts were chosen to participate in this study and the summary of expert demographics is displayed in Table IV.

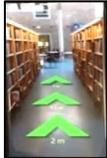

**D. Phase II – Instrument and Procedures**

The second phase involved model validation by the experts. However, before the validation procedure begins, a set of questionnaire has been prepared as the review instrument. This study employed *Kansei* Engineering (KE) approach to guide the review process due to its applicability in emotional design research. KE procedures entail delivering product specimens for evaluation in order to elicit an emotional response [34]. The specimens are also used to identify whether a particular product design can evoke emotions when using the AR-based products. Therefore, the experts were supplied with six specimens, as depicted in Table III. All specimens are provided in video format with specific links to AR-based products to enhance expert understanding of the relationship between emotions and AR mobile application design. All experts are required to fill out

the questionnaire when evaluating the model, and use the specimens as a reference. The choices of specimens were made based on the relevant market-available products, as suggested by [34]. Since the conceptual design model proposed in this study focused on designing AR mobile application, therefore, the samples of its type were provided as reference to the reviewers, as represented in Table III.

After all the instruments and materials were prepared, the experts were provided with the review form which comprised of five parts: 1) demographic information and research description, 2) consent form, 3) the proposed ARMAD model for their review, 4) list of specimens with working link, and 5) questionnaire. The questionnaire was designed in accordance with the research questions pertaining to why the model was constructed, as stated in Section 1. Since the main concern of the model development was to identify the relevant components for AR mobile application design and to assess if the design components presented in the model are appropriate for emotion elicitation, therefore the questionnaire has been tailored to address these questions. The questionnaire was divided into three sections, which are, 5A) the model's primary components, along with their descriptions, 5B) the relevance of each component to the augmented reality mobile application, 5C) expert's overall opinion which include the model's logical connections and flow, appropriateness of each component, the overall design readability, their agreement with the proposed model, and whether all of the components are suitable for eliciting users' emotions. In addition, they were encouraged to further comment in the provided sections, particularly for the overall opinion part. Since some of the experts are based on international company, therefore the review processes were conducted through email and some through physical meeting. Experts were given two weeks to review the model and complete the questionnaire. In the final step, the review forms were analyzed in order to determine the applicability of the model to be incorporated in the design of AR mobile application that enhances UX via emotions.

TABLE III. LIST OF PROVIDED SPECIMENS FOR EXPERT USE

Specimen UI	Specimen ID & Link	Specimen UI	Specimen ID & Link
	SR001 <a href="#">Specimen Link</a>		SR004 <a href="#">Specimen Link</a>
	SR002 <a href="#">Specimen Link</a>		SR005 <a href="#">Specimen Link</a>

	SR003 <a href="#">Specimen Link</a>		SR006 <a href="#">Specimen Link</a>

#### IV. FINDINGS AND ANALYSIS

##### A. Expert Review Identification

As previously stated, the purpose of this study is to validate the proposed model through expert review. Following identification process, five experts were selected to participate in this study based on their expertise and specialized knowledge in the fields. This number is adequate according to [83], who suggested that the number of reviewers could range from three to five experts. Table IV displays the demographic information of the experts.

TABLE IV. THE EXPERT DEMOGRAPHICS

Expert	Gender	Field of Expertise	Experience
E1	Male	AR, UI/UX Design, Mobile App Design	9
E2	Male	UX Design	7
E3	Male	AR, UI/UX Design	8
E4	Female	UX Design, HCI	21
E5	Female	AR, HCI	17

##### B. Analysis of Expert Review

The review results are presented in Table V to Table VII, and in Fig. 3. For part 5A of the questionnaire, all of the experts agreed that the descriptions of the model's components as presented in Table II are correct and should be maintained. While in 5B, the relevance of each component to AR mobile application was rated by the experts, as shown in Table V.

The results of part 5B are depicted in Table V, which indicated that majority of experts are in agreement that the proposed conceptual design model is applicable to the research focus and has pertinent relationship among the components. However, there is an exception for the 'context' component, which according to one of the experts, although relevant to this study, context may not be grouped with other design components. According to the expert, the context however, remains significant in this research to ensure that all design components are designed within a particular system context.

Part 5C sought expert opinions on the model's readability, relationship, and appropriateness, and the findings are shown in Fig. 3. The findings showed that all of the experts agreed that the conceptual design model is readable and understandable, the relationship between each and every component is appropriate and sensible, and the proposed model is practical for the affective design of AR-based mobile applications.

TABLE V. EXPERTS FEEDBACK ON THE RELEVANCE OF EACH MODEL COMPONENT

No.	Proposed Components	(No. of experts = 5)		
		Relevant	Maybe Irrelevant	Not Relevant
1	User Interface Design	5	0	0
2	Interaction Design	5	0	0
3	Content Design	5	0	0
4	Context	4	1	0
5	Emotion	5	0	0

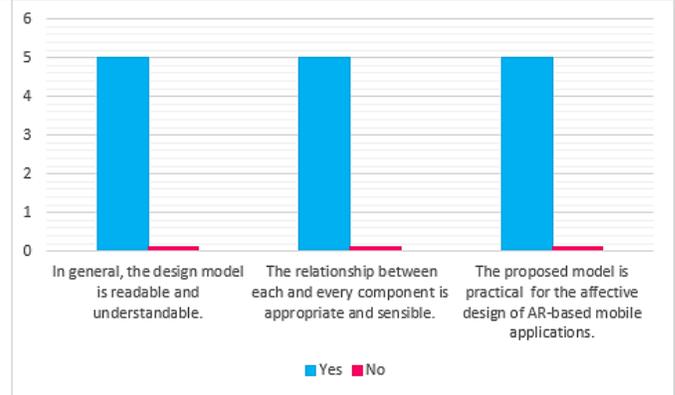

Fig. 3. Expert Opinion on the Model Readability, Relationship, and Appropriateness.

TABLE VI. EXPERTS RESPONSE ON THEIR AGREEMENT WITH THE PROPOSED MODEL

Expert	Summary of Response
E1	Yes, the model is applicable and relevant to various types of AR mobile applications. The model consists of all the important components for augmented reality and has covered the most influential AR parts such as user interface. The UI, as the user's first station, plays a very important role, to allow users interact through it, and to boost user's interest to explore further.
E2	The proposed model meets my agreement. The UX design needs to have sufficient, relevant contents that are customised to particular system context in order for interactions to take place. Since the goal is to enhance the user's experience, this approach is a good fit.
E3	Overall, the model looks good and workable as it emphasis on the UI/UX design. However, I would like to suggest that the context may not be grouped together with other design components, rather, it may stand by itself to support the entire system design in a particular system context.
E4	Yes. The model is well-defined, and its constituent parts are well-suited to the study of emotional design as intended by the researcher.
E5	Agree. Each of the proposed components is vital to the design of a system. The UI, is the core component in system design since it supports communication between user and the system. The interaction component is able to support various kinds of interaction in AR system context, it could be the way the touch the screen to manipulate the digital elements, etc. in addition, the AR system should be supplied with the right contents in order to get the system works. Well, all of the components presented in the model are the essence of a system design. However, since designers have to design AR systems according to a specific AR environment, it is good to consider the inclusion of context as well.

In addition, experts were also asked about the acceptability of the design model. Table VI presents the feedback and comments of experts in response to the question, "Overall, do you agree with the proposed model? Please state reasons for your response". As shown in the table, experts agreed with each component proposed to be associated with any mobile augmented reality application. According to their feedback, the UI, interaction, and content are the essence of AR application design, which should be built within a particular system context or environment, and the user's emotions will play a major role in shaping the user experience.

TABLE VII. EXPERTS FEEDBACK WHETHER THE PROPOSED MODEL COULD ELICIT EMOTION

Expert	Comments
E1	In my view, the user's degree of satisfaction with a product may be impacted by their emotions, at least in part. Designers may achieve user pleasure via thoughtful creation of the UI, interactions, and content. However, for anything to be helpful and satisfying to its intended audience, the design must be appropriate to its context of usage. As demonstrated in specimen 004, design aesthetics have the power to make us feel good.
E2	The UX design cares about the user experience, and it is influenced by the user's emotions. These components appear to meet the design requirements, and as UI/UX designers, we are always thinking about how to improve the user experience and for that reason, we carry out user research on a regular basis.
E3	I've accessed all the specimens supplied to get a feel for the product. Having handled a wide variety of specimens, I've had a wide range of experiences, each of which has influenced my feelings. Some specimens made me feel happy because I found them entertaining, while others made me feel confused.
E4	After reviewing all the specimens, SR006 caught my interest because of its well-designed interface and interactivity it provides. I am very certain that this specimen will be useful for augmented reality type of applications.
E5	The combination of these components is able to stir the user's emotions, and I have personally experienced this after evaluating all of the provided specimens. It is also important that the user interface give clear and concise instructions for user friendliness and understanding.

Table VII presents the experts' response to the question, "Are the components of this conceptual design model (user interface, interaction, content, and context) suitable for eliciting users' emotions?". For this question, experts are required to refer to the provided specimens. The experts found that the specimens have evoked a range of emotions from positive to negative, which led them to agree with the question.

Overall, the findings of the expert review indicated that most of the experts agreed with the proposed conceptual design model with minor modification required, and they considered that the combination of the model's components is capable of eliciting user emotions and is suitable to this research.

### C. The Revised Conceptual Design Model

As can be seen in Table V to Table VII and Fig. 3, the majority of experts agreed that the proposed conceptual design model exhibits appropriate components and relationship for the study. However, the goal of this expert review was to obtain complete agreement from all experts in all sections; if

at least one expert disagrees with or is unsure about a model or component, the model should be revised accordingly. Based on the recommendations of the experts, the initial version of the model was refined for better comprehension and to fit the context. The expert E3 has suggested that the 'context' component may not be appropriate to be grouped with other design components since it is not a design component but rather serves to support the design process on a particular system context. Therefore, the expert suggested to remain the context in the model but keeping it separate from other design components. The AR conceptual design model has been revised and redesigned based on the expert's feedback and recommendations. The revised ARMAD model is presented in Fig. 4.

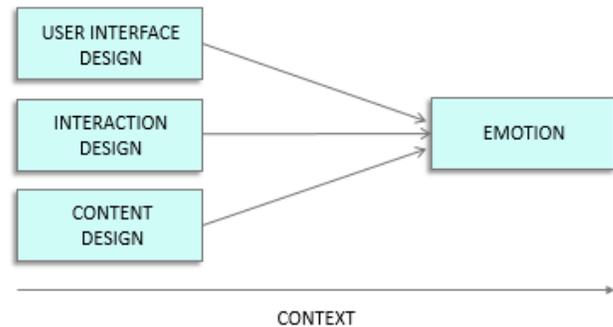

Fig. 4. Augmented Reality Mobile Application Design (ARMAD) Model.

ARMAD model suggested that all the design components; UI, interaction, as well as content should be designed within AR system context in order to make it purposeful. The UI design in this model suggested that the AR mobile application should be designed with interface-environment harmony using suitable visual cues in order to let the user feel presence in the virtual world. In order to enhance positive user experience, the interaction of AR application should be designed with lively interaction that able to provide instantaneous feedback while the users engage with the application. In addition, the design of AR applications needs to take into account the form of virtual content in order to provide insightful information and instructions to users in an immersive environment. The main idea of this model is to understand the influence of the user interface, interaction, as well as content design on the users' emotional experience with augmented reality mobile application.

### V. CONCLUSION

Motivated by the advanced technology research and trends in UX and AR, as well as the absence of models in the research area, this study proposed a conceptual model for AR mobile application design (ARMAD) that caters to the users' emotional experiences. The proposed conceptual design model intends to fill the gap of previous AR models that did not address the user emotions in improving the UX. This study sought consultation from experts to validate the initial ARMAD model. In light of this, the expert review methods and procedures involved in this study are outlined in depth. Findings of the expert review are collected and presented in order to improve the ARMAD model. Overall, findings showed that the majority of experts agreed that the conceptual

design model proposed in this study is a useful guide and practical for use in designing the AR mobile application. All of the expert reviewers agreed that the proposed model is suitable for eliciting users' emotions and that the relationship between the model's components are comprehensible, sensible and practical to the research focus. The final step involved refining the model based on reviewers' recommendations. Objectively, this model contributes to defining design elements towards enhancing the emotional UX of AR mobile applications. Understanding user emotions is crucial because it influences the user satisfaction and most importantly, establishes a baseline for designing for a positive UX. This study concludes that the objective of validating the ARMAD model has been met.

The limitation of this research involved the difficulty in obtaining specimens for evaluation since the majority of accessible specimens are in video form. Therefore, only video samples were used as specimens for the reviewer.

Future work should entail creating an AR prototype that incorporates the design components and guidelines proposed in the ARMAD model. Kansei Engineering method may be employed to determine the influence of design elements on user emotions using a self-reporting quantitative approach. The outcomes of the research design may be used to verify the effectiveness of this model.

#### ACKNOWLEDGMENT

The authors would like to acknowledge the Faculty of Computer and Mathematical Sciences, Universiti Teknologi MARA (UiTM), the Research Initiative Group for Emotion, Kansei and Design Engineering (RIG EKDE), UiTM for all their assistance to the research paper. This work was partially supported under UiTM grant scheme 600-RMC/GPM SS 5/3 (094/2021).

**Abstract**—Compiler designer needs years or sometimes months to construct programs using heuristic optimization rules for a specified compiler. For every novel processor, the modelers require readjusting the heuristics to get the probable performances of processor. The most important purpose of the developed approach is to build a prediction approach with optimization constraints for transforming programs with a lesser training overhead. The problem has occurred in the optimization and it is needed to address it with novel prediction model with derived features & neural network. Here, a novel Compiler Optimization Prediction Model is developed. The features like static and dynamic features as well as improved Relief based features are derived, which are provided as input to Neural Network (NN) scheme, in which the weights are tuned via Honey Badger Adopted BES (HBA-BEO) model. Finally, the NN offers the final predicted output. The analysis outcomes prove the superiority of HBA-BEO model.

**Keywords**—Compiler; prediction; improved relief; HBA-BEO model; neural network

## NOMECLATURE

Abbreviation	Description
ALO	Ant Lion Optimization
AOA	Arithmetic Optimization Algorithm
BES	Bald Eagle Search
BWO	Black Widow Optimization
HBA	Honey Badger Algorithm
HBA-BEO	Honey Badger Adopted BES
LP	Learning Percentage
MSDTM	Multithreaded SPM Data Transfer Model
ML	Machine Learning
NN	Neural Network
SSA	Shark Smell Optimization

## I. INTRODUCTION

In response to similar needs in many difficult situations, compiler analysts have devised and implemented a significant variety of optimization compilation option. In reality, it's difficult for the compiler's regular compilation optimization step to adapt to the programme requirements that must be compiled in complex scenarios [6] [7] [8]. On the one hand, compiled programmes have different semantics and compiler aims, making it difficult to achieve the best optimization result using the typical compilation optimization step [9] [10] [11]. If an incorrect optimization pass is utilised, it may have bad consequences for programme performance, among other things [12] [13] [14].

Although these dynamic techniques have been quite effective and appear to be naturally ideal for task-parallel programmes with high input and output flow, they do have significant drawbacks [15] [16]. They can't change settings that have to be resolved at compilation time, such as the layout of data structures in memory, and dynamic monitoring at the library level can't completely rule out future programme behaviour, attempting to prevent some kinds of optimization techniques, and any type of feedback loop will cause some runtime overhead [17] [18]. While the effect can be reduced by proper implementation, simply adding a few more hops and branches to see if any adjustments are needed has a meaningful influence in highly fine-grained circumstances [19] [20] [21] [22]. To address these issues, we present a set of static analyzes that may be used to directly alter a runtime's execution parameters by determining aspects of a task parallel programme [23] [24]. The main problem is compiler optimization and tried to get its solution through A Novel Prediction Model for Compiler Optimization with Hybrid Meta-Heuristic Optimization Algorithm.

The key objectives of this works are:

- To Extracts varied features along with improved relief features from input data.
- To Introduces HBA-BEO model for optimal weight selection in NN.

The paper is arranged as: Section II addresses review. Section III and IV correspond to feature extraction and HBA-BEO based NN for prediction. The Section V and VI describe the results and conclusion.

## II. LITERATURE REVIEW

### A. Related Works

Jiang *et al.* [1] provided a graph-based compilation optimization pass modelling approach that learned heuristics for programme dependability, as well as a combined programme feature extraction approach. The clang compiler tool was used in this research. For optimization pass election for programme dependability, the model enhanced accuracy rate by 5 percentage points to 11 percentage points. The investigations also showed that the suggested paradigm was quite adaptable.

Nuno et al. [2] presented a new compiler-assisted data streaming mechanism to achieve this goal. It was a substitute to prefetching schemes to conservative code structure; it combined static study and code modification with data stream ability. Memory access were encoded and identified with a particular depiction by means of static study. Then, using a code transformation method, data indexing and addresses computation were separated from computation, resulting in considerable code minimization.

Peter et al. [3] offered a series of new static compiler studies aimed at identifying programme properties that influenced the best settings for a task-parallel runtime environment. The parallel configuration of job spawn, the precision of specific activities, the memory capacity of closures needed for task variables and an estimation of the stack dimension necessary each task were all examples of such aspects. A variety of runtime system settings were then modified at constructing time depending on the outcomes of these investigations.

Xiaohan et al. [4] presented a compiler-directed MSDTM to improve data transmission in a heterogeneous many-core system. Further, compile-time analysis was employed for classification. The recommended MSDTM model reduced appliance implementation time by 5.49 and saves energy by 5.16 based upon test resultants.

Matthew et al. [5] believed that compilers should handle data transfer management, decreasing programmer workload and improving programmes speed and efficiency by lowering the amount of bytes exchanged. We showed that with entire transmit scheduling on accelerated data transfer might eradicate around 99 percent of bytes transferred from accelerator than all data during kernel implementation for all collected data.

### III. PROPOSED MODEL WITH IMPROVED FEATURES

A novel compiler prediction model is developed, where features like static and dynamic features and improved Relief features are derived. The derived features are provided as input to NN, in which the weights are tuned via HBA-BEO model. The NN offers the final predicted outcome. Fig. 1 illustrates the picture of deployed scheme.

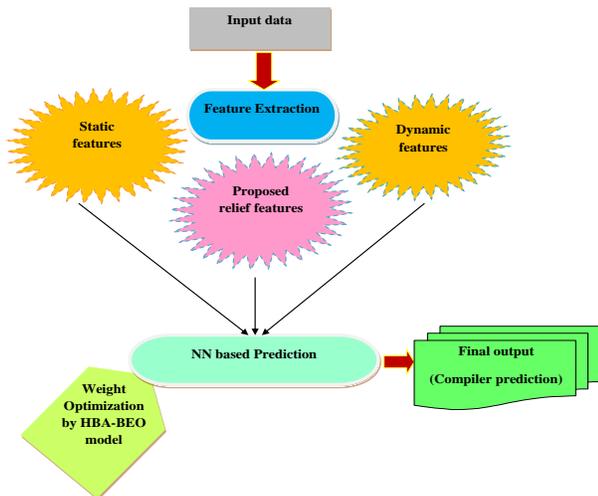

Fig. 1. Developed Compiler Prediction Model.

#### A. Static Features

The static features [23] extracted in this work are listed in Table I.

TABLE I. STATIC FEATURES

$fe_{29}$	“Number of basic blocks with phi nodes in the interval [0, 3]
$fe_{28}$	Number of basic blocks with no phi nodes
$fe_{27}$	Average of arguments for a phi-node
$fe_{26}$	Average of number of phi-nodes at the beginning of a basic block
$fe_{25}$	Average of number of instructions in basic blocks
$fe_{24}$	Number of instructions in the method
$fe_{23}$	Number of binary floating point operations in the method
$fe_{22}$	Number of binary integer operations in the method
$fe_{21}$	Number of assignment instructions in the method
$fe_{20}$	Number of conditional branches in the method
$fe_{19}$	Number of direct calls in the method
$fe_{18}$	Number of abnormal edges in the control flow graph
$fe_{17}$	Number of critical edges in the control flow graph
$fe_{16}$	Number of edges in the control flow graph
$fe_{15}$	Number of basic blocks with number of instructions greater then 500
$fe_{14}$	Number of basic blocks with number of instructions in the interval [15, 500]
$fe_{13}$	Number of basic blocks with number of instructions less than 15
$fe_{12}$	Number of basic blocks with more than two successors and more than two predecessors
$fe_{11}$	Number of basic blocks with two successors and two predecessors
$fe_{10}$	Number of basic blocks with a two predecessors and one successor
$fe_{09}$	Number of basic blocks with a single predecessor and two successors
$fe_{08}$	Number of basic blocks with a single predecessor and a single successor
$fe_{07}$	Number of basic blocks with more than two predecessors
$fe_{06}$	Number of basic blocks with two predecessors
$fe_{05}$	Number of basic blocks with a single predecessor
$fe_{04}$	Number of basic blocks with more than two successors
$fe_{03}$	Number of basic blocks with two successors
$fe_{02}$	Number of basic blocks with a single successor
$fe_{01}$	Number of basic blocks in the method”

#### B. Dynamic Features

The dynamic features [23] extracted in this work are listed in Table II.

TABLE II. DYNAMIC FEATURES

“Cache line access	CA-CLN, CA-ITV, CA-SHR
Level 1 cache	L1-DCA, L1-DCH, L1-DCM, L1-ICA, L1-ICH, L1-ICM, L1-LDM, L1-STM, L1-TCA, L1-TCM
Level 2 and 3 cache	L2-DCA, L2-DCM, L2-DCR, L2-DCW, L2-ICA, L2-ICH, L2-ICM, L2-LDM, L2-STM, L2-TCH, L2-TCR, L2-TCW, L2/L3-TCA, L2/L3-TCM
Branch related	BR-CN, BR-INS, BR-MSP, BR-NTK, BR-PRC, BR-TKN, BR-UCN
Floating point DP/FP/ SP-OPS	FDV/FML/FP-INS
Interrupt/stall	HW-INT, RES-STL
TLB	TLB-DM, TLB-IM, TLB-SD, TLB-TL
Total cycle/insts.	TOT-CYC, TOT-IIS, TOT-INS
Load/store insts.	LD-INS, SR-INS
SIMD insts.	VEC-DP, VEC-INS, VEC-SP”

### C. Improved Relief Features

The Relief feature aids in estimating the superiority of attributes based on how fine their values differentiate among instances, which are nearer to one another. Initially, relief chooses the instances arbitrarily [24]. The arbitrary elected instances are  $RS_i$ . The Relief search for its two nearer neighbours: “one from the same class, called nearest hit ( $NH$ ), and the other from the different class, called nearest miss ( $NM$ )”.

The steps of improved relief are:

<b>Algorithm 1</b>
for $i = 1$ to run count $m$
Automatically evaluate $k$
Arbitrarily choose $RS_i$ features
Compute hit ( $NH$ ) and nearest miss ( $NM$ )
for $i = 1$ to $n$ do
$we[1] = we[i] - dif(i, RS_i, NH)^2 / m + dif(i, RS_i, NM)^2 / m$
end

As per improved concept, weight  $we[i]$  can be computed using tent map. The average of  $we[i]$  signifies the harmonic mean.

The extracted features are implied by  $fe$ .

## IV. HBA-BEO BASED NN FOR PREDICTION

### A. Optimized NN

It [16] considers features ( $fe$ ) as input, as in Eq. (1), wherein  $nu$  symbolizes entire feature count.

$$fe = \{fe_1, fe_2, \dots, fe_{nu}\} \quad (1)$$

The NN [16] included “output, hidden and input layers”. The hidden layer  $z^{(H)}$  and network outputs  $\hat{Q}_\delta$  are exposed in Eq. (2) and (3). Here, “ $AF \rightarrow$  activation functions,  $\hat{i}$  and  $j \rightarrow$

neurons of input & hidden layers,  $We_{(Bi)}^{(H)} \rightarrow$  bias weight to  $\hat{i}^{th}$  hidden neuron,  $n_{\hat{i}} \rightarrow$  count of input neurons and  $We_{(ji)}^{(H)} \rightarrow$  weight from  $j^{th}$  input neuron to  $\hat{i}^{th}$  hidden neuron,  $\hat{o} \rightarrow$  output neurons,  $n_h \rightarrow$  hidden neuron count,  $We_{(Bo)}^{(P)} \rightarrow$  output bias weight to  $\hat{o}^{th}$  output layer, and  $We_{(\hat{i}\hat{o})}^{(P)} \rightarrow$  weight from  $\hat{i}^{th}$  hidden layer to  $\hat{o}^{th}$  output layer”. The error is approximated in Eq. (4), in which,  $n_G \rightarrow$  count of output neuron,  $\hat{P}_\delta$  and  $P_\delta \rightarrow$  predicted & actual output. Here, the weights  $We$  are optimally chosen via HBA-BEO model. The minimization of Eq. (4) is set as objective in this work.

$$z^{(H)} = AF \left( We_{(Bi)}^{(H)} + \sum_{j=1}^{n_i} We_{(ji)}^{(H)} fe \right) \quad (2)$$

$$\hat{P}_\delta = AF \left( We_{(Bo)}^{(P)} + \sum_{\hat{i}=1}^{n_h} We_{(\hat{i}\hat{o})}^{(P)} z^{(H)} \right) \quad (3)$$

$$er^* = \arg \min_{\left\{ We_{(Bi)}^{(H)}, We_{(ji)}^{(H)}, We_{(Bo)}^{(P)}, We_{(\hat{i}\hat{o})}^{(P)} \right\}} \sum_{\delta=1}^{n_G} |P_\delta - \hat{P}_\delta| \quad (4)$$

The output from NN offers final classified output.

### B. Proposed HBA-BEO Algorithm

The developed HBA-BEO is the hybrid conceptual of BES [17] and HBA [18]. It was established that the grouping of two typical optimizations will progress the convergence speed [19] [20] [21] [22].

Selecting stage: This stage decided the optimum region as per the food quantity. As per HBA-BEO, this behaviour is modelled as per HBA update as in Eq. (5), in which  $Dis_i$  signifies distance information,  $flag \rightarrow$  flag to alter searching direction,  $ra$  refers to random constraint,  $Y_{prey} \rightarrow$  best position”. As per HBA-BEO, density factor  $\alpha$  is computed as in Eq. (6).

$$Y_{new} = Y_{prey} + flag * ra * \alpha * Dis_i \quad (5)$$

$$\alpha = \frac{1.5 * (it_{max} - it + 1)}{it_{max}} \quad (6)$$

Searching stage: This stage is computed in Eq. (7). In Eq. (7), “ $Y_{best}$  refers to elected searching space depending upon best position of eagle,  $Y_{mean}$  refers to mean distance amid every positions of bald eagle (population mean),  $Y_i$  refers to present position of eagle,  $ran$  refers to random constraint produced among [0 - 1],  $\beta$  refers to constant constraint among [0.5, 2],  $Q$  refers to constant constraint among 0.5 to 2, and  $ran1$  and  $ran2$  refers to two arbitrary constraints”. Conventionally,

V. RESULTS AND DISCUSSION

A. Simulation Set Up

The novel prediction model for compiler optimization using NN + HBA-BEO was executed in “Python. Training set: SPEC CPU2006 is developed by the standard performance evaluation organization for the evaluation of general-purpose CPU performance [11]. The input scale of SPEC2006 benchmark can be divided into test, train and reference scale, we use the reference scale to test”. Here, analysis was done for varied metrics like accuracy and varied error metrics like MSE, MSLE and so on. Also, NN+HBA-BEO was proven over NN + BES, NN + HBA, NN + ALO, NN + BWO, NN + AOA and NN + SSA.

B. Performance Analysis

The study on diverse metrics is detailed here. Here, the analysis was done for LPs of 60, 70, 80 and 90 over NN + BES, NN + HBA, NN + ALO, NN + BWO, NN + AOA and NN + SSA models. From Fig. 2, the considered metrics like specificity, sensitivity, accuracy and precision are examined, which were established to be much better over NN + BES, NN + HBA, NN + ALO, NN + BWO, NN + AOA and NN + SSA models. The accuracy of NN + HBA-BEO is high at 90<sup>th</sup> LP, while precision is high at 80<sup>th</sup> LP. However, at all LPs, NN + HBA-BEO have established higher outcomes over NN + BES, NN + HBA, NN + ALO, NN + BWO, NN + AOA and NN + SSA models. Thus, NN + HBA-BEO is proven to be enhanced than NN + BES, NN + HBA, NN + ALO, NN + BWO, NN + AOA and NN + SSA models.

$r(i)$  is computed as in Eq. (11), however, as per HBA-BEO,  $r(i)$  is computed as in Eq. (12), wherein,  $ran$  is computed using chaotic cubic map.

$$Y_{new} = Y_i + Z(i) \times (Y_i - Y_{i+1}) + p(i) \times (Y_i - Y_{mean}) \tag{7}$$

$$p(i) = \frac{pr(i)}{\max(|pr|)}, Z(i) = \frac{Zr(i)}{\max(|Zr|)} \tag{8}$$

$$pr(i) = r(i) \times \cos(\theta(i)), Zr(i) = r(i) \times \sin(\theta(i)) \tag{9}$$

$$\theta(i) = \beta \times \pi \times ran1 \tag{10}$$

$$r(i) = \theta(i) + Q \times ran2 \tag{11}$$

$$r(i) = \theta(i) + Q \times ran \tag{12}$$

Swooping stage: This stage is modelled as in Eq. (13).

$$Y_{new} = rand3 \times Y_{best} + pl(i) \times (Y_i - it1 \times Y_{mean}) + Zl(i) \times (Y_i - it2 \times Y_{mean}) \tag{13}$$

$$pl(i) = \frac{pr(i)}{\max(|pr|)}, Zl(i) = \frac{Zr(i)}{\max(|Zr|)} \tag{14}$$

$$pr(i) = r(i) \times \sinh(\theta(i)), Zr(i) = r(i) \times \cosh(\theta(i)) \tag{15}$$

$$\theta(i) = \beta \times \pi \times ran3, r(i) = \theta(i) \tag{16}$$

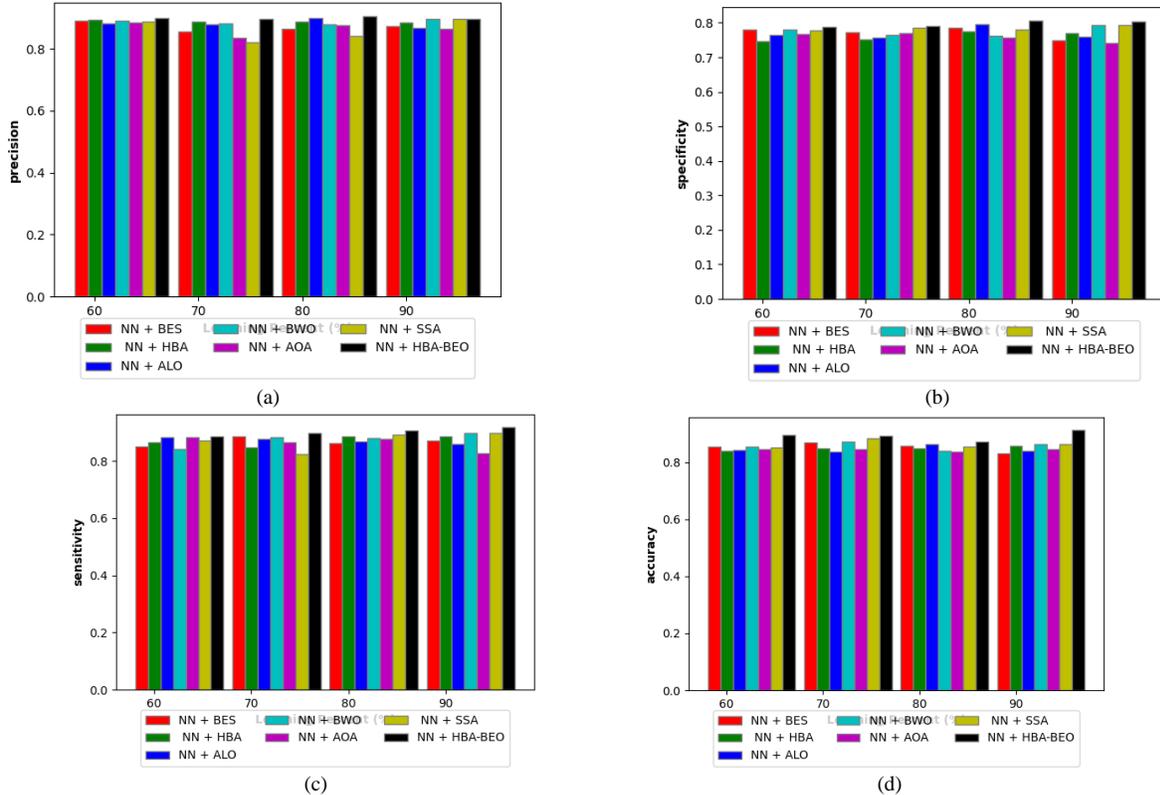

Fig. 2. Analysis on (a) Precision, (b) Specificity, (c) Sensitivity and (d) Accuracy for NN + HBA-BEO over others.

C. Analysis on Error Measures

The performance of adopted NN + HBA-BEO for diverse error (MSE, MSLE, MAE and MAPE) is calculated over conservative NN + BES, NN + HBA, NN + ALO, NN + BWO, NN + AOA and NN + SSA schemes in Fig. 3. The NN + HBA-BEO method is scrutinized for numerous LPs from 60, 70, 80 and 90 over NN + BES, NN + HBA, NN + ALO, NN + BWO, NN + AOA and NN + SSA models. “In statistics, MAE is a measure of errors between paired observations expressing the same phenomenon”. The MAE needs to be less for improved prediction accuracy. As required, the MAE obtained by NN + HBA-BEO is lesser for every LP. The MSLE using NN + HBA-BEO over NN + BES, NN + HBA, NN + ALO, NN + BWO, NN + AOA and NN + SSA is signified in Fig. 3(b). “MSLE can be interpreted as a measure of the ratio between the true and predicted values”. For every LP, the MSLE gained by NN + HBA-BEO is lesser. The assessment of NN + HBA-BEO for MAPE and MSE over MSE, MSLE, MAPE and MAE is signified in Fig. 3(c) and Fig. 3(d). “The MAPE, also known as MAPD, is defined as a measure of prediction accuracy of a forecasting method in statistics”. “In statistics, the MSE or MSD of an estimator measures the average of the squares of the errors, that is, the average squared difference between the estimated values and the actual value”. The MSE and MAPE have to be less for better prediction, which is found to be

accomplished by NN + HBA-BEO for all LPs over NN + BES, NN + HBA, NN + ALO, NN + BWO, NN + AOA and NN + SSA schemes.

D. Study on RMSE

The RMSE values with parameters for each benchmarks in the dataset is exposed in Table III.

TABLE III. RMSE FOR VERIFIED BENCHMARK IN DATASET

Parameters	RMSE
400.perlbench	0.75
401.bzip2	0.661438
403.gcc	0.75
429.mcf	0.75
445.gobmk	0.829156
456.hmmer	0.661438
458.sjeng	0.661438
462.libquantum	0.829156
464.h264ref	0.661438
471.omnetpp	0.707107
473.astar	0.707107
483.xalancbmk	0.661438

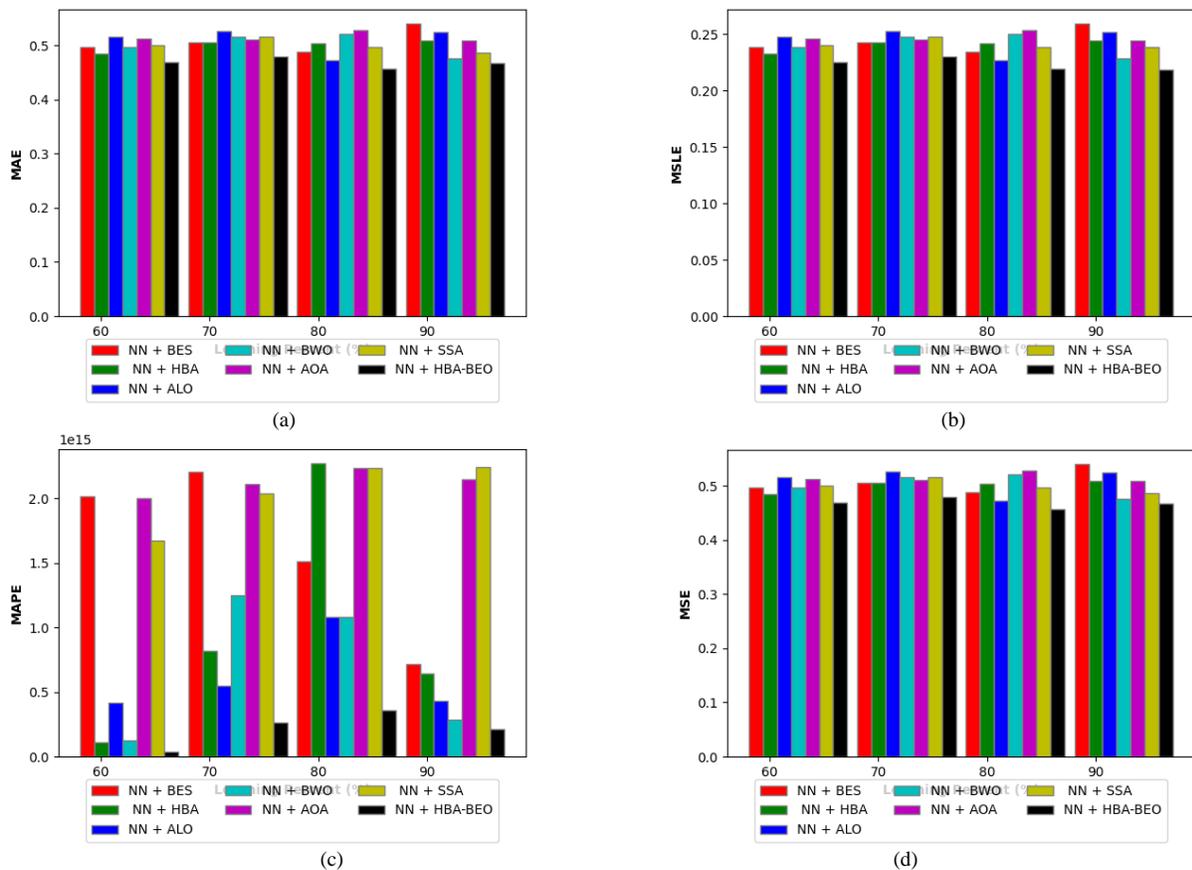

Fig. 3. Attacks Analysis (a) MAE (b) MSLE (c) MAPE and (d) MSE for NN + HBA-BEO Scheme Over Others.

## VI. CONCLUSION

This work developed a novel Compiler Optimization Prediction Model. In this research, optimization [25] is the key factor considered and it is achieved through derived features and neural network. The features like static and dynamic features as well as improved Relief based features were extracted. The derived features were given to NN scheme, in which the weights were tuned via NN + HBA-BEO. Finally, the NN offered the final predicted output [26]. Here, the considered metrics like specificity, sensitivity, accuracy and precision were examined, which were established to be much better over BES, HBA, ALO, BWO, AOA and SSA models. The accuracy of NN + HBA-BEO was high at 90<sup>th</sup> LP, while precision was high at 80<sup>th</sup> LP. However, at all LPs, NN+HBA-BEO has established higher outcomes over NN + BES, NN + HBA, NN + ALO, NN + BWO, NN + AOA and NN + SSA models.

**Abstract**—Multimedia images are the primary source of communication across social media and other websites. Multimedia security has gained the attention of modern researchers and has posed dynamic challenges such as image forensics, image tampering, and deep fakes. Malicious users tamper with the image embedding noise, leading to misinterpretation of the content. Identifying and authenticating the image by detecting the forgery operations performed on it is essential. In our proposed model, we detect the forged region using the machine learning model SVM in the first iteration and Convolution Neural Network in the second iteration with Discrete Cosine Transform (DCT) for feature extraction. The proposed model is tested with a Corel 10K dataset, and an average accuracy of 98% is obtained for all kinds of image operations, including scaling, rotation, and augmentation.

**Keywords**—Support Vector Machine (SVM); Discrete Cosine Transform (DCT); Convolution Neural Network (CNN); Image Forensics and Image Forgery

## I. INTRODUCTION

With the invention of high-speed networks and advanced storage technologies, the internet used in almost every domain has increased drastically. Significant technological innovations have occupied every area with intelligent technologies and devices. The use of multimedia in social networking and other applications has invited other challenges where intruders modify or forge the data for illicit usage. Digital transformations have opened up a new domain of image forensic analysis. The need for providing authentic documents with integrity is a much-needed research area.

Recent Information and Communication Technology (ICT) has a vast spectrum of applications imbibing from each machine to pools of networks by large organizations. Users over the globe are not limited to work applications but are used for various applications such as personal banking transactions, multimedia data sharing across social media platforms, etc. [1] Larger companies regularly conduct their every transaction and operation across the internet, and more extensive data migrations across the firms occur via the networks comprising lesser secured public internet.

The drastic inventions in the cloud and big data technology solutions have seen exponential usage in social networking and mobile communication applications, leading to more extensive organization information flow operations. This limited the organization's security architecture for handling manipulated and tampered data. The increased activity of users and organizations has led to the misuse of computers and network-related applications ranging from simple password hacks to unauthorized access to servers.

Increased misuse of network and computer-related applications has led to increased research in computer-related investigations. Traditionally auditing the logs was a simple way to trace fraud operations, and the advanced hacking techniques are so powerful that no traces are found in the records. Hence the need for an automated and intelligent way of forensics is necessary. Digital forensics has made advanced developments over the years. The primary reason for the development is intelligence in tools and techniques that use local hardware machines to perform complex auditing tasks more precisely. The difficult task of auditing the logs is automated using machine learning models.

The rapid increase in the digital content comprising images over the internet has challenged the retrieval efficiency of several applications. The content-based image retrieval (CBIR), the effective and modern method for retrieval of images from the web, has addressed the challenge to some extent. CBIR is defined as the operation for retrieving images over the more extensive database in an effective and timely manner using dominant features of stored images such as texture, color, shape, etc. The effectiveness and efficiency of any CBIR model rely entirely on the identified extracted feature subset, as these values are used in the computation of similarity among the stored and retrieved images. Fig. 1 shows the classic examples of image tempering instances.

The primary purpose of the research is to secure the machine learning-based models for forensic analysis in the training and testing phase of the proposed architecture. The primary model experiments with the Support Vector Machine and the transformation functions applied with feature reduction for training the classifier. In the next level, forensic analysis is

performed on the images, which have the specific traces acquired by the operations, such as coding, acquisition, and preprocessing. To enhance the robustness of the model, the Convolution Neural Network (CNN) has been integrated for additional training of the model. CNN is the programming model that aids the machine in learning from the operational data provided. It is a subset of the class for a deep neural network that proactively addresses several image processing operations such as pattern matching and recognition. The model is treated to be complex and interconnected with several neurons in each of the layers.

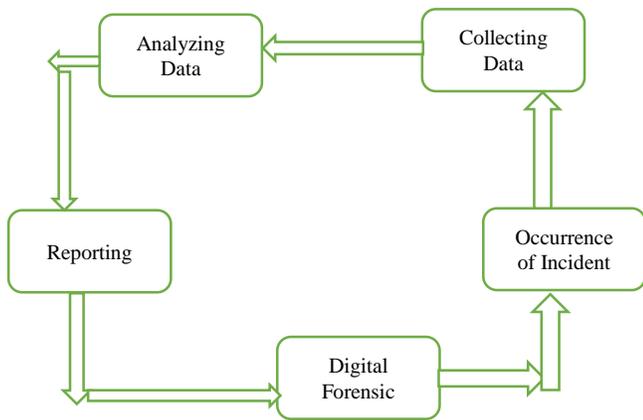

Fig. 2. Dimensions of Digital Forensics.

Fig. 2 provides the dimensions of digital forensics. Digital forensics involves the process of incident occurrence, analyzing collected data, and reporting the traces of anomalies in it.

## II. RELATED WORKS

In [2] the work used pre-trained models for the lifecycle of forensic digital imaging tools. The work focused on the detection of a gun in a set of images. The work focused on the four pre-trained models, such as ImageNet-trained models: InceptionV3, Xception, ResNet, and VGG16, on the Adhoc realistic datasets without any of the fine-tuning of the models

used. The results were on par with the realistic determination of guns in the images. The work was limited to a particular class and could be extended with a few more classes to make the model more realistic.

In [3][4] the authors discussed the various needs for using machine learning and deep learning models and their implications. The various experimentations in the article show the augmenting of the performance of traditional models with the integration of machine learning models and the development of the conceptual framework for digital forensics.

The work in [5][6] proposed the support vector machine learning model with DWT and PCA as feature reduction models. The proposed model has experimented with an Adhoc dataset comprising 10000 images, and the proposed work was compared against the decision tree and Bayesian model. The proposed architecture gave the optimized performance of an accuracy of 97% in a limited subset of training images.

In [7] they worked on detecting tampering on the images using the CFA artifacts. The model provided optimal results in the detection of forged region localizations. The model has experimented on the UCID dataset and several images pulled from various social media websites. The model used the scalar-based approach with forensic analysis by machine learning. The experimental results were optimized with this approach and limited to a few classes. The procedure failed when experimented with multi-class label datasets.

The model in [8] addressed image forgery on social media and other prominent websites. The work focused on copy-move forgery detection using block processing and extracted the features transformed from the blocks. The convolutional neural network was for detecting the forgery. The serial pairs of convolutions are used for extracting the features and then enable the classification of images as tampered and originals, including the consideration of transformation operations. For Experimentation, various trigonometric transforms for 1D and 2D are considered. The model gave the optimum accuracy but was limited to the specifically trained dataset and required a robust model to deal with all kinds of images.

The experiments in [9] discussed the significant risks and shortcomings of using CNN models in clinical applications. The research focused on noise discovered in medical images and its impact on deteriorating the model's performance. They proposed a defense mechanism to such noises by incorporating the sparsity of denoising methods performed inherently in the CNN models to enhance the model's accuracy and overall performance. The model gave an accuracy of up to 97%.

The model in [10] discussed the impacts of adversarial perturbations on CNN and its challenges. The model is designed on the new architecture that specifically increases the robustness of the adversarial effects by using feature denoising. The network design consists of blocks that denoise each feature using various nonlocal means and a combination of other filters. The model has experimented on Imagenet, and the model's performance is enhanced by embedding this method in machine learning models.

The work by authors in [11] addressed the problem with the authenticity of the images shared across social media and other

websites. They proposed a digital image forensics model to identify the images' averaging and gaussian filtering. The model first normalized the image and computed the difference in array values for calculating the co-occurrence features. The model achieved higher accuracy for even small-size images with less resolution, but the results were minimal for the higher-size images.

The authors in [12] proposed a model based on the pixel-pair histogram (PPH) and coefficients of an autoregressive moving average model (ARMA). These features are extracted from various directions in an image for computing the median filters. Experimentations were done on multiple single and compound databases, and the model enhanced the accuracies of the models, especially for the JPEG formats and compressed versions of the images.

### III. PROPOSED METHODOLOGY

The proposed methodology works in two layers. In the initial phase, the support vector machine is used with the RBF kernel in training the images. In the second layer, CNN is used for training the model for making the classification more robust. Fig. 3 shows the proposed model for forensic image detection.

#### A. Dataset

To test the proposed model's robustness, experimentations were conducted on a target set of 100000 images. The images span different categories, such as oceans, mountains, fruits, etc. Every image is scaled to 192 X 128. The dataset is spread across 100 categories, composing 100 images in each type. Fig. 4 shows the sample images in the dataset.

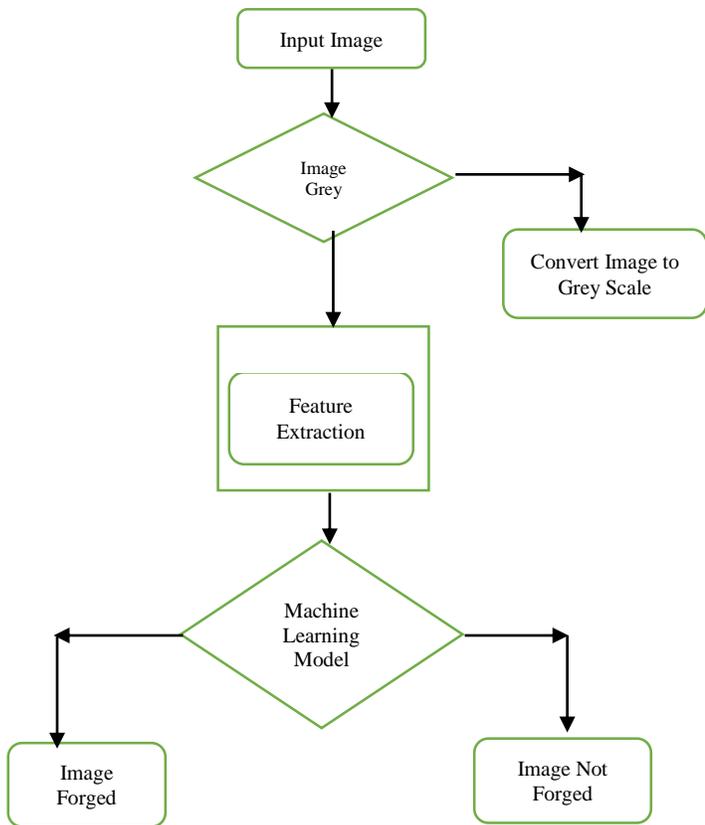

Fig. 3. Proposed Model for Forensic Image Detection.

Fig. 4. Sample Images in the Corel -10K Image Dataset.

Each image has been extracted with 89 features. These features are composed of four sets based on color histogram layout, histogram, co-occurrence, and color moments.

TABLE I. FEATURE SET DESCRIPTION

Feature	Dimensions	Description
Color Histogram	32	HSV is divided into 32 subspaces. 8 for H and 4 for S.
Color Histogram layout	32	Image is divided into four sub-images
Color Moments	9	3 for H, S, and V
Co-occurrence Texture	16	co-occurrence in 4 directions is computed (horizontal, vertical, and two diagonal directions)

#### B. Feature Extraction and Feature Reduction

##### Algorithm: Feature Extraction

Input: Image I

Output: 89 Features  $i_1, i_2, \dots, i_n$

Step 1: Convert RGB to HSV Image.

Step 2: Split the input image into H, S, and V sub-image spaces  
Step 3: Canny Operator is used for edge detection and segmentation

Step 4: Discrete Cosine Transform (DCT) is used for feature extraction

Step 5: 89 feature sets are extracted from the image

The DCT coefficient entities signify the spatial frequency components in an image, and every pattern of the blocks in an image is augmented with various magnitudes. The extracted features depend on the prominent edge, and the values extracted signify the image's lowest frequencies.

Fig. 5 (a) shows the original image and the extracted features from HSV subspaces in images. Fig. 5 (b) shows the sample extracted feature matrix.

In computing the DCT coefficients matrix, the major component for the spectral coefficients of images represent the lower frequency sections and higher frequency sections with amplitude of areas across the image. Since the most dominating area of interest is around the lower frequency, we discard the values closer to 0. The coefficients of DCT are reduced w.r.t to (1).

$$D\_C(u,v,s)=F(u,v) \quad u,v=1,2,3,\dots,s \quad 1 \leq s \leq 8 \dots \quad (1)$$

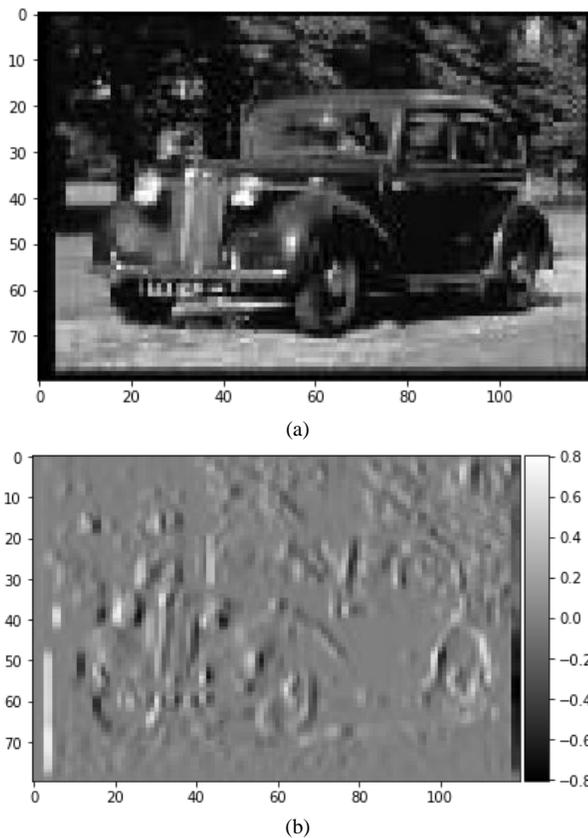

Fig. 5. (a) Original Image. (b) Image Feature Extraction.

Where  $F(u,v)$  Represents the DCT coefficients of image block  $I$ .  $D_C(u,v,s)$  Represent the reduced DCT Coefficient.  $S$  represents the reduction scale for the image.

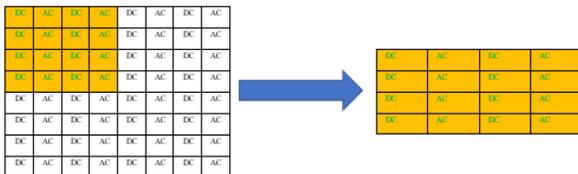

Fig. 6. DCT Reduced Coefficients from 8 X 8 to 4 X 4.

Since the DC coefficients among the adjacent blocks of images are redundant and the AC coefficients are small, these values are ignored. DCT transforms the correlation among the adjacent 8 X 8 blocks of images and is quite dominant. Hence smoothing these edges is necessary. The operation is performed using DCT coefficient values, which will uniformly distribute the frequency across the images. The reduced and smoothed coefficients of DCT are computed as of (2). The sample features extracted using DCT are shown in Fig. 7.

$$D_C = \begin{cases} F(u, v) & (u, v) = 1 \\ F(u, v) + \frac{F(1,1)}{8} & (u, v = 2, \dots, s) \end{cases} \quad (1 < s \leq 8) \quad (2)$$

#### IV. MACHINE LEARNING MODELS

In the first phase, the support vector machine with the configuration in Table II is used to train the model. Support Vector Machine (SVM) is majorly used in classification, and recognition tools are embedded to avoid computational complexities. Our work proposes a methodology for detecting the forged image, which might comprise any subpart if the image has been added, removed, or altered. The SVM is used for identifying the similar neighboring regions of an image by matching with other blocks of the image computed. To identify a forged part in an image, the features are extracted w.r.t to HSV, texture, pixel value, and the edges of several regions in an image. The process works in two iterations. In the first iteration, the model is trained with the images without forged parts. The second iteration tests the model with the sample set of images containing the forged part. The SVM model is used to classify the images into two classes: forged or genuine. The model initially identifies the edges and decides the decision boundaries in the training phase. This information will be used for generalizing the images with higher dimensions. A decision space (support vectors) for the set of images is generated using the larger space of trained images which separates the objects belonging to a different class.

All the experiments were conducted on Ubuntu 22.0 LTS 64-bit Operating System with 24GB Ram, intel core i5 @3.40Ghz with python 3.0. The entire dataset was divided in the ratio of 70:30 for the training and testing dataset. In the initial phase, the training is done with a support vector machine with rbf kernel, as mentioned in Table II.

TABLE II. CONFIGURATION OF SVM MODEL

Model	Kernel	$\gamma$
Support Vector Machine	rbf	1/n

To make the model more robust, it is trained with the CNN model as specified in Table III in the second phase.

TABLE III. CNN MODEL CONFIGURATION

Image Layer	Filters	Feature map size	Size for filter	Strides	Padding
1 <sup>st</sup> CNN Layer	664	224*224*64	3*3*3	1	1
2 <sup>nd</sup> CNN Layer	64	224*224*64	3*3*64	1	1

## V. CONCLUSION

In recent research, many researchers proposed various methods for forgery detection, which can be further categorized into supervised and unsupervised classification models. The two models experimented with, in our work, support vector machine and the convolution neural network have performed well, with an accuracy of 75% and 95%. The CNN model wrongly classified the few forged images to non-forged. These misclassifications were handled correctly in the SVM. Hence the model proposed is trained in two iterations with respect to

SVM and CNN. The combined classifier gave an accuracy of over 98%. The proposed model can be further enhanced with an optimal feature reduction mechanism, and using unsupervised models may augment the model's performance.

**Abstract**—Spatial data analytics is an emerging technology. Artificial neural network techniques play a major role in analysing any critical dataset. Integrating remote sensing data with deep neural networks has led a way to several research problems. This paper aims at producing land use land cover map of Bangalore region, Karnataka, India with various band combinations of sentinel satellite imagery obtained from google earth engine. LULC map classes include water, urban, forest, vegetation and openland. Band combinations of satellite images represent different characteristics of spatial data. Hence, several band combinations are used to build LULC maps. Also, classified maps are generated using different neural networks with pixel-based classification approach. Appropriate performance metrics were identified to evaluate the classification results such as Accuracy, Precision, Recall, F1-score and Confusion Matrix. Among neural networks, Convolutional Neural Network technique outperformed with 98.1 % of accuracy and less error rates in confusion matrix considering RGBNIR (4328) band combination of satellite imagery.

**Keywords**—Sentinel-2; neural networks; convolutional neural networks; remote sensing data; land use land cover maps

## I. INTRODUCTION

Monitoring the Earth's surface has undergone a radical change as a result of advances in satellite remote sensing technology. Sentinel-2 multispectral products, created as a result of the European Space Agency's (ESA) [2] and European Union's (EU) [3] Copernicus Programme, have helped to effectively monitor the Earth's surface [1]. The ESA Sentinel-2 satellite constellation, which includes multispectral scanners on board [35], is the second iteration of the Sentinel satellite programme. Sentinel-2's main goal is to supply high resolution [33] satellite data for observing changes in climate [34], monitoring natural disasters, and tracking changes in land cover and use. It also aims to supplement previous satellite missions like Landsat.

Sentinel level-2A dataset acquired is of one of the metropolitan cities of India i.e., Bangalore which was obtained from Google earth engine. A wide-swath, high-resolution, multi-spectral [2] imaging mission from Europe is called SENTINEL-2. The twin satellites' complete mission specification calls for a high return frequency of five days [33] at

the equator when they are in the same orbit but phased at 180°. With a spatial resolution of four bands at 10 m, six bands at 20 m, and three bands at 60 m, the optical payload on SENTINEL-2 will sample thirteen spectral bands [34]. It is possible to use the 290 km-wide orbital sweep. Based on Level-1C data with atmospheric correction for reflectance from the Bottom of the Atmosphere (BoA), data are used to create the Level-2A product [3]. They are routinely manufactured by ESA as of January 2019, exactly like the level 1C products previously mentioned.

The open access Sen2Cor processor allows users to continue producing their own BoA data from Level 1C. Water vapour map [35], Aerosols optical thickness map and a basic scene classification map [2] are among the extra Sen2Cor algorithm outputs that are included in Level 2A data. Sentinel Satellite Image Time Series (SITS) [3] have recently been productively utilised in the perspective of LULC mapping, illuminating the advantages of having access to such optical and radar SITS in this field. A few noteworthy examples include the creation of country-scale land cover maps using optical Sentinel SITS [4].

The following Table I shows the important features of Sentinel level-2 image.

The ideas of LULC laid the foundation to understand how people interact with the environment [6]. The term "Land Use" describes the purposes for which humans use the land cover, such as anthropogenic activity-induced changes. The term "land cover" describes the natural elements [5] that make up the surface of the Earth, such as agricultural land, aquatic sources, and topsoil. [7].

As deep learning techniques automate feature extraction and classification, it is more suitable and efficient for satellite imagery [8]. Each layer of deep learning model computes new data pattern from previous layers' data understanding of artificial neurons, resulting in order of data generalisations [9]. Convolution [32] and pooling layers [31] are typically followed by a fully connected neural network layer [19] and a suitable activation function [37] in CNNs, finally corresponding LULC class is predicted by softmax function as an output [10].

TABLE I. SENTINEL LEVEL-2 IMAGERY'S CHARACTERISTICS [3]

Spatial Resolution	Band Number	Central Wavelength (nm)	Bandwidth (nm)	Lref (reference radiance) ( $W m^{-2} sr^{-1} \mu m^{-1}$ )	SNR @ Lref

### A. Study Area

The great capital of the Indian Karnataka state, Bangalore [36] is one of the cities with the greatest population growth. The most populated district in the state, accounting for 15.8% of the state's total population, is located in Karnataka's only metropolitan region, which has a total population of 96,21,551 (as of the 2011 census). The district's total area is 2196 sq. km, with 4381 people residing in each sq. km. In terms of both land and population, it is the largest district in the state of Karnataka. The majority of Bangalore's population lives in urban areas, making it the most urbanised district.

Bengaluru as showed in Fig. 1 is located on the Deccan Plateau [28], in the Karnataka state's south eastern part. The Bengaluru district lies between 120 58' to 130 0' North Latitude and 770 37' to 780 18' East Longitude. The district's elevation is typically about 1000m above the mean sea level which bestows it with a healthy climate. The district has four taluks namely Bengaluru North, South, East, and Anekal. The famous IT and BT Electronic City situated in Anekal taluk [36].

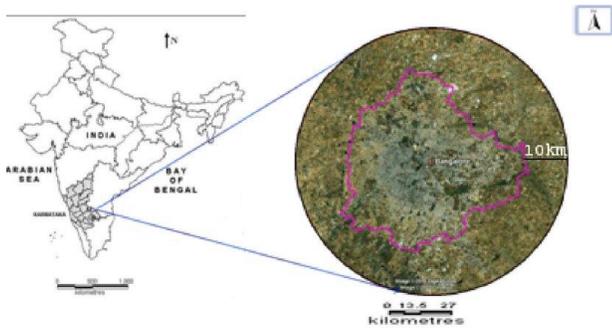

Fig. 1. Bangalore BBMP Limits Study Area [28].

## II. RELATED WORK

Sentinel-2 image of Bangalore region was tiled into patches and for the identified land use land cover classes of trained patches, CNN architectures such as DenseNet201, VGG16 and Resnet50 were applied. This yielded better classification results. [27].

Quick Bird datasets of the regions Rome, Las Vegas and Florida were used for the scene classification using Support Vector machine's margin sampling approach and Entropy query by bagging which is a classifier independent method [13]. Kappa index was mainly used along with accuracy to evaluate the pixel based classification in this study.

Four classes (Water, Cropland, Forest and built-up) of LULC generated for the region Mandya, Karnataka using five bands of Sentinel-2A namely SWIT, NIR, Blue, Red and Green with F1-Score of 0.84 using modified Segnet architecture of deep learning [11].

High resolution image datasets of urban areas of China, Italy and Germany were used with Deep Convolutional neural network techniques for the classification of land use and achieved accuracies of about 90% using object-based and pixel-based approaches [12].

Sentinel 2 image bands of 4, 3, 2, 8 were used for the land cover classification of central java region of Indonesia. With the ArcMap tool and supervised classification approach, a very high accuracy of 1 and moderate kappa value of 0.4896 [14] were achieved. Maximum Likelihood classifier used in this research is then assessed by comparing raster values of classified image and actual google earth engine image. For this, acquisition dates of two images are kept same.

Maximum Likelihood Classifier (MLC) and Support Vector Machine (SVM) classifiers of ERDAS imagine tool were applied on Sentinel-2 and Landsat-8 dataset of Istanbul metropolitan city of Turkey's LULC classes [15]. Among these two classifiers, SVM achieved highest accuracy and kappa coefficient of 84.17% and 0.8190 respectively for the sentinel-2 data. Error matrix was calculated against classified random points and reference points of google earth also as an assessment.

Zonguldak, Turkey [16] was considered as the study area in this research. Sentinel -2 MSI and Landsat OLI were used as satellite imageries. MLC was used to generate LULC map. Classification using Sentinel-2 data yielded highest accuracy and kappa coefficient than Landsat-8. Accuracy was assessed with 460 stratified random points.

LULC maps and correlation matrix were generated for the Ahmedabad city of Gujarat state, India from the period 1991 to 2010 so as to know the change of certain land use classes. The main intension of this was to monitor population dynamics, urban expansion. [17].

This study presents application of LULC maps for the prediction of change and spatial distribution for the year 2027 of Ahmedabad city, Gujarat using the integration of cellular automata and artificial neural network model from temporal series of data from 1976 to 2017. [18].

Most of the recent research work focused on the LULC classification of satellite image patches (part of an image) of the interested areas. They were trained and fed to various neural, CNN architectures. But, LULC classification is required for the entire study area to perform change or any other spatial analysis. Only few GIS automated tools could do such classification for the entire study area rather than part of satellite image.

The main objective of this research is to generate optimal [29] land use land cover map using deep neural networks and convolutional neural networks approaches. In addition to this, various combinations of sentinel-2 image were evaluated to know the significance of each band. Finally, proposed model is evaluated using various metrics such as confusion matrix, precision, recall and F1-score. Model is validated with few randomly generated points which are then compared with google earth engine.

### III. METHODOLOGY

The Fig. 2 process explains the data preparation before it is fed into the neural network. Firstly, Bangalore data is being extracted from sentinel portal through google earth engine using JavaScript. This requires date and year, proper selection of the region of interest, bands information. For the research we have downloaded, 2019's January till March data and used band combinations such as 843 (NIR, Red and Green), 432 (Red, Green, Blue) [14] and 8432 (NIR, Red, Green, Blue).

There are two important factors to select only Bruhat Bengaluru Mahanagara Palike (BBMP) limits within Bengaluru/Bangalore data. First, is to focus more on the urbanised areas so that change detection of LULC maps would be more interesting for further studies and second, is to reduce the study area image dimension so that computation time can also be lessened greatly. This phase is achieved by clipping only BBMP limits from whole Bangalore data.

As this research is done for medium spatial resolution image of 10m, pixel-based approach is more suitable [30]. Supervised classification approach is considered. For the same, training suites are generated based on the classes (Water, Urban, Forest, Vegetation and Open land). These suites are divided into train and test for the model evaluation. They are normalised within a scale of 255 so as to bring them into uniform range.

#### A. Neural Networks

The Fig. 3 shows the schematic representation of neural networks made use in the current work.

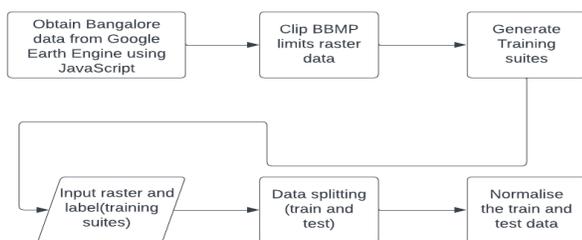

Fig. 2. Data Preparation Process.

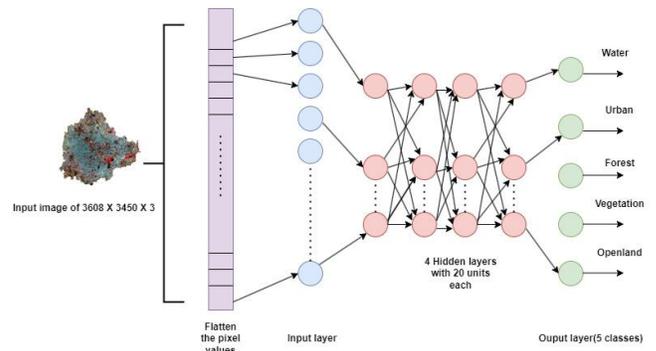

Fig. 3. Proposed Model of Deep Neural Networks.

Deep Neural Networks (DNN) are most efficiently used for multi-class classification [21]. As indicated in the above figure, we have used six layers in our proposed model. Firstly, input image is fed into the network. To ease the task, we have considered 80% of the input image pixels known as trained data out of the entire image. Pixel values are flattened and they are fed as neurons to the input layer. At hidden layer, sum of these inputs along with weights and bias as shown in equation (1) [19] is computed.

Relu activation function is applied to this sum as shown in equation (2) to activate neurons so that vanishing gradient problem could be overcome to some extent [20]. In this case, neuron values less than zero never gets activated. Likewise, process is repeated at next three hidden layers producing 20 units at each layer. Final hidden layer is connected output layer, wherein softmax function as represented in equation (3) finds the final predicted LULC class out of five as mentioned in the above figure.

$$z = \sum_i^n w_i x_i + b \tag{1}$$

here, n is number of input pixels

$$\delta(z) = \frac{1}{1 + e^{-(\sum_i^n w_i x_i + b)}} \tag{2}$$

$$\sigma(z_i) = \frac{e^{z_i}}{\sum_{j=1}^k e^{z_j}} \tag{3}$$

here, k is 5 (number of classes).

Model's hyperparameters include learning rate of 0.001, 100 epochs, batch size of 128. Dropout of 20% and 12 regularisation are considered [38]. We have used keras library to implement this model in python.

#### B. Convolutional Neural Networks

The Fig. 4. shows the CNN model used in this work.

Convolutional, pooling, and affine layers combine to form Convolutional Neural Networks (CNN). When it comes to visual identification tasks, CNN's perform fantastically and at the cutting edge of technology [22]. CNN's are also used to classify remote sensing images with its extensive features. Here, we have used two layers of convolution and two pooling layers. Basically these layers are used to create feature maps of image size of 1247600 with three channels and 7X7 patch size [9]. Using a filter with a stack of fixed-size kernels (here, 5X5), the feature maps are produced at each layer of convolution and

passed into non-linearity using an activation function. The feature maps are then calculated as the weighted sum of the preceding layer of feature patches (e.g., ReLU) [32]. In this way, they maintain location invariance within the input data array while detecting local correlations (fitted in the kernel size) [37].

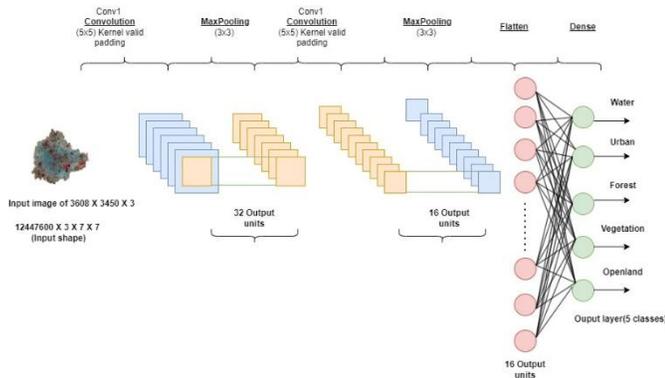

Fig. 4. Proposed Convolutional Neural Network Model.

By computing the maximum or average of nearby units to produce invariance to scaling, minor shifts, and distortions, the pooling layer (3X3) is utilised to minimise the dimension of the resulting feature map. A fully connected neural network and an activation function eventually complete the phases of convolution and pooling layers (32 and 16 units in first and second stage respectively), taking over control of the network's classification phase of five classes as described in the figure by further modeling non-linear relationships [23] of input features.

To train the model and to optimise the input features learnt, we have utilised learning rate of 0.001, epochs of 100, batch size of 128, loss function as Categorical Cross Entropy and Adam as optimiser [38]. The implementation was carried out using Pytorch for its robustness and Speed. Of course, high end system with GPU support was used for the research.

#### IV. RESULTS AND DISCUSSION

In this section, firstly we have explained the results obtained using neural networks and then convolutional neural networks. For both the methodologies used in this study, BBMP region's sentinel level2 image of the period January to March 2020 data is fed as an input. Corresponding Predicted LULC maps are listed from Fig. 5-10. To create typical LULC map as in Geographical Information Systems (GIS), we have added latitude, longitude, scale bar, text, north arrow [26] to the classified image.

Error matrix is tabulated for all the five LULC classes i.e., Water, Urban, Forest, Vegetation and Openland for both DNN and CNN methods in terms of pixels. To compute this, only test data (20% of 12447600 pixels i.e., 2489520) obtained from the input as depicted in Fig. 2. is considered. Table II to IV and Table V to VII are the error matrices of DNN and CNN respectively.

In addition to above results, CNN predicted LULC map of band combination RGBNIR is validated. This was done by generating 50 random points in the predicted image 10 for each class, then it was manually classified using google satellite

imagery. This classification was compared with the predicted image and error matrix for the same is as shown in Table X:

TABLE X. ERROR MATRIX GENERATED AGAINST 10 RANDOM POINTS FOR EACH CLASS WHICH ARE MANUALLY CLASSIFIED WITH GOOGLE SATELLITE IMAGE AGAINST PREDICTED CNN LULC MAP

	Classified (CNN Prediction)	Water	Urban	Forest	Vegetation	Openland	Total
Reference (10 Random points for validation)	Water	10	0	0	0	0	10
	Urban	0	8	0	0	2	10
	Forest	0	0	7	3	0	10
	Vegetation	0	1	2	7	0	10
	Openland	0	1	0	1	8	10

### V. CONCLUSION

This study was conducted to examine the LULC maps obtained from neural networks techniques. The main objective was to determine the best suited neural network algorithm and the corresponding band combination with the highest accuracy, precision, recall and less error rate in the confusion matrix. To test all these, we chose Bangalore BBMP limits as the input image to the network and obtained land use and land cover of the typical classes Water, Urban, Forest, Vegetation and Openland. Among CNN and DNN and the sentinel-2 image band combinations RGB, RGBNIR and RGNIR, CNN with RGBNIR outperformed with accuracy 98.1 with less error rates in confusion matrix. Also, LULC map generated by the highest accuracy model (CNN with RGBNIR combination) was assessed with the help of google satellite imagery and confusion matrix was computed where in, error rate was very less.

LULC laid the foundation for further analysis. Mainly, change analysis will be performed and the predictive model would be developed in the upcoming research work mainly applications of LULC.

### ACKNOWLEDGMENT

I would like to thank Dean Research and Innovation, Presidency University, Bangalore for providing high end systems to complete the second phase of my research as per the above mentioned results.

### Conflicts of interest

The authors have no conflicts of interest to declare

**Abstract**—Unlike traditional recommendation systems that rely only on the user's preferences, context-aware recommendation systems (CARS) consider the user's contextual information such as (time, weather, and geographical location). These data are used to create more intelligent and effective recommendation systems. Time is one of the most important and influential factors that affect users' preferences and purchasing behavior. Thus, in this paper, time-aware recommendation systems are investigated using two common methods (Bias and Decay) to incorporate the time parameter with three different recommendation algorithms known as Matrix Factorization, K-Nearest Neighbor (KNN), and Sparse Linear Method (SLIM). The performance study is based on an e-commerce database that includes basic user purchasing actions such as add to cart and buy. Results are compared in terms of precision, recall, and Mean Average Precision (MAP) parameters. Results show that Decay-MF and Decay-SLIM outperform the Bias CAMF and CA-SLIM. On the other hand, Decay-KNN reduced the accuracy of the RS compared to the context-unaware KNN.

**Keywords**—Time-aware recommender system; context-aware recommender system; matrix factorization; K-Nearest Neighbor (KNN); and Sparse Linear Method (SLIM)

## I. INTRODUCTION AND BACKGROUND

Recommender systems (RS) are intelligent tools and techniques used to recommend items to a user based on his/her preferences [1]. In Ecommerce Applications, a Recommender system is used to predict the product that a user is most likely to purchase. Companies like Netflix and Amazon use recommender systems to help their users to identify the correct product or movies based on their history[2].

Context-aware recommender systems (CARS) produce more significant recommendations by optimizing preferences to suit the current situation and conditions of the user (e.g., location, time, weather, device, etc.) [15,17]. This method has been proven to be effective in improving the performance of the recommendation system [3]. One of the most important contextual information that has been used in recommender systems is time, especially in the context of e-commerce applications. The winning team of the Netflix Prize competition [5] found that using time context can significantly increase the reliability of the recommendations. As users' preferences change over time, new fashions and interests are constantly emerging [4]. For example: seasonal changes (specific holidays) leading to different shopping patterns. Also, Product popularity are in a constant change. This leads consumers to constantly change their taste. Therefore, it was necessary for the recommendation systems to consider these changes in the

behavior of users. One of the factors that facilitated research on the use of time in recommendation systems is the ease of extracting it, which does not require special devices or effort.

The time Aware Recommender system (TARS) 's primary purpose is to deal with user preferences changes over time [18]. There are two types of user's feedback that can be used with the time: implicit feedback and explicit feedback. In the explicit feedback the system must ask users to provide their ratings for items directly mostly using stars. However, in the implicit feedback approach, the system automatically tracks users' preferences by monitoring the performed actions, such as which item they visited, where they clicked, which items they purchased, or how long they stayed on a web page. In the real word applications, any store can include a time-aware recommender system to work offline without the need to collect new data from users because it can simply use the user's implicit feedback (purchase data) with its timestamp. As it has been proven in this research, choosing the appropriate algorithm to use with the time data will improve the performance of the recommendation system, which will be reflected in the store's revenues. Some research discussed the impact of using time with user's explicit feedback. However, research that consider purchasing information such as [3, 4, 6] did not address the time dimension. Due to the lack of datasets that uses implicit feedback (purchase information) with time factor in the field of e-commerce, the impact of linking these two parameters in the field of e-commerce has not been studied in the literature. Thus, many of the TARS research findings don't apply to e-commerce. As this type of recommender system is concerned with not only the preferences of the user but also with the act of purchasing, which leads to increasing the store's earnings which is the main goal of any business. This work analyzes TARS with purchasing actions on an online shopping domain to achieve the goal of increasing the store revenue by enhancing the accuracy of the top 20 recommended items.

In previous research [51] we incorporated time with the Matrix Factorization (MF) algorithm to improve the recommender system accuracy. In this research, we have used the Decay function method with two other states of art algorithms to compare the results and find out the most appropriate algorithm in the field of e-commerce that can be used with the common actions (add to cart and buy). The work's key contribution is to combine time with RS using two separate methodologies (Bias and Decay) and purchasing actions for online shopping recommendations.

Bias is the first method, which uses time as the third dimension in the (user\*item) rating matrix. The Decay function,

on the other hand, generates predicted ratings by combining implicit feedback (add to cart and buy) with temporal dynamics, giving the newly purchased items a higher weight than older ones. Then generating new predicted rates to replace the old rates.

In this research, we evaluated the two techniques using three cutting-edge algorithms: Matrix Factorization (MF) [7], K-Nearest Neighbor (KNN) [8], and Sparse Linear Method (SLIM) [9]. Precision, recall and Mean Average Precision (MAP) were used to evaluate the experimental results.

#### A. Time-Aware Recommender System Categories

Authors in [19] identified seven methods on how time factor may be used with recommender systems as follow:

- Bias: In this method, the system records the time of the user's rating. Then Time will be added to the collaborative filtering algorithm as the matrix's third dimension. Collaborative filtering will compare users, identify similar users, and then predict user ratings for unrated items.
- Decay: In this method, the system prioritizes new things above those with more recent interactions.
- Micro-profile: The system saves distinct profiles for each user at different times. For example, a user can have two profiles, one for weekends and the other for weekdays.
- Restriction: In this case, the recommender system (RS) matches the user's available time to the time when the item will be used. For example, if the user wants to eat dinner, the algorithm will only suggest restaurants that are open late.
- Time Rating: Time is used to infer user preferences using implicit feedback. For example, the longer a user spends on a product page, the more the consumer likes that product.
- Novelty: The recommendation system defines a limit date and will not recommend any items that are older than this date. For example, on a news website, RS will only recommend news that was published at least one day ago.
- Sequence: The RS tracks items that are consumed one after another or in a certain order. For example, the system will recommend more products that are typically purchased along with the consumed product.

In this paper, we investigated and compare the Bias and Decay categories by incorporating them with RSs Algorithms.

#### B. Recommender Systems Algorithms

There are three main techniques used in RS: content-based filtering, collaborative filtering, and hybrid filtering. However, our research scope is in Collaborative filtering algorithms (CF) which can be categorized into three main categories: neighborhood-based algorithms such as KNN, latent factor-based algorithms such as MF, and non-neighborhood or latent

factor algorithms such as Sparse Linear Method (SLIM) algorithm [11-14].

- Neighborhood Based Algorithms

The K-Nearest Neighbors (KNN) algorithm depends on finding users who are similar to the current user. The behavior of the current user is thus predicted based on his/her closest neighbors [20]. The interaction matrix serves as the algorithm's initial input. The correlation between users is then used to compute similarity. The cosine similarity is applied and computed in this study as given in equation (1) [8]:

$$sim(u_a, u_b) = \frac{\sum_i r_{u_a,i} r_{u_b,i}}{\sqrt{\sum_i r_{u_a,i}^2 \times \sum_i r_{u_b,i}^2}} \quad (1)$$

Where  $sim(u_a, u_b)$  is the correlation between user a and user b and  $r_{u_a,i}$  is the rate by the user a for item i. k (number of the nearest neighbors) is a hyper-parameter that must be manually adjusted and cannot be learned by the system. The final step is to use the formula (2)[8] to calculate the rating prediction:

$$P_{u_a,i_x} = r_{u_a}^- + \frac{\sum_{n \in V} (r_{u_n,i_x} - r_{u_n}^-) sim(u_a, u_n)}{\sum_{u_n \in N} |sim(u_a, u_n)|} \quad (2)$$

$N$  is the set of closest neighbors, while  $r_{u_n}^-$  is the average rate that one of the users in the  $N$  set has provided.  $P_{u_a,i_x}$  denotes the predicted rate of user  $a$  for item  $x$ ,  $r_{u_a,i_x}$  is the actual rate by user  $a$  for item  $x$ .

- Matrix factorization Algorithm

Matrix factorization (MF) is a form of latent factors technique used in RSs that uses Collaborative Filtering (CF). MF method begins by randomly initializing two matrices. The first is a (users\*factors) matrix, while the second is a (factors\*items) matrix. When these two matrices are multiplied together, we get the (users\*items) matrix, which is the same size as the Rating Matrix that we're attempting to forecast [21]. The number of latent components we're utilizing to estimate the rating matrix is represented by dimension  $f$  (factors).  $f$  is usually between 10 and 250.

This method, as stated in equation (3), seeks to fill the matrices  $P$  and  $Q$  by predicting the ratings in the training set [7].

$$\min \sum_{(u_a,i_x) \in \tau} (r_{u_a,i_x} - P_{u_a,i_x})^2 = \min_{p,q} \sum_{(u_a,i_x) \in \tau} (r_{u_a,i_x} - q_{i_x}^T p_{u_a})^2 + \lambda (\|q_{i_x}\|^2 + \|p_{u_a}\|^2) \quad (3)$$

Where  $\lambda (\|q_{i_x}\|^2 + \|p_{u_a}\|^2)$  is a regularization term intended to prevent overfitting.  $p$  and  $q$  are the two factors matrices.

- Sparse Linear Method (SLIM) Algorithm

Similar to the neighborhood-based approach, the sparse linear method (SLIM) method [9] tries to reduce the error rate by using the loss function rather than similarity to determine the difference between the training set and the test set. Equation (4)[9] illustrates the error function's definition as follows:

$$\min_{w_*} \sum_{(u_a, i_x) \in \tau} (r_{u_a, i_x} - r_{u_a}^T w_{i_x}) + \lambda_1 \|w_{i_x}\|^2 + \lambda_2 \|w_{i_x}\|_1$$
$$s. t \|w_{i_x}\|_1 \geq 0 \quad (4)$$

Where  $w$  is the item-item similarity learned by minimizing the error function,  $w_{i_x}$  is a column from the  $w$  matrix,  $r_{u_a}^T$  is the user rate in the training set,  $r_{u_a, i_x}$  is the predicted rate for item  $x$ , and  $\lambda_1 \|w_{i_x}\|^2 + \lambda_2 \|w_{i_x}\|_1$  are regularization terms to prevent overfitting.

### C. Evaluation Matrices

There are several measures for defining the quality of the Top-N Recommender system. However, the main three are precision, recall, and MAP [10].

- Precision

The percentage of recommended items in the Top-N set that are relevant is known as precision. For example, if precision at 10 in a top-10 recommended items is 90%. This indicates that 90% of the suggestions are useful to the user. According to [22], precision is calculated as follows:

$$p = \frac{\# \text{ relevant recommended items}}{\# \text{ recommended items}} \quad (5)$$

- Recall

Recall is the percentage of relevant items in the top-N recommended items. For instance, if we measured recall at 10 and discovered that it is 40%. This indicates that the top-N results contain 40% of the entire number of relevant items. The following is the definition of mathematical recall [22]:

$$r = \frac{\# \text{ relevant recommended items}}{\# \text{ all the possible relevant items}} \quad (6)$$

- Mean Average Precision (MAP):

MAP is the mean of average precision, of all users. MAP can be calculated as follows [22]:

$$MAP = \sum_{i=1}^N \frac{P@i}{N} r_i \quad (7)$$

where  $N$  is the length of the list of recommended items and  $P@i$  is the precision at item  $i$ .

The remainder of the paper is structured as follows:

Section II provides a summary of related works. Section III explains Incorporating time context into RS algorithms. The implementation and experiment are found in Section IV. Section V explains the findings and discussion. Finally, in section VI, the conclusion is presented.

## II. RELATED WORK

Many scientists investigated how time is used in RS. Some used it with rating prediction recommenders [29,27,30,33], while others used it with Top-N recommendations [25,26,37]. Precision, recall, and MAP may be applied for Top-N recommendations, whereas Mean Absolute Error (MAE) and Root mean squared error (RMSE) can be used for recommendation prediction. We will focus on Top-N recommendations in this study because they are commonly

used in the commercial field, where the purpose of the recommender system is to select a few specific things that are most attractive to the user.

The recommendation process may be carried out in different ways and using a variety of algorithms. Neighborhood-based algorithms and latent factor algorithms are the most popular types of traditional recommender systems. The recommender was applied using Matrix factorization and user-based K-nearest neighbor (KNN) in [23]. They created a simulated rating utilizing the decay function to aggregate implicit feedback datasets with time dynamics. The experimental findings showed that their suggested technique is successful in the multimedia domain for rating prediction and top-N recommendation. The study's [24] objective was to enhance the performance of neighborhood-based recommender systems using the time context with the decay function in addition to ratings. The author [25] employed content-based and collaborative filtering algorithms with pre- and post-filtering that considered the time context. However, they do not provide any experimental tests on a dataset. Researchers in [25] classified the methods of using time context with RSs as decay, restriction, and novelty. Other researchers added the sequence context with the decay function [26].

the research [27] exploited using the time context to enhance the user-based collaborative filtering algorithm and proposed a weight formula to account for changes in the group users' preferences over time. Their technique raises the accuracy of the collaborative filtering (CF) algorithm on a movie dataset. A proactive Context-Aware RS is suggested by [28] for lecturers and scientists who would be providing learning resources for students. In [28], time is employed in the same way as Restriction; the RS seeks to locate learning materials that correspond to the real user's time. [29] suggested a method for predicting user preferences in a recommender system by learning the sequence of purchase history and taking preference changes into account. Using the micro profile technique, they use a Kalman filter to forecast user preference vectors from user characteristics.

Time is widely implemented in the multimedia domain [23, 24, 30-34,52] and learning domain [28, 35-37] [25, 26] according to the literature. However, in the e-commerce field, it is rarely utilized to study purchase data rather than just rating data. We can also see that user preferences fluctuate depending on the season and application domain. As a result, the method for dealing with time in one domain may not apply to another. We used the decay function to apply to the purchase date (add to cart & buying or transactions) in an online shopping system in this study.

Many studies in the literature [24,26,27,30-33,53] used the MovieLens dataset, which contains the rating from the MovieLens website (movielens.org). The ratings are connected to the timestamp. Other research [23, 29] examined the Last.fm dataset, which includes a timestamp and a user's history of listings in addition to the user's properties. The Yelp dataset in [24] only gives a comprehensive perspective of restaurants, including overall user ratings. Finally, the D-Lib Magazine dataset [26] includes articles and numerous shorter items, as

well as digital collections, calls, and notifications from its 265 issues.

According to the literature, most of the datasets used do not include the implicit feedback of purchase data (buy and add-to-cart) linked with time in the e-commerce environment. Table I shows a summary of the related work.

TABLE I. RELATED WORK

In this research, we have used the Decay function method with three states of art algorithms in the field of e-commerce with two main implicit actions (add to cart and buy). The work's key contribution is to analyze the effect of combining the time context with RSs using two separate methodologies (bias, and decay) and user's implicit feedback for online shopping recommendations.

### III. INCORPORATING THE EXPONENTIAL DECAY FUNCTION INTO RECOMMENDER SYSTEM

Our approach consists of three major phases as illustrated in Fig. 1. The first phase is data pre-processing where dataset converted to binary format. The second is the half-life decay function [30,31,33]. Finally, the contextual modeling where

Multidimensional recommender (MD) is generated to produce the Top-N recommended items. the three phases are explained as follows:

#### A. Pre-Processing Phase

This phase involves converting the dataset in a compact format which includes the interaction condition and its value into a binary format that only uses 0s and 1s as shown in Fig. 2. Converting the event types (add to cart and buy) to numerical numbers is also included in this phase.

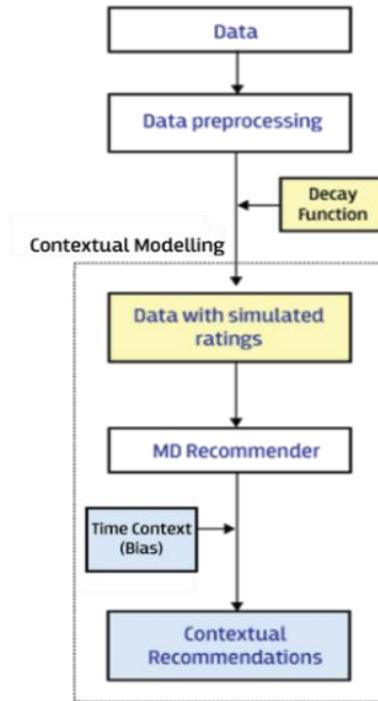

Fig. 1. Incorporating Time Dynamic with Recommender System.

Day of the week	Hour of the day	VisitorID	Event	ItemID
Sun	21	189384	Transaction	299044
Mon	3	287857	Addtocart	5206
Sat	1	158090	Addtocart	10572

Compact Format

Sun	Mon	Tue	Wed	Thru	Fri	Sat	VisitorID	Event	ItemID	1	2	3	...24
1	0	0	0	0	0	0	189384	5	299044	0	0	0	...
0	1	0	0	0	0	0	287857	4	5206	0	0	1	...
0	0	0	0	1	0	0	158090	4	10572	1	0	0	...

Binary Format

Fig. 2. Compact Format to Binary Format.

We assume that user preferences are between one and five, which is the standard scale of user ratings in the literature. The value of purchasing action is set as five in this study as it represents the maximum number of prefaces a user would give to an item. The add-to-cart action is set to four as it represents lower interest than the purchase action.

### B. Half-life Decay Function

Generally, Exponential decay is a mathematical term that defines the process of reducing a value with constant percentage rate over time as shown in formula (8), where  $n$  represents the decay factor as shown in equation (9) [40].

$$final\ amount = \frac{initial\ amount}{2^n} \quad (8)$$

Where

$$n = (elapsed\ time)/(half\ life) \quad (9)$$

$$half\ life = \frac{\log_2(elapsed\ time)}{\log\left(\frac{initial\ amount}{final\ amount}\right)} \quad (10)$$

In our scenario, we assume that the user's interest in an item decreases over time by a fixed amount of value. We use the elapsed time to determine the half-life in equation (10). The elapsed time is the period between the present date and the time when the user gave an item a rating. The half-life is defined as the number of days required to reduce the weight of a user rate by half. For rating an item, the highest rate is five and the minimum rate is one.

### C. Contextual Modeling

In this phase, the filtering according to context is applied as a part of the recommendation algorithms as follows.

- Context-Aware Matrix Factorization (CAMF)

To simulate the interaction between the items and the context, Context-Aware Matrix Factorization (CAMF) adds a factor B, as illustrated in equation (11)[2]:

$$P_{u_a, i_x, c_a} = q_{i_x}^T (p_{u_a} + |N(u_a)|^{-\frac{1}{2}} \sum_{j \in N(u_a)} y_j) + B_{i_x, c_a} \quad (11)$$

These factors B are learned using the error function which can be calculated as shown in equation (12)[2]:

$$\min_{p_*, q_*, y_*, B_*} \sum_{(u_a, i_x, c_a) \in \tau} \left( r_{u_a, i_x, c_a} - q_{i_x}^T \left( p_{u_a} + |N(u_a)|^{-\frac{1}{2}} \sum_{j \in N(u_a)} y_j \right) - B_{i_x, c_a} \right)^2 + \lambda (\|q_{i_x}\|^2 + \|p_{u_a}\|^2 + \sum_{j \in N(u_a)} \|y_j\|^2 + B_{i_x, c_a}^2) \quad (12)$$

where  $N(u_a)$  in (11),(12) is the set of items on which the user  $u_a$  has given implicit feedback, the vector  $y_j$  in (11),(12) represents the value of implicit feedback, and  $T$  is the set of all items  $i$  that both users  $U_a$  and  $U_b$  have rated. To avoid overfitting, the regularization term.  $\lambda(\|q_{i_x}\|^2 + \|p_{u_a}\|^2)$  is added to the error function.

- Context-Aware Neighborhood Based Algorithm (CA-KNN)

Similar to the Context-Unaware Neighborhood Algorithm, the Context-Aware Neighborhood Algorithm, also known as Differential Context Weighting (DCW) [42], begins by determining the similarity between users. The set  $T$  - the set of

all items  $i$  that both users  $u_a$  and  $u_b$  have rated- is used for the summations in the similarity computations. The algorithm then maintains them along with the  $c_1$  and  $c_2$  time contexts where these ratings occurred. Equation (13) shows the incorporation of time in the similarity equation [42]:

$$sim_{ca}(u_a, u_b) = \frac{\sum_{(i, c_1, c_2) \in T} r_{u_a, i, c_1} r_{u_b, i, c_2} J(c_1, c_2, \sigma_1)}{\sqrt{\sum_{(i, c_1, c_2) \in T} r_{u_a, i, c_1}^2 \sum_{(i, c_1, c_2) \in T} r_{u_b, i, c_2}^2 \sum_{(i, c_1, c_2) \in T} J(c_1, c_2, \sigma_1)^2}} \quad (13)$$

Where  $J$  is the weighted Jaccard metric which can be computed as given in equation (14)[42] and the set  $\sigma$  contains the weights for each of the potential contexts: [42]:

$$J(c_1, c_2, \sigma) = \frac{\sum_{f \in c_1 \cap c_2} \sigma_f}{\sum_{f \in c_1 \cup c_2} \sigma_f} \quad (14)$$

Finally, the predicted rates can be determined in the same way as the context-unaware method as illustrated in equation (15) [23]:

$$P_{u_a, i_x, c_a} = r_{u_a, c_a}^- + \frac{\sum_{(u_b, c_1) \in V} (r_{u_b, i_x, c_1} J(c_1, c_2, \sigma_2) - r_{u_b, c_a}^-) sim_{ca}(u_a, u_b)}{\sum_{(u_b, c_1) \in V} sim_{ca}(u_a, u_b)} \quad (15)$$

Where  $(r_{u_b, c_a}^-)$  is the average user ratings in the active context and the rating  $r_{u_b, i_x, c_1}$  is weighted by the Jaccard metric. the context in which the nearest neighbors have rated the item  $i_x$  stored in the set  $V$  represented by  $c_1$ .

- Context-Aware Sparse Linear Method (CA-SLIM)

Context-Aware Sparse Linear (SLIM) changes the prediction equation based on the context of the rating ( $c_a$ ) applying equation (16)[41]:

$$P_{u_a, i_x, c_a} = (r_{u_a}^T + d_{c_a}) w_{i_x} \quad (16)$$

In this equation,  $d_{c_a}$  is the column in matrix D that contains the rating difference for each item-context interaction, which is referred to as the contextual rating deviations (CRD). The CRDs for all items in the context ( $c_a$ ) are stored in the vector  $d_{c_a}$ . By adding it to the error function, the vectors  $d_*$  and the matrix D are learned simultaneously with the matrix W, as illustrated in equation (17)[41]:

$$\min_{w_*, d_*} \sum_{(u_a, i_x, c_a) \in \tau} (r_{u_a, i_x} - (r_{u_a}^T + d_{c_a}) w_{i_x}) + \lambda_1 \|w_{i_x}\|^2 + \lambda_2 \|w_{i_x}\|_1 + \lambda_3 \|d_{c_a}\|^2 + \lambda_4 \|d_{c_a}\|_1 \quad (17)$$

s. t.  $|w_{i_x}| \geq 0$

## IV. IMPLEMENTATION

The data was taken from a real-world e-commerce website (Gift Shop) and is part of the "Retailrocket" public dataset [39]. A visitor can do three sorts of actions: "view," "add to cart," and "transaction.". interactions are collected over a period of 4.5 months. There are around 8k buy events and approximately 28k add-to-cart events. The day of the week and hour of the day

where the event happened were determined using the user id, item id, and Unix time. For example: “1439694000000, 1, view,100,” means visitorId = 1, clicked the item with id = 100 at 1439694000000 (Unix timestamp). Then, for each of the user's events, we assume a rating value. For example, the transaction event has a value of five and the add-to-cart event has a value of four. We computed the elapsed time for each occurrence. Then we utilized it to calculate a new anticipated rate by giving less weight to the earlier event and finding the half-life value as explained in the previous section.

### A. Implementation Tools

The CARSKIT Java Library is used to implement and expand the state-of-art context-aware algorithms. Numerous research [20, 45, 46] have used CARSKIT [44, 47] which is a Java-based open-source package for the context-aware recommendation. As a hardware tool, AZIZ High-Performance Computer (HPC) with 30GB RAM has been used. We modified the CARSKIT code to calculate the precision, recall, and MAP for a different number of recommended items N (from 1 to 20) to be able to track how the algorithms behave as N increases.

### B. Algorithm's Hyper-parameters

The parameters applied for each of the recommendation algorithms are shown in Table II. Number of factors parameter is used in MF, If the number of latent variables (number of factors) equals one, we are selecting the most popular things with the most interactions with no regard for personalization. Increasing the number of latent variables (the number of rows or columns associated with a single product or user) would increase personalization, and hence the RS's quality. However, if the number of latent components grows too large, it will generate an overfitting problem, lowering the quality of the recommendations. To avoid the overfitting problem, we'll need some regularization terms which is used to minimize overfitting while increasing the number of latent factors. In MF and SLIM, without a predefined stopping condition, iterative steps will continue forever. A limitation on running time or the number of iterations is often used to interrupt the infinite loop. In KNN which is known as Differential Context Weighting (DCW) [42] the threshold is applied to distinguish between frequent and infrequent variables and Particle Swarm Optimization (PSO) [43] is used to determine how much weight to give to each potential context. PSO iteratively seeks to enhance potential solutions based on a specified quality metric to find the best answer to an issue [16].

Based on the default parameters for CARSKIT [44] and the suitable values for our dataset, we determined the algorithm's hyper-parameter values for our experiment as shown in Table II. We used a factor count of 10 to ensure that we had enough factors to adequately capture the variability in the data, but not too many that the training data would be overfitting. The maximum number of iterations required to obtain an accurate result is 100. Based on the "Retailrocket" dataset, which includes customer data from May 2015 to August 2015, we estimate a half-life of 43 days. The hyper-parameters for the three algorithms (MF, KNN, SLIM) with the three distinct techniques (baseline, bias, and decay) are shown in Table II.

TABLE II. EXPERIMENT CASES AND ASSUMPTIONS

	Algorithms with cases	Hyperparameters	Values
Matrix Factorization	Case#A1: MF (Time un-aware)	Regularization factor	default value
		# of iterations	100
		# of factors	10
	Case#A2: CAMF (Time aware (Bias))	Regularization factor	default value
		# of iterations	100
		# of factors	10
	Case#A3: Decay CAMF (Time aware Decay)	Regularization factor	default value
		# of iterations	100
		# of factors	10
Half-life		43	
Sparse Linear Method	Case#B1: SLIM (Time un-aware)	Regularization factor	default value
		# Of iterations	100
		# Of neighbors	10
	Case#B2: CASLIM (Time aware (Bias))	Regularization factor	default value
		# Of iterations	100
		# Of neighbors	10
	Case#B3: Decay CA-SLIM (Time aware (Decay))	Regularization factor	default value
		# Of iterations	100
		# Of neighbors	10
Nearest Neighbor Algorithm	Case#C1: User-Based KNN (Time un-aware)	# Of neighbors	10
	Case#C2: DCW (Time aware (Bias))	PSO parameters	default value
		Threshold	0,5
	Case#C3: Decay DCW (Time aware (Decay))	PSO parameters	default value
		Threshold	0,5
	Half-life	43	

## V. RESULTS

The application of the three RS algorithms Matrix Factorization (MF), K-Nearest Neighbor (KNN), and Sparse Linear Method is examined in this section (SLIM) using two different methods (Bias and Decay) as shown in Table II. The metrics used to analyze the experiment are Precision, Recall, and MAP. N is the number of suggested items, and the metrics are calculated for N=1 to N=20.

### A. Case A: Matrix Factorization (MF)

This section uses two methods – Bias (traditional) and Decay- to illustrate the effect of introducing time into the matrix factorization algorithm. The accuracy, recall, and MAP for the MF are shown in Fig. 3, 4, and 5, respectively. The decay technique outperformed the Bias-CAMF and MF in terms of accuracy, recall, and MAP, with a 0.05 percent in precision,

0.45 percent recall, and 0.16 percent MAP as shown in Table III.

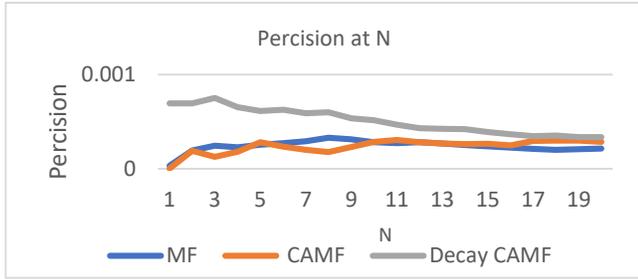

Fig. 3. MF, CAMF, and Decay CAMF Precision.

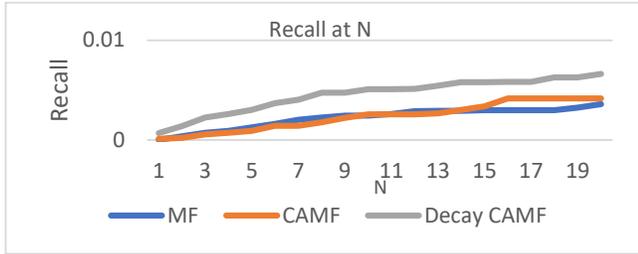

Fig. 4. MF, CAMF, and Decay CAMF Recall.

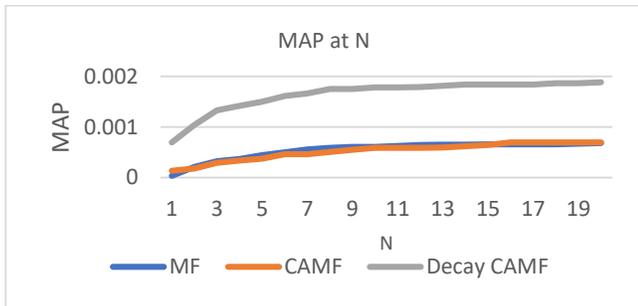

Fig. 5. MF, CAMF, and Decay CAMF MAP.

TABLE III. AVG MF PRECISION, RECALL, AND MAP

	AVG Precision percentage	AVG Recall percentage	AVG MAP percentage
MF	0.020	0.220	0.050
CAMF	0.020	0.240	0.050
Decay & CAMF	0.050	0.450	0.160

### B. Case B: Sparse Lanier Method (SLIM)

Using two approaches (Bias and Decay), this section highlights the effect of adding time with the Sparse Lanier Method (SLIM) algorithm. Fig. 6, 7, and 8 depict the SLIM's precision, recall, and MAP, respectively. Table IV shows that the decay technique outperformed the time unaware SLIM and bias CA-SLIM in terms of accuracy, recall, and MAP, with precision, recall, and MAP of 0.22 percent, 1.40 percent, and 0.78 percent, respectively.

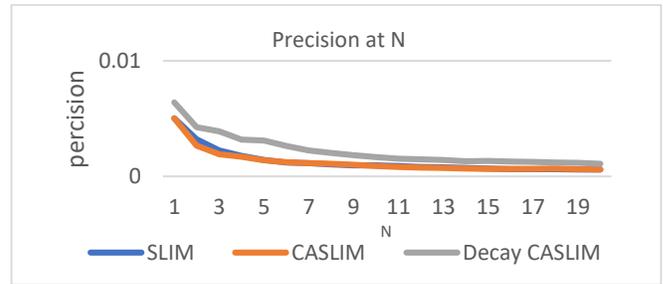

Fig. 6. SLIM, CA-SLIM, and Decay CA-SLIM Precision.

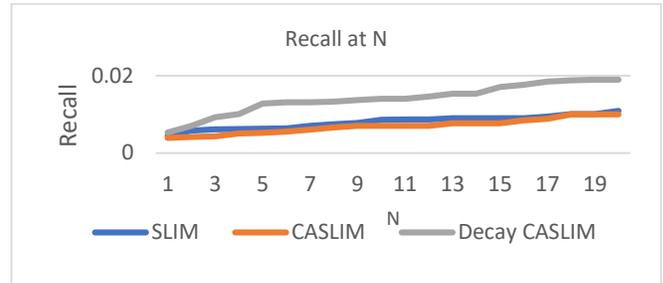

Fig. 7. SLIM, CA-SLIM, and Decay CA-SLIM Recall.

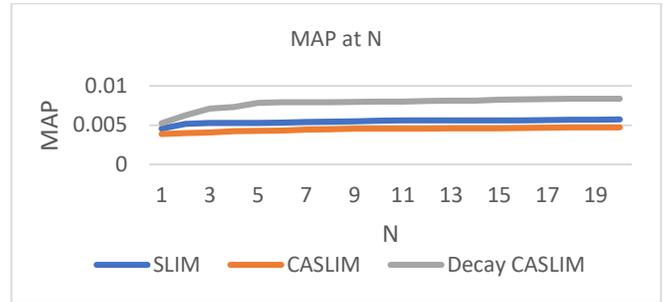

Fig. 8. SLIM, CA-SLIM, and Decay CA-SLIM MAP.

TABLE IV. AVG SLIM PRECISION, RECALL, AND MAP

	AVG Precision Percentage	AVG Recall Percentage	AVG MAP Percentage
SLIM	0.130	0.800	0.550
CA-SLIM	0.130	0.690	0.450
Decay & CA-SLIM	0.220	1.400	0.780

### C. Case C: Nearest Neighbor (KNN)

Using two approaches, this section highlights the effect of adding time with the KNN algorithm. Fig. 9, 10, and 11 depict the KNN's precision, recall, and mean absolute deviation, respectively. As shown in Table V, the average results indicate that using the time context in Bias and decay method decreases the efficiency of the RS with Avg precision, recall, and MAP of 0.04%, 0.37%, and 0.10% respectively.

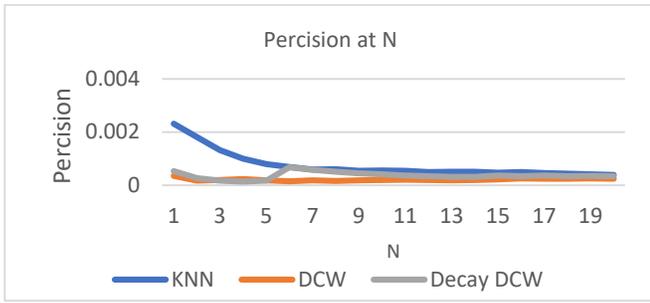

Fig. 9. KNN, DCW, Decay DCW Precision.

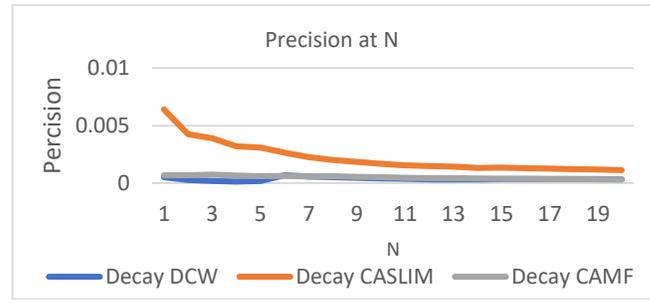

Fig. 12. The Decay Time-Aware Algorithms' Precision.

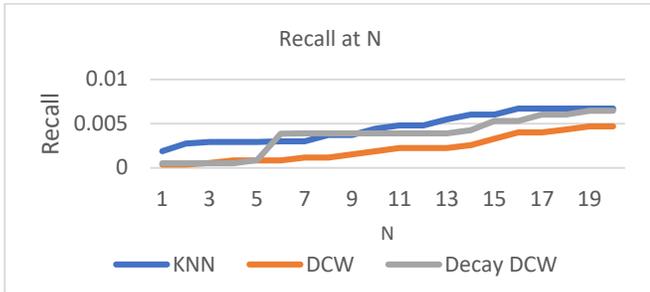

Fig. 10. Fig 1 Recall for KNN, DCW, Decay DCW

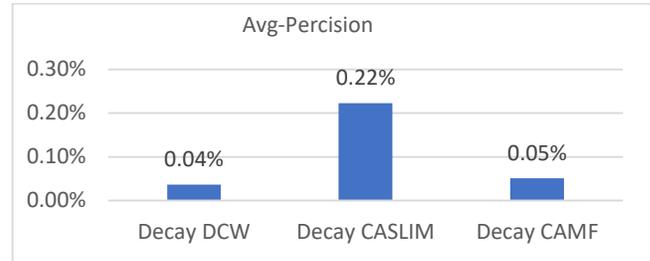

Fig. 13. The Decay Time-Aware Algorithms' Avg- Precision.

As seen in Fig. 14 and 15, Decay CA-SLIM outperformed the other algorithms by a significant margin. With 0.45 percent and 0.37 percent, respectively, while CAMF and DCW have a similar Average-performance.

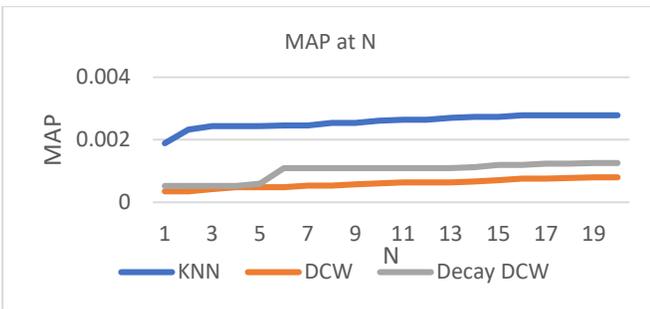

Fig. 11. Fig 2 MAP for KNN, DCW, Decay DCW

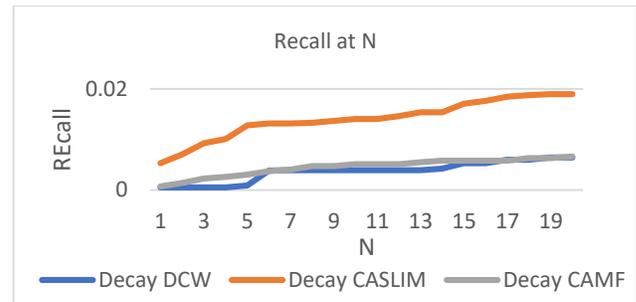

Fig. 14. The Decay Time-Aware Algorithms' Recall.

TABLE V. AVG KNN (RECALL, PRECISION, AND MAP)

	AVG Precision Percentage	AVG Recall Percentage	AVG MAP Percentage
<b>KNN</b>	0.070	0.460	0.260
<b>DCW</b>	0.020	0.220	0.060
<b>Decay DCW</b>	0.040	0.370	0.100

D. Half-Life Decay with All Algorithms (MF, SLIM, KNN) Comparison

The outcomes of three RS techniques (Matrix Factorization (MF), K-Nearest Neighbor (KNN), and Sparse Linear Method (SLIM)) are compared in this section: Fig. 12 and 13 illustrate the accuracy of the three RS methods with The Decay factor. With a significant difference, Decay CA-SLIM outscored the other methods. CAMF and DCW, on the other hand, have approximately similar Average-performances.

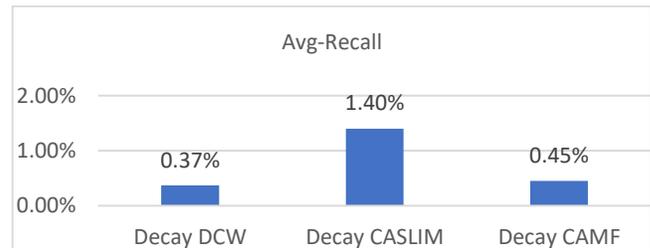

Fig. 15. The Decay Time-Aware Algorithms' Average Recall.

Fig. 16 and 17 depict the MAP for Decay DCW, Decay CAMF, and Decay CA-SLIM, respectively. For the three approaches, the avg-MAP values are 0.1 percent, 0.7 percent, and 0.16 percent, respectively.

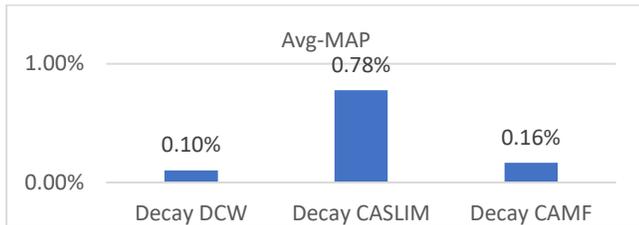

Fig. 17. The Decay Time-Aware Algorithms AVG-MAP.

### E. Findings

Based on the experiment results, we conclude that in the e-commerce domain that uses purchasing data, the item-oriented, decay time-aware recommender algorithms outperform baseline context-aware algorithms and context-unaware algorithms. This conclusion is based on the fact that the overall effectiveness improves when time information is used. Furthermore, we arrive at the conclusion that the sparse linear approach, which has proven positive performance for the top-N recommendation in this research may not necessarily transition well to other datasets in the literature.

- The average findings show that the decay technique outperformed the Bias CAMF and time unaware MF, with precision, recall, and MAP of 0.05 percent, 0.45 percent, and 0.16 percent, respectively.
- The decay technique outscored the Bias CA-SLIM and time unaware SLIM approach, with precision, recall, and MAP of 0.22, 1.40, and 0.78, respectively.
- Adding the time context reduces the accuracy of the recommendation process in the KNN technique. In addition to the algorithm's incredibly high running time (weeks to execute one single run), which obstructed us from running all combinations of hyper-parameters.
- Running the KNN and SLIM with no limit on the number of neighbors had to be left out because it took weeks to execute one single run.
- Given that our utilized dataset has a density of = 0.0124 percent. The results suggest that adding decay context-awareness to KNN algorithms reduces the accuracy of the algorithms for all recommendation list lengths N. However, decay context-awareness improves the efficacy of the Sparse Linear Method (SLIM) and Matrix Factorization.
- In the online shopping area, the SLIM method outperforms both the KNN and MF algorithms using the half-life decay function. It also performs well in terms of Top-N recommendations. The increase in

effectiveness was proven to be related to the average number of interactions per item[48].

- In our dataset the number of interactions per user is limited. Therefore, item-oriented algorithms like SLIM perform better than user-oriented algorithms like KNN.
- Because the SLIM method bases its predictions on item similarity coefficients, it works well on our dataset. Due to the data sparsity (limited numbers of interactions per user), some algorithms (e.g., KNN) perform poorly in terms of recommendations accuracy because it depends on the user's similarity.
- Our research results are consistent with the research [9, 49, 50] that reported increases in effectiveness when using SLIM instead of KNN or MF. This is since SLIM is specifically designed for the top-N recommendation task.

Overall, we conclude that, for the datasets with limited numbers of interactions per users the use of item-oriented decay time-aware recommender systems lead to better performance when compared to bias context aware recommender systems and time-unaware recommender systems.

## VI. CONCLUSION

This paper used the user implicit feedback (add to cart and buy) associated with time context to improve the RS performance in online shopping systems. Bias and Decay methods were used to incorporate the time data into RSs. The experiment included incorporating time with three state-of-art algorithms (MF, KNN, and SLIM). To compare the performance of the RSs we applied three cases for each algorithm (time unaware RS, Bias time aware RS, and Decay time aware RS). Precision, Recall, and MAP were used to compare the performance between the different algorithms and between the three cases in each algorithm. As a result, Decay-MF and Decay-SLIM outperform the time Bias MF and SLIM. On the other hand, Decay-KNN reduced the accuracy of the RS compared to the context UN-aware KNN. The results that were reached from the study achieved the goal of the research, which is analyzing and finding the most appropriate algorithm in the field of e-commerce to build a time-aware recommendation system using the user's implicit feedback (purchasing data). As a future work, this study might be applied to a larger dataset with all combinations of algorithms' parameters and with unlimited number of neighbors. This study might also be expanded by combining the decay function approach with other RSs algorithms and on different domains datasets.

# A Comprehensive Assessment Framework for Evaluating Adaptive Security and Privacy Solutions for IoT e-Health Applications

Waqas Aman, Fatima Najla Mohammed

Department of Information Systems, College of Economics and Political Science  
Sultan Qaboos University, Muscat, Sultanate of Oman

**Abstract**—There exist numerous adaptive security and privacy (S&P) solutions to manage potential threats at runtime. However, there is a lack of a comprehensive assessment framework that can holistically validate their effectiveness. Existing Adaptive S&P assessment efforts either focus on privacy or security in general, or are focused on specific adaptive S&P attributes, e.g. authentication, and, at certain times, disregards the architecture in which they should be comprehended. In this paper, we propose a holistic assessment framework for evaluating adaptive S&P solutions for IoT e-health. The framework utilizes a proposed classification of essential attributes necessary to be recognized, evaluated, and incorporated for the effectiveness of adaptive S&P solutions for the most common IoT architectures, fog-based and cloud/server-based architectures. As opposed to the existing related work, the classification comprehensively covers all the major classes of essential attributes, such as S&P objectives, contextual factors, adaptation action aptitude, and the system's self-\* properties. Using this classification, the framework assists to evaluate the existence of a given attribute with respect to the adaptation process and in the context of the architectural layers. Therefore, it stresses the importance of where an essential attribute should be realized in the adaptation phases and in the architecture for an adaptive S&P solution to be effective. We have also presented a comparison of the proposed assessment framework with existing related frameworks and have shown that it exhibits substantial completeness over the existing works to assess the feasibility of a given adaptive S&P solution.

**Keywords**—Internet of Things; Adaptive Security; IoT Architecture; e-Health; Effectiveness; Privacy

## I. INTRODUCTION

IoT has become an integral part in the automation and extension of various IT-based services. In healthcare, IoT has shown huge potential. Spending on e-health solutions in IoT is expected to stretch 1.1 Trillion dollars by 2025 [1]. IoT in e-health is a developing research area as the world moves towards remote monitoring, real-time and rapid diagnosis and management of illnesses [2]. It is aiding in real-time identification of ailments, attaining more precise health readings, better reach-out to patients in emergencies, and medical care for patients while they are roaming or having mobility difficulties [2]. The range of functionalities provided by IoT in e-health applications has been significantly beneficial and high in demand, especially in the current COVID-19 pandemic situation where hospitals are running at total capacity, requiring more efficient remote healthcare solutions.

Despite the multiple benefits offered by IoT-enabled e-health applications, there is an increasing concern about the potential security and privacy (S&P) threats as it primarily utilizes personal and sensitive information, which can be of considerable value for the attacker, for instance in blackmailing and identity frauds [3],[4]. By nature, IoT devices are dynamic because of the frequent environmental changes, mobility, and their heterogeneous and constantly evolving technology. Such properties can result in a more evolved threat spectrum requiring real-time threats handling. To adapt to such circumstances, many studies have proposed adaptive S&P mechanisms. Adaptive S&P is a system's capability to maintain S&P in the presence of contextual changes [5]. It continuously maintains an optimal S&P level of a managed system through an automated monitor, analyze, and adapt feedback loop, unlike traditional S&P controls such as IDS, anti-malware, firewalls, etc., which have limited protection scope and enforce manual and inflexible threat mitigation strategies [5].

IoT e-health is a critical infrastructure consisting of devices, applications, and individuals that handle sensitive patients' data. Adaptive S&P mechanisms are highly essential, mainly to protect and manage actions, such as access, sharing, and disclosing of the information assets and provide effective S&P within the IoT e-health architecture [6, 7]. Hence, the system needs to be flexible, adaptable, and robust to make real-time S&P decisions based on the requirements of the entities associated with the system [6]. When designing and developing adaptive S&P solutions for IoT e-health, it is vital to consider a set of significant attributes; such as privacy and security objectives, contextual factors, self- properties, adaptation action aptitude and analysis, and adaptation mechanisms to develop a solution that is capable of providing holistic S&P in such dynamic contexts. Moreover, these attributes needs to be realized at particular levels with respect to the different phases in the process and to the underlying architectural needs. If a certain attribute or requirement is improperly enforced in the architectural layers, it may adversely affect the competency of the corresponding adaptation phase. Such misconfiguration may lead to, for instance, scope creep or scope crush of the managed devices, resulting in the adaptive system disorganization and ineptitude.

Regardless of the availability of multiple studies and solutions on adaptive S&P, for instance, [8, 9, 10] emphasize on the need to assess their effectiveness. To validate the efficacy, it is vital to recognize and evaluate the essential factors

necessary for an adaptive S&P solutions and the extent to which they are employed as per adaptation and architectural needs. The existing assessment frameworks focus on a particular set of factors irrespective of the underlying architecture [9,13,14,15] and have a limited scope that only address a part of the problem, [9,13,14,15]. Hence, there is a need of an evaluation framework that can holistically assess the feasibility of a given adaptive S&P mechanism for IoT e-health applications.

In this paper, we present the design of an assessment framework that can guide us to comprehensively assess the feasibility of a potential adaptive S&P solution. It, therefore, also provides a reference model to understand and consider the underlying vital aspects of S&P adaptation. The framework is based on a proposed classification of factors that we have compiled from the existing works. These factors were scattered across the literature under different concerns and with limited scope. We have unified them in a classification of five distinct classes: security objectives, contextual factors, adaptation aptitude, and self-\* properties and privacy objectives required for effective S&P adaptation. The proposed framework mainly assesses which factors should be covered, where they should be realized in the adaptation process, i.e., monitoring, analysis, or adaptation, and at which layer of the common IoT e-health architectures, fog or cloud/server, should they be employed. Furthermore, we present a detailed comparison of the proposed framework with the potential equivalent works. We have concluded that our framework provides a more comprehensive platform for assessing a given adaptive S&P solution. The fundamental contribution that our framework dispenses is a set of diverse and inclusive factors required for S&P adaptation and evaluates them in the architecture context is particularly vivid.

## II. THE ASSESSMENT FRAMEWORK

In this section, we provide a comprehensive description and illustration of the proposed classification and assessment framework. The classification mainly identifies and groups the key attributes (factors) necessary for a given adaptive S&P system. The assessment framework utilizes this classification by determining their need and purpose based on two key aspects: the overall adaptation process (Monitor, Analyze, and Adapt phases) and the IoT e-health architecture. These two aspects are necessary to be considered because certain attributes necessary for the S&P adaptation needs to be addressed uniquely in various architectures. For instance, for fog-based architectures it is vital to conduct S&P analysis at the gateway than at a centralized server to fulfil the rapid and personalized threat assessment objectives for which fog-based architectures are devised [11], [12]. Moreover, the scope managed by a given gateway in fog-architecture is limited as compared to one managed by a centralized server. This structured approach of the framework design assists in assessing the feasibility of an adaptive S&P solution in its respective architecture.

### A. The Proposed Classification

The classification aims to identify and group the fundamental factors necessary for a given adaptive S&P solution. It employs conceptual modeling and provides a basis for comprehending the factors that need to be monitored or

managed, essential to effectively achieve security and privacy objectives, and the ones that may trigger the need of adaptation or may be affected by the adaption processes. Hence, it provides a more comprehensive list of essential factors. The proposed classification, as illustrated in Fig. 1, is developed using the steps followed as:

- Key factors were identified in the current literature on adaptive S&P for IoT e-health.
- Factors that have similar semantic and objective(s) were unified into a common factor. For instance, events per second (eps), productivity, and throughput factors are transformed into a more common and distinct label, throughput.
- To be more comprehensive, certain generic factors are broken down into more detailed and vital factors. For example, QoS is further categorized into response time, latency, and throughput.
- The final list of factors was then grouped into distinct classes. Factors were mapped to the relevant classes based on their overall objectives. Table I provides a brief summary describing each class, listed in Fig. 1, in the context of adaptive S&P solution for IoT e-health

### B. The Proposed Assessment Framework

The primary objective of the proposed assessment framework is to holistically assess the feasibility of an adaptive S&P solution for IoT e-health. It considers four essential concepts: The proposed classification, detailed earlier, the adaptation processes, the IoT e-health architecture in which an adaptive S&P is employed, and a Mapping Criteria. A brief description to the later three concepts in the framework are detailed as follows.

1) *The adaptation process:* The adaption process in an adaptive S&P system can be typically divided into three main functionalities or phases [8, 13, 16, 17]: Monitoring, Analysis, and Adaptation. They enable a system to adapt the S&P configurations based on the dynamic changes in the IoT e-health infrastructure in an automated manner. These phases are briefly described as follows:

a) *Monitoring:* The main goal is to observe, gather and transform contextual information. This includes information about the adaptive system itself (internal factors), such as information related to the software and hardware components responsible for the adaptation process. Monitoring also observe external factors such as those related to the monitored devices, users, network and applications. Therefore, it attempts to collect data essential for a context-aware analysis and adaptation [8, 16, 17].

b) *Analysis:* Analysis aims to determine potential threats, assess potential vulnerabilities, and analyze the protection level of security and privacy from the related contextual information gathered during the monitoring phase. Hence, the analysis process involves the intelligence by applying a range of methods needed to investigate, correlate, and analyze the context of the potential threats [8, 16, 17].

TABLE I. A SUMMARY OF THE CLASSIFICATION CLASSES

Factors	Summary
Security Objectives	Include the attributes responsible for ensuring the basic security of the IoT e-health resources covered by the adaptive system, from security threats, e.g., authenticating users based on their biometric information, authorizing users based on their role, e.g., medical staff accessing the staff portal, patients accessing the patient's portal.
Privacy Objectives	Refers to the factors that ensure essential privacy, including access, usage, and collection of the information assets in an IoT e-health environment, e.g., collecting, accessing, and using patient's health records such as x-rays and CT scans.
Contextual Factors	Contextual factors can potentially trigger the need for adaptive S&P. This can include internal factors such as architectural factors and external factors such as user preferences. Hence, in the context of adaptive S&P solution, assessing these attributes is essential mainly to ensure that the adaptive solution can consider contextual aspects to respond to the changing context and respond to S&P threats, thus providing holistic S&P.
Self-*Properties	Self- * Properties are the basis for the adaptive S&P system itself, as they are capabilities responsible for the adaptive nature of such solutions. These properties enable the adaptive solution to adjust its S&P settings in response to a context and adapt and manage the adaptive solution itself in response to S&P threats. For instance, introducing additional encryption mechanisms in response to a low battery event from one sensing device
Adaptation Action Aptitude	A set of factors that may have a negative impact due to the potential adaptation action. For instance, if a low battery occurrence is detected in a monitoring device, the adaptive solution should adjust the encryption mechanisms to ensure trade-offs amongst confidentiality and the availability of the services.

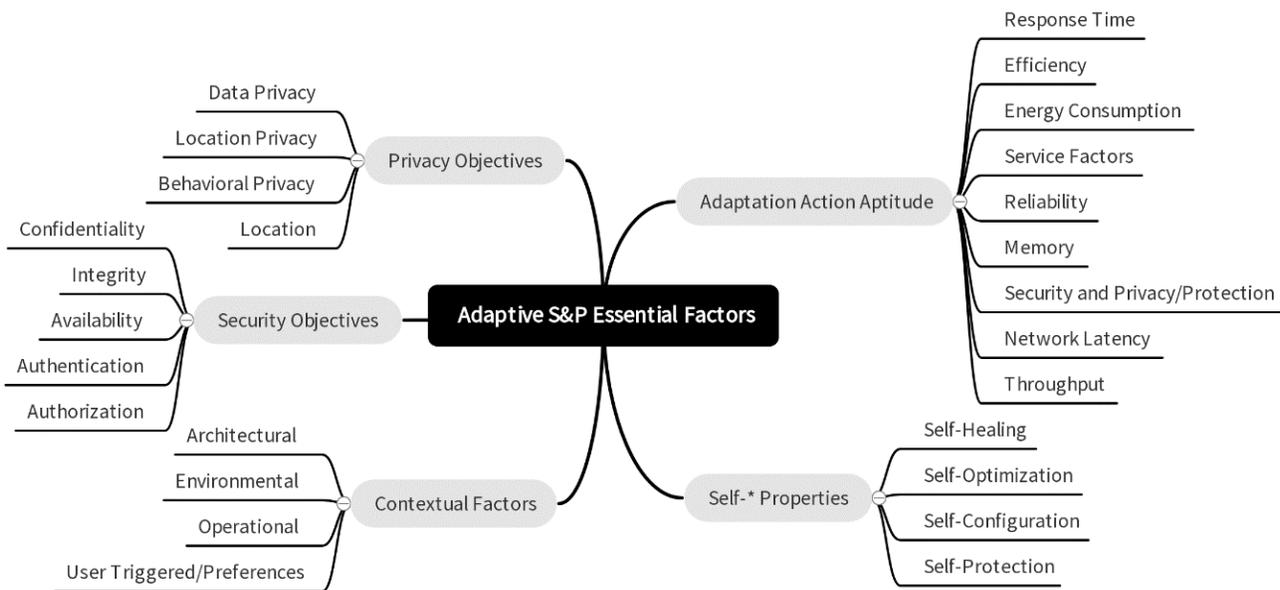

Fig. 1. The Proposed Classification.

c) *Adaptation*: In the adaptation phase, decisions are made to adapt to any given threat situation. The corresponding functionalities identifies a recommended adaptation configuration based on the threat faced and instructs the monitored asset(s) for its adoption. It is recommended that the system is capable of identifying several adaptation actions and select the optimal one [13]. The adaptation process is responsible for the adaptation decision making whereas the actual adaption action is implemented at the monitored object level [8].

2) *IoT eHealth Architecture*: The IoT e-Health architecture specifies the nature of data processing within the overall system [18], [19]. This study considers the two major IoT e-health system architectures, cloud/ server and fog-based system architecture, which are commonly used in the IoT e-Health settings.

a) *Cloud/Server Architecture*: In Cloud/Server architectures, illustrated in Fig. 2, data processing is performed

in a centralized manner, typically using cloud computing or centralized servers controlled by the healthcare service provider [6], [20]. To enforce S&P adaptation in a cloud/server architecture, the monitoring is carried out within the gateway and health systems layer. This includes data collection, filtration, transformation, and further communication, etc., to the upper layers. Device Layer merely act as events generators. However, in certain instances, monitoring is performed at the device layer. For instance, GPS sensors and authentication interfaces can monitor and send out events to the gateway layer, which are further processed by the gateway. In contrast, the analysis and adaptation decision-making is performed at the health systems layer, comprising the cloud/centralized servers [13, 21].

b) *Fog architecture*: Fog architectures, shown in Fig. 3, use the computing resources at the gateway level to carry out the processing of the data gathered from the sensors [22]. The fog nodes, the gateways, perform data normalization, which

consist of storage, computing, and network connectivity, thus enabling them to analyze and make time-sensitive decisions on the time-sensitive data collected [23]. In the context of S&P adaptation, in fog architectures, threat monitoring, analysis, and adaptive decision-making are typically performed at the gateway layer [8, 24]. However, as established earlier, in certain instances, monitoring can also be performed in the device layer. In fog architectures, health-related data collected from the device layer is sent to the cloud. It is part of the primary storage and computing resource, performing data analytics and visualization [23].

3) *The mapping criteria:* The mapping criteria, detailed in Table II, describes information on what and where different attributes should be realized within the different IoT system architectural layers and whether and what adaptation process should be applied on them to enforce effective S&P adaptation. Therefore, it maps a given attribute to the respective architectural layer and adaptation phase based on its requirement in an adaptive S&P solution. Table III – VII illustrate the proposed assessment framework, and shows how the different attributes in the proposed classification have been mapped based on the adaptation process and the IoT e-health architectural layers. For convenience, below we describe how the table structure should be interpreted to comprehend the

architectural and process level requirements of a given attribute:

- The Class and Attributes columns corresponds to the classes and respective factors, as detailed in the proposed classification, which are essential for S&P adaptation.
- The Process column indicate whether or not a given attribute is required be monitored (M), Analyzed (A), or Adapted (Ad). Moreover, it also reflects whether the respective mechanism(s) of the attribute is Utilized (U). An absence of a label indicate that it is not required.
- The System Architecture column, further categorized into Fog and Cloud/Server architecture, indicates where, specifically, in the respective architectures should an attribute is required to be utilized, monitored, analyzed, adapted. For instance, GM depicts that a given attribute needs to be monitored at the Gateway Layer, HU indicates that the mechanism(s) related to the factor should be utilized at the Health System Layer, and GAd shows that the corresponding factor needs to be adapted at the Gateway Layer.

The assessment framework for individual class is illustrated and detailed underneath.

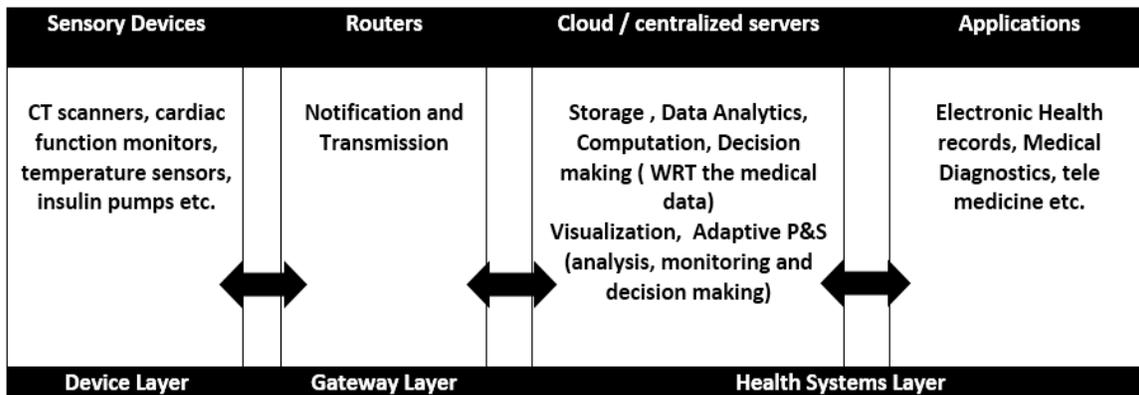

Fig. 2. Figure 2. IoT e-Health Cloud/Server Architecture.

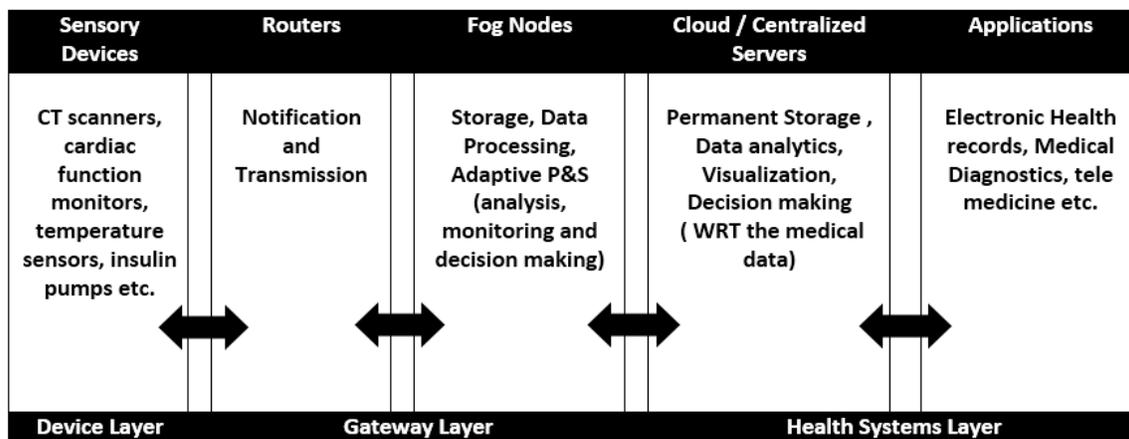

Fig. 3. IoT e-Health Fog Architecture.

TABLE II. THE ASSESSMENT FRAMEWORK'S MAPPING CRITERIA

Criteria #	Criteria for mapping an attribute with the adaptation process
1	<b>Utilized (U):</b> Reflects that the corresponding mechanism or attribute is utilized either as a mechanism to ensure S&P or as a factor/attribute to be evaluated for optimal adaptation decision in the adaptation phase.
2	<b>Monitoring (M):</b> Attributes are mapped to monitoring process when they are required to be <i>observed or monitored</i> for security and privacy threat/risk analysis or when they are utilized in the monitoring process.
3	<b>Analysis (A):</b> Attributes are mapped to the analysis process when they are <i>assessed</i> for the security and privacy threat/risk analysis or when are they utilized in the analysis process.
4	<b>Adaptation (Ad):</b> Attributes are mapped to the adaptation process when they are required to be adapted, evaluated during the adaptation decision, or utilized in the process.
<b>Criteria for mapping an attribute with the adaptation process IoT e-health architecture</b>	
	Attributes are mapped within the fog and cloud/server architecture, with regards to where in the architecture, <b>Device layer (D)</b> , <b>Gateway layer (G)</b> and <b>healthcare service provider controlled layer (H)</b> , Cloud/Central servers, these attributes are required to be <b>(M)</b> , <b>(A)</b> , <b>(Ad)</b> and <b>(U)</b> .

TABLE III. CLASS – SECURITY OBJECTIVES

Class	Attributes	Process	System Architecture				
			Fog Architecture		Cloud/server Architecture		
			Layers				
			D	G	D	G	H
Security Objectives	Confidentiality	M,A,Ad,U	DU	GM,GU GA,GAd	DU	GM,GU	HM,HU, HA,HAd
	Integrity	M,A,Ad,U	DU	GM,GU, GA,GAd	DU	GM,GU	HM,HU, HA,HAd
	Availability	M,A,Ad,U	DM,DU, DA	GM, GU, GA,GAd	DM, DA, DU	GM,GU	HM,HU, HA,HAd
	Authentication	M,A,Ad,U	DM,DU, DA	GM,GU, GA,GAd	DM, DA, DU	GM,GU	HM,HU, HA,HAd
	Authorization	M,A,Ad,U	DU	GM,GU, GA,GAd	DU	GM,GU	HM,HU, HA,HAd

### C. Assessing Security Objectives

As highlighted in Table III, mechanisms related to security attributes, e.g. encryption, integrity checks, etc., should be utilized within all the layers to ensure the respective objectives. Authentication, which may consist of a user, API, or service identity confirmation, monitoring and analysis is typically performed at the device level. Similarly, availability, which involves the accessibility and constancy of data, services and devices, are monitored and analyzed at the device layer, particularly when using smart devices. For all other attributes, the gateway layer, within fog architecture, handles all the adaption phases. Availability and Authentication related may be further normalized and correlated for analysis at this layer. In a cloud/server based architecture, the gateway layer mainly serves as an agent to monitor (M) the devices and services under its authorization or scope. Whereas, the health systems layer performs the analysis and adaptation phases for all devices and services. It also handles complex or high level monitoring and analysis of events arriving from potential multiple gateways as well this generated by its native applications or services.

### D. Assessing Privacy Objectives

As illustrated in Table IV, similar to the security objectives class, methods or mechanisms related to each highlighted privacy attribute should be utilized within all the layers in both architectures. In a fog-based architecture, the gateway layer is responsible for performing all the adaptation phases for its

underlying devices and services. Location is typically monitored at the device layer, as there can be devices that would require monitor to send out alerts, hence it needs to be monitored at the device layer and further normalized at the gateway. In a cloud/server- based architecture, a particular gateway monitors its respective devices and services. The health systems layer carries out all the adaptation phases for the entire scope including its own hosting services.

### E. Assessing Contextual Factors

The Contextual factors focuses on the importance of any internal or external changes that may be experienced at any layer of the architectures. Such changes may trigger the need of S&P adaptation. Therefore, all related factors should be monitored at every layer within both architectures, as reflected in Table V. However, environmental factors, which mainly refer to changes that may occur outside a monitored device, should be monitored at the gateway layer [11, 13, 14, 25, 26, 27, 28]. Users (patient, practitioners, and system admins) should be permitted to change their preferences, and therefore, the corresponding mechanism should be enforced for utilization at all layers. typically monitored at the device layer, as there can be devices that would require monitor to send out alerts, hence it needs to be monitored at the device layer and further normalized at the gateway. In a cloud/server- based architecture, a particular gateway monitors its respective devices and services. The health systems layer carries out all

the adaptation phases for the entire scope including its own hosting services.

F. Assessing Factors Affecting Adaptation Action Aptitude

Adapting any attribute, for example adapting to new confidentiality settings, may have a negative impact on the

system’s performance, usability, or S&P objectives. Therefore, it is essential to evaluate the aptitude of a potential solution to a faced threat in the adaptation phase. Attributes corresponding to this notion are captured in the Adaption Actions Aptitude class. Table VI illustrates the most common and vital attributes that are necessary to be evaluated in the adaptation phase (Ad).

TABLE IV. CLASS – PRIVACY OBJECTIVES

Class	Attributes	Process	System Architecture				
			Fog Architecture		Cloud/server Architecture		
			Layers				
			D	G	D	G	H
Privacy Objectives	Data Privacy	M,A,Ad, U	DU	GM,GU,GA,GAd	DU	GM,GU	HM,HU,HA,HAd
	Communication Privacy	M,A,Ad, U	DU	GM,GU,GA,GAd	DU	GM,GU	HM,HU,HA,HAd
	Behavioral privacy	M,A,Ad, U	DU	GM,GU,GA,GAd	DU	GM,GU	HM,HU,HA,HAd
	Location Privacy	M,A,Ad, U	DM,DU	GM,GU,GA,GAd	DM,DU	GM,GU	HM,HU,HA,HAd

TABLE V. CLASS – CONTEXTUAL FACTORS

Class	Attributes	Process	System Architecture				
			Fog Architecture		Cloud/server Architecture		
			Layers				
			D	G	D	G	H
Contextual Factors	Architectural Factors	M,A,Ad	DM	GM,GA,GAd	DM	GM	HM,HA,HAd
	Environmental Factors	M,A,Ad	-	GM,GA,GAd	-	GM	HM,HA,HAd
	Operational Factors	M,A,Ad	DM	GM,GA,GAd	DM	GM	HM,HA,HAd
	User preferences	M,A,Ad, U	DM, DU	GM,GA,GAd, GU	DM, DU	GM,GU	HM,HU,HA,HAd

TABLE VI. CLASS – ADAPTION ACTION APTITUDE

Class	Attributes	Process	System Architecture				
			Fog Architecture		Cloud/server Architecture		
			Layers				
			D	G	D	G	H
Adaption Actions aptitude	Response Time	Ad	-	GAd	-	-	Had
	Efficiency	Ad	-	GAd	-	-	Had
	Energy Consumption	Ad	-	GAd	-	-	Had
	Service factors	Ad	-	GAd	-	-	Had
	Reliability	Ad	-	GAd	-	-	Had
	Memory	Ad	-	GAd	-	-	Had
	Security & Privacy	Ad	-	GAd	-	-	Had
	Network Latency	Ad	-	GAd	-	-	Had
	Throughput	Ad	-	GAd	-	-	Had

TABLE VII. CLASS – SELF-\* PROPERTIES

Class	Attributes	Process	System Architecture				
			Fog Architecture		Cloud/server Architecture		
			Layers				
			D	G	D	G	H
Self-* Properties	Self-Healing	M,A,Ad, U	DM	GM, GU, GA, GAd	DM	GM	HM, HU, HA, HAd
	Self- Configuration	M,A,Ad, U	DM	GM, GU, GA, GAd	DM	GM	HM, HU, HA, HAd
	Self-Optimizing	M,A,Ad, U	DM	GM, GU, GA, GAd	DM	GM	HM, HU, HA, HAd
	Self-Protecting	M,A,Ad, U	DM	GM, GU, GA, GAd	DM	GM	HM, HU, HA, HAd

Since, the adaptation phase is conducted at the gateway in the fog architecture, and at the health system layer in the Cloud/Server architecture, the highlighted attributes should be evaluated at the respective layers. Assessing these attributes enables to determine if the adaptive S&P solution can ensure trade-offs amongst these attributes during adaptation, especially in a critical environment such as e-health, where time-sensitive decisions are made.

### G. Assessing the System's Self-\* Properties

To ensure self-management, the adaptive system has to enforce the monitor, analyze, and adaptation loop feedback in its own processes. This implies that the system has to manage the respective adaptation phases and corresponding functions on the corresponding devices and layers. As reflected in Table VII, the self-\* properties for all components responsible for monitoring, analysis and adaptation should be monitored at their respective layer where they are implemented. However, further monitoring (high level), analysis, and adaptation should be handled by gateway in the fog architecture whereas the hospital system layer in the Cloud/Server architecture will manage the same.

## III. RESULTS AND DISCUSSION

This section critically evaluates the proposed classification and existing assessment frameworks that are proposed for the purpose of assessing adaptive S&P solutions for IoT and/or IoT e-health. The main objective of this effort is to compare our proposed framework with the existing frameworks to evaluate their aptitude in addressing the essential attributes for S&P adaptation with respect to the adaptation process and system architecture. The frameworks that are compared here are: MST [9], AFAS [13], SAS [14] and SMAS [15]. Although there are less numbers of models to be considered for comparison, they are the most related and current efforts with our work and the concept at hand. Furthermore, we intend to reflect on the current practices rather to assess a comprehensive list of existing efforts.

### A. The Comparison Approach

The comparison of the frameworks has been made using two dimensions; the evaluation criteria and the comparison score. The criteria intend to determine the comprehensiveness and applicability the reviewed models in the context of Adaptive S&P and aims to conclude:

- Whether or not and to what extent do the reviewed frameworks or models cover the phases in the adaptation process?
- Whether an evaluation framework is suitable to assess Adaptive S&P in a particular IoT-eHealth architecture or both fog-based and server/Cloud-based?
- Which required/identified attributes and to which extent are they addressed by a given evaluation framework or model?

The Comparison score illustrated in Table VIII is an analytical indicator of the level of conformance of an evaluation framework with the comparison criteria, after it is validated.

The higher the score is, the better is the evaluation framework. Hence, it enables us to comprehend the comprehensiveness, applicability, and, therefore, the feasibility of the proposed and existing assessment frameworks in assessing adaptive S&P solutions for IoT e-health. The following table describes the criteria on how each aspect of the comparison approach is scored, in order to evaluate each of the candidate frameworks.

### B. Analysis of Security Objectives

The major processes; monitoring, analysis and adaptation has been addressed by all the frameworks, however, AFAS, MST and the proposed framework addresses the utilized (U) process as well as illustrated in Fig. 4. AFAS, SAS and SMAS claim to assess all the attributes under security objectives. However, they provide abstract or insufficient information on the architecture and the architectural layers that the framework assesses. Hence it is unclear on how the adaptation requirements are evaluated within the different architectural layers. Whereas MST considers all the adaptation processes, as well as majority of the security objectives, however the framework is only designed to assess cloud/server based architecture's. Hence having a better comprehension of security objectives for Cloud/Server based architectures as opposed to AFAS, SAS and SMAS. Amongst the assessed frameworks, the proposed framework has a better comprehension of the security objectives, as it evaluates these attributes in the context of both, cloud/ server based and fog architectures. Moreover, the assessed frameworks have addressed the majority of the security attributes. However, the authorization attribute is somehow underestimated, which is concerning.

### C. Analysis of Privacy Objectives

As illustrated in Fig. 5, SAS and the proposed framework have addressed all the major processes. Additionally, the proposed framework addresses the utilized (U) process as well. None of the frameworks, except from the proposed framework, addresses all the privacy attributes in the context of architecture. SAS highlights the data privacy attribute however, its realization in the context of the architectural aspects is unclear to draw further conclusions. Furthermore, amongst the privacy attributes, data privacy has been mostly addressed in the evaluated frameworks. However, those discussing it only state its importance and consequences and fail to provide details of it, to be addressed at the corresponding architectural layers to ensure effective S&P adaptation.

### D. Analysis of Self-\* Properties

Similar to the privacy objectives class, the self-\*properties classes as shown in Fig. 6 have been widely ignored by majority of the frameworks. The frameworks AFAS and the proposed framework that do consider this class have addressed all the major adaptation processes. Although it claims to assess all the self-\*properties attributes, it provides abstract information on the architectural aspects within its assessment.

Hence it is unclear on how the framework assesses the given attributes within the different architectural layers.

Whereas the proposed framework evaluates the self-\*properties attributes amongst different architectural layers for both fog and cloud/server based architectures.

TABLE VIII. COMPARISON SCORE DESCRIPTION

Attribute Context	Criteria Description	Score
Adaptation Process (P)	1 point for each process when an attribute is clearly addressed by an identified adaptation process. <b>Note:</b> maximum points for a process conformance of an attribute vary from attribute to attribute. Refer to <i>The Mapping Criteria</i> for the required processes for each attribute under various classes.	1-4
Architectural (A)	All or the majority of the requirements related to a given attribute are addressed at the corresponding layers for <b>both</b> architectures ( fog and Cloud/server)	5
	Few of the requirements related to a given attribute are addressed at the corresponding layers for <b>both</b> architectures (Fog and Cloud/ Server)	4
	All or the majority of the requirements related to a given attribute are addressed at the corresponding layers for a <b>single</b> architectures ( fog or Cloud/server)	3
	Few of the requirements related to a given attribute are addressed at the corresponding layers for a <b>single</b> architectures ( fog or Cloud/Server)	2

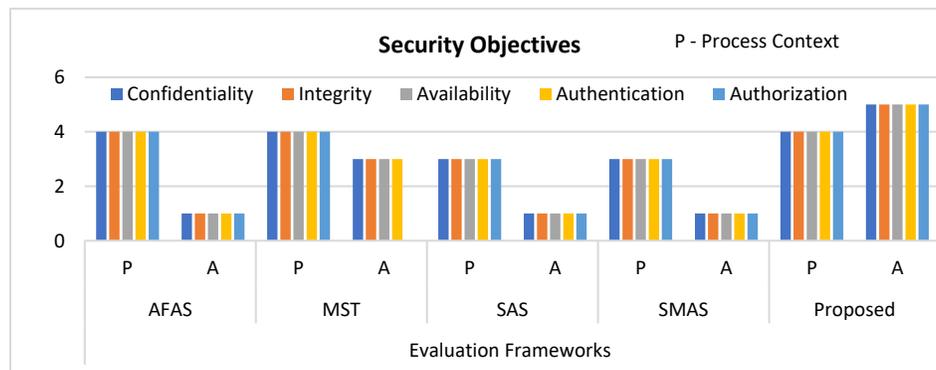

Fig. 4. Comparative Scores of Security Objectives.

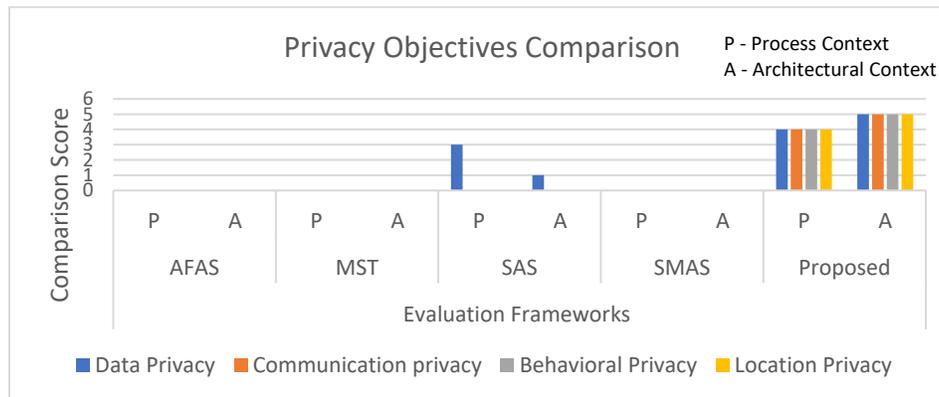

Fig. 5. Privacy Objectives Comparison.

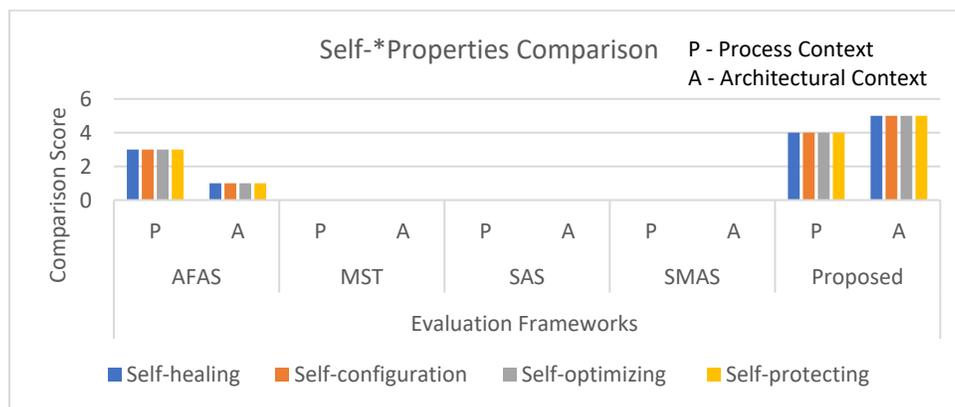

Fig. 6. Self-\*Properties Comparison.

E. Analysis of Contextual Factors

The major processes; monitoring, analysis and adaptation have been addressed by all the frameworks as illustrated in Fig. 7. However, the proposed framework addresses the utilized (U) process essential for the user preferences attribute. AFAS and SMAS addresses' majority of the contextual attributes, however the details on the architectural aspects are abstract thus. Hence assessment of these attributes on the architectural layers is indistinct. MST and SAS only consider environmental and operational factors, where MST provides sufficient information on the assessment of these attributes within the layers of cloud/server based architecture. However, SAS provides unclear information on the assessment of these attributes within architectural layers. While the proposed framework considers all the contextual factors within the layers of both architectures.

Amongst the attributes within this class, architectural factors have been ignored by MST and SAS. It is essential to consider architectural factors when assessing adaptive S&P solutions, especially since IoT e-health is a diverse, dynamic,

and mobile architecture where new devices can be added or existing devices can be updated or removed more frequently. Hence, the system should be able to handle such changes [13], [25].

F. Analysis of Adaptation Action Aptitude

As shown in Fig. 8, all the frameworks that consider the adaptation action aptitude attributes consider the main process which is adaptation AD, where these attributes are evaluated. SAS does not consider this class in its evaluation, whereas SMAS only considers Energy consumption, Reliability and S&P attributes but lacks architectural details.

However, AFAS, MST and the proposed framework considers all the attributes under this class. However, in terms of the architectural aspects, the proposed framework assesses these attributes within both architectures, while MST only assess these attributes within cloud/server based architecture, and, AFAS provides abstract information on the assessment of these attributes from an architectural perspective.

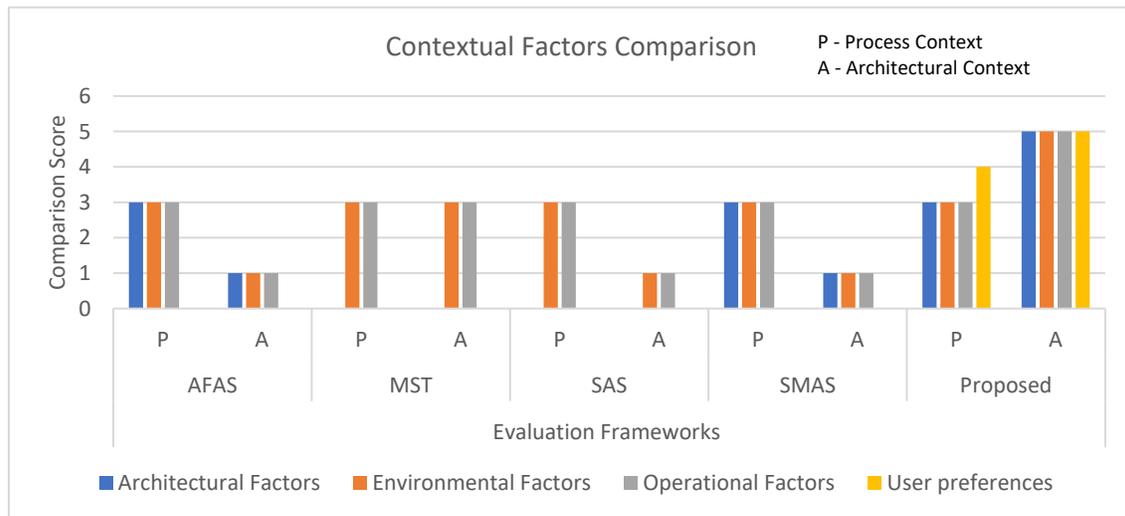

Fig. 7. Contextual Factors Comparison (Note: the Maximum Points for a Process Conformance for Architectural, Environmental and Operational Factors Attributes is 3, Whereas the Process Conformance for user Preferences Attribute is 4).

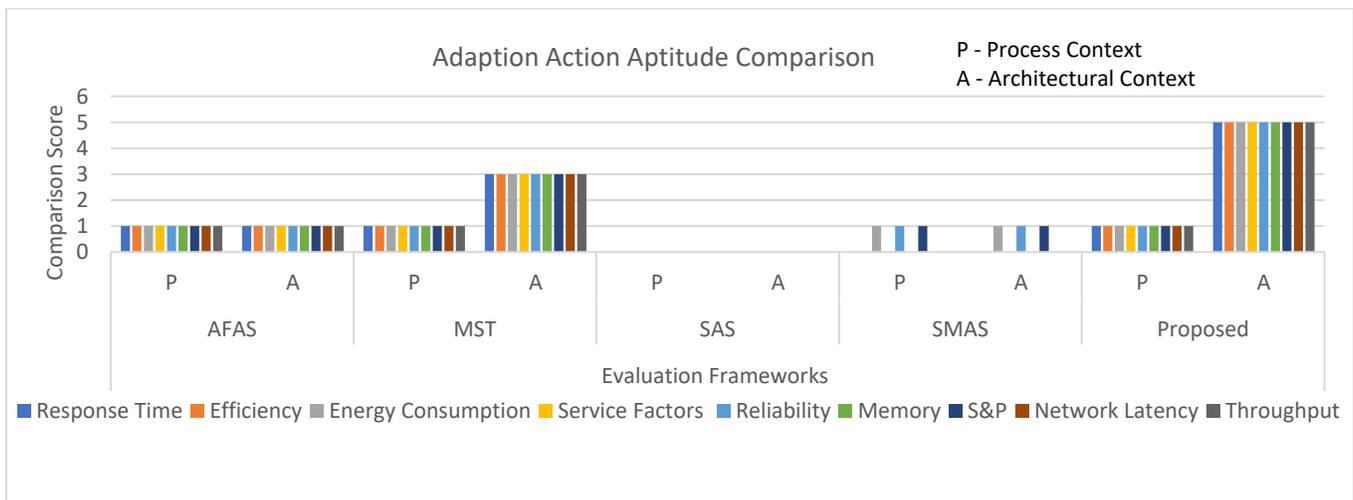

Fig. 8. Adaption Action Aptitude Comparison (Note: The Maximum Points for a Process Conformance for Attributes in this Class is 1).

#### IV. DISCUSSION ON THE OVERALL COMPARISON

This section highlights the overall outlook of the compared frameworks at the class level. The underneath discussion is based on the observations reflected in Fig. 9, which depicts the maximum points achieved by each compared framework by aggregating their attributes' points in each class, as a result of the above comparison.

It can be observed that although the proposed framework offers a more in-depth view of the security objectives, overall, there seems to be an above average comprehension and consensus on achieving the related attributes. Moreover, except for the proposed framework, all other frameworks have considerably overlooked the privacy aspects. Apparently, privacy objectives are assumed to be enforced with security mechanisms, which should not be exercised as they have different purposes, scopes, and mechanisms. Alongside security objectives, it is vital to address the privacy objectives from different perspectives. The lack of privacy objectives can potentially lead to misuse of patient's sensitive information, such as unauthorized disclosure or usage and even potential identity frauds [3], [4].

Similar to the privacy objectives, the adaptive system's self-\* properties are also underestimated. Doing so may lead to the compromise of the system itself. It can be seen that the proposed framework exceptionally stressed on the need of considering the self-\* properties. Whereas, AFAS provides fair details of the related properties at the adaptation process level, it lacks to provide enough information on the architectural aspects within its assessment.

MST assesses majority of the attributes for cloud/ server based architectures only. Although AFAS, SMAS, and SAS consider majority of the contextual attributes, these frameworks provide very abstract information on the architectural aspects. It is apparent that the proposed framework fully suffices the adaption action aptitude requirements for both fog and cloud/Server architectures. While, MST assesses all of the attributes for cloud/ server based architecture only. Although AFAS and SMAS consider all the attributes under this class, the frameworks provide unclear information on the architectural requirements.

#### V. CONCLUSION AND FUTURE PLANS

The proposed framework assists us to recognize, realize, and assess the essential factors for adaptive S&P solutions in the context of the IoT e-health architecture and the adaptation process. It lets us evaluate related solution in a broader spectrum, the overall needs, therefore providing a comprehensive understanding of the overall problem. The comparison made with the existing assessment frameworks reflects that our work introduces considerable improvements by how essentials attributes should be managed in the context of architecture and the adaptation process, which is the key contribution. Most of the frameworks discounted the architectural aspects and their importance, which may negative affect the whole purpose of an adaptive system. Moreover, current assessment frameworks are more focused on a particular set of essential factors or generally highlight them. In contrast, the presented framework provides a holistic set of attributes or requirements that address all the major aspects of an adaptive S&P system and assess them in the context of underlying architecture and the adaptation process. Thus, offers a comprehensive mechanism to assess the feasibility of a given adaptive S&P solution.

Although this study primarily studies e-health as an IoT application, it can be generalized to similar IoT-based architectures. Nevertheless, it needs further investigation to consummate this hypothesis. Furthermore, assessing specific performance and QoS factors of adaptive S&P solutions for IoT e-health from a quantitative perspective could result in a more considerable attempt. In addition, the proposed framework could have added more value if common practices or mechanisms for each attribute were highlighted. This would have offered a sense of trending mechanisms and made the criteria more mature and comprehensive.

In future, we plan to extend this research by addressing the limitation discussed. We plan to study other IoT architectures to investigate if the proposed assessment framework can be utilized or requires further refinements. Moreover, we intend to further improve the proposed assessment framework by investigating the commonly utilized mechanisms for each attribute and analyzing the trends in the mechanisms utilized to make the framework more beneficial and inclusive. Lastly, we intend to work on a more rigor assessment to present a more acceptable capability maturity model.

**Abstract**—Evolutionary algorithms are suitable techniques for solving complex problems. Many improvements have been made on the original structure algorithm in order to obtain more desirable solutions. The current study intends to enhance multi-objective performance with benchmark optimisation problems by incorporating the chaotic inertia weight into the current multi-objective Jaya (MOJaya) algorithm. Essentially, Jaya is a recently established population-oriented algorithm. Exploitation proves to be more dominant in MOJaya following its propensity to capture local optima. This research addressed the aforementioned shortcoming by refining the MOJaya algorithm solution to update the equation for exploration-exploitation balance, enhancing divergence, and deterring premature convergence to retain the algorithm fundamentals while simultaneously sustaining its parameter-free component. The recommended chaotic inertia weight-multi-objective Jaya (MOiJaya) algorithm was assessed using well-known ZDT benchmark functions with 30 variables, whereas the convergence matrix (CM) and divergence matrix (DM) analysed the suggested MOiJaya algorithm performances are inspected. As such, this algorithm enhanced the exploration-exploitation balance and substantially prevented premature convergence. Then, the proposed algorithm is compared with a few other algorithms. Based on the comparison, the convergence metric and diversity metric results show that the recommended MOiJaya algorithm potentially resolved multi-objective optimisation problems better than the other algorithms.

**Keywords**—MOJaya; chaotic inertia weight; ZDT benchmark function; convergence metric; diversity metric

## I. INTRODUCTION

As a mathematical instrument that adequately models and solves real-life complexities with multiple objectives and simultaneous enhancement, multi-objective optimisation and its relevant intricacies have garnered much scholarly attention across various disciplines, specifically engineering and sciences. Multiple population-oriented metaheuristic algorithms were recommended for multi-objective problem (MOP) solving. As MOP goals must simultaneously optimise the conflicting nature of multiple objectives given the absence of one distinct alternative to optimise all collaborative counterparts [1], a set of optimal trade-off alternatives (Pareto) was employed as a solution. Thus, a single and optimal solution is non-existent in this regard. Evolutionary algorithms or EAs imply some of the most extensively-utilised algorithms to solve MOPs and numerous issues with competing objectives across industrial, engineering, and research disciplines [2]. Robust optimisation algorithms serve to resolve intricate real-world

MOPs in one run. Relevant research has demonstrated the successful application of multi-objective optimisation, which has extended EAs entailing MOPSO [3], [4], MODE [5], MOACO [6], and MOGA [7] for improved performance in multi-objective optimisation problem solution.

Recent EA developments in the past few decades have rendered the algorithms an efficient means of solving intricate multi-objective evolutionary algorithms (MOEAs). Their competence in simultaneously examining different regions of the Pareto front (PF) and generating a set of Pareto solutions in one run facilitates scholars toward multi-objective and real-life optimisation problems using distinct domains. Nevertheless, the algorithms types rely on algorithm-centric parameter refinements with common controlling parameters. Such specific parameters entail multiple purposes and impact the convergence rates, diversity, efficiency, scalability, exploration, and exploitation within the solution. For example, MOGA constitutes a mutation and crossover operator to attain the exploration and exploitation mechanism. Rao and colleagues established the parameter-free Jaya and MOJaya algorithms in 2016 to address scholars' complexities and control specific parameters for algorithm simulation.

The aforementioned algorithms prove adequate in engineering areas, which entail i) multiple variables and parameters that require observation and ii) control or uncontrol parameters that are deemed challenging to manage without expertise and experience. Specifically, the Jaya algorithm or EA optimisation, which only requires several turning control parameters (population size, number of generations, and design variables), could only alleviate specific complexities. The EAs optimisation has recently solved applications for a single objective, whereas MOJaya resolved multi-objective optimisation problems. The solution consistently shifts towards the most and least optimal solutions that are avoided in simulation under the Jaya algorithm concept. The Update phase serves to modify the solution from earlier generations compared to other algorithms, which require two phases to refine solutions involving teaching-learning optimisation (TLBO), artificial bee colony (ABC), and differential evolution (DE). Intriguingly, the Jaya algorithm optimally manages continuous, discrete, and integer variables [8].

Hence, in this study, the improved MOJaya algorithm is proposed to solve multi-objective optimisation problems, while the properties of MOJaya are preserved. The non-dominated

sorting (NDS) approach with a reference point is used to find dominance relation, where NDS is performed according to the Euclidean distances between each possible solution of the front and reference point. The solution update equation is modified by incorporating the chaotic inertia weight. Finally, the recommended algorithm's performance were tested using ZDT benchmark test problems. The convergence metric and diversity metric evaluate the performance of the recommended algorithms.

The remaining paper is organized as follows: Section II, discusses the improvement Jaya Algorithm and its variations by the previous researcher. Then, the recommended algorithm methodology is presented in Section III. Next, Section IV presents the obtained results and analysis. Finally, the conclusion and future research are presented in Section V.

## II. MOJAYA ALGORITHM

Rao's [9] Jaya algorithm is a novel, astute, population-oriented, and parameter-free solution that manages constrained and unconstrained optimisation-related problems. Resultantly, the number of function assessments required to obtain a solution is lesser than that of TLBO. Several limitations have been ascertained despite its consistent attempts to omit the least optimal solutions and iterate the most optimal solution search space. For example, the Jaya algorithm becomes trapped in local optimal solutions where exploitation overrides exploration [10]. The basic Jaya algorithm is updated to relieve researchers (specifically in complex engineering fields) from refining algorithm-centric parameters.

Following past literature, the Jaya algorithm functions to solve multiple real-time and standard benchmark functions with distinct components and variants. This section elaborates on several parameter-free Jaya algorithm variants that were published in relevant research. The MOJaya, a posteriori version of Jaya, was developed in 2017 to solve multi-objective optimisation problems. Although MOJaya algorithm solutions are similarly updated to that of Jaya, MO-Jaya incorporates non-dominated sorting and the crowding distance computing mechanism for successful multi-objective management.

Past scholars demonstrated inconsistent outcomes in terms of multi-objective Jaya algorithm enhancement. Rao and Pawar (2020) recommended a novel and upgraded version (Rao's quasi-oppositional approach) under the Jaya algorithm with multi-objective and quasi-oppositional-oriented-learning techniques to address the diversity in the algorithm searching process. Three multi-objective optimisation case studies involving real-world and intricate engineering optimisation problems were applied with a single-layered microchannel heat sink (SL-MCHS), a double-layered microchannel heat sink (DL-MCHS), and a plate-fin heat sink (PFHS) to examine the recommended algorithm efficiency. The findings derived through the recommended algorithms were compared against those elicited with advanced optimisation algorithms: GA, ABC, DE, PSO, TLBO, MOGA, NSGA-II, real-coded GA (RCGA), direction-based GA, and basic and self-adaptive multi-population (SAMP) Rao algorithms. Essentially, the recommended algorithms proved superior and competitive compared to other optimisation counterparts [11].

The discrete multi-objective Jaya algorithm potentially addresses the flexible job-shop scheduling problem (FJSSP) by regarding the minimisation of makespan and total and critical machine workload as performance measures. Dynamic mutation operator and modified crowding distance measures were proposed to improve search process diversity. In-depth computational experiments were performed by regarding 203 FJSSP instances from past research. A comparison between the recommended algorithm and the weighted sum version demonstrated higher performance than the other approach and other MOEAs. Based on the computational outcomes, the proposed algorithm efficiently obtained diverse and enhanced Pareto-optimal solutions [12].

Rao and Hameer (2019) presented an adaptive multi-team perturbation with multiple teams to navigate the Jaya algorithm and examine its search space. The recommended algorithm was investigated with two multi-objective optimisation case studies of a solar dish Stirling heat engine system and one counterpart of the Stirling heat pump. The suggested algorithm utilised various perturbation equations with dominance principles and the crowding distance estimation approach for simultaneous multiple objective management. As a decision-making approach, the 'technique for order of preference by similarity to ideal solution' was also utilised for optimal solution identification. The computational outcomes elicited by the suggested algorithm proved superior to those attained by other study algorithms [13].

Rao and Saroj (2018) recommended a novel and unique Jaya algorithm for multi-objective design optimisation problem solution. The aforementioned algorithm was applied to resolve the heat exchanger design problem where two conflicting objectives (optimise heat exchangers' total annual cost and effectiveness) were simultaneously regarded. The least optimal Jaya algorithm solutions were substituted with an elitist value at the end of each iteration. As such, local trapping was prevented by arbitrarily selecting duplicate solution parameters. The recommended algorithm also optimally solved the multi-objective heat exchanger design compared to GA and TLBO [14].

The drawbacks inherent in the basic Jaya algorithm were highlighted in past studies. The exploration-exploitation balance implies one of the success criteria for any nature-oriented algorithm. Exploitation depicted a more significant impact than exploration as this algorithm catalyses objective function value towards the most optimal solution space. In this vein, local minima are trapped with less diverse solutions. The Jaya algorithm, which causes premature convergence and impacts solution quality, only upgrades the solution with the most and least optimal solutions from past iterations. Another shortcoming denotes the basic Jaya algorithm weakness regarding information exchange among individuals with no local minima mechanism in the event of a trapped algorithm. Palpably, relevant scholars have strived to integrate multiple methods for the optimal performance of balancing exploration and exploitation capacities and solving multiple real-time and benchmark problems. Exploration-exploitation balance is a pivotal mechanism that efficiently assesses the optimisation algorithm [15]–[17]. The numerous Jaya algorithm refinements

presented in this study primarily emphasised mitigating the basic Jaya algorithm limitations.

However, the results produced inconsistent results while comparing the performance with other results. Hence, the current research strived to (i) employ and assess the proposed techniques for improved MOJaya algorithm performance, (ii) solve multi-objective optimisation problems, and (iii) introduce a chaotic sequence. Inertia chaotic weight was initially adopted in the solution for the updated equation to be elicited from the local optimal solution. Regarding MOJaya, the most optimal solution was derived from the sorted list through non-dominant sorting and a crowding distance mechanism to eliminate the least optimal counterparts, thus leading to local region searches, premature convergence, and lesser diverse solutions.

The previous study observed that researchers are working to improve the MOJaya algorithm's performance. Various techniques are adopted to improve performance and also focus on real-life MOP. The motivation for this paper is as follows. First, the recommended study strategies for the algorithm is presented to improve the exploration of the existing MOJaya algorithm. The recommended algorithm development towards high performance while balancing exploration and exploitation is adopting inertia chaotic weight in the solution for an updated equation provides the best solution for promising and sparse search space regions. Then, the recommended algorithm's performance is evaluated using a two-objective ZDT test performance. Finally, the exiting MOJaya and MOiJaya algorithm with other multi-objective optimization algorithm performance are compared using the convergence and diversity metrics.

### III. THE MOIJAYA ALGORITHM

The MOJaya, a posteriori Jaya algorithm version, was employed for stochastically updated Multi-objective optimization problems (MOOP) solutions. The most optimal solution denoted maximum fitness, whereas the worst counterpart implied minimum fitness. The MOJaya algorithm was incorporated into a non-dominant ranking and crowding distance evaluation method to resolve multi-objective algorithm. The MOJaya algorithm pseudo-code is depicted in Algorithm 1.

#### A. Chaotic Random Inertia Weight Mechanism

The chaos mechanism, a well-established logistic map, was integrated with TLBO and the basic Jaya algorithm for single optimisation. Meanwhile, the chaotic sequence implied two attributes (ergodicity and randomness) that drove the algorithm away from the optimal local solution and enhanced solution quality [18], [19]. The fundamentals of chaotic inertia weight aimed to establish the inertia weight coefficient with chaotic mapping, which is integrate Logistic mapping, the method used in this paper. Inertia weight denotes one of the PSO algorithm parameters that substantially affect global and local searches and PSO algorithm performance through simultaneous particle retention in inertial motion and search space expansion [20]. The chaotic random inertia weight generated as (1) and (2) was incorporated into this study, given its value in demonstrating particle velocity shifts.

Logistic mapping,

$$z = 4 \times z \times (1 - z) \quad (1)$$

Chaotic Inertia weight

$$\varpi = 0.5 \times \text{random}(\ ) + 0.5 \times z \quad (2)$$

---

#### Algorithm 1 : MOJaya algorithm 1

---

##### Begin

- Step 1 Initialize the algorithm's control parameters, such as population size (N) and the maximum number of iterations (Gmax). Also initialize the problem-specific parameters such as a number of objectives (M).
- Step 2 Generate the initial solution randomly and evaluate it for each individual. Identify the best and worst solutions.
- Step 3 Find the new solution for all the individuals in a population using the modified solution update equation.
- Step 4 Evaluate the modified solution using Non-dominated sorting with a and ranking method solution using Non-dominated sorting with ranking method.
- Step 5 Combine the new solution with the old one. Sort the combined solution in ascending order. Identify the best and worst from the selected solution to update the solution in the next iteration.
- Step 6 Update the global best solution by comparing the old global best solution with the new best solution.
- Step 7 If the number of iterations reaches the maximum, stop the procedure and report the global best solution; otherwise, repeat the procedure from Step 3.

##### End

#### B. Proposed Modification in MOiJaya

The MOJaya algorithm, which entails a non-dominated sorting scheme and crowding distance from the NSGA-II counterpart, is developed to solve the multi-objective optimisation problem by integrating components from current MOEAs. The MOJaya algorithm performs sorting in ascending order by integrating the solutions from present and past iterations. The best solutions for the first N (population size) were selected through the non-dominated ranking scheme from the sorted list. Meanwhile, the most and least optimal solutions were selected from the N (population size) to update the following iteration. The most optimal and random solutions were chosen as the next search direction to explore more space in the early iteration of the algorithm process. The most optimal solution candidate in the algorithm functions to navigate the population towards a better region, whereas a random solution facilitates search space expansion. Searching local region

outcomes results in premature convergence and low diversified solutions as this approach disregards the least optimal solution.

The recommended algorithm and solution update equation was refined by integrating the chaotic sequence to alleviate MOJaya limitations. The random number employed in the MOJaya solution for an updated equation was substituted with a chaotic random inertia weight. The chaotic random inertia weight attributes entailing ergodicity and randomness enabled the algorithm to drive away from the optimal local solution: a regulation to balance the stochastic search and local search probabilities. Additionally, the recommended algorithms were improved in terms of convergence metric and diversity metric. The refined solution for an updated equation is expressed in (3) below:

$$x_{(i+1,j,k)} = x_{(i,j,k)} + \varpi_{(i,j,1)} * \left[ x_{(i,j,w)} - |x_{(i,j,k)}| \right] - \varpi_{(i,j,2)} * \left[ x_{(i,j,w)} - |x_{(i,j,k)}| \right] \quad (3)$$

The pseudocode for MOiJaya is depicted in Algorithm 2. Fig. 1 illustrates the flowchart parallel to the previously-mentioned refinements.

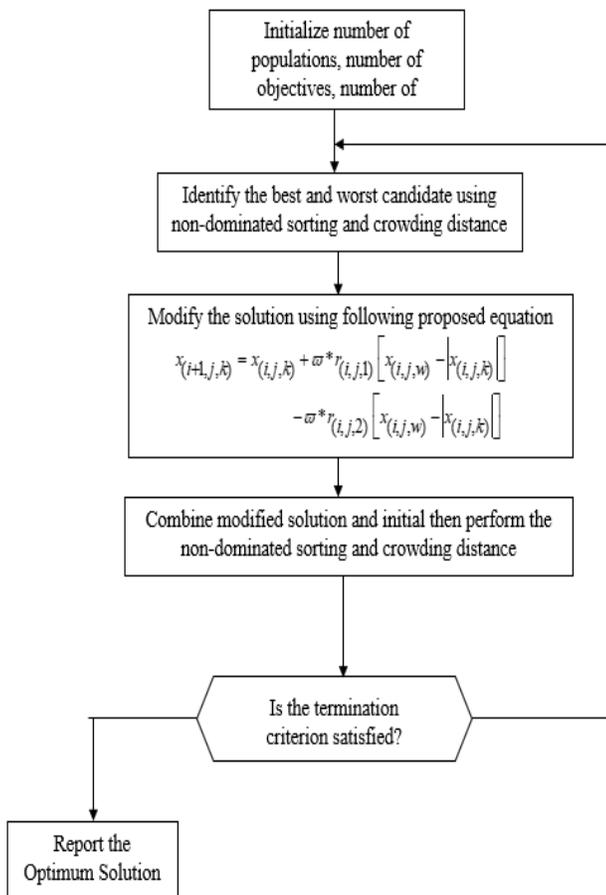

Fig. 1. The Flowchart of MOiJaya Algorithm.

Algorithm 2: MOiJaya algorithm

**Begin**

Input: Population size N, number of objectives, number of design variables, number of iterations, constrain, and function

Output: Solution f<sub>1</sub> and f<sub>2</sub>

1: Initialize population size, initialize the best and worst

2: Generate initial population randomly

**For** i < var

Generate initial population for variable and objective

**End**

Find the best and worst candidates using non-dominated sorting and crowding distance

**While** t < iter.max

Generate new solution using modified solution update equation as equation 3

Evolve

Merge the new and old solution

Perform non-dominated sorting and crowding distance

Select the first N solution

t+1;

**End**

**End**

IV. COMPUTATIONAL RESULTS AND ANALYSIS

This section highlights the recommended MOiJaya algorithm assessment. The suggested chaotic-oriented MOJaya algorithm was incorporated into Matlab2020 and examined with ZDT1-ZDT6 for multi-objective benchmark functions using two objectives with 30 variables. The outcomes elicited by the MOiJaya algorithm were compared against those identified in past empirical works with well-known CM and DM. The ZDT functions in PF demonstrated diverse attributes (separable, multimodal, linear, concave, mixed, and biased) that rendered it challenging to solve the problems with MOEAs (Deb et al., 2005). Table I presents the ZDT1-ZDT6 objective test problems.

The suggested MOiJaya algorithm extends to a renowned basic Jaya algorithm that only requires common controlling parameters. The following common controlling parameters are utilised to perform experiments:

Population size : 100

Maximum iteration : 10000

The recommended chaotic-based MOJaya algorithm was compared against SPEA2, NSGA-II, and EDATCMO [21] with two popular MOEA performance metrics (DM and CM) to assess the convergence and diversity solution for Pareto-front.

A. Performance Measures

The common trend in various successful solution methodology development, including MOEAs, involves performance comparison on multiple test problems. Two goals

(discover solutions with close proximity to the Pareto-optimal solutions and alternatives that are distinctly diverse in the elicited non-dominated front) were identified in multi-objective optimisation, unlike the single counterpart. A minimum of two performance metrics proves vital towards the actualization of both multi-objective optimisation goals to ascertain an effective MOEA (Deb, 2001). One performance matrix analyses the progress towards the Pareto-optimal front while the other assesses the solution spread. Three common metrics were employed in this study despite the numerous performance metrics highlighted in past literature, two of which would be implemented for MDEA analysis: CM and DM.

The CM was recommended by [22] to assess the distance between the obtained non-dominated (NF) front and optimal PF. The mathematical equations are expressed as follows (4):

$$d = \min_{j=1}^N \sqrt{\sum_{k=1}^M \left( \frac{f_k(i) - f_k(j)}{f_k^{\max} - f_k^{\min}} \right)^2} \quad (4)$$

$$CM = (P(t)) = \frac{\sum_{i=1}^{|F(t)|} d_i}{|F(t)|} \quad (5)$$

Specifically, M denotes the number of objectives,  $f_k^{\max} - f_k^{\min}$  imply the maximum and minimum function values of  $k^{th}$  and the objective function in the reference set, respectively, and N indicates the reference set size. The minimum value of CM, (5) reflects improved multi-objective optimisation algorithm performance.

The DM was suggested by [22] to assess the extent of solution spread, not unlike DM where optimal algorithms denote lower diversity metrics for evenly-spread solutions on PF. The spread was ascertained by computing each solution gap in PF with the neighbouring solution. The mathematical equation is expressed as follows:

$$DM = \frac{d_f + d_l + \sum_{i=1}^{N-1} d_i - \bar{d}}{d_f + d_l + ((N-1))\bar{d}} \quad (6)$$

Based on the Euclidean distance between the consecutive solutions within the obtained non-dominated set of solutions,  $\bar{d}$  denotes the average of all distances,  $d_i (i = 1, 2, \dots, N)$  assumes the N solutions in the derived non-dominated set, and  $d_l$  reflects the Euclidean distance between extreme and boundary solutions. The  $(N-1)$  is utilised as the solution distance that constitutes two solutions.

### B. Results on Zdt Test Functions

In this section, five benchmarks are used to test the proposed algorithm and analyzed the obtained results. The five well-known benchmarks of optimization problems have been

listed in Table I. The optimal values of all minimization objective function given in Table I is zero, which is,  $f(x_1) = 0$  where  $x_1$  is the optimal solution.

The recommended MOiJaya algorithm was performed 30 times for the chosen test function and corresponding number of objectives. In Table II-VI, we compared the proposed algorithm with the five others algorithm. The purpose of this test is to evaluate the quality of the solutions of purposed algorithm in different benchmarks compared to other algorithms. The mean and standard deviation (sd) values of DM and CM through SPEA2[22], NSGAI [23], FastPGA, and EDATCMO [21], MOJaya, and suggested MOiJaya algorithms on multi-objective benchmark functions ZDT1, ZDT2, ZDT3, ZDT4, and ZDT6. The MOJaya algorithm employs the solution for an updated equation from the basic Jaya counterpart [24]. The common controlling parameters remain the same for both MOJaya and MOiJaya.

### C. Results on Zdt Test Functions

In this section, five benchmarks are used to test the proposed algorithm and analyzed the obtained results. The five well-known benchmarks of optimization problems have been listed in Table I. The optimal values of all minimization objective function given in Table I is zero, which is,  $f(x_1) = 0$  where  $x_1$  is the optimal solution.

The recommended MOiJaya algorithm was performed 30 times for the chosen test function and corresponding number of objectives. In Table II-VI, we compared the proposed algorithm with the five others algorithm. The purposed of this test is to evaluate the quality of the solutions of purposed algorithm in different benchmarks compared to other algorithms. The mean and standard deviation (sd) values of DM and CM through SPEA2[22], NSGAI [23], FastPGA, and EDATCMO [21], MOJaya, and suggested MOiJaya algorithms on multi-objective benchmark functions ZDT1, ZDT2, ZDT3, ZDT4, and ZDT6. The MOJaya algorithm employs the solution for an updated equation from the basic Jaya counterpart [24]. The common controlling parameters remain the same for both MOJaya and MOiJaya.

In Fig. 2, Pareto optimal for MOiJaya are presented. It is found that the generated Pareto optimal front for MOiJaya quite close to True Pareto front. The convergence metric and divergence metric results for ZDT1 problems in Table II show that MOiJaya has lower values in the metric than all the other algorithms. This shows that MOiJaya is better in diversity and converge than other algorithms.

Fig. 3 shows the Pareto optimal fronts MOiJaya for test problems ZDT2. It is found that from MOiJaya is better in the uniform spread. Though MOiJaya pareto optimal slightly close to True pareto, MOiJaya is better diversity than MOJaya. Table III shows the results of convergence and divergence metric for ZDT2 problems. It is found that MOiJaya is better in diversity than all the other algorithms. From the results, the MOiJaya is worse in convergence metric than SPEA, NSGA-II, FastPGA and EDATCMO but better than MOJaya.

TABLE I. THE ZDT TEST PROBLEMS [22]

Problem	N	Variable bounds	Objective Functions	Optimal Solutions	Comments
ZDT 1	30	[0,1]	$f_1(x) = x_1$ $f_2(x) = g(x) \left[ 1 - \sqrt{x_1 / g(x)} \right]$ $h(f_1) = 1 + 9 \left( \sum_{i=2}^n x_i \right) (n-1)$	$x_1 \in [0, 1]$ $x_1 = 0$ $i = 2, \dots, n$	Convex
ZDT 2	30	[0,1]	$f_1(x) = x_1$ $f_2(x) = g(x) \left[ 1 - (x_1/g(x))^2 \right]$ $h(f_1) = 1 + 9 \left( \sum_{i=2}^n x_i \right) (n-1)$	$x_1 \in [0, 1]$ $x_1 = 0$ $i = 2, \dots, n$	nonconvex
ZDT 3	30	[0,1]	$f_1(x) = x_1$ $f_2(x) = g(x) \left[ 1 - \sqrt{x_1 / g(x)} - \frac{x_1}{g(x)} \sin(10\pi x_1) \right]$ $h(f_1) = 1 + 9 \left( \sum_{i=2}^n x_i \right) (n-1)$	$x_1 \in [0, 1]$ $x_1 = 0$ $i = 2, \dots, n$	Convex Disconnected
ZDT 4	30	[0,1]	$f_1(x) = x_1$ $f_2(x) = g(x) \left[ 1 - \sqrt{x_1 / g(x)} \right]$ $h(f_1) = 1 + 10(n-1) + \sum_{i=2}^n x_i^2 - 10 \cos(4\pi x_i)$	$x_1 \in [0, 1]$ $x_1 = 0$ $i = 2, \dots, n$	Convex
ZDT 6	30	[0,1]	$f_1(x) = 1 - \exp(-4x_1) \sin^6(6\pi x_1)$ $f_2(x) = g(x) \left[ 1 - (x_1/g(x))^2 \right]$ $h(f_1) = 1 + 9 \left[ \left( \sum_{i=2}^n x_i \right) (n-1) \right]^{0.25}$	$x_1 \in [0, 1]$ $x_1 = 0$ $i = 2, \dots, n$	Nonconvex Nonuniformly spaced

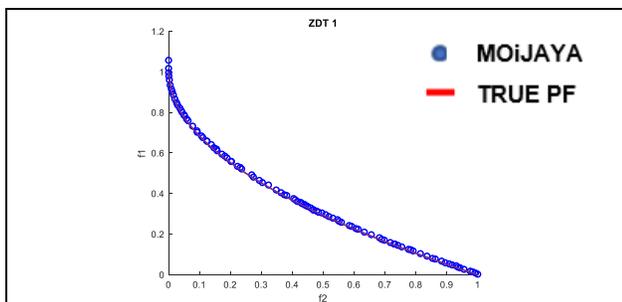

Fig. 2. The Results of Test Problem ZDT1.

TABLE II. COMPARISON OF CM AND DM VALUES OBTAINED WITH ALL ALGORITHMS FOR ZDT1 PROBLEMS

Case	Algorithm	Convergence	Diversity
		(mean±sd)	(mean±sd)
ZDT1	SPEA	0.09462±0.04511	0.42209±0.01012
	NSGA-II	0.10872±0.00362	0.50827±0.02446
	FastPGA	0.09154±0.00621	0.70009±0.01174
	EDATCMO	0.02363±0.00146	0.21738±0.00368
	MOJAYA	0.23346±0.05597	0.02044±0.04281
	MOIJAYA	<b>0.02226±0.00287</b>	<b>0.00168±0.00232</b>

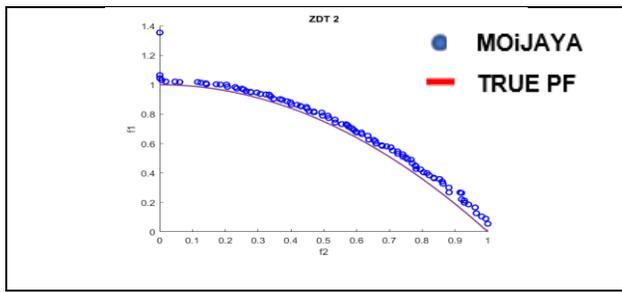

Fig. 3. The Results of Test Problem ZDT2 MOiJaya.

TABLE III. COMPARISON OF CM AND DM VALUES OBTAINED WITH ALL ALGORITHMS ZDT2 PROBLEMS

Case	Algorithm	Convergence	Diversity
		(mean±sd)	(mean±sd)
ZDT2	SPEA	0.08073±0.06101	0.50013±0.01612
	NSGA-II	0.09023±0.00401	0.30163±0.01503
	FastPGA	0.02067±0.00702	0.60034±0.2984
	EDATCMO	<b>0.00821±0.00472</b>	0.20022±0.00863
	MOJAYA	0.26564±0.22560	0.04489±0.02727
	MOiJAYA	0.15267±0.27201	<b>0.03300±0.02923</b>

From the Fig. 4, it is found that the generated Pareto optimal front for MOiJaya quite close to True Pareto front. This is also confirmed with the results of convergence and diversity in Table IV. Comparison with other algorithms shows that MOiJaya outperforms all of them in both metrics.

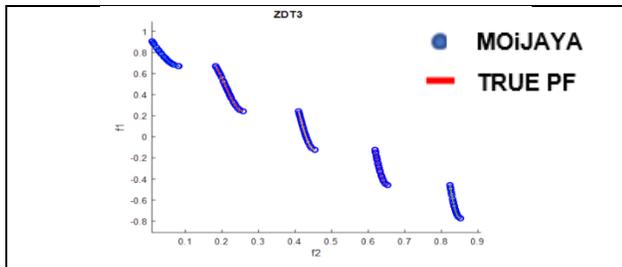

Fig. 4. The Results of Test Problem MOiJaya.

TABLE IV. COMPARISON OF CM AND DM VALUES OBTAINED WITH ALL ALGORITHMS ZDT3 PROBLEMS

Case	Algorithm	Convergence	Diversity
		(mean±sd)	(mean±sd)
ZDT3	SPEA	0.13996±0.07603	0.74932±0.05006
	NSGA-II	0.04208±0.09104	0.85061±0.09025
	FastPGA	0.07024±0.06541	0.85061±0.06453
	EDATCMO	0.02005±0.01843	0.50064±0.06132
	MOJAYA	0.04657±0.00559	0.06691±0.12251
	MOiJAYA	<b>0.03764±0.05113</b>	<b>0.02896±0.00584</b>

It is found in Fig. 5 that MOiJaya is far from True Pareto for this problem. Table V shows the results of convergence and divergence metrics. It is found that MOJaya is better in convergence than all the other algorithm but very close to MOiJaya. But, from the results of diversity, MOiJaya is better than all the other algorithms.

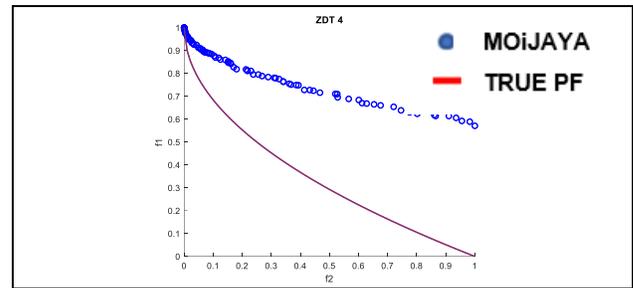

Fig. 5. The Results of Test Problem ZDT4 MOiJaya.

	MOiJAYA	<b>0.07094±0.11630</b>	<b>0.02013±0.02014</b>

In Fig. 2-6, MOiJaya has achieved the two goals of multi-objective optimization: convergence to the true Pareto-front (ZDT 1 and ZDT3) and uniform spread of solution along the front (ZDT1-ZDT6). In all the Tables II-VI, MOiJaya demonstrated better “optimal” values for CM involving ZDT1, ZDT3, and ZDT6 and DM involving all benchmark functions: ZDT1, ZDT2, ZDT3, ZDT4, and ZDT6. Additionally, the results are achieved the following points; in basic MOJaya algorithm, the exploitation is dominate, the recommended algorithm was modified to balance the exploration and exploitation by reducing the dominance of exploitation behavior. Other, using the chaotic inertia weight improve the converge rate and balance the exploration and exploitation. Specifically, the MOiJaya outcomes proved comparable to MOJaya. The MOiJaya curves in all the aforementioned figures were comparable to that of MOJaya regarding convergence and diversity. Conclusively, the performance of MOiJaya in solving multi-objective optimisation problems is deemed encouraging and comparable to other MOEAs.

## V. CONCLUSION

The current study introduced an enhanced MOiJaya algorithm to solve multi-objective optimisation problems. Specifically, the proposed method enhanced the current MOJaya algorithm through the chaotic inertia weight-oriented logistic chaotic sequence. The chaotic inertia weight was incorporated into the solution for an updated equation of the current MOJaya to mitigate the dominance of exploitation in this algorithm. The recommended modification also enhanced the multi-objective Jaya algorithm searchability. Chaotic inertia weight was integrated with MOJaya to improve exploration and the exploitation-exploration balance. The proposed MOiJaya approach efficiency was analysed with a benchmark performance ZDT test that was assessed with CM and DM. The recommended algorithm outcomes were compared to the most established findings following past research. Post-comparison, MOiJaya outperformed MOJaya with relatively good performance compared to advanced empirical algorithms. Nevertheless, there is much room for improvement although the suggested MOiJaya algorithm optimised the exploration-exploitation balance. Further research could assess the recommended method with other multi-objective benchmark datasets and real-time multi-objective optimisation problems from various domains.

## ACKNOWLEDGMENT

Special appreciation to reviewers for the useful advice and comments. This research was supported by Ministry of Higher Education (MOHE) through Fundamental Research Grant Scheme FRGS/1/2019/ICT02/UTM/02/13 and Research Management Centre (RMC), UTM.

**Abstract**—The COVID-19 epidemic has caused great impact on the entire society, and the spread of novel coronavirus has brought a lot of inconvenience to the education industry. To ensure the sustainability of education, distance education plays a significant role. During the process of distance education, it is necessary to examine the learning situation of students. This study proposes an academic early warning model based on long- and short-term memory (LSTM), which firstly extracts and classifies students' behavior data, and then uses the optimized LSTM to establish an academic early warning model. The precision rate of the optimized LSTM algorithm is 0.929, the recall rate is 0.917 and the F value is 0.923, showing a higher degree of convergence than the basic LSTM algorithm. In the actual case analysis, the accuracy rate of the academic early warning system is 92.5%. The LSTM neural network shows high performance after parameter optimization, and the academic early warning model based on LSTM also has high accuracy in the actual case analysis, which proves the feasibility of the established academic early warning model.

**Keywords**—COVID-19; Student behavior data; Distance education; Academic early warning model

### I. INTRODUCTION

Due to the impact of the COVID-19, teachers' teaching methods and students' learning models in many regions have been transformed into distance education [1]. The online learning mode of distance education involves computer and other technologies. This new teaching mode requires students and teachers to change traditional teaching methods and learning concepts, and adapt to online education and learning mode through new teaching and learning practice approaches [2]. Distance education ensures the continuity of education and provides an effective way for students to learn professional knowledge [3]. Although distance education provides students with a new way of learning, there are obvious problems in online education, which lead to the poor effect of online education. First of all, in online education, students lack the learning atmosphere of offline teaching, and teachers are difficult to manage students' learning behavior, so they generally show a lack of learning initiative. Some research shows that keeping the classroom active during online learning is conducive to improving students' academic performance [4].

In addition, in the survey of distance education for students, it is found that the learning level and self-confidence of students in online education environment are lower than those in offline environment. [5]. This has brought great challenges for students to successfully complete their homework. In order to solve these problems and improve the teaching effect of online teaching, this research uses artificial intelligence technology to establish a learning management system to evaluate students' academic achievements and homework [6]. A reasonable evaluation method can improve students' confidence in learning. An effective evaluation method will strengthen the management effect of teachers on students. The research establishes the academic early warning model of online learning platform using neural network technology, and confirms the validity of the model through experiments. The model can give early warning to students with poor learning conditions with high accuracy. The research is of positive significance to the improvement of academic performance and other comprehensive abilities, and it can help students successfully complete their studies.

### II. LITERATURE REVIEW

Early warning systems have been effectively used in medical, ecological and other fields. Ginestra et al. established a sepsis early warning system using machine learning to help nurses and patients predict sepsis symptoms and severe septic shock. Experiments have shown that the early warning system can effectively identify alerts for sepsis symptoms, helping nurses and patients to detect sepsis symptoms in advance [7]. The academic early warning system plays an important role in the analysis of students' learning situation. Through the academic early warning system, the early warning of students' problems in their learning can be realized, and intervention policies and measures can be proposed based on the obtained information and data to help students successfully complete their studies [8]. In the existing literatures, researchers have investigated students' learning motivation and used the learning analysis dashboard to analyze students' learning motivation and academic performance. By taking e students' academic performance as a reference, it is possible to intuitively analyze students' academic performance through the early academic early warning system. However, the early academic warning

\*Corresponding Author.

system has a poor degree of automation, cumbersome operation and low accuracy, so it has not been popularized in practical applications [9]. The application of machine learning technology in the early warning system can effectively improve the accuracy of early warning, and realize automatic monitoring and rapid response. Cho optimized and improved the early warning system on the basis of deep learning. The optimized early warning system had a higher accuracy rate and recall rate, which can be used to accurately judge patients' condition [10]. Lin et al. established a bridge scouring early warning system composed of the Internet of things and artificial intelligence. The researchers encapsulated the water level sensor in a stainless-steel ball. The early warning system uses neural networks for deep learning and real-time recording according to the changes of water level [11]. In the application of students' academic early warning system, Rashid et al. used a hybrid system including recurrent neural network and gray wolf optimizer to identify students' weaknesses, predict students' academic performance, and put forward corresponding suggestions. This improved academic early warning system can help teachers to improve the teaching model and improve the learning experience of students at the same time. Although this model has good performance, it is the same as most such systems. It mainly serves offline teaching, and the application effect in online teaching is not good [12]. In general, the academic early warning system has been applied to a certain extent at present, but most of them serve offline, and the accuracy and timeliness need to be improved.

LSTM is a neural network model, which belongs to the field of machine learning. It can effectively save and analyze time series information with strong dependence on time. Among various forecasting models, LSTM-based hybrid models can be used for forecasting foreign exchange fluctuations. Researchers have used LSTM technology to optimize the forecasting model, and the experimental results show that the method combined with LSTM has a high accuracy in foreign exchange volatility forecasting [13]. LSTM combines the convolutional neural network, retains the advantages of the LSTM method itself and time-frequency information, which can be used for the prediction of remaining lifespan and help solve health management problems [14]. In the early warning of industrial systems, Dorgo et al. used LSTM to predict rare operations in chemical technology when processing the information obtained by data mining, and at the same time analyzed time series information to predict the possible consequences of rare operations [15]. Based on its excellent analytical ability, LSTM is also used in the field of education. There are many courses in online education, and the information is miscellaneous. When students face many course data, it is difficult to accurately locate the courses. The researchers proposed a learning framework based on LSTM, and introduced attention mechanism on the basis of LSTM to predict and recommend courses according to students' behavior data [16].

The LSTM neural network retains time-dependent time series information, which can optimize the model in the establishment of early warning models. It is widely used in the establishment of early warning systems in medical, geological, economic and other fields. Students' performance and relevant data in the online learning process show obvious time series

nature, so LSTM network is a more suitable analysis tool. However, after the discussion of literature review, it is found that the application of LSTM in distance education academic early warning model is less. Therefore, this study proposes to use LSTM neural network to analyze students' behavior data, and establishes an academic early warning model for students' learning evaluation in online education.

### III. RESEARCH ON THE ACADEMIC EARLY WARNING MODEL OF DISTANCE EDUCATION BASED ON LSTM NEURAL NETWORK

#### A. Academic Early Warning Model based on LSTM Neural Network

The information is input to the signal  $X_t$  in the conventional recurrent neural network and output as  $h_t$ , and the input and output of the information are continuously circulated to realize the preservation of the information. However, the recurrent neural network does not have the ability to process long time series. When the distance between the input and the output is large, the output quality of the network will be reduced. LSTM can improve the capacity of the cyclic neural network in time series processing, and store long-term series information by increasing the complexity of the cyclic neural network structure [17]. The standard LSTM consists of three parts: input gate, output gate and forget gate, as shown in Fig. 1.

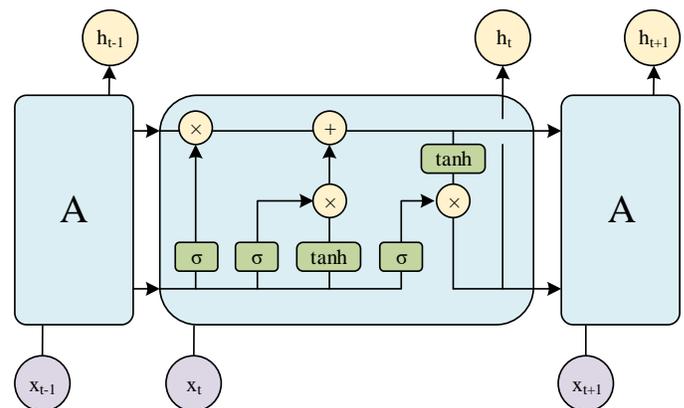

Fig. 1. LSTM Neural Network.

Although LSTM overcomes the gradient loss problem of traditional recurrent neural network, it still faces the problem of gradient decrease when processing longer-period time series [18]. LSTM has a large amount of computation and a deeper network, which takes more time in computation and training [19]. Combining the superiority of LSTM algorithm, this paper presents an academic early warning model of distance education based on student behavior data, and optimizes the method for the problems existing in LSTM. First, collect and clean the relevant distance education data of students, and organize the cleaned data into the format required for input. Second, high-order mapping of data is performed, so that the impact of the experiment on the neatness of the data is reduced. Next, feature extraction is performed according to the data characteristics of students, and classification and training are performed. Then, the long- and short-term neural network input

incentives are optimized, and the results of the optimized network output are cascaded and fused so as to improve the accuracy of the output. Fig. 2 shows the schematic diagram.

To reasonably distribute the attention of administrators to students' studies and facilitate students' self-awareness of their own studies, the academic warnings are divided into green, yellow, orange and red warnings according to the actual situation. Different early warning methods are used for students at different levels in the early warning system, and factors that actually affect learning, such as family circumstances, are fully considered in the early warning process.

**B. Research on Feature Extraction and Classification Methods**

The deepening of datafication has reformed students' learning methods, and distance education has been widely used in the context of COVID-19. It is necessary to mine data information such as students' achievements in distance education. Based on the distance education network database, the scores of each subject of the students are collected in the cloud. The score table of each student is generated using Excel, and each student is abstracted into a class containing variables such as score information and corresponding credits. See formulas (1) and (2) for the calculation formulas of the average score and the weighted average score of the students' original grades.

$$M = \frac{a_1 + a_2 + a_3 + \dots + a_n}{n} \tag{1}$$

$$B = \frac{a_1m_1 + a_2m_2 + a_3m_3 + \dots + a_nm_n}{m_1 + m_2 + m_3 + \dots + m_n} \tag{2}$$

Where  $a$  represents the score of the corresponding subject, the number of subjects is  $n$ , and the weight value of the subject

score is  $m$ . The variance of the student's grade can be obtained through the above formula, as shown in formula (3).

$$S = \frac{\sum (a_i - M)^2}{n}, i = 0, 1, \dots, n \tag{3}$$

The calculated average scores and weighted average scores of the corresponding subjects of the students are added to the abstract class. The grades and credits corresponding to each subject of the students are saved as float data, and the average scores and weighted average scores are saved as double data. In distance education, in addition to collecting students' subject scores for academic evaluation, students' online course learning information and other information are also collected for academic evaluation. Amplify the corresponding variables in the formed class to generate a 9\*N source data matrix. However, information loss is easy to occur during data collection. In this experiment, the RBF kernel function is used to process the data information. In this method, low-dimensional data is mapped to generate high-dimensional data, and high-dimensional vector operations are maintained, so as to solve the problem of accuracy decline caused by missing data. Using data mapping can ignore the problem of linear inseparability, while preserving the integrity of the data. In the source data matrix, the information vector of each row of students is mapped to the high-dimensional space using formula (4) to generate the corresponding vector label.

$$k(a', b') = (\phi(a'), \phi(b')) = e^{-ha^2} \begin{bmatrix} 1 \\ \sqrt{\frac{2h}{1!}} a' \\ \sqrt{\frac{(2h)^2}{2!}} a'^2 \\ \vdots \end{bmatrix} e^{-hb^2} \begin{bmatrix} 1 \\ \sqrt{\frac{2h}{1!}} b' \\ \sqrt{\frac{(2h)^2}{2!}} b'^2 \\ \vdots \end{bmatrix} \tag{4}$$

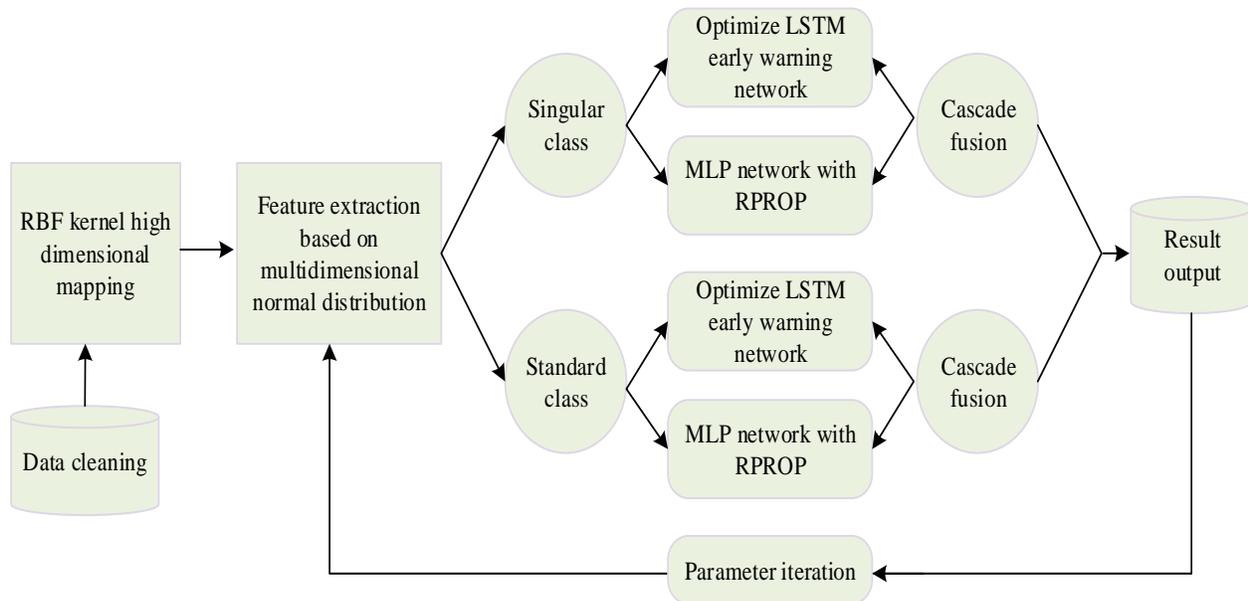

Fig. 2. Early Warning Model based on LSTM.

Where,  $a^i = A_i, (i = 1, 2, \dots, n)$  and  $b^i = B_i, (i = 1, 2, \dots, n)$  represents the student information vector represented by each row in the source data matrix, and  $h$  is a constant value. The representation method of elements in high-dimensional space is shown in formula (5).

$$e_n(a) = \sqrt{\frac{(2\alpha)^2}{n!}} a^n e^{-\alpha a^2}, n = 0, 1, 2, \dots \quad (5)$$

Where, the kernel parameter gamma value of the RBF kernel function is expressed as  $\alpha$ . Through function mapping, the vacant data information in the source data matrix can be filled to obtain a full data matrix. In the evaluation of academic tests, the normal distribution can be used to grade the outstanding and backward situations, so as to determine the corresponding number of people, score lines, and winning rates. When the students' grades conform to the normal distribution, the RBF function in formula (6) is used to map the grade information to the high-dimensional space for feature extraction of the multi-dimensional normal distribution, and the students who meet the multi-dimensional normal distribution are divided into standard classes. Students who meet the multidimensional normal distribution are classified as singular.

$$f_a(a_1, \dots, a_k) = \frac{1}{\sqrt{(2\pi)^k |\sum a_i|}} \exp(-\frac{1}{2}(a - \mu)^T \sum a_i (a - \mu)) \quad (6)$$

Where, the mean value is expressed as  $\mu$ ,  $k$  is a constant. In the classification based on multi-dimensional normal distribution, data feedback is used to adjust the parameters of multi-dimensional normal distribution, as shown in Fig. 3.

The selection of the threshold in the normal distribution has an important impact on the accuracy of network training results. The optimal solution of the threshold parameter is selected by the parameter iteration method of gradient descent. After repeated attempts of the gradient descent method, the global optimal solution  $\mu$  of the average threshold can be obtained, which is then normalized by formula (7).

$$X = (Y - \mu) / (Max - Min) \quad (7)$$

Where,  $Y$  represents the matrix that needs to be normalized,  $X$  represents the matrix obtained after normalization, and  $Max, Min$  represent the maximum and minimum vector values of all elements in  $X$ , respectively.

### C. Research on Early Warning Algorithm based on Improved LSTM

LSTM performs well in processing long time series information. In distance education, the information is recorded as a long time series, which shows a strong dependence on time. The modelling of Multilayer perceptron (MLP) network is easy to realize, and neurons can be constructed according to the actual situation [20]. In this experiment, the MLP network is used to train students' grades. The MLP-based LSTM network uses time to divide the length of information in different dimensions, which reduces the complexity and polymorphism of information on the basis of retaining data features. The other data is back-propagated using the function to increase the speed at which the network operates. At the same time, the LSTM neural network is used to train other data, and the weighting function is introduced to solve the problems of gradient disappearance and gradient explosion. Then, cascade fusion is used to train students' behavioral data to further improve the accuracy of prediction results and solve the problem of academic early warning.

By using multi-dimensional normal distribution to extract the features from student data matrix, two matrices of singular class and standard class can be obtained. The data with high time-series dependence is more sensitive to time. The LSTM with adaptive excitation function is used to train the data with high time-series dependence. The schematic diagram of the neural network unit is shown in Fig. 4. The sum function is introduced into the adaptive excitation function, and the expression of **relu** and **tan** is shown in formula (8).

$$z = \frac{1}{v} \text{relu}(w \frac{x^t}{h^{t-1}}) + \frac{1}{u} \tanh(w \frac{x^t}{h^{t-1}}) \quad (8)$$

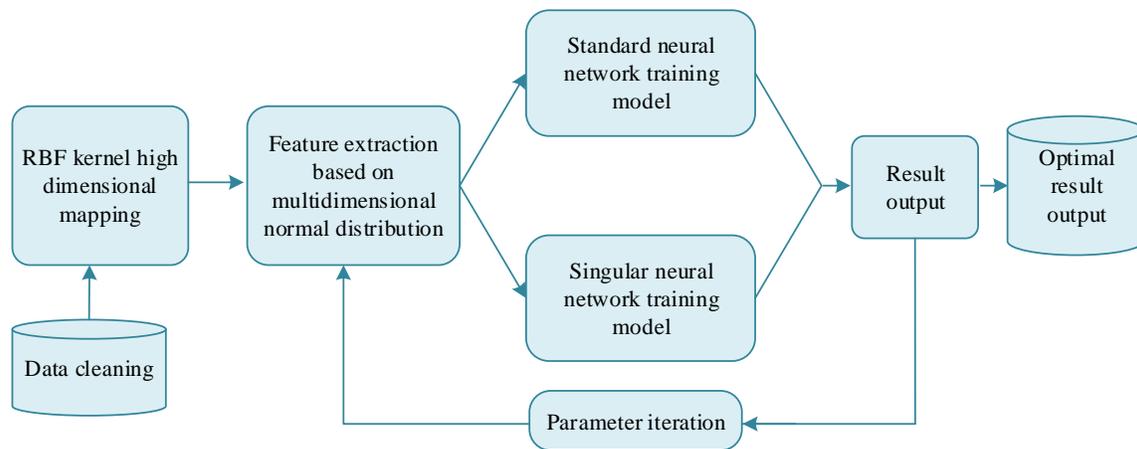

Fig. 3. Feedback-based Parameter Adjustment Process.

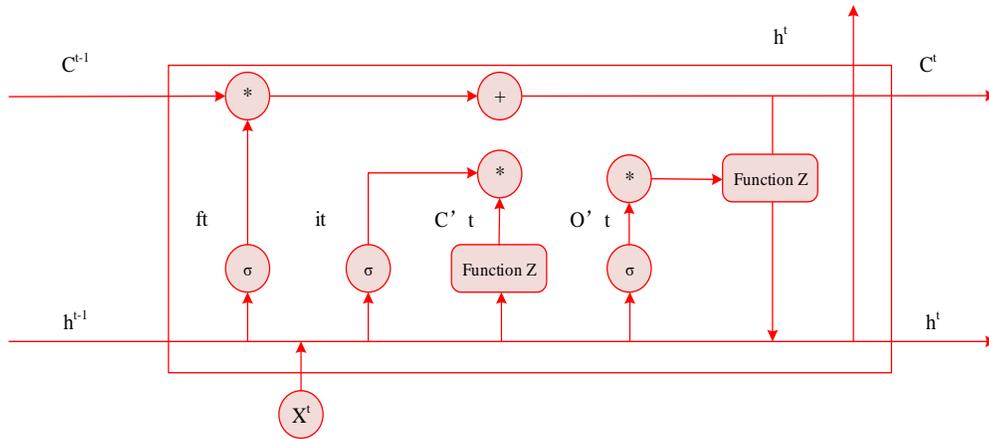

Fig. 4. LSTM Unit with Adaptive Excitation Function.

Where,  $W$  represents the function vector,  $v$  and  $u$  are the weight coefficient,  $v+u=1$ . The input module of LSTM includes the previous round of information carrier  $c^{t-1}$ , the previous round of state quantity output  $h^{t-1}$  and the current round of input  $x^t$ ; the output module includes the current round of information carrier  $c^t$ , the current round of state quantity output  $h^t$  and the current round of output  $y^t$ . Inputting  $\tanh$  function yields a vector  $z$ , and then, the state quantity output  $h^{t-1}$  of the previous round and the input  $x^t$  of the current round are combined into a vector, which is multiplied by  $W$  and then by the forgetting gate's matrix weight  $W^f$ , the input gate's matrix weight  $W^i$ , and the output gate's matrix weight  $W^o$  respectively, thus obtaining the output  $z^f$  and  $z^i$  sum  $z^o$  of each door. Thus, the calculation formulas of the current round information carrier, the current round state quantity output and the current round output can be obtained, as shown in formulas (9) to (11).

$$c^t = z^f c^{t-1} + z^i z \quad (9)$$

$$h^t = z^o * \left( \frac{1}{v} \operatorname{relu}\left(w \frac{x^t}{h^{t-1}}\right) + \tanh\left(w \frac{x^t}{h^{t-1}}\right) \right) * c^t \quad (10)$$

$$y^t = \sigma(wh^t) \quad (11)$$

The adaptive excitation function is to obtain the weighted average function after the function is weighted. The adaptive excitation function in formula (12) is used to excite the incoming data in each gate, and the data with high time series dependence is trained. Academic warnings are classified as follow.

$$f(x) = \frac{1}{u} \frac{e^x - e^{-x}}{e^x + e^{-x}} + \frac{1}{v} \max(0, x), u + v = 1 \quad (12)$$

Use formula (8) to iteratively calculate the values of weight coefficients  $v$  and  $u$  in the adaptive excitation function. When  $v=0.643$  and  $u=0.357$ , the optimal data training results are obtained. RProp is a resilient backpropagation algorithm, and the MLP network with RProp can be used to train data with low time-series dependence such as the scores of various subjects. First, assign an initial value to the weight change and determine its acceleration and deceleration factors. Then, according to the feedback that the error gradient sign change or does not change during the iteration process, the training is decelerated or accelerated respectively to ensure the stable convergence of the system. Finally, backpropagation is performed by combining the sign of the error gradient with the changing step size. When the sign of the error gradient is negative, the weight needs to be appropriately increased to obtain the minimum value, as shown in formula (13).

$$\begin{aligned} \Delta w_{i,j} &= -\eta_{i,j}(t), \text{if } g(y) > 0 \\ \Delta w_{i,j} &= +\eta_{i,j}(t), \text{if } g(y) < 0 \\ \Delta w_{i,j} &= 0, \text{otherwise} \end{aligned} \quad (13)$$

Where,  $\eta_{i,j}(t)$  denotes the learning rate of the algorithm. When the directions of the error gradient functions of two adjacent moments are inconsistent, it indicates that the minimum value of the current moment is missed, and the learning rate  $\eta_{i,j}(t)$  of the current moment is smaller than the learning rate  $\eta_{i,j}(t-1)$  of the previous moment, then multiply  $\eta_{i,j}(t-1)$  by  $\eta^{up}$  in the range (0, 1) to obtain the current learning rate. When the directions of the error gradient functions of two adjacent moments are consistent, it indicates that the minimum value of the error function has not been reached. At this time, multiply  $\eta_{i,j}(t-1)$  by  $\eta^{down}$  with a range greater than 1 to obtain the current learning rate, as shown in the formula (14).

$$\begin{aligned}\eta_{i,j}(t) &= \eta^{up} \eta_{i,j}(t-1), g(t-1)g(t) > 0 \\ \eta_{i,j}(t) &= \eta^{down} \eta_{i,j}(t-1), g(t-1)g(t) < 0 \\ \eta_{i,j}(t) &= \eta_{i,j}(t-1), otherwise\end{aligned}\quad (14)$$

The neural network system performs classification operations, and then combines the output results and uses formula (15) to fuse the results, so as to present different academic warnings for students.

$$p * a + (1 - p) * b = c \quad (15)$$

Where,  $P$  is the weight coefficient,  $a$  represents the LSTM prediction result,  $b$  represents the MLP prediction result, and the  $c$  represents graduation probability.

#### IV. SIMULATION ANALYSIS OF ACADEMIC EARLY WARNING MODEL BASED ON LSTM

The construction and training of the academic early warning system model of distance education is the key to the development of the system, and the accuracy and running time of the system are affected by the model construction and training results. Determining the number of layers and the number of nodes in the neural network is the main step that affects the construction of the system. In the experiment, the root means square error (RMSE) and the mean absolute error (MAE) are used to verify the number of layers in the neural network. The LSTM-based academic early warning model is repeatedly trained in the training set, and the parameters of the model are continuously adjusted in the process. Fig. 5 shows the training trend of RMSE and MAE values when different models predict time-dependent time series information. The abscissa represents the number of iterations of model training, and LSTM-1 to LSTM-5 represent the number of layers in the neural network, which are 1 to 5, respectively.

In Fig. 5(a), the number of iterations for LSTM-1 and LSTM-2 to start to converge is about 200. The minimum RMSE value of LSTM-1 with 1 neural network layer is 31.84, and the minimum RMSE of LSTM-2 with two neural network layers is 31.84. When the number of layers of the neural network increases to three, the RMSE value decreases more significantly. When the number of iterations is 225, LSTM-3 obtains the lowest RMSE value of 20.17, and the RMSE value remains at this level in subsequent iterations of training. When the number of layers of the neural network increases to four and five layers, the RMSE value has no obvious downward trend. In Fig. 5(b), the change trends of MAE value and RMSE value are consistent. The number of iterations when LSTM-1 and LSTM-2 begin to converge is about 200, the minimum MAE

value of LSTM-1 is 22.91, and the minimum MAE value of LSTM-2 is 18.96. When the number of layers of the neural network increases to three, the downward trend of the MAE value is more significant. When the number of iterations is 225, LSTM-3 obtains the lowest MAE value of 15.17, and the MAE value remains at this level in subsequent iterations of training. When the number of layers of the neural network increases to four and five layers, the MAE value has no obvious downward trend. It can be seen from Fig. 5 that in the training data set, the lowest error values RMSE and MAE are obtained when the number of layers of the LSTM neural network is set to 3 layers. When the number of layers is one or five, underfitting or overfitting may be encountered.

When the LSTM neural network is embedded in the academic early warning model, the embedding size is also one of the important factors affecting the performance of the early warning model. In the experiment, the number of layers of the neural network is set to three, and each neural network layer has different embedding sizes. Fig. 6 shows the training variations of the RMSE and MAE values of the LSTM neural network layers under different embedding sizes. In Fig. 6, LSTM-100 represents a three-layer neural network with an embedding size of 500-250-100, LSTM-150 is 500-300-150, LSTM-200 is 500-350-200, and LSTM-250 is 500-400-250, 500-400-300 for LSTM-300. The number of iterations at which the LSTM-100 and LSTM-150 models start to converge in Fig. 6(a) are 225 and 200, respectively, and the minimum RMSE values are 30.89 and 24.76, respectively. The RMSE value converges faster in the LSTM-200 model, reaching the lowest value of 20.68 after 250 iterations. In LSTM-250 and LSTM-300, there is basically no downward trend of the RMSE value, and the performance of the model is no longer improved. In Fig. 6(b), the MAE value and the RMSE value have the same change trend. The number of iterations at which the LSTM-100 and LSTM-150 models start to converge are 200 and 225, respectively, and the minimum MAE values are 20.03 and 14.98, respectively. The MAE value converges faster in the LSTM-200 model, reaching the lowest value of 13.09 after 200 iterations. When the embedding size increases, there is basically no downward trend of the MAE value. When the LSTM neural network is embedded in the academic early warning model, the size of the embedding size is proportional to the predictive ability of the model. The larger the embedding size, the stronger the data fitting ability. Fig. 6 shows that when the embedding size is 200, the minimum RMSE and MAE are obtained. Combined with the experimental results of the algorithm in different configurations, and considering the complexity and prediction effect, this study selects the embedded size of 200 and the number of neural network layers of three as the default settings for subsequent verification experiments.

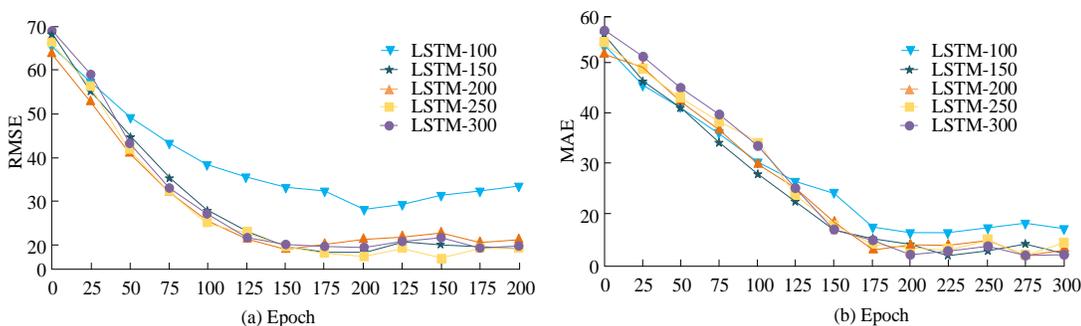

Fig. 6. Change Trends of RMSE and MAE under different Embedding Sizes.

TABLE I. COMPARISON OF EXPERIMENTAL RESULTS OF TIME SERIES STATE PERCEPTION

Algorithm	P	R	F
HC	0.673	0.622	0.646
HN	0.612	0.530	0.568
HM	0.405	0.492	0.444
LC	0.831	0.806	0.818
LN	0.678	0.713	0.695
LM	0.462	0.562	0.507
LSTM	0.886	0.812	0.847
This paper	0.929	0.917	0.923

The basic LSTM algorithm and the optimized LSTM algorithm proposed in this experiment are comparatively analyzed in terms of accuracy (P), recall (R) and the ratio F. Table I shows the experimental results of the HTM algorithm, the basic LSTM algorithm and the optimization algorithm proposed in this experiment in time series state perception. In Table I, H represents the HTM algorithm, L represents the basic LSTM algorithm, and LSTM represents the prediction model based on the basic LSTM algorithm; C represents the system parameter CPU, M represents the system parameter MEM, and N represents the system parameter NET. The sensitivity of the algorithm to abnormal situations can be judged by the accuracy rate, the detection ability of the algorithm to abnormal situations can be judged by the recall rate, and the F value is used to evaluate the overall performance of the algorithm. The

results in Table I show that the accuracy of the optimized LSTM algorithm is 0.929, the recall is 0.917 and the F value is 0.923, which are significantly higher than those of the basic LSTM algorithm. The comparative experimental results show that the accuracy rate of the optimized algorithm is higher, and the probability of false positives of the model is significantly reduced; the recall rate of the optimized algorithm is outstanding, and the probability of false negatives of the model is significantly reduced; the accuracy rate and recall rate of the optimized algorithm are higher, indicating that the overall performance of the optimized algorithm is higher. Based on the experimental parameters set above, the convergence rates of the basic algorithm and the optimized algorithm are compared.

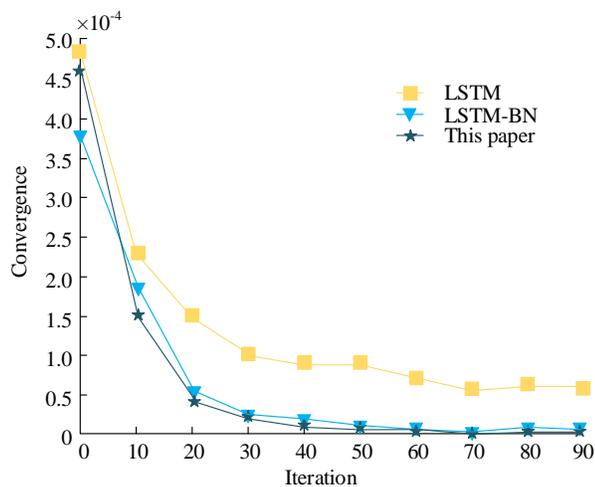

Fig. 7. Comparative Analysis of Convergence Rate.

Whether the model satisfies the convergence condition is mainly judged by comparison with the preset value, judgment of the weight value and the comparison of the maximum number of iterations. The purpose of training the model is to reduce the loss value, and it is necessary to set a threshold in advance to determine whether the training is over. The preset threshold will affect the convergence of the neural network model. When the loss value is less than the preset value, it is considered to end the training. When there is no significant change in the weights between two adjacent iterations, it can be considered that the model has reached a state of convergence with no need to adjust the weights. There are many preset applications for the maximum number of iterations. The iteration period is selected according to the actual situation, and the model is trained to achieve the optimal solution. Fig. 7 shows the comparison results of the convergence rate of the basic method and the optimized method in this experiment. It can be clearly seen that the convergence effect of the optimized method is significantly better than that of the basic method. 80

college students in distance education were randomly selected for the comparative evaluation of the academic early warning system, and the results obtained by the academic early warning prediction model based on the optimized LSTM algorithm were compared with the actual situation.

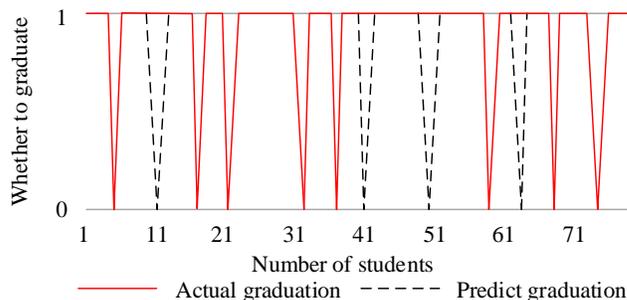

Fig. 8. Comparison of the Actual Results and the Results Predicted by the Academic Early Warning Prediction Model based on Optimized LSTM Algorithm

In Fig. 8, the abscissa represents the number of students, 0 in the ordinate represents ungraduated, and 1 represents graduation. The figure shows that among the 80 college students, six are inconsistent with the actual number of graduates, and the accuracy rate of the academic warning system is 92.5%. In addition, the academic early warning system is used to predict students' enthusiasm for active learning in distance education, and the predicted value is compared with the real situation. Fig. 9 shows the results.

Fig. 9 shows that during distance education, the number of submissions in the academic early warning system is consistent with the actual trend, reflecting that prediction results of learning enthusiasm by the academic early warning system are consistent with the actual situation. The academic early warning system in distance education designed in this experiment has high prediction accuracy and can be applied to students' academic early warning.

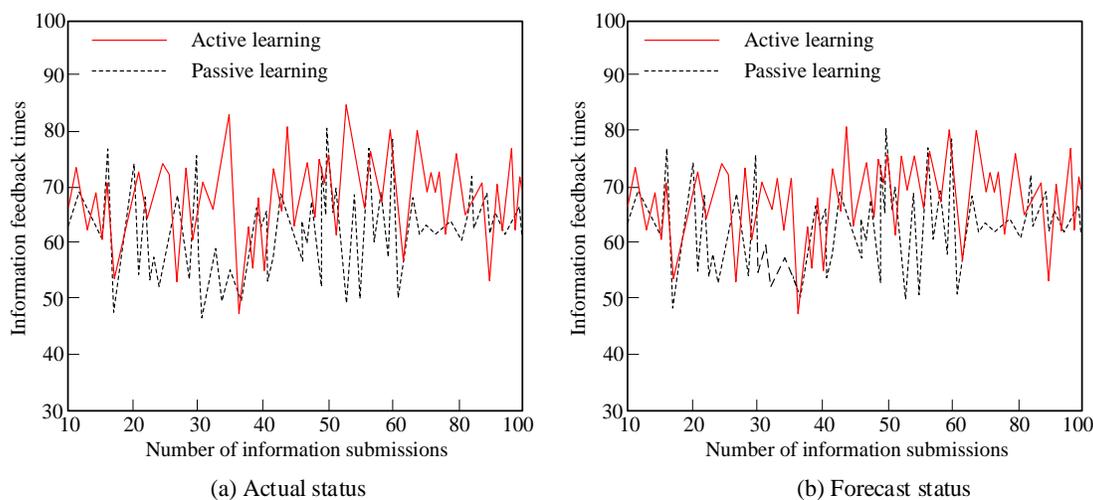

Fig. 9. Interactive Comparison Results of the Two Systems.

## V. DISCUSSION

At present, the proportion of middle line education in the whole education industry is gradually increasing. In the online education environment, students' learning behavior is difficult to be monitored. And according to the information in literature [4] and [5], students under online education generally lack initiative and learning self-confidence, and their overall performance is lower than that of offline teaching. The early warning system is mainly a system to detect signs and warn relevant personnel at the early stage of or before the beginning of a negative situation. The quality of current academic early warning systems is uneven. The early warning system in literature [9] has been applied in some colleges and universities, but its operation has a low degree of automation, and its accuracy also has a large room for improvement. The early warning system in [12] and the proposed early warning model both use neural network models, but the performance of the latter is slightly higher than that of the former. In addition, the early warning model in literature [9] and [12] pays more attention to the academic early warning of offline teaching. When the teaching scenario is online, its performance will be further limited. The early-warning model proposed in this study is specially designed for online teaching, which has great application potential in the current social context. From the results of the performance test, the model proposed in this study also has a high degree of early warning accuracy and automation, which can be applied to online teaching scenarios.

## VI. CONCLUSION

In the simulation analysis experiment of the academic early warning model based on LSTM, the number of layers of the neural network is set to three and the embedding size is set to 200 through parameter optimization and comprehensive consideration. The accuracy rate of the optimized LSTM algorithm is 0.929, the recall rate is 0.917 and the F value is 0.923, which are significantly higher than those of the basic LSTM algorithm, which has the accuracy rate of 0.886, the recall rate of 0.812 and the F value of 0.847. Comparing the results obtained by the academic early warning prediction model based on the optimized LSTM algorithm with the actual situation, the accuracy of the academic early warning system is 92.5%. To predict the enthusiasm of students for active learning, the number of submissions in the academic early warning system is consistent with the actual trend. The LSTM-based academic early warning model proposed in this experiment has high performance after parameter optimization, and also has high accuracy in actual case analysis, which can be applied to academic early warning in distance education. This research discusses the application of LSTM network in online teaching evaluation, and broadens the application field of LSTM network. At the same time, the research results have brought a practical model to the field of online education, which can improve the teaching effect through accurate and timely warning, and help students learn and teachers teach. However, the running time of the model was not verified, and it was not compared with other existing models in terms of the running time. Therefore, the proposed model may not be the optimal solution in terms of time, and there is still room for further improvement. In the follow-up work, we need to further improve the relevant experimental content.

## VII. FINDINGS

The research is supported by: Innovation Team of Digital Communication and Cultural Soft Power (Grant No. TD2021002); Scientific Research Program Funded by Shaanxi Provincial Education Department (Program No. 22JZ0016).

# Dynamic Polymorphism without Inheritance: Implications for Education

Ivaylo Donchev, Emilia Todorova  
Department of Information Technologies  
St Cyril and St Methodius University of Veliko Tarnovo  
Veliko Tarnovo, Bulgaria

**Abstract**—Polymorphism is a core OO concept. Despite the rich pedagogical experience in teaching it, there are still difficulties in its correct and multifaceted perception by students. In this article, a method about a deeper study of the concept of polymorphism is offered by extending the learning content of the CS2 C++ Programming course with an implementation variant of dynamic polymorphism by type erasure, without using inheritance. The research is based on an inductive approach with a gradual expansion of functionalities when introducing new concepts. The stages of development of such a project and the details of the implementation of each functionality are traced. The results of experimental training showed higher scores of the experimental group in mastering the topics related to polymorphism. Based on these findings, recommendations for the construction of the lecture course and the organization of the laboratory work are suggested.

**Keywords**—Inheritance; polymorphism; object-oriented; C++; type erasure; pointers; templates; lambda expressions; teaching

## I. INTRODUCTION

The study of the concept of polymorphism is widely used in programming courses. Students encounter its forms already in the introductory course and use them successfully, even if they do not perceive them as such at first. This is where function overloading and type casting (coercion polymorphism) come in. Later, parametric polymorphism (templates, generics) is added. However, when one says polymorphism, without specifying what kind, one usually means the inherent OOP inclusion (subtype) polymorphism, implemented through inheritance, virtual methods and dynamic linking (dynamic polymorphism). Subtype polymorphism is a cornerstone of object-oriented programming. By hiding variability in behavior behind a uniform interface, polymorphism decouples clients from providers and thus enables genericity, modularity, and extensibility [1]. This type of polymorphism, together with parametric, forms the more general universal polymorphism category of the popular classification of polymorphism types given in [2], and overloading and coercion form the ad-hoc category.

Bjarne Stroustrup defines polymorphism as “providing a single interface to entities of different types” [3] and distinguishes between dynamic (run-time) polymorphism, implemented through virtual functions through an interface provided by a base class, and static (compile-time) polymorphism through overloaded functions and templates. It is considered useful to differentiate between the two types. The focus is on three matters: time when the selection of the specific

method occurs (run-time or compile-time); different behavior, based on dynamic or static type; means by which it is usually achieved – inheritance in case of dynamic and overloading and templates in case of static.

Virtual functions and inheritance are typical means of achieving dynamic polymorphism, but they have their drawbacks in terms of performance and flexibility. The authors believe that in order to build deep understanding of the concept of dynamic polymorphism, students should have an idea that it can be achieved by other means, such as type erasure. Such an implementation with the currently available capabilities of C++ is cumbersome and error-prone, requires the definition of many types and functions, and provides no distinguishable advantages over inheritance, but has a beneficial impact on developing the programming competencies of computer science students, especially regarding the proper use of pointers.

In this paper, experience of implementing dynamic polymorphism without inheritance is shared (with manual implementation of virtual tables and the implementation of copy and move semantics) within the elective course “Programming in C++” for students majoring in Software Engineering. Their curiosity and previous experience with C# provoked to try to implement a familiar sample project in a new way. The project evolves incrementally with the addition of new functionalities as the relevant concepts are studied. The audience is later expanded to include Computer Science students with no .NET experience in the mandatory C++ Programming course. The difficulties which students encounter are explored and the effect of deeper study of concepts is tracked.

## II. METHODOLOGY

### A. Motivation

A classic example of inheritance polymorphism that our students have covered in the C# course is the hierarchy shown in Fig. 1. The base class declares a virtual method `Accelerate()`, which the two derived classes override. The classes can be used as follows:

```
Vehicle vehicle = new Car();
vehicle.Accelerate();
vehicle = new Truck();
vehicle.Accelerate();
List<Vehicle> vehicles = new() {
```

```
new Car(), new Truck(), new Truck(), new Car()
};
foreach (var v in vehicles){
    v.Accelerate();}
```

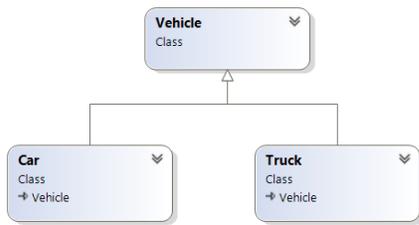

Fig. 1. The Hierarchy that will be Implemented.

With no major changes to the client code, by implementing an interface `IVehicle`, declaring the method `Accelerate()`, the same functionality without inheritance can be obtained. The C++ hierarchy implementation is even shorter – an abstract base class with pure virtual method `Accelerate()`, which is inherited and overridden by the classes `Car` and `Truck`. However, the client code requires use of pointers (dynamic allocation – one of the problems with inheritance), not objects, because abstract class cannot be instantiated:

```
Vehicle *vehicle = new Car{};
vehicle->Accelerate();
delete vehicle;
vehicle = new Truck{};
vehicle->Accelerate();
std::vector<Vehicle*> vehicles{
    new Car{} ,
    new Truck{} ,
    new Truck{} ,
    new Car{}
};
for (auto&& v : vehicles){
    v->Accelerate();
}
```

However, students want to write the code as they are used to with C#:

```
Vehicle v = Car{};
v.accelerate();
v = Truck{};
v.accelerate();
std::vector<Vehicle> vehicles{
    Car{} , Truck{} , Truck{} , Car{} };
for (auto&& v : vehicles) {
    v.accelerate();
}
```

If a default implementation of the method in the class `Vehicle` is added, it is no longer abstract, this code will be

compiled, but there will be not polymorphic behavior – the same method will always be executed – that of the class `Vehicle`. For this code to work correctly, it is needed to implement manually the virtual functions mechanism, which will be done in the following sections.

### B. Inheritance Problems

To prove why it is necessary to look for inheritance-free design possibilities, it is needed to look at some of the problems it raises. In his talk at CppCon 2020, Simon Brand summarizes and analyzes five issues related to inheritance [4]:

- Often requires dynamic allocation

This problem is encountered when implementing the hierarchy of Fig. 1. The attempt to store in `vector<Vehicle>` objects of the derived classes `Car` and `Truck` leads to what's called "slicing" – just the inherited from `Vehicle` (base) part of the object are got, and we slice of the dynamic part of the derived object. Usually this is not what is needed. The same is the situation when a function returns an object of the base class by value. To avoid this problem, it is needed to allocate and return a pointer dynamically (in the case of the function), or store a pointer (raw or smart) in a vector:

```
std::vector<std::unique_ptr<Vehicle>> vehicles;
```

- Ownership and nullability considerations

When working with pointers their ownership and validity must always be considered. If `unique_ptr` is used, then the ownership is clear. It is not so clear, however, if a function is returning `unique_ptr`. Questions arise: can it return null? Is it necessary to check? If the function accepts a `unique_ptr` argument, what happens if null is passed? Is that valid? What's the behavior? Too many questions to take care of.

- Intrusive: requires modifying child classes

Supporting inheritance requires modifying child classes.

```
namespace LibOne {
    class Base {
    public:
        virtual void Foo();
    };
}
```

```
namespace LibTwo {
    class Other {
    public:
        virtual void Foo();
    };
}
```

There is a Base class in `LibOne` and then there is some other library `LibTwo` which has an `Other` class. They both have `Foo()` method which returns void and they're virtual. It is not possible to allocate an instance of `LibTwo::Other` and take a pointer to it through a `LibOne::Base`.

```
LibOne::Base* b = new LibTwo::Other{};
```

This will not work because LibTwo::Other does not say it inherits from LibTwo::Other. This can be a problem. Maybe LibTwo::Other cannot be changed like if we could just decorate it to inherit from Base. For example, the code may not be available or there may be other restrictions that prevent from doing so. So, polymorphism with inheritance is intrusive.

- No more value semantics

Again, the question comes to the pointers. If we want value semantics, then something on top must be built. For example, virtual Clone() function which uses the correct dynamic type, dynamically allocate a pointer, and pass it back. That's a way of getting a copy behavior but still it is not the usual C++ value semantics which a lot of code depends on.

- Changes semantics for algorithms and containers

Inheritance changes semantics for algorithms and containers. If a std::sort() is done, maybe sorting on pointers is on, and custom comparator object must be supplied. The same situation is when these things are stored in a std::set. Another situation that must be thought about is that not usual C++ values are used, but it is desirable for most of the C++ development to use value semantics.

### C. Implementing Virtual Functions by Hand

The start is with an implementation of the hierarchy of Fig. 1 in the traditional way, by inheritance.

```
class Vehicle {
public:
    virtual ~Vehicle();
    virtual void Accelerate() const = 0;
};
class Car : public Vehicle {
    virtual void Accelerate() const override;
};
class Truck : public Vehicle {
    virtual void Accelerate() const override;
};
```

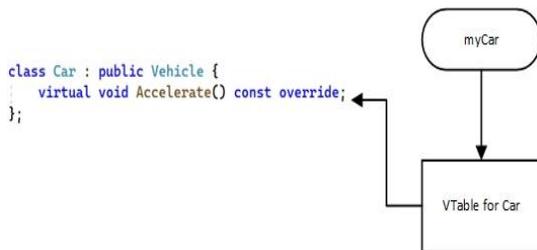

Fig. 2. Situation with an Object of the Car Class.

It is important for students to understand how virtual functions works internally. In Fig. 2 myCar is an object of the Car class. Then it is going to have a pointer to a VTable – a virtual table. This table takes care of how to call virtual functions in a polymorphic object. VTable in turn has a pointer to the Accelerate() function for Car. So, there is a couple of indirections that are gone through when Accelerate() is called. First, the VTable must be grabbed, then the VTable must be

read through to get the Accelerate() function. That can be a performance bottleneck.

The interface to be implemented includes a Vehicle class, which should provide all the necessary functionality for polymorphic behavior. The other two classes Car and Truck just need to have accelerate() functions. These two classes should not inherit Vehicle, but there is a need to support this use case. It should be possible to create a Vehicle from a Car and call accelerate(). The aim is ability to create a Vehicle from a Truck and have it accelerate() and all this should be done without doing any slicing.

```
Vehicle c = Car{};
v.accelerate();
Vehicle t = Truck{};
t.accelerate();
```

To implement the virtual functions manually several steps have to be made:

- Declare virtual table for the abstract interface

First, it is declared what the virtual table layout looks like for Vehicle class.

```
struct VTable {
    void (*accelerate)(void* ptr);
    void (*destruct)(void* ptr);
};
```

VTable has two function pointers – one for accelerate and one for destruct, which will be called by the destructor of the specific object. And since memory within the object will be allocated, it's going to reclaim that memory. The arguments of the two function pointers are void pointers, because in this way the concrete object will be stored internally. Void pointers will be passed, and then the concrete objects are going to cast those pointers internally.

- Define virtual table for a concrete type

```
template<typename T>
VTable vtable_for {
    [](void* p) {
        static_cast<T*>(p)->accelerate(); },
    [](void* p) {
        delete static_cast<T*>(p); }
};
```

This is a variable template (available since C++14). There is an instance of a VTable and it's templated on the concrete type T, i.e., Car or Truck. So, a function which is going to call the correct version of accelerate() is needed, and a function which deletes the object and calls the destructor. Lambdas can be used for this purpose. For a given concrete object the first function pointer is just going to static cast to the concrete type and then call accelerate(). And then the second function is going to static cast and then calls delete. This all works because lambdas which don't capture can decay to function pointers.

- Capture the virtual table pointers on construction

When a Vehicle class is constructed, it is needed to fill in the pointer for the concrete object and pointer to the virtual table. The constructor will be implemented as a template that accepts any type as an argument. In a real situation, of course, it would be good to limit the possible types. Memory will be allocated dynamically for the object received as an argument and a copy of it in p\_obj will be saved, and after that a pointer to our virtual table will be taken and stored inside vehicle (in the p\_vtable field).

```
class Vehicle {
public:
    void* p_obj;
    VTable const* p_vtable;
    template<typename T>
    Vehicle(T const& obj) :
p_obj(new T(obj)),
p_vtable(&vtable_for<T>)
{}
};
```

It is noted that since there is current access to what type the obj is (Car or Truck), that information is saved for later by grabbing the right VTable pointer and by dynamically allocating a copy of our obj. This technique is called “type erasure”.

- Forward calls through the virtual table

Finally, it is needed to forward the calls through the virtual table.

```
class Vehicle {
    //...
    void accelerate() {
        p_vtable->accelerate(p_obj);
    }
    ~Vehicle() {
        p_vtable->destruct(p_obj);
    }
};
```

Inside the Vehicle class if accelerate() is called, then we indirect through p\_vtable and pass it the void pointer. And that is then going to cast inside the function and call the right version. And then similarly for the structure we call destruct().

So now the students have something which works for that use case. It remains to define the classes Car and Truck with the corresponding implementations of the function accelerate().

```
class Car {
public:
    void accelerate() {
        std::cout << "The car accelerates.\n";
    }
};

class Truck {
```

```
public:
    void accelerate() {
        std::cout << "The truck accelerates.\n";
    }
};
```

It is possible to construct car; it is possible to construct vehicle from a car and a truck and make them accelerate and all it works. The goal set at the beginning of the section has been achieved.

#### D. Adding Copy and Move Semantics

So far, some of the inheritance problems discussed in section B have been solved. There are no more problems with ownership and nullability, because now all memory allocations are handled inside the Vehicle class. There are no pointers externally. We're just dealing with the values. Intrusivity is avoided as well, because now Car and Truck don't inherit from anyone. However, the problem with value semantics remains, because these objects can't be copied or moved, but the VTable can be extended with a copy\_() and a move\_() function pointers and solve this problem.

```
struct VTable {
    //...
    void* (*copy_)(void* ptr);
    void* (*move_)(void* ptr);
};
```

The first function will allocate a copy, and the second will allocate by moving from the object. This functionality should be implemented by adding two new lambda functions to the variable template vtable\_for.

```
template<typename T>
VTable vtable_for {
    //...
    [](void* p) -> void*{
        return new T(*static_cast<T*>(p)); },
    [](void* p) -> void*{
        return new T(std::move(*static_cast<T*>(p))); }
};
```

Now it is only needed in the copy constructor and move constructor of Vehicle to call from the virtual table p\_vtable the corresponding functions.

```
Vehicle(Vehicle const& other) :
    p_obj(other.p_vtable->copy_(other.p_obj)),
    p_vtable(other.p_vtable)
{}
Vehicle(Vehicle&& other) noexcept :
    p_obj(other.p_vtable->move_(other.p_obj)),
    p_vtable(other.p_vtable)
{}
```

The same is done for copy assignment and move assignment operators.

```
Vehicle& operator=(Vehicle const& other) {  
    p_obj = other.p_vtable->copy_(other.p_obj);  
    p_vtable = other.p_vtable;  
    return *this;  
}  
Vehicle& operator=(Vehicle&& other) noexcept {  
    p_obj = other.p_vtable->move_(other.p_obj);  
    p_vtable = other.p_vtable;  
    return *this;  
}
```

Now a much more complete interface is created, and a lot of actions can be performed – create vehicle from car and accelerate it; we can reassign it to a truck and make that accelerate. A new vehicle can be created from an old one. All works and there is value semantics even though we're doing dynamic polymorphism. It's just all handled under the covers. Students can even experiment by defining and traversing the vector of cars and trucks because we defined copying and moving.

```
Vehicle v = Car{};  
v.accelerate();  
v = Truck{}; // move assignment!  
v.accelerate();  
Vehicle t{ v }; // copy construction  
t.accelerate();  
std::vector<Vehicle> vehicles {  
    Car{}, Truck{}, Truck{}, Car{} };  
for (auto&& v : vehicles) {  
    v.accelerate();  
}  
t = std::move(v); // move assignment
```

Another inheritance problem is solved. There are already normal copy semantics and container semantics. The problem is that the code written to implement this functionality is too much and must be repeated for each class that needs to be handled dynamically. In addition, it's weird code and it's easy for something to go wrong.

### III. IMPLICATIONS FOR EDUCATION

Teachers and students often consider learning programming a difficult pursuit [5]. Inheritance and polymorphism are arguably the most advanced and abstract subjects in object-oriented programming [6]. Their study involves many difficulties, which we will not consider here. The study in [7] identifies as the main cause of most problems the students' inability to understand what is happening with their program in memory, since they cannot build a clear mental model of the program's execution. Therefore, we believe that manually implementing the virtual tables will help overcome these issues. Our experience from the last two academic years shows progress in this direction. Students see that pointers are a very powerful tool and are motivated to study them. They look for literature and consult with the assistants, solve tasks

independently. The result is a deeper understanding of memory management and program execution.

For students who have not studied C++ in the introductory course, after the topics related to the new-to-them syntax in terms of program structure, class definition, object instantiation, and message exchange, one should move on to learning about working with pointers and dynamic memory (something everyone else studied in the introductory C++ course). At an early stage, the topics of implementing the important OOP relations of composition and inheritance, which students know from the introductory course, should also be included. After that comes the time for an in-depth study of polymorphism. For students the goal is to learn to recognize polymorphism and model with it, not just to know its implementation in the specific language.

Dynamic binding and virtual functions should be seen as a mechanism in OOP languages to implement dynamic polymorphism, but not polymorphism to be considered as a consequence of using the mechanism. It is recommended to give a correct classification of the types of polymorphism in lectures in order to clarify the understanding of the concepts and distinguish them from the means of implementation.

A common mistake made by novice programmers is always to try to use the inheritance relationship. Undoubtedly, it is the most important and defining for the paradigm, but its application should not be overexposed in the course. After learning about the disadvantages of inheritance, students themselves will begin to look for alternative designs using other relations. In particular, it provoked interest for generic and functional programming.

Modern programming languages offer concepts from several programming paradigms. It is impossible to learn OOP in isolation from generic, functional, and procedural programming. Therefore, in parallel with OO concepts, other means like templates, lambdas, containers, and algorithms from STL should also go.

An important condition for successful training in OOP is the correct selection of the tasks that are considered in laboratory classes and given for homework. They should be such that polymorphism is a natural part of the solution. Suitable hierarchies to implement (both with and without inheritance) are as follows:

- base class Animal and derived classes Fish, Frog, Bird and polymorphic method Move(),
- base class Pet, derived classes Cat and Dog and polymorphic method MakeNoise(),
- base class Shape, derived Circle, Triangle, Rectangle and polymorphic methods Area() and Circumference(),
- basic class Publication, derived Magazine, Book and polymorphic method Print().

Examples can be both from real life and more abstract. Examples with GUI components can also be used. It is a good idea to add a new class to an already implemented hierarchy, for example adding Motorcycle to Car and Truck. This can be

done as work to do by themselves within the lab exercise or given for homework.

Learning about abstract classes provides a good foundation to demonstrate the full power of polymorphism with perhaps its most typical application – the creation and manipulation of heterogeneous data structures. The vector of Car and Truck objects is such a structure as well. If there is enough time, a manual implementation of a heterogeneous singly linked list or binary tree can also be demonstrated in the training course.

Since the complete implementation of the Vehicle, Car, Truck hierarchy given in this paper covers many topics, it cannot be covered in a single lecture and practiced in a single lab session. It is recommended to teach incrementally, starting with an implementation with inheritance, and going through the type erasure option after discussing pointers, constructors, destructors, type conversion, lambda functions, function templates, variable templates. After the initial version, the project can be extended with an implementation of copy semantics only. This requires first familiarity with operator overloading and copy construction. Move semantics is not required for the classes to work correctly because it can be successfully replaced by copy. But since the choice of the C++ language in most cases is related to the increased requirements for speed and efficiency of code, it is recommended not to neglect it and to give and comment the described implementation of move semantics for the sample hierarchy. When learning the STL library, one can experiment with using different containers of Car and Truck objects and applying algorithms to them.

Since enough empirical data is not collected yet, the classic pedagogical experiment of proving the advantages of extended polymorphism learning is not completed. However, in Table I a comparison of the results for the academic year 2021-2022 is given of the start tests (in the beginning of the course) and the tests conducted immediately after the completion of the section devoted to polymorphism. The experimental group includes the students of the Software Engineering majors, for whom “Programming in C++” is an elective course in the 4th semester (12 people) and the Computer Science major, for whom the course is mandatory, but in the 2nd semester (35 people).

TABLE I. TEST RESULTS

Grade	Bachelor Program					
	SE		CS		Informatics	
	Start level	End level	Start level	End level	Start level	End level
A	25.0%	25.0%	14.3%	20.0%	9.1%	9.1%
B	16.7%	33.3%	22.9%	25.7%	27.3%	27.3%
C	33.3%	25.0%	28.6%	25.7%	18.2%	27.3%
D	16.7%	8.3%	22.9%	22.9%	36.4%	27.3%
F	8.3%	8.3%	11.4%	5.7%	9.1%	9.1%

In order not to distort the results, only data from face-to-face training is used – after the symbolic end of the pandemic. The control group consists of the students of the Informatics major (11 people), who in the 2nd semester are studying a mandatory course OOP in C++. The fact that the experimental

group is heterogeneous is taken into account – for one major, the course is CS1, and for the other, CS2, but with an introductory C# course. Therefore, the first test is slightly different for the Software Engineering major. Language dependent questions are minimized as much as possible. The questions and tasks of the second test are the same for all and entirely related to the correct use of pointers, dynamic memory, and implementation of polymorphism, without specifying in what way.

Another circumstance that prevents accurate interpretation of the data is the small number of students in the control group. The Informatics major is currently the least desired of the three, and it has students ranked second and third preference, which is a demotivating factor.

Nevertheless, both the results of the control tests (Table I) and the direct observations of the students' activity in lectures, laboratory work, project work and homework, indicate that it makes sense to pay more attention to polymorphism in the OOP course. The experimental training conducted helps students to discover the exact relations between objects in the subject area more easily and correctly choose the operations that need to be implemented polymorphically. They are more adept at handling pointers and have a better understanding of the memory model. They recognize the situations in which they need to implement move semantics. They have no problem using lambda expressions in STL algorithms instead of function objects.

At the end of the course, a survey is conducted to determine students' satisfaction with the experiential learning and to specify what they found difficult. The answers are of interest. The question asked to the Software Engineering students was “Why did you choose C++?” (open question). 1/3 of them made such a choice, and 2/3 preferred PHP. Among the answers, it stands out that they read that it is suitable for Video game development, Embedded systems, Compilers and Enterprise software. The syntax of the methods implementing copy and move semantics – copy and move constructors and copy and move assignment operators – is indicated as the most difficult. Students find it difficult to navigate what is what just by the type of parameters. In second place are variable templates, and in third place – the many details of defining lambda expressions. When asked if what they learned about alternative ways of implementing polymorphism was useful, 73% answered yes.

#### IV. CONCLUSION

In this paper, the need for a more in-depth study of dynamic polymorphism is discussed. Problems associated with its implementation through inheritance and virtual functions are analyzed and a method of training is presented through a step-by-step project development with an alternative to inheritance design based on manual implementation of the functionality achieved with virtual tables. Specific guidelines for organizing training involving this topic are suggested.

As a recommendation to lecturers, it is useful to pay attention to the concept of polymorphism already in the introductory course. Although it is not dynamic there, it is good for students to recognize it early.

REFERENCES

Regarding this implementation of polymorphism with type erasure, the most serious drawback is considered to be that, with the means currently available, it requires writing too much code – a code of high complexity. This is demotivating. Implementation with inheritance is much shorter and straight forward, even more so for students who have studied C#, where alternatives can easily be implemented – implementing interfaces can make it much easier to avoid inheritance. Such an implementation, of course, also has its drawbacks. However, if the proposals made to The C++ Standards Committee to introduce scalable reflection [8] and metaclasses [9] are implemented in the future, the code will be much shorter and clearer, because much of it will be automatically generated and will remain hidden from the client.

In studying the problem, it was found that not many researchers emphasize the weaknesses of inheritance as a tool to achieve polymorphism, and therefore there are not many proposals to overcome these weaknesses. The details in this area are mostly discussed at technical conferences rather than in scientific publications. This, on one hand, limited the possibilities of the research, and on the other, motivated the authors to tackle this problem.

Future work includes monitoring of the development of the language in this direction, although there has been some stagnation in the last 1-2 years. Also, in the future, it is planned to expand the experiment with formal statistical processing of accumulated empirical data.

**Abstract**—With the enhancement of data mining technology, competitive sports informatization has become an inevitable development trend. It has become a common phenomenon to use data mining technology to help athletes train scientifically, assist coaches in rational decision-making, and improve team competitiveness. In competitive sports, cyclists' adaptation to training has a complex relationship with their physical performance. In order to explore the correlation between data and provide better training data for athletes, this study proposes a load prediction model based on BP neural network (Back propagation, BP). Considering the local convergence and random assignment of traditional BP model, an adaptive genetic algorithm with improved selection operator is used to determine the initial weights and thresholds of BP neural network to improve the accuracy of the prediction model. The experimental results show that the improved adaptive genetic algorithm improves the overall optimization ability of the BP neural network, the improved BP neural network model has good stability in the convergence process, and the algorithm can search for better weight thresholds. Compared with the basic BP neural network prediction model, the accuracy of the optimized prediction model is increased by 11.86%, and the average error value is reduced by 26.21%, which is a guide to improve the training effect of the cycling team's competitive sports.

**Keywords**—BP neural network; adaptive genetic algorithm; selection operator; training load

## I. INTRODUCTION

In competitive sports, effective and scientific training is an important means to improve the performance of athletes. Athletes dedicate most of their professional training to improving fitness, competitiveness and self-confidence [1]. In particular, the physical fitness testing and evaluation of professional athletes, as well as the analysis of physiological and biochemical indicators, are of great significance for understanding the athlete's endurance, current physical fitness, and the scientificity and effectiveness of training interventions [2]. However, the traditional physical fitness index evaluation of athletes is mainly based on manual evaluation, and the accuracy is poor. Data mining is an interdisciplinary technique that can be used to analyze data and gain insights into specific problems [3]. Applying data mining technology to cycling, by analyzing the correlation between a series of physiological and biochemical indicators of cyclists, athletic ability indicators and athletes' training load levels, a cyclist training load prediction

model is established, which not only helps coaches and athletes evaluate them in advance training readiness, while also assisting in training analysis and decision-making [4]. This study uses the information collected by the International Cycling Federation to develop a training load prediction model based on BP neural network. Since the BP neural network is nonlinear and easily trapped in local minima, this study uses an optimized adaptive genetic algorithm to determine the optimal initial weights and thresholds of the BP neural network to solve the problems associated with randomly assigning values [5]. Therefore, it is expected that the rationality of the training plan will be evaluated in advance to prevent adverse consequences for athletes due to unreasonable training plans. The research content can better ensure the safety and effect of athletes' training, and promote the progress of sports evaluation methods.

## II. RELATED WORKS

Artificial Neural Network is an intelligent method for processing nonlinear relational data [6]. Due to its good adaptability, good nonlinear mapping and robustness, it is widely used in image processing, image recognition and other fields [7]. The BP network algorithm is simple, easy to implement, small in computation and good in parallelism. It is one of the most widely used and mature neural network algorithms. Because the fastest descending backpropagation method in the BP neural network is to correct the weights based on the negative gradient of the error function, it leads to problems such as low learning efficiency, slow convergence, and easy to fall into local miniaturization. [8]. Scholars at home and abroad have carried out the following researches on the shortcomings of BP neural network; Wu Jie and others. A BP network based on the improved particle swarm optimization algorithm is proposed. By adjusting the adaptability of the learning factor, the convergence speed of the BP neural network and the performance of the global optimal solution are improved. The simulation results show that the improved particle algorithm is better than the standard BP algorithm and particle swarm algorithm [9]. In order to improve the classification accuracy of ECG signals, Wang Li et al. the BP neural network is optimized using an additional momentum adaptive learning rate adjustment algorithm. The simulation results show that the improved BP neural network has better classification and recognition ability, and the accuracy rate of the whole sample classification is 98.4%. The optimization

algorithm has fast convergence speed and high classification accuracy, which is helpful for the detection and diagnosis of heart disease [10]. Zhang D's team proposed that increasing the number of sample locations for training the BP network can improve the accuracy, and as the number of sample locations increases, the rate at which the fitting error decreases will decrease. The simulation results show that increasing the number of sample locations for training the BP neural network can improve the accuracy, and the fitting error decline rate decreases with the increase of the number of sample locations [11]. According to Cy A et al. the problem that BP neural network is easy to fall into the local minimum is solved. The empirical results show that the improved genetic algorithm is better than the traditional genetic algorithm in terms of convergence speed and prediction accuracy [12].

The BP network has in-depth applications in many complex scenarios, and its application in athletes' training provides an important reference for the improvement of athletes' physical and mental fitness. Chen W et al. found that clothing fatigue will affect the effect of sports. At present, there is little research on sports clothing. Therefore, based on the theory of BP and surface electromyography, they predicted the fatigue of athletes and built a prediction model. Finally, the experiment found that the model can provide technical support for athletes' training and development [13]. Zhang Y. et al found that with the arrival of information technology, sports data is becoming more and more important. How to collect human motion data is the key, so based on neural network and density peak clustering algorithm, a motion data model is constructed. After experimental verification, compared with the traditional principal component dimensionality reduction method, the proposed scheme can obtain better feature data, and the effect is better [1, 4]. Li T et al. found that the intelligent sports management system is beneficial to improve the overall training effect of the players, so they built a sports posture recognition model based on BP, and analyzed the motion feature extraction and experimental results. The final experimental results show that this scheme has better performance than other sports management algorithms, providing important data reference for the development of athletes [15].

Based on the above literature research, BP network is competent in many complex environments, and scientific and

effective sports training is the key to ensure the level of sports competition. BP network has outstanding advantages in the field of diagnosis and prediction. Applying it to the field of sports training will provide significant help for effective sports training and promote the development of information technology in the field of sports.

### III. CONSTRUCTION OF TRAINING LOAD PREDICTION MODEL BASED ON IMPROVED BP NEURAL NETWORK

#### A. Design of Training Load Prediction Model based on BP Neural Network

Training is an important daily activity for athletes. Appropriate training can improve their competitive performance, but too much training can lead to injuries, and too little training will not achieve the desired training effect [16]. In this study, a BP network was used to design a training load prediction model for cyclists, which was optimized by an improved adaptive genetic algorithm to evaluate whether the athlete's training plan was reasonable. In cycling training load prediction, the cyclist's load level should be predicted from the athlete's basic physiological and biochemical data, exercise level goals, and exercise content to determine whether the currently planned training load is appropriate. The research required analyzing and processing the data and selecting relevant metrics before building a model to predict the training load of cyclists. The filtered data is divided into a training set and a test set, and the test set data is used to test the accuracy and performance of the full training model in predicting the training load of athletes. For athlete training load prediction, the study selected 25 factors that have an impact on training load based on the recommendations of professional cycling coaches, as shown in Fig. 1.

Exponential differences between the filtered parts of the data, they must be normalized before feeding them into the BP neural network. The core of normalization is to project all data to the same interval after the algorithm has run. The formula for the Min-max normalization process is shown in Equation (1).

$$X = \frac{x_i - x_{\min}}{x_{\max} - x_{\min}} \tag{1}$$

	Height	Weight	Age	Gender		
	Body mass index					
	Functional threshold power					
	Maximum oxygen uptake					
	Average step frequency		Maximum step frequency			
	Average power		Maximum power			
	Leukocyte count	Hemoglobin	Platelet	Red blood cell count	Urea nitrogen	Urine pH
	Creatine kinase	Testosterone	Blood oxygen saturation	Urinary protein	Urobilinogen	Urobilin
	Training items		Training volume			

Fig. 1. Factors Affecting Athletes' Training Load.

In Equation (1),  $x_i$  denote the current value of these data,  $x_{\max}$  and  $x_{\min}$  denote the maximum and minimum values of these data, respectively, which are uniformly distributed in a certain interval after normalization. The number of input and output layers is fixed at one layer, while the hidden layer can have multiple layers. The number of neurons in the input layer is determined by the dimension of the input signal, and the number of neurons in the output layer is defined by the problem to be solved. Function. Through the iterative alternation of these two processes, the connection weights and thresholds of the BP neural network are continuously optimized. Suppose there are  $m$  training samples  $X$ ,  $x_1, x_2, \dots, x_m$ , the expected output is  $t_1, t_2, \dots, t_m$ , the actual output is  $y_1, y_2, \dots$ , There are  $y_m$  neurons in the hidden layer.  $s$  After the activation function is transformed, the expression of the output of the  $i$ th neuron in the hidden layer is shown in formula (2).  $i$

$$a_i = f(\text{net}_i) = f\left(\sum_{g=1}^n w_{ig} x_g - \theta_i\right) \quad (2)$$

In formula (2),  $f$  represents the activation function, represents the neuron in the output layer, represents  $g$  the weight factor  $g$  from neuron  $w_{ig}$  to neuron  $i$ , and represents  $\theta_i$  the threshold of the neuron. The output of neurons in the output layer is shown in formula (3).  $g$

$$y_g = f\left(\sum_{r=1}^m a_r w'_{gr} - \theta'_r\right) \quad (3)$$

In formula (3),  $w'_{gr}$  is the connection weight between the hidden layer and the output layer, which  $\theta'_r$  represents the threshold of the neurons in the hidden layer. Let  $\text{net}'_g = \sum_{r=1}^m a_r w'_{gr} - \theta'_r$ , convert equation (3) to equation (4).

$$y_g = f(\text{net}'_g) \quad (4)$$

The error function is shown in equation (5).

$$E(w, \theta) = \frac{1}{2} \sum_{g=1}^m (t_g - y_g)^2 \quad (5)$$

Equation (6) can be derived from equations (3) and (5).

$$E = \frac{1}{2} \sum_{g=1}^m (t_g - y_g)^2 = \frac{1}{2} \sum_{g=1}^m \left(t_g - f\left(\sum_{r=1}^m a_r w'_{gr} - \theta'_r\right)\right)^2 \quad (6)$$

The output layer is shown in equation (7).

$$\frac{\partial E}{\partial \text{net}'_g} = \frac{\partial E}{\partial y_g} \cdot \frac{\partial y_g}{\partial \text{net}'_g} = \frac{\partial E}{\partial y_g} \cdot f'(\text{net}'_g) \quad (7)$$

The implicit layer is shown in Equation (8).

$$\frac{\partial E}{\partial \text{net}_i} = \frac{\partial E}{\partial a_i} \cdot \frac{\partial a_i}{\partial \text{net}_i} = \frac{\partial E}{\partial a_i} \cdot f'(\text{net}_i) \quad (8)$$

If the error between the desired output and the neural network is too large, gradient descent is used to correct the weights of the layers of the network. The adjustment amount of the weight between the hidden layer and the output layer is  $\Delta w'_{gr}$  shown in formula (9).

$$\Delta w'_{gr} = -\eta \frac{\partial E}{\partial w'_{gr}} = -\eta \frac{\partial E}{\partial \text{net}'_g} \cdot \frac{\partial \text{net}'_g}{\partial w'_{gr}} = \eta (t_g - y_g) \cdot f'(\text{net}'_g) \cdot a_r \quad (9)$$

The amount of weight adjustment from the input layer to the hidden layer is  $\Delta w_{ig}$  shown in formula (10).

$$\Delta w_{ig} = -\eta \frac{\partial E}{\partial w_{ig}} = \eta \sum_{g=1}^m (t_g - y_g) f'(\text{net}'_g) w'_{ig} f'(\text{net}_i) x_j \quad (10)$$

Since both the activation functions of the input layer and the output layer use this function, the *Sigmoid* sum  $\Delta w_{ig}$  transformation is shown in equation (11).  $\Delta w'_{gr}$

$$\begin{cases} \Delta w_{ij} = \eta \left(\sum_{g=1}^m (t_g - y_g) y_g (1 - y_g) w'_{ig}\right) a_i (1 - a_i) x_j \\ \Delta w'_{gr} = \eta (t_g - y_g) y_g (1 - y_g) a_r \end{cases} \quad (11)$$

In order to build a model for predicting the training load of athletes, it is first necessary to define the structure and covariates of the BP neural network, that is, the number of layers of the BP neural network, the number of neurons, the data set processed, and the selection of initial weights and thresholds.

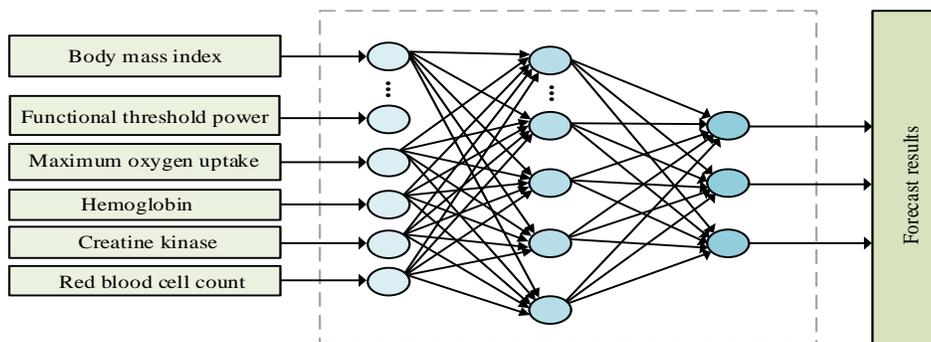

Fig. 2. The Topology of the Network Structure of the Training Load Prediction Model.

In Fig. 2, it can be seen that the structure of the BP neural network consists of an input layer, a hidden layer and an output layer, and the hidden layer can be composed of one or more layers. Since the three-layer BP neural network can approximate any continuous function in the closed interval, the basic three-layer hidden layer is selected as the basis for constructing the network prediction model. In the input layer, the input variables should not be highly correlated, and the input variables should significantly interfere with the output results.

Based on the above analysis of training load intervention factors, a total of 25 related factors were considered as input variables for the study, so the number of neurons in the input layer was set to 25. The prediction purpose of the model is to express the training load level of athletes through the training load results, which can be divided into too little training volume, moderate training volume and too much training volume. Therefore, the number of neurons in the output layer is determined to be three. The number of neurons in the hidden layer can be calculated according to formula (12), and then the optimal number of neurons in the hidden layer is determined by the trial and error method.

$$\begin{cases} n = \sqrt{ml} \\ n = \log_2 m \\ n = \sqrt{m+l} + a \end{cases} \quad (12)$$

In formula (12),  $n$ ,  $l$  and  $m$  represent the number of neurons in the hidden layer, the output layer and the input layer, respectively, which  $a$  is a constant and its value is in the interval (1,10). Since  $l = 3$ ,  $m = 25$ , the number of neurons in the hidden layer is in the range of [5, 15] above. Based on this, heuristics are applied to determine the number of neurons in the hidden layer. The number of neurons in the hidden layer is preset to five, and one neuron is added for each experiment. The prediction performance and convergence of the hidden layer with different numbers of neurons are compared in each experiment. The optimal number of neurons in the hidden layer is the final. The trial was determined to be 10.

### B. Introducing an Improved Adaptive Genetic Algorithm to Optimize the BP Neural Network

Adaptive genetic algorithm is an improved genetic algorithm, which is characterized by automatically changing the probability of crossover and mutation based on chromosome fitness, reducing the possibility of crossover and mutation of individuals with high fitness, and improving the probability of crossover and mutation of somatic individuals, thereby increasing population diversity and retaining high-value chromosomes [17]. Since BP neural network is nonlinear, model convergence, occurrence of local minima and training time are closely related to the choice of initial weights and thresholds [18]. Initial weights and thresholds are usually randomly generated, and if not chosen properly, the network may not converge or may be constrained by local minima [19]. In order to better solve the random assignment problem of BP neural network, an improved adaptive genetic algorithm is used

to find the optimal initial value and threshold of the network. Real encoding not only eliminates the need for decoding, but also facilitates the computation of genetic operations. Assuming a topological neuron network of 3-2-1, the number of weights and thresholds of the network used in the study is 293. In this neural network, the connection weights between the input and hidden layer neurons are  $W_{11}^1, W_{12}^1, W_{21}^1, W_{22}^1, W_{31}^1, \dots$  and  $W_{32}^1$  the connection weights between the hidden layer and output layer neurons are  $W_{11}^2, W_{21}^2$ , between the hidden layer and output layer neurons The thresholds are  $\theta_1, \theta_2, \theta_3$ . Both connection weights and thresholds are real numbers in the range 0 to 1. By ordering these weights and thresholds in order,  $W_{11}^1 W_{12}^1 W_{21}^1 W_{22}^1 W_{31}^1 W_{32}^1 W_{11}^2 W_{21}^2 \theta_1 \theta_2 \theta_3$  real numbers can be encoded, and the resulting real numbers are chromosomes [20]. The BP neural network adjusts the weights and thresholds of the connections with the aim of minimizing the prediction error of the athlete's training load. The adaptive genetic algorithm applied in the study aims to find a set of weights and thresholds that minimize the prediction error, so the fitting function is negatively correlated with the sum of squares of the network output error, that is, the smaller the error, the greater the fit. The calculation of individual fitness is shown in Equation (13).

$$F(x) = \frac{1}{E(x)+1} \quad (13)$$

In formula (13),  $x$  represents the current chromosome, which  $E(x)$  is the sum of the squared errors of the network output generated by the BP neural network using the current weight-threshold combination represented by the chromosome. For population selection, the roulette method is widely used due to its simplicity and convenience. However, roulette is used to randomly select individuals based on their fitness relative to the ensemble, which may result in individuals with high fitness being ignored. Although the main purpose of the optimization strategy is to select the best individuals from the population, only starting from the best individuals and discarding the individuals with universal fitness will eventually lead to the problem of homogeneous population structure, which is prone to local convergence phenomenon. This study improves the selection operator by introducing an optimal conservation strategy based on a sorted list selection method. The population is first initialized by sorting the individuals in the population from the lowest fitness to the highest fitness and equally dividing the sorted individuals into four parts, as shown in Fig. 3, steps 1-3 for improving the selection operator.

As can be seen from Fig. 3, each segment was selected at a ratio of 0.4, 0.6, 0.8 and 1, resulting in individual numbers of  $0.4*5=2$ ,  $0.6*5=3$ ,  $0.8*5=4$  and  $1*5=5$ . Since six individuals were lost during the selection process, starting from paragraph four, one additional individual was randomly selected at a time, resulting in a final number of six individuals. Insert the selected individual to the end of the individual selected in step 5 to form a new population, steps 4-7 are shown in Fig. 4.

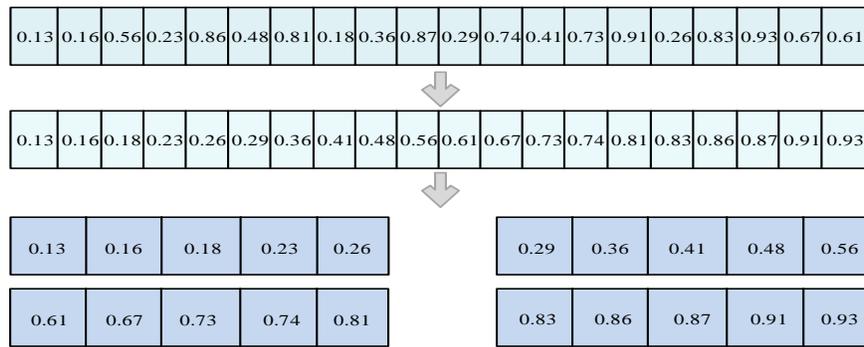

Fig. 3. Introduce the Best Preservation Strategy based on the Sorting List Selection Method to Improve the Selection Operator.

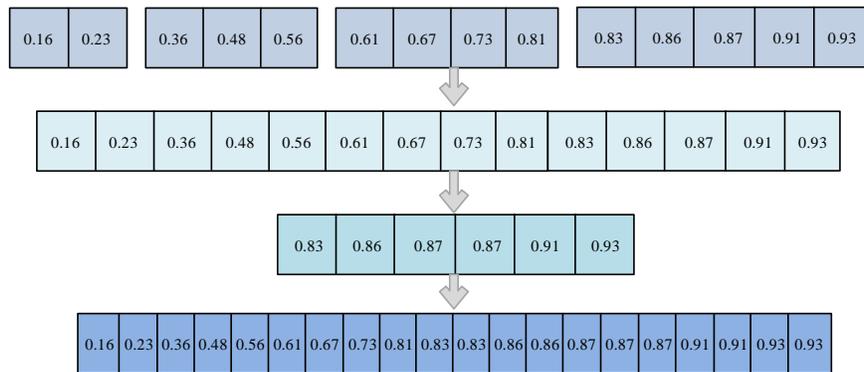

Fig. 4. Introduce the Best Preservation Strategy based on the Sorting List Selection Method to Improve the Selection Operator.

The improved selection operator ensures population diversity by retaining the best individuals and selecting others according to their size. It is also easy to operate because only the fitness is calculated and the best individuals are selected by basic operations like sorting, grouping and insertion. In contrast, the roulette method is computationally intensive because it requires first calculating the fitness of individuals, then calculating the proportion of individual fitness, and then solving for the selection probability. Therefore, improving the selection operator can theoretically improve the selection and convergence ability of the network. New individuals are generated by performing adaptive genetic algorithm operations on crossover and mutation between populations. In order to construct individuals with higher fitness, in the process of crossover mutation operation, the individuals to be processed are selected according to the crossover mutation rate. The crossover rate is  $\rho_c$  shown in Equation (14).

$$\rho_c = \begin{cases} \rho_a - \frac{(\rho_a - \rho_b)(f - f_{avg})}{f_{max} - f_{avg}}, & f \geq f_{avg} \\ \rho_a, & f < f_{avg} \end{cases} \quad (14)$$

In equation (14),  $\rho_a = 0.9$ ,  $\rho_b = 0.6$ .  $f$  represents the current individual fitness,  $f_{max}$  is the maximum fitness of all individuals in the population, and is  $f_{avg}$  the average fitness of

all individuals in the population. The rate of change is  $\rho_m$  shown in equation (15).

$$\rho_m = \begin{cases} \rho_i - \frac{(\rho_i - \rho_j)(f_{max} - f)}{f_{max} - f_{avg}}, & f \geq f_{avg} \\ \rho_i, & f < f_{avg} \end{cases} \quad (15)$$

In equation (15),  $\rho_i = 0.1$ ,  $\rho_j = 0.001$ . IAGABP is an optimized BP neural network algorithm based on an improved adaptive genetic algorithm. It is divided into a genetic algorithm part and a BP neural network part. The specific flowchart of the algorithm is shown in Fig. 5.

As shown in Fig. 5, in the genetic algorithm part, N chromosomes are randomly generated through real-value coding to form the initial population of the algorithm, and the fitness of the entire population is improved through continuous genetic operations until the algorithm terminates in the population after several generations. After the evolution in the BP neural network, the network structure and other parameters are solved first, and the optimal individual in the genetic algorithm is decomposed into a series of initial values and thresholds of the BP neural network. Finally, the network is weighted and thresholded using error backpropagation until the initial error of the network reaches the final state, which constitutes the final model of the BP neural network.

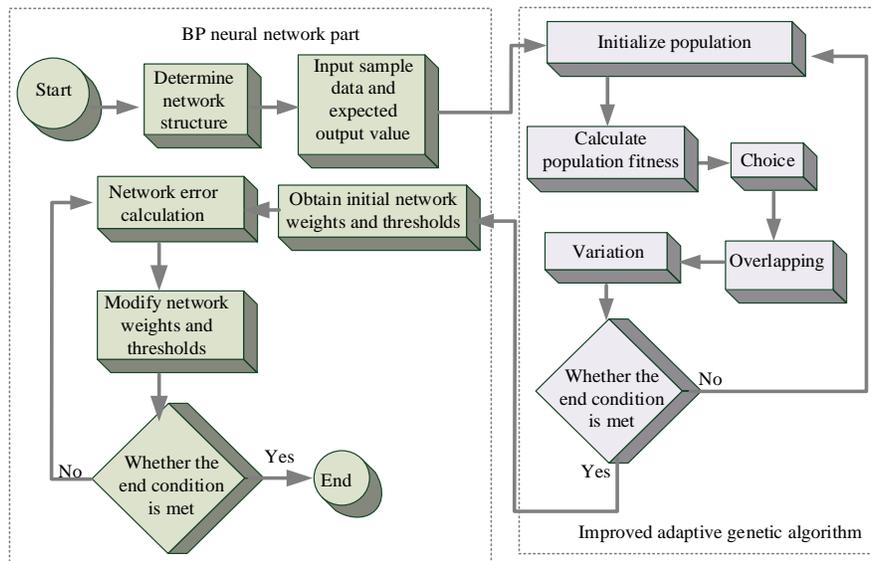

Fig. 5. BP Neural Network based on Improved Adaptive Genetic Algorithm.

#### IV. FOUR PREDICTION PERFORMANCE TEST OF BP NEURAL NETWORK MODEL BASED ON IMPROVED ADAPTIVE GENETIC ALGORITHM

An improved adaptive genetic algorithm was applied to a BP (Improved Adaptive Genetic Algorithm Back Propagation, IAGABP) neural network to create a predictive model of cyclist training load. The performance of the proposed optimization model is compared with the traditional BP neural network model and the traditional neural network model based on Adaptive Genetic Algorithm Back Propagation (AGABP). The topology of the BP neural network is set to 25-10-3, the target accuracy is 0.001, the maximum number of iterations is 1000, and the learning rate is 0.1. The initial population size of the genetic algorithm is 40, the maximum evolutionary generation is 25, and the prediction results are divided into overtraining, medium training and undertraining. The 5000 pieces of exercise training data recorded are selected as the training sample set, and the other 1985 pieces of training data are used as test samples. The comparison of the error accuracy between the BP neural network model and the IAGABP model is shown in Fig. 6(a), and the comparison of the fitness between the AGABP and IAGABP models is shown in Fig. 6(b).

From Fig. 6(a), it can be seen that the IAGABP model achieves the target accuracy of 0.001 after about 480 iterations, while the BP network model achieves this target accuracy after about 1000 iterations. The IAGABP model exhibits significant advantages and stability in the convergence process. This is because the improved genetic algorithm can obtain better initial weights and thresholds, thereby reducing the time spent by the BP neural network in the process of finding the optimal solution. It can be seen from Figure 6(b) that the fitness of the AGABP model is still unstable after 15 generations of evolution, while the fitness curve of the IAGABP model is gradually stable after 14 generations. The optimal chromosome fitness of the IAGABP model is compared with that of AGABP, improved by 0.24. The results show that the group search performance of the adaptive genetic algorithm can be improved

by improving the selection operator to obtain a better weight threshold.

In deep learning, the loss function curves of the three models trained on the dataset are shown in Fig. 7. The loss function of the AGABP model drops at the fastest speed, and after 20K training steps, its loss function drops rapidly to within 100. The curves of the AGABP model and the IAGABP model are basically the same, and the loss function fluctuates smoothly after 100K steps and remains in the range of 80-100. The loss function of the BP model decreases more slowly, within 120 after 60K steps, and the function value fluctuates between 100 and 110. To sum up, the curve of the IAGABP model is smooth and has good stability and accuracy. The precision-recall curves of the three models are shown in Fig. 8.

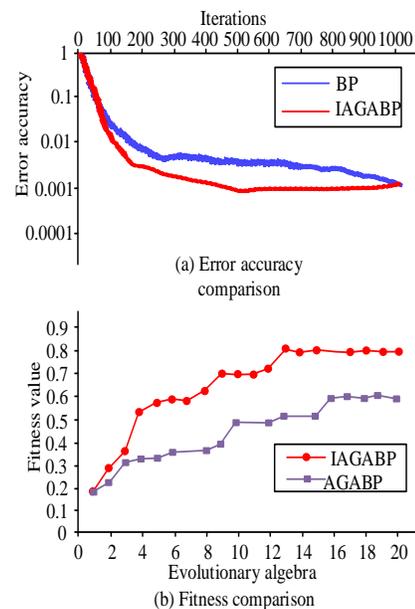

Fig. 6. Performance Test Comparison of Different Models.

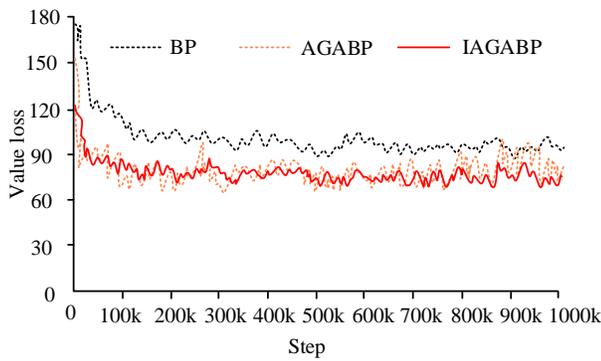

Fig. 7. Loss Functions for Different Models.

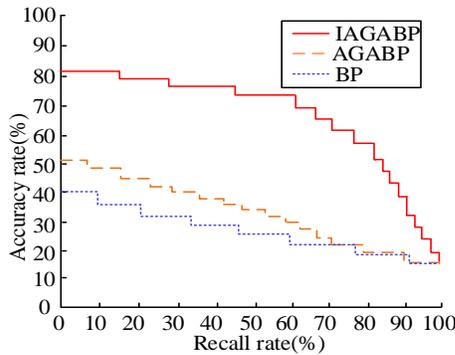

Fig. 8. Precision-Recall Curves for Different Models.

The precision-recall curve can be used to reflect the performance of the model on the task of retrieving similarity. It can be seen from Fig. 8 that the accuracy of the model decreases as the recall rate increases, in which the model IAGABP decreases at the slowest speed in the recall rate interval of 0-70%, and as can be seen from the figure, in this region the precision-recall curve of the model IAGABP is significantly larger than the other two models. This shows that the model IAGABP has the highest accuracy on the similarity search task on the same dataset. The prediction results of the three models based on 2486 test samples are shown in Fig. 9.

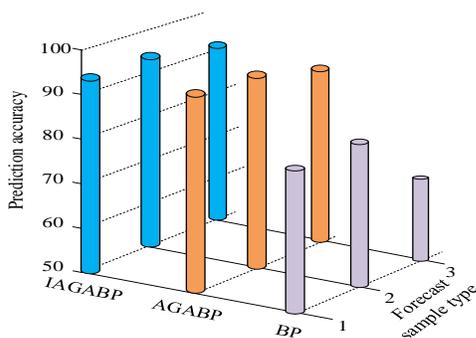

Fig. 9. Prediction Results of the Three Models.

The first type of prediction samples is the accuracy of a small number of trained test samples, the second is the accuracy of a moderately trained test sample, and the third is the accuracy of a large number of trained test samples. From the results in Fig. 9, it can be seen that the AGABP model improves the prediction accuracy by 9.55% compared with the BP neural network model. On the other hand, the IAGABP model with the

improved selection operator is 2.31% more accurate than the AGABP model. This shows that the BP neural network optimized by the improved genetic algorithm is superior to the traditional BP neural network in terms of prediction accuracy and performance, and meets the requirements of athletes' training load prediction.

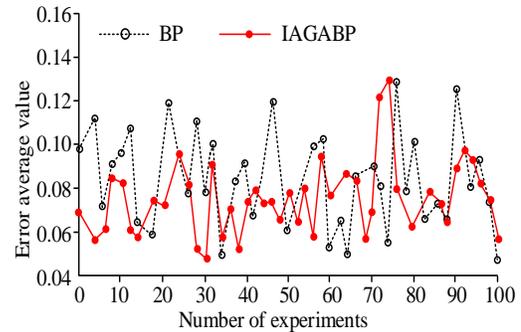

Fig. 10. Average Experimental Error.

In terms of fitting effect and prediction accuracy, the BP neural network based on the improved adaptive genetic algorithm has greatly improved the prediction accuracy. To further evaluate the predictive validity of the model proposed in the study, the study derives the average error of the model using 100 iterations, as shown in Fig. 10. It can be seen that the average error of IAGABP prediction is lower than that of BP neural network which is 0.0867, while the average error of BP neural network is 0.1175.

A comprehensive comparison of the above results shows that the improved IAGABP model has obvious improvements in error accuracy, model accuracy and prediction accuracy compared with the traditional BP model and the AGABP model. Compared with the traditional artificial exercise load index evaluation scheme, its innovation lies in that the IAGABP model is based on more advanced intelligent neural network technology, and performs secondary optimization on the basis of the traditional BP model, avoiding the local convergence of traditional BP and exercise monitoring data. The IAGABP model can realize real-time and effective detection of the physical and mental state data of athletes. At the same time, the relevant monitoring data will be analyzed and diagnosed through the network big data technology to provide athletes with more scientific physical training skills and opinions, avoid physical injuries to athletes, and improve the effect of sports training.

## V. CONCLUSION

With the development of big data, many sports are using data mining technology to determine the relationship between athletes' training load and physical fitness, which provides new opportunities for the development of national cycling events. Competitive sports informatization has become an inevitable development trend. Since many factors intervening in the relationship between athletes' training load and physical fitness show nonlinear relationship, this study designed a training load prediction model based on BP neural network as the basic algorithm. In order to further improve the accuracy and convergence of the BP network prediction model, this study

uses the adaptive genetic algorithm to optimize the initial value and threshold of the BP network, and improves the selection operator of the adaptive genetic algorithm. The results show that the BP neural network model based on the improved adaptive genetic algorithm has significant advantages and stability in the convergence process, and the algorithm can search for better weight thresholds. The accuracy rate of athletes' training load prediction is 95.76 %, the average error is 0.0867, which is 11.86% better than the standard BP neural network model, and the average error is 26.21% lower. This meets the requirements of athletes' training load prediction. This study can establish a scientific and reasonable bicycle training load prediction model based on the actual physical condition of non-professional groups, and provide an important reference for scientific sports training. However, there are also shortcomings in the research. Only the indicators of exercise routine training are considered, and the training environment, such as temperature and altitude, is not considered.

**Abstract**—Population growth has resulted in a decrease in readily available sources of potable water. Desalination is one of many approaches that has been studied and proposed as a way out of this predicament. In this study, multistage Reverse Osmosis desalination process is used in the model, since it has the potential to achieve a higher purity percentage than the single-stage RO desalination process. Some researchers have studied the distinctive tools of AI, specifically Artificial Neural Network as regression model and the genetic Algorithms as an optimization technique in the process of desalination and water treatments. This paper aims to examine multistage RO desalination by employing various artificial intelligence (AI) techniques, including Artificial Neural Network (ANN) and Support Vector Machine (SVM). Both training methods used for this research come under the category of regression algorithms, which are used to establish a predictive link between variables and labels. The main finding of this study was the noticeable decrease of Mean Square Error (MSE) in second stage when data was trained using the ANN. While on the other hand the MSE increased in second stage when the data was trained using the SVM. It can be concluded that the results of this research indicate that applying ANN and SVM to RO desalination process modelling would yield substantial improvements. Future work will be focusing on predicting and improving the performance of ANN and SVM prediction with other function variables.

**Keywords**—Artificial intelligence; artificial neural network; desalination; regression; reverse osmosis; support vector machine

## I. INTRODUCTION

The problems of water scarcity, which have plagued our world since ancient times, persist today. Clean water is becoming increasingly difficult to come by, and its quality is deteriorating to the point where it is being blamed for the deaths of people in some countries. The demand for and consumption of clean water would rise as a result of the fact that not only humans but also animals and plants require it [1]. The concern is also rising around the world because the current supply of fresh water is insufficient to meet the needs of the global population [2]. We live in a world that is 71% water, with almost 97% of that water held by oceans, yet we have a water shortage [3]. Through a variety of processes that scientists have tried to solve, desalination is one of the most common methods for converting salt water into potable water. Reverse osmosis (RO), which employs a specialized membrane, is a frequently employed desalination method.

Reverse osmosis desalination is a rapidly expanding and popular method used to produce water, and it now accounts for around 70% of the world's water supply.

Reverse Osmosis desalination is a method of separating brackish water from dissolved salts by pumping it under high pressure through a water-permeable membrane. Initially, seawater (brackish water) flows into a primary settling tank. This brackish water is then pumped into the reverse osmosis feed tank. Part of the permeate (clean) water and the strong concentrated brine solution is recycled into the water storage tank with the proper pressure, temperature, and feed [4].

Despite the outstanding performance, the application of RO has some limitations. Those limitations include high pressure required, high cost of membrane replacement, low permeation flux, low membrane durability, high equipment and operating cost that affects the process economically[3]. Therefore, ongoing efforts and studies are needed to be carried out to increase pure water recovery by developing new process configurations that use multi-stage RO and optimization processes (see Fig. 1).

According to studies [5][6] AI has proven to be a versatile tool for learning complex patterns. As explained in that paper, to learn those complex patterns it employs two methods, namely: supervised and unsupervised learning. The supervised learning algorithm is the most commonly used machine learning algorithm, in which a dataset trains an algorithm with known input and responses to make the desired predictions.

This supervised learning algorithm is further classified as Classification and Regression, with Classification being used when categorical response values are separated into specific classes. When you have numerical continuous-response values, you use Regression. According to [7] and [8] research papers, RO dataset responses which had numerical values were implemented, where the Regression algorithm was used for AI techniques. To train the data, they used the Artificial Neural Network (ANN) and the Support Vector Machine (SVM) as Regression algorithms [7]. Both of the techniques were implemented to analyze and compare the performance of the RO desalination process [9].

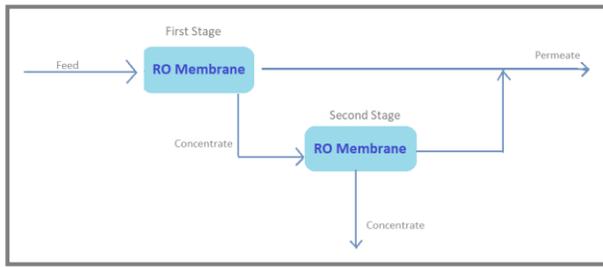

Fig. 1. Multi-Stage RO.

The RO process is used in this paper to convert brackish water to fresh water via a selected membrane. It also investigates how AI can be used to control the factors that contribute to this process. To achieve the best possible result, the various factors that affect these processes were managed using Artificial Intelligence technology.

In this study, a multi-stage RO process is used to achieve permeate water by inhibiting multiple RO membrane stages. This improves water recovery and reduces RO rejection. The concentrate water is collected in a brackish tank obtained from previous cycles, whereas the permeate water is collected in a water storage tank after passing through the multistage membranes.

## II. MATERIALS AND METHOD

In this research, a multi-stage RO process is proposed as a means to produce potable water. This research into its acquisition will consist of three stages. First, the study goes over the steps that are taken to collect information for the RO procedure.

For both steps of the RO procedure, the efficacy of data that has been trained using an ANN is discussed. Both sets of simulated data are used to train a Support Vector Machine (SVM) MATLAB will be used by these two AI methods to analyze the water quality that is achieved after several steps have been taken.

### A. Acquiring Data from Simulating Reverse Osmosis

Starting with a good simulator, the Reverse Osmosis process is run to get a feel for how it works. The ASPEN Plus platform was suitable for modeling the entire procedure because it provides a realistic insight by allowing the model to be fed brackish water and subsequently yielding clean water.

The information obtained from ASPEN Plus was useful because it mimics the physical RO process, as discussed in the prior study "Using Artificial Intelligence for Reverse Osmosis Desalination." In order to plan for and acquire the data, the actual effect of temperature, pressure, salt concentration, and feed flow rate would be studied and monitored [10].

While holding all other variables constant, a simulation in ASPEN Plus was run to determine the impact of each individual variable on the operation (see Fig. 2). For instance, in Table I, the effect of changing the pressure while holding the other parameters constant was examined in order to better understand the RO.

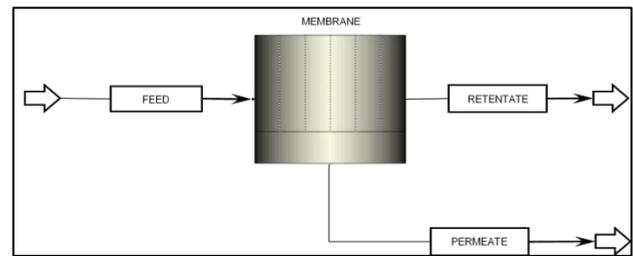

Fig. 2. Schematic Diagram of RO Membrane using ASPEN Plus.

Water flux and salt rejection are both influenced by the pressure that is applied, as shown in Fig.3 and Fig. 4, which depict the performance of stream pressure and the permeate flux, respectively. As can be seen in the graphs, there is a direct correlation between the water flux and the operating pressure. In order to verify the accuracy of the ASPEN Plus experiment and develop an algorithm to aid in the prediction of the parameters in the future, it can be fed into AI training tools. In addition, the AI tools investigate and make predictions about how various elements influence the quality of the membrane's output water (permeate).

A data set of inputs (temperature, pressure, and salt concentration) and outputs (percentage of pure water) is used to train, validate, and test the ANN and SVM tools.

### B. Maintaining the Integrity of the Specifications

In this part, an Artificial Intelligence method commonly referred to as an ANN is used to train the data that had been collected so far. An artificial neural network (also known as a neural network) is a type of adaptive system that acquires knowledge through the use of interconnected nodes or neurons arranged in a hierarchical framework similar to the human brain. Because neural networks are data-driven, they can be taught to perform a wide range of tasks, including pattern recognition, data classification, and event prediction [5].

TABLE I. RO MODELLING CONDITION FOR ALTERED PRESSURE

Parameters	Feed Water Temperature, 0C	Flow rate, m3/h	Feed Water Salt Concentration, g/l
	20	8	30

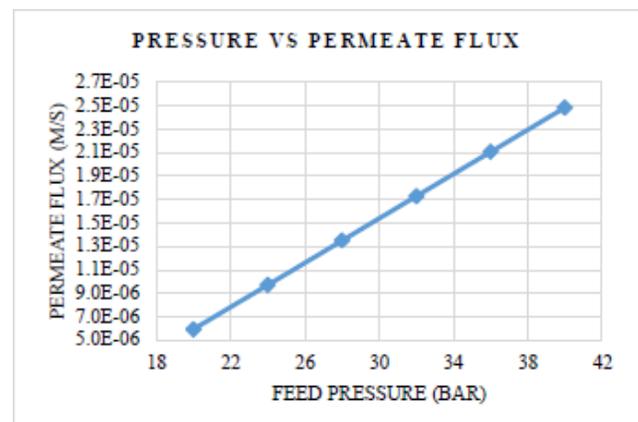

Fig. 3. Effect of Operating Pressure on Water Flux.

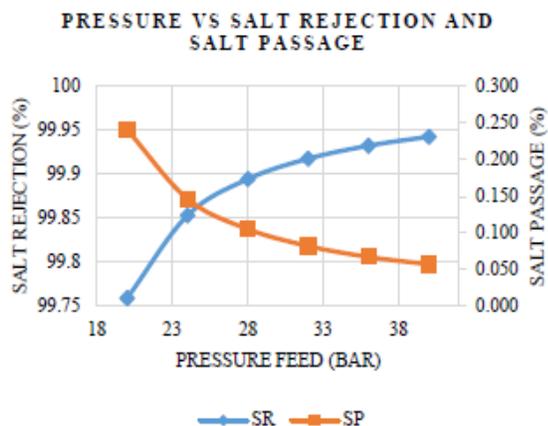

Fig. 4. Effect of Feed Pressure on Salt Rejection and Salt Passage.

In order to better process the input, a neural network can abstract it in layers. Similar to how the human brain learns, it can be trained with lots of examples to recognize patterns in things like speech or images. How its parts are linked together, and how strongly they are linked together (the weights), determine its behavior. During training, these weights are continuously fine-tuned in accordance with some predetermined learning rule until the artificial neural network achieves the desired performance level.

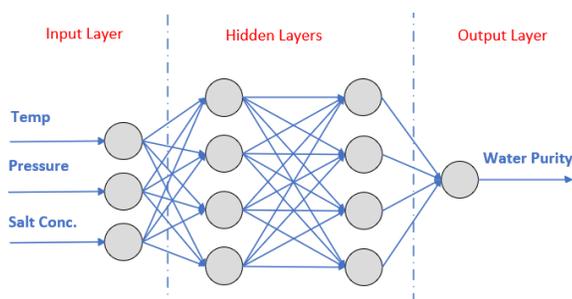

Fig. 5. Architecture of Artificial Neural Network.

The data collected by the ASPEN Plus is used for neural training. The learning technique is then used to train the data in two stages. This promotes to analyze and compare data in order to obtain clean water from the process and predict (Fig. 5).

1) *First stage data training:* In the first phase, the neural network is fed the three variables that together define the RO (see Table II). Those factors are heat, moisture, and saltiness. Training results can be obtained by treating the percentage of pure water as a response and the aforementioned variables as predictors. The initial stage included the implementation of a three-layer hidden layer. 70% was used as the training set, 15% as the validation set, and 15% as the test set. While the Levenberg-Marquardt training algorithm does require more memory than some other methods, it is typically the fastest training algorithm available. The weight and bias values are recalculated using the Levenberg-Marquardt algorithm. (Table III).

2) *Second stage training:* In this project, the Multistage Reverse Osmosis uses a two-stage RO process to obtain clean

water. Following the completion of the first stage RO process, the permeate received is subjected to a second stage RO process (Table IV). This improves clean water recovery while decreasing rejections from the second RO stage (Table V).

### C. Training With Support Vector Machine

In this section, the data acquired is going to use SVM to train and predict the purity of water using the RO process. Support Vector Machine (SVM) is one of the supervised learning algorithms that solves regression problems by learning objects and assigning labels.

As it is noted in [1] and [11], SVM's big data environment can be used to help applications with multidomain. Additionally, [12] has been popular as it is simple and flexible to address various classification problems, where SVM specifically affords balanced predictive performance [5]. The objective of this algorithm is to find a plane that maximize the margin between the training data, where to be optimized the hyperplane must yield a maximum margin. According to Fig. 6, the SVM selects the maximum-margin hyperplane which gives the highest accuracy of prediction [13] and [14].

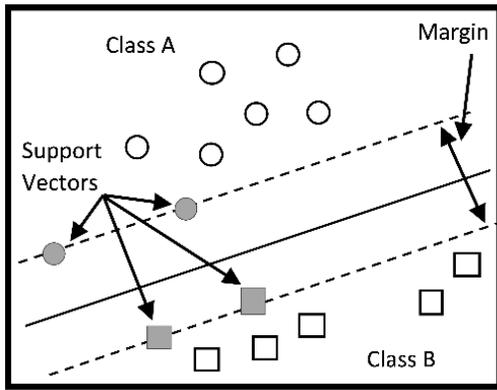

Fig. 6. Hyperplane Margin Selection.

The aim of this research is to predict the purity of water from the three features that determine the RO process. The ‘fittersvm’ function is used to fit an SVM regression model. It is used to cross-validate or train the data set on a low-through moderate dimensional predictor. This function uses kernel function to map predictor data.

The MATLAB R2021b version was used to train the SVR model as it offers a built-in function ‘fittersvm’ to train the given data sets. To get the SVR model, the right input parameters should be provided, such as the training set, kernel function, epsilon, and penalty coefficient. Similarly, the input for this RO desalination process temperature, pressure and salt concentration were given to yield the purity of water in percentage. Using the same ‘fittersvm’ built-function, MATLAB was able to generate the model for the first and second processes. The same data obtained from the ASPEN Plus simulation were used for the training process using the SVM algorithm.

### III. RESULT AND DISCUSSION

Two types of Artificial Intelligence techniques were used to analyze the performance of Reverse Osmosis desalination in this research. The ANN and SVM algorithms were used to compare the performance of the desalination process. The aim is to have an efficient prediction learning algorithm from both of the techniques [15]. The results obtained are viewed in two categories for the multistage RO desalination.

#### A. Analyzing Performance of Multistage RO using ANN

The results from the first stage RO of the variables for temperature, pressure and salt concentration is given in the ASPEN Plus simulation model again for the second RO stage to obtain data on the purity of water in percentage.

This result data is then taken and fed to the neural network software to be trained for prediction. In the second stage of the RO, three layers were implemented for the hidden layer. The data was divided into 70% training data, 15% validation data and 15% test data selected randomly. They were trained in the neural network to give out these results (Table VI).

The graph from Fig. 8 represents the performance of the Mean Square Error (MSE) with respect to each epoch the training of ANN undergoes in the first stage RO process. The MSE is achieved by calculating the mean of the square of the

difference between the actual and the ANN output for all the data points. It can be seen the best validation performance of this RO desalination process was achieved at the 35th epoch(iteration). In the model summary for the first stage (Fig. 7), information about the training algorithm and the result for each data set is presented for the inputs and outputs of the RO desalination process.

The second stage RO dataset of the variables for temperature, pressure and salt concentration is given to the ASPEN Plus simulation model again for the second RO stage to obtain data on the purity of water in percentage.

This result data is then taken and fed to the neural network software to be trained for prediction. In the second stage of the RO, three layers were implemented for the hidden layer. The data was divided into 70% training data, 15% validation data and 15% test data selected randomly. They were trained in the neural network to give out these results. The same Levenberg-Marquardt training algorithm was used in the second stage of training to receive the following results (Table VII).

TABLE VI. MODEL SUMMARY FOR STAGE 1 TRAINING

<b>Responses</b>	[Purity2]
<b>Data division</b>	Random
<b>Training Algorithm</b>	Levenberg-Marquardt
<b>Performance</b>	Mean squared error

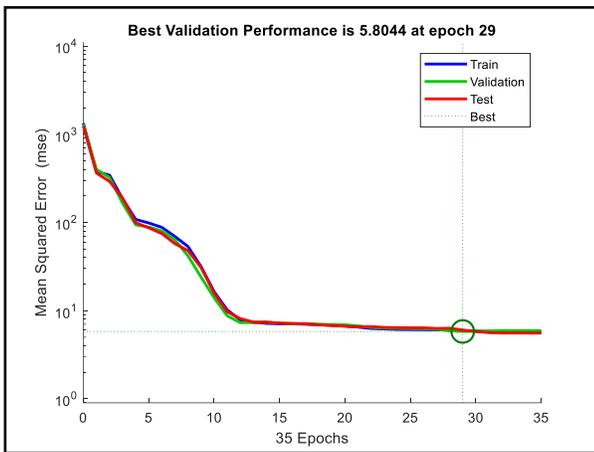

Fig. 8. Second Stage Best Validation Performance.

On the other hand, when referred to Fig. 10, it could be seen a graph plot of MSE vs epochs run to train the second stage RO desalination process using the ANN. As a result, the best validation performance of the second stage training was achieved at 29<sup>th</sup> epoch which was much better validation performance than the first stage training. The same data division and training algorithm was used to help in comparing both stages of the RO process which can be seen in Fig. 9.

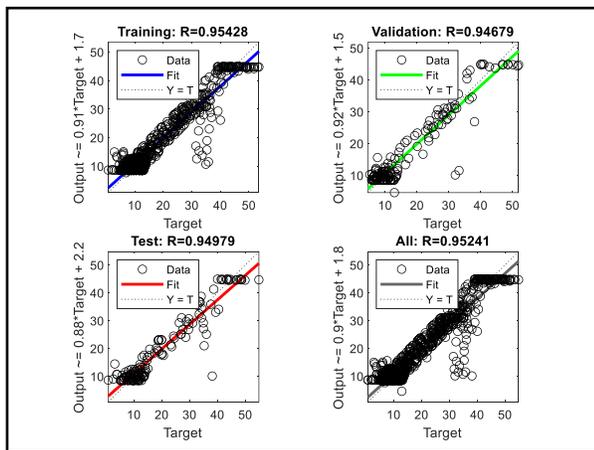

Fig. 9. First Stage RO Training Regression Plot.

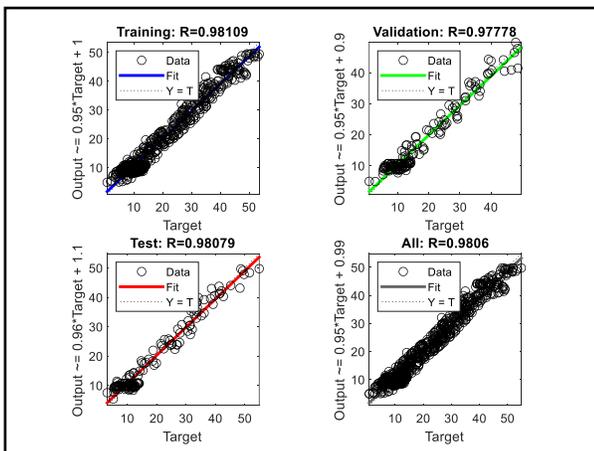

Fig. 10. Second Stage RO Training Regression Plot.

In Fig. 9 and 10, the regression plots can be seen to show the network prediction with respect to responses. Both these graphs test the relation between the actual output with respect to the target for training, validation, and test sets. In these graphs, it can be seen the output (from ANN) is very close to the target (actual purity of water from the process). It can be concluded that the close relationship between ANN output and target can be from the high correlation reflected in the R-value. Moreover, when the graphs are compared for the first stage and second stage, it could be seen that the correlation of the second stage RO process has good performance and would aid better in predicting more accurately.

**B. Analyzing Performance of Multistage RO using SVM**

The data from the first stage was loaded to MATLAB workspace to go on with the training process. It was trained using a standardized data. This means the software centers and scales each column of predictor data(X) by the weighted column mean and standard deviation. This trains the model by a standardized predictor matrix, while storing the unstandardized data in the model property X. Moreover, the convergence information of the model was set to 'Converged'. When computed the optimizing routine of the Solver was found to be 'SMO' (Sequential Minimal Optimization) and the mean-square error of the model was 0.2630. Each element of the initial estimates of alpha coefficients corresponds to an observation in X. As the Alpha cannot contain any NaNs, it can be observed the model had run properly as it listed all elements (Table VIII).

The data from the second stage RO process was also loaded into MATLAB and trained using the same SVM (Table IX). Temperature, pressure, and salt concentration were all grouped together and trained to produce water purity. This dataset was trained with the 'fitsvm' function and the 'Standardized' model training method [16]. The computed mean square error of the second stage was 1.0451. The resulting epsilon, known as half the width of the epsilon-insensitive band, stores a nonnegative scalar value of 1.2149. Because the Standardize option was set to true during training, the Mu value is also provided, with the length equal to the number of predictors.

TABLE VIII. FIRST STAGE SVM TRAINING

Property	Value
Epsilon	0.9032
Solver	'SMO'
Bias	17.9891
Kernel Parameter	Linear function, scale 1
Alpha	[1;1;0.572330238305089;-0.275138601731484;-0.297191636573605;-1;-1]
Beta	[-0.001485696802116;9.495296357877216;-3.931750668547228]
Mu	[23.555762711655710,23.548202705561412,28.190442046205046]
Sigma	[5.977559943498434,5.982586319655137,5.794770001389037]

TABLE IX. SECOND STAGE SVM TRAINING

Property	Value
Epsilon	1.2149
Solver	'SMO'
Bias	17.74008
Kernel Parameter	Linear function, scale 1
Alpha	105 x 1 double
Beta	[-0.013834278784691; 0.362070130142010;11.741070351439940]
Mu	[24.765164217883978,28.057443299385262,37.792 550502075830]
Sigma	[6.400203608352864,2.922463103239594,5.838943 078299873]

After training the first and second stages of RO desalination with cross-validation SVM, the results for both sets were displayed in Tables VI and VII. When trained with the 'fitsvm' function, the Mean-Squared Error of the loss function was measured for both stages to evaluate the performance of the training. The MSE for the first trained model was 0.2360 and for the second trained model it was 1.0452. This indicates that the output obtained from the first stage of RO desalination training is more similar to the actual output, as it has a lower MSE than the output obtained from the second stage of training. Although the MSE of the second stage was found to be slightly higher, it could be trained to predict the actual water purity when given the correct RO desalination process parameters.

#### IV. CONCLUSION

This paper used Artificial Neural Network and Support Vector Machine algorithms to train multi-stage Reverse Osmosis desalination data. Both techniques used ASPEN Plus simulation data to predict the entire RO process. ANN trained RO's first and second desalination stages. Training resulted in a high correlation between actual and obtained output and increased water purity.

The trained ANN predicted multistage RO desalination well given the inputs. The SVM can train and predict multistage RO desalination. It used ASPEN Plus simulation data. ANN had a higher classification and prediction rate than SVM despite its shorter execution time. ANN outperformed SVM with multistage RO alignment based on AI function implementations.

This study signifies that the use of Artificial Intelligence techniques could bring ease of processes if implemented well. In this case, the multi-stage RO process was made to be trained both using the ANN and SVM to determine the prediction of water purity. Both techniques would yield an accurate prediction rate based on the data fed previously but exhibit slight differences on their output. This research aimed to study what the differences are amongst both techniques and help determine which to implement on the research. MSE, regression correlation, and other functions can be used to compare the two stages of RO desalination. These findings from training the collected data using ANN and SVM could lead the research to further use other training models on future work to find the best training model that would align with the multi-stage RO process. Future research could focus on predicting multistage RO desalination properties and factors

using ANN and improving SVM prediction performance. Moreover, the exploration and validation of new prediction techniques for different applications could be of great importance for future research.

#### ACKNOWLEDGMENT

We are appreciative to Higher Colleges of Technology for funding this study and allowing us to use their resources. The funding for this study came from HCT Interdisciplinary Research Grant Fund No.97960.

**Abstract**—Current smartphones meet all the criteria for university application. This technology opens the door to develop new techniques to enhance teaching methods. In addition, it presents an interest solution for students' guidance and helping. Thus, the idea of this proposal aims to provide a platform around smart phone based on android to help student and teachers managing their courses. It is based on the Internet of Things to increase digital interaction and improve the teaching process while delivering traditional lectures. The system encompasses three main parts. The first step is carried out for guiding students to find their classroom and teacher's desk. The second part was developed to help teachers to monitor the attendance of students. The third part is dedicated for improving e-learning in classroom by managing the educational process with the purpose of providing the adequate platform for data management. The platform, therefore, succeeded to provide the adequate solution to prevent the misuse of smart phone in classroom, and to enhance the learning methods using smart technologies.

**Keywords**—Android; classroom; e-learning; data management; IoT; smartphone

## I. INTRODUCTION

Today, smartphone immersion phenomenon of almost all students becomes a critical problem from an educational point of view. Obviously, the presence of a mobile phone decreases performance during and negatively affects the ability to concentrate. Unfortunately, smartphone can be a tool for students' distraction. Social Medias are among reasons that cause lack of course follow-up. Gowthami, S., and Kumar, S. V. K, discussed the factors that lead the loss of concentration for students in classroom, such as, the use of smartphone for chatting, playing online and checking e-mails [1]. In addition, Masadeh, T. S. Y, tackled the same problem of students' distraction in classroom by providing the barriers of using smartphones [2]. Furthermore, another research analyzed four hypotheses for the effects of smartphones usage of different cultures including, distraction, addiction, the non-usage of smartphones and the effects of female users [3]. This research conducted to prove the defects of using smartphone in classroom. In addition, Al-Furaih, S. A., & Al-Awidi, H. M. proved the disengagement cause of students when using their smartphones in classroom [4]. Otherwise, a research focused on the use of smartphone even in online courses, proved that students who learn using their smartphone showed a stronger negative effect in academic performance [5].

According to this brief analysis, these factors lead to ensure compliance with the rules and the law. The use of telephones is prohibited in class. It's a way to protect students from loss of concentration due to tablets and phones. Should you or shouldn't you have your cell phone at university? The question, which is a matter of discussion in many universities in the country, leads to a larger problem.

In fact, prohibiting students of using smartphone presents a real challenge. This leads to study the aspects of using smartphones in the classroom, to propose solutions to turn the smartphone into classroom aid. UNESCO in a series of documents on mobile learning paints an excellent portrait of the perceived advantages and disadvantages of using mobile devices in a learning context. Two documents are particularly interesting, namely Policy Guidelines for Mobile Learning [6] and Turning on Mobile Learning in North America: Illustrative Initiatives and Policy Implications [7]. They highlight a number of pedagogical benefits, but also more personal benefits to the use of smartphones in the classroom.

- Possession of a mobile device in the classroom would make it possible to personalize learning by offering the flexibility to pace one's learning and to learn according to one's preferred mode [8].
- Mobile devices in the classroom would facilitate immediate feedback and assessment by leveraging the interactive capabilities of the devices [9].
- Mobile devices would promote productivity and active learning by maximizing the time spent in class and moving away from more passive modes of knowledge transmission [9].

UNESCO also addresses barriers perceived by policy makers and teachers to the use of mobile devices in the classroom for educational purposes [10].

- Issues of behavior and civility are often raised.
- The disruptive and distracting nature of AMCs. For example, a 2013 research report demonstrated that the use of laptops in the classroom can impact concentration and learning both for the student they use it and for the students who are close to the user [11].
- The heterogeneity of mobile devices and the size of screens can be a barrier to their use in class.

\*Corresponding Author.

Thus, applications around Smart phone should be developed to prevent its misuse. Incorporating technology into education is a great way to actively engage students, especially as digital media surrounds young people in the 21st century. Interactive white boards or mobile devices can be used to display images and videos, which help students visualize new academic concepts. Learning can become more interactive when technology is used as students can physically engage during lessons and instantly research their ideas, which develops their autonomy.

Therefore, many searches were well developed to include technologies in classroom [12]. These led to prove the reliable ways to use smartphone in classroom preventing its misuse. Here, G. McKinley reviewed the benefits of using smartphone in classroom and how it can be a source of distraction [13]. Therefore, it is pivotal to extract the application of smartphone to be used as learning aid such as, incorporating multitasking by smartphone in order to prevent the blank time [14], accessing supporting information or teaching materials [15].

These projects led to develop application around the smartphone for the real time interaction in classroom, which is the main objective of the proposed idea. It is aimed to turn the smartphone as a learning aid in classroom. The proposed application provided a reliable platform for e-learning improvement. It guides new students to find their classroom or teacher's desk, it helps teachers to monitor attendance of students automatically, it helps students to download daily courses and follow-up from their smartphones and it offers the possibility to perform chatting group for classroom activities.

## II. RELATED WORKS

The use of mobile phones in education is both a controversial and fascinating subject. For many, these devices appear as inconvenient objects in the classroom, which disrupt the smooth running and promote the dispersion of the concentration of the students. In addition, there are charters, internal regulations, which explicitly mention the prohibition to bring his telephone in the enclosure of the school establishment, which in the effective uses results in a use outside the courses. This idea is very beneficial during distance learning, which was relied heavily in the period of COVID-19 pandemic. In some reasons, the classroom can be accessed from home relying on interfaces of virtual classroom, including, course materials and homework [9]. In fact, this period proves the efficiency on using technologies in classroom. As cell phones continue to advance in power and functionality and prove their usefulness as an educational tool, the inherent limitations of these technologies should not be ignored. Already not everyone trusts the digital revolution: the supporters of the traditional school and the blackboard are of course opposed to it, but also the defenders of alternative education systems in which the press has often been interested in recent years. More and more voices are raised against these innovations which aim to impose the intensive use of digital technology in schools [16]. Thus, introducing smartphone in classroom is critical, that lead to develop the adequate application and systems around this device. This maintains the advantages of using smartphone in classroom as aid tool. K. Machmud, et al. developed a fruitful method to overcome the

anxiety related to whom learning English as foreign language [17]. In this contest, the use of such application like "Let's talk" can be useful to practice English language [18]. In addition, several applications around smartphone support the theory of using this device in classroom can be beneficial [19] that help to manage course materials. Otherwise, smartphones' applications can be used for attendance monitoring in classroom [20]. In fact, almost applications tackled some aspects of effective uses of smartphone in classroom. This led to develop an application around the smartphone which encompasses the management of attendance, assessments, and course materials management, focusing on students' interaction in classroom using their smart devices.

## III. SYSTEM ARCHITECTURE

Fig. 1 presents the entire system's architecture of the proposed application.

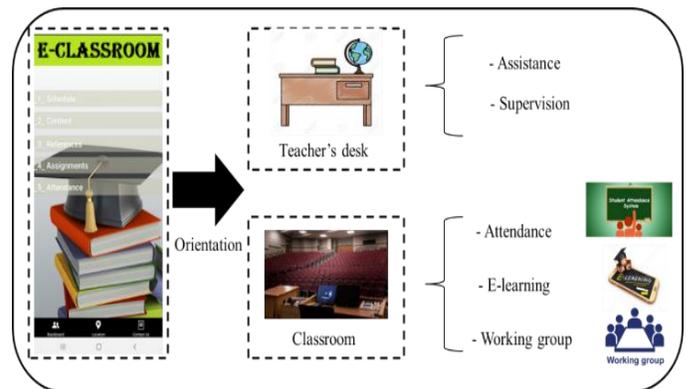

Fig. 1. System Architecture.

The first step is carried out for students' guidance. The student login with his university ID. The application, therefore, moves to the second step by guiding the student to the teacher's desk for assistance or the classroom for attendance. Here, the application provides a new technique to facilitate hand over the assignment. In fact, the Google map was applied to achieve this goal as illustrated in the application interface under the item "location".

The third step will be performed when student find its classroom. It is a great platform to improve techniques of e-learning and attendance monitoring. This technique confirms that the student is part of this course and records the entry time. When the confirmation is done, the application enables student to participate at the course interface which contains the lecture. In addition, it provides the possibility of making discussion groups when assigning activities. Thus, this method offers a new technique to improve e-learning and to use technology to fully engage student physically during the lesson.

## IV. METHODOLOGY

In order to ensure the feasibility of the proposed architecture, a multilayer structure was adopted as shown in Fig. 2. The application structure is composed by three layers, including, main, data service and data analysis layers.

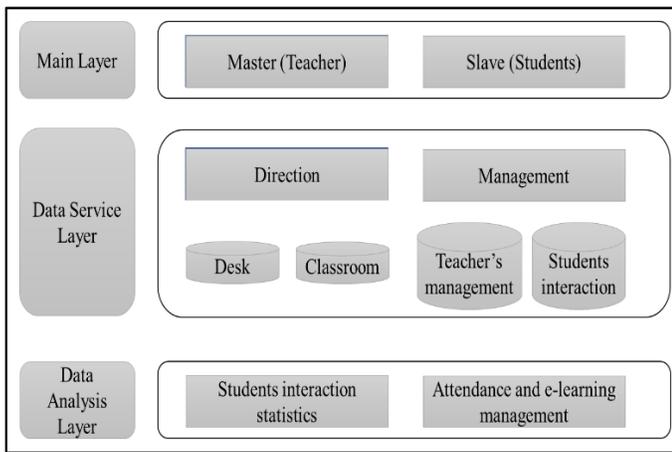

Fig. 2. Multilayer Structure of the Application.

Fig. 3. Application's Interface.

The main layer presents the application's parts, which consists of master-slave architecture; the master (teacher) manages the students' interactions during classroom lesson.

The second layer is composed by the services of the application provided. It is adopted here to aid students for attending their classroom and/or teacher's desk. When student attend his classroom, he will benefit by the system of e-learning maintaining the objective of interaction during the lesson, which will be managed by the teacher.

The last layer ensures the connectivity of the data for analyzing of its statistic.

Based on the smartphone application, this platform encompasses the real-time classroom interaction and evaluation of learning quality. The main parts of the system include teacher data management, student response management, and data statistical analysis, as explained below.

- Teacher data management includes data import, question and exercises management, students' answers, etc.
- Student answer management, including, teacher's exercise answering, submission, results displaying, etc.
- Data analysis including statistical analysis of learning situation, of student attendance, of marks, etc.

## V. IMPLEMENTATION AND RESULTS

The platform is implemented based on iBuildApp [21]. The data stored in the server provided by this application. The main interface of the application is presented in Fig. 3. It helps students to attend their classroom. It contains the lessons schedule, the content which will be available upon attending, the course references and assignments that depends on needs.

The application was applied for computer sciences' students of first level. The number of participants reached 25 students. For accessing the platform, students should login with their university ID. Therefore, the teacher can manage attendance easily. In addition, he can hold statistics of students' participations in assignments.

Upon student logs in to the platform, he can upload the content of the course as mentioned in Fig. 4.

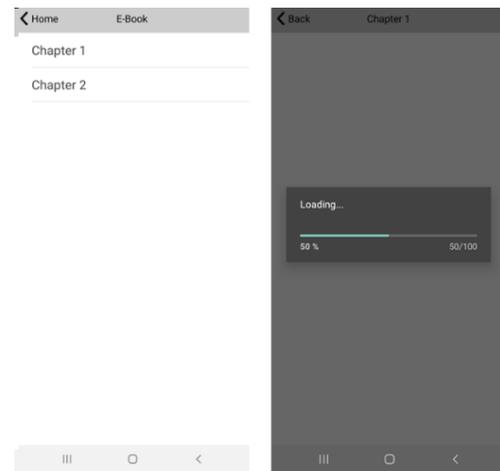

Fig. 4. Course's Content Uploading.

Indeed, the method proposed for accessing the content from the smartphone imposes students to use their devices for learning in classroom. It is proved by the statistics accumulated by the master's platform (Fig. 5).

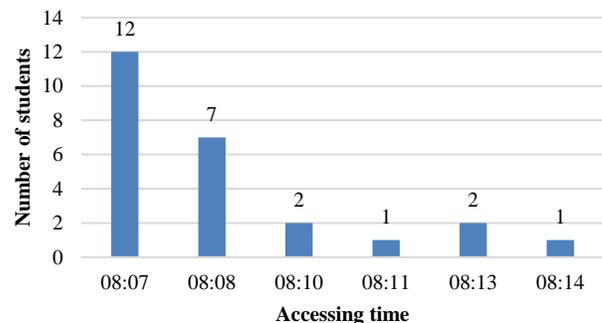

Fig. 5. Content Accessing Time by Students.

The upload of content by students takes about 7 minutes. The time spent is caused by the internet connection for some students. Basically, almost of all students were succeeded to upload the content autonomously. Indeed, the result proves the possibility of transferring the pocket smartphone on classroom aid, without the need of providing training. Otherwise, the master's platform was developed to monitor the participation of students during the lesson, including the online/offline identifications.

In order to fully benefiting the use of smartphone, 8 exercises were conducted for students' evaluation and for applying the teamwork. The exercises were distributed for 8 groups of students. According to Fig. 6, almost all students actively participate in answering assignment. This proves the good effect of students' interaction using this platform. Based on this platform, the student interaction in class was significantly improved. When comparing with the traditional methods, the proposed platform is more efficient.

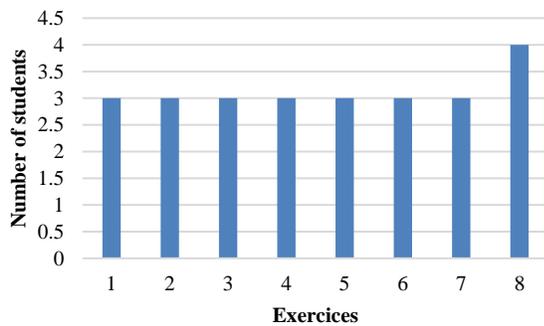

Fig. 6. Groups of Students by Exercises.

To demonstrate the efficiency of the proposed method for teamwork, the master's platform was developed to provide assignments' marks by application. In fact, the instantly evaluation encourages students for interacting. In addition, this method improves the feedback.

## VI. DISCUSSIONS

The application was conducted to ensure the adequate evaluation of students preventing the misuse of smartphone in classroom. Thus, the evaluation was performed in three steps: At the beginning, the mid and the end of course.

### A. The Evaluation at the Beginning of the Course to

- Become aware of the initial level of the students, so as to adapt their teaching according to their achievements.
- Starting from their devices management to ensure benefiting the platform.
- Engage their interest by asking a cryptic or problematic question.
- Recall, remember, the concepts covered in the previous session.

In fact, smart devices and tablets have invaded markets, homes and even schools, and it has become necessary to take advantage of these modern technologies to benefit the students

in their academic achievement, especially if taking into account the motivation shown by most of them to use their personal devices in the classroom and the long time wasted in front of them. Thus, the quick response of platform accessing by students proves the efficiency of using the proposed application with the targeted users, and to adopt smartphone in classroom. It took all students to get in and start learning about 7 minutes (Fig. 5). In addition, students' enthusiasm for using their devices was noted. It is proven by the participation of students in recalling the main parts of the previous lesson. This ensures that students remain fully focused during the lesson.

### B. Mid-Course Assessment for

- Maintain students' attention.
- Make the student active and actor, he participates in his learning for a better appropriation of knowledge.
- Foster discussion and collaboration among groups. They can be asked to think and answer a question.
- Engage all students.

As the students' aspiration to everything technological facilitates the process of their response to the lessons, and then consolidates the educational materials for them in the long run.

In fact, the use of mobile phones in classrooms may result in many problems and inconveniences, especially in light of the predominance of the negative nature of the use of them which is represented in violating the rules of the education system. During the class, isolation from the teacher, sending and receiving messages, exchanging information, and joking with each other, which can lead to a lower level of academic achievement among students. Thus, the master platform was developed to ensure the connection during the lesson. An indicator assigns the log out of student if he opens another application. In addition, the developed platform broadcasts lectures and discussions in a sophisticated way that students can interact with each other and with the teacher. This prevents the misuse of smartphone in classroom, providing the adequate solution to engage students.

### C. The Evaluation at the End of the Course for

- Check the students' understanding and be able to readjust their teaching the next session if the concept has not been well understood. It can be a question or an application exercise.
- Promote the recall, and therefore the appropriation, of the main concepts that were discussed during the session.

Regardless of the wide controversy that characterizes mobile education and the differences between academics and those interested in educational affairs around it (mobile education between supporters and opponents), technological development imposes itself on everyone, especially if it is accompanied by great interest and knowledge on the part of the center of the education process, who are the students.

Indeed, the proposed idea succeeded to build a knowledge system, in which the features of the image of mobile learning technology, its environment, characteristics, and benefits

become clear. It is based mainly on telecommunications, so that the learner can freely access educational materials, lectures, and assignments in order to be an active element in the educational process.

Finally, the marks achieved by the students at the end of assignment proved the success of the applied educational process (Fig. 7). It is proved that all students were engaged during the lesson. Reviewing and evaluating the duties and achievements of the students, presenting the results of the assessment and providing feedback to the students, contributed to further enriching the advantages of using the smartphone during the lecture.

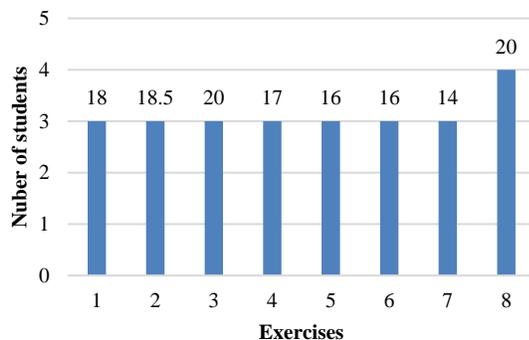

Fig. 7. Assignment's Marks.

## VII. CONCLUSION

Smart devices have become necessary to exploit these modern technologies for the benefit of students in their academic achievement, especially if taking into account the motivation factor that most of them show in using their personal devices in the classroom. In fact, the cost of this technology is relatively low; education by mobile phones will not cost students additional financial burdens.

In this paper, a novel technique was applied using this smart device in order to be the main tool of the educational process in classroom. Thus, an application around Android platform was developed to achieve the idea's goal. It provided many layers for teachers to manage their classroom, and the possibility for students to be active element in the educational process.

In addition, the method of assignment answering and evaluating led to the success of adopting smart phone as educational tool in classroom. Adding more activities to the traditional lessons led to the attractiveness of the scientific material and the learning environment.

This platform, therefore, can open the door to develop more applications around smart phones for other courses.

# A Novel Architecture for Community-Sustained Cultural Mapping System

Chong Eng Tan, Sei Ping Lau, Siew Mooi Wong

Faculty of Computer Science and Information Technology  
Universiti Malaysia Sarawak (UNIMAS), 94300, Kota Samarahan, Sarawak, Malaysia

**Abstract**—This paper presents a novel system architecture for implementing a cultural mapping system for the community of Buayan, a remote rural village in Sabah, East Malaysia. By considering various shortcomings of the local environment and the need for a community-sustained system, the cultural mapping system was designed to leverage a new set of architecture to achieve minimal implementation cost and higher reliability to survive the rural environment. The new architecture evolves from previous Telecentres' design and implementation experience that was targeted at larger scale ICT systems. This paper also highlights the critical influence of power provision on the digital system implementation in rural areas, which always incurs a significant amount of the overall implementation cost. An efficient ICT system architecture will significantly reduce the cost of its associated power provision. The implementation of the cultural mapping system using the new ICT architecture at Buayan is also being described.

**Keywords**—Rural system architecture; telecentre; cultural mapping; sustainability

## I. INTRODUCTION

Modern Information and Communication Technology (ICT) advancements have made thousands of online services possible, and the well-established cloud architecture has also enabled more and more highly accessible cloud-based services. The high speed and massive deployment of various means of communication networks, such as optical fibre and mobile cellular data networks, allow access to online systems anywhere and anytime. While the developed world moves rapidly to offer more comprehensive solutions by integrating different services, remote rural places in other parts of the world still struggle with basic amenities and communication access. The development of these remote places can never be treated as equal, as the same online services may not be practical for those living in these areas. The digital divide gap between the rural and urban areas can get more prominent, especially when infrastructure development is driven by commercial entities based on return-on-investment (ROI). The relatively small rural population can be a disadvantage in obtaining the same level of infrastructure development. Due to the different levels of readiness in basic infrastructure, deploying digital systems in remote rural areas would require a more rural-friendly architecture to achieve a more practical and sustainable system implementation in such an environment. In this paper, we describe our work on designing, prototyping, and deploying a custom-made cultural mapping system for the community of Buayan, a remote village in East Malaysia. The village is located at the edge of

mobile network coverage, where the overall network connectivity is relatively poor and slow. On top of that, the relatively inconsistent micro hydropower system used in the village adds a further challenge to deploying service hosting that requires a stable and consistent power source. Hence, we proposed an all-in-one architecture solution inclusive of power, ICT system, and cultural mapping software application that enables the local community to better self-sustain. The proposed architecture is tailored to the Buayan environment and is a smaller-scale version of our previous work on Telecentre design [3]. Apart from enjoying the common benefits of cultural mapping, the Buayan community has another more crucial intention: to inventory the local cultural heritage and community living continuously. These efforts enable the community to better inform the authorities in support of their fight to protect the local heritage and live against the planning of the mega-dam project in the same area. This paper is organised by highlighting the need for cultural mapping in Buayan in Section II, and followed by background on rural ICT system deployments for rural areas in Section III. Section IV summarises the important challenges of ICT system implementation in rural areas that lay the design foundation and consideration for the proposal of the cultural mapping system architecture in Section V. Section VI describes the actual system implementation in Buayan.

## II. NEED FOR CULTURAL MAPPING

Cultural mapping is a systematic approach to identifying, recording, classifying, and analysing a community's cultural assets and resources [1]. A software system has been developed to assist with cultural mapping activities for the community of Buayan. Buayan is a remote village in the Ulu Papar region of Sabah in East Malaysia. Although the Dusun people have inhabited the area for at least six generations, the record of their cultural assets and resources has been minimal and incomplete. Access to Buayan requires going through the Crocker Range of a mountain on a bumpy drive. The journey during the monsoon season can be very challenging, even for the most powerful 4-wheel drive vehicles [2]. For the past ten years, the government has had plans to build a hydropower dam that would flood everything, including all cultural heritage within the area. Hence, the villagers have been working hard to convince the government to change the plan for the hydropower dam by justifying to the government agencies the rich heritage and the vast community activities within the sites. The cultural mapping system came in to ease the process of identifying and recording cultural assets of the Buayan community. The cultural mapping system is an

independent system that manages, maintains, and keeps all data locally for the community's sole interest. The community's concern for data privacy is one of the primary considerations of the cultural mapping system design to prevent a third party having ownership or access to the data that might be used against the community itself. As a result, the entire cultural mapping system will be hosted locally within Buayan and accessible only to the Buayan community. In order to achieve such a goal, a robust ICT system architecture must be designed and developed to support the cultural mapping system that is sustainable by the local community in such an environment.

### III. BACKGROUND

For the past two decades, the most promising solution towards bridging the digital divide in rural areas has been to erect Telecentres in strategic locations to enable various computer and communication services to serve the surrounding populations. The development of telecentres enables ICT services in the middle of nowhere and acts as a social and economic development centre for the local communities. The complete computer systems, printers, and telephony connected through Very Small Aperture Terminal (VSAT) satellite communication links have made electronic communications such as the Internet and email possible for rural communities. The initial design of telecentres was simply to deploy existing urban computing and communication architecture into rural areas; thus, such deployment is typically very expensive because the telecentre architecture must include a complete power supply infrastructure solely to support the day-to-day operation of the entire telecentre. The eBario Telecentre, deployed in 2002 for the Bario community at the Kelabit Highland in East Malaysia [3], adopted this design. Its power supply infrastructure is a hybrid diesel power generator and a standalone solar power system. The overview of the eBario Telecentre architecture is shown in Fig. 1.

The solar power system was backed by the diesel power generator when it could not provide sufficient power to the

Telecentre. As the cost of diesel and transportation rises year after year, more solar panels and batteries are added to compensate for the reduction in diesel power generators. The battery sub-system of the solar power system has also undergone replacement after five years due to wear and such replacement was very costly. The battery replacement could cost as much as 50% of the entire solar power system implementation due to the conventional solar power system using multiple high-capacity lower voltage modules to form the specific battery bank required by the solar power system. For example, a 24V solar system would require 12 units of 2V battery modules to form a 24V battery bank needed for the 24V solar system. For a 500Ah battery bank, 12 units of 500Ah deep cycle Seal Lead Acid (SLA) are required, and each battery unit can weigh up to 130kg. As a well-known fact, transportation into the rural area is already very costly, and Bario can only be accessed via air during deployment time. Transporting such batteries into Bario requires a Twin-Otter cargo plane into Bario. The biggest drawback of adopting the urban ICT architecture for rural deployment will be the overwhelming requirement for power supply. Table I shows how much the national grid and the standalone solar system cost for the same average daily energy use of 13 kWh.

TABLE I. COMPARISON OF ENERGY COSTING FOR THE SAME AVERAGE DAILY USAGE OF 13KWH BETWEEN THE STANDALONE SOLAR POWER SYSTEM AND THE NATIONAL POWER GRID

Estimated Energy Usage	
Daily usage: 13kWh (six 250W personal computers with eight daily hours of operation) Total usage for ten years: 46,800kWh	
Energy Costing	
Standalone Solar Power System	National Power Grid
First 5 years + initial installation (4kW Solar): RM180k	RM7k (based on RM0.30 per kWh)
Next 5 years (battery replacement): RM50k	RM12k (based on RM0.50 per kWh)
Total expenditure for ten years:	
RM230k	RM19k

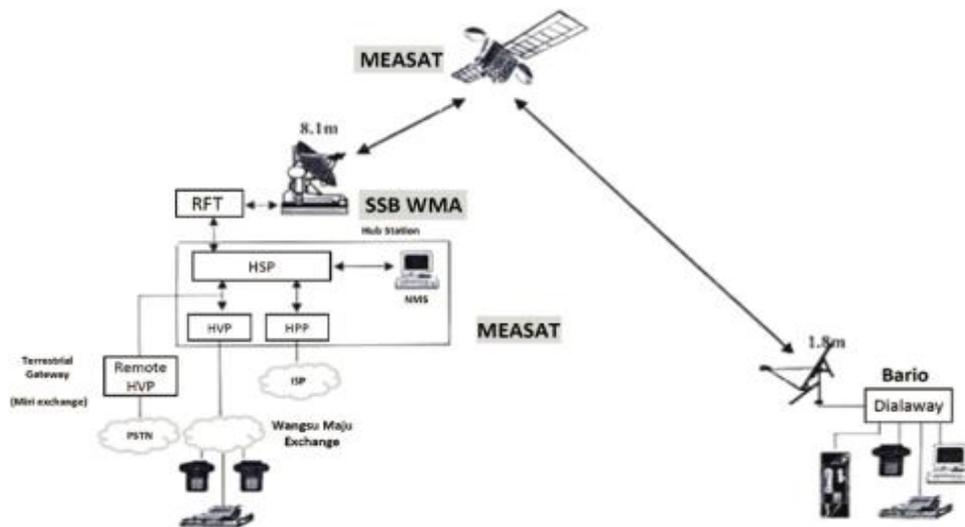

Fig. 1. The eBario Telecentre Architecture [3].

The above comparison shows that the energy cost for 10 years while using the national power grid is less than 10% of the total investment of deploying a standalone solar power system. The rural areas have no access to the national power grid, so the standalone solar system is the only viable power option. Therefore, power provision contributes to a significantly high percentage of the overall ICT implementation cost in rural areas. The overall cost of the solar system is determined largely by its designed power capacity. The higher the power requirements, the more expensive the system is. This includes the higher cost of transporting more solar panels, batteries, and supporting structures into rural areas. Hence, in order to reduce the overall rural ICT deployment cost, a more power-efficient ICT architecture is crucial.

The newer Telecentre model, deployed for rural sites such as Long Lamai, Ba'Kelalan, Buayan, and Larapan in East Malaysia in 2009 [4], has included an upgrade to a more power-efficient computing hardware platform. Instead of adopting conventional desktop computers with energy-hungry cathode-ray tube displays, the new Telecentre model adopted a mixture of energy-efficient desktop computers with liquid crystal displays (LCD) and laptop computers to strike a balance between energy efficiency and hardware cost. Fig. 2 shows the improved eLamai Telecentre computing platform. Portable computers, such as laptops, were still relatively expensive, and mobility of computers was not required by the Telecentres during the time of implementation. With the new computing platform, the average daily energy consumption was a mere 3kWh. This figure shows a significant reduction in energy consumption of about 10kWh per day compared to the previous Telecentre implementation. This reduction would bring down the standalone solar system deployment to as low as RM60k instead of RM230k, as shown in Table II. Hence, the overall maintenance cost could reduce almost three times compared to the previous eBario Telecentre. In the actual eLamai Telecentre implementation, a 4kW solar system was deployed instead of the estimated 3kW system to provide power for other appliances' usage.

TABLE II. COMPARISON OF ESTIMATED OPERATING COST BASED ON THE NEW eLAMAI TELECENTRE'S SOLAR POWER SYSTEM AND THE NATIONAL POWER GRID

Estimated Energy Usage	
Daily usage: 2.88kWh (three 80W desktop computers and three 40W laptop with eight hours daily operation)	
Total usage for 10 years: 46,800kWh	
Energy Costing	
Standalone Solar Power System	National Power Grid
Approximate RM60k	RM4320 (Based on RM0.30 per kWh for first five year, and RM0.50 per kWh for the second five year)

In 2016, a new Telecentre architecture for the Orang Asli Telecentre programme (TPOA) was deployed [5]. The Telecentres consist of a mix of ICT systems with dedicated power supply modules and others that share the centralised

power supply. The introduction of the dedicated power supply module for specific ICT systems, such as local content hosting and critical ICT appliance charging, was to further enhance the reliability of continuous service provision in the rural environment and compensate for the shortcoming of the power-sharing system that could be brought down by overwhelming usage and prolonged bad weather. The overall architecture for the Telecentre model is shown in Fig. 3.

The TPOA Telecentre architecture consists of two solar power systems: one for centralised power provision for non-critical but relatively high power consumption equipment such as VSAT modem/router, management desktop, networked projector, and lighting. Another solar power system is a modular design to support specific and more critical equipment such as content hosting servers, WiFi networks, and charging of tablets. By having a separate power provision architecture, service reliability of critical equipment could be achieved as a centralised power system can be brought down from time to time for many reasons, such as overwhelming usage and bad weather.

Unlike our design, the rural ICT implementations in other parts of the world were primarily focused on implementation strategies and models that did not consider the change in fundamental ICT system architecture that addressed the domestic problems of the rural environment. For example, a software-defined IPv6 network paradigm has been proposed for Nepal [6], but the context of the proposal is very much leveraging on the existing urban network efficiency paradigm for greener ICT. This proposal failed to take the local environment into account in its design considerations.

Most proposed models and strategies rely on existing urban technology building blocks to form solutions for rural implementation. The main research drivers for rural ICT deployment are still in the provision of better quality and cost-effective network accessibility to rural communities. For example, the VillageCell approach [7] focuses on enhancing the current mobile network provision to achieve a better voice call experience that does not address local limitations. In short, the system architecture should adapt to the implementation environment to achieve overall efficiency and minimise over-provision that could cause a hike in overall implementation cost. We are making reference to our previous works on green power architecture considerations for rural computing to customise a novel ICT system architecture for the application of cultural mapping in Buayan. Among the considerations are efficiency of power conversion, storage technology, and microprocessor power mode [8].

#### IV. CHALLENGES OF ICT SYSTEM IMPLEMENTATION IN THE RURAL

Many factors influence the implementation of ICT systems in the rural environment. Usually, these factors determine the design of the system and also its associated power supply. The following challenges are to be addressed for the specific case of implementing the cultural mapping system for Buayan.

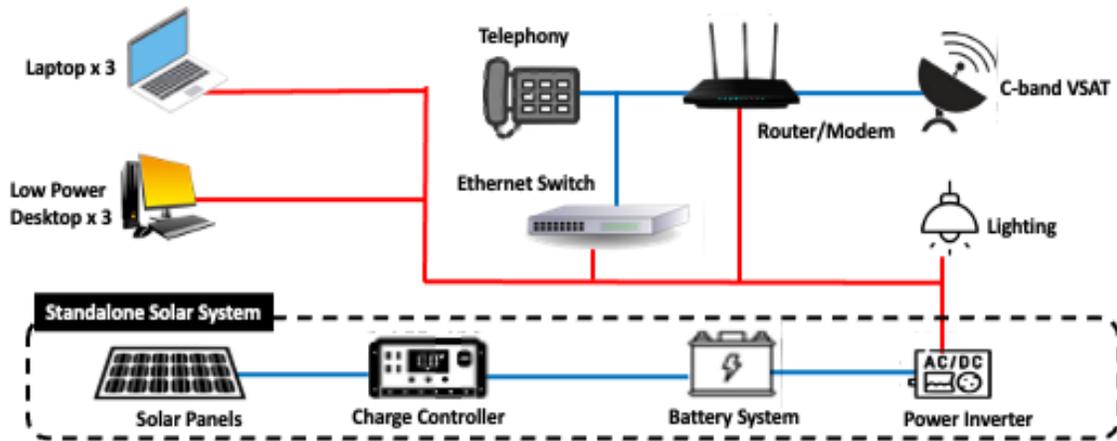

Fig. 2. The eLamai Telecentre Architecture.

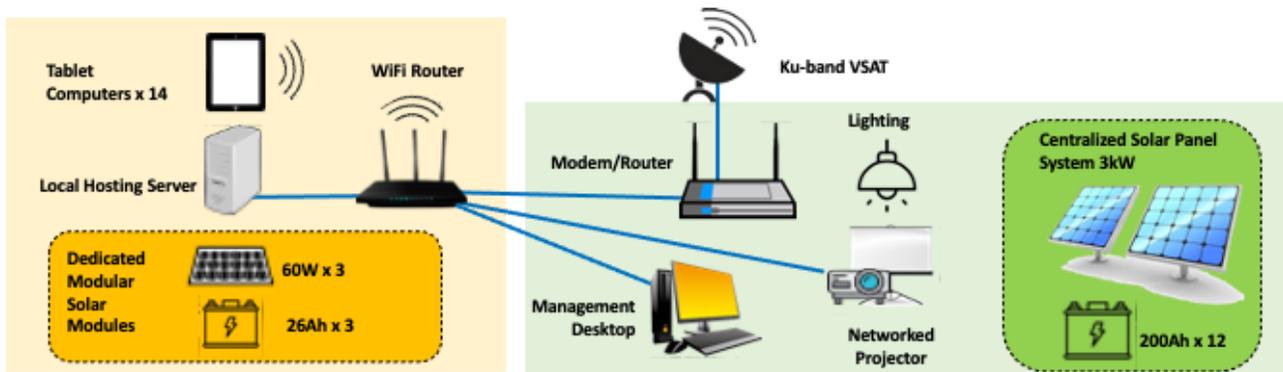

Fig. 3. The TPOA Telecentre Architecture.

#### A. Reliability and Stability of the Local Electrical Power Supply

The village of Buayan is powered by a community-operated micro hydro system with limited capacity. The operation of the micro hydro system is greatly influenced by the change of seasons: during the drought season, the village will have an intermittent power supply. The intermittent power supply could last for days or weeks if the drought season is prolonged. Such an unreliable and unstable power supply is unsuitable for digital service hosting in the village, as the frequent power cuts could damage the system or corrupt the data. The micro hydropower supply system is community-operated; thus, the community also bears high maintenance costs, resulting in expensive per-kWh charges. Hence, it would be good to have a more reliable power supply module to power the cultural mapping system independently.

#### B. Difficult Physical Access to the Village

The limited accessibility to the village will lead to higher transportation costs for transporting goods and technical personnel. Hence, the entire digital system and its power supply module should be small enough to be carried easily by the 4-wheel drive vehicle. In such a remote rural area, it can be hard to get technical support for the digital system. Not only does transportation cost more, but it also depends on the weather and the state of the roads.

#### C. IT Literacy of the Local Community

The adoption of technology in the village is relatively slow due to patchy network connections via the cellular network. Hence, a software system with a steep learning curve is a no-go as any encountered technical problem will render the system useless because no one can resolve the issue. Furthermore, patchy communication access makes providing support over the phone even harder. The community may even have a problem reporting any issues encountered and technical difficulties could take weeks or months to resolve.

### V. PROPOSED CULTURAL MAPPING SYSTEM ARCHITECTURE

New system architecture will be proposed that addresses all the shortcomings of the current implementation environment in Buayan. The new system architecture should have the following characteristics:

a) *Highly Efficient in Power Consumption*: The more efficient the system's power consumption, the smaller the power supply system can be used, resulting in a lower cost of maintaining the system and its associated power supply system. Hence, the system design uses an IoT-based CPU with extremely low power consumption (4W to 6W). NAND-based solid state drive storage is adopted for its energy efficiency as well.

b) *Small System Footprint*: The system's footprint should be as small as possible to facilitate transportation into the remote village. With a smaller power requirement, the power supply system can also be made smaller in its physical size. With less than 10W in mind, a renewable energy solar power system has been designed to support the system's operation for 24 hours a day, 7 days a week, and the size of the system is still relatively small for off-road transportation.

c) *Low-Maintenance Software*: Software glitches, such as those in the operating system and the software application for cultural mapping, should be kept to a minimum. A Linux-based command-line interface operating system environment has been used to eliminate graphical user interface-originated problems and to reduce the processing and memory requirements for the system. All services, such as web hosting, database, network sharing, secure socket shell, etc., were executed automatically without user intervention every time the system started. Whenever there is a power cut to the system, the system will be back online automatically once the power is restored.

The cultural mapping system hardware architecture is shown in Fig. 4. The integrated application hosting and the portal system consist of both the IoT computing system with its NAND storage appliance for cultural mapping applications and the solar power controller that provides power to both the IoT system and the external WiFi router that acts as the wireless network interface for user device access, such as an iPad. The renewable solar power system is an appropriate power source owing to the solar power availability in the Buayan region, which has direct normal irradiation of more than 3kWh/m<sup>2</sup> daily [9]. The proposed solar power system design uses five sets of 30W panels and is configured for a 40Ah lead-acid car battery. The reason for adopting a car battery is that the battery is a consumable item and needs to be replaced every two years. Hence, to enable easy replacement by the community, the battery shall be the type that can be easily found in the nearby town. The solar system-specific battery is relatively more challenging to obtain. The adoption

of the solar power system with charging ports is to create a self-sufficient ecosystem where the same system can also charge the iPad used for accessing the cultural mapping system.

## VI. SYSTEM IMPLEMENTATION AT BUAYAN

The system was successfully implemented in one of the households in Buayan in August 2022. Fig. 5 shows the proposed system's implementation, which includes an integrated application hosting and portal system module, a battery bank, and installed solar panels. Fig. 6 shows the community interacting with the cultural mapping system via the iPad.

The deployed system has been observed to be running well 24 hours a day. The solar power supply is consistent, and the hosted cultural mapping service is stable. Local communities have been using the system for cultural inventory every few hours a day. We look forward to further feedback from the users if any new system-related issues are discovered.

## VII. CONCLUSION AND FUTURE WORKS

This paper presents the implementation of a new system architecture specifically designed to overcome local limitations to ensure a more reliable, cheaper, and community-maintainable system for the purpose of cultural mapping. The proposed architecture evolved from previous Telecentres design experience to address the community's need for a specific application. By being able to design and implement a system architecture that scales down significantly to minimise power requirements based on its application, the crucial renewable energy solar system design will also be designed into a smaller and portable system, which is critical for rural implementation. The significant costs incurred in digital system implementation in remote rural areas are the provision of power supply and transportation. Although cloud computing might not be suitable based on the patchy and slow network connection in Buayan, remote management will be a good initiative to provide technical support to the Buayan community remotely.

**Abstract**—With the advent of the era of big data, the phenomenon of information overload is becoming increasingly serious. It is difficult for academic users to obtain the information they want quickly and accurately in the face of massive academic resources. Aiming at the optimization of academic resource recommendation services, this paper constructs a multi-dimensional academic user portrait model and proposes an Academic Resource Recommendation Algorithm Based on user portrait. This paper first, combs the relevant literature and information; Secondly, to obtain the attribute tags of multi-dimensional user portraits, a set of questionnaires are designed to collect the real information of academic users, and the corresponding academic user portrait model is constructed; Then, the collected data is processed through certain rules, and the user is quantitatively modeled based on the data through mathematical means; Finally, through the construction of the completed academic user portrait model, combined with collaborative filtering algorithm, provide personalized academic resource recommendation services for academic users. Through the verification and analysis of simulation experiments, the Academic Resource Recommendation Algorithm Based on the user portrait proposed in this paper plays a great role in expanding users' interest fields and discovering new hobbies across fields and disciplines.

**Keywords**—Personalized recommendation system; user portrait; academic resources; collaborative filtering

## I. INTRODUCTION

Academic users are increasingly finding it difficult to obtain the information they want quickly and accurately in the face of massive academic resources, which often require a lot of time and energy. Therefore, the research of personalized recommendation services for academic resources is particularly important. Personalized recommendation services of academic resources can mine users' potential interests according to the personalized attributes of academic users, to actively recommend the academic resources users need [1]. Therefore, personalized recommendation service of academic resources has greatly improved the shortcomings of traditional retrieval systems, such as redundant information and difficult screening, and can meet various preferences and needs of academic users.

### A. The Statement of the Research Problem

At present, most of the recommendation systems in the academic field adopt Content-Based Recommendation methods. The Content-Based Recommendation method focuses on the similarity of content features, which ignores most user preference features, such as the level of academic resources, the

author of academic resources, etc. There are still many common problems in the recommendation of academic resources. For example, the recommendation of multiple types of academic resources, the preferences and needs of users with different identities, etc., resulting in unsatisfactory recommendation results [2].

1) Traditional search engines rely too much on keywords, and do not take into account the retrieval users' own attributes, such as interest preferences, research fields, retrieval purposes and other factors, which do not meet the requirements of personalized recommendation services.

2) The diversity of academic resources in the existing academic recommendation system is low, and it is impossible to recommend interdisciplinary and heuristic resources.

### B. Research Objectives

1) To study the existing personalized recommendation algorithms of academic user modeling, academic resource modeling and academic resources.

2) To propose appropriate academic resource recommendation strategies, find the deep connection between user personalization and literature diversity, and recommend users with personalized and diversified recommendation results.

3) Accurately reflect user characteristics, meet users' diverse reading needs, build a multi-dimensional academic user portrait model, and form an Academic Resource Recommendation Algorithm Based on user portrait on the basis of collaborative filtering algorithm.

### C. Research Question

There are two important issues that need to be addressed. First, how to calculate the similarity between students through behavioral data, and require that the similarity reflect the interests and learning characteristics of student strengths. Second, after identifying a new sample of near-neighbor students, how to determine the set of recommended courses to be selected based on the near-neighbor students' course selection records [3].

### D. Rationale of the Study

In view of the insufficient characteristic information of the current academic resource database, which leads to the incomplete recommendation system, based on the current relatively mature database, this paper uses the literature research method, questionnaire survey method, big data

\*Corresponding Author.

analysis and other related research technologies to lay the foundation for the follow-up recommendation system research. At present, the existing recommendation methods are mainly divided into content-based recommendation methods, collaborative filtering-based recommendation methods and hybrid recommendation methods. Based on the previous research, this paper builds a multi-dimensional academic user portrait for academic users, adopts the optimized collaborative filtering recommendation model, and tries to find cross domain academic resources that users are potentially interested in and have certain guiding significance for users [4].

### E. Research Gap

From the current status of research, we can see that in recent years, there have been numerous studies on recommendation in education at home and abroad, but most of these studies are on K12 education, i.e., basic education, and fewer studies on learning resource recommendation algorithms for students in higher education. Therefore, it is more difficult to recommend learning resources for students in higher education than for students in basic education. In previous studies on learning resource recommendation, most of them improve the classical collaborative filtering algorithm to achieve the effect of improving the recommendation accuracy, and the user profile is not systematically utilized, which will be affected by factors such as cold start and sparse data matrix, resulting in poor recommendation effect.

To sum up, recommendation system is very crucial to solve the problem of resource overload, which attracts the majority of enterprises and scholars to conduct research. However, the application of recommendation system in the field of online education is not widespread and the recommendation algorithm is not perfect, and there is no integration of user portrait into the process of recommendation algorithm, especially there is no recommendation algorithm of learning resources for college students, and college students, as the backbone of online education, are an important part of online learning users, so it is necessary to realize the recommendation algorithm of learning resources integrating user portrait for college students, and Complete the design and development of the learning resource recommendation platform.

## II. LITERATURE REVIEW

Academic resource recommendation service is a relatively mature service in the field of scientific research, and the existing research focuses on different aspects, which cannot meet the diversified needs of users. For example, CiteULiket focuses on maintaining the citation relationship of papers, Google Academic provides a complete paper search function, and Aminer platform uses data mining algorithms and analyzes social networks to provide academic users with not only basic academic resource retrieval services, but also current hot academic topics, visualization of trends in research directions, and deep mining of scholars' social networks and other functions. In order to further improve the academic resource recommendation service. Scholars build recommendation algorithms for academic resources by studying users' academic behaviors to tap users' interests, research directions and other academic preferences. S. Bhaskaran et al. used content filtering algorithms to analyze user behavior, such as citing papers and

displaying ratings, to recommend academic papers of interest to users [5]. M. Venkatesh et al. used machine learning algorithms to construct a user requirements model that can adaptively match user preferences with a target library repository to complete user-oriented personalized recommendations of digital library resources [6].

In recent years, research trends in information behavior models have shown the following four aspects.

First, the research content is further refined, both for a certain type of information behavior and for the characteristics of information behavior models; Second, the research object is further subdivided, the academic user group is divided into multi-level and multi-dimensional, and information behavior models for different subject areas; Third, the factors affecting information behavior are more explored, and efforts are made to explore the micro-level; Fourth, the research methods are diversified, mainly survey and interview methods are used in data collection, supplemented by literature analysis and experimental methods, etc.

In general, the existing domestic and foreign academic resource recommendation systems and recommendation algorithms have met users' personalized needs to a certain extent. However, there are still some problems: firstly, the recommendation algorithms are mostly based on users' academic preferences, which makes the range of academic resources recommended relatively single and the diversity of academic resources low. First, the recommendation algorithms are mostly based on users' academic preferences, which makes the range of academic resources recommendation results relatively single and the diversity of academic resources low, and cannot achieve cross-disciplinary and cross-domain heuristic resources. The recommendation algorithm is mostly based on users' academic preferences. Secondly, in the face of the growth of massive academic resource data, the processing capability and machine learning capability of the system have become the key issues that must be addressed in the future academic resource recommendation system. In the future, the processing capability and machine learning capability of the system become the challenges that must be solved for academic resource recommendation systems.

This section will elaborate and introduce the relevant background knowledge of this research content, including personalized recommendation and user portrait theory and their application in the field of academic resources. Finally, the commonly used evaluation indicators of the recommendation system and the subsequent chapters of this paper are briefly explained, which paves the way for the proof of measuring the scientific effectiveness of this paper.

### A. Personalized Recommendation Theory

The purpose of the recommendation system is to use the collected user information and item information to establish user models and item models, and match them according to specific rules. The recommendation algorithm plays a bridge role in this matching rule. Finally, the rules contained in the algorithm are used to filter the calculation results, to find the products that users may be interested in, and recommend them to users. This section selects three types of recommendation

systems related to the research content of this paper for a brief introduction, which are: content-based recommendation system, collaborative filtering-based recommendation system, and hybrid recommendation algorithm.

1) *Content-based recommendation system*: Content based recommendation is also called attribute based on recommendation. In the process of recommendation system, it can be seen that both items and users contain certain attribute information. Because the attribute information of items is relatively static and objective, it is very easy to calculate the correlation between the degrees of similarity. The content-based recommendation algorithm is to discuss whether the actual attributes of the two items to be recommended are similar. As the basis for judging whether to recommend or not, the core task of the algorithm is to calculate the similarity of the attributes of the items as shown in Fig. 1.

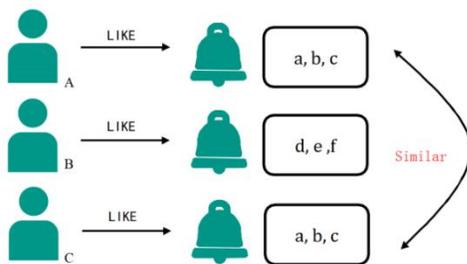

Fig. 1. Content based Recommendation System.

The disadvantages of content-based recommendation are as follows:

- a) Relying on the classification of the objects to be recommended, the quality of recommendation is greatly affected by the nature of the objects to be recommended.
- b) For users, the recommendation process is based on the analysis of existing content, and the recommendation results are difficult to innovate. Therefore, it is difficult to develop new product fields, and the ability to inspire users' interests and hobbies and promote users to contact new things is insufficient.
- c) In front of a new user who has no historical reading record at all, there is no interactive item record, and there is no way to analyze the characteristics of items, so it is impossible to match the content to achieve recommendations, and only provide content to users in a way similar to the "popular list".
- d) It requires a large amount of data of the object to be recommended, takes up large storage and computing space, and increases the cost of recommendation services.

2) *Recommendation system based on collaborative filtering*: In the field of Resource Recommendation Based on collaborative filtering, resources are mainly based on traditional collaborative filtering algorithms. Recommendation work, establish user documents based on the semantic analysis of users' reading literature, find similar user documents and predict users' interests through traditional collaborative filtering methods, and realize personalized recommendation the accuracy of such recommendation algorithms is vulnerable to data sparsity and cold start problems [7]. Therefore, integrate users

according to the types of scoring items and user scoring items, the user similarity is calculated, and the corresponding collaborative filtering algorithm is designed to improve the accuracy of recommendation results [8]. Niu et al. used three different types of information (users, items, user items) to deal with the problem of data sparsity, predicted the item score, and produced high-quality recommendation results [9]. L. Antony Rosewelt et al. proposed to integrate the intimate relationship between friends into the recommendation model to recommend resources for new users under the same interest topic [10].

Collaborative filtering recommendation research has obvious deficiencies in two aspects:

On the one hand, these studies mainly use users' explicit and implicit behavior data to model users' interests, which is prone to the problem of data sparsity; on the other hand, these studies are often based on static scenarios, and it is difficult to cope with the real needs of online mobile recommendation of academic resources under the situation of constantly updating user data and changing user needs.

### B. Academic user Portrait

User portraits for academic users are more focused. In order to more accurately recommend academic resources, it is necessary to obtain and describe the characteristics of academic users' interest in academic resources, so as to depict accurate academic user portraits. All the interest characteristics of users can be divided into different types [11]. One classification method is to divide user portraits into explicit features and implicit features according to different acquisition methods. Explicit features refer to a kind of academic user features that can be obtained directly without deep mining, such as name, age, education, major, identity, etc., and also include research directions and research fields independently defined by users. Such features can be collected manually, or automatically retrieved by software on the basis of user consent. The implicit feature is the feature attribute calculated and analyzed after deep mining a series of academic behavior and other information of academic users. Generally, it needs to be collected by software such as web crawlers and obtained by using the relevant algorithms of data mining. Explicit features are simple and fast to obtain, but the level is shallow and the flexibility is not high. Implicit features can mine more interesting features of users, but rely on higher cost calculation, which is a complementary role of explicit features. Users' academic behavior refers to academic related interaction behavior, which can be the retrieval, download, collection, quotation and other behaviors of academic resources. The purpose of analyzing these academic behaviors is to infer users' academic interest tendency, further supplement users' interest characteristics, and improve academic user portraits. The purpose of analyzing these academic behaviors is to infer users' academic interest tendency, further supplement users' interest characteristics, and improve academic user portraits [12].

Before designing an academic resource, recommendation service based on user portrait, it is necessary to establish a multi-dimensional academic user portrait model, which can obtain user attributes in an all-round and multi-level way, accurately reflect user characteristics, and meet users' diverse

reading needs. The multi-dimensional academic user portrait is mainly composed of two parts: dimensional analysis and model construction.

C. Dimension Analysis of Academic User Portrait

The establishment of user portrait dimension is the basis of establishing user portrait model. An ordinary academic user will have a series of information that can affect the acquisition of academic resources, including the most basic attributes of a person, as well as academic preferences fed back from academic behavior. In addition, there are some additional factors that can be defined and distinguished, user information that can optimize the recommendation service of academic resources. This kind of information has obvious personal style, so this paper calls this kind of dimension "academic personality"[13-17].

Accordingly, this paper selects the following three dimensions: basic information, behavioral characteristics and academic personality as the components of the multi-dimensional academic user portrait as shown in Fig. 2.

D. Construction of Multi-dimensional Academic User Portrait Model (MAUPM)

In order to obtain the real data needed in the process of academic user portrait modeling, this paper designs a set of questionnaires for data collection. For the two dimensions of basic information and academic personality, the questionnaire is divided into two parts: The first part mainly adopts the form of multiple-choice questions, including age, gender, education background, major, identity, time engaged in scientific research, research direction and other questions, which are used to collect basic information. In the second part, through the further investigation of users, including the scientific research progress and the proficiency of using the academic resource platform, combined with the identity, professional title, working time and other information obtained in the first part, we can get the users' academic motivation and domain knowledge. For the investigation of cognitive style, the scale test commonly used in the field of psychology is used to set up eight scenarios and let users choose the situation that is consistent with themselves. In order to supplement and verify the authenticity of the results of the scale, the questionnaire also set up a mosaic graphic experiment, which requires users to find the specified simple graphics in a complex graphics. Users who prefer field independent cognitive style can find simple graphics in complex graphics faster [18].

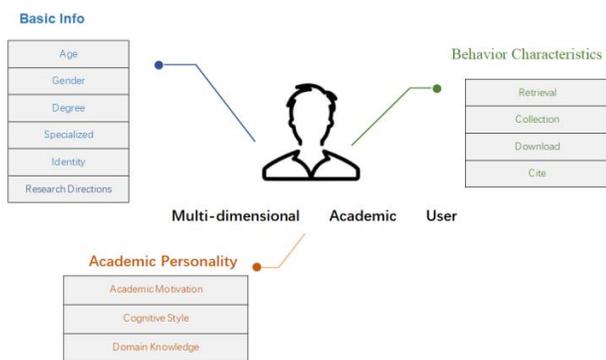

Fig. 2. Multi-dimensional Academic user Portrait Structure.

The results of these questions can finally feedback the "academic personality" of the surveyed users. For the dimension of behavior characteristics, it is obtained by viewing the behavior logs of academic users on the academic resource platform. Based on the collected data, this paper constructs a multi-dimensional academic user portrait model [19].

1) *Basic information model*: It is divided into six sub dimensions: age, gender, education, major, identity and research direction. In order to simplify the information, the age dimension adopts the form of age group, and the research direction is described by the data filled in by users in the questionnaire. The basic information model is shown in Table I.

TABLE I. BASIC INFORMATION MODEL

Sub Dimension	Value
Age	Under 30 years old, 31-40 years old, 41-50 years old, 51-60 years old, under 60 years old
Sex	Male / Female
Education	Bachelor's degree or below, Bachelor's degree, Master's degree, Doctor's degree or above
Profession	Philosophy, Economics, Law, Pedagogy, Literature, History, Science, Engineering, Agriculture, Medicine
Identity	Students, Teachers
Research Direction	Fill in by yourself, such as "control theory".

Behaviour characteristics are composed of four dimensions: user's retrieval, collection, download and reference.

The values of each dimension are as follows:

- Search dimension: the user's search term K, the time to visit the page t (unit: minutes), and the document name P of the search page.
- Collection dimension: user's collection page document name C.
- Download page: user's download page document name D.
- Citation dimension: user's citation name R.

The behavioural characteristic model is shown in Table II.

TABLE II. BEHAVIORAL CHARACTERISTIC MODEL

Sub Dimension	Value
Retrieval	Search term K
	Access time T
	Search page document name P
Collection	Collection page document name C
Download	Download page document name D
Quote	Reference name R

2) *Academic personality model*: The three sub dimensions of academic motivation, cognitive style and domain knowledge are described by the data obtained from the questionnaire, in which academic motivation and domain knowledge can be obtained directly from the results checked by users. The academic personality model is shown in Table III.

TABLE III. ACADEMIC PERSONALITY MODEL

Sub Dimension	Value
Academic Motivation	Explicit, Fuzzy
Cognitive Style	Field Independent, Field Dependent
Domain Knowledge	Junior User, Experienced User

In order to accurately judge the cognitive style of academic users, this paper converts some literality in the questionnaire into specific values (scores). Three variables were defined: scale value  $n$ , speed value  $V$  and cognitive style index  $s$ . The  $n$  value represents the score of the user in the scale test. The higher the score of each question, the more consistent it is with the described situation, and the user is more inclined to the field independent cognitive style in the situation of this question; The  $V$  value represents the user's response in the mosaic graphic experiment. The faster the user completes the mosaic graphic experiment, the more it can reflect the user's field independent cognitive trend; the cognitive style index  $s$  reflects the final situation of the user's cognitive style. The higher the  $s$  value of the user, the more the user prefers the field independent cognitive style. The lower the  $S$  value, the more the user prefers the field dependent cognitive style [20-22].  $S$  value is positively correlated with  $n$  value and  $V$  value, and the calculation formula of  $s$  value is  $S = N \times V$ .

$S$  is the cognitive style index,  $n$  is the score of the scale test questions, and  $V$  is the score of the graphic mosaic experiment.

It can be predicted that with the development of new technology, academic personalized recommendation will produce new ideas, models and methods, and the results of recommendation will be more and more satisfactory. In order to solve the problem of information overload, this method will become one of the research contents in the academic field for a long time [23].

### III. METHODOLOGY

The portrait constructed above is a three-dimensional map based on semantic information. This chapter will quantify all dimensions in the three-dimensional map, fuse and reconstruct, store each user's information in the form of vectors, and construct a vector-based user portrait. Then, combined with the user based collaborative filtering algorithm, the similarity between vectors is calculated, so as to predict the list of academic resources recommended by users to be recommended [24].

#### A. User Attribute Vector

This paper divides the academic user portrait into three dimensions: basic attributes, academic personality and behavioral characteristics. Among them, the basic attribute and academic personality are relatively static objective attributes, which can reflect the user's personal attributes over a period of time, and can be clearly expressed through discrete and unique values, for example, the gender can only be "male" or "female". Therefore, in the process of practical application, the basic attributes and academic personality dimensions are combined and deleted to form the user attribute vector. User Info={Age, Gender, Education, Profession, Identity, Motivation, Style} There are two (2) parts deleted: 1. Change the "age" label

to "age range" in order to reduce the number of discrete data and reduce the amount of calculation; 2. The sub dimension of "domain knowledge" is deleted because the domain knowledge level of an academic user has been reflected in the attributes of age, identity, education and major. Deleting this dimension can reduce the workload and avoid defining evaluation indicators, so as to avoid the error loss caused by subjective judgment [25]. According to the multi-dimensional academic user portrait model, the reconstructed and fused user attribute vector and its values are shown in Table IV.

Because the total number of dimensions of user attributes is not large, this paper uses "one-hot" to encode vectors. One hot encoding, alias is an effective bit encoding. The encoding idea is to set  $n$ -bit status registers to represent in different states. Each bit register has only "0" and "1" states. No matter how many bits the register has, when representing each state, only one bit is valid, that is, the position representing the state is "1", and the other positions are "0"[26]. For example, if the "age range" attribute has five values, the attribute code form is a Five-Dimensional vector. When the value is "under 30 years old", the attribute code is: age = {1, 0, 0, 0, 0}. When the value is "over 60 years old", the code is: age= {0, 0, 0, 1}.

TABLE IV. USER ATTRIBUTE VECTOR VALUE AND CODING

User Attribute Vector	Value	Code
Age Group	Under 30 years old	{1, 0, 0, 0, 0}
	31-40 years old	{0, 1, 0, 0, 0}
	41-50 years old	{0, 0, 1, 0, 0}
	51-60 years old	{0, 0, 0, 1, 0}
Sex	Male	{1, 0}
	Female	{0, 1}
Education	Below bachelor degree	{1, 0, 0, 0, 0}
	bachelor degree	{0, 1, 0, 0, 0}
	Master degree	{0, 0, 1, 0, 0}
	Doctor degree	{0, 0, 0, 1, 0}
Profession	Philosophy	{1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0}
	Economics	{0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0}
	Law	{0, 0, 1, 0, 0, 0, 0, 0, 0, 0, 0, 0}
	...	...
Identity	Student	{1, 0, 0, 0, 0}
	Assistant	{0, 1, 0, 0, 0}
	Lecturer	{0, 0, 1, 0, 0}
	Associate Professor	{0, 0, 0, 1, 0}
	Professor	{0, 0, 0, 0, 1}
Academic motivation	Explicit Type	{1, 0}
	Fuzzy Type	{0, 1}
Cognitive style	Field Dependence	{1, 0}
	Field Independent Type	{0, 1}

### B. Similarity Calculation

The cosine similarity formula is used in this paper, so the similarity formula of user attribute vector is:

$$\text{Sim\_Info}(a, b) = \cos(A, B) = \frac{\sum_{i=1}^n A_i B_i}{\sqrt{\sum_{i=1}^n A_i^2} \sqrt{\sum_{i=1}^n B_i^2}} \quad (1)$$

where,  $a$  and  $B$  are the user attribute vectors of  $a$  and  $B$  users, and  $A_i$  and  $B_i$  are the attribute values of each dimension of the two users respectively. The formula of vector similarity in the research field is:

$$\text{Sim\_Area}(a, b) = \cos(X, Y) = \frac{N(X) \cap N(Y)}{\sqrt{N(X) \times N(Y)}} \quad (2)$$

$N(X)$  and  $N(Y)$  are the number of keywords in the research field vector of users  $a$  and  $B$  respectively. Suppose that the research field vectors of users  $a$  and  $B$  are respectively:  $\text{User\_area\_a} = \{\text{User portrait, Recommendation system, Education system}\}$   $\text{User\_area\_b} = \{\text{User portrait, Marketing, Business Administration}\}$  The denominator is  $\sqrt{N(A)} \times \sqrt{N(B)}$  in form according to the similarity formula. [27].

### C. Generate Recommendation List

Finally, the user group with high similarity to the users to be recommended is called the "most similar user set", and the academic resources that the "most similar user set" likes but the users to be recommended have not interacted with are recommended to them. Let user  $A$  mark the thesis set as  $P_A$ , the most similar user set of  $a$  as  $U_A$ , the recommended thesis set as  $R$ , and the thesis set as  $P$ . Then user  $A$ 's recommended thesis collection is  $R_A = \{p \mid p \in P_i, i \in U_A, p \notin P_A\}$ .

This recommendation algorithm does not consider the users' scores on the papers, because the collection of papers adopts a single implicit feedback data, and takes the "interaction" between collections, downloads and academic resources as the basis of users' interest [28].

## IV. ANALYSIS AND RESULTS

### A. Experimental Environment

Experimental Platform: Windows10 64-bit operating system, 11th Gen Intel(R) Core (TM) i7-11800H @ 2.30GHz 2.30 GHz3.40GHz, 16.0 GB RAM. Tools: Java, Python, SPSS.

### B. Data Acquisition and Processing

In order to verify the accuracy of the academic resource's recommendation algorithm proposed in this chapter, 100 users of the questionnaire were selected, and the historical reading list of academic resources was manually collected from them. Each person had a total of five documents, including title, abstract and keyword information. Three of the five papers are used as training sets and two test sets, that is, three papers are the user's "historical reading list" and two papers are the "future real reading list". The questionnaire survey results are obtained from the "questionnaire star" website background management system, stored in SPSS files, and the user attribute vector of each user can be obtained after encoding the data. From the data, the selected 100 users have the same educational background,

major and identity, which provides a practical basis for subsequent recommendations based on collaborative filtering. After grouping and numbering the manually collected user history reading papers, we use python3.0 programming language and TF-IDF algorithm to extract keywords from the title and abstract of the literature. Combined with the keyword information of the literature itself and manual verification, after duplication and error correction, a total of 689 keywords of 350 documents were finally obtained.

1) *Collect questionnaire analysis:* From the questionnaire collected, the proportion of men and women in the surveyed population is 55.48% to 44.52%, about 1:1; Users' majors are mainly engineering, and they are academic users of philosophy, law, pedagogy, science, medicine and management; In terms of academic qualifications, 81.66% are masters, 19.34% are undergraduates, and the user groups are students. The following mainly analyzes the survey results of the third dimension "academic personality" in the user portrait proposed in this paper.

In the survey results of the scientific research stage of this questionnaire, 39.93% of users choose the scientific research preparation stage, 49.72% of users choose the scientific research progress stage, and 10.35% of users choose the scientific research publication stage. It can be seen that academic users will indeed experience different stages of scientific research on the road of scientific research, and they will also have different academic motives in the search process of academic resources. Count the cognitive style index  $s$  of the surveyed users and calculate the benchmark value  $s = 11.316$ , the results show that 55.17% of the academic users participating in the survey have field independent cognitive style, and 44.82% of the users have field dependent cognitive style. For the statistics of domain knowledge level, the information sources include the user's age, education background, professional title, time engaged in scientific research, proficiency in using academic resource platform, etc. In this questionnaire survey, users with bachelor's degrees without exception chose "directly use one or several keywords to search and try to expand the search scope", while nearly half of users with master's degrees chose the same common search methods as users with bachelor's degrees, and 38.46% of users chose "select certain restrictions (phrases, tags, etc.) while using keywords", Another 11.54% of users made the choice of "traversing relevant academic resources with the author or publishing unit and the journal as the search tag". It can be seen that with the gradual accumulation of scientific research experience, academic users' domain knowledge is also expanding, and there are certain differences between primary users and experienced users in the acquisition of academic resources. Therefore, it is essential to integrate the academic experience level of academic users into user portraits. Through the analysis of the questionnaire results, academic users have different academic personalities, and the user portrait integrated into academic personality is more three-dimensional, which can greatly improve the personalization and accuracy of academic resource recommendation services.

### C. Implementation of Recommendation Algorithm

The test papers contain the user's real reading list in the future, which can analyze and verify the predicted value and the real value to obtain the accuracy of the recommended algorithm.

Based on the above, the complete recommendation steps for a user to be recommended is shown in Fig. 3.

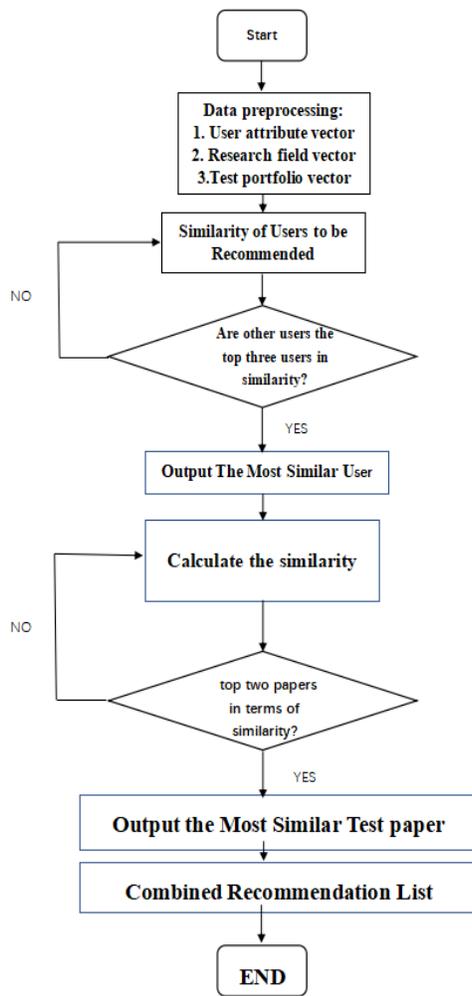

Fig. 3. Algorithm Experiment flow Chart.

## V. RESULT AND DISCUSSION

### A. Offline Test

Finally, each 100 users will get six recommended papers, and a total of 600 papers will be generated from the recommendation list number the test papers from 1 to 600, and the number of the recommended papers of 100 users and their corresponding test papers, that is, the number of "future real reading list", is shown in Table V.

In this article, "recall rate" and "accuracy rate" will be used as the basis for scoring. Let  $R(u)$  represent the user's real reading list in the future, that is, the test paper collection, and  $T(u)$  represent the recommendation list finally predicted by the algorithm.

$$\text{Recall} = \frac{\sum_{u \in U} |R(u) \cap T(u)|}{|T(u)|} \quad (3)$$

$$\text{Precision} = \frac{\sum_{u \in U} |R(u) \cap T(u)|}{|R(u)|} \quad (4)$$

TABLE V. COMPARISON BETWEEN RECOMMENDED PAPERS LIST AND REAL READING LIST

No.	Recommended Paper No.	Real reading paper No.	Number of Correct Predictions
1	20,12,3,19,3,15	1 2	0
2	8,6,11,9,3,20	3 4	1
3	9,1,14,13,17,18	5 6	0
4	8,6,9,1,14,13	7 8	1
5	6,5,14,13,17,18	9 10	0
6	8,6,20,12,3,15	11 12	1
7	6,5,9,1,17,18	5,9,17	3
8	8,6,9,1,14,13	6,9,13,14	4
9	6,5,9,1,14,13	1,18	1
10	8,6,9,1,3,20	19 20	1
...	...	...	...

It is calculated that the recall rate of the proposed algorithm in the offline test is 70% and the accuracy rate is 78.7%.

### B. User Research Method

This article will pay a return visit to 80 test users. The recommendation list generated by the algorithm is conveyed to the test users to collect their real evaluation. The contents of the return visit and investigation include the following:

1) Satisfaction with the number of papers: Are you satisfied with the number of papers in the recommendation list (Dissatisfied, Generally Satisfied, Relatively Satisfied, Very Satisfied).

2) Thesis title reading interest evaluation: Just observe the title of the paper in the recommendation list. Do you want to click to read it? (No, generally, quiet, very much).

3) Cross domain reading interest evaluation: Have you found any papers that are different from the current research field but still interested in from the list of recommendations? (In conformity, general conformity, relatively conformity, very conformity).

The return visit results are shown in Fig. 4.

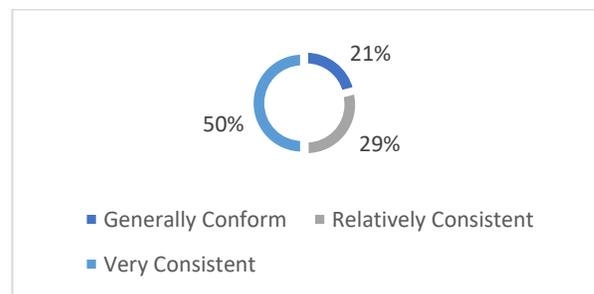

Fig. 4. Satisfaction with the Number of Papers and Reading Interest Evaluation.

The result analysis of the three problems has the following conclusions.

Most of the revisited users are very satisfied with the number of papers in the recommendation list, indicating that the

number of five to six recommended papers can meet the reading needs of ordinary academic users. On the academic resources of retrieval website, the most intuitive part presented to users is the title of the paper. Most revisiting users are satisfied with the recommendation results from the perspective of the title of the paper, of which 84% of the recommended papers are favored by users. 3.53.7% of the revisited users believed that the literature resources in the recommendation list were different from the current research field, but they still had great interest, and 39% of the users were also more willing to read the recommended papers in the interdisciplinary field. It can be seen that the Academic Resource Recommendation Algorithm Based on user portrait proposed in this paper can expand users' research interests, improve users' interdisciplinary and interdisciplinary reading tendency, and help academic users inspire new research directions.

### C. Innovation Points

Aiming at the current trend of more and more cross domain cooperation in scientific research, this paper explores the potential interests of users, analyzes the cognitive style trend of users from the perspective of psychology, so as to measure the cross domain academic resource needs of academic users, expand the factors of academic resource recommendation, and further improve the theoretical system of personalized recommendation of academic information resources.

This paper adopts interdisciplinary research, combines computer related technologies such as statistics, psychology, library and information science and data mining, adopts research methods such as questionnaire survey and empirical analysis, and integrates the research ideas of social science into the research of recommendation system, which has strong progressiveness and applicability.

### D. Future Work

In the research process, the real user data used are phased static data, and the dynamic time factor is not considered, so the changes of academic users cannot be reflected in the user portrait. In the next work, it can use the existing computer technology to realize the dynamic tracking of user information, which can make up for this shortcoming.

## VI. USER INTERFACE OF THE SYSTEM (GUI)

The implementation effect of the academic resource module based on personalized user portrait is shown in Fig 5.-Fig 7.

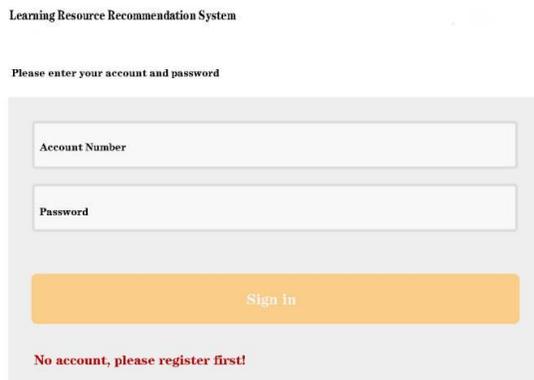

Fig. 5. Learning Resource Recommendation Login Interface.

Fig. 6. User Interest Tag Acquisition.

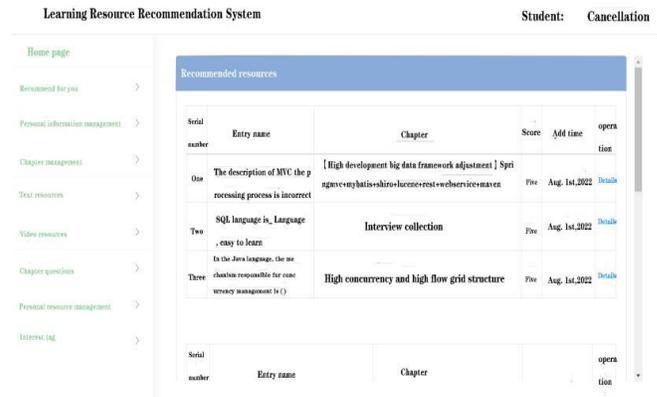

Fig. 7. Personalized Academic Resources Recommendation Display Interface.

## VII. CONCLUSION

In recent years, it is more and more difficult for academic users to obtain the information they want quickly and accurately in the face of massive academic resources. Personalized recommendation system can solve this problem. The existing personalized recommendation system improves the shortcomings of the traditional retrieval system, such as information redundancy and difficulty in screening. To a certain extent, it can meet the various preferences and needs of academic users, but it also lacks the deep characterization of users' personal attributes. Therefore, from a new perspective, this paper attempts to mine the attributes of individual users, broaden the dimension of academic user portraits, and enhance the objectivity of academic resource recommendation services. Firstly, this paper studies the relevant knowledge of personalized recommendation system and user portrait theory, focusing on the definition, classification and evaluation indicators of recommendation system, and the construction method of user portrait. Then, in order to integrate the idea of user portrait into the personalized recommendation service of academic resources, based on the construction of a diversified and three-dimensional academic user portrait, the concept of "academic personality" is proposed on the basis of two basic dimensions of users' basic attributes and behavioral characteristics." Academic personality" includes three parts: users' academic motivation, cognitive style and domain knowledge. Through the infiltration of psychological theory, it further complements the portrait dimension of academic users and constructs a multi-dimensional academic user portrait model.

Finally, using the constructed multi-dimensional academic user portrait model, combined with the user based collaborative filtering method, an Academic Resource Recommendation Algorithm Based on user portrait is proposed, which optimizes the existing academic resource recommendation strategies. The experimental results show that the Academic Resource Recommendation Algorithm Based on user portrait proposed in this paper can play a great role in expanding users' interest fields and finding new hobbies across fields and disciplines.

# An Inspection of Learning Management Systems on Persuasiveness of Interfaces and Persuasive Design: A Case in a Higher Learning Institution

Wan Nooraishya Wan Ahmad<sup>1</sup>, Mohamad Hidir Mhd Salim<sup>2</sup>, Ahmad Rizal Ahmad Rodzuan<sup>3</sup>  
Faculty of Computing and Informatics, University Malaysia Sabah, Labuan, Malaysia<sup>1,3</sup>  
Institute of IR4.0, Universiti Kebangsaan Malaysia, Selangor, Malaysia<sup>2</sup>

**Abstract**—An effective Learning Management System (LMS) is an essential factor that can increase e-learning persuasiveness. One of the components that need to be addressed to design an effective LMS is design interfaces. Instead of developing a new LMS that requires a high cost, evaluating and improving the existing LMS is the best option. Issues like low completion rates and procrastination are common issues related to e-learning usage. These issues can be solved if academic institutions provide a proper LMS for students to change their learning behaviors positively. Many previous studies claimed they managed to implement persuasive technology into e-learning platforms to encourage positive learning behaviors. However, the claims can be questionable if the persuasive e-learning systems are not gone through a proper evaluation phase. This study will use the heuristic evaluation method to assess the persuasiveness level of LMS interfaces. The persuasive Systems Design Model (PSD), on the other hand, is used to evaluate persuasive strategies in LMS. The assessment involves students' perspectives as the primary users to identify potentially behavior change factors, especially on engagement. Thus, the objectives of this study are i) to investigate the persuasiveness of LMS interfaces and ii) to identify persuasive strategies in the LMS design. Apart from that, this study also produces a) recommendations on design examples to increase the persuasiveness of LMS interfaces and b) the mapping of LMS interfaces to PSD framework that can be utilized by higher learning institutions.

**Keywords**—Learning management system; e-learning; persuasive design; persuasiveness; interface design

## I. INTRODUCTION

E-learning or electronic learning is a learning medium which involves processes of delivering learning materials, communicating knowledge, tasks and learning instructions through online mediums [1]. Some examples of the commonly used tools for e-learning include video conferencing solutions, virtual tutoring, and digital libraries [2]. Previous studies reported that the effectiveness of e-learning is high, up to 60% of retaining learning materials compared to a traditional classroom which is up to only 8% to 10% of retention [3]. Because of the potential of e-learning as a platform for future learning, this study focuses on one of the e-learning technologies, which is Learning Management Systems (LMS).

LMS is a platform or medium used to provide learning features such as distributing learning materials and training activities while tracking students' progress [4]. One of the famous examples of LMS is Moodle. An effective LMS can

connect students with instructors outside of traditional classrooms via technology. Other than that, students can also be involved in online discussions through LMS. It even allows asynchronous conversation and facilitates problem-solving to improve the understanding of their enrolled subjects [4]. According to [5], incorporating LMS technology into teaching and learning enhances the accuracy of teaching attempts, student performance, and learning effectiveness. Thus, the LMS interface should be designed by considering students' perspectives as the end-users to prevent students from becoming discontent.

Almost every tertiary education institution worldwide uses LMS in its learning process [6]. Some tertiary education institutions in Malaysia use Moodle as their LMS platform due to its flexibility and versatility in fulfilling learning functions. On the other hand, some institutions develop their own LMS platforms for different reasons, such as cost and other preferences [7]. Despite the benefits that e-learning technologies offer to the learning process, some educational experts argue that there are flaws in e-learning because a significant percentage of students reported dissatisfaction with how technology is used in education [8]. They claimed that the lack of direct interaction between students and teachers is an important issue that needs to be solved to increase the effectiveness of the technology, or else it is worth noting. User acceptability and use are important indicators of the system's success. As a result, student admission must be considered; otherwise, information systems are prone to failure [8]. Persuasive technology is a technology developed that aims at users' behavior change without coercion [9]. A low completion rate due to procrastination is one of the issues related to e-learning that require changing students' behaviors [10]. A previous study claimed they integrated persuasive technology into e-learning platforms to encourage positive learning behaviors [11]. However, the claim can be questionable if the persuasive systems are not going through the proper evaluation phase. Students' evaluation is crucial since they are the primary users of e-learning technology.

This research study used the heuristic of persuasion in interface [12] to assess the persuasiveness of LMS interface and Persuasive Systems Design Model (PSD) [9] to evaluate persuasive strategy in LMS of a higher learning institution. The assessment is made from students' perspective as the primary entity potentially related to behavior changes on engagement. Thus, the objectives of this present study are i) to investigate

the persuasiveness of interface of a learning management system and ii) to identify persuasive strategy in the design of a learning management system. This study contributes to the following: a) recommendation on design examples to increase persuasiveness of LMS interface, and b) the mapping of LMS interface to PSD framework for LMS that can be utilized by higher learning institution particularly to the six most visited interface in the LMS.

The rest of the study is followed by Section II, which provides an outline of the background study and explains past related works. Section III describes the method, materials, and data collection and analysis procedures. Section IV presents two parts of the result and Section V is the discussion to describe the observed scenario. Lastly is the conclusion.

## II. BACKGROUND STUDY

### A. Persuasion

Persuasion is a form of influence as the technique tries to convince the persuadee of something [9]. There are two forms of persuasion: indirect and direct persuasion [13]. Indirect persuasion is a method that does not make persuasive intent clear. The intent is not expressed clearly without condemning or confronting a person's attitude or endorsing another person who has already accepted the offered message or notion. Direct persuasion is where persuasion has apparent intentions. It provides clear direction to a person with goal setting, including the process and clear instructions to achieve their goal despite their agreement. The LMS is supposed to have direct persuasion because the use of LMS in learning will eventually modify a student's learning habit [14].

Persuasion is the core process of persuasive technologies that modify users' behavior and perceptions through various techniques [15]. Therefore, it has been studied in various domains such as education [14], tourism [16], and health [17]. In addition, the Persuasive Systems Design Model (PSD) [9] has served as the guideline in designing and evaluating persuasive systems. The PSD framework is composed of four types of persuasive design principles: (i) primary task support, (ii) dialogue support, (iii) credibility support, and (iv) social support. The primary task principles are concerned with assisting the user's principal actions and goals. Dialogue support principles relate to human-computer dialogue aid in reaching the system's aim. The credibility support principles address how to design a more credible and convincing system. Finally, the design principles of social support utilize various components of social influence to ensure that the build system inspires the users.

Apart from becoming the core process in persuasive technology, persuasion has become one of the critical user experience attributes in interface design [18]. The potential persuasive impact of these dynamic interfaces is much more significant than a static information display where no interaction is possible. Interface properties are necessary but insufficient to change behaviors and attitudes since change can be constructed by considering user specifications [12]. Although we can enhance efficiency by applying traditional usability techniques, just because people can do something does not guarantee that they will. They must get motivated and

persuaded. A user will become more emotionally involved through repetitive interactions with an interface. Thus, [12] constructed a persuasiveness criteria grid to evaluate the persuasiveness of interfaces. The grid consists of static and dynamic criteria. Static criteria are the features required to start user acceptance and confidence to develop user engagement. The four static components are credibility, privacy, personalization, and attractiveness. Dynamic criteria incorporate substantial temporal factors where the interface elements encourage the user to commit to higher degrees of engagement. The dynamic components comprise solicitation, priming, commitment and ascendancy.

### B. Related Works

The two main concerns of persuasiveness studies in human-computer were on persuasive technology [15, 17, 20-23] and interface design [12, 19, 24]. Thus, the focus of persuasiveness is either on a system's perceived persuasiveness [15, 17, 20-22] or the receptiveness of a system's persuasion strategy [12, 19, 23-24]. Persuasiveness or perceived persuasiveness has been defined differently based on the context of the study. The persuasiveness of persuasive technology is defined as persuasive systems' ability to persuade or encourage users to modify their behavior in a good direction [21, 22], while the persuasiveness of interfaces refers to the perceived persuasive design of multimedia interfaces [24].

The following studies explained the previous works related to a system's perceived persuasiveness. Ref [15] concerned about the factors that affect perceived persuasiveness. Survey items were developed based on the construct of PSD framework that measured primary task support, dialogue support, perceived credibility, unobtrusiveness, and design aesthetics. The study conducted on a web-based health program found that the persuasive system categories of the PSD framework affect the perceived persuasiveness of a system. On the other hand, [20] investigated factors influencing the perceived persuasiveness of a web-based health program and whether perceived persuasiveness predicts intention to utilize the intervention and actual system use. The report also indicated that the PSD categories [9] influence perceived persuasiveness and system usage. The study developed survey items to measure perceived persuasiveness and the categories in the PSD framework. After that, the items were used in several studies to assess perceived persuasiveness [21-23]. In addition, [17] adapted the Perceived Persuasiveness Questionnaire [15] to evaluate the perceived persuasiveness of a Nurse Antibiotic Information App (NAIA) using user tests and expert assessments. The expert assessment approach discovered primary task support, credibility, unobtrusiveness, perceived persuasiveness, perceived effort, and perceived effectiveness in the app. A similar outcome was obtained using the user test approach, with good remarks on primary task support, perceived persuasiveness, and unobtrusiveness. Ref [21] studied the impact of perceived persuasiveness of behavior model design on self-efficacy, self-regulation, and result expectancy. The study adopted [20] questionnaire items to measure the perceived persuasiveness of a fitness app. The findings revealed that the perceived persuasiveness of a behavior model design increased users' outcome expectations positively for their engagement in the target exercise behavior.

The study [22] investigated if integrating perceived persuasiveness in the TAM will result in a better model and the moderating effect of culture. According to the findings, individuals in individualist cultures were more likely to recognize the persuasiveness of a fitness app. As a result, incorporating a persuasive construct into the TAM is likely to be relevant compared to collectivist culture. Individualist group involving perceived persuasiveness are more likely to result in long-term persuasive system adoption than the collectivist group with no perceived persuasiveness. The author [23] studied users' susceptibility to the perceived persuasiveness of the fitness app and each persuasive element. The study developed a model to understand better the relationship between perceived UX design traits (such as perceived usefulness, credibility, and aesthetics) and users' susceptibility to persuasive features included in persuasive technologies. Persuasive features from the PSD framework [9], such as Goal setting/Self-Monitoring, Reward, Cooperation, Competition, Social Comparison, and Social Learning, were evaluated, and survey items from [20] were used to assess the fitness app's perceived persuasiveness. According to the findings of the study, perceived usefulness, followed by perceived aesthetics, has the most significant association with users' susceptibility to the persuasive elements.

Meanwhile, the persuasiveness of interfaces lacks attention from HCI researchers except those listed in the first paragraph in Section B. In [19] the authors have developed a set of guidelines to assess the persuasiveness of interfaces. The study examined 15 website and application interfaces to provide a criteria-based approach to classifying and evaluating the persuasive power of interfaces. Eight criteria were established and identified from the 15 interfaces. The criteria were divided into a static and dynamic category; each consisted of four criteria. The static category, which consists of credibility, privacy, personalization, and attractiveness, are related to the content impact to engender user adoption and engagement experience. Static criteria are all the interface elements required to kickstart a process of user engagement. The dynamic category consists of solicitation, priming, commitment and ascendancy. The dynamic criteria serve as an approach to immerse the users in an interactive process that gradually engages them with the interface to motivate users to change their behavior. The criteria for interactive persuasion emphasize the social and emotional aspects of interfaces, complementing the traditional inspection criteria (e.g., clarity, consistency, homogeneity, compatibility, and usability). These criteria involved the temporal aspects of the interface. The study [12] used a set of instructions [20] from an existing e-learning program for self-regulated middle school mathematics learning to conduct a persuasiveness assessment. The findings demonstrated that personalization, attractiveness, solicitation, initiation, and commitment criteria explained the low engagement when using the e-learning program. In addition, the ascendancy criteria were found to be irrelevant for educational interfaces. Credibility and privacy criteria dominated the user engagement with the e-learning program. The author [24] conducted a study based on user time spent to assess the usability and persuasion of social networking mobile

applications such as YouTube and Facebook. The analysis on persuasion reveals that Facebook and YouTube utilize a series of persuasion strategies to engage the user in an engaging cycle and keep them online for a longer time. Using the persuasion criteria [19], the study discovered some criteria emphasize being subtle and obtrusive. The subtle strategies rely on targeted suggestions to distract the user's attention and prompt engagement. In contrast, an obtrusive mechanism, such as a notification system, was used even when the user was not linked to the software.

In summary, health seems to be the domain concern of the previous works investigating persuasive technology's perceived persuasiveness. The persuasiveness of interfaces has been studied diversely, including websites, mobile apps, an e-learning system, and social networking applications. However, this present study focused on the LMS used in a higher learning institution since persuasive learning has become a concern among HCI researchers [14, 25]. Compared to the previous works, this study will conduct an integration study on the persuasiveness of interfaces and persuasion design strategy. Both perspectives are essential in determining user engagement towards using the LMS [14, 25].

### III. METHODOLOGY

The methodology approaches in performing the study are described in this section, which includes (a) participant, (b) material, (c) measures and analysis, and (d) procedure. The following are the subsections:

#### A. Participant

Two experts in Human-Computer Interaction (HCI) and one expert in E-learning were recruited for the evaluation study. They were picked based on their five years of expertise in those research fields, as well as their consistent journal publications in the field. To prevent bias, the hired experts were chosen not among the system's users.

#### B. Material

SMART2 and SMARTv3 were the two versions of the learning management system from Universiti Malaysia Sabah used as the case study (refer Fig. 1). The SMART2 refers to an older version of the LMS, whilst the SMARTv3 refers to the most recent version. Both system versions have comparable capabilities, although the SMARTv3 has a modest upgrade in the interface design. SMART2 has been used for ten years in UMS before the ICT Department came out with SMARTv3 in the year 2020 on Semester 2. For the last ten years, SMART2 has received complaints from the students and lecturers regarding functionality and interface design. These have made some of the lecturers switch to other platforms for their blended learning.

Six interfaces of both LMS versions were selected based on the frequency of students visiting or using the interface. The interfaces are the homepage before login, course page, assignment view, assignment submit view, forum, and quiz. Fig. 2 illustrates the six selected interfaces of the LMS versions.

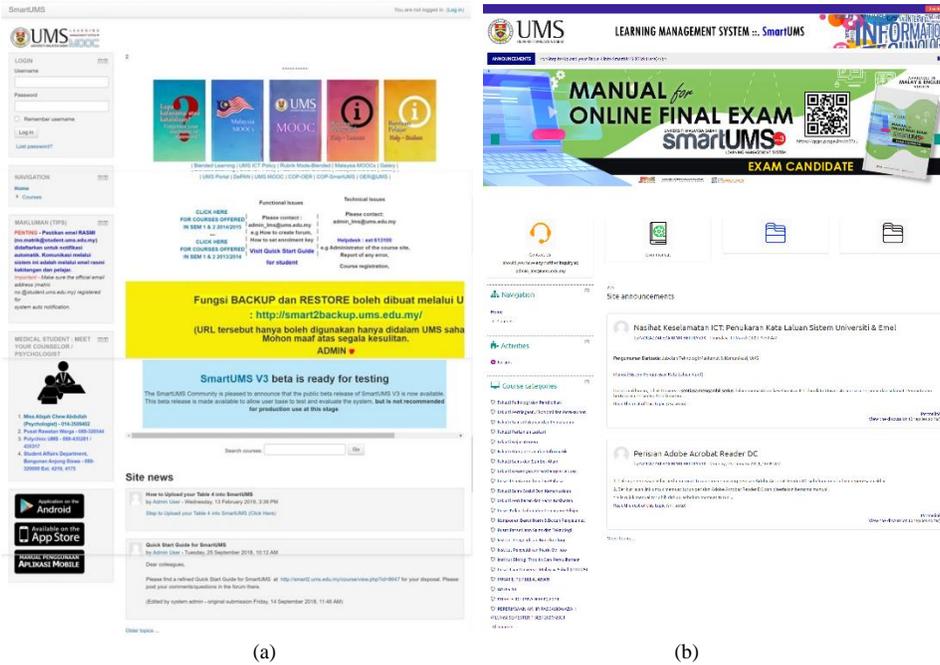

Fig. 1. Learning Management System: (a) SMART2; (b) SMARTv3.

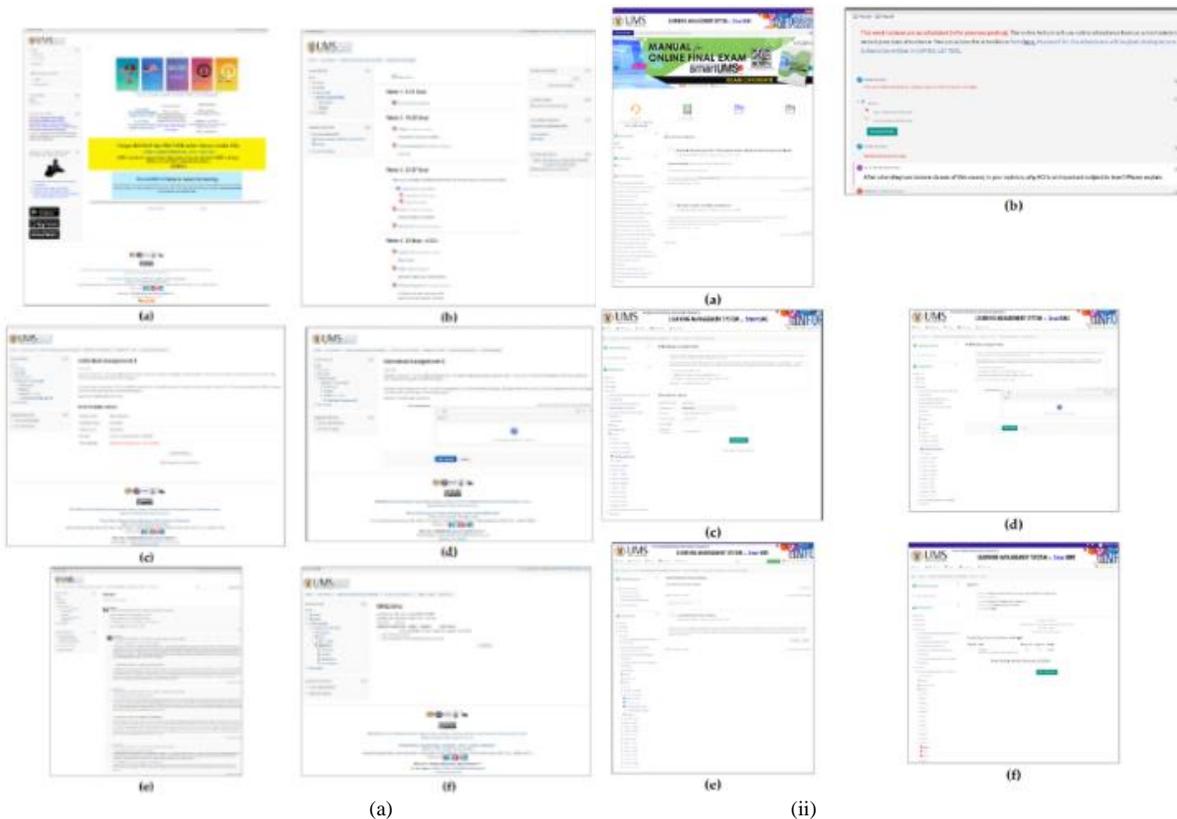

Fig. 2. Interfaces of (i) SMART2; (ii) SMARTv3. The Interfaces are (a) Homepage; (b) Course Page; (c) Assignment View; (d) Assignment Submission; (e) Forum; (f) Quiz.

### C. Measures and Analysis

In the evaluation study, a heuristic inspection is performed to assess both persuasiveness of interface and persuasive strategy design to obtain insight from professionals in an

independent walkthrough using established persuasive grid criteria [12] and PSD model [9]. The grid contains eight criteria and 23 sub-criteria. In addition, the experts examined the six selected interfaces of both LMS versions using evaluation

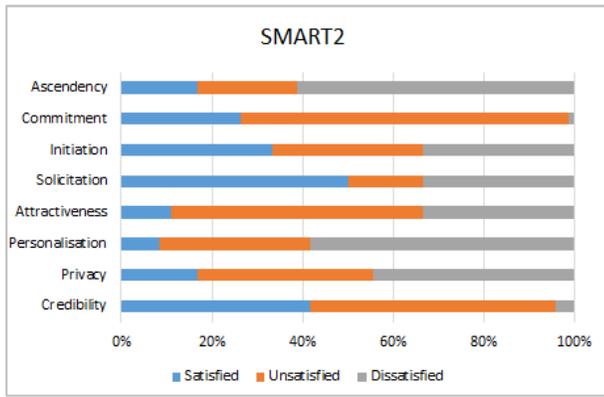

Fig. 4. Compilation of Persuasive Interface Criteria for Smart2.

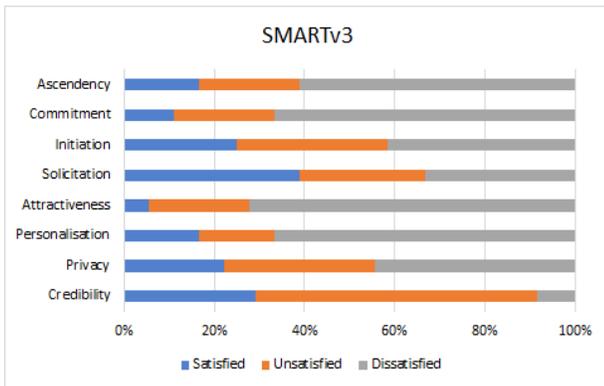

Fig. 5. Compilation of Persuasive Interface Criteria for Smartv3.

Table I outlines some of the critical concerns from both systems that were discovered during the inspection, as well as the corrective suggestions that were made as a result of the findings.

TABLE I. CRITICAL CONCERNS FROM PERSUASIVENESS INSPECTION

Persuasion Interface Criteria	General Comments	Design Examples
Credibility	<ul style="list-style-type: none"> <li>- Improve the surface design of the interface in terms of layout and navigation to increase trustworthiness and legitimacy on user perception towards the system</li> <li>- Allow for various searching approach based on the course code and name, lecturer and course program and faculty</li> </ul>	Use UI elements such as dropdown menu to list the courses users have taken instead of listing everything on the page
Privacy	Make the privacy elements immediately visible to the user without making them to scroll until the end of the page or having them to click on a link.	Use a banner or images that symbolises user's data privacy and security is protected.
Personalisation	<ul style="list-style-type: none"> <li>- Should allow users to tailor the interface according to the their needs to create the sense of belonging.</li> <li>- Lack in mechanism to provide a personalise</li> </ul>	<ul style="list-style-type: none"> <li>- Personalise message that welcome or praise user will attract and engage user to use system.</li> </ul>

	message that compliment students progress or achievement - Recommend system to provide a personalised suggestion that can enhanced learning based on student's past activities	-Screen customisation that allow users to change screen display or information layout of their preferences. -Compliment message that show personalise encouragement to students on progression and achievement. -Personalised proposal that reflect from past activities achievement.
Attractiveness	Make use of different color or color themes for emotional design elements such as images, font, icons and emoticons to attract user graphically.	- Using attractive colors or color themes for font and background color. - Pictures, icons, and various emoticons that attract user to initiate actions.
Initiation	Make use of multimedia elements that can persuasively trigger and initiate user to start first action.	- Using blinking graphic to emphasis importance on such links or tasks. - Use motivational element such as reward, badges that encourage user to complete tasks.
Commitment	Improve the interaction by utilising tunnelling approach to make the user involved and engaged with the whole process in order to access the next task and able to invite or remind their coursemates who have not yet completing the task.	-Regularly create tasks to let the user get involved frequently. - Propose a pop-up list to invite or remind other user to complete the next course material.
Ascendancy	- Improve UI by applying emotional design elements to create emotional attachment and trigger positive emotion among user. - Should adopt social network design to create immersive interaction and repetative use.	- Utilise emotional design elements such as images, graphic, animation, video, text, navigation and layout to trigger positive emotion. - User profile page should be design according to social network that allow connection with other user.

**B. Persuasive System Design**

The result on the inspection of PSD categories is presented in Fig. 6. Finding shows that all four PSD categories; primary task support, dialogue support, system credibility and social support were found in Smartv3, while for Smart2 LMS, social support category were not found from the six screen interfaces, making only three PSD categories namely primary task support, dialogue support, system credibility existed. Both LMSs scored high in implementing system credibility principles, while social support principles were the least PSD implemented.

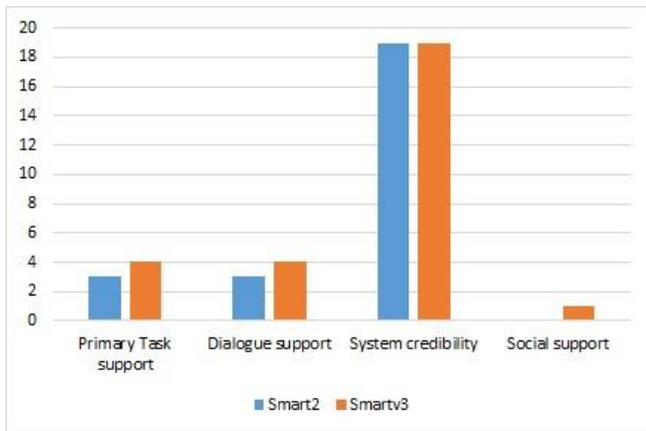

Fig. 6. Summary of PSD in Smart2 and Smartv3.

Fig. 7 illustrated the number of PSD principles implemented in six screen interfaces. It is found that PSD principles were merely implemented in the course page interface compared to others for both LMSs.

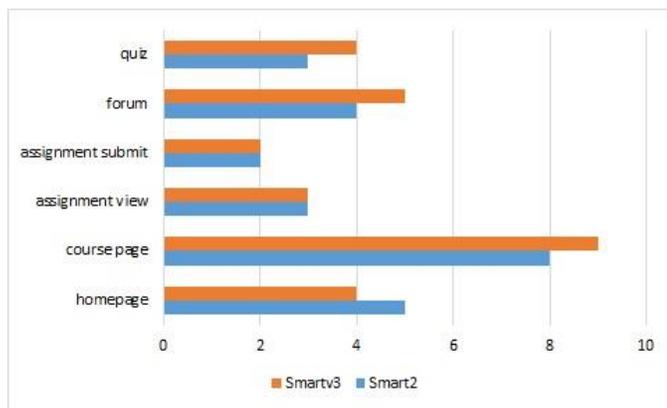

Fig. 7. Numbers of PSD Principles in Smart2 and Smartv3.

A summary of PSD principles found in both systems during the experts' evaluation study is presented in Table II. The findings show that PSD principles are not necessarily implemented in every interface. The implementation of PSD principles depends on the purpose of interface and activities conducted in it. The homepage interface applied system credibility principles in both Smart2 and Smartv3 system according to its function as the introductory interface. The principles are mainly Surface credibility, Real-world feel, Authority, and Third-party endorsement. All four PSD categories were implemented in the course page interface for Smartv3 system, except for Smart2 where none of social support principles is implemented. The course page interface is an instructional component in LMS where it allows for the instructor to create various learning tasks implemented using various forms and deliverables such as animation, games, or video [25]. The interface of assignment view enables student to view and read the assignment provided by the course instructor. The dialogue support and system credibility principles were found in this interface. Those principles are Reminder, Trustworthiness and Surface credibility. The assignment submit's interface consists of two system credibility principles which are Trustworthiness and Surface credibility. Meanwhile,

the forum interface applied PSD principles of primary task support, dialogue support and system credibility, except for Smart2 system where none of primary task support principles are found. The principles consist of Self-monitoring, Liking, Surface Credibility, Real-world feel, and Authority. The same PSD categories were also found in quiz interface where principles of dialogue support and system credibility were implemented in both systems except for Smart2 system only implemented system credibility principles. The applied principles were Reminder, Surface Credibility, and Real-world feel.

TABLE II. PSD PRINCIPLES IN SMART2 AND SMARTV3

Interfaces	PSD Principles		PSD Category
	Smart2	Smartv3	
Homepage	Surface credibility, Real-world feel, Authority, Third-party endorsement	Surface credibility, Real-world feel, Authority, Third-party endorsement	System Credibility
Course page	Reduction, Tailoring, Self-monitoring	Reduction, Tailoring, Self-monitoring	Primary Task Support
	Reminder	Reminder	Dialogue Support
	Trustworthiness, Surface credibility, Real-world feel, Authority	Trustworthiness, Surface credibility, Real-world feel, Authority	System Credibility
	n/a	Social learning	Social support
Assignment view	Reminder	Reminder	Dialogue Support
	Trustworthiness, Surface credibility	Trustworthiness, Surface credibility	System Credibility
Assignment submit	Trustworthiness, Surface credibility	Trustworthiness, Surface credibility	System Credibility
Forum	n/a	Self-monitoring	Primary Task Support
	Liking	Liking	Dialogue Support
	Surface credibility, Real-world feel, Authority	Surface credibility, Real-world feel, Authority	System Credibility
Quiz	n/a	Reminder	Dialogue Support
	Surface credibility, Real-world feel	Surface credibility, Real-world feel	System Credibility

Persuasive design and learning generally have a positive impact to motivate students to learn [25, 26]. The principles of reduction, tailoring and self-monitoring are used in course page to enable course development and implementation. These principles were found to excite students by stimulating intrinsic motivation, assisting students in completing tasks, and encouraging a continuous cycle of online learning [26]. Even though the social learning principle is implemented in both systems, social learning should be the least important concept to adopt in supporting students' learning progress [27] and in promoting student learning engagement [28]. Trustworthiness depicts a reliable system that gives accurate, impartial, and fair information to accomplish the desired behavior [9]. It specifies

an approach for allowing a user to trust the system such as using logo of the organization to show that the system is owned or prepare a list of references or information sources connected to the course material [25]. Generally, the surface credibility is more on the firsthand look of an interface that makes a system looks credible to use. The inspection result shows that all the six-screen managed to portray a surface credibility to its users.

### V. DISCUSSION

This study shows that persuasive designs have been implemented in the LMS for higher education. However, the effectiveness of persuasive design principles applied in the interfaces may be argued. Therefore, we mapped a persuasive design framework for LMS that consist of 13 strategies based on the LMS components and activities comprises the four dimensions of PSD. Further reading on the framework can be found in [25]. Table III summarizes the mapping of six screen LMS interfaces with the framework we have previously developed by aligning the interfaces to LMS components and activities.

The study's drawback is limited to one higher learning institution and the five most viewed websites by students. Having two separate versions of an LMS, on the other hand, is sufficient to disclose insights regarding LMS design in a higher learning institution. Nonetheless, future research might be broadened to investigate additional LMS design in different higher education institutions.

TABLE III. MAPPING OF SIX SCREEN INTERFACES WITH PSD FOR LMS

Interfaces	PSD Framework for LMS		
	LMS components	Activities	PSD Principles
Homepage	Administrative	Student enrolment	Praise
	Visual	Interface design	Liking, Trustworthiness, Personalization
Course page	Administrative	Monitor learning progress	Self-monitoring, Reward, Competition, Social comparison
	Instructional	Course development	Tailoring
		Course implementation	Reduction, Self-monitoring
	Support	Tracking learning process	Suggestion, Tunnelling, Self-monitoring
	Visual	Interface design	Liking, Trustworthiness, Personalization
Assignment view	Instructional	Course implementation	Reduction, Self-monitoring
Assignment submit	Instructional	Course implementation	Reduction, Self-monitoring
Forum	Interactive	Communication	Social role, Praise
Quiz	Instructional	Course implementation	Reduction, Self-monitoring
	Interactive	Communication	Social role, Praise

Despite those limitations, this study contributes to the establishment of design recommendations to increase persuasiveness of LMS interfaces in order to ensure that the LMS can capture and engage its users. Furthermore, this study also proposes a framework that can be utilized by higher learning institution, specifically in designing the six most visited interfaces in the LMS by mapping LMS interfaces to PSD.

### VI. CONCLUSION

This study examined the persuasiveness of interface and the application of persuasive design in the case of higher learning institution with two versions of learning management system: Smart2 and Smartv3. The results show that both system versions successfully meet the solicitation criteria that managed to establish relationship and prompt user action through its interface design. However, both system versions are lacking in other persuasiveness of interface criteria such as credibility, privacy, personalization, attractiveness, initiation, commitment, and ascendancy. The ascendancy criteria which supposed irrelevant in educational interface happened to be found in both system versions making previous literature and our finding contradict. This study discovered that minimal persuasive design principles have been utilized in LMS for higher education. This has contributed to the development of persuasive LMS framework which can be used as a guideline to design an effective persuasive LMS. In the future, development of a prototype based on the developed framework can be used to assess the framework empirically. The study contributes to the body of knowledge in human-computer interaction in the educational area where the framework can be used to improve the LMS design in encouraging positive learning behavior.

### ACKNOWLEDGMENT

This study is part of the research work funded by Universiti Malaysia Sabah under the Grant Scheme Acculturation (SGA) (SGA0017-2019).

Pathumthani, Thailand

**Abstract**—This study aims to develop the semantic ontology of information knowledge about ethnic groups by analyzing information from the collection of documentary sources from libraries, research, and the museum for learning about people on the highlands located in Chiang Mai Province. The study is based on the classification theory of ethnic groups in Chiang Mai Province with the intention of establishing the relationship between knowledge structure regarding ethnic groups. The study procedures consist of three stages: 1) Establishing ontology requirements from online data to analyze the data of the keyword from the research database of Chiang Mai University Library's Online Information Resource Database (OPAC) and Ratchamangkhaphisek National Library, Chiang Mai to group the words by studying information resources in Thai language, such as books, textbooks, research papers, theses, research articles, academic articles, and reference books related to ethnic groups. Stage 2) Designing classes, defining main classes, subclasses, hierarchies, and properties in order to establish the relationship of data in each class using the Protégé program. Stage 3) Ontology evaluation, which is divided into two parts: an expert's evaluation of the suitability of the ontology structure using the Inter-Class Relational Accuracy Assessment Scale and an examination of ethnic grouping data. The findings reveal that specifying, definition, scope, and objectives of development are appropriate (average score = 0.97) in three areas: grouping and ordering of classes within the ontology (score value = 0.98), defining affinity names and class properties (score value = 0.96), and suitable overall ontology content (score value = 0.97).

**Keywords**—Information retrieval; ontology development; ethnic groups; knowledge organization; Chiang Mai

## I. INTRODUCTION

The term "Ethnic Group" refers to a group of people who have a long history in Thai society, with different aspects and having their own culture and customs. It is a group in which the population is related to one another, sharing the same racial characteristics, culture, traditions, and language, and is devoted to the conservation, development, and inheritance of ancestral land and ethnic identity from one generation to the next. Ethnicity is the classification of people and their relationships between different groups in society based on cultural differences and inferiority in political power, society, and the economy. However, it may not be a minority that has a smaller population than a society [1], [2], [3]. Formerly, ethnic groups

were diverse and settled in various provinces throughout Thailand [4]. There are currently 67 ethnic groups in 56 provinces with a total population of around 6,100,000 people. Settlements are categorized into four types as follows:

1) The highland ethnic groups, or "hill tribes", consist of 13 groups: Karen, Hmong (Miao), Yao (Mien), Lisu (Lesu), Lahu (Muser), Akha, Lua, Tin, Khmu, Chinese Hor, Tong Su, Kachin, and Palaung (Dara-ang).

2) Ethnic groups that settled on the plains consist of 38 groups, namely Mon, Tai Lue, Tai Song Dam, Tai Yai, Tai Khuen, Tai Yong, Tai Ya, Tai Yuan, Phu Tai, Lao Krang, Lao Ngaew, Lao Ka, Lao Ti, Lao Wiang, Saek, Sere, Prang, Bru (Chao), Song Vo (Tawing), Umpi Kong Kula Chou Oj (Chu Oong), Kui (Suay), Nyah Kur (Chao Bon), Nyaw, Yoy, Khmer Thai, Vietnam (Yuan), Nye Mee Sor (Bizu), Chong, Krachong, Malay, Kaleang, and Lao Song (Tai Dam).

3) Ethnic groups that settled on coastline or "Chao Lay" consist of three groups, including Moken, Moklen, and Urak Lawoi.

4) Ethnic groups that live in the forest consist of two groups: Mlabri (Tong Luang) and Sakai (Mani).

Ethnic groups are people who share a similar way of life, beliefs, culture, customs, and language, as well as a shared history. In addition, each ethnic group organizes its way of life differently. The manner in which each group interacts with each other and their relationships is distinctive [5], [6]. The separation of an ethnic group is essential in a society based on diverse ancestral teaching practices, a group of people with different biological characteristics, histories, and roles in society. Therefore, behavior and beliefs, occurring in human society and referred to as "culture," are different as well. A study of relational ethnography emphasizing ethnic groups as cultural groups that share ancestors or a long history is a study of the organization of social and governance, beliefs, customs and rituals, spoken language, clothes, and so on of each ethnic group. Currently, new generations of ethnic groups are taking a greater role in studying their own ethnic groups, providing them with more opportunities to learn about ethnic cultures [7]. Research information on ethnic groups is abundant and diverse, such as language, culture, literature, history, archeology, pottery, anthropology, folklore, habitation, and way of life,

---

This research was funded and supported by the Faculty of Humanities, Chiang Mai University. The researcher would like to give special thanks for such support for this research.

which are mostly separated into specific areas. For example, the study of language attitudes of Tai ethnic group toward their own language in the lower northern region and the study of the use of various Tai dialects in the lower northern region. It is a comparison of tendencies and situations in language usage and language attitudes toward their own dialects of Thai people who speak Tai dialect in the lower northern region and a study of the way of life of the Hmong ethnic group in Mae Rim District, Chiang Mai Province [8], [9]. Therefore, searching for relational and related information is limited.

Ontology is a concept applied in knowledge management. It is widely used and studied, and it is able to organize and present knowledge in the form of conceptual groups and interrelationships within the scope of interest [10]. It creates a hierarchical relationship by using the concept of grouping and segmentation [11], [12]. Applying ontology concept to ethnic groups, namely Ethnicity Ontology (EO), was developed as an extension of the Basic Formal Ontology two standard for general reference to ethnographic concepts. It combines semantic datasets from different knowledge sources to compile definitions for interpretation [13]. Gathering data and building relationships in a hierarchical form is often used in the fields of artificial intelligence, semantic web, software engineering, and biomedical informatics [14]. To design and develop ontology for information retrieval of ethnic groups in Chiang Mai, the researcher gathered knowledge of different ethnic groups by having the information integrated according to the concept of ontology, which is a type of knowledge management system that plays an important role in semantic explanations. This is to create a common understanding of a particular field of knowledge using a single concept. This study defined or created a vocabulary system that can be used to illustrate knowledge that represents a comprehensive scope of knowledge. It can be used as a base for semantic searches for the development of knowledge-based systems, as well as a semantic search system for specific information systems related to ethnic knowledge in Chiang Mai province.

## II. CONCEPTUAL FRAMEWORK AND METHODOLOGY

### A. Objectives

1) Design and develop ontology for information retrieval about ethnic groups in Chiang Mai.

2) Evaluate ontology for information retrieval about ethnic groups in Chiang Mai.

### B. Conceptual Framework

The objectives of this study is to design, develop, and evaluate ontology for information retrieval about ethnic groups in Chiang Mai. The researcher conducted the study according to the conceptual framework as shown in Fig. 1.

### C. Methodology

1) *Concept and theory*: The development of ontology was based on the basic ontological of knowledge sharing approach [15], which the researcher employed primarily to develop Domain Ontology as the main framework. There are three stages of development as follows.

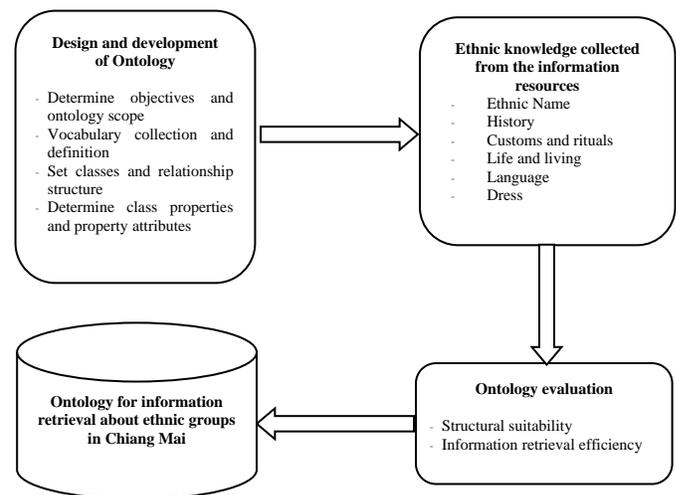

Fig. 1. Conceptual Framework.

a) Determine ontology objectives by studying the ontology requirements from online data to analyze the data of the keyword from the research database of Chiang Mai University Library's Online Information Resource Database (OPAC) and Ratchamangkhaphisek National Library, Chiang Mai for grouping the words.

b) Protégé program was utilized to establish word correlations related to ethnic groups.

c) Ontology evaluation is divided into two parts: the evaluation of the suitability of the ontology structure using the Inter-Class Relational Accuracy Assessment Scale by five experts (two ontology specialists) and an examination of ethnic grouping data (three ontology specialists).

The development process of ontology has applied knowledge engineering theory for developing the ontology to make domain assumptions explicit as a framework [16]. The development process consists of seven stages: 1) determining domain and scope of ontology; 2) lexical clarification; 3) class and class hierarchy establishment; 4) defining relationships; 5) defining properties; 6) defining views on class properties; and 7) creating sample data within that class.

### 2) Research development process

a) *The development of ontology has three phases*: Phase 1: Determine the objectives and scope and ontology's scope to present a set of terms and concepts related to ethnic groups in Chiang Mai from the online data to analyze the keyword data from the research database from the Online Information Resource Database (OPAC), research database (e-Research), thesis database (e-Thesis), and journal database (e-Journal) of Chiang Mai University Library for 330 items, as well as the National Library of Thailand's Online Information Resource Database (OPAC) for 453 items, for a total of 783. This is to study the term group and apply it suitably for the design and development of ontology, along with the group of obtained words used in interviewing three experts in ethnology to collect information from them. Furthermore, it is to evaluate the correctness of the data obtained from the conceptual and vocabulary analysis processes to classify knowledge

(Knowledge classification approach) of Broughton [12] from the document and systematically prepare it before taking it to the next phase.

Phase 2: From the collection of word groups in phase 1 for developing ontology that consists of vocabulary grouping, setting main classes and subclasses, determining properties and attributes of classes, and creating representative data within classes for defining the vocabulary value and data attributes, the Protégé program was applied to design and develop the ontology, class design, main class and subclass setting, hierarchy, properties, and relationships between classes in a technical connection form.

Phase 3 Ontology evaluation. It is to confirm the academic authenticity of information about ethnic groups in Chiang Mai from experts and use the evaluation results to improve the ontology appropriately. The ontology evaluation is separated into two parts, which are the evaluation of the vocabularies of ethnic groups in Chiang Mai. Then, three ethnic experts would evaluate the structured vocabulary's coherence in the correlation grouping. Additionally, the evaluation of class relationships and class properties would be tested by two experts in ontology, using the accuracy, consistency, and suitability assessment scale of the structure and word relationships by finding the consistency value. To be more accurate and complete, the researcher utilized expert advice to gather, organize, and summarize the results.

b) *Research tool*: Protégé program is a free, open-source knowledge management system program developed by Mark Musen in 1987 and a team at Stanford University [17]. It has established an ontology evaluation approach using the evaluation of Obrst and team [18]. It consists of the evaluation of 1) a process of identifying definitions, scope, and objectives of development; 2) a method of defining a concept or class; 3) a process for defining a class's properties; 4) a process for creating a model or representative data; and 5) applications and development guidelines in the future.

c) *Data analysis*: The researcher analyzed the data by evaluating the Index of Conformity or IOC (Index of item objective congruence) based on advice and suggestions from three experts in ontology and semantic web and two experts in ethnic groups in Chiang Mai, a total of five people. Upon seeking the experts for this study, the researcher required experts who are qualified as academics or researchers in a relevant field with research papers, academic papers, or other works that have been published continuously to date, or who are recognized nationally or internationally, or qualified people with experience doing research or teaching in a related field. The criteria that are acceptable and considered to be consistent or appropriate are a score of 0.5 or higher, whereas a score of less than 0.5 must be improved [19].

### III. RESULT AND CONCLUSIONS

The development of ontology for information retrieval about ethnic groups in Chiang Mai aims to design, develop, and evaluate the ontology for information retrieval about ethnic groups in Chiang Mai. The summary of the findings is divided into three parts as follows:

#### A. Development of a Semantic Ontology of Knowledge about Ethnic Groups in Chiang Mai

The results of the study on ethnic groups in Chiang Mai revealed that the scope of knowledge of ethnic groups in Chiang Mai can be divided into nine groups: 1) ethnic Name; 2) history; 3) customs and rituals; 4) life and living; 5) language; 6) religion and faith; 7) dress; 8) entertainment; and 9) economy and society. The knowledge structure of ethnic groups in Chiang Mai can be divided into nine main classes, 29 subclasses, and 37 subgroups. An example of knowledge structures is shown in Table I.

According to Table I, it shows the main classes and their descriptions of the nine main classes, each with subclasses, subgroups, and properties to describe their relationship to the main class in more detail by dividing 29 subclasses, 37 subgroups, and 37 class properties. An example of the design of ontology can be seen in Table II.

Table II demonstrates the main classes and subclasses, as well as the description of subgroups and their properties, to show the relationship after the design of the ontology and then to establish the relationship with the Protégé program, which illustrates an example of ontology design and shows the relationship between main classes and subclasses as shown in Fig. 2.

TABLE I. CLASS STRUCTURE AND THE DESCRIPTION OF THE MAIN CLASS OF THE ONTOLOGY

<b>Ethnic groups (Ethnic Group: thing) in Chiang Mai who have their own names, customs, religion, dress, etc. can be shown according to the ontology's main classes and subclasses divided by relationships.</b>		
<i>Class no.</i>	<i>Class name</i>	<i>Class description</i>
1.	Ethnic Name	A group of people who are officially named according to documents and research.
2.	History	History, origins, migrations, and settlements of ethnic groups.
3.	Customs and Rituals	The expressions, behaviors, worship, role models, or patterns that most people hold in their ethnic groups serve as a pattern for future generations to follow.
4.	Life and Living	The way of life of people in ethnic groups, such as food, medication, way of life, occupation, animal husbandry, wisdom, utensils, accessories, and social values.
5.	Language	Phonetic characters, words, speech, and symbols are used in place of speech to express one's ethnicity.
6.	Religion and Faith	Forms of belief, faith, religiosity, or cult of belief in regard to many matters in ethnic groups.
7.	Dress	Elements or dress styles of people in ethnic groups.
8.	Entertainment	Grouping together to communicate certain things, emotional expressions, and stories for entertainment and pleasure.
9.	Economy and Society	Earning money, exchange system, economic system of people in ethnic groups that generate income for each other, social organization of people in ethnic groups from the household level to the community level.

TABLE II. AN EXAMPLE OF THE DESIGN OF ONTOLOGY FOR INFORMATION RETRIEVAL ABOUT ETHNIC GROUPS

No .	Main classes	Subclasses	Subgroups	Properties	
1.	Ethnic name	Self-name	Name Meaning	Creating a group name	
		Official name	Official name	Difference	
		Other name	Other name		
2.	History	Origin	Origin	Route of immigration	
		Original settlement	Original settlement		
		Immigration to Thailand	Route		
		Story/myth	myth	Name	Story

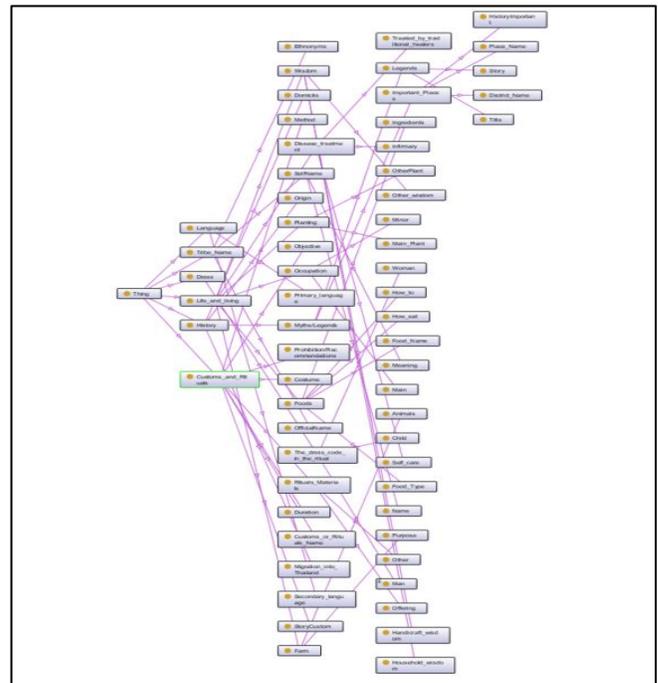

Fig. 2. Relationships between Ontology's Main Classes and Subclasses for Information Retrieval about Ethnic Groups in Chiang Mai.

**B. Results of Ontology Evaluation for Information Retrieval about Ethnic Groups in Chiang Mai**

Ontology evaluation is divided into two parts, which are the evaluation of the ontology structure by experts and an examination of the data analysis by evaluating the consistency index. The details are as follows:

1) The results of the evaluation of the suitability of the ontology structure for information retrieval about ethnic groups in Chiang Mai by experts found that the suitability of the ontology scored at 0.93. Class grouping, class ordering, class name, property name, the relationship between classes, the name of the relationship between classes, the accuracy and appropriateness of ontology content, and ontology overview were appropriate at 1.00. Followed by ontology class and its properties or attributes, the appropriateness was 0.66, respectively. These results are as shown in Table III.

TABLE III. RESULTS OF ONTOLOGY EVALUATION OF ETHNIC GROUPS

Items	IOC	Results
1. Class grouping within the ontology	1.00	Appropriate
2. Class ordering within the ontology	1.00	Appropriate
3. Ontology classes	0.66	Appropriate
4. Name of classes within the ontology	1.00	Appropriate
5. Properties or attributes of classes	0.66	Appropriate
6. Name of properties	1.00	Appropriate
7. Relationships between classes	1.00	Appropriate
8. Name of the relationships between classes	1.00	Appropriate
9. Accuracy and appropriateness of ontology content	1.00	Appropriate
10. Ontology overview	1.00	Appropriate
<b>Total</b>	<b>0.93</b>	<b>Appropriate</b>

2) The evaluation of data analysis was conducted by determining the Index of Conformity, or IOC (Index of item objective congruence), with an acceptable average score of IOC. If a value is 0.50 or higher, the content is consistent and applicable [20]. The evaluation by two ethnic and cultural experts assessed the analysis of the data by determining the conformity index used to connect and group information of ethnic groups. The overall evaluation results revealed that the ontology structure was consistent and had definition value, scope, and objectives of development. The results were also found to be consistent (score value = 0.89) in three areas: defining relation name and class properties (score value = 0.88), grouping, and ranking of classes within the ontology (score value = 0.90), and the accuracy and appropriateness of the overall ontology content (score value = 0.90), as demonstrated in Table IV.

TABLE IV. RESULTS OF THE ONTOLOGY CONSISTENCY EVALUATION FOR INFORMATION RETRIEVAL ABOUT ETHNIC GROUPS

Items	IOC	Results	
Specifying, definition, scope, and objectives of development are appropriate	1. Name of classes within the ontology	0.95	Consistent
	2. Properties or attributes of classes	0.98	Consistent
	3. Name of properties	0.98	Consistent
	4. Relationships between classes	0.96	Consistent
	5. Name of the relationships between classes	0.98	Consistent
<b>Consistency average</b>	<b>0.97</b>	<b>Consistent</b>	
Class grouping and ordering within the ontology	1. Class grouping within the ontology	0.98	Consistent
	2. Class ordering within the ontology	0.97	Consistent
	3. Ontology classes	0.98	Consistent
<b>Consistency average</b>	<b>0.98</b>	<b>Consistent</b>	
Accuracy and appropriateness of the overall ontology content	1. Accuracy and appropriateness of ontology content	0.97	Consistent
	2. Ontology overview	0.95	Consistent
<b>Consistency average</b>	<b>0.96</b>	<b>Consistent</b>	
<b>Total</b>	<b>0.97</b>	<b>Consistent</b>	

The results of the evaluation can be used in class design, relationships between classes, and properties of classes within the ontology for information retrieval about ethnic groups in Chiang Mai, making the developed ontology more suitable and consistent with the query requirements.

### C. Conclusions

The structural classification resulting from this research is based on the principle of main classes and subclasses and by stratification based on the knowledge found in the source material. Ontology of ethnic groups covers many dimensions and reflects the content of ethnic groups in Chiang Mai Province of Thailand. The classification of ethnic groups in Thailand is detailed in many aspects which grouped the population according to the cultural and ethnic group. This is classified by using the criteria of the original topographic location and other similar factors, such as social characteristics, customs, history, etc. The structure is concluded three groups: (1) cultural and ethnic similarities according to the classification criteria; (2) identification of ethnic groups or groups; the culture is more detailed than the first two levels and (3) livelihoods of knowledge classification and knowledge structure of ethnic groups in Thailand focuses on data extraction. Named ethnic groups of Thailand as the main constituent groups with similar and related topics. This research apart from others is the effort to categorize details under each main class and subclasses. For example, in Class 7, subsistence, the class of dress care has four subclasses, i.e., Shirt, Pants, Accessories, Foot. This research organizes classes and subclasses of knowledge margins and creates a knowledge structure that delves into the content of various researches. Details are given hierarchically from subclasses to different properties and it will be useful in the future, although this ethnic knowledge structure is for an ontology developed to support semantic web for searching capabilities and recommendation system [21], [22]. Also can be applied to data extraction in other ways, such as for a large number of ethnic sources, for example, semantic web construction. Therefore, ethnic classifications in Thailand can be combined with and used to expand the assigned classification notation. To categorize ethnic group outcomes appropriate to an automated retrieval system that provides access to the content of information resources rather than lists, the researchers also saw that the methods used in the study could be applied to improve knowledge classification.

### IV. DISCUSSIONS

The ontology design for information retrieval about ethnic groups in Chiang Mai is developed to define the classification structure of knowledge subjects arising from the classification structure based on the source of knowledge and ethnic and cultural experts. This is in accordance with the principle of grouping as well as sub-components of ethnic knowledge, which is comprehensive and reflects the content of ethnic groups of Chiang Mai. It is also in line, where there is a detailed grouping of the ethnic structure of Thailand with a hierarchical structure analysis that includes the original geographic location and other similar factors, such as social characteristics, customs, history, etc. [23] These include structures that can be divided into three levels: (1) geography; (2) cultural and ethnic similarity according to classification criteria; and (3) ethnic

identification, group, or culture with details. When cultural grouping is conducted in accordance with the process for grouping and retrieval of the body of knowledge, which consists of a body of knowledge derived from wisdom and culture, such as religion, art, and culture, as well as important historical sites, it can also be applied to the body of knowledge derived from other fields [24].

Eventually, the researcher has synthesized a guideline derived from the conceptual process of studying knowledge about ethnic groups in Chiang Mai Province, which contains the semantic ontology of knowledge about ethnic groups in Chiang Mai as a model that can be applied as a source of information. Furthermore, the researcher has applied SPARQL language to retrieve information rather than the relational database system and using SQL language in the original pattern, which will assist in obtaining more information in ethnic areas according to the ideas [25], [26].

## V. RECOMMENDATIONS

1) Increasing the class's attributes to support ethnic group data collection in other Northern provinces can expand the scope of learning and data storage even more.

2) An ontology may be used to develop a semantic search program by providing search methods or alternatives that allow users to make better use of information resources.

**Abstract**—Since the beginning of 2020 and following the recommendation of the Emergency Committee, the WHO (World Health Organization) Director General declared that the Covid-19 outbreak constitutes a Public Health Emergency of International Concern. Given the urgency of this outbreak, the international community is mobilizing to find ways to significantly accelerate the development of interventions. These interventions include raising awareness of ethical solutions such as wearing a face mask and respecting social distancing. Unfortunately, these solutions have been criticized and the number of infections and deaths by Covid-19 has only increased because of the lack of respect for these gestures on the one hand, and because of the lack of awareness and training tools on the spread of this disease through simulation packages on the other. To give importance to the respect of these measures, the WHO is going to try to propose to his member states, training and sensitization campaigns on coronavirus through simulation packages, so that the right decisions are taken in time to save lives. Thus, a rigorous analysis of this problem has enabled us to identify three directions for reflection. First, how to propose an IT tool based on these constraints in order to generalize training and awareness for all? Secondly, how to model and simulate these prescribed measures in our current reality? Thirdly, how to make it playful, interactive, and participative so that it is flexible according to the user's needs? To address these questions, this paper proposes an interactive Agent-Based Model (ABM) describing a pedagogical (training and educational) tool that can help understanding the spread of Covid-19 and then show the impact of the barrier measures recommended by the WHO. The tool implemented is quite simple to use and can help make appropriate and timely decisions to limit the spread of Covid-19 in the population.

**Keywords**—Multi-agent system; covid-19; CoSiT; modeling-simulation; barrier measures; complex systems

## I. INTRODUCTION

To sensitize everyone in the fight against the spread of the new virus through the respect of non-pharmaceutical measures while waiting for a pharmaceutical solution to be set up, the WHO in a report entitled "SituationReport-156" [1], recommends through tabletop exercises and textual presentations to its member states, the implementation of educational training and awareness-raising campaigns through seminars and symposiums on the coronavirus (Covid-19). For this purpose it will put at their disposal, different packages of textual simulation, to form and sensitize in the fight against the Covid-19, with the help of textual plans and presentations with slides [2]. At the WHO, for that matter, the Department of Health Security and Preparedness has set up the various table top exercise programs

named SimEx (Simulation Exercise) Covid-19 [3] as part of the coronavirus training (Covid-10), which it defines in its 2017 Simulation Exercise Manual [4], as an exercise that uses progressive scenarios, with series of scripted messages to allow participants to consider, the impact of a potential public health emergency on existing plans, procedures and capabilities: in these words that "A TTX (Table Top Exercise) simulates an emergency situation in an informal stress-free environment". Although these plans (non-pharmaceutical measures), in a textual format, are easy to manipulate by individual stakeholders, there are no accessible tools and pedagogical means to train and sensitize all stakeholders on the importance of respecting these measures, as these actors may have different interpretations of these measures and the protocol set up, in an environment where they are geographically distributed and distant from each other, and these training course are only held in the organization's offices around the world, and are purely professional, which considerably restricts listening, and limits training and awareness.

Taking into account the above mentioned observations, and with the increase in contamination, the need for training and sensitization, especially of political decision-makers and populations who are not always able to understand the merits of these measures, is becoming increasingly necessary and important, so that they can make early decisions on the adoption of these measures to save lives. This solution could also be very useful to avoid any misinterpretation of what these textual response plans mean. It is therefore essential to propose an educational tool that can simulate the current reality with all its aspects (particularly social) to understand, control and monitor this disease throughout its life cycle.

The aim of this paper is to contribute to the engineering of coordination and decision making, in a multi-agent universe, and this in the fields of epidemiology, while providing a global approach that takes into account without confusing them and by articulating them, the essential aspects of crisis management: ethical measures (social distancing and wearing of protective masks) and social behavior.

To achieve this, we used the Simple Reflex Agent model to simulate the propagation of the pandemic and to visualize the impact of barrier measures. We then specified and formalized this approach with the UML and AML languages, and documented it with the ODD (Overview, Design concepts and Details) protocol. Then, we proposed a pedagogical architecture, centered on interactive and participative agents, to allow

users to play themselves on the existing parameters, according to the context in which they are, and to visualize the results of the simulation in an interface provided for this purpose.

The implementation and simulation of the system was done on the GAMA (GIS and Agent-Based Modelling Architecture) modeling and simulation platform. To validate the obtained model, we defined and simulated several real-life scenarios which revealed results similar to what is observed today.

This paper is organized as follows: in the second section, we propose a review of the literature on infectious diseases, then on the mathematical and computer models existing in the fight against the spread of these diseases, and finally on the educational tools that can play the role of training support in the current context. In the third section, we propose a description and formalization of the agent model we propose as a solution, after which we document it using the ODD protocol. Section four concerns the implementation and experimentation as well as the validation tests through the defined scenarios. The fifth section concerns the general conclusion and outlook.

## II. KEY CONCEPTS

### A. Complex Systems

A system is complex when it is made up of a large number of differentiated autonomous components that interact with each other in a non-trivial way. This system is also characterized by the emergence at the global level of new properties, not observable at the level of components system and by a global operating dynamic difficult to predict from the observation of the constituents and their elementary interactions [5].

### B. Modeling - Simulation

Modeling – simulation, first of all, consists of the designing of a model. It is a way of making explicit the complexity of a system to better understand its functioning and to make good decisions [5].

### C. Model

A model is a mathematical, or graphic and computerized representation of the objects and the relations between them in a confined zone of the real world. A model can also be viewed as a simplified representation of a complex reality. To be useful, models must be adapted to their objects and be conveniently studied and validated [6].

### D. The New Coronavirus

The new Coronavirus named Covid-19 is caused by the SARS-CoV-2 virus, which is spread through close contact with an infected person when small liquid particles are expelled through the mouth or nose of an infected person or when people are in direct or close contact with an infected person. Transmission can also occur in specific settings, particularly in crowded, poorly ventilated indoor spaces where one or more infected persons spend long periods with others. People with the virus can leave infectious droplets when they touch objects or surfaces, such as tables, door knobs and railings. We can then become infected with the virus if we touch these contaminated surfaces before washing our hands [7].

### E. Measures to Control the Spread of Covid-19

To limit the risk of contracting Covid-19, the WHO recommends that everyone follows certain basic precautions such as [7]:

- Follow local recommendations.
- Keep at least one meter away from others.
- Wear a mask, in public places.
- Avoid touching surfaces, especially in public places.
- Wash your hands regularly with soap and water or with a hydroalcoholic solution.
- Cough and sneeze into your elbow or a tissue.

In the following, the system that will be modeled will take into account only two of these measures: the wearing of the mask, and the respect of the distancing.

## III. RELATED WORKS

Several solutions in the field of infectious disease control through mathematical modeling have been well established. Among these solutions, we can mention the one proposed by Kermack and McKendrick in the paper entitled “A contribution to the mathematical theory of epidemics” [8]. The aim was to understand the evolution of the epidemic in large populations of constant size. The application of this mathematical modeling technique was motivated by the need for more accurate predictions of the spread of infections at the population level. This has contributed to a better understanding of the mechanisms of spread to help develop optimal control strategies through public health interventions. In [9], the authors address the problem through a representation in the form of compartments of the various stages of infection. We find several of these compartment models in the literature [10], [11], [12], among which we can cite the SI, SIR, and SEIR models.

The work of Kieczkowski & Grenfell [13], presents a new approach based on an increased interest in modeling the interactions between people in a network with a mixture of local and global interactions, by proposing a stochastic model called Mean-field, to demonstrate that even in the presence of a high level of local correlation their model can succeed. To achieve this, they referred to the work of Watts & Strogatz, [14], in which they analyzed some properties of mesh networks, and showed that they behave like a network model, even for a relatively small mesh parameter.

Another similar model was analyzed by Boccaro & Cheong, [15], where individuals were allowed to change places on a two-dimensional network. Thus, they proved that when the interactions between the agents are over a long-range, it causes a very fast spread of the epidemic in the population. In the work of Kieczkowski [13], the authors studied the effects of local spatial correlations of a temporal epidemic spread as a function of the increasing proportion of global contacts in a cellular automaton (CA) model. They deduce that even in the presence of high local correlations, the model (Mean field types equations) can be quite suitable if the contact rate is treated as a free parameter. They conclude that the contact rate reflects not only a microscopic and epidemiological situation,

but also a complex social structure, including short and long term contacts following a hierarchical structure of the society. Among the works that are based on this small-world network principle, we can mention [13], [14].

While these approaches (compartmental and stochastic) rely on mathematical models and representations to propose solutions in the field of epidemiology, the Agent-Based approach is relatively new and more powerful, more realistic in simulating the spread of diseases and predicting the impacts in the population and especially regarding the effectiveness of interventions. According to [16], this model is classified as a solution to model complex social interactions in a real world.

In the same perspective, in [17] authors present an Agent-Based approach for modeling dynamics of contagious disease spread. The aim here was to overcome the limitations of different approaches, such as cellular automata and classical epidemic models. In this paper the authors also allow the modeling of interactions between individuals, which facilitates the study of specific spatial aspects of the spread of epidemics and to address the stochastic nature of the epidemic process. In [18] authors present a tool, EpiSimdemics which is different from the other systems and allows to simulate the propagation of contagious diseases. According to this work, all of these simulators have been widely evaluated and used in dozens of large-scale public health studies.

Among the computer tools used in the fight against Covid-19, the literature informs us that several tools are already available for this purpose, among which: The most powerful computer in the world Fugaku [19], that works particularly at the molecular level, and at the macroscopic level. In addition, the MODSIR19 project [20] developed within the framework of research for the fight against Covid-19, allowing to model the various factors which influence an epidemic, and to visualize the effects on a graph, according to the R0 factor. It also allows to better predict the evolution of the pandemic, to simulate the number of hospitalizations, the needs in resuscitation beds, and the effects of confinement and de-confinement, and is also for pedagogical purposes. Learn to fight: “Good practices when treating patients”, on the other hand, is a digital training simulator for the management of patients with the symptoms of Covid-19 [21]. Another powerful tool is the COMOKIT which is a GAMA model on the evaluation and comparisons of policy responses to the Covid-19 [22] pandemic. Its goal is to help policymakers and researchers answer questions such as: Does closing schools decrease peak transmission? What is the impact of wearing masks on the dynamics of the epidemic? How long should a lockdown ideally last?

However, with the increase in the number of cases from day to day, several public health organizations and mainly the WHO have found it necessary to train and sensitize people on coronavirus through various training and sensitization packages through so-called tabletop exercises (TTX) [2]. Although this training is necessary to sensitize and train decision-makers and individuals to curb the spread of the virus. The means and tools of the training set up by the WHO remain a hindrance, and a limit as to the objectives to be reached, for several reasons. Firstly, these simulations are done on paper and through presentations, there are no specialized software tools for this. Secondly, it is restricted to the members of the organization

and takes place only in its premises around the world, which reduces the target to be reached. Third, it is targeted and concerns only one category of people. Moreover, the actors being geographically distributed, each of them can have a different interpretation of these measures, and more seriously, the disease changes phase each time and new measures must be adopted each time. Thus, proposing a computer simulation tool for educational purposes to train and raise awareness on the measures prescribed by the WHO becomes an urgent task.

Our work will consist in conducting an in-depth study on the impact of these measures in the fight against the virus, by looking at the training through simulations proposed by the WHO.

## IV. PROPOSED MODEL

### A. Analysis and Design

To answer the questions raised by the literature, we propose a solution to create an educational, simple, interactive, participative and generalist computer tool that can help in the fight against infectious diseases. This tool named CoSiT (Covid-19 Simulation Tools) is based on the GAMA (GIS and Agent-based Modelling Architecture) modeling and simulation platform and follows a set of principles and requirements as follows :

- It is first and foremost an educational tool for training and raising awareness on the importance of respecting barrier measures in the fight against the spread of Covid-19.
- It is also and above all an interactive and participative tool.
- CoSiT is based on the so-called non-pharmaceutical measures prescribed as part of the fight against Covid-19, to produce simulations of our daily lives and to visualize the results obtained in an interface provided for this purpose.
- CoSiT is based on a detailed and realistic representation of the impact of barrier measures in controlling the spread of Covid-19 in the environment of our choice.
- CoSiT is generic, flexible and applicable to any case study.
- CoSiT is open and modular enough to support interdisciplinary cooperation.
- CoSiT provides easy access to small-scale training, experimentation and sensitization, making it easy to explore its parameters.

To do so, we followed the following process as shown in Fig. 1.

Fig. 2 gives us an overview of the structure of the model to be implemented in the form of a UML class diagram.

In Fig. 3 we can see the AGR representation with AML of our model.

The design of the simulation environment is done upstream of the simulation according to the plan of the place where we

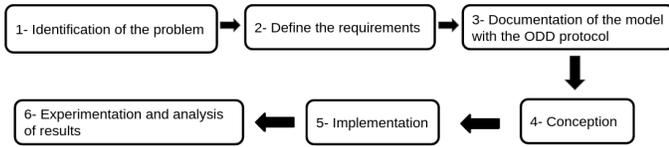

Fig. 1. Solution Implementation Process.

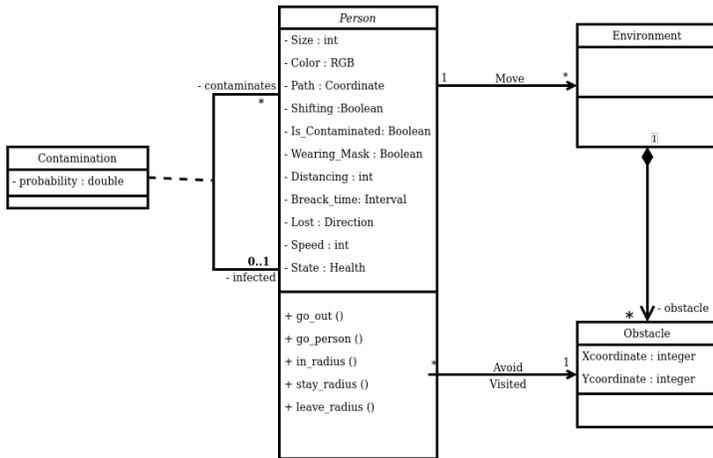

Fig. 2. Overview of the Model Structure in the Form of a UML Class Diagram.

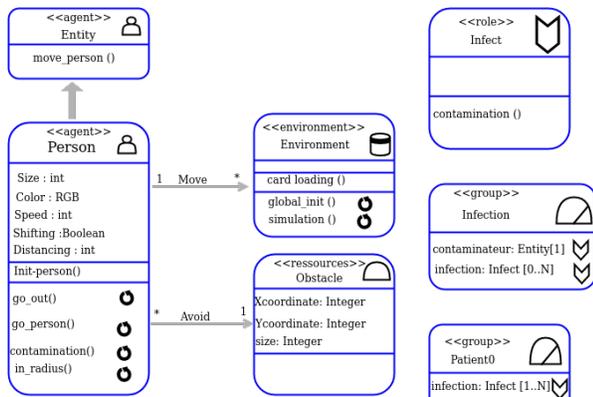

Fig. 3. AGR Representation with AML of the Model.

want to define a scenario, to do this, we have defined some basic rules.

Fig. 4 shows the design of the simulation environment. It is after this step that the file can be exported in CVS (Comma Separated Values) format and imported into our model as a simulation environment.

### B. Model Description using ODD Protocol

To describe the model that we propose as a solution, we have used as a tool, the ODD protocol [23], [24].

#### 1) Overview :

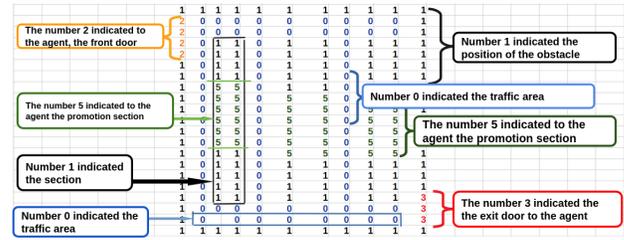

Fig. 4. Design of the Simulation Environment using Libre Office Calc Spreadsheet.

- **Purpose:** The objective of the model is to explore, in a low-scale real environment of our choice, the impact of barrier measures in the fight against Covid-19.

- **Entities, state variables, and scale:** The model is composed of a single variable, the human agent, which represents the different people in the considered area with their characteristics and epidemiological status. Each agent is localized in space by its coordinates, and can recognize objects in the environment.

It should be noted that the environment is composed of a set of obstacles which are the objects of the living world, and of agents which are people. It corresponds to a cell of 70m x 70m that can be parameterized.

As for the temporal resolution, the simulation is done by a succession of iterations for which the time step is fixed at one second. This time step is defined in such a way that the displacement distance during an iteration of an agent does not exceed the dimension of a cell. The simulated duration is not defined by default, because it depends on the type of environment and the number of initial agents. This duration corresponds to a day of work and activities.

The simulation is divided into four phases, which are distinguished by the agents' behaviors:

- A "Life without constraint" phase, which includes two types of agents: "infected and susceptible". A phase of "Life with a constraint of wearing face mask", during which agents are forced to wear the mask. A phase of "Life with constraint, respect of social distancing", during which they must respect a certain distance from each other. And a phase of "Life with a constraint of facial mask-wearing, and respect of social distancing", which combines the two previously mentioned.
- Several other variables are also defined as parameters of the model: the number of people who can intervene throughout the simulation, the probability of contamination within a population, the measure of social distancing, the simulation environment. The model gives the user the possibility to act on the behavior of the agents before and during the simulation through the activation and deactivation of these barrier measures.

#### 2) Design Elements:

- **Basic Principles:** The aim is to show, through modeling and computer simulation, the importance of barrier measures in the fight against Covid-19. The aim is to provide an educational tool that can be used as a training and awareness support.
- **Emergence:** There is a phenomenon of spatial spread of disease that is conditioned by the movements and behaviors of human agents. **Perception:** Agents can perceive other agents in their vicinity, as well as objects in the world they are in.
- **Interaction:** The only interactions present in the model are the interactions between human agents.
- **Stochasticity:** The model contains some stochasticity in both the initialization and the dynamics. The position of the agents in the space is random on one of the cells. The number of initially sick agents is also chosen randomly. During the simulation, when a new agent is created, its status is chosen randomly according to a probability. Moreover, an agent moves a more or less constant distance but in a randomly chosen direction according to its objectives.
- **Observation:** The main display of the simulator is an environment containing the different types of agents, as well as the obstacles. It is updated at each time step, allowing to visualize the dynamics of the disease propagation. During the simulation, we can observe the evolution of the number of contamination with the help of a curve representing these values as a function of time, and also in textual form for the non-professionals of the domain.
- **Adaptation:** the individual behavior of each agent is a process of adaptation at each time step, it adapts to evolve within its environment and to reach its objectives.
- **Objectives:** the objective of the agents is to move according to the established rules. These objectives are not fixed but depend on the parameters and the scenario we want to simulate.

3) Details:

- **Initialization:** During this phase, we have to define the basic parameters of the simulation such as: importing the simulation environment, creating and initializing the agents, setting the parameters of the behavior of these agents.
- **Input Data:** The main input data is in CSV format previously provided by the user.

V. IMPLEMENTATION

The aim is to develop a tool capable of simulating the propagation of the Covid-19 in a public environment such as supermarkets, bars, or restaurants, and then to display the results obtained in a clear and accessible way for everyone. The solution implemented here is a simple reflex agent-based model, documented by the ODD protocol, implemented, modeled and simulated using GAMA Platform [25]. Its interface has different parts and offers two solutions:

the CoSiT1 solution which is an interactive and customizable training environment and the CoSiT2 solution, which is more generalist, and uses the parameters of CoSiT1 to offer on a single screen, all possible results.

The Gama modeling and simulation platform is the one with which we implemented this solution. Fig. 5 gives us a descriptive overview of this solution.

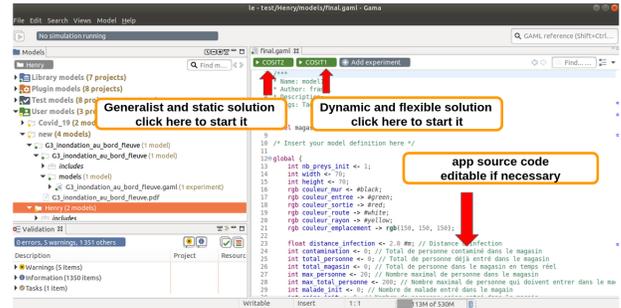

Fig. 5. Gama Modeling and Simulation Platform Uses

The CoSiT1 interface The main requirements implemented in this part are summarized in Fig. 6.

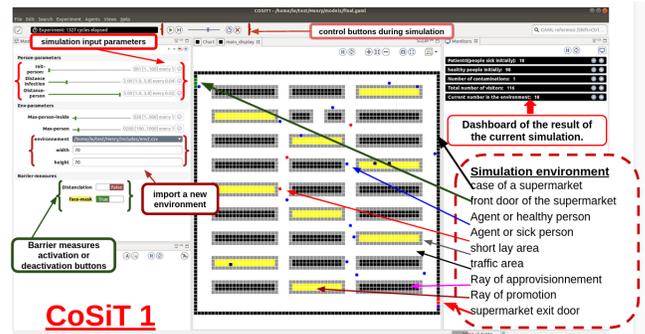

Fig. 6. CoSiT1 Simulation Interface.

The CoSiT2 interface The main requirements implemented in this part are summarized in Fig. 7.

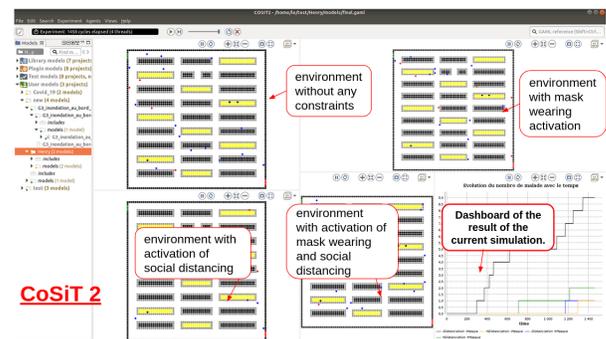

Fig. 7. CoSiT2 Simulation Interface.

VI. NUMERICAL SIMULATION AND EXPERIMENTATION

In this section, the simulations performed are presented. Table I describes the parameters used and the estimated baseline values.

TABLE I. PARAMETER VALUES AND THEIR MEANINGS

Parameters	Estimated baseline values
Distance infection	[0 – 2.0] meters
Maximum persons inside the supermarket	50
Maximum visitor per day	500
Distanciation value	[0 – 4.0] meters
Respect of wearing face mask	Yes/No
Respect for distancing	Yes/No
Probability of infection	0.05
Probability of wearing a face mask	[0.5 – 1.0]
Probability of distancing respect	[0.5 – 1.0]

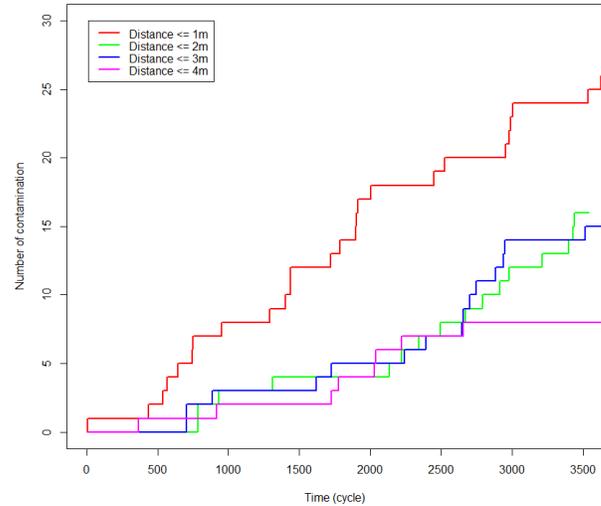

Fig. 9. Impact of Social Distancing.

A. Experimentation 1: Influence of Wearing a Mask on the Spread of the Virus in a Supermarket

There is scientific debate about their use, one study showed the ability of surgical masks to prevent the exhalation of respiratory viruses. Therefore, the use of masks by the population could reduce peak contamination.

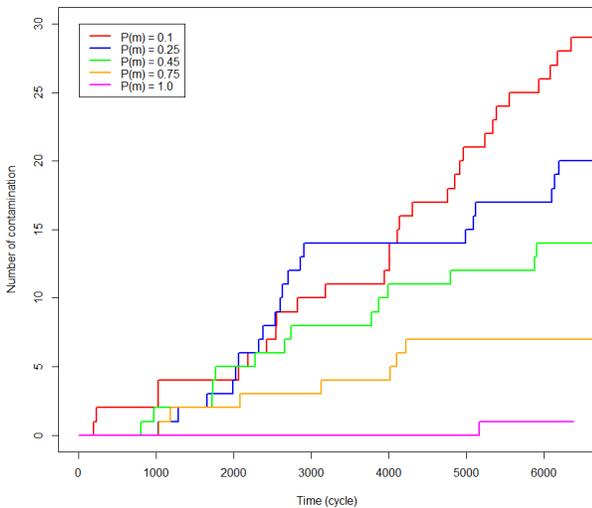

Fig. 8. Several Probability of Wearing Masks are Considered (0.1, 0.25, 0.45, 0.75 and 1) and the Social Distancing is not Respected.

B. Experimentation 2: Influence of Social Distancing on the Spread of Covid-19 in a Supermarket

Like the wearing of masks, maintaining a certain distance has been recommended. The positive effects of such actions are visible on the number of contaminations, depending on whether one practices it or not.

C. Experimentation 3: Influence of Mask Wearing and Respect of Social Distancing on the Spread of Covid-19 in the Environment

The main objective of this experiment is to find the best protocol that can have an optimal impact on the spread of the pandemic, reducing the spread factor R0. To do this, we decided to simulate a scenario in which the two previous barrier measures are found under the same conditions.

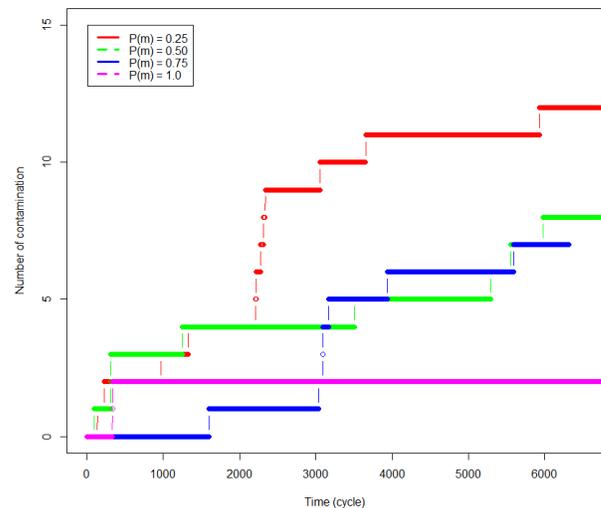

Fig. 10. Impact of Wearing Face-Mask and Respect of Social Distancing. Several Probability of Wearing mask are Considered while the Social Distancing Considered is 2 Meters

As shown in Fig. 10, we start this exploration with the simplest possible scenario, i.e. a free spread of the disease with a percentage of 25% as the probability of wearing a face

mask, and 2 meters as the distance measure to be respected.

#### D. Experimentation 4: Consideration of Promotion Area in the Supermarket Environment

This experimentation attempts to display the dynamics of the pandemic in a supermarket that contains promotion areas.

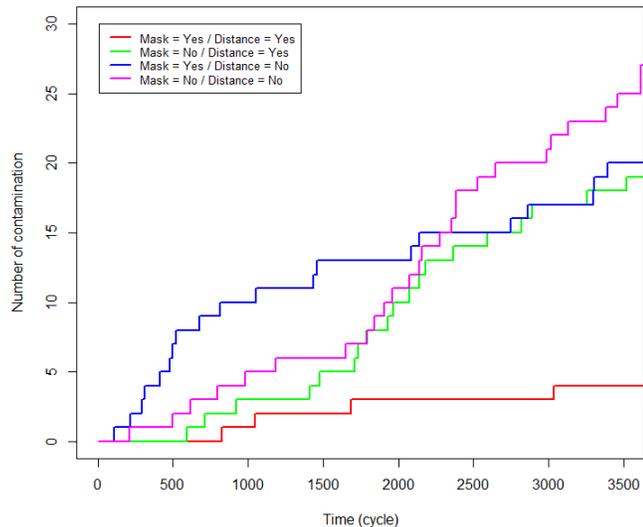

Fig. 11. Impact of Wearing Face-Mask (Yes/No) and Respect of Social Distancing (Yes/No) in the Environment with Promotion Area.

In Fig. 11, we consider a percentage of 25% as the probability of wearing a face mask, and 2 meters as the distance measure to be respected.

### VII. DISCUSSION OF THE RESULTS

In Fig. 8 it can be seen that the use of masks does indeed reduce the peak of contamination. Therefore, recommending the use of face masks would avoid overloading hospitals and intensive care units as much as possible, and would contribute to slowing down the speed of spread of the virus while reducing the  $R_0$  factor. The greatest change was achieved with a face mask probability of 0.75 and above, which avoided the sudden increase in cases that were still noticeable with a face mask probability of 0.5.

As presented in Fig. 9 the social distancing would act on the extent of the propagation. It also shows us that the smaller the radius of propagation of the virus (e.g. 1 meter), the fewer contaminations there are. For large distances, the results show that it is not always obvious to adopt such behavior in society, which justifies the high epidemiological peak when the distance increases. If social distancing also appears to be one of the best ways to reduce the spread of the virus and to relieve the health centers, it raises several questions about the right distance to adopt in order not to be contaminated. As in the case of wearing a mask, the simulations were run several times with a distancing measure varying from 1 to 5 meters.

Based on the results described in Fig. 10, we can compare the two different measures. It seems that these two policies taken individually correlate with the behavior of the individuals according to the environment where they are. On the other hand, these two measures taken together allow us to observe an antagonistic reaction (when the mask does not work, the distancing protects and vice versa, and when both work the protection is of high quality).

The presence of promotion areas has an impact on the spread of the disease as shown in Fig. 11. It appears that even if the supermarket contains promotional areas, the application of the two barrier measures is recommended to avoid the spread of the disease.

### VIII. CONCLUSION AND PERSPECTIVES

Based on the results obtained in this paper, we confirm that the objectives assigned at the beginning of this work have been successfully achieved. Results clearly show that the adherence to the WHO prescribed barrier measures influences the spread of the virus and is a means of controlling Covid-19, which supports the hypothesis of this research. Public health experts also claim to be already aware of this solution. However, it is not clear what the average distance would be in the general case, and how long it would take to change masks. These factors would therefore deserve to be examined more systematically. The main advantage of CoSiT over the WHO TTX tabletop simulation schemes is that it is user-centered, educational, interactive, participatory, general-purpose, and flexible, with a quick learning curve.

However, making this tool available through a web portal so that it can be accessed and used by all in contexts of their choice, remains a challenge because the GAMA technology we used does not yet allow it.

Therefore, we recommend that technologies for deploying simulation models in the Cloud (online) be explored more systematically to facilitate mass remote training and awareness in real-time when an epidemiological crisis occurs. This would allow everyone to be aware in time of the need to adopt certain measures and would also help policymakers and political actors in making timely decisions to save lives. This solution will also help public health organizations in their training and awareness campaigns in the fight against infectious diseases.

**Abstract**—Geometric shape detection in an image is a classical problem that leads to many applications, in cartography to highlight roads in a noisy image, in medical imaging to localize disease in a region and in agronomy to fight against weeds with pesticides. The Hough Transform method contributes effectively to the recognition of digital objects, as straight lines, circles and arbitrary objects. This paper deals with the theoretical comparisons of object dual based on the definition of Standard Hough Transform. It also focuses on parallelism of Hough Transform. A generic pseudo-code algorithm, using the Openmp library for the parallel computing of object dual is proposed in order to improve the execution time. In simulation, a triangular mesh superimposed on the image is implemented with the pymp library in python, in considering threads as inputs to read the image and to update the accumulator. The parallel computing presents reduction of the execution time accordingly to the rate of lit pixels in each virtual object and the number of threads. In perspectives, it will contribute to strengthen the development of a toolkit for the Hough Transform method.

**Keywords**—Hough transform; parallel computing; pattern recognition

## I. INTRODUCTION

Digital object recognition in an image is a classical problem that arises many applications in cartography to highlight noisy roads, in medical imaging for disease detection, in agronomy for weed detection and in cyber-security, as Facial Recognition using deep learning through convolutive neural network application. That supposes the definition of a model for digital objects and establishment of its adequate recognition method. In this sense, Bresenham's line in [18], Reveilles in [9], Andres in [10] have established several digital models, particularly for analytical straight lines. Parallel algorithms such as parallelization Bresenham Line and circle in [19] have been introduced to improve the execution time to draw digital object.

The Hough Transform method has been initially introduced by Paul Hough in [3] in 1962 and applied to the detection of straight lines in an image : It transforms a point in an image space to a straight line in a parameter space. It transposes the problem of straight line detection in the image space to an intersection of straight lines in the parameter space. But this method is limited in the detection of vertical straight lines.

Another variant of the Hough transform method named the standard Hough Transform, associates continuous points in an image space to sine curves in a parameter space. It allows to overcome the problems of vertical straight line recognition

that occurs in the case of the classical Hough Transform, which transforms a continuous point in the image space to a straight line in the parameter space.

Forward, the Hough Transform method has been extended to the detection of others shapes such as circles, ellipses. Duda and others in [4] have also proposed the recognition of arbitrary shapes in an image.

In 1985, Henri Maître in [1] has also proposed a survey on the Hough Transform method with an unified definition of Hough transform. Several works have studied the application of Hough Transform, for instance to mouth recognition in [11] and to action detection in [12].

Moreover, extensions of Hough transform for straight line recognition have been proposed by scientists. For instance, in 2006 Martine Dexet in [2], [6] introduced a new method based on the initial definition of Hough Transform, computing the Hough transform of continuous points in a square. Then, the dual of a square is a set of continuous straight lines in the parameter space.

By analogy to the works of Dexet in [2], SERE and others in [5] extends the standard Hough transform, to define the dual of a square and the dual of a triangle. Others extensions followed these works in [5] with the dual of a rectangle in [14], the dual of an hexagon in [16] and the dual of an octagon in [15]. All these works will lead to build a toolkit for the Hough Transform methods.

The serial execution of Hough transform consists of the serial execution of each real pixel or each virtual cell defined by the mesh generation, layed on an image.

Many works have carried out improvements of Hough transform to reduce the execution time. Acceleration of Hough transform has been studied by Jošth and others in [21] to allows real time line detection.

Parallelization of the Hough Transform method is also an alternative in order to improve the execution time. For instance, SERE and others in [7] have demonstrated the application of Hough Transform with the map-reduce algorithm for straight line recognition. These works have been extended by Mateus Coelho and others in [8] to deal with circle recognition.

Through recent innovations precisely in deep learning on Convolutive Neural Network, scientists have worked to combine the Hough Transform method with Convolutive Neural

Network to improve algorithms working in object detection, as studied by Spratling in [20].

In Traffic Management on roads, various techniques of Hough Transform have been proposed in Detection of Traffic Saturation, Traffic Light and Traffic Sign. For instance, SERE and others in [16] have introduced an application of the Hough Transform method in Traffic Saturation using GPS.

Our motivation is the study of parallel processing for the dual of geometry shapes related to squares, triangles, rectangles, hexagons and octagons with pypm library in python, in considering a set of threads as input parameters to compute different duals and to update the accumulator data in order to reduce the execution time.

Here, the parallel execution is outside the framework map-reduce in [7]. It takes into account previous works in a serial execution on :

- improvements of standard Hough transform in [13],
- straight line recognition in a rectangular grid in [14],
- straight line recognition in a triangular grid in [22]

But it considers the parallel execution of object dual for any grid to shorten the execution time.

This paper is organized as follows : the Section II recalls the definitions of geometric shape duals and analytical straight lines. The Section III focuses on parallelization of object dual. Experimental results in Section IV use the pypm library to implement parallelism in python on real images.

## II. PRELIMINARIES

As previously introduced in Section I, Standard Hough Transform (SHT) associates a point in the image space to a sine curve in the parameter space, to achieve straight line recognition, as defined by :

*Definition 1:* (Standard Hough Transform)

The dual  $S(x,y)$  of the point  $(x,y)$  in a two dimensional space where  $(x, y) \in R^2$ , is the Standard Hough Transform defined by the set of points :

$$\{(\theta, r) \in [0, \pi] \times [-\sqrt{l^2 + h^2}, \sqrt{l^2 + h^2}] / r = x \cos \theta + y \sin \theta\} \quad (1)$$

Duality is described as establishment of the relation between a digital object in the image space and the set of standard Hough transform of its internal points in the parameter space. For instance, let  $O$  be a digital object such as  $O = \cup_{i=1}^n P_i$  where  $P_i \in O$ .  $P_i$  could be a discrete point or a set of discrete points. The dual of  $O$  is the union of the dual of each element ( $P_i \in O$ ), accordingly to the standard Hough transform of  $P_i$  in definition 1.

That means formally :

$$Dual(O) = \cup_{i=1}^n dual(P_i) \quad (2)$$

The relation 2 has been specialized precisely to obtain the definitions for the dual of geometric shapes, such as rectangles,

triangles, as defined by SERE and others in [5], [13], [15] as follows :

*Definition 2:* (Rectangle dual) the dual of a square (or a rectangle) is the area localized between the curves corresponding to the duals of its two internal diagonal segments in the parameter space.

*Definition 3:* (Triangle dual) the dual of a triangle is the area localized between the curves corresponding to the duals of its two adjacent sides in the parameter space.

An octagon is the union of four internal rectangles. While a hexagon is the union of three internal rectangles. Definition 2 leads to establish hexagon dual and octagon dual as follows :

*Definition 4:* (Hexagon dual) the dual of an hexagon is the area localized between between the curves corresponding to the duals of its three internal diagonal segments in the parameter space.

*Definition 5:* (Octagon dual) the dual of an octagon is the area localized between the curves corresponding to the duals of its four internal diagonal segments in the parameter space.

The dual contributes to analytical straight line recognition, particularly those proposed by Reveilles in [9] related to standard analytical straight line and extended by Andres in [10] to have the supercover model.

*Definition 6:* analytical digital straight line ([9], [10]) with parameters  $(a,b,\mu)$  and thickness  $w$  is defined by the set of integer points  $(x,y)$  verifying :  $\mu \leq ax + by < \mu + w$ ,  $(a,b,\mu,w) \in Z^4$ ,  $pgcd(a,b) = 1$ .

Thus, Analytical digital straight line is then :

- thin, if  $w < \max(|a|, |b|)$
- naive, if  $w = \max(|a|, |b|)$
- thick, if  $w > (|a| + |b|)$
- standard, if  $w = (|a| + |b|)$

Parallel computing of object dual will be described in Section III and applied to analytical straight line recognition in Section IV.

## III. METHOD DESCRIPTION

This section is focusing on parallel computing of object dual, previously defined in Section II. It also proposes pseudo-algorithms using openmp library to compute object dual in the parallel context.

As an object dual is defined previously by the relation :

$$Dual(O) = \cup_{i=1}^n dual(P_i) \quad (3)$$

Where  $O$  is extracted from an image and  $P_i \in O$ . Then, parallel computing of Dual ( $O$ ) consists firstly of splitting an object to several components and secondly to apply parallel computing to each elementary components  $P_i$ . Threads will assume easily these elementary tasks. Let  $n$  and  $v$  be respectively the number of components in an initial object  $O$  and

the number of threads. Each thread will compute normally almost  $\lfloor \frac{n}{v} \rfloor$  elementary components. That means if the number of threads is superior to the number of elementary components, some threads will not be launched.

Moreover, instead of parallel computing for the dual of all the components  $P_i$ , a constraint is introduced by the rate of lit components in  $O$  : If an object  $O$  has the rate of lit components, superior to the rate  $\alpha$ , the dual of this object will be computed in the accumulator data.

Let  $O_l$  be a subset of  $O$ , constituted only of lit components. Suppose that  $lc$  is the number of lit components. We have  $lc = \text{card}(O_l)$  and  $\alpha \leq \lfloor \frac{lc}{n} \rfloor$ . Then, the dual( $O$ ) will be approximately the dual( $O_l$ ).

Moreover, suppose that  $\alpha = \lfloor \frac{m}{n} \rfloor$ . We constitute the subsets of  $O_l$  that contain exactly  $m$  elements of  $O_l$ , denoted  $P(O_l)$ . There are  $C_{lc}^m$  subsets (as a combination) in  $O_l$  that verify the constraint  $\alpha = \lfloor \frac{m}{n} \rfloor$ . As  $O_m \in P(O_l)$ . Now, the dual( $O$ ) also becomes approximately the dual( $O_m$ ).

Finally :

$$Dual(O_m) = \cup_{i=1}^n dual(P_i) \quad (4)$$

Where  $O_m$  is extracted from  $O_l$  ( $O_l$  is a subset of  $O$ ) and parallelization will concern with the  $dual(P_i)$ , where  $P_i \in O_m$ .

Let us explain the dual of an object with more details through different algorithms in the following sections.

#### A. Theoretical Comparisons of Computing Object Dual

Definitions 2, 3, 4, 5 extend Standard Hough Transform in two ways :

- the first one is to achieve object detection in virtual grid based on geometry shapes in computing its duals in the accumulator : digital objects pass through this virtual grid. Thus, parallel computing is applied to elementary shapes issued by this virtual grid in order to improve the execution time.
- the second one is to analyze the internal structure of points inside these duals in the accumulator data to highlight properties or characteristics for square, rectangle, triangle, hexagon, octagon recognition in the image. The future works will analyzed in details the internal structure of these dual.

Let us focus on the first case. Computing the dual of an hexagon and the dual of an octagon, could take more time than the dual of a square or the dual of a triangle. Because the number of internal diagonal segments in an hexagon or an octagon, building the area between different segment dual is important. For instance, according to SERE and others in [15], the dual of an hexagon and the dual of an octagon depend respectively on the dual of four internal segments and the dual of three internal segments. The dual of internal segments in objects can be realized through threads computing simultaneously the dual of each segment.

Our purpose is to use the dual of geometric objects in the parallel context to improve the execution time of Hough transform.

Hough Transform uses two spaces, namely an image space and a parameter space ( or accumulator data). Proposed parallel Hough Transform takes into account these two spaces : that means the parallel reading of data in the image space and the parallel updating of the accumulator data

#### B. Analysis of Parallel Algorithm to Read the Data in the Image Space

Mesh generation establishes a virtual grid, superimposed on an image to bring out internal elementary virtual objects. For instance, An elementary object could be a rectangle, a triangle, an hexagon or an octagon. Fig. 1 presents an example of a virtual grid with triangles, created by Ouedraogo and others in [22], an extension of the method proposed by Cheick and others in [14] to generate rectangles, where the triangles are its components.

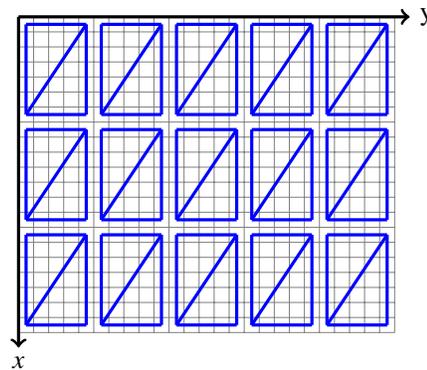

Fig. 1. An Example of the Triangular Mesh, Used by Ouedraogo and Others in [22] to Compute the Dual of a Triangle

Consider an image with (w x h) pixels. Algorithm 1 presents a generic serial execution. It uses a virtual mesh to perform an image, where each elementary object is referenced by the references Image(i, j). For instance, it takes particularly the dual of rectangles into account, as defined by SERE and others in [5] ( see in preliminaries) where dual(Object x) corresponds precisely to dual(Rectangle x).

In this way, generalization is done by substitution of an object by any geometric shape .

---

#### Algorithm 1: Computing the Dual of Objects

---

```

Result: the dual of objects
image: Matrix ;
ob:Object ;
i, j : Integer ;
Image=pretreated(load(URL)) ;
for (i=1; i ≤ w; i++) do
  for (j=1; j ≤ h; j++) do
    ob=(Object) extract(Image(i, j));
    if light(ob) then
      | dual(ob);
    end
  end
end

```

---

Let  $\alpha$  and  $\beta$  be parameters corresponding to the number of threads to read data in the initial image. Data parallelism

is introduced in algorithm 1 by OPENMP primitives as ” # pragma omp parallel for” to define the parallel section as illustrated precisely in algorithm 2.

**Algorithm 2:** Data Parallelism with Openmp Primitives in a Pseudo-Code Algorithm

```

Result: the dual of objects
image: Matrix ;
ob:Object ;
i, j : Integer ;
Image=pretreated(load(URL)) ;
omp_set_num_threads( $\alpha$ ) ;
# pragma omp parallel for ;
for (i=1; i  $\leq$  w; i++) do
    omp_set_num_threads( $\beta$ ) ;
    # pragma omp parallel for ;
    for (j=1; j  $\leq$  h; j++) do
        ob=(Object) extract(Image(i, j));
        if light(ob) then
            | dual(Ob);
        end
    end
end
    
```

In both the algorithm 1 and the algorithm 2, there are different functions :

- the function load(String URL) loads an image, according to its URL;
- the function pretreated (Matrix m) uses operators of binarization and filtering on the image ;
- the function extract(Matrix m) allows to get an elementary object generated by the grid superimposed on the image;
- The function light(Object x) consists of verifying if or not all the pixels in the object ob respect certain constraints to make it eligible for computing its dual ;
- the function dual(Object x) executes effectively the dual of the object ob, in application of the standard Hough Transform to an object. It updates the accumulator data, discussed forward in details in section III-C.

On the other hand, Fig. 2 presents a graph to modelize threads created by algorithm 2 with  $\alpha=3$  and  $\beta=3$ , following the Fork/Join model.

Let us study this model of graph in Fig. 2. Suppose that  $I=\{1,2,\dots,w-1,w\}$  and  $J=\{1,2,\dots,h-1,h\}$ . We have obviously  $i \in I$  and  $j \in J$  where  $i, j$  are the counters of two loops :

- At the first level of loop with the counter  $i$ , the number of threads being  $\alpha$ , each thread  $t_k$  manages at average  $\lceil \frac{w}{\alpha} \rceil$  iterations with different value  $i \in I$ .  $\lceil \frac{w}{\alpha} \rceil$  is an integer value and  $k \in \{1,2,\dots,\alpha-1,\alpha\}$ . If  $\alpha > w$ , there will be some  $k \in \{1,2,\dots,\alpha-1,\alpha\}$ -I, corresponding to the threads  $t_k$  that will never be created. But thread creation depends on availability of resources such as microprocessor and memory. That means even if  $\alpha \leq w$ , threads will be created according to availability of resources. The future works will

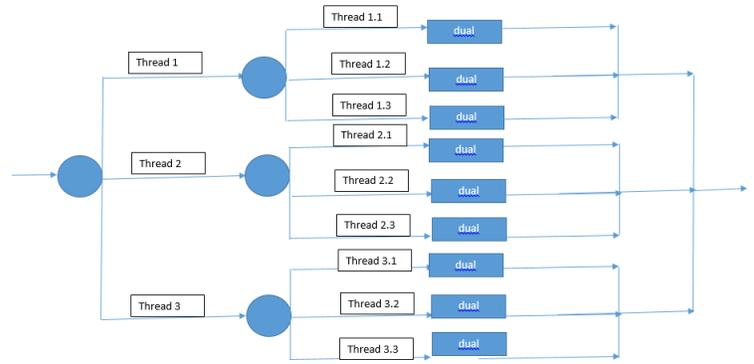

Fig. 2. Threads Created by Openmp Primitives with  $\alpha=3$  and  $\beta=3$ , Accordingly to Algorithm 2

study predictions of availability of resources to manage threads that could even be used in thread management in operating system and in security to detect malicious software, using additional resources.

- At the second loop with the counter  $j \in J$ , each thread with a new iteration on  $i \in I$ , creates  $\beta$  threads to manage some iterations on  $j \in J$ . For instance, the thread with the iteration  $i=1$ , creates  $\beta=3$  threads to manage together all the iterations on  $j \in J$ . Among  $\beta$  threads, in the same manner as the first level, each thread will compute  $\lceil \frac{h}{\beta} \rceil$  iterations. As a conclusion, in considering an initial image  $I$  with its size height  $x$  width : The number of pixels is then determined by (height  $x$  width), to be submitted and shared for analysis by all the threads.

image, corresponding to the size width. While the second loop is associated to the column of the image, corresponding to the size height . Finally,  $\alpha \times \beta$  threads work together on the same image and each thread will process approximately  $\lceil \frac{w}{\alpha} \rceil \times \lceil \frac{h}{\beta} \rceil$  pixels.

The function dual(Object x) updates the accumulator and is studied in more details in section III-C.

**C. Analysis of Parallel Algorithms to Update the Accumulator Data**

This section focuses on data processing in the accumulator : it concerns precisely computation of dual(Object), as mentioned previously in calling, in algorithm 1. The number of threads used to update the accumulator is defined by the parameters  $\gamma, \theta$ , as described in details in algorithm 3. Consider a accumulator with the size (wacc  $x$  lacc).

By analogy previously to section III-B related to the proposed algorithms, in algorithm 3, the number of  $\gamma$  threads is created, just before beginning the first loop with the counter  $m$ . These threads share iterations on a table that contains the number of lacc cells.

Algorithms 2 and 3 are generic : they can be specialized and adapted to any grid with its specific geometric shape, through computing object dual. For instance, the main specialized algorithm 6 in appendix is based on a triangular grid, implemented in Section IV.

**Algorithm 3:** dualObject(m, n : integer)

```

Result: the accumulator accc
acc: Matrix;
m, n : Integer ;
omp_set_num_threads( $\gamma$ ) ;
# pragma omp parallel for ;
for (m=1; m  $\leq$  lacc; m++) do
    omp_set_num_threads( $\theta$ ) ;
    # pragma omp parallel for ;
    for (n=1; n  $\leq$  wacc; n++) do
        if verify(m, n) then
            | acc[m][n]=acc[m][n]+1;
        end
    end
end
return acc;
    
```

IV. SIMULATION AND DISCUSSIONS

Simulation considers the case study of a triangular mesh superimposed on an image. It follows and extends the initial works on the Hough Transform method, applied to triangular shapes in a serial execution, introduced by Ouedraogo and others in [22], similar to compute the dual of rectangles proposed by Traore and others in [14], also in a serial execution.

At the present time, computers have several microprocessors as Dual Core, Quad Core, i5, i7, i9 and super calculators with a shared memory that allows and increases performance to execute multiple threads.

In both the serial execution and the parallel execution, simulation uses a computer with the following characteristics :

- Processor : Intel(R) Core(TM) i5 CPU M 480@2.67GHz 2.67GHz
- Memory usable : 4,00 Go
- operating system : Kali Linux

Different tests have been realized on the initial images in figures 3 and 4. Illustrations take into account parameters as the threshold to indicate the number of vote in the accumulator, the rate of pixels in each triangle represented by the value  $\alpha$ , the height and the base of the triangle and the number of threads.

The previous generic algorithms 2 and 3 have been detailed and specialized by the main algorithm 6 calling algorithms 4, 5 and 7, all in appendix for recognition in a triangular mesh. Implementations of parallelization have been realized in python, using opencv and pypm available in [17] to bring openmp-like functionality to python.

A. The Case of the Parameters (Threshold =100, the Number of Threads =2, The Height of the Triangle =4 Pixels, The Base of the Triangle=4 Pixels)

An analysis of the execution time for the parallel case and the serial case in varying the value  $\alpha$ , has been summarized in the Tables I and II. It reveals effectively that the parallel

Fig. 3. A Building Image

Fig. 4. A Road Image

computing of object dual is obviously better than the serial case.

TABLE I. THE EXECUTION TIME (IN SECOND) IN THE SERIAL CASE AND THE PARALLEL CASE FOR THE BUILDING IMAGE WITH THE PARAMETERS (THRESHOLD =100, THE NUMBER OF THREADS =2, THE HEIGHT OF THE TRIANGLE =4 PIXELS, THE BASE OF THE TRIANGLE=4 PIXELS)

$\alpha$	Number of detected lines	Serial case	Parallel case	Time difference
0.1	370	8.7	6.5	1.8
0.15	243	7.8	5.6	2.2
0.2	243	5.6	5.6	0
0.25	62	6.5	4.6	1.9
0.3	62	6.5	6.5	0
0.35	6	4.5	3.5	1
0.4	6	4.5	3.5	1
0.45	2	3	2.5	0.5
0.5	2	3	2.5	0.5
0.55	0	2.4	2.1	0.3

TABLE II. THE EXECUTION TIME (IN SECOND) IN THE SERIAL CASE AND THE PARALLEL CASE FOR THE ROAD IMAGE WITH THE PARAMETERS (THRESHOLD =100, THE NUMBER OF THREADS =2, THE HEIGHT OF THE TRIANGLE =4 PIXELS, THE BASE OF THE TRIANGLE=4 PIXELS)

$\alpha$	Number of detected lines	Serial case	Parallel case	Time difference
0.1	236	5	4	1
0.15	169	4.8	3.85	0.95
0.2	169	4.8	3.85	0.95
0.25	37	4.1	3.4	0.7
0.3	37	4.1	3.4	0.7
0.35	3	3.3	2.7	0.6
0.4	3	3.3	2.7	0.6
0.45	0	2.2	2.1	0.1

Difference between the processing time in the serial case and the parallel case, also appears in the Fig. 6 and 8, where the curve of the serial case is more up on the curve of the parallel case with the small values of  $\alpha$ .

The Fig. 5 and 7 show decreasing the number of straight lines for increasing values of  $\alpha$ .

Moreover, the surface of each triangle of the grid is determined by  $(\text{height} \times \text{base})/2$  : that means  $\frac{(4 \times 4)}{2} = 8$  pixels.

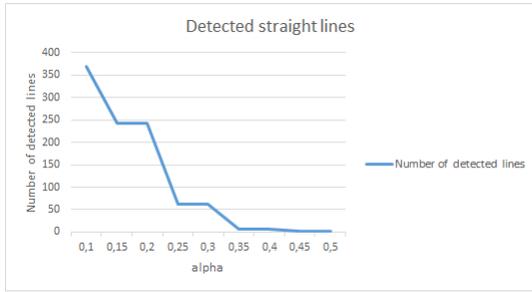

Fig. 5. The Number of Detected Lines in the Building Image Related to the Table I, Accordingly to the Values  $\alpha$

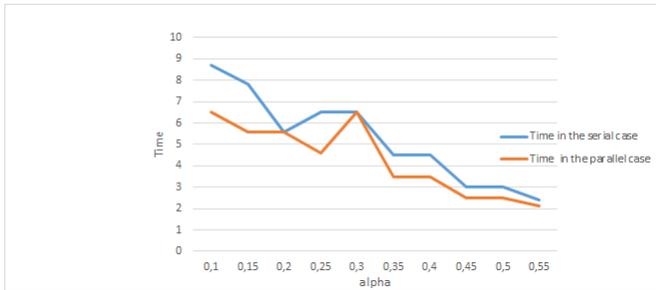

Fig. 6. The Curves of the Execution Time for the Building Image Related to the Table I

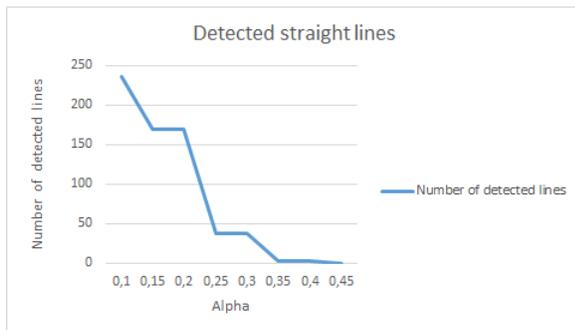

Fig. 7. The Number of Detected Lines in the Road Image Related to the Table II, Accordingly to the Values  $\alpha$

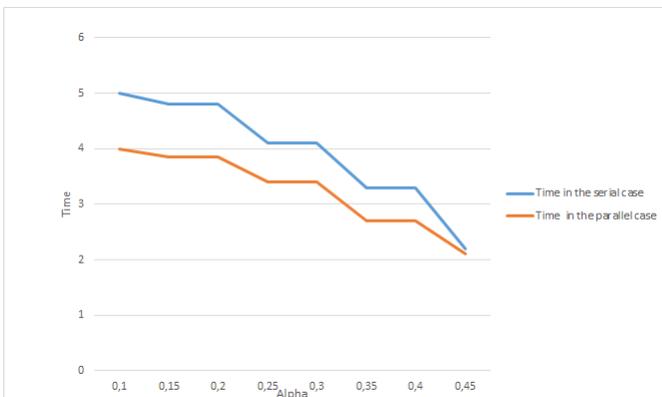

Fig. 8. The Curves of the Execution Time for the Road Image Related to the Table II

An image has  $(w \times h)$  pixels, divided into  $\lceil \frac{(w.h)}{8} \rceil$  triangles.

Valid triangles have the number of internal lit pixels, superior to  $\lceil 8 \cdot \alpha \rceil$ : they will be considered for computing dual. For instance, with  $\alpha=0.5$ , it appears at least  $(8 \cdot \alpha)=4$  lit pixels for each triangle, to be valid.

Thus, if the number of valid triangles is the value  $nv$ , then the loose triangles will be  $(\lceil \frac{(w.h)}{8} \rceil - nv)$  in computing dual. That leads to loss approximately  $((\lceil \frac{(w.h)}{8} \rceil - nv) \cdot 8)$  pixels (for all the image), representing a possibility to reduce the execution time.

If the value  $\alpha$  is increasing, then the number of pixels  $(8 \times \alpha)$  to be considered for triangle validation will be reduced: that reduces effectively the number of straight lines to be detected and the execution time for any case (serial case and parallel case). In more details, with the value  $\alpha$  increasing, the surface to be respected in each valid triangle will become small, but included more triangles that are engaged in the process: more straight lines passes through a reduced number of aligned triangles. More aligned triangles indicate reduced corresponding straight lines that pass through them, accordingly to the value of the threshold applied to the accumulator.

**B. The Case of the Parameters ( $\alpha = 0.1$ , The Number of Threads =2, The Height of the Triangle =4 Pixels, The Base of the Triangle=4 Pixels)**

With a fixed  $\alpha = 0.1$ , in varying the threshold, the Tables III and IV show respectively the execution time for the building image and for the road image: it presents naturally reduction in the number of detected lines and the execution time. Because the number of cells, having the maximum vote is reduced and the time taken to read the accumulator data is short for the serial case and for the parallel case.

TABLE III. THE EXECUTION TIME (IN SECOND) IN THE SERIAL CASE AND THE PARALLEL CASE FOR THE BUILDING IMAGE WITH THE PARAMETERS ( $\alpha = 0.1$ , THE NUMBER OF THREADS =2, THE HEIGHT OF THE TRIANGLE =4 PIXELS, THE BASE OF THE TRIANGLE=4 PIXELS)

Threshold	Number of detected lines	Serial case	Parallel case
100	370	8.7	6.5
125	53	7.6	5.6
150	13	7.6	5.4
175	7	7.6	5.3
200	5	7.4	5.3
225	2	7.8	5.3
250	1	7.4	5.4
275	0	7.7	5.4

TABLE IV. THE EXECUTION TIME (IN SECOND) IN THE SERIAL CASE AND THE PARALLEL CASE FOR THE TOAD IMAGE WITH THE PARAMETERS ( $\alpha = 0.1$ , THE NUMBER OF THREADS =2, THE HEIGHT OF THE TRIANGLE =4 PIXELS, THE BASE OF THE TRIANGLE=4 PIXELS)

Threshold	Number of detected lines	Serial case	Parallel case
100	236	5	4
125	24	4.83	3.8
150	6	4.8	3.7
175	1	4.7	3.7
200	0	4.7	3.7

C. The Case of the Parameters (Threshold =100, Number of Threads =2, The Height of the Triangle =8, The Base of the Triangle=8 )

Tables V and VI illustrate the case of a large triangle with the parameters ( height = 8 pixels, base =8 pixels).

TABLE V. THE EXECUTION TIME (IN SECOND) IN THE SERIAL CASE AND THE PARALLEL CASE FOR THE BUILDING IMAGE WITH THE PARAMETERS (THRESHOLD =100, NUMBER OF THREADS =2, THE HEIGHT OF THE TRIANGLE =8, THE BASE OF THE TRIANGLE=8 )

$\alpha$	Number of detected lines	Serial case	Parallel case	Time Difference
0.1	140	7	5.3	1.7
0.15	79	6.7	4.8	1.9
0.2	57	6.2	4.5	1.7
0.25	19	5.3	4	1.3
0.3	5	4.1	3.2	0.9
0.35	3	3.1	2.5	0.6
0.4	3	2.4	2	0.4
0.45	3	1.9	1.8	0.1
0.5	3	1.8	1.7	0.1
0.55	3	1.8	1.7	0.1
0.6	3	1.8	1.7	0.1
0.65	3	1.8	1.7	0.1
0.7	3	1.8	1.7	0.1
0.75	3	1.8	1.7	0.1

TABLE VI. THE EXECUTION TIME (IN SECOND) IN THE SERIAL CASE AND THE PARALLEL CASE FOR THE TOAD IMAGE WITH THE PARAMETERS (THRESHOLD =100, NUMBER OF THREADS =2, THE HEIGHT OF THE TRIANGLE =8, THE BASE OF THE TRIANGLE=8 )

$\alpha$	Number of detected lines	Serial case	Parallel case	Time Difference
0.1	97	4.5	3.6	0.9
0.15	55	4.3	3.5	0.8
0.2	29	4.1	3.2	0.9
0.25	8	3.6	3	0.6
0.3	0	2.9	2.6	0.2

As a conclusion, for any case of triangle, the difference between the parallel execution time and the serial one will be more large, in favour to the parallel case that has a short reduced time with the small values of  $\alpha$ .

D. Straight Line Recognition in Real Images

This section is focusing on the application of parallel Hough Transform to real images.

1) *Straight Line Recognition in the Building Image with a Triangle 4 x 4*: For the building image, the accumulator data and the results of straight line recognition are respectively illustrated in Fig. 9 in Fig. 10.

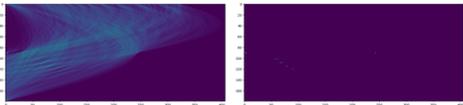

Fig. 9. The Accumulator Data after Application of the Parallel Computing: On the Left Image, The Sinusoid Curves and on the Right the Maximum Votes Superior to the Threshold =150

2) *Straight Line Recognition in the Road Image with a Triangle 4 x 4*: For the road image, the accumulator data and the straight line detection also appear respectively in Fig. 11 and 12, in considering the parameters (thread=2, threshold=100,  $\alpha=0.3$ ).

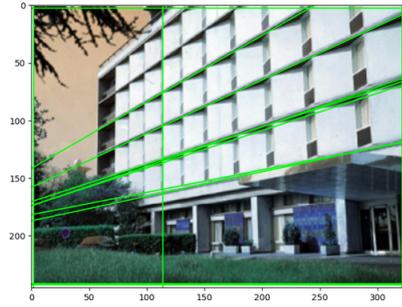

Fig. 10. Straight Line Recognition in the Building Image with the Parameters (Threads =2, Threshold = 150,  $\alpha=0.1$ )

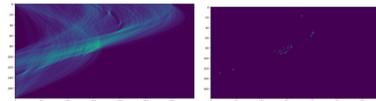

Fig. 11. The Accumulator Data after Application of the Parallel Computing: On the Left Image, The Sinusoid Curves; On the Right Image the Maximum Votes is Superior to the Threshold =100

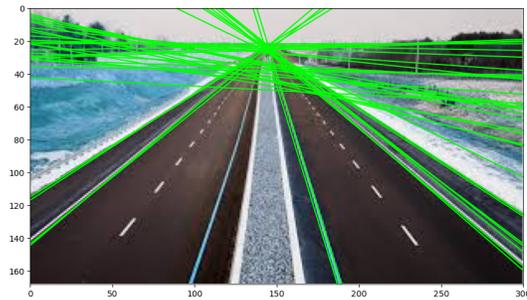

Fig. 12. Straight Line Recognition in the Road Image with the Parameters (Threads =2, Threshold = 100,  $\alpha=0.3$ )

V. CONCLUSION AND PERSPECTIVES

A new parallel Hough method has been proposed effectively to compute the dual of objects based on the standard Hough transform, through algorithms using openmp library to create threads. An image is analyzed with a meshing technique and different threads, computing the dual of virtual generated objects for updating the accumulator data.

Experimental results have been realized with the pypm library in python for parallelization and reveal reduction on the execution time in parallel execution than in the serial one. As outputs, the detection of straight lines is effectively realized in a building image and a road image. But optimizations of the proposed algorithms to improve more the execution time in the parallel case and comparisons with similar parallel methods still remain to do .

In perspectives, the study of parallelism will focus on straight line recognition in a rectangular grid, in an hexagonal grid or in an octagonal grid.

The future works will also analyze in detail, the internal structure of object dual to determine recognition for rectangles, triangles, hexagons and octagons in the image.

All these works will contribute forward to strengthen the building of a toolkit for the Hough Transform method, being integrated to a software for image processing, to bring out extensions for new functionalities, as a plug-in or a library for programming languages.

# Prototyping a Mobile Application for Children with Dyscalculia in Primary Education using Augmented Reality

Misael Lazo-Amado<sup>1</sup>, Leoncio Cueva-Ruiz<sup>2</sup>, Laberiano Andrade-Arenas<sup>3</sup>  
Facultad de Ciencias e Ingeniería  
Universidad de Ciencias y Humanidades<sup>1,2,3</sup>

**Abstract**—Dyscalculia is a disorder of difficulty in understanding, understanding of numbers and mathematical operations in such a way that the child has a greater stress by not solving the exercises proposed by the teacher, leading to the objective of the research in making an innovation plan dedicated to the mobile prototype with augmented reality for children with dyscalculia in primary education. Design Thinking was used as a methodology that allows us to know the needs of users and implement new solutions to their problems, so that the project team makes decisions to choose the best idea proposed, likewise this idea must be applied to a model or design, for this the Miro application was used for the mobile prototype, for the 3D design TinkerCad was used for educational games and finally the App Augmented Class application that was responsible for the visualization of augmented reality. The results were obtained through interviews with parents, indicating that the mobile prototype with augmented reality is a great contribution of impact and should be applied for children, finally this prototype is validated by five experts who mentioned that the final prototype has 86% acceptance. The conclusion of this research is to make an innovation model to solve the problems of dyscalculia, improving understanding and comprehension in mathematics.

**Keywords**—App augmented class; design thinking; dyscalculia; miro app; TinkerCad

## I. INTRODUCTION

Dyscalculia is a disorder that demonstrates learning difficulties in understanding, learning and performing subjects involving mathematical numbers, and also affects reading and writing, as well as attention deficits and visual problems [1]. Dyscalculia exists in every 5-8% of children in schools worldwide with symptoms of this disorder [2], in schools in India, between 13% and 14% of school-aged children are reported to have these learning disabilities. In such a way that covid-19 also influences the process of this disorder in school children when virtual classes are established, students do not have a monitor to guide them in their educational process, and children with symptoms of dyscalculia tend to be easily distracted [3].

In Latin America there are learning difficulties in children in such a way that the teaching of mathematics has a low performance of 49.9% to 70.3% and in this way the schools do not provide a good quality of teaching in their schools, considering a serious problem for dyscalculia to indicate the low preparation in education regarding mathematics is why children do not have highly trained teachers to provide good teaching [4]. In Brazil, which considers that dyscalculia

impairs school performance and achievement in mathematical operations [5], it also considers that out of every 304 schoolchildren aged 7-12 years of both sexes are assessed and 22 children are diagnosed with dyscalculia [6].

The majority of children with dyscalculia in Peru have difficulties in their academic development, thus indicating that students have teachers who are not trained to meet the needs of children [7]. In the Covid-19 pandemic, because they are not prepared to establish virtual classes, they do not have enough materials to carry out their activities, which is a big problem for many students, especially in rural areas of Peru, where they have problems in mathematics [8][9]. This is why the level of stress in children with dyscalculia can greatly affect their concentration to perform their activities [10].

These problems have been identified in the world, and we can see the need for a strategic plan to solve the problems related to dyscalculia, so that students with these disorders can improve their understanding and comprehension of subjects, strengthening their attention span. Proposing this solution for children with dyscalculia is affecting education in Peru as it requires the support of parents or teachers for its use. It also makes serious learning more affectionate as the child feels more confident to improve these learning problems.

The aim of the project is to develop a prototype of a mobile application for children with dyscalculia in primary education using augmented reality. Cognitive games or therapies will be made to solve mathematical problems with certain learning levels, in order to capture the attention of children with dyscalculia. The structure of the following: in Section II the literature review is explained, in Section III the methodology to be developed, in Section IV the results of our work, in Section V the discussions, in Section VI the conclusions and finally in Section VII the future work.

## II. LITERATURE REVIEW

Augmented reality in mobile applications for the treatment of dyscalculia or strengthening skills in education meets the expectations to improve learning. So they implement augmented reality to help students with dyscalculia to perform their activities in the subject of arithmetic, fulfilling learning in addition, subtraction, multiplication and division [11]. They also carry out an evaluation of children with dyscalculia and how it interacts with augmented reality since it indicates that the use of these technologies such as augmented reality draws the attention of students and facilitates the understanding

of mathematical activities [12]. The educational plan to use augmented reality has many advantages that will help teachers to understand the problems of children with dyscalculia also involves the dedication and patience it takes this process since they claim in their research that 92% of students interacting with augmented reality, improves their ability to understand [13].

Similarly, augmented reality in mobile applications can be more effective as people have a mobile phone in their homes giving them the opportunity to transmit education from the mobile application using augmented reality, as well as children with problems are treated with the help of their parents or loved ones without the need to have a specialist for these problems [14]. That is why this research makes a mobile prototype with augmented reality, giving a simulation of learning for children with learning disabilities, fulfilling the objective of helping them to perform their activities of their subjects in their respective classrooms [15]. For this reason, they indicate that the mobile application is very effective in attracting the attention of the child with dyscalculia, making it easier for them to concentrate during the treatment process, accompanied by educational games to increase the effectiveness of the treatment [16]. In this way this research in Arequipa, Peru uses this method of creating educational video games with 3D animations in their respective implemented in a mobile application giving in conclusion that these tools are very good to improve the education of the country [17].

There are tools for the implementation of augmented reality in mobile applications, in which programmers use Unity Game for the development of games with the purpose of optimising visual and auditory learning, by using this application children with learning disabilities can improve their reading and mathematics [18]. Similarly it is understood in this research that has problems with attention and comprehension in their primary level students as they have low performance in their chemical activities, with the help of augmented reality helps them to understand easily also 87.90% students in Indonesia validate their improvement [19]. The analysis of augmented reality applications for dyscalculia or any problem that involves education, meets its objective of supporting their treatment or improvement in their learning, which is why they also use tools such as surveys where they indicate how valuable these innovative solutions are in education [20].

The mobile application with augmented reality indicated by the authors in this literature review, in dyscalculia as well as in education. They show the importance that are tools that they use to improve their understanding and attention in children, in such a way that applying these innovative methods can solve problems in education, science, research, business, security among others. By finding problems in education and investigating solutions in different researchers, it is proposed that in our research we propose to improve the understanding of children with dyscalculia in primary education in Peru with the help of augmented reality.

### III. METHODOLOGY

For the use of the meta-logic we use the Design Thinking that is in charge of realising creative solutions for the user, which is divided into 5 stages (Empathise, Define, Ideate, Pro-

tototype and Test), these stages have tools for their development that are explained in detail in this section.

#### A. Design Thinking

It is a very pleasant methodology with the aim of solving the problems of the users using innovative ideas with the use of technologies to improve the expectation of those involved [21], It is a methodology that can be carried out in a short time and it is also necessary to have the approval of the final product and possible improvements [22]. It is a methodology of great interest to improve or create new products to improve the user's lifestyle using strategies and a variety of solutions, it is highly recommended by designers dedicated to innovation [23], the steps to be followed are shown in Fig. 1.

1) *Empathise*: This is the first stage of the Design Thinking methodology that fulfils its objective of finding user needs and it is necessary to use information gathering techniques to identify them [24]. This is why the best way to carry out this stage is to use tools such as surveys or interviews to get an in-depth understanding of people's relevant needs [25].

2) *Define*: This is the second stage of the methodology, which is responsible for organising or aggregating the data from the first stage in order to identify or understand the most important user problems. To do this, it is necessary to use techniques to group and prioritise these problems [26].

3) *Ideate*: This is the third stage, which has the main function of producing a greater number of ideas or solutions that respond to the problems of the second stage, it is necessary that the design or innovation team has a clear idea of the problems in order to assign impactful solutions for the users [27].

4) *Prototype*: This is the fourth stage which is in charge of making a prototype, mock-up or design according to the impacting idea of the third stage. The prototype will serve to show the user the solution to their problem that fits their needs, for this it is necessary to use prototyping applications or as well as using physical mock-up [28].

5) *Testing*: This is the last stage of the methodology that fulfils the main objective of validating that the user is completely satisfied with the prototype that is the design of the solution to their problems as well as helping us to provide new improved versions of the proposed solution, it is necessary to use tools that interact with the end users [29].

#### B. Tools for Mobile Prototype Design with Augmental Reality

In this part it is necessary to know the tools to implement the design of the mobile application and the augmented reality model, as well as to visualise in detail the interaction of the applications that are in charge of fulfilling the objective as shown in Fig. 2.

1) *Miro APP*: It is a collaborative platform that its main function is teamwork in real time, is widely used for project management, has a number of free templates for efficiency and understanding of the meetings among them are mind maps, whiteboards, charts, flowcharts, wireframe web and mobile [30].

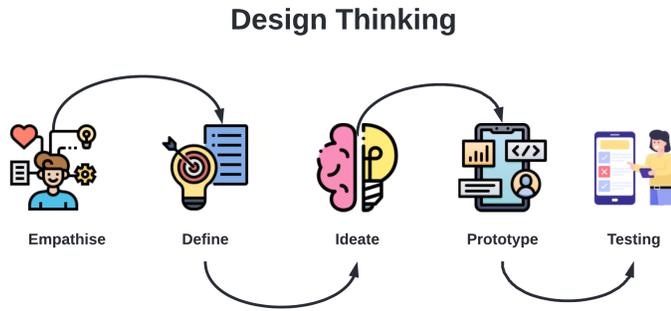

Fig. 1. Methodology Design Thinking.

2) *Tinkercad*: It is an application that takes care of real 3D modelling or design for free and online. It is built precisely for any user with no experience or with experience in design allowing you to create complex models [31]. It has a variety of features so that your 3D modeller can visualise using augmented reality as well as use programming for arduino circuits, import and export files, among others [32]. Tinkercad can be used in any browser as the main basic requirement for the use of the user is to have a mobile device, tablet, computer or laptop [33].

3) *App Augmented Class*: This application can be found in the play store for free and allows you to visualise projects with augmented reality, for which it is not necessary to have basic technical knowledge and its use is simple and intuitive. App Augmented Class has its own designs to learn about augmented reality and also add your own 3D designs [34].

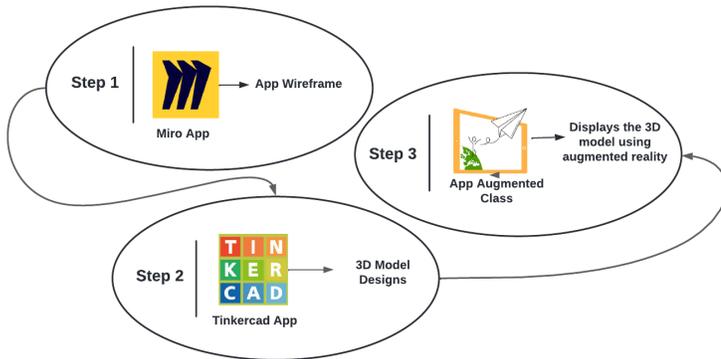

Fig. 2. Application Design Steps and Augmented Reality Modeling.

#### IV. RESULTS

This section of the results shows how to develop the phases of the Design Thinking methodology that will allow us to know the problems of users and provide the solution in the short term, as well as using the proposed tools to implement mobile design with augmented reality, on the other hand will have the validation of experts who ensure the efficiency and impact that has the mobile design with augmented reality and finally will share the advantages, disadvantages and comparisons that our methodology has.

#### A. Results of Empathise

To understand the results of the first phase of the methodology it is necessary to identify the six questions proposed (Q1 to Q6) by the project team that are addressed to the parents, in order to find out their children’s problems in mathematics as shown in Table I.

TABLE I. QUESTIONS

Questions	
ID	Questions
Q1	What grade is the child in?
Q2	Sex ?
Q3	In which district of Lima is the child located
Q4	Does the child have difficulties in understanding and comprehension?
Q5	Does the child experience stress when not solving the problems proposed by the teacher?
Q6	Does the child have difficulty recognising numbers?

#### B. Results of Define

In the results of the second phase of the methodology which is in charge of verifying the answers of the questionnaire (R1 to R6) of the parents, there are a total of 70 answers for analysis as shown in Table II.

TABLE II. PARENTS’ RESPONSE TO THEIR CHILDREN

Answers	
ID	Answers
R1	First Grade Primary 35.7%, Second Grade Primary 15.7%, Third Grade Primary 8.6%, Fourth Grade Primary 17.1%, Fifth Grade Primary 14.3%, Sixth Grade Primary 8.6%
R2	Male 68.6% Female 31.4%
R3	Los Olivos 28.6%, San Martín de Porres 18.6%, Carabayllo 14.3%, Lima 12.9%, Independencia 11.4%, Comas 14.3%
R4	Yes 74.3% , No 25.7%
R5	Yes 70% , No 30%
R6	Yes 71.4% , No 28.6%

a) *R1*: The first response which refers to the 70 respondents in which parents indicate that their children were questioned in the first grade of primary school has 35.7%, second grade of primary school has 15.7%, third grade of primary school has 8.6%, fourth grade of primary school has 17.1%, fifth grade of primary school has 14.3% and sixth grade of primary school has 8.6%.

b) *R2*: The responses to the second question indicate that male students 68.6% and female students 31.4% were correctly answered.

c) *R3*: The answers to the third question indicate the districts of Peru-Lima that have been surveyed, indicating that in Puente Piedra 8.6%, Los Olivos 27.1%, Carabayllo 28.6%, San Martín de Porres 15.7%, Comas 17.1%, Rimac 2.9%.

d) *R4*: The answers to the fourth question indicate that children have greater difficulty in understanding and comprehension, with 74.3% of respondents saying this is the case and 25.7% saying it is not.

e) *R5*: The answer to the fifth question indicates that 70% of the respondents have more stress when they do not solve the problems proposed by the teacher and 30% have a solid education without stress.

f) R6: The answer to the fifth question indicates that 71.4% of respondents have difficulty with number recognition and 28.6% do not have this problem.

C. Results of Ideate

For the results of the third phase of the methodology, plans or solutions are developed for the problems found in the surveys in Fig.3 shows the graph where the innovation developers make their score to decide which of the ideas show the greatest impact for the user, likewise the idea with the highest score is: Develop a mobile application with augmented reality.

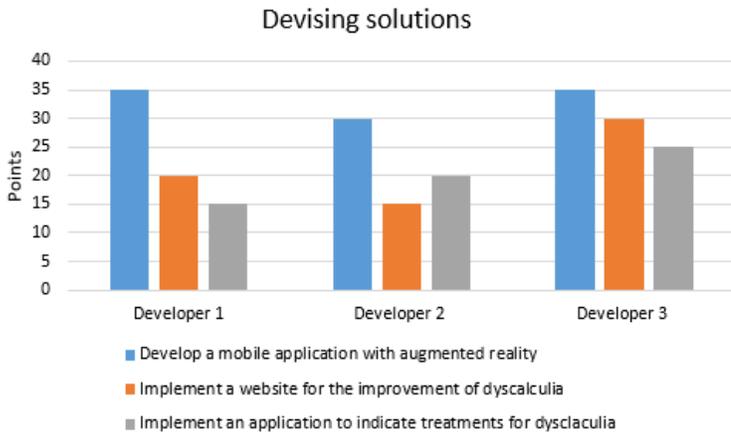

Fig. 3. Results of Ideate.

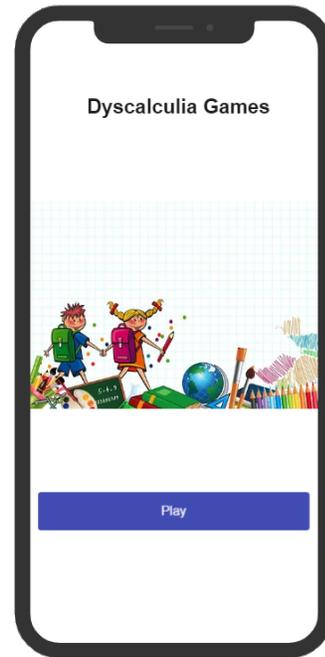

Fig. 4. Start of the Mobile Application.

D. Results of Prototyping

For the results of the prototype that was made with the tools indicated in Fig. 2, it will show the main functions that the mobile application with augmented reality will have, therefore in Fig.4 it will start with the welcome to the application to start the educational game with augmented reality where the user with dyscalculia problems must press the play button to advance with the following steps.

The second prototype refers to the selection of the child's level as shown in Fig. 5, click on the child's primary school grade and then look for the child's age, and we will continue with the next step.

Fig. 6 shows the first game to be developed for the first grade of primary school where the child can learn thanks to augmented reality with a dynamic design for better understanding and comprehension. In this way, it will have stars that indicate how the first game is developing, which tries to complete the sequence of numbers and finally the child can indicate whether he/she likes or dislikes the game.

Fig. 7 shows the addition in augmented reality so that the child can select the correct answer. The aim is not to guess the result, but to allow the child to mentally develop the sum or to have the support of the teacher to supervise the child's understanding of the exercise.

Similarly, Fig. 8 shows the same dynamics of the second game, the difference is that it shows the subtraction with augmented reality.

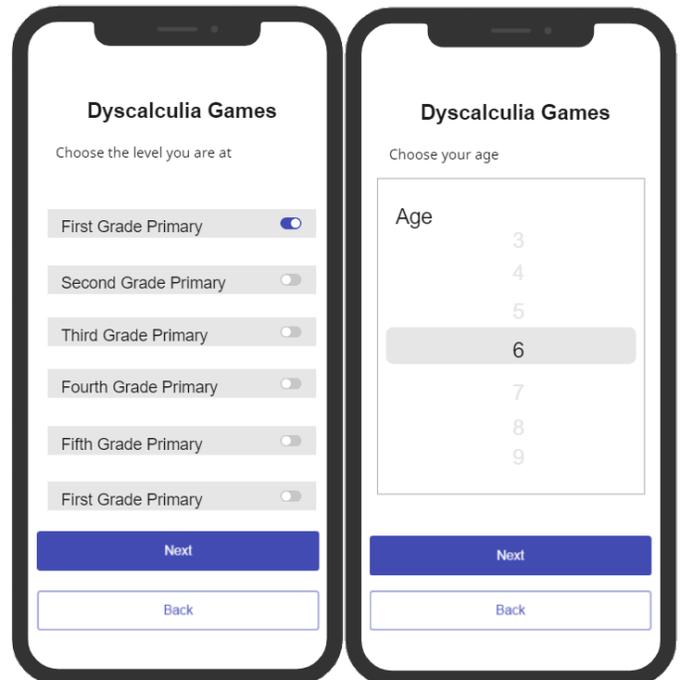

Fig. 5. Level and Age Selection.

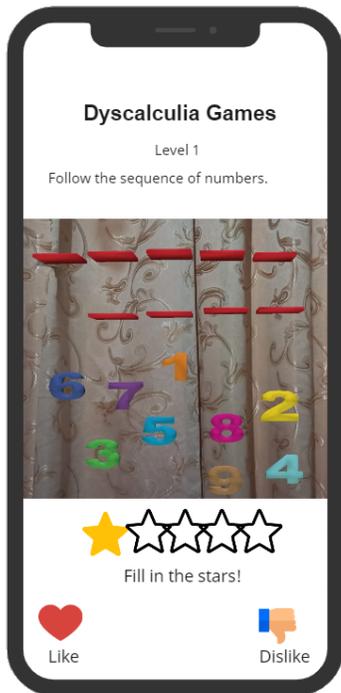

Fig. 6. First Game of the Mobile Application with Augmented Reality.

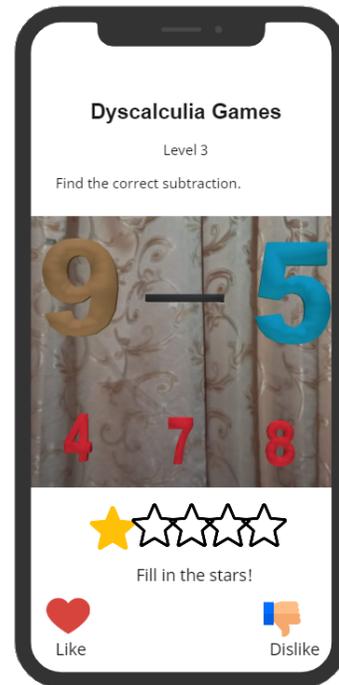

Fig. 8. Third Game of the Mobile Application with Augmented Reality.

Finally, Fig. 9 shows the game that will try to display the figures in such a way that you must identify or select the total number of figures for each row.

Fig. 7. Second Game of the Mobile Application with Augmented Reality.

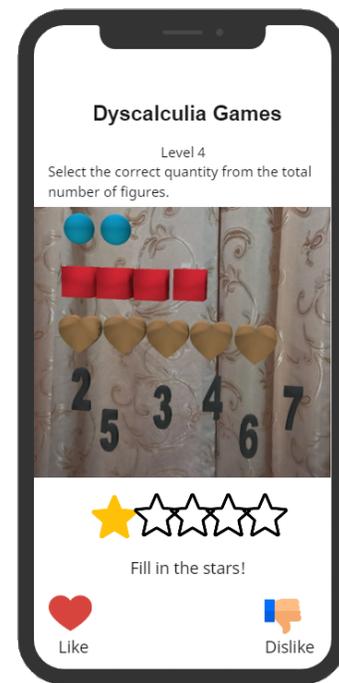

Fig. 9. Fourth Game of the Mobile Application with Augmented Reality.

E. Results of Testing

To develop this last stage of the Design Thinking methodology it is necessary to carry out a survey to validate that our prototype with augmented reality is correct for the user, in such a way that Table III identifies the five questions (Q1 and Q5) that will be sent to the users for their corresponding analysis.

TABLE III. TESTING QUESTIONS

Questions for parents about the augmented reality prototype	
ID	Questions
Q1	Does the prototype meet the goal of comprehension and understanding?
Q2	Do you think that by developing this design you can improve your child's dyscalculia?
Q3	Do you think this mobile application will have a great impact on society?
Q4	Do you think that the mobile application with augmented reality should be used with the teacher or parents for better understanding or doubt?
Q5	Do you recommend the use of the augmented reality mobile application to schools and health centres for the treatment of dyscalculia?

According to the questionnaire that was carried out, 70 parents indicate their answers for each question as shown in Fig. 10, in the first question indicates that 79% say that the prototype meets the objective of comprehension and understanding and 21% say it does not. In the second question, it indicates that developing the application with augmented reality will improve the dyscalculia of their children, 83% and 17% say no. In the third question, 77% of the respondents say that the mobile application will have a great impact on society and 23% say no. In the fourth question, it indicates that 89% of the respondents say that the mobile application will have a great impact on society and 23% say no. In the fourth question, 89% indicated that the mobile application with augmented reality should be used by the teacher or guardian to check the development of their child and 11% that it should not. In the last question, parents indicated that the mobile application with augmented reality should be implemented in schools and health centres for the treatment of dyscalculia, with 84% stating this and 16% stating that it should not.

and Integration) must be taken into account, which will serve to define that the prototype has the security and acceptance by the experts.

For this it is necessary to consider that to score these criteria you must have a representative level: Low, Moderate and High. In the low level it will have as a result in the 0% to 49% shows the little interest and the low acceptance by the prototype. In the moderate level it will have the result of 50% to 79% that indicates that the prototype must obtain some improvements for its acceptance and finally the high level will have the 80% to 100%, as a result it will indicate that the prototype is considered a good project of innovation and accepted by the expert, as well as it shows in the Table IV.

TABLE IV. LEVEL OF ACCEPTANCE

Level		
Under	Moderate	High
0% - 49%	50% - 79%	80% - 100%

To find the total level of acceptance it is necessary to perform an equation, so that the criteria (Functionality, Usability, Coherence and Integration) are added up and divided by the number of criteria, so that the level of acceptance (Low, Moderate and High) is obtained.

Once the levels of acceptance are understood, the scoring of each expert should be done in such a way that each criterion is scored from 0% to 100%, and finally the total sum for each criterion and the level of acceptance of the prototype is displayed, as shown in Table V.

TABLE V. SCORING BY EXPERTS

Question about the prototype with augmented reality						
Experts	Functionality	Usability	Consistency	Integration	Total	Level
Expert 1	82%	95%	79%	80%	84%	High
Expert 2	83%	93%	86%	92%	89%	High
Expert 3	87%	85%	81%	87%	85%	High
Expert 4	89%	91%	88%	83%	88%	High
Expert 5	82%	86%	83%	91%	86%	High

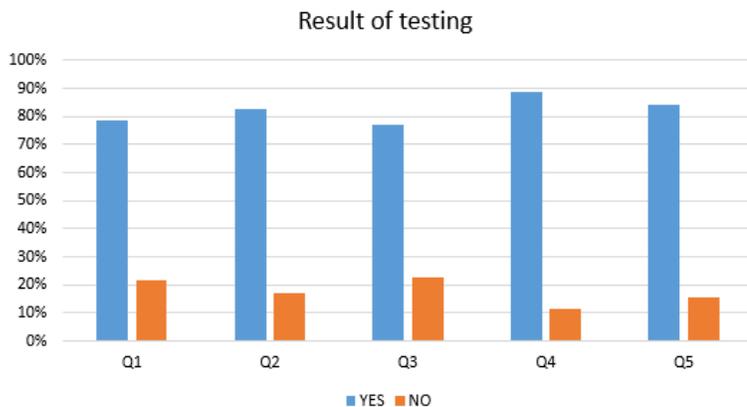

Fig. 10. Application Design Steps and Augmented Reality Modeling.

F. Expert Validation of the Prototype

To verify these validation results, which must be verified by 5 experts, the 4 criteria (Functionality, Usability, Consistency

In such a way Fig. 11 shows the validation by experts who have the high level of acceptance, indicating that the final prototype is a good innovation project, in detail it is shown that expert 1 shows the high level with 84%, expert 2 shows the high level with 89%, expert 3 shows the high level with 85%, expert 4 shows the high level with 88% and expert 5 shows the high level with 86%. As total average of all validations by all experts counts 86%.

G. About the Methodology

1) *Advantages:* The advantages of the Design Thinking methodology help us to know the needs of the users in order to solve their problems, using technology. Likewise, working in a group is effective to get to know different points of view in such a way that we reach the same objective of satisfying the client. Creativity and innovation are the main characteristics of this methodology, which involves research and analysis to come up with new ideas to contribute to society.

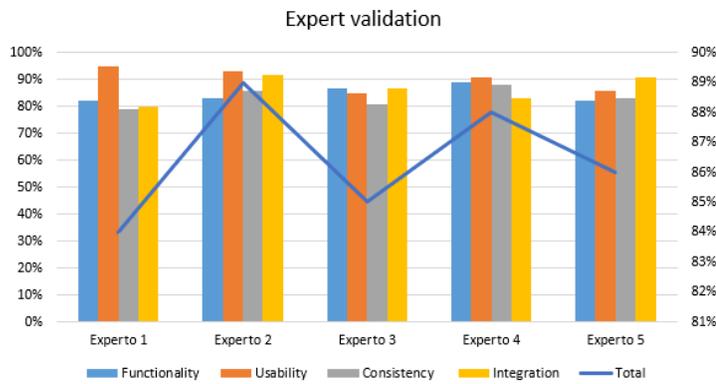

Fig. 11. Expert Validation.

2) *Disadvantages:* The main disadvantage of the Design Thinking methodology is the prototyping that it involves as a final solution and not in its development, so that this methodology can be grouped with other types of methodology dedicated to the development of the application in order to carry out a complete project.

3) *Comparison:* The Design Thinking methodology gives us the facility to use innovation and creativity to reach the needs of people, compared to other methodologies that are only responsible for the development and implementation with more complex phases [35],[36], this methodology is dedicated to the contribution to society and its ease of understanding is totally simple.

## V. DISCUSSIONS

In the research work that proposes to make a mobile prototype with augmented reality for dyscalculia, it turns out to be a very effective plan for the treatment of the student in such a way that there is a variety of similarities in different works that have the same objective of improving the treatment and quality in their teachings for children with problems in their understanding of mathematical operations, this coincides with the author [13],[37] which is in charge of developing augmented reality to improve children's comprehension skills in such a way that they become familiar with technology, and it is also discussed that their work makes a great contribution to society, implying that by using these technologies they can help solve different problems. On the other hand, augmented reality should be visualised by a device in such a way that the author [14], affirms the ease of having a mobile device and that when using it with augmented reality it is more effective since there are millions of users with a mobile phone in their homes, it is in this way that together the two points of view of different authors can be similar in my project giving the assurance that the development will generate a great impact on education. to know or understand the needs of users is necessary to establish multiple solutions to their problems so that the author [20], the methodology of the methodology matches our strategy, indicating that tools such as interviews and surveys are a fundamental part of the analysis with respect to the mobile application with augmented reality.

## VI. CONCLUSIONS

The mobile prototype with augmented reality that is carried out in this project, proposes the improvement and treatment of dyscalculia in children in primary education, precisely a variety of problems identified by the surveys, indicating the problems that children have with their learning and the difficulty in performing their mathematical operations, for this dynamic games are made with augmented reality giving ease of understanding and comprehension. The Design Thinking methodology was a fundamental part to know the needs of the parents and the decision making by the team for the analysis of the problem, giving an infinity of ideas for the search of its solution. The prototype will not only be dedicated to education, but can also be easily integrated into health centres and clinics, in such a way that its contribution with the use of technology will be effective for the adequate treatment of children with dyscalculia. The main limitation of our project is the development of the mobile application with augmented reality, since our methodology does not focus on development, it is only used for design and prototyping.

## VII. FUTURE WORK

For future work, it is suggested that this prototype with augmented reality be developed with the methodology focused on implementation or also be able to develop virtual reality technology with artificial intelligence for greater experience with the technology. In such a way that the development meets the objective of improving and treating dyscalculia in children, it is suggested that the work should be done in conjunction with specialists who have knowledge about dyscalculia for a better understanding of these learning disorders.

## ACKNOWLEDGMENT

This work was sponsored by the University of Sciences and Humanities and the research direction. Thank for the unconditional support.

# Adaptive Lane Keeping Assist for an Autonomous Vehicle based on Steering Fuzzy-PID Control in ROS

Hoang Tran Ngoc, Luyl-Da Quach  
Software Engineering Department  
FPT University Can Tho city, Vietnam

**Abstract**—An autonomous vehicle is a vehicle that can run autonomously using a control. There are two modern autonomous assistant systems that are proposed in this research. First, we introduce a real-time approach to detect lanes of the streets. Based on a series of multi-step image processing through input data from the camera, the vehicle's steering angle is estimated for lane keeping. Second, the steering control system ensures that autonomous vehicles can operate stably, and smoothly, and adapt to various road conditions. The steering controller consists of a PID controller and fuzzy logic control strategy to adjust the controller parameters. The simulation experiments by Gazebo simulator of the Robot Operating System (ROS) not only indicate that the vehicle can keep the lane safely, but also demonstrate that the proposed steering angle controller is more stable and adaptive than the conventional PID controller.

**Keywords**—Autonomous vehicles; automated steering; lane detection; fuzzy PID control; ROS, Gazebo

## I. INTRODUCTION

Every year nearly 1.25 million people die in traffic accidents. Therefore, safety is the most important criterion when driving on the road. Traffic accidents are caused by human errors up to 90% according to National Highway Traffic Safety Administration (NHTSA) statistics [1]. In recent five years, autonomous vehicles, and many advanced driver assistance systems (ADAS) have been developed to help drivers to drive safely. It attracts great attention not only in academia but also in automotive industries such as Google, Tesla, BMW, and Hyundai. In there, lane boundary detection and steering control systems play a key role in autonomous vehicles (AVs).

To detect the lanes as well as the steering angle, common sensors are used such as radar, light imaging detection and ranging (LIDAR), laser sensors, and even global positioning systems (GPS) [2-5]. However, sensors with high accuracy of distance measurement are very expensive. Therefore, numerous studies have been developing vision-based systems using camera sensors for lane detection [6-7] in recent years. These studies indicate that the lane detection process has major challenges such as lighting and background clutter.

Along with the studies of determining steering angle based on lane detection via vision, approaches to improve the stability and accuracy of the steering angle controller are also interesting in several studies around the world. For example, a basic steering control algorithm based on a PID controller was proposed in [8]. Moreover, to address a repeated problem of steering control, a robust PID controller is designed in

[9]. Another approach was nested conventional PI and PID controllers to improve the accuracy of the steering angle controllers [10-15]. However, the damping effect of the conventional PID controller is not good enough to keep the vehicle running smoothly for lane tracking. Therefore, to develop the autonomous system without mentioned problems, we have two main goals: estimating the steering angle and designing the steering controller with high stability.

In this research, the steering angle is estimated through a sequence of image processing steps and computer vision approaches. The image will be filtered, determined the region of interest (ROI), and finally extracted the line segments using the simplified Hough Transform technique. After obtaining the estimated steering angle, this paper proposed a method to optimize the performance of the steering control system. The idea is to use the fuzzy logic control strategy to tune the parameters of the PID controller. The fuzzy controller adjusts the parameters of the PID based on the steering angle error and previous information. The effectiveness of the two proposed systems is verified by the robot simulation results in the Gazebo environment.

The structure of this research paper is organized as follows. First, in Section 2, the vehicle steering model is introduced. In Section 3, lane detection and steering angle estimation are presented. The proposed steering control system using a Fuzzy-PID controller is analyzed and designed in Section 4. Then, the simulation results and analysis of the corresponding system are compared in Section 5. Finally, the conclusions in Section 6 will summarize the content of this research.

## II. VEHICLE DYNAMIC MODEL

The vehicle dynamics and vehicle steering behavior are considered in the 2D bicycle model [16]. The linear vehicle steering model is described as follows:

$$\begin{bmatrix} \dot{y} \\ \dot{\beta} \\ \dot{\psi} \\ \dot{\psi} \end{bmatrix} = \begin{bmatrix} 0 & V & V & 0 \\ 0 & -\frac{D_r+D_f}{MV} & 0 & \frac{D_r L_r - D_f L_f}{MV^2} \\ 0 & 0 & 0 & 1 \\ 0 & \frac{D_r L_r - D_f L_f}{L_z} & 0 & \frac{D_r L_r^2 - D_f L_f^2}{L_z V} \end{bmatrix} \begin{bmatrix} y \\ \beta \\ \psi \\ \psi \end{bmatrix} + \begin{bmatrix} 0 \\ \frac{D_f}{MV} \\ 0 \\ \frac{D_f L_f}{L_z} \end{bmatrix} \delta \quad (1)$$

where  $y$ ,  $\beta$ ,  $\psi$ ,  $\dot{\psi}$ ,  $V$ ,  $L_z$ ,  $M$ ,  $L_f$  and  $L_r$  are vehicle position, side slip angle, yaw angle, yaw rate, vehicle speed, vehicle inertia, vehicle mass, and the center of gravity distance from front tires, and rear tires. The lateral forces with

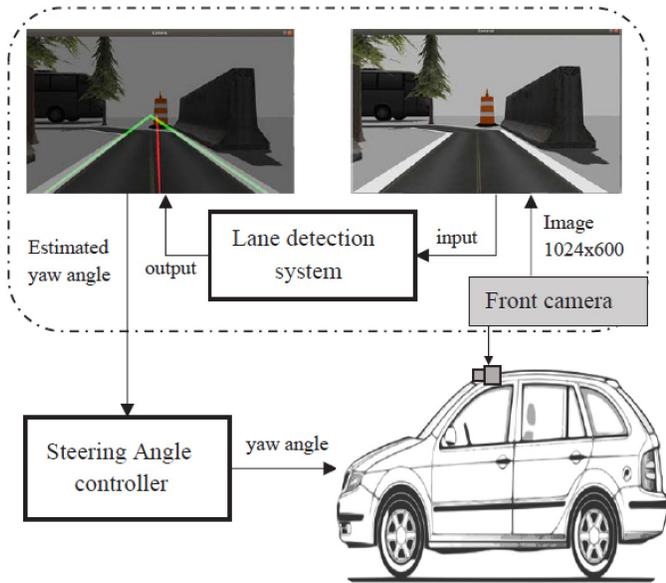

Fig. 1. Block Diagram of the Proposed System.

linearized cornering stiffness of the front, and rear wheel ( $D_f$  and  $D_r$ ) are shown in (2) below:

$$\begin{cases} F_{yf} = D_f \alpha_f = D_f \left( \delta - \beta - \frac{L_f \dot{\psi}}{V} \right) \\ F_{yr} = D_r \alpha_r = D_r \left( -\beta + \frac{L_r \dot{\psi}}{V} \right) \end{cases} \quad (2)$$

where  $\alpha_f$ ,  $\alpha_r$ , and  $\delta$  are front, rear tire slip angle, and steering angle from the forward direction of the vehicle.

The proposed system and variables of the vehicle model are presented in Fig. 1 and Fig. 2. In this research, the yaw angle is estimated from the lane detection system and used as the steering angle to control the robot model in the Gazebo simulator environment. In the real system, the front wheel steering angle ( $\delta$ ) will be converted from a yaw angle ( $\psi$ ).

#### A. Lane Detection Algorithm

To control the proposed autonomous vehicle to keep the lane accurately, we used algorithms [17] and adapted them to match our system by using the following steps: First, to detect the white lanes, we isolate all the white areas on the image. To do this, we converted the color space of the image from RGB (Red/Green/Blue) to the HSV (Hue/Saturation/Value) and created the mask image for a range of white colors. Second step, we extracted edges in the white mask by using the Canny edge detector [18-19]. This algorithm is developed by John F. Canny that can detect edges and reduce the number of erroneous edges detected in mask images. In the third step, we need to detect a few white edge areas that are no lane lines. The extraction of an Isolate Region of Interest (IROI) is performed in this step. We cropped the detected edges in the top half of the image. Fourth step, line segment detection is applied. We extracted the coordinates of the lane lines from white pixels by using the Hough Transform technique [20]. The Hough Transform is a common algorithm, used in image processing to find features such as lines, circles, and ellipses.

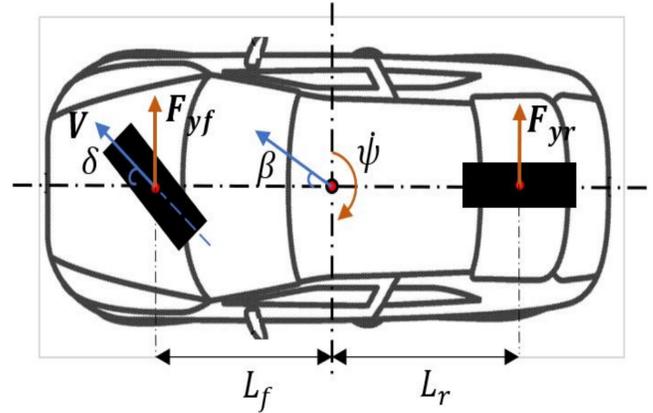

Fig. 2. Block Diagram of the Proposed System.

We applied it to detect straight lines from pixels that seem to line up.

The Hough Transform is the transformation from points to curves, which converts the Cartesian coordinate system of the image to the polar coordinate Hough space as (3):

$$\rho = x \cos(\theta) + y \sin(\theta), \quad \theta \in [-\pi \quad \pi] \quad (3)$$

where  $(x, y)$  is the pixel coordinates;  $(\theta, \rho)$  is the polar coordinates;  $\rho$  the distance of the straight line from the coordinate origin;  $\theta$  is the minimum angle of the straight line in the normal direction with the positive direction of the x-axis. Points on the same line satisfy the (3) with a set of  $(\theta, \rho)$  constants. Fig. 3 shows the basic principle of the Hough Transform. From this basic principle, line segments are determined.

### III. LANE DETECTION AND STEERING ANGLE ESTIMATION

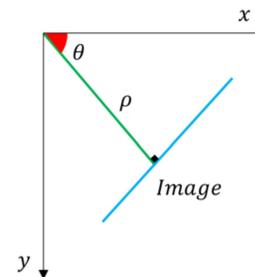

Fig. 3. Basic Principle of Hough Transform.

The final step is to combine line segments into two-lane lines. We classified small line segments into two groups by their slope. All the line segments of the left lane line have an upward slope ( $\theta$  range from  $15^\circ$  to  $85^\circ$ ), whereas all line segments of the right lane line have a downward slope ( $\theta$  range from  $-15^\circ$  to  $-85^\circ$ ). We then averaged the slope and the intersection point to detect the left and right lanes. Fig. 4 shows the lane detection stages and results of our system in the Gazebo simulation environment.

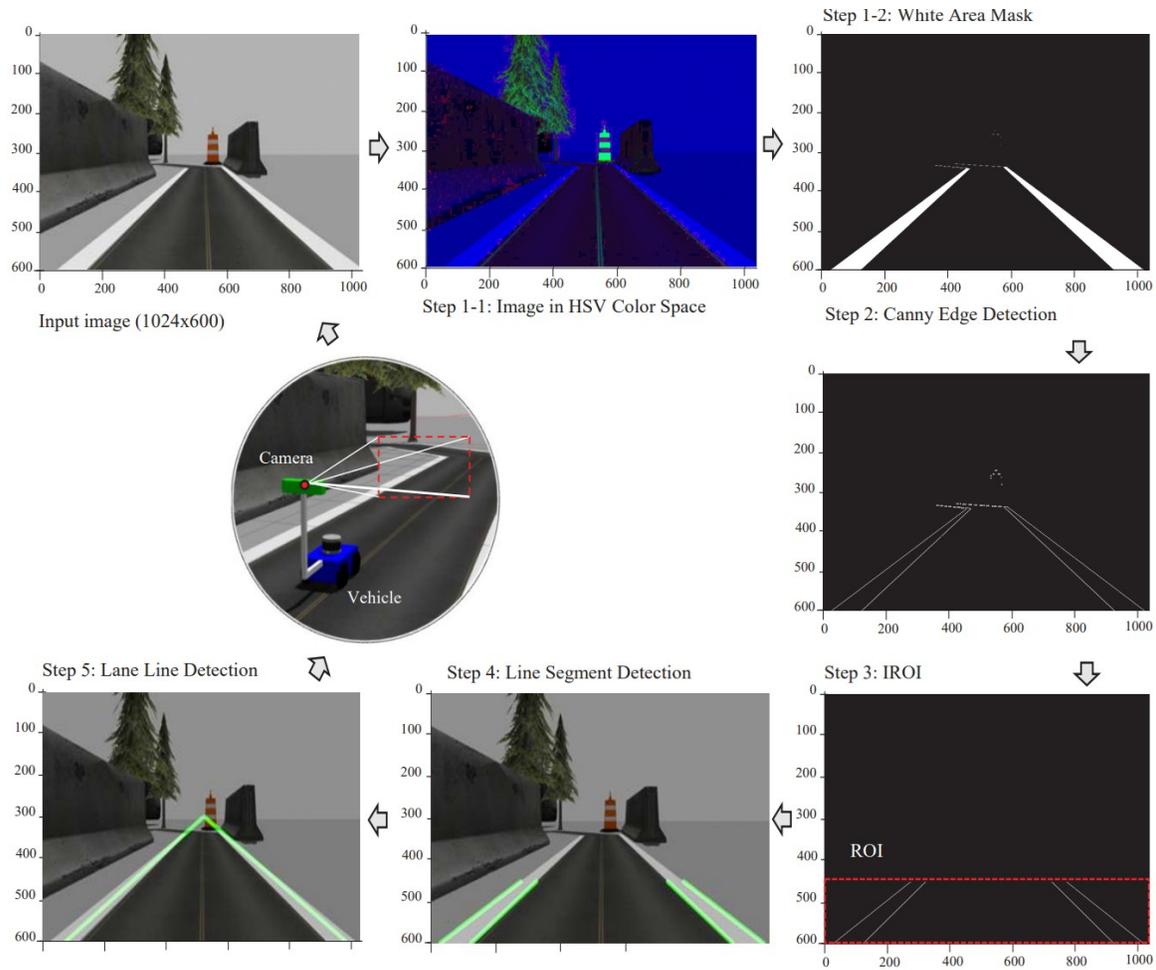

Fig. 4. Lane Detection Steps and Results of our System.

### A. Steering Angle Estimation

After using the lane detection algorithm, we have the coordinates of two lanes. We need to estimate the steering angle to steer the car so that it keeps in the middle of the two lanes. We have two cases where the vehicle drifts to the left side or the right side of the road, and the vehicle is already in the middle of the lane. From the coordinates of the two lanes, the steering angle will be determined according to the following (4):

$$\hat{\psi} = \tan\left(\frac{x_{offset}}{\frac{H_i}{2}}\right) \quad (4)$$

$$\hat{\psi} = \begin{cases} \tan\left(\frac{\left(\frac{x_{1(R)} - x_{1(L)}}{2} + x_{1(L)}\right) - \frac{W_i}{2}}{H_i/2}\right), & \text{if } \begin{cases} < 0, \text{ right side.} \\ > 0, \text{ left side.} \end{cases} \\ 0, & \text{vehicle on center,} \end{cases}$$

where  $\hat{\psi}$  is the yaw angle estimated for use as the steering control angle in the Gazebo simulator;  $x_{offset}$  is the distance from the vehicle's center to the line between the two detected lanes;  $(x_{1,2(L)}, y_{1,2(L)})$  and  $(x_{1,2(R)}, y_{1,2(R)})$  are the start points and endpoints of the left lane and the right lane;  $W_i$  and  $H_i$  are width and height of the image input (unit: pixel).

Fig. 5 shows the sample coordinates of the system on the right side (a) and the left side (b).

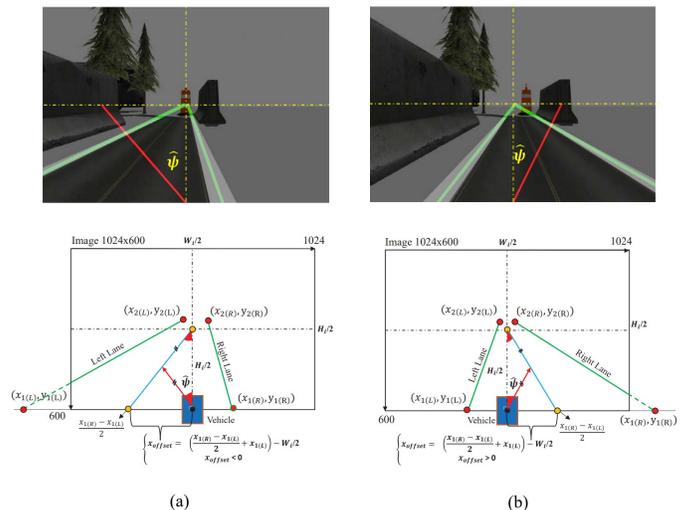

Fig. 5. Sample Coordinates of the System on the Right Side (a) and the Left Side (b).

#### IV. STEERING CONTROL SYSTEM

The steering control system controls the vehicle to keep the center of the lane. To achieve this, the desired steering angle ( $\psi_{des}$ ) must be controlled at 0. However, the damping effect of ordinary PI and PID controllers is not good enough to keep the vehicle running smoothly and stably, so a fuzzy PID controller is proposed to tune the PID parameters for further improvement. Fig. 6 shows the fuzzy PID control algorithm structure diagram for our vehicle autonomous system. A mathematical equation for controlling the steering angle of a typical PID controller is expressed in (5).

$$\psi_{Tuning}(t) = K_p e(t) + K_i \int_0^t e(t) + K_d \frac{de}{dt} \quad (5)$$

where  $K_{p,i,d}$  are the proportional gain, integral gain, and derivative gain;  $\psi_{Tuning}$  is the tuning steering angle;  $e$  is the angle error between the estimated steering angle ( $\hat{\psi}$ ) and the desired steering angle ( $\psi_{des} = 0$ ).

The fuzzy logic controller is designed with two input signals the error and the derivative of the error, while the three outputs are  $K_p, K_i$ , and  $K_d$ . The range of  $e$ , and  $\Delta e$  are limited as  $-45, 45$  and  $-10, 10$ , respectively. The fuzzy rule base is shown in Table I. The membership functions are  $N$  (Negative);  $NM$  (Negative medium);  $Z$  (Zero);  $PM$  (Positive medium);  $P$  (Positive) for error input, and  $Z_e$  (Zero);  $L_o$  (Low);

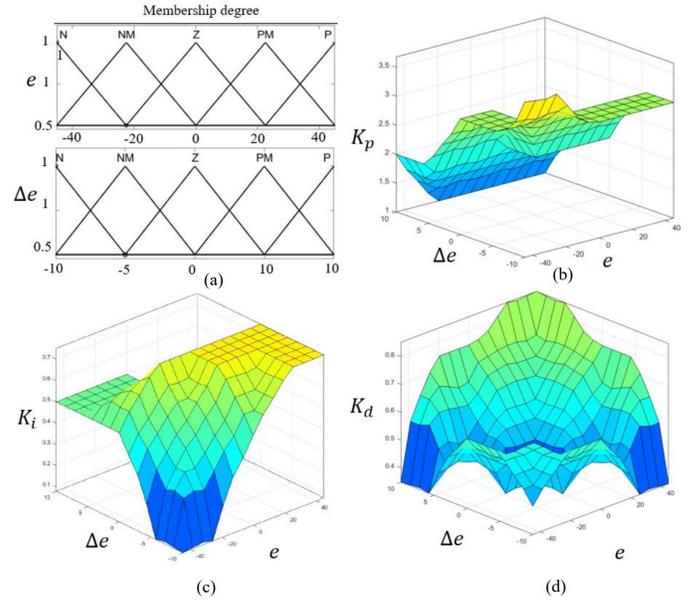

Fig. 7. Fuzzy Logic. (a) Membership Function of  $e$  and  $\Delta e$ . (b), (c) and (d) View of the Fuzzy Rule-Base of  $K_p, K_i$ , and  $K_d$ .

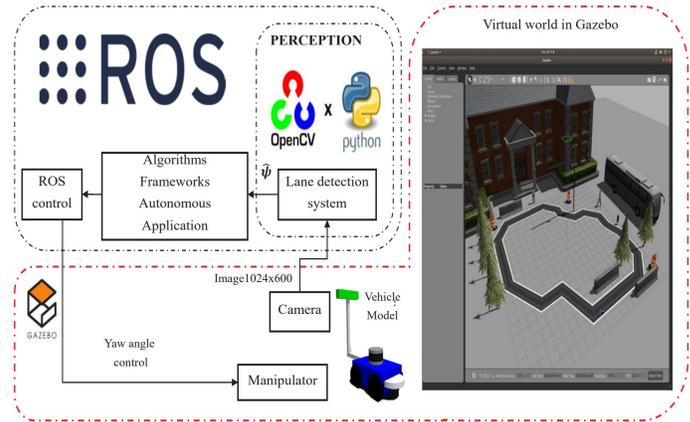

Fig. 8. Architecture of Simulation System.

$M_e$  (Medium);  $H$  (High);  $V_h$  (Very high) for parameters output. The Segeno model is applied to the fuzzy logic structure to obtain the best value for PID parameters.

By using the Scikit-Fuzzy library for the Python computing language, the steering angle controller was tuned based on the designed rule, so that the best dynamic response of the vehicle is achieved with the smallest overshoot and steady-state error when comparing centerline lane keeping. Fig. 7(a) shows the membership function and Fig. 7(b)-(d) the rule base of the fuzzy logic controller.

The simulation results of vehicle operation in the Gazebo environment are provided later to demonstrate the effectiveness of the two proposed systems.

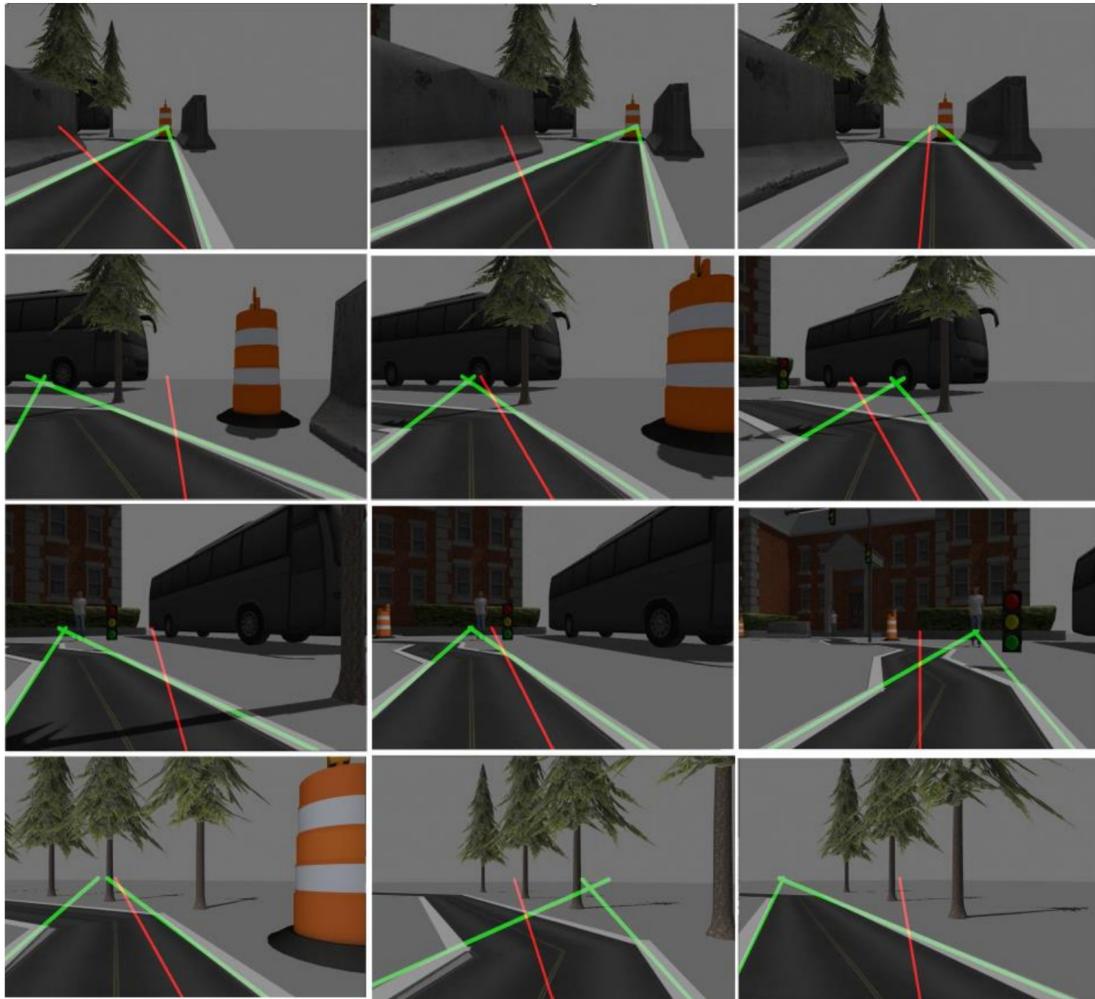

Fig. 9. Results of our Lane Detection System in the Virtual World.

## V. SIMULATION AND RESULTS

The virtual world is designed by using the software Gazebo/ROS. Fig. 8 shows the vehicle model, Gazebo environment, and the software used to apply the two proposed algorithms. We have performed two kinds of experiments to verify our lane detection algorithm and our steering control algorithm with the operating system Ubuntu 18.04.4, and CPU: Intel i7 3.4 GHz, GPU: Nvidia GTX 1650-4GB, RAM 16 GB. Our algorithm is implemented in Python language using the open source OpenCV and rospy library. The camera is simulated from the actual parameters of the WGE100 camera. The image size is 1024×600; the image was recorded at 30 frames per second. We tested that the lane detection algorithm is applied according to [17].

The lane detection results are like previous approaches. In the virtual world, the image data obtained with two-lane detection results are correct, as shown in Fig. 9. We also achieve good results for the estimated yaw angle when applying the steering angle estimation algorithm in Section 3.

We also verify the performance of the proposed steering angle controller by reading the odometry information of

vehicle autonomous over ROS including trajectory and yaw angle. Fig. 10 and Fig. 11 show the lane-keeping performance of the PID steering controller, and the fuzzy-PID steering controller under low-speed, and high-speed conditions. It is easy to see that the proposed method can minimize the desired angle error and reduce the damping effects better than another method. Table II shows the performance comparison of the PID controller and fuzzy-PID controller. The overshoot of the fuzzy-PID controller is less than 5%, however, with the conventional controller, it is 25% more than 5 times. Therefore, we concluded that the proposed assist system obtains higher accuracy of lane-keeping performance and better stability.

## VI. CONCLUSION

In this research, we develop a lane-keeping assist for an autonomous vehicle. The algorithm is based on a sequence of image processing, filtering, determination ROI, line segments detection, and steering angle estimation to detect lanes in the virtual world. All lanes are detected in still images at a high rate of 30Hz. Then, the steering controller with the fuzzy-PID algorithm is also proposed to reduce the steering angle error and minimize the damping effects. In the future, the algorithms

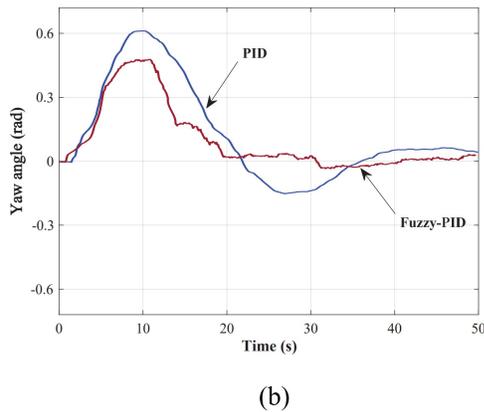

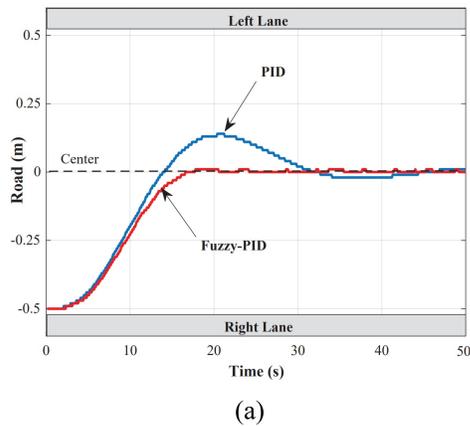

Fig. 10. Performance Comparison of the PID Steering Controller and Fuzzy-PID Steering Controller at Low Speed (2m/s). (a) The Vehicle's Trajectory on the Road, and (b) the Yaw Angle of the Vehicle.

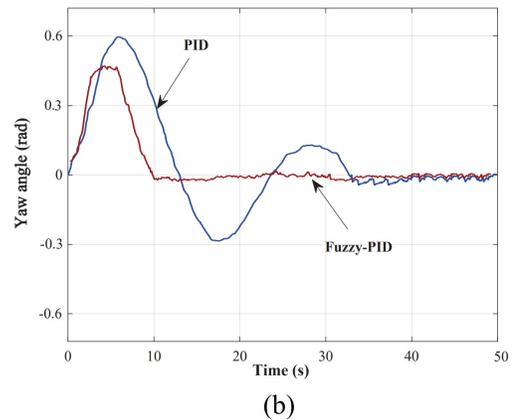

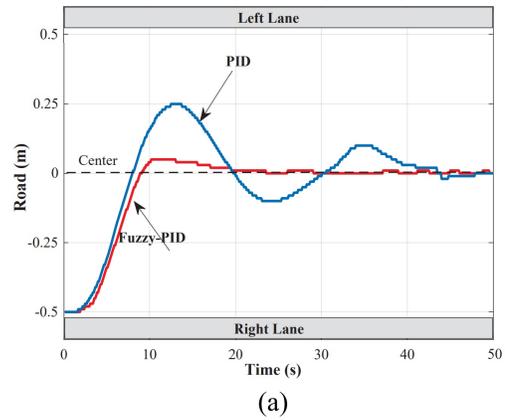

Fig. 11. Performance Comparison of the PID Steering Controller and Fuzzy-PID Steering Controller at High Speed (4m/s). (a) The Vehicle's Trajectory on the Road, and (b) the Yaw Angle of the Vehicle.

will be tested and evaluated on real systems. In addition, deep learning algorithms will also be studied and applied.

TABLE II. OVERSHOOT AND SETTLING TIME OF THE PERFORMANCE COMPARISON

	Overshoot (%)		Settling time (s)	
	Low speed	High speed	Low speed	High speed
PID	25%	51%	28s	43s
Fuzzy-PID	1%	5%	12s	15s

**Abstract**—In recent years, money laundering activities have shown rapid progress and have indeed become the main concern for governments and financial institutions all over the world. As per recent statistics, \$800 billion to \$2 trillion is the estimated value of money laundered annually, in which \$5 billion of the total is obtained from cryptocurrency money laundering. As per the financial action task force (FATF), the criminals may trade illegally obtained fiat money for the cryptocurrency. Accordingly, detecting and preventing illegal transactions becomes a serious threat to governments and it has been indeed challenging. To combat money laundering, especially in cryptocurrency, effective techniques for detecting suspicious transactions must be developed since the current preventive efforts are outdated. In fact, deep learning and machine learning techniques may provide novel methods to detect suspect currency movements. This study investigates the applicability of deep learning and machine learning techniques for anti-money laundering in cryptocurrency. The techniques employed in this study are Deep Neural Network (DNN), random forest (RF), K-Nearest Neighbors(KNN), and Naive Bayes (NB) with the bitcoin elliptic dataset. It was observed that the DNN and random forest classifier have achieved the highest accuracy rate with promising findings in decreasing the false positives as compared to the other classifiers. In particular, the random forest classifier outperforms DNN and achieves an F1-score of 0.99%.

**Keywords**—Anti-money laundering; machine learning; supervised learning; cryptocurrency

## I. INTRODUCTION

Money laundering is one of the most concerning threats to the stability and progress of the global economy [1]. Such activity is defined as the use of money acquired from illegal activities by hiding the identity of the person and making that money appear legal [2]. Money laundering can also be described as the method of cleaning suspicious money, which represents money collected from illicit or criminal activities, such as illegal gambling, tax evasion, and drug trafficking [3] [4]. Moreover, Integration, layering, and placement are the three primary phases of money laundering. In the placement phase, money is obtained through illicit activities and presented to the system. In the second phase, which is the layers, the source of the funds is hidden through distributing the funds by different intermediaries. In the final phase, the illicit money is transmitted to the criminal [5] [4] [6].

In recent years, money laundering has become more common in news headlines and other forms of media. It has been a fundamentally global problem with social ramifications and economic severe since the mid-1980s [7]. Thus, governments strive to reduce illegal transactions that impact capital [8].

Furthermore, governments around the globe have recommendations and issued regulations for anti-money laundering [3] and are expanding them involving cryptocurrencies [9].

Money laundering has obtained particular attention with the appearance of cryptocurrencies. Bieler illustrates assessed that money laundering earnings are between \$ 800 billion to \$2 trillion worldwide [10]. About \$5 billion of the total is obtained from cryptocurrency money laundering [11].

Because of the anonymity of cryptocurrencies, Campbell-Verduyn [12] discusses that combat money laundering efforts currently require to be improved, because it does not detect money laundering in cryptocurrencies such as Bitcoin, Ethereum, Ripple, and Litecoin. Traditional systems were used by financial institutions specifically on cryptocurrency exchanges, to detect illegal transactions. The results of these traditional systems indicated high low detection rates and high false-positive rates. This means that traditional systems are ineffective at detecting errors and are prone to bias [13]. Traditional systems in financial institutions must be improved and developed in order to detect suspicious transactions [14]. Accordingly, machine learning approaches began being utilized to detect suspicious transactions in 2004 [15]. Thus, studies in recent years have illustrated that the results of using deep learning and machine learning techniques in combating money laundering are indeed promising [16]. Based on machine learning techniques, an anti-money laundering monitoring system is employed at a financial institution in [17] and evaluated using real-life data and feedback from specialized experts. In view of the same, we aim to apply the KNN, NB, RF, and DNN algorithms to the Elliptic Bitcoin dataset to recede the effect of financial crimes on governments and the financial sector. The evaluation models' performance depends on recall, F1-score, and precision, RUC to detect money laundering activities and fraud in cryptocurrency. In addition, it compares the findings with related studies in the same field.

This study is organized as follows. The second section II provides information around the reviews of relevant literature for the study, the reviewed literature covers three major concepts. The third section III presents the research methodology and the deep learning and machine learning techniques used to achieve the results. The fourth section IV presents the details of the data and the preprocessing of the data. The fifth section V presents the final results obtained from the models and compares the previous studies with our results. The final section VI, concludes with a summary of the evaluation of the results obtained and describes the study's limitations and future work.

## II. LITERATURE REVIEW

In this section, existing literature related to using of machine learning and deep learning techniques for anti-fraud and money laundering activities in cryptocurrency is reviewed. In fact, cryptocurrencies pose a serious threat to anti-money laundering efforts. In addition, lawbreakers attempt to exploit cryptocurrencies to provide illegal services. As a result, governments such as FATF have developed advanced techniques for anti-money laundering [18]. In view of the same, various techniques and strategies have been widely studied in literature to investigate multiple activities in cryptocurrency data. Essentially, machine learning (ML) and deep learning (DL) are eminent techniques that are capable of investigating vast amounts of data to discover the patterns of illegal financial behavior that have gone undetected [19].

Canhoto [18] and Weber et al. [20], [21] stated that deep learning and machine learning beats the traditional methods of anti-money laundering. Particularly, Weber et al. [21] highlighted the significance of ML regulations and provided the Elliptic dataset for detecting illegal Bitcoin transactions. Different machine learning techniques were used to evaluate the Elliptic dataset, including logistic regression (LR), multilayer perceptrons (MLP), random forest (RF), and graph convolutional networks (GCNs). It was observed that RF technique achieved the high results with a precision, recall-store and F1-score of 0.95, 0.67, and 0.788, respectively. To classify and detect suspicious currency on the Bitcoin network, Lee et al. [22] implemented the artificial neural network (ANN) and RF algorithms. The illegal and legal Bitcoin data were collected from various websites such as Blockchain Explorer and Silk Road. The F1-scores showed that the RF algorithm achieved a high rate of 0.98, while the ANN algorithm achieved a lower rate of 0.89. In the same regard, a novel method for predicting illegal currencies in the Bitcoin currency is proposed by Alarab et al. [23] using a graph convolutional neural network (GCN). The MLP and GCN were combined to enhance the model's performance for which a 0.974 of accuracy was achieved under the proposed method. However, The same author [24] used RF, Extra Trees, Gradient Boosting, XGBoost, LR, and MLP, where RF outperformed with a rate of 0.82. Along similar lines, Ostapowicz and Zbikowski [25] implemented different algorithms on the Ethereum network to identify fraudulent accounts based on supervised learning approach. The accounts were classified and analyzed as "not fraudulen" or "fraudulent" using SVM, XGBoost, and RF. It was observed that the RF algorithm achieved the best results with a detection precision of 85.71. In another study, eight different supervised machine learning techniques were presented and analyzed by Bhowmik et al. [26] to investigate illegal transactions on the blockchain network. These include Naive Bayes (NB), LR, MLP, SVM, RF, Ada Boost, etc. The results of the comparison study found that among the five algorithms, SVM, RF, and NB algorithms obtained the best results with an accuracy of 97%. In view of the same, Monamo et al. [27] also employed an unsupervised learning method based on trimmed k-means and a k-means in order to track down illegal behavior and detect fraudulent activity on the Bitcoin transactions. To classify these transactions, Monamo et al. [28] applied clustering algorithms and machine learning techniques in which several assumptions were imposed to categorize transactions into illegal and legal categories. In addition, different Bitcoin fraud activities were

illustrated from both global and local perspectives by using kd-trees and trimmed k-means. To further investigate these two methods, three classification algorithms were used including the maximum likelihood-based, random forests, and boosted binary regression. Based on the obtained results, it was found that the random forest outperformed the other two classification models. Related to the detection and classification of suspected Bitcoin network addresses, several studies have been reported in literature based on different approaches and techniques [13], [29]–[31]. In fact, the unsupervised models for detecting money laundering activities were found to be inadequate for the Bitcoin network as per Lorenz et al. [13]. Therefore, they have developed supervised learning models to identify illegal money laundering activities in the network. In their study, a rule-based technique was employed that showed low detection rates and high false-positive rates. By Lin et al. [29], suspected Bitcoin network addresses transactions were detected and classified by adding the distribution data of transactions, detailed transaction summaries, and time series as new statistics. The model performance was improved and the variance in data was increased. In this study, various machine learning techniques, including LR, SVM, AdaBoost, XGBoost, and LightGBM were implemented. However, LightGBM achieves the best results as compared to the other techniques. A novel method based on a cascade of classifiers and entity characterization to assail bitcoin anonymity was proposed by Zola et al. [30]. In this study, three different algorithms, including the gradient boosting, random forest, and Adaboost, were used to identify illicit transactions on the Bitcoin blockchain network. The inter-entity transactions (organizations or people with multiple accounts) were also investigated, and the classification performance was improved by utilizing 34 features. Bartoletti et al. [31] used data mining and machine learning-based approaches to detect Ponzi schemes related to the Bitcoin addresses. In their study, three machine learning algorithms were provided for evaluation including the Bayes network, random forest, and RIPPER. As a result, the random forest has been proven to detect 96% of addresses. However, it is worth mentioning that the proposed approach was tested against Ponzi schemes.

Kumar et al. [32] classified a 10000-transaction dataset to identify money laundering activities using Naive Bayes algorithms. The obtained results showed that the proposed model achieved 81% accuracies. In another study, the light gradient boosting machine (LGBM) is proposed by Aziz et al. [33] to detect fraudulent transactions. The MLP, RF, and KNN were compared with the LGBM approach for the identification and classification of fraudulent Ethereum datasets. Relative to the other techniques, the LGBM algorithm has achieved the highest accuracy of 99.03.

Based on the above discussion related to existing literature, it is evident that machine learning algorithms play a vital role in the detection of suspicious transactions in money laundering activities. However, it is worth mentioning that there are still several problems and challenges associated with the detection process that require further improvements. In addition, it seems that there exist very few studies on using deep learning approaches to detect money laundering activities. In view of the same, this paper mainly aims at using deep learning methods with machine learning to detect such suspicious activities in Cryptocurrency.

### III. METHODOLOGY

The money laundering transaction detection model includes five main stages i.e. data understanding, data preprocessing, data splitting, model training, model testing, and model evaluation. Fig. 1 illustrates the methodological framework of the study. Several ML and DL algorithms are employed in this chapter for transaction classification e.g. NB, RF Classifier, KNN Classifier, and DNN.

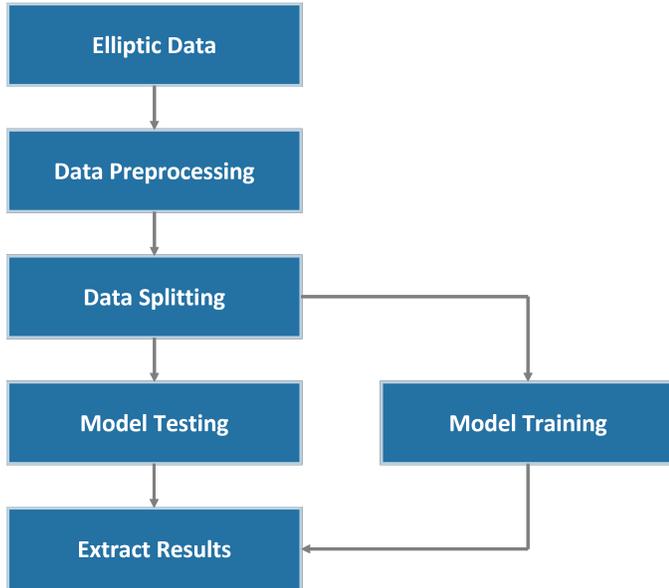

Fig. 1. Methodology.

#### A. KNN

This approach is considered as a simple instance-based learning algorithm in which the new case/instance is compared with all existing instances and then classified based on a similarity measure. Accordingly, a class is assigned for the new instance based on the nearest available instance. The idea of the instance-based KNN method was first presented by [34]. The measure used is the Minkowski distance.

- Minkowski distance represents the distance between a couple of points in a normalized vector space, and it is defined as following:

$$d(x, y) = \left( \sum_{i=0}^{n-1} |x_i - y_i|^p \right)^{\frac{1}{p}} \quad (1)$$

#### B. RF

Single trees are highly sensitive to training data and might become unstable in certain cases. To overcome this issue, the ensemble strategy is introduced to determine the class label for each data point by enhancing a collection of aggregating and modeling their predictions. On the other hand, decision trees become very popular in data mining due to their simplicity, flexibility, and interpretability especially in handling various data feature types. A RF is represented by a group of regression or classification trees [35]. These groups perform efficiently in case of individual members are not identical.

#### C. NB

Gaussian Naive Bayes, which uses the Bayes' theorem, is common to the Naive Bayes (NB) algorithms. The Bayesian theorem represents the possibility that an event will happen if you have prior information about a condition associated with the specified event. The method is intended to deal with continuous attributes that are associated with each category and are distributed using a Gaussian distribution. The main advantage of the Naive Bayes is to effectively train in supervised learning, and are used for practical classification problems. A main disadvantage of the Naive Bayes is that the attributes are presumed to be independent, which is nearly impossible to achieve. With Naive Bayes it is considered that all features are independent given the value of a class, this is indicated as conditional independence. There are two categories in this study, illegal transactions = 0 and legal transactions = 1. The Equation 2 shows the likelihood that sample x belongs to a category c

$$P(c|x) = \frac{p(x|c) * p(c)}{P(x)} \quad (2)$$

#### D. DNN

DL is a form of ML technique that does not require the construction of feature representation to learn the hierarchical data representation. Instead, it merely uses the training data to automatically learn such representation [36]. This method is based on DNN, which is made up of essential elements including perceptrons, convolutions, and nonlinear activation functions. These elements are structured as layers and trained to understand different complex concepts based on the available raw data. These layers might construct from only a few to over a thousand layers [37]. Lower network layers are typically associated with the low-level features (for example, edges and corners). On the other hand, the higher layers are associated with high-level important features [38].

#### E. Evaluation Metrics

We use evaluation metrics to evaluate the performance of the model in DL and ML. The evaluation metrics employed for implementing the algorithms are F1-Score, Recall, Precision, and ROC curve. These metrics are commonly applied when dealing with imbalanced datasets, as in the data set used in this study.

**Precision** refers to the measurement of correct positive predictions in the positive class. The mathematical equation 3 illustrates the concept of precision as follows:

$$Precision = \frac{TruePositive}{TruePositive + FalsePositive} \quad (3)$$

**Recall** indicates the number of actual positive data the model was able to correctly predict. The mathematical equation 4 illustrates the concept of recall as follows:

$$Recall = \frac{TruePositive}{TruePositive + FalseNegative} \quad (4)$$

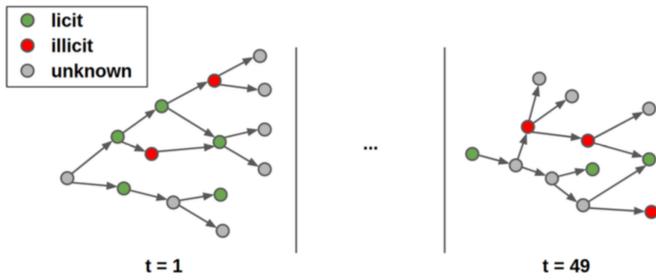

Fig. 2. Structure of the Dataset [39].

**F1-score** is calculated by the precision and recall value. The mathematical equation 5 illustrates the concept of F1-score as follows:

$$F1 - score = 2 * \frac{Precision * Recall}{Precision + Recall} \quad (5)$$

**ROC Curve** is a graph that measures the performance of a binary classifier across all classification thresholds. The mathematical equations 6 and 7 illustrates the concept of the ROC curve as follows:

$$FPR = \frac{FP}{FP + TN} \quad (6)$$

$$TPR = \frac{TP}{TP + FN} \quad (7)$$

- where FPR stands for False Positive Rate
- where TRP stands for True Positive Rate

#### IV. EXPERIMENTS

In this section, a brief overview of the data set used for this study and preprocessing of the data.

##### A. Dataset

In this study, the Ellipse dataset<sup>1</sup> created by Weber et al. [21] is employed to detect the cryptocurrency activities. Elliptic is a cryptocurrency monitoring company aimed to protect cryptocurrencies from illegal activity, and it has the largest publicly available dataset for transactions in cryptocurrencies. The dataset contains 49 graphs of BTC transactions obtained at different periods of time. Each graph illustrates a directed acyclic graph (DAG), which means that each edge describes a single directional flow, and there are no loops in the graph. The graph begins from a single transaction and expands to include all the following related transactions, containing two weeks of transaction data created during such period as shown in Fig. 2. As shown in Fig. 2, the BTC transactions are represented in the graph network by nodes (with 203,769 nodes). On the other hand, the flow of BTC are represented by edges (with 234,355 edges). The nodes are classified into illegal, legal, and

<sup>1</sup>Available At: <https://www.kaggle.com/datasets/ellipticco/elliptic-data-set>

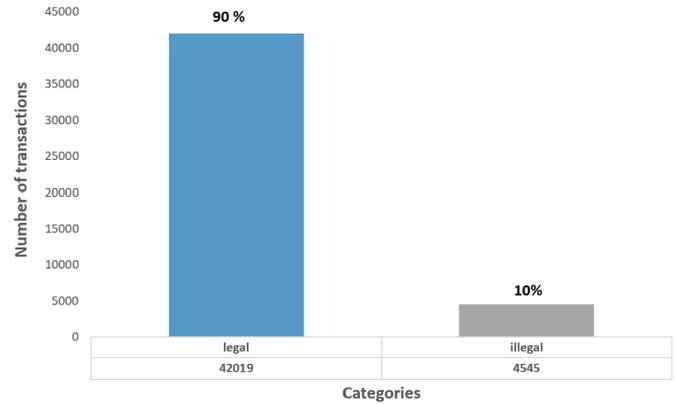

Fig. 3. Distribution of the Transactions.

unknown categories. The unknown labels are not considered in this study due to the following reasons:

- The techniques used in this study are based on supervised learning, which requires the ground truth for each data point. Accordingly, supervised learning cannot be used when transactions have unknown labels.
- The number of unknown labels (with 157205 transactions) requires highly efficient hardware resources to train and test models. Unfortunately, such resources are currently not available for the author.

Fig. 3 illustrates the distribution of the elliptic dataset after removing the unknown transactions.

It can be observed that about 10% of the transactions (4,545 samples) are classified as illegal, while 90% (42,019 samples) are classified as legal transactions. Essentially, the legitimate category contains legitimate services, exchanges, and wallet providers, while the illegal category contains scams, Ponzi schemes, terrorist organizations, ransomware, etc. In fact, there exist 166 features associated with each transaction to specify whether they are legal or illegal. Due to the intellectual property rights, the elliptic company has not revealed the nature of the features.

##### B. Preprocessing of Data

As the model performance can be affected by irrelevant features, it is indeed necessary to detect and select the important features. Particularly, there are 166 features associated with each transaction in the elliptic dataset. Due to intellectual property rights, the elliptic company has not disclosed the details and nature of the features. The class distribution of the dataset is provided in Table I.

TABLE I. CLASS DISTRIBUTION OF ELLIPTIC DATASET

Label	Number of Samples
Unknown	157,205
legal transactions	42,019
illegal transaction	4,545

It can be observed from Table I that the dataset is unbalanced and contains 157,205 samples with unknown labels.

To handle this issue, these unknown samples are eliminated in the first step of data preprocessing. Accordingly, only the samples with legal label (42,019 samples) and illegal label (4,545 samples) are kept for further steps. Fig. 3 illustrates the distribution of categories after removing the unknown samples. In fact, the dataset contains 166 features which is indeed a large number of features and may consequently lead to overfitting and computational problems. Essentially, the classification techniques require the most relevant features only, which have a high correlation to the class label. In view of the same, a correlation matrix is employed in this study to show the relationship between the features. Accordingly, all features with a correlation greater than 0.90 are eliminated except for the class label. It is worth mentioning that such samples have almost the same effect on the dependent features, and the performance of the model will be significantly affected if no one of them is removed. Based on that, 77 features out of 166 are dropped. However, the number of the remaining features is still large, which is 89 features. Therefore, a preprocessing step has been further implemented to select the most important features based on feature selection techniques through the scikit-learn package. Consequently, the best 53 features have been selected. After choosing the suitable features, we utilize the StandardScaler from scikit-learn for normalizing all features with a standard deviation of 1 and an average value of 0; the purpose is to eliminate bias in classification results.

### C. Training and Testing

In this subsection, the model training and testing for transaction classification are discussed. Consequently, the transactions in Elliptic dataset will be classified into legal and illegal transactions. Particularly, the techniques employed in this study are based on supervised learning, which cannot be used when transactions have unknown labels. Therefore, such labels are omitted and not included in the training and testing phases as previously discussed. Essentially, the training set is utilized for model training and hyperparameter tuning. On the other hand, the testing set is utilized to evaluate the performance of the trained model. In the Elliptic dataset, there exist 46,564 transactions which includes both legal and illegal transactions. The dataset was divided into two parts (70% for training and 30% for training). This is equivalent for 32,594 transactions for training and 13,969 transactions for testing including both legal and illegal transactions. The main purpose here is to check and evaluate how the trained model will perform under new transaction data. In fact, a random seed of 42 was determined for splitting the data, which ensures that the data split does not change each time the program is implemented. The data split task was implemented in python through test-train-split from the sklearn library. It is worth noting that two crucial problem associated with machine learning (ML) methods are consequently eliminated under the utilized approach. The first problem is the under-fitting, which is the inability of a ML model to remember the correlations. The second one is the over-fitting, which occurs when a ML algorithm memorizes the patterns.

### D. Choice of Algorithms and Hyperparameters

In existing literature, several ML algorithms are used and employed for transaction classification of the elliptic dataset

[13], [21], [23], [24], in which the RF algorithm was found to achieve promising results. In [32], [33], NB and KNN algorithms were also used to classify the suspicious transactions and achieved satisfactory results although they were implemented on different data. Based on that, NB, RF, and KNN algorithms are selected in this study in order to achieve high results. On the other hand, DNN techniques are also tested and used in the experiments of this work. It is worth mentioning that DNN techniques have not yet explored and applied on the Elliptic dataset in existing literature. Table II summarizes the hyperparameters utilized in the selected algorithms.

TABLE II. SELECTED ALGORITHM AND HYPERPARAMETERS

Algorithm	Hyperparameters	Description
RF	N-estimatorsint(default=100)	Number of trees
	Max-depth (default=None)	Maximum depth of the tree
	Min_samples_split(default=2)	Minimum of samples
KNN	N-neighbors = 3	Number of neighbors
	weights(default=uniform)	Uniform weights
NB	Algorithm (default=auto)	Calculate the nearest neighbors
	Var-smoothing (default=1e-9)	Portion of the largest variance
DNN	Epoch=10	Total number of iterations
	Optimizer=adam	Adam is an optimization algorithm
	Layer=2	Architecture of the model

In fact, different values are selected during the experiments for hyperparameters of the four models. However, the obtained results were generally unsatisfactory. The results are further improved by choosing the values presented in Table II.

### E. Experimental Setup

In this work, the experiments are performed on Core(TM) i7-1065G7 CPU @ 1.30GHz 1.50 GHz based processor, windows 11 with 16.0 GB of RAM. Anaconda environment have been downloaded. In addition, Python 3.7.1 is used as it has a large number of models and libraries available for classification. Some examples of the libraries used in this work include pandas, numpy, seaborn, and matplotlib. The implemented metrics and techniques are obtained by scikit-learn. Tensorflow 2.3.1 and Keras version 2.4.3 are also utilized.

## V. RESULTS AND DISCUSSION

The study explores how DL and ML can be used for anti-money laundering using cryptocurrency. This is achieved by using different most common algorithms, including DNN, RF, KNN, and NB, to classify the bitcoin elliptic dataset. discusses the findings obtained in terms of F1 score, recall, precision, and ROC curve and compares our results with previous studies.

### A. Results

The machine learning technique has outperformed DNN in classifying legal and illegal transactions. The RF has shown its ability to classify well with an F1 score, precision, ROC curve, and recall of 0.99, the reason for the RF achieving a proper value is the ability to handle an unbalanced dataset. The DNN came in second, which performed an F1 score of 0.98, followed by the KNN with an F1 score of 0.97. When it comes to the NB model, the value is low compared to the RF, KNN, and DNN, it achieved 0.90 in ROC curve and 0.99 in precision. However, the F1-score and recall are only 0.74

and 0.59, respectively. Table III illustrates F1 scores, precision, recall, and ROC curve for each model, using a bold font to highlight the highest value. The RF model has the highest overall value, with an F1 score, precision, recall, and ROC curve. The NB model had the lowest value.

TABLE III. COMPARISON OF THE RESULTS OF THE FOUR MODELS

Models	Measures			
	ROC curve	F1-score	Precision	Recall
NB	0.90	0.74	<b>0.99</b>	0.59
RF	<b>0.99</b>	<b>0.99</b>	<b>0.99</b>	<b>0.99</b>
KNN	0.92	0.97	0.97	0.98
DNN	0.97	0.98	0.98	0.98

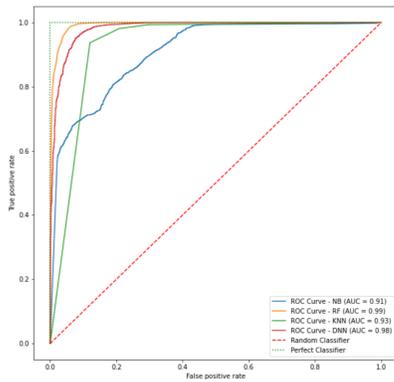

Fig. 4. Comparison of the Results of the Four Models with AUROC Curve

Based on Fig. 4 for the AUROC value for NB, KNN, RF, and DNN, it is shown that the AUC of RF is better than the other three classifiers as it scored in training (1.00) and testing 0.99 while the other models achieved less than 1.00 in training and testing models, but AUROC value in NB model is 0.91, these are the lowest values out of the three models.

B. Discussion and Comparison with Related Works

In comparison to previous studies’ results, some studies used DL and ML for the purpose of detecting money laundering in cryptocurrency. Table IV compares the findings of the four previous studies with F1-scores, in [13] which achieved a high value with an f1-score of 0.83 in the RF model, while [23] achieved a value of 0.77% and in [21] achieved a value of 0.78%. Our model outperforms studies by achieving the highest total F1 score of 0.99, as shown in Table IV.

TABLE IV. COMPARISON WITH RELATED WORKS

Ref.	Method	Dataset	Evaluation
Weber et al. [21]	RF - LR - GCNs - MLP	Elliptic dataset	(RF) F1 score =0.78%
Alarab et al. [23]	GCN		(GCN) F1 score =0.77%
Alarab et al. [24]	RF - ExtraTrees - GB - XGBoost - LR -MLP		(RF) F1 score = 0.82%
Lorenz et al. [13]	RF - XGBoost - LR		(RF) F1 score = 0.83%
<b>Current study</b>	<b>NB-RF -KNN-DNN</b>		(RF) <b>F1 score = 0.99%</b>

VI. CONCLUSION

Money laundering represents a serious threat to governments all over the world and it has been indeed challenging. Various ML and DL techniques have been employed in literature to detect illegal transactions. However, there is still a serious need to further explore and develop suitable algorithms for detecting money-laundering activities, which was the main purpose of the study. Essentially, this research aims to determine the appropriate DL and ML algorithms for detecting money laundering using Elliptic BTC Dataset. To achieve this objective, the results of four algorithms are extensively analyzed and compared. These algorithms include three ML algorithms (RF, KNN, NB), and one DL (DNN). In addition, four key evaluation metrics were used to quantify the performance. These metrics include the precision, recall, F1-score, and ROC curve. the ML technique (RF) proved to be better at classifying fraudulent activities than DL. It was observed from the obtained results that the RF algorithm achieved the best results as compared to other algorithms. It results in 0.99 of the average F1 score. In fact, this technique outperformed the classification due to its ability in handling an unbalanced data set. On the other hand, DNN technique achieved an average F1-score of 0.98 and was placed in the second position followed by the KNN algorithm with an average of 0.97. However, the F1-score for the NB model was found to be 0.74, which is the lowest value as compared to the other three models.

VII. LIMITATIONS AND FUTURE WORK

In fact, the classification model in this study was trained on approximately 46546 bitcoin transactions. However, the dataset contains unlabeled data. To handle this situation, it is more appropriate to use a semi-supervised learning model. However, the unlabeled data will require more CPU power, and therefore, cloud computing services such as Amazon Web Services (AWS) could be used. As the considered model indicates an adequate performance of the algorithms, it would be interesting to conduct the experiment once again with a different data set to prove the validity of the obtained results.

**Abstract**—The Minimum Variance Distortionless Response (MVDR) beamforming algorithm is frequently utilized to extract speech and noise from noisy signals captured from multiple microphones. A frequency-time mask should be employed to compute the Power Spectral Density (PSD) matrices of the noise and the speech signal of interest to obtain the optimal weights for the beamformer. Deep Neural Networks (DNNs) are widely used for estimating time-frequency masks. This paper adopts a novel method using Graph Convolutional Networks (GCNs) to learn spatial correlations among the different channels. GCNs are integrated into the embedding space of a U-Net architecture to estimate a Complex Ideal Ratio Mask (cIRM). We use the cIRM in an MVDR beamformer to further improve the enhancement system. We simulate room acoustics data to experiment extensively with our approach using different types of the microphone array. Results indicate the superiority of our approach when compared to current state-of-the-art methods. The metrics obtained by the proposed method are significantly improved, except the Scale-Invariant Source-to-Distortion Ratio (SI-SDR) score. The Perceptual Evaluation of Speech Quality (PESQ) score shows a noticeable improvement over the baseline models (i.e., 2.207 vs. 2.104 and 2.076). Our implementation of the proposed method can be found in the following link: <https://github.com/3i-hust-asr/gnn-mvdr-final>.

**Keywords**—Multi-channel speech enhancement; graph convolutional networks; minimum variance distortionless response beamformer; complex ideal ratio mask

## I. INTRODUCTION

Speech enhancement is a subject studied and applied in many applications, e.g., automatic speech recognition, teleconference, or aided hearing [1-4]. There are two algorithm categories of speech enhancement: single-channel algorithms (using a single microphone) [5-8] and multi-channel algorithms (using multi microphones) [9], [10]. The performance of multi-channel algorithms is generally better than that of single-channel algorithms because they use not only statistical information related to signals but also more spatial information [11].

Speech enhancement using microphone array beamforming is a type of multi-channel approach. The basis of these techniques is to enhance signals from desired directions (signals of interest) and attenuate signals from uninterested directions (noise signals). One of the beamforming algorithms used in speech enhancement is the MVDR beamforming [12-14]. There are two conventional approaches to determine MVDR filter weights for noise reduction and/or dereverberation.

The first approach is to estimate the characteristic vector of Acoustic Transfer Functions (ATF) from the speech source to the microphone array based on a priori assumptions such as the position of the desired signal source, the microphone array's configuration, and room acoustics. In a real environment, the performance of this approach is reduced since the effect of multi-paths [15], [16].

The second approach does not involve any such a priori assumptions. Instead of using an ATF vector, a Relative Transfer Function (RTF) vector is estimated based on data collected from the microphone array. The (RTF) vector is defined as the (ATF) vector normalized to a reference microphone of the microphone array. The (RTF) vector estimate is calculated from (PSD) matrices of noise and desired signal. A time-frequency mask is used to estimate the matrices. There are some techniques to create the mask [17], [18].

Recently DNNs have been widely used for speech-related task for better robustness and performance [10], [19-23]. GCNs are considered a generalization of Convolutional Neural Networks (CNNs) [24]. In [23], the GCNs are used to learn spatial features and incorporate them with a U-net to estimate a cIRM. The cIRM is used directly to estimate clean speech based on spectral information obtained from multi-channel. Some experiments in [23] show that speech enhancement using GCNs and U-Net has results that outperform the prior state-of-the-art approach.

This paper adopted the idea of using GCNs and U-Net architecture of [23] for a speech enhancement system with two contributions. Firstly, instead of using the number of nodes of GCNs in [23] as the number of microphones, we increase the node number of GCNs. It helps GCNs learn spatial features more precisely. Therefore a cIRM can be better estimated by incorporating GCNs in the U-Net architecture. Secondly, we use an MVDR beamformer based on the obtained cIRM to estimate the clean speech rather than the attention layer as in [23].

These works are implemented and tested on the dataset provided from ConferencingSpeech2021 Challenge [25]. The results demonstrate that the combination between MVDR beamforming and GCNs improves the performance of the speech enhancement system. The metrics obtained by the proposed method are significantly improved, except for the SI-SDR score. The PESQ score shows a noticeable improvement over the baseline models (i.e., 2.207 vs. 2.104 and 2.076).

The rest of the paper is organized as follows. In Section II, a brief basis of speech enhancement, MVDR beamformer, GCNs, as well as evaluation metrics is described. In Section III, we review some related works. In Section IV, the proposed speech enhancement approach is detailed. In Section V, we explain some experimental setups and analyze the results of the proposed approach. Finally, the conclusions are presented in Section VI.

## II. PRELIMINARY

### A. Speech Enhancement

The noisy speech signal can be represented in the Short-Time Fourier Transform (STFT) domain:

$$X(t, f) = S(t, f) + N(t, f) \quad (1)$$

where  $X(t, f)$  represents the complex-valued time-frequency  $(t, f)$  bin of noisy speech,  $S(t, f)$  denotes the reverberated signal received at the microphone and  $N(t, f)$  indicates the interference noise at time frame  $t$  and frequency bin  $f$  with  $t = 0, \dots, T-1$  and  $f = 0, \dots, F-1$ .  $T$  and  $F$  are the number of frames and frequency bins, respectively. The neural beamformer here focuses on the task of suppressing noise. The objective is to remove the interference noise  $N(t, f)$  and retrieve the speech signal  $S(t, f)$ .

Deep learning-based speech enhancement approaches are usually designed in a supervised manner. Based on how to obtain the target, the applied techniques can be classified into *mapping-based* or *masking-based* methods. In *mapping-based* approaches, the goal is to approximate a non-linear function from the noisy speech into the desired speech through a learning process. Meanwhile, the most popular methods recently used are *masking-based*, where the target is masks computed between desired and noisy speech.

The masking-based approaches try to approximate a non-linear function from an observed noisy speech spectrum  $X(t, f)$  to a Time-Frequency ( $T - F$ ) mask  $M(t, f)$  through the learning/training process. The commonly used masks in recent researches include: binary-based mask [17] and ratio-based mask [18].

The binary-based mask usually indicates the Ideal Binary Mask (IBM). Each entry of the  $T - F$  mask is set to 1 when the local Signal-to-Noise Ratio (SNR) is greater than a pre-defined threshold value  $R$  (indicates that speech is dominated over noise), or 0 if otherwise (indicates that noise is dominated over speech). In particular,

$$M_{\text{IBM}}(t, f) = \begin{cases} 1, & \text{if } \text{SNR}(t, f) > R. \\ 0, & \text{otherwise.} \end{cases} \quad (2)$$

here  $\text{SNR}(t, f)$  indicates the SNR at the frame index  $t$  and the frequency bin  $f$  within the  $T - F$  mask.

Typical ratio-based mask commonly refers to Ideal Ratio Mask (IRM), where each entry of the  $T - F$  mask is set by the soft ratio of the reverberated speech over the observed noisy signal, that is:

$$M_{\text{IRM}}(t, f) = \frac{|S(t, f)|^\alpha}{|S(t, f)|^\alpha + |N(t, f)|^\alpha} \quad (3)$$

here  $|S(t, f)|$  indicates the magnitudes of reverberated speech,  $|N(t, f)|$  denotes the noise in the  $T - F$  domain, and  $\alpha$  is a factor over the magnitudes, which is to scale the value of each entry of the mask or change the dynamic ranges of the features. From Eq. 2 and 3, we could deduce that IRM-based methods could provide an enhanced signal with less distortion, while it may possibly lead to much computation [26].

Williamson et al. [27] further improved this approach, called cIRM. The complex ratio mask (CRM), demonstrated to be more effective than the ideal ratio mask (IRM) [28-30]. Given the complex spectrum of noisy speech,  $X(t, f)$ , we get the spectrum of reverberated speech,  $S(t, f)$ , that is:

$$S(t, f) = X(t, f) \odot M_{\text{cIRM}}(t, f) \quad (4)$$

where  $\odot$  is the element-wise multiplication. Note that,  $X(t, f)$ ,  $S(t, f)$  and  $M_{\text{cIRM}}(t, f)$  are complex-valued matrices.

Given the observed input noisy signals  $X(t, f)$  from the  $T - F$  domain and the target mask  $M(t, f)$ , the deep neural networks are optimized by the Mask Approximation (MA) objective function, which minimizes the Mean Squared Error (MSE) loss between the estimated and the target mask. On the other hand, recently, more approaches have been starting to employ Signal Approximation (SA) objective functions [31-33]. This objective aims to minimize the MSE loss between the estimated and the target reverberated speech spectrum. Besides, another approach minimizes MSE between the estimated reverberated signal and the target one in the time-domain by additionally applying inverse STFT. Furthermore, the conclusions in [31], [34] show that mixing the objectives (i.e., MA and SA) could lead to further improvement in both the magnitude and the spectral domains.

### B. MVDR Beamformer

The separated speech can be obtained as

$$\hat{S}_{\text{MVDR}}(t, f) = \mathbf{h}^{\text{H}}(f)X(t, f) \quad (5)$$

here  $\mathbf{h}(f) \in \mathbb{C}^M$  denotes the weights of MVDR beamformer at frequency index  $f$ ,  $M$  denotes the number of channels and  $(\cdot)^{\text{H}}$  indicates Hermitian operation. The main target of the MVDR beamformer is to suppress the interference noise while keeping the desired signal undistorted as much as possible, that is:

$$\begin{aligned} \mathbf{h}(f) &= \underset{\mathbf{h}}{\text{argmin}} \mathbf{h}^{\text{H}}(f)\Phi_N(f)\mathbf{h}(f) \\ \text{s.t. } &\mathbf{h}^{\text{H}}(f)\mathbf{v}(f) = 1 \end{aligned} \quad (6)$$

Here  $\Phi_N(f)$  is the PSD matrix of the noise, and  $\mathbf{v}(f) \in \mathbb{C}^M$  represents the steering vector to the target source.

Different approaches could be adopted to find the optimal weights of the MVDR beamformer. To reduce the computation in the beamforming block, we employ the MVDR solution of Souden et al. [12]:

$$\mathbf{h} = \frac{(\Phi_N(f))^{-1}\Phi_S(f)}{\text{trace}((\Phi_N(f))^{-1}\Phi_S(f))} \mathbf{u} \quad (7)$$

where  $\Phi_S(f) \in \mathbb{C}^{M \times M}$  is the PSD matrix of speech,  $\Phi_N(f) \in \mathbb{C}^{M \times M}$  indicates the PSD matrix for noise.  $\mathbf{u} \in \mathbb{R}^M$  is a one-hot vector representing a reference microphone.

Two masks,  $M_S(t, f)$  and  $M_N(t, f)$ , will be used to estimate the desired PSD matrices:

$$\Phi_S(f) = \sum_{t=1}^T (X(t, f) \odot M_S(t, f))(X(t, f) \odot M_S(t, f))^H \quad (8)$$

$$\Phi_N(f) = \sum_{t=1}^T (X(t, f) \odot M_N(t, f))(X(t, f) \odot M_N(t, f))^H \quad (9)$$

where  $\odot$  is the element-wise multiplication.

### C. Evaluation Metrics

The standard metric to measure the performance of Automatic Speech Recognition (ASR) systems is Word Error Rate (WER). However, other objective metrics are also employed to evaluate the performance of the front-end techniques, such as denoising. The typical metrics include Short-Time Objective Intelligibility (STOI) [35], Extended Short-Time Objective Intelligibility (ESTOI) [36], SI-SDR [37], and PESQ [38]. It is worth looking at [39] for more detailed definitions and explanations of the objective metrics.

### D. Graph Neural Networks

1) *Definition:* Graph Neural Network (GNN) [24] is a new type of deep neural network designed to work with graph data. Graphs provide a much more flexible way to process and aggregate information. GNN allows for generalizing DNN operations to graph-structured processing [40], [41]. By aggregating information from neighboring nodes, GNN models encode structural-relational information into the representation, which then is applied in a wide range of tasks, including biochemical structure discovery [42], [43], computer vision [44], and recommendation systems [45].

A specific variance of GNN is the convolutional GNN (so-called GCN) which is similar to CNN [46] with the basis of shared weights through training. There are two approaches for building GCN, Spectral GCN and Spatial GCN [47-49]. Spectral GCN, infrequently used nowadays, is based on the Eigen-decomposition of graph Laplacian. Spatial GCN defines convolution operations that work directly on a graph through the nodes and edges and aggregate spatial information between neighboring nodes and edges. Therefore, Spatial GCN is less computational and complex and can generalize better than spectral GCN. Recently, new convolutional GNN structures [47] have drastically leveraged the performance of GNN by employing various techniques, including normalization [46], attention [50], and activation [51].

2) *Graph Convolutional Network:* Given a graph  $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ , where  $\mathcal{V}$  represents the set of nodes  $v_i$  of the graph and  $\mathcal{E}$  represents the edges of the graph between two nodes  $(v_i, v_j)$ . The GCN applies non-linear transformation on the input  $\mathcal{X} \in \mathbb{R}^{|\mathcal{V}| \times N}$ , where  $|\mathcal{V}|$  is the number of nodes and  $N$  is node feature size. In particular, GCN can be mathematically represented as follows:

$$\mathcal{H}^{(l)} = g(\mathcal{D}^{-1/2} \mathcal{A} \mathcal{D}^{-1/2} \mathcal{H}^{(l-1)} \mathcal{W}^{(l-1)}) \quad (10)$$

where  $\mathcal{D} \in \mathbb{R}^{|\mathcal{V}| \times |\mathcal{V}|}$  is the diagonal matrix,  $\mathcal{A} \in \mathbb{R}^{|\mathcal{V}| \times |\mathcal{V}|}$  is the adjacency matrix,  $\mathcal{H}^{(l)} \in \mathbb{R}^{|\mathcal{V}| \times K}$  is the  $l^{th}$  GCN layer with  $K$  hidden features,  $\mathcal{H}^{(0)} = \mathcal{X}$ ,  $\mathcal{W}^{(l-1)}$  is the trainable parameters at the  $l-1^{th}$  layer, and  $g$  is a non-linear activation function.

## III. RELATED WORK

### A. LSTM-Based Speech Enhancement

For the recognition of sequence-based data, context information is essential. Certain straightforward approaches for processing context-dependent data have been adopted, such as concatenating several consecutive features to construct long-context input features [52]. Moreover, Recurrent Neural Networks (RNNs), especially the Long Short-Term Memories (LSTMs), have been experimented with to be able to capture the information of the long sequence [53-56].

ConferencingSpeech 2021 Challenge<sup>1</sup> [25] adopted LSTM to suppress noise in distorted input signal. In particular, the multi-channel noisy speech is converted into frequency-domain by STFT transformation.

The STFT features were stacked with ‘‘cosIPD’’ features [57], a smoother version of Inter-channel Phase Difference (IPD), to obtain the input features, and then used to train the model. A 3-layer real-valued LSTM is used to capture the temporal information of input features. The output of the LSTM model is treated as the cIRM then a real-valued fully connection layer is added to map the output into real and imaginary components of the mask, respectively.

The cIRM mask was multiplied with the first microphone channel of STFT features of noisy speech to filter out the noise. The model was trained with SA objective functions, minimizing MSE between the estimated reverberant signal and the target signal in time-domain. Code and samples can be found in this repository<sup>2</sup>.

### B. GCN-Based Speech Enhancement

Recently proposed solutions are introduced to tackle the problem of speech enhancement by employing DNN models with spatial post-filtering techniques such as the filter-and-sum beamformer [23], [58-60]. Tzirakis et al. [23] proposed a novel approach by treating each audio channel (microphone) as a node of a graph structure.

The well-known U-Net architecture was incorporated to learn representations for the inputs, especially in speech improvement problems [61], [62]. GCN was used in the embedding space of a U-Net architecture to learn spatial correlations between the different nodes (or channels/microphones).

This approach utilizes both real and imaginary parts of the complex features in the STFT domain. Complex spectrograms from each channel are fed into the encoder part of the architecture. The higher level features obtained after the Encoder part are used to construct the multi-channel GCN. After that, the Decoder produces the estimated cIRM for a reference microphone with the same dimension as the input. Finally, cIRM for noisy STFT features is computed, which is used to estimate the desired clean speech.

#### IV. PROPOSED MULTI-CHANNEL PROCESSING METHOD

##### A. Proposed System

This paper proposes a novel pipeline for multi-channel speech enhancement tasks by incorporating GNN with a neural MVDR beamformer. GNN is successfully applied in a wide range of tasks with structural data, including computer vision [44] and speech processing [23]. At the same time, MVDR demonstrates its superior performance over the Filter-and-Sum technique [63]. However, to the best of our knowledge, no prior work focuses on integrating both these techniques to tackle the speech enhancement problem.

The overall proposed model is schematically depicted as Fig. 1. The whole pipeline consists of three main processes:

- 1) Signal transformation includes signal conversion from the time domain to the STFT domain (STFT block) and signal inversion from the STFT domain back to the time domain (iSTFT block);
- 2) Mask estimation for both clean speech and noise (Mask Estimator block);
- 3) Applying MVDR for noise suppression (MVDR block). However, only the parameters in the Mask Estimator block are trainable (details illustrated in Algorithm 1).

The two signal transformation blocks are trivial, while the mask estimation and the MVDR blocks are more advanced and described below.

*1) Mask Estimator Block:* Firstly, we employ the well-known U-Net architecture for mask estimation blocks. The u-Net model has been shown very successfully in many computer vision tasks and used in some recent approaches in speech processing [64]. In addition, U-Net architecture comprises an encoder/decoder part with an embedding layer. The encoder/decoder parts in U-Net are set to be cascaded CNN layers, while the GCN is used as a core embedding layer. We adopt this idea from the currently published approach of [23].

Secondly, our proposed U-Net model is unique and different from [23] because we use other graph construction methods for the embedding layer. In [23], the input channels, denotes as  $M$ , is preserved as GCN nodes, so that, GCN has only  $M$  nodes ( $M = \{2, 4\}$  as reported in [23]). With such a few nodes, we realize that GCN's ability to capture spatial information is restricted.

From that deduction, we propose a novel graph construction method such that GCN's nodes are now set equal to the number of channels (kernels) of the last CNN layer in the encoder part of U-Net. In detail, suppose that the STFT features with the shape of  $(M \times T \times 2F)$  dimensional feeds to the encoder. The latter then represents with the dimension of  $(H \times T' \times F')$ , where  $H$  is the number of kernels of the last CNN layer in the encoder, while  $T'$ ,  $F'$  are the reduced size of  $T$  and  $F$  after all layers of CNN in the encoder, respectively. As a result, the number of nodes in GCN is  $H$ , allowing us to choose an appropriate number of nodes during the training process. For more detail about the graph construction process, see Section IV-C.

Finally, outputs of the mask estimation process are two masks for clean speech and noise, denote as  $mask\_speech$  and  $mask\_noise$  in Fig. 1, respectively.

*2) MVDR Beamformer:* We utilize a neural MVDR beamformer as posterior filtering to leverage the enhancement performance. The MVDR uses these aforementioned estimated masks from the previous step to compute beamforming weights on-the-fly. The detailed computation is introduced in section II-B. The process of MVDR beamformer is integrated with mask estimation and trained as a unified model so that, making the enhancement system more robust.

##### B. System Procedure

The overall procedure of this approach in Fig. 1 is shown in Algorithm 1.

First, the multi-channel speech signals are transformed into the time-frequency domain with STFT transformation. The components of the complex STFT features are stacked together to create a new feature with a two-channel of size  $(T \times F \times 2)$ , where  $T$  denotes the number of frames, and  $F$  indicates the number of frequency bins, in total.

Considering  $M$  channels, the input features will have the shape of  $(M \times 2 \times T \times F)$  dimensional, in which each entry is a real value. After that, these STFT input features are fed to the Encoder of Mask Estimator, which produces more complex and high-level representations. The feature is reshaped into  $(M \times T \times 2F)$  dimensional to fit the requirement of our proposed method. The Encoder then produces representations with the dimension of  $(H \times T' \times F')$ , where  $H$  is a number of filters of the last CNN layer in the encoder. At the same time,  $T'$  and  $F'$  are the reduced size of  $T$  and  $F$  after the entire layers of CNN in the encoder, respectively. Next, the GCN is used as a core embedding layer between the encoder and decoder parts. The representations produced from the Encoder are utilized in constructing a graph with  $H$  nodes, which captures the spatial information by aggregating the information of its nodes and edges. The GCN construction process is described in detail in Section IV-C.

The output of GCN layers is forwarded through the decoder part, which converts the hidden features to the original dimension. The decoder outputs could be treated as two cIRM masks for clean and noisy speech, then used to compute the PSD matrices and MVDR weights. Estimated STFT features of reverberant speech  $\hat{S}$  are computed by applying MVDR processing as in Section II-B. Finally, the inverse STFT transformation is applied to obtain the estimated reverberant speech in the time domain.

##### C. Graph Construction

We adopt a recently published approach that captures multi-channel signal information with graph structure [23]. The graph structure is first constructed using the hidden feature representations obtained after the Encoder. We construct an undirected graph,  $\mathcal{G} = (\mathcal{V}, \mathcal{E})$ , where  $\mathcal{V}$  represents the set of nodes  $v_i$  of the graph. For example, with hidden features of shape  $(H \times T' \times F')$  from the previous step, a graph with  $H$  nodes with a feature size is  $N = T'F'$  will be constructed by flattening function.  $\mathcal{E}$  represents the edges of the graph

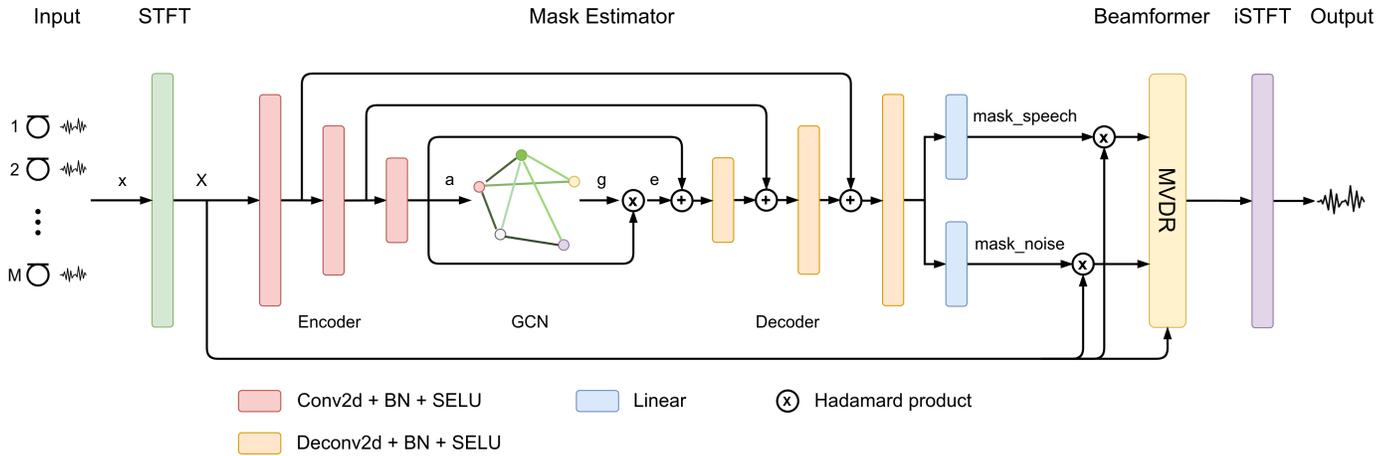

Fig. 1. Proposed MVDR System using GNN-Based U-Net Architecture as mask Estimator. The Estimated Masks are then used to Compute the Beamformer Weights and Applied to a Noisy Signal to Provide the Enhanced Signal.

between two nodes  $(v_i, v_j)$ . Then, an adjacency matrix of the graph,  $\mathcal{A} \in \mathbb{R}^{H \times H}$ , is computed.

We also employ a learnable adjacency matrix, where each entry of  $\mathcal{A}$  is treated as a weighted obtaining from edge  $(v_i, v_j) \in \mathcal{E}$ . Intuitively, each entry represents a similarity between two nodes in the graph. In our approach, the learnable weights,  $w_{ij}, \{i, j \in \mathcal{V}\}$ , of the adjacency matrix  $\mathcal{A}$  are optimized during the training process. For two nodes  $v_i$  and  $v_j$ , their representations will be concatenated,  $\mathbf{f}_{v_i}, \mathbf{f}_{v_j} \in \mathbb{R}^N$  as  $[\mathbf{f}_{v_i} \parallel \mathbf{f}_{v_j}]$  and then passed through a non-linear layer  $F([\mathbf{f}_{v_i} \parallel \mathbf{f}_{v_j}])$ . The node degree matrix  $\mathcal{D}$  is a diagonal matrix, where  $\mathcal{D}_{ii} = \sum_j \mathcal{A}_{ij}$ .

The graph constructed  $\mathcal{G}$  provides an efficient way to capture the structured information from its nodes (e.g., microphones). We use the GCN to produce high-level abstraction for the hidden node representations by learning aggregated features for each node w.r.t its neighbors. The mathematical detail of the GCN layer can be seen in Section II-D2.

#### D. Loss Functions

In the training process of the proposed network, we adopt loss computations in different forms. We use a loss function with magnitude features and raw signals in the time domain. More specifically, these losses are:

$$\mathcal{L}_{mag} = \left\| \left| \hat{S} \right| - |S| \right\|_1 \quad (11)$$

$$\mathcal{L}_{raw} = \left\| \hat{s} - s \right\|_1 \quad (12)$$

$$\mathcal{L} = \mathcal{L}_{mag} + \mathcal{L}_{raw} \quad (13)$$

where  $\|\cdot\|_1$  indicates the L1 norm,  $|S|$  indicates the magnitude spectrogram of the complex spectrogram  $S$ ,  $s$  indicates reverberant signal, and  $\hat{\cdot}$  sign indicates the corresponding predicted entities.

## V. EXPERIMENTAL EVALUATION

### A. Dataset

With some missing information about the dataset configurations and the authors did not publish the implementation of their proposed model in [23], we decided to utilize the dataset provided from ConferencingSpeech 2021 Challenge [25]. The simulation set was provided for all participants to develop the enhancement systems and estimate the objective scores. To focus on the development of algorithms, the authors designed the challenge with the *close* training condition. In other words, only the provided list of open-source clean speech and noise datasets could be used in the training process.

1) *Training Set*: Clean training speech set signals are chosen from three open source speech databases: AISHELL-1<sup>3</sup> [65], AISHELL-3<sup>4</sup> [66], and Librispeech [67]. The speech utterances with SNR higher than 15 dB are selected for training. The total duration of the clean training example is around 550 hours. The noise set is selected from MUSAN [68] and AudioSet [69]. The total duration is around 120 hours.

The imaging method is used to simulate Room Impulse Response (RIR) for three types of microphone arrays: (i) a linear microphone array with uniformly distributed 8 microphones, (ii) a circular microphone array, and (iii) a linear microphone array with non-uniformly distributed 8 microphones. The room size ranged from  $3 \times 3 \times 3 \text{ m}^3$  to  $8 \times 8 \times 3 \text{ m}^3$ , and provided RIR set contains more than 2500 rooms.

The microphone array is randomly placed in the room with a height ranging from 1.0 to 1.5 m. The sound source, including speech and noise, comes from any possible position in the room with a height ranging from 1.2 to 1.9 m. The angle between two sources is wider than 20°. The distance between the source and microphone array are ranged from 0.5 to 5.0 m. The total number of RIR is more than 10000 for each microphone array. The simulated SNR ranges from 0 to 30 dB, and the duration of each clip is 6 seconds.

```

---

2) *Development Set*: The development set is categorized into three parts: Simulation clips, Semi-real recordings, and Real recordings. In this experiment, we only experiment with simulated audio with a single microphone array scenario (there also exists another task using multiple microphone arrays). 1588 clips are simulated for three types of the microphone array. 1624 clean speech selected from AISHELL-1, AISHELL-3, and 800 noise clips selected from MUSAN are used to simulate these sets. The simulated SNR ranges from 0 to 30 dB, and the duration of clips is 6 seconds.

### B. Experimental Setup

For a convenient comparison with other approaches, we set up the training configurations as follows. The AdamW [70] optimization algorithm is adopted to optimize the proposed models with a fixed learning rate of  $10^{-4}$  and a mini-batch of size 16. The number of microphones in the experiments is set to  $M = 8$ . The complex features are the STFT computed with a window of length 1024, the window's type is set to Hanning, and an overlap size of 512.

Our proposed model (MVDR-GCN) uses the optimized configuration. Each block in the Encoder (Decoder) part of U-net architecture comprises one CNN layer, followed by batch normalization and a SELU activation function. Each Encoder block's kernels of CNN layers are set to  $\{64, 128, 128, 128, 32\}$ , respectively. The blocks in the Decoder have the same configurations as the Encoder but in reverse order. All the kernel sizes of CNN layers are  $3 \times 3$ , and the stride is  $2 \times 2$ , with no padding.

For the embedding layer of U-Net, GCN, a bottle-neck layer is used with the hidden size of 64, then two GCN layers are integrated with hidden units as same as the dimension of the bottle-neck layer. In order to generate two masks for speech and noise, after the Decoder part, two Linear layers are added with an input size equal to the hidden size of the last CNN layer in the Decoder, while the output size is set to the same as feature size of STFT features.

The LSTM-based baseline model (Section III-A) is set up as same as the model in [25]. The model is composed of three layers of RNN with 512 hidden units. The input features are

Proposed System (MVDR-GCN)	<b>2.207</b>	<b>0.879</b>	<b>0.794</b>	11.866

STFT stacking up with cosine of IPD features.

The GNN-based baseline model (Section III-B) has the same configurations as our proposed system, which includes input STFT features and parameters of layers in Encoder/Decoder blocks, except that number of kernels in each CNN layer, are slightly different from our proposed model ( $\{64, 128, 256, 128, 32\}$ ). Note that this is the optimized configuration in [23].

Finally, a noisy scenario is obtained by directly computing the metrics with noisy data, simulated with SNR ranging from 0 to 10, and scaling from 0.2 to 0.9.

### C. Enhancement Results and Evaluation

Our proposed approach's results are compared with Tzirakis et al. [23], a novel GCN-based multi-channel enhancement model. The detailed enhancement results are presented in Table I.

For overall comparison, the result of scenarios is averaged and reported as in Table II. Combining the MVDR algorithm showed an improvement in scores. The metrics obtained by the MVDR method are significantly improved, as expected, except for the SI-SDR score. The PESQ score achieved by the MVDR system shows a noticeable improvement over the baseline or GCN-based model (i.e., PESQ 2.207 vs. 2.104 and 2.076).

However, in the linear array scenario, our proposed system obtains worse scores than others, except for the PESQ metric, because of the distribution of the microphone in arrays. In circular and non-uniform scenarios, the position of microphones is various to capture more spatial information. The masks are more accurately estimated, and the model can achieve decent overall metrics. Conversely, the microphones are placed equidistant for the linear array, the information may be symmetric, and the mask estimator model may receive less information than others and get worse scores.

### VI. CONCLUSION

In this approach, we propose a new method of using a graph neural network to exploit the spatial correlations among the different channels in the speech enhancement task. We use the U-Net architecture with the encoder, which tries to produce higher-level representations for each channel. After that, the GCN is constructed using these hidden features. GCN is used to learn spatial features by propagating and aggregating information in the graph. Then the features are fed to the decoder to reconstruct into the original forms of each channel. By integrating the GCN-based U-Net into the MVDR system, the experimental results validate our approach's effectiveness when compared with recent state-of-the-art approaches.

**Abstract**—Energy demand continues to increase with no prospect of slowing down in the future. This increase is caused by several sociological and economical factors such as population growth, urbanization and technological developments. In view of this growth, it becomes crucial to predict energy consumption for a more accurate management and optimization. Nevertheless, consumption estimation is a complex task due to consumer behaviour fluctuation and weather alterations. Several efforts were proposed in the literature. Almost, all of them focused on improving the prediction model to increase the accuracy of the results. They use the LSTM (*Long-Short Term Memory*) model to reflect the temporal dependencies between historical data despite its spatial and temporal complexities. The main contribution in this paper is a novel and simple Convolutional Neural Network energy prediction model based on input data structure enhancement. The main idea is to adjust the structure of the input data instead of using a more complicated deep learning model for better performance. The proposed model was implemented, tested using real data and compared to existing ones. The obtained results showed that the proposed data structure has a great influence on the model performance measurement.

**Keywords**—Deep learning; convolutional neural network; energy consumption; energy prediction

## I. INTRODUCTION

The demand for energy increases with population size and economic growth and also depends on the consumers' behavior and their deployed appliances. Faced with this growth, consumption prediction is a crucial task that enables efficient and optimized energy management. Several techniques have been developed to predict demand for the next hours, days, weeks, months and even years. Most of them are based on historical data [1] and use Machine Learning or Deep learning models such as Artificial Neural Networks (ANN) [2], Support Vector Machine (SVM) [3], Convolutional Neural Network with Long- Short Term Memory (CNN-LSTM) [4], etc.

Deep Learning (DL) is an advanced Machine Learning approach that has been widely applied in many fields and has shown great performance for many problems such as image processing [5], [6], computer vision [7], [8], natural language processing [9], [10] and time series prediction [11], [12]. Also, the DL approaches have provided good accuracy for energy systems such as solar irradiance forecasting [13], [14] and wind speed prediction [15], [16]. Recently, DL approaches have been widely applied to predict the quantity of energy to be consumed. In most of the time, the consumed energy data are presented in time series. Energy consumption forecasting is

therefore a multivariate time series forecasting problem. LSTM is a Recurrent Neural Network (RNN) specification that is characterized by the capacity to control the flow of separate information [17] and mainly to detect temporal dependencies between data [18]. These advantages make LSTM effective for short-term or near-real-time forecasting. Consequently LSTM has been widely used for energy consumption prediction.

All these efforts focused on enhancing the ML/DL existing models for a better accuracy regardless of the complexity of the resulting one. However none of them dealt with adjusting the input data to attain same and even better performance. The main contribution of this paper is to propose a new DL based model that shows the impact of the input data structure on the prediction results.

The remaining of the paper is structured as follows: the next section describes the various existing researches that deal with energy consumption prediction using CNN and LSTM. Section III defines the CNN model and explains the proposed one. Section IV discusses the experimental evaluation and the conclusion is presented in Section V.

## II. RELATED WORKS

During the last two decades, several researchers have contributed to the solving of energy consumption prediction problems, resulting in a wide range of studies. These studies can be divided into two categories: those that use static methods, while others apply physical methods. Among static methods, Machine Learning techniques have been widely applied for predicting energy consumption. In [19], authors applied to the Support Vector Machine (SVM) while in [20], authors proposed Artificial Neural Networks (ANN) based solutions. ANN based models were also applied to different datasets in order to analyze them and select the relevant ones. However, recent trends are oriented towards applying Deep Learning models as Recurrent Neural Network (RNN), Convolutional Neural Network (CNN), LSTM, etc.

In [21], the authors presented two approaches based on LSTM for energy load prevention, and tested them on both data steps of one hour and one minute. The first approach uses the standard LSTM while the second one uses the Sequence to Sequence architecture. In [22], the authors applied CNN to predict the energy load per hour within a smart grid. Their aim is to demonstrate the effectiveness of their proposed CNN compared to other convolutional models. Another CNN model for energy load prediction was discussed in [23]. The authors

proposed the use of a set of historical input loads on which they applied convolutions. The obtained results were passed to a fully connected layer that produced the final output. Experimental tests showed that the results of their proposed model are similar to ANN, but outperforms those of Support Vector Regression model. As for [24], the objective was to solve the problem of load profile uncertainty for predicting household energy consumption. To do this, the authors proposed a model based on RNN where they grouped the load profiles in an input pool. The results showed that this model performs better than the classical RNN, Support Vector Regression and Auto Regressive Integrated Moving Average in terms of RMSE. The authors of [25] provided a Recurrent Inception Convolution Neural Network RICNN to solve the problems of existing RNN methods for daily energy load prediction. The proposed model combines RNN and one-dimensional CNN (1-D CNN). The obtained results proved the efficiency of the proposed model compared to benchmarked multi-layer perceptron, RNN and 1-D CNN.

In the context of a short-term prediction for residential energy consumption, an LSTM model has been proposed in [26]. This model is called Quantile LSTM (Q-LSTM) whose objective is to predict the probabilistic residential load with LSTM in quantile term. The results showed the efficiency of the proposed method compared to traditional ones in terms of averaging quantile score. As for the prediction of future energy demand, the authors in [27] defined and tested two types of approaches, the first one based on CNN and the second one based on neural networks and two optimization algorithms, the Genetic Algorithm (NNGA) and the Particle Swarm Optimization algorithm (NNPSO). The authors in [28] proposed a model based on feed forward back propagation neural network named FFBPNN. The proposed model involves four layers which are data collection layer, preprocessing layer, prediction layer and evaluation layer. The last layer provides the performance measures MAE, MAPE and RMSE. In 2021, in [29], authors presented a multi-seasonal short-term memory network LSTM-MSNet for time series forecasting with multiple seasonal models. The evaluation of the LSTM-MSNet model shows that this model has the best execution time and accuracy compared to existing ones. A new hybrid model for energy consumption prediction named DB-NET was presented in [30]. The proposed model combines the dilated CNN (DCNN) and bidirectional LSTM (BiLSTM). Experimental tests proved the efficiency of the DB-Net model.

In [4], the authors proposed a CNN-LSTM model combining both CNN and LSTM. This model extracts (1) spatial features using the CNN layer which allows feature extraction between multiple variables and (2) temporal features using LSTM which models irregular temporal information. Although this latter yielded to a good prediction performance, an improved EECP-CBL version has been presented in [31]. The experimental results of EECP-CBL proved that it is more efficient in predicting energy consumption than the CNN-LSTM model and other existing ones. The authors of [32] presented a new hybrid M-BDLSTM method combining CNN with the multi-layer bidirectional long-term memory method. Recently, in 2021, the authors of [33] proposed a meta-heuristic based on LSTM and Butterfly Optimization Algorithm (BOA) for the prediction of energy consumption. Butterfly Optimization Algorithm was used to discover the dynamic time series. This

model showed a lower error rate on the IHEPC dataset [34] compared to existing one. In 2022, [35] they proposed a hybrid model combining CNN and echo state network allowing both power generation and consumption forecasting. In this model, CNN performed the extraction of features from historical data while the echo state network ensured the learning of temporal features. The experimental results of this model on the IHEPC dataset showed a good performance in terms of RMSE, MSE, NRMSE, and MAE.

All these efforts contributed to improve the efficiency of energy prediction models. Their main goal focus on updating and enhancing previous ML/DL models for a better performance. They proceeded by combining several Machine Learning and Deep Learning techniques or/and adding optimization algorithms to increase the results accuracy. Nevertheless and despite the effectiveness of these models, we believe that it is possible to improve the prediction performance by using a less complex Convolutional model and different input data structures. The idea is to focus on finding the optimal data structure for the input data that may improve the results of prediction without resorting to sophisticated, complex and time/space consuming ML/DL models.

### III. PROPOSED CNN MODEL

An accurate prediction model for energy consumption is essential to simulate an energy management system between consumers and suppliers in order to optimize the energy use and to minimize its waste. However, the estimation process is a complex task due to the influence of several environmental factors and to the users' behavior.

Traditional network-based techniques are the main models to predict future energy consumption [36]. These models are based on the short-term memory for considering dependencies between the input data. Other models involve the LSTM network for integrating historical context. Nonetheless, these solutions would increase the time and space complexities of the estimation process.

In this article, we focused on simplifying the temporal and spatial complexity of existing models. Therefore, the principal contribution of our research is to reflect temporal dependencies between historical data without using the LSTM model. For this purpose, we tried to turn our investigation towards the input data rather than the deployed models. Hence, we thought of *i*) adjusting the input structure representation to emerge the time-series relationship between the historical data, *ii*) applying a simple CNN-based model to predict the future energy consumption with higher accuracy. We choose the CNN model presented in [37] and [38] for its promising results in both electricity consumption prediction [37] and load forecasting [38].

#### A. Input Data Proposed Structures

Since the meteorological seasons divide the year into four periods (Spring, Summer, Autumn and Winter) more or less equal, their duration varies from 89 to 93 days. Hence the energy consumption varies according to the weather characteristics of each season; For example in summer the temperature is high and therefore the need to use air conditioners increases. In addition, the climate of one season has a great impact on

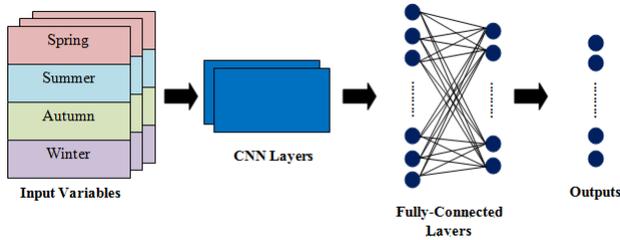

Fig. 1. Overview Architecture of Proposed Model using the Serial Matrix.

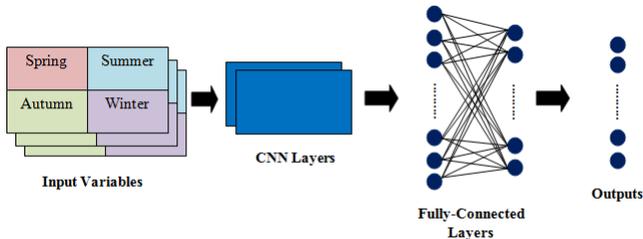

Fig. 2. Overview Architecture of Proposed Model using the Cycle Matrix.

the climate of the following ones. Generally, a too cold winter is usually followed by a too hot summer.

All existing researches manipulates the historical information of the energy consumption in a sequential form. No physical link between same season of different years, despite their intrinsic logical one. Most efforts rely on the LSTM model to take into consideration the logical relationships among consumption data. Our idea is to find a simpler way to reflect the logical link between the same season through several years. Therefore, we thought about improving the structure input data instead of investigating on the underlying prediction model. So the main idea of this paper is to present the data in a 3-dimensional matrix to be able to (1) maintain the different states of the same season over several years and (2) model the temporal dependencies between the different seasons.

In this paper, we will employ two different data structures for the input data. For the first data structure, we will use a matrix that indicates the four seasons of a year in a series manner. In this case the height of this matrix is the number of days in a year, its width is the number of features and its depth represents the number of years in the dataset. Fig. 1 shows the overall architecture of the proposed model using the first matrix form.

For the second proposed data structure, the data are organized in a cycle, i.e. in the same row we include the data of two consecutive seasons (Spring and Summer followed by Autumn and Winter). In this matrix the number of rows is half the number of days in a year, the width is twice the number of variables and the depth is the number of years in the dataset. The architecture of the model using this matrix is given by the Fig. 2.

The input of our model is the 3-D matrix on which two CNN layers are applied to extract the input variables which

are transmitted to the two fully connected layers to generate the prediction of future energy consumption.

### B. CNN-based Model

In our model we used convolutional 3D Layers, Pooling 3D Layers and fully connected Layers. In detail, we used two convolutional layers with a filter number equal to 64 and a kernel size (3,3,2). These two layers are followed by two max-pooling layers with a kernel size of (3,2,1). The max-pooling layer allows reducing the network computational cost as it selects only the most important features. Then flatten layer is applied to flatten the feature vector. Finally, two fully connected layers are used to adjust the result by providing the estimated energy consumption. The architecture and configuration of the proposed model are detailed in Table I.

TABLE I. ARCHITECTURE OF THE PROPOSED MODEL

Layer Type	Kernel size	Filter size	Parameters
Convolution3D	(3,3,2)	64	832
MaxPooling3D	-	-	0
Convolution3D	(3,2,1)	64	24640
MaxPooling3D	-	-	256
Flatten	-	-	0
Fully connected(128)	-	-	221312
Dropout	-	-	0
Fully connected(364)	-	-	45440

## IV. EXPERIMENTAL EVALUATION

In this section, first, we will describe the used dataset. Then, we will exhibit the obtained experimental results expressed in terms of performance measures, including MSE (Mean square error), RMSE (Root MSE), MAE (Mean Absolute error), MAPE (Mean Absolute Percentage Error) and the CPU time (training and testing times). Finally, we will compare the obtained results with existing energy prediction models in the literature.

### A. Dataset Description

To evaluate the proposed model and compare its performance with the models described in [4] and [31], we have applied our model to the same dataset used by aforementioned ones. The IHEPC dataset [34] available at UCI (University of California, Irvine) Machine Learning Repository. The data of this dataset are collected from a house located in Sceaux in France over five years from December 2006 to November 2010. This set contains 2,075,259 measurements with 25979 missing values equivalent to 1.25% of the total amount of data. The missing data have been processed in the pre-processing phase.

IHEPC contains nine variables e.i., day, month, year, hour, minute, global active power, global reactive power, voltage and global intensity. In addition to three variables collected from the energy consumption sensors which are sub metering 1, sub metering 2 and sub metering 3. Table II presents all these variables and their meanings as defined in the literature [39].

TABLE II. THE FEATURES OF THE IHEPC DATASET

Variable	Description
Day	A value from 1 to 31
Month	A value from 1 to 12
Year	A value from 2006 to 2010
Hour	A value from 0 to 23
Minute	A value from 1 to 60
Global active power	The household global minute-averaged active power (in kilowatt)
Global reactive power	The household global minute-averaged reactive power(in kilowatt)
Voltage	The minute-averaged voltage (in Volt)
Global intensity	The household global minute-averaged current intensity (in Ampere)
Sub metering 1	This variable corresponds to the kitchen, containing mainly a dishwasher, an oven and a microwave, hot plates being not electric, but gas powered (in watt-hour of active energy)
Sub metering 2	This variable corresponds to the laundry room, containing a washing machine, a tumble-drier, a refrigerator and a light (in watt-hour of active energy)
Sub metering 3	This variable corresponds to an electric water heater, and an air conditioner (in watt-hour of active energy)

### B. Evaluation Metrics

Energy consumption prediction is a time-series data problem. Several metrics are used to evaluate the performance of a prediction model. These metrics are based on analyzing the correlation and error between the actual values and the estimated ones. These performance metrics are detailed in [40]. For the proposed model, we used the same metrics as given in [4] and [31] to be able to perform a fair comparison on the same scale, i.e. MSE, RMSE, MAE and MAPE.

- 1) *Mean Square Error*: MSE is used to measure the average difference between the actual and estimated values as shown in the equation 1.

$$MSE = \frac{1}{N} \sum_1^N (a - p)^2 \quad (1)$$

- 2) *Root Mean Square Error*: RMSE is the most widely used one for evaluating current forecasts. It allows finding the difference between the current values and the predicted ones(equation 2).

$$RMSE = \sqrt{\frac{1}{N} \sum_1^N (a - p)^2} \quad (2)$$

- 3) *Mean Absolute Error*: MAE measures the mean distance between the actual and predicted values as given in the equation 3.

$$MAE = \frac{1}{N} \sum_1^N |(a - p)| \quad (3)$$

- 4) *Mean Absolute Percentage Error*: MAPE expresses the percentage accuracy of the prediction as stated in the equation 4.

$$MAPE = \frac{1}{N} \sum_1^N |(a - p)| * 100\% \quad (4)$$

with,  $a$  and  $p$  represent the actual and predicted values, while  $N$  is the total number of records.

### C. Performance Comparison

From the IHEPC set, we created a daily dataset for the period between March 2007 and February 2010. From this set we have created the two different proposed structures of matrix. For the first one, the matrix in series, we associate the model called *New Model-1* and for the second matrix structure, the model named *New Model-2*. To evaluate these two models, we performed three different experiments. For the first experiment, we considered the first and second years for the training set and the second and third years for the testing set. For the second experiment and in order to avoid duplicating the use of the second year for both training and testing sets, we used the first two years for the training set and we kept only the third year for the testing set. For the last experiment, the first year only is used for the training set and the other two years for the testing set. The two models were implemented with the tensorflow and keras libraries of Python and trained in 100 epochs with Adam optimization. The obtained experimental results were compared with the results given by LSTM, CNN-LSTM [4] and EECP-CBL [31] in terms of the four previously described performance metrics, i.e. equations 1, 2, 3 and 4.

TABLE III. MODEL-1: PERFORMANCE OF THE EXPERIMENTAL METHODS

Model	MSE	RMSE	MAE	MAPE	Training time (s)	Prediction time(s)
LSTM	0.241	0.491	0.413	38.72	106.06	2.97
CNN-LSTM	0.104	0.322	0.191	31.38	42.35	1.91
EEPC-CBL	0.065	0.225	0.191	19.15	61.36	0.71
<b>Exp. 1</b>	<b>0.017</b>	<b>0.131</b>	<b>0.022</b>	<b>2.29</b>	<b>6.01</b>	<b>0.18</b>
<b>Exp. 2</b>	<b>0.023</b>	<b>0.154</b>	<b>0.008</b>	<b>0.841</b>	<b>6.18</b>	<b>0.179</b>
<b>Exp. 3</b>	<b>0.017</b>	<b>0.131</b>	<b>0.018</b>	<b>1.844</b>	<b>5.87</b>	<b>0.19</b>

#### 1) Model-1 Evaluation Results:

a) *Experiment 1*: In this experiment we selected the first and second years for the training set and the second and third years for the testing set. The performance measures of the proposed model and of the LSTM, CNN-LSTM and EECP-CBL models are presented in Table III. Thus, Fig. 3 and 4 present a comparison of the MSE, RMSE, MAE and MAPE values of our model with existing models. We conclude that the proposed model achieves best results compared to the other models. The MSE value of our approach (0.017) is improved by more than 50% compared to the EECP-CBL model (0.65). Meanwhile, the LSTM and CNN-LSTM models achieve very high MSE values of 0.104 and 0.241 respectively. For the RMSE and MAE measures, the proposed model obtains respectively 0.131 and 0.022 which are the best results compared to the other models. The MAPE value of the proposed model is equal to 2.297 and that of LSTM, CNN-LSTM and EECP-CBL is respectively 38.72, 31.83 and 19.15, we note that this value is improved by about 80% compared to the last model.

Table III and Fig. 5 compare the training and prediction time of the proposed model with the LSTM, CNN-LSTM and EECP-CBL models. The training time of the proposed model is equal to 6.014 seconds while the LSTM, CNN-LSTM and EECP-CBL models require 106.06, 42.35 and 61.36 seconds respectively to train. We can see that the gap in training time is very large between our model and the other models.

In Machine Learning, the most important thing is not the

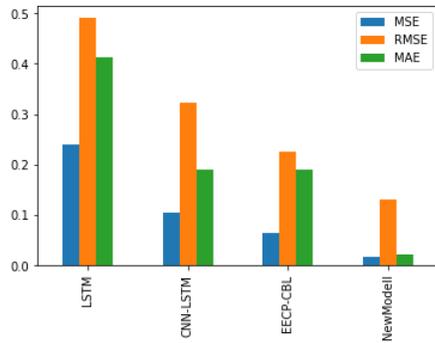

Fig. 3. New Model-1-Experiment-1 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of MSE, RMSE and MAE.

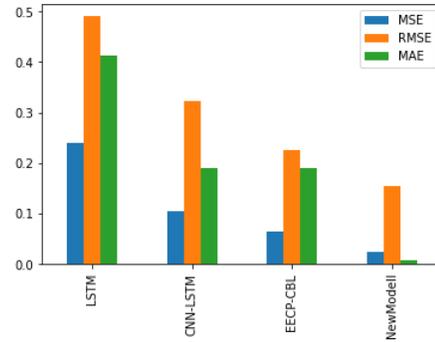

Fig. 6. New Model-1-Experiment-2 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of MSE, RMSE and MAE.

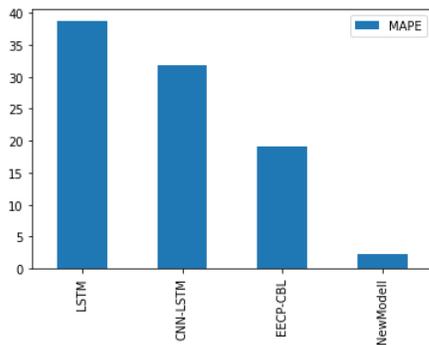

Fig. 4. New Model-1-Experiment-1 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of MAPE.

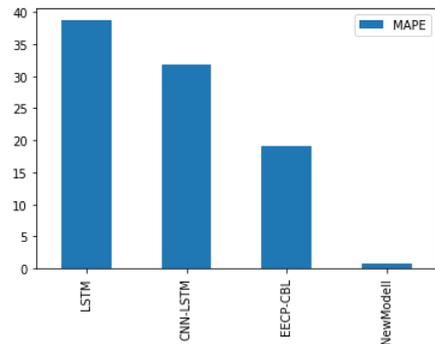

Fig. 7. New Model-1-Experiment-2 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of MAPE.

training time, but the prediction time because a model is trained only once while it is used for prediction several times. For our model, the prediction time is reduced from 0.71 seconds for EEPC-CBL to 0.18 seconds. However, this time is high for the LSTM (2.97 seconds) and CNN-LSTM (1.91 seconds) models. Consequently, the proposed model required the best training and prediction times to estimate future energy consumption.

*b) Experiment 2:* For the second experiment, the training set is formed by the first and second years while the third year is used for the testing set. Table III and Fig. 6 and 7 show that for this experiment our model reaches the best values of MSE, RMSE, MAE and MAPE which are respectively 0.023,

0.154, 0.008 and 0.841.

Moreover, referring to Table III, we observed that the proposed model was trained for 5.69 seconds and required 0.175 seconds for prediction. From Fig. 8 we can see that our model has spent the shortest time for training and for predicting.

*c) Experiment 3:* By modifying the training set (one year) and the test set (2 years), the results of the proposed model remain better than the existing models in terms of performance measures (Fig. 9 and 10) with the values 0.017, 0.131, 0.018 and 1.844 of MSE, RMSE, MAE and MAPE,

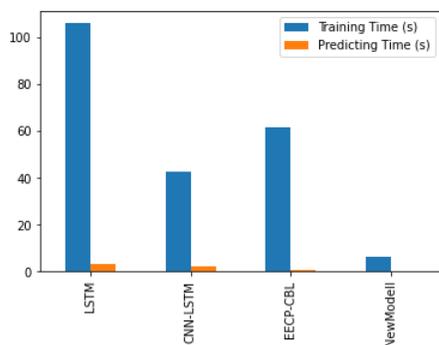

Fig. 5. New Model-1-Experiment-1 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of Training Time and Prediction Time.

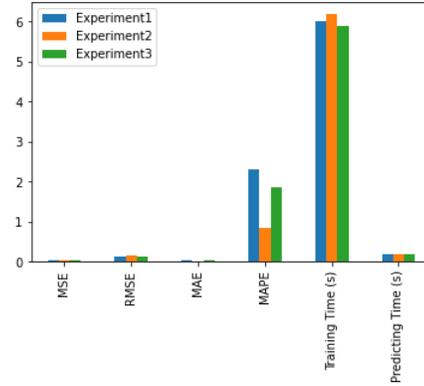

Fig. 12. Summary of New Model-1 Results.

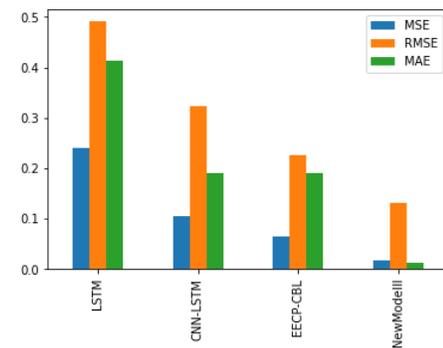

Fig. 13. New Model-2-Experiment-1 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of MSE, RMSE and MAE.

respectively (Table III).

Also, we deduce from Table III and Fig. 11 that the proposed model has the shortest prediction training time.

d) *Model-1 Experiments' Comparison:* Fig. 12 compares the results of the three experiments to evaluate the proposed model. We see that the MSE and RMSE values of experiments 1 and 3 are similar while the MAE and MAPE values are slightly different. On the other hand, the values of the performance measures of experiment 3 are slightly different from those of the other experiments. Additionally, the training and prediction times of the three experiments are too close together. We conclude that our model achieves the best

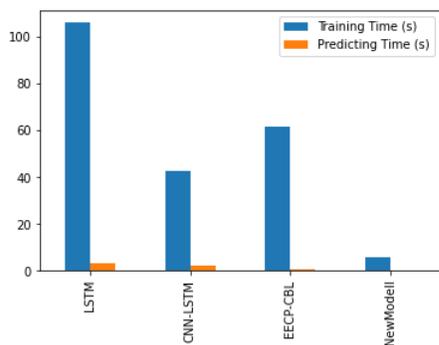

Fig. 11. New Model-1-Experiment-3 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of Training Time and Prediction Time.

performance measures and the shortest training and prediction times, regardless of the choice of training and testing sets.

TABLE IV. MODEL-2: PERFORMANCE OF THE EXPERIMENTAL METHODS

Model	MSE	RMSE	MAE	MAPE	Training time (s)	Prediction time(s)
LSTM	0.241	0.491	0.413	38.72	106.06	2.97
CNN-LSTM	0.104	0.322	0.191	31.38	42.35	1.91
EEPC-CBL	0.065	0.225	0.191	19.15	61.36	0.71
<b>Exp. 1</b>	<b>0.017</b>	<b>0.131</b>	<b>0.013</b>	<b>1.386</b>	<b>5.22</b>	<b>0.17</b>
<b>Exp. 2</b>	<b>0.023</b>	<b>0.154</b>	<b>0.008</b>	<b>0.841</b>	<b>5.69</b>	<b>0.17</b>
<b>Exp. 3</b>	<b>0.017</b>	<b>0.131</b>	<b>0.0122</b>	<b>2.552</b>	<b>4.81</b>	<b>0.16</b>

2) *Model-2 Evaluation Results:*

a) *Experiment 1:* The second proposed model also achieved the best values of the performance measures MSE, RMSE, MAE and MAPE comparing to the LSTM, CNN-LSTM and EEPC-CBL models as shown in Fig. 13 and 14. All values are detailed in Table IV.

Similar to the previous experiments, Table IV and Fig. 15 show that our model spends the shortest time for training and for predicting.

b) *Experiment 2:* From Table IV, we can observe that the value of MSE is improved by more than 25% compared to the EEPC-CBL model and the values of RMSE, MAE and MAPE are approved by almost 20% compared to the EEPC-CBL model. Fig. 16 and 17 demonstrate that our model

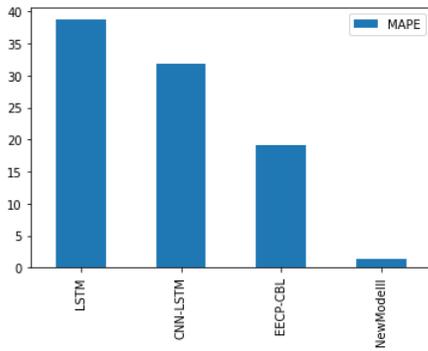

Fig. 14. New Model-2-Experiment-1 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of MAPE.

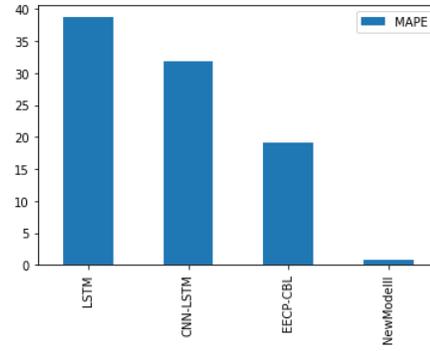

Fig. 17. New Model-2-Experiment-2 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of MAPE.

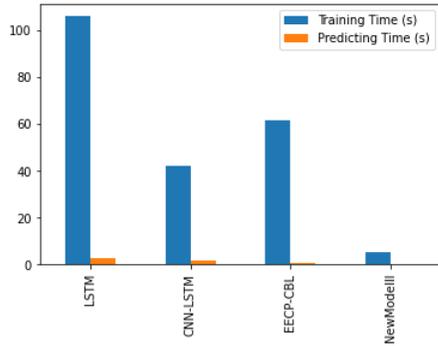

Fig. 15. New Model-2-Experiment-1 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of Training Time and Prediction Time.

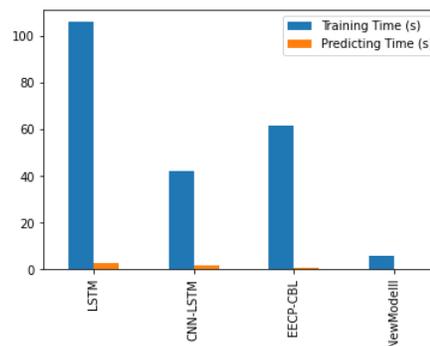

Fig. 18. New Model-2-Experiment-2 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of Training Time and Prediction Time.

achieves the best accuracy performance compared to other models.

Referring to Table IV and Fig. 18, our model achieves the shortest training and prediction time.

c) *Experiment 3:* Finally, the evaluation results of Experiment 3 are presented in Table IV. For the values of MSE, RMSE, MAE and MAPE, our model reaches better values than the improved EEPC-CBL model. Fig. 19 and 20 show that our model has the best performance measures.

In terms of training time and prediction, our approach gives better results as shown in Table IV and Fig. 21.

d) *Model-2 Experiments' Comparison:* Fig. 22 presents a synthesis of the results obtained by the second model proposed in the three experiments. We can see that the values of MSE, RMSE and MAE are almost equal with a slight difference between the values obtained by the second experiment and the two other experiments. We also notice that the value of MAPE differs slightly from one experiment to another with the best value being obtained for two years of training and one year of testing. In terms of training and prediction time, the three experiments reach very close duration. Consequently, we conclude that our model achieves the best performance for all experiments. To conclude, for the two proposed models we

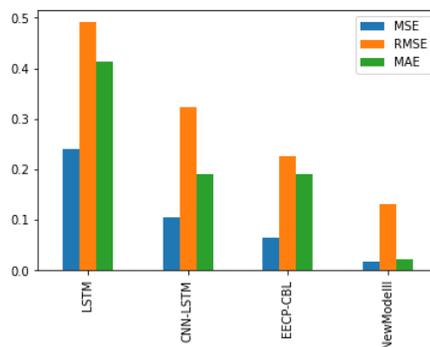

Fig. 19. New Model-2-Experiment-3 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of MSE, RMSE and MAE.

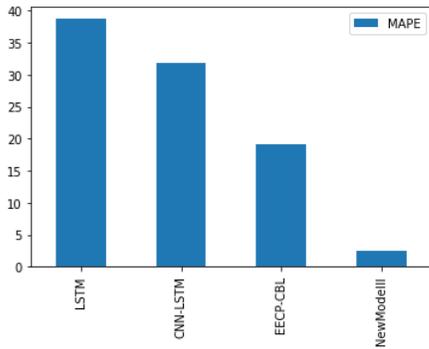

Fig. 20. New Model-2-Experiment-3 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of MAPE.

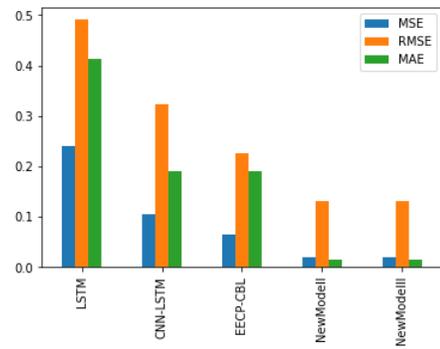

Fig. 23. Average of Model-1 and Model-2 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of MSE, RMSE and MAE.

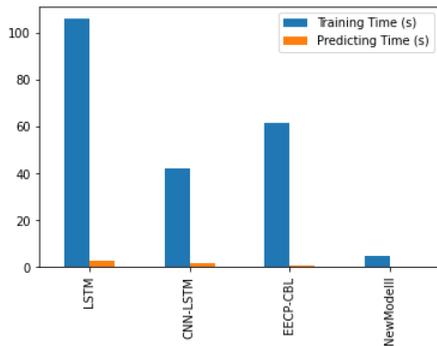

Fig. 21. New Model-2-Experiment-3 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of Training Time and Prediction Time.

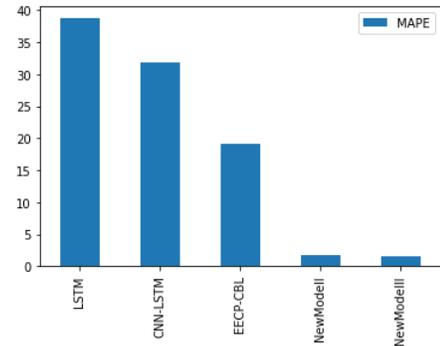

Fig. 24. Average of Model-1 and Model-2 vs. LSTM/CNN-LSTM/EEPC-CBL in Terms of MAPE.

calculated the average of the results obtained and compared them to those of the LSTM, CNN-LSTM and EECP-CBL models. The comparison of the MSE, RMSE, MAE and MAPE measurements is presented in Fig. 23 and 24. While Fig. 25 shows the comparison of all models in terms of training time and prediction time.

We observe that for the two proposed models reach the best values of MSE, RMSE, MAE and MAPE compared to the existing models LSTM, CNN-LSTM and EECP-CBL which proves the effectiveness of our model in terms of accuracy performance. Moreover, we studied the learning and

prediction time of the proposed models in both models. The learning time of our models is equal to 70% of the best time obtained by the CNN-LSTM model. Moreover, our approach requires only 39% of the time required by the EECP-CBL model.

Therefore, we conclude that the results obtained from the new models significantly outperform the other models in terms of predictive efficiency. In addition, our models improve the training time, but most importantly, they deemphasize the prediction time. Therefore, the proposed models enhance energy consumption prediction results on the daily dataset derived

from IHEPC in terms of performance measures MSE, RMSE, MAE and MAPE and in terms of training and prediction time.

## V. CONCLUSION

Since the demand for energy is growing more and more following the demographic and technological development, it has become imperative to manage and optimize the use of energy between consumers and suppliers. For an efficient energy management system, it is necessary to predict the future demand of users in energy which is a difficult target due to several factors. Various techniques based ML/DL for predicting energy consumption were proposed in the literature. However, most of them combine several models to be able to reflect temporal and logical dependencies between data. The focus of most researchers is how to make their models able to deal with these relationships by integrating recurrent mechanism. Nevertheless, the resulting models are often costly in terms of time and space. In this paper, we proposed a new research direction that deals with improving the structure of the input data rather than emphasizing on upgrading the model itself. The proposed model for energy consumption prediction is a simple 3-dimensional CNN that uses a new structure based matrices for the input data that physically reflects its logical dependencies. The experimental evaluation with the existing models LSTM, CNN-LSTM and EECF-CBL showed that our model outperforms existing ones in terms of MSE, RMSE, MAE, MAPE and required time for training/testing.

In a future work, we will integrate this model into the intelligent A-RESS system proposed in [41].

**Abstract**—The Non-Orthogonal Multiple Access (NOMA) technique has enormous potential for wireless communications in the fifth generation (5G) and beyond. Researchers have recently become interested in the combination of NOMA and cooperative relay. Even though geometric-based stochastic channel models (GBSM) have been found to provide better, practical, and realistic channel properties of massive multiple-input multiple-output (mMIMO) systems, the assessment of Cooperative Relay NOMA (CR-NOMA) with mMIMO system is largely based on correlated-based stochastic channel model (CBSM). We believe that this is a result of computational difficulties. Again, not many discussions have been done in academia about how well CR-NOMA systems perform when large antenna transmitters with the GBSM channel model are used. As a result, it is critical to investigate the mMIMO CR-NOMA system with the GBSM channel model that takes into account channel parameters such as path loss, delay profile, and tilt angle. Moreover, the coexistence of large antenna transmitters and coding methods requires additional research. In this research, we propose a two-stage, three-dimension (3D) GBSM mMIMO channel model from the 3GPP, in which the transmitter is modelled as a cylindrical array (CA) to investigate the efficiency of CR-NOMA. By defining antenna elements placement vectors using the actual dimensions of the antenna array and incorporating them into the three-dimension (3D) channel model, we were able to increase the analytical tractability of the 3D GBSM. Bit-error rates, achievable rates, and outage probabilities (OP) are investigated utilizing the decode-and-forward (DF) coding method: the results are compared with that of a system using the CBSM channel model. Despite the computational difficulties of the proposed GBSM system, there is no difference in performance between CBSM and GBSM.

**Keywords**—CR-NOMA; 3D GBSM; DF coding scheme; Cylindrical Array (CA); cooperative relay

## I. INTRODUCTION

One of the major hurdles for future wireless communication systems is to facilitate large data traffic whilst maintaining reasonable communication latency [1]–[3]. This is due to the development of information and communication applications and a rapidly expanding user base. It also requires concurrent

access to various network resources from anywhere and at any time while maintaining a good quality of service.

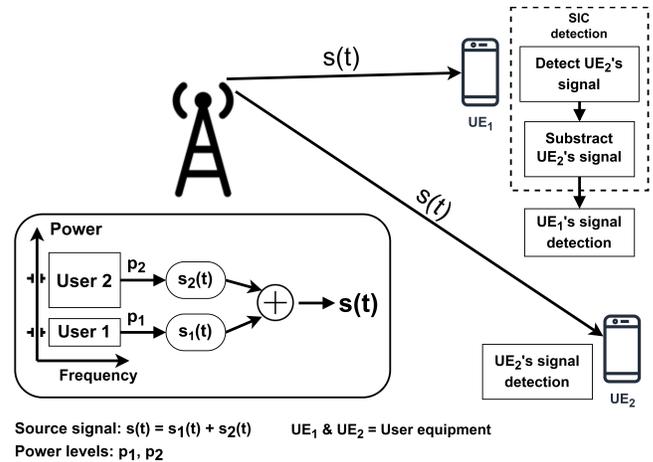

Fig. 1. NOMA System Architecture for Downlink Communication.

In a cellular system where the channel conditions vary for various users due to the near-far effect, Nonorthogonal multiple access (NOMA) provides performance improvement regarding the trade-off between the system's capacity and user fairness [4]–[7]. Fig. 1 Figure 1 illustrates the NOMA system architecture for downlink (DL) communication. According to the NOMA concept in the power domain, users share the same resource block such as frequency, code or time. The users, however, are assigned different power levels per the channel conditions. Users with a poor channel are given more power than those with a good channel state. The data signal of various users in the NOMA system is added together by using superposition coding into a single data signal that is transmitted to all users within the network. This will be seen in later sections of this work. At the destination, the users employ successive interference cancellations to mitigate interference and recover individual data signals. NOMA, which has been

incorporated into the new 5G standard, is a promising method that is anticipated to meet the requirements and also deliver a greater spectrum efficiency [6], [7].

Given the incredibly high number of IoT devices enabled by 5G (such as Smart Cities or Autonomous Vehicles), this trait is important in situations where the spectrum is limited. Users who are nearer the transmitter utilize lower transmit powers, but users who are farther away need greater transmit powers. As a result, NOMA employs these attributes to distinguish between signals since transmissions from various users who share the same spectrum have varying received power levels. Naturally, in addition to the near-far issue, fading and power regulation are other elements that cause variances in the received power levels of users. These characteristics are also taken into consideration by the NOMA receiver. When using NOMA, a user receiving the superposition broadcast with its signal delivered at a lower power level decodes the stronger signal components of other users and then cancels them out. This allows for a considerable spectral efficiency increase over standard orthogonal multiple access [8]. Some of the major technologies that enable 5G communications to achieve the initial targets in terms of throughput, spectrum efficiency, and network capacity are massive multiple-input, multiple output (mMIMO), millimeter-wave (mmWave) Communications, Cooperative relay NOMA (CR-NOMA), and so on [9], [10].

The advantage of mmWave, which uses carrier frequencies of about 60 GHz, is that it has a substantially larger channel coherence bandwidth but also has significantly higher path loss. Additionally, the relatively short wavelength of mmWave makes it easier to deploy mMIMO since it allows for smaller antennas and closer spacing between mMIMO antenna components (typically 3 to 4 wavelengths for the signals in adjacent antennas to be uncorrelated).

Recent works have seen the integration of NOMA and different transmission techniques, such as mMIMO, mmWave, block transmission techniques, and cooperative-relay communication. This is to achieve better system performance. Cooperation among network users is crucial in wireless communication since it reduces fading effect, increases capacity, and broadens the coverage area. Cooperative communication occurs when a node works with the source to forward data to the destination as indicated in Fig. 2 and 3. Two types of cooperation, namely cooperation among NOMA users and cooperation via specialized relays, can be employed to create cooperative diversity in the NOMA system. By utilizing idle users to relay data to other users, the previous method is used to increase the data rate and data dependability for the weak users. The latter is used to serve cell edge NOMA customers effectively within a network and to increase wireless network coverage [11].

## II. LITERATURE REVIEW

1) *Channel Models for 5G Massive MIMO*: A channel model is a mathematical depiction of the impacts of a communication channel used to transmit wireless communications. The channel model can reflect the signal's power loss as it passes via the wireless link. There are two types of channel models that are typically used to evaluate the performance of 5G wireless communication systems: correlation-based

stochastic models (CBSMs) and geometry-based stochastic models (GBSMs) [12].

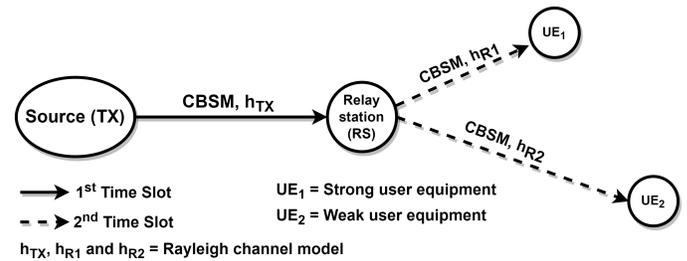

Fig. 2. Downlink cooperative-Relay NOMA Network with CBSM Channel Model.

Table I gives further details of these channel models and their applications. The former is less accurate and is mostly used to study the theoretical performance of MIMO systems. The exactitude of a true MIMO system, on the other hand, is limited, and simulating wireless channels with the nonstationary phenomenon and wavefront effects is difficult [12], [13]. GBSM, on the other hand, has more processing complexity, but it can accurately represent actual channel characteristics and is ideally adapted for mMIMO channel estimation [12].

For performance improvements and evaluation, GBSM combines channel features such as angle of arrivals, delay profile, tilt angle, path-loss, and so on into the channel models [12], [14]–[16].

2) *CR-NOMA with CBSM Channel Model*: As explained previously, the effectiveness of CR-NOMA has been thoroughly investigated using a variety of network coding methods. However, the vast majority of CR-NOMA performance assessments are only based on CBSM, which is mainly used for theoretical MIMO channel analyses. Cooperation among devices in a network has been studied in numerous literature, where some network nodes act as a relay to other devices by using network coding strategies. The network coding strategies improve system performance and allow the far or network edge users to improve their quality of services. For instance, [17] investigated network coding techniques such as amplify-and-forward and decode-and-forward. One of the most well-known relaying protocols is Decode-and-forward (DF). In this protocol, a relay decodes the message from a source and resends the decoded symbols to a destination. DF MIMO relay systems' transmission strategy and performance analyses have been done in [18]. Additionally, the compress-and-forward (CF) and compute-and-forward (CpF) techniques have been examined in [19], [20] and [21]–[24], respectively. The above coding schemes were used to analyze resource allocation optimization in [25]–[30].

CR-NOMA using MIMO as well as mMIMO have been investigated in [31], [32] to increase system spectral efficiency and lessen difficulties in acquiring channel state information (CSI). The applicability of relay to mMIMO NOMA has been researched by the authors of [32]. However, CBSM was the foundation of the analyses with mMIMO cooperative relay NOMA. According to [12], the authors' circular array at the transmitter (TX) can not be considered as a typical antenna array arrangement for mMIMO systems.

### A. Motivation

According to research, CBSM [23], [33]–[36] is the only focus of the approaches and analyses utilized to enhance CR-NOMA system performance. Due to nonstationary phenomena and spherical effects, CBSM is used for theoretical study and has lower accuracy for real-world mMIMO systems [12], [37]. Table I provides a comparative study of CBSM and GBSM that clearly outlines the drawbacks of the CBSM channel model. GBSM on other hand provides accurate and realistic channel characteristics for the mMIMO system. In this regard, the authors in [31] have, as far as we can determine, used GBSM to examine CR-NOMA performance based on the Saleh-Valenzuela channel model. The authors considered the channel for beamforming analysis without network coding strategies. Again, a user relay rather than a specialized relay station was the focus of their investigation. The purpose of this study is to fill in the gap in the literature on CR-NOMA related to the adoption of the 3GPP’s 3D GBSM channel model with large antenna transmitters like cylindrical antenna array (CA), as well as its implications for wireless communications. To meet future demands of wireless communication technologies

the paper addresses the following research challenges: 1) What are the effects of large antenna transmitters such as CA on the performance of mMIMO CR-NOMA systems when the communication links from the transmitter to users are modeled as 3D GBSM channel model? 2) How will mMIMO CR-NOMA performance be impacted by the combination of large antenna transmitters, 3D GBSM channel models, and coding schemes on outage probability, achievable rate, and bit-error rate (BER)?

### B. Contribution

By taking into account a two-stage downlink network model system with a dedicated relay, we can address the challenges above. We use 3GPP and WINNER+ models, which adhere to the GBSM strategy, see [38], [39] for more information [14], [40]. Therefore, according to [41], defining propagation paths in azimuth does not enhance performance. By combining a space-time signal with scanning acceleration, CA may be utilized to lessen clutter and enables concentrated beams in any horizontal direction [14]. By defining the antenna element placement vector using its physical structure and

including it in the three-dimension (3D) channel model, we were able to minimize the computing complexity of the 3D GBSM. To improve the functionality of the mMIMO CR-NOMA system, the RS employs a DF coding scheme to obtain results regarding achievable rate, outage probability, and bit-error rate through simulation. The main contribution this work are:

- i. We determine the placement vector of the antenna element based on the physical structure of the antenna array to reduce the computational complexity of the model.
- ii. We analyze a two-stage downlink mMIMO CR-NOMA system and offer a new 3D GBSM channel model when the transmitter is modelled as CA.
- iii. We use DF coding scheme with the 3D channel model to improve on the performance of the mMIMO CR-NOMA system.
- iv. For the two-stage CR-NOMA system's performance study, we report the outage probability, achievable rate and bit-error assessment. We compare these results with similar existing work that uses CBSM.
- v. Results are shown to demonstrate the potential benefits of the joint contribution of large antenna transmitters and coding schemes using 3D GBSM model with mMIMO CR-NOMA to future communications systems in terms of achievable rate, outage probability, and bit-error rate (BER).

The paper is structured as follows. Section II gives the literature of prior work where the communication channel in the system is modeled as CBSM. It also establishes the motivation and contribution of the work. The proposed system model of the mMIMO CR-NOMA network and the proposed 3D GBSM model when the transmitter is cylindrical array (CA) is present in Section III. Sections IV and V contain the system's performance analysis, as well as numerical findings. Section VI concludes the paper, and state future works using 3D GBSM in NOMA and 5G systems.

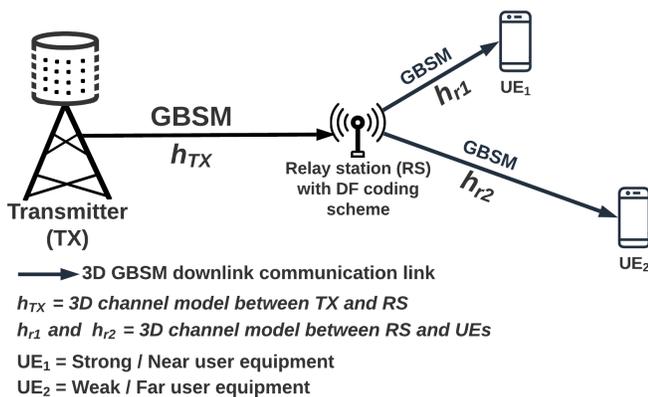

Fig. 3. Proposed Model of the Downlink Cooperative Relay NOMA Network with mMIMO.

### III. SYSTEM MODEL

As shown in Fig. 3, this section considers a two-stage downlink (DL) communication system in which the transmitter

(TX) transfers messages to user equipment (UE) via a dedicated relay. The TX has a large-scale antenna array such as CA for high spectral-efficient massive access, whereas the UEs and relay station (RS) each have a single antenna. Unlike the CR-NOMA model in Fig. 2, where the channel connecting the TX, RS, and UEs is modelled with CBSM, the proposed model substitutes the CBSM channel with a 3D GBSM, as illustrated in Fig. 3. The strong user equipment (UE<sub>1</sub>) in the proposed system shown in Fig. 3 is located near to the RS, whereas the weak user equipment (UE<sub>2</sub>) is located further away from the RS. We employ a fixed power allocations, and assign  $\alpha_1$  to UE<sub>1</sub>, and  $\alpha_2$  to UE<sub>2</sub> according to NOMA principles where  $\alpha_1 < \alpha_2$ . TX combines the signal of the two UEs into one according to superposition principles. The combined signal ( $\mathbf{x}$ ) of two is given by

$$\mathbf{x} = \sum_{i=1}^2 \sqrt{\alpha_i} s_i \quad (1)$$

where  $i^{\text{th}}$  user transmit power allocation and the source signal are  $\alpha_i$  and  $s_i$  respectively. Noticeably  $\sum_{i=1}^2 \alpha_i \leq P_s$ , where  $P_s$  is the total transmit power at TX. We assume that TX uses a pilot signal to estimate the downlink (DL) channel. Additionally, we take advantage of channel reciprocity using the traditional time division duplex mode [42]. The system uses two-time slots to transmit the combined signal to the user. During the first, the received signal ( $y$ ) at the relay with DL data transmission is given by

$$y = \mathbf{H}\mathbf{x} + n \quad (2)$$

where  $\mathbf{x}$  is an  $N_t \times 1$  data signal from (1),  $\mathbf{H}$  is the channel matrix generated in (11) and  $n$  is the additive Gaussian white noise with zero mean and variance,  $\sigma^2$ .

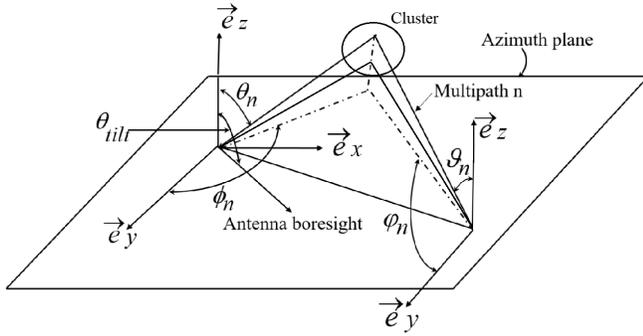

#### A. Proposed 3D GBSM Models

We assess the GBSM-based 3GPP standard and offer a 3D channel model in which the TX antenna is treated as a CA. The main parameters of significance in the 3D channel model are the delay spread (DS), angle of arrival (AoA), azimuth of departure (AoD), the elevation angle of arrival, and elevation angle of departure [12], [43], [44].

Additionally, the proposed 3GPP standard allows for dynamic adaptation of the antenna's downtilt angles and the elevation angle of the boresight into the channel. According to [40], this offers several benefits for 3D beamforming, which can significantly boost system performance. Fig. 4 illustrates the 3D channel model, where the key parameters have been listed.

The effective channel between  $s^{\text{th}}$  TX antenna port with  $M$  subpath and  $u^{\text{th}}$  UE antenna port can be expressed as stated in [14], [39] as

$$[\mathbf{H}_{s,u}^{3D}] = \sqrt{\frac{P_n \sigma_{SF}}{M}} \sum_{n=1}^N \alpha_n \begin{bmatrix} \sqrt{G_{TX}^{3D}(\phi_n^{AoD}, \theta_n^{AoD}, \theta_{tilt})} \\ \times \sqrt{G_{RS}^{3D}(\varphi_n^{AoA}, \vartheta_n^{AoA})} \\ \times [a_{RX}(\varphi_n^{AoA}, \vartheta_n^{AoA})]_u \\ \times [a_{TX}(\phi_n^{AoD}, \theta_n^{AoD})]_s \end{bmatrix} \quad (3)$$

$\theta_{tilt}$  = Elevation angle of the boresight  
 $\theta_n, \vartheta_n$  = Elevation AoD & AoA of the  $n^{th}$  path respectively  
 $\phi_n, \varphi_n$  = Azimuth AoD & AoA of the  $n^{th}$  path respectively

Fig. 4. 3D Channel Model.

where  $\alpha_n$  is the complex random amplitude of the  $n^{th}$  path.  $s = 1, \dots, N_{TX}$ ,  $u = 1, \dots, N_{RS}$ ,  $(\phi_n^{AoD}, \theta_n^{AoD})$  are the azimuth and elevation angles-of-departure (AoD) respectively.  $(a_{RX}(\varphi_n^{AoA}, \vartheta_n^{AoD}))$  and  $(a_{TX}(\phi_n^{AoD}, \theta_n^{AoD}))$  are the antenna array response of transmitter and receiver antenna respectively. The azimuth and elevation AoA of the  $n^{th}$  path respectively  $(\varphi_n^{AoA}, \vartheta_n^{AoD})$ , and  $\theta_{tilt}$  are the downtilt angles of the antenna. The gain of the antenna array at the TX is  $(\varphi_n^{AoA}, \vartheta_n^{AoA})$ , and  $\theta_{tilt}$ .

$$G_{TX}^{3D}(\phi_n^{AoD}, \theta_n^{AoD}, \theta_{tilt}) \approx G_{TX,H}(\phi_n^{AoD}) G_{TX,V}(\theta_n, \theta_{tilt}) \quad (4)$$

where the  $G_{TX}^{3D}$  and  $G_{TX}^{3D}$  are given by the method in [14] and [45].

$$G_{TX,H}(\phi^{AoD}) = -12 \left( \frac{\phi^{AoD}}{\phi_{3dB}} \right)^2 \quad (5)$$

and

$$G_{TX,V}(\theta^{AoD}, \theta_{tilt}) = -12 \left( \frac{\theta^{AoD} - \theta_{tilt}}{\theta_{3dB}} \right)^2 \quad (6)$$

where  $\phi^{AoD}$  is the azimuth angle between the user and the boresight of the array in the horizontal domain,  $\theta^{AoD}$  is the elevation angle between the user and the boresight of the array in the vertical domain,  $\varphi_{3dB}$  and  $\theta_{3dB}$  are the half-power beamwidth in horizontal and vertical domains, respectively. Equation (5) and (6) provide accurate 3D antenna radiation pattern in both the horizontal and vertical planes respectively.

We consider CA at the TX serving a single antenna RS and UEs with half duplex connection in this model. The path between TX and RS has a single bounce cluster giving us  $N$  number of paths. Using CA structure in Fig. 5, we consider the array dimension radius given by  $\rho = 4\lambda/l$ , where  $l = 4\lambda$ . If  $d_z = 4\lambda/M$  is the wavelength distance in meters between the first and second antenna elements in the  $z$  direction, then  $4\lambda(m-1)/M$  wavelengths may be used to estimate the placement of the third and fourth antenna components; where  $m = 1, \dots, M$  is the number of antenna elements on a ring in the  $z$ -axis.  $\lambda$  is the wavelength in meters. The angular position

of the  $n^{th}$  element of the  $m^{th}$  of the CA on the  $x$ - $y$  plane is

$$\varphi_s = 2\pi(n-1)/N \quad (7)$$

Consequently, the location vector of the elements can be expressed as

$$v_t \cdot x_s = \cos(\phi - \varphi_s) \sin \theta \quad (8)$$

Furthermore, the array response of  $s^{th}$  transmit antenna port of the CA is given by

$$[a_{TX}(\phi_n^{AoD}, \theta_n^{AoD})]_s = \exp \left( ik\rho \frac{4\lambda(m-1)}{M} \times \cos(\phi_n - \varphi_s) \sin \theta_n^{AoD} \right) \quad (9)$$

Similarly, the response of the  $u^{th}$  UE antenna port with regards to the 3D channel model is

$$[a_{RX}(\varphi_n^{AoA}, \vartheta_n^{AoA})]_u = \exp(ik(u-1)d_r \sin \varphi \sin \vartheta) \quad (10)$$

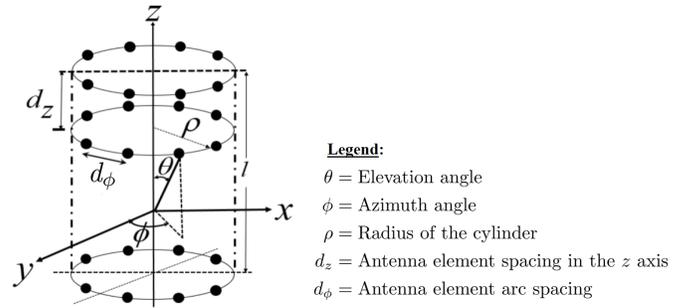

Fig. 5. Cylindrical Array Geometric Structure.

The final 3D GBSM channel model [33], [46], [47] of the communication link in the proposed system in Fig. 3 between a single antenna receiving port  $u^{th}$  and a CA transmitter antenna port  $s^{th}$  [14] is

$$H_{s,u}^{CA} = \sqrt{\frac{P_n \sigma_{SF}}{M}} \times \sum_{n=1}^N \alpha_n \left[ \begin{array}{l} \sqrt{G_{TX}^{3D}(\phi_n^{AoD}, \theta_n^{AoD}, \theta_{tilt})} \\ \times \exp \left( ik\rho(4\lambda(m-1)/M) \right. \\ \left. \times \cos(\phi_n - \varphi_s) \sin \theta_n \right) \\ \times \sqrt{G_{RX}^{3D}(\varphi_n^{AoA}, \vartheta_n^{AoA})} \\ \left. \times \exp(ik(u-1)d_r \sin \varphi \sin \vartheta) \right] \quad (11)$$

#### IV. SYSTEM ANALYSIS

##### A. Transmission between TX and RS

We presented a 3D GBSM mMIMO CR-NOMA system model [46], [48] with large antenna transmitters such as CA, as shown in Fig. 3 The system model takes into consideration two fundamental presumptions. First of all, TX and UEs cannot directly communicate with one another. Second, in a half-duplex communication mode, users are outfitted with a single antenna. There are two phases to the communication between TX and UEs. During the first step, the TX sends a superposition of two unique signals ( $\mathbf{x}$ ) to the relay, which

relays it to all UEs after decoding. The received signal ( $y_{RS}$ ) at the relay is

$$y_{RS} = \sqrt{\alpha_R} \mathbf{h}_{S,R} \mathbf{x} + \eta_R \quad (12)$$

where  $\eta_R$  is the additive white Gaussian noise (AWGN) with unit variance,  $\mathbf{h}_{S,R}$  is the proposed 3D GBSM channel coefficient between the TX and RS presented in (11). The distance-dependent path loss, denoted by the expression  $\alpha_R$ , depends on the distance between TX and RS and the path loss exponent. The use of the NOMA scheme necessitates that the power coefficients must be placed in the order  $\alpha_1 < \alpha_2$ , which corresponds to the channel gains.

### B. Transmission between RS and UE

1) *Application of DF Coding Scheme:* The TX sends a superimposed signal to the relay during the first time slot in accordance with NOMA concepts. The achievable rates ( $R_{x_1}^{RS}$  and  $R_{x_2}^{RS}$ ) for the relay to decode  $x_1$  and  $x_2$  are given [49] by

$$R_{x_1}^{RS} = \text{Blog}_2 \left( 1 + \frac{\alpha_1 \gamma |\mathbf{h}_{S,R}|^2}{\alpha_2 \gamma |\mathbf{h}_{S,R}|^2 + 1} \right) \quad (13)$$

and

$$R_{x_2}^{RS} = \text{Blog}_2 \left( 1 + \alpha_2 \gamma |\mathbf{h}_{S,R}|^2 \right) \quad (14)$$

where  $\alpha_1$  and  $\alpha_2$  are power allocation associated with  $x_1$  and  $x_2$  respectively.

Given that, the relay can decode the signal from the TX of the two NOMA users, the observable signal ( $y_k^{\text{DF}}$ ) at UE<sub>1</sub> and UE<sub>2</sub> in the second slot may be stated as

$$y_k^{\text{DF}} = \mathbf{h}_{R,k} \sqrt{\beta_k} \mathbf{x} + \eta_k \quad (15)$$

where  $k = 1, 2$  of users and  $\beta_k > 0$  is the power allocation coefficient of the  $k^{\text{th}}$  user, where  $\beta_1 + \beta_2 = 1$ .

Following the principle of NOMA scheme, the decoding order at the relay is  $x_1 \rightarrow x_2$ . The relay first detects  $x_1$  by treating  $x_2$  as noise. It then removes  $x_1$  from the  $y_{RS}$  in (12) to detect  $x_2$ . By employing successive interference cancellation (SIC), the signal-to-interference ratio (SINR) ( $\gamma_{1,2}^{\text{DF}}$ ) at UE<sub>1</sub> to detect  $x_2$  is given [49] by

$$\gamma_{1,2}^{\text{DF}} = \frac{\beta_2 \gamma |\mathbf{h}_{R,1}|^2}{\beta_1 \gamma |\mathbf{h}_{R,1}|^2 + 1} \quad (16)$$

The SINR ( $\gamma_{R,1}^{\text{DF}}$ ) for UE<sub>1</sub> to detect its own signal is given by

$$\gamma_{R,1}^{\text{DF}} = \beta_1 \gamma |\mathbf{h}_{R,1}|^2 \quad (17)$$

Similarly, the SINR ( $\gamma_{R,2}^{\text{DF}}$ ) at UE<sub>2</sub> is given [49] by

$$\gamma_{R,2}^{\text{DF}} = \frac{\beta_2 \gamma |\mathbf{h}_{R,2}|^2}{\beta_1 \gamma |\mathbf{h}_{R,2}|^2 + 1} \quad (18)$$

### C. Achievable Rates Analysis

The system's maximum achievable rate in the channel is when the BER goes to zero. The achievable rates of UEs may be determined based on the SINR values when the CSI is unknown at the transmitter with independent equi-powered transmissions. With regards to DF coding scheme, the achievable rates at the destination nodes from (16)–(18) are given by

$$\begin{aligned} R_{UE_1}^{\text{DF}} &= \min[R_{x_1}^{\text{RS}}, \text{Blog}_2(1 + \gamma_{R,1}^{\text{DF}})] \quad \text{and} \\ R_{UE_2}^{\text{DF}} &= \min[R_{x_2}^{\text{RS}}, \text{Blog}_2(1 + \gamma_{R,2}^{\text{DF}})] \end{aligned} \quad (19)$$

The relay transmits the decoded signals to all UEs during the second time slot.

### D. Outage Probabilities Analysis

To estimate the possibility of an outage event occurring in a data stream where the achievable data rate is lower than the encoded data rate [20], [50], we investigate the outage probability when the UE<sub>1</sub> is capable of detecting  $x_2$  and  $x_1$ . The outage probability ( $P_1$ ) of UE<sub>1</sub> in relation to the threshold signal-to-noise ratio (SNR) for CR-NOMA users UE<sub>1</sub>, UE<sub>2</sub> (denoting  $\Omega_1$ ,  $\Omega_2$ , respectively) may be characterized as follows based on the preceding definition:

$$\begin{aligned} P_1 &= [1 - P_r(\xi_{RS} \geq \xi'_{\Omega_2}, \xi_{RS} \geq \xi'_{\Omega_1})] \\ &\times [1 - P_r(\xi_{1,2}^{\text{DF}} \geq \xi'_{\Omega_2}, \xi_1^{\text{DF}} \geq \xi'_{\Omega_1})] \end{aligned} \quad (20)$$

where  $\xi'_{\Omega_1} = 2^{2\bar{\mathcal{R}}_1} - 1$  and  $\xi'_{\Omega_2} = 2^{2\bar{\mathcal{R}}_2} - 1$  are the decoding threshold with  $\bar{\mathcal{R}}_1$  and  $\bar{\mathcal{R}}_2$  being the target rate of UE<sub>1</sub> and UE<sub>2</sub> respectively.  $\xi_{RS}$  is the SINR between TX and RS,  $\xi_{RS}$  is the decoding threshold of the direct transmission to the RS.  $\xi_1^{\text{DF}}$  and  $\xi_2^{\text{DF}}$  are the SINR defined at (17) and (18). Similarly, the outage probability ( $P_2$ ) of UE<sub>2</sub> can be expressed as

$$P_2 = P_r(\xi_{RS} < \xi'_{\Omega_2}, \xi_2^{\text{DF}} < \xi'_{\Omega_2}) \quad (21)$$

### E. Bit-Error Rates Analysis

We provide the bit-error analysis for the proposed CR-NOMA system in accordance with the recommendations in the [51]. According to [51], the average percentage error ( $P_e^{\text{UE}_1}$ ) of the UE<sub>1</sub> under the assumption that its symbols are successfully and mistakenly recognized by using SIC processing is

$$\begin{aligned} P_e^{\text{UE}_1} &= \frac{1}{2} \left( 1 - \sqrt{\frac{\gamma_{B_1}}{2 + \gamma_{B_1}}} \right) \\ &+ \frac{1}{8} \left[ \sqrt{\frac{\gamma_{B_2}}{2 + \gamma_{B_2}}} - \sqrt{\frac{\gamma_{B_3}}{2 + \gamma_{B_3}}} \right] \\ &+ \frac{1}{8} \left[ \sqrt{\frac{\gamma_{B_4}}{2 + \gamma_{B_4}}} - \sqrt{\frac{\gamma_{B_5}}{2 + \gamma_{B_5}}} \right] \end{aligned} \quad (22)$$

where, for various constellation points of  $x_1$  and  $x_2$ , the SNRs are provided by with signal energies ( $\varepsilon_1$ ,  $\varepsilon_2$ ).

$$\begin{aligned} \gamma_{B_1} &= \frac{\varepsilon_1}{N_0} E \left[ |\mathbf{h}_{R,1}|^2 \right] \\ \gamma_{B_2} &= \frac{(\sqrt{2\varepsilon_2} + \sqrt{\varepsilon_1})^2}{N_0} E \left[ |\mathbf{h}_{R,1}|^2 \right] \\ \gamma_{B_3} &= \frac{(\sqrt{2\varepsilon_2} - \sqrt{\varepsilon_1})^2}{N_0} E \left[ |\mathbf{h}_{R,1}|^2 \right] \end{aligned} \quad (23)$$

and

$$\begin{aligned}\gamma_{B_4} &= \frac{(2\sqrt{2\varepsilon_2} + \sqrt{\varepsilon_1})^2}{N_0} E \left[ |\mathbf{h}_{R,1}|^2 \right] \\ \gamma_{B_5} &= \frac{(2\sqrt{2\varepsilon_2} - \sqrt{\varepsilon_1})^2}{N_0} E \left[ |\mathbf{h}_{R,1}|^2 \right]\end{aligned}\quad (24)$$

Equation (24) reflects the circumstance in which UE<sub>1</sub> is unable to detect its signals properly, whereas (23) describes the circumstance in which the signals are successfully detected. Comparably, the UE<sub>2</sub>'s overall average BER ( $P_e^{UE_2}$ ) performance from citation [51] is

$$P_e^{UE_2} = \frac{1}{4} \left[ \left( 1 - \sqrt{\frac{\gamma_{A_1}}{2 + \gamma_{A_1}}} \right) + \left( 1 - \sqrt{\frac{\gamma_{A_2}}{2 + \gamma_{A_2}}} \right) \right] \quad (25)$$

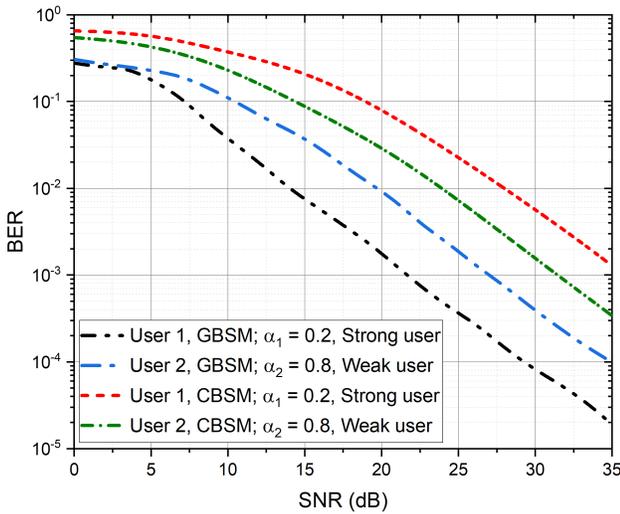

Fig. 6. BER of DF Schemes of the Proposed 3D Channel Model with CA.

where  $\gamma_{A_1}$  and  $\gamma_{A_2}$  are the SNRs of different signal constellation points expressed as

$$\begin{aligned}\gamma_{A_1} &= \frac{(\sqrt{2\varepsilon_2} + \sqrt{\varepsilon_1})^2}{N_0} E \left[ |\mathbf{h}_{R,2}|^2 \right], \\ \gamma_{A_2} &= \frac{(\sqrt{2\varepsilon_2} - \sqrt{\varepsilon_1})^2}{N_0} E \left[ |\mathbf{h}_{R,2}|^2 \right]\end{aligned}\quad (26)$$

## V. NUMERICAL RESULTS AND DISCUSSION

In this section, we validate the proposed 3D channel model for mMIMO CR-NOMA applications using simulation and numerical assessment. By setting the AoA cluster to 0.7 and the AoA offset standard deviations to ( $\sigma_{\Delta_\phi}, \sigma_{\Delta_\theta}$ ) at 2.6 GHz carrier frequency, we are able to analyze the proposed 3D GBSM models. Adjacent antenna elements on the  $z$  axis are separated by  $l = 4\lambda$  and are situated at a maximum radius of  $\rho = 2\pi/l$  from the cylinder centre with respect to the  $x, y$  plane. There were two circular arrays in the azimuth domain, each with  $N_t = 4$  elements, making up the  $2 \times N_t$  number of elements of the CA. Summary of other simulation parameters is listed in Table II

For the TX antenna topology, we calculated the channel coefficient based on the channel realization between the  $s$ th

TABLE II. 3D GBSM CR-NOMA MMIMO SIMULATION PARAMETERS

Parameter	Value
Frequency	2.6 GHz
$\theta_{tilt}$	$95^\circ$
$\theta_{3dB}$	$15^\circ$
$\phi_{3dB}$	$70^\circ$
Number of clusters	1
Number of users	2
Path-loss exponent	4
Environment	Urban Macrocell
Fixed power allocation	$\alpha_1 = 0.3, \alpha_2 = 0.7$

transmit antenna port and  $uth$  receive antenna port.  $\theta_{tilt} = 95^\circ$ ,  $\theta_{3dB} = 15^\circ$  and  $\phi_{3dB} = 70^\circ$  were taken into consideration to validate the proposed model for the 3D channel modeling from the TX to UEs through RS in Fig. 3. Furthermore, the 3GPP-specified Laplacian distributions are used to describe the power of the azimuth spectrum reaching the RS, multipath components for each AoA, and the multipath delay related to each AoD. We examined the DF in conjunction with the 3D GBSM channel. The outage probability (OP), achievable rate and BER are calculated for the DF coding scheme of Fig. 2 and compared with the outcomes of a system using theoretical channel models such as CBSM throughout.

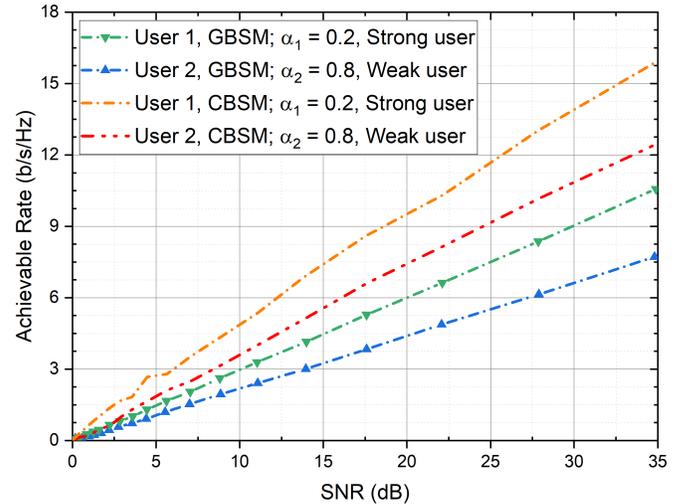

Fig. 7. Achievable Rates of DF of the Proposed 3D Channel Model with CA.

### A. BER Performance

The channel coefficients between both the transmitter and the relay have been produced using (11), respectively, for BER performance evaluation. Using (22) and (25), respectively, the BER of UE<sub>1</sub> and UE<sub>2</sub> was calculated. The BER for different SNR values in dB for the proposed 3D GBSM channel model of CA uses 68 antenna components is shown in Figs. 6.

In Fig. 6, the performance of UE<sub>1</sub> is better than that of UE<sub>2</sub>, which is owing to the fact that UE<sub>1</sub> is closer to the RS and has a good channel condition than that of UE<sub>2</sub>. It should be noted that 3D GBSM models have high computational complexity with unpredictability parameters which could affect

TABLE III. COMPARISON OF OP AND BER WITH PRIOR WORKS AT SNR OF 20 dB

Ref	Antenna Type	No. of Users	BER	OP
Proposed	Multiple antenna TX, single antenna RS and UE	2	$10^{-2.85}$	$10^{-2.50}$
[20]	Single antenna TX, RS and UE	2	$10^{-2.10}$	$10^{-1.50}$
[52]	Single antenna TX, RS and UE	2	-	$10^{-0.80}$
[53]	Single antenna TX, RS and UE	1	$10^{-2.70}$	-
[54]	Single antenna TX, RS and UE	2	$10^{-4.96}$	-
[55]	Multiple antenna TX, single antenna RS and UE	1	-	$10^{-2.45}$
[56]	Multiple antenna TX, UE, single antenna RS	1	-	$10^{-0.28}$

the performance of the system. However, our results on the BER using DF coding strategy at 20 dB are comparable to prior works done in the literature that employs the CBSM channel models (Table III). This may be due to the use of the antenna element placement vector, which we defined based on the physical structure of the antenna as described in Fig. 5. Table III compares the proposed system’s outage probability and BER performance to previous research studies that employ the CBSM channel model which confirms the results of Fig. 6. Except for [52], which contains  $M$  relays, all other references including the proposed system employ a single relay device.

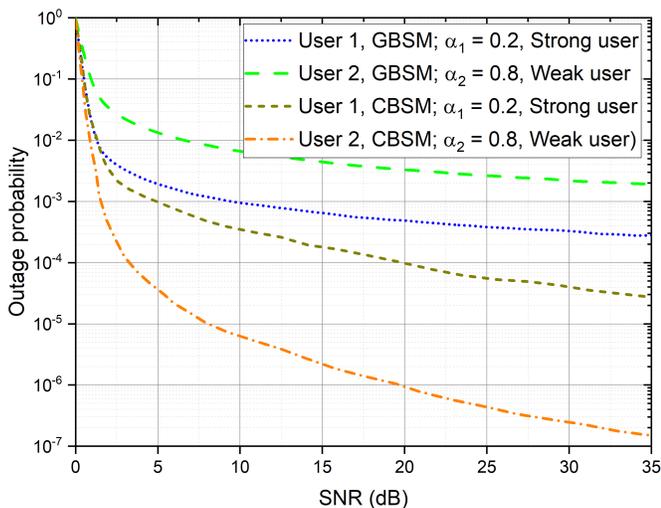

Fig. 8. Comparison of OP of Two Users using DF Scheme of the Proposed Channel Models with CA.

In contrast to GBSM, which has high computational complexity, a high proportion of random propagation, and channel parameters like path-loss, delay profile, tilt angle, angle of arrival, angle of departure, etc. that reflect realistic and practical mMIMO systems, CBSM is primarily used for link-level simulation and to analyze the theoretical performance of mMIMO systems. Consequently, CBSM performance is

superior to GBSM as indicated in Table III and the figures above.

### B. Achievable Rate and Outage Probability Performances

Equation (19) calculates the achievable rates of DF for the achievable rate analysis. In Fig. 7, the achievable rate of using DF coding scheme shows considerable improvement as compared with the results of CBSM. We demonstrate the outage performance of the proposed system as a function of transmit SNR in Fig. 8 by using 3D GBSM channel model with CA in (11). The performance differences between two users, UE<sub>1</sub> and UE<sub>2</sub>, extends over the entire SNR range. The system outage performance may be significantly improved by changing the transmitter array configuration, increasing the TX’s antenna capacity, and maintaining a single antenna at the relay node. Furthermore, it reveals that UE<sub>2</sub> has a worse outage than UE<sub>1</sub>. This is expected since further from the RS than UE<sub>1</sub>, and therefore, it has poor channel condition.

Again, the system uses less transmit power at the relay for RS–UEs links to process the second-hop signal, which decreases the performance of the hop’s outage. Fig. 8 gives the outage probability of the two users using the 3D GBSM channel and the DF relay coding strategy. It can be demonstrated that the OP of the DF coding scheme performs better with the 3D GBSM channel model.

## VI. CONCLUSION AND FUTURE WORK

We provided a 3D GBSM channel model between TX–RS and TX–UEs in this study. We investigated a two-stage mMIMO CR-NOMA downlink system with a 3D GBSM channel model, where the transmitter is represented by CA. We defined the antenna placement vector based on the physical structure of the antenna design to reduce the computational complexity of the channel. For improved channel performance, the proposed 3D GBSM channel model uses a DF network coding scheme. For the two-stage system, we calculated the probability of an outage, the achievable rate, and the BER. In terms of outage probability, attainable rate, and other crucial network performance parameters, integrating NOMA with cooperative relay transmission mechanism guarantees a notable boost to the performance of the 5G networks. The outage probability of cooperative relay integrated NOMA over a 3D GBSM channel is explored in this work. Lastly, despite the fact that the proposed 3D GBSM channel model has a greater computational cost in terms of complexity, the results show that the differences in performance between CBSM and GBSM channel models are marginal. The marginal performance of CBSM over the GBSM model is due to the channel model’s lower computing complexity and less random channel parameters, which makes it suitable for theoretical analysis of mMIMO systems. The research may be expanded to include millimetre-wave CR-NOMA with multiple antennas at the TX, RS, and UE. The influence of spatial correlation of antenna array arrangement on 3D GBSM performance in CR-NOMA system may be explored for certain applications such as high-speed train communication, unmanned aerial vehicle, the vast internet of things, and so on.

**Abstract**—House hunting, or the act of seeking for a place to live, is one of the most significant responsibilities for many families around the world. There are numerous criteria/factors that must be evaluated and investigated. These traits can be both statistically and qualitatively quantified and expressed. There is also a hierarchical link between the elements. Furthermore, objectively/quantitatively assessing qualitative characteristics is difficult, resulting in data inconsistency and, as a result, uncertainty. As a result, ambiguity must be dealt with using the necessary processes; otherwise, the decision to live in a particular property would be incorrect. To compare criteria, the Analytic Hierarchy Process (AHP) is employed, evidential reasoning is used to evaluate houses based on each criterion, and TOPSIS is used to rank house sites for selection. It was necessary to analyze qualitative and quantitative elements, as well as economic and social features of these residences, in order to arrive at the final order of houses, which was not an easy process. As a result, the authors developed a decision support model to aid decision makers in the management of activities related to finding a suitable dwelling. This study describes the development of a decision support system (DSS) capable of providing an overall judgment on the location of a house to live in while taking into account both qualitative and quantitative factors.

**Keywords**—AHP; multiple criteria decision Making (MCDM); uncertainty; evidential reasoning

## I. INTRODUCTION

Chittagong is a lovely town with a business district that looks out over the port. Because of its tranquil and secure environment, Chittagong attracts a large number of families. However, house seeking is a tedious activity in Chittagong and around the world. It's difficult to find the right neighborhood to reside in without first conducting extensive research into the city's many communities. For a home buyer or renter, selecting the most amazing house is a multi-step procedure. It necessitates the measurement and evaluation of a large number of criteria at the same time. Because several of these criteria are linked, they frequently collide, with one improvement usually resulting to a decrease in another [1]. Furthermore, because house features are quantifiable and qualitatively expressed, decision-makers must consider both quantitative and subjective data [2]. House hunting in Bangladesh is a terrible since various real estate businesses employ static ways to find houses

in databases [1], such as the typical search methodology as shown in Fig. 1. This is a time-consuming procedure that yields no relevant results. As a result, potential homeowners may still miss out on their desired property.

In real life, MCDM issues are fairly common. One of the issues is house hunting. Many concepts have been proposed to address the home hunting dilemma but no model provides proper ranking or human level accuracy due to some limitation. Analytical Hierarchical Process technique can handle both quantitative and qualitative information [1, 2]. A multiple criteria decision model with a hierarchical structure is provided for the house-buying process, in which both quantitative and qualitative information is represented in a combined manner [3, 4]. After that, the AHP [5] approach is used to fully investigate the house hunting problem. As a result, the paper discusses the design, development, and implementation of a Decision Support System [6] that can accurately find a suitable house in a short amount of time at a low cost but this paper could not address the uncertainty.

Research [7] contains a lot of evidence. Using a belief structure to characterize an assessment as a distribution is advised for house seeking with 16 criteria and 5 alternatives. Four alternative evaluation grades were used to calculate the degree of belief: excellent, good, average, and bad. The ER approach was used to compute the cumulative degree of trust for a hierarchy's top level attribute based on its bottom level

Fig. 1. Scenario in Bangladesh.

attribute. After that, the utility function was used to rank the various options. Many authors have solved various problems using AHP. The AHP technique was presented by Lakshmanan [8] for the condition ranking of reinforced concrete bridges. Rashidi et al. [9] developed a decision-making system for steel bridge asset management that meets acceptable safety, functionality, and sustainability criteria. Mahmoud et al. [10] demonstrated how to conduct a genuine bridge evaluation, which includes visual examination and data collection in order to provide an accurate estimate of the bridge's restoration and road network priority. As a result, a Bridge Overall Need Indicator was developed, which assigns a rating to bridges depending on their condition and priority for maintenance. For the selected bridges and their rehabilitation priority ranking, the Approach for Order Preference by Similarity to an Ideal Solution (TOPSIS) [11] technique is also used as a multi-criteria analysis tool. The Euclidian distances between each option from the ideal and anti-ideal alternative are determined when the ideal and anti-ideal alternatives have been found. Finally, the relative closeness (RC) of the bridges is shown, with the bridge with the lowest RC obtaining the highest repair priority. Paper [12] experiments with *Temnothorax albipennis* ant colonies in order to select the best one, compare and contrast huge and tiny colonies. The ant [13] colony house-hunting challenge has been approached from a distributed computing standpoint [14]. Where two different types of algorithms are shown.

There has never been a study that combined the AHP, TOPSIS, and evidential reasoning to develop a house priority ranking that has been shown to be more precise and accurate than previous methods. In this approach, a new concept for selecting outstanding houses is suggested. The goal hierarchy [15] structure is developed in three stages with the help of interactive groups [16]. Real estate professionals, economic specialists, and users make up four different types of decision makers. Each expert developed criteria based on their knowledge and experience. The Analytic Hierarchy Process (AHP) method is used to compute Saaty's scale criteria weights [17, 18]. Depending on whether the criterion is qualitative or quantitative; it is assigned an interval rating. These ratings are also used to rate the houses within each category. Each group developed a set of common evaluations based on feedback from all of the participants. The evidential reasoning approach is used to determine the house assessments based on each criterion. The aggregated belief judgment matrix is used to determine the final house evaluations. Furthermore, the Technique for Order Preference by Similarity to an Ideal Solution (TOPSIS) [17] technique is utilized to rank the shortlisted houses based on a multi-criteria analysis. The Euclidian distances between each option from the ideal and anti-ideal alternative are determined when the ideal and anti-ideal alternatives have been found. Finally, the relative closeness (RC) is displayed, with the option with the lowest RC being chosen first. The proposed solution is based on a multi-criteria analysis, which would improve decision-making quality in the home site selection process.

The study is broken into five sections. Sections II, III and IV covers the theoretical basis of multi-criteria procedures like AHP, TOPSIS, and evidential reasoning, followed by a discussion of the suggested model. Section V states the proposed concept. In Section VI, the obtained results are

provided, and throughout the discussion and the obtained results are compared to those of previous studies. This section also examines the new proposed model's advantages and disadvantages.

## II. AHP FOR HOUSE HUNTING

In Bangladesh and around the world, the home hunting problem (HHP) is a big concern [2]. It takes into account both qualitative and quantitative criteria, such as closeness to hospitals, major roads, educational institutions, shops, offices, recreation centers, and police precincts. Multiple criterion's decision-making (MCDM) is a technique for determining the "best" home for a customer by balancing a number of aspects. The majority of these factors are linked in some way. Furthermore, as one criterion improves, it is common for many others to improve as well. Using language traits, DMs can make subjective assessments more easily. However, merging these two sorts of indicators, one quantitative and the other linguistic, can be difficult, which could generate issues when evaluating solutions. As a result, any MCDA method must be capable of aggregating these two types of measures consistently and reliably, resulting in a ranking of all decision options [19]. We gave some of the house searchers the same list of criteria they used for the house hunting problem [2] and asked them to choose the factors they consider when purchasing a property. We found that 80% of house hunters failed to meet the following criteria: pleasant neighborhood, proximity to stores, proximity to bus and rail stations, proximity to recreation center, police precincts, property insurance, and population density [2]. Qualitative and quantitative parameters such as proximity to a main road, a hospital, an office, a school, and cost per square foot [1] impact house hunting.

The nine comparisons in Fig. 2 were combined into a matrix. We have a 9 by 9 matrix because we have 9(nine) comparisons. We just need to fill up the upper triangular matrix because the diagonal components of the matrix are always 1. The following two rules [1, 20] are used to fill the upper triangular matrix:

1. Utilize the true judgment value if the judgment value is on the left side of one.
2. Utilize the reciprocal value if the judgment value is on the right side of 1. utilize the reciprocal values of the top

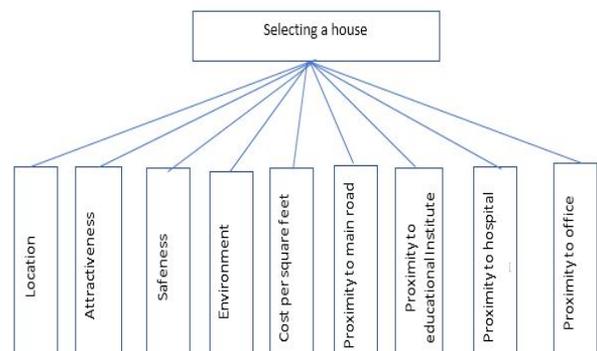

Fig. 2. Structure of Problem.

TABLE I. COMPARISON MATRIX OF CRITERIA

Criteria	Location	Attractiveness	Safeness	Environment	Prox. edu. org.	Prox. hospital	Prox. main roads	Prox. office	Cost per sq. ft
Location	1	2	1/3	1/4	1/5	1/6	4	1/5	1/2
Environment	4	3	1/4	1	4	1/3	7	1/3	1/2
Safeness	3	2	1	4	5	2	3	2	2
Prox. edu. org.	5	6	1/5	1/4	1	1/8	9	5	2
Prox. hospital	6	4	1/2	3	8	1	8	1/7	1/5
Prox. main roads	1/4	1/2	1/3	1/7	1/9	1/8	1	5	2
Prox. office	5	4	1/2	3	1/5	7	1/5	1	1/2
Cost per sq. ft	2	4	1/2	2	1/2	5	1/2	2	1

diagonal [1] to fill the lower triangular matrix. If  $a_{ij}$  is a row  $i$  and column  $j$  element in the matrix, the bottom diagonal is filled using eq. (1):

$$a_{ij} = \frac{1}{a_{ji}} \quad (1)$$

Users define their preferences for one criterion over another is illustrated in Table I, in the form of a comparison matrix. The comparison matrix's entries, which range from 1 to 9, represent the degree to which one criterion is preferred over another. For example, the 9 in the "Proximity to education institution" row against "Proximity to main roads" column indicates that "Proximity to education institution" is preferred over "Proximity to main road".

#### A. Criteria Weights

It is important to normalize the prior comparison matrix in Table I, in order to evaluate and assign relative weights to each condition. Normalization is performed by dividing each table value by the total column value, as shown in eq. (2).

$$Z_{ij} = A_{ij} / \sum_{i=0}^n A_{ij} \quad (2)$$

The sum of all elements in a column in the normalized primary Eigen vector displayed in Table II is 1. Because it is normalized, the total of all elements in a column is 1.

The priority vector is then calculated by averaging each row in Table I and setting the overall priority vector to 1.

TABLE II. CRITERIA WEIGHTS

Location	0.05
Attractiveness	0.04
Safeness	0.17
Environment	0.10
Prox. edu. org.	0.15
Prox. hospital	0.16
Prox. mainroad	0.08
Prox. office	0.14
Cost per sq.ft	0.12

The priority vector represents the relative weights of the items we've compared. 5% for location, 4% for attractiveness, 17% for safety, 10% for the environment, 15% for proximity to education, 16% for proximity to hospital, 8% for proximity to main road, 14% for proximity to office, and 12% for cost per square foot. The most important selection criterion for a property buyer is safety, which is followed by the other elements. More than their rating is required in this scenario. The relative weight, in reality, is a ratio scale that can be divided among them. Customers value safety 3.4 (=17/5) times more than location and 2.1 (=17/8) times more than accessibility to a major route, for example.

### III. EVIDENTIAL REASONING

The evidential reasoning algorithm lies at the heart of the ER approach. This method was created using an evaluation analysis model [1, 21] and the Dempster-Shafer theory's evidence combination rule [22, 23], which is well-suited to dealing with incomplete uncertainty [24]. The ER method models an assessment as a distribution using a belief framework. It differs from prior Multi Criteria Decision Making (MCDM) modeling systems in that it reaches a result using evidence-based reasoning [15]. This method has the advantage of being able to deal with the uncertainties that arise in MCDM situations when dealing with quantitative and qualitative data [1, 2].

#### A. Assessment

The ER algorithm has strategies for dealing with such ignorance, as will be demonstrated. It's also important to distribute the degree of confidence throughout evaluation classes for some quantitative input data. If the hospital is within 1 kilometer of the residence, it is considered great, average if it is within 1.5 kilometers, ordinary if it is within 2 kilometers, and horrible if it is within 3 kilometers. However, when a hospital is only 1.3 kilometers away, it can be both beneficial and dangerous. It is crucial, however, that we recognize the distinction between exceptional and regular belief. This phenomena can be calculated using the method provided below [1, 23].

$$\beta_{n,i} = \frac{h_{n+1} - h}{h_{n+1,i} - h_{n,i}}, \beta_{n+1,i} = 1 - \beta_{n,i} \text{ if } h_{n,i} \leq h \leq h_{n+1,i} \quad (3)$$

As a result, equation (3) can be used to evaluate the distribution of degree of belief within 1.3 km of the hospital's

position from the residence, obtaining the following results: (Excellent, 0.4), (Good, 0.6), (Average, 0), (Bad,0).

**B. Weight Normalization**

Determining the value of the traits is crucial since each characteristic serves a specific purpose in the decision-making process. At level , there are eight sub attributes in the “Facilities” category, including proximity to educational institutions, major roads, hospitals, shops, offices, bus and railway stations, police precincts, and recreation centers. When evaluating their parent characteristic “Facilities”, it’s critical to determine which of the eight features is the most important. This can be accomplished using a variety of weight normalization approaches, including Eigenvector, AHP, and Pairwise comparison [1, 24].

$$\omega_i = \frac{y_i}{\sum_{i=1}^j y_i}; i = 1 \dots \dots \dots j \tag{4}$$

$$\sum_{i=1}^L \omega_i = 1 \tag{5}$$

Equation (4) is used to estimate the significance of an attribute ( $w_i$ ). This has been designed by dividing the significance of an element ( $y_i$ ) by the  $\sum_{i=1}^j Y_i$  summation of significance of all the elements. Equation (5) is to see if the sum of the importance of all the qualities was one or if they were normalized.

**C. Basic Probability Assignment**

Not resembles to Dempster-Shafer [25] evidence theory finding degrees of belief in the attribute evaluation grades must be converted into fundamental probability masses using equation (6). The fundamental probability mass represents the precise belief provided to an attribute’s n-th evaluation grade. It also demonstrates how strong the evidence is in support of the attribute’s n-th evaluation grade( $H_n$ ) [23].

$$m_{n,i} = m_i(H_n) = w_i \beta_{n,i}(a_i), \tag{6}$$

$n = 1, \dots, N; i = 1, \dots, L$

After the i-th attribute has been examined, the residual probability mass unassigned to any given grade can be calculated using the equation below.

$$m_{H,i} = m_i(H) = 1 - \sum_{n=1}^N m_{n,i} = 1 - w \sum_{n=1}^N \beta_{n,i}(a_i), i = 1, \dots, L \tag{7}$$

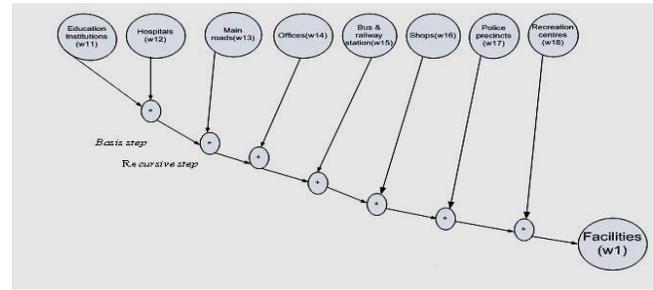

Fig. 3. Recursive Assessment.

**D. Kernel of ER Approach**

The ER approach calculates the cumulative degree of confidence at the top level attribute of a hierarchy using the hierarchy’s bottom level features, also known as fundamental attributes. An excellent information synthesizing/aggregation process achieves this. A recursive ER algorithm is used to aggregate fundamental attributes, which can be stated as  $A(S) = \{(H_n, \beta_n), n = 1, \dots, N\}$  evaluating the cumulative degree of confidence of the top level attribute in a hierarchy. In this recursive ER algorithm, all the basic attributes are aggregated recursively in the following manner as shown in Fig. 3.

$$M_1 = \begin{bmatrix} m_{11} & m_{21} & m_{31} & m_{41} & m_{H1} \\ m_{12} & m_{22} & m_{32} & m_{42} & m_{H2} \\ m_{13} & m_{23} & m_{33} & m_{43} & m_{H3} \\ m_{14} & m_{24} & m_{34} & m_{44} & m_{H4} \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ m_{18} & m_{28} & m_{38} & m_{48} & m_{H8} \end{bmatrix}$$

From matrix  $M_1$ , it can be seen that each sub-attribute is associated with five basic probability assignment (bpa), where four first four bpa ( $m_{11}, m_{21}, m_{31}, m_{41}$  are associated with four evaluation grades ( $H_1, H_2, H_3, H_4$ ) and final bpa i.e. is showing the remaining probability mass unassigned to any individual grades after the assessments on sub-attribute have been considered. The aggregation is carried out in a recursive way. This aggregation can be achieved by using the following equation(8) , which will yield combined bpa (such as  $m_{1I(2)}, \dots, m_{4I(2)}$ ) as shown in the first row of the second matrix [1, 23].

$$m_{1I(2)} = K_{I(2)}(m_{11}m_{12} + m_{H1}m_{12} + m_{H2}m_{11}) \tag{8}$$

Similarly  $m_{2I(2)}, m_{3I(2)}, m_{4I(2)}$  can be calculated.

Where  $K_{I(2)}$  is a normalization factor used to resolve the conflict and this can be calculated using the equation (9) [1, 23].

$$K_{I(i+1)} = \left[ 1 - \sum_{n=1}^N \sum_{t=1, \frac{t}{2} \neq n}^N m_{n,(i)} m_{t,i+1} \right], i = 1, \dots, L - 1 \dots \tag{9}$$

Equation (9) represents the more generalized version of equation (7) [1, 23].

$$\{H_n\} : m_{n,(i+1)} = K_{I(i+1)} [m_{n,T(i)} m_{n,i+1} + m_{n,(i)} m_{H,i+1} + m_{H,T(i)} m_{n,i+1}] \quad (10)$$

$$m_{H,I(i)} = \overline{m_{H,I(i)}} + \tilde{m}_{H,I(i)} \quad n = 1, \dots, \dots, N \quad (11)$$

$$\{H\} : \tilde{m}_{H,I(i+1)} = K_{I(i+1)} [\tilde{m}_{H,I(i)} \tilde{m}_{H,i+1} + \tilde{m}_{H,T(i)} \tilde{m}_{H,i+1} + \tilde{m}_{H,(i)} \tilde{m}_{H,i+1}] \quad (12)$$

$$\{H\} : \bar{m}_{H,I(i+1)} = K_{I(i+1)} [\bar{m}_{H,I(i)} \bar{m}_{H,i+1}] \quad (13)$$

The combined degree of belief is calculated using equation 14 based on the final combined basic probability assignment, which in this case is “facilities”.

$$M_2 = \begin{bmatrix} m_{1/(2)} & m_{2/(2)} & m_{3/(2)} & m_{4/(2)} & m_{HI/(2)} \\ m_{13} & m_{23} & m_{33} & m_{43} & m_{H3} \\ m_{14} & m_{24} & m_{34} & m_{44} & m_{H4} \\ m_{15} & m_{25} & m_{35} & m_{45} & m_{H5} \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ m_{18} & m_{28} & m_{38} & m_{48} & m_{H8} \end{bmatrix}$$

$$\{H_n\} : \beta_n = \frac{m_{n,I(L)}}{1 - \bar{m}_{H,I(L)}}, n = 1, \dots, \dots, N \quad (14)$$

$$H : \beta_H = \frac{\tilde{m}_{H,I(L)}}{1 - \bar{m}_{H,I(L)}}, \text{ Where } m_{n,I(1)} = m_{n,1} (n = 1, \dots, N) \quad (15)$$

$\beta_n$  and  $\beta_H$  represent the belief degrees of the aggregated assessment, to which the general factor (such as “facilities”) is assessed to the grade  $H_n$  and H, respectively. The combined assessment can be denoted by  $S(y(a)) = \{(H_n, \beta_n(a_i)), n = 1, \dots, N\}$ . It has been proved that  $\sum_{n=1}^N \beta_n + \beta_H = 1$ . As shown in Table II, the recursive ER technique runs over each piece of evidence one by one. The belief decision matrix was created by combining all of your beliefs using equation (16) [2, 23].

$$\beta_j = \frac{\mu \times \left[ \prod_{k=1}^L \left( (\omega_k \beta_{jk} + 1 - \omega_k \sum_{j=1}^N \beta_{jk}) \right) - \prod_{k=1}^L (1 - \omega_k \sum_{j=1}^N \beta_{jk}) \right]}{1 - \mu \times \left[ \prod_{k=1}^L (1 - \omega_k) \right]} \quad (16)$$

#### IV. THE TOPSIS METHOD

TOPSIS is a method for rating preferences based on how near they are to the ideal solution, not as A Belief Rule Base (BRB) [26, 27] it is a conceptual modeling structure that facilitates the capturing of ambiguous information. TOPSIS is a helpful and practical non-linear decision-making method for real problems [11]. In accordance with this theory, ideal alternative is the one that is closest to the positive ideal option rather than

negative one [11]. The positive ideal choice increases benefits while decreasing costs, whereas the other one (negative) increases costs while decreasing benefits. Hence the positive ideal option contains all conceivable ideal criteria values, rest one contains all attainable worst criterion values [11]. Each criteria is expected to increase or decrease over time. If each criterion has a monotonic ascending (or falling) efficient mechanism, the positive ideal option with the best assessment criteria and the rest one with the lowest criteria values may be determined [28]. To find the distance between positive and negative ideal decision Euclidean distances is being used. Best order of possibilities is determined by comparing Euclidean distances.

#### V. THE PROPOSED DECISION CONCEPT

Vagueness predominates in real-life decisions due to insecurity, inaccessible, and ambiguous information such as fuzziness, imprecision, incompleteness, and ignorance [28]. Rather than being made by a single decision maker, the bulk of decisions are made by a group of decision makers. As a result, the focus of this research is on decision-making under uncertainty and the use of multiple decision-makers in groups to solve a belief multi-criteria decision-making problem. The decision concept was created to describe decision makers’ judgments in ambiguous decision situations [29]. The decision concept was developed and is used to describe decision makers’ judgments in unclear choice circumstances. Because of the aforementioned setting, the AHP-evidential reasoning-TOPSIS approach is employed to develop the choice concept for the group multi criteria decision making problem using 13 phases [29].

Phase 1: Addressing the issue and bringing together the required expertise and parties. Organizing them into groups and deciding on a study subject.

Phase 2: The second part involves locating and mapping old pedestrian bridges.

Phase 3: Establish a goal hierarchical system by establishing the core goal and then dividing up it into objectives, criterion, and choices at the bottom level.

Phase 4: Using the AHP approach, create a comparison matrix for every group.

Phase 5: The priority vector and highest eigenvalue of each matrices are obtained once each group has defined its criterion weights.

Phase 6: Using the consistency ratio to determine the reliability of comparison matrices.

Phase 7: Create a belief choice matrix for every group and assign weights to the decision-makers’ groupings.

Phase 8: Create a belief choice matrix that includes all of your beliefs.

Phase 9: Normalize the group belief choice matrix once it has been aggregated.

Phase 10: Specify the A+ and A- characters, which represent positive and negative ideal alternatives.

Phase 11: Using the Euclidean distance, , calculate the distance( $E_i^+$  and  $E_i^-$ ) between the existent options and the positive and negative ideal alternatives.

Phase 12: Use the following method to determine the degree of resemblance to the ideal alternative.

Phase 13: Prioritize the options using RCi.

### VI. RESULTS AND ANALYSIS

A numerical representation of the suggested decision notion is included in this section in Table V. The AHP method is used to calculate the criteria weights. The distance between each choice and the positive-ideal and negative-ideal alternatives is determined using the multi-criteria TOPSIS technique, which scores the options. Each criterion has a minimum and maximum value, allowing benefit and cost criteria to be distinguished. Houses are given a priority rating as a result of the proposed method. The ranking results are then presented to the final decision maker, who is now better equipped to make decisions concerning the next steps in the home selection process. We looked at the ER strategy and how to put it into practice in the previous section. As a result, we'll look at the results of applying the proposed idea to dwelling quality in Chittagong in this part. As shown in Fig. 1, house quality can be divided into two categories: objective and subjective qualities, with each attribute weighted. Positive and negative ideal alternatives are found form Table III.

As a result, the residential site with the shortest relative closeness receives the lowest score. Table III shows the priority ranking of housing locations with RC = 0.81 and 0.05, Devpahar is ranked first, whereas Jamal Khan is ranked last. These studies were compared to a proposed decision concept based on the AHP-evidential reasoning-TOPSIS methodology, in which collected data is run through the AHP, TOPSIS, and AHP-TOPSIS, and the results are compared to a proposed decision concept based on the AHP-evidential reasoning-TOPSIS methodology. The results are presented in the Table IV From the given outcomes, it is obvious that the combination of the two multi-criteria methods gain more precise ranking, but still not quite similar as obtained by the proposed approach. Table V shows belief determination matrix created using the alternate assessments of all groups.

### VII. CONCLUSION

The AHP-evidential reasoning-TOPSIS approach was used to handle multiple criteria house hunting challenges with unclear, incomplete, imprecise, and/or missing information. It is fair to argue that our proposed notion is a mathematically accurate technique for measuring housing quality since it uses

a belief structure to characterize a judgment as a distribution. In several aspects, this technique varies from previous Multi Criteria Decision Making systems. As a result, because the attribute can be ordered or numbered at random, the AHP-evidential reasoning-TOPSIS technique can accommodate new attributes without having to redo the previous assessment. As a result, the order in which the essential qualities are collected has no bearing on the final findings. In contrast to Saaty's AHP technique, any number of additional homes can be analyzed without triggering a "rank reversal problem". The proposed decision paradigm's merits include the correctness and assurance of the achieved outcomes. Using a mix of multi-criteria approaches, more specific findings can be determined. The concept is simple to put into practice and may be applied to any decision-making problem.

### VIII. FUTURE WORKS

In a future study an expert system [30, 31] will be implemented into the suggested decision concept to reduce human involvement because stakeholders and experts must be involved throughout the process.

**Abstract**—In recent decades, it has been shown that epidemiological surveillance is one of the most valuable tool that public health has, since it allows us to have an overview of the population general health, thus allowing to anticipate outbreaks of epidemics by helping in timely interventions. Currently there is an increase in cases of dengue disease in several regions of Peru. Therefore, to control this outbreak and to help population centers and human settlements that are far from the city this work puts forward a drone system with an object recognition algorithm. Drones are very efficient in terms of surveillance, allowing easy access to places that are difficult for humans. In this way, drones can carry out the field work that is required in epidemiological surveillance, carrying out photography or video work in real time, and thus identifying infectious foci of diverse diseases. In this work, an object detection algorithm that uses convolutional neural networks and a stable detection model is designed, this allows the detection of water reservoirs that are possible infectious sources of dengue. In addition the efficiency of the algorithm is evaluated through the statistical curves of precision and sensitivity that result of the training of the neural network. To validate the efficiency obtained, the model was applied to test images related to dengue, achieving an efficiency of 99.2%.

**Keywords**—Epidemiological surveillance; drones, neural networks; recognition algorithms

## I. INTRODUCTION

Currently there is an increase in dengue cases in several areas of Peru, and for this does not exist a rapid surveillance system to detect areas where there is possibly dengue. At the moment Peru carries out traditional surveillance of going from house to house to carry out the detections of cases of dengue, through blood tests, filling out symptom files, etc.

The large increase in dengue cases in Peru occurs because the epidemiological focus of dengue is not being taken into account as before the pandemic, given that during the pandemic health personnel have focused mainly on COVID-19 leaving aside this disease that has afflicted Peru for approximately 30 years. Therefore, the most affected are the population centers and human settlements that have roads or accesses far from the city and with narrow main roads. Faced with this, there are various solutions through prevention campaigns against dengue, but in terms of the use of algorithms for the detection of dengue, they are very unusual and at the same time efficient.

Currently, the National Center for Epidemiology, Disease Prevention and Control (CDC - MINSa), shows in its epidemiological bulletin that there is currently a considerable increase in dengue cases in several regions of our country. Therefore,

there is a way to support the surveillance carried out by the prevention system, using drones, since these devices can carry out aerial surveillance in areas of difficult access that detect dengue infectious foci.

## II. RELATED WORKS

Regarding the technology of drones currently used, in [1] they provide in their article a complete review of current and future drones applied in medicine. For example, in 2013, drones were used in the aftermath of Typhoon Haiyon in the Philippines to assess initial storm damage and prioritize relief efforts. Another example mentions a study conducted in southern Italy, they used drones equipped with high-resolution photogrammetry software to accurately access and predict cancer risk from high-level copper concentrations in agricultural areas. And like other studies mentioned in the article, it highlights the advantage of using the drone as an aerial surveillance tool to assess biological risk areas and natural disaster areas. In addition, in [2], they carried out a project in which the design and construction of a drone with optimal characteristics to carry out photogrammetric plans to later be used in telecommunication networks, such as work in fiber optic networks, is proposed, because these they are found in places of difficult access such as high forests and steep mountains, for the design of both the chassis and the electronic part, easily accessible materials were used, which helps to design the drone according to the calculations made to take advantage of its resources and dimensions, since they were evaluated with commercial devices.

Regarding the drones used in epidemiological surveillance, in [3] the “IRIS PX4” drone was used as an identifier of violations of social distancing rules for an intelligent surveillance system against COVID-19, which the device uses two cameras, a frontal one for the detection of obstacles and another ventral one for the detection of people, in addition that it has an integrated GPS that locates the area observed by the drone. On the other hand, in [4] drones were used to transport blood samples, medicines, supplies in cases of disasters such as humanitarian aid and even as a portable laboratory. To carry out these tasks, Quadcopter drones (4 rotors, 20km range, 36km/h speed and with a maximum payload of 2kg) were used, most of DJI brands, for example, the DJI Phantom 4 Pro drone. It is mentioned that the models of medical drones made by the Zipline company, which are fixed-wing drones capable of flying at a speed of 128km/h with a range of 160km (round trip) while carrying a payload of 1.75 kg, are efficient

in terms of transporting medicines, laboratory samples, blood donations, etc. Also in [5], drones are used to review assigned areas infected with malaria, which are sent by GPS to only capture images within the assigned geographic space, in this way they compare the progress of malaria in that area with respect to previous years such as the of 2013 and 2014.

In reference to its application in image and video acquisition, a study was carried out in [6] that aims to produce accurate geospatial 3D data by acquiring images captured by the drone or unmanned aerial vehicle. For this reason, an image of an area of the Najran University campus in Saudi Arabia was captured using a DJI Mavic Pro Platinum drone. Similarly in [7], they mention that the use of unmanned aerial vehicles (UAV) provides the option of collecting detailed spatial information in real-time at a relatively low cost and thus avoids limitations associated with satellite data (such as cloud pollution, low resolution, bad camera angle and shooting time for taking pictures). Therefore, in their inspection of breeding habitats through drone surveillance, they used a low-cost Phantom 4 Pro DJI model drone, which integrates a 20-megapixel camera with a focal length of 35 mm and a theoretical resolution of 1 cm, which has a battery for a flight of 12 to 15 minutes, which allowed them to take photos of 15 to 20 houses per day.

Regarding the use of convolutional neural networks, in [8] they propose an efficient surveillance based on radiofrequency to detect and classify drones, for which they used the RF-UAVNet network, said network is characterized by having grouped convolutional layers because reduce the size of the network and the computational cost, these were tested in drones of the Phantom and Bebop brands. In addition, in [9], they propose to identify weapons through surveillance applications based on Convolutional Neural Networks (CNNs) and Convolutional Long-Short-Term Memory (ConvLSTM). Simulation tests are performed on the data set using Python 3.5, Tensor Flow and Keras, which will be captured by wireless sensors distributed in networks for military applications.

Since the system has object detection and recognition techniques in the algorithm, in [10] they designed a deep YOLO-v3 model to detect small objects. The project consists of training the YOLO-v3 model previously trained with drone images, 106 convolution layers with several feature maps were designed to learn the small objects of the drones. The proposed deep YOLO-v3 revealed 99.99% accuracy because it used multi-scale predictions and backbone classifiers to better classify them. Likewise, in [11] they propose to use the YOLOv4 program to differentiate drones from birds through images captured by a digital camera which will have a visible sensor that has a resolution between 96 dpi and 300 dpi, the images will be captured in different environments and with different illumination. Similarly, in [12] they perform a vehicle detection using deep learning in UAV, which is proposed to record videos using the DJI drone, where the results show that the use of HSV for transformation data can enrich the set of samples. Thus, improving the detection accuracy, likewise, the SSD model can act on multiple feature layers, and its detection effect is better.

Finally, in relation to the current situation of dengue, in [13] studies related to coinfections of Dengue and COVID-19 were found. Most of the studies were case reports with

a detailed description of clinical and co-infection features. Common symptoms were fever, dyspnea, headache, and cough. The cases were found in Brazil, Indonesia, India, France, Argentina, Pakistan, Thailand, among others. Because both diseases are present in several places, the study is necessary to verify the differences between both infections. On the other hand, in [14], he presents two cases of patients with dengue and coronavirus coinfection, due to severe acute respiratory syndrome. This research found that severe dengue infection is common in young adults, while coronavirus disease is generally asymptomatic. They also comment that, in older people, the severity of this disease will depend on their comorbidities or the infectious serotype, but contagion by coronavirus is consistently more serious.

In this work, it is proposed to carry out a drone system with an algorithm that detects and recognizes pools of water that are possible foci of dengue. To check its efficiency, a database that contains images of objects that store water will be used.

### III. METHODOLOGY

For the development of the methodology, the efficiency of the design of the detection algorithm for epidemiological surveillance of dengue will be evaluated using drones, for which the research will be developed based on the following strategy shown in Fig. 1; a database, which will have images of the objects to be detected, the selection of a suitable drone, the software, which will carry out the programming, and the model of the algorithm that will be used for the detection and recognition of objects.

Therefore, for its procedure, as shown in Fig. 2, the drone will perform an acquisition of images and/or videos of the area for its evaluation, the use of a database containing images of objects that store water, in addition to the model of the object detection and recognition algorithm, which is one of the applications of convolutional neural networks. All this will be programmed in software that the computer will have, which will process the images to identify the pools of water in the photos or videos that the drone captured. In this way, the possible transmitting sources of dengue will be detected.

#### A. Database

To carry out this procedure, there will be a database of the objects to be detected, for example: buckets, pots, bottles, tires, tubs and vases.

#### B. Dron Selection

To select a suitable drone for the field of epidemiology, you must be able to take good resolution images and/or video in places or areas of difficult access that are affected by some type of disease. Therefore, the following technical specifications will be analyzed as indicated in Fig. 3, to select a suitable drone for this field.

Considering the main points necessary for the selection of an optimal drone in the investigation, they are the following: the camera must have a maximum of 12MP, because the smaller the image size, the shorter the processing time; Regarding the operating range, a range of [4 – 10] km of maximum transmission distance will be chosen. As a last point,

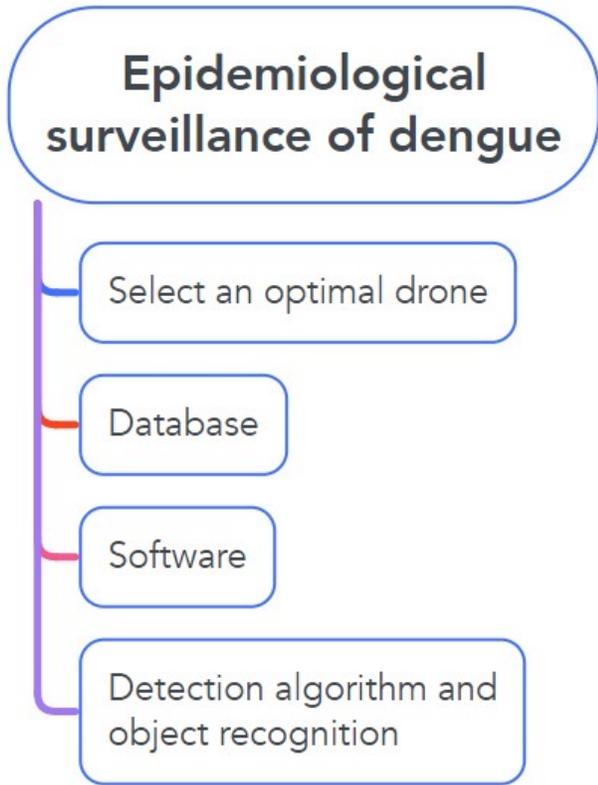

Fig. 1. Diagram of the Strategy of Research.

cost and accessibility will be taken into account, since most drones are acquired by import, therefore, the search for brands available for our country was carried out, obtaining DJI drones as a result.

Taking into account the importance of a drone with an affordable cost, as well as the criteria of the main technical specifications of the drone, DJI MINI 2 is chosen as the first option, since it has a maximum operating range of 10km, in comparison to the DJI MAVIC Mini drone, as a second option, which has only 4km.

*C. Software*

Since the object detection algorithm needs software that contains libraries on neural networks for its training, it is decided to choose the free software “Google Collaborate”, which is compatible with the Yolo algorithm, and its environment is developed using the language of Python programming. Its environment is very friendly to users, it does not require configuration, it gives free access to GPUs for fast code execution.

*D. Detection Algorithm*

In the case of the algorithm required for object detection, some main detection techniques were found: SORT, YOLO and SDD.

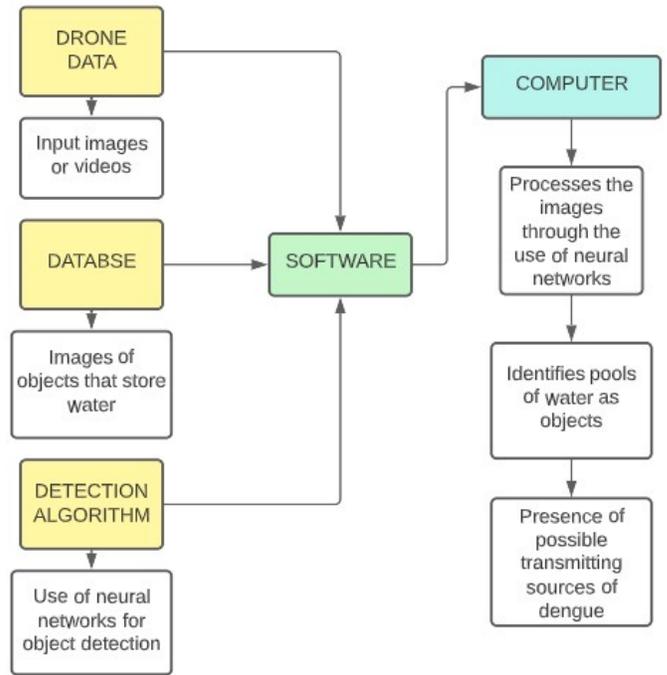

Fig. 2. Diagram of the Design of the System.

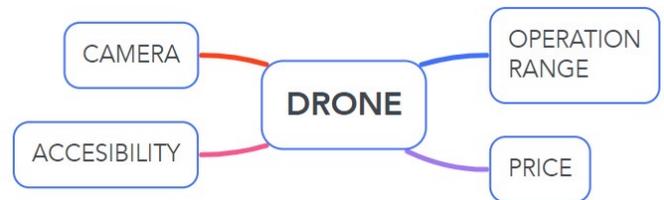

Fig. 3. Characteristics Considered to Select the Drone.

In the case of YOLO, compared to other detection techniques, it makes predictions with a single network evaluation through the use of CNN. In addition to having continuous updates or versions to improve its efficiency in terms of detection in both images and videos in real time. For this reason, the Yolo algorithm will be applied in its version 3 “Yolov3”, due to its stability and precision for object detection, as shown in Fig. 4, the Yolov3 algorithm in the Google Colab environment.

This algorithm requires “labels” of the images found in the database, which will be obtained through “Makesense”, a tool to label photos and thus organize the images into classes, as shown in Fig. 5, an example of classifying images of the “buckets” type.

In addition, Makesense allows you to export the labels in a “.txt” file for the operation of the YOLO algorithm. This will allow pre-training of the neural network for image classification.

YOLOv3 ALGORITHM FOR OBJECT DETECTION AND RECOGNITION

```
[ ] 1 !git clone https://github.com/ultralytics/yolov3 # clone
    2 %cd yolov3
    3 %pip install -qr requirements.txt # install
    4
    5 import torch
    6 from yolov3 import utils
    7 display = utils.notebook_init() # checks
```

Fig. 4. Algorithm YOLOv3.

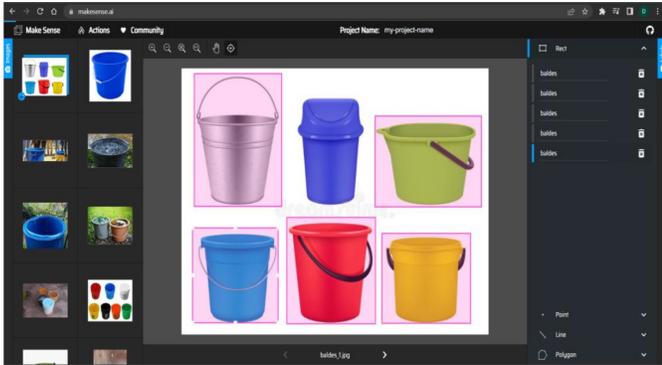

Fig. 5. Images Classification using Makesense.

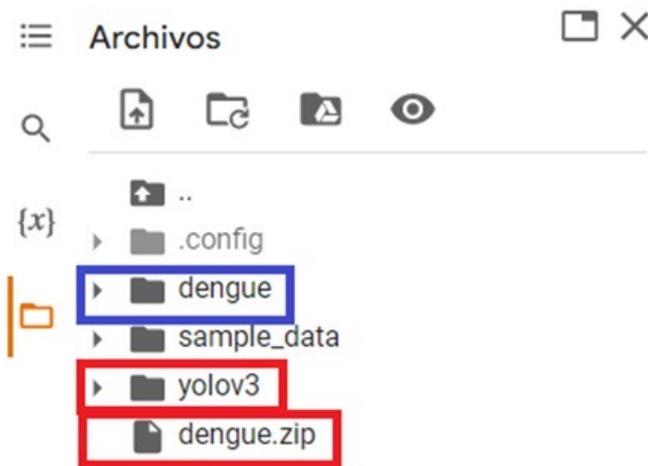

Fig. 6. Adding YOLOv3 Folder to the Database dengue.zip.

E. Programming

Given that at this stage the necessary elements are already available to carry out the recognition of dengue, the programming part will be developed, which will carry out the identification of the possible infectious foci of said disease.

As a first step, the database will be added in .zip format to extract it in the section and in turn compile the “Add Yolov3 algorithm” cell, as shown in Fig. 6 in the Files section, the yolov3 folder and the dengue.zip database highlighted in red.

```

```

Fig. 9. Training Expression using an Image or Video.

As a second step, the “.yaml” file is created, in which the classes and locations of the images that will be trained and validated by the neural network are declared. As can be seen in Fig. 7, the training variables “train” and “val”, followed by the classes associated with the objects to be detected in the images.

As a third step, the convolutional neural network training command will be executed, which is made up of the size of the image, the number of epochs, the data and the weights provided by the yolov3 algorithm, as can be seen in Fig. 8.

Finally, Fig. 9 presents the command for the validation of the Yolo algorithm through an image or video, for the detection of water pools, using the weights of the trained network.

IV. RESULTS AND DISCUSSION

Regarding the technical characteristics that a drone must have to adapt an epidemiological surveillance system, the drone selected in the methodology is evaluated, the DJI MINI 2 drone, which offers greater stability despite being very light (250gr), it has an acceptable wind resistance (29 – 38 km/h), however in [4] it mentions a study that used the DJI Phantom 4 Pro drone for epidemiological surveillance of malaria in the Peruvian Amazon, identifying breeding sites through multispectral images captured by the drone, said drone has an autonomy greater than 30 minutes, in the same way in [7] they used the same drone to capture images in an endemic city of Tapachula in Mexico. Likewise, in [6] the use of the DJI Mavic Pro Platinum drone is mentioned to obtain images of a test area, which has a flight time of 30 minutes, considered

Fig. 10. Drone DJI MINI 2 and its Remote Control.

very high, it also has GPS, a 12.35 MP camera, among other features. Taking into account the mentioned specifications, both studies considered autonomy or flight time as the main characteristic. In Fig. 10, the DJI MINI 2 drone is shown.

Regarding the development of the database, in [7] a database acquired by the drone of a total of 2579 images of various house roofs was used to identify *Aedes Aegypti* breeding sites, divided into 10 categories. On the other hand, in [15] they use Microsoft's COCO data set, which contains a base of 330,000 images, divided into 91 categories that can be freely used by any user. Instead, [11] mentions the use of a database of 3,000 images, including 1,000 of birds, 1,000 of helicopter-type drones, and 1,000 of multi-rotor drones. Therefore, it is recommended to use a greater number of possible images to carry out an optimal detection. Since a total of 86 images were used in the investigation for six classes or types of objects, which are buckets, bottles, vases, pots, tires and tubs.

With respect to the simulation, images containing the objects to be detected were used, for example buckets, tubs, bottles, pots, vases, tires, etc., which were extracted from the internet. Similarly in [7], for the detection of dengue it is recommended to identify these objects.

From the training carried out in Fig. 11, it is visualized that 60 images were used for the validation of the training, the different classes used, the number of labels of each class, the "P" value of total precision and of each class, the value "R" for recall (Sensitivity) total and of each class and the Accuracy value "mAP" total and of each class. Similarly, in [11] and [12], the use of these variables is highlighted to evaluate the accuracy and sensitivity of the proposed model. Furthermore, in [11], they obtained a 90% accuracy "P" to identify drones and birds in test images. On the other hand, the proposed model has an accuracy value "P" of 98.6% to identify water reservoirs.

Fig. 12 shows the graphs of the curves F1, P, R and PR that indicate the combination of P and R in a single measure, the quality of prediction, the quantity that can be identified and the performance of the predictive model, respectively.

Of the curves, the most important is the P-R curve that generally indicates the efficiency of the Yolov3 model applied to the detection of dengue, whose value is 99.2%, this indicates that the use of the algorithm for the detection of dengue is efficient. and that the simulation helps in part to validate its

efficiency.

In Fig. 13 it can be seen that each class is detected in reference to the image of the database, in addition to showing a number between 0 and 1, which means the value of precision that it has when recognizing the object, said value will be higher if the number of epochs increases.

The design of the detection algorithm proposed for dengue surveillance using drones allowed the recognition of objects or containers that store water to identify the infectious foci of the disease through the precision and sensitivity value which are the result of training the neural network. In addition, through test images, which contain figures of buckets, bottles, vases, pots, tires and tubs, it was possible to identify these objects with a total efficiency value of 99.2%. This design is an important contribution, since, in terms of disease surveillance in the country, this type of technology is not available, due to the fact that there is little research regarding drones dedicated to epidemiological surveillance.

The information on the technical specifications of the drones is important for their selection in cases of epidemiological surveillance, since, according to the authors, they consider the MP of the camera for the images, the flight time or its autonomy, and the cost of the device. Therefore, taking into account these considerations, it is concluded that the DJI MINI 2 drone is optimal to perform the image acquisitions required for the development of the proposed detection algorithm.

Fig. 13. Validation of the Neural Network with the Test Images.

## V. CONCLUSIONS

The test simulation was optimal for the evaluation of the detection algorithm, using some input images to detect the pools of water that are possible infectious foci of the disease. Resulting in the value of 99.2% total efficiency of the detection algorithm.

The design of the detection algorithm uses the Yolov3 model, since it is more stable, but the following versions such as Yolov4 and Yolov5 could be used to improve its efficiency, precision and sensitivity. As for drones, the recommendations for their selection vary according to the field, since most of these devices cover the military field, agriculture, archeology, medicine, home deliveries, etc.

Regarding the simulation of the evaluation of the algorithm, it is recommended to use software that runs without the need for an internet connection, for example, Octave, Visual Studio, among others, that have libraries applied to the detection and recognition of objects.

**Abstract**—Natural disasters such as earthquakes, avalanches, landslides, among others, leave in their path people who may be trapped in the rubble, which are hardly found by rescue agents, so a reliable system in the operation of an exploration and rescue robot is essential. This paper aims to evaluate the systems proposed for the operation of the TxRob exploration robot. The teleoperated control systems that were developed for the manipulation of the robot are: a multimodal system feedback with information through different sensors, and a GUI control system using joystick buttons. These systems were analyzed using subjective metrics such as NASA-TLX, Scale Utility System (SUS) and Microsoft Reaction Cards, which provide interesting data when evaluating the performance of an interface, as well as the workload, user satisfaction and usability; these aspects are used to conclude which system is the most intuitive when performing rescue operations in case of a disaster, among others. 15 operators were evaluated to validate this system; the age range of the operators was between 20 and 43 years old and 20% of them had previously used VR headsets. Priority is given to the most immersive, easy to use and the most efficient system to perform the task of handling the robot.

**Keywords**—Multimodal interface; immersive teleoperation; exploration robot; gyroscope and subjective measurements

## I. INTRODUCTION

In Peru there is a constant interaction between the Nazca and South American plates that generate natural disasters such as earthquakes, which put the population at risk of possible trapping due to landslides. According to the “Instituto Geofísico del Perú” (IGP), a total of 811 earthquakes were reported in 2020, 834 earthquakes in 2021 and approximately 581 earthquakes so far in 2022. The average of these earthquakes is of magnitude greater or equal to 4.5 ML (Richter scale), and also that the average number of earthquakes that occur per month is greater or equal to 58 earthquakes [1]; on average there are at least 2 earthquakes per day which is a constant risk to the Peruvian population. In the event that an earthquake has a greater magnitude, it would result in trapped people, uninhabitable houses or houses on the verge of collapse, at any time generating greater difficulty for the various rescue groups such as firefighters or members of the police who are also exposed to these dangers. Because of these problems, several robots are currently used for exploration and rescue, which reduce the exposure of the rescue agents, but do not reduce the mental load of the operators when making decisions [2].

For a successful operation there must be trust between the operator and the robotic partner, the cobots are designed

with the purpose that the robot can support the various tasks of the operator, for them the human-robot interaction (HRI) is paramount. HRI covers the various fields such as design, understanding and evaluation of robotic systems, which involve humans and robots interacting through communication [3], [4]. The trust with a cobot can decrease drastically if it provides constant wrong information in risky situations, therefore a good robotic system that increases the trust with cobots is necessary [5].

For a robotic system in rescue operations to be classified as good, it should not miss proprioceptive sensors, nor should it miss good image processing, otherwise it would decrease the usability of search and rescue (SAR) robots and the performance of the operators by increasing the work performed using minimal information from the sensors. SAR robots should also have modular sensors and modular payloads increasing the usability of the robots and robot feedback can create more levels of competence [6]. The need for robotic interventions in hazardous environments is high, due to the presence of dust, fire, pressurized water or radioactivity; for that reason, robotic platforms must be reliable and user interfaces appropriate due to the complexity of the environment, for them the use of different inputs such as visual user interfaces help a better understanding of the environment for the operator [7], [8].

This paper presents an analysis of the user interface developed for the operation of the TxRob robot using subjective metrics such as NASA-TLX, SUS and Microsoft Reaction Cards [9]. It is believed that a developed bidirectional multimodal feedback system will help to decrease the operator’s workload, resulting in less stress and better teleoperation. The TxRob robot was presented by our team in a previous article [10]; this robot has the advantages of being low cost, its compact size allows it to enter into confined spaces for the search of possible people trapped in the rubble, it also has a sensor feedback system, in addition to a graphical interface that generates a greater immersion in his teleoperation.

The distribution of information in this document is divided as follows: In Section II the works related to this research are presented, the methodology is developed in Section III, the description of the proposed multimodal interface and the interfaces used for comparison are described in Section IV, the description of the experimentation used in this paper is presented in Section V, the results and discussions obtained are presented in Section VI, and the conclusions of this research are found in Section VII.

## II. RELATED WORK

According to [11], the combination of different tools such as stereo vision, haptic feedback and auditory feedback increases the manipulation performance of a robotic system. For this, the multiple information that we can provide to the operator would generate a more immersive system for the teleoperation of a robot. For that reason, the use of multi-modal interfaces generates a higher performance in robotic teleoperation. In [12] they propose a method to organize the presentation of information and a set of visual assistance to facilitate the visual communication of data in teleoperation control panels, seeking to make them understandable and not generating a greater workload to the operator to understand the different information of the system where their interface combined immersive visualization, three-dimensional mixed reality and visual assistance.

With a gyroscope it is possible to know, maintain or change the orientation in space of an object; a gyroscope provides angular velocity readings usually in  $^{\circ}/s$  on the x, y and z axes to determine the rotational speed of the object on which it is located; in addition, the use of the gyroscope in immersive virtual reality systems can be seen in [13] where making use of the gyroscope of a mobile device the manipulation of objects in a virtual environment is achieved, in [14] where to obtain continuous visual effects a gyroscope was incorporated, being very helpful for the detection of the direction of vision of a person in a virtual environment and in [15] where the gyroscope is used to estimate the posture of an operator to integrate the virtual environment with the real environment.

In [16], they use a haptic interface for robotic control in which immersive interaction with the person being rescued significantly improves task performance compared to other control systems; and visual feedback further increases user performance metrics. In [17], they evaluate different multi-modal interfaces to find the system with the most intuitive and least operator workload; using visual interfaces, GUI interfaces and NUI interfaces. It is shown that a multimodal interface helps considerably in an intuitive teleoperation improving robotic efficiency. In [18] they present a new haptic mediator interface for teleoperative mobile robotic platforms that have a variety of manipulators and functions; employing identical bilateral master-slave teleoperation of robotic manipulators is achieved by representing them in virtual reality and allowing the operator to interact with them using a multipoint haptic device. As a result, the operator can perform a wide range of control functions and achieve functionality similar to that of conventional teleoperation schemes using a single haptic interface.

In [19], they measure the effects of working with autonomous robots on perceived workload and work performance, measuring both objective and subjective tests such as NASA-TLX, with the results of the study showing the viability of applying fully autonomous mobile robots to improve the productivity of the human-robot team while prioritizing physical safety and reasonable increases in mental workload.

In [20], they present an HMI which they developed to be able to control virtual forearm prostheses for extended periods of time. By calculating the physical performance for the given tasks, they develop an algorithm that adapts to the mental states

of a user, thus improving its usability. According to the NASA-TLX evaluation, a better physical performance was improved.

## III. METHODOLOGY

This document explains the two systems that will be analyzed for the manipulation of the TxRob robot. The control system for the movement of the robot is done by the joystick control which has functions that will be detailed later. For the vision system we present two interfaces:

- Traditional Interface: Uses a display screen that shows in real time the graphical interface developed for the TxRob.
- VR interface: Uses virtual reality (VR) glasses for visualization of the developed graphical interface and a gyroscope system for feedback, see Fig. 1.

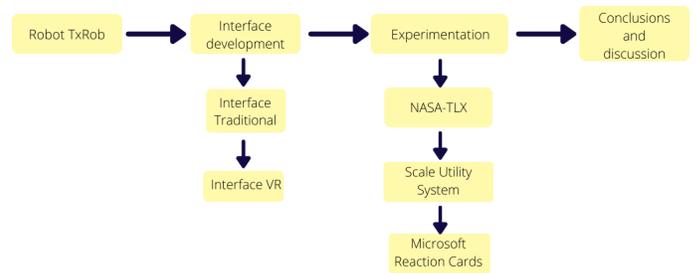

Fig. 1. Methodology Performed.

In addition, the evaluation procedure to be applied to the operators in the teleoperation of a simulated rescue is explained. The objective is to find an immersive and intuitive multimodal interface for the operator, understanding all the information obtained by the proximity and gas sensors, the images from the cameras and the microphone of the TxRob robot. To determine which of the proposed interfaces is better for the user, both interfaces are tested to 15 operators, which are evaluated by subjective metric tests that help to obtain the value of the workload generated by each interface in the immersive teleoperation; the usability as well as the utility of the system and the satisfaction of the operator when manipulating the proposed systems.

## IV. PROPOSED MULTIMODAL INTERFACES

Fig. 2, shows the distribution of the two developed interfaces. The traditional interface is the HMI interface that performs the motion control of the TxRob robot by means of a joystick control and the vision is given by a graphical interface displayed on a screen. On the other hand, the VR interface performs the same motion control as the previous interface but the vision is provided by VR glasses and a feedback system generated by a gyroscope and a two-axis turret for the camera.

### A. TxRob Control Interface

The motion control of the TxRob was previously developed by means of a joystick control as shown in Fig. 3(a), in this work we have optimized the motion control by increasing the

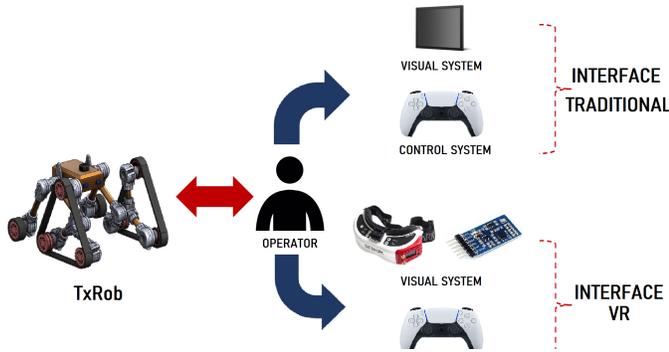

Fig. 2. Visuals and Control Interfaces.

control of a turret where the cameras are located. The turret was implemented in order to obtain the video in real time and to be able to manipulate it in two axes to cover the largest possible space of vision for the operator in the occlusion points without the need to move the TxRob. In this way, images of the upper part of the TxRob robot were obtained.

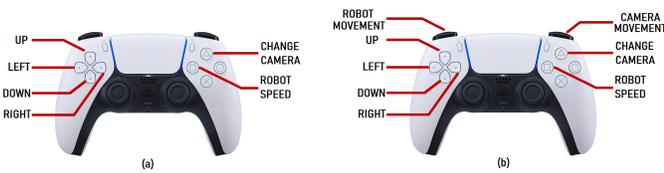

Fig. 3. Button Assignments. (a) First Configuration. (b) Last Configuration.

In the section (a), the change of cameras is controlled by pressing the triangle button; to choose the speed of movement of the robot the square button must be pressed and then by means of the two direction buttons (Up and Down) we regulate the speed of the TxRob. In section (b), to choose the robot movement control, press the L1 key (Robot Movement) and control by means of the four direction buttons (Up, Down, Left and Right); to choose the turret movement control, press the R1 key (Camera Movement) and control by means of the four direction buttons. The rest of the functions of the first configuration were maintained.

### B. Traditional Teleoperation Multimodal Interface

In most teleoperated robot vision systems, the interfaces presented consist of cameras and a screen where the video can be observed in real time. In the previous work [10], a control system was realized by means of a screen, which shows the developed interface. This interface shows the images captured from the cameras in addition to the values sampled by the various sensors incorporated.

In Fig. 4, the previously presented interface is improved, in this new interface the collected images are shown on the left side together with the developed motion detection system. The upper right side shows the real-time measured values of the gas sensors ( $CO_2$ ,  $O_2$ ,  $NO_X$ ) and the lower part shows an anti-shock system, which indicates the proximity of different objects around the TxRob.

Fig. 4. Improved Teleoperation Interface.

### C. Proposed Multimodal Teleoperation Interface

This developed system works by means of specular imitation, that is to say that all the movement made by the operator in the X and Y axis detected by the gyroscope of the VR lenses, will be replicated in the camera turret. This turret consists of two servomotors, each servomotor manages to control the movement in each respective axis, see Fig. 5.

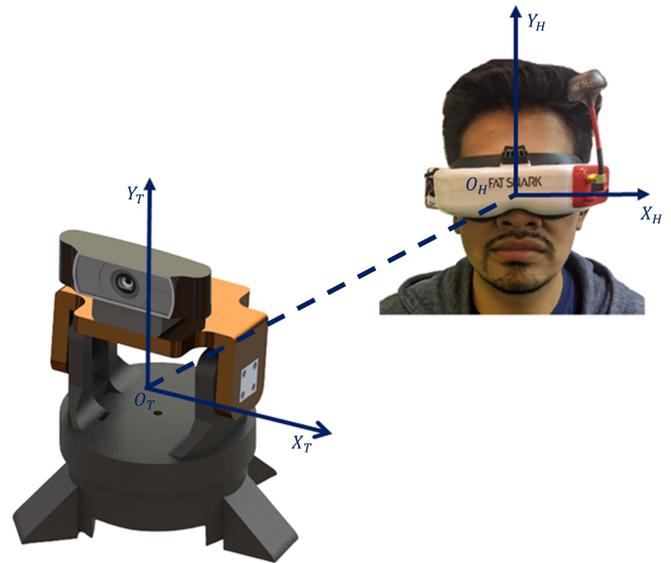

Fig. 5. Coordinates System.

When using VR lenses, the visual interface developed can become overloaded for the operator due to the FPV resolution that this system uses and at the same time the viewing space is reduced, our priority is to have an immersive and intuitive multimodal interface for the user. According to the literature reviewed, the overwhelming amount of data in teleoperation tends to confuse the user, decreasing the effectiveness of the task. For them, a more intuitive interface was developed for this system as shown in Fig. 6.

The interface proposed for the VR glasses is a first-person-view (FPV) interface, this format makes the proposed interface

Fig. 6. Display Shown to the User.

more immersive and the immersion is complete; to avoid saturating the operator's view we prioritized the real-time image of the cameras and in the corners we displayed the data from the different sensors of the robot that will help the teleoperation.

## V. EXPERIMENTATION

In order to confirm that the VR system with gyroscope feedback can achieve a high performance, it was evaluated by taking measurements in two stages: the first stage consists of the gyroscope attached to the VR device, the measurements recorded in the three axes for 20 seconds; the second stage consists of the measurement of the gyroscope attached to the camera, the movement of the motors are regulated with encoders after receiving the signal from the first gyroscope. In order to compare these two proposed multimodal systems, a debris entrapment rescue environment was simulated. A mirror environment was created for each multimodal interface. The proposed circuit is in the shape of an "S" for the traditional interface and for the proposed interface it is in the shape of an "inverse S" so that the experience is equal in both. This teleoperation test of the TxRob was performed on 15 operators, who ranged in age from 20 to 43 years old and 20% indicated that they had experience in handling VR systems. Each operator must manipulate the two multimodal systems to find the person trapped in the rubble, for this purpose they were given 5 minutes of tests so that they could familiarize themselves with the interfaces to be evaluated. At the time of the real tests, the time it takes to perform the search with each interface is measured, the time increases due to the presence of debris in the test scenario. At the end of the test, each operator performs the three subjective metric tests: NASA-TLX, SUS and Microsoft Reaction Cards; these data are used to obtain the values and scores of both multimodal systems.

## VI. RESULTS AND DISCUSSION

### A. Gyroscope Measurements

Fig. 7 shows each of the gyroscope axes with the VR lenses on the operator; where the operator moved his head for 20 seconds, making a total of 500 samples taken for each axis of the gyroscope. These measurements correspond to the angular velocity of motion recorded during the experimental phase. Fig. 8 shows each of the gyro axes with the turret camera

on the TxRob .Where the motors simultaneously triggered the movement of the camera according to the data recorded by the gyroscope attached to the VR device.

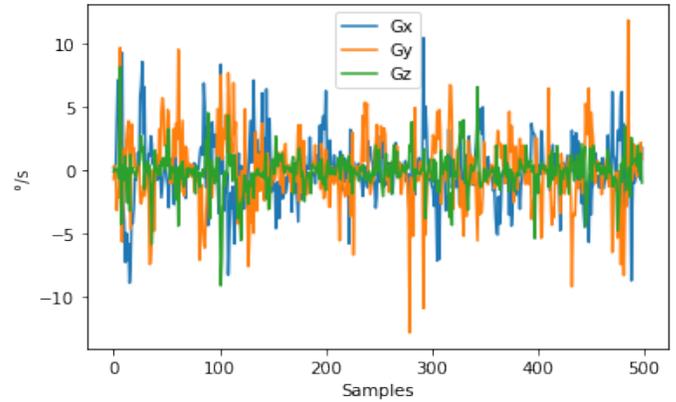

Fig. 7. 3-Axis Plot for the First Gyroscope.

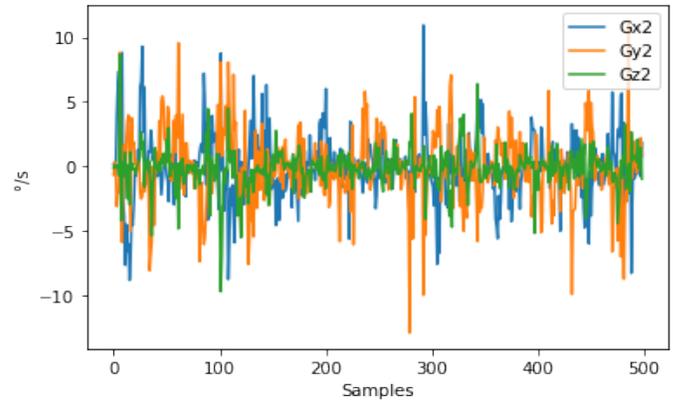

Fig. 8. 3-Axis Plot for the Second Gyroscope.

A comparison was also made between the measurements of both gyroscope divided on each axis defined as Gx, Gy and Gz. Data obtained from both the X-axis lens and turret camera gyroscopes are shown in Fig. 9, while Y-axis data are shown in Fig. 10 and Z-axis data are shown in Fig. 11. On average, a 4.13% variation is found due to the configuration of the motors driven by the encoders.

### B. Subjective Measurements

The following values were obtained from Fig. 12, where an improvement in time per task performed with the new proposed multimodal interface is noticeable. We consider this improvement to be relevant because in human rescue operations, time is the most important element. As long as an operation is performed in the shortest time, the possibility of saving more people increases considerably.

The overall workload per operator evaluated was reduced when using the multimodal VR interface. The traditional interface showed an average of 60.66 of overall workload appreciated in performing the experiment as opposed to the VR interface which showed 50.56 of overall workload presented. It

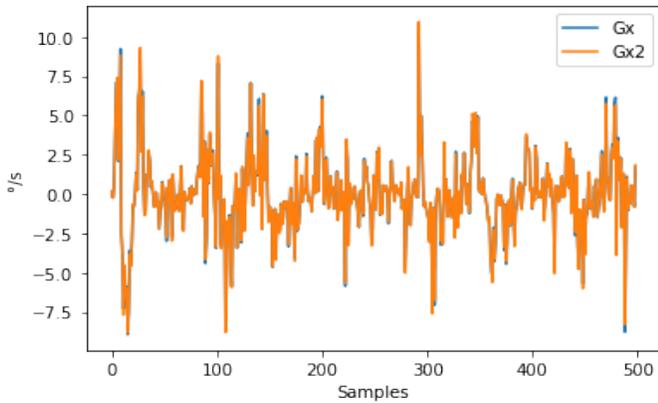

Fig. 9. Comparative Graph between Gx of Both Gyroscopes.

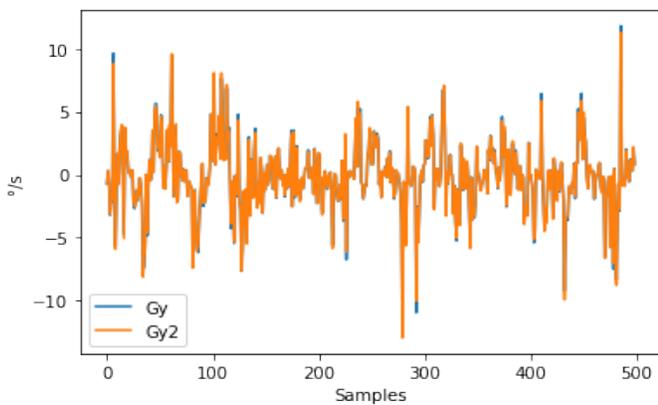

Fig. 10. Comparative Graph between Gy of Both Gyroscopes.

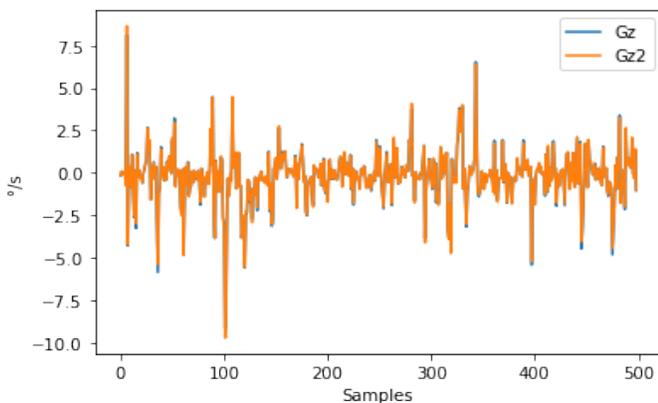

Fig. 11. Comparative Graph between Gz of Both Gyroscopes.

was also noted that the overall workload was higher for people with no experience in manipulating teleoperated systems and older people. This reduced workload helps make teleoperation more intuitive and easier for operators to manipulate. In Fig. 13 the blue bar is the first interface evaluated and the orange bar is the VR interface.

In Fig. 14 we present the dimensions evaluated by the NASA-TLX subjective method such as mental demand, phys-

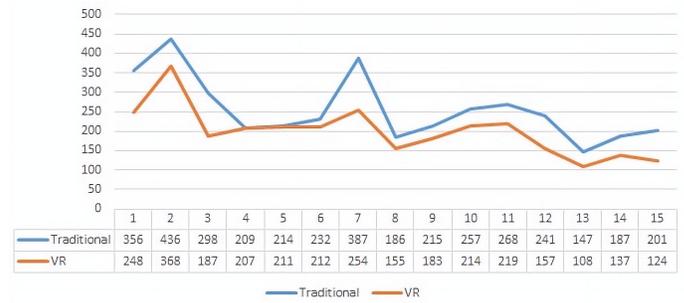

Fig. 12. Time Taken in the Corresponding Tests.

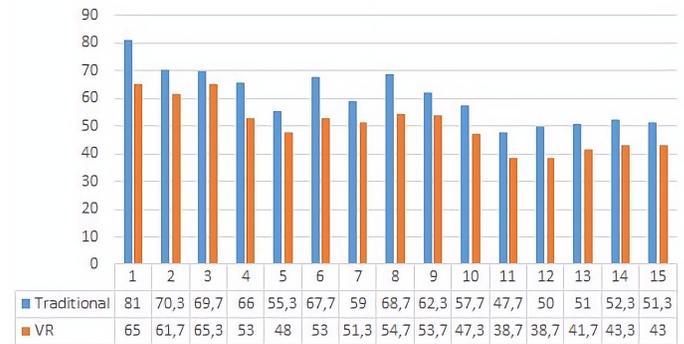

Fig. 13. General Workload - NASA TLX.

ical demand, temporal demand, effort, performance and level of frustration that may occur in the task. We have taken the average of the 15 operators to evaluate each dimension independently. According to the results obtained, the physical demands are lower because both systems are teleoperated and do not require physical labor. The mental demand is higher because the systems require most of the senses of people to manipulate both interfaces. When comparing the results of both interfaces, a reduction is observed when using the VR interface, in some dimensions this difference is more noticeable, such as the effort and frustration presented by the operators.

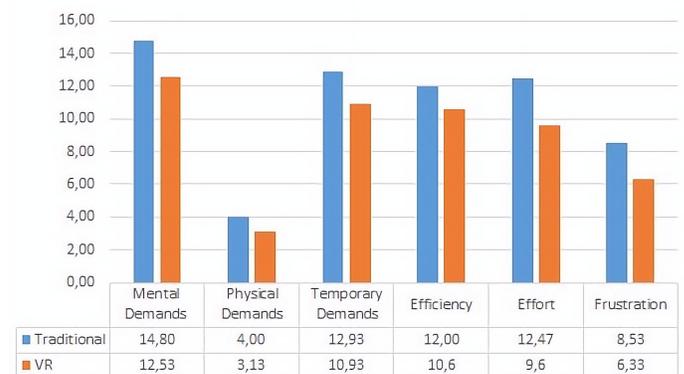

Fig. 14. Average Dimensions - NASA TLX.

The operators were also evaluated with the SUS metric, which will help us to see the usability of the systems, for

the first interface an average of 85.33 was obtained, which indicates that the interface has a wide usability in the tasks of the experiments carried out. In addition, the second interface obtained an average of 95.66, a much more favorable result; in Fig. 15 you can see the scores obtained by each operator, it can be seen that most of them are above 80 points in the traditional interface and above 90 points in the VR interface.

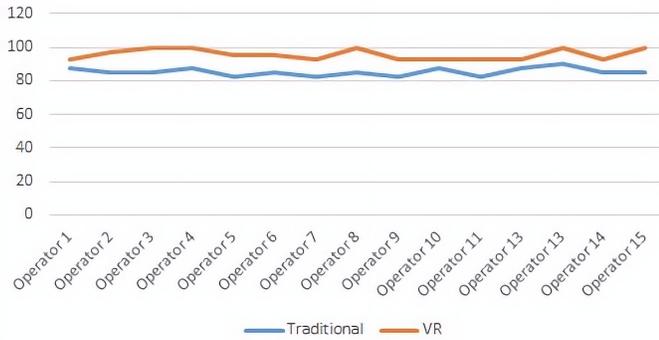

Fig. 15. SUS Results.

Microsoft's product reaction cards are, in essence, a list of 118 words that are used to describe a product or a completed good. The list includes positive words such as 'Useful', 'Comfortable' and 'Innovative', along with negative words, such as 'Stressful', 'Complex' and 'Dull'. The test consists of asking the robot operators to choose words from the list that they would use to describe the robot and, for each one, asking them why they chose that particular word. In these tests each of the 15 operators were limited to choosing 5 words that they felt best qualified the traditional system with joysticks to control the robot (light blue color), while on the other hand, in orange color are the results of the proposed system, see Fig. 16; only the cards with scores were considered, the rest of the words were ignored.

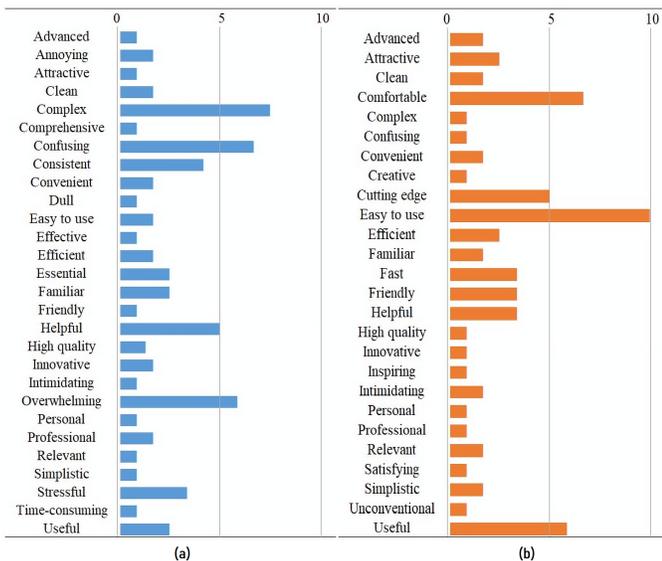

Fig. 16. Results of Microsoft Reaction Cards: (a) Traditional System. (b) VR System.

It can be seen in Fig. 16 that the words that were most chosen by the users were: "Complex", "Confusing", "Overwhelming", "Helpful" and "Consistent". Although some of the words are positive, it is clear that most of the operators feel that the traditional system with joysticks is not as comfortable to use, unlike the proposed system which in its absence most of the words selected were positive, of which the most chosen were: "Easy to use", "Comfortable", "Useful", "Cutting edge", "Fast", "Friendly" and "Helpful". This information shows that the proposed system is the one preferred by the operators who carried out the TxRob robot handling tests.

## VII. CONCLUSION

In this paper an evaluation of the multimodal interface developed for the operation of the TxRob robot was performed. The teleoperated control systems that were developed for the manipulation of the robot are: multimodal system fed back information through the different sensors and a GUI control system using joystick buttons. These interfaces were analyzed using subjective metrics such as NASA-TLX, Scale Utility System (SUS) and Microsoft Reaction Cards, which provided us with data such as workload, experiences such as user satisfaction and usability of each system in order to designate the most intuitive when performing rescue operations in case of a disaster. The results of the NASA-TLX tests showed that the multimodal system with gyroscope feedback for camera control is the best because it greatly reduces stress generation when manipulating robots. In the SUS tests, the proposed system obtained an average score of 95 points, demonstrating that it is a better interface than the joystick control system, which only obtained an average score of 85 points. Finally, the Microsoft Reaction Cards tests showed that the majority of operators chose the proposed interface as more comfortable and easier to use, unlike the majority of words chosen to qualify the traditional joystick system.

# Exploring Power Advantage of Binary Search: An Experimental Study

Muhammad Al-Hashimi<sup>1</sup>, Naif Aljabri<sup>2</sup>  
Department of Computer Science  
King Abdulaziz University, Jeddah, Saudi Arabia

**Abstract**—As exascale systems come online, more ways are needed to keep them within reasonable power budgets. This study aims to help uncover power advantages in algorithms likely ubiquitous in high-performance workloads such as searching. This study explored the power efficiency of binary search and its ternary variant, comparing consumption under different scenarios and workloads. Accurate modern on-chip integrated voltage regulators were used to get reliable power measurements. Results showed the binary version of the algorithm, which runs slower but relies on a barrel-shifter circuit, to be more power efficient in all studied scenarios offering an attractive time-power tradeoff. The cumulative savings were significant and will likely be valuable where the search may be a substantial fraction of workloads, especially massive ones.

**Keywords**—Binary search; ternary search; time-power tradeoff; exascale computing; barrel shifter

## I. INTRODUCTION

The fastest supercomputers in the world today are capable of solving problems at the petascale level, i.e.,  $10^{15}$  floating point operations/second (flops). Complex simulations of more realistic models are becoming less feasible on current petascale supercomputers. These workloads need exascale ( $10^{18}$ ) machines. The main obstacle to exascale was the projected power consumption [1]–[4]. If petascale-era technology had been scaled, it would have consumed absurd amounts of power in the order of gigawatts. The US Defense Advanced Research Projects Agency (DARPA) specified that the peak power consumption should be below 20 megawatts (MW), which led [4] to conclude that substantial advances in hardware, software, and algorithms were needed to meet that requirement. Some experts [5], [6] had predicted that a complete exascale system would enter service by 2020. The first one that also meets the DARPA provision arrived in 2022 [7]. The Frontier supercomputer (Oak Ridge National Lab, USA) made its official debut on the 2022 Top500 list as the first supercomputer to exceed 1.0 exaflops [8], [9]. Engineers project reaching 1.5 exaflops peak at 29 MW (19.33 MW/exaflop) [10].

The previous studies on power and energy reduction focused on architecture, chip technology, algorithm optimization, and management. This study aims to explore the inherent power advantages in algorithms, i.e., those stemming from the method. It pays particular attention to the power (the time rate), which once was an obstacle in the path to exascale and likely will continue to be a significant concern. The work relies on direct measurement and observations at the micro-architectural level. It encourages rethinking time optimization, which has long been a classic interest in computing, as it may sometimes interfere with the power concerns of systems where

saving power may be of primary interest. With those concerns in mind, [11] examined the power efficiency of mergesort against that of quicksort, the standard general-purpose sorting algorithm. Their results showed that the power consumption of the mergesort was significantly better than an optimized quicksort when it exploited the barrel shifter, a digital binary shift circuit, to do the partitioning phase. The barrel shifter is a simple, power-efficient component in modern processors utilized to perform powers (exponent) of two divisions and multiplications in one clock cycle. The quicksort ran faster on average, as expected. Hence switching sorting methods did involve a time-power tradeoff.

The preceding encouraged a look into more algorithms that rely on the shifter hardware to see if similar power trends hold elsewhere. Accordingly, binary search should perhaps have a power advantage against a ternary version since it divides search lists by two, which could utilize the power-efficient barrel shifter. This study attempts to investigate and quantify that advantage. Binary search is a log-efficient procedure for unordered querying an array of ordered keys based on an implicit optimal binary tree [12, see S. 6.2], which is very useful for multiple random queries. It is a significant part of various general workloads [13]. Conceptually, it looks for a key value  $X$  in a sorted list as follows:

```
if ( X == middle element )
    X is found
else if ( X < middle element )
    search 1st half of list using the same method
else
    search 2nd half of list using the same method
```

A ternary search algorithm works as outlined next:

```
if ( X == middle1 element )
    X is found
if ( X == middle2 element )
    X is found
else if ( X < middle1 element )
    search 1st third of list using the same method
else if ( X > middle2 element )
    search 3rd third of list using the same method
else
    search 2nd third of list using the same method
```

The rest of the paper is organized as follows: Section II reviews related work in chronological order. Section III describes the experiments. In Section IV, findings are presented and discussed. Finally, concluding remarks and suggestions for further research are in Section V.

## II. RELATED WORK

The research in [14]–[16] introduced a new energy management component and used it to select the best energy-saving sorting algorithm on mobile platforms. The energy management component selects the best algorithm dynamically. The results show good energy saving and encourage more investigation.

The author in [17] presented a new methodology to estimate power consumption for parallel computation in a multicolor environment. They also prove that the total power consumption for the computation is not equal to the sum of each core individually. The results show that their measurement accuracy was 95%. In [18], the author enhanced the performance and energy consumption for a parallel program running on the Intel Core i7-2600 processor by increasing the data locality. They increased energy efficiency by more than six times.

The author in [19] presented a methodology to predict the energy consumption for algorithms using the algorithm atomic operations analysis. They use it to evaluate the energy consumption for the classical bubble sort algorithm. Their prediction methodology accuracy was more than 95%. The author in [20] used the scheduler control information to estimate the needed number of cores to execute the waiting program threads. Their results show some power savings. The author in [21] developed a power-efficient algorithm based on mathematical modeling for sorting on a mesh-connected network that utilized an optical pyramid layout (on chips equipped with optics capabilities). They showed a reduction in energy consumption due to data movement based on energy modeling vs. time. There was no direct assessment of power. The author in [22] presented a new methodology to save power in mobile platforms using Intel Core i5 processor by running different workloads on a limited number of cores. They reduce the power consumption by 40%.

In [23], the author presented a methodology to save power consumption in multicore environments by reducing the thread idle time. They applied it to the concurrent execution of ILU-PACK (an *LU* decomposition software). The results showed that they achieved good savings in power. In [24], the author presented a new method to save energy by adopting an energy-efficient I/O management approach in supercomputers. They examined three radically different I/O schemes, including time partitioning, dedicated cores, and dedicated nodes. They also characterized how different configurations of the application and the system can impact performance and energy consumption. Reference [25] translated the CPU dissipated power into tokens to select the best power-saving technique. The dissipated power was predicted at cycle level and basic block level. They enhanced the energy consumption by 11%.

The authors in [26] and [27] observed power efficiency characteristics of the barrel shifter circuit in the context of digital signal processing where powers of two divisions and multiplications are dominant.

The author in [28] investigated power and energy consumption of mergesort against that of quicksort running on the Intel Xeon E5-2640 (Sandy Bridge). That study had two drawbacks. First, it eliminated some, but not enough, side activities that could contribute to the readings. Second, it relied on an older

part that did not support fine power control or detailed internal instrumentation, including crucial cache activity information. Nevertheless, their results identified a statistically significant power advantage for basic mergesort. The author in [29], [30] developed a methodology for evaluating power and energy consumption on the NVIDIA Tesla K40c GPU and used it to compare GPU-optimized bitonic mergesort and quicksort. Their results showed that the mergesort outperformed quicksort in power consumption. The bitonic mergesort was further analyzed in [31] for power and energy consumption on the NVIDIA platform. They identified the factors that caused the mergesort to have a power advantage (in a follow-up study, [32] showed that varying the block size on the GPU further improved the power performance of the mergesort).

In [11], the author developed a rigorous experimental procedure to eliminate sources that could taint measurements based on a CPU with improved power instrumentation. They showed natural mergesort to have a clear power advantage against a highly optimized 3-way quicksort. A meta-analytical comparison of the energy consumption of mergesort and quicksort was conducted in [33] based on an extensive literature review that included [11]. The study concluded that there was no significant difference in energy needs. Results in [11] had earlier agreed on energy but found the mergesort to consume less power based on direct measurement, stressing a concern when two systems go through the same energy budget at different rates. It is the basis of time-power tradeoffs. In some applications, the time rate, i.e., power, is perhaps more consequential.

## III. EXPERIMENTAL DESIGN AND PROCEDURES

Realistic measurement of the power consumption of a program running on a CPU is not easy. In a modern run environment, a program runs on a CPU with many other pieces of code that share the CPU and other resources. Programs run on many CPU cores under OS control. Therefore environmental factors, which confound measurement that may credibly be attributed to the experiment's code, had to be eliminated. Some challenges are not unlike those faced when profiling program run time or studying the time behavior of an algorithm. In addition, empirical assessment of power characteristics presents extra challenges. Ambient and CPU-generated heat act as thermal noise that can distort measurements. A modern CPU actively manages power, adjusting its cooling fan speeds, internal voltages, and frequencies to maintain health and keep power consumption in check, which changes power performance unpredictably. In this study, the authors strove to eliminate as many external factors and sources of power consumption as needed to ensure proper, consistent readings that serve the purpose of the study. The classic generic iterative versions of the binary and ternary search algorithms, hereafter referred to as BS and TS, respectively, were used. Finally, timing data was collected as an experimental control to verify programming and expected complexity behavior.

The following describes the experimental environment, the tools used to profile power, the executables that code the algorithms, and the datasets and related test procedures.

TABLE I. SPECIFICATIONS OF THE TEST BED WORKSTATION

<b>Processor</b>	Intel Xeon E5-2680 v3 (Haswell-EP) 12 Cores (24 Logical) TDP Limit = 120 W
<b>Cache Memory</b>	L1/core: 32 KB Instruction, 32 KB Data L2/core = 256 KB L3 Shared = 30 MB
<b>OS</b>	Linux Ubuntu 16.04 LTS 64-bit
<b>Physical Memory (RAM)</b>	8.00 GB

A. The Environment

The test bed machine was a FUJITSU HPC workstation kept under consistent server-room conditions to control ambient thermal effects. Specifications are listed in TABLE I. The experiments ran with the power supply fan ON. The processor environment is an HPC-grade Intel Xeon CPU that appears in machines such as the SGI ICE X supercluster, which ranked 40 in the 2015 Top500 list.

The following settings were applied to the CPU and the OS to eliminate thermal noise and other factors that could contaminate the power readings:

- Disabled hyper-threading (architectural optimization).
- Disabled power management options (architectural optimization).
- Disabled the CPU fan to eliminate effects of cooling (an external fan was used between runs to bring the CPU back to a consistent initial thermal state).
- Closed unnecessary OS services and processes to run the OS with minimum resources.
- Moved the necessary OS processes and services to cores 2 and above to dedicate core 0 for the experiments.
- Left core 1 idle to reduce thermal interference from the other cores.

B. The Profiler

The Linux *perf* tool was used to profile the CPU. The profiler, part of the Linux kernel, provides a wealth of information about the CPU, including power and energy consumption. It largely depends on the RAPL (running average power limiting) interface, which, in turn, depends on the quality of CPU state control and probe components embedded in the processor. The HPC-grade 2600v3 Haswell-series, including the part used in this work, featured [34]: 1) a shift from an indirect model-based reporting to actual measurement based on fully integrated voltage regulators (FIVR), and 2) the addition of per core voltage regulators that control the frequency and power states of cores individually. Previous generations relied on one mainboard regulator to infer detailed information. A 2018 study found that RAPL closely matched plug power readings in the Haswell architecture [35]. As a result, the profiler can provide reliable, higher-resolution instrumentation on the Xeon 2680v3. The tool was configured to obtain an average of 300 runs and used the following command for each one.

```
perf stat -e power/energy-pkg ./algorithm
```

TABLE II. DATASETS AND RUN SCENARIOS

Dataset Size	Number Datasets	Number Runs	Total Runs	
Set 1	48,000	20	300	20×300 = 6000
Set 2	64,000	20	300	20×300 = 6000
Set 3	512,000	20	300	20×300 = 6000
Set 4	8,000,000	20	300	20×300 = 6000

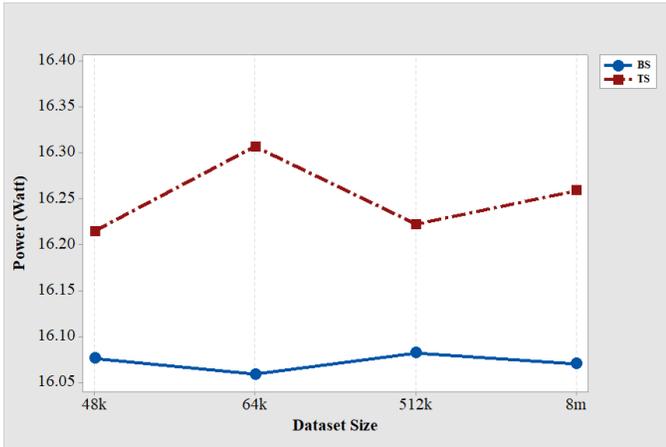

C. The Executable Files

The search code was generated using the GCC 64-bit compiler in release mode. All optimization options in the compiler were disabled to avoid those that replace bare code with parts optimized for specific architectural features. Optimizations do not serve the purpose of the experiments. They may result in readings that reflect the machine or the compiler more than the algorithms in principle. The authors consider bare code a fair rendition of the algorithm on machines from the same instruction set architectural (ISA) style. Turning off power features in an otherwise power-efficient CPU also fits that concern. Finally, disassembled code from the BS executable was examined to confirm that it utilized the shifter circuit instructions to halve the sizes of search lists (Fig. 1).

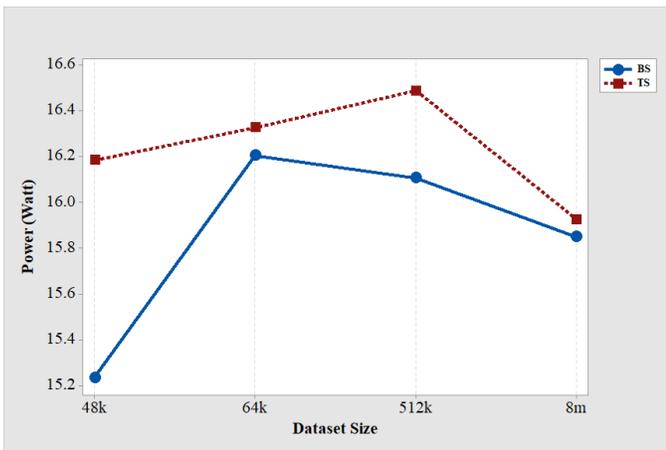

TABLE IV shows the average power consumption for various dataset sizes under the different run scenarios for each search algorithm. The averages were calculated from 290 runs/list (after discarding the first ten of 300) for 20 different lists. So each power value in the table represents 5800 runs. Fig. 2 show these findings comparatively.

TABLE III. NUMBER OF ITERATIONS FOR SIMILAR-ITERATIONS AND SINGLE-ELEMENT SEARCH SCENARIOS

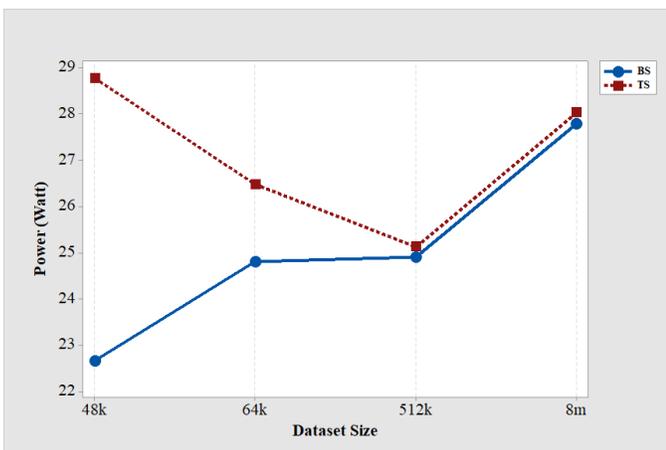

Dataset Size	Similar-Iterations		Single-Element	
	BS	TS	BS	TS
48k	9	9	14	9
64k	9	9	16	9
512k	11	11	19	11
8M	15	15	23	15

(a) Similar-Iterations

(b) Single-Element

(c) All-Elements

Fig. 2. Average Power Consumption in Watts for Search Scenarios.

#### D. The Datasets

Lists of unique random integers, sorted in ascending order, were generated in four size sets, each comprising 20 different lists. Each dataset ran 300 times for a total number of 24,000 runs. The first ten runs/dataset were discarded to avoid effects from the initial thermal state of the CPU. See TABLE II for a summary of the datasets and run scenarios.

The authors chose 300 after running test trials and found that averages tended to start converging after 230 runs. Dataset sizes were chosen based on cache miss data from [11], where they used the same CPU. Some experimentation with different sizes confirmed that power readings for datasets located in the same cache level were reasonably similar. So sizes were based on crossing L1, L2, and L3 cache boundaries. Sizes of sets 1 and 2 represent lists in L1 and L2, respectively, and those of sets 3 and 4 represent small and large lists in the L3 cache, taking care not to cross over to DRAM. The DRAM was excluded for two reasons. First, to maintain comparable readings since the on-chip SRAM-based cache levels likely share the same physical characteristics, hence the power profile. Second, to better discern effects from algorithmic operations that the off-chip DRAM access may further drown. Data movement along communication links is a known prominent contributor to power consumption, so the decision works for the authors' approach to emphasizing the algorithm.

## IV. RESULTS AND DISCUSSION

To avoid unpredictable effects from the best and worst cases on averages and to gain better insights, the experiments ran in three controlled search scenarios:

- 1) **Similar-iterations search:** The scenario picks an element near the middle of the randomly-generated list, then calculates the iterations needed to find this element. Each algorithm needs a different number of iterations to find it. The smallest is selected to set both to run iterations equal to that number. For example, if BS needed nine iterations and TS needed eleven, both are set to run nine iterations. It represents the minimum run cost to find the key. It also quantifies the power cost of searches/finds that take the same amount of iterating, which may be a fair basis to compare the algorithms. TABLE III shows the number of iterations used for this scenario.
- 2) **Single-element search:** Again, set the two algorithms to search for an element near the middle of the list. Here each algorithm runs all the needed iterations to find it. This scenario quantifies the full cost of a find that can compare with the first scenario. The number of iterations for this scenario is in TABLE III.

TABLE IV. AVERAGE POWER IN WATTS (COLUMN  $\Delta\%$  SHOWS PERCENT INCREASE FROM BS TO TS)

Dataset Size	Similar Iterations			Single Element			All Elements		
	BS	TS	$\Delta\%$	BS	TS	$\Delta\%$	BS	TS	$\Delta\%$
48k	16.08	16.21	<b>0.81</b>	15.23	16.18	<b>6.24</b>	22.65	28.77	<b>27.02</b>
64k	16.06	16.31	<b>1.56</b>	16.20	16.33	<b>0.80</b>	24.80	26.48	<b>6.77</b>
512k	16.08	16.22	<b>0.87</b>	16.11	16.49	<b>2.36</b>	24.90	25.13	<b>0.92</b>
8M	16.07	16.26	<b>1.18</b>	15.85	15.92	<b>0.44</b>	27.78	28.03	<b>0.90</b>

- 3) **All-element search:** This scenario sets each algorithm to search for all the elements in the dataset in each run. For example, if the dataset size is 100, the algorithm searches for element 1, then 2, until 100. Some element locations are the worst for the algorithms, while others are the best. The power consumption of all searches is measured to avoid the impact of the element's location on the power consumption and averaged to find the average power consumption for all the positions for each algorithm.

The results show that BS was consistently more power efficient, with slim margins in the similar-iterations and single-element search scenarios (datapoint 64k-single-element appears anomalous). Power savings, however, were substantial in the all-elements case. The savings seem to depend on the cache level. They seem to diminish as the computation spills to the next cache level and then stabilize at around 1% in L3.

Before discussing the results, readers are minded that both algorithms are incredibly fast, with TS holding a slight runtime edge. They go quickly through keys to reach either a found or not found outcome. The run times are comparable since both belong to the logarithmic efficiency class (TS in base 3, hence its edge). Therefore, it is perhaps unsurprising to see close power readings in the similar-iterations and single-element search scenarios. They both depict an isolated query. Notably, BS still manages to hold a consistent edge in power consumption. In the similar-iterations case, had BS taken as few iterations as TS, it would have consumed less power, i.e., it had a lower power cost of iterating. The all-elements search scenario paints a more realistic picture of what to expect as a cumulative effect likely to be experienced during an extended period. It is where those seemingly minor differences observed in the other two scenarios come into play.

Furthermore, cache memory interferes with the run time performance of the binary search (likewise the TLB, if DRAM is involved) [13]. With large subarrays, binary search is prone to generating indices to elements in distant memory. The effects of weaker locality increase as datasets grow in size. Power consumption should follow a similar trend. Power overheads due to cache miss rise as more physical circuits are engaged to satisfy the misses. Interactions with cache memory generally may explain the decline in power savings as the effects from misses increase. Therefore, limiting list sizes was conducive to the aims of the experiments. The L1 cache is expected to yield the most realistic view of power from the algorithmic operations since it suffers the least from the power overheads of misses.

Little differences in power consumption may not look promising when viewed from a single application standpoint. In a large-scale system, however, the cumulative effect should be significant, especially for a computation likely a good frac-

tion of the general workload for extended times like searching. The savings may be substantial, which may be more valuable for a power-sensitive system like an exascale supercomputer. Moreover, those savings were really due to the algorithm. BS calls for an inherently inexpensive operation on a binary computer, which reflects in simple power-efficient hardware, not the other way around. If not mindful, it may be tempting to pick the ternary version to speed up runs, especially since the cost of implementation is negligible.

The findings seem to support the idea that some algorithms have a power (not energy necessarily) advantage over those that need to work harder, i.e., expend energy at a higher rate, to achieve the same results. The inherent power efficiency of an operation reflects in the hardware, as is the case with the division by two on a binary device. One may expect an algorithm that relies on that operation to be more power efficient. This observation should be interesting where power savings are more significant than some runtime gains, such as those offered by TS. Eventually, interactions with microarchitectural features, such as those underlying the memory, may erode those savings in the real world. However, the savings can add up system-wide in pervasive computations. Thus a massive exascale system may be in a better position to benefit from the cumulative savings. Mobile systems should also benefit from power-focused optimizations since they relate to the critical concern of how quickly a battery drains. A power-efficient *workload* helps a smaller (lighter) battery go a long way.

## V. CONCLUSIONS

This work experimentally explored the power efficiency of two variants of binary search: the classic binary decision (BS) and the faster-running ternary decision version (TS), both in the same time efficiency class. The authors tuned the experimental environment to focus on the search code while eliminating other run environment factors. Under the experimental conditions, the results showed that BS outperformed TS in power consumption under different search scenarios. The BS could take advantage of the more efficient shift hardware. The findings seem to corroborate the authors' initial suspicions about BS, which stemmed from work reported in [11]. The savings in BS were likely inconsequential for individual searches, but the cumulative effects may be significant.

The study has been an early attempt to establish the binary decision version of binary search as a preferred alternative for exascale applications. It quantified a power advantage and exposed a potentially interesting tradeoff with time, especially from a workload-wide view. Further investigation with different scenarios and environments may be needed to argue that the reported findings stem from the method (algorithmic) rather than the run environment, i.e., a binary decision is inherently efficient in terms of power consumption on any binary computer. Future investigations in other processor environments

would be interesting, for example, later core processors or GPUs whose importance in HPC continues to grow. Higher resolution instrumentation and better reporting tools should provide deeper insights. Such studies may uncover trends independent of architecture. Eliminating other microarchitectural interferences help further amplify behaviors due to the algorithm. For example, basic binary search is quite branchy, so it may be helpful to turn off branch prediction. Other algorithms that rely on the binary shift hardware may be worth exploring. Finally, this work focused on average power. It may be interesting to observe peak power, which should be of interest from a system-wide workload in a massive supercomputer viewpoint.

#### ACKNOWLEDGMENT

This work was funded by King Abdulaziz University, under grant No. (1-611/1433 HiCi). The authors, therefore, acknowledge technical and financial support of KAU.

# CertOracle: Enabling Long-term Self-Sovereign Certificates with Blockchain Oracles

Shaoxi Zou, Fa Jin, Yongdong Wu\*

Jinan University, Guangzhou, China

\*Corresponding author

**Abstract**—Identity certificate is an endorsement of identity attributes from an authority issuer, and plays a critical role in many digital applications such as electronic banking. However, the existing certificate schemes have two weaknesses: (1) a certificate is valid only for a short period due to expiry of the issuer's private key, and (2) privacy leaks because all the attributes have to be disclosed in the attribute verification process. To overcome the weaknesses, this paper proposes a blockchain-based certificate scheme called CertOracle. Specifically, CertOracle allows a traditional certificate owner to encrypt the off-chain certificate attributes with fully homomorphic encryption algorithms. Then, the uploading protocol in CertOracle enables to post the encrypted off-chain attributes into the blockchain via a blockchain oracle in an authenticated way, i.e., the off-chain attributes and on-chain encrypted attributes are consistent. Finally, the attribute verification protocol in CertOracle enables anyone to verify any set of on-chain attributes under the control of the attribute owner. As the on-chain certificate attributes are immutable forever, a traditional short-term certificate is transformed into a long-term one. Besides, the owner of the on-chain certificate attributes can arbitrarily select his/her attributes to meet the requirements of target applications, i.e., the on-chain certificate has the self-sovereign merit. Moreover, the proposed scheme is implemented with fully homomorphic encryption and secure two-party computation algorithms, and its experiments show that it is viable in terms of computation time and communication overhead.

**Keywords**—Digital certificate; blockchain oracle; fully homomorphic encryption; secure two-party computation

## I. INTRODUCTION

As an important way to identify persons or other objects, an identity certificate is a set of electronic credentials that are used to verify the certificate owner's identity. It can be an electronic ID card, an electronic graduation certificate, a health certificate, or other identity certificate issued by a Certificate Authority(CA) such as a government, university, hospital, etc. Since most digital identity schemes use digital certificates to uniquely identify people on the Internet, this will lead to the frequent use of digital certificates in daily lives.

Most existing digital certificate schemes are based on public-key cryptography. During the issuance of a certificate, the CA's private key will be used to sign on the attributes of the certificate. However, according to the specification of NIST, the private key of CA should be updated within three years [1], otherwise the security of certificate scheme may be compromised. Usually, the period of a private source-authentication key, such as signing key, is the same as the period of associated public key. Therefore, once the key of CA is refreshed, the verification on previously issued digital

certificates (e.g., electronic ID card or electronic graduation certificate) may fail, and hence cause inconvenience or security vulnerability. Therefore, it's necessary to extend the life cycle of these digital certificates and verify identity attributes even if the CA's private key has expired.

Usually, digital identity certificates contain multiple user attributes, including user's private information. When users want to use certain services supported by verifiers, they have to present a part of attributes in their certificates. However, if the identity certificate is presented straightforwardly, all the attributes in the certificate will also be exposed. This is a coarse-grained representation that does not satisfy the principle of least leakage. Meanwhile, someone can't verify the certificate's authenticity when only some attributes of the certificate are displayed. Therefore, it is necessary to propose a method to perform fine-grained verification of attributes in certificate.

To solve the above problems of expiry of CA's private key and privacy leakage of user's attributes, Self-Sovereign Identity(SSI) [2] solutions are proposed to enable the owners to control their attributes with decentralized technologies [3] such as blockchain or distributed ledger. Presently, there are many mature decentralized identity schemes, such as Hyperledger *Indy* and *Civic* built on consortium blockchains and *ION* built on public blockchains. However, these proposed solutions mostly rely on on-chain issuers. It is difficult for them to tackle the off-chain certificates, i.e., the traditional digital identity certificates.

Since the blockchain is characterized by decentralization, immutability and openness, the on-chain certificate lifetime will be extended to long-term. Nonetheless, since the information on the blockchain is public and traceable, storing digital certificates on the blockchain in plaintext can lead to privacy leakage. Therefore, the attributes of on-chain certificates should be encrypted. To ensure the encrypted traditional certificates are uploaded into a blockchain authentically, blockchain oracle can be played as a middleware role in building a bridge between off-chain and on-chain.

This paper presents CertOracle, a management scheme for long-term and fine-grained certificates by transforming an off-chain traditional digital certificate into an on-chain certificate. Technically, CertOracle enables users to encrypt their digital certificates by themselves and ensures that the encrypted identity certificate is uploaded into the blockchain in an authentic way via a blockchain oracle. The on-chain encrypted attributes can be arbitrarily selected for verification under the control of the attribute owner. CertOracle ensures that on-chain certificate attributes are fine-grained verifiable and

long-term. Additionally, CertOracle is implemented with fully homomorphic encryption and secure two-party computation algorithms, and the experiments demonstrate that CertOracle is practical.

The remainder of this paper is organized as follows. Section II shows recent work. Section III introduces the preliminaries. Section IV describes the system model, security model, and the protocol details of CertOracle. Section V analyzes CertOracle. Section VI elaborates the CertOracle implementation and evaluates CertOracle with abundant experiments. Finally, Section VII draws conclusions.

## II. RELATED WORK

To feed blockchain with encrypted certificates, blockchain oracles need to verify the correctness of the encrypted certificate. According to recent research, the implementation of blockchain oracles could be divided into three categories [4]: TLS-based scheme, Enclave-based scheme, and Voting-based scheme.

TLS-based schemes are conducted to construct a protocol based on Transport Layers Security (TLS), such as TLS-N [5], DECO [6], etc. TLS is a protocol instrumented to guarantee message integrity and server authentication through the exchange of certificates during TLS-handshake. TLS-N, as a practical and decentralized blockchain oracle, enhances the audibility and reliability of web content based on the TLS. However, the scheme is less deployable, which requires some improvements to TLS. Therefore, DECO proposes a three-party protocol based on modifications of TLS client, which minimizes the modification requirements of the TLS protocol and enhances compatibility. CanDID [7] uses TLS-based oracles to fetch identity information securely from outside systems. However, the oracles are not viable for protecting the digital identity certificates issued by traditional identity systems.

Enclave-based oracle is constructed with Trusted Execution Environment (TEE), such as Intel Software Guard Extensions (Intel SGX) and TrustZone. Using the technology of Intel SGX, Town Crier [8] can encrypt and decrypt data requests from smart contracts and external data from data sources, securely managing sensitive information. But Town Crier highly depends on the trusted execution environment and may be vulnerable to side-channel attack [9].

Voting-based schemes, such as Augur, Oraclize [10], Chainlink [11] and Augur [12], motivate oracles to vote for data honestly through monetary rewards and penalties. Oraclize provides proof for the data it fetches, ensuring that the original data source is real and untampered. But its centralized model cannot guarantee that the service will always be available. ChainLink is a decentralized oracle solution on Ethereum. By querying multiple sources, ChainLink can avoid dependency of a single oracle. Augur is a prediction market platform oracle built on Ethereum. It allows users to vote on information from the outside world based on their tokens. Therefore, the prediction accuracy is limited by the scale of the platform, and the uneven distribution of tokens affects the credibility of results. Apart from that, voting-based schemes do not provide authenticity of the data and are not suitable when data is not publicly available, especially digital certificates.

## III. PRELIMINARIES

### A. Digital Certificate

Digital certificate such as X.509 [13] is an electronic document issued by CA. Since the user's digital identity certificate is issued by a trusted center, it can be used to prove personal attributes such as age, gender, and country. To produce a certificate, the attributes will be compressed using a one-way hash algorithm such as 256-bit Secure Hash Algorithms (SHA256) [14] first. Then a CA adopts a digital signature algorithm such as ECDSA and its private key to sign on the hash value. As a result, anyone can verify the signature with the CA's public key.

Taking the hash algorithm SHA256 and digital signature algorithm RSA as examples, CA chooses randomly two large prime numbers  $p$  and  $q$ , and computes  $N = pq$  and  $\phi = (p - 1)(q - 1)$  first. Secondly, it chooses a random integer  $e$  ( $1 < e < \phi$ ), so that  $\gcd(e, \phi) = 1$ , and computes  $d$  ( $1 < d < \phi$ ), so that  $ed \equiv 1 \pmod{\phi}$ . Then CA owns public key  $(N, e)$  and private key  $d$ . Thirdly, to generate hash value of certificate content  $M$  with  $l$  bits, CA adds a bit "1" at the end of the message, then add  $k$  "0", and finally, fills in 64 bits representing the length of the message.  $k$  is the smallest non-negative integer that satisfies:

$$l + 1 + k + 64 = 0 \pmod{512}$$

The padded message is divided into several message blocks  $M_0, M_1, \dots, M_n$  in unit of 512 bits, and the  $M_i$  is encoded using big-endian and represented as  $W_i^0, W_i^1, \dots, W_i^{15}$ . Then CA construct  $W_i$  tables for every block according to  $W_i^0, W_i^1, \dots, W_i^{15}$ . Then, for  $t = 16 \dots 64$ ,

$$W^t = \sigma_1(W^{t-2}) + W^{t-7} + \sigma_0(W^{t-15}) + W^{t-16}$$

After initializing  $A \dots H$ , CA runs 64 rounds of compression function with  $W_i$  table for every block, denoted as  $A_{64} \dots H_{64} = Com(A \dots H, W_i)$ , where  $Com(\cdot)$  is the hash operation of one block. The  $A_{64} \dots H_{64}$  will be assigned to  $A \dots H$  for compressing the next message block. After performing  $Com(\cdot)$  on every block sequentially, CA gets the hash value  $h$ .

Finally, CA computes  $\sigma = h^d \pmod{N}$  (Hereafter, we omit the padding processing in the digital signature algorithm for the sake of simplicity) and obtains  $\sigma$  as signature. To verify the signature, any entity can compute  $h = \sigma^e \pmod{N}$  and calculate  $h'$  using SHA256 with certificate to be verified. If the value of  $h = h'$ , it means that the certificate has not been tampered with and is indeed issued by the CA.

### B. Secure Multi-Party Computation

Secure multi-party computation (SMPC) protocol [15], is a cryptographic primitive that allows several participants to jointly calculate some functions and outputs correct results without revealing the original input data of the participants. It is suitable for distributed networks like blockchain because it deals with security and trust issues in a distributed environment.

As the simplest one in SMPC, a two-party computation (2PC) ensures that two non-trusted parties attempt to securely evaluate a function. Technically, it specifies a random

process that maps pairs of inputs to pairs of outputs, i.e.,  $f : \{0, 1\}^* \times \{0, 1\}^* \rightarrow \{0, 1\}^* \times \{0, 1\}^*$ , where each party has one private input and one output. For example, Goldreich-Micali-Wigderson (GMW) [16] protocol is a secret-shared-based 2PC scheme and can evaluate NOT, XOR and AND. For instance, for an XOR gate with input values  $x = \{x_i\}$  and  $y = \{y_i\}$  and output value  $z = \{z_i\}$ , two parties can compute their shares of the output value as  $z_i = x_i \oplus y_i$  locally, where  $\oplus$  is eXclusive OR (XOR). The evaluation of AND gate can be achieved using multiplication triples [17]. Multiplication triples are random shares  $\{a_i, b_i, c_i\}$ ,  $i \in \{1, 2\}$  with  $(c_1 \oplus c_2) = (a_1 \oplus a_2) \wedge (b_1 \oplus b_2)$ . They can be generated using 1-out-of-4 oblivious transfer protocol in the offline set-up phase which precedes the online phase. During online phase, the parties can use these multiplication triples to mask the input shares of the AND gate. Both parties exchange  $u_i = x_i \oplus a_i$  and  $v_i = y_i \oplus b_i$ , and compute  $u = u_1 \oplus u_2$  and  $v = v_1 \oplus v_2$ . Then the output can be computed as

$$z_1 = (u \wedge v) \oplus (b_1 \wedge u) \oplus (a_1 \wedge v) \oplus c_1 \quad (1)$$

and

$$z_2 = (b_2 \wedge u) \oplus (a_2 \wedge v) \oplus c_2 \quad (2)$$

for each party from their private input  $x$  and  $y$ .

### C. Fully Homomorphic Encryption

A Fully homomorphic encryption(FHE) scheme allows homomorphic evaluation of ciphertext addition and multiplication an arbitrary amount of times without decrypting the ciphertext or revealing the secret key [18]. That is to say, for any messages  $x$  and  $y$ , and a constant  $\alpha$ ,

$$\text{FHE}(\alpha x + y) = \text{FHE}(\alpha) \cdot \text{FHE}(x) + \text{FHE}(y) \quad (3)$$

for a fully homomorphic encryption algorithm  $\text{FHE}(\cdot)$ .

TFHE(Torus-FHE) [20] is the third generation of FHE based on the hardness of Learning with Errors(LWE) problem and its ring variant(Ring LWE). Running over the real Torus  $\mathbb{T} = \mathbb{R} \bmod 1$ , TFHE can fix the message space as a discrete subset  $\mathcal{M} \subseteq \mathbb{T}$ . A message  $\mu \in \mathcal{M}$  can be encrypted by computing

$$b = s \cdot a + \mu + e \quad (4)$$

where  $s \in \{0, 1\}^n$  is the secret key,  $a \in \mathbb{T}^n$  is uniformly random and  $e$  is sampled from an error distribution over  $\mathbb{T}$ . Then, the ciphertext is a pair  $c = (b, a) \in \mathbb{T}^{n+1}$ . In order to decrypt, phase  $\varphi_s$  is introduced to compute

$$\varphi_s(c) = b - a \cdot s \quad (5)$$

After rounding  $\varphi_s(c)$  to the nearest point in  $\mathcal{M}$ , message  $\mu$  can be obtained.

TFHE can transform an arbitrary function into a boolean circuit, then uses bit-wise homomorphic evaluation on ciphertext  $c_1, c_2$  as each gate's input. For example, the AND gate in TFHE is done by evaluating  $c = \text{BootsAND}(c_1, c_2, bk)$ , in which  $bk$  is a key used for bootstrapping. Other operations are also supported with similar gate operations, such as NOT, NAND, OR, XOR, etc. Since TFHE can evaluate arbitrary boolean circuits, it is very suitable for functions that can be represented by several logical operations.

## IV. THE PRESENT SCHEME CERTORACLE

CertOracle aims to feed the blockchain-based system with encrypted identify attributes so as to provide long-term self-sovereign identity. That is to say, the on-chain encrypted attributes can be used for fine-grained verification, ensuring that the attribute holder can have complete autonomy over their personal identity attributes for a long time. Thus, the scheme shall achieve the following goals:

- **Privacy:** The user's attributes in certificate are protected during the on-chaining process and on the chain.
- **Unforgeability:** The user's encrypted on-chain certificate attributes are verifiable as the traditional certificates and cannot be forged when uploading.
- **Fine-grained verification:** The on-chain attributes of certificates can be verified in a fine-grained way securely.

The parameters of CertOracle are shown in Table I.

TABLE I. NOTATIONS

Variable	Definition
$Attr_i$	: The $i$ -th attribute
$V_i$	: The $i$ -th attribute set $V$
$h_i$	: The $i$ -th bit of hash value $h$
$X'$	: The FHE encryption of a message $X$
$\hat{X}$	: The obfuscated value of a message $X$
$\{X_i\}$	: Vector $X = \{X_0, X_1, \dots, X_{ X -1}\}$
$cert$	: Identity certificate
$\sigma$	: Signature of a certificate

### A. System Model

As shown in Fig. 1, the blockchain-based identity system supports the management and control of users' identities. When a user has a digital identity certificate generated by an off-chain CA, he/she can upload the digital identity certificate to the system through blockchain oracle of CertOracle. To ensure users' self-sovereign of the on-chain certificates, CertOracle permits users to encrypt private information of digital certificates by themselves. Technically, oracle verifies the encrypted certificate, in order to confirm that the on-chain certificate is produced authentically. Then any verifier can check the selected attributes in a trusted and privacy-preserving way.

With reference to Fig. 1, CertOracle includes four components as follows.

- **User:** A user owns a certificate which can be represented as  $cert = (ID, \mathcal{M}, \sigma)$ , where  $ID$  is an identifier of the user,  $\mathcal{M}$  is the attributes of certificate and  $\sigma$  is signature generated by CA.  $\mathcal{M}$  can be seen as an array of  $\{Attr_i, V_i\}$ , where  $V_i$  is the value of the attribute  $Attr_i$ , and signature  $\sigma = \text{sign}(\text{hash}(\mathcal{M}))$  for attributes in the certificate with hash algorithm  $\text{hash}(\cdot)$  and signing algorithm  $\text{sign}(\cdot)$ . The user has a pair of self-generated FHE keys  $(pk_U, sk_U)$ , and can cooperate with the oracle to prove his encrypted attributes in the certificate.

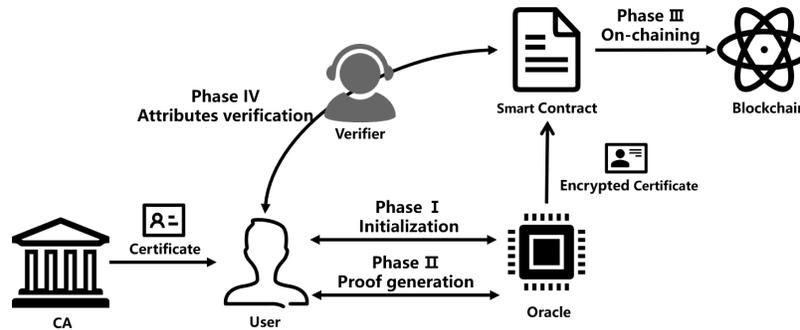

Fig. 1. The System Model of CertOracle.

- Oracle: Oracle has the trusted public keys of the CAs so as to verify the signatures of the certificates. In addition, by cooperating with users, oracle will prove/disapprove the encrypted certificate submitted from the user.
- Smart Contract: It can upload the encrypted attributes of certificates after attributes verification. Meanwhile, It can fetch any set of on-chain attributes and provide them to the verifier to check user's claims.
- Verifier: When a user likes to prove his attributes to a verifier, a verifier can validate on-chain encrypted attributes by interacting with the user and smart contract.

### B. Security Model

With reference to Fig. 1, there are 5 components or participants. CA is assumed to be honest and trusted by all. However, CA's private key may be updated irregularly, resulting in a decrease in the credibility of the old digital certificate. Therefore, only when the CA's private key is valid, the digital certificate issued by the CA is credible, otherwise the verification of the previously issued digital certificate will be considered to be unreliable. The security assumptions of the other components are as follows:

- Oracle is semi-honest. It honestly follows the protocol of CertOracle and will not be corrupted by users, but is curious about the personal attributes of the certificate.
- User is untrustworthy. A malicious user wants to 1) upload a forged digital certificate to blockchain through oracle; 2) deceive the verifier with fake attributes in order to obtain unauthorized services. In addition, the ciphertexts sent to the user are assumed to be well-formed. This assumption can be met with padding such as OAEP (Optimal Asymmetric Encryption Padding).
- Smart contract, as a part of the blockchain system, is trusted and can provide reliable services.
- Verifier is semi-honest. He follows the protocol to verify some attributes of the users but attempts to obtain user's attributes that do not need to be verified

### C. CertOracle Protocol

In Fig. 1, CertOracle comprises of four phases. 1) *Initialization* (Phase I) configures the parameters in CertOracle; 2) *Proof generation* (Phase II) validates the authenticity of the encrypted certificate; 3) *On-chaining* (Phase III) uploads the verified attributes in the certificate; 4) *Attribute verification* (Phase IV) checks the on-chain encryption of the user attributes. In this protocol, assume that the size of hash value is  $(n_1 + 1)$ . Without loss of generality, assume every attribute is binary, and the number of attributes is  $(n_2 + 1)$ .

1) *Phase I (Initialization)*: In the initialization stage, a user firstly sends a request to establish a connection with the oracle, and runs FHE key generation function to get public/private key pair  $(pk_U, sk_U)$ . The user keeps the private key  $sk_U$  during the proof generation and verification process for the encrypted attributes, and publishes the public key  $pk_U$  to oracle. Then the user encrypts some private attributes  $\{Attr_i, V_i\}$  in *cert* bit by bit using  $pk_U$ , and publishes other attributes of certificate, such as Version, Certificate Serial Number, Algorithm Identifier, and Validity Period in Certificate Information in the certificate format like X.509. In this paper, the public attributes are omitted, unless otherwise stated. Denote the ciphertexts  $V'_0, V'_1, \dots, V'_{n_2}$ . Denote the encrypted certificate  $cert' = (ID, \{Attr_0, V'_0\}, \dots, \{Attr_{n_2}, V'_{n_2}\}, \sigma)$ . The user constructs *ProofRequest* as

$$(op, ID, \{Attr_0, V'_0\}, \dots, \{Attr_{n_2}, V'_{n_2}\}, pk_U, \sigma)$$

and sends *ProofRequest* to the oracle. In *ProofRequest*, *op* is the operations on each attribute  $\{Attr_j, V'_j\}$ , such as Insert, Update and Delete operation on attributes.

After receiving *ProofRequest*, the oracle will verify the signature  $\sigma$  against the encryption of attributes. To this end, the oracle calculates the hash value of the ciphertext and runs the signature verification function with the public key of CA. If the verification result is positive and the certificate is not on the blockchain, the oracle starts to run the following phases.

2) *Phase II (Proof Generation)*: For any digital certificate generated from the hash-then-sign algorithm, the proof process of CertOracle can be divided into two solutions. If the user cannot keep connected with the oracle during proof generation, non-interactive proof protocol can be used; otherwise, interactive proof protocol is recommended

*Non-interactive proof protocol*: As shown in Fig. 2, if user can not stay online during proof generation, the ora-

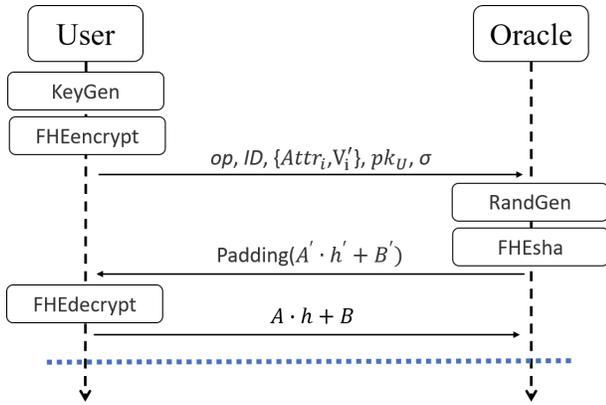

Fig. 2. The Non-Interactive Proof Protocol in CertOracle.

cle utilizes properties of fully homomorphic encryption to realize the proof process. Specifically, the oracle holds the  $cert' = (ID, \{Attr_i, V'_0\}, \dots, \{Attr_{n_2}, V'_{n_2}\}, \sigma)$ . It uses  $pk_U$  to encrypt each attribute  $\{Attr_i, V_i\}$  bit by bit.

To calculate the hash value of the fully homomorphic encryption of the certificate attributes, the oracle will run algorithm FHEsha whose input is the encryption of messages and whose output is the fully homomorphic encryption of hash of the messages<sup>1</sup>. That is to say, the oracle gets the encrypted hash

$$h' = \{h'_0, h'_1, \dots, h'_{n_1}\} = \text{FHEsha}(V'_1, V'_2, \dots, V'_{n_2}) \quad (6)$$

where  $V'_i$  is an FHE encryption of the  $i^{\text{th}}$ -bit message  $V_i$ , and  $h'_i$  is an FHE encryption of the  $i^{\text{th}}$ -bit of the hash value  $h = \text{hash}(V_0, V_1, \dots, V_{n_2})$ .

Moreover, the oracle generates two random arrays  $A = \{a_0, a_1, \dots, a_{n_1}\}$ , and  $B = \{b_0, b_1, \dots, b_{n_1}\}$ , and encrypts  $A$  and  $B$  to  $A' = \{a'_0, a'_1, \dots, a'_{n_1}\}$  and  $B' = \{b'_0, b'_1, \dots, b'_{n_1}\}$  using user's public key  $pk_U$  respectively, for all  $i = 0, 1, \dots, n_1$ ,

$$a'_i = \text{FHEncrypt}(a_i) \quad \text{and} \quad b'_i = \text{FHEncrypt}(b_i) \quad (7)$$

and obfuscates  $h'$  as<sup>2</sup>

$$\hat{h}'_i = a'_i \cdot h'_i + b'_i. \quad (8)$$

Oracle can pack<sup>3</sup>  $\{\hat{h}'_i\}$  into  $\hat{h}'$  and pad the ciphertext by<sup>4</sup>

$$BLOB = \text{FHEncrypt}(2^k) \cdot \hat{h}' + \hat{h}', \quad (9)$$

in which  $k$  is the number of bits of  $\hat{h}'$ , and obtains a blob equivalent to  $\hat{h}' || \hat{h}'$ .

<sup>1</sup>A hash function of plaintext can be translated into the encryption of the hash function of FHE ciphertext with google transpiler. Please refer to <https://research.google/pubs/pub50428/>

<sup>2</sup> $\{h'_i\}$  can be obfuscated in batch for quick process in Eq.8. Similar for  $\{V'_i\}$  in Eq.12 and  $\{\Delta'_i\}$  in Eq.15.

<sup>3</sup>Multiple LWE ciphertexts can be packeted into a ciphertext.

<sup>4</sup>Assume that the value of  $\hat{h}$  is less than half of the FHE domain. Similar for  $\hat{V}$  in Eq.13 and  $\hat{\Delta}$  in Eq.16

Afterwards, the oracle sends  $BLOB$  to the user for decrypting. The user uses his  $sk_U$  to decrypt the  $BLOB$  by

$$blob = \text{FHEdecrypt}(BLOB) \quad (10)$$

and determines that the  $blob$  conformed to the format of  $\hat{h} || \hat{h}$ . If the format is correct, the user returns  $\hat{h}$ . The oracle can recover

$$h_i = (\hat{h}_i - b_i) / a_i \quad (11)$$

and the hash value  $h = \{h_0, h_1, \dots, h_{n_1}\}$  for proving the authenticity of the encryption  $\{V'_i\}$  of the certificate attributes.

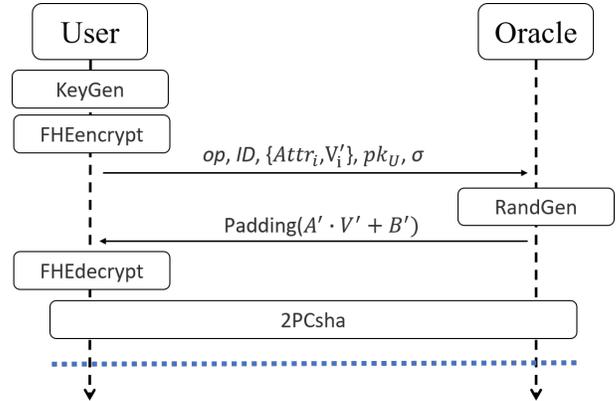

Fig. 3. The Interactive Proof in CertOracle.

*Interactive proof protocol:* as shown in Fig. 3, the oracle will interactive with the user using secure two-party computation based on secret sharing. The oracle holds the  $cert' = (ID, \{Attr_0, V'_0\}, \dots, \{Attr_{n_2}, V'_{n_2}\}, \sigma)$ . Similar to the non-interactive solution, the oracle generates two random arrays  $A = \{a_0, a_1, \dots, a_{n_2}\}$ ,  $B = \{b_0, b_1, \dots, b_{n_2}\}$ , and encrypts them to  $A' = \{a'_0, a'_1, \dots, a'_{n_2}\}$ ,  $B' = \{b'_0, b'_1, \dots, b'_{n_2}\}$  using  $pk_U$  as Eq.7. The oracle obfuscates the encrypted attribute  $V'$  as

$$\hat{V}'_i = a'_i \cdot V'_i + b'_i \quad (12)$$

After obfuscating, the oracle can pack  $\{\hat{V}'_i\}$  into  $\hat{V}'$  and send the padded ciphertext

$$BLOB = \text{FHEncrypt}(2^k) \cdot \hat{V}' + \hat{V}', \quad (13)$$

in which  $k$  is the number of bits of  $\hat{V}'$ , to the user. The user uses  $sk_U$  to decrypt  $BLOB$  according to Eq.10 and determines that the  $blob$  is equivalent to  $\hat{V}' || \hat{V}'$ , that is, equivalent to  $\{\hat{V}'_i\} || \{\hat{V}'_i\}$ .

To calculate the digest value of the encrypted certificate, the oracle and user jointly run 2PCsha based on boolean sharing. According to Subsection III-B, the user provides  $\{\hat{V}'_i\}$  and the oracle provides  $A = \{a_0, a_1, \dots, a_{n_2}\}$  and  $B = \{b_0, b_1, \dots, b_{n_2}\}$  to complete the 2PCsha protocol.

$$\{h_0, \dots, h_{n_1}\} = 2\text{PCsha}\left(\frac{\hat{V}'_0 - b_0}{a_0}, \dots, \frac{\hat{V}'_{n_2} - b_{n_2}}{a_{n_2}}\right) \quad (14)$$

In the 2PCsha scheme, the deobfuscation circuit will securely produce  $V_i = (\hat{V}_i - b_i) / a_i$  in the internal wires of the boolean circuit, and then perform the hash circuit to output the hash value  $h$  for attribute proof.

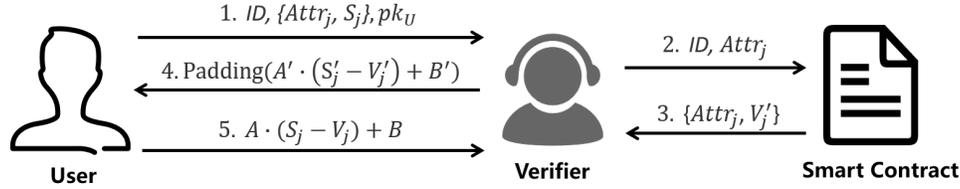

Fig. 4. The Workflow of Attribute Verification.

3) *Phase III (On-Chaining)*: After recovering the hash value  $h$ , the oracle can check the authenticity of the certificate signature with the signature verification algorithm. If and only if the recovered hash  $h$  matches the signature, the oracle determines that  $\{Attr_0, V_0'\}, \{Attr_1, V_1'\}, \dots, \{Attr_{n_2}, V_{n_2}'\}$  in *ProofRequest* are authentic and then uploads the encrypted certificate to the blockchain.

After oracle generates the proof of the encrypted certificate, smart contract checks if the user has certificate attributes on the blockchain. If not, it creates a DID (Distributed IDENTITY) for the user. If the user already exists, the smart contract verifies whether the user has permission to perform the specified operation through *op* such as Insert, updates or deletes the corresponding attributes in the blockchain.

4) *Phase IV (Attribute Verification)*: As the certificate attributes are encrypted and stored in the blockchain, anyone can query and verify user's attributes publicly without compromising the privacy of the attribute owner. Furthermore, in order to meet the requirement of self-sovereign identity, querying and verifying need the assistance of the owner as shown in Fig. 4.

Technically, when the verifier needs to check whether the value of the attribute  $Attr_j$  is  $S_j$ ,  $j = 0, 1, \dots, n_3$ ,  $n_3 \leq n_2$ , it will encrypt  $S_j$  to  $S_j'$  using the user's public key  $pk_U$ . After that, the verifier generates two random arrays  $A = \{a_0, a_1, \dots, a_{n_3}\}$  and  $B = \{b_0, b_1, \dots, b_{n_3}\}$ , and retrieves the encryption  $V_j'$  of the attribute  $Attr_j$  from the blockchain. To securely authenticate the user, the verifier computes

$$\hat{\Delta}'_i = \Delta'_i \cdot a'_i + b'_i \quad (15)$$

where  $a'_i, b'_i$  are ciphertext of  $a_i, b_i$  according to Eq.7 and  $\Delta'_i$  represents  $i^{th}$ -bit of  $S'_j - V'_j$ . Then the verifier packs  $\{\hat{\Delta}'_i\}$  into  $\hat{\Delta}'$  and sends padded blob

$$BLOB = FHEncrypt(2^k) \cdot \hat{\Delta}' + \hat{\Delta}', \quad (16)$$

in which  $k$  is the number of bits of  $\hat{\Delta}'$ , to the user.

After the user decrypts  $BLOB$  with private key  $sk_U$ , confirms that the decryption result conforms to the structure of  $\hat{\Delta} || \hat{\Delta}$ , and returns the obfuscated plaintext  $\hat{\Delta}$  to the verifier, the verifier deobfuscates  $\hat{\Delta}_i$  as

$$\Delta_i = (\hat{\Delta}_i - b_i) / a_i. \quad (17)$$

The verifier confirms the selected attributes of the user if and only if all the  $\Delta_i$  are 0 (The decision policies may depend on the applications).

## V. ANALYSIS OF CERTORACLE

As trust in identity certificates is transferred to the blockchain, the life cycle of these certificates can be extended to be the same as the lifetime of the blockchain. So these certificates become long-term certificates. This section discusses how CertOracle meets the goals to enable long-term self-sovereign certificates.

### A. Privacy

In our protocol, the attributes of the certificate are encrypted bit by bit using TFHE. The attributes of on-chain certificates are protected to guarantee user's self-sovereign over his identity. When CertOracle is running, oracle is semi-honest. It wants to know the plaintext of encrypted attributes in *ProofRequest*. Since oracle just gets  $pk_U$ , it cannot learn the plaintext  $V_i$  from  $\{Attr_i, V_i'\}$ . Meanwhile, oracle can't know the plaintext of  $V_1', V_2', \dots, V_{n_2}'$  through *hash* because of the non-reversibility of hash function.

In the non-interactive solution, the security is based on TFHE. There are many bit-wise operations in hash function. With the public key  $pk_U$ , the oracle of CertOracle can encrypt the attributes of certificate bit by bit so that it can calculate the hash value of the ciphertext message by itself. In the interactive solution, the security of the scheme is based on the GMW protocol. During 2PCsha,  $\hat{V}_i, A$ , and  $B$  are shared between oracle and user using boolean sharing. Thus, they look like uniformly distributed random data and this prevents the leakage of the data. A semi-honest adversary corrupting at most one of the participants can just observe secret shares of other's inputs. Meanwhile, the oracle can't learn the internal states of the circuit.

Moreover, we pad the output of Eq. 8, Eq. 12 and Eq. 15, that is, repeat the plaintext before encrypting it. By letting the decryptor check whether the decryption result meets a specific format, our system is resistant to potential fault injection attacks [19] from oracles and verifier.

### B. Unforgeability

Before users encrypt their certificates, malicious users may forge attributes by modifying the critical payload  $\{Attr_i, V_i'\}$  into another attribute's ciphertext  $\{Attr_i, \tilde{V}_i'\}$ . However, because of the collision resistance of hash function, it is impossible to find a  $\tilde{V}_i'$  replacing the true data  $V_i'$  to get the same hash. In the non-interactive solution, malicious users may submit forged *ProofRequest* but return true  $h$  when oracle sends  $h'$  back to decrypt after FHEsha. This may result in fake attributes being successfully verified. However, CertOracle obfuscates the  $h'$  by multiplying and adding a random number. It is

hard for malicious users to find out the relationship between obfuscated data and real data, and then forge data to pass verification. In the interactive solution, malicious users may submit forged *ProofRequest* but provide true data in the process 2PCsha. But they can't achieve because of obfuscation. In conclusion, CertOracle can effectively prevent forged certificates from being uploaded.

### C. Fine-Grained Verification

User can upload multiple certificates to the blockchain and aggregate the attributes of certificates. When a user needs to use some attributes from different certificates to meet the requirement of a target application, he can construct a claim about the attributes based on the on-chain certificate. The on-chain attributes are encrypted and the verification process requires user's assistance which prevents all attributes from being exposed. Meanwhile, CertOracle ensures that the user attribute can be verified in a fine-grained manner, thereby ensuring the principle of least leakage. In addition, when a verifier checks the users' attributes  $\{Attr_i, V'_i\}$ , he obfuscates the attributes to be verified. Since the malicious user does not know the random array  $A, B$ , they cannot forge  $\hat{V}$  to pass verification. However, verifiers may utilize deobfuscation to learn attributes that do not need to be verified. This can be mitigated by limiting the number of interactions between the verifier and the same user.

## VI. IMPLEMENTATION

The scheme is implemented and tested with an AMD Ryzen 7 4800U CPU with 1.8 GHz and 4 GB RAM, running Ubuntu 20.04 LTS. The implementation adopts TFHE library and ABY [21]. Although the scheme is suitable for all secure hash algorithms, SHA256 is used as an example in the implementation. In the experiments, the attribute value is an integer, and one user may have certificates from different CAs. As shown in Fig. 5, when a user clicks "Upload Certificate" button, the certificate will be uploaded to the chain via CertOracle. When a user clicks "Create Claim" button, an attribute verification process will be activated and the off-chain certificates can be uploaded through Oracle and shown in *CertificateList*. Thus, the user can select an on-chain certificate and create a claim according to the service's requirement.

### A. TFHE Setting

In CertOracle, we encrypt the certificate bit by bit using TFHE library. In the TFHE library, it needs at least one FFT processor to run the library. We choose FFTW3, which claims to be the fastest free FFT processor available, as the component. Meanwhile, the library provides two types of keys: cloud key and secret key. The cloud key is essentially a bootstrapping key used for cloud to perform homomorphic operations as well as encrypt constants, whereas the secret key is for encrypting the initial message and decrypting. Although addition and multiplication are not directly provided in TFHE library, we can utilize logical operations to build addition and multiplication of arbitrary bits.

In the TFHE library, the parameters are only implemented for 80-bit and 128-bit of security. Both these parameters are estimated using LWE estimator so that they can resist known

attacks integrated in LWE estimator, such as primal attack and dual-lattice attack. As cryptographers recommend at least 128-bit security in practice [22], we use the 128-bit security version of parameter set in the implementation. However, the TFHE library does not yet support ciphertext packing. Therefore we ignore the realization of padding in the experiment. Instead, the user directly decrypt the output of Eq. 8, Eq. 12 and Eq. 15 using FHEdecrypt.

### B. Basic Bitwise Operators

In the SHA256, there are many additional operations in the algorithm. The efficiency of CertOracle will be mainly limited by three basic operators: adder, multiplier and obfuscator.

1) *Bitwise Addition*: Addition between two integers can be implemented using two XOR gates, a AND gate and a MUX gate. The adder is based on the simple logic equations

$$S = X \oplus Y \oplus V'_{in} \quad (18)$$

and

$$V'_{out} = MUX_{(X \oplus Y)}(V'_{in}, X \cdot Y) \quad (19)$$

where  $X$  and  $Y$  are binary,  $V'_{in}$  is a bit that is carried in from the one less significant bit, and  $V'_{out}$  is a bit that is to be carried to the next significant digit. In  $MUX_{(X \oplus Y)}(V'_{in}, X \cdot Y)$ , the gate outputs  $V'_{in}$  if  $X \oplus Y = 1$  and outputs  $X \cdot Y$  otherwise. As the addition in our protocol is 16-bit addition or 32-bit addition, a 16-bit addition costs about 1.33s.

2) *Bitwise Multiplication*: It can be implemented using a combination of adder and multiplexer. The multiplexer, worked as  $MUX_{B[i]}(0, A)$  with  $A$  and  $B$  are 16-bit, outputs 0 if  $i$ -th bit of  $B$  is equal to 1 and outputs  $A$  otherwise. With the multiplexer worked on 16-bit, it will run 16 times and then perform addition every time. In short, the 16-bit multiplier includes 16 multiplexers and  $16 \cdot 16$  adders and takes about 11.457s on average which is expensive in time consumption.

3) *Bitwise Obfuscation*: With the bitwise adder and multiplier, we can evaluate the process of obfuscation. In both proof solutions, we need to obfuscate the data to be decrypted by users to prevent users from cheating. According to the number of obfuscated data, the oracle generates  $A, B$ . After the oracle selects the bytes to obfuscate, the data multiply and add different random numbers to get the same amount of obfuscated data. When deobfuscating, the oracle performs one subtraction and division to recover the original data. In the experiments, the obfuscation protocol takes about 127.939s to randomly obfuscate 10 bytes.

### C. Non-Interactive Proof Protocol

The non-interactive solution relies on TFHE library using parameters with security level of 128-bit. Since the additions modulo  $2^{32}$  in SHA256 need many gates, it is time-consuming for the oracle to perform a complete SHA256. To improve the efficiency of the protocol, a user may perform some steps of SHA256, including message padding, dividing, and W table construction. The user creates the W table for each block, and then sends the W tables to the oracle. The oracle only needs to perform the compression function.

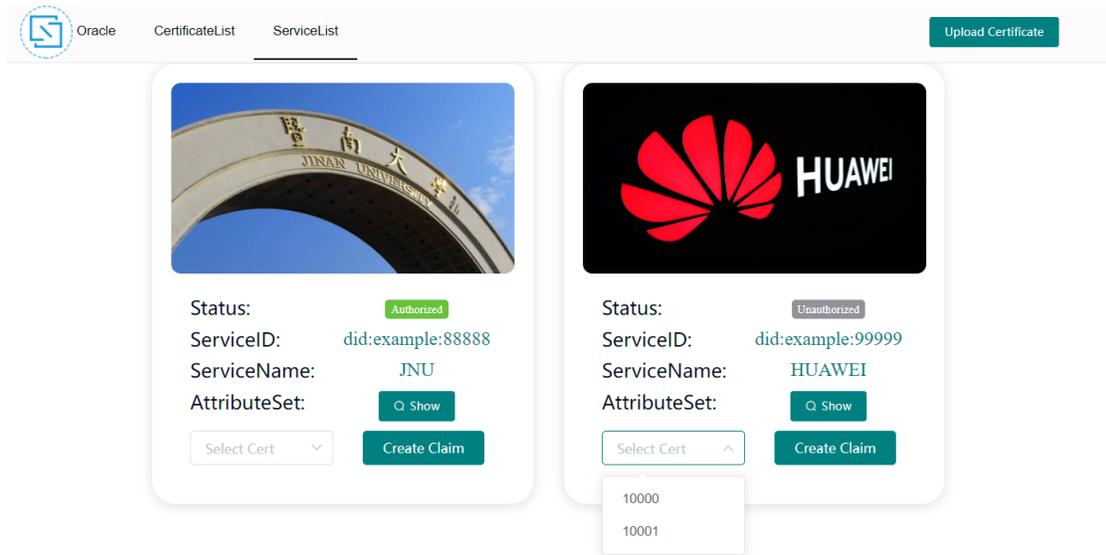

Fig. 5. The User-Interface of CertOracle.

The protocol is evaluated from two aspects. On the user side, we evaluate the function of key generation, procedure of partial SHA256(Message padding, Message dividing, and W table construction), encryption of 32 bits, and decryption of 16 bits. First, cloud key and secret key are generated in KeyGen. Secondly, PartialSHA256(64bytes) is to perform partial SHA256 calculation on 64bytes message and generate two blocks message. Thirdly, the time of certificate encryption is the time of multiple Enc(32bits) and the Dec(16bits) is a part of FHEdecrypt. On the oracle side, the result of running FHEsha with 64bytes and 128bytes messages are investigated. For instance, FHEsha256(64Bytes) is a homomorphic compression function for 64 bytes messages.

In the Table II for the evaluation results, the computation time of FHEsha in Table III doesn't include the time of obfuscation. Meanwhile, since the time spent in FHEsha is relatively large, the time on the user side is almost negligible. In all, the total time of the solution is the sum of FHEsha time plus obfuscation time.

TABLE II. EVALUATION OF NON-INTERACTIVE PROOF

Procedure	Time	Size
KeyGen	682.1ms	108.4MB / 108.4MB
PartialSHA256(64bytes)	0.041ms	2048bits
Enc(32bits)	0.42ms	0.077MB
Dec(16bits)	0.06ms	16bits
FHEsha(64bytes)	1834s	4.953MB
FHEsha(128bytes)	3668s	4.953MB

#### D. Interactive Proof Protocol

ABY is a framework for efficient mixed-protocol secure two-party computation in the interactive solution. It combines secure computation schemes based on arithmetic sharing, boolean sharing, and Yao sharing. The boolean sharings are used to evaluate functions represented as boolean circuits using the GMW protocol. Though ABY allows developers to manually specify which part of a function should be computed in

which sharing to achieve the best overall efficiency, we use the boolean sharing part of ABY to test the present protocol. This framework, using the semi-honest adversary model, works like a virtual machine that abstracts secure computation protocols. Thus, the implementation of CertOracle constructs 2PCsha using GMW protocol [16] in the ABY.

Using an XOR-based secret sharing scheme to share a variable, the boolean sharing can perform the evaluation on NOT, XOR, AND, and others. While XOR gate and NOT gate can be evaluated locally, AND gate is evaluated using a precomputed boolean multiplication triple which reduces the impact of the latency during the online time. Next, we introduce the evaluation of the interactive solution in a local area network(LAN) environment.

In the ABY framework, the OT (Oblivious Transfer) extension protocol uses few base-OTs to quickly compute a large number of OTs so as to generate multiplication triples. As the base-OTs are performed once when the connection between the client and the server is established, their computation time is omitted in the total time. As a result, the average run-time is 377.595s and the communication overhead is 49,964 bytes.

The main part of 2PCsha comprises setup phase and online phase. The setup phase includes the pre-computation of some nonces generation for one-time pad operation and the multiplication triples for the AND gates. The run-time and communication overhead depend on the AND depth of the circuit, that is the number of messages. The online phase takes place after the setup phase is done and the inputs to the circuit are supplied by both parties. During online phase, two independent 2-bit messages have to be transmitted per layer of AND gates. This interaction in online phase causes a performance bottleneck, especially in high latency networks. Meanwhile, the ABY framework implements load balancing for the setup phase. As a consequence, the computation and communication cost are equally distributed among the two parties.

TABLE III. RUN-TIME AND COMMUNICATION OVERHEAD OF INTERACTIVE PROOF

Message Size	Time[ms]			Communication[bytes]		
	Setup phase	Online phase	Total	Setup phase	Online phase	Total
64	262.579	3,507.48	3,770.07	6,607,027	113,993	6,721,020
128	380.033	4,991.22	5,371.27	10,774,766	185,713	10,960,479
196	435.822	6,505.23	6,941.07	14,948,640	257,417	15,206,057

In the circuit of 2PCsha, the oracle and user will jointly perform subtraction and division to deobfuscate data provided by the user. Then both get the intermediate wires and run the SHA256 circuit. On average, the run-time and communication overhead in 2PCsha for different message sizes are shown in Table III. And each part is also divided into the setup phase and the online phase to display separately. Clearly, the interactive solution has better performance than non-interactive solution.

## VII. CONCLUSION

This paper presents CertOracle, a management scheme that provides long-term and self-sovereign certificate to solve the problem of traditional certificate expiration and privacy leakage. Specifically, CertOracle allows users to encrypt the private data of the digital certificate by themselves, ensuring that the encrypted certificate is uploaded to blockchain authentically via oracle. Therefore, the blockchain-based identity system can achieve privacy, unforgeability and fine-grained verification. Meanwhile, the uploading method of the certificate can be selected according to the latency of the network between the oracle and the user. The implementation and experiments of CertOracle show that both non-interactive proof and interactive proof protocols can satisfy the requirements of the long-term and self-sovereign certificates.

**Abstract**—Electricity theft-induced power loss is a pressing issue in both traditional and smart grid environments. In smart grids, smart meters can be used to track power consumption behaviour and detect any suspicious activity. However, smart meter readings can be compromised by deploying intrusion tactics or launching cyber attacks. In this regard, machine learning models can be used to assess the daily consumption patterns of customers and detect potential electricity theft incidents. Whilst existing research efforts have extensively focused on batch learning algorithms, this paper investigates the use of online machine learning algorithms for electricity theft detection in smart grid environments, based on a recently proposed dataset. Several algorithms including Naive Bayes, K-nearest Neighbours, K-nearest Neighbours with self-adjusting memory, Hoeffding Tree, Extremely Fast Decision Tree, Adaptive Random Forest and Leveraging Bagging are considered. These algorithms are evaluated using an online machine learning platform considering both binary and multi-class theft detection scenarios. Evaluation metrics include prediction accuracy, precision, recall, F-1 score and kappa statistic. Evaluation results demonstrate the ability of the Leveraging Bagging algorithm with an Adaptive Random Forest base classifier to surpass all other algorithms in terms of all the considered metrics, for both binary and multi-class theft detection. Hence, it can be considered as a viable option for electricity theft detection in smart grid environments.

**Keywords**—Smart grid; power loss; electricity theft; online machine learning

## I. INTRODUCTION

Utilizing energy resources effectively and efficiently is a crucial part of every nation's social and economic growth due to the high cost of energy acquisition and the scarcity of energy resources [1]. Future energy monitoring may now be used to its fullest potential thanks to the smart grid. The smart grid system can be characterized as a whole electrical network made up of the power system infrastructure, computers to control and monitor energy usage, and a sophisticated monitoring system that keeps track of the behavior and usage patterns of all system users [2]. Today, one of the most obvious problems affecting both traditional power grids and smart grids is electric power loss. Countries experience different levels of electricity losses. For instance, 6%, 10%, 16%, and 18% of each country's total energy production was lost in the USA, Russia, Brazil, and India, correspondingly [1]. In the transmission and distribution of electricity, there are two different categories of losses: technical and nontechnical. Energy losses in the machinery required for power transmission and distribution are referred to as technical losses. Power theft, fraud on the part of

utility employees, and irregular billing practices all contribute to non-technical losses (NTL) [3]. The NTL is estimated to cost utilities around the world US\$96 billion annually [4]. Power providers, engineers, and academics are working to reduce NTL in a number of creative and effective ways due to the significant economic loss [5]. One of the most effective strategies to prevent energy theft is the use of smart meter-based Energy Internet (EI) [6]. Such a technique may be used to remotely track consumption data from customers, record any suspicious activity, and quickly send the data to the utility. Despite their many benefits, smart meters are impractical for countries experiencing severe economic difficulties due to the significant costs associated with their deployment and maintenance. Before these tools are extensively deployed, it is also necessary to adequately manage the expanding cyber dangers. It is difficult to secure the information flow of the EI because of the unique characteristics of advanced metering infrastructure (AMI). By deploying intrusion tactics, the unauthorized users can alter data from smart meters. Because of this, power thefts on the EI are distinct from those that occurred on the traditional grid and were primarily the result of physically avoiding or extinguishing the mechanical [3]. The energy usage patterns of consumers may be automatically tracked by machine learning (ML) algorithms. When examining the data from smart meters, it may help to identify power thieves with greater accuracy. In other words, Machine learning technologies, such as decision trees, random forests, support vector machines, neural networks, and others, can be used to create classification models in order to assess the daily electricity usage habits of customers [7], [8]. Typically, machine learning algorithms can be applied in either offline or online scheme. In the offline (i.e. batch) learning, a dataset of electricity consumption patterns is assumed to be available offline. Thereafter, a classification model is trained and evaluated to classify users as either malicious or benign based on their consumption patterns [9], [10]. The developed model can then be deployed in a real environment to make online predictions. On the other hand, the online (a.k.a incremental) learning scheme relies on the fact that smart meters reading arrive as a continuous stream of data. Hence, a classification model needs to be incrementally constructed by examining one instance at a time. Apparently, the batch learning scheme assumes that the whole dataset is stored in memory while building a machine learning model. However, it is well recognized that the batch learning approach has a number of drawbacks. First, the training phase could take a very long time and use up a significant portion of computer resources. Second, the amount of the training dataset has an

impact on the trained model's performance. Third, after the model is trained, it cannot acquire new experience from new input instances since in a offline (i.e., batch) learning scheme, the training data are assumed to be static and unchanging over time. To put it another way, it is necessary to build a new model whenever the statistical characteristics of the model's input change (i.e., a concept drift is encountered). Online classification algorithms are advantageous over off-line (i.e. batch) classification algorithms for a number of reasons, especially given that the smart meter readings in smart grids provide a constant stream of data. First off, algorithms for online classification are built to handle infinite amounts of data and gradually pick up new information. While creating projections as necessary, they are continuously updated. Second, real-time applications that conventional (i.e. batch) learning algorithms cannot handle can be addressed by online data stream classification systems. Online classification is thus viewed as a viable technique for classifying electricity consumption patterns in smart grid systems because user behavior may change over time in an unanticipated way. Numerous techniques have been put forth for the classification of data streams [11]–[13]. To the best of the authors' knowledge, no study has ever been done on how well these algorithms perform in detecting electricity theft in smart grids, despite the fact that some of them have been studied in various fields [14]–[21]. In addition, previous research efforts have tackled electricity theft detection using batch learning algorithms [9], [22]–[25]. Hence, the contribution of this paper is threefold. First, implementing online machine learning models for electricity theft detection, based on a recent specialized dataset. Second, performing an extensive set of experiments under both binary and multi-class theft detection scenarios. Third, identifying the most viable online machine learning model for theft detection in smart grids, considering a representative set of performance metrics.

The rest of this paper is organized as follows. Section II provides background information on the considered algorithms. Section III explains the research tools and evaluation methodology. Evaluation results are shown in Section IV. Finally, Section V concludes and summarizes this paper.

## II. BACKGROUND

Models from static datasets have traditionally been created using ML techniques. The need for models that can handle enormous data streams is, nevertheless, expanding. This means that additional data samples might appear at any time, and it is unsuitable to store them in a static dataset.

On the one hand, learning from continuous and evolving data streams necessitates the development of the ML model and continual stream upgrades. Additionally, it is crucial to combat concept drift, in which the statistical characteristics of the evolving data change with time [26], [27]. The resultant ML model must also be immediately updated for smart grid environments, needing algorithms with appropriate levels of accuracy subject to constrained memory and processing capacity.

### A. Bayes Learning Algorithms

The Naive Bayes (NB) algorithm is used in this category. The NB method uses Bayesian prediction on the presumption

that each input feature included within an input instance is independent. An NB model predicts every incoming data sample's class with a high degree of certainty. The NB algorithm is distinguished by its simplicity and minimal processing demands [12].

### B. Lazy Learning Algorithms

The k-Nearest Neighbors classifier (kNN) and the self-adjusting memory combined with the kNN classifier (SAM-kNN) [28], [29] are two well-known lazy learning algorithms that are taken into consideration in this work. In online learning environments, the kNN algorithm relies on maintaining track of a window with a fixed number of recently encountered input data samples. The kNN algorithm looks within the recently stored window and, using a predetermined distance metric, determines the closest neighbors whenever a new input data sample is observed. The current input sample's class label is then allocated appropriately. The SAM-kNN, on the other hand, is an improvement over the standard KNN. A self-adjusting memory (SAM) model creates an ensemble of classification models for either current or prior concepts in SAM-KNN. Depending on the needs of the present concept, several models can be used. A short-term (STM) and long-term (LTM) memory are built specifically by the SAM model. The STM is built to represent the current concept, whereas the LTM is used to represent earlier concepts. A cleaning procedure is utilized to regulate the STM's size and keep the LTM and the STM consistent.

### C. Tree-based Learning Algorithms

Online machine learning applications frequently employ tree-based methods. The Hoeffding Tree (HT) [30] and the Extremely Fast Decision Tree (EFDT) from [31] are the two main tree-based algorithms employed in this work. The HT method is a decision tree induction method that, under the premise that the distribution that yields the entering data samples is constant and does not evolve over time, may learn gradually and whenever from immense online data streams. It is based on the observation that choosing the best splitting attribute may frequently be done with only a limited quantity of input samples. This statement is supported theoretically by the Hoeffding bound, which counts the number of input instances needed to estimate a particular set of statistics with a given precision. The HT technique is potentially more enticing than other incremental (i.e., online) tree-based algorithms because it provides high performance guarantees. It can be demonstrated that the outcome of an HT model is asymptotically identical to that of a batch-based learner employing infinitely many input data samples by depending on the Hoeffding bound. Additionally, the EFDT classification algorithm incrementally constructs a tree. Once it is certain that a split is useful, it looks for picking and deploying that split. Later, it reviews that split choice and replaces it if it becomes clear that a more advantageous split is there. If the distribution that generates the input instances is stable, the EFDT can quickly pick up on static distributions and finally learn the asymptotic offline tree.

### D. Ensemble Learning Algorithms

Two ensemble learning methodologies are assessed in this article including Leveraging Bagging LB [32] and Adaptive

Random Forest ARF [33]. Leveraging bagging is an enhanced online bagging algorithm. In this regard, online bagging mimics conventional offline Bagging to cope with incremental learning. For offline bagging scheme,  $N$  samples are taken from an  $N$  sized training dataset with replacement creating  $N$  separate datasets for  $M$  classifiers to be trained on. Since there is no training dataset but only a stream of samples in online learning environments, drawing input samples with replacement is not an easy task. The online bagging simulates the batch based training process by training each base estimator on each incoming instance over  $k$  times, where  $k$  is drawn from the binomial distribution. Given that the input stream may be considered endless and that the binomial distribution approaches a Poisson  $\lambda = 1$  distribution with infinite samples, the work in [34] has found that the procedure used by the on-line bagging algorithms is a good "drawing with replacement". The LB algorithm makes an effort to enhance classification outcomes when assuming an infinite input data stream by modifying Poisson distribution's parameters produced from the binomial distribution. The LB technique causes the  $\lambda$  value of the Poisson distribution to change from 1 to 6. The new value of  $\lambda$  would broaden the input space's diversity by giving the input data samples a variety of weights. In order to achieve even greater improvement, the LB approach uses output detecting codes. Each bit in the  $n$ -bit long binary code used to encode the detection codes for each class label corresponds to a particular one of the  $n$  classifiers. Every classifier is trained on its corresponding bit while a new input instance is being looked at. This helps the LB algorithm reduce linked errors to a certain extent.

The standard batch based random forest technique has been modified for the online learning scope by the ARF algorithm. A weighted voting method is used in ARF to decide how to categorize each incoming data instance after many decision trees have been built. The classification choice is prioritized and the voting procedure is weighted more heavily in favor of the decision tree that performs the best in terms of Kappa or the accuracy statistic.

### III. RESEARCH TOOLS AND METHODOLOGY

#### A. Dataset

This work is based on the Theft Detection Dataset (TDD2022) proposed in [3]. The dataset was gathered using the Open Energy Data Initiative (OEDI) platform which is a consolidated repository for high-value energy research datasets collected from the Programs, Offices, and National Laboratories of the United States Department of Energy [35]. The information in TDD2022 stems from various domains such as private industrial parties, laboratories, institutions, etc. The dataset is composed energy consumption data for 16 different consumer types. It encloses several energy consumption measurements for distinct customer types during a one-year period. Those measurements are recorded on hourly basis during the day. This data was then used to implement a theft generator for six different types of electricity theft. Each instance in the dataset contains 11 meter readings, consumer type, and a class label as either normal consumption or one of the six theft types. Tables I, II, III and IV illustrate the dataset general statistics, feature types, customer types and instances distribution on classes, respectively.

TABLE I. GENERAL STATISTICS

Item	values
Number of instances	560640
Number of categorical features	1
Number of numerical features	10
Customer types	16
Instances per customer type	35040
Number of classes	7

TABLE II. CUSTOMER TYPES

Type	Integer code
Full service restaurant	1
Hospital	2
Large hotel	3
Large office	4
Medium office	5
Medrise apartment	6
Primary school	7
Outpatient	8
Warehouse	9
Secondary school	10
Small hotel	11
Small office	12
Stand-alone retail	13
Strip mall	14
Supermarket	15
Quic service restaurant	16

TABLE III. FEATURE TYPES

Name	Type
Electricity-Facility (KW/Hr)	Numeric
Fans-Electricity (KW/Hr)	Numeric
Cooling-Electricity (KW/Hr)	Numeric
Heating-Electricity (KW/Hr)	Numeric
Interior lights-Electricity (KW/Hr)	Numeric
Interior equipment-Electricity (KW/Hr)	Numeric
Gas-Facility (KW/Hr)	Numeric
Heating-Gas (KW/Hr)	Numeric
Interior equipment-Gas (KW/Hr)	Numeric
Water systems-Gas (KW/Hr)	Numeric
Consumer Type (KW/Hr)	Categorical

TABLE IV. INSTANCES DISTRIBUTION

Class name	Total number of instances
Normal	331824
Theft-1	51083
Theft-2	22958
Theft-3	44349
Theft-4	41460
Theft-5	33553
Theft-6	35413

The first theft type consists of a pronounced reduction of electricity consumption during the day. Such reduction is attained by multiplying the consumption by a uniformly distributed random number in the interval[0.1,0.8]. For the second theft type, electricity consumption is randomly dropped to zero throughout an arbitrary period. In addition, the third theft type resembles the first type except the fact that each hourly consumption is multiplied by a random number. Moreover, a random portion of the mean consumption is generated for the fourth theft type. Furthermore, the fifth type of theft reports the mean consumption. Finally, the sixth theft type reverses the order of the consumption values.

### B. Evaluation Methodology

This section outlines the key procedures used to assess the effectiveness of the online machine learning (i.e., classification) algorithms on the TDD2022 dataset. The evaluation process using the scikit-multiflow evaluation platform [36] is shown in Fig. 1. Every online classification algorithm goes through this review process. As seen, the dataset is initially loaded as an input stream and then sent to the classification algorithm after that algorithm’s initialization for online testing, incremental learning, and evaluation.

The prequential or the interleaved test then train method is used in this study to assess the classification algorithms. As each incoming input sample (i.e. instance) serves two purposes and is analyzed sequentially in order of arrival before becoming instantly inaccessible, the prequential assessment approach was created specifically for online learning environments. In prequential evaluation, each observed input instance is first employed to test the classification model (i.e. to generate a prediction), and then the same input instance is used to train that classification model. Each tested model’s performance is continuously updated after each encountered instance and its capacity to handle unobserved cases is continuously monitored in real-time. As a result, a classification model that has been instantiated is constantly tested and the metrics that go with it are updated for input instances that it has not yet encountered. A number of commonly used performance metrics including accuracy, precision, recall, F-1 score and the kappa statistic derived from online learning models are used to quantify the performance of the classification algorithms. These measures are defined as follows:

- **Classification accuracy:** is the proportion of correctly classified input instances.

$$Accuracy = \frac{TN + TP}{TP + FP + FN + TN} \times 100\% \quad (1)$$

where, respectively, TP, TN, FP, and FN stand for true positive, true negative, false positive, and false negative. TP is the total number of cases that were successfully identified as positive (i.e., theft). The number of successfully identified negative (i.e., normal) events is referred to as TN. FP is the total number of positive samples that are mistakenly labeled as negative ones. The total number of negative occurrences that are mistakenly labeled as positive occurrences is known as FN.

- **Precision:** determines the proportion of predictions for the positive class that are in fact members of the

positive class.

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

- **Recall:** calculates the proportion of correctly predicted classes that are positive out of all occurrences that are positive in the observed stream.

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

- **F-score:** is the precision and recall harmonic mean.

$$F - score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (4)$$

- **Kappa statistic ( $\kappa$ ):** is a reliable classification accuracy metric that takes the likelihood of agreement by chance into account. It indicates the superiority over the majority class classifier, which assume that all

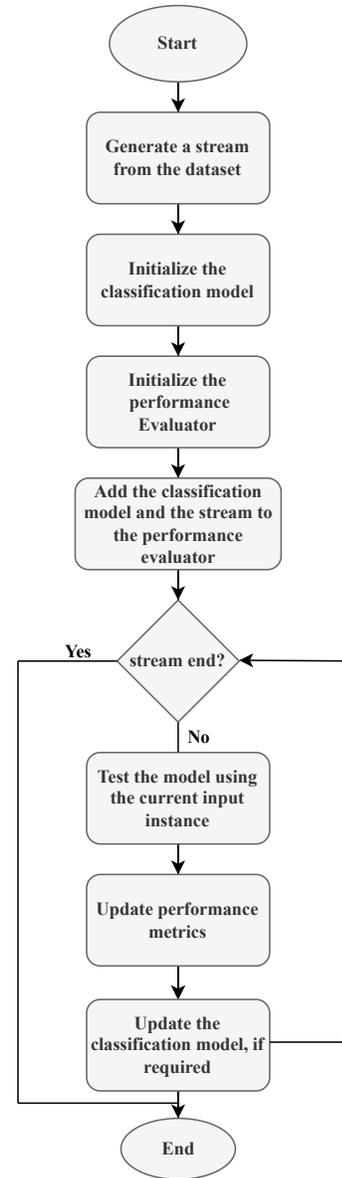

Fig. 1. Evaluation Flowchart.

incoming cases will fall within the majority class [37]. In particular for data streams with unbalanced class distribution, it is crucial in assessing classification accuracy.

$$\kappa = \frac{p_0 - p_c}{1 - p_c} \quad (5)$$

where  $p_0$  denotes the classifier's predictive accuracy and  $p_c$  denotes the likelihood that a random classifier will produce an accurate prediction [38]. The classification procedure is always correct if  $\kappa = 1$ .

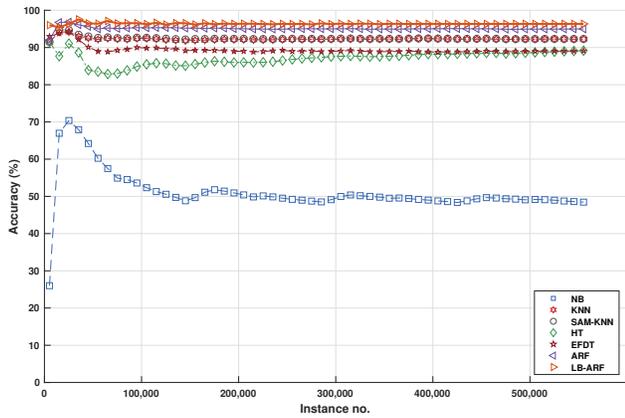

#### IV. RESULTS AND ANALYSIS

This section shows the predictive performance of the considered online machine learning algorithm on a data stream generated from the TDD2022 dataset. The considered algorithms were tested under both binary and multi-class classification settings. In binary classification, each instance in the TDD2022 dataset is labelled as either normal or theft instance regardless of the theft type. For the multi-class classification, the consumption instances retain their original labelling (i.e., normal, Theft-1, Theft-2, Theft-3, Theft-4, Theft-5 or Theft-6). Fig. 2(a), 2(b), 2(c), 2(d) and 2(e) depict the running mean prediction accuracy, precision, recall, F-1 score and kappa statistics of the considered learning algorithms under binary classification settings. They considered algorithms were pre-trained on the first 5000 samples and then prequentially evaluated and trained on the remaining part of the consumption stream. As shown, the KNN, SAM-KNN, ARF and LB-ARF algorithms have steadily maintained high mean values of accuracy, precision, F-1 score and kappa statistic, as compared to the NB, HT and EFDT algorithms. In addition, the NB, HT and EFDT algorithms demonstrate fluctuating performance during the first 100,000 instances. On the other hand, the NB, ARF and LB-ARF have maintained higher mean recall values, when compared to the other algorithms. However, the NB algorithm exhibits fluctuating behaviour during the 200,000 instances. Furthermore, the relatively high kappa values of the ARF and LB-ARF algorithms indicate reasonable reliability of their predictive performance. In other words, they are able to incrementally learn the statistical characteristics of the incoming normal and theft instances adapt reliably to unseen instances. Overall, the LB-ARF algorithms outperforms the other algorithm under all the considered performance metrics. Fig. 3(a), 3(b), 3(c), 3(d) and 3(e) depict the running mean prediction accuracy, precision, recall, F-1 score and kappa statistics of the considered learning algorithms under multi-class classification settings. On the one hand, Fig. 3(a) depicts that the KNN, SAM-KNN, ARF and LB-ARF have achieved relatively acceptable accuracy levels ( $\geq 80\%$ ), as compared to the other algorithms, taking into account the complexity of multi-class classification as compared to the binary one. On the other hand, Fig. 3(b), 3(c) and 3(d) demonstrate the ability of the LB-ARF algorithm to maintain acceptable precision, recall and F-1 score, when compared to the other algorithms. Similar to the case of binary classification, the relatively high kappa value of the LB-ARF demonstrate its superior performance reliability over other algorithms. Fig. 4(a), 4(b), 4(c), 4(d) and 4(e) compare the predictive performance of the considered algorithms on binary and multi-class theft detection settings. In general, the predictive performance of all

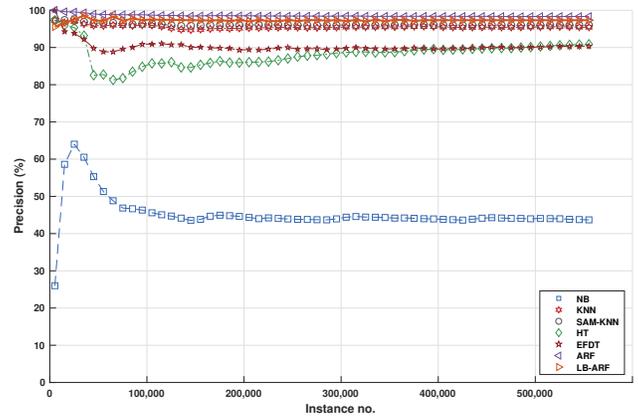

algorithms in binary classification is higher as compared to that of multi-class classification. Unlike other algorithms, the LB-ARF algorithm has maintained comparable performance levels under all metrics for both binary and multi-class classification. It is worth noting that the tree-based algorithms exhibit higher performance drop when moving from binary to multi-class classification, as compared to the other categories.

In summary, the LB-ARF (i.e., Leveraging Bagging algorithm with an Adaptive Random Forest base classifier) demonstrates consistent competence to perform theft detection under both binary and multi-class classification scenarios. This algorithm keeps a collection of  $n$  ARF base classifiers, where  $n$  in the used evaluation platform is set by default to 10 [36]. In order to classify an incoming instance, each classifier will make a prediction (i.e., a vote), and the ultimate classification result is produced by combining the individual forecasts. The Condorcet's jury theorem has a theoretical demonstration, assuming two criteria are satisfied, that the error rate of a particular ensemble tends to zero in the limit [39]–[41]. First, Individual base classifiers must outperform random guessing. This requirement is attained as the ARF algorithm achieves relatively high predictive performance that is better than random guessing as shown in Fig. 2, 3 and 4. Typically, the accuracy of a random classifier (i.e., random guess) is equal to  $1/k$  where  $k$  is the total number of classes. In this work, the total number of classes is equal to 2 in case of binary classification and 7 in case of multi-class classification.

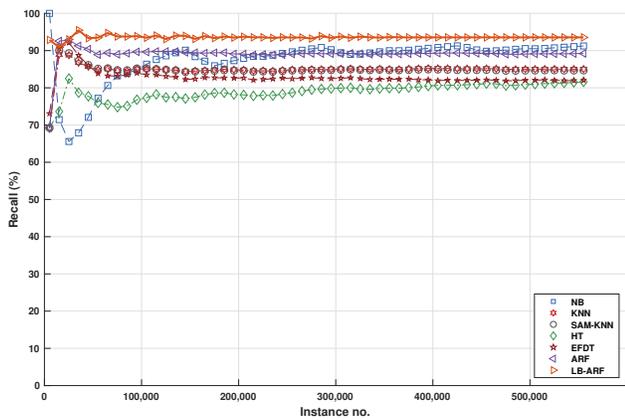

Second, each classification model must be diverse; that is, it must not generate correlated errors. For the LB-ARF method, online bagging is used by the LB algorithm to train its associated base classification models. In this context, an online re-sampling is carried out as each incoming classification case is noticed by showing that instance to every model  $k$  *sim* Poisson ( $\lambda$ ) times and updating every model in accordance. The value of  $k$  is treated as the incoming instance's weight. In order to increase online re-sampling, the  $\lambda$  value of the Poisson distribution is typically set to 6 in the LB algorithm. The LB ensemble algorithm is making the incoming instances weights more random with such a value of  $\lambda$ . As a result, it increases the diversity of the input space by giving each incoming instance a new range of weights. The LB technique further improves bagging performance by applying output codes to add randomization to the ensemble's output. As seen in Section II-D, Each prospective class label is given an  $n$ -bit binary string, where  $n$  is the total number of base classifiers in the ensemble. Each base classifier learns a single bit from the binary string. The LB algorithm utilized random output codes instead of deterministic ones, in contrast to typical ensemble approaches. To put it another way, employing output codes enables each classifier in the LB ensemble to predict a separate function, whereas the base classifiers in the traditional approaches predict the same function [32]. This would reduce the impact of correlations among base classifiers and, as a result, improve the ensemble's diversity [42], [43]. The ensemble thus partially satisfies the second criteria of the Condorcet's jury theorem by adding randomization to both the input and the output of the ensemble's base classifiers. Additionally, the LB method employs the ADWIN method to handle concept drift, employing ADWIN instance per classifier in the ensemble [28]. The poorest classifier is reset whenever a concept drift is found. As a result, the LB algorithm con-

(e) Kappa

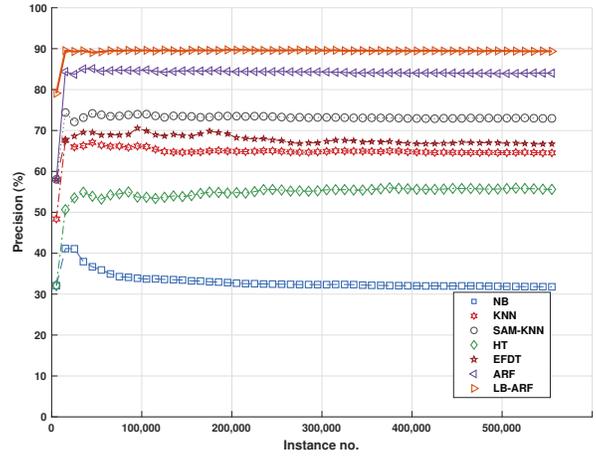

Fig. 2. Performance Results - Binary Classification

tinuously assesses the effectiveness of its learning procedure and follows the current distribution of class labels within the incoming classification examples. The classification errors caused by any given classifier would typically be offset by the LB-ARF's diversity among its basic classifiers. This can be observed in Fig. 2, 3 and 4 wherein an LB ensemble of ARF classifiers always achieve higher predictive performance

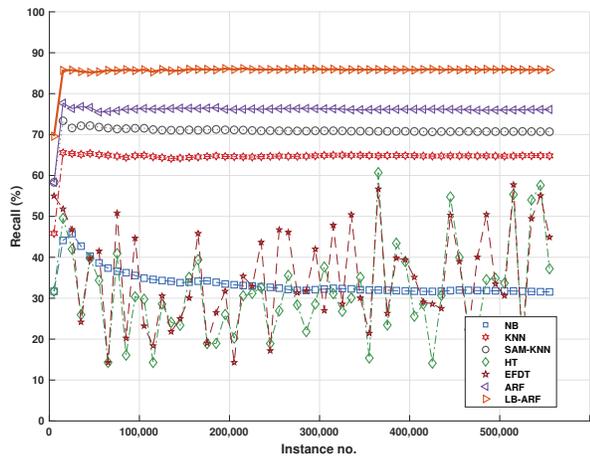

than a single ARF instance. Overall, the LB-ARF algorithm has demonstrated its ability to sustain an audible performance under all taken into account performance metrics. This makes it a viable option for online theft detection (i.e. classification) in real-world smart grids.

## V. CONCLUSION

Power loss brought on by electricity theft is a critical issue in both traditional and smart grid settings. Smart meters can be used in smart grids to monitor power usage patterns and spot any questionable activities. However, using hacking techniques

or cyber attacks can undermine smart meter readings. In this sense, machine learning algorithms can be employed to evaluate client daily consumption patterns and identify probable instances of electricity theft. This work studied the application of online machine learning algorithms for electricity theft detection in smart grid systems, based on a recently

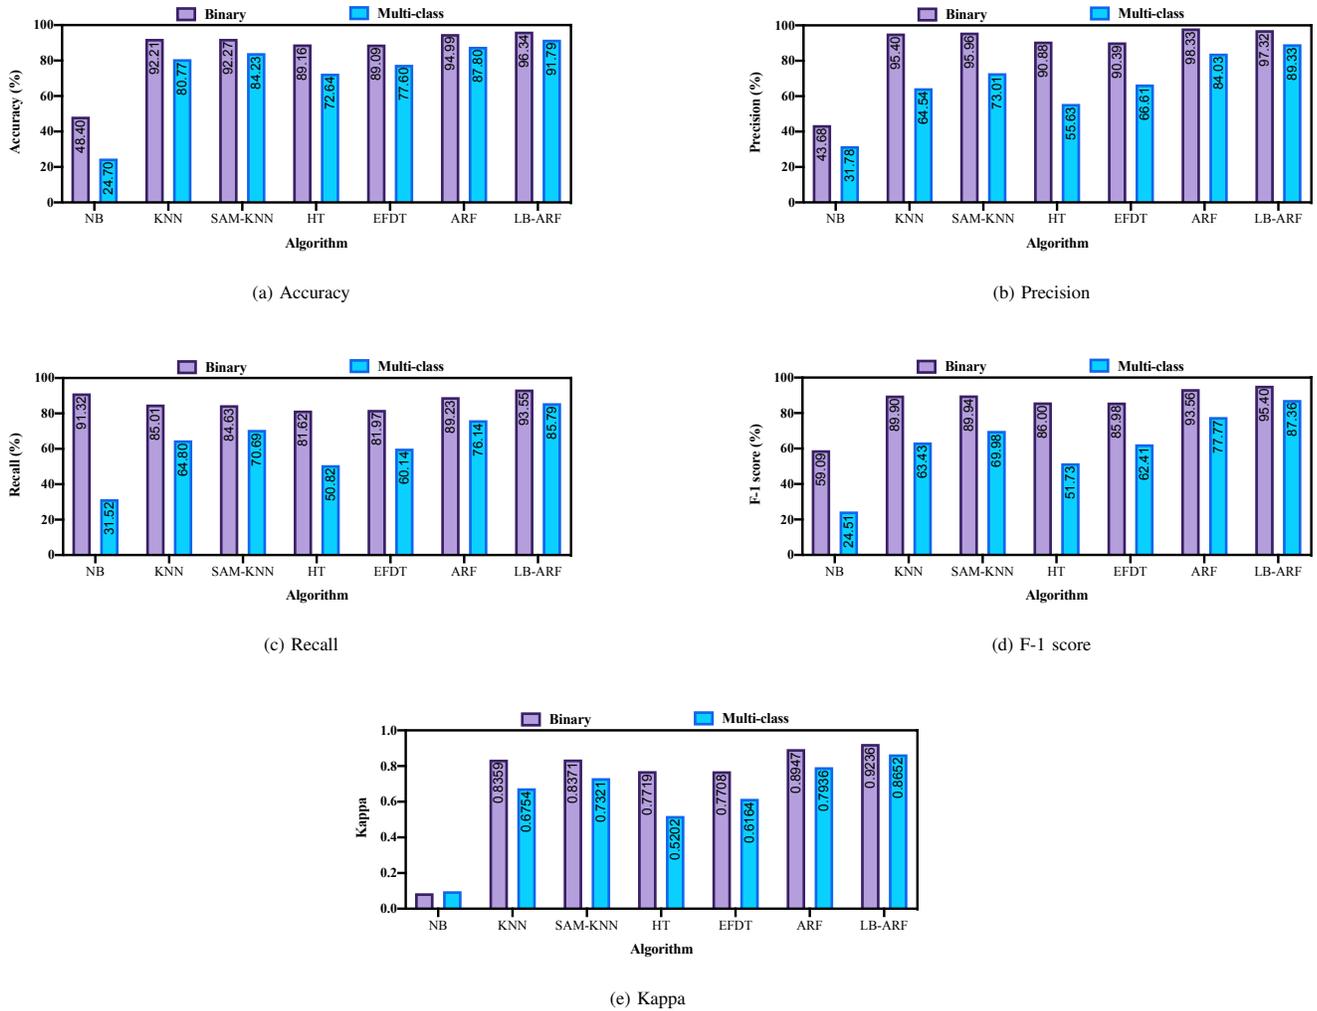

Fig. 4. Performance Comparison - Binary vs. Multi-Class

proposed theft detection dataset. Evaluation results showed that leveraging bagging with an adaptive random forest base estimator surpassed its online machine learning counterparts in both binary and multi-class theft detection. Hence, it can be viewed as a promising online learning model for electricity theft detection in smart grids.

**Abstract**—Plants are very important for life on Earth. There is a wide variety of plant species and their number increases each year. The plants identification using conventional keys is complex, takes time and it is frustrating for non-experts because of the use of specific botanical terms/techniques. This creates a difficult obstacle to overcome for novices interested in acquiring knowledge about species, which is very important to develop any environmental study, like climate change anticipation models for example. Today, there is an increasing interest in automating the species identification process. The availability and omnipresence of relevant technologies, such as digital cameras, mobile devices, pattern recognition and artificial intelligence techniques in general, have allowed the idea of automated species identification to become a reality. In this paper, we present a review of automated plant identification over all significant available studies in literature. The main result of this synthesis is that the performance of advanced deep learning models, despite the presence of several challenges, is becoming close to the most advanced human expertise.

**Keywords**—Plants identification; species; artificial intelligence; machine learning; deep learning

## I. INTRODUCTION

Species diversity of vascular plants is relatively important on the scale of global biodiversity. There are no less than 390000 distinct species known around the world. This number is very approximate, insofar as there is at least an equivalent number of taxa cited in the literature but in fact only falling under simple synonymies. This clearly shows the difficulty that exists in the determination and taxonomy of plants. Species identification is the essential step to properly identify biodiversity and better act in terms of conservation.

Among techniques used in biosystematics to diagnose discriminant characters, that allow us to differentiate taxa and draw practical keys of determination, absolutely herbariums remain an indispensable tool for the botanist daily work. Indeed, research in botanical taxonomy cannot be considered without the presence alongside us of a rich herbarium with collections of references and specimen's types that provide basic information very important for systematic research.

In general, botanists use various methods that involve memory and observation. They may have implicit knowledge of morphology and variability of species, as a result of experience and learning. Other elements may also be involved in the identification process and especially in the wild field, for example, botanists must take into account abiotic factors,

edaphic characters, climate and seasonal change that influence the morphology, appearance and distribution of species. These elements also provide useful information for identification. In addition to morphology, taxonomists can use a range of characters or taxonomic arguments including anatomy, palynology, chromosomes, biochemistry and molecular systematics to estimate the actual evolution of the species, to define it and to place it in its correct taxonomic rank.

In practice, each species has its own evolutionary history marked by genetic, ecological or morphological changes. There are several differences between species in morphology, ecology, reproductive system, interfertility, pollination, disease resistance, genes and many other traits. Systematics comes to find the product of this evolutionary history. To do this, taxonomists base themselves, in addition to morphology, on a set of characters or taxonomic arguments, in particular: odor, chromosomes, anatomy, molecular and biochemistry, to estimate the real evolution of species, grouping them into entities called taxa, to also give them scientific names according to the international code of botanical nomenclature and classify them, according to precise determination keys, in their correct taxonomic ranks starting with Kingdom then Phylum, Class, Order, Family, Gender and finally Species (Fig. 1).

In addition, there is the constraint in term of the specialized training required by the discipline and in particular the language of botany and its works (Flores, checklists, synopsis, monograph, etc.). That is why despite its importance, plant taxonomy remains a barely known and available notion to the majority of biologists. Indeed, defining taxa is a very complex task requiring a serious biosystem study based on the confrontation of several techniques.

This demanding situation by scientific, material and human needs push botanists to think about the idea where plants can be an object perfectly adapted to an automatic recognition system, able to make decisions about the belonging of a presented plant to any of the learned species [1][2]. In fact, accelerating the identification process and making possible for everyone is highly suggested, especially if we consider the continuous loss of plant biodiversity day after day. More than sixteen years ago, authors of [3] have argued that the developments of artificial intelligence and digital image processing would make automatic species identification from digital images real in the near future. Today, artificial intelligence, omnipresent mobile technologies and the emergence of smart phones make it possible to propel technological applications and make the

idea of automatic species identification close to reality.

In this paper, we will categorize and present the different proposed approaches for automated plant identification, then we will discuss and answer questions like: how far can automated systems be from human expertise? Can they completely take the place of botanists and provide accurate results even for difficult groups that require more than just image observation? What is the best methodology currently and how can it be optimized? Are there still other alternatives?

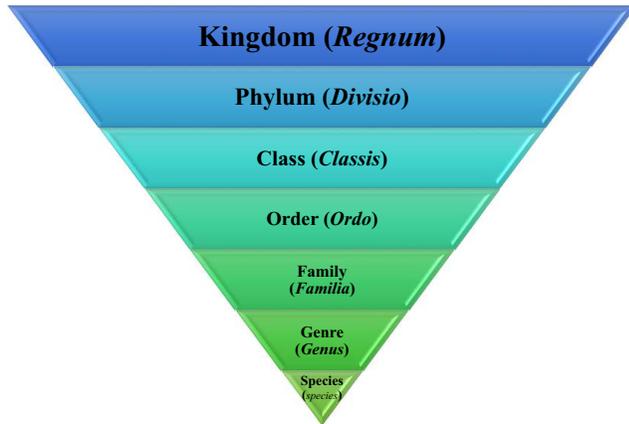

Fig. 1. The Seven Main Taxonomic Ranks Recognized by the International Code of Botanical Nomenclature (ICBN). Names in Italics are Latin Names.

It should be noted here that for our search strategy of papers that deal with the automated plant identification issue using AI, we have searched the Web of Science database to find relevant articles and books up to April 2022. The systematic search of the published literature was conducted using several keywords related generally to AI and plant identification.

The rest of the paper is organized as follows. In Section II, we will review automated plant identification categories / approaches. Our discussion is provided in Section III. Finally, we conclude the paper in Section IV.

## II. LITERATURE REVIEW

The term of Artificial Intelligence (AI) was proposed and used for the first time by the late American programming expert John McCarthy in 1956, and it meant the ability to perform intelligent tasks by machines, especially tasks that mimic human intelligence.

Now that artificial intelligence techniques have developed and its uses have expanded, the definition of artificial intelligence can be developed as making computer system able of performing tasks that normally require simulating human intelligence, such as visual perception, pattern recognition, speech recognition, decision-making and translation between languages.

The use of artificial intelligence techniques has expanded in the last decade very significantly, and this is due to many reasons, the most important of which are: the power of modern computers (i.e., evolution of hardware) and their very large capabilities, which made the possibility of implementing very complex algorithms, that were not previously able to solve.

We cannot ignore as well the spread of sensors connected to the web service that transfer huge quantity of data in a fast way. These sensors are also a huge source of data that are very necessary to improve the functioning of the AI techniques.

We can divide the artificial intelligence according to the amount of intelligence that the machine has reached into three categories:

- **Artificial Narrow Intelligence:** It means that computers perform one specific task with high efficiency and high repetition capacity that exceeds the ability of humans to accomplish, but at the same time it has not yet reached the level of human intelligence. Indeed, all that we see now of applications and devices are of this type.
- **Artificial General Intelligence:** It means that machines reach a level of intelligence that simulates human intelligence. It is possible that we will see its first “complete” applications during the few coming years, and absolutely the reason for not reaching this level yet is that we still do not know the details of many aspects of the human brain.
- **Artificial Super Intelligence:** It means that machine intelligence surpasses the human intelligence. It is absolutely not clear when humanity can reach that, but we can hear already scientists today warn of and fear that machines will control humans with this level of intelligence.

In this paper, we are talking exactly about the “Artificial General Intelligence” techniques. We can distinguish here two main categories: 1) Machine Learning (ML) techniques and Deep Learning (DL) techniques. To be simple, we can say that the main difference between Machine Learning and Deep Learning is that ML models get progressively better, and they always need human intervention to give them an outline of how they learn from the data, while deep learning models learn itself, without relying on human intervention. For example, if a ML algorithm is taught to open a gate when it hears the word “open”, the algorithm will respond only when it hears that word. If the model receives data such as “I am unable to enter” then Machine Learning techniques will not respond, however Deep Learning algorithms can infer that the meaning is the same, and then respond and open the door.

Technically speaking, in the context of automated plant identification (Fig. 2), generally all proposed AI techniques or systems use *plant images* as an input and the output, after several processing operations (i.e., feature extraction + classification), will be of course the identification result of the entered plant (i.e., the species or any other taxonomic rank). For all systems, we can consider two stages, the *training* stage where the system will learn about all available plants, then the *identification* stage where the system will be able to give answers about entered plants. In the next two subsections, We will give more details about the difference between Machine Learning and Deep Learning techniques and we will present all significant approaches proposed in literature for each category.

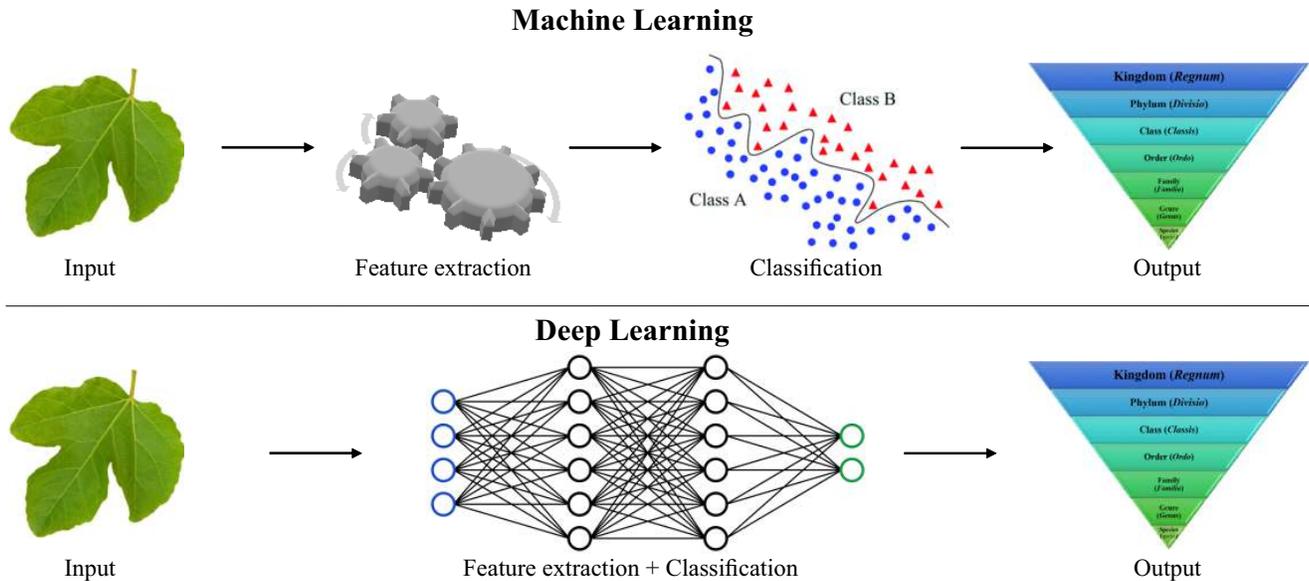

Fig. 2. The Main Modules of Machine Learning and Deep Learning Techniques.

### A. Machine Learning Techniques

Speaking about automated plant identification using ML techniques (Fig. 3), we can say that during the *training* stage, all Machine Learning techniques apply, on the input images of all learned plant species, several classical feature extraction techniques, like PCA [4], to create plant *templates* (most of the time are “numerical vectors”) that will be stored in the system database. Then, during *identification* stage, users can submit any test plant image to the system, this last will apply the same feature extraction technique of the training stage then will match the query template with all stored templates in the system database, matching can take place using some classical classifier like SVM [5]. It should be noted that the majority of proposed ML techniques in literature add a pre-processing step on input images before applying the feature techniques to enhance data quality (i.e., to remove noisy information and keep the most useful data for learning and identification). In the next paragraphs of this sub-section, we will present the most significant works of this category according to an ascending chronological order.

In the context of the first edition of the PlantCLEF challenge, authors of [6] have used a dataset containing almost 5436 images belonging to 71 species of the French Mediterranean region. The dataset images are subdivided into three categories: scans, pseudo-scans and digital photos. Authors of this study focused on the identification of tree species from leaf images, with the aim of associating the correct tree species to each test image. The best results were obtained on scans and pseudo-scans, with accuracy equals to 53.8% and 68.5% respectively, while identification using digital images has not exceeded 52%.

As a continuation of the 2011 PlantCLEF challenge, the number of plant species in [7] has been increased from 71 to 126 and so the number of data has reached 11572 images subdivided always into three categories: scans, pseudo-scans

and photos. The scores are globally lower than those obtained during the 2011 campaign, of which the best for scans, pseudo-scans and photos are successively: 58%, 51% and 45%. During the same year, a technique that use the fuzzy local binary pattern and fuzzy color histogram as extracted features and a probabilistic neural network (PNN) for classification task has been proposed in [8]. A dataset of 2448 leaf images, obtained from medicinal plants in Indonesian forests, has been used for the experimentation. Authors have achieved a classification accuracy of 74.5%.

During the third edition of the PlantCLEF challenge, [9] moved towards the use of organ images for the identification of tree and grass species and not only their leaves. The number of used species in this challenge edition is about 250 with a total of 26077 photos belonging to two categories: SheetAsBackground (i.e., photos of leaves taken in front of a uniform background) and NaturalBackground (i.e., natural photographs in the wild). The results obtained are slightly higher than those obtained during the 2012 challenge, and as expected the results for NaturalBackground are significantly lower than for SheetAsBackground due absolutely to the noisy backgrounds. In the same year, the authors of [10] have proposed an approach that uses the fractal dimensional features of leaf shape and vein patterns for the feature extraction step. A KNN classifier [11] is used for comparison. Authors achieved an identification accuracy of 87.1%. Using the same Flavia dataset, but this time with only 930 images belonging to 31 species, [12] have obtained an accuracy of 97.6%, using a neuro-fuzzy classifier (NFC) with a 44 element texture vector and a 3-element shape vector. [13] achieved almost a similar accuracy of [12] using only the shape features frequencies of 1865 leaves taken from the Flavia dataset. The features are extracted using the Fourier transform followed by a traditional dimensionality reduction technique like Principal Component Analysis (i.e., PCA) technique for example. Then the selected features are submitted to test several classification models:

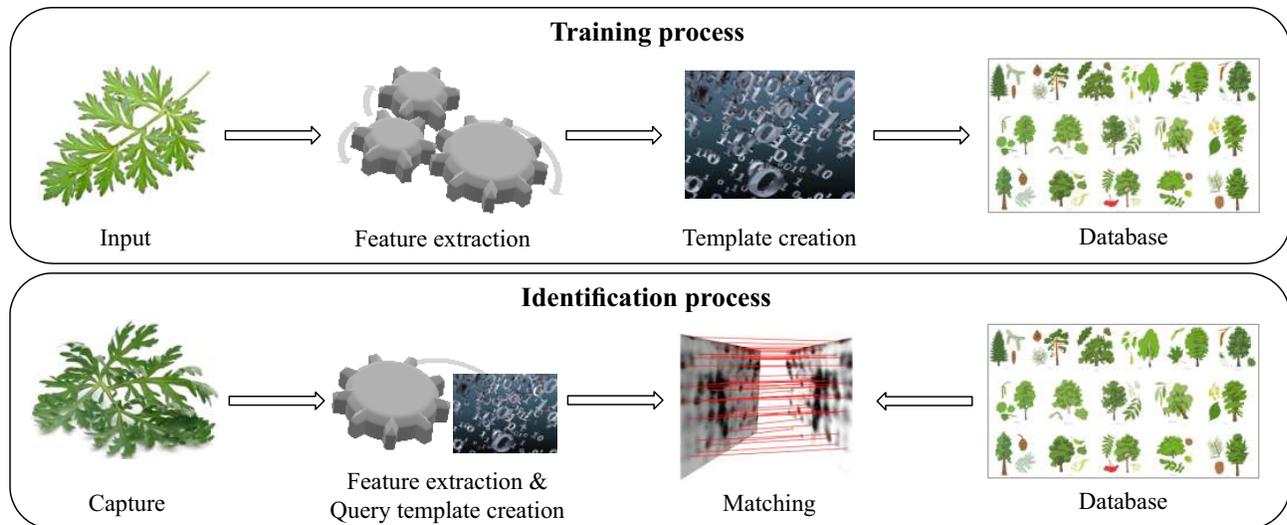

Fig. 3. The Main Steps of Machine Learning Techniques.

Pattern Net (feedforward neural network), Random forest, Rotation forest, Bayes Network, Model trees, Naive Bayes and C4.5 decision tree. The highest accuracy was achieved using the Pattern Net model with the vectors in the PCA space. Always during 2015, [14] developed an algorithm based on 817 leaf images of 14 tree species. This algorithm uses an artificial neural network (ANN) with backpropagation. An input vector of morphological features and Fourier descriptors (FDs), was fed into the ANN, resulting in a classification accuracy of 96% for their own dataset. To verify its effectiveness, they tested their algorithm on the Flavia and ICL datasets and achieved an accuracy of 36% for the both databases. For the fourth edition of the PlantCLEF challenge [15], the task of species identification has focused on observation and not on images, which means that the same person takes several photos of detailed views of different organs during the same day using the same camera under the same lighting conditions of the same plant. The constructed dataset for this challenge contains 113205 images of 1000 species. Experiments have showed that systems that combine different views of the same plant observation have proved a higher accuracy compared to those that use single images, up to 66.7%.

The authors of [16] have created two datasets with the same species: a clean one and a noisy one. They used the histogram of curvature on scale (HCoS) and local binary pattern variance (LBVP) algorithms to extract contour and texture features. Authors have claimed that the accuracy levels of the two datasets are very close, and they conclude that images taken directly without preprocessing can produce satisfactory results. [17] authors were the first team that uses images of old herbarium specimens of 26 tree species to classify them into categories. Using the support vector machine (SVM) after preprocessing, normalization and character extraction, they obtained an accuracy of 73.23% using a test set (I) that contains 24 species, and an accuracy of 84.88% using a test set (II) containing 17 species.

In [18], authors have used a set of leaf images of 24 different medicinal plant species collected from Mauritius. They extracted several features of each leaf such as: length, width, perimeter, color, number of vertices and shell area. A number of classifiers such as: KNN, naive bayes, SVM, neural networks and random forest were tested, of which the random forest classifier achieved the highest accuracy of 90.1%. [19] have focused on three Ficus species with similar leaf shapes. They used two classification models: an artificial neural network (ANN) and a support vector machine (SVM). Based on the morphological characteristics of the leaves, both models achieved the same accuracy of 83.3%.

The authors of [20] have lunched their experiments on 1125 leaf images of 15 Swedish species. Pre-processing was done using Gaussian filtering mechanism, then color and texture features were extracted and finally the classification was executed using a multi-class support vector machine. They obtained an accuracy of 93.26%. Finally, the team of [21] have used the ICL dataset to test a method that performs classification by automatically extracting shape features. The classification is then performed using a back propagation neural network. This experiment has achieved an accuracy of 96% for the test images and 99% for the training image.

Table I provides a comparison of all studies based on Machine Learning techniques. We will discuss the results of this comparison in Section III.

### B. Deep Learning Techniques

We can say that the concept of Deep Learning is a discipline of Machine Learning which in turn is a discipline of Artificial Intelligence. The Deep Learning is the field concerned with the study of Artificial Neural Networks (i.e., ANN) that simulate neural networks in the human brain. As we know, the basic processing unit in the human brain is the neuron, and the artificial neuron in the DL techniques

TABLE I. SUMMARY OF STUDIES BASED ON MACHINE LEARNING TECHNIQUES

	Features	Dataset	Accuracy (%)
Goeau et al. (2011) [6]	Shape	5436 images (71 species)	52 53.3 68.5
Goeau et al. (2012) [7]	Shape	11572 images (126 species)	45 51 58
Herdiyeni and Wahyuni (2012) [8]	Texture, color	2448 images (51 species)	74,5
Goeau et al. (2013) [9]	Shape, color, texture	26077 images (250 species)	60.7 39.3
Du et al. (2013) [10]	Shape, curvature, veins	2422 images (30 species)	87,1
Chaki et al. (2015) [12]	Shape, texture	930 images (31 species)	97,6
Siravenha and Carvalho (2015) [13]	Shape	1865 images (32 species)	97,5
Aakif and Khan (2015) [14]	Shape	817 images (14 species)	96
Go"eau et al. (2015) [15]	Shape, texture, color	113205 images (1000 species)	66.7
C.-Rojas and M.-Montero (2016) [16]	Curvature, texture	2345 images (184 species)	87.2
Unger and Merhof (2016) [17]	Shape, veins	260 images (26 species)	73.23 84.88
Begue et al. (2017) [18]	Shape, color, shell area	720 images (24 species)	90.1
Kho et al. (2017) [19]	Shape	54 images (3 species)	83.3
Kaur and Kaur (2019) [20]	Texture, color	1125 images (15 species)	93.26
Amlekar and Gaikwad (2019) [21]	Shape	No details are available!	96

corresponds to it. An assembly of artificial neurons is known as an Artificial Neural Network. The discipline of Deep Learning emerged as an extension and development of Machine Learning when traditional ML algorithms were unable to perform some complex tasks (e.g., learning from large datasets such as different sound waves and high resolution images dimensions).

Generally, as shown in Fig. 4, DL techniques consist of a multi-layer structure where the layer on the left end is the input layer, the layer on the right is the output layer, and in the middle are several hidden layers responsible for processing. Each layer consists of some *neurons*, *weights* and *activation functions*. Indeed, unlike the traditional Machine Learning algorithms that require a lot of human intervention to adjust and improve, the deep learning algorithms requires a lower level of human intervention in optimizing the algorithm's results, because they learns and improve from their mistakes on their own thanks to their special architectures. However, these last make DL techniques require a lot of time and high computing power to learn from huge data set to build a viable model.

Speaking about automated plant identification using DL techniques (Fig. 4), we can say that during the *training* stage, unlike ML methods, the set of images of all species will be used as inputs in a recursive way to train the system. In fact, the weights will be adjusted until an optimal model is built for identification. Then, during identification stage, users can submit any test plant image to the trained model that will extracts features and perform the matching to give an identification result.

Depending on the network architecture, we can define several categories of DL methods, like: Multi-Layer Perceptron (i.e., MLP), Recurrent Neural Networks (i.e., RNN) and Convolutional Neural Networks (i.e., CNN). For example, MLP networks are *fully connected layers* where each neuron in a layer often communicates with all the neurons in the layers that precede it. For RNN networks, they are suitable for ap-

plications that must take into account the relationship between data and the temporal context, such as speech recognition for example. RNN networks solve this problem by remembering what has been learned from previous inputs, so that the past state can be learned and used with the current input. For CNN networks, they mostly deal with two-dimensional matrices, which are most time likely images. We can say that in the context of automated plant identification, CNN are is the most used category of DL techniques.

In the context of the fifth edition of the PlantCLEF challenge [22], it was the first time where participants introduced the use of the deep learning techniques, plant identification task was based on the use of a dataset that contains 113205 images representing plant organs and whole plants as well, covering 1000 woody and herbaceous species. 94 groups of participants have tried to use CNNs and only eight of them have submitted successfully their models. The highest classification accuracy was 72.4%. Always during 2016, in order to provide information on weeds for the good management of agricultural fields, [23] have trained and tested a convolutional neural network using a database that contains 10,413 images of 22 weed species. These images were taken from six datasets that present variations in terms of lighting, resolution and soil type. The developed CNN has provided an accuracy of 86.2%. In other work, [24] proposed to use the CNN for plant identification based on the morphological characters of the leaf veins of three legume species. After segmentation of the veins and extraction of the central spot to eliminate all possible influences of leaf shape, two scenarios (S1 and S2) were studied. In the first one only one image per sample was provided to train the CNN model, while in the second one three resized images (100%, 80% and 60%) were used as input to the CNN. They obtained almost similar average accuracy: 92.6% for S1 and 96.9% for S2.

The PlantCLEF challenge of 2017 [25], was organized on a dataset that contains 10000 plant species and 1.1 million

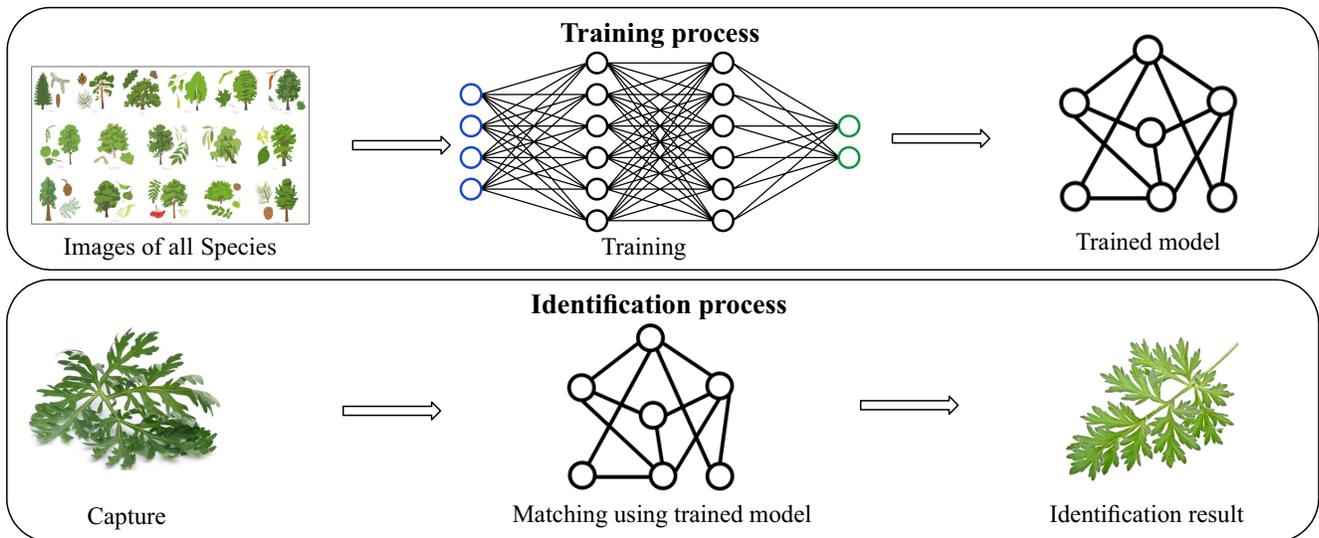

Fig. 4. The Main Steps of Deep Learning Techniques.

image in total. This was the first evaluation at this scale in the world where the test data to be analyzed was a large sample of raw query images. This dataset is divided into two sub-datasets: 1) the first one is huge and built using noisy web crawlers collected via the web; 2) the second one is smaller than the first sub-dataset and built using reliable training package verified by experts. The results obtained are almost similar, with systems using the reliable training set achieving almost 84% and systems processing a noisy training set exceeding 80%. While the systems that use both datasets achieved astonishing results of up to 92%. During the same year, [26] developed a plant identification system based on a Convolutional Neural Network called *LeafNet*. To evaluate it, they used three datasets: LeafSnap [27], Flavia [28] and Foliage [29]. On the LeafSnap dataset they obtained an accuracy of 86.3% for the top-1 and 97.8% for the top-5. Using the Flavia dataset, they obtained an accuracy of 97.9% for the top-1 and 99.99% for the top-5. Finally, for the Foliage dataset they obtained an accuracy of 95.8% for the top-1 and 99.6% for the top-5. Based on leaf features, [30] have used a Convolutional Neural Network to identify the most relevant features for a correct classification. They used two datasets: D1 and D2 with the same species, except that in the first one the images represent leaf shape as a classification feature, while in the second one venation and divergence between different venation orders are considered as selected features. They have obtained an accuracy of 98.1% for D1 and 99.5% for D2. In other work, [31] have proposed a 26-layer ResNet model for plant identification in a natural scene. They have used the BJFU100 dataset where images are taken using mobile phone cameras. It contains 10000 images of 100 plant species. The proposed model has achieved an accuracy of 91.78%. Always during 2017, [32] were the first team that has tested the classification of plant species using a large number of herbarium leaves and a Convolutional Neural Network. They have used five datasets: two of them (i.e., Herbarium255 and Herbarium1K) contain images of herbarium sheet images of leaves token from iDigBio; two others (i.e., CRLeaves and PlantCLEF 2015) contain images of leaves taken by a digital

camera; and the last one is the ImageNet database [33] which is used to train the CNN model. They have conducted a series of experiments to evaluate the effectiveness of herbarium leaves alone for plant species identification and to see if the combination with plant photos in the wild field is relevant in terms of accuracy. The best results are obtained when combination is considered. For example, the top1 accuracy of the H1K herbarium sheets is 72.6% and the accuracy of the H1K sheets combined with ImageNet is 79.6%.

Same team [34] has tested several Deep Learning models to identify plant species using herbarium leaves. The identification task in this work take place not only at the species level, but also at other taxonomic levels such as genus and family. They used the Herbaria1K dataset and ImageNet (for pre-training of the Deep Learning model). The tested architectures are the Flat Classification Model (FCM), the Multi-Task Classification Model (MCM) and the Hierarchical Classification Model (TaxonNet). They obtained in general almost similar results using the different architectures. For FCM, they obtained 63.02% for the species; 70.51% for the genus and 75.55% for the family. For MCM the results are 64.32%, 75.95% and 88.17% for species, genus and family respectively. TaxonNet showed an accuracy of 62.39% for species, 76.23% for genus and 86.92% for family. The family classification was still the best of the three which is evident since the number of classes will be less in this scenario of test. In the same year, [35] have used a deep Convolutional Neural Network consisting of 19 layers in combination with linear SVM for plant classification using the database of the PlantCLEF 2015 edition that contains images of different plant organs. They obtained better results, up to 90.20%, compared with other models that use the same database.

In addition to plant identification using images, Convolutional Neural Network models have also been developed to identify and diagnose plant pathologies. In this context, [36] has developed a CNN model to detect plant diseases using images of diseased and healthy leaves. The author has used an open database of 87848 images of 25 species containing

in a set of 58 combination classes (Plants, Diseases). He obtained an accuracy of 99.53%. [37] have tested several pre-trained Convolutional Neural Network architectures using the PlantVillage dataset [38] for plant disease identification. The tested architectures are: AlexNet [39], DenseNet-169 [40], Inception v3 [41], ResNet-34 [42], SqueezeNet-1.1 [43] and VGG13 [44]. The results obtained are globally high with an accuracy of up to 99.76%.

In the same context, [45] have developed a plant pathology identification model based on a Deep Convolutional Neural Network composed of 9 layers. Authors have used an open database contains 39 combination classes (Healthy Plant / Diseased Plant). The proposed model was trained using 55636 images and tested using 1950 images. Data augmentation methods [46] such as image flipping, rotation to scale, etc., were used. An accuracy of 96.46% was obtained. The result obtained shows that the use of augmentation methods can improve the performance of CNN models. To identify large-scale plants in a natural environment, [47] have tested a five-layer deep Residual Neural Network using a database that contains 185 classes of leaf images taken from the Columbia University, the University of Maryland and the Smithsonian Institution. They achieved an accuracy of 93.09%. In the 2019 edition of the PlantCLEF challenge, [48] have extended the challenge to flora in data-poor countries such as the Amazon rainforest. The results obtained illustrate the difficulty of species identification using a single image. The top accuracy of human experts ranges from 15.4% to 67.5%. However, the best automated system achieves an accuracy of 32% which can be explained by the fact that there is generally much diversity in tropical regions and by other reasons that we will discuss in the Section III. Always during 2019, [49] have carried out a series of experiments that compare five Convolutional Neural Network models, one of which was developed individually and the remaining four are transfer learning models. Four publicly available plant datasets were used for experimentations: Flavia, Swedish Leaf [50], UCI Leaf [51] and PlantVillage. The obtained results show that the transfer learning approaches perform better than the developed model for all datasets. For example, using the UCI Leaf dataset, the end-to-end model accuracy is 76.15%, while it reached up to 90.56% in a transfer learning model.

To answer this question: “among the images of plant leaves and flowers, what kind of perspectives contain more characteristic information and allow a high accuracy of identification?”, the study of [52] was conducted. They developed an image capture system to create observations of flowering plants. Each observation contains images of whole plants, front and side views of flowers, top and back views of leaves. The collected data set includes 101 species that are morphologically similar. They have used a Convolutional Neural Network to perform experiments. They obtained top-1 accuracies ranging from 77% (whole plant) to 97% (when merging all features). Flowers achieved the highest accuracy of 88%. The fusion between flowers and leaves gives an accuracy of 96%. In other work during 2019, [53] have studied automated plant classification at the genus and family level. They have tested a CNN model using a dataset that contains 1000 images of representative species of the Western European flora belonging to 516 genera and 124 families. The classification accuracy of the trained species increased from 82.2% at the species level

to 85.9% and 88.4% at the genus and family level. While the accuracy decreases considerably to 38.3% and 38.7% at genus and family level for untrained species.

We can say that the 2020 edition of PlantCLEF challenge [54] is entirely different from all previous editions. It is based on a large collection of over 60000 herbarium sheets of 1000 species from the Guiana Shield region of South America. A valuable asset of this collection is that many herbarium sheets are accompanied by a few photos of the same specimen in the field. For the test set, they used field images from different sources, including Pl@ntNet and Encyclopedia of Life. The metrics used for the evaluation of the task are classification accuracy and Mean Reciprocal Ranking (MRR) which is calculated according to the following equation:

$$MRR = \frac{1}{|Q|} \sum_{i=1}^{|Q|} \frac{1}{Rank_i} \quad (1)$$

where  $|Q|$  is the total number of specie occurrences in the test set.

Authors of [54] claimed that the highest accuracy is MRR= 0.18 for ITCR PlantNet Run 10, followed by MRR= 0.17 for ITCR PlantNet Run 9. Always during 2020, [55] have organized a sub-competition hosted on the Kaggle platform to encourage the development of an automated species identification algorithm using herbarium leaves. 22 teams have participated with 254 models for species identification of Melastomataceae. They have used a large collection of photographed herbarium specimens for experiments (46469 specimens representing 683 species). Four models out of 254 obtained the highest accuracies exceeding 88% of correct identification.

For the 2021 edition of PlantCLEF challenge [56], we can say that the training dataset is based on the same visual data used during the previous challenge of 2020. Indeed, the 2021 task was particularly challenging, focusing on species rarely photographed in the field in the northern tropical Amazon. PlantCLEF 2021 introduces also new data related to five “traits” covering exhaustively all the 1000 species of the challenge. Traits are very valuable information that can potentially help to improve prediction models. Indeed, it can be assumed that species which share the same traits also share to some extent common visual appearances. The five most exhaustive traits (“plant growth form”, “habitat”, “plant life form”, “trophic guild” and “woodiness”) were verified and completed by experts of the Guyanese flora, so that each of the 1000 species have a value for each trait. The main evaluation measure for the challenge was the MRR.

Finally, to build an reliable system, the authors of [57] have proposed an efficient method of behavioral similarity developed through three models based on deep learning. To train their models, they have used the MalayaKew dataset that includes 44 classes of plant species and the FLavia dataset that contains 32 plant species. The results obtained for all the proposed models using the two datasets are respectively 99.67% and 99.81%.

Table II provides a comparison of all studies based on Deep Learning techniques. We will discuss the results of this comparison in Section III.

TABLE II. SUMMARY OF STUDIES BASED ON DEEP LEARNING TECHNIQUES

	Dataset	Accuracy (%)
Dyrmann et al. (2016) [23]	10413 images (22 species)	86.2
Goeau et al. (2016) [22]	113205 images (1000 species)	72.4
Grinblat et al. (2016) [24]	15 images (3 species)	92.6 96.9
Barré et al. (2017) [26]	LeafSnap (7719 images of 185 species) Flavia (60 images of 32 species) Foliage (120 images of 60 species)	86.3 97.9 95.8
Goeau et al. (2017) [25]	1.1 million images of 10000 species	92
Lee et al. (2017) [30]	MalayaKew (2816 images of 44 classes)	98.1 99.5
Sun et al. (2017) [31]	10000 (100 species)	91.78
C.-Rojas et al. (2017) [32]	Herbier255 (11071 images of 255 species) Herbier1K (253733 images of 1204 species)	79.6
C.-Rojas et al. (2018) [34]	Herbier1K, ImageNet (1 Million arbitrary hand-annotated images)	63.2
		64.32
		62.39
		70.51
		75.95
		76.23
		75.55
88.17		
86.92		
Zhu et al. (2018) [35]	113205 (1000 species)	90.2
Ferentinos (2018) [36]	87848 (25 species)	99.53
Brahimi et al. (2018) [37]	PlantVillage (54323 images of 14 species)	99.76
G. and J. (2019) [45]	55636 images of 13 species	96.46
Bodhwani et al. (2019) [47]	27000 images of 185 leaf classes	93.09
Goeau et al. (2019) [48]	434251 images of 10000 species	32
Kaya et al. (2019) [49]	Flavia, PlantVillage UCI Leaf (443 images of 40 species) Swedish Leaf (1125 images of 15 species)	90.56
Rzanny et al. (2019) [52]	9090 images of 100 observations (no data about species)	97.1
Seeland et al. (2019) [53]	500000 images of 1000 species	82.2 for specie 85.9 for genus 88.4 for family
Joly et al. (2020) [54]	60000 images (1000 herbarium species)	MRR = 0.18
Ambrose et al. (2020) [55]	46469 images of 683 species	≥ 88
Goeau et al. (2021) [56]	60000 images of 1000 species	MRR = 0.18 MRR = 0.158
KBeikmohammadi et al. (2022) [57]	MalayaKew (2816 images of 44 classes)	99.67
	Flavia (60 images of 32 species)	99.81

### III. DISCUSSION AND FUTURE DIRECTION

It should be noted that while several results are discussed separately here, they are interrelated in many ways. Therefore, this discussion tends to overlap in some parts.

Before discussing any of the results of Section II, we can immediately draw these six observations: 1) Most of results do not give a clear and sure view on the indicators that can improve the accuracy of plant identification. 2) There is no better approach for automated plant identification (with a priority of DL techniques compared to ML approaches); and the current available identification systems are not yet mature enough for a large-scale deployment. 3) There are no common protocols of test, no common performance indicators or metrics and no common databases used and shared between all proposed approaches, which make any comparison of results not fair or even wrong. 4) No information are given about the taxonomy of each family / genus / specie which is very important to specify the degree of resemblance between

classes (i.e., intra- and inter- subject variations) that gives as well an idea of the complexity of any identification task. 5) Recent automated plant identification systems might be in the way to surpass the ability of the human expert botanists. 6) Most of proposed systems are developed by computer science experts and only very few of botanists.

For our first observation, we believe that the clearest results that we can get are:

- **Image type and identification accuracy:** We can say that the systems analyzed during the first edition of PlantCLET challenge [6] have provided good classification scores, especially using scans and pseudo-scans categories, while using digital photos performance has been degraded. Thus, the evidence conclusion here is that the images type influences the identification accuracy. The same observation can be drawn from the results of the 2012 edition [7], even that the difficulty of the challenge has increased and that the

technological progress made by the participants has not compensated for the increased difficulty.

- **Feature extraction and identification accuracy:** We can say that for Machine Learning techniques, the improvement and the fusion of several methods of feature extraction / selection can improve identification accuracy. For example, the improvement of classification accuracy in [8] was due to the effective fusion between the FLBP and the FCH methods. The same result can be confirmed in [9] where most of approaches focused on the extraction of shape, texture and color. In the same context, [18] added more characters to be extracted such as length, width, perimeter, number of vertices, and hull area to get better results.
- **Image view and identification accuracy:** Always for Machine Learning techniques, we believe that observing different plant organs, using different views of the same plant specie, which is a current practice of botanists, can improve the identification accuracy. This is slightly confirmed in [15] where systems that combine different views of the same plant observation showed higher accuracy compared to systems that use single images.
- **Image pre-processing and identification accuracy:** We believe that adding a pre-processing of images before feature extraction can improve performance. This can be confirmed in the experiments of [16] and [17] who obtained good scores even if the used herbarium images were old, thanks to the added pre-processing step.
- **CNNs and identification accuracy:** Without any doubt, performance of automated plant identification systems has started to increase concretely since the 2016 PlantCLEF challenge [22]. Knowing that the database used during this edition is the same one used in the previous edition, the proposed systems gave higher scores in 2016. These systems were based on Convolutional Neural Networks. This definitely confirms the supremacy of Deep Learning approaches over the Machine Learning methods previously adopted for plant identification. In addition, all CNNs systems can use a huge database with a very high number of images. These last can be noisy, collected via the web, taken by digital cameras or cell phones and do not undergo any pre-processing step.
- **Taxonomic levels and identification accuracy:** The idea of moving to the classification at higher taxonomic levels has also given good performance whether in the experiment of [34] or that of [53]. The main idea to note here is that the higher the taxonomic level, the more relevant the classification accuracy becomes.
- **Species diversity and identification accuracy:** The remarkable decrease in the results of the 2019 challenge [48] dedicated to regions lacking data. This can be explained by the fact that there is generally much more diversity in tropical regions compared to temperate regions, already studied in the previous challenges, for the same reference areas. In addition, tropical plants in high forests are much less accessible to

humans who have much more difficulty in improving their knowledge of these ecosystems. The decline in results is continuing despite attempts to improve data in 2020 [54] and 2021 [56] challenges, the tasks were particularly difficult, focusing on rarely photographed species in the field from data deficient regions (while CNNs require huge number of images per class for the training step).

For our second observation, as we have said before, performance of automated plant identification systems has started to be increased with the first uses of Deep Learning techniques in the 2016 PlantCLEF challenge [22], which means already that DL techniques have proven a superiority compared to ML techniques. However, we believe that all current available identification systems are not yet mature enough for a large-scale deployment.

For the third observation, we believe that, before giving any judgment about the best approach or the good practices to follow to improve accuracy of automated plant systems, the community of research of this field must establish a common evaluation protocol to make researchers able to compare their results. In this context, we think that even the basic metrics of evaluation, like the ROC curve and the Error Equal Rate (ERR), are not used by all proposed technique of literature. In addition, we believe as well that a common database must be built to make the use of the common evaluation protocol fair and correct as well. The best example in this context to be followed is the Fingerprint Verification Competition (FVC) [58]. This is an international competition that has been organized by academic laboratories to evaluate fingerprint verification algorithms developed by both academics and industry. Several databases (i.e., FVC2000, FVC2002, FVC2004 and FVC2006), which are acquired with various types of sensors while increasing difficulty, were provided to the participants to allow them to test and compare their techniques according to a predefined test protocol<sup>2</sup>. The proposed protocol / databases are used until now by all researchers in fingerprinting field. We believe that the same strategy must be adopted for automated plant identification.

For our fourth observation, we can say that the majority of works in literature do not give any information about the taxonomy of each family / genus / specie in the used dataset, such information is very important for any identification system to define the degree of resemblance between classes and therefore define the difficulty of the database. All that confirm again the need to build common databases of test while taking in consideration the complexity of identification that is related to the chosen plant for every database.

For the fifth observation, we think that the current automated plant identification systems might be in the way to surpass the ability of the human expert botanists. This can be confirmed especially in the results of the 2019 PlantCLEF challenge [48] and in Fig. 5 taken from the same challenge. We can notice also that the results of automated systems improves well in the Top 5 scenario compared to human experts, which means that if we are looking for a tools to minimize the list of candidate plants during a classic systematic identification (top

<sup>2</sup><https://biolab.csr.unibo.it/fvcongoing/UI/Form/Home.aspx>

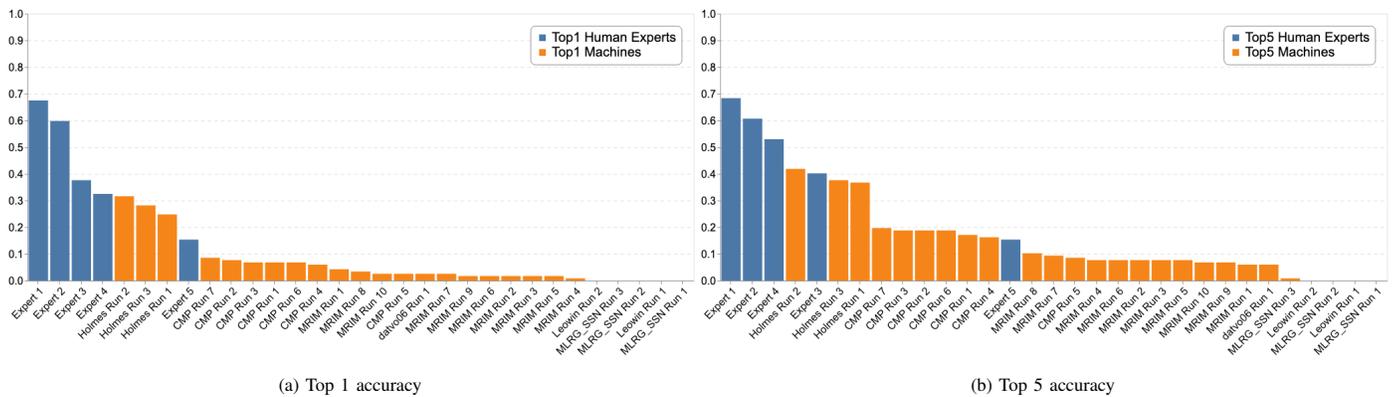

Fig. 5. Results of Automated Plant Identification Systems vs the Human Experts (Taken from <sup>1</sup>).

10 or top 20 list for example), absolutely automated systems can be this very useful / fast tool.

For our last observation, we have noticed that the majority of proposed systems are developed by computer science experts and only very few of botanists which is absolutely not a good practice to build successfully a robust automated system. This prove why all works of literature have a huge lake of taxonomic information about tested plant species. We believe that All teams of work on this challenge must contain computer scientist and botanist to optimize the design and results of automated plant identification systems.

#### IV. CONCLUSION AND PERSPECTIVE

In this paper, we present a review of automated plant species identification issue over all significant available studies in literature. The main result of this synthesis is that the performance of advanced deep learning models is becoming close to the most advanced human expertise. However, we have to mention that several fundamental challenges are remaining to be solved to achieve the design of an efficient system. This is exactly the objective of our future works. First, we have a plan to propose an efficient evolution protocol to be used with any plant identification system. Second, we will publish several databases (with different level of difficulty) for tests while giving all needed taxonomic information, including a national database of Moroccan toxic plants species. Third, we will test our first identification system (as a personalized architecture of Convolutional Neural Network) using the Moroccan toxic plants database since the complexity of this last will be low because the degree of similarity is weak due to the high diversity of families / genus of Moroccan toxic plants. Finally, we will perform and optimize our system using harder databases with high degree of similarity.

**Abstract**—Fostering children’s problem-solving and computational programming competencies is crucial at the current time. Like in other in-developing nations, children grew up with technology in Chile. Developing programming and problem-solving competencies in children seems a reachable task using high-level block-based programming languages. However, programming and electronics competencies often emerge at higher educational levels. This article presents that using Arduino can enhance the development of programming and problem-solving competencies in children and encourages them to think in new ways. This article uses TinkerCAD, an online emulator of Arduino, to teach fundamental electronic circuits and computer programming components. Using TinkerCAD effectively addresses various computing and electrical difficulties, such as turning on and off a group of lights and reading sensors to respond to the acquired values. This article seeks to develop problem-solving and computer programming competencies in primary school students, given the significance of both competencies, the open nature of Arduino, and the applicability of TinkerCAD, which permits using a block-based programming language. Children that took part in the trial saw an increase in their academic performance on average, which is a critical concomitant finding. The essential drawbacks of this project were the children’s lack of knowledge of electronics and programming principles and the need to use a computer with an internet connection.

**Keywords**—Arduino; competencies; programming; problem-solving; children

## I. INTRODUCTION

The ability to use other skills to achieve objectives and solve complex and specified problems are traits of problem-solving competency [1]. It refers to the skills students need to acquire to discover efficient, sophisticated, and worthwhile solutions to issues in the interest of long-term learning. Informally, a computing method with clear boundaries, known as an algorithm, accepts an input value or set of values and produces an output value or set of values. An algorithm is a series of precise, constrained, and obvious procedures for attaining a particular goal or objective [2]. Because programs created in programming languages reflect algorithms, algorithms are the foundation of programming [3]. So, programming is the process of giving a computer a set of instructions it needs to follow to do a certain job. As Knuth [4] proposes, programming can be a fun endeavor like writing poetry or music. Similarly, Vidal

et al. [5] stress the need to acquire logical and computational abilities for problem analysis and solution delivery in both computer-based and real-world settings. Getting young people to think logically and algorithmically is one of the goals of the education systems in several European and South American countries [6].

High-level abstraction, main-focus skills, and algorithmic reasoning are necessary for developing programming skills in textual programming languages [6]. Contrarily, students who use textual programming languages usually spend more time understanding and adhering to syntactic conventions than comprehending, learning, mastering algorithmic abilities, and resolving issues. One strategy is to use the block-structured programming language Scratch [7], which is kid-friendly, to develop algorithmic skills. Come up with electrical computer solutions. Due to the programming requirements and the necessity to be wary about compromised physical components in the final execution of the electrical circuit, a reducible risk by employing simulators, it seems to be a challenging operation. As an open-source electronics platform built on simple hardware and software, Arduino intends to increase accessibility for interactive computing-electronic applications [8]. Aside from the warning about working with physical electronics, the essential parts of Arduino’s programming approach for kids are the syntax, and semantic instructions of the C/C++ programming language [9].

TinkerCAD circuits [10], [11] seem to be intended to address issues with Arduino-based computing-electronic systems in terms of design and programming: When combined with Arduino-compatible electrical components, TinkerCAD, a block-structured programming language, may be used to build computer solutions.

The simplicity with which computing-electronic devices can be built and programmed using TinkerCAD platforms seems to be a feasible goal. Similar to that, the primary objective of this article is to respond to the following research question: Can people use Arduino to educate youngsters to enhance their problem-solving and programming skills? This article provides proof by outlining the positive results of a TinkerCAD and Arduino workshop for children of a primary school in Valparaiso, Chile. This paper presents TinkerCAD and highlights the results obtained to persuade students and instructors to use TinkerCAD in developing algorithmic and problem-solving abilities.

\* Corresponding author

In today's connected and computerized environment, programming and creating computing-electronic systems are challenging tasks [12], [13]. As Vidal et al. [10] highlight, developing children's programming and electronic abilities should be a stimulating challenge for their interest and motivation in computer and electronic systems. You may construct algorithmic and computing-electronic conditions, for example, to turn on a light using resistance or without it while properly understanding physical and scientific principles.

This article may be summed up as follows: In Section II, the TinkerCAD platform, Arduino, and an example of its block-structured programming language are introduced. The participants and setting of the workshop "Programming and Electronics for Everyone" conducted in Valparaiso, Chile, are explained in Section III. One of the experiments made by students is shown in Section IV. The academic performance enhancements of the workshop participants are highlighted in Section V. Section VI describes related work. Section VII presents conclusions of this work. Section VIII presents the main findings and suggests research directions.

## II. TINKERCAD CIRCUITS AND ARDUINO

To create computing-electronic solutions using Arduino, TinkerCAD is a free, user-friendly web platform [14] for 3D design, electronics, and scripting [15], [10]. To enable students to combine computers and electronics in low-cost, open-hardware settings easily, Arduino was established in Italy in 2005 [16]. As Peace [17] argued, a vast selection of inexpensive hardware and software compatible with Arduino is available on the market. Liquid Crystal Displays (LCDs), sensors, and integrated web development platforms like TinkerCAD are available. TinkerCAD-based solutions are facilitated and supported by TinkerCAD. TinkerCAD considers a design area for the solution's hardware parts, a classification of the many more hardware parts, and a coding area for the software. Fig. 1a shows a straightforward example of how to turn on a led by connecting it to a 9-volt battery, which is analogous to the electrical "Hello World" program [6]. Fig. 1b, on the other hand, illustrates an unsuccessful operation for the same purpose without using a resistor.

Fig. 2a shows a hardware design created in TinkerCAD to turn on a red LED. It is similar to Fig. 1, except the Arduino is in charge of the positive and ground signals. This method may be modified to cyclically turn on the light for  $t_1$  seconds and then turn it off for  $t_2$  seconds by adding code. Creating Arduino solutions requires extensive programming abilities because of the new syntax and semantics of the related C/C++ programming language. Like Scratch, TinkerCAD supports programming solutions utilizing block-structured languages [18]. Fig. 2a and 2b presents the color-coded division of blocks: output (blue), input (purple), notation (gray), control (yellow), mathematics (green), and variables (rose). That figure additionally shows the block-structured code for turning on and off the LED for times  $t_1$  and  $t_2$  along with the variables declaration section.

Fig. 2b shows a semaphore simulator that is an extension of Fig. 2a. This figure also presents the associated block-structure code for the semaphore functioning. Fig. 2b does not use variables to define the light-time of each LED: the green

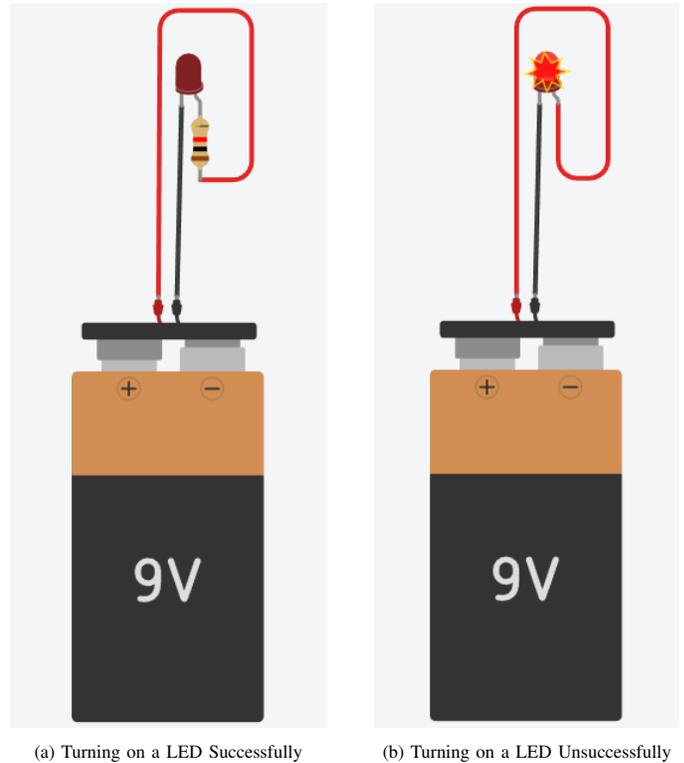

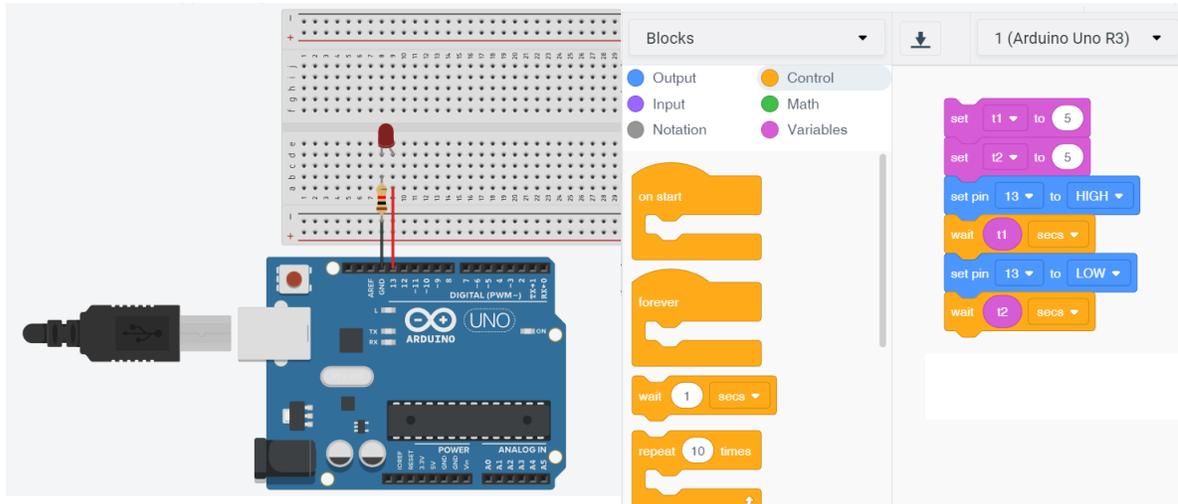

Fig. 1. Flipping a Led Both Successfully and Unsuccessfully with an Arduino.

LED will be turned on for 5 seconds (pin 2), the yellow LED for 3 seconds (pin 3), and the LED red for 5 seconds (pin 4), respectively.

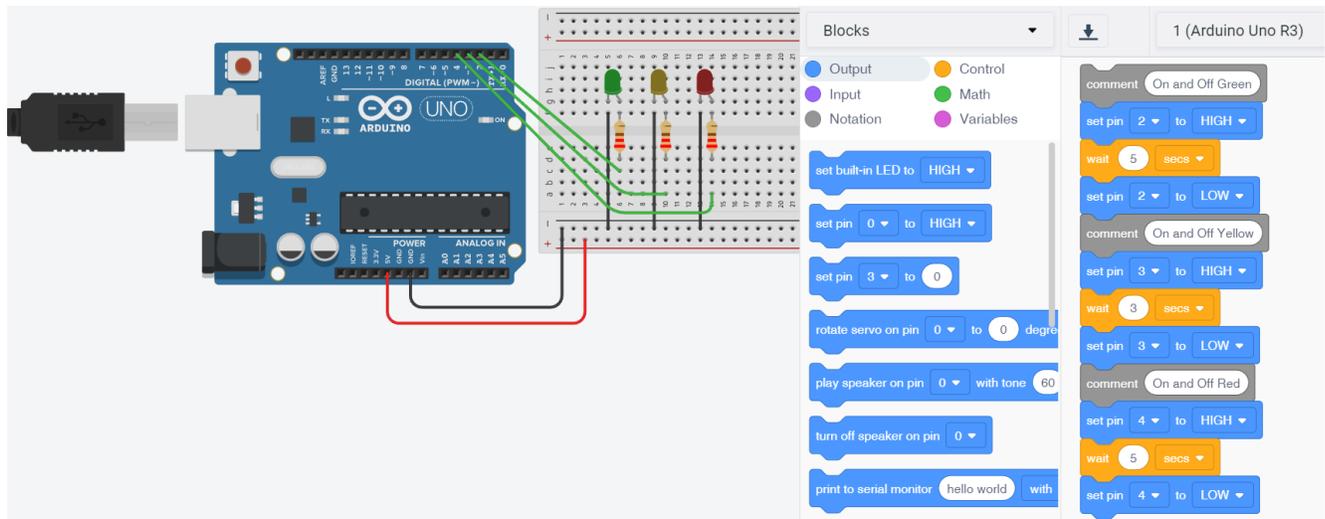

Another amazing feature of TinkerCAD is the ability to produce Arduino C/C++ code from a block-structured code solution. TinkerCAD is a great online tool for researching Arduino-based computing and electronics solutions.

## III. WORKSHOP ON PROGRAMMING AND ELECTRONICS FOR EVERYONE

A project called "Future Education" links universities, basic colleges, and schools in Chile's Valparaiso region to provide seminars in various subject areas at participating higher education institutions [19]. "Future Education" develops activities that include students in experiments and debates with academics and researchers from various subjects using a rigorous and active approach. To help nine primary school students from four different schools and cities in the Valparaiso region develop their programming and computing-electronic skills, "Programming and Electronics for Everyone" was included in the 2020 edition of "Future Education". Specifically, there were two schools with three students (schools A and B), one school with two students (school C), and one school with one student (school D). The 5-session program, titled "Programming and Electronics for Everyone", had a start date of October and a finish date of mid-November 2020. The first two days of the training covered the fundamentals of Arduino and TinkerCAD programming environment. After that, students went over basic sensor tools and response ideas as the

(b) Simulate a Semaphore in TinkerCAD.

Fig. 2. Turn On and Off a Red LED and Simulate a Semaphore in TinkerCAD.

course progressed with intermediate Arduino and Tinkercad (3 sessions). The course ended with a final presentation to share the results with the community. Students who took part in the session had no knowledge of programming and much fewer electronics and associated physical principles. Their prior academic record at those institutions was above average (6.0 on a scale of 1.0 to 7.0). Consequently, the workshop's objectives appear a touch too ambitious. Participants were nonetheless encouraged to participate physically and primarily for the live results while utilizing the Arduino simulation in TinkerCAD. The first two workshop sessions taught students about the Arduino inputs and outputs (structure). Authors experimented using a real battery and Arduino to turn on and off a light (Fig. 1 and 2a), and implementing a semaphore (Fig. 2b). The Arduino loop cycle, in which this code is continually executed, was grasped by the students. Students studied more about conditional structures, variables, and sensors in the next three sessions.

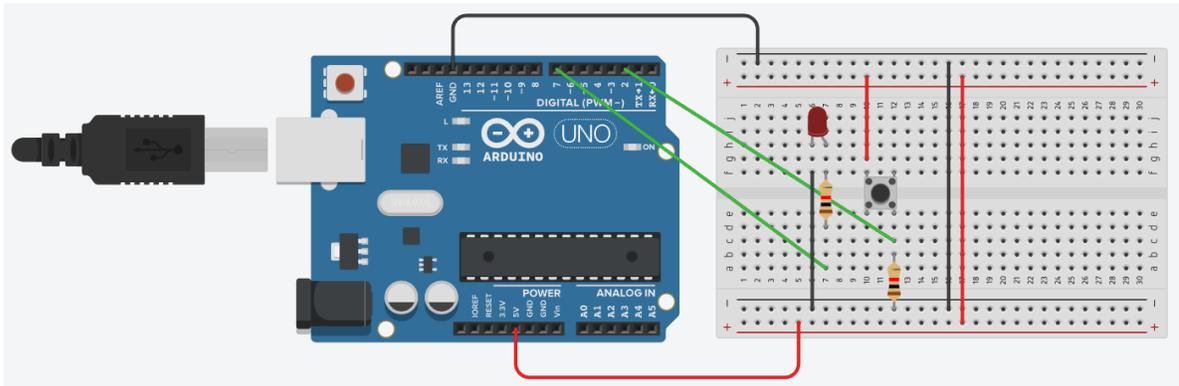

This project proved that by using Arduino, people could effectively educate and develop students' programming and problem-solving skills. This page displays the primary school test scores from various Chilean primary schools, a nation that is still growing. These findings may inspire other institutions and countries to do comparative research to enhance and develop these skills in elementary school children. The researchers of this project want to conduct a more extended experiment with younger primary school pupils to help them develop their programming and problem-solving skills.

#### IV. SUCCULENT STUDENT EXPERIMENTS

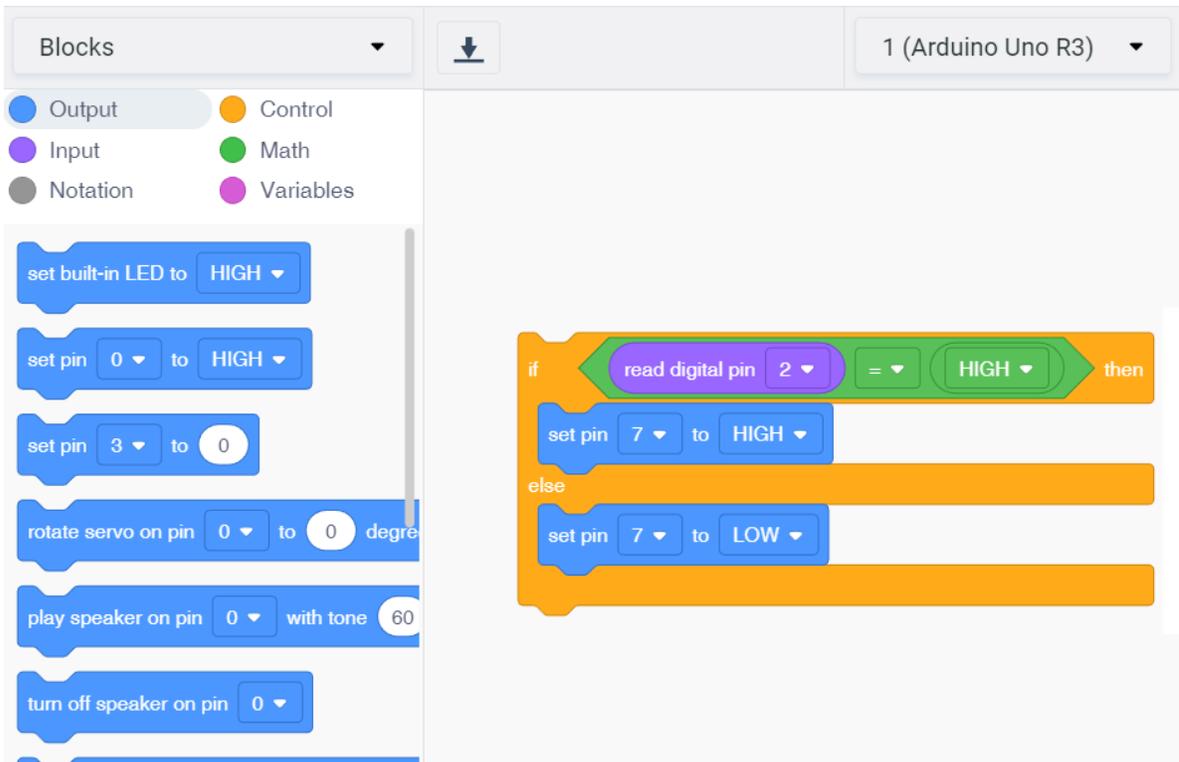

Students were considerably more enthusiastic about studying electronics using Arduino after learning about using TinkerCAD to build circuits and its block-structured programming environment. A TinkerCAD method to turn on a red led when pushing a button and turn it off in another situation is shown in Fig. 3.

The circuit is shown in part a of this solution, and part b shows the block-structured code. Students go through the key concepts of the Arduino loop cycle once again to determine whether or not the button is pushed to turn on and off the red LED accordingly. Students were, therefore, able to distinguish between input and output signals. In the fourth lesson, students received examples of how variables are used in human life (for example, to record a friend's phone number) and on the Arduino (e.g., to know what the previous button pressed was for a circuit with a set of buttons). Students also knew about a few distinctions between digital and analog signals using sensors. In this lesson, the authors created a TinkerCAD solution with the primary objective of turning on the red light when the temperature exceeds a particular value (Fig. 4

illustrates the circuit and the block-structured code). The block-structured code defines the maximum temperature using the MaxTemp variable (35 Celsius). In another instance, the red led is switched on and off when the read temperature, using a mathematical calculation, exceeds that maximum value. This TinkerCAD exercise was completed by seven students, while the remaining two were assisted. Thus, all pupils could understand how their first sensor system worked. As a motivation for using an ultrasonic sensor to calculate the distance of an object concerning the sensor position and turn on a led concerning the current distance of that object, the authors went over the main steps of the previous TinkerCAD temperature systems in the final session of the workshop. There are three variables for the detected value (distance), the lowest distance

(b) TinkerCAD Block-Structured Code for Reading a Temperature Sensor and Activating a Light when the Temperature Rises over a Certain Threshold, Called MaxTemp.

Fig. 4. Using TinkerCAD for Reading a Temperature Sensor and Activating a Light when the Temperature Rises over a Certain Threshold, Called MaxTemp.

allowed (minDistance), and the maximum distance allowed (maxDistance) in the block-structured code. The authors are grateful for the circuit's red, yellow, and green-led instances that can be turned on individually. If the distance is less than the minimum distance, the red led turns on; if it is between the minimum and maximum distance, the yellow led turns on; and if it is more than the maximum distance, the green led turns on. Some of the experimental findings that students obtained during the last three workshop sessions are summarized in Fig. 3 and 4.

## V. ACADEMIC PROGRESS

According to their primary school records, students who participated in the workshop demonstrated improved academic performance from their prior academic performance, particularly in the math and science classes. The authors understand

that these pupils might significantly benefit from courses where developing algorithmic thinking and problem-solving skills is relevant. The following lines provide further information about such upgrades.

### A. Improved Math Test Results

The primary academic gains made by pupils in the math class are shown in Table I. Authors may acknowledge that pupils improved their scores by 9.21% on average. All of the pupils also scored close to their post-test records. Because algorithmic and problem-solving skills are closely related to logical and mathematical reasoning, these results are expected to rise.

TABLE I. MATH COURSE ACADEMIC RESULT - CHILEAN SCORE RECORDS FROM 1.0 TO 7.0

# Students	School	Academic Performance		
		Previous record	Post record	Improvement
3	School A	5.8	6.3	8.62%
3	School B	5.6	6.1	8.92%
2	School C	5.7	6.2	8.77%
1	School D	5.5	6.1	10.53

TABLE II. SCIENCE COURSE ACADEMIC RESULT: CHILEAN SCORE RECORDS FROM 1.0 TO 7.0

# Students	School	Academic Performance		
		Previous record	Post record	Improvement
3	School A	6.0	6.4	6.66%
3	School B	6.1	6.4	4.92%
2	School C	5.8	6.2	6.90%
1	School D	5.9	6.3	6.78

### B. An improvement in science test results

The primary academic gains made by pupils in the science class are shown in Table II. Authors may acknowledge that pupils improved their scores by, on average, 6.32%. Regarding the arithmetic course, every student received a post-record score close to the maximum. Authors could say that algorithmic and problem-solving skills help students improve in science, even though this improvement is not as significant as in math.

## VI. RELATED WORK

Research about developing programming and problem-solving competencies in university students and children exists. Lineros et al. [20] present positive experiences developing electronic and computing architecture competencies using Arduino. Vidal et al. [21] highlight experiments in the same academic experience at the Viña del Mar University. The work of Vidal et al. [10] shows positive experiences with school children in Viña del Mar, Chile, using Scratch and Arduino to develop programming and electronic competencies. Tupac et al. [22] describe positive experiences and results using Arduino in a first programming course with university students in Huancayo, Perú. Tupac et al. [23] highlight results and academic performance regarding previous experiences in Huancayo, Perú, even more during the pandemic time applying online education.

Regarding programming competencies in university students, Ortega et al. [24] and Vidal et al. [25] remark on the usefulness of Python for developing multiprogramming and web development competencies, respectively, not necessarily for computer science students. Likewise, Vidal et al. [26] describe the positive results and experience developing multiprogramming and programming competencies applying Python in two majors with the different primary focus, computer engineering, and business administration. Even though those works are not related to Arduino, they also demonstrate confidence in applying high-level programming languages to develop programming and problem-solving competencies.

## VII. CONCLUSIONS

This project proved that by using Arduino, people could effectively educate and develop students' programming and

problem-solving skills. This page displays the primary school test scores from various Chilean primary schools, a nation that is still growing. These findings may inspire other institutions and governments to do comparative research to enhance and develop these skills in elementary school children. The people doing this research want to do a more extended experiment with younger kids in primary school to help them learn how to code and solve problems.

TinkerCAD's online functionality goes hand in hand with the global education trend. For example, the universities of the authors of this work are currently offering programs applying partially or fully to that system. Hence, TinkerCAD can be part of those programs for developing programming, circuit design, and problem-solving competencies.

## VIII. FUTURE WORK

This research invites us to investigate the usefulness of Arduino and TinkerCAD for first-year primary school and first-year university students to develop programming, circuit design, and problem-solving competencies. That is a current project in the universities of the authors. They expect to publish the obtained results.

The authors will also investigate Arduino and TinkerCAD's impact on developing programming, circuit design, and problem-solving competencies in kindergarten children. The block-based programming language seems attractive, and appreciating results after coding seems useful for learning purposes. Nowadays, children are born in a computer and information world that invite them to use and learn about technology.

The block-based language of TinkerCAD for developing programming, electronics, and problem-solving competencies also motivates researchers to apply tools in videogame development, such as Unity [27] and Unreal Engine [28]. Videogames attract children, teens, and adults; their development can motivate them to develop programming and problem-solving competencies.

The main issue of this work was the requirement for internet connection and computer availability, although it seems an irrelevant problem nowadays.

## ACKNOWLEDGMENT

The authors would like to thank the positive experience developing programming and electronics competencies in primary school children. Educating children represents a marvelous task overall for university professors. After that, the authors want to continue applying this teaching-learning experience in their Chilean cities, specifically in Viña del Mar, Santiago, and Talca.

# An Integrated Hardware Prototype for Monitoring Gas Leaks, Fires, and Remote Control via Mobile Application

Md. Ashiqur Rahman, Humayra Ahmed, Md. Mamun Hossain  
Computer Science and Engineering  
Bangladesh University of Business  
and Technology  
Dhaka, Bangladesh

**Abstract**—Liquefied petroleum gas (LPG) is used in a wide range of applications such as home and industrial appliances, vehicles, and refrigerators. However, leakage of gas can have a dangerous and toxic effect on humans and other living organisms. In this paper, an IoT based system is employed for this purpose to monitor gas leakage, detect flames, and alert users. The MQ-5 gas sensor was used to understand the concentration level of a closed volume of gas, while the infrared flame sensor was used to detect the spread of fire in this study. The proposed system has the capacity to detect fire and gas leaks as well as take additional action to lower gas concentration by air ventilation with exhausted fan and put out fires with fire extinguisher. The suggested approach will contribute to increasing safety, lowering the mortality toll, and minimizing harm to the environment. Overall system is implemented with IOT cloud-based remote controls to prevent gas leakage by using android application in response to individual feedback or feed-forward commands. The controller used here is Arduino Uno Rev3 SMD. This study provides design approaches to both software and hardware.

**Keywords**—Gas leakage; infrared flame detection; IoT; android; arduino UNO

## I. INTRODUCTION

When natural gas or another gaseous product escapes from a pipeline or cylinders into an area where it is not supposed to is referred to as gas leakage. These gasses are usually colorless and some are odorless, so there is no way to know if there has been a gas leakage in the environment. It may result in life threatening explosions if these leakage can not be detected [1]. Gas leaks have been a common occurrence in recent years, owing to a combination of poor equipment maintenance and a lack of public knowledge [2]. Therefore, a gas leakage detection system is needed to be introduced to detect gas leakages from domestic or industrial gas pipes or cylinders. It is essential to prevent loss of lives and properties. With the help of Wireless Sensor Networks (WSN), Radio Frequency Identification (RFID), and cloud computing, IoT device communication has become more practical than it once was[3].IoT is a system of web-enabled devices that use sensors to gather data from their environment, process it, and transmit it over the network [4]. Everything is becoming more connected to the internet, which is causing the Internet of Things to grow exponentially [5].

Nowadays a great number of people around the world are using smartphones. So it will be greatly convenient if we can

use smartphones as a surveillance device in order to detect gas leakage. Therefore, we have developed a gas leakage detection system accompanied by an android application. However, this system does not only detect the gas leakage but also it can take actions against the explosions that might happen due to leakage.

Currently, the gas leak detection system is a widely used mechanism. These function nicely and substantially reduce damage. If they adopt additional safety measures in addition to looking for gas leaks, they may be more effective. Existing gas leak detection systems can find leaks, sound audible alarms, and text or contact users to alert them to a leak. However, there is no safety precaution, which means that if there is no user, any accident could occur. Our recommended system, however, has safeguards. For instance, the user can promptly take action by utilizing their Android mobile phone in the event of a gas leak, such as cutting off the gas and power supply to lessen the likelihood of an accident. Using our developed app on their phone, they can remotely operate the entire system.

Our system's main goal is to create a gas leakage detection system and take the required actions to avoid disasters caused by gas leakage. The entire system is powered by Arduino. When a gas leak, smoke, or flame is detected, the proper procedures can be performed to notify the users. The entire system can be controlled from remote location by designing an Android app using cloud database. In addition, an automatic fire extinguishing mechanism has been incorporated to provide more reliability to the system's user.

This paper presents the latest IoT and app based intelligent system and provides a substantial new research direction. Some significant contributions of this paper are outlined as follows:

- **Smart Management:** A smart system is developed using edge cutting technology to monitor and control the gas leakage and fire break out.
- **Remote Controlling:** A mobile application is developed to control the system remotely.
- **Smart Decision Making:** A decision tree algorithm is developed based on the data to help the user making intelligent decision.
- **System Integration:** This system's components and integration are both cost-effective and dependable.

The rest of the paper is segmented as follows. Section II discusses about related works. Section III provides a detailed description of the hardware that we have used to build our proposed system. Section IV provides a detailed description of our proposed system. Section V presented the whole scenarios of implementation of our proposed system and Section VI, provides a detailed view whether our system works properly or not. Section VII shows performance evaluation of our system with the existing system and Section VIII gives a detailed view of how security is provided in our IoT system. Section IX concludes the paper.

## II. RELATED WORKS

Srivastava et al. [6] presented a home automation system for consumer safety in . The suggested system automatically cuts off the gas supply whenever a gas leak is identified. Customers can also keep track of their gas consumption and bring refills before the gas runs out by using the system. They did not employ LPG cylinders in practice due to budgetary and timing constraints. They used a water container and lighters to demonstrate gas leaking in the test case experiment. In [7], Keshamoni et al. built an IOT based system for monitoring gas levels, booking new cylinders, and detecting gas leaks to avoid mishaps. The device reduces gas accidents by informing users of leaks and pre-alerting them to schedule a replacement cylinder. They just alert the users that there is a leakage happening in the system but no remote controlling or monitoring is not implemented there. In [8], Varma et al. presented an IoT based system for detecting harmful gasses. The system notifies customers through personal call, SMS, and email when a gas leak is detected by the gas sensor. The system uses relays to turn off the main power supply when the gas concentration is likely to reach the Lower Explosion Limit (LEL). However if relays fail to perform, there is no alternate way to cut down the main power supply which may lead to a great accident. In [9], Siddika et al. build a microcontroller-based system for monitoring LPG gas leaks and warning users using an Arduino and a MQ-135 sensor. The device activates and sounds an alarm by buzzing the buzzer when the gas sensor detects a gas leak. It also sends a message labeled "GAS LEAKAGE" to a predefined mobile number through the GSM module. They didn't provide any sort of automatic safety system in place.

In [10], Tamizharasan et al. proposed an IoT-based automated system for monitoring gas density in LPG cylinders. The gas sensor delivers information to the micro controller, which activates the buzzer when a gas leak is detected. They employed a load sensor to measure the weight of the LPG cylinder in this arrangement. When this weight drops to a dangerously low level, the system alerts the user and instantly orders a replacement cylinder by contacting the registered gas booking number. They just monitor the gas density level but they do not detect the leakage occurred in the cylinder. In [11], Tharad et al. proposed a method for detecting LPG leakage using an Arduino-based microcontroller. MQ2 gas sensors, an Arduino microprocessor, a GSM module, an LCD display, a temperature and humidity module, as well as a buzzer were all employed in the system. The gas concentration in the surrounding area will be displayed on the LCD display, and a buzzer will sound when leakage is found. With the aid of a stepper motor, the power source is turned off. But, if the stepper motor fails to perform its action there is no such other

option in it which can protect from destruction. Dmitry et al. [12] developed an architecture using Wavelength Modulation Spectroscopy instrument to identify the presence of gas and estimate the gas concentration. The output is sent via Bluetooth protocol to the developed application running on a LG G2 D802. The application was developed to access the HITRAN database in real-time. But there isn't any automatic action put in it that can be crucial if a user doesn't receive the notification or take the action. Rahul et al. [13] implemented a system to detect the liquefied petroleum gas (LPG). The system used the high sensitivity sensors to detect the gas leakage as early as possible. They did not include in their system such as cut off power supply, alert system, flame detection, etc.

Anindya et al. [14] presented a new approach for detection of domestic cooking gas leakage. During the experiment the humidity and temperature maintained in a fixed value. Different concentration of LPG has been tested under coated and uncoated conditions. Then the concentration was analyzed for different situations. However, this system doesn't do anything in response to the presence of gas in the surroundings. Noor et al. [15] proposed a gas leakage detection system using two Internet of Things (IOT) platforms. In this system, MQ-2 gas sensor is used to detect the gas leakage. Then the sensor sends the signal to microcontroller and after that microcontroller sends it to an external device such as cell phone. Blynk IoT application is used to alert the concerned person using alarm and Thingspeak IoT cloud is used to record and visualize the data. To monitor LPG leakage, Malviya et al. [16] presented an LPG gas leakage detection and indication system. This setup uses a gas sensor to detect LPG gas leaks and simultaneously sounds an alarm. After the gas leakage equals or exceeds the predetermined threshold, it also uses a Wi-Fi module to send a message to mobile phones. But they didn't provide any suggestion how to control the leakage using mobile phone or any other device.

In order to facilitate user engagement with the suggested system, QI Sarhan et al. [17] employed an Arduino Uno microcontroller in conjunction with a number of suitable sensors, actuators, and GSM as a wireless communication channel. Users may be alerted to events like fire, gas leaks, and home invasions via SMS messages, emails with attachments, etc. In this research, MR Habib et al. [18] suggested an automatic fire alarm system with an extinguishing device that is based on Arduino for fire protection. Smoke detector and temperature sensor support the flame sensor in the proposed system, which is explained together with a thermal model of a dwelling. They didn't use the cloud server and automated decision making approach in their system.

## III. SYSTEM HARDWARE

### 1) Arduino UNO (Fig. 1):

Fig. 1. Arduino UNO.

Features:

- Operating voltage : 5V
- Input voltage range : 6v to 20V
- Input/Output pins : 14
- Analog i/p pins : 6
- DC Current for each input/output pin : 40 mA
- DC Current for 3.3V Pin : 50 mA

2) Gas sensor(MQ-5) (Fig. 2):

Fig. 2. Gas Sensor (MQ-5).

Features:

- Good sensitivity to harmful gasses in a wide range.
- Long life and low cost.
- Possesses high sensitivity to ammonia, benzene, sulfide gases.
- Simple drive circuit.

3) Sim module (Sim 800L) (Fig. 3):

Fig. 3. Sim Module.

Features:

- Works between the voltage range 3.4V to 4.4V and it works in low power mode.
- Operates in 2 mode: Sleep Mode, Ideal Mode.
- Consumption of power is less than 2 mA in Sleep Mode and less than 7 mA in Ideal Mode.
- Supports micro SIM card.
- Searches its corresponding network.
- Helps to send and receive call and SMS.
- Indicates different states by using LED such as: first blinking(no network coverage or searching), slow blinking (logged in), not blinking (power problem).

4) Infrared Flame Detection Sensor (Fig. 4):

Features:

- The sensor can detect fires with wavelengths ranging from 760 to 1100 nm.
- It can detect a lighter flame from 80cm, the larger the flame the farther the sensing distance.

5) ESP Module (ESP 8266) (Fig. 5):

Features:

- Integrated with TCP/IP protocol stack.
- Build in temperature sensor.
- Power consumption - 70 mA.
- Voltage range - 3V to 3.6 V.
- We need to program our device and communicate with the ESP8266 chip by converting USB signals to serial.

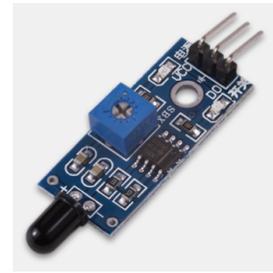

Fig. 4. Infrared Flame Detection Sensor.

Fig. 5. ESP Module.

#### IV. PROPOSED METHODOLOGY

Arduino UNO micro controller is the main component of our proposed system. It works as the brain of our system. As it is a low cost device, and easily programmable, we use it as the integrator of our system. It is connected with every other component shown in Fig. 7.

##### A. System Architecture

The product consists of an outer wooden casing in the shape of a box to carry the Arduino controller, LCD Display, GSM Module, MQ-5 gas sensor, ESP Wi-Fi module, a Buzzer, servo motor and exhaust fan. The gas sensor is placed right above the mouth of the cylinder and the pipeline. Fig. 6 shows the overall architecture of our system.

A servo motor is placed in such a way that whenever there is a signal, it will close the pipe to stop the flow of gas and with help of ESP Wi-Fi module it can stop electricity supply also. Arduino acts as the brain of control. GSM module, ESP Wi-Fi module, LCD display all are connected to Arduino controllers. An LCD display is connected which always shows how much gas is present in the air. There is a Buzzer and two exhaust fans in our system which will be helpful in case of emergency. The GSM module is connected to the Arduino UNO to send alert messages.

##### B. Operational Principle

- **Collecting Data from Sensor:** The sensors we have used in our system are MQ-5 gas sensor and fire sensor.

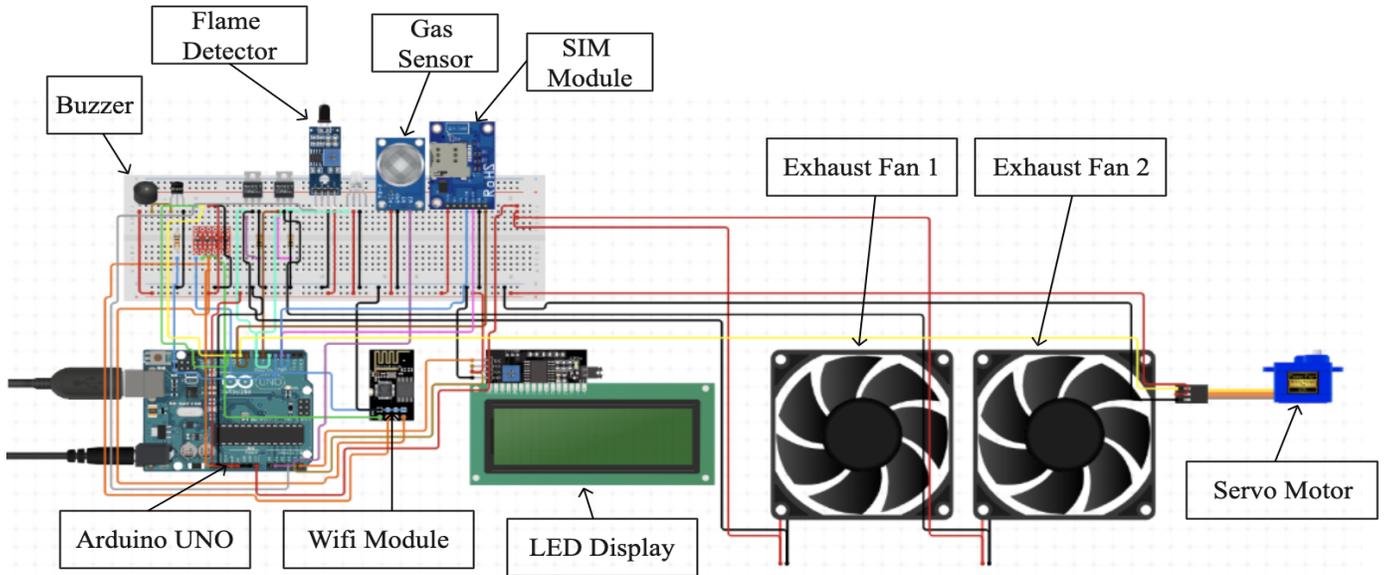

Fig. 6. System Architecture.

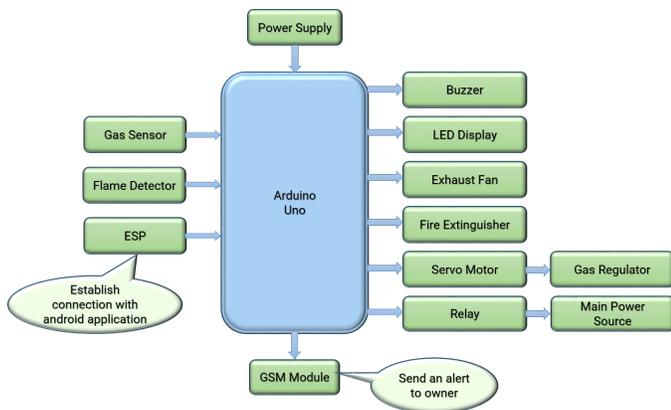

Fig. 7. Block Diagram of the Proposed System.

MQ-5 gas sensor is used to detect whether gas leakage occurs or not. It can also detect toxic gasses like ammonia gas, sulfide, benzene series steam and also trace the smoke and other gasses. The primary material of the MQ-5 gas sensor is SnO<sub>2</sub>. It possesses very low conductivity in clean air. When the gas leakage occurs, the gas concentration in that place gets higher. So when it comes into contact with SnO<sub>2</sub> its conductivity changes. Its conductivity rises along with the level of the gas in the air. This is how the MQ-5 gas sensor works and produces a corresponding output voltage from which we can understand the level of gas in the air.

The fire breakout is detected using an infrared flame sensor. Flame detectors that use infrared (IR) or wide-band infrared (greater than 1.1 m) sense and analyze the infrared spectral band to locate predetermined patterns emitted by hot gases.

All of these sensors are connected with the Arduino

UNO board and data from the sensors has been displayed on the LCD monitor. If the gas leakage occurs in the system, an alarm or buzzer rings to alert everyone within the house. And an alert message is sent to the user's phone using GSM module shown in Fig. 8.

- Sending Data to Cloud Server:**  
All of the data that is collected from the sensor has been sent to the cloud server using the Wi-Fi module that is associated with the Arduino UNO server. For cloud service, we have used the Firebase database. The Firebase saves the data as parent child combination pair. The cloud server is basically used for remote controlling of our system.
- Data Extraction and Mobile Application Development:**  
All of these data that is stored in the cloud has been collected and sent to the mobile application that we have been built using the MIT app inventor. By using this application, the user can control the system from anywhere. The sensor data is visible to the user through the application interface.
- Remote Controlling:**  
A decision tree algorithm is applied in the data that is collected from the cloud server and a suggestion is visible in the interface of the mobile application. Then the user can easily take the decision of turning the gas regulator off or turning on the exhaust fan or cutting off the electric supply or turn on the fire extinguisher depending on the situation. When the user gives command in the mobile application, it immediately sends the signal to the cloud database and from that the signal is executed in the Arduino UNO board. This is how remote controlling is done in our system using mobile application.

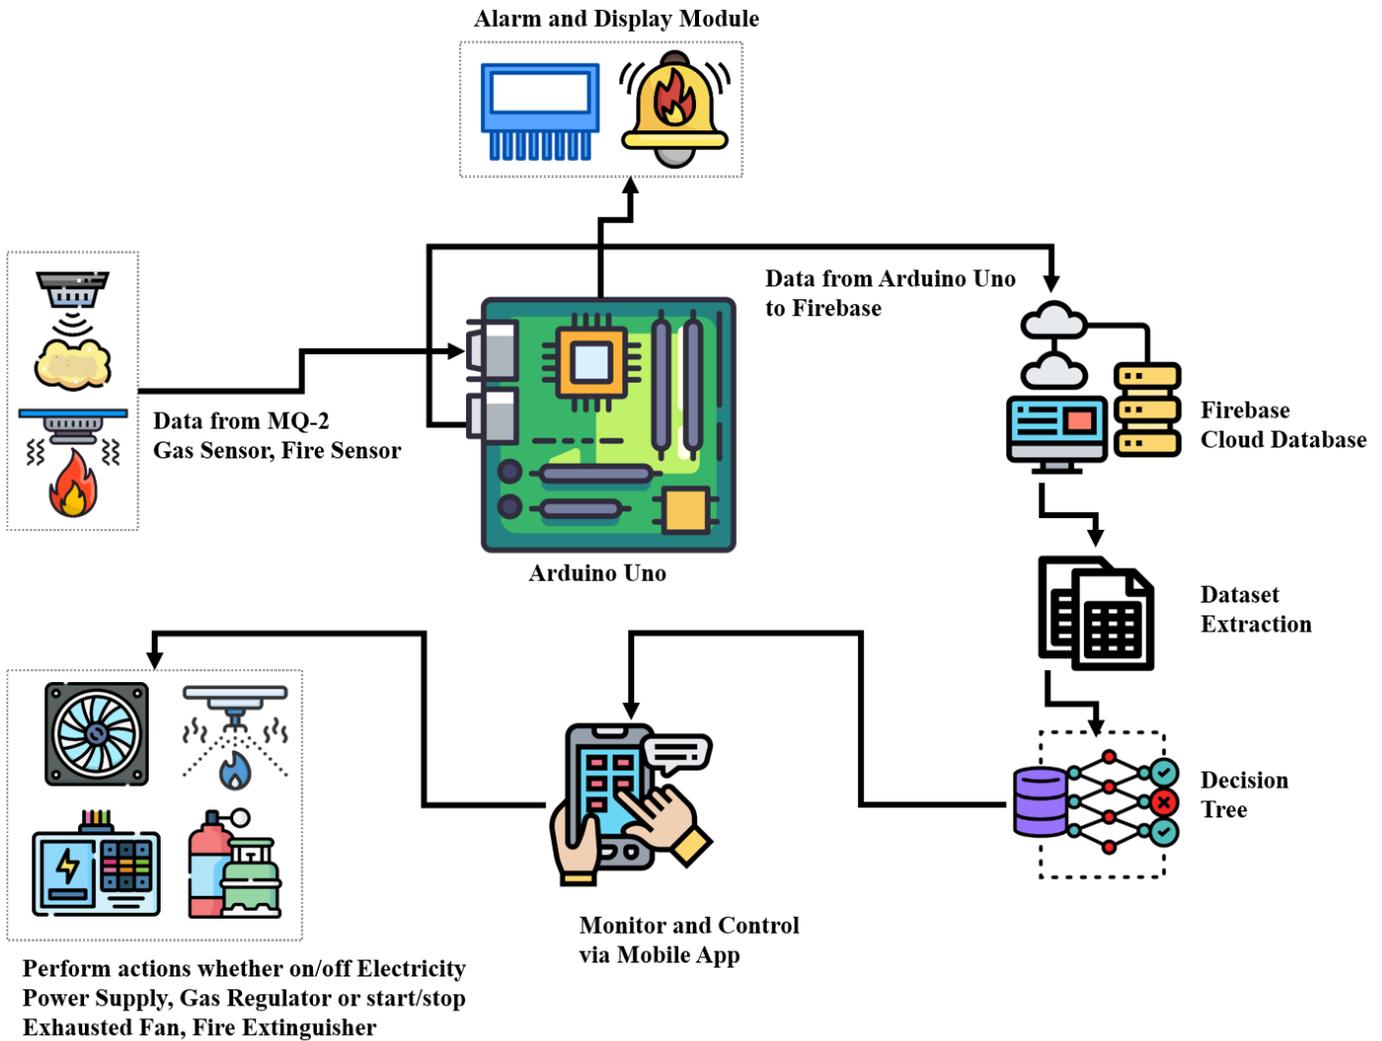

Fig. 8. Operational Flow of Detecting Gas Leakage.

## V. IMPLEMENTATION

### A. System Implementation

The below Fig. 9 represents our whole system implementation. Before implementing the overall system, we have tested every single component. In place of exhaust fans and fire extinguisher, we have used LED bulbs to minimize our implementation cost and simplification. To monetize the power supply, we have used a single LED bulb. Arduino UNO is connected with every single component of the system and acts as a brain of our system.

### B. Android Mobile App Implementation

Here we have developed an android app which helps to control our leakage system from a remote distance. The user may turn the gas and electricity off and exhaust fan on in case of found leakage through apps. Fig. 10 the interface of our android app. We have implemented the decision tree algorithm 1 in the mobile application to provide suggestion about taking action to control the gas leakage.

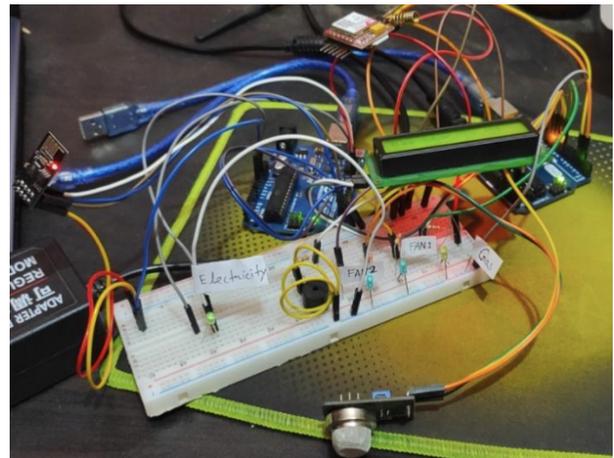

Fig. 9. System Implementation.

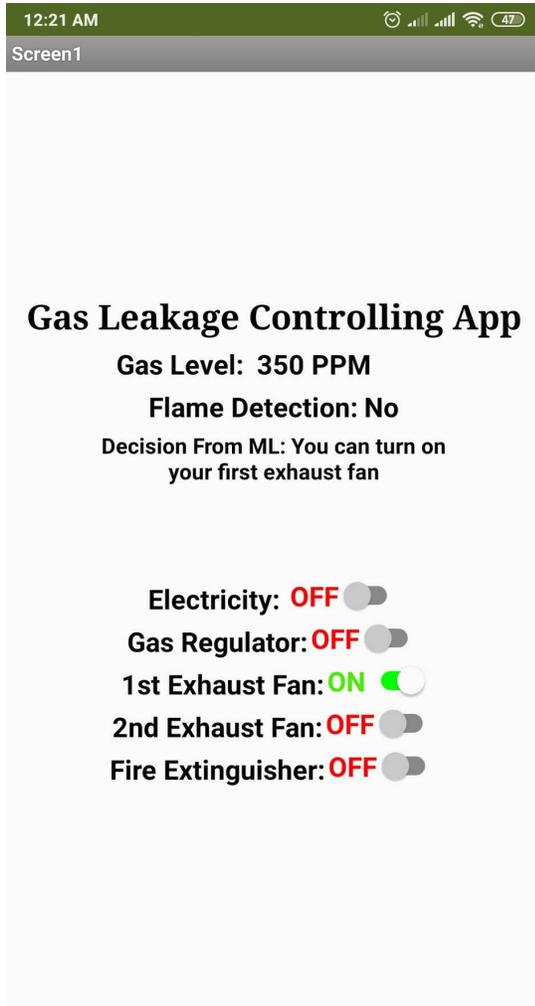

Fig. 10. Mobile Application Interface.

## VI. TEST AND RESULTS

This system has been examined by taking a small amount of LPG gas near to the sensor. The MQ-5 gas sensor detects the LPG gas and then it sends a signal to the micro controller. The sensor detects gas leakage once the system is launched, if there is no gas leakage, it displays “Gas Level Normal” on the display which is shown in Fig. 11.

When gas is leaked and it crosses its limit which we set (300ppm) a signal from the micro controller goes to the display and shows “Leakage Found” which is shown in Fig. 12. Simultaneously the buzzer rings.

Then the sensor data goes to the cloud and gives a notification or alert message “Leakage Found on your kitchen” to the owner’s phone to let him know about the incident shown in Fig. 13.

After getting from leakage found message, we can stop the gas and power supply by the help of our android app. When the owner stays at home and wants to be sure of his safety, he can turn off the gas supply with his mobile through this

### Algorithm 1: Decision Tree for Gas Leakage Controlling

1. Enter the gas level
2. Enter the flame status
3. **if**  $gaslevel \geq 300 \ \&\& \ gaslevel \leq 3000$  **then**
  - if**  $flamestatus == true$  **then**
    - suggestion = 1st Exhaust Fan on & Buzzer on & Fire Extinguisher on
  - else**
    - suggestion=1st Exhaust Fan on & Buzzer on
4. **else if**  $gaslevel > 3000 \ \&\& \ gaslevel \leq 7000$  **then**
  - if**  $flamestatus == true$  **then**
    - suggestion = 2nd Exhaust Fan on & Gas Regulator Off & Fire Extinguisher on
  - else**
    - suggestion=2nd Exhaust Fan on & Gas Regulator Off
5. **else if**  $gaslevel > 7000 \ \&\& \ gaslevel \leq 10000$  **then**
  - if**  $flamestatus == true$  **then**
    - suggestion = Power Supply off & Fire Extinguisher on
  - else**
    - suggestion=Power Supply off
6. **else**
  - suggestion = Gas Level Normal

precautions or actions to avoid severe accidental cases happen due to gas leakage which is absent in the existing systems.

### VIII. SECURITY

The majority of internet technologies and networking protocols have been created exclusively for unrestrained items, which has presented significant security concerns when integrating IoT objects into the standard Internet [19]. We must ensure security in order for the various sensors attached to our system and the data saved in the cloud database to function properly. The security measures put in place in our system to keep it secure are listed below.

- **Providing Authentication and Password:** For our smartphone application that we designed to allow remote operation of our IoT system, we have enabled authentication and strong passwords. It aids in protecting our system from brute-force attacks.
- **Monetizing and Updating System:** We have a frequent update option installed in our system and regularly monitor to detect the vulnerabilities of our system.
- **Ensuring Security of Data:** Our data is stored in the Firebase database. To protect the data, we have used their built-in authorization mechanism. In order to safeguard the data from manipulation or tampering from other sources, we have additionally deployed rule-based permission of the Firebase database for data retrieval. This makes our data secure when retrieving.

Fig. 13. Alert Message about Leakage of Gas.

using the mobile app can turn on the fire extinguisher.

### VII. EVALUATION

We have evaluated our system with other existing systems in respect to the feature that they have introduced in their system. The Table I shows the difference between our proposed system and existing system.

Here, Y represents ‘Yes’ and N represents ‘No’.

Comparing the proposed system to the other systems it can be clearly seen that from Table I, the proposed system incorporated more features in comparing with the other system. It can not only detect the gas leakage but also take necessary

### IX. CONCLUSION

In this research, we proposed a gas leakage detection approach for home safety reasons to reduce the accidental cases occur owing to gas leakage and a flame detection system is provided to manage the fire outbreak. To remotely operate the entire system, we also developed an android application. Additionally, it accomplishes some important properties that the current approaches do not. A more potent gas sensor, such as MEMS, can be used to increase system effectiveness. If a Philips micro controller is utilized, the micro controller’s efficiency and memory can be improved. To generate intelligent decisions, advanced machine learning algorithms might be introduced.

#### ACKNOWLEDGMENTS

We would like to acknowledge the support of the Bangladesh University of Business and Technology and IoT lab for their suggestion and resource sharing.

**Abstract**—The Raspberry Pi has evolved in recent years into a popular, low-cost, tiny computer for a wide range of IoT applications. Raspberry Pi is not only successful for data collection but also for data processing, including data storage and analysis. Thus, this study investigates the capability of Raspberry Pi as an edge processing device for capturing lightning strike signals in predicting flash flood locations. An electric and magnetic sensor (EMS) is connected to a Raspberry Pi in the experiment setup. The Raspberry Pi is then used to process digitised lightning signals. From the experiment, Raspberry Pi's performance is measured using the performance metrics: central processing unit (CPU) usage and temperature. The results revealed that the Raspberry Pi could handle the real-time collection and processing of lightning signals from the EMSs without affecting the hardware capability.

## I. INTRODUCTION

The Internet of Things (IoT) is changing how we live, work, travel and do business. It is also the cornerstone of a modern industrial revolution known as Industry 4.0 and the key to the digital transformation of businesses, communities, and society. An IoT ecosystem comprises web-enabled intelligent devices that use embedded systems, such as processors, sensors, and communication hardware. These intelligent devices collect, transmit and act on data they acquire from their environments. The devices then share the sensor data they acquire by connecting to an IoT gateway or other edge device, where the data is either transferred to the cloud for analysis or locally analysed. According to Priceonomics.com, the number of connected devices is projected to rise from 8.7 billion in 2012 to 50 billion in 2020 [1]. Huawei predicts that 100 billion connected devices will be used in every business and living area by 2025 [2]. Consequently, the data generated by the IoT is projected to reach 4.4 zettabytes by 2020 from just 0.1 zettabytes in 2013 [1].

The value of IoT goes further than data collection and real-time monitoring. Companies can gradually see the need to upload vast amounts of data to the cloud and support flexible resource management and visualised operations. They will also

strive to process their data using machine learning and predictive analytics in order to introduce better technologies that will bring them success. Previously, placing all computational tasks on the cloud has proved to be an efficient way to process data since the power of cloud computing outperforms the capacity of the IoT. However, over the past few years, the significant increase of data generated by smart devices has put a strain on bandwidth utilisation [3].

Furthermore, digital traffic jams are almost anticipated, with the world estimated to generate up to 4.4 zettabytes of data by 2020. There is also the "last mile" bottleneck problem. Essentially, the last mile defines the final networking segment, which connects an organisation's local network to the Internet. Since all network traffic destined for a particular organisation is channelled through that connection, it can be a bottleneck in networking throughput [4].

Due to the miniaturisation of processing and storage technology, current IoT devices have become more potent in collecting, storing, and processing data. This scenario has opened opportunities for organisations to optimise their networks and relocate more processing functions closer to where data is collected at the edge of the network. Gartner defines *edge computing* as a "part of a distributed computing topology where information processing is located close to the edge, where things and people produce or consume that information" [5]. In essence, edge computing brings computation and data storage closer to the smart devices rather than depending on a central location that might be thousands of kilometres away. Edge computing allows the data from the IoT devices to be analysed before being sent to the data centre. The main objective of edge computing is to prevent data, especially real-time data, from suffering latency issues that can affect the performance of an application [6].

Recent years have seen the development of Raspberry Pi as a popular, low-cost, tiny computer for several IoT applications. Raspberry Pi, referred to as a Single Board Computer (SBC), can run a complete operating system and has sufficient peripherals like memory, central processing unit (CPU), and power to initiate execution without additional hardware. In the present

TABLE I. TABLE OF ABBREVIATIONS

Abbreviation	Meaning
CAPPI	Constant Altitude Plan Position Indicator

RPi	Raspberry Pi
SDRAM	Synchronous Dynamic Random-Access Memory
SBC	Single Board Computer
VLF	Very Low Frequency

society, Raspberry Pi is not only an essential data-gathering device, but it can also analyse and store data in a server-like fashion.

In this study, Raspberry Pi devices are used as one of the components in the proposed architecture to illustrate its viability as an edge computing device and to evaluate its performance in terms of CPU system-wide utilisation and temperature. In this study, we believe Raspberry Pi devices may function as data processing edge devices, given their current CPU, memory, and storage capacity. If Raspberry Pi devices merely function as data collectors without additional processing and transfer all data to the cloud, then a significant amount of computer power is squandered. Consequently, in this study, our aim is not only to cut data transfer time by using Raspberry Pi's local processing capacity but also efficiently uses the otherwise underused distributed computing power. This study's contribution is to reveal the viability and potential of edge computing by doing hands-on experiments and analysing the performance in terms of CPU usage and temperature.

The rest of the paper is organised as follows. An overview of the Raspberry Pi as an edge device and similar studies on Raspberry Pi's performance as an edge device is discussed in Section II. Section III presents this study's background works. The experiment setup for the performance evaluation is presented in Section IV. Section V reports and discusses the results of the experimental evaluation. We conclude the paper in Section VI.

## II. RELATED WORKS

On March 14, 2018, the Raspberry Pi Foundation introduced the Raspberry Pi 3 Model B+ as an upgrade to its predecessor [7]. It is also known as a Single Board Computer (SBC) with a Linux-based operating system, and a micro SD card is often required for boot file system storage. General Purpose Input-Output (GPIO) connectors are meant to control a vast array of electrical components in addition to being a small, low-cost computer programmatically[7]. In addition to its usage in education, it has become a popular edge processing device for other IoT applications.

The research articles in [8], [9], [10], [11] are examples of the existing literature on edge computing research utilising Raspberry Pi. The authors of [8] have created a lightweight edge computing-based distributed system that uses

Raspberry Pi to directly handle the raw picture data from each camera. Consequently, the identified emotions may be easily communicated to the end user. In this study, the optimised and bespoke algorithms in the edge devices increase data processing speed, reduce network bandwidth requirements, and enhance application performance. The authors of [9] propose an automated service and resource discovery technique to effectively deploy nano services on local IoT nodes. Using a scenario involving remote healthcare monitoring, the authors offer a Raspberry Pi platform prototype implementation of the suggested method.

Several works in [12], [13], [14], [15], [16], [17] are related to performance evaluation on Raspberry Pi as edge devices. A study in [12] comparing data processing in various network setups and data stream speeds has been done in semantic data enrichment. It implemented a tiered IoT-Edge-Cloud system employing automotive sensor data at the IoT layer, Raspberry Pi at the edge layer, and Node-Red server at the cloud level in real architecture. The outcome demonstrates that data processing at the edge layer has enhanced efficiency, memory utilisation, and round-trip time.

Deep learning-based voice recognition applications have been studied in [13] to compare the performance and efficiency of Raspberry Pi with Nvidia Jetson Nano edge devices. Even if the Nvidia Jetson Nano is superior to Raspberry Pi, the word error rate for real-time inference on the Raspberry Pi CPU slightly degrades. The word error rate on the edge layer is generally more significant than the server inference, although it is not too far behind.

The objective of [14] is to conduct a comparative and experimental investigation of the performance of five distinct Raspberry Pi models (RPi Zero W, RPi Zero 2 W, RPi 3B, RPi 3B+, and RPi 4B) under a variety of situations and configurations. In conclusion, RPi 4B is significantly surpassed by competitors. In the meanwhile, the performance of the RPi Zero 2 W, RPi 3B, and RPi 3B+ is comparable, and the RPi Zero W is suggested for applications with minimal CPU and RAM capacity.

In [16], the authors demonstrate how to implement a cloud Platform as a Service (PaaS) architecture on a Raspberry Pi cluster. The main goal of the implementation is to make the cluster a suitable platform for more complex data gathering and analysis applications placed at the edge of a cloud. The findings show that while this is technically feasible, there are still some performance issues due to a relatively weak CPU, a limited network bandwidth, and problems with the file system.

Unlike the previous studies, this study aims to present the robustness and feasibility of Raspberry Pi as an edge-processing device for real-time data.

## III. BACKGROUND

### A. Proposed Architecture

In this paper, we are motivated to develop a real-time flash flood forecasting system utilising Raspberry Pi as an IoT edge processing device. The proposed system uses a new technique to forecast the flash flood-affected locations using the following parameters:

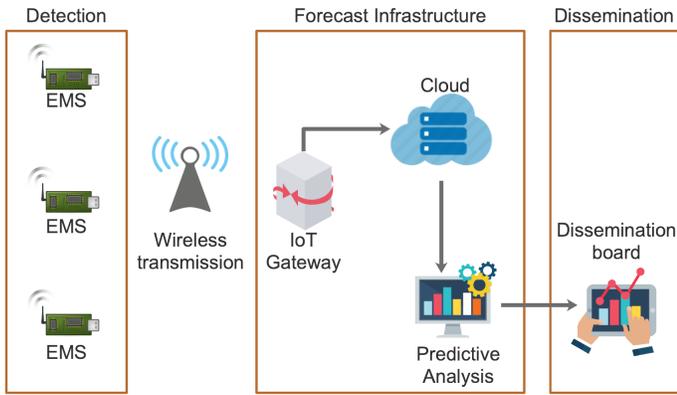

Fig. 1. The Proposed System Architecture.

- 1) Negative narrow bipolar event (-NBE) electric and magnetic fields signal.
- 2) Positive cloud-to-ground flash (+CG) electric and magnetic fields signal.
- 3) Cloud top height data [18]
- 4) Constant Altitude Plan Position Indicator (CAPPI) data [18]
- 5) Wind speed
- 6) Wind direction

Briefly, the -NBE and +CG lightning signals are collected and located by several lightning sensors in real-time [19]. Our research group at Universiti Teknikal Malaysia Melaka (UTeM) built these homemade sensors from scratch. These sensors have been working since 2015, tested, and calibrated [20][21]. The signal coverage for a single sensor is within a 300 km radius. Together with the rest of the parameters, real-time tracking can be done for any storms in Malaysia that can lead to flash floods. Specifically, cloud top height and CAPPI data are used to monitor rainfall and lightning flash rate intensity. The wind speed and direction are used to predict where a particular storm is heading and at what rate. By monitoring the occurrences of +CG and -NBEs produced by a storm in real-time, together with cloud top height and CAPPI rainfall rate, the proposed system will be able to forecast the rainfall intensity and rate for the next 1-3 hours period. Facilitated by wind speed and direction, the system can forecast the location where the downpour would impact most significant. Additional details for real-time forecasting of flash floods using the above technique are given in [19], [20], [21].

Fig. 1 illustrates the architecture of the proposed Flash Flood Early Warning System. Fig. 1 provides a general view of the proposed system that includes the three components. The three components are detection, forecast architecture and dissemination. The first component falls under the detection category, which contains the lightning sensors. The lightning sensor is called *Electric and Magnetic Field Sensor (EMS)*. The main purpose of this sensor is to detect and locate lightning signals, particularly +CG and -NBE, within a 300 km radius. The signal is a combination waveform of electric and magnetic fields that are used to identify different types of lightning signals [19][21]. As shown in Fig. 2, there are five major components (or subsystems) in EMS system:

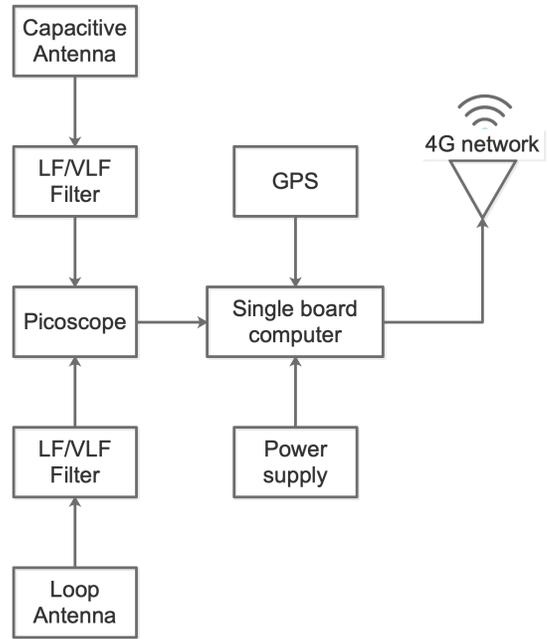

Fig. 2. Five Major Components or Subsystems of Electric and Magnetic Fields Sensor (EMS).

- 1) Antenna part with capacitive antenna to detect Electric field and two loop antennas to detect orthogonal components of magnetic field [20].
- 2) Filter circuits designed for detection of electric and magnetic fields at low frequency/very low frequency (LF/VLF) bands (or below than 1 MHz) [20].
- 3) Digitizer to digitize the captured analog lightning signals. Currently we are using the PicoScope and it is reliable.
- 4) A single board computer is used convert the digitized lightning signals to the coordinates of the lightning strikes and stream the EMS data in real time back to Forecasting Infrastructure via 4G network (or any available network infrastructure). Currently, the conversion and real time data streaming are implemented using Raspberry Pi platform.
- 5) Power supply from solar power, batteries, and power bank.

The focus of this paper is to evaluate the performance of the detection component, specifically the single board computer, in analysing and converting the digitised lightning signals to coordinates of the lightning strikes.

#### IV. EXPERIMENT ENVIRONMENT

As previously mentioned, this study aimed to evaluate the performance of the single board computer in the EMS system of the detection component (refer to Fig. 2). Fig. 3 presents the flowchart for the EMS system processes. As shown in Fig. 3, the antennas in the EMS will capture the lightning signals whenever the lightning event occurs [20][21]. The analogue signals are then digitised using the PicoScope. Next, the digitised lightning signals using a custom-written Python program that synchronises the signals with the Global Positioning System (GPS) clock and produces the coordinates

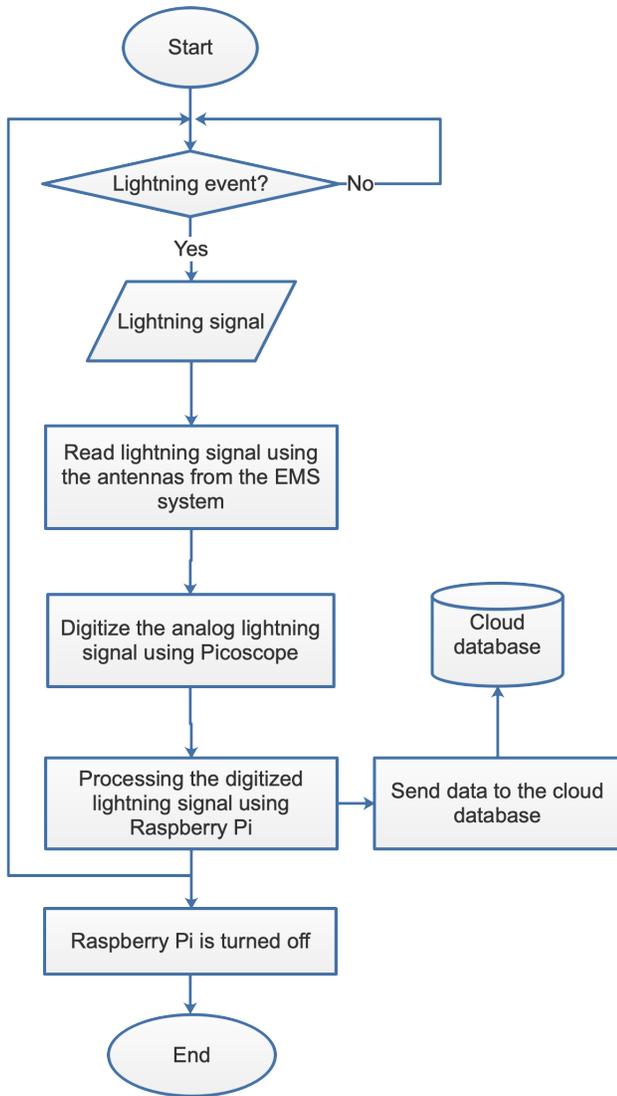

Fig. 3. The Flowchart for the EMS System.

of the lightning strikes [20][21]. Subsequently, the resulting coordinates are sent to the cloud database via IoT Gateway using any available wireless transmission (refer to Fig. 1).

#### A. Experiment Setup

In our experiment, as shown in Fig. 4, the components were integrated around the Raspberry Pi 3 as the main computer. The integration is done by connecting the EMS to the Raspberry Pi with the specification listed below in Table II. Fig. 3 shows that the digitised lightning signal is being fed into the Raspberry Pi to be processed by the custom-written Python program (refer to Algorithm 1) and produce the lightning strike locations. The resulting lightning strike locations are sent to the cloud database via an IoT gateway.

In the experiment, the process of converting the lightning signals into the lightning strike locations is repeated for 50 iterations in one cycle. The cycle is then repeated five times for statistical validity. However, in the actual scenario, the

    end if
end for
    
```

process in Fig. 3 only happens during a lightning storm. The main goal of this experiment is to observe the Raspberry Pi's performance if the lightning signal processing in Fig. 3 is executed repeatedly by measuring the Raspberry Pi's CPU

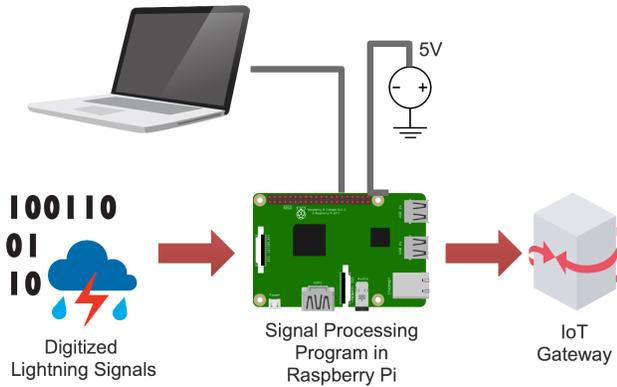

Fig. 4. The Experiment Setup.

TABLE II. HARDWARE SPECIFICATION FOR RASPBERRY PI

Hardware Specification	Raspberry Pi 3B+
CPU	ARMv8 Cortex-A5, 1.4GHz
CPU Cores	4
Memory	1GB LPDDR2 SDRAM
Integrated Wi-Fi	2.4GHz and 5GHz IEEE 802.11.b/g/n/ac wireless LAN

usage and temperature.

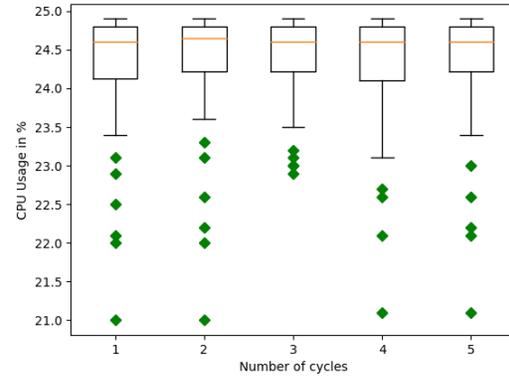

In each iteration, the CPU usage and the Raspberry Pi's temperature are measured using Python cross-platform library for retrieving information on running processes and system utilisation called psutil[22] library. In the experiment, the "cpu\_percent()" function from the psutil library is used to measure the Raspberry Pi's system-wide CPU utilisation [22]. Another function called "CPUtemperature()" is used to monitor the Raspberry Pi's current temperature. This function is called from an application programming interface library for Raspberry Pi devices' general-purpose input/output (GPIO) devices [23]. In essence, the CPUtemperature function returns the Raspberry Pi's current temperature in degrees Celcius.

## V. RESULTS AND DISCUSSION

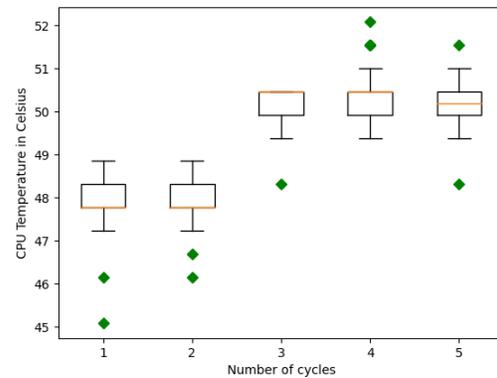

This section presents the performance evaluation results on the Raspberry Pi for digitised lightning signal processing. As mentioned in the previous section, the processing is repeated in 50 iterations in each cycle. Box plots in Fig. 5 show the statistic of the CPU usage and temperature measured in the experiment. For each data set, the first and third quartiles are represented by a box, with the median indicated in the box's centre. Whiskers, the lines extending from the box's edges, display the minimum and highest CPU utilisation and temperature.

Figs. 5a and 5b show the boxplots for the Raspberry Pi's system-wide CPU utilisation percentage and the Celcius's CPU temperature, respectively. In Fig. 5a, the interquartile range for Raspberry Pi's CPU usage is consistently between 23% and 25%, with a median of approximately 24.6% for each cycle. Each of the box plots for the CPU usage in Fig. 5a skews toward the value of 25%, which indicates that the processing of the lightning signals uses only 25% of the Raspberry Pi's CPU.

Fig. 5b shows the Raspberry Pi's CPU temperature distribution. The box plots in Fig. 5b demonstrate an increase in

(a) CPU Usage

(b) Temperature

Fig. 5. The Raspberry Pi CPU Usage and Temperature Distributions.

the CPU temperature from 47 degrees Celcius to a maximum of 51 degrees Celcius. The median for cycles 1 and 2 is approximately 48 degrees Celcius with an increment to 50 degrees Celcius for cycles 3, 4 and 5. According to the Raspberry Pi official documentation [24], the Raspberry Pi is constructed with commercial-grade chips that are qualified for varied temperature ranges to keep prices down; the manufacturers indicate the USB and Ethernet controller of the Pi 3+ (Microchip LAN7515) as being qualified from 0°C to 70°C. The operating temperature range for the SoC (System on Chip - the integrated circuit that performs the Pi's processing, a Broadcom BCM2837B0) is -40 to 85 degrees Celsius [24], [25], [26]. Based on the official specification [24], the current workload in the experiment that is subjected to the Raspberry Pi is not enough to spike the temperature to a level that can damage the hardware.

Figs. 6 and 7 shows the distribution for system-wide CPU utilisation and temperature for each cycle in the experiment. Figs. 6 show that the system-wide CPU utilisation is consistently at a maximum of 25% in each cycle, whereas Figs. 7 show an increment in the CPU temperature from Cycle 1 until Cycle 5. The distributions of CPU utilisation and temperature for 50 iterations in each cycle shown in Figs. 6 and 7 are consistent with the boxplot statistical distribution shown in

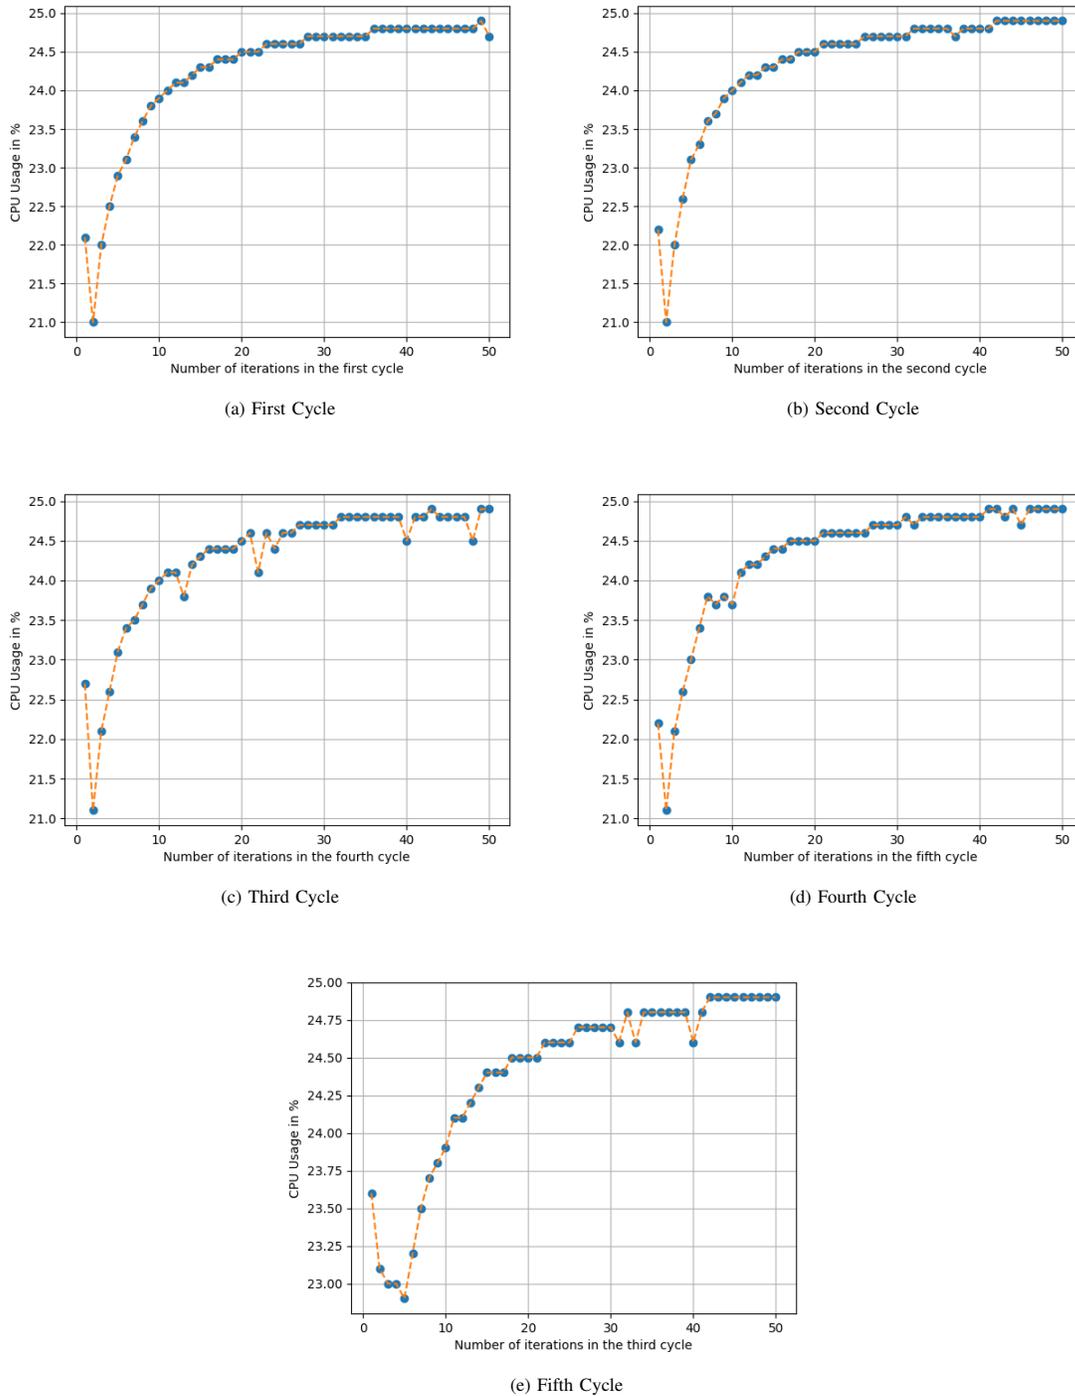

Fig. 6. The Raspberry Pi System-Wide CPU Utilisation for Five Cycles.

Figs. 5.

As mentioned in the previous section, the experiment conducted in this study involved the processing of converting lightning signals to lightning strike locations are run for fifty iterations throughout a single cycle where the cycle is repeated five times. Based on the workload introduced to Raspberry Pi in this experiment and the results obtained (Refer to Figs. 5

- 7), it can be ascertained that the Raspberry Pi can function as an IoT edge processing device. Figs. 5 - 6 demonstrate that Raspberry Pi maintains only 25% system-wide CPU utilisation with a maximum temperature of 51 degrees Celcius. As stated in the preceding section, the Raspberry Pi will not be subjected to a persistent heavy workload in a practical scenario since the collection and conversion processes are done during a

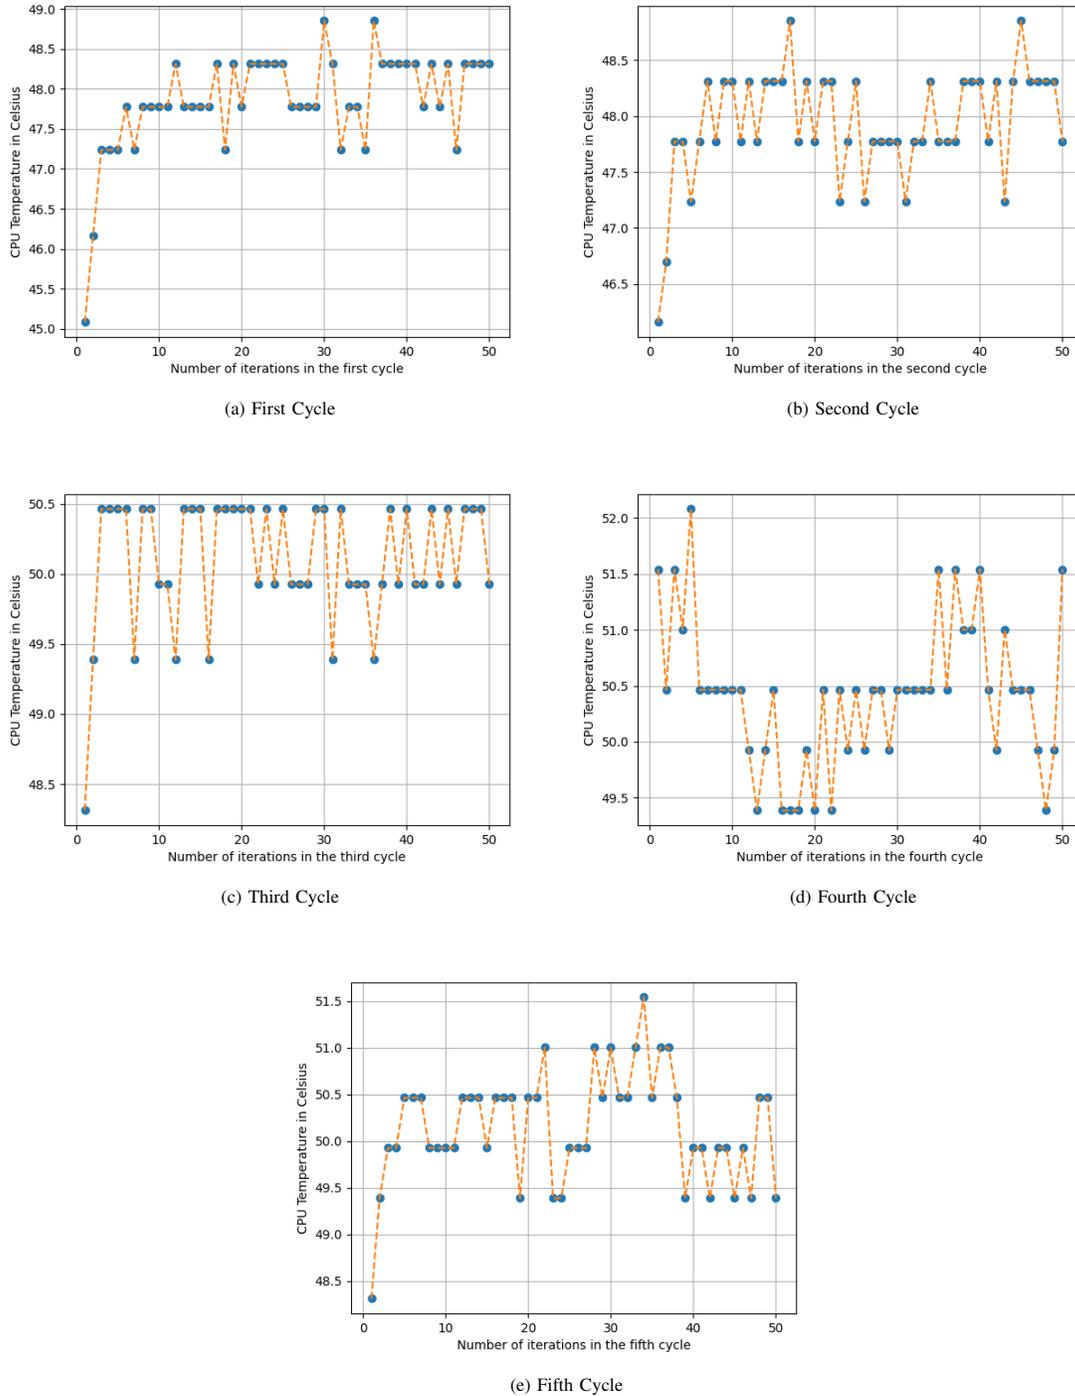

Fig. 7. The Raspberry Pi CPU Temperature for Five Cycles.

thunderstorm only.

## VI. CONCLUSION

This research analysed the CPU utilisation and temperature of Raspberry Pi as an edge device that processes lightning strike signals to anticipate the location of flash floods. The experiment aimed to transmit continuous digital signals for

processing to Raspberry Pi. The data indicate that the CPU is only utilised to a maximum of 25%, with a maximum temperature of 51 degrees Celsius. In a real-world scenario, data collection and processing are only performed during a thunderstorm. Therefore, these findings demonstrate Raspberry Pi's capability to handle a persistently substantial workload. As less processing is needed in a real scenario because the

processing occurs only when a thunderstorm strikes, the results prove the Raspberry Pi's capability to process real-time signals.

Currently, this study only focuses on the performance evaluation of Raspberry Pi as an edge processing device in the proposed architecture. The proposed architecture will be implemented and evaluated in a real scenario for future work.

#### ACKNOWLEDGEMENTS

**Abstract**—Blockchain has become a great trend and very popular in the present era. There are two types of Blockchain technology, centralized and decentralized. In this research, the main concern is about the decentralized payment gateway, which is a trustworthy architecture and does not depend on third parties. For recording the transaction, decentralized payment systems use distributed ledger. Previously, Bitcoin and Ethereum payment systems were used to verify the consistency of the ledger of blockchain and also the transaction data along with the sender-receiver address and transaction value, but as all the payment system is public, so the transaction mode is also public. However, here the main concern is privacy and security. Because anyone can easily access the network, the attacker can also attack the network and the identity and transaction records and the address of the user identity, which is a privacy challenge. This research incorporates the Hyperledger Fabric, which is private, to overcome this challenge. Moreover, no one can access it from outside of the network. The transaction cost is low and the timing is fast during transactions. Considering the above scenario, this research proposes a decentralized payment system architecture using Hyperledger Fabric.

**Keywords**—Blockchain; decentralized; hyperledger fabric; bitcoin; payment system

## I. INTRODUCTION

In the present world, transactions have become one of the communication mediums. So it is imperative to ensure that the transaction should be safe and secure. Because of the many uses of distributed ledger technology, some companies have built their version of Blockchain systems to meet their requirements, resulting in the in-house creation of many blockchain solutions using multiple systems and architectures. Such projects use various technologies and consensus methods tailored to specific applications and use cases. Because of the vast number of initiatives, development has become increasingly fragmented, with no or little compatibility across various blockchain protocols [1]. In the earlier, third-party interference was the only medium for transactions. However, it was proven to be very insecure. The increasing number of

online platforms has raised the necessity of payment systems. Payment gateways enabled online platforms to integrate multiple payment methods at once, often leading to more sales and engagement to the online platform. In short, many payment gateways are available, including international and local ones. Currently, they are built on a centralized system and use several strategies to minimize the cost of each transaction. They often tend to save up the money received from customers and hold the money for several days to earn revenue from the saved money. This method causes the merchants not to be able to receive money immediately but reduces the cost of the transferred money. Hyperledger Fabric, a distributed ledger platform, solves the problem of reducing third-party dependencies and removes double spending issues. It is a successful innovation that ensures money is spent only once. Decentralized systems are a platform where they can interact with other parties without involving the third party or any intermediaries. Hyperledger Fabric is a decentralized permissioned blockchain infrastructure and the fastest open source permissioned blockchain [24]. It is challenging to hack because it uses mathematical computation. Chaincode is the primary smart contract in the Hyperledger Fabric. Chaincode is executed by the peer nodes of a Fabric network, accessing the ledger data and endorsing transactions. Mainly the architecture of Hyperledger Fabric provides flexibility and a high degree of resilience in implementation and design. The flexibility of design achieves privacy, scalability, and other essential attributes. Blockchain service is the central part of the Fabric. Hyperledger Fabric chain code allows any programming language but commonly used Go language, JavaScript and Java, but appropriate modules should be installed [2]. This paper aims to construct a decentralized payment gateway that allows unlimited payments of any amount, is more secure, low cost in transactions, gives the best performance, and the main thing that Hyperledger Fabric ensures is the system's security. The problems of a centralized payment gateway can be understood from the above discussion and how decentralized payment gateways can solve them. In the Asian subcontinent, there is no

service to address the issues of a centralized payment gateway. To address this issue, this work presents a gateway to improve the payment service.

#### A. Research Goal

1) *Research Objective:* This research aims to construct a decentralized payment system that will solve the loopholes that come with the centralized payment system.

2) *Significance of Research:* Currently, centralized payment systems are using several strategies to lessen the cost of transactions and earn revenue from pending transactions. A decentralized payment system can eliminate this issue and make the process more secure and efficient. This research is taking place to improve the payment service by introducing a decentralized payment system.

3) *Research Question:* The main purpose of conducting this research can be expressed as below:

- 1) What are the problems of centralized payment systems?
- 2) Will decentralized payment systems eliminate or lessen the existing problems?
- 3) How will people be benefited from a decentralized payment system?
- 4) What will be the challenges of introducing a decentralized payment system?

## II. RELATED WORKS

Decentralized cryptocurrencies like as Bitcoin [3], Hyperledger Fabric [4], Zcash [5] and Ethereum [6] have been a trending issue, and blockchain technology, received increasing attention. Currently, the blockchain plays a significant role also in financial sector [7]. In previous before blockchain invention, many authors proposed different protocols and solutions to make the transaction procedure secure and easy way. Such as, The authors of [8] presented is a payment mechanism for peer-to-peer (P2P) commercial transactions. It facilitates electronic currency transactions between purchasers and vendors. In this arrangement, financial companies become collaborators in their clients' Internet-based e-commerce transactions [23]. The uniqueness of the proposed approach is the restriction of the finance sector' engagement to supplementary services and support but in that circumstance there were some drawbacks regarding the security. Blockchain invention by S.Nakamoto [9] brought also progress in the financial sector where A peer-to-peer formed of electronic currency which would enable internet payments to be transmitted through one party to another, bypassing banking institutions. The main concern of the solution was to remove double-spending issue [10]. All the transactions are hashed into a chain which is hash-based proof-of-work of that network and after establishing record cannot be modified without repeating the proof-of-work. It provides the main security issue. In article [11] the authors describes a distributed payment method which is based in payment tokens that uses Blockchain technology to safeguard consumers from data theft caused by illegal use of their payment card information owing to payment system inefficiency. Furthermore, the privacy and security of the system is consolidated by a permissioned Blockchain consortium. Using blockchain technology, the authors [12] create a centralized payment

counter money transfer mechanism. Blockchain technology inherent decentralization, distributed verification, transparency on transmission, as well as other features, the method not only recognizes that transaction records can also increases payment security, and completely protects client privacy. It eliminates the issues of money usage security and danger created by inappropriate teller operation in the standard counter cash withdrawal method. In [13] the authors proposed a method called Fastpay where the authors combined the concepts of blockchain technology and IoT [14]. FastPay, which ensures the security of quick payments in blockchain-powered edge and IoT systems. FastPay is based upon the smart contract concept, which is implemented by several well-known blockchain platforms, including Ethereum [15]. The system ensures quick payments by requiring consumers and guarantors to produce transaction proofs before payment is done. With these evidence, consumers and guarantors will face harsh fines if they attempt double-spending scams [25]. A payment takes 9 seconds to confirm. The authors [16] approach a system that supports late payments using our novel idea known as latent-transactions. This study also incorporates the tools for making effective off-chain contracts between the entities engaged in a transactions. As a result, one may profit from a service before paying for it. Furthermore, the system provides a service expansion mechanism by offering a catalog to which any Blockchain user can register and one may offer services with flexible pricing based on the context such as need, activity at execution time, etc. The authors proposed an algorithm using blockchain concept. The algorithm will enable users to operate on blockchain networks using cryptocurrencies. It differs significantly from the current system in that customers would be able to exchange without the assistance of third parties, and merchants will also be eased with their transaction. This form of transaction will be highly convenient for both buyers and sellers. Consumers and suppliers may both have this whole transaction time, date and all the things they engaged with while the transaction has been taken place [17].

## III. BACKGROUND STUDY

#### A. Blockchain

Blockchain service contains P2P Protocol, Distributed Ledger and Consensus Manager, these three major components. P2P Protocol provides capabilities like flow control and bidirectional streaming as it uses Google RPC [18]. It works along with existing internet system [9].

Distributed ledger calculates a crypto hash after each block, transmits minimal delta of changes of out of sync peers and minimize the size of data efficiently to manage the world state and blockchain. It uses a special database environment called RocksDB [19] to preserve the dataset. Other large files are not stored on the ledger but their hashes can be stored on the ledger. There are two types of transaction Hyperledger supports: code-deploying and code-invoking. Code-deploying transactions are to install, update or remove a Chaincode. On the other hand, code-invoking transactions are to execute a Chaincode function through API call. Consensus Manager accepts transactions and decides the way to organize and the time to execute a transaction depending on algorithm. If a transaction is successfully executed, it causes the ledger to be changed. Hyperledger has implementation of PBFT (Practical

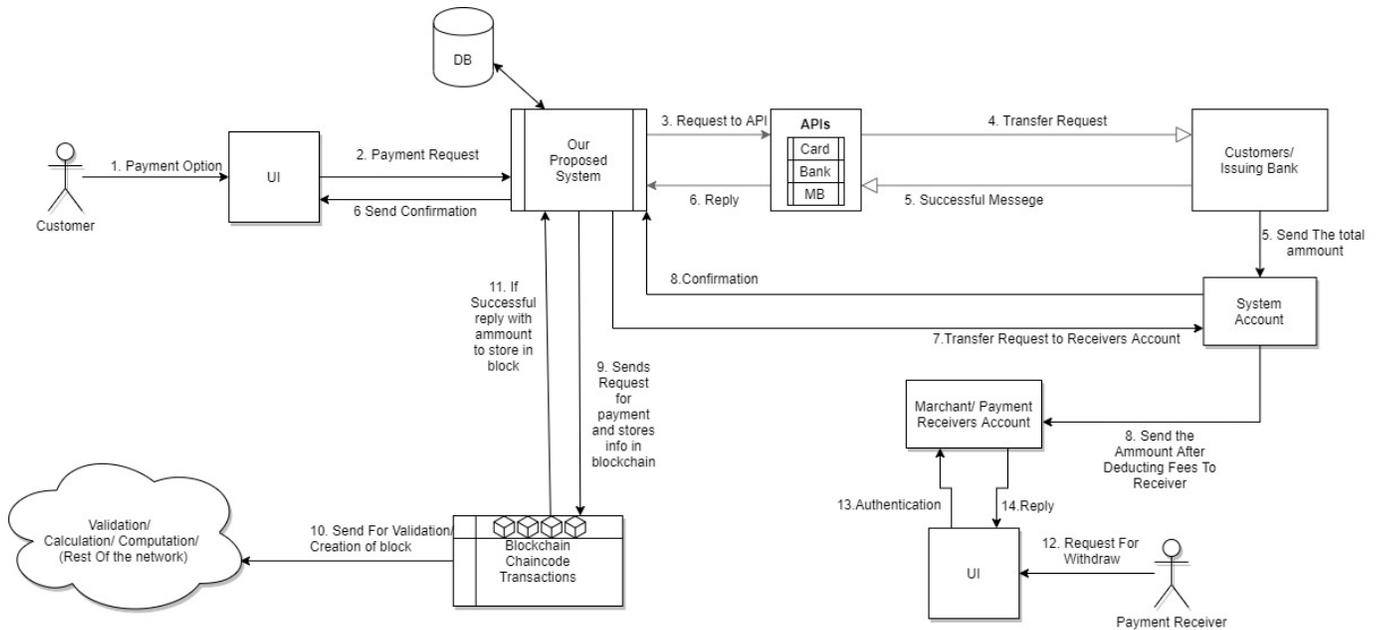

Fig. 1. Architecture of Proposed System.

Byzantine Fault Tolerance) which ensures advanced scalability and fault tolerance.

### B. Hyperledger Fabric

Now a days blockchain technology is the most emerging technology and it can be implemented in many different ways. Research is going on this field and researcher create different types of DLT(distributed ledger technology) for different purposes and construction [26]. In present moment three of the most popular DLT's are "Ethereum"<sup>2</sup> [6], "R3 Corda"<sup>3</sup> (Corda) [20], "Hyperledger Fabric"<sup>4</sup> (Fabric) [6]. These DLT's have different visions of the application of blockchain in different fields. Ethereum is the independent and it is a less and public approval DLT. On the other hand, Hyperlagger Fabric and Corda DLT are allowed. Corda focuses on the financial services industry; Fabric focuses on developing a modular and extensible architecture that can be used in various industries, with a focus on banking and healthcare services, the supply chain.Hyperlenger takes a unique method to the traditional blockchain model, in part by manipulating the admission of participants to its base. In other words, Hyperlagger is an authorized shared ledger. Hyperlegger records computational cycles, reduces scales and meets the multitude of case requirements. Hyperlenger is based on the expectation that there will be many blockchain networks, with each network registration serving a different purpose. Although there is a single popular instance of a common network, it is not necessary for a network registry to rely on another network for its basic functionality. Despite this network independence, Hyperledger still needs an addressing system that allows transactions in one registry to identify and use appropriate transactions and chain code in other registers.

### C. Chaincode

Chaincode service hosts the Chaincode using Docker which yields a lightweight and secure system for Chaincode execution. Secured Docker Registry of Hyperledger images and Chaincode containing custom images are enabled by Secure Registry Services. Alike invocation of webservice or database call, Chaincode transactions are configured while deploying the Chaincode and they are time bounded [27]. The ledger will not update if a transaction runs out of time. After reaching consensus for a block, the database is committed with the changes and number of world state block increments. If peers fail to reach consensus, the update is discarded and database no not change.

## IV. PROPOSED SYSTEM MODULES

As discussed earlier, the proposed system designed a payment gateway that will allow Sender to pay directly to the receiver using a decentralized network. The proposed have designed the system in a manner that if any organization or individual wants to receive payment they can integrate our API to their website and Immediately start getting payment. Unlike other centralized payment gateways it doesn't delays the payment. The system will autonomously handle all the account creating process, transactions, building blocks, Committing to the blockchain and retrieving data from the blockchain [29].

### A. Architectural Infrastructure

The proposed system has used the linux foundations Hyperledger Fabric [28] as a framework for this project. The whole architecture is designed according to that. Hyperledger Fabrics architecture allows us to create a private network for all the organizations. All the automation part will be handled by the Chaincode. This is the smart contract of Hyperledger Fabric. There will be a central database which will keep the

data while the whole process ends, but to make sure the safety and privacy our system doesn't give access to the database to anyone only accessed by the system itself and also data can't be manipulated because only big data is kept here, and all the information about this is referred to the blocks of blockchain.

Fig. 1 shows how the whole system works from taking the sender/customer sends the money and the receiver receives their payment. The first step is the customer uses the user interface to send money that uses our API to communicate with out automated system. Customer sends the payment request by using their preferred method. Full details about this is discussed in the next modules section.

When the system gets request from the UI then it immediately forwards to the respective bank or card processors. It handles the communication with the bank verifies all the information. If everything is verified and ok then at the same time bank transfers the whole amount to our systems bank and a notification of confirmation to this system.

After the system gets successful transfer notification from the bank, at the same time it sends confirmation to the customer that the payment is complete. At this time our system sends requests to commit this change of asset from customer through different type of payment methods to our bank account. This data flow will be discussed in the net section.

While the first phase is complete it is ready to send the money to the receiver. Receivers will have a fixed account to receive money that he gives while registering. It checks if enough balance is available to be transferred to the receivers account or not. If not, then it waits for some times before transferring. Meanwhile it collects all the money from the all types of payment methods and transfers it to the systems main bank account. Then when there is enough money, Our system makes another request to systems bank to send the rest of amount after deducting the fees from the whole amount to the receivers account.

Bank sends the amount to the receivers account and at the same time gives confirmation to our system. This whole time all the information was kept safe in our system and when these two confirmations are received by our system, it sends the whole request to add them to the blockchain. Then it gets verified and also confirmation is sent back to our system after the transitions is added to the block. This whole verification process is also described later in the modules section.

At the same time there can be more than one transaction from more than one customer. And also, this system is designed to accept all the transactions for all the registered company. For example, two customers from "XYZ" Company is paying online. Both of the transaction will happen individually and as different transaction but it doesn't mean that will create individual blocks. There can be more than one transaction in the block. But using the hashes and timestamp of the block it can easily be found each individual transaction.

Organizations can register with valid information to integrate and use our service and that will also happen using our UI and that information are also saved in to blockchain so that no one can temper those data. The whole operation will run autonomously once the system is up in the network. Here is the Short Pseudocode the of whole operation is provided.

---

**Algorithm 1** Payment Operation for a Customer

---

```
1: Output: Transfer money from senders account to receivers account and store the transaction information
2:  $m \leftarrow$  Payment Method (Card, Bank, etc.)
3:  $r \leftarrow$  The Receiver
4:  $a \leftarrow$  The Amount To Be Transacted
5: if  $m$  is card then
6:   Check Card Validity
7:   Attempt to perform money transfer to system account
8:   Set status received from card API
9: else if  $m$  is bank then
10:  Get redirection URL from bank API
11:  Redirect to URL with System account number and amount
12:  Bank API listens to response from the bank
13: end if
14: if successful transaction then
15:  Generate token
16:  Update Ledger
17:  Calculate charge from set of rules
18:  Attempt money transfer (deducting charge) from system account to  $r$ 
19:  if successful transaction then
20:    Update token
21:    Update Ledger
22:    Broadcast Ledger
23:    Return to origin website with status true and token
24:  else
25:    Broadcast Ledger
26:    Return to origin website with status partial
27:  end if
28: else
29:  Return to origin website with status false
30: end if
```

---

### B. Data Flow:

As in this proposed system have used hyperledger Fabric as our framework while designing the whole architecture we are following the convention and rules of hyperledger Fabric. In our system two transactions will be committed against each payment or money sending.

The first one is the asset transfer from customer or the sender to our bank. In the figure, this first step is represented by Org 1 and Org 2. There are multiple users in Org 1. They represent the payment methods. Our system will get an API response from them when any transfer is done then it will take those information and commit them to the blockchain.

In the 2nd part the system will request a transfer, from our bank to the receivers bank. This asset transfer part is represented using Org 2 and Org 3. Also there are different uses in the Org 3. They represent a company or event. If a company wants to receive the money the endorsement are handled by the p2 and p3 peers. And if events want to receive money then P2 and P4 is the endorsers because there might be different permissions set to different type of peers.

So, the transaction flow for both of the committing steps are like this:

The transaction request is generated from application and

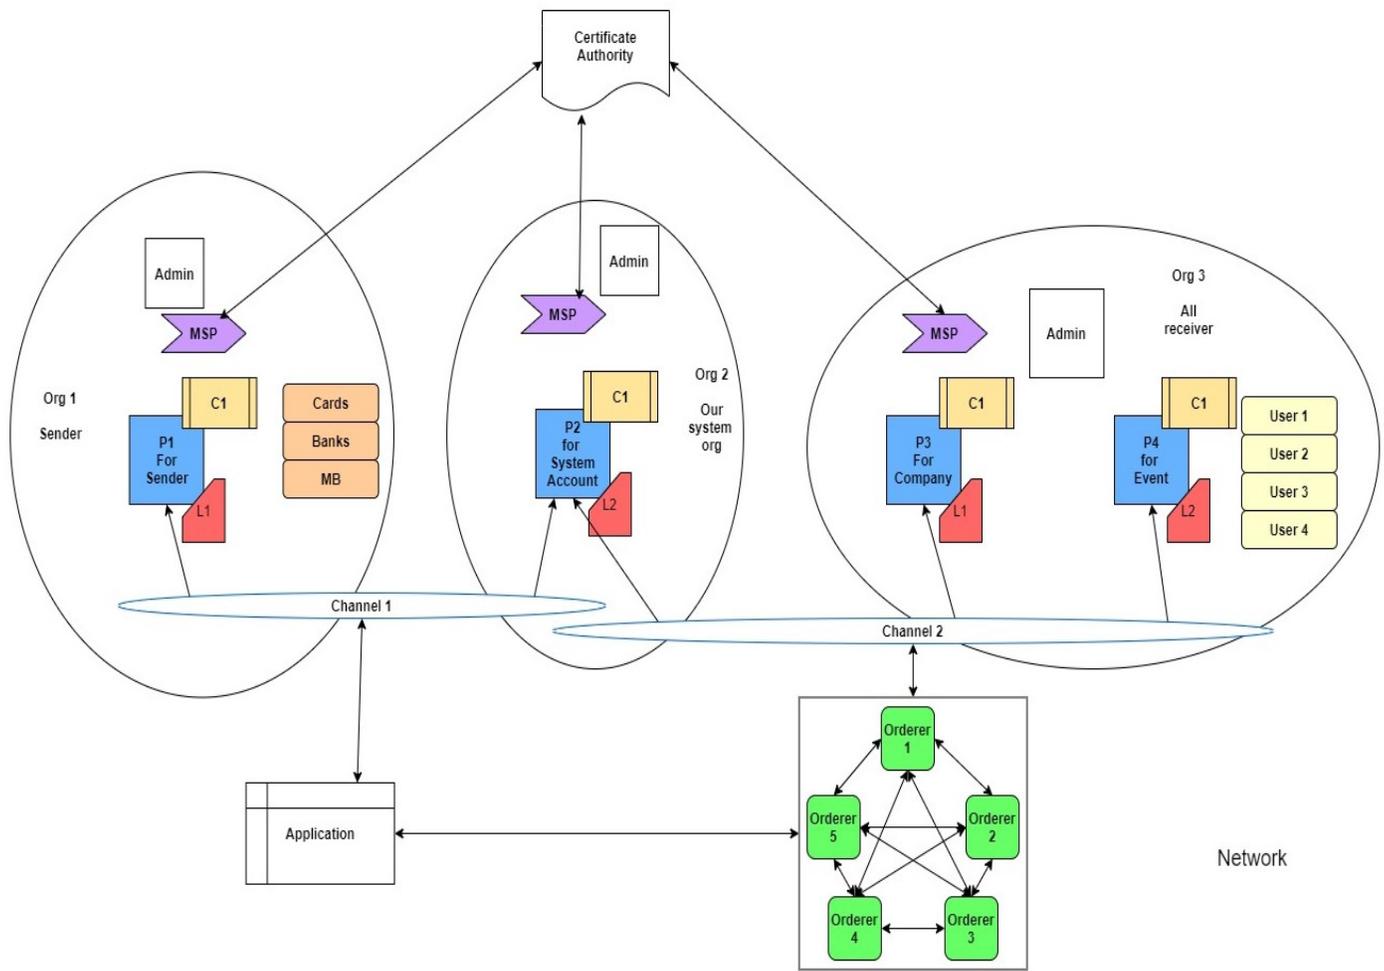

Fig. 2. Data Flow and Committing Procedure into Blockchain.

this application leveraging a supported SDK utilizes one of each Organizations peers to generate transaction proposal. This transaction proposal is send to the peer and these peers are registered through certificate authority. But the responsibilities of the peers are defined by the MSP. That means which transaction is belong to which peer and this peers endorsing and committing permissions are defined by MSP. In each peer there is also a ledger where all the transactions are stored. When the transaction is transfer to the peer, the peer executes the chaincode and validates the transaction but this transaction is not stored in the ledger yet. Only a validate proposal with valid sign is generated and this proposal is verified by the application. If both signed proposal from both peer is matched then it sends this updated proposal to the orderer node.

Meanwhile as there are multiple orderer nodes available, the RAFT consensus protocol is used to choose which orderer will commit the next block. Also, as there are multiple nodes so if one node is down rest of the nodes can build the block.

These orderer node at a time can accept multiple transaction from various application and check the validity of these nodes and generate a block. These blocks are sent to the endorsing peer again to check all those transactions which are endorsed using endorsing peers. If any transactions are

remaining in any block which is not endorsed before then this block will consider as invalid block. Otherwise the block will be considered as valid block and add in the ledger of every peer of the network. A pictorial presentation of the scenario is given in Fig. 2.

- 1) Balance transfer request is generated from the application and it's broadcast through channel 1 to peer1 or p1 which is the peer of org1 and peer2 or p2 which is the peer of org2.  
Note: Every peer is registered or generate an authorized signature through certificate authority and the responsibility of each peer is defined by MSP.
- 2) This peer actually performs four things 1st one is that the if transaction proposal is well formed or not 2nd one is this proposal is new or has been submitted at past. 3rd one is if the signature is valid. 4th one is that the submitter is fully authorized to perform this specific transaction.
- 3) This p1 and p2 endorsing peer uses the transaction request as argument to invoke the chaincode.
- 4) The chaincode is then executed against the current state database to produce transaction results including a response value, read set, and write set but not update

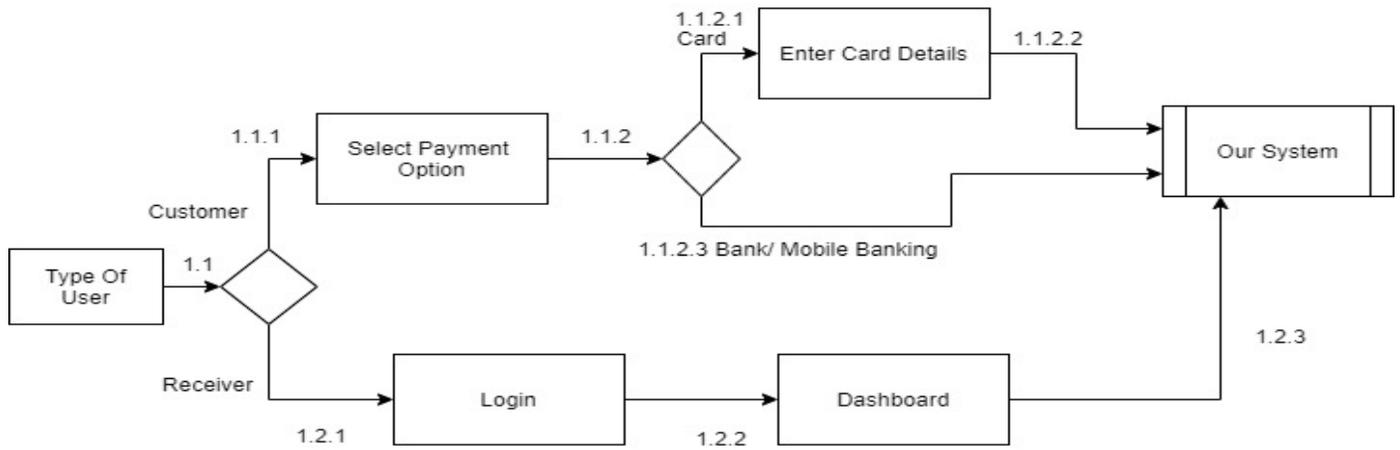

Fig. 3. Data Flow of User Interface Module(Part-1).

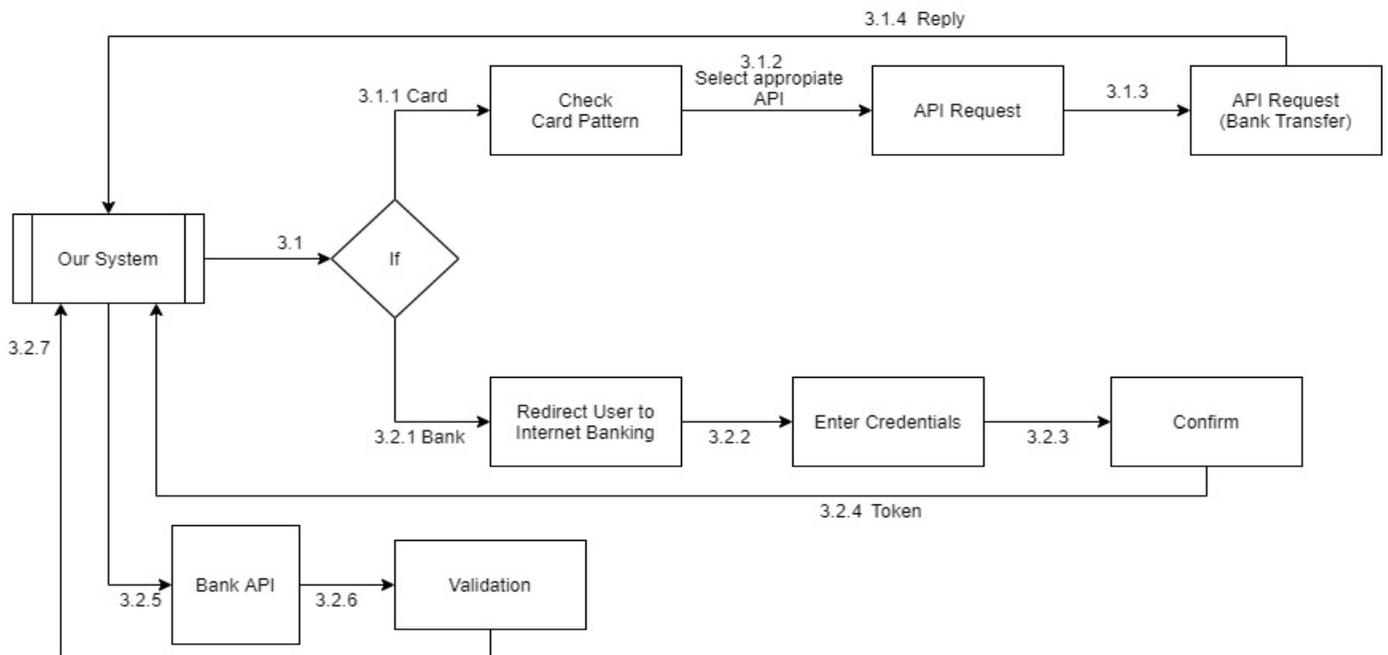

Fig. 4. Data Flow of User Interface Module(Part-2).

the ledger.

- 5) The set of these values, along with the endorsing peer's signature is passed back as a "proposal response" to the application.
- 6) The application verifies the endorsing peer signatures and compares the proposal responses to determine if the proposal responses are the same.
- 7) Then the application sends it to the orderer nodes and in this step the application choose a leader orderer node and remains as follower.
- 8) After receiving the proposal response the orderer node make a block.
- 9) After creating the block the orderer node then transfer it to all the peers that means p1(org1), p2(org2) and p3, p4(org3) through a global channel.
- 10) Then these endorsing peers check the signature and

the channel ID and if match then commit the block is valid and finally add it in every peers ledger.

### C. Modules:

All the operations in the main architecture, We have separated into 3 different modules. These are,

- User Interface Module
- Bank API Module
- Blockchain Module

1) *User Interface Module:* This module uses our UI to do all the interaction. Customer uses this to select payment method and pay to the receiver. On the other hand, Receiver or the organization can login to their account to see all the

history and other information in their dashboard. The data flow is shown in Fig. 3.

If customer wants to pay, it redirects to the payment option. There are multiple options, for simplicity we are representing bank/mobile banking option and direct card option here. If user selects card option then they put their card details. They can choose to save the details for further use. We use our system to also store the card info to the blockchain if needed. Then the card details is send to system to communicate with the card API. Else if customer choose to pay direct through bank then it requests to out system and it forwards the customer to the internet/mobile banking site for further steps.

From the receiver side, organizations can register to use our service and after successful registration, they can use our interface to login to their account and see their dashboard. In there, all their information is stored and all the histories and all the transactions are displayed.

2) *Bank API Module*: Whether the customer chooses the card or bank our system requests to the proper API to communicate with the bank. The data flow is shown in Fig. 4.

When the customer chooses the Card option it checks the card pattern and requests to the proper API, Like if pattern is for VISA then it sends request to VISA API, which completes all the processing with the bank and transfers the money to our bank and sends success reply to our system.

If the customer chooses bank, then our system redirects it to the internet banking site or mobile banking site and there they give their credential and follow the steps to transfer money to our system's bank account. When successful, it returns a token. Our system takes that token and verifies with the bank API and if all goes right then the transaction gets completed.

3) *Blockchain Module*: This module validates and adds data to the block and adds the block to the blockchain [?]. As Hyperledger Fabric is used, their system is also being used as the architecture of this module. The data flow is shown in Fig. 5.

- 1) Initiate to complete the transfer request to Our System (SDK)
- 2) The SDK sends a transaction proposal to the Peers for the endorsement
- 3) The proposals are sent to the peers to execute solve and validate.
- 4) The Peers endorses, performs Chaincode / Smart Contract execution at this point, before endorsing the transaction proposal.
- 5) After Success it returns to the peers.
- 6) Then they sign the transaction proposal and returns it to the SDK. (SDk Checks for the validation by comparing to the proposal with the response).
- 7) If the proposal and Response matches SDK sends request to the Orderer for ordering service.
- 8) Executes and creates new block.
- 9) After ordering the transactions, forming block, it broadcasts the block to the Peers
- 10) The Peers notifies the SDK — the block is committed in the Blockchain for the data also the Peer performs transactions validation and block commitment at this point, before notifying the SDK.

- 11) The SDK sends a response to the customer and receiver — the block is committed in the Blockchain for the transfer.

This is how the full cycle is done. This gateway uses the decentralized network of Hyperledger Fabric and all the process happens synchronously any autonomously. The system is designed in such a way that no central authority is needed for the operation. And no one can even change any data as there is no control or access over the system. The system only gives read-only data as a query result and only writes data when chaincode is executed, validated and added to the blockchain.

## V. CHALLENGES

During the time of research, we faced some challenges. We have established the architecture of the network and its working procedure in this research paper. However, we could not implement the network in a physical device due to time constraints and a lack of proper documentation on the chosen technology. Research should be carried on by implementing the network in a physical device for a better understanding of the network [22]. Due to the nature of the blockchain network, the transactions' validation process takes longer than in a centralized system, leading to a slow completion time for any transaction. Nevertheless, it provides a more secure environment than a centralized system. It is a trade-off between time and security. Blockchain network does not recommend storing large data, as extensive data makes the network vulnerable. As a result, centralized data storage was necessary for extensive data.

## VI. CONCLUSION

In this research, a payment system based on decentralized ledger technology is proposed to keep transactions more secure and allow merchants to receive payment as soon as a transaction is verified. Saving time on receiving the payments and security was the primary concern in this research. We focused on the security and reliability part by using Hyperledger Fabric. A blockchain-based decentralized network gives each user high security and an immutable ledger. Furthermore, private network like Hyperledger Fabric allows reliability by keeping sensitive data private. Current progress indicates the foundation towards building a decentralized payment gateway. This fundamental architecture will help to build a more secure and fast payment gateway and will be able to overcome the shortage of traditional methods.

## VII. FUTURE WORK

In future, this research can be used to build an actual working gateway and storage system independent from any centralized storage by making the data structure more efficient. Some improvements and more efficient data management can be made in the future. Error handling, such as when the customer successfully sends money to the system account, but our system fails to transfer money to the desired merchant account, is not shown in the research. Future research can work on how the errors should be handled.

**Abstract**—The adoption of High-Performance Computing (HPC) applications has gained an extensive interest in the Cloud computing. Current cloud vendors utilize separate management tools for HPC and non-HPC applications, missing out on the consolidation benefits of virtualization. Non-HPC applications executed in the cloud may interfere with resource-hungry HPC applications, which is a key performance challenge. Furthermore, correlations between application major performance indicators, such as response time and throughput, with resource capacities reveal that conventional placement strategies are impacting virtual machine efficiency, resulting in poor resource optimization, increased operating expenses, and longer wait times. Since applications often underutilized the hardware, smart execution of HPC and Non-HPC applications on the same node can boost system and energy efficiency. This research incorporates proactive dynamic VM consolidation to enhance the resource usage and performance while maintaining energy efficiency. The proposed algorithm generates a workload-aware fine-grained classification by employing machine learning techniques to generate complementary profiles that alleviate cross-application interference by intelligently co-locating non-HPC and HPC applications. The research used CloudSim to simulate real HPC workloads. The results verified that the proposed algorithm outperforms all heuristic methods with respect to the metrics in key areas.

**Keywords**—Cloud computing; HPC (High-Performance Computing); virtual machine consolidation; placement; optimization

## I. INTRODUCTION

Cloud computing [1] provides organizations with an affordable, high-performance computing [2] infrastructure. HPC programs have a repetitive and predictable nature and based on the characteristics of the data that is utilized as input, their resource consumption patterns (CPU and memory, I/O, and network) are predictable. Strategies can be developed to increase queue throughput and resource utilization while reducing performance impacts on applications. HPC applications' performance can be adversely affected by virtualized layers, heterogeneous hardware, HPC-agnostic schedulers such as MOAB [3] or Load Leveler [4], and resource sharing policies. Currently, cloud providers for HPC either offer specialized clouds with dedicated nodes, lacking the consolidation advantages of virtualization, or cloud scheduling that is HPC-agnostic, resulting in inadequate performance. Although modern systems have enormous compute power per node, HPC applications seldom use all of the resources assigned to them. Other applications, such as non-HPC applications, can make use of this feature by utilizing underutilized resources.

Separate technologies have been used to manage the resources and applications on dedicated systems for HPC and Non-HPC applications. This isolation has become an increasing burden, and hence there is an increased demand for the adoption of a standardized shared platform. Execution of both HPC/Non-HPC applications on the same cluster boosts the system efficiency, allowing programs to take advantage of all the available hardware resources. However, even with these advantages, there is still a hindrance in using the full potential of sharing the resources. It is vital that the researcher must devise a method of bridging the gap between dedicated infrastructures and standardized shared platforms by balancing the trade-off between resource utilization, performance, and energy usage, by choosing a suitable VM to physical machine placement methods, with the intention of exploring the best physical machine (PM) that can be used to host the virtual machines. Workload heterogeneity has become norm in cloud computing [5]. Workload characterization is critical since it can group various resource-intensive workloads based on their defining qualities. Classifying workloads that have common consumption patterns can enhance resource management, which improves system performance while maintaining Quality of Service. Clustering techniques are frequently used to cluster workloads in the cloud data center to reduce energy usage and SLA violations for resource allocation.

In terms of VM placement strategies, there are two types: reactive and proactive/predictive strategies. Reactive strategies enhance the initial VM after the system reaches a certain undesired state. While proactive/predictive strategies attempt to enhance VM placement results by projecting future workloads or resource demands using prediction techniques. Identifying proper co-allocated combinations of applications that can be run on the common platform guarantees optimum utilization of resources [6]. The optimum utilization of active resources will allow the reduction of the number of operating servers, which will lead to saving energy spent on computation [7]. Hence, the total energy consumed by a data center will be reduced and optimum utilization of hardware will maintain the performance of applications. Most of the earlier well-established research refers to VM consolidation as a key approach for data centers to save energy and achieve a balance between utilization and SLA violations. The goal behind this strategy is to carefully consolidate VMs or workloads onto a smaller number of PMs and then convert the unused (idle) PMs into a power-saving state or shut them down when they are no longer needed.

Available literature indicates that there have been only a few attempts that proposed automatic workload clustering, virtual machine placement and VM consolidation techniques [8] to eliminate or at least reduce the impact of energy [9], performance [10], and interference [11] in co-located HPC and Non-HPC applications. Moreover, the HPC application characteristics of the strongly coupled processes that perform constant interprocess communication and synchronizations have also rarely been studied.

This study aims to combine and execute both HPC and non-HPC applications on cloud resources using a smart and innovative technique which can balance the trade-off between energy, performance, and resource utilization [12]. The researchers have proposed proactive dynamic VM consolidation for co-scheduling of HPC and non-HPC applications that is based on utilization predictions and an application's profile employing machine learning techniques. Our approach looks for applications that work well together and can be deployed on the same hardware, and the execution profiles for these applications do not compete with each other. This will allow for more efficient usage of the hardware. As part of the VM consolidation process, the proposed approach to VM consolidation also examines the application's resource usage requirements across multiple dimensions, such as the CPU, RAM, and the network. By co-locating suitable virtual machines on hosts during consolidation, resource contention and virtualization overhead can be reduced on application performance without losing the benefits of VM consolidation. Thus, the major contributions to this study can be stated as follows:

- 1) Introduces and implements HPC and energy-aware, efficient proactive dynamic virtual machine (VM) consolidation technique in cloud datacenter that makes cloud schedulers as well as VM placement HPC-aware.
- 2) Attempt to make VM consolidation application-centric while considering the requirements of the applications' resource utilization (i.e., CPU, memory, and bandwidth). The paper explores automatic clustering of workload and virtual machines using k-mean cluster technique. It also aims to explore smart VM placement strategies to intelligently schedule HPC and non-HPC applications on a single pool of resources to increase utilization of resources and overcome the performance issues caused by resource contention.
- 3) Explicitly examines the real-world HPC workload in order to demonstrate the reliability of our numerical analysis in terms of how well our proposed approach is suited to both HPC and non-HPC applications.

This paper is structured as follows: Section II presents the background and motivation for the study. Section III presents the related work to gain knowledge of contemporary research and discusses the importance of the proposed algorithm. while Section IV demonstrates the proposed energy-efficient HPC aware proactive dynamic VM consolidation (EAMDOBP). Section V introduces the evaluation methodology. Section VI discusses the simulation results and analysis. Lastly, the conclusion and future work is discussed in Section VII.

## II. BACKGROUND AND MOTIVATION

One of the primary goals of modern datacenter architecture is to cut down on energy usage. Data center energy demands are expected to rise to 752 TWh in 2030. This means that data centers consume 2.13% of total global electricity demand [13]. The inefficient utilization of hardware resources is the root cause of high energy consumption. Idling servers might use 60% of their maximum power [14]. Clustering of workload [15] and Virtual machine consolidation are the most effective and crucial approach for optimizing resource consumption and improve energy efficiency in cloud datacenters. VM consolidation can be implemented in two ways, static and dynamic. Fig. 1(a) is static consolidation. When a job arrives, the size and location of virtual machines on physical machines (VMs) are explicitly pre-determined, and the placement does not change during execution. Static VM placement resembles the N-dimensional bin-packing issue where the bins symbolize physical machines (PM). The items for packing represent the VMs and the size of the bin depends on the volume, types and nature of resources. Static VM consolidation is better suited for small jobs spanning a few hours, where PMs resources for various kinds of VMs can be defined explicitly [16]. Simple heuristics or historical VM demand patterns are the basis of energy minimization. However, during low-demand resource periods, an increase in the cost of application providers is likely to occur. Similarly, the available resources may be insufficient in high utilization periods [17].

On the other hand Fig. 1(b) shows dynamic VM consolidation. To improve the effectiveness of a placement, dynamic VM consolidation allows relocation during execution. Mostly virtual machine workloads are bursty in nature, dynamic VM consolidation is highly beneficial in a cloud computing environment, assuming that monitoring is in place to prevent any violations of Service-Level Agreements (SLAs). Accordingly, dynamic VM consolidation conserves energy and enhances the consumption of resources by using the minimum resources necessary to meet the workload requirements. Consequently, if the workload requirement decreases, unused servers are shut down or kept in low-power mode. Similarly, as consumption grows, additional servers are brought online.

The VM migration and VM placement are considered as the backbone of the VM consolidation technique. The problems like scalability of resources, heterogeneity, migration cost, and unpredictable workloads cause that the VM consolidation process becomes very challenging. The virtual machines (VMs) placement to physical machines (known as VM-Placement) can significantly impact performance. It is very important to choose an appropriate host to enhance power efficiency, better use of resources and support for QoS to attain Resiliency in the Cloud [34].

Clustering is an unsupervised learning strategy for subdividing a big group into multiple smaller groups. As a result, it may be used to find patterns in massive datasets. In current research, the advantages of this group building technique of clustering have been applied to locate groupings in the jobs (incoming request). The ability to locate groupings within jobs based on the number of resources consumed is helpful since this methodology allows to find groupings within jobs.

Cross application interference can occur when different

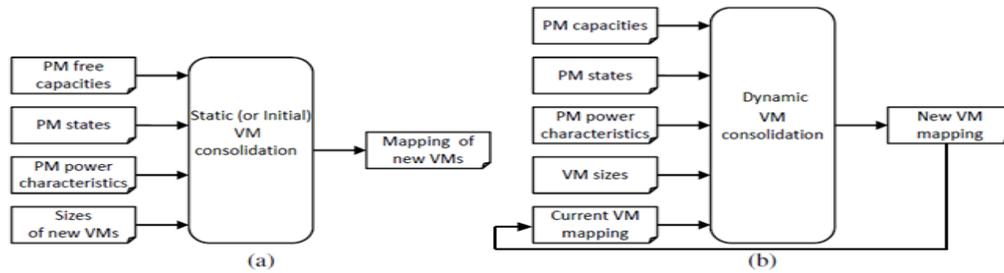

Fig. 1. Inputs and Outputs of (a) Static VM Consolidation and (b) Dynamic VM Consolidation.

cloud workload compete for shared resources, resulting in considerable performance degradation and, results in increase Service Level Agreement violations. Despite this, state-of-the-art VM scheduling still relies heavily on resource capacity, employing heuristics like bin-packing and ignoring the cross application interference overhead. To the best of our knowledge, only a few studies were made for VM scheduling algorithms that consider the tightly connected processes that perform frequent inter-process communication and synchronizations. Improved resource efficiency, cost savings, and, ultimately, broader acceptance of high-performance computing in clouds can be achieved by the strategic placement of virtual machines and the execution of HPC and non-HPC workloads in cloud environments.

Hence, this study focused on a multi-objective challenge that seeks to explore automatic online workload clustering using machine learning, smart VM consolidation and placement strategies to intelligently schedule or provision HPC and non-HPC applications on cloud resources to overcome the aforementioned gap and issues of rigorous consolidation.

### III. RELATED WORK

Primarily due to the enhanced efficiency, a significant number of heuristic algorithms have already been suggested for handling VM consolidation challenges in recent years. Among them, Mosa et al. [18] suggest the solution to virtual machine placement that dynamically reallocates virtual machines depending on their actual request for the individual VMs. The suggested approach evaluates various resource categories (particularly CPU and memory) to minimize under and over-utilization in cloud-based data centers. The conducted experiments highlighted the significance of incorporating a variety of resource types. Finally, they concluded for dynamic VM placement, the genetic algorithm outperforms the Best-Fit algorithm. However, the paper neither takes into account the HPC workload nor discusses the issues of cross-application interference. Kraemer et al. [19] developed a job migration mechanism for transferring jobs from the cloud environment to the high-performance computing environment. The primary goal is to reduce the amount of response time violations associated with cloud jobs while not interfering with the execution of HPC jobs.

V. Antonenko [20] developed a strategy for migrating jobs from the cloud environment to the high-performance computing environment. The major objective is to reduce cloud job response time violations without conflicting HPC

task execution. The author's study discusses the suggested job scheduling methods using the SimGrid simulator in various execution scenarios, and recorded findings revealed no reaction time violations. However, the authors did not incorporate support for parallel jobs and did not run experiments with higher rates of incoming cloud jobs.

Alves et al. [11] describes the Interference-aware Virtual Machine Placement Issue (IVMPP) in small-scale High-Performance Computing (HPC) applications executing in Clouds. When applications run on a common physical machine, cross-interference is likely to happen, which harms the application's performance. This problem is very common in HPC that is executed in clouds. The iterated local search framework is proposed as a new solution to prevent the Interference-aware Virtual Machine Placement Problem (IVMP) from happening in HPC applications in clouds. In this study, they limited the interference that happens to HPC applications when sharing common physical machines. The results indicated that the proposed method limited interference by more than 40% in contrast to the most commonly applied heuristics to address the issue. However, the energy and the effect of consolidation are not taken into consideration.

A. Souza [12] proposed a hybrid resource management system for both DI (Data-Intensive) workload systems and HPC systems that will allow combining both of them on the same platform. The most significant feature between HPC systems and DI (Data-Intensive) systems is the fixed set of resources allocated completely to an application in HPC systems. Contrary to the DI (Data-Intensive) systems, in which allocation of resources and control are dependent on application needs. It also describes the design of a hybrid framework which helps for dual-level scheduling of DI jobs on the HPC infrastructure. The core benefit of this hybrid system is that it relies on real-time resource utilization monitoring that could successfully co-schedule high-performance computing (HPC) and data-intensive workloads. It can easily be adapted and extended to different types of workloads. For HPC and DI workloads, the architecture is based on the resource managers Slurm and Mesos. In a particular cluster, the hybrid architecture raises resource consumption by 20%, allowing it to meet all the constraints for HPC jobs, with a 12% reduction in queue makespan. Nevertheless, the paper does not explore ways to reduce the interference and co-location effects on energy as well as resource utilization.

Gupta et al. [21] presented scheduler for cloud platforms that is HPC-aware and incorporates topological needs for

HPC applications. Their scheduler uses benchmarking data to classify the application's network requirements and how resource sharing affects performance. Using three apps and NAS benchmarks, their scheduler outperformed the HPC-agnostic scheduler. Despite all the benefits, Gupta et al. [21] ignored SLA and energy breaches in their study. Furthermore, the trade-off among optimal HPC performance and ideal resource usage is primarily discussed in terms of throughput. Static VM consolidation techniques and Off-line applications profiling were used for classification. Hence, it is necessary to investigate the trade-off in terms of other dimensions as well. As part of earlier research, the researchers investigated CloudSim's default VM placement technique for energy consumption in contrast to the VM placement technique proposed by Gupta, which uses Multi-Dimensional Online Bin Packing (MDOBP). Fig. 2 illustrates that MDOBP uses more energy than CloudSim's default VM placement technique. The findings show an increase in energy consumption due to the possible restrictions of static VM placement. The findings of this experiment served as the foundation for the current research.

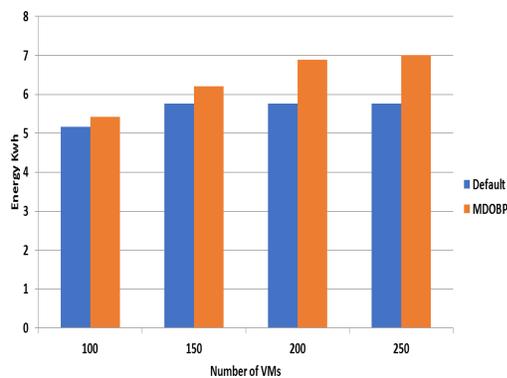

Fig. 2. Energy Comparison of Default vs MDOBP.

Cluster analysis is critical for detecting workloads with similar resource usage patterns. Several approaches for clustering workloads using K-Means have been proposed. Di, Sheng et al. [22] characterize a one-month Google cluster trace by CPU and memory utilization using the Forgy approach for centroid initialization. A merge ratio threshold is used to calculate the optimal number of clusters. Moreno et al. [23] employ K-Means clustering to group workloads based on user behavior and task characteristics. The number of clusters is obtained by comparing the variability of all items within a cluster to a threshold value.

In a previous project [24], the authors studied and implemented the Hybrid Local Regression Host Overload Detection algorithm (HLRHOD). An innovative energy efficient VM consolidation method that uses hybrid factors for host overload detection in cloud datacenters. We concluded that using hybrid factors (CPU, Memory, Bandwidth) can provide a more accurate indication of host utilization and outperform the techniques based on single factors. Thus, using the HLRHOD, the server in operation can be optimally minimized and, hence

helps in the reduction of energy utilization. Nevertheless, the paper does not explore ways to reduce the interference and co-location effects of the HPC and non-HPC applications on resource utilization as well as energy.

In this study, Gupta et al. [21] heuristics for initial VM placement for high-performance computing (HPC) applications were followed and expanded. Additionally, this study expands VM consolidation work [24] by making VM consolidation application-centric while simultaneously taking into account the requirements of the application's resource consumption (i.e., CPU, memory, and bandwidth). We also explore smart VM consolidation and placement strategies to intelligently schedule or provision HPC and non-HPC applications on cloud resources to increase utilization of resources and overcome the aforementioned issues of consolidation. Furthermore, automatic and dynamic classification of the application workload using k-mean is implemented.

#### IV. ENERGY-AWARE MULTI-DIMENSIONAL ONLINE BIN PACKING (EAMDOBP)

HPC applications are often constructed to operate in a homogenous as well as dedicated environment to eliminate unwanted interference by apps that are located concurrently. This is due to the fact that the performance of high-performance computing applications are significantly dependent on the slowest node. In contrast, cloud infrastructure is changing from homogeneous to heterogeneous. Heterogeneity dramatically lowers performance in parallel applications, especially in repetitive and bulk concurrent workloads. VM scheduling for HPC is challenging because of the trade-off between better HPC performance and improved resource consumption. A technique for intelligently optimizing the placement and execution of virtual machines (VMs) for HPC and non-HPC applications can improve resource usage, improve energy efficiency, and hence promote HPC cloud acceptance.

Sharing resources typically causes critical interference. Contention of shared resources has poor impact on applications performance. Caches are small stores of temporary memory. Cache memory has an impact on the program execution because its access time is less than the access time of the other memories. It is the fastest component in the memory hierarchy and approaches the speed of CPU components. They can degrade system performance if they become too large. System performance is a decreasing function of the cache miss rate, the cache access time, and the number of processor cycles taken to service a miss. They also can consume memory that other applications might need, negatively impacting application performance. Cache, memory, I/O channels, and network access are all shared resources, but cache are one of the most significant applications performance degradation factors [25]. It is advantageous to have cache-intensive applications; endure more LLC misses per second; co-located with applications that use little or no cache on the same node. Cache-sensitivity awareness assists in the avoidance of interference.

Most of the studies reviewed recently, a static classification of the behavior of different workloads/applications is created to examine their studies in order to find solutions for interference scheduling issues in cloud environments. EAMDOBP algorithm presents an automatic workload clustering using machine

learning techniques. The EAMDOBP classifier initially cluster the workload based on memory utilization and workload length then VMs are grouped based on their processing capacity. Afterwards the individual cloudlets in each cluster is scheduled to the appropriate VM in the VM groups. The flowchart in Fig. 3 depicts the execution flow of the proposed algorithm EAMDOBP, which is detailed in the following subsections.

### A. Clustering of Workload and VM

A workload can be defined as a certain amount of work operated inside the data center while consuming specific limited resources. In the current context, cloud computing data centers are defined as computer resource pools that can bear variable workloads whether long scientific jobs (HPC) or transactional operations (non-HPC). Normally, workloads are different in heterogeneous environments because of the placement constraints they have and the number of resources they consume [26]. In fact, the amount of resources a job consume is defined as job resource requirements, while the type and characteristics of resources are defined as job placement constraints. Therefore, these main elements must be addressed for intelligent and efficient scheduling. The proposed EAMDOBP initially classifies incoming requests according to job characteristics. This classification further is used to make crucial scheduling decisions, such as scheduling jobs from various clusters based on the amount of resources they consume.

#### 1) Clustering Jobs using K-Means and Silhouette Method:

The EAMDOBP classifier divides workload into specified classes by using the k-means algorithm [35] and the silhouette approach [36]. K in k-means algorithm denotes the quantity of pre-defined clusters that must be produced during the process. It is a centroid-based technique, with each cluster having its own centroid. The algorithm's main goal is to minimize the sum of distances between data points and their respective clusters. As input, the EAMDOBP classifier takes memory utilization and its length from METACENTRUM-02.swf logs of the parallel workload archive, separates it into  $k = 4$  clusters, and then continues the procedure until the centroids don't change. The technique for creating job clusters using the K-Means clustering algorithm is summarized in Algorithm-1. Once the clustering process is completed, the average memory utilization for each cluster is calculated.

---

#### Algorithm 1 Basic K-Means Algorithm

---

- 1: Select k points as initial centroid
  - 2: **repeat**
  - 3:   Form k clusters by assigning each point to its closest centroid
  - 4:   Re-compute the centroid of each cluster
  - 5: **until** the centroids don't change
- 

Clusters presented in Table I are obtained applying k-means algorithm in cloudSim on the first 250 logs from METACENTRUM-02.swf logs of the parallel workload archive [27]. K-means algorithm clusters data into four clusters. From the cluster centroid analysis, four different types of workloads can be outlined. These have been labeled as "IntenseHPC", "ConcurrentHPC", "DiscreteHPC", and non-HPC.

Table II displays the input (memory use and length) classified into each cluster using k-means algorithm. The number of objects by cluster represents the total number of objects per cluster. Within-cluster variance is the sum of squared distance between the average point (centroid) and every point of the cluster. The smaller the within-cluster variance value the better is the clustering. The average distance between observations and the cluster centroid is a measure of observation diversity within each cluster. A cluster with a smaller average distance is generally more compact than one with a bigger average distance. Clusters with higher values show more variation in the observations within the cluster. A larger maximum value of maximum distance to centroid, especially when compared to the average distance, suggests a cluster observation that is located further away from the cluster centroid.

Furthermore, silhouette score is utilized to determine the quality of clusters formed by using K-means clustering algorithms. The silhouette approach analyzes the quality of clustering by determining how well each point fits into its cluster. Using Eq. 1, the silhouette score is calculated for each cluster data (i.e. memory utilization and its length). where (a) is mean intra-cluster distance and (b) is the mean nearest-cluster distance. Fig. 4 depicts the mean silhouette score of each cluster. When the silhouette score equals 1, it means that the clusters are very dense and well separated. When the silhouette score equals 0, it means that clusters are overlapping. If the score is less than 0, this indicates that the data could be incorrect.

$$SilhouetteScore = (b - a) / \max(a, b). \quad (1)$$

Subsequent workload clustering, the processing capability of each virtual machine is determined based on its MIPS, size, bandwidth, and RAM. The virtual machines are then grouped into four clusters Extreme High (EHVMs), High (HVMs), Medium (MVMs) and Low (LVMs), using the modified K-means clustering algorithm. Afterwards, all cloudlet clusters are mapped to Virtual Machine (VM) clusters. The cloudlet with the high memory consumption is assigned to high processing capability. For example, IntenseHPC applications are assigned to Extreme High (EHVMs). Fig. 5 shows the simulation time with kmeans and without kmeans. As depicted in the Fig. 5 the simulation time has shown improved result.

### B. Virtual Machine Placement

EAMDOBP selects the PM that will host the VM based on the VM's class. The EAMDOBP begins the process with the target that IntenseHPC applications VMs can be assigned to the same host and rack as much as possible to reduce cross-interference for HPC/ Non-HPC applications. When applications share a physical machine, cross-interference can occur, negatively impacting their performance. EAMDOBP VM request contains the application's cluster name, as well as any existing parameters, unlike traditional VM requests. Based on the VM provisioning request, VM and cloudlets are generated depending on the Application type, capacity (number of CPU, RAM, and bandwidth), and instance type. VMs are allocated to a host and the cloudlet is allocated to VM. The algorithm then calculates the current host and rack free capacity, which is the number of extra VMs of the

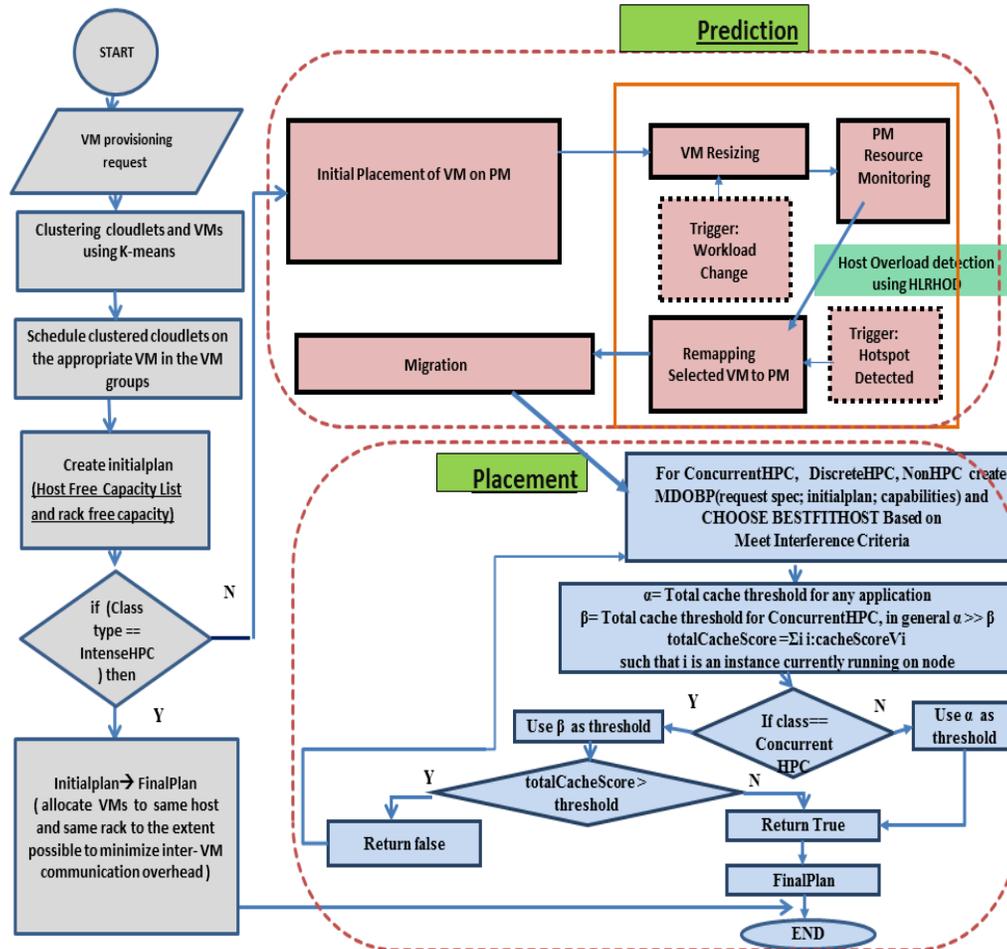

Fig. 3. Energy-Aware Multi-Dimensional Online Bin Packing (EAMDOBP).

TABLE I. POPULATION AND DESCRIPTION OF CLUSTERS RESULTING FROM CLUSTERING FIRST 250 DATA OF METACENTRUM-02.SWF LOGS OF THE PARALLEL WORKLOAD ARCHIVE

Cluster	Population	Memory usage	Clustering description
IntenseHPC (Cluster-4)	2	26749856.000	This cluster shows high memory consumption
DiscreteHPC (Cluster-3)	15	326042.000	This cluster shows moderate memory consumption
ConcurrentHPC (Cluster-1)	17	4732608.750	This cluster shows memory consumption is lower then DiscreteHPC.
non-HPC (Cluster-2)	215	86285.953	This cluster shows low memory consumption

TABLE II. K-MEAN CLUSTERS RESULT

Cluster	1	2	3	4
Number of objects by cluster	17	215	15	2
Sum of weights	17	215	15	2
Within-cluster variance	-0.223	-0.582	1.472	-0.667
Minimum distance to centroid	1.397	-0.540	-0.870	0.013
Average distance to centroid	0.276	-0.711	1.296	-0.860
Maximum distance to centroid	-0.384	0.713	0.906	-1.234

requested specification which can be deployed on a specific host and rack. To assure that IntenseHPC is only run on dedicated nodes, it sets all hosts with a active VM to zero,

if the required VM category is IntenseHPC. The scheduler then prepares a initial plan, which is a list of hosts sorted by rackCapacity and hostCapacity for hosts in the same rack, if

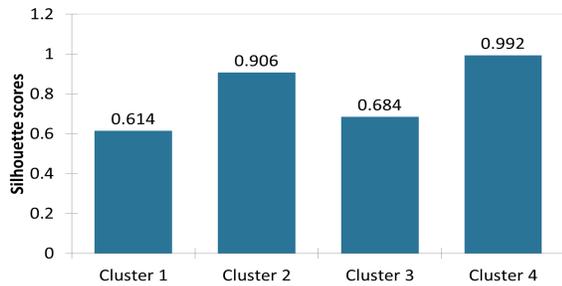

Fig. 4. Mean Silhouette Score of Clusters.

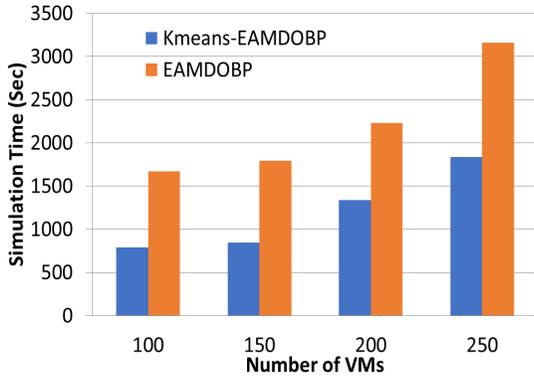

Fig. 5. Simulation Time with Kmeans and Without Kmeans

the required VM cluster is IntenseHPC or DiscreteHPC. The idea is to keep as many VMs on the same host and rack as possible to avoid inter or cross-VM communication overhead for these application types. This initialPlan is used for VM provisioning in IntenseHPC, whereas for the other classes (DiscreteHPC, ConcurrentHPC, and NonHPC), the method does multi-dimensional online bin packing to group VMs with variety of attributes on the same host.

### C. Virtual Machine Consolidation

Since changing workloads modify VM resource utilization over time, initial VM placement should be complemented by a regular VM consolidation procedure. Status is examined for every scheduled interval by using the EAMDOBP proactive dynamic consolidation technique. Notably, the detection of host overload/underload is the initial stage in virtual machine consolidation whose main target is energy reduction. The default underload detection algorithm is applied every scheduled interval, and underutilized hosts are deactivated after moving all VM to other active PM. Afterward, Hybrid Local Regression Host Overload Detection algorithm (HLRHOD) [24] is applied to detect the overloaded hosts. VM is chosen from the overloaded hosts to migrate to available hosts. HLRHOD calculates host utilization based on hybrid factors by utilizing a metric which measures the combined CPU-network-memory load of physical and virtual servers. Following the calculation of host utilization, the program employs local regression. The basic concept behind the process of local regression is that it involves fitting simple models to confined subsets of data in order to construct a curve that approximates the original data. To identify whether the host is overloaded or underloaded,

HLRHOD estimates the host utilization based on a hybrid factor. VM consolidation requires two more phases after the overloaded hosts are identified. The first phase is to identify the virtual machines (VMs) that will be migrated from the overloaded hosts to other hosts (known as VM migration), and the second phase is to replace the VMs that were selected for migration on new hosts (known as VM placement).

### D. Virtual Machine Placement

Multi-dimensional online bin packing (MDOBP) algorithm is used for VM placement and it allows VMs with diverse characteristics to be placed on the same host to reduce energy and enhances the consumption of resources. MDOBP treats hosts as bins, and virtual machines as objects that must be packed into the bins. A host is represented as a d-dimensional vector, which is referred to as the host's vector of capacities. Each dimension indicates the host's capacity corresponding to a specific resource, such as CPU utilization, memory utilization, or disk bandwidth. Similarly, each virtual machine is represented by a vector of requirements. The aim is to place all of the VMs on as few hosts as appropriate, while ensuring that, across all dimensions, the total demand of VMs placed on a host does not exceed the capacity of the host.

Additionally, each job is assigned a cache score from (0-30) The cache score represents the amount of pressure being placed on the both memory controller subsystem as well as shared cache. The chosen host is furthermore verified for compliance with the interference requirements i.e estimated demand for contested resources from the physical hosts. If the sum of cache scores for the requested VM and all other VMs running on the host exceeds a certain threshold  $\alpha$  (Total cache threshold for any application), the request will be denied. which needs to be determined through experimental analysis. A different threshold  $\beta$  (Total cache threshold for DiscreteHPC) is used when a requested virtual machine (VM) or one or more virtual machines operating on that host are of the class DiscreteHPC, because applications of this type can tolerate less interference compared to IntenseHPC. When the cache threshold  $\beta$  is too high, the efficiency is decreased as cache-intensive applications on the same node are aggressively packaged. Furthermore, very low thresholds lead to an excessive waste of certain CPU cores if very small cache scores do not exist. A record of interference indices is saved to examine interference between the applications that face a big performance penalty when being executed on the same host. Having this information is beneficial in avoiding co-locations, which are detrimental to the performance of high-performance computing (HPC) applications. Following that, a FinalPlan is established, which contains a list of hosts on which the virtual machines should be provisioned. After each repetition, a log is also created, which can be used to track energy consumption and quality of service.

## V. EVALUATION METHODOLOGY

### A. Experimental Setup

As it is very challenging to conduct repeatable large-scale experiments on a real infrastructure [28], simulations are recommended to show the improvement of our suggested algorithms. The CloudSim toolkit facilitates the modeling of

cloud system resources from both a system and a behavior perspectives specifically virtual machines, data centers, and resource management policies. It incorporates common application delivery techniques that can be extended quickly and with minimal effort. Therefore, the experiments were conducted with the CloudSim 3.0 simulation toolkit [29] using four VM types and two PM types. Cloudsim is extended with energy-aware simulations, originally not present in the core framework [29].

Furthermore, while implementing our scheduling and migration techniques the researchers identified multiple limitations in the CloudSim 3.0, that need to be addressed. They include that CloudSim is designed and implemented for the cloud, and primarily operates for tasks involving just one processor while HPC machines require quite a huge number of processors. In this research work, the researchers extended CloudSim 3.0 to provision the simulation of HPC in the cloud. Hence, the key change performed to enhance the execution of multi-core jobs to simulate HPC in a cloud thus the PowerDatacenter class that empowers simulation of power-aware data centers in the cloud environment.

In order to efficiently map jobs to virtual machines (VM), a predetermined number of virtual machines (of various types) will be constructed at the beginning of the simulation, and jobs (cloudlets) will be submitted to the DatacenterBrokerEAMDOBP broker. The cloudlets class is also modified, in addition to existing parameters, it includes the application class and name for VM provisioning. Furthermore, for cache-awareness, used a uniform distribution random number generator by giving a cache value from 0 to 30 to each job.

Further, DatacenterBroker class was also extended to DatacenterBrokerEAMDOBP, with two additional features: i) it allocates a cloudlet to VM after determining the characteristics of both VM and Cloudlets, to assign lengthy cloudlets (jobs) to the more efficient VMs so that the VM is not idle in a data center and the cloudlet execution time will be reduced. This does not only results in the efficient and improved utilization of the system but also helps to overcome the drawbacks of the default cloudSim 3.0 DatacenterBroker policy. ii) Furthermore, cache-awareness is also added to DatacenterBrokerEAMDOBP policy to efficiently address the issue of cross-interference. The cross-interference problem arises at a high scale when high-performance applications are executed in clouds. The proportion of additional time spent by one program when it runs simultaneously with another is known as the slowdown of that application. Thus the accurate forecasting of the slowdown due to interference in each application has many advantages: for example, it can help to enhance efficient shared resource utilization to avoid unreasonable application slowdowns from consolidation. DatacenterBrokerEAMDOBP policy will allocate cloudlets to VM that do not surpass the criteria of interference. Similar approach as Gupta [21], the interference is calculated based on following criteria: The sum of cache value of the VM requested does not exceed a threshold for any VM running on a host. The value of the threshold value is set to 60 after careful and thorough experimentation. If the threshold is set to a large value, it will decrease efficiency as a result of aggressive cache-intense applications packaged on the same node. On the other hand, too small value of threshold will result in an unreasonable waste of certain CPU cores if few applications are having insignificant

cache values. Interference indices maintained to record and save interference between applications that experience high-performance penalties when hosts are shared. While DatacenterBrokerEAMDOBP policy assigns suitable cloudlet(job) to VM, the knowledge of recorded interference indices is used to prevent co-locations of HPC/non-HPC applications that consumed more resources.

Furthermore, the default CloudSim VmAllocationPolicySimple class extended to PowerVmAllocationPolicyMigrationEAMDOBP which manages a user request encompasses multiple types of VM. Two methods findHostForVm (for initial VM allocation) and optimizeAllocation (for VM consolidation) in the PowerVmAllocationPolicyMigrationEAMDOBP class carries out proposed Energy-aware multi-dimensional online bin packing scheduling. When HLRHOD [24] detects a host overload, certain VMs will be chosen to be migrated from the overloaded host to other hosts.

Furthermore, the researchers compare the proposed Energy-Aware Multi-Dimensional Online Bin Packing (EAMDOBP) algorithm against the following algorithms from the literature:

- The Power-Aware-Best-Fit Decreasing algorithm (PABFD) algorithm [28].
- The Modified- Worst-Fit Decreasing algorithm (MWFD) algorithm [30].

### B. Power Model

The CPU, disk storage, memory, and cooling systems utilize the majority of the power in cloud data centers [28]. Establishing exact analytical models for modern multicore CPUs is a difficult research problem due to the complex power model of modern multicore CPUs. Hence, we employ real data on power rate obtained from the results of the SPECpower benchmark [28] as an alternative to the use of an analytical model of a host's power consumption. The host overload is evaluated on a regular basis according to the scheduling interval, which is set at 300 seconds. The host types are: HP ProLiant ML110 G4 (Intel Xeon 3040, 2 cores 1860 MHz, 4 GB), and HP ProLiant ML110G5 (Intel Xeon 3075, 2 cores 2660 MHz, 4 GB). The power consumption features of the chosen hosts are presented in Table III.

### C. Performance metrics

To conduct in-depth analysis of the suggested algorithm and to evaluate and contrast the algorithm's performance, several number of experiments were carried out and examined in the current research using the following metrics:

**Simulation Time (ST):** It is defined as the amount of time spent conducting an experiment in seconds, commonly known as the makespan. Based on the number of applications that were processed, the total time required to generate the simulation was calculated. The simulation time (MakeSpan) is used to determine the efficiency of the algorithm.

**Throughput:** In computing, it is the quantity of work that a computer or a system of computers is able to perform in a given period of time. Increasing throughput is an ongoing challenge that IT managers, researchers, and scientists must

TABLE III. POWER CONSUMED BY THE CHOSEN HOSTS AT VARIOUS LOAD LEVELS IN WATTS [28]

SERVER	0%	10%	20%	30%	40%	50%	60%	70%	80%	90%	100%
HP PROLIANT G4	86	89.4	92.6	96	99.5	102	106	108	112	114	117
HP PROLIANT G5	93.7	97	101	105	110	116	121	125	129	133	135

meet and exceed. The throughput of a system is used to evaluate its overall performance.

**Efficient Resource Utilization (ERU):** It is used determine how much CPU, memory and network bandwidth are needed for HPC and non-HPC workloads deployed in cloud-based data centers

**Power Usage Effectiveness (PUE):** The Power Usage Effectiveness (PUE) is used as indices for measurement of datacenter performance. PUE is considered the most used datacenter metric. The PUE is calculated using Eq. 2, where  $P_{CS}$  is the cooling power, and  $P_C$  is the computing power of the host. This calculation is iterated over each host.

$$PUE = \frac{P_{CS} + P_C}{P_C} \quad (2)$$

Table IV shows the PUE values based on several experiments which were performed in a small datacenter [31]. Low PUE indicates higher efficiency as a significant amount of the power has been consumed by computing power [32].

TABLE IV. PUE EFFICIENCY VALUES [31]

PUE	Level of efficiency
3.0	Very inefficient
2.5	Inefficiency
2.0	Average
1.5	Efficient
1.2	very Efficient
1.1	Standard

**The number of VM migrations:** For dynamic VM consolidation, when the overloaded or under-loaded hosts are detected, the VMs are then chosen to move. Reducing the VM migration time is the most significant obstacle in the migration step and the default method to achieve that is by reducing the total number of VM migrations.

**Energy and SLA Violations (ESV):** There is an adverse relation between the energy consumed by physical hosts and SLAV because energy can be frequently reduced by allowing more SLA violations. The objective of the host management framework is to decrease both energy consumption and service level agreement violations. Thus, a mixed metric denoted by Energy and SLA Violations (ESV) is proposed in [28] and is shown in Eq. 3. For the ESV metric lower is better.

$$ESV = E \times SLAV \quad (3)$$

#### D. Workloads

The workload contains several months of accounting records from the national grid of the Czech Republic, called Metacentrum. This grid is composed of 14 clusters (called nodes), each with several multiprocessor machines, for a total of 806 processors [27]. The workload data contains CPU and memory usage [33]. Standard workload format (SWF) includes the log. METACENTRUM-2013-1.swf. is used while relying on accounting data collected by the scheduler. three utilization models rebuilt to examine the CPU and RAM, and calculate the BW, respectively, from the workload and send it to the cloudlets.

## VI. SIMULATION RESULTS AND ANALYSIS

Memory utilization, workload length and number of VMs are crucial parameters that are used to configure the algorithms implemented besides the performance metrics presented in Section V

#### A. Sensitivity Analysis

The effect of changing the number of VMs on the performance of the proposed algorithms in terms of metrics is provided in Section 5.3.

##### 1) Number of VMs:

Our sensitivity analysis is based on changing the number of virtual machines while fixing the number of hosts to 800 and scheduling interval to 300 sec. The effect of varying the number of VMs using Metacentrum workload traces on the energy consumption and other system and performance metrics for different algorithms are examined.

Algorithms comparison are performed on (CPU, RAM, and Network) traces using Metacentrum HPC workload. Measurement of simulation time is one of the most critical indicators for measuring performance in a dynamic system. Observe in Fig. 6(a), EAMDOBP algorithm reduces the execution times better than the other algorithms. This proves that application awareness results in fewer contentions for resources as only the most compatible VMs are consolidated. The new EAMDOBP algorithm results in the lowest simulation time compared to PABFD and MWFD regardless of the number of VM. The simulation time is the highest in the case of PABFD when the number of VM is high. Besides, the simulation time is always less in the case of MWFD when compared to PABFD.

The HPC framework involves the co-scheduling of tasks with the same nature to make some synchronous development. In the present virtualized environment, all VMs progress independently of each other, so that the need that all VMs of the same HPC function must be arranged together using EAMDOBP algorithm. Results are shown in Fig. 6(b) indicate

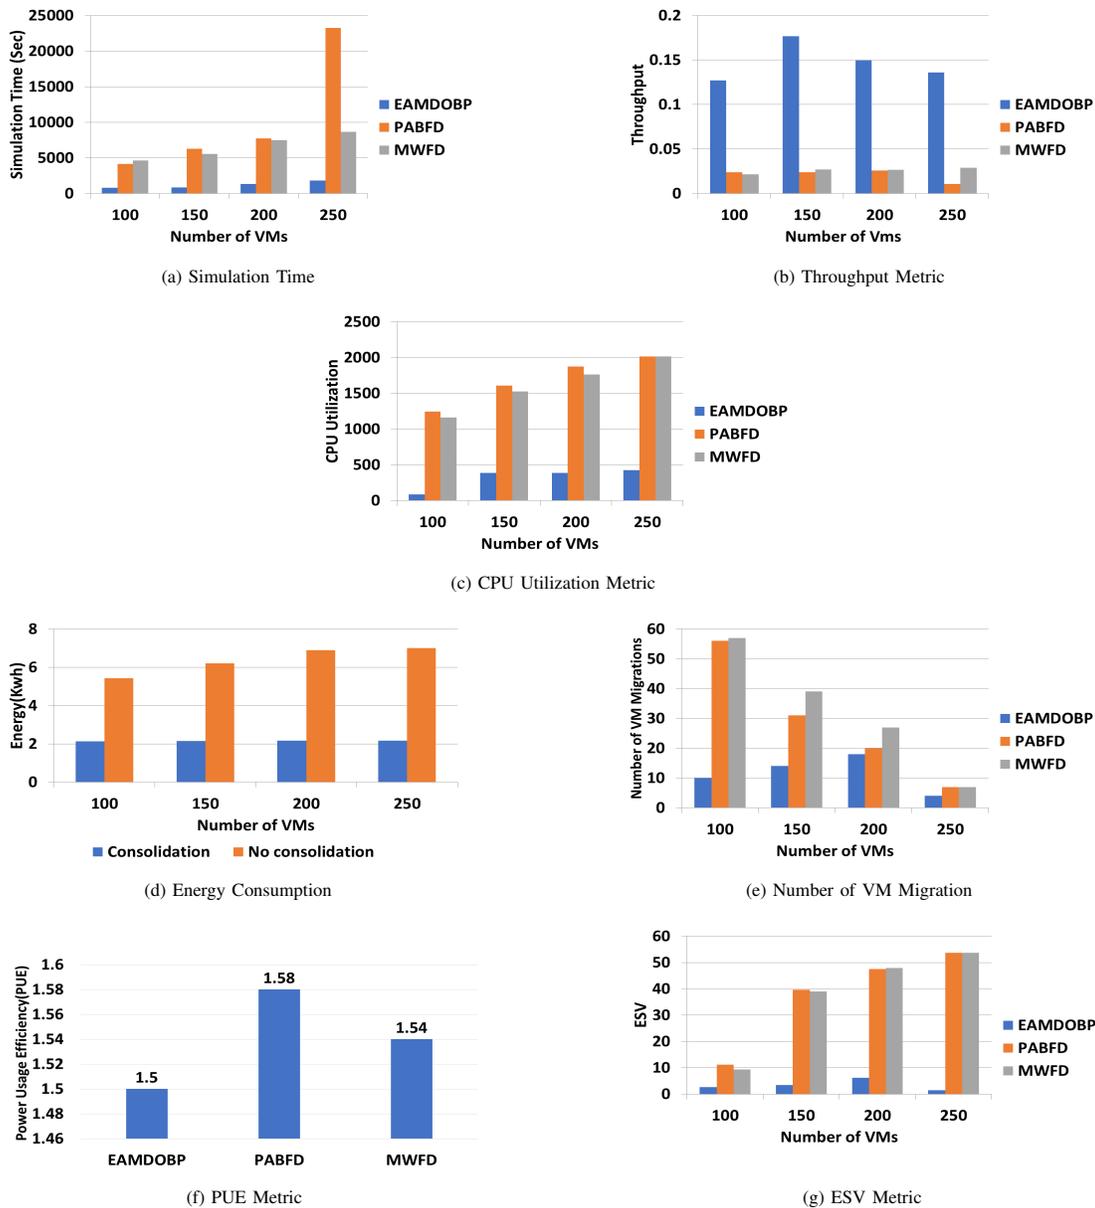

Fig. 6. Algorithms Comparison for Metacentrum HPC workload, where the various metrics are depicted in log-scale

that the throughput levels are the highest when the EAMDOBP algorithm is used. While throughput levels are almost equal when using PABFD and MWFD algorithms.

It is important to address the issue of machine utilization or “busy” time that is commonly used to evaluate throughput effectiveness. It is often only moderately correlated with a hardware measure such as utilization. The prediction method of the resource utilization based on HLRHOD is used, Fig. 6(c) indicates better CPU utilization. The use of HLRHOD prediction technique improves CPU utilization as well as increase the effectiveness of HPC-application execution

### B. Algorithms Comparative Analysis

The EAMDOBP forehead has the expertise to forecast the best node for VM allocation without venturing with the

energy consumption. While the energy and interference-aware co-location of the VMs is used for all the workload allocations to the VMs running on the system nodes. The need for rising VM migrations is therefore low and it helps to reduce energy depletion. The same is shown through Fig. 6(d) and (e). The graph in Fig. 6(d) indicates how energy usage increases with the increase in the number of VM when no consolidation is allowed. Significantly, energy consumption is fixed regardless of the increase in the number of VMs when consolidation is allowed, meaning that the VMs are allowed to migrate to run on fewer physical servers. Thus, VM consolidation helps reduce energy consumption. As observed in Fig. 6(e) VM migrations are the lowest when using the EAMDOBP algorithm compared to PABFD and MWFD. VM migration is the highest when using MWFD. Each host’s cooling and

processing power, as well as its power utilization efficiency (PUE), are measured after each migration, and the impacts are averaged. Results depicted in Fig. 6(f) indicate that PUE is the lowest in the case of EAMDOBP compared to PABFD and MWFD. It is worth mentioning that low PUE indicates better efficiency. This is because a considerable part of the power is consumed by computing power. However, PUE is the highest in the case of PABFD. Results revealed in Fig. 6(g) indicate that ESV is the lowest when using the EAMDOBP algorithms compared to PABFD and MWFD. ESV levels increase significantly with the increase in the number of VM when using PABFD and MWFD algorithms.

## VII. CONCLUSION

Cloud computing has become a popular solution for the exponential growth in the demand for high-performance computing. Huge data centers use a considerable amount of energy, which leads to an increase in operating costs. Therefore, virtual machine consolidation is a perfect solution as it allows VM live migration to run on fewer physical servers to save energy consumption. Many studies have tried to investigate the currently available cloud service architectures for running HPC applications in the most effective approach. The major obstacles are cross-application interference, energy concerns, and guaranteeing SLAs in different metrics, e.g. response time (web application) vs. execution time (HPC application). However, for a successful VM consolidation host overload detection is necessary to predict if a physical server will be overloaded with VMs. This paper proposes new algorithm named Energy-Aware Multi-Dimensional Online Bin Packing (EAMDOBP) algorithm that will provide better results. Specifically, In comparison to PABFD and MWFD, experiments reveal that the Energy Aware Multi-Dimensional Online Bin Packing (EAMDOBP) has improved CPU, RAM, and bandwidth consumption by a relative improvement of 77%, 84%, and 70%, respectively. The Energy Aware Multi-Dimensional Online Bin Packing (EAMDOBP), according to experiments, improves CPU usage, lowers PUE, and rationalizes energy consumption. Additionally, EAMDOBP achieves faster throughput, less VM migration, and lower ESV when compared to PABFD and MWFD. According to the results analysis, the EAMDOBP algorithm outperforms PABFD and MWFD in terms of all the parameters employed. In current paper the researcher has focused on bridging the HPC-cloud gap by enhancing application performance and resource and energy efficiency however, there are two important limitations in this study that could be addressed in future investigations. First, the only information provided by current performance analysis tools is the application's performance. They don't go into depth about the additional tasks that could have used up other parameters such the network and I/O. Also, the work should be extended to be run on a real cloud system not simulation. In future, we plan to run our algorithm on a real cloud system; also we will consider other factors such as I/O which can affect performance of VMs. We can apply other machine learning techniques such as Naive Bayesian classifiers for classification of VMs.

**Abstract**—The rapid growth of Computer vision and Machine Learning applications, especially in Health care systems, assures a secure, innovative lifestyle for society. The implication of these technologies in the early diagnosis of lung tumors helps in lung cancer detection and promises the survival rate of patients. The existing general diagnosis method of lung radiotherapy, i.e., Computed Tomography imaging (CT), doesn't spot exactly affected parts during injuries on lung malignancy. Herein, we propose a computer vision-based diagnostic method empowered with machine learning algorithms to detect lung tumors. The primary objective of the proposed method is to develop an efficient segmentation method to enhance the classification accuracy of lung tumors by implementing a Triple Support Vector Machine (SVM) for the classification of data samples into normal, malignant, or benign, Random Region Segmentation (RSS) for image segmentation and SIFT and GLCM algorithms are applied for feature extraction technique. The model is trained considering the dataset IQ - OTH or NCCD with 300 epochs, with an accuracy of 96.5% achieved under 200 cluster formations.

**Keywords**—Benign; computed tomography; malignant; lung cancer; radiation; triple support vector machine

## I. INTRODUCTION

According to WHO results nearly 10 million death occurred due to cancer. Among 10 million cancer types, about 2.21 million cases are of lung cancer. The most common cancer deaths of 2020 were of lung cancer as per WHO. The deadliest pandemic Covid19 has also affected the Lungs very badly. Hence under these circumstances, it is vital to predict and thereby prevent any onset of cancer in the human body. Early detection of cancer can considerably reduce the mortality rate[1]. In general, cancer is observed with the presence of growth of cells (nodules) in the lungs and if it can spread to the remaining cells of the body is called to be as malignant. The nodules are termed benign if the cells restrain from spreading yet are harmful to the specific organ alone. The development in technology can be utilized in a scalable manner to detect and diagnose the disease [2] [3] [4].

When cells in the lungs grow uncontrollably, lung cancer develops into a tumor and this can cause respiratory problems and spread to other sections of the body. Lung cancer is caused mostly by smoking and drinking alcohol [5]. Around 80% of the people who are observed with lung cancer are habituated to drinking and smoking. People who have the habit

of smoking in past are the ones getting lung cancer mostly and only a few of them are never smoked. Lung cancer is mainly caused by the factors such as radiation, smoking from nearby people, living in a polluted environment and other related factors in cases of people who don't smoke [6] [7] [8]. In addition, there is a greater chance of the possibility of spreading into the lungs if any other place of the body is affected with cancer. As an overall result, the detection of cancer and predicting the probability of survival requires timely help in case of malignancy in the early stages. The chance of survival for the detection and progress of treatment at the early stages of cancer is higher when compared to severe stages (Borel 1997). Hence, the proposed research develops a system that detects cancer-free people, and the cancer portions which are benign and do not spread to other portions of the body. The proposed research also determines the malignancy in cancer regions which can spread to further parts of the body to diagnose early and provide appropriate treatment. For diagnosis of lung cancers, a variety of imaging has been used including sputum cytology, CT, chest x-ray, and magnetic resonance imaging (MRI) (<http://colah.github.io/posts/>). The tumors can be classified as benign or malignant types of cancer and the prognosis of the identified tumor is carried out by an expert like a doctor who can look over the individuals based on the causes. During detection, the number of false positives is reduced significantly which will have a severe impact on the patient's mental or financial well-being.

Manual detection of lung cancer is a very tedious task. To aid in detection, several machine learning approaches to aid in early diagnosis. The input to such approaches can be MRI, CT scan, and X-ray of the affected organ. These inputs are being fed to detect whether the organ is benign, malignant, or normal. Several types of research have already been conducted in the underlying area using different algorithms and techniques. A considerable amount of studies on image processing applications [1] [9] in lung cancer detection paves way for data processing easier for Machine learning classification. With the advent of image segmentation for separating cancerous nodules, the task of detecting the type of cancer and stages of cancer has become quite simpler. In region growth segmentation, watershed segmentation provides an effective result in CT image processing of lung cancer. The SVM and neural networks play a key role in the identification

of the type of cancer in the lungs.

The crucial issues are developing a system for automatically identifying lung illness and accurately segmenting the precise region. Additionally, the heterogeneity of the tumor makes segmentation a difficult task [10]. Due to the low feature of photographs, it is difficult to notice impacted areas that are small in size [11]. The aforementioned problems serves as a motivation for effective lung tumor identification using RRS segmentation and supervised machine learning algorithm namely triple SVM.

The contributions of this research are summarized as follows:

- 1) The median and Weiner filters are used to preprocess the input images. The reason to choose median filter is that it preserves the sharp edges and Weiner filter removes the additive noise.
- 2) Subsequently, the precise segmentation is done by using RRS followed by SIFT and GLCM that are used to perform the feature extraction. The features from SIFT is invariant to light and viewpoints and GLCM is used to extract texture features.
- 3) Further, the triple SVM is used to perform an effective classification of lung tumor based on its comprehensible margin of dissociation.

The paper's organization of the paper is given as follows: Section II describes the image processing concept of region growth segmentation of lung tumors and later Section III has the methodology of a proposed model of segmentation. Section IV describes the experimental set up which includes the dataset description and model building. Section V concludes the final research output.

## II. LITERATURE SURVEY

A boosted deep CNN concept for lung tumor classification was introduced by Rani *et al.* [12] For segmentation purposes, the Advance Target Map Superpixel-based Region was suggested. The tumor region was then quantified using the nanoimaging theory. Image recognition was possible using the idea of boosted deep convolutional neural networks, which provides 97.3% accuracy. The current methodology demonstrated the stated efficacy which proved to greatly increase the execution of the recommended technique. Moreover, the data was handled quickly with deep learning.

Xie *et al.* [13] presented a method for epidermal growth factor receptor (EGFR) prediction with the lung cancer-based alterations. The system employs CNN with the layers counts upto 6 to learn the characteristics of the image deeper, and the process is followed by a Support Vector Machine (SVM) classifier for prediction. Yu's system was evaluated on two kinds of datasets, for which Dataset 1 attains an accuracy score of 76.16% and Dataset2 attains accuracy score of 67.55% respectively. Typical machine learning algorithms are performing inferior to the deep learning models by utilizing the learning obtained through the hierarchical data and deep-layered nature (chaudhary, & Sukhraj Singh 2012). Moreover, the data is being handled quickly with deep learning.

The approaches followed in Kareem *et al.* [14] preserve the fundamental structure of the data while using approaches

similar to autoencoder and the approaches also uncover the analysis information via the deep learning approach. When it comes to picture categorization, CNN is the most preferred option and to categorize pictures efficiently, the process of convolution and the traditional process of the neural network is combined effectively in the design of the CNN model.

Lung cancer detection process using the deep learning algorithm has been examined for efficacy by the author da Silva *et al.* 2021 through the database named Lung Image Database Consortium (LIDC). The findings of the research demonstrated that the potential evaluation performance of models with deep learning possesses a better accuracy value of about 79.40%. The authors wanted to examine if the deeper layers network schemes might be used to diagnose lung cancer and if there were any more efficient techniques to reduce the downsample impact. Using the same dataset, they are evaluated in comparison with the techniques of Stacked Denoising Auto Encoder (SDAE) and the model of Deep Belief Networks (DBNs). On using DBN and SDAE, the models possess the accuracy value of 81.19% and 79.29%, respectively. The findings of the study showed that deeply layered network algorithms and automatic learning image features have a numerous amount of potential in the field of medical imaging.

A deep neural network model with the help of reinforcement learning has been developed for the early-stage detection of lung cancer by the authors of Ali *et al.* (The IQ-OTHNCCD lung cancer dataset Published: 19-10-2020, Version 1, DOI:10.17632/bhmdr45bh2.1 Contributor:hamdalla alyasriy.) And the performance has achieved the accuracy of 99.1% and 64.44% for training and testing respectively for the employed model on LIDC/IDRI subsets of data.

Another technique was suggested by (The IQ-OTHNCCD lung cancer dataset Published: 19-10-2020, Version 1, DOI:10.17632/bhmdr45bh2.1 Contributor:hamdalla alyasriy), in which the authors built a CAD system based on a CNN network with multi-view and multi-scale nature for lung nodule categorization. On the datasets of ELCAP and LIDC/IDRI, the system obtained the values of 92.3% and 90.3% accuracy for detection, respectively. According to the aforementioned research work, CNN performance might be enhanced in many cases to improve accuracy performance and also aids in the detection process of early diagnosis of the lung cancer disease with minimal error [15].

Humayun *et al.* [16] presented the transfer learning (TL) with Convolutional Neural Network (CNN) to classify the lung disease. This work comprised three stages: Initially data augmentation was accomplished followed by pretrained CNN which was used to ensure the classification. Further, the localization was completed, once the classification was done. There are three TL methods such as VGG 16, VGG 19, and Xception that were used with fine-tuning hyperparameters to generate the network for training and testing process. The developed TL with CNN achieved higher accuracy in training and low accuracy in testing process.

Kareem *et al.* [14] developed the lung cancer detection using SVM classifier. In this work, the preprocessing techniques of bit plane slicing, Gaussian filtering, erosion technique and outlining operation were used to enhance the CT images. Subsequently, the Otsu's thresholding was used to separate the

nodules followed by SVM that was used to perform the classification. This work mainly concentrated on the preprocessing approach for classifying the lung cancer.

The following are some of the issues with the most recent ways to classifying lung diseases: In classification, it is necessary for testing accuracy to exceed training accuracy [16]. Because training uses the same input data for analysis while testing uses a different input data for categorization. When segmentation is inadequate, classification performance suffers [14]. As a result, developing an efficient segmentation and classification is necessary to improve the classification of lung tumors.

### III. PROPOSED METHOD

The primary objective of the work is to detect and classify lung cancer using image processing and machine learning techniques. In this research, the RRS based segmentation is proposed for separating the tumor portions from the input image. The SIFT and GLCM extracts optimal features from the segmented image. In that, the SIFT features are invariant light viewpoints whereas GLCM extracts statistical texture descriptors. Further, the triple SVM is used to perform the classification based on extracted features. The methodology can be outlined as shown in Fig. 1.

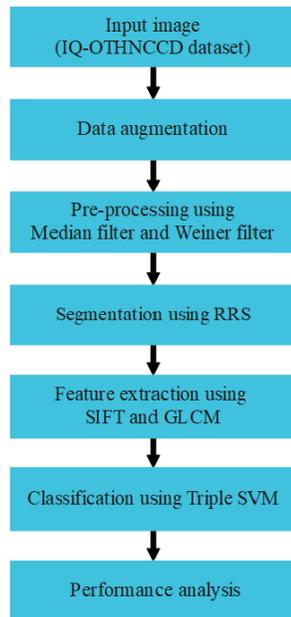

Fig. 1. Architecture of the Proposed Methodology.

Six stages of the proposed methodology have shown in Fig. 1. The procedure of the proposed method begins with collecting the input image data, then the image is augmented, which helps modify the input image to be ready for processing. Using ensembling filters like Weiner and median, the clarity of the vision is enhanced. RRS algorithm is applied to the resultant image, and after the segmentation, we adopt hybrid feature extraction techniques like SIFT and GLCM. The SVM is trained to classify the image into benign or malignant depending on the features. The obtained results are compared with existing techniques in the last phase. The detailed explanation is done in the following sections:

#### A. Dataset Description

The data for lung cancer has been collected at Iraq- Oncology Teaching Hospital or National Center for Cancer Diseases (IQ-OTH or NCCD) (The IQ- OTH-NCCD lung cancer dataset Published: 19-10-2020, Version 1,DOI:10.17632/bhmdr45bh2.1 Contributor:hamdalla alyas-riy). The data collected constitutes three different stages of lung cancer CT scans of patients along with scans of healthy patients over 3 months. For the categories of benign, normal, and malignant groups of lung cancer, 110 patients are providing 1190 CT scans. By analyzing the images of lung cancer, the proposed model can be trained to detect cancer that can spread (malignant) or which cannot spread (benign) or it is a healthy tissue (normal) with the help of this dataset. Among the total data, 55 cases are normal, 40 cases are malignant and 15 cases are benign. The dataset is in DICOM format. The task is to classify the segmented lung nodules into benign, normal, or malignant [17].

#### B. Data Preprocessing and Morphological Features

The original CT scan images are preprocessed to remove noise to improve the image quality. Before performing the preprocessing, the data augmentation techniques such as cropping, flipping, rotation, translation, contrast, color augmentation are used to increase the number of inputs to meet the real-world requirements in classification. This is achieved by using an image processing technique called filtering. Two types of filters are used in this project to understand the underlying clarity. Fig. 2 and Fig. 3 represent the image after application of median filter and Weiner filter respectively. In the process of lung nodule segmentation, morphology [18][19] is one of the prominent techniques, especially when it comes to handling the cases of tumors that are attached to regions that are not on target for example paranchymal wall or the diaphragm (juxtipleural) or vessels (juxtavasular). The representation of 0's and 1's as a matrix for a binary view of images on which 1's are called the neighbors.

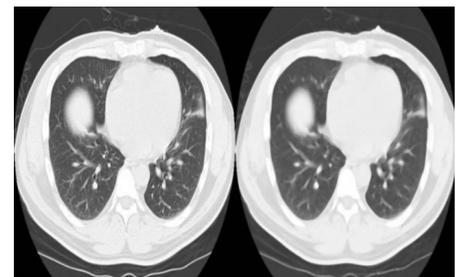

Fig. 2. Original Image and Median Filtered Image.

According to a comparison of the detected region with the corresponding pixel on the input image with respect to neighbor pixels of the output image as equals the value of every pixel. In the process of dilation for the given image pixels are added at the boundaries of the object, whereas it's the reverse process in erosion where in which the pixels are removed. The removed or added amount of pixels has been determining the shape and size of the element structure. Neighboring pixels

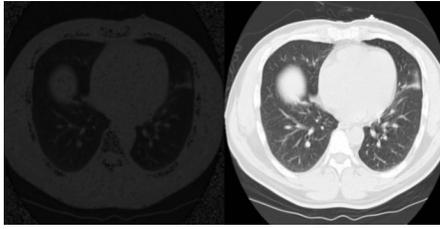

Fig. 3. Original Image and Weiner Filtered Image.

in the input image and the determined pixel through applying rules of morphological operations for the output image. Fig. 4 represents the identification of tumors by using morphological operations.

Cancerous nodules are recognized from the image segmentation in the upcoming stage of analysis and it is being depicted in Fig. 5 as left and right lungs. By using the proposed approach, the extraction of lungs from the images is done with the help of the region growing segmentation approach. The output of the nodule segmentation for one of the lung CT scans is shown in Fig. 6.

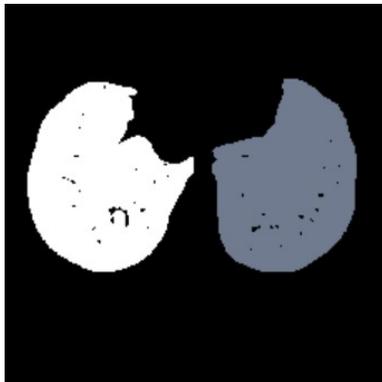

Fig. 5. Left and Right Lung Segmentation.

Fig. 6. Segmentation of Cancer Nodules.

Fig. 6 illustrate the segmentation output of the entire dataset. Fig. 7 shows the original CT scan images and Fig. 8 shows the segmented output using region growth algorithm.

### C. Segmentation

Image segmentation [6] [2] [3] is the process to partition the image into multiple segments used to locate objects and boundaries. The region growth segmentation examines the neighboring pixels to determine whether it is to be added to the region or not. This is continued until no more regions can be added. The region is grown iteratively by considering all the neighboring pixels to the region.

The difference between the region means and pixel intensity is used as the similarity measure. A certain threshold value is set for the image. The region growth commences from the dark region of the image taken for segmentation. From Fig. 6 one can see that the cancerous nodules are segmented from the original image. Hence this segmentation helps in understanding the shape and size of the cancer nodules. Therefore, by using region growth segmentation, the tumor cells are identified. The following equations depict the operation of region growth segmentation. For every pixel in a region, the neighboring pixels are compared and if the difference is less than the threshold, then the neighboring pixel is added to the region.

Segmenting the image  $R$  into  $n$  non-empty subsets ( $R_1, R_2, R_3, \dots, R_n$ ) in this segmentation. The following conditions given in equation (1) and (2) are required to be met during the segmentation.

- $R_i, i = 1, 2, \dots, n$  is digitally connected that is the regions has the contiguous lattice points.

$$U_{i=1}^n R_i = R \text{ --- } > (1)$$

$$R_i \cap R_j = \phi, i \neq j \text{ --- } > (2)$$

Where,  $\phi$  defines the null set. Equation (1) defines the segmentation is complete i.e., each pixel must be in the desired region whereas the equation (2) states that the points in a region is connected in the predefined sense. The RRS gives the capability to segment an image into any number of objects, where is the user-specified arbitrary number of objects. Also treats the image as a graph, with the pixels acting as its nodes or vertices. Hence, the proposed RRS is used to segment lung tumor from the input image.

The main goal is to calculate the similarity of images in different regions

### D. Feature Extraction

After performing the RRS based segmentation, the segmented lung tumor ( $SI$ ) is given as input to the feature extraction. Image feature extraction is the most important stage in any classification problem.

SIFT determines the local features of an image. These are often termed as key points and constitute of scale and rotation

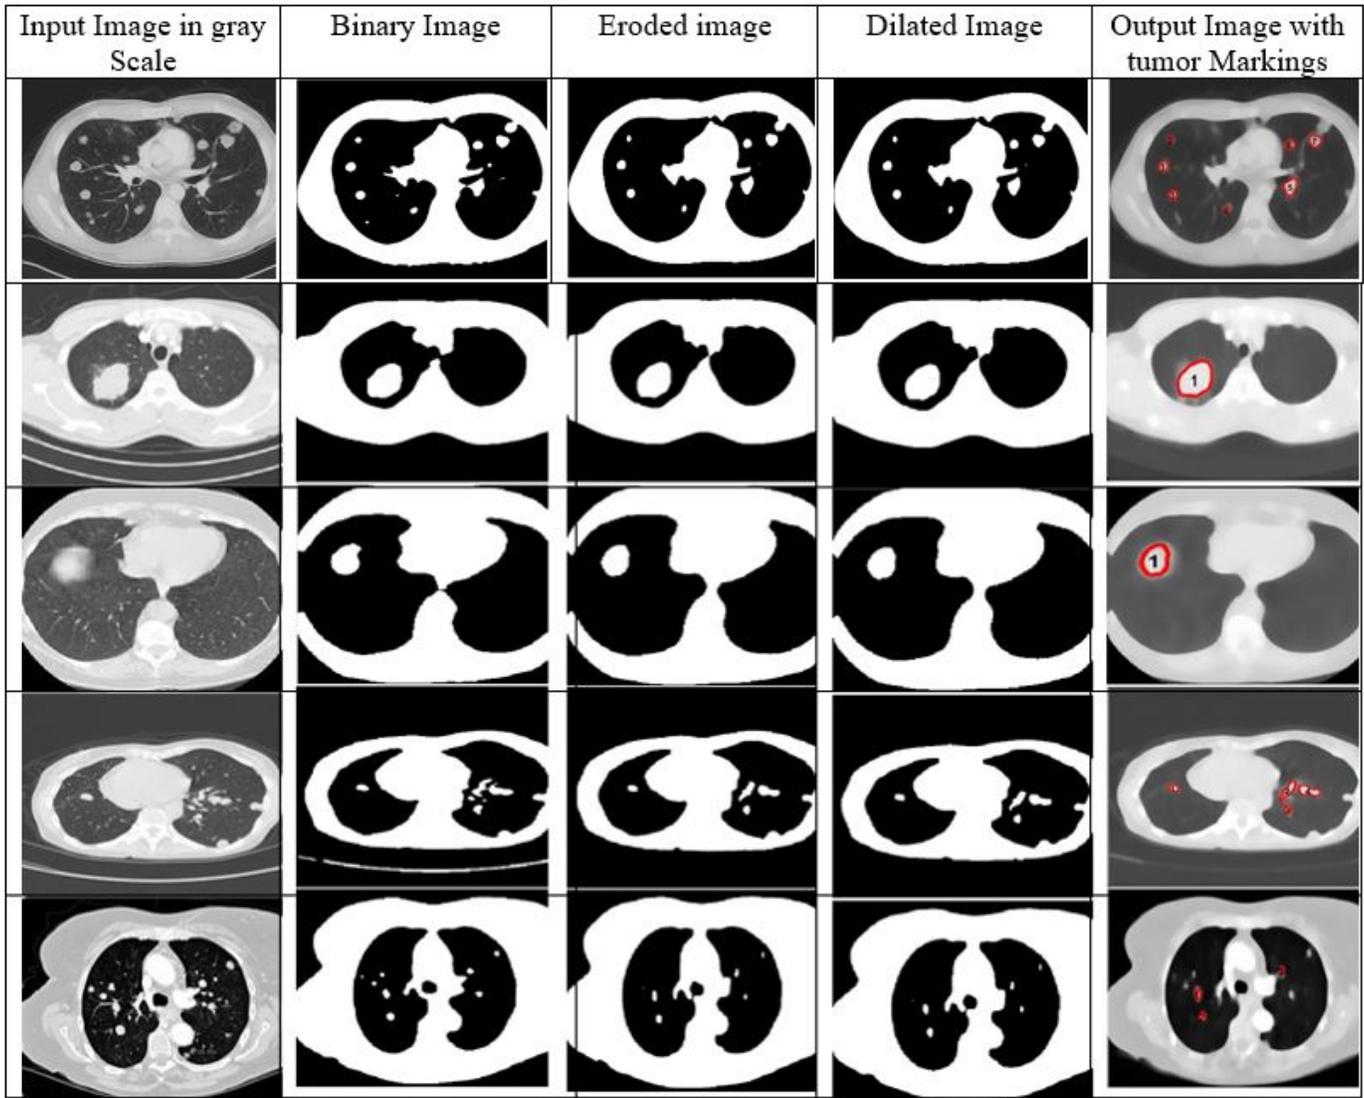

Fig. 4. (a) Represents the Input Image in Gray Scale Format. (b) Represents the Binary Image of the given Input Image. (c) Represents the Image after Applying Erosion Operation. (d) Represents the Image after Applying Dilation Operation. (e) Represents the Output Image along with the Tumor Markings.

invariant. The advantage of using SIFT is that it is independent of the size and orientation of an image. Gaussian blur is used to compute the scale of an image. The idea is to find out the local maxima and local minima for the images and then remove the low contrast key points. Finding the keypoint descriptor is the final stage for SIFT and it computes the orientation and magnitude of a descriptor which are expressed in equation (3) and (4), respectively. According to the local image gradient directions, the keypoints are allocated orientations.

$$m(x, y) = \sqrt{(Diff_x)^2 + (Diff_y)^2} \text{ --- } > (3)$$

$$\theta(x, y) = \tan^{-1} \frac{Diff_x}{Diff_y} \text{ --- } > (4)$$

where, x and y are the dimensions of segmented lung tumor image (SI) ;  $Diff_x$  and  $Diff_y$  are pixel differences; The

calculations of magnitude and direction are performed for an each pixel in an adjacent region around the keypoint at the Gaussian-blurred image.

GLCM (Grey Level Co-occurrence Matrix (Mohanaiah et al. 2013) determines the spatial relationship of image pixels. This calculates how often the pixel pairs and spatial relationships occur in an image. The statistical measures are obtained from the GLCM matrix. The most common measures obtained are contrasted (local variation in the matrix), correlation (joint probability of the pixel pairs), energy (sum of squared elements), homogeneity (closeness of the distribution) and entropy. Hence, this GLCM provides the statistical texture descriptors for the segmented lung tumor image (SI). Further, the features from both the SIFT and GLCM are concatenated together as shown in equation (5).

$$F_{ca} = \{m, \theta, GLCM\} \text{ --- } > (5)$$

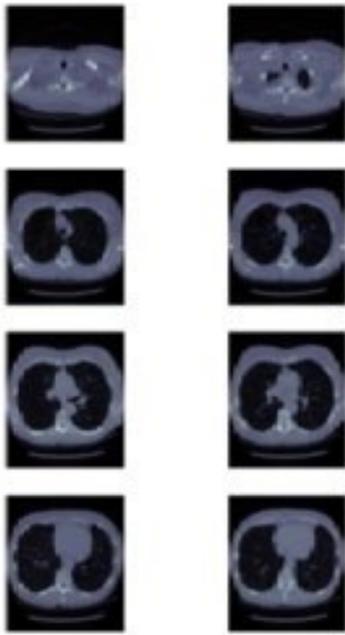

Fig. 7. Original CT Images.

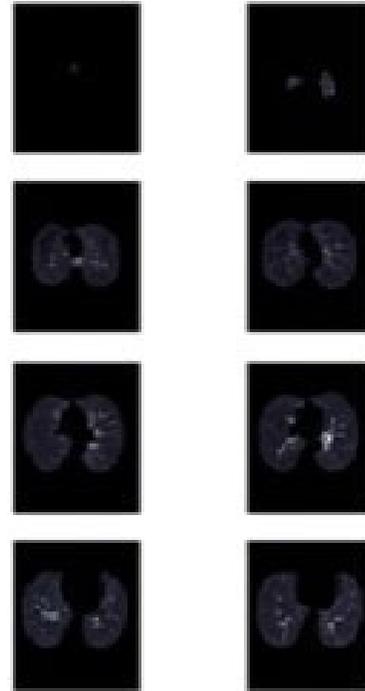

Fig. 8. Segmented Output.

The concatenated features are given to the Triple SVM to perform the classification.

#### E. Triple Support Vector Machine Classification

Initially, the features from the SIFT and GLCM are taken as input to the triple SVM to perform the classification. SVM is a supervised machine learning algorithm that uses a hyperplane to classify the data. The task is to find out a best-fitting hyperplane that segregates data based on the given input features and the process is termed a marginal classifier. The SVM has proved to achieve good performance in the data which has no prior knowledge from the related study. The basic idea is to map the input data (i.e., concatenated features of SIFT and GLCM (FFFFFF)) onto a higher dimensional feature space and determine the separate margin between the classes in the feature space. SVM is built using a kernel function that has the best fitting hyperplane [7] [20]. In the current work, Triple SVM is used for multi-class classification, which helps in preventing the loss of information where class data is considered against each of the other classes. Further, Triple SVM achieves better performances in the IQ-OTH or NCCD dataset, because it minimizes the inter-class and maximize the intra-class. The linear classifier is depends on the linear discriminant function

$$f(F_{ea})$$

which is expressed in equation (6).

$$f(F_{ea}) = w^T F_{ea} + b - - - - > (6)$$

Where,  $w$  is the weight vector and  $b$  is the bias value.

Building the model involves classifying the images into normal, benign, or malignant cases. The classification algorithm named SVM has been employed as the technique to be carried for the current phase [14] [21] [22]. The dataset is split into train and test sets. The classification is achieved by optimal separating hyperplane. The data after feature extraction is fed to the SVM kernel function as input. The model is built using a polynomial SVM kernel.

#### IV. RESULTS AND DISCUSSION

The proposed system is implemented using Google Co-lab software (<http://colab.github.io/posts/>). The model is trained for 100 iterations and achieved an accuracy of 96.5%. The f1-score for normal, Benign and Malignant cases are 0.92, 1 and 0.93, respectively. It is likely to achieve validation accuracy of over 99% when the number of iterations is increased by 300 epochs. Table I and Fig. 9 shows the classification report and accuracy plot of triple-SVM, respectively.

TABLE I. CLASSIFICATION REPORT

	Precision	Recall	f1-Score	Support
Normal Cases	1.00	0.86	0.92	7
Benign Cases	1.00	1.00	1.00	7
Malignant Cases	0.88	1.00	0.93	7
Accuracy			0.965	21
Macro Avg	0.96	0.95	0.95	21
Weighted Avg	0.96	0.95	0.95	21

**Algorithm 1 Region Random Segmentation Algorithm**

- Step 1:** The lung CT is uploaded as the input image.
- Step 2:** The coordinate of the lung(left and right) is specified.
- Step 3:** Contrast enhancement is done so that the lung region can be easily extracted.
- Step 4:** The threshold value is considered as a 20% gray threshold of the entire image.
- Step 5:** The seed value to be selected for both lungs and a point value which is the neighboring pixel is considered.
- Step 6:** The point value is verified against seed value and threshold value and repeatedly moved across the pixel till it reaches edges.
- Step 7:** A graph represented with edges and vertices is extracted from the resultant lung image on which edges are the relationship between pixels and vertices are the image pixels.
- Step 8:** To do nodule localization and for the lung region representation two seed points are user defined.
- Step 9:** Differences in intensity between the pixels which are unlabelled are being computed by utilizing the euclidean method distance as the seed point.
- Step 10:** Gaussian weight computation and normalization of resultant value.
- Step 11:** Gaussian weighting function used by seeded pixels of lung region and the reached nodule by the probability of walking across each pixel by computation two probabilities with the help of 2 predefined pixels.
- Step 12:** The maximum probability ( $p_n > p_l$ ) pixel will be selected as nodule pixel and label that pixel from the vector of probabilities.
- Step 13:** Nodule representation as the region is separately considered as nodule label pixels to segment.

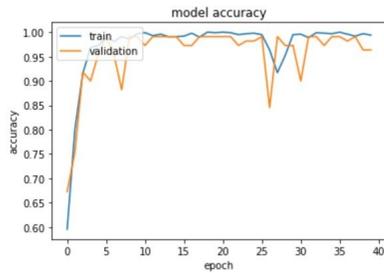

Fig. 9. Accuracy Plot of Triple-SVM Model (300 Epochs).

For classification, 80% of the data is used for training, while the remaining 20% of the data is used for testing. The correlation matrix for the classification accuracy is shown in below Fig. 10.

Table II displays the study of the proposed RRS and triple SVM model’s results in relation to the suggested segmentation methodology, variation with various feature extraction methods, and region-based segmentation. Utilizing triple SVMs, the suggested RRS together with selected features from SIFT and GLCM provided higher accuracy of 96.5%. However, when the background has a comparable texture, the segmentation using standard region growth is compromised. Next, little modifications to the input data have an impact on the classification performed using decision trees.

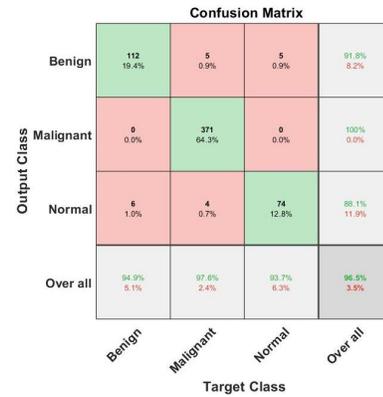

Fig. 10. Correlation Matrix.

TABLE II. RESULT ANALYSIS

Methods	Result Obtained
Particle Swarm Optimization, Genetic Algorithm, SVM	Accuracy : 89.50%
K-NN Classification using Genetic Algorithm	Accuracy : 90%
Artificial Neural Network Approach	Accuracy : 90%
Region Growing Approach with GLCM and Decision Trees	Specificity : 68% Sensitivity : 70% Accuracy : 69%
Region Growing Approach with GLCM and Triple SVM classifier	Specificity : 90% Sensitivity : 93% Accuracy : 89%
Region Growing Approach with SIFT, GLCM and Decision Trees	Specificity : 85% Sensitivity : 84% Accuracy : 93%
Region Growing Approach with SIFT, GLCM and Triple SVM classifier	Specificity : 91% Sensitivity : 87% Accuracy : 96.5%
Proposed Segmentation RR algorithm with SIFT, GLCM and Triple SVM classifier	Specificity : 94% Sensitivity : 89%

The comparative analysis of RRS with Triple SVM with existing researches such as TL-VGG 16 (Humayun *et al.* [16]), TL-VGG 19, TL-Xception and SVM (Kareem *et al.* [14]) are shown in the Table III. From the Table III, it is concluded that the RRS with Triple SVM achieves better results than the TL-VGG 16 (Humayun *et al.* 2022), TL-VGG 19, TL-Xception and SVM. But, the proposed RRS is used to perform precise segmentation of lung tumor portions which leads to improve the classification using triple SVM. The capacity of handling higher dimensional spaces of triple SVM is used to increase the classification accuracy.

TABLE III. COMPARATIVE ANALYSIS

Methods	Accuracy
TL-VGG 16[16]	83.39 %
TL-VGG 19 [16]	80.97 %
TL-Xception[16]	89.68 %
SVM [14]	89.88 %
RRS with Triple SVM	96.5 %

Table III shows the comparative analysis of various methods. RRS with Triple SVM has been compared to previous researches such as, TL-VGG 16, TL-VGG 19 and TL-Xception [16], and SVM [14]. This comparison is given in Table III. According to Table III, the RRS with Triple SVM outperforms the existing TL-VGG 16, TL-VGG 19, TL-Xception and SVM in terms of accuracy (96.5%). Also, the exact segmentation of lung tumor sections were carried out using the proposed RRS which enhances the classification using triple SVM. Triple SVM's ability to handle greater dimensional spaces is employed to improve classification accuracy.

From the overall analysis, the classification is improved by the precise segmentation of lung tumor sections which is carried out utilizing the proposed RRS. To increase classification accuracy, Triple SVM is used because of its capacity for handling higher dimensional spaces. The recommended RRS and a few SIFT and GLCM features combined with triple SVMs produced a greater accuracy of 96.5%. Further, the proposed RRS with Triple SVM was evaluated with existing models such as TL-VGG 16, TL-VGG 19, TL-Xception and SVM in terms of accuracy. From that study, it clearly shows that proposed RRS with Triple SVM has achieved higher accuracy of 96.5%.

## V. CONCLUSION

A lung cancer detection and classification model is built using an effective segmentation and triple SVM classifier. The CT scan images are preprocessed and segmented to obtain the cancerous nodules in the lungs. The features are extracted using SIFT and GLCM. The input is then fed to triple SVM classifier with SIFT and GLCM extracted features. The classification accuracy of lung tumor is enhanced based on precise segmentation achieved by RRS. The triple SVM is trained for 300 epochs initially and achieved an accuracy of 96.5% with 200 clusters. If the cluster size is increased to 500, then the model achieves more accuracy. The technique can be enhanced by using multiple algorithm comparisons as well as incorporating deep learning algorithms into this dataset. The proposed methodology can also be implemented using different lung cancer datasets to study the efficiency of the proposed methodology. The prediction accuracy of the proposed model can be varied according to the number of epochs, clusters, and varying preprocessing feature extraction used in building the SVM model. However, the proposed RRS with triple SVM doesn't predict the size of affected portion and classify the supplementary abnormality of tumor. Therefore, the future work involves identifying the volume of the lung and classifying it with any other abnormality and also identifying the thoracic tumor.

# Optimized Automatic Course Timetabling Service Architecture for Integration with Vendor Management Systems

Marwah M. Alansari

Department of IT, College of Computing and Informatics  
Saudi Electronic University,  
Riyadh, Saudi Arabia

**Abstract**—Generating university course timetables is a complex problem, especially in large environments such as institutions. Currently, some universities in Saudi Arabia manually generate timetables for classes because they use Vendor Management Systems (VMS) for registration and management. Manually generating course timetables is time-consuming and laborious for the academic staff. Although various methods have been proposed to generate timetables, they address specific environments or systems that can be extended to or work as separate components of the university management system. In this paper, we propose a service-based system with a decentralized architecture that can fully automate the process of course timetable generation and can be easily integrated into VMS. The proposed service-based system employs a genetic algorithm to optimize the process of scheduling courses and generating timetables. The system was implemented using JAVA RESTful web services, and the algorithm was tested by generating various course timetables with various constraints. The results showed that the proposed decentralized architecture is applicable to and can be fully integrated with any VMS. Furthermore, the use of genetic algorithm set up to 200 generations and iterate 1000 times produces acceptable timetables without violating any of the defined constraints.

## I. INTRODUCTION

Some universities in Saudi Arabia use vendor management systems (VMS) such as Banner [1] to enroll and manage students. The main architecture of a VMS constitutes a database management system deployed on the server side and a web portal for accessing the system from the client side. However, a VMS implements only common generic requirements related to registration and management processes. Therefore, such systems can only function for general use cases, such as publishing, presenting, and manipulating student timetables. Currently, university vendor management software cannot consider specific requirements related to course management at universities. Examples of these requirements include the registration and timetable generation processes, which typically comprise many essential periodic tasks that have been performed manually thus far. Although extensive studies by artificial intelligence (AI) communities and operational research have focused on performing timetable generation through various algorithms [2] [3], VMS developers have not considered applying automatic algorithms to their systems for handling specific tasks. Extending and implementing specific

tasks lengthens the development process and makes it costlier. Although such systems are being continuously developed, it is still costly to implement the specific cases and scenarios required by universities to automatically generate complete course timetables. Therefore, most universities prefer using VMS to perform general tasks and manually perform specific tasks.

Universities are encouraged to apply digital transformation and use AI solutions to reduce repetitive processes and move toward their complete automation. We discovered that generating course timetables is one of the repetitive, costly, and time-consuming tasks. Generally, generating university course timetables is considered complex and categorized as an NP-hard problem. This means that they entail exponential growth in search time and effort, wherein the problem factors such as the number of courses or students increases in size [4]. Therefore, we must pursue heuristic approaches that can handle different numbers of constraints, both hard and soft, that can vary from one institution to another. Thus, the objective of this study was to fully automate the process of preparing and allowing students to register on a timetable. This process is performed by generating the term timetable using heuristic approaches, which are elucidated in this study.

We encountered another characteristic of the generic architecture of VMS: they have a centralized architecture that primarily depends on a centralized database management system. By contrast, universities comprise several colleges, each of which comprises several departments. Therefore, a centralized architecture can result in various performance and availability problems, and the staff is unable to automate or enhance the registration process effectively. This research motivation is to improve and fully automate the registration process by overcoming the following two essential challenges:

- 1) Creating a service-based system that can be deployed in the form of decentralized architecture.
- 2) Designing and implementing an algorithm to generate course timetables effectively.

The structure of the paper is as follows. Section II includes a brief background of service-oriented architecture (SOA) and genetic algorithms (GAs). Section III covers related research on auto-generating university timetables. Section IV presents description of the problem. Section V contains an explanation of the proposed solution and introduces the design of the

proposed service-based automatic timetable generation architecture. Section VI presents the proposed GA design. Section VII describes the implementation of the architecture and the proposed GA. Section VIII discusses the results, figures, and findings, and Section IX presents our suggestions for future research directions and conclusions.

## II. BACKGROUND

SOA is a design paradigm employed to support distributed business applications, whereas a GA is an evolutionary algorithm that can be applied to solve optimization problems. In this section, we present a brief background of both SOA and GAs and the methods applied in our research.

### A. Service-based System

The concept of SOA is applied to engineering business processes within large distributed systems. It ensures that a system has various characteristics, such as being interoperable, service-based, loosely coupled, usable, and fault-tolerant [5]. In an SOA, services are considered self-contained logical functionalities and designed through web services [6]. Furthermore, the backgrounds of the services can be encapsulated in different programming languages, wherein the service client only uses the description for the service without any knowledge of its implementation. There are two types of web service implementations: simple object access protocol (SOAP) and representational state transfer (REST). Another feature of the SOA is that it can provide an enterprise service bus (ESB), which is an infrastructure that enables high interoperability between deployed distributed services. ESBs are managed through business processes. The final feature of SOAs addressed in this section is loose coupling. SOAs enable delivering a service-based system with a reduced number of dependencies [5] [6]. It is important to remember that a single service can offer various capabilities grouped together if they relate to a functional context established by the service [6].

In an SOA, a distributed system is designed and built based on a basic software engineering concept: the theory of concerns. The strategic goals associated with service-oriented computing services indicate their purpose and capabilities through a service contract [6] that emphasizes the positioning of services as enterprise resources within agnostic functional contexts. Numerous design considerations have been proposed to ensure that individual service capabilities are appropriately defined based on an agnostic service context utilities are appropriately defined in relation to an agnostic service context [5].

The two common implementations of services are REST and SOAP. The REST service is required to identify resources that include one or more representations, either expected or provided, an address to uniquely locate the resource, a set of HTTP methods exposed at the interface-level metadata included in headers for requirements such as security tokens or caching information, and a REST-based service interaction. Standard HTTP methods are used in conjunction with HTTP response codes to establish a communication framework based on a uniform contract that can invoke service capabilities and communicate success, failure, and error conditions [6]. Resources that represent a resource in JavaScript object notation

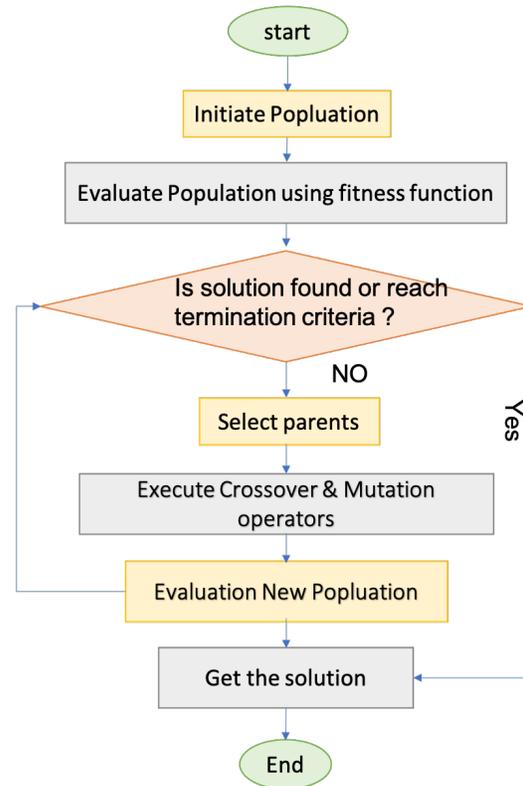

Fig. 1. General Steps of a Genetic Algorithm [7].

(JSON) can be considered as an alternative. In JSON, data are described in the name-value format [6].

The specific method of encoding data “on the wire” and passing them among services is captured in SOAP services. In a SOAP service, both service requests and responses are encoded into XML documents [6]. SOAP-based web services rely heavily on the web services description language, which provides a method of expressing the service contract as a collection of operations with corresponding request/response messages [6].

### B. Genetic Algorithm

GAs are evolutionary algorithms proposed by Holland in 1975 and recommended for solving optimization problems by Goldberg in 1975, who later suggested in 1989 that they can be used for solving optimization problems [7]. GAs are based on the Darwinian principle of the survival of the fittest among animals exposed to predators and environmental threats. The fittest entities are those that can adapt to evolving conditions, and their offspring inherit their characteristics and learn their skills, resulting in the creation of the best possible future generations. Furthermore, genetic mutations occur randomly among members of the same species, and some of these alterations may enhance the long-term stability of the superior individuals and their evolutionary offspring [8]. of the parent population that comprises surviving individuals (chromosomes) from previous generations and their offspring. The offspring, which represent new solutions, are generated through genetic operators such as crossover and mutation.

Parents that are selected to produce a new generation are those whose probability of selection is proportional to their fitness values. The higher the fitness value, the better the chance of surviving and reproducing [7] [8]. The algorithm begins with randomly generated initial population solutions, and the generated population gradually improves over time. It uses special criteria to select optimal individuals, who are then used to produce offspring. Offspring are generated using crossover and mutation operators [7] [8]. Fig. 1 shows the steps of a GA.

### III. RELATED WORK

The generation of university timetables is a well-studied problem in literature. It is considered a complex NP-hard problem owing to the complexity of the university environment. In this section, we describe some algorithms proposed in various studies to address the problem of generating university timetables.

A new version of the simulated annealing algorithm to address the problem of examination timetabling was proposed in [9]. The algorithm employs an acceptance criterion to move a selected exam and assess the moves by evaluating their acceptance through a temperature bin. The algorithm comprises 10 temperature bins to evaluate the number of evaluations uniformly. It uses the crystalized concept, which is assigned to the selected exam, and does not record any future acceptance moves in the temperature bins. It employs saturation degree-based heuristics combined with conflict-based statistics to eliminate the looping effect during initialization [9].

The authors of [10] proposed using particle swarm optimization (PSO) for generating university timetables. Unlike GAs, PSO simulates social behaviors to evaluate solutions. The evaluation is performed by determining the positioning and velocity of each particle by using the fitness value of the selected particle. The algorithm uses an initial step to assign time slots to the exam, whereas the remaining steps are used to assign rooms to time slots and solve exam timetabling problems at universities.

A modified event-grouping algorithm for finding the best solution by ordering events into groups was developed in [11], wherein events and conflicts are presented on an undirected graph. It should be noted that the execution time of the event-grouping algorithm increases when the number of groups increases [11].

The author in [12] proposed using an AI expert system to automatically generate a scheduling system for the course timetable problem. The auto-generated scheduling system was developed such that no conflict could occur among all the input facts, and features were provided to customize the timetable as required. The rule is executed based on the priority and ranking of the constraints. No specific information regarding the designed rule used in the expert system or definitions of hard and soft constraints were provided.

The author in [13], proposed reformulating an existing integer programming model. It employed the XML for high school timetabling (XHSTT) format to formulate a mathematical model of the problem. The authors developed a model for the problem and a set of models to formulate the constraints and operative functions to avoid clashes. The computational

experiments also showed that the integer programming models resulting from the proposed formulation solved most of the instances in the XHSTT model more effectively. However, this algorithm cannot be generalized to other university models [13].

In [14], there is a suggestion to a hybrid method based on the improved parallel genetic algorithm and local search (IPGALS) to solve the course timetabling problem. The local search (LS) approach proposed in this work supports GA. The distance to feasibility (DF) criterion is applied to measure the hard constraints and ensure that they are never violated. The results showed that using DF improved performance for finding a feasible solution. A parallel approach is used to handle a higher number of constraints. The LS and elitism operators were implemented after applying the crossover and mutation operators. Therefore, the major limitation of IPGALS is that it cannot ensure the generation of a feasible timetable for large groups [14].

The author in [15] proposed applying two methods to solve the room-optimization problem in timetable generation [15]. The first method involves two-stage integer linear programming (ILP), which applies lexicographic optimization. The objective is to maximize the number of students seated and then apply it to optimize room allocation. The ILP is suitable for smaller domains; however, the computation time increases for larger domains. A greedy algorithm was proposed to enhance the first approach. The lecturer is assigned to a room based on the computation of the cost function. The objective is to maximize the number of allocated students. Cost function identification enhances the performance of the greedy algorithm [15].

Guo et al. proposed a new algorithm based on the greedy method combined with a GA to solve the course timetabling problem, wherein the greedy algorithm is applied to generate the initial population [16].

In [4], a design and implementation of timetable generation based on GA were proposed using different combinations of selection algorithms and mutation types. The system uses tournament and roulette wheel selections to evaluate two cases and determine the selection technique that provides a better solution. Furthermore, the study also applied a mutation error to determine if it can retrieve a better solution faster. A similar approach was proposed in [17], wherein a GA model was applied to automatically arrange a university timetable and further study the effect of changing the crossover and mutation rates. Their simulation results showed a crossover rate of 0.70, and no hard constraints appeared in the timetable, but the authors did not mention the effect of changing the mutation rate [17].

In [18], a hybrid genetic hill-climbing algorithm with an embedded elitist mechanism was used to solve the lecturer course timetable problem. Hill-climbing optimization was implemented in the mutation phase to enable an LS. Hill-climbing optimization offers fast convergence and the capability to avoid local optima. The algorithm requires a longer time because hill-climbing optimization is frequently used. However, it does not achieve a fitness value of one, which indicates no conflict. It reaches when the population size reaches 80, but the execution time increases significantly [18].

A pragmatic algorithm implementation is presented in [19] to solve the university course timetabling problem. The algorithm was implemented as a web application deployed on the Azure cloud. The system was based on the manual assignment of courses to time slots and rooms. The objective was to engineer a timetable system programmatically as a web-based system [19]. A man-machine interaction system based on modeling the problem. The proposed algorithm uses column-generation heuristics to collect generated timetable columns by employing the relaxed integer programming method. The modeling timetable works for a reasonable number of instances; however, it may face computational complexity at a larger scale [20].

The authors in [21] presented a greedy algorithm combined with a genetic fusion algorithm to efficiently solve the course timetabling problem. It can obtain the local optimal solution using the greedy algorithm, which is efficient for generating the initial population used in GAs. A greedy algorithm includes an adaptive heuristic search combined with an evolutionary search algorithm. The approach was implemented on simulated data with a small population of approximately 20. Therefore, its effectiveness on a larger population must be evaluated and the fitness values must be compared [21].

Automatic timetable generation using GA with dynamic chromosomes was implemented in [22]. The algorithm suggests using a nonfixed chromosome size, which is adjusted according to the number of courses in the department. The algorithm implements the roulette wheel algorithm to select chromosomes. It uses harder and softer constraints to solve the room-allocated-to-time-slot problem. The performance results and implementation process of the algorithm showed that it was ineffective [22].

A hybrid genetic-based discrete PSO algorithm with two LS algorithms, LS and tabu search, was used in [23]. The objective was to enhance the performance for search solutions. The concept of PSO is based on a swarm of birds (particles) that search for food in an open space. Without any prior knowledge of the space, the birds spread and begin their search in a random space, and the position of all particles corresponds to the candidate solution for an optimization problem. Therefore, all particles are assigned a fitness function, which is determined according to the corresponding problem. Even if each particle moves to a new location in the search space, it maintains the optimal local information. Furthermore, each particle maintains its own information, shares information with the other particles, and maintains the best global information. Subsequently, each particle updates its velocity and position to correspond to the optimal local and global information, moves forward to the optimal value, and seeks the optimal solution. Tabu search is used to improve the solution quality after the LS operation is completed. the GA operation is applied (crossover and mutation) to enhance the global search. However, the execution time of the algorithm increases when a complex timetable model is introduced. This algorithm can be used for the room allocation problem [23].

#### IV. THE DESCRIPTION OF THE PROBLEM

The process of generating course timetables is classified as repetitive or periodic. However, we discovered that the

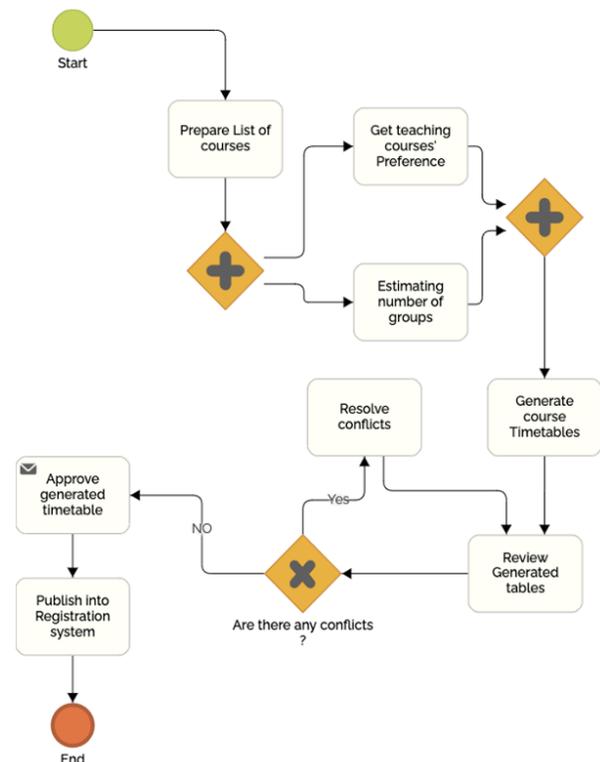

Fig. 2. The Business Process for Generating Course Timetables.

academic departments in some universities in our region still manually generate course timetables. The entire procedure depends on humans playing the primary role in creating and maintaining such timetables.

Fig. 2 shows the framework of business process modeling used to capture the common activities for producing course timetables. The process starts when the staff in a department prepare a list of courses to be taught in the next term. This is followed by collecting course preferences from teaching staff and estimating the number of students who will register for a course. Professors must also be assigned to their selected courses. After the preparation process, timetables are manually generated using spreadsheet software. This process is time-consuming because it requires several review cycles to ensure that timetables do not include any conflicts among groups of students, as shown in Fig. 2. Following the timetable generation step, the faculty administration approves the created course timetables and publishes them on a university course management system with a centralized software architecture.

The student course registration procedures also employ manual processes. It is the students' responsibility to create their entire timetable using the university registration system. At the beginning of each term, students should follow the curriculum plan published by the department after the selected courses are approved by their academic advisers. The student searches for targeted courses and selects a suitable teaching group based on their preferred time slots. If any conflict occurs in time slots, the student keeps changing the teaching groups until a conflict-free timetable is created. We noticed that manually creating and maintaining course timetables re-

sults in serious issues. One such issue is the occurrence of time-slot conflicts among courses, which affects the student registration process. Another problem is the increased number of groups in courses that contain a small number of students, because students have complete freedom to select their desired group at a suitable time slot. Hence, we have observed a misdistribution of student problems, which appears after the registration process is completed. This leads to insufficient resource allocation. After examining these common issues over several years, we conclude that manually generating timetables is time-consuming, laborious, and complex. The process creates stress among staff and students and thus needs to be addressed. Universities use VMS, wherein it is difficult and expensive to include automatic features. Thus, a system that includes optimization methods for timetable generation is required, which can be easily integrated with the registration management system.

## V. PROPOSED SOLUTION

This study aimed to solve the problems mentioned in the previous section by developing a service-based system comprising components responsible for publishing and generating timetables. The service-based approach is characterized by a decentralized architecture that is scalable and sufficient for the architecture used by universities. The system interacts with a university management system only to request data and publish the student and staff timetables it generates. The interaction is achieved through messages/requests and responses using RESTful web services. The data are transmitted in the JSON format. Therefore, the proposed service-based system works as a standalone feature that can be used by university departments. Each department has its own deployed service-based component to generate a timetable. In the next section, we explain service-based architecture in more detail. Furthermore, the proposed solution includes the design of a suitable algorithm for automatically generating timetables. Our objective was to eliminate the number of manual activities performed by the staff. Therefore, we designed a heuristic GA to create a departmental timetable that considers a set of hard and soft constraints. A detailed explanation of the proposed GA is presented in Section VI.

### A. The Architecture of the System

Fig. 3 shows the main components of the automatic service-based system used to generate timetables. The system comprises five main components: a data notification center, notification service, data communication center, data communication service, and faculty autogen timetable service.

- 1) **Data Notification Center:** This component is responsible for broadcasting a scheduled and timed notification to all active notification services. It also receives replies and notification messages from notification services when the timetable generation processes are completed.
- 2) **Data Communication Center:** This is the communication channel between the university management system and the communication service. The communication center is responsible for filtering the requests

for data from the communication services and transforming them into query passed as a message to the university management system.

- 3) **Notification Service:** This is an active component deployed in each university academic department. It is responsible for sending and receiving notification messages from the data notification center.
- 4) **Data Communication Service:** This component filters student and academic staff data and generates a timetable data format to send and receive data from the data communication center.
- 5) **Faculty Autogen Timetable Service:** This is the primary component responsible for automatically generating course timetables based on a set of requirements. It includes a GA to create an optimized timetable. The following Section provides a detailed explanation of this component.

### B. The Architecture of the Faculty Autogen Timetable Service

The component responsible for automatically generating an optimized course timetable comprises various elements, as shown in Fig. 3. The service consists of two components: a **data filtering service** and **timetable generator**. The **data filtering service** handles received and sent data and is composed of three separate entities: course description filtering, department student filtering, and assigning student and faculty timetables.

- 1) *Course Description Filtering:* This entity is used to store the program course plan. The department can add courses, course details, and any updates regarding the program plan. The courses and plans are stored as JSON files.
- 2) *Department Students Filtering:* All the student data required to generate a timetable is received from the university management system database through the data communication service and filtered in this component. Filtering is required to determine the courses that students are expected to register for in the next term. Additionally, the component generates groups of students expected to opt for a course in the next term.
- 3) *Assigning Students and Faculty Timetable:* This component is responsible for assigning each student and academic staff member a timetable after the general timetable generated by the timetable generator component is approved.

The second component of the faculty autogen timetable service is a **timetable generator**. This is an essential service that creates an optimized course timetable. As shown in Fig. 4, this service comprises the following five entities:

- 1) *Department Criteria and Hard and Soft Constraints Configuration:* This entity configures the algorithm parameters, as well as the hard and soft constraints used in the customized scheduling algorithm.
- 2) *Customized Scheduling Algorithm:* This entity is the core of the timetable generator. It includes the implementation of the GA used to generate the expected timetable for the specific teaching plan of a department. Section VI describes the design of the GA in detail.

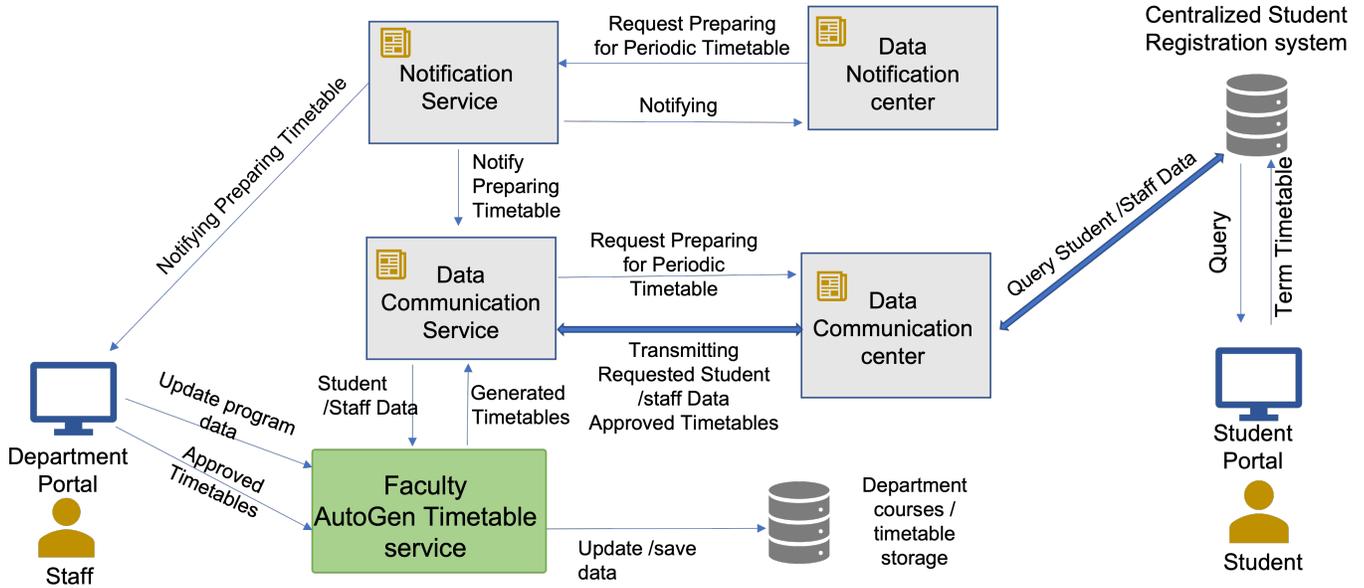

Fig. 3. The Architecture of the Service-Based System for Auto-Generating Course Timetables

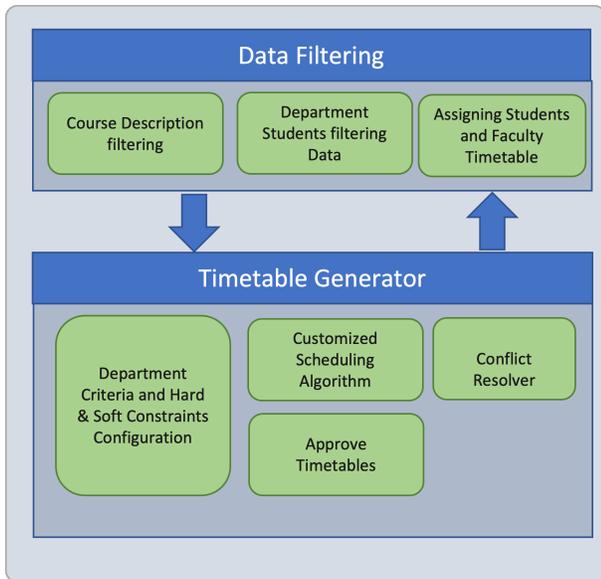

Fig. 4. The Architecture of the Faculty AutoGen Timetable Service

- 3) *Conflict Resolver*: This component runs if the timetable generator is suitable for the department but contains several soft constraints that are violated. It allows for manual resolution of timetable conflicts.
- 4) *Timetable Approval*: This component obtains approvals of the generated timetables and divides them into sub-timetables based on the level to which they can be suitably applied.

## VI. GENETIC ALGORITHM DESIGN

This section explains the design and implementation of the GA in detail. Before presenting the designed algorithm, it is

necessary to mathematically model the operating environment. Furthermore, we are required to extract the possible hard and soft constraints required for optimization.

### A. The Courses Timetable Mathematical Model

We mathematically modeled the courses timetable problem based on the common requirements and environments of our universities as follows :

A teaching program of a department was divided into levels. These levels comprised a set of courses. During the autumn term, all odd levels are taught, whereas during the spring term, even levels are taught. For simplicity, the summer term or special cases were not included. These levels are denoted as  $L = \{l_1, l_2, l_3, \dots, l_n\}$ .

Any level  $l_i$  includes several courses  $C = \{c_1, c_2, c_3, \dots, c_m\}$ , and student groups  $G = \{g_1, g_2, g_3, \dots, g_k\}$ . Additionally, there should be no more than three groups per level. Any course  $c_i$  has one or more and no more than three sessions per week. Therefore, the sessions are denoted as  $S = \{S_1, S_2, \dots, S_l\}$ . Moreover, two types of sessions were defined, theoretical and practical, based on course type and number of teaching hours. Any course  $c_i$  is associated with teaching professor  $tp_i$ . The teaching professor  $tp_i$  who was selected from  $TP = \{tp_1, tp_2, \dots, tp_k\}$ .

The environment model can be summarized as follows:

- 1) Any teaching program comprises a set of levels as follows:

$$L = \{l_1, l_2, l_3, \dots, l_n\} \quad (1)$$

- 2) Any level  $l_i$  has several courses and groups of students and is associated with a teaching professor as

follows:

$$\begin{aligned} C &= \{c_1, c_2, c_3, \dots, c_m\} \\ G &= \{g_1, g_2, g_3, \dots, g_k\} \\ TP &= \{tp_1, tp_2, \dots, tp_r\} \end{aligned} \quad (2)$$

3) Any course  $c_i$  has one or more sessions as follows

$$\begin{aligned} S &= \{S_1, S_2, \dots, S_l\} : l \leq 3 \\ s_i &= \textit{Theoretical} \textit{ or } s_i = \textit{Practical} \end{aligned} \quad (3)$$

We want to emphasize that the algorithm proposed in this study does not consider the allocation of lecture rooms. This will constitute a further step in the system in the future, or will be handled as a separate problem. The existing timetable algorithms discussed in Section III consider room allocation to be an essential part of the course timetable allocation algorithm. However, in our case, room allocation always occurs after a suitable timetable is generated. Furthermore, our algorithm contains some factors related to building management, for which course timetables with courses and time slots assigned must be generated first.

### B. The Hard Constraints

To create a suitable timetable, we defined a set of hard constraints that must be satisfied and a set of soft constraints that should not be violated. We denoted the set of hard constraints as  $H$ . The teaching professors and groups of students are defined as follows:

- 1) A teaching professor,  $tp_i$  must not teach two different courses in the same time slot on the same day.
- 2) A group of students  $g_i$  must not be assigned two different courses at the same time slot on the same day.
- 3) A group of students must not have two sessions of the same course on the same day. This condition has also been applied to the teaching professors assigned to the course.
- 4) Teaching professor  $tp_i$  who is an assistant professors or above, should have at least one day off.
- 5) Group of students  $g_i$  must not have more than six hours of theoretical lectures per day.

### C. The Soft Constraints

A finite set of soft constraints  $S$ , which incur a small weighted plenty value when violated, is defined.

- 1) Teaching Professor  $tp_i$  might prefer to start the day in the morning or afternoon, according to their conditions.
- 2) Any practical session  $s_i \in P$  for a course  $c_i$  can be started in the late morning time slot.
- 3) A group of students  $g_i$  should not have a gap longer than two hours between lectures.

### D. Objective Function

The optimization problem is to maximize the assignment of all available classes to the sets of defined time events, sections, and teaching professors to assign the maximum number of

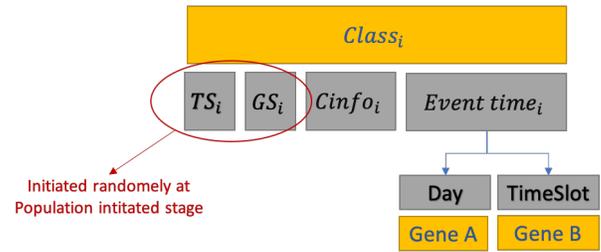

Fig. 5. Class Representation.

courses possible from the preferred list. It can be expressed as:

$$f(x) = \textit{Maximize} \sum_{i=1} \textit{Classes}_i \quad (4)$$

The following are the defined decision variables:

- 1)  $v_1$  = event day
- 2)  $v_2$  = event time slot

### E. The Algorithm Design

A GA must contain chromosomes. To encode chromosomes with a course timetable, a set of classes must be generated. Using the mathematical model, specific courses and sessions at each level are defined as described in Section VI-A, and a set of targeted classes is formulated and denoted as  $Classes$  as follows:

$$\textit{Classes} = \{\textit{class}_1, \textit{class}_2, \textit{class}_3, \dots, \textit{class}_m\} \quad (5)$$

Fig. 5 shows the class representation and its formulation. As shown in the figure, any  $class_i$  is assigned a teaching professor  $TP_i$ , a group of students  $g_i$ , a type that can be theoretical or practical, and a duration  $d_i$ . Additionally,  $class_i$  such as course name and number. The class type, duration, and other details are combined into class information  $Cinfo_i$  as shown in Fig. 5. Moreover, these classes must be allocated to a particular time event. A time event includes assigning one of the five working days and a time slot,  $ts = \{t_{start}, t_{end}\}$ .

The algorithm starts with an initialization stage, where in objective is to determine the number of student groups and generate the classes possible, including sessions. Furthermore, the initialization step entails assigning teaching staff to the classes. The selection of teaching staff is based on the ranking obtained from the preference table. Based on this knowledge, a vector class that comprises all classes that can be taught for all programs at all levels is generated, as shown in Fig. 5 .

The GA must allocate the day and time slots for each class in the vector class without violating the hard constraints and no or minimum violation of the soft constraints. After formulating the real class timetable model, the chromosome and genes used in the algorithm must be formulated, as explained in the following section.

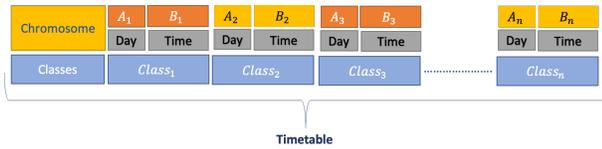

Fig. 6. The Chromosome Representation.

### F. The Chromosome Representation

As shown in Fig. 6, a timetable comprises a set of classes and a chromosome. The chromosome contains a vector consisting of genes. There are two types of genes. The first, denoted as  $A_i$ , contains a numerical integer that represents the day of a week. The second, denoted as  $B_i$ , is a collection of two numerical values representing the time slot. The time slot represents the start and finish times of a class. Chromosome length is twice the class vector length, which is calculated as follows:

$$chromosome_{length} = \sum_{i=0}^n Class_i * 2 \quad (6)$$

### G. The Fitness Function

It is important to include a fitness function in the GA because it is used to measure the accuracy of a specific solution. In our case, a good solution should have a fitness value of one, which indicates that the generated timetable does not violate either the hard or soft constraints. Thus, the fitness value is computed as follows:

$$fitness = \frac{1}{(\sum_{i=1}^n \omega_i V_{hard} + \sum_{j=1}^m \sigma_j V_{soft}) + 1} \quad (7)$$

Both  $V_{hard}$  and  $V_{soft}$  represent the violations of hard and soft constraints, respectively, occurring in the solution.  $\omega$  and  $\sigma$  denote the penalty weights associated with the hard and soft constraint violations, respectively. Any violation of the hard constraints is assigned a larger weight, whereas that of the soft constraints is assigned a lower weight.

### H. Parent Selection and Genetic Operations

Crossover and mutation are the two basic operators of GAs. We used a uniform crossover and uniform mutation, as shown in Fig. 7 and 8, respectively. The crossover operation continues throughout the population and employs the parent selection process, which is based on the tournament selection technique [7] [24]. After parents with effective fitness values are selected, crossover is performed on them. Half of the genes from each parent are randomly selected to generate new offspring. Fig. 7 shows an example of a crossover operation, wherein genes are randomly selected from chromosome parents 1 and 2. In this example, the first gene, which represents the day for class 1, is obtained from parent 2, whereas the time slot is obtained from the time-slot gene of parent 1. We want to emphasize that the class ordering is similar for both parents. Thus, we ensured that no conflicts occurred. If the chromosome does not go through crossover, it will be inserted directly into the new population.

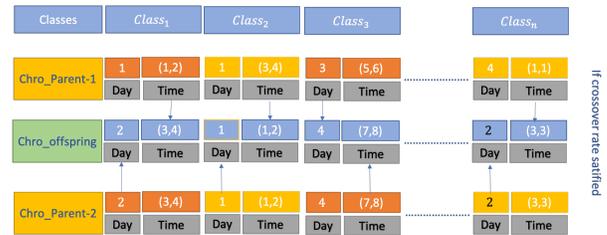

Fig. 7. Representation of the Crossover Operation.

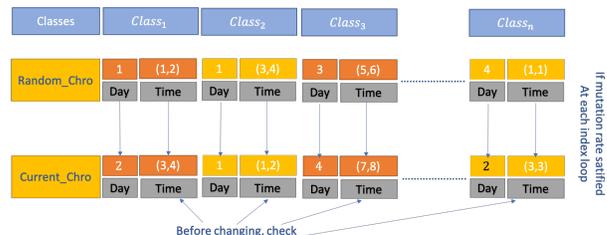

Fig. 8. Representation of the Mutation Operation.

The elitism method was applied to ensure that the best solution from the old population was not lost and the GA was optimized between class duration when the time slots are changed. If the chromosome does not undergo crossover, it is inserted directly into the new population. This method allows individual chromosomes with the best fitness values to be kept unaltered and moved to the next generation. However, we retained only a small number of elite chromosomes compared with the population size and controlled the value using the elite window size.

For the mutation operation, we used the value of mutation rate. When satisfied, a chromosome that allocates the days and effective time slots for the intended classes. The gene values of the chromosome selected for alteration were then replaced with the values generated by the random chromosome. Fig. 8 an example of replacing the gene values of the chromosome selected for mutation with those of a randomly generated chromosome.

## VII. IMPLEMENTATION AND EXPERIMENTS

The designed GA was implemented as an application programming interface (API) written in JAVA programming language. The API can be integrated into services that can be easily integrated into any university management system. The course, staff, and student data were included in a JSON file, which enables easy transmission to and from the university management system. All system components were implemented as RESTful web services when deployed on a docker container. They include the faculty autogen timetable service, data communication service, notification service, data notification center, and data communication center. However, a more challenging problem is the implementation of a customized scheduling algorithm, which depends on the GA implementation, as explained in Section VI. Therefore, this component was constructed as a standalone JAVA program for testing and experimentation, as explained in the following section. After the experiments, the program was transferred

TABLE I. THE EXPERIMENTS' CONFIGURATION

Tests	Timetable Parameters				Algorithm Parameters					Tests #
	Courses #	Level #	staff #	Groups	Population Size	Crossover Rate	Mutation Rate	Elite #	Elite Size

into a module included in timetable generator APIs. The following subsection explains the experimental environment and configuration.

#### A. The Experiment Environment

A MacBook Pro laptop with a 2.8 GHz Quad-core Intel Core i7 processor and 16 GB RAM was used. During the testing process, all ineffective processes were terminated. A tool was integrated within the API to measure the execution time of the algorithm and record the time required to obtain a solution. Furthermore, the algorithm was configured to enforce termination if it reached 1,000 generations without finding a solution.

#### B. The Configuration for Experiments

The objective of the experiment was to determine the ideal settings for the algorithm parameters (population size, crossover rate, and mutation rate) that are suitable for creating a course timetable without violating either hard or soft constraints. Furthermore, we wanted to assess the impact on the algorithm performance when the number of student groups increased. Therefore, we focus on the following two special impacts:

- 1) Factors that might affect the algorithm if the number of soft and hard constraints increases.
- 2) The extent to which an increased number of student groups might affect the execution time of the algorithm.

The experiment was divided into four sub-experiments: Experiments 1, 2, 3, and 4, each of which comprised 12 tests. Each test assumed a population configuration and tested few constraints. For example, in Test 1, Experiment 1 assumed a population size of 100 and tested eight constraints (five hard and three soft), whereas in Test 2, Experiment 1 assumed a population size of 100 and tested six constraints (five hard and two soft). The same process was followed for all the tests in each experiment. Each test was performed 15 times to ensure the accuracy. Experiment 1 assessed the execution time and average of conflicts when the mutation and crossover rates were fixed at 0.01 and 0.7, respectively, with respect to the changes in population size and the numbers of soft and hard constraints. We selected population sizes of 100, 150, 300, and 500; 3, 2, and 0 soft constraints; and five hard constraints. The experimental configurations are listed in Table I.

Experiments 1 and 2 aimed to measure the execution times and average conflicts when the mutation and crossover rates were set at 0.01 and 0.7, respectively. Both experiments included four tests, each of which was used to examine the effects of different population sizes and configurations of the number of soft constraints. Each test was performed 10 times. The difference between Experiments 1 and 2 was the number of students groups: Experiment 1 was performed with each level containing only one student group, whereas Experiment 2 was performed using various numbers of student groups, where the three levels contained two student groups. Experiments 3 and 4 followed a similar strategy as the first two experiments, but the mutation and crossover parameters were changed to 0.1 and 0.5, respectively. The objective was to determine the effect on the execution time and average conflicts when this conflict rate was used and the population size was changed. In the final two experiments, we focused on the effect on execution time and conflict rate if the number of courses was increased from 21 to 30 (a major effect on the increasing number of courses). Both experiments were performed using two population sizes, 100 and 200, and changing the number of soft constraints.

## VIII. RESULTS AND DISCUSSION

After conducting the experiments described in Section VII, we measured the average execution time and the average number of conflicts with either hard or soft constraints. The results of all four experiments are shown in Fig. 9 and Fig. 10. Fig. 9 contains four subfigures that show the average execution times in milliseconds for all experiments, whereas Fig. 10 contains four subfigures that show the average numbers of constraint conflicts that occurred in the experiments.

Fig. 9a and Fig. 9b show the average execution times of Experiments 1 and 2, respectively, indicating that the average overall execution time of Experiment 1 was lower than that of Experiment 2. Both experiments were performed using crossover and the mutation rates of 0.7 and 0.01, respectively. The main difference in Experiments 1 and 2 was the number of student groups. In Experiment 1, each level contained only one

student group for each teaching course, whereas in Experiment 2, the number of student groups in each course varied. Hence, the algorithm required a longer execution time to obtain a solution. Additionally, an increase in the number of hard and soft constraints affected the execution time.

Fig. 9a shows the effect of increasing the population size and number of tested hard and soft constraints on the execution time. In Case A, the execution time resulted from testing five hard and three soft constraints; in Case B, it resulted from testing five hard and two soft constraints; and in Case C, it resulted from testing only five hard constraints.

For sub-figures Fig. 9b - 9d, we observed that the execution time for the path in Case C1 was lower than those for both Cases A1 and B1. The execution time for Case A1 path was the longest, whereas that for Case B1 was between those of the others. Looking deeply in Fig. 9b, the execution times were longer in the paths shown in these figures because the number of student groups and crossover and mutation rates were changed. Currently, we have determined that the algorithm execution time is affected by an increase in the number of tested constraints. However, if five hard constraints are considered to not have been violated, the average algorithm execution time can be maintained below 30 ms in all sub-figures. In Fig. 9c and Fig. 9d, execution time for the Case C paths was less than 100 ms, owing to the alterations in the algorithm parameters.

We observed that the execution time was affected when the population and the number of tested constraints were increased. Regarding the execution paths of Cases A1-A4 shown in Fig. 9a - 9d the execution time increases dramatically when the population exceeded 300. Thus, we conclude that if the population is set at 500, the algorithm would not obtain effective results in terms of time execution. In fact, it will take approximately 1,000 ms, as shown in Fig. 9a and close to 4,500 ms if the number of student groups is increased, as shown in Fig. 9b. These results would not be affected if the crossover and mutation rates were changed; the execution time for a population of 500 could be above 3,000 ms for a single student group in each course, as shown in Fig. 9c, and can reach over 12,000 ms for various numbers of student groups, as shown in Fig. 9d.

Therefore, it can be determined that the algorithm can generate the best results if the population size is set between 100 and 150 with single or varied number of student groups. This result can be maintained even if both the crossover and mutation rates are changed. Furthermore, the algorithm can produce effective results if a lower number of constraints is maintained, close to five. Furthermore, we assume that the algorithm can generate a reasonable solution if the number of constraints is set to six. However, if the number of constraints is set to eight or more, the algorithm can execute within a reasonable time if the population rate is maintained between 100 and 150, which will reduce the search time.

The conflict rates shown in Fig. 10 for each course are lower than those for the various numbers of student groups assigned to each course. The average number of conflicts shown in Fig. 10a is lower than those in the other figures. We observed that, if the population size was set to 100, the algorithm generated a solution without violating any of the

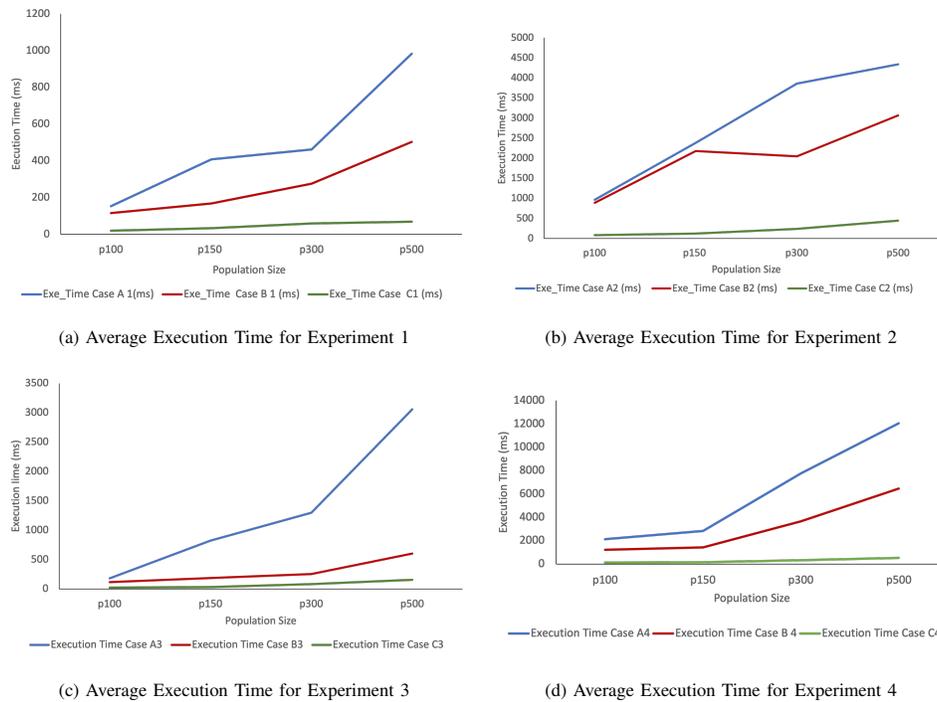

Fig. 9. The Average Execution Time in Milliseconds for All Performed Experiments Experiment 1, Experiment 2, Experiment 3 and Experiment 4

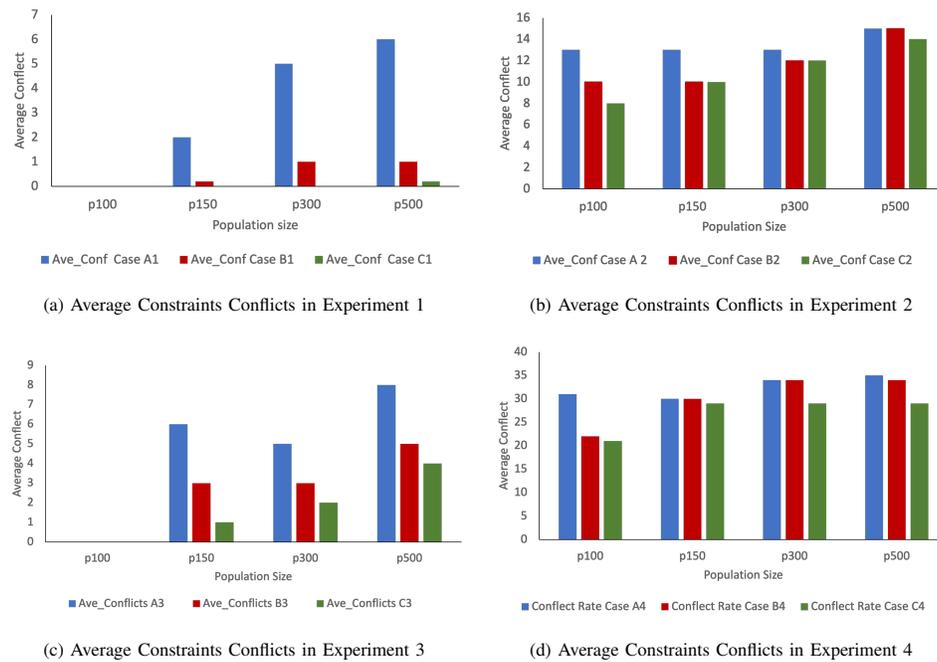

Fig. 10. Averages of Hard / Soft Constraint Conflicts in All Experiments Performed

eight tested constraints. Furthermore, relatively lower number of conflicts can occur if the number of violations is between zero and two. This could have occurred if the population size was 150

and there were six to eight tested constraints. We observed that if the number of tested constraints was five,

there would be no conflicts. A similar result was obtained by setting the population sizes to 300 and 500. We observed that conflicts appeared six or more constraints were applied, and the number of conflicts were higher than those when the population size was set to 150. Thus, we can conclude that the algorithm can produce effective results if the population size is

set to 100, even if the numbers of courses and staff increase. Furthermore, the algorithm would obtain a reasonable result when the population size was set at 150.

The conflict rate results shown in Fig. 10b were used to test the violating number of student groups using similar settings for crossover and mutation rates, as shown in Fig. 10a. We observed that the conflict rate appeared for all quantities of tested constraints. For example, while examining the conflict rate for a population size of 100, the average number of conflicts for testing five constraints was close to eight. If the number of tested constraints was between 6 and 8, the conflict rate was between 10 and 14. Nevertheless, when the population was set at 150, the conflict rate was higher than when it is set at 100. Similar results were obtained when the number of tested constraints was five and above. As shown in Fig. 10b, if the population size is set at 300 and 500, the conflict rate for all the tested constraints is between 12 and 16. Therefore, for a situation wherein various numbers of student groups are tested, a good result can be obtained if the number of tested constraints is maintained at five or lower for a population size of 100. However, the algorithm must be improved to handle various situations more effectively by partitioning the search for each level. However, this requires further investigation and will be addressed in a future study.

The final test involved changing the crossover and mutation rates, as shown in Fig. 10a and 10c. By comparing the results shown in Fig. 10a and 10c it can be observed that there the conflict rates did not differ if the population size was set at 100 in both situations. However, the conflict rate shown in Fig. 10c is higher than that in Fig. 10a.

To summarize our findings:

- 1) The effective population size that will lead the algorithm to produce results without any violation of the constraints and with minimum execution time is 100, and the crossover and mutation rates are set at 0.7 and 0.01, respectively. This occurs even if both the courses and the number of teaching staff are increased at each level. However, we aim to make the algorithm work with more constraints, especially user-defined constraints. This requires further improvement, which will be the subject of future study.
- 2) We also discovered that if the number of student groups is increased at each level, the execution time and conflict rates increase significantly. To handle more student groups at each program level, we will develop a partitioning process for inclusion within the proposed algorithm, which will be executed only if more groups need to be allocated. However, this also requires further investigation.

## IX. CONCLUSION

In this study, we looked at the problem for manual generation for courses timetable at universities that uses Vendor Management System (VMS) as centralized system for course registration. To solve the problem, we proposed a decentralized automatic course-timetable-generation service architecture uses Genetic algorithm as a core for generating courses timetable. The system can easily be integrated into university

management systems. The architecture comprises several components: a data notification center, data communication center, notification service, and faculty autogen timetable service. The faculty autogen timetable service comprises several components, of which an essential component is customized timetable generation, which implements using Genetic Algorithm. The proposed decentralized software architecture in the paper can handle scalability issues introduced by integrating architecture with universities VMS. In addition, to make automatic generation a customized course model was used as implemented component. The customized course model includes a set of defined common hard and soft constraints.

However, the objective was to customize the constraint definitions based on the requirements of each department. The purpose of the GA is to allocate the courses that the student groups have signed up for to teaching staff in feasible time slots. During the initialization step, the class population was generated based on the number of student groups that had signed for it, and the teaching staff were randomly allocated based on their rankings. The objective was to allocate these classes to events. The algorithm was tested through a number of experiments to determine the suitable parameters for generating feasible solutions. The algorithm generated a feasible solution with a fitness value of 1 when the population number was set to 100, and the crossover and mutation rates were set to 0.7 and 0.01, respectively. Furthermore, we observed that if the number of student groups increased with no increase in the number of teaching staff, the conflict rate increased. Therefore, to improve the algorithm, we must analyze cases wherein the number of students groups taking a course is increased, which will be the subject of a future study. If a timetable is selected and the number of conflicts is constrained, the auto-generation component has a conflict resolution algorithm that either manually fixes the department staff conflicts or suggests enhancement by omitting soft constraints that can be violated.

A future direction for this study is to propose a parallel GA to enhance the component and handle a higher number of student groups taking the same course. We will also investigate the possibility of building customized hard and soft constraints to add more flexibility in generating course timetables. This requires a method to define a domain-specific language to build constraints and automatically transform them into executable constraints.

**Abstract**—In recent years, many investors have used cryptocurrencies, prompting specialists to find out the factors that affect cryptocurrencies' prices. Therefore, one of the most popular methods that have been used to predict cryptocurrency prices is sentiment analysis. It is a widespread technique utilized by many researchers on social media platforms, particularly on Twitter. Thus, to determine the relationship between investors' sentiment and the volatility of cryptocurrency prices, this study forecasts the cryptocurrency prices using the Long-Term-Short-Memory (LSTM) deep learning algorithm. In addition, Twitter users' sentiments using Support Vector Machine (SVM) and Naive Bayes (NB) machine learning approaches are analyzed. As a result, in the classification of the bitcoin (BTC) and Ethereum (ETH) datasets of investors' sentiments into (Positive, Negative, and Neutral), the SVM algorithm outperformed the NB algorithm with an accuracy of 93.95% and 95.59%, respectively. Furthermore, the forecasting regression model achieves an error rate of 0.2545 for MAE, 0.2528 for MSE, and 0.5028 for RMSE.

**Keywords**—Sentiment analysis; cryptocurrencies; forecasting; bitcoin; ethereum

## I. INTRODUCTION

Recently, the prices of financial assets have been dynamically changing, which means it changes asynchronously as new information becomes available [1]. Therefore, the future prediction of finance growth in stocks, shares, and digital currency flow data is difficult for speculators and investors; these cryptocurrencies have skyrocketing and sudden fall characteristics, which means they have high price volatility over time [2].

In addition, cryptocurrencies are an alternative medium of exchange consisting of numerous decentralized crypto coin types. The essence of each crypto coin is in its cryptographic foundation. Secure peer-to-peer transactions are enabled through cryptography in this secure and decentralized exchange network based on blockchain technology [3]. Since its inception in 2009 [4], BTC has become a digital commodity of interest as some believe the crypto coins' worth is comparable to that of traditional fiat currency [5]. Unlike our usual currencies, cryptocurrencies are free from regulatory norms and do not have a central governing authority [6]. Therefore, the cryptocurrency market is investor-driven. Thus, it can be said to be affected by socially constructed opinions, and future expectations of the cryptocurrency holders and future investors [7].

Many currency users share stock price recommendations via electronic platforms. According to Abualigah et al. [8], Twitter is one of the essential sources of users' opinions on various topics. Thus, individuals can express their opinions and share alternative viewpoints on any topic. As a result, it is

necessary to use modern technologies and advanced artificial intelligence methods to analyse Twitter users' opinions.

The research contributions are as follows: (i) Apply machine learning (ML) algorithms to analyse the cryptocurrency users' sentiments, (ii) Apply deep learning (DL) models to forecast the cryptocurrencies' prices, (iii) Analyse the correlation between cryptocurrency users' sentiments and price volatility in the cryptocurrency market, and (iv) Evaluate the performance of the proposed method and compare the results with those of state-of-the-art algorithms and previous studies in the same field.

This paper is structured as follows: Section II provides a literature review of the previous studies on cryptocurrency price forecasting and sentiments analysis. Section III illustrates the overall structure of the research model and the methods utilized to achieve the results. Section IV contains the collected datasets and the pre-processing techniques. Section V presents the experimental results in tables and figures and compares the results with other previous studies. In the final Section VI, we provide a conclusion, limitations, and future work.

## II. LITERATURE REVIEW

Cryptocurrencies are a form of alternative currency comprised of various types of decentralized crypto [9]. These cryptocurrencies exhibit rapid growth and rapid downturn characteristics, implying a high degree of price volatility over time [10]. Many studies focused on predicting the "Price" of cryptocurrency by using various techniques such as the Autoregressive Integrated Moving Average (ARIMA) time-series model [11]. They aim to predict the prices using daily, weekly, and monthly time series. On the other hand, several recent studies have analyzed the sentiments of cryptocurrency users using ML [12] and DL models [5]. Additionally, These studies examined whether public sentiment measured by social media datasets are related to or predictive of cryptocurrency values. In particular, it is possible to predict the volatility of cryptocurrencies price by analyzing public sentiment on Twitter and determining the relationship between the sentiments expressed by investors on Twitter.

Accordingly, Rahman et al. [12] presented ML models based on the Twitter dataset. The researchers aim to find an association between user sentiment and BTC price. However, they use a variety of algorithms, such as Support Vector Regression, Decision Tree Regression DTR, and Linear Regression LR. As a result of the experiment, there is a discernible relationship between sentiment on Twitter and price change, based on the highest accuracy obtained from the decision tree algorithm compared with other algorithms is 75%. Similarly,

Sattarov et al. [13] examined the extent to which BTC prices are influenced by investors' sentiments using a ML model. Twitter and the BTC price datasets were collected over a 60-day period, from March 12 to May 12. Additionally, the researchers used the Random Forest RF algorithm to determine a correlation between cryptocurrency users' opinions and feelings and price variation. The implemented model achieves 62.48% accuracy and a minimum error of 21.84%.

In another study conducted by Mittal et al. [14], The interrelationships between BTC price and Twitter and Google search were identified using the BTC price, tweets, and Google search patterns. According to the investigation, there is a correlation between BTC pricing, Twitter, and Google search behaviors. In addition, the authors apply Linear regression LR, polynomial regression PG, Recurrent Neural networks, and LSTM based analysis of different datasets collected from 9 April 2014 to 07 January 2019. The polynomial regression method outperforms the other techniques by achieving an accuracy of 77.01% and 66.66% of Tweet Volume and Google trends, respectively. Thus, the findings show a significant association between Google Trends and Tweet volume data and the price of BTC, but no significant correlation with tweet sentiments.

Other studies applying sentiment analysis technology to cryptocurrency trading had similar results. For example, Pant et al. [5] developed a novel DL algorithm by combining the BTC sentiment score and historical price. Their objective is to establish a link between user emotions and BTC price volatility using the Recurrent Neural Network RNN model. The datasets chosen covered the same time period, from January 1 to December 31, 2015, in order to investigate the correlation between them. According to the experiment results, the distinction between positive and negative tweets is 81.39 percent accurate. The same proposed model achieves a 77.62 percent accuracy in predicting BTC prices. Moreover, Pathak and Kakkar [15] present DL trained model using LSTM networks. They intend to forecast the overall price trend by analyzing BTC and Twitter data spanning 450 hours. Their study established a link between Twitter users' sentiments and the BTC trading currency's pricing, as the relationship between them was 77.89% accurate.

Furthermore, Aggarwal et al. [16] utilized a symmetric-deep learning approach with value parameters to assess the impact of BTC price prediction on socioeconomic indicators. In particular, they investigated the effect of Gold price and investors' sentiments on the price of BTC by using DL models such as Convolutional Neural Network (CNN), LSTM, and Gated Recurrent Unit (GRU). To enhance the results, they used a variety of datasets from January 15, 2017, to May 12, 2017. Researchers have noticed the significant effect between Twitter users' sentiments and BTC price volatility as the posting of tweets containing positive feelings leads to an increase in the price of BTC. And vice versa. In another study conducted by [17], DL models based on the StockTwits platform and cryptocurrencies datasets are utilized. The authors applied efficient language modeling tools such as recursive neural networks (RNNs) using datasets from March 2013 to May 2018. The findings show a significant association between speculators' posts and cryptocurrency volatility prices.

Most studies used either deep neural network models such

as LSTM or conventional ML models such as RF to forecast cryptocurrency price volatility. Additionally, they employ various preprocessing strategies when developing a cryptocurrency models. However, only a few studies conducted a comparative analysis of DL to identify an optimal preprocessing strategy. These studies were conducted over various timeframes, making them relatively old in this rapidly evolving cryptocurrency market. Thus, additional research is required on forecasting cryptocurrency prices and analyzing investor sentiments using DL approaches, as the literature has not been extensively exploited. Therefore, new studies must be conducted to ensure that these results remain valid in 2022 and to discover new patterns.

### III. METHODOLOGY

This section explains the proposed cryptocurrency forecasting model using DL and ML. The sentiments analysis model pre-processes the tweets, calculates the sentiment score using ML algorithms, and classifies them into (Positive, Negative, and Neutral). In contrast, the forecasting model uses the historical price dataset and works on predicting the next three months using the DL algorithm. The methodology of the classification and regression models used to forecast the prices and find the correlation between investors' sentiments and cryptocurrency historical price is presented in Fig. 1.

#### A. Sentiment Analysis Model

This step aims to apply the primary goal of the research, which is sentimental characteristics tweets measurements such as polarity and subjectivity. The TextBlob3 Python library was utilized to process the Twitter dataset by providing the natural-language processing NLP features [18]. This strategy classifies the polarity of the tweet into positive, neutral, and negative groups as '1', '0', and '-1'. Table I presents the sentiments divided process into three groups (positive, negative, and neutral) depending on the tweets' polarity.

TABLE I. POLARITY CLASSIFICATION

Value of Polarity	Sentiment
>0	Positive
0	Neutral
<0	Negative

The sentiments analysis model of cryptocurrency users was utilized using supervised ML approaches, including SVM, and NB chose these approaches for modeling because it is faster and more lightweight in the classification processes.

1) *Support Vector Machine (SVM)*: is a supervised ML algorithm utilized for classification and regression purposes. Both linear and nonlinear classification is executed by SVM. It is created the line between two classes. That means all points in the same part has the same category. Moreover, It can be more than two lines to separate the categories. The vectors near the hyperplane are the support vectors. In addition, to solve classification problems, there are four kernel functions (linear, polynomial, radial-based, and sigmoid) [19]. The advantages of the SVM algorithm are the better classification accuracy and the best analysis performance if the input data is correctly labeled before the process [20].

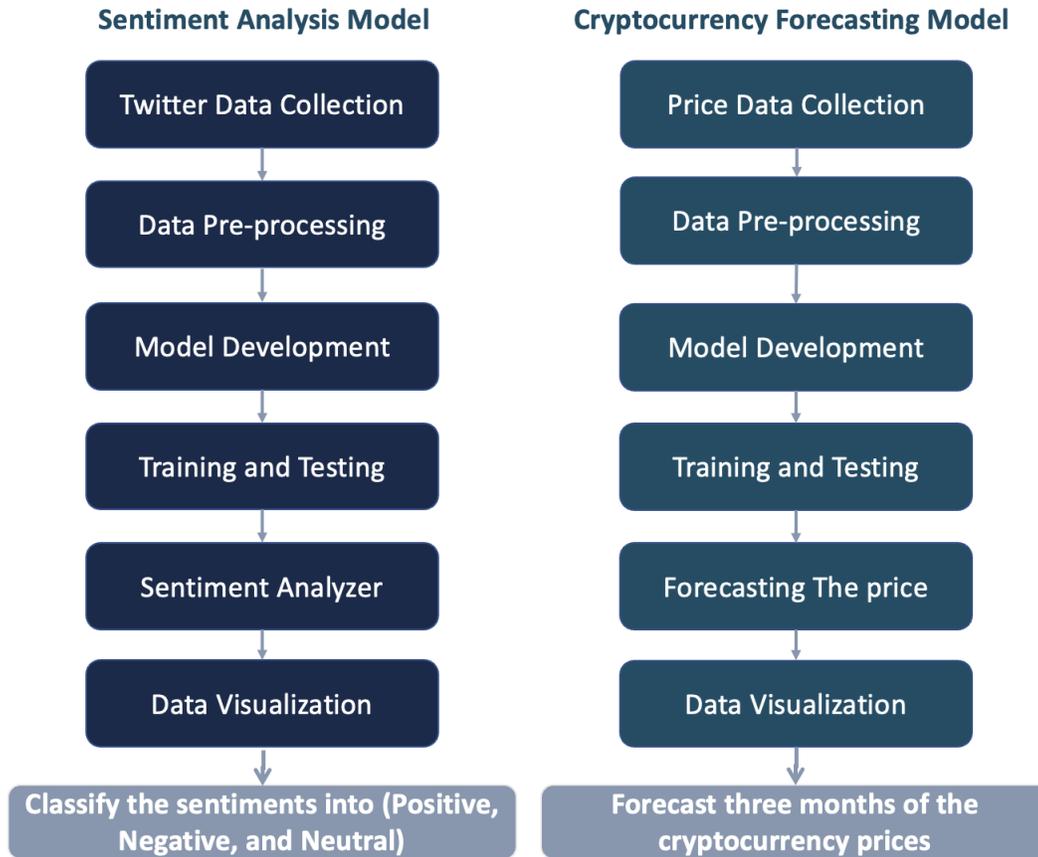

Fig. 1. Forecasting Model Structure.

2) *Naive Bayes (NB)*: is a generative learning algorithm that solves text classification and sentiment analysis ML models based on Bayes' theorem. All features assumed as independent thought give the class value [21]. The term "Naive" directs to data points that are unrelated to one another. The advantages of the NB algorithm, multinomial classifier NB is commonly utilized in text categorization cases, and capable to build, use, train, and ignoring useless variables [22]. The (1) presents in the mathematical equation of NB.

$$P(c|x) = \frac{P(x|c)p(c)}{P(x)} \quad (1)$$

**Where:**

- $P(c | x)$  is the probability posterior of the given class value.
- $P(c)$  is a prior probability of class.
- $P(x)$  is a prior probability of value.
- $P(x | c)$  is the probability of value given class.

**B. Cryptocurrency Forecasting Model**

LSTMs were chosen for modeling the cryptocurrency forecasting model since it is an ideal algorithm for time series forecasting and works well with historical data by storing

memory. Furthermore, it solves complex problems that earlier recurrent network algorithms have never been able to solve. Therefore, Table II presents the hyperparameter, the values that control the learning process for the LSTM model.

TABLE II. HYPERPARAMETER VALUES

Activation Function	Sigmoid
Epochs	150
Hidden layers	One hidden layer
Batch size	256
Optimizer	Adam
Learning rate	0.00050

1) *Long-Term-Short-Memory (LSTM)*: is a form of RNN with extra elements for memorizing sequential input. The cell state, which transmits information across the sequence chain, is a crucial component of LSTM. It serves as the network's memory. Because information can be withdrawn or added via gates, the cell state can truly hold only the necessary information in the sequence. During training, the gates learn what information is important to keep or forget. As a result, information from previous stages now influences later stages in the sequence [23].

**C. Evaluation Metrics**

There is a need to evaluate the performance of the models involved.

- **Regression**

In the regression model, the accuracy of forecasts can only be determined by considering how well a model performs on new data that were not used when fitting the model. Scale-dependent errors are commonly used, such as Mean Absolute Error (MAE), Mean Squared Error (MSE), and Root Mean Squared Error (RMSE) [24] as follows:

**Mean Absolute Error (MAE):** calculated the average of the original and forecasted values [24]. This is expressed in mathematical terms as (2):

$$MAE = \frac{1}{n} \sum_{n=1}^{t=1} |e_t| \quad (2)$$

**Mean Squared Error (MSE):** calculated the square average of the difference between original and forecasted values [24]. This is expressed in mathematical terms as (3):

$$MSE = \frac{1}{n} \sum_{n=1}^{t=1} e_t^2 \quad (3)$$

**Root Mean Squared Error (RMSE):** The forecast errors standard deviation. That means the residuals measurement of far points from the regression line data [24]. This is expressed in mathematical terms as (4):

$$RMSE = \sqrt{\frac{1}{n} \sum_{n=1}^{t=1} e_t^2} \quad (4)$$

**Where:**

- n is the sample's forecast total number.
- e is the real value of the sample.
- t is the forecasting value of the sample.

- **Classification**

On the other hand, the evaluation metrics used for classification models the performance of the algorithms are Accuracy, Precision, Recall, and F1-Score [25] as follows.

**Precision** The positive quantification, which are True Positives (TP) and False Positives (FP) number of predictions [25]. This is expressed in mathematical terms as (5):

$$Precision = \frac{TP}{TP + FP} \quad (5)$$

**Recall** The number of positive class predictions made from all positive cases in the dataset that can be counted. And when there is a large cost related to False Negatives (FN) [25]. This is expressed in mathematical terms as (6):

$$Recall = \frac{TP}{TP + FN} \quad (6)$$

**F1-Score** Precision and Recall have a harmonic mean [26]. This is expressed in mathematical terms as (7):

$$F1 - Score = \frac{2 * Precision * Recall}{Precision + Recall} \quad (7)$$

**Accuracy** The intuitive performance measure, which is the observed the correctly forecasted ratio to the total observations [26]. This is expressed in mathematical terms as (8):

$$Accuracy = \frac{(TP + TN)}{TP + TN + FP + FN} \quad (8)$$

#### IV. EXPERIMENTS

This section illustrates the selected dataset in this research and the pre-processing steps.

##### A. Dataset

According to Coinmarketcup [27], there are 10111 various types of cryptocurrencies in circulation, such as BTC, ETH, Binance (BNB), and Cardano (ADA). Furthermore, BTC is still the prevalent cryptocurrency that has been widely used since its creation. Then ETH followed it as the top cryptocurrency compared to other currencies. Thus, this study focuses on the two most-traded currencies: BTC and ETH.

- **Twitter Dataset**

An open-source Python library known as Tweepy [28] is used to access the Twitter API and extract the Twitter dataset. Therefore, tweets were collected using three hashtags and three keywords for two cryptocurrency types: The BTC cryptocurrency collection process used keywords "Bitcoin", "BTC", and "BTCUSD" along with their respective hashtags ["#Bitcoin", "#BTC", "#BTCUSD"]. And, the ETH cryptocurrency collection process used keywords "Ethereum", "ETH", and "Etherum" along with their respective hashtags ["#Ethereum", "#ETH", "#Etherum"]. Furthermore, the period we focus on is five months, and assigned to extract (2000 tweets) every seven days for 150 days, between January 1, 2022, and May 9, 2022. The final dataset was around 37,998 for BTC cryptocurrency tweets and around 37,997 for ETH cryptocurrency and separately saved in a CSV file. Hence, the dataset for all tweets with different cryptocurrencies is around 75,995 posted in the English language.

- **Cryptocurrency Dataset**

The dataset of the two currencies was collected from CoinMarketCap [27], the world's most-referenced price-tracking website for crypto assets in the rapidly increasing cryptocurrency market [10]. The BTC dataset starts from September 17, 2014, to March 31, 2022. On the other hand, the ETH dataset starts from November 9, 2017, to March 31, 2022. However, in this research, the 1-minute interval trading exchange data rate in USD is focused on. In addition, the two datasets consist of the Date, Opening, Closing, Low, Adj Close, and Volume of transactions which increase over time. Additionally, the BTC and ETH datasets are saved in CSV files separately.

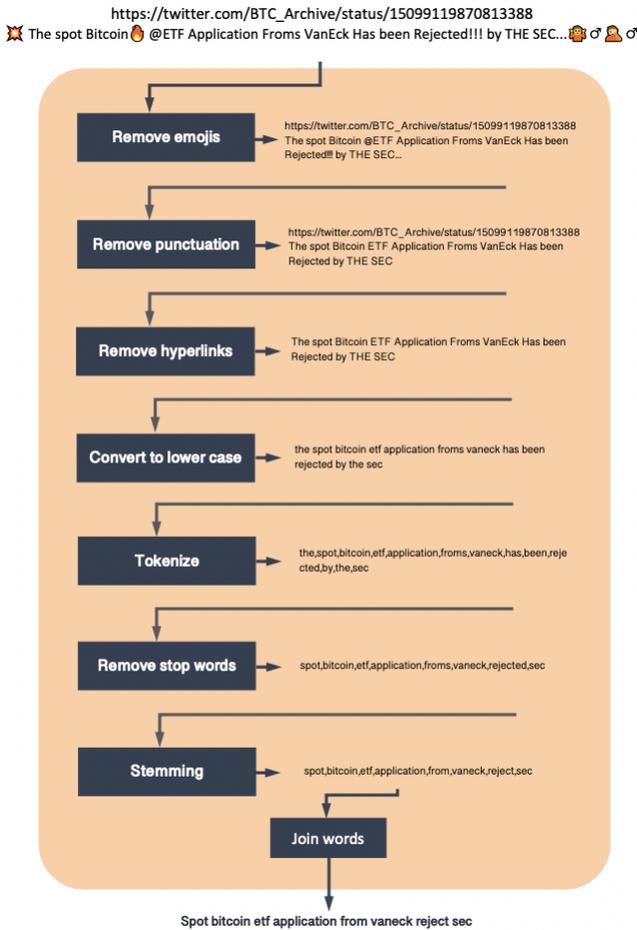

Fig. 2. The Pre-Processing of the “Cleaned” Function over BTC Sample Tweet Text.

### B. Data Pre-Processing

Pre-processing the data is an important step in enhancing the model’s predictive accuracy and getting better results. The pre-processing techniques were applied in the Twitter and cryptocurrency datasets.

- Twitter Dataset Pre-Processing**  
 The pre-processing data phase contains multiple procedures that remove parts of tweets that may excessively or unnecessarily impact the sentiment score. To achieve the goal, Python’s String methods and the library Natural Language Toolkit (NLTK) was utilized [29]. NLTK library allowed the text to process for classification, tokenization, stemming, tagging, parsing, and semantic reasoning. Fig. 2 presented the pre-processing steps applied in the BTC dataset with a tweet example. In addition, ETH follows the same pre-processing steps. As a result, the total number of tweets decreases from 37,998 to 17,608 on the BTC dataset and 37,997 to 17,373 on the ETH dataset.
- Cryptocurrency Dataset Pre-Processing**  
 In the stage of pre-processing, as given in Table III, seven features were selected out of eight to forecast the

cryptocurrencies’ prices. The cryptocurrency dataset is updated daily. Therefore, trades where the date value is from September 17, 2014, to March 31, 2022, for BTC and November 9, 2017, to March 31, 2022, for ETH are considered. In addition, according to the collected dataset period, the Close column is modified in the Adj Close column. Thus, the Close column were removed and depending on the Adj Close column as the final result of the latest trade recorded day.

TABLE III. FEATURES SELECTION

Features	Definition
Date	recorded time of the price
Open	Opening trade (Open price on recorded day)
High	Opening trade (Open price on recorded day)
Low	Lowest trade (Least price on recorded day)
Adj Close	Adj Close price on recorded day
Volume	Volume of transactions

### C. Experimental Environment

The experimental environment is Google Colaboratory [30], known as “Colab”, a suitable Python environment for ML and data analysis purposes. It provided free accessibility to GPU computing resources. Among the used tools and technologies in the experimental environment are statistical libraries used are NumPy [31] and Pandas [32]. Furthermore, the experiment is conducted on a MacBookPro laptop with 8 GB RAM, an M1 chip, and Macintosh 12.0.1 operating system. In addition, Open-source Neural Network libraries TensorFlow [33] and Keras [34] were implemented to cryptocurrencies’ future price prediction model.

## V. RESULTS AND DISCUSSION

This section presents the results of the sentiments analysis model and the cryptocurrency forecasting model, implemented using BTC and ETH cryptocurrency datasets.

### A. Result of Sentiment Analysis Model

To better understand the public opinion towards cryptocurrencies and find the relationship with the price volatility. The sentiment is classified into three groups. Fig. 3 presents the distribution of BTC and ETH users’ sentiments: (A) shows the bar graph of the BTC result. The tweets expressed an observed positive opinion that might have happened because most of the tweets contained sentences that did not express negative or neutral emotions. In addition, the rest are due to the BTC currency having a large number of transactions compared with the other cryptocurrencies. On the other hand, (B) presents the bar graph of the ETH result. The tweets expressed an observed neutral opinion towards ETH currency.

Moreover, Table IV presents the macro average of the employed SVM and NB methods to classify the BTC sentiments. While Table V presents the macro average of the employed SVM and NB methods to classify the ETH sentiments. The SVM method outperforms the NB by achieving an accuracy of 93.95% and 95.59%, respectively.

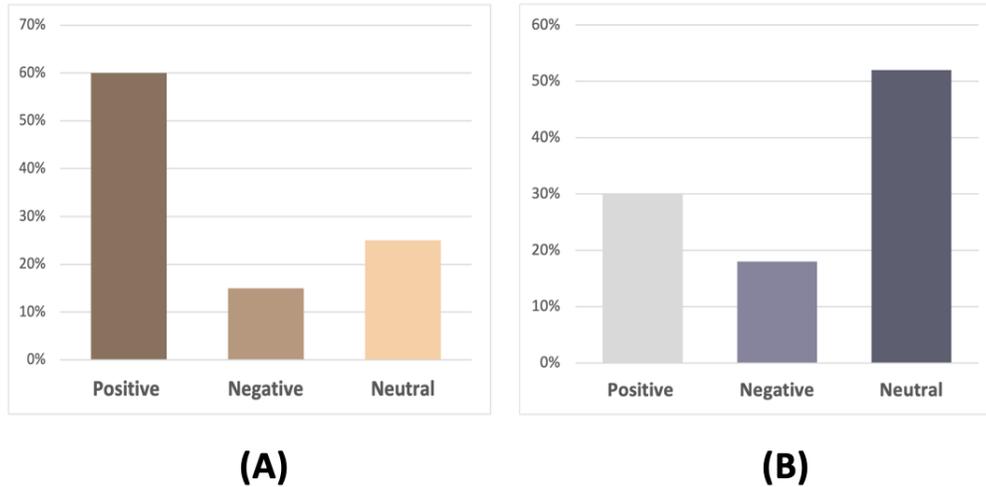

Fig. 3. Distribution of BTC and ETH Sentiments.

TABLE IV. COMPARISON BETWEEN SVM AND NB METHODS ON BTC DATASET

Models	Accuracy	Precision	Recall	F1-score
SVM	<b>93.95%</b>	<b>0.90</b>	<b>0.94</b>	<b>0.91</b>
NB	80.56%	0.67	0.84	0.69

TABLE V. COMPARISON BETWEEN SVM AND NB METHODS ON ETH DATASET

Models	Accuracy	Precision	Recall	F1-score
SVM	<b>95.59%</b>	<b>0.91</b>	<b>0.95</b>	<b>0.93</b>
NB	83.74%	0.69	0.88	0.72

### B. Result of Cryptocurrency Forecasting Model

The results of the LSTM regression model for the BTC and ETH cryptocurrencies are presented in Fig. 4 and 6. Fig. 4 presented the BTC model, trained and tested from September 17, 2014, to March 31, 2022, to forecast the three following months (April, May, and June). As a result, BTC prices fall in the predicted months, as shown in Fig. 5. On the other hand, Fig. 6 presented the ETH model, trained and tested from November 9, 2017, to March 31, 2022, to forecast the three following months (April, May, and June). As a result, ETH prices fall in the predicted months, as shown in Fig. 7.

The MAE, RMSE, and MAPE are used to evaluate the performance of regression models. Table VI summarizes the results of training and testing errors. We observed that the BTC forecasting model outperformed the ETH model in terms of MAE, MSE, and RMSE, whereas the LSTM model's error in ETH is worse due to the smaller dataset size. It is noted that the small resample of time series data may get the worst result on MAE, MSE, and RMSE tests.

Fig. 8 and 9 introduced the study of the correlation between cryptocurrency users' opinions and price volatility in the cryptocurrency market from January 1, 2022, and May 9, 2022. Fig. 8 illustrates the relationship between BTC volatility prices and BTC users' sentiments. As well, Fig. 9 shows the

TABLE VI. PERFORMANCE OF LSTM REGRESSION MODELS WITH DIFFERENT CRYPTOCURRENCIES FOR PREDICTING THE DAILY CLOSING PRICE

Cryptocurrency type	MAE	MSE	RMSE
<b>Bitcoin (BTC)</b>	<b>0.2545</b>	<b>0.2528</b>	<b>0.5028</b>
Ethereum (ETH)	0.3838	0.4677	0.6839

relationship between ETH volatility prices and ETH users' opinions. We observe that the correlation in the BTC is close compared with ETH, which means when the BTC investors have a positive sentiment, the price of BTC cryptocurrency will be increased. Vice versa, when they have a negative emotion toward the BTC cryptocurrency, the price will be decreased. On the other hand, the ETH prices and users' sentiments do not have a relationship. Therefore, we may conclude that emotion is not always related to investor satisfaction.

### C. Comparing with Related Works

Several researchers used various ML [12], [13] and DL [15], [5] techniques to analyze the cryptocurrency users' sentiments. As a result, Table VII compared the result of the current study with the previous studies which used the same dataset in different periods and techniques. In addition, They aim to analyze the sentiments of cryptocurrency users. The SVM appears to be a more appropriate method of classifying the sentiments depending on the accuracy result. To the researchers' knowledge, the reason for the superiority of this study's results is the followed pre-processing techniques that were used to clean the Twitter dataset [13], [15]. In addition, the classification of cryptocurrency sentiments is divided into negative and positive, and neutral, unlike the classification process used in other studies [5], [12], they excluded the presence of normal feelings for cryptocurrency users.

On the other hand, ML and DL techniques were applied to forecast cryptocurrency prices. Table VIII presents the error rate result of two cryptocurrencies compared to Alahmari et al. [11]. The current research outperforms another study and achieves good results for BTC and ETH cryptocurrencies. To

TABLE VII. COMPARISON WITH RELATED WORK STUDIES ON SENTIMENT ANALYSIS

Study	Period	Methods	Accuracy
Pant et al. [5]	Jan 2015, to Dec 2015	RNN	81.39%
Rahman et al. [12]	Mar 2018, to Mar 2018	DTR	75%
Sattarov et al. [13]	Mar 2019, to May 2019	RF	62.48%
Pathak & Kakkar [15]	March 2019	LSTM	77.89%
<b>This study</b>	<b>Jan 2022, to May 2022</b>	<b>SVM</b>	<b>95%</b>

TABLE VIII. COMPARISON WITH RELATED WORK STUDIES ON FORECASTING

Study	Model	Crypto Type					
		BTC			ETH		
		MAE	MSE	RMSE	MAE	MSE	RMSE
Alahmari et al. [11]	ARIMA	313.8	294.5	542.7	12.9	410.1	20.3
<b>This Study</b>	<b>LSTM</b>	<b>0.254</b>	<b>0.25</b>	<b>0.50</b>	<b>0.38</b>	<b>0.46</b>	<b>0.68</b>

the researchers’ knowledge, the reason for the superiority of this study’s results is the volume of historical data and the time-series DL model applied in the experiment. It is noted that the small resample of time series data may get the worst result on MAE, MSE, and RMSE tests.

## VI. CONCLUSION AND FUTURE WORK

Experiments were conducted using two datasets about two cryptocurrencies, BTC and ETH, to study the relationship between traders' sentiment and the price of cryptocurrencies. To study the impact of the proposed method and confirm its superiority, we analyzed Twitter users' sentiments about these cryptocurrencies and classified their polarity (positive, negative, and neutral) using ML classification algorithms. The SVM classification method outperformed NB with 93.95% and 95.59% accuracy, respectively. In addition, the expected price for the next three months for the two selected currencies has been forecast using the LSTM model; the BTC prediction model outperformed the ETH model with an error rate of 0.2545 for MAE, 0.2528 for MSE, and 0.5028 for RMSE, whereas the LSTM model's error in ETH is worse due to the smaller dataset size. It is noted that the small resample of time series data may get the worst result. Furthermore, the relationship between cryptocurrency volatility prices and its users' sentiments was studied to achieve the research aims. We observe that the correlation in the BTC is close compared with ETH, which means when the BTC investors have a positive sentiment, the price of BTC cryptocurrency will be increased and vice versa. On the other hand, the ETH prices and users' sentiments do not have an observed relationship. Therefore, we may conclude that cryptocurrency price volatility is not always related to investor satisfaction.

Due to a lack of resources and time, the datasets and the selected cryptocurrency types restrictions were imposed to keep the research relevant. The Twitter data set utilized to train and test the sentiment analysis model was limited to five months because of computational power limitations. Although the prices of cryptocurrency are impacted by investors' sentiments worldwide, the Twitter dataset focuses on tweets written in the English language only. On the other hand, this study focuses on forecasting the prices of the two most-traded currencies: BTC and ETH, although thousands of different cryptocurrencies are in circulation. It will be necessary to cover other factors that may impact the cryptocurrency market instead of focusing on the investors' sentiments in future works. Furthermore, conducting experiments using more than two types of the most popular cryptocurrencies and improving the pre-processing steps to study the correlation between cryptocurrency price volatility, news events, and investors' sentiments on different social media platforms that might directly relate to cryptocurrency prices. Additionally, to further study cryptocurrencies' price forecasting, we intend to examine more time-series methods; one of them is ARIMA, a statistical

analysis model widely used to predict future trends through the time-series dataset.

**Abstract**—Non-dominated sorting genetic algorithm has shown excellent advantages in solving complicated optimization problems with discrete variables in a variety of domains. In this paper, we implement a multi-objective genetic algorithm to guide the design of the laminated structure with two objectives: minimizing the mass and maximizing the strength of a specified structure simultaneously, classical lamination theory and failure theory are adopted to compute the strength of a laminate. The simulation results have shown that a non-dominated genetic algorithm has great advantages in the design of laminated composite material. Experiment results also suggest that optimal run times are from 16 to 32 for the design of glass-epoxy laminate with non-dominated sorting genetic algorithm. We also observed that two stages involve the optimization process in which the number of individuals in the first frontier first increases, and then decreases. These simulation results are helpful to decide the proper run times of genetic algorithms for glass-epoxy design and reduce computation costs.

**Keywords**—Non-dominated sorting genetic algorithm; optimization; failure theory; laminated composite material; classical lamination theory

## I. INTRODUCTION

Non-dominated sorting genetic algorithm (NSGA-II) provides [1], [2], [3] a collection of techniques to maintain multiple solutions in the mating pool and has shown excellent performance in domains [4], [5], [1], [6], [7], [8], [9], [10], [11], [12], [13]. Slowik and Kwasnicka [9] present the family of evolutionary algorithms for real-life application, such as genetic algorithms, genetic programming, differential evolution, and evolution strategies. Lu [10] et al. adopt NSGA for neural architecture search and has demonstrated the ability in finding competitive neural architecture with less computational resources. Kou [11] et al. propose a two-stage multiobjective feature-selection method for bankruptcy prediction of small and medium-sized enterprises.

The design of a laminate in nature is a tricky optimization problem involving several discrete variables and additional constraints. The traditional wisdom [14], [15], [16], [17], [18], [19], [20], [21], [22] suggests using an evolutionary algorithm to solve this problem with a single objective function, appending additional constraints to the objective function as punishment items, in which the coefficient of each punishment is a random number with a range from 0 to 1. Adams [23] et al. use a genetic algorithm approach by locally reducing a thick laminate to generate and evaluate valid globally blended

designs for composite panel structure optimization. Cho and Rowlands [24] implement a genetic algorithm to minimize tensile stress concentrations in a perforated laminated structure, obtaining more than one favorable stacking sequence with different fiber orientations. An [25] et al. present the two-objective design of composite laminates: minimizing cost and maximizing fundamental frequency and frequency gaps.

Although the non-dominated sorting genetic algorithm has demonstrated great efficiency in fields, there is rare literature on the application of NSGA-II for the design of a laminated structure. In this work, we implement this algorithm to guide the design of laminated composite material with multiple constraints. The experiment results have shown that NSGA offers great advantages in assisting the design of a laminate, where it provides a set of solutions. As far as we know, this is the first time to adopt a non-dominated sorting genetic algorithm for laminate design.

The rest of this work is organized as follows: Section II reviews the non-dominated genetic algorithm; Section III gives a brief introduction to laminate and covers the strength calculation process; in Section IV, we formulate the objective functions; in Section V, we present the experiment; finally, we analyze the simulation result and give the conclusion.

## II. NON-DOMINATED SORTING GENETIC ALGORITHM AND LAMINATE REPRESENTATION

Non-dominated sorting genetic algorithm is an evolutionary algorithm that maintains solutions in the mating pool. The solutions are in the same frontier if none of them dominate each other, and NSGA-II can reserve frontiers in the population. NSGA-II outperforms other multiobjective algorithms in three aspects: 1)  $O(MN^2)$  computational cost, where  $M$  is the number of objectives and  $N$  is the population size; 2) without specifying sharing parameters; 3) new selection operator which combines parents and children and selects individuals from the combination. Fig. 2 shows the process of NSGA-II in which the non-dominated sorting technique reduces the sorting time complexity from  $O(MN^3)$  to  $O(MN^2)$ . The crowding distance sorting trick ranks the individual according to the values of the individual's objective function. We propose to adopt these techniques to guide the design of a laminate.

Fig. 1 shows individuals in the mating pool with two objective functions,  $f_1$  and  $f_2$ . In this figure, the cuboid is to measure the distance of individuals in the same frontier instead

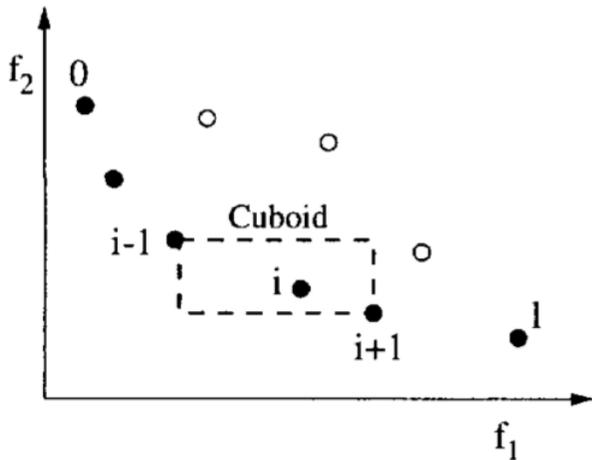

Fig. 1. Frontiers in the Population in which Individuals Marked with the same Color belong to One Frontier [26].

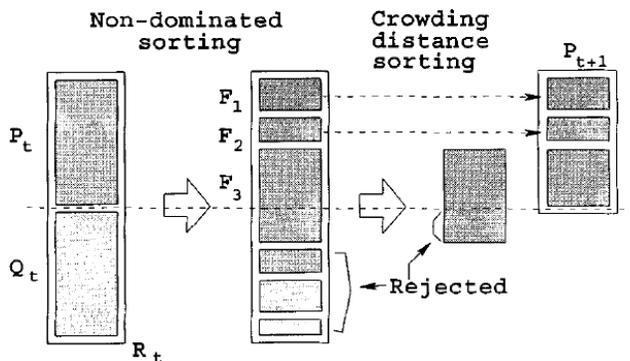

Fig. 2. NSGA-II Procedure[27].

of using sharing function. This technique can also measure the distance of laminates because the distance calculation only requires the value of objective functions. And a sequence of integers is able to represent the structure of a laminate. So we can evaluate the objective function according to the integer representation of a laminate.

### III. A LAMINATE AND THE STRENGTH PREDICTION

As shown in Fig. 3, a laminate sequence of lamina binding together along the thickness direction, and lamina is a special composite material whose properties are determined by several variables: ply angle, ply thickness, and material properties. In this paper, to decide the strength of a laminate, it is necessary to know how to compute the strength of a single lamina.

A lamina's strength is highly related to the stress and strain within it. For a lamina under load, it is straightforward to calculate the stress and strain in a lamina by using of three-dimensional stress and strain model, as shown in

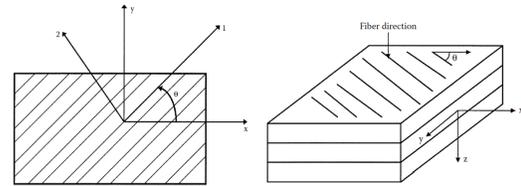

Fig. 3. A Lamina and the Structure of a Laminate.

$$\begin{bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{bmatrix} = \begin{bmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \gamma_{12} \end{bmatrix}. \quad (1)$$

In this equation,  $Q_{11}, Q_{12}, Q_{22}, Q_{66}$  are engineering constants,  $\sigma_1, \sigma_2, \tau_{12}, \varepsilon_1, \varepsilon_2, \gamma_{12}$  are stress and strain along different directions.

Then failure theories can predict the strength of a lamina according to obtained stress and strain. Various failure theories have been proposed to compute the strength of lamina, and each has its advantage and disadvantages. Here we adopt the two most widely adopted criteria to calculate the strength: Tsai-Wu [28], [29] failure theory and Maximum stress [30], [31] failure theory.

The Tsai-Wu failure theory can compute the strength ratio of a laminate with the following equation. The strength ratio is an indicator of a material's strength under load.

$$H_1\sigma_1 + H_2\sigma_2 + H_6\tau_{12} + H_{11}\sigma_1^2 + H_{22}\sigma_2^2 + H_{66}\tau_{12}^2 + 2H_{12}\sigma_1\sigma_2 < 1 \quad (2)$$

In this equation,  $H_1, H_2, H_6, H_{11}, H_{22}, H_{66}$  are coefficients related to five engineering constants  $\sigma_1^T, \sigma_2^T, \sigma_1^C, \sigma_2^C, \tau_{12}$ . The relation among them are as follows:

0
90
90
0
90

Fig. 4. Cross-Ply Laminate.

$$\begin{aligned}
 H_1 &= \frac{1}{(\sigma_1^T)_{ult}} - \frac{1}{(\sigma_1^C)_{ult}}, \\
 H_{11} &= \frac{1}{(\sigma_1^T)_{ult} (\sigma_1^C)_{ult}}, \\
 H_2 &= \frac{1}{(\sigma_2^T)_{ult}} - \frac{1}{(\sigma_2^C)_{ult}}, \\
 H_{22} &= \frac{1}{(\sigma_2^T)_{ult} (\sigma_2^C)_{ult}}, \\
 H_{66} &= \frac{1}{(\tau_{12})_{ult}^2}, \\
 H_{12} &= -\frac{1}{2} \sqrt{\frac{1}{(\sigma_1^T)_{ult} (\sigma_1^C)_{ult} (\sigma_2^T)_{ult} (\sigma_2^C)_{ult}}}.
 \end{aligned} \tag{3}$$

The five engineering constants are as follows:  $(\sigma_1^T)_{ult}$  ultimate longitudinal tensile strength(in direction 1);  $(\sigma_1^C)_{ult}$  ultimate longitudinal compressive strength;  $(\sigma_2^T)_{ult}$  ultimate transverse tensile strength;  $(\sigma_2^C)_{ult}$  ultimate transverse compressive strength; and  $(\tau_{12})_{ult}$  and ultimate in-plane shear strength.

A laminate consists of laminae with a specified sequence, in which the ply angle, thickness, and composite material of one lamina could be different from another; Therefore, the strength computation of a laminate is more complicate than the strength prediction of a lamina. Classical lamination theory [32] is an analytical tool to compute the stress and strain for every lamina in a laminate. For a laminate, the relation between stress and strain is formulated as

$$\begin{bmatrix} \sigma_x \\ \sigma_y \\ \tau_{xy} \end{bmatrix} = \begin{bmatrix} \bar{Q}_{11} & \bar{Q}_{12} & \bar{Q}_{16} \\ \bar{Q}_{12} & \bar{Q}_{22} & \bar{Q}_{26} \\ \bar{Q}_{16} & \bar{Q}_{26} & \bar{Q}_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_x \\ \varepsilon_y \\ \gamma_{xy} \end{bmatrix}. \tag{4}$$

In this equation,  $\sigma_x, \sigma_y, \tau_{xy}$  and  $\varepsilon_x, \varepsilon_y, \gamma_{xy}$  are stress and strain in global coordinate. And we can compute  $\bar{Q}_{11}, \bar{Q}_{12}, \bar{Q}_{16}, \bar{Q}_{22}, \bar{Q}_{26}, \bar{Q}_{66}$  with the following equations.

$$\begin{aligned}
 \bar{Q}_{11} &= Q_{11} \cos^4 \theta + 2(Q_{12} + 2Q_{66}) \sin^2 \theta \cos^2 \theta + Q_{22} \sin^4 \theta \\
 \bar{Q}_{12} &= (Q_{11} + Q_{22} - 4Q_{66}) \sin^2 \theta \cos^2 \theta + Q_{12} (\cos^4 \theta + \sin^2 \theta) \\
 \bar{Q}_{22} &= Q_{11} \sin^4 \theta + 2(Q_{12} + 2Q_{66}) \sin^2 \theta \cos^2 \theta + Q_{22} \cos^4 \theta \\
 \bar{Q}_{16} &= (Q_{11} - Q_{12} - 2Q_{66}) \cos^3 \theta \sin \theta - (Q_{22} - Q_{12} - 2Q_{66}) \sin^3 \theta \cos \theta \\
 \bar{Q}_{26} &= (Q_{11} - Q_{12} - 2Q_{66}) \cos \theta \sin^3 \theta - (Q_{22} - Q_{12} - 2Q_{66}) \cos^3 \theta \sin \theta \\
 \bar{Q}_{66} &= (Q_{11} + Q_{22} - 2Q_{12} - 2Q_{66}) \sin^2 \theta \cos^2 \theta + Q_{66} (\sin^4 \theta + \cos^4 \theta)
 \end{aligned} \tag{5}$$

The mid-plane strains and curvature of laminate global

coordinates are obtained with the following equation:

$$\begin{bmatrix} N_x \\ N_y \\ N_{xy} \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} & A_{16} \\ A_{12} & A_{22} & A_{26} \\ A_{16} & A_{26} & A_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_x^0 \\ \varepsilon_y^0 \\ \gamma_{xy}^0 \end{bmatrix} + \begin{bmatrix} B_{11} & B_{12} & B_{16} \\ B_{11} & B_{12} & B_{16} \\ B_{16} & B_{26} & B_{66} \end{bmatrix} \begin{bmatrix} k_x \\ k_y \\ k_{xy} \end{bmatrix}. \tag{6}$$

We can use Equation 7 to calculate every entry in matrix A, B, and D.

$$\begin{aligned}
 A_{ij} &= \sum_{k=1}^n (\bar{Q}_{ij})_k (h_k - h_{k-1}) i = 1, 2, 6, j = 1, 2, 6 \\
 B_{ij} &= \frac{1}{2} \sum_{k=1}^n (\bar{Q}_{ij})_k (h_k^2 - h_{k-1}^2) i = 1, 2, 6, j = 1, 2, 6 \\
 D_{ij} &= \frac{1}{3} \sum_{k=1}^n (\bar{Q}_{ij})_k (h_k^3 - h_{k-1}^3) i = 1, 2, 6, j = 1, 2, 6
 \end{aligned} \tag{7}$$

In Equation 7,  $h_k$  is the local coordinate of every lamina. With these equations, we can obtain the strength ratio of a laminae.

In this work, the experiment material is a laminate with 0 and 90 ply orientation, also known as cross-ply laminate, as shown in Fig. 4.

#### IV. PROBLEM FORMULATION

Our problem is to design cross-ply laminate whose strength ratio should be greater than two. So the ply orientation is 0 and 90. So the search problem can be reformulated as follows:

- (1) design variable:  $\{\theta_k, n\} \theta_k \in \{0, 90\}$ ;
- (2) objective: maximization of strength ratio and minimization of mass
- (3) constraint: strength ratio should be greater than two.

#### V. SIMULATION RESULTS AND DISCUSSION

This section presents the experiment. Glass/epoxy is the experiment material and its properties are shown in Table I. The dimension of a lamina is  $1000 \times 1000 \times 0.165 \text{ mm}^3$ , and the load applied to the laminate is 2MPa. There are two objectives in this experiment: maximization of the strength ratio and minimization of the mass.

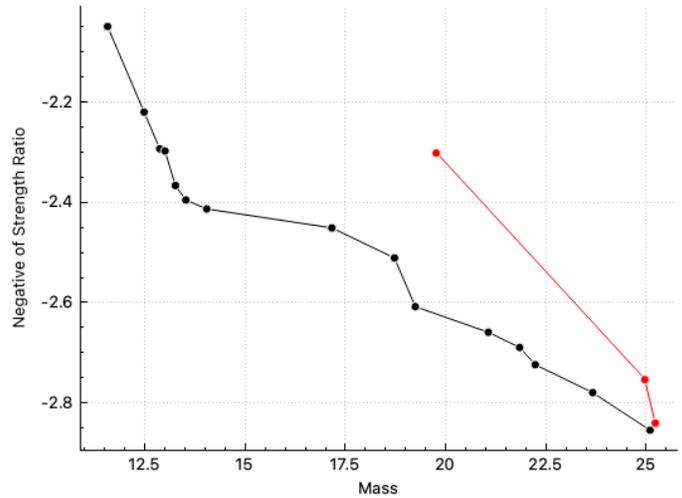

The Fig. 5 displays individuals in the mating pool during the NSGA-II process. In this figure, the x-axis is the mass, and the y-axis is the negative strength ratio because NSGA-II can only deal with minimization problems. Each individual corresponds to one feasible solution which represents the sequence of a laminate. In this figure, individuals are marked with a different color if they belong to a different frontier, then connect individuals in the same frontier, and there are two frontiers: the black and red frontiers. In the same frontier, no individual dominates the rest. For our problem, no individual is better than the other both in mass and strength ratio. This figure demonstrated that NSGA-II could maintain multiple solutions in the mating pool with one-time simulation.

TABLE I. GLASS/EPOXY PROPERTIES

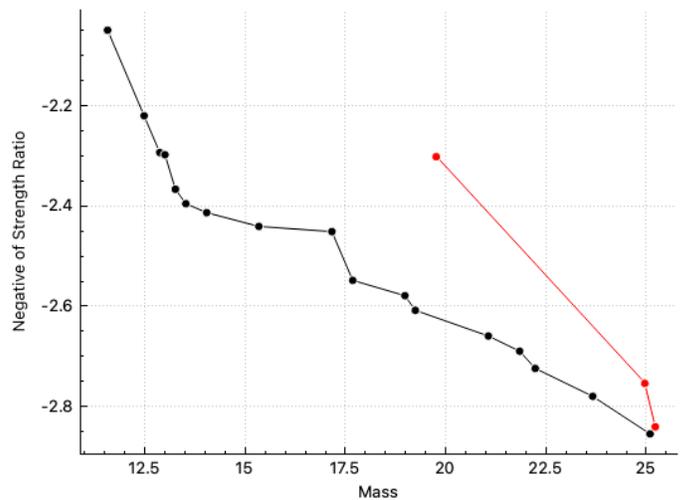

Property	Symbol	Unit	Glass/Epoxy
Longitudinal elastic modulus	$E_1$	GPa	38.6
Traverse elastic modulus	$E_2$	GPa	8.27
Major Poisson's ratio	$\nu_{12}$		0.26
Shear modulus	$G_{12}$	GPa	4.14
Ultimate longitudinal tensile strength	$(\sigma_1^T)_{ult}$	MP	1062
Ultimate longitudinal compressive strength	$(\sigma_1^C)_{ult}$	MP	610
Ultimate transverse tensile strength	$(\sigma_2^T)_{ult}$	MPa	31
Ultimate transverse compressive strength	$(\sigma_2^C)_{ult}$	MPa	118
Ultimate in-plane shear strength	$(\tau_{12})_{ult}$	MPa	72
Density	$\rho$	$g/cm^3$	1.903

It also clearly shows that the whole NSGA-II process is consist of two stages: 1) in the first stage, the number of individuals in the first frontier keeps increasing. At the beginning of this process, there are only 10 individuals in the first frontier, and the number of individuals comes to a peak when the generation is 24th. 2) In the second stage, the number of individuals in the first frontier begins to decrease. As shown in Fig. 5(e), (f), (g), and (h), the number of individuals in the first frontier is less than the number in the previous figure.

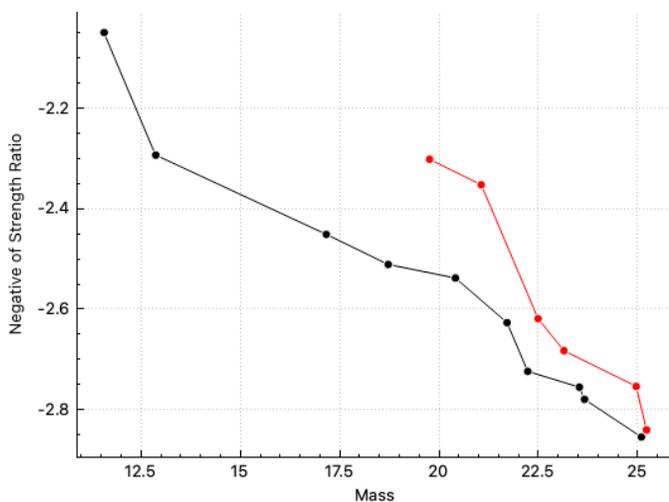

In this experiment, a set of feasible solutions is obtained using NSGA-II, which satisfies different strength requirements. In Javidrad [33] et al. work, only one feasible solution is found after one simulation with a hybrid PSO-SA algorithm, and therefore it is necessary to run this algorithm many times according to different constraints. Using non-dominated sorting genetic algorithms to optimize the design of laminates could reduce simulations times and improve efficiency.

Fig. 5. The Variation of Individuals' Number in each Frontier in the Population as the NSGA-II Proceeds.

## VI. CONCLUSION

In this work, we implement the non-dominated sorting genetic algorithm to guide the design of the laminated composite structure with two objectives: minimizing the mass and maximizing the strength ratio simultaneously. The experiment results have demonstrated that NSGA-II is an efficient algorithm to obtain multiple solutions in the first frontier. In our experiment, this algorithm obtains 19 individuals in the mating pool where each individual represent a feasible solution for solving the design problem. No solution dominates others in these individuals.

This simulation also demonstrated that the optimal run times for NSGA-II are from 16 to 32 for the design of glass/epoxy laminates. We also observe that the NSGA-II optimization process is consist of two stages: in the first stage, the number of individuals keeps increasing; however, during the second stage, the number in the first frontier keeps decreasing. The number of individuals in the first frontier comes to a peak if the run times of NSGA-II are from 16 to 32, which would significantly reduce computation cost and obtain an optimal result.

**Abstract**—Modern system architecture may increase the maintainability of the system and promote the sustainability of the system. Nowadays, more and more organizations are looking towards microservice due to its positive impact on the business which can be translated into delivering quality products to the market faster than ever before. On top of that, native support of DevOps is also desirable. However, transforming legacy system architecture to modern architecture is challenging. As manual modernization is inefficient due to its time-intensive and the significant amount of effort required, the software architect is looking for an automated or semi-automated approach for easy and smooth transformation. Hence, this work proposed a semi-automated approach to transform legacy architecture to modern system architecture based on static analysis techniques. This bottom-up approach utilized legacy source code to adhere to the modern architecture framework. We studied the manual transformation pattern for architectural conversion and explore the possibility of providing transformation rules and guidelines. A task-based experiment was conducted to evaluate the correctness and efficiency of the approach. Two open-source projects were selected and several software architects participated in an architectural transformation task as well as in the survey. We found that the new approach promotes an efficient migration process and produces correct software artifacts with minimum errors rates.

**Keywords**—Static analysis; software architecture; software modernisation; microservices

## I. INTRODUCTION

Monolithic architecture is a typical cohesive paradigm for the construction of a software system. In this perspective, Monolithic means that it's all composed in one piece. Monolithic technology is developed to be self-contained; program components are strongly interconnected instead of decoupled, as is the case with modular software programs. Each element and its related accessories must be available in a tightly linked design for the software to be functional.

Microservices are a type of architecture of systems in which a huge and complex system is designed as a series of lightweight services (i.e. loosely coupled). Every module serves a common business purpose and provides a simple, excellently defined endpoint to connect with all other resources.

Modern architecture such as microservices is introduced to increase the maintainability of a system. However, the transition from monolith to modern architecture is challenging as the manual migration process is inefficient due to its Time intensive and the significant amount of effort required. Researches [1] [2] [3] [4] have confirmed that the manual migration process is complex and lacks automated (or semi-automated) tools supported. Nowadays, more and more organizations are looking towards microservice due to its positive impact on the business which can be translated into delivering quality products to the market faster than ever before. On top of that native support of DevOps is also desirable.

The study aims at providing a semi-automated platform to guide software architects in transforming legacy architecture to modern system architecture. Furthermore, we aimed to fulfil the research gaps in software modernization by developing a semi-automated tool that may increase the efficiency of the software modernization process which may satisfy the need of software companies that are looking forward to such a tool to minimize the resources of the software modernization and deliver more value to their prospects. Thus, we perceive that providing a practical solution is crucial. The refactoring rules should be formulated based on the practitioner's and experts' practice. Hence, the refactoring rules are extracted from the refactoring practice that was discussed by the microservices experts from online discussion forums. Several possibilities on (semi-)automating the refactoring task in modernising legacy systems to microservices are investigated.

The main contributions of this study are the following: (i) Refactoring rules to transform legacy to microservices; (ii) Legacy to microservices refactoring framework and metamodel and (iii) Semi-automated legacy to microservices tool.

The remainder of this paper is structured as follow: Section II discusses the related research. Section III explains the research methodology while Section IV describes the correctness and efficiency evaluation. Section V discusses our findings and Section VI presents the conclusions and future work.

## II. RELATED WORK

This section discusses the transformation of the monolith to microservices architecture from the perspective of techniques

that were used such as model-driven, static analysis, dynamic analysis. We also discuss the other works that are related.

#### A. Model-Driven

There are several work that used model-driven technique in migrating monolith to microservices, such as [1], [4], [10], [23] and [24]. We detail some of these works in this paper.

Fritsch et al. [1] has presented 10 refactoring methods in scientific literature to migrate monolithic systems into microservice. The methods are subdivided into four classes. The result has shown that most of these techniques shall only apply under several situations. The limitations have been identified such as input data size and the need for an implementation tool.

Kamimura et al. [4] discussed the efforts to distinguish candidates from monolithic systems to microservices, i.e. endpoints or sometimes called webservice resources which could be turned into coherent, work-alone smaller services. This is a long and complicated manual endeavor that involves the review of several aspects of information engineering and always relies heavily on the professional performer's knowledge and expertise. To solve this issue, they established a method that distinguishes microservice applicants from the codebase using the SARF technology clustering algorithm with the given application classes and information's to be able to generate microservice candidates. The approach also captures the candidates derived to demonstrate the connection between the candidates being extracted with the whole system.

#### B. Static Analysis

Several works have used static analysis as the main technique for the monolith to microservices migration. The work includes [5], [6], [2], [3] and [11]. We discuss some of this work in more detail.

Mazlami et al. [2] focus on the failure of automated support instruments and formal models in the area of software migration. They proposed a formal extraction model as a form of an algorithm suggestion to identify the microservices candidates as a web application prototype. They applied their proposed algorithm to 21 open-source projects (developed using different programming languages, e.g Java, C++, Python) and showed that the generated microservice can decrease the size of the development team to half.

Gysel et al. [5] introduced Service Cutter, a service decomposition based on 16 coupling criteria distilled from the literature and industry experience. Service Cutter offers a service extractor framework that implements graph aggregating algorithms along with includes ranking based on scoring beginning from building blocks and structured documents such as domain model with its use-cases.

Li et al. [3] proposed a semi-automatic decomposition approach that used data flow to extract services from the legacy monolith that relates to business logic. The decomposition has been specified into three stages: (i) define the use case along with business logic is assessed as a baseline of specifications; (ii) comprehensive DFD over various rates and its process-datastore are constructed through the business logic based on functional requirements; (iii) developed an

algorithm to instantly bind the DFD to an undependable DFD. A comparative analysis that focused on relevant cohesion metrics and coupling metrics showed that a data flow-driven methodology is ideal in providing fair, repeatable, and readable microservice applicants. However, two (2) major limitations have been identified: (i) the dataflow method largely relies on the precise DFDs at all levels, and (ii) secondly do not put into consideration the non-functional requirements (NFR) of the microservices.

Levcovits et al. [6] outlined a strategy for describing and distinguishing microservices on a monolithic enterprise application. The assessment indicated that their methodology may recognize successful microservice candidates on a 750 KLOC financial system in which decreased the size of the code base modules and took full advantage of the architecture of microservices, such as the independent development and deployment of services and technological freedom. However, in certain situations, extra effort would be necessary to move mutual subsystems to a collection of microservices.

#### C. Dynamic Analysis

This subsection discussed the related work that uses dynamic analysis and also the combination of dynamic and static analysis.

Mayer and Weinreich [14] proposed an approach to constantly extracting services from a legacy software system based on REST microservices. Their approach relies on static and dynamic data collection, gathering input at runtime execution, and merging static and dynamic analysis. This customizable analysis technique captures runtime information to one dimension, allowing an analysis of the architectural design transformation over a longer period. Evaluated the proposed technique of a system, by establishing an empirical test that included several communicating services. The findings demonstrated the feasibility of the process of collecting and aggregating data.

Carrasco et al. [12] have discussed nine (9) potential mistakes in terms of specific bad smells. Such mistakes can be noticed and fixed along the way while transitioning to the new architectural style. As an illustration of a common mistake, when team members are separated across layers, for example, a front-end, code business Logic, and operation department, basic changes can require resources and time between the members of the team in authorizing the required action. From that point of view, a team member may propose a change on which level of the application they possess direct exposure to which can be limited by dividing responsibilities within specific services only. This work offers a strong foundation for relevant insights on the effective transition of monolithic architecture to the new architectural style.

ToLambda is a tool created by Kaplunovich [13] that dynamically allows the generation of system base code, turning the existing systems into healthier architectures, and continually improving. The tool converts existing java code into Nodejs code and changing the code structure to more modular using a microservices architecture. No experiment has been conducted to evaluate the correctness of the conversion and the architectural change.

#### D. Other Related Work

There are several works that related such as [7], [8], [9], [15], [16], [17], [18], [19], [20], [21] and [22]. We discuss some of these works in more detail.

Ahmadvand and Ibrahim [8] introduced a scientific method for breaking up monolithic applications into microservice applicants, aimed at an optimal level in safety and scalability as a quality attribute. Using this methodology, requirements engineers should carefully compare security and scalability criteria. This initiates design decisions at the requirement engineering activity and thereby extends the vision of the software architect's point of view regarding the system to be.

Meanwhile, Ren et al. [9] introduced a program-based research approach for moving the traditional monolith code to cloud applications. They suggested merging dynamic and static analysis of the binary code to derive the properties of the existing monolith program. The reactive tracing has been used to trace the functionality of the application, the user input data, the called methods and the accessed database information, and the rate of the method invocation throughout tracing. The experimental findings indicated that the new approach was successfully addressed the re-designing issue of the legacy system.

Tyszberowicz [15] proposed a systemic and rational approach to identify Microservices based on requirements in use and functional breakdown of those specifications. This method offered highly cohesive and tight decomposition coupled. The evaluation was conducted by implementing the approach on three different systems.

Meanwhile, Jin et al. [16] suggested a feature-oriented microservice retrieval approach to automatically create microservices candidates through a monolithic legacy system. Execution traces are used to facilitate the classification of features. Compared to the conventional approaches (which use static analysis), traces of execution can better represent software functionalities.

### III. METHODOLOGY

This section provides the study design and methodology of every stage and ethical considerations, in order to develop a supporting tool that can assist software architects while modernizing applications. The methodology of this study consists of the following four stages.

#### A. Stage 1 - Framework Development

At this stage, we develop the overall architecture of the framework that consists of several components that define the framework which will define the rules of software modernization. The relationship between the framework components will be depicted and describe briefly. Each component of the framework will follow the single responsibility principle so that components reuse is easy for further enhancement. The overall framework processes will be summarized in short and consist of an algorithm written in pseudo-code. Furthermore, the refactoring rules that will be applied on the web layer will be listed in detail as a table along with the UML class diagram that depicts how rules work.

#### B. Stage 2 - Tool Design and Development

For this first step, we will concentrate on developing our framework and the overall architecture to better understand the system elements, and we will use UML diagrams and IntelliJ as an integrated development environment platform to implements these design architectures. The tool would include features that allow users to import the legacy application to our current tool, then be able to re-architect the legacy applications using basic drag-and-drop features and automatically refactor rules to modernize the legacy features on the web layer and create compatible cloud artifacts.

#### C. Stage 3 - Evaluating Correctness and Efficiency of the Tool

We will conduct an experiment that is favorable in software engineering research to enable us to verify the proposed tool's correctness and efficiency. We will use 2 open source projects in this experimental research as a laboratory for this study. In this case, for a broader view of the problem anatomy, 2 open-source projects were both built-in java with distinct requirements. Selections will be made for the two open-source initiatives and further information will be given. In addition, with our latest proposed tool, we are also preparing to conduct an expert assessment and the participants will first be told of the general purpose of the analysis and asked to perform software migration using the semi-automated built tool and manual migration, then metrics will be guided by the outcomes of migration to compare both the manual and semi-automated solution. In addition, a structured questionnaire will be used to invite the participants selected for the research to participate in the survey and to share their views on the effectiveness of the process in the industry.

#### D. Stage 4 - Findings and Conclusion

Results from stage three (Experiment and expert assessment of the correctness and efficiency of the tool) will be addressed in this segment to see how the outcome fits the targets based on our established tool and eventually, conclusions will be drawn and potential work progress will be explored next.

#### E. Framework Architecture

Fig. 1 illustrates the framework components and how they interact to achieve a common goal which is modernizing legacy java application that is built on top of spring framework. A brief explanation of the Fig. 1 is as follows:

- **Legacy Code Container** is responsible for holding the legacy code and passing it to the filter component to be filtered.
- **Filter** is responsible for filtering incoming legacy codebase on the web Layer where controllers are located. Once controllers are identified they will be passed to the Refactoring component to be refactored.
- **Refactoring** is responsible for modernized legacy code to a new modern way it consists of four sub-components which are:
  - *Refactoring Rules* contains all the rules which will be applied to the legacy code

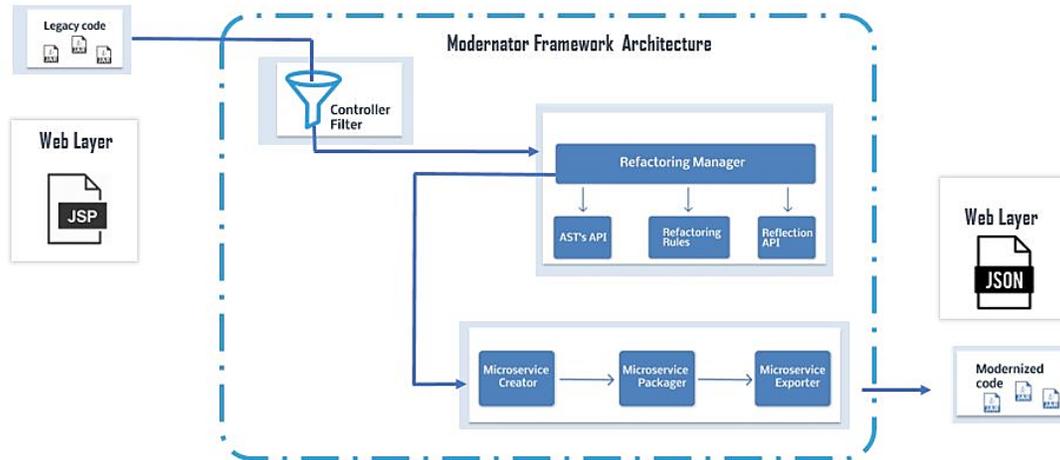

Fig. 1. Modernator Framework.

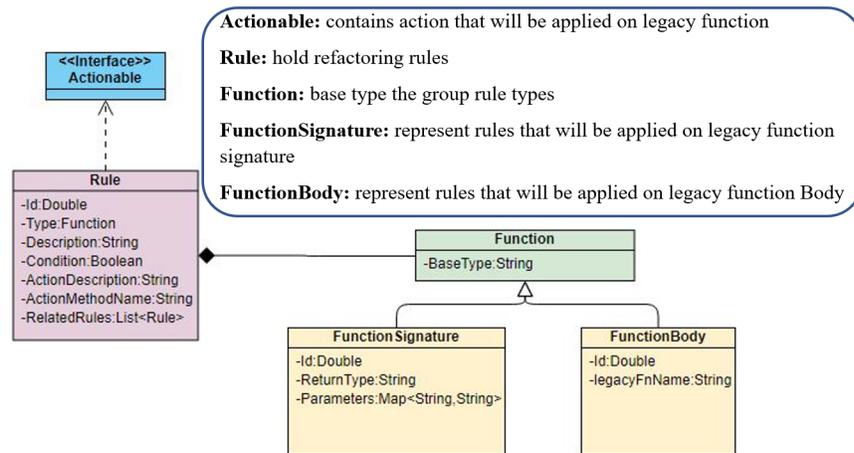

Fig. 2. Refactoring Rules Metamodel.

- *Refactoring Manager* process and takes care of the refactoring processes.
- *AST's API* contains needed API to understand the structure of the legacy code.
- *Reflection API* contains needed API to call rules that will be applied at runtime.
- **Microservices Creator** is responsible for taking refactored code and organize it and auto-generate the new microservices.
- **Microservices Packager** is responsible for taking newly created service and package it as a Docker image or jar/war.
- **Microservices Exporter** is responsible for exporting ready service to the user.

#### F. Framework Refactoring Rules Metamodel

Fig. 2 illustrates the metamodel of refactoring rules that are used in the framework. This figure shows that each rule

is associated with a function. Either it is associated with a function signature or a function body. Each rule should have an Id, Type, Description, Condition, Action Description, Action Method Name and Related Rules.

#### G. Framework Refactoring Rules Table

The below table contains all the rules that will be applied to a legacy code. The rules are categorized into two types as follow:

- **Function Signature** rules that will be applied on the legacy function signature which is either on the function parameter or function return type.
- **Function Body** is rules which will be applied in the body of the legacy function.

The main target of this work is designing and developing a tool that can modernize java applications. The legacy application will be used as input to the tool. The refactoring task will be performed at the controller's level in the web layer.

TABLE I. SET OF REFACTORING RULES

Rule ID	Rule-Condition	Related Rules	Before Refactoring	After Refactoring
<b>Rule Type: Function Signature</b>				
R1	Applied when : ModelMap object is presented as function parameter	R [2, 3, 4, 5, 6, 7, 8, 9, 10]	<i>String FunX (ModelMap map)</i>	<i>String FunX ()</i> {}
R11	Applied when: ModelAndView object is presented as function parameter	R [12 – 36]	String FunX(ModelAndView MAV){}	String FunX(){}
R37	Applied when: ConcurrentModel object is presented as function parameter		String FunX(ConcurrentModel CM){}	String FunX(){}
R38	Applied when: ExtendedModelMap object is presented as function parameter		String FunX( ExtendedModelMap EMM){}	String FunX(){}

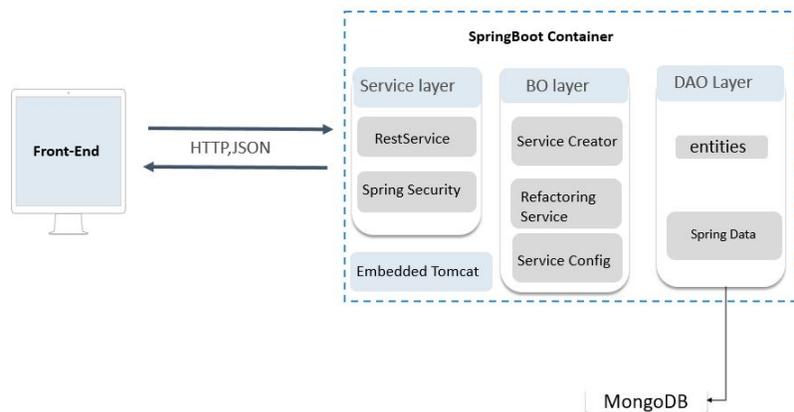

Fig. 3. Tool's Backend Architecture.

The refactoring task will be based on a set of rules (as shown in Table I) predefined by the tool to modernize the legacy application. Right after the refactoring, the tool can package the new application into a container which enables it to be cloud compatible, and in the final stage, the software architect will be able to download the newly modernized application.

The main target of this work is designing and developing a tool that can modernize java applications. The legacy application will be used as input to the tool. The refactoring task will be performed at the controller's level in the web layer. The refactoring task will be based on a set of rules (as shown in Table I) predefined by the tool to modernize the legacy application. Right after the refactoring, the tool can package the new application into a container which enables it to be cloud compatible, and in the final stage, the software architect will be able to download the newly modernized application. The proposed tool has been divided into two separate architectures: front-end architecture which represents the tool views and the Back-End architecture which represents the backbone of the developed tool and its functionalities. The front-end architecture is being developed using the Angular framework and comprises four (4) main modules:

- App Module: represent the starting point of the application such as index.html.
- Core Module: contains singleton components and services such as toolbar components.
- Feature Module: provides a feature that the application offers such as file upload.
- Shared Module: contains highly reusable components and services such as services that communicate with the back-end.

The core components (as illustrated in Fig. 3) of the back-end architecture are the following:

- Service Layer: handle incoming requests and security mechanisms such as authorization and authentication.
- Business Layer: concerned with service creation, refactoring, and packaging.
- Data access object layer: persist data into database.

#### IV. CORRECTNESS AND EFFICIENCY EVALUATION

In this study, we have conducted a survey to conduct an initial evaluation of the proposed semi-automated approach. The subsequent questions are formulated based on the research problem:

- Q1: Does the semi-automated approach promote efficiency in transforming legacy architecture into modern system architecture?
- Q2: How is the correctness of the generated system using a semi-automated approach?

##### A. Evaluation Setting

Since this work is an initial work of microservice modernisation, we conducted an initial expert evaluation to evaluate the effectiveness and the correctness of our approach. We

selected three (3) experts to evaluate our approach (based on our developed tool). All of the selected experts have at least five years of experience and have a software engineering background. The evaluation setting is the following:

- Step 1: The experts were asked to manually modernise a simple architecture module of software to microservice architecture.
- Step 2: The experts were introduced to the tool and allowed to use the tool.
- Step 3: The experts were asked to modernise a simple architecture module of software to microservice architecture by using the semi-automated tool.
- Step 4: The experts were required to answer several questions regarding the tool's correctness and efficiency in performing the modernisation task.

##### B. Results

As mentioned above, we aim at evaluating the correctness and the effectiveness of our approach (by using the semi-automated tool) in performing modernisation tasks. The result is based on the experts' answers to our survey.

1) *Correctness*: After performing all the required steps, we asked the experts about the error found (on average) when they use the manual approach and the error found after performing the modernisation task using our approach. In terms of the manual approach, one (1) expert mentioned that the 0 errors were found and the other two (2) experts stated that 1 – 5 errors were found in the manual approach. On the other hand, when we asked the experts on the correctness of our approach, all experts mentioned that (on average) they found 1 – 5 errors after they used our approach. From this result, we can summarize that the manual approach still produces better accuracy than using our approach. However, the result shows that the difference is not far (as illustrated in Fig. 4).

2) *Efficiency*: To evaluate the efficiency of our approach based on the semi-automated tool, after performing all the steps in Section IV, the experts were required to answer on the time to complete the tasks. By using a manual approach, all experts mentioned that they need to spend more than 4 hours to complete the microservice modernisation task. In contrast, by using the semi-automated approach, the experts stated that the modernisation task will be faster. One (1) expert mentioned that it takes 1-2 hours, one (1) expert mentioned that it takes 2-3 hours and another expert stated that it will take 3-4 hours. With this, we can summarize that by using our semi-automated approach, the modernisation task will be faster to complete compared to the manual approach (as illustrated in Fig. 5).

#### V. DISCUSSION

This chapter discusses the implications of the practical and theoretical implications of the study as well as a list of the limitation of this approach.

##### A. Practical Implications

To better understand the practical implication of this study will compare it to previous studies from an enterprise's point of

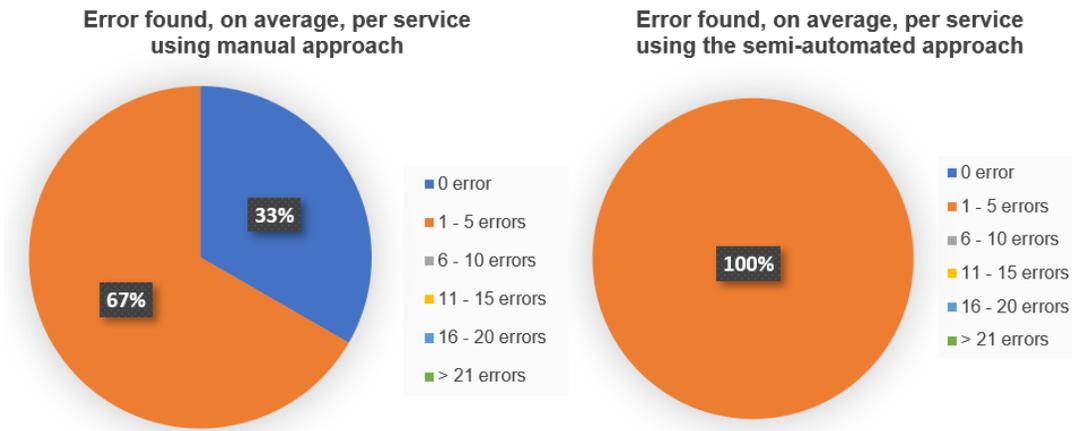

Fig. 4. Evaluation on the Tool's Correctness.

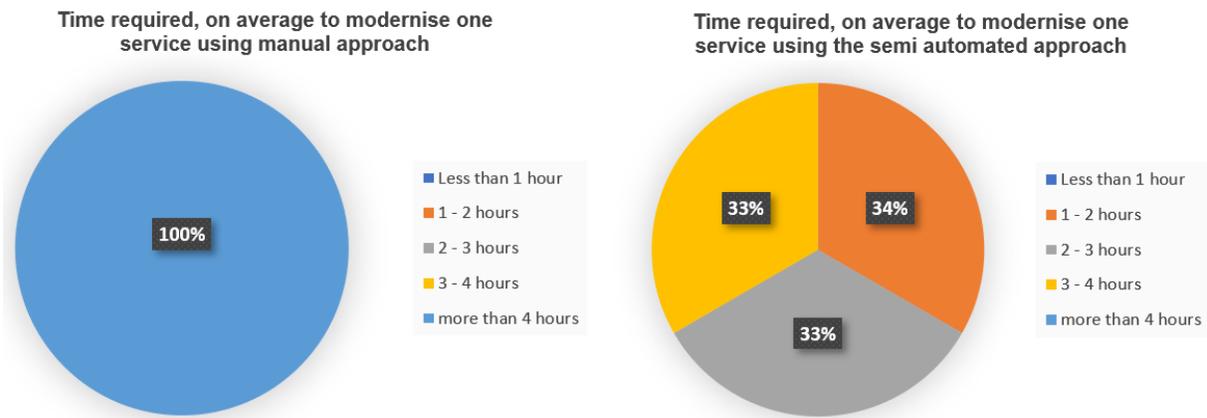

Fig. 5. Evaluation on the Tool's Efficiency.

view. Service cutter is a tool that assists in software transition from monolith to microservice by taking monolith domain model as input and suggested new decomposed domain model as microservices. On the other hand, our approach, Modernator is a tool that has been proposed and developed by this study which takes as an input monolith application (spring MVC) and does refactoring on the web layer, and produces microservice (spring boot) as an output.

We believe as organizations are looking to ease the transition from monolith to microservice while reducing the number of resources allocated to the transition in this case Modernator will have a positive impact on their transition as it produces production source code that can be alerted if needed comparing to service cutter that will produce domain model that needs to be implemented from scratch. However, Modernator will be useful only in the spring framework environment but since spring framework is widely used by enterprises as the backbone of their information systems that give Modernator a high rate to be widely used as well.

### B. Theoretical Implications

This study has introduced a list of refactoring rules that can be used to refactor legacy spring MVC controllers that in nature returns JSP pages to modern spring boot controllers

that return data in JSON format that is compatible with modern architecture such as microservice.

The construction of the rules has been made by following spring framework documentation and by identifying spring MVC legacy classes and mapping them to spring boot classes. The proposed rules can be divided into two type function signature which focuses of refactoring legacy function signature and function body that find legacy function calls. We were able to construct around 40 rules, however; these rules do not include all possible cases there might be other legacy classes that we did not discover in this study.

### C. Limitation

Since this work is an initial work for this study, we see a lot of possibility to improve this work based on the following limitations:

- Lack of boarder Evaluation.
- Support limited to java and more specifically application built with spring framework.
- Did not test all proposed refactoring rules.
- Refactoring focused only on Web Layer.
- Did not propose all possible refactoring rules.

## VI. CONCLUSION AND FUTURE WORK

The motivation behind this study is to fulfill the need of the industry to have a semi-automated approach for easy and smoothly transforming legacy system architecture to modern architecture. As the manual transition is inefficient due to its time-intensive and the significant amount of effort required. Therefore, this research proposed to develop a semi-automated tool to provide transformation rules and guidelines. An Expert Evaluation was conducted to evaluate the correctness and the efficiency of the approach. Lastly, this research has proved that the new approach promotes an efficient migration process and produces correct software to some extent.

For future work, we plan to conduct a Broader Evaluation of the proposed refactoring rules to further validated their correctness as well as constructing new rules for refactoring other layers such as the business layer and data access object layer.

**Abstract**—In recent decades, Intelligent home systems are popular because they improve comfort and quality of life. A growing number of homes are becoming "smarter" by incorporating Internet of Things (IoT) technology to improve comfort, energy efficiency, and safety. Increases in resource-constrained IoT devices heighten security threats and vulnerabilities connected with them. Using SDN and virtualization, the IoT's size and adaptability can be managed at a lower cost than ever before. Using these intelligent security solutions, we can achieve real-time detection and automation for attack detection and prevention using artificial intelligence. Consequently, a large variety of solutions utilizing machine learning and deep learning have been developed to mitigate attacks on the IoT. Thus, the goal of this work is to use machine learning and deep learning to defend smart homes with SDN-based. We have designed smart home environments using Software-Defined Networking and Mininet that provide Instant Virtual networks for IoT in smart homes. Two datasets were used in this work: the first SDN dataset, which we acquired from smart homes by launching real attacks and creating normal traffic, and the second IoTID20 dataset, which is publicly available online. On both datasets, conducted ML and DL experiments. The best accuracy on SDN Dataset was 99.9% using Xgboost classifier, and on IoTID20 was 98.9% LSTM in binary classification, and ANN 85.7% on multiclass.

**Keywords**—SDN; smart home; security; machine learning; deep learning

## I. INTRODUCTION

The Internet of Things (IoT) paradigm attracted a lot of attention from the scientific and business communities throughout the last decade [1]. Basically, such a technique is responsible for transferring massive data over a large network without the need for human intervention. The environment of the IoT consists of a huge number of smart devices that communicate with one another for sending and collecting massive sensing data, including wearables devices, sensors, actuators, mobile phones, smart home devices, etc. In 2021, the total number of installed smart devices in the world was 35.82 billion devices, while the total number of smart devices might increase to 75.44 billion by 2025 [2]. An environment will

change the way we work, communicate, and interact with one another.

At the same trend, IoT devices in the Smart Home provide some facilities, such as monitoring temperature, air condition, humidity, gas leakage, and fire. The IoT devices furthermore can be used in smart Refrigerators to automatically check the available or missing foods and to automatically lock and open doors. The mentioned facilities are just some of many that can be provided by the IoT devices in the smart home environment. Therefore, the Internet of Things (IoT) is the core of Smart Homes that provides electronic, sensor, software, and network connectivity within a home. Smart home technology has revolutionized human life by allowing access to information and services from anywhere and at any time [3]. On the other hand, some limitations existed in the Smart Home environment because of using IoT devices. The IoT devices have limited resources and are vulnerable to various attacks, so much research has been investigated to lessen such attacks by taking into account the limited resources of the IoT devices. Machine and deep learning have been utilized to protect against various cyber-attacks in the Smart Home environment, such as distributed denial of service (DDoS) attacks, eavesdropping, Man in the middle attacks (MiTM), and many others. Furthermore, Software-Defined Networking (SDN) is a technique used for enhancing security in the Smart Home domain.

Large-scale IoT networks in smart homes provide new issues in areas including device management, data storage, transmission infrastructure, computation, and privacy protection due it has different connectivity methods, transmission protocols, architecture, and applications that make it a security and privacy challenge so have been extensively researched to improve it. Various types of attacks come from different resources due to the lack of security mechanisms in the architecture of smart homes such as attacks on application layer-based, attack network layer-based, attack perception layer-based, and attack on middleware layer.

Machine learning algorithms are support vector machine (SVM), Random Forest (RF), and XGboost. For deep learning algorithms, we use Artificial neural networks (ANN), Long

short-term memory (LSTM), and Convolutional neural networks (ConvNet/CNN). The main contributions of this work are as follows:

- We built a suitable framework that integrates machine learning or deep learning with SDN, which makes the framework able to detect and prevent various type of attacks like DDoS, Man-in-the-middle, Jamming, and SQL injection.
- Designed a smart home system to provide security at a low cost based on minicomputer Raspberry Pi and Zodiac-Fx OpenFlow Switch.
- The effectiveness of the proposed technique was verified utilizing a recent publicly available dataset.
- We selected an appropriate SDN controller that was compatible with our needs and implemented simulation for the proposed system and tested the result.

The remainder of this paper is formulated as follows. Section II reviews related works. Section III is the proposed methodology. Section IV presents the discussion of the experiment results. Finally, Section V presents a conclusion of our work and highlights our future research directions.

## II. RELATED WORK

In [4], X. Huang et al. have proposed a Deep Reinforcement Learning paradigm, which combines two algorithms; Deep Learning and Reinforcement Learning which is based on learning by the concept of trial and error. This paradigm is proposed to be applied in SDN-based IoT networks to control the data overflow. This paradigm consists of three components, the environment, the SDN-enabled network, and the agent, which is the central controller of the network where Deep Reinforcement Learning is applied. The third component is the customer, who provides feedback regularly, where the agent responds immediately and controls the flow of the data accordingly to meet the customer's satisfaction. Their experimentation shows that this paradigm significantly enhanced the Quality of Experience of users compared to previously proposed studies. The simulated network topology was built using OMNET++, which is consisted of 65 nodes and 108 links, and the resulting confidence interval was 95%.

Another work conducted by G. Stampa et al.[5], also utilized the same concept of applying Deep Reinforcement Learning, but for the sake of optimizing the traffic routing, by learning on the go the normal and abnormal behavior of the flow of the network and keeping reconfiguring the network settings accordingly. For simulating the network topology, OMNET++ was used, and as stated by the authors, the results indicate a better user experience within SDN-based IoT networks in terms of network performance optimization.

In [6], T. Tang et al. have proposed a deep learning approach for SDN-based IoT networks to work as flow-based anomaly detection. Their proposed approach utilized the Deep Learning Network in Open Flow Controllers as the central network controller, where they applied it to a dataset called NSL-KDD. They worked on features selection and extraction, where they selected only six out of forty-one features, namely:

Duration, Protocol-type, Src-bytes, Dst-bytes, Count, and Srv-count. After that, they trained and tested the controller against common networking attacks. For the performance analysis, they used the following evaluation metrics: precision: 83, Recall: 75, and F1 score: 74, where the learning rate was set to 0.0001. for the accuracy, it was 75%, while the loss was 20%, compared to previously implemented algorithms such as Naïve bias, Random Forest, multi-layer perception, and support vector machine.

In [7], M. Ahmed et al. have proposed a mitigating DDoS attacks approach in SDN-based IoT networks, using machine learning algorithms such as Support Vector Machine, Gaussian Mixture Model, and Artificial neural networks. These algorithms are applied to the central controller of the network. The dataset used was a real dataset captured from the traces of a real network, where it contained 80,000 TCP connections, and these connections are split into three classes, 87% for HTTP, 6% for FTP, and 7% for attacks. The features of the data set are only three, which are being selected for training and testing the model that will classify the traffic of the network as either benign or malicious. The three features are the Total number of packets, Connection Duration Time, and the ratio of source and destination bytes. To prove the feasibility of their proposed approach, simulations were conducted by creating a prototype that utilizes the Dirichlet process mixture model for two web protocols, HTTP and FTP.

In [8], A. Al-Zahrani and M. Alenazi have proposed a machine learning-based Intrusion Detection system for SDN-based IoT networks. In their experimentations, they used the dataset NSL-KDD, and they selected only five features out of 41 features, namely: Duration, protocol type, Src-byte, Srv-count, Dst-host-same-src-port-rate. For the machine learning algorithms, they utilized the classical and advanced tree-based algorithms such as decision tree, random forest, and XGBoost, where they applied these algorithms at the OpenFlow switches to analyze the network traffic against network attacks such as Denial of service attacks, User to Root attacks, Remote to Local attacks, and probe attacks. The used dataset was split for training and testing, where the number of samples was 125.973 for training and 22.554 for testing. The results gave an accuracy of 95.95%, which indicates a high classification rate.

In [9], Q. Niyqz et al. have proposed a DDoS Detection System in IoT-based Software Defined Networks (SDN) using a stacked autoencoder as the deep learning algorithm used to build a classification model to analyze the network traffic against DDoS attacks. The dataset contains regular internet traffic with DDoS attacks in the protocols TCP, UDP, and ICMP. For performance analysis, all evaluation metrics were measures such as precision, recall, f1 score, and accuracy, where the last gave a value of 95%, indicating a high rate of classification that is suitable to be used in real networking environments. Moreover, an average computational time was computed where the training time took 524s, while the classification time took 0.0835s.

In [10], S. Sen et al. have proposed a DDoS detection system for SDN-based IoT networks using a Machine learning approach in the central controller of the network. For the experimentations, they applied a virtual SDN environment by

using the Adaboost decision stump to train the model on a dataset that contains private networking data. Their experimentation gave an accuracy value of 93%, with a low false-positive rate.

In [11], Y. Qin et al. have proposed an anomaly detection scheme based on machine learning algorithms to be applied in IoT-based SDN networks. An ensemble deep learning algorithm was used combining Convolutional Neural Network and Recurrent Neural Network, where this ensemble algorithm is used to deeply learn the main features of the traffic being analyzed against malicious attacks. The proposed method was implemented using Graphic Process Unit enabling a Tensor-Flow as the main controller of the SDN-based network. The experimentation was conducted on three datasets, namely: CTU-13, CSIC, and Sim\_data. For performance analysis, evaluation metrics were computed, such as accuracy, recall, and F1-score, where the accuracy given was 99.86%.

In [12], S. Mohammed et al. have proposed a DDoS Detection system based on machine learning in an SDN-based IoT network to protect such networks from such threatening attacks. The machine-learning algorithm used is Naïve Bayes, and the data set was NSL-KDD. Precision, Recall, and F1 score were calculated for performance evaluation measurements.

In [13], S. Dey et al. have proposed an anomaly detection system based on machine learning to be also applied in the OpenFlow controller of the SDN-based IoT networks. The machine-learning algorithm that was used is the Random Forest Classifier, which was applied to NSL-KDD dataset that contained 41 features. These features were processed for features selection and extraction using automatic tools such as Info Gain, Gain Ration, and CFS Subset Evaluator. The resulting accuracy is 82%.

In [14], J. Wu et al. have proposed a network link congestion prediction methodology for predicting whether the links are congested or not in SDN-based networks. The proposed methodology used machine learning to learn the information that features network congestion. During their implementation, they simulated a network topology that consists of 12 hosts and 13 switches, using a Mininet Simulator, and produced 559929 records of data being recorded from this simulated network and saved as the dataset to be preprocessed and learned to be used later for congestion classification. For the learning process, four algorithms were used, SVM, MLP, KNN, and IDCNN, where the last one gave the highest accuracy of 98.3%.

In [15], T. Tang et al. have proposed an Intrusion Detection System based on Machine learning for SDN-based networks to classify the flow of data in the network into legitimate and anomaly to check against many types of attacks such as DoS, R2L, U2R, and Prob. They used the dataset NSL\_KDD and two learning algorithms, namely: Gated Recurrent neural network and a Fully connected deep neural network. For performance analysis, they got 90% for GRNN. In addition, they evaluated the performance of their intrusion detection model over their simulated network in terms of resource utilization, throughput, and latency.

In [16], B. Susilo and R. F. Sari have proposed an Intrusion Detection Mechanism using Machine and Deep learning in SDN-based IoT networks, where their proposed methodology consists of three tiers, namely: Data plane that is responsible for the packet flow in a network, Control Plane that is responsible for network configuration and management, and Application plane that is responsible for the end-user applications. For implementation, they used three virtual machines: Kali Linux VM, Minimet VM, and Metasploitable VM, all installed on a Windows OS. For controlling the dataflows to classify and detect anomalies and network attacks, the Random Forest algorithm was used as a machine learning algorithm, and the Convolutional Neural network as a deep learning algorithm; both algorithms were applied to two datasets, BoT-IoT to be used for classifying Botnet Attacks, and CIC-IDS-2018 for classifying Intrusion attacks. Experimentations gave accuracy values of 90% for Bot-IoT and 99.95% for IDS-2018 when using CNN.

In [17], M. M. Raikar et al. have proposed a data traffic classification using supervised machine learning algorithms in SDN-based IoT networks, such as Support Vector Machine, Nearest Centroid, Gaussian Naïve Bayes (NB) over a dataset containing traces from a real network. The experimentation results gave accuracy values of 92.3% for SVM, 91.02% for nearest centroid, and 96.79% for NB.

In [18], Y. Handa and A. Mudanna have proposed an intrusion detecting model using deep learning to be applied in SDN-based IoT networks. As the network is split into three tiers, the data layer, controller layer, and application layer, the proposed model will be applied in the data layer of the network to check the data flow and classify it and filter it against anomalies and malicious attacks such as DoS attack, Probe Attack, User to root attacks (U2R), and Remote to Local attacks (R2L). For deep learning, Convolutional Neural Network was used first to do the feature extraction and then to do the learning and classification. The dataset used was called KDD 99, and the learned features were six; Duration, Protocol-Type, Src\_bytes, Dst\_bytes, Count, and Srv\_Count, where the data being examined in these features are learned to classify the data in packets flow into normal or malicious and hence detect intrusion attacks in SDN based networks.

The authors in [32] suggest a deep learning classifier-based SDN-based intrusion detection system for the Internet of Things. The suggested study is carried out in a simulated setting, with test accuracy of IDSIoT-SDL compared using a number of different matrices. From previous studies, gaps in IoT security solutions are costly and occur during a realistic attack environment. So, it is of the utmost need to develop low-cost solutions that can detect and prevent cyber-attacks in simulation environments that are carried out against or through IoT devices in real attacks.

### III. MATERIAL AND METHODS

A secure, adaptable architecture is proposed in this section for intelligent homes and is based on where monitoring network traffic. SDN architecture is examined from a security standpoint in this study. The proposed intelligent system for detecting attacks based on machine learning deep learning and utilizing SDN for security purposes SDN will be the suitable

technique for implementing SDN-based smart homes architecture. The proposed smart system uses the recent technique to classify network traffic and prevents attacks.

The proposed system consists of software or hardware that monitors traffic in real-time to detect and prevent security breaches as shown in Fig. 1. The system architecture consists of three layers: the First Layer sensor or data flow layer, the Second is the OpenFlow layer, and the third is the SDN controller. In our system, the Raspberry Pi will be used as a gateway for connecting sensors that use different protocols to the Internet via Wi-Fi, Ethernet, or Zigbee, Bluetooth, and cellular communications via protocol translation. OpenFlow switch called Zodiac-OpenFlow FX's it represents the second layer to forward data and control IoT device: There are four physical ports on Zodiac-OpenFlow FX's switch: port 4 for connecting the controller to the switch, and ports 1 to 3 for connecting switches with each other [19]. The controller in the system will be Raspberry Pi installed inside it ubuntu OS with Ryu controller. Data processing and forwarding are both under the control of the controllers.

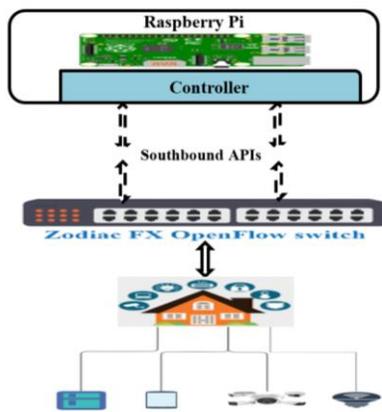

Fig. 1. Proposed System.

### A. SDN Controller

SDN controller was used as middleware or as framework for our system. There are a lot of type of controllers such as ONOS, Open Daylight Controller, Ryu. In our study, we have used Ryu for high traffic and network agility, so the Ryu controller is the best choice in our study. APIs and well-defined software components were incorporated into Ryu. Python was used as the coding language of choice for the Ryu game controller. We suggested installing Ryu on Raspberry Pi 4, which will minimize the cost. A decision is made by the controller about how each flow is forwarded. The data plane's flow table stores the decision, which can be made either reactively to newly discovered flows or proactively in the flow table. The controller function as the following:

- Data collection by Information snooper based on statics features for each type of attack this snooper is a python script.
- Send a request to open for the switch to start collecting the static feature from data table entry via southbound API.

- Extract some features related to attacks like MITM DDoS attacks.
- Select the critical feature for attacks that were predefined previously, like packet size, number of hops, etc.
- Automatically call the Machine learning or deep learning classifier to identify if traffic is abnormal; if yes, add a flag to the header in the data flow entry to take any action to block the host and drop the packet.

### B. Proposed System Simulation

The simulation and experimentation will be described in the following part. It is possible to prototype and conduct research quickly and easily with Ryu Controller's python-based fork of Ryu Controller, thanks to the language's ease of learning and short development cycle. We created a virtual network using the Mininet OpenFlow network to test our machine learning algorithm shown in Fig. 2.

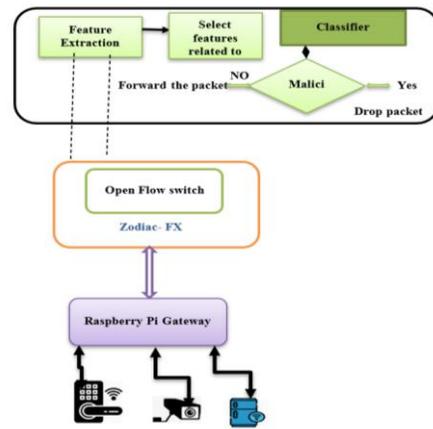

Fig. 2. System Scenario.

### C. Mininet OpenFlow Emulator

Mininet is a network emulation tool used to create a network of virtual hosts, links, and switches. To facilitate software-defined networking and bespoke routing, the Linux distribution provides Networking software for Mininet hosts. Tir switches support OpenFlow [20]. Our study used this simulator to test the proposed system and its effectiveness in providing a secure environment for the Internet of Things devices that make up intelligent homes. This system can detect cyber-attacks with high accuracy and prevent them in real-time. We have created 20 virtual hosts representing the IoT devices in smart homes and 20 OpenFlow switches, as shown in Fig. 3.

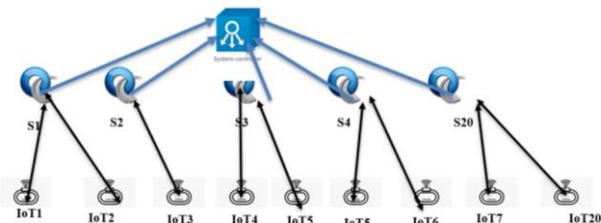

Fig. 3. Mininet Topology.

1) *Triggering attack*: Smurf attacks are distributed denial-of-service attacks in which huge numbers of Internet Control Message Protocol packets with the target victim's faked source IP are broadcast to a computer network using an IP broadcast address." In our experiment, we have triggered this type of attack for purpose traffic generation and collection. Parallelism is applied in traffic generation via the usage of the threading module, which allows several threads to execute at the same time. To produce faked IP addresses for non-existent nodes that are then used to flood targets, the `rand` function of the `Random` module is utilized, as is the `random` module. 0-255 is the range of the first, second, third, and fourth octets. It is also possible to utilize the `OS` module to allow. To specify the target IP address, port, and even the SYN TCP flag for the destination port. `Hping` tool has been used to generate this type of attack.

2) *Ryu controller*: Ryu is an open-source controller Python-based. Ryu can support a wide range of protocols. Ryu provides a well-defined API for software components. Network management and control apps may be quickly developed by developers [21]. RYU controller has been installed on a VMware machine that contains ubuntu OS. SDN is the system's brain to manage open flow switches and hosts. This controller works by sending a flow stats req message to the OpenFlow switch and asking the controller to send a flow stat to reply message back. Requests for data from the Ryu controller module are made every five seconds, which was considered the best time frame for detecting assaults early enough to safeguard the controller. There is a "Flow Removed" message that the switch sends the controller when a flow entry is deleted, either because of a hard timeout or because of a period of inactivity. Only if the "OFPPF SEND FLOW REM" flag is set in the Flow Mod message will the "Flow Removed" message be delivered. FlowMod messages from the controller may also remove flow entries, resulting in the "Flow Removed" message. It is possible that "Flow Removed" is caused by a timeout, which may be either an idle timeout, which occurs when there are no matching packets for some time or a hard timeout, which occurs when there is a predetermined amount of time remaining.

#### D. Data Processing and Models

1) *Dataset collection*: We have used two datasets; the first one is called the SDN dataset. It has been collected by training real attack on the SDN environment, and the second one it's available publicly on the internet for research purposes.

For SDN dataset, the data was captured using the Wireshark app as (pcap). This monitored all ports and captured the incoming and outgoing data in all ports with different protocols. The Wireshark program (pcap) captured the data by listening to all ports and capturing the incoming and outgoing data in multiple protocols. Protocols, flow duration flags, byte count per Second, and the source and destination IP port numbers. Python controller module accepts the flow monitor's data and extracts it into a format that the trained model can use for prediction. Then we utilize entropy (statistics features) to estimate the distribution of these variables and train the model

using normal and atypical traffic data for smurf or DDoS assault.

In this work, we have collected by triggering attacks and normal traffic. The Attack was performed on the Mininet host that represents Internet of things devices. The Attack is implemented using the `Hping` tool and "pingall" command and Normal traffic is collected by ping command between each device. Then data is collected as a CSV file on the SDN controller (RYU) that enables the socket to listen on all ports on the Open flow switch that is included on Mininet topology as shown in Fig. 8. The process iterated till we reached the required size of data. the data size reached above 250 MB that size is enough to train the model. The Normal traffic collection process shown in Fig. 4 and the attack traffic shown in Fig. 5.

For IoTID20 Dataset, we have used the IoTID20 dataset, collected by Imtiaz [22]. This dataset was collected using the SKT NGU and EZVIZ Wi-Fi cameras, which are smart home devices. The dataset contains 86 features; after pre-processing the features have been reduced to 80 features. We performed pre-processing; First, we removed all nulls and invalid values, then we labelled and scaled the data using a stander scaler, label encoder, and a data splitting using K-fold to 10 groups to combat overfitting in the second experiment splitting data by ratio of 25 %for testing and 75 for training.

2) *Data Pre-processing*: Data pre-processing is the process of transforming unstructured data into a form that can be read, accessed, and analyzed. The raw data cannot be used in data mining; therefore, this is a critical step. Check the data quality before using machine learning or other methods. The primary purpose of data pre-processing is quality control.

Fig. 5. Attack Traffic Collection in Mininet.

The following are ways to evaluate the level of quality to ensure that the data entered is accurate.

- Checking for completeness: determining whether the data has been captured.
- To ensure that all the data is maintained in the same location, one must ensure that all information is consistent.

3) *Data normalization*: Normalization is generally required when we are dealing with attributes on different scales because, if it is not done, it may lead to a dilution in the effectiveness of an important equally important attribute on a lower scale because of another attribute having values on a larger scale. Normalization is generally required when we are dealing with attributes on different scales. When there are several attributes, but those attributes have values that are measured on different scales, this can result in inadequate data models when executing data mining activities. Therefore, they must be normalized so that all the properties may be measured on the same scale.

4) *Feature extraction*: The goal of feature extraction is to cut down on the total number of features in a dataset by generating new features based on the ones that are already there and skipping the original features. After being trimmed down, this new collection of features ought to be capable of summarizing most of the information that was included in the initial set of features. By combining the components of the original set in this way, it is possible to generate a condensed version of the original features.

5) *Feature selection*: The act of selecting the features that will most significantly contribute to the prediction variable or output that you are interested in can be done either automatically or manually and is referred to as "feature selection." Feature selection reduces the amount of predictive model input variables. Reducing the amount of input variables can minimize modelling costs and increase model performance. Statistical-based feature selection approaches evaluate each input variable's relationship to the target variable and select those with the strongest association. The choice of statistical measures depends on the input and output data types.

6) *Machine learning models*: The project model's primary goal in the IoT-smart homes-based collection is to detect whether a traffic flow is normal or abnormal based on learning from an existing labelled data. The flow-based detection module needs a model that can distinguish an attack from a regular flow to work.

7) *Xgboost*: Extreme Gradient Boosting (Xgboost) Learning techniques are used to transform weak models into strong estimators that function sequentially as circular iterations [23]. As in neural networks, each one seeks to rectify a mistake in its preceding model in order to minimize the loss function. There are several ways to increase your model's performance, but Gradient Boosting is one that focuses on fitting the new predictor to fit on the pseudo-residuals (errors) of its predecessor, rather than modifying the weights for each

wrong classification at each iteration. In order to attain the best possible accuracy, ensemble machine learning uses a variety of ML models. An ensemble machine learning methodology for classification, regression, and ranking problems, XGBOOST is a current ensemble machine learning method. Fast and efficient implementation of Gradient boosting structure to identify the best tree models. On August 1st, 2016, Tianqi Chen and Carlos Guestrin launched the project. Uses Gradient Boosting to discover the best and most accurate tree model, emphasizing computation speed. Parallelization, Cache Optimization, Distributed Computing, and processing a vast dataset are all supported by XGBoost.

We have used this algorithm in our study. After training the model, we tested the pre-trained model's performance on actual attacks on IoT devices in an intelligent home virtual environment using the Mininet with SDN controller. The captured data from the OpenFlow switch passes through this classifier to identify if traffic is benign or malicious. If the traffic is malicious, add a flag to the packet in SDN to take any action and send a request to open the flow switch to drop it, as shown in Fig. 6.

Fig. 6. Packet with Flag.

8) *Support Vector Machines (SVM)*: SVM is a set of supervised learning techniques applied for classification or regression. SVM classifier has been adopted in our model for intelligent home security. A key objective of the SVM technique is to find the optimum decision boundary or line that can divide n-dimensional space into classes [24], allowing us to classify new data points quickly. A hyperplane denotes the border of optimal decision-making inside a problem domain. To create the hyperplane, the SVM uses the most extreme points/vectors in the dataset. So-called "support vectors" refer to these extreme circumstances, and the process is known as a Support Vector Machine.

9) *Random Forest (RF)*: It is commonly utilized in Classification and Regression issues as a supervised Machine Learning Algorithm. It creates decision trees on various samples and uses their majority vote to classify and average the data[25, 26]. The Random Forest Algorithm's ability to handle data sets with continuous variables, such as regression, and categorical variables, such as classification, is critical. When it comes to categorization challenges, it does a better job.

10) *ANN classifier*: Computerized Brains ANN is a computer system component that attempts to simulate the human brain by personifying the nervous system. Many neurons link to one other. Every node or neuron in an artificial neural network follows the same paradigm for receiving information. An artificial neural network (ANN) consists of input neurons, weights, biases, hidden layers, activation functions, and an output layer that can be fed-forward or back-propagated.

11) *Long short-term memory*: Schmid Huber and Hoch Reiter proposed the LSTM deep learning algorithm in 1997 as a variant of the RNN network. It's made to store previously entered data. Classification and forecasting of time series are both possible applications most frequently used on Sequential data, such as speech recognition, translation, and picture captioning, which are well-suited to LSTM. LSTM is a good choice for applications related to the period. It types a back-propagation neural network. Forget, input, and output are the three gates of the LSTM [27].

The input gate picks the appropriate value from input samples to adjust the cell's memory and input. For three gates, the Sigmoid function is employed as a combining function that returns a value between 0 and 1. Calculated values are given additional weight by the Tanh or Relue functions. Sigmoid is a forget gate that decides whether new information should be stored in the cell state or discarded. Sigmoid input gate layers pick Tanh and Relue to update next. The next concealed state that should be remembered when the output gate is closed is selected. The concealed state decides what data should be preserved for the following phase and the hidden state is used for predictions.

We will use two layers of LSTM with 200-500 neurons and various optimizers, such as Adam, Rmsprob, Nadam, -SGD, loss sparse categorical cross-entropy, Activation Relu, and Activation Relu. Dropout = 0.2 or 0.5, 6 Dense layers with varying values, SoftMax for towing and four classes.

12) *Convolutional neural network*: ConvNet/CNN) is a deep learning system that can feed an image or numerical data and apply a filter, adding adjusted weights and minimizing biases to various objects in the picture and be able to discern one from the other. This approach requires less pre-processing than previous classification methods. Rather than relying on hand-engineered or traditional technique filters, CNN may be trained to learn these filter characteristics over time. The arrangement of the Visual Cortex served as inspiration for the design of the CNN architecture, which is similar to the neuronal connection pattern found in the human brain [28]. A visual field area known as the Receptive Field is where neurons respond to visual input. The whole visual field is covered by a group of such fields that overlap. Neurons in convolutional neural networks are geometric functions that calculate the weighted sums of numerous inputs, output and initiation values. The first layer of CNN commonly detects essential visual characteristics. Data is then passed from one layer to the next, allowing for increasingly complex features each time. The layers of CNN can recognize more complex characteristics, such as faces, objects etc.

#### IV. EXPERIMENTAL RESULTS

In this experiment, four machine learning algorithms have been used KNN, Xgboost, SVM, and random forest. Each classifier is trained to classify the IoT traffic as either normal or abnormal. The binary classification shows excellent results in detecting the attack in passive mode and real-time mode, the result is shown in Table I.

TABLE I. PERFORMANCE METRICS IN MACHINE LEARNING

Classifier	Accuracy	Confusion Matrix
SVM	99.8	[[ 6860 1] [ 0 217712]]
RF	99.9	[[ 6861 0] [ 1 217711]]
XGBOOST	99.9	[[ 6861 0] [ 0 217712]]
KNN	99.7	[[ 6861 2] [ 0 217703]]

1) *Artificial Neural Network (ANN)*: Artificial neural network model consists of three layers with 100 neurons for each layer, input shape 78, and RELU Activation function. And sigmoid for binary classification. The same architecture has been used on multi-classification but with differences in last layer SoftMax for five classes. The model was trained with 200 epochs by the Adam optimizer. the obtained accuracy reached 98.9 for binary classification and 83.2 % for multi-classification as shown in Fig. 7 and Fig. 8. Confusion matrix of ANN binary classification shown in Fig. 9.

In the LSTM model the architecture consists of two layers with 200 neurons for first one and 50 neurons for second. The next layers are dropout with 0.2, four dense layers with activation Relu, and the last layer is softmax for two classes. The model trained on binary classes and multiclass with five classes on different optimizers. The best result was obtained for the binary classes with an Adam optimizer, 200 epochs, and batch size 3000. The performance of the two models for LSTM shown in Fig. 10 and Fig. 11. The accuracy reached to 99% on binary classification and 84.7% for multiclassification. Confusion matrix of LSTM with multi classification shown in Fig. 12.

## V. DISCUSSION

After running an experiment, we triggered attacks for data collection purposes and trained three Machine Learning algorithms on the training set. In the Software-Defined Networking (SDN) environment we have made simple attacks to test the machine learning models in real-time. The second section shows the result deep learning experiment. The evaluation of the two experiments on two datasets is shown below. The result shows an excellent performance to detect the attack on IoT devices on smart homes that have been simulated on SDN and open virtual open flow switches and (Hosts) that represent IoT devices. Five machine learning classifiers have been used; the highest obtained accuracy achieved by Xgboost classifier. In the second experiment on IoTID20. Several experiments have been conducted using machine learning and deep learning:

- On binary classification two classes normal and attack.
- Multiclassification for five classes ("Mira, Dos, Scan cat, Normal, MTM ARP Spoofing").
- Binary classification with 5-k fold cross-validation and 10-k fold cross-validation.
- Multiclassification with 5-k fold cross validation and 10-k fold cross-validation.

The result shows the superiority of deep learning in detecting electric attacks, Internet of things devices in smart homes as shown in Table II and Table III. The output has been evaluated using accuracy, precision, f1-score, Sensitivity, and Specificity. Two models have been implemented for each neural network. The evaluation on stander data splitting using traditional method 70% and 30 % is shown in Table IV. The second experiment conducted by splitting date to 10-k fold groups the result was better than 5-k fold groups is shown in Table IV. According to the results of our model compared to the results of previous studies shown in Table III, the proposed model achieved high accuracy results and it is recommended to apply it to actual discovery in IoT environments.

## VI. CONCLUSION

There is a rapid expansion of the Internet of Things (IoT) into previously unimagined areas and domains. In addition to factories, agriculture, cities, and transportation are included in this. In recent years, the Internet of Things (IoT) has grown in popularity as a growing number of applications and devices, such as medical devices, home sensors, wireless sensors, and other closely linked IoT gadgets, have been implemented. IoT security is sometimes overlooked since it takes time to fully assess a device's vulnerabilities. Widespread use and quick adoption of such technologies raises security concerns. Cyberattacks affect resource availability, causing financial and material damage. As a result, fresh strategies are needed to increase not only IoT's security against cyberattacks, but also their identification and mitigation from IoT networks. Smart-home security IoT is a big concern due to lack of computing power and device heterogeneity. IoT devices can't handle computationally intensive and latency-sensitive security tasks due to their low processing power. Our research aimed to defend smart home-based Internet of Things devices from hacking. It is of the utmost need to develop low-cost solutions that can detect and prevent cyber-attacks that are carried out against or through IoT devices. We thus proposed in this work a smart system to guard against attacks on smart homes utilizing Software-Defined Networking, Machine learning, and Deep learning at a cheap cost to prevent threats on devices from both the inside and the outside.

We have implemented the classification process of the IoT traffic in a simulation environment using Ryu SDN controller and Mininet for detection attacks on traffic using Machine learning classifiers; SVM, KNN, RF, Xgboost, we collected data by triggered real attacks on IoT devices and generated normal traffic also, then we have trained the models and test them on testbeds environment (SDN). The result showed the ability to identify the normal and abnormal traffic with accuracy reached 99.9 %. Then we introduced deep learning as proof of concept to detect the attack in a smart home environment, IoTID20 dataset has been used for training the deep learning models, ANN, LSTM, and CNN. The turning process was conducted on the binary classification to classify their traffic as normal or abnormal, and multi-classification to identify the attack type on IoT. The highest achieved accuracy for binary classification was 98.9 % using long short-term memory (LSTM), 85.7 % on multiclass using Convolutional Neural Network (CNN). Other deep learning classifiers can be investigated for use in the improvement of future work. The suggested model's simulation results can be put to the test in a live setting with both heavy attack and typical traffic.

## ACKNOWLEDGMENT

The authors would like to thank the Deanship of Graduate Studies at Jouf University for funding and supporting this research through the initiative of DGS, Graduate Students Research Support (GSR) at Jouf University, Saudi Arabia.

# Skin Melanoma Classification from Dermoscopy Images using ANU-Net Technique

Vankayalapati Radhika, Dr. B. Sai Chandana

School of Computer Science Engineering, VIT-AP University, Amaravati, Andhra Pradesh, India

**Abstract**—Cells in any area of the body might develop cancer when they begin to grow uncontrollably. Other body regions may become affected by it. Skin cancer known as melanoma develops when melanocytes, or cells that create melanin, the pigment that gives skin its appearance of color, start to develop out of control. Melanoma is deadly because, if not caught early and addressed, it has a high propensity to spread to other regions of the body. Analyzing digital dermoscopy images, create a unique approach to categorizing melanocytic tumors as malignant or benign. Every single newly formed mole has a unique shape and colour compared to the pre-existing moles and given few more issues to classify the melanoma. To overcome all of these issues, this paper uses deep learning techniques. In this paper, a four-step system for classifying melanoma is described. The first stage is pre-processing, followed by the removal of hair from dermoscopic images using a Laplacian-based algorithm and then removing noise from the images using a Median filter. The second method is feature extraction from pre-processed images. Extracting features including texture, shape, and color using the Principal Component Analysis (PCA) technique. Thirdly, the LeNet-5 approach is utilized to locate the lesion location and segment the skin lesion. Fourth, the ANU-Net technique is used to categorize the lesion as cancerous (melanoma) or non-cancerous (non-melanoma). Evaluated based on performance parameters such as precision, sensitivity, accuracy, and specificity. Results are compared to those of current systems and show higher accuracy.

**Keywords**—Melanoma; LeNet-5; ANU-Net; dermoscopy images; benign; classification

## I. INTRODUCTION

Melanoma is a prevalent form of malignant that develops in the epidermal layer of the skin from abnormal cells caused by exposure to UV light. In an area with intense sunlight, one in five Americans (US) is at risk of developing skin cancer. Melanoma is the nineteenth most prevalent malignancy overall among all forms of skin cancer, with around 3.0 million new cases reported in 2018 [1]. In the US alone in 2019, melanoma claimed the lives of 2,490 females and 4,740 males on average. In 2020, there will likely be 1.0 million new cases of melanoma, according to projections. 2020 is expected to see an estimated 6,850 additional cases of melanoma deaths in the US alone, with 2,240 females and 4,610 males [2]. Skin cancer is currently diagnosed using a variety of imaging methods, including dermoscopic images, magnetic resonance imaging, optical coherence tomography, and confocal scanning laser microscopy. Dermatologists examine those images visually, which is frequently a laborious and time-consuming operation.

Melanoma is the worst type of cancer among skin cancers, and its prevalence is rising quickly globally. Early detection is crucial since skin cancer can be treated with a straightforward excision. Most of the time, the visual analysis could be inappropriate and result in a false identification because the different skin lesions (non-melanoma and melanoma) are similar to one another [3-5]. A non-invasive skin imaging procedure called dermoscopy enables a magnified view of the skin's surface and subdermal processes. By aiding in the early detection of MM, dermoscopy images have significantly increased the survival rate of patients. While still the undisputed top standard, expert human diagnoses are nevertheless prone to bias.

The number of skin cancer diagnoses is increasing in past years. Melanoma and benign skin cancer are the two main varieties. Melanoma is one of the worst forms of skin cancer and is a major cause of death in young people each year [6, 7]. The severity and symptoms of skin disorders vary; for instance, a nevus is a normal skin lesion caused by the growth of pigment-producing cells also known as melanocytes, but melanoma is a severe form of skin cancer that can arise from a benign lesion [8].

The same nevus cells that produce pigment can give rise to melanoma. Melanoma is a fast-evolving disease that is responsible for a high death rate among the global population, according to research in both the medical and analytical fields [9-11]. With the early-stage discovery, the skin lesion can be treated. If melanoma is detected early, the survival percentage will be higher and it will be treatable. However, the manual diagnosing process necessitates dermatology specialists with appropriate training. An experienced dermatologist is very expensive and takes a lot of time. The most important phase in these systems is feature extraction, where several features can be utilized to check the pigmentation, shape, or evolution of skin lesions or to distinguish melanomas from benign lesions [12]. These features include asymmetry, border irregularity, and color. Dermoscopy technology offers a further improvement in diagnosis. Applying the dermoscopy approach to the skin will allow you to highlight locations by taking illuminated, magnified images of the skin lesion without making any incisions. Additionally, if the skin surface reflection is eliminated, the visual impact of the deeper skin layer can be enhanced. However, due to a variety of problems, classifying melanoma dermoscopy images is a challenging task [13]. In this paper, proposed four steps to classify the melanoma. They are pre-processing, feature extraction, segmentation, and classification. Initially, utilize a Laplacian-based algorithm to remove hair from dermoscopic images

during the pre-processing stage, and then a Median filter to eliminate noise to segment the dermoscopic images. The principal component analysis method is used for feature extraction to extract features including texture, shape, and color. After feature extraction completed, the skin lesion is segmented using the LeNet-5 technique to identify the lesion region, and the classification process is then carried out. Using the ANU-Net approach, categorize the lesion into benign (non-melanoma) and malignant (melanoma) during the classification stage. The key contribution of this paper is:

- This paper uses deep learning techniques for classifying melanoma into malignant and benign by using dermoscopic images. First, do pre-processing to remove hairs on images to get better segmentation and also remove noise on images.
- A PCA method using for feature extraction process to obtain the features such as shape, color, and texture of the image.
- Then utilizing LeNet-5 technique for segment the skin lesion area in dermoscopic images and after that classify the skin lesion into non-melanoma or melanoma using ANU-Net technique. Here collect dermoscopic images from ISIC 2020 dataset.

This paper is structured as follows. The related research on deep learning-based melanoma classification is covered in Section II. The proposed methodology and its components are covered in detail in Section III. The experimental strategy is described in Section IV. The study is reviewed in Section V along with suggestions for additional research.

## II. LITERATURE SURVEY

A literature review is presented and discussed in this paper to offer a speculative background about melanoma skin cancer classification. Hosny et al. [14] suggested a classification method based on DCNN. There are three primary steps in the suggested procedure. In the beginning, the ROI is segmented in the input color skin images during preprocessing. Second, translation transformations and rotation are used to enhance the segmented ROI images. Third, various deep convolutional neural network (DCNN) designs are used, including GoogleNet, Alex-net, and ResNet101. To better suit the task of classifying lesions, the final three layers are removed and replaced with fresh ones. DermIS & DermQuest, MED-NODE, and ISIC 2017 are three separate datasets that were used to assess the performance of the suggested technique.

To detect and categorize dangerous skin lesions (melanoma type), Ponomaryov et al. [15] introduced a computer-aided detection (CAD) system that combines handcrafted features from the medical algorithm Asymmetry Borders-Colors-Dermatoscopic Structures (ABCD) rule with DL features using Mutual Information (MI) measurements. Pre-processing, extraction of features, feature fusion, and categorization are the steps in a CAD system that may be distilled into a single phrase. To identify the Region of Interest (ROI), a lesion image is improved, segmented, and filtered during the preprocessing stage. The feature extraction method is then carried out. Shape, color, and texture are examples of

handcrafted features that are utilized to represent the ABCD rule. DL features are obtained using a CNN framework that has been pre-trained on ILSVRC ImageNet. Utilizing MI denotes a fusion rule, the most crucial data from both kinds of characteristics are gathered. Finally, numerous techniques are used during the classification process, including Relevant Vector Machines (RVMs), Linear Regression (LR), and Support Vector Machines (SVMs). The public dataset from ISIC 2018 was used to evaluate the developed system.

An excellent and efficient melanoma detection approach was presented by Masood et al. [16]. Three steps make up the suggested approach: 1) image preprocessing, 2) use of a Faster-RCNN for skin cancer localization, and 3) application of an SVM for the categorization of customized skin cancer regions into malignant and benign classes. The suggested technique's effectiveness is assessed utilizing data from the benchmark ISIC-2016 dataset, which was made available by the ISBI Challenge 2016. This dataset is diverse in terms of differences in color, luminescence, melanoma size, and texture, as well as the noise presence, blurring, small blood vessels, and hairs, among other things. Additionally, they validated the technique across multiple datasets using the ISIC-2017 dataset to demonstrate its effectiveness in practical settings.

The Automated Skin-Melanoma Detection (ASMD) system with Melanoma-Index (MI) was presented by Tang et al. [17] as being unique and original. The system includes binary classification, entropy, and energy feature mining, image pre-processing, Bi-Dimensional Empirical Mode Decomposition (BEMD), and image texture improvement. The system's design was influenced by feature ranking, and the quality of the system was evaluated using Student's t-test and other statistical techniques. Using benchmark databases, the proposed ASMD was applied to 600 DD malignant and 600 benign images.

Four steps are included in the Kumar et al. [18] proposed system for melanoma identification and categorization: pre-processing, which includes dermoscopic images being resized, and noise and hair being eliminated; image segmentation, which involves locating the site of the lesion; extraction of feature, which involves obtaining features from the segmented lesion and then categorization; and classifying the lesion as benign or malignant. To produce skin lesions, a modified GrabCut algorithm is used. Using machine learning techniques like ANN, k-NN, SVM, and logistic regression, segmented lesions are categorized, and their performance is assessed in terms of specificity, accuracy, and sensitivity.

Rahman et al. [19] introduced an automated approach for pixel-based seed-segmented images with multilevel and fusion characteristics downsizing for the recognition and detection of skin lesions. The suggested approach entails four crucial steps: Implemented methods include: (a) mean-based function feeding input to bottom-hat and top-hat filters that were later fused for contrast increasing; (b) graph-cut method-based lesion segmentation and seed region growing and fusing both segmented lesions through pixel-based fusion; (c) simple concatenation and multilevel feature extraction; The method's effectiveness is tested in two independent experiments.

From the literature survey, some of common problems are noticed. They are, every single newly generated mole differs from the pre-existing moles in terms of shape and colour. The mole's outline or outer covering is uneven, largely asymmetrical, and appears gritty. It states that around half of the moles present do not match the other half of the moles. Accurately determining the importance of a specific feature is challenging. For effective medical image diagnosis, a collection of more sophisticated deep-learning architectures should be used. To overcome these issues this paper used effective recent proposed methodologies to classify the melanoma clearly.

### III. PROPOSED METHODOLOGY

The most dangerous type of skin cancer, melanoma is on the rise all over the world. Melanoma incidence has increased globally during the past ten years. The proposed methodology has four steps: Pre-processing, Feature Extraction, Segmentation, and Classification. And every step is evaluated below. Initially, pre-processing for removing hair from the dermoscopic images using the Laplacian-based algorithm, and then removing noise from the images using the Median filter. In addition, feature extraction from pre-processed images using the Principal Component Analysis (PCA) approach for extracting the characteristics like texture, shape, and color. Furthermore, the segmentation process for identifying the lesion area and segmenting skin lesion using the LeNet-5

technique, and then, classification; here categorizing lesion as benign and malignant using the ANU-Net method. It is classified into benign (non-melanoma) and malignant (melanoma).

The complete performance of the melanoma classification process is displayed in Fig. 1.

#### A. Pre-processing

In pre-processing step, remove the hair from input images and then denoise the images for better segmentation of melanoma. Initially, remove the hair from dermoscopic input images because some melanoma is significantly or partially obscured by body hairs using Laplacian-based algorithm to every image. A sharpening filter based on the Laplace operator is applied to the image is made grayscale. Then the original input image is separate from the filtered image. It employs a 3x3 Wiener filter adaptive noise removal to eliminate any potential noise. After hair removal done, here remove noise from dermoscopic images.

Such noise is removed from dermoscopic images using the median filter, which uses a weighted average sum of the nearest pixels. The median filter performs well in terms of maintaining an image's edges. After hair removal, images are given to a median filter to eliminate noise. Fig. 2 illustrates the effectiveness of the noise and hair removal processes during the pre-processing stage.

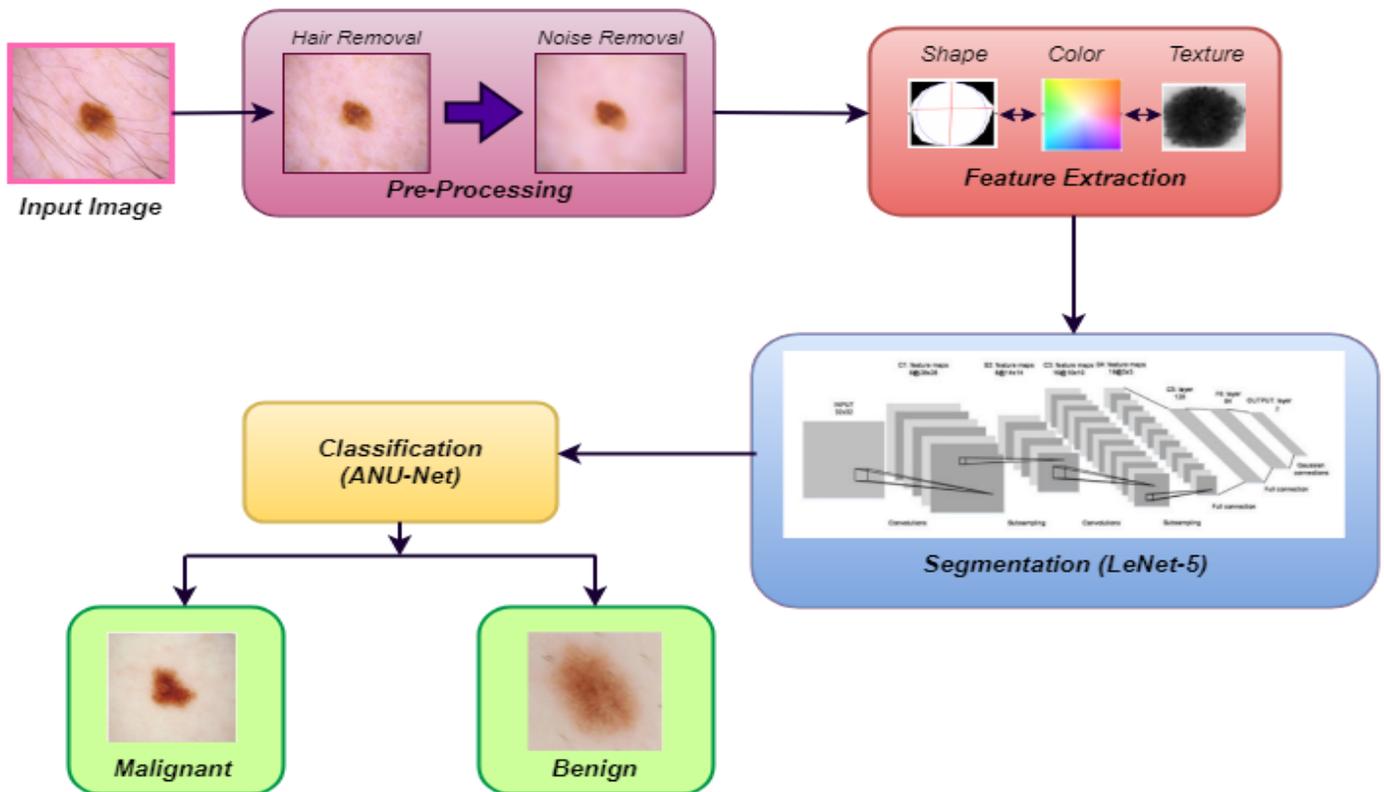

Fig. 1. The Proposed Architecture for Melanoma Classification.

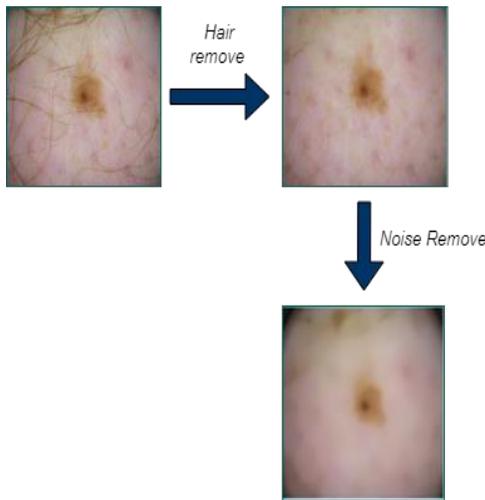

Fig. 2. Process of Hair Remove and Noise Removal in Pre-processing Step.

### B. Feature Extraction

After pre-processing, the characteristics that would be useful in features of the images are extracted using feature extraction techniques. For better prediction of melanoma from dermoscopic images, features like shape, color, and texture should be extracted. In this step, the features were extracted by using Principal Component Analysis (PCA). The obtaining of features is a significant phase in the model construction process. A system can be built using a variety of features, including color, shape, and texture, as well as SURF (speeded-up robust features). The PCA method is utilized to increase explainable while simultaneously reducing the loss of details to reduce the dimension of the dataset being used. The goal of PCA, a mathematical approach that uses a principal component examination, is to reduce the dataset dimension. An orthogonal linear transformation is another name for the process of transforming data into a new coordinate system. With the aid of linear combinations, the native features show new features. The traits with increasing variance are appropriate for dispatching. Accordingly, the PCA method converts the  $n$  vectors  $x_1, x_2, \dots, x_n$  from the  $d$ -dimensional space to the  $n$  vectors  $x_1, x_2, \dots, x_n$  in a new  $d$ -dimensional space.

$$x'i = \sum k = 1d'ak, iek, d' \leq d, \quad (1)$$

Where,  $d'$  is a space with  $n$  dimensions,  $n$  vectors, and  $ek$  eigenvectors that are the greatest eigenvectors for  $ak$ ,  $i$  are the projections of the original vector  $x'i$  and scatter matrix  $S$  on the eigenvector  $ek$ .

In PCA, Single Value Decay (SVD) is typically established on the input data matrix. Based on the optimization algorithm, a PCA technique may be developed. During the optimization process, the data reconstruction error and variance maximization of the projected input data can be examined.

$\overline{W}_i \in S^n, i = 1, 2, 3, \dots, o, o < n$  information variance can be estimated in the orthonormal direction with a constrained amount of options using PCA to determine the orthonormal

direction  $O$  in a given space. Without losing any data in the resulting structure of dimension  $d \in S^n$ , the input vector is translated into  $O$ -dimensional space. In the input data, which consists of vector  $d$ , the  $O$ -Dimension is projected using  $\overline{W}$ , where the inner product  $(d^T \overline{W}_i)$  is obtained and the misplaced outcome dimension is obtained. Since PCA calculates unit directions, the information can be anticipated into the input vector. Where  $Y = d^T \overline{W}_i$ , it has a large variance and is signified by greater variance. It will be written as:

$$\sigma_{PCA}(W) = \sigma[y^2] = d^T C \overline{W}_i = \frac{W^T C W}{\|W\|^2} \quad (2)$$

where  $\overline{W} = W / \|W\|$

Apply the estimation in the linear square estimation after reconstructing the input data, or  $\hat{d}$ .

$$\hat{d}_t = \sum_{i=1}^o g_{i(t) \overline{W}_i} \quad (3)$$

With the use of data reconstruction, the error can be recreated and identified by comparing the differences between the original and corrected data.

$$e = d - \hat{d}_t = \sum_{i=O+1}^n a_i \overline{W}_i \quad (4)$$

To predict this issue, implement a novel method for dimension restricting and increasing the entertainment of PCA following in overall presentation development. Based on PCA, the reconstruction error can be reduced. When extending  $k$ -dimensional data to subspace, calculations are visible.

$$\begin{aligned} \text{PCA reconstruction} \\ = PC \text{ scores. Eigenvectors } T + \text{Mean} \end{aligned}$$

Based on the proposed technique, a maximum likelihood-based model may be used to map the underlying space into the data space.

$$x = \varepsilon + \mu + \int \Lambda \quad (5)$$

In a linear transformation, the variable  $(p * 1)$  is designated as the variable,  $x$  is denoted as the high-dimensional factor and is also defined as  $(p \times O)$ ,  $f$  is  $(O \times 1)$ ,  $\Lambda \rightarrow x$ ,  $\mu(p \times 1)$  is defined as the mean vector, and  $\varepsilon$  is defined as Gaussian random error, the  $\mu(p \times 1)$  denoted as the input signal vector of noise. The feasible result's input vector is represented by

$$p(\varepsilon; \sigma^2) = \left(2\pi\sigma^2\right)^{-\frac{p}{2}} \exp\left(\frac{-1}{2} \varepsilon' \varepsilon\right) \quad (6)$$

It will increase by the conditional probability of

$$p\left(\frac{x}{f}; \Lambda, \mu, \sigma^2\right) = \left(2\pi\sigma^2\right)^{-\frac{P}{2}} \exp\left(-\frac{1}{2}\|x - \mu - f\Lambda\|^2\right) \quad (7)$$

The dataset of the absolute distribution of a specific space is delivered by such a model without changing any errors or data that were not distributed for the specified probabilistic limit. The PCA model's primary goal can be achieved by fully revealing unknown parameters like  $\Lambda$  and  $\mu$ , maximum noise variance  $\sigma^2$ -based likelihood observations.

$$L\left(\Lambda, \mu, \sigma^2 \mid x\right) \\ (2\pi)^{-\frac{np}{2}} |\Sigma|^{-\frac{n}{2}} \exp\left[-\frac{1}{2} \sum_{i=1}^n (x_i - \mu)' \Sigma^{-1} (x_i - \mu)\right] \\ \left(x_i - \mu\right)' \Sigma^{-1} (x_i - \mu) \quad (8)$$

Another way to express maximum likelihood observation is in  $tr\left(\Sigma^{-1}S\right)$  where S is a possible expression,

$$S = \frac{1}{n} \sum_{i=1}^n (x_i - \hat{\mu})(x_i - \hat{\mu})' \quad (9)$$

The maximum log-likelihood can be expressed using the equation below.

$$L\left(\Lambda, \mu, \sigma^2 \mid x\right) = -\frac{np}{2} \log(2\pi) - \frac{n}{2} \log |\Sigma| - \frac{n}{2} tr\left[\Sigma^{-1}S\right] \quad (10)$$

Based on PCA's data reconstruction,  $\Lambda$  and  $\sigma^2$  the error can be minimized while still producing a superior answer. The highest possible possibility of  $\sigma^2$ .

$$\hat{\sigma}^2_{ML} = \sum_{j=m+1}^p \lambda_j \times \frac{1}{p-m} \quad (11)$$

Effective parameters are reduced in the feature reconstruction process by applying the maximum likelihood model, which is based on the above-mentioned model's decreased error and increased production in feature extraction based on PCA. The PCA method giving significant results as expected and extract the feature of melanoma or benign dermoscopic images well. The major benefit of PCA for index generation over traditional techniques is that it does not assign arbitrary and subjective weights to various indicators. The results of a multivariate statistical analysis of a few chosen indicators are used to determine the weights allocation in PCA for the construction of the index. The principal component analysis method extracted the features such as shape, color, and texture very well. And this method work better to feature extraction without any issues.

### C. Segmentation

Following feature extraction, the image segmentation procedure separates the scene into the background and foreground. After extracted the features from dermoscopic images, at next step need to segment the issue part from images. Because segmentation of issue part is more important to predict that if it's melanoma or not. In this research, the segmentation process was carried out using LeNet-5 technique. When the background and foreground colors of an image are highly similar, the LeNet-5 method is used. Because the other technique's results are unsuccessful. Below is a description of the LeNet-5 method.

Using this segmentation network, the effective deep skin lesions are divided into groups. Many other CNN types can be used for segmentation depending on the objectives of the application, and the melanoma was segmented using a LeNet-5 pre-trained network. An input layer, two pooling levels, one fully connected layer, two convolutional layers, and an output layer made up a total of seven layers in LeNet-5 [21]. Table I displays the precise design of the LeNet-5. LeNet-5's weighted layers are constructed using the idea of removing convolution layer blocks by utilizing shortcut connections. The "bottleneck" blocks, which are the fundamental construction blocks, follow two design principles: The same amount of filters are used to create the same output feature size. The convolution layers down-sample at a rate of two strides per layer. Batch normalization is carried out both before and after each convolution and before the rectified linear unit (ReLU) is activated.

An identity shortcut is used when the input and output dimensions are identical. The projection shortcut utilising 1x1 convolutions is used to match the dimensions when the dimensions are enhanced. The segment of the skin lesion region is transmitted to the classification and RPN networks from the last convolutional layer. In the LeNet-5 segmentation network, only the 49 convolutional layers are utilized; fully connected and average pooling layers are not. Because only the segmentation network, not the final classification is required by the RPN and classification network.

These region proposals are used by the final segmentation network to classify objects. In the RPN, anchor boxes with various scales and aspect ratios are first formed across each pixel of the feature map. Usually, nine anchor boxes with aspect ratios of 1:1, 1:2, and 2:1 and scales of 128, 256, and 512 are used. RPN forecasts the likelihood that a backdrop or item will appear in an anchor box. The necessary object proposals are forwarded to the following stage as a list of filtered anchor boxes. To convert the final anticipated region proposals from the anchor boxes, apply Eq. (12) and (13). Equation illustrates the scale-invariant translation between the center coordinates (12). The height and width are translated into log space using equation (13).

$$V_x = \frac{x_p - x_a}{w_a}, V_y = \frac{y_p - y_a}{h_a} \quad (12)$$

$$V_w = \log\left(\frac{w_p}{w_a}\right), V_h = \log\left(\frac{h_p}{h_a}\right) \quad (13)$$

TABLE I. LeNET-5 SEGMENTATION NETWORK

Layers	Name of the Layers	Input size	Output size	Pooled area	Convolution kernel size	Step size
Input	Input layer	32*32	28*28		5*5	1
Layer1	Convolutional layers	6@28*28	6@14*14	2*2		2
Layer 2	Pooled layers	6@14*14	16@10*10		5*5	1
Layer 3	Convolutional layers	16@10*10	16@5*5	2*2		2
Layer 4	Pooled layers	16@5*5	120@1*1		5*5	1
Layer 5	Fully connected layer	1*120	1*84			
Layer 6	Fully connected layer	1*84	1*7			
Output	Output layer	1*7				

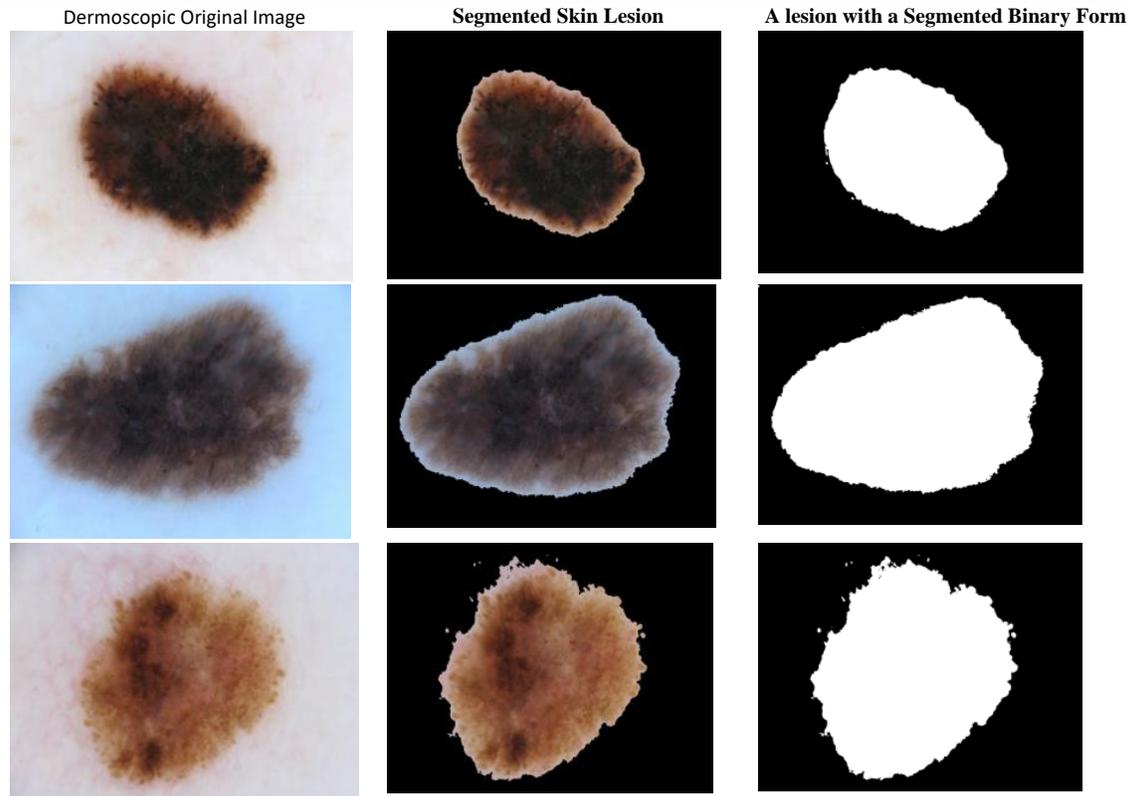

Fig. 3. Sample Segmentation Performance using the LeNet-5 Technique.

Where the bounding box regression vectors are represented by  $V_x$ ,  $V_y$ ,  $V_w$ , and  $V_h$ , and coordinates for the height, width, and center in x and y are depicted by  $h$ ,  $w$ , and  $x$ ,  $y$ . Additionally,  $x_a$ ,  $x_p$  are the corresponding centers of the anchor and proposal box. The convolutional layers and fully connected layers of LeNet-5 technique are utilized in segmentation step to segment the melanoma issue part in dermoscopic images based on extracted features. The LeNet-5 method segments the skin lesion area accurately.

Some of the sample processes of segmentation of skin lesion performance are shown in above Fig. 3. It shows the segmented skin lesion area from dermoscopic images and also given the binary form of segmented skin lesion area using segmented technique LeNet-5.

#### D. Classification of Benign and Malignant

In the classification step, classify the segmented skin lesion into malignant or benign using the ANU-Net technique. It uses the skin lesion from segmented images for classifying whether the issue part is melanoma or not. Images with closely matched foreground and background colors are used with the ANU-Net technique. The ANU-Net technique is described below.

Develop an integrated network called Attention U-Net++ for medical image classification. Using nested U-Net architecture, which takes it from DenseNet, a series of U-Nets with different depths are integrated. In contrast to U-Net, which used nested convolutional blocks and constructed dense skip links between the decoder and encoder at various levels, the nested Framework makes use of convolutional blocks that are layered within each other [20]. Every nested convolutional

block in layered U-Nets employs numerous convolution layers to gather semantic data. The concatenation layer can integrate semantic data from different levels since each layer in the block is connected via connections. The following are some benefits of the new nested design:

- Layered architecture may avoid the time-consuming procedure of choosing deep and shallow features by assessing the value of features at various depths on its own.
- Only an encoder must be trained because the feature extractor is shared by all of the U-Nets in a nested arrangement.
- Since different decoder paths independently restore distinct layers of features, they can collect hierarchical decoded masks from a variety of levels in tiered architecture.

1) *Attention Gate (AG)*: Attention Gate employs the PASSR net's model and includes an effective AG into nested architecture.

The AG feature selection Phase is described as follows:

$$F = \sigma_1[(W_f^T \times f + b_f) + (W_g^T \times g + b_g)] \quad (14)$$

$$\alpha = \sigma_2(W_\theta^T \times F + b_\theta) \quad (15)$$

$$\text{output} = f \times \alpha \quad (16)$$

The effective function of the Attention Gate allows it to classify the task-related target region more effectively while suppressing the task-unrelated target region. In research, Attention Gate is used to enhance the capability of semantic data propagation across skip links in the creatively recommended network.

2) *Attention-based nested U-Net*: The ANU-Net is a network that is integrated for classifying medical images and is based on the Attention mechanism and Nested U-Net architecture. In the ANU-Net, which utilizes nested U-Net as its main network architecture. Then, additional helpful hierarchical characteristics can be retrieved. The encoder sends the context data it has gathered to the appropriate layers' decoder via the wide skip connections.

For each convolutional block, the decoder receives two equivalent image features when there are multiple dense skip connections: The preliminary feature maps are produced by earlier Attention Gates with residual connections at the same depth, while the final feature map is produced by a deeper block deconvolution procedure. The decoder reconstructs features starting at the bottom and adding up all received feature maps.

The extracted feature map from ANU-Net may be expressed as follows: Let  $X_{i,j}$  indicate the outcome of the convolutional block, while the feature depth is denoted as  $i$  and the convolution block's sequence as  $j$ .

$$X_{i,j} = \begin{cases} \Phi[X_{i-1,j}] & , j=0 \\ \Phi[\sum_{k=0}^{j-1} \text{Ag}(X_{i,k}), \text{Up}(X_{i+1,j-1})] & , j>0 \end{cases} \quad (17)$$

$\text{Up}(X_{i+1,j-1})$  and  $\text{Ag}(X_{i,k})$  the attention gate and mean up-sampling selection accordingly,  $\sum_{k=0}^{j-1} \text{Ag}(X_{i,k})$  indicate that concatenate the outcome of the AG from node  $X_{i,k=0}$  to  $X_{i,k=j-1}$  in the  $i^{\text{th}}$  layer.

After the concatenation operation, the decoder's convolution blocks will only employ the encoder's chosen same-scale feature maps rather than all of the feature maps that were acquired via dense skip connections. This layer's output from the  $j$  previous blocks acts as an input, while the second layer's up-sampling function of block X1 provides additional input. The network transfer of features gathered by the encoder is one of two significant ANU-Net innovations. Furthermore, Attention Gate is used in the decoder path between layered blocks that are recovered at different layers and can be connected with a specific choice. As a result, ANU-Net accuracy ought to be raised. The proposed classification technique works well and classify the dermoscopic image as malignant or benign. The ANU-Net techniques improved the time complicity of classification and given better classification accuracy.

#### IV. RESULTS AND DISCUSSION

This section's compares the approach to “state-of-the-art” techniques by categorizing melanoma using the dataset's analysis and technique for extracting features from skin lesions. Given are the assessment findings based on experimental data in the following subsections to evaluate methodology.

##### A. Dataset Description

There are 33,126 dermoscopic images of benign and malignant skin lesions in the ISIC-2020 dataset, with a high percentage of benign lesions. Only 584 of the 33,126 skin lesion images were classified as malignant melanoma. The primary factor that led to the selection of this dataset above others was the fact that the skin lesions are discernible and are not masked by any artifacts. Furthermore, the skin lesions' micro-features are distinct and easy to see. The efficiency of feature extraction is improved by this. The dataset sample images are seen in Fig. 4.

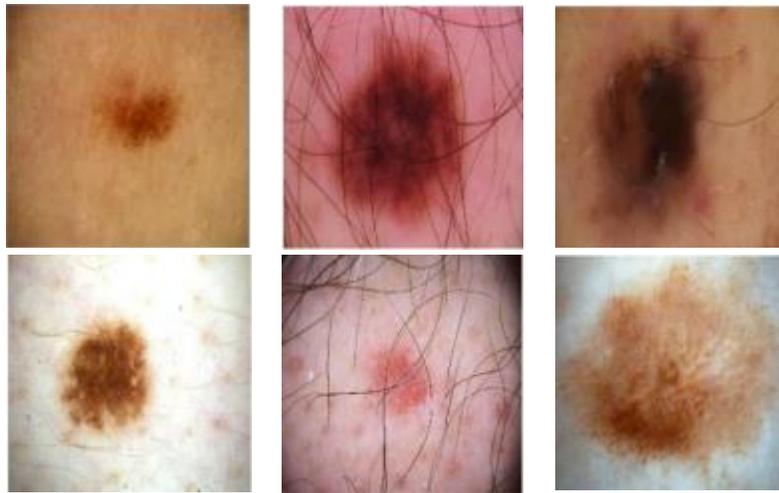

Fig. 4. Shows Various Images of Skin Lesions in the Dataset.

				Melanoma Affected

Fig. 5. The Experimental Outputs: (a) Original Image, (b) After Hair Removal Image, (c) After Noise Removal Image, (d) Segmented Images, (e) Classification of Melanoma.

### B. Quantitative Metrics

The performance of the proposed method for classifying the skin lesion into malignant or benign is to give a better result. Here, first, are given an input dermoscopic image from ISIC 2020 dataset. For a better segmentation process, remove the hair from input dermoscopic images and then the noise from this input image in pre-processing step. Segment the skin lesion portion from the dermoscopic image using LeNet-5 technique. It determines the skin lesion's malignant (melanoma) or benign (benign) status using this segmented image (non-melanoma) utilizing the classification technique ANU-Net. The experiment performed well and produced superior results. The findings of the experiment are displayed in Fig. 5.

### C. Evaluation Metrics

In terms of performance measures, looked at the proposed method's Accuracy (A), Precision (P), F1-score (F), and Recall (R). These metrics indicate:

#### Accuracy

The percentage of samples that were correctly identified relative to all samples is known as accuracy. In general, a classifier performs better the higher accuracy. Eq. (18) illustrates the meaning of accuracy.

$$Accuracy = \frac{TP+TN}{TP+FN+FP+TN} \quad (18)$$

#### Sensitivity

Sensitivity, also known as recall, measures how well a classifier can identify positive samples by representing the percentage of all positive samples that are predicted. Eq. (19) defines sensitivity.

$$Sensitivity = \frac{TP}{TP+FN} \quad (19)$$

#### Specificity

Specificity measures the classifier's capacity to identify negative samples by representing the percentage of all negative samples that are successfully classified. Eq. (20) illustrates the definition of specificity.

$$Specificity = \frac{TN}{TN+FP} \quad (20)$$

#### Precision

Precision is defined as the ratio of precisely anticipated positive occurrences to all anticipated positive observations. Precision is the capacity to do the following things:

$$Precision = \frac{TP}{TP+FP} \quad (21)$$

### D. Performance Evaluation

In experimental performance, the proposed technique has the highest classification accuracy compared with other existing techniques. Table II shows the results for DenseNet-121, ResNet-50, Inceptionv3, and the proposed ANU-Net on the ISIC 2020 dataset in terms of accuracy, specificity, sensitivity, and Precision. Based on the results, the proposed methodology has higher classification accuracy values than

other existing approaches. It is consistent with the experimental findings for the melanoma classification into two types, malignant and benign. By using the proposed ANU-Net classification technique, the time complexity is reduced, effective training is performed, and the overall performance of the classification is improved compared with other existing techniques.

Here, for comparison three other existing methods are chosen to compare with the proposed technique. Compared with other techniques, the proposed methodology gives high accuracy values for classification. In Table II, the classification accuracy achieved 98.78% utilizing the proposed methodology ANU-Net technique compared with other techniques DenseNet-121 has 93.65%, ResNet-50 has 96.96%, and Inceptionsv3 has 97.17%. The proposed methodology provide effective outcomes and the classification accuracy is higher than others. Additionally, when compared to other existing methodologies, DenseNet-121 has the lowest accuracy rate at 93.65%. This accuracy comparison model is shown in Fig. 6.

In Table II, the sensitivity metric achieved 98.39% using the proposed method ANU-Net technique compared with other techniques DenseNet-121 has 95.83%, ResNet-50 has 96.53%, and Inceptionsv3 has 96.32%. This sensitivity comparison model is shown in Fig. 7.

TABLE II. THE PERFORMANCE OF CLASSIFICATION TECHNIQUE

Models	Accuracy	Sensitivity	Specificity	Precision
DenseNet-121	93.65	95.83	93.48	96.13
ResNet-50	96.96	96.53	96.53	95.32
Inceptionv3	97.17	96.32	96.46	97.74
Proposed (ANU-Net)	98.78	98.39	97.98	98.12

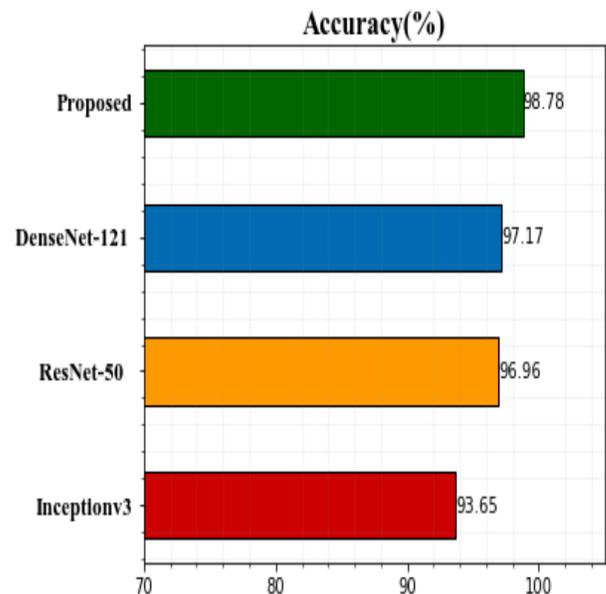

Fig. 6. Analysis of Accuracy based on different Techniques.

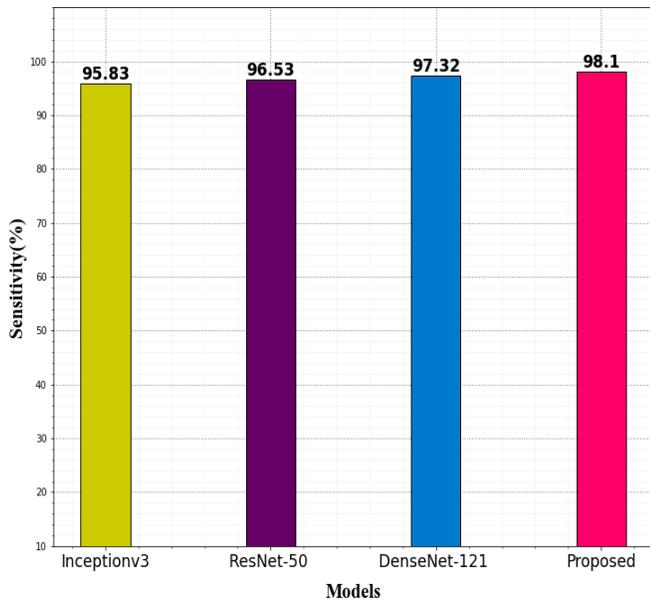

Fig. 7. Analysis of Sensitivity based on different Techniques.

The specificity metric achieved 97.98% using the proposed method ANU-Net technique compared with other techniques DenseNet-121 has 93.48%, ResNet-50 has 96.53%, and Inceptionsv3 has 96.46%. This sensitivity comparison model is shown in Fig. 8.

The precision metric achieved 98.12% using the proposed method ANU-Net technique compared with other techniques DenseNet-121 has 96.13%, ResNet-50 has 95.32%, and Inceptionsv3 has 97.74%. This sensitivity comparison model is shown in Fig. 9.

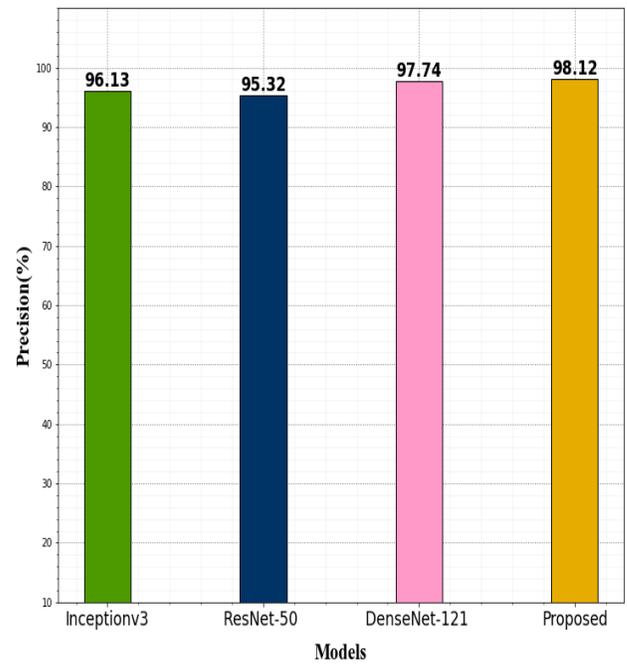

Fig. 9. Analysis of Precision based on different Techniques.

The analysis made by the different classification techniques is illustrated in the above figures. Compared with InceptionV3, ResNet-50, and DenseNet-121, the sensitivity value of ANU-Net is high and accurate the values are very clear and deep as shown in Fig. 7. And the same time also gives a better specificity percentage compared with other techniques as shown in Fig. 8. And also Fig. 9 shows the recall comparison of the ANU-Net technique.

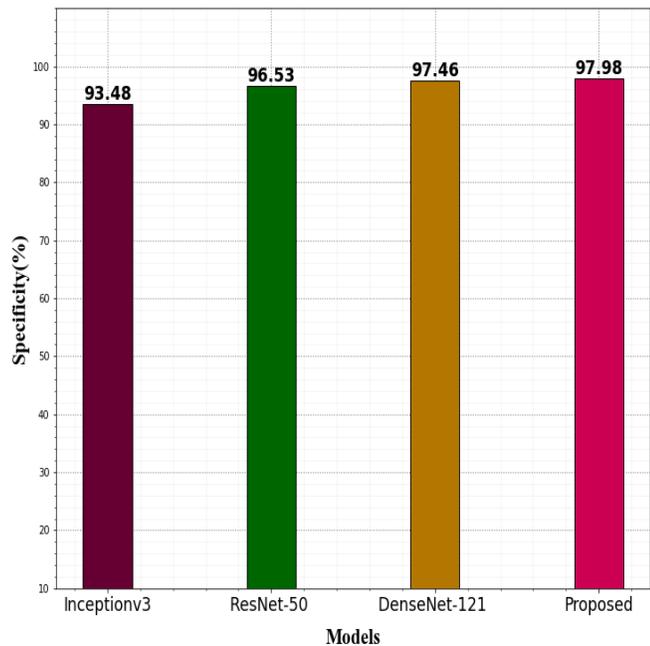

Fig. 8. Analysis of Specificity based on different Techniques.

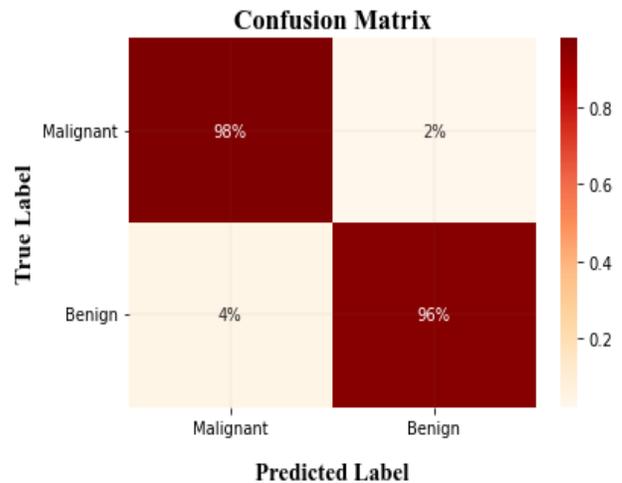

Fig. 10. Confusion Matrix of ANU-Net for Classification.

The confusion matrix is the most common tool for evaluating classification errors. Developed the confusion matrix for the ANU-Net proposed model based on the confusion matrix explanations offered. The graphic illustrates that the ANU-Net model can correctly categorize the two melanoma states (Malignant and Benign), with melanoma having a high ratio to malignant images and melanoma having

the lowest ratio to benign images. This indicates the classification of the two statuses has been completed appropriately. Fig. 10 presents the retrieved confusion matrix for the classification cross-validation test.

## V. CONCLUSION AND FUTURE WORKS

Melanoma is the worst type of cancer among skin cancers, and its prevalence is rising globally. Early detection is crucial since skin cancer can be treated with a straightforward excision. But the mole's outline or outer covering is uneven, largely asymmetrical, and appears gritty. It states that around half of the moles present do not match the other half of the moles. To overcome all of this issues, proposed an effective methodology in this work. In this paper, the proposed system for melanoma classification involves four steps: Initially, pre-processing, removing hair from the dermoscopic images using a Laplacian-based algorithm, and then removing noise from the images using a Median filter. In addition, feature extraction from pre-processed images. Using the principal component analysis approach for extracting the characteristics like texture, shape, and color. These features for help to segment the skin lesion accurately from dermoscopic images. Furthermore, the segmentation process for identifying the lesion area and segmenting skin lesion using the LeNet-5 technique, and then, classification; categorizing lesion as benign (non-melanoma) and malignant (melanoma) using the ANU-Net method from the segmented skin lesion. It is classified into benign and malignant. The proposed technique solve these challenges in melanoma classification and given higher classification accuracy compared to other existing approaches. Therefore, based on the experimental findings, the ANU-Net method's accuracy for the ISIC2020 dataset is 98.78%. Since the ANU-Net model has the maximum level of accuracy, it can be effectively employed as a classifier to distinguish between malignant and benign skin lesions. It was established that the proposed model's categorization output was more accurate than that of the approaches under comparison. In the future, will work on new optimization techniques for better classification accuracy.

Research Center, Bungo-Ohno City, Oita, Japan

**Abstract**—Method for determination of tealeaf plucking date with cumulative air temperature and Photosynthetically Active Radiation: PAR which is provided by the remote sensing satellites: Terra/MODIS and Aqua/MODIS is proposed. Also, a confirmation of thermal environment at the intensive study tea farm areas with Landsat-9 TIR (Thermal Infrared) image is conducted. Through a regressive analysis between the harvested tealeaf quality and the cumulative air temperature and PAR at the intensive study areas, it is found that there is a highly reliable relation between both. Also, an importance of air temperature environment at the sites is confirmed with Landsat-9 TIR image.

**Keywords**—Plucking date; elapsed days after sprouting; cumulative air temperature; Landsat-9 TIR; theanine; regressive analysis

## I. INTRODUCTION

It is obvious that nitrogen rich tealeaves taste good while fiber rich tealeaves taste bad. Theanine: 2-Amino-4-(ethyl carbamoyl) butyric acid that is highly correlated to nitrogen contents in new tealeaves are changed to catechin [1],[2],[3] due to sun light. In accordance with sunlight, new tealeaves growth up so that there is a most appropriate time for harvest to maximize harvest amount and taste of new tealeaves simultaneously. On the other hand, fiber content indicates the age of the tealeaf in concern. Fiber content is getting large in accordance with the age and old tealeaf is getting harder. Therefore, young tealeaf is much tasty rather than the old taleaf.

Depending on the elapsed days after sprouting, tealeaf quality (theanine content) is decreased. On the other hand, tealeaf yield is increased with increasing of the days after sprouting. Therefore, there is most appropriate plucking date and is very important. Usually, it is determined by the Normalized Difference Vegetation Index: NDVI derived from handheld NDVI cameras, drone mounted NDVI cameras, and visible to Near Infrared: NIR radiometer onboard satellites because NIR reflection and NDVI depend on tealeaf quality and yield. It, however, does not work so well in terms of poor regression accuracy ( $r^2$  value: determination coefficient) and there is a species dependency. Moreover, it takes time consumable works for finding appropriate tealeaves for determination from the acquired camera images [4].

Although the previous method for determination of most appropriate plucking date using the elapsed days after sprouting is effective in some extent, reliability of the method is not good

enough. The method proposed here for determination of most appropriate plucking date is using the cumulative air temperature together with Photosynthetically Active Radiation: PAR derived from Terra and Aqua satellites at the tea farm areas. PAR represents much more directly connected with the tealeaf quality (theanine content) than the other factors, air temperature, sunshine duration time a day. This approach is totally new and is expected to improve reliability of the method. Experiments with the proposed method are conducted and confirmed its reliability with the thermal environment at the areas with Landsat-9 TIR image (thermal environment). Plucking date determination with PAR and cumulative air temperature is the first attempt, brand new approach.

In the following section, the research background is described followed by the proposed method. Then, the experimental method together with experimental results are described. After that, concluding remarks and some discussions are also described.

## II. RELATED RESEARCH WORKS

There are some related research works to the determination of the most appropriate plucking date determination for harvesting the best quality of tealeaves, theanine content rich tealeaves. This section describes such those research works from a methodology point of view.

A method for estimation of grow index of tealeaves based on Bi-directional Reflectance Distribution Function: BRDF measurements with ground-based network cameras is proposed [5]. Wireless sensor network for tea estate monitoring in complementally usage with Earth observation satellite imagery data based on Geographic Information System: GIS is also proposed and validated through a plenty of experiments [6]. A method for estimation of total nitrogen and fiber contents in tealeaves with ground-based network cameras is, on the other hand, proposed [7].

Monte Carlo Ray Tracing: MCRT simulation for BRDF and grow index of tealeaves estimation is conducted with the ground truth data [8] together with fractal model-based tea tree and tealeaves model for estimation of well opened tealeaf ratio which is useful to determine tealeaf harvesting timing of plucking date [9]. Grow index can be measured with green meter of instruments. Using this, growing processes are monitored.

Meanwhile, a method for tealeaves quality, theanine content estimation through measurements of degree of polarization, Leaf Area Index: LAI, photosynthesis available radiance (PAR) and normalized difference vegetation index (NDVI) for characterization of tealeaves is proposed [10]. On the other hand, optimum band, and band combinations for retrieving total nitrogen, which is closely related to the theanine content, water, fiber, etc. in tealeaves through remote sensing based on regressive analysis is discussed [11].

Appropriate tealeaf harvest timing (plucking date) determination based on NIR images of tealeaves is attempted [12] together with appropriate harvest timing determination referring fiber content in tealeaves derived from ground based NIR camera images [13].

Method for vigor diagnosis of tea trees based on nitrogen content in tealeaves relating to NDVI is proposed [14]. In the meantime, cadastral and tea production management system with wireless sensor network, GIS, based system and IoT technology is created [15].

BRDF model for new tealeaves and tealeaves monitoring with network cameras is well reported [16] together with BRDF model for new tealeaves on old tealeaves and new tealeaves monitoring through BRDF measurement with web cameras [17].

Estimation method for total nitrogen and fiber contents in tealeaves as well as grow index of tealeaves and tea estate monitoring with network cameras is proposed [18]. Meanwhile, multi-layer observation for agricultural (tea and rice) field monitoring is overviewed [19]. Furthermore, Tealeaf plucking workloads and environmental studies is conducted [20].

### III. RESEARCH BACKGROUND

Accelerating market-in product creation is desired so that strengthening production area power to win the competition between production areas. Also, special crop is focused. Meantime, further expansion of strategic items is required together with enhancement of safe and secure product supply system and promotion of environment-friendly agriculture, forestry, and fisheries. Further acceleration of structural reform for realization of smart agriculture, forestry, and fisheries. Also, labor saving and efficiency improvement of work.

With the conversion of tea gardens to adultery, the development of base tea factories is underway, and it is important to secure a stable supply of actual demand and profitability commensurate with investment.

The management scale of the contracted tea plantation exceeds 40 ha per corporation, and it is an issue to achieve both work efficiency and proper management at the production site.

Therefore, it is important to establish management technology for the second tea season, when working conditions are strict, and improve quality. The following items are, therefore, major concern,

- 1) Clarification of criteria for determining the appropriate time for plucking.
- 2) Development of technology for extending the optimum plucking period.

- 3) Introduction of physical control technology.

For that, it is developed a diagnostic imaging technology that is supposed to be installed in a field management system and improve labor productivity through advanced use of the system. Development of ichiban-cha<sup>1</sup> (first plucking tealeaves of a year) sprouting day specific technology by image diagnosis is needed which results in the following steps are needed.

Sprouting date identification → Growth diagnosis → Optimal plucking time → Appropriate prediction management

After sprouting (after plucking), the growth of each tea season is diagnosed from the accumulated temperature. Thus, the following items are getting much important,

- 1) The first tea sprouting day is the reference date for the start of tea growth.
- 2) In the annual management system until winter dormancy.
- 3) An important element of growth diagnosis.

In the past, experienced people made judgments based on their own perspective.

To realize the following economic effects by introducing new technology for tea producers, profit improvement by quality improvement for second plucking tealeaves in particular, improvement of labor productivity is needed.

### IV. PROPOSED METHOD

Although the previous method for determination of most appropriate plucking date using the elapsed days after sprouting is effective in some extent, accuracy and reliability of the method are not good enough. Another attempt for determination of most appropriate plucking date using the cumulative air temperature which is obtained from the meteorological agency in Japan and PAR derived from Terra and Aqua satellite at the tea farm areas is proposed here together with a confirmation of its validity with the thermal environment at the areas with Landsat-9 TIR image. Plucking date determination with PAR is the first attempt, brand new approach together with the cumulative air temperature.

A component with a wavelength of 400 to 700 nm (effective photosynthesis wavelength range) used for photosynthesis of green leafy plants. Normally, the light that passes through clouds and the atmosphere from the sun and reaches the surface of the earth has a wavelength range of 300 to 4,000 nm, of which the energy ratio of the wavelength range of photosynthetically active radiation is about 45%. Some of the light that hits the leaves is not absorbed but is reflected on or inside the leaves or passes through the leaves. Since the photosynthetic pigment absorbs the red and blue wavelength regions of the photosynthetically active radiation well, the reflected light contains a large amount of the green wavelength region. That is why the leaves look green. Photosynthetically active radiation is measured in units of energy (W/m<sup>2</sup>) or mol/m<sup>2</sup>/s as the photosynthetic effective wavelength region photosynthetic flux density (photosynthetic effective photon flux density). In tea cultivation, around 88 nights, counting from the beginning of spring, is the time to pick the shoots that contain plenty of nutrients stored during the winter. The climate

<sup>1</sup>Tea is called "Cha" in Japanese.

differs depending on the production area, so there are various times when new tea is picked. In warm Kagoshima, early April, in Shizuoka, mid-April, and in Kyoto, etc., new tea picking often starts from late April to early May. Therefore, plucking date determination using cumulative days after Lichen: the first day of spring is meaningful but not so accurate. Meanwhile, PAR is directly present a required light energy from the sun. Therefore, it is expected that much accurate plucking date determination can be done with PAR rather than cumulative date from the Lichen.

In order to investigate a relation between nitrogen content in the harvested tealeaf and cumulative air temperature, regressive analysis is conducted together with a relation between NDF: fiber content in the harvested tealeaf. Cumulative air temperature can be gathered from the meteorological agency of Japan. Also, Landsat-9 TIR image can be gotten through EO browser site provided by European Space Agency: ESA<sup>2</sup>. On the other hand, PAR data can be downloaded from the NASA Earth Data Search site<sup>3</sup>. It is MODIS/Terra and MODIS/Aqua Photosynthetically Active Radiation Daily/3-Hour L3 Global 5km SIN Grid V006 data.

## V. EXPERIMENT

### A. Intensive Study Area

The intensive study area is situated at Oita Prefectural Agriculture, Forestry and Fisheries Research Center, Bungo Ohno in Oita Prefecture, Japan (32.99 N, 131.59 E). The institute is established by Oita prefectural local government for promoting agriculture, forestry and fisheries as well as training and guidance of farmers and fishermen. Fig. 1 shows the location of the intensive study area. There is experimental tea farming area in which several species of tea trees (Okumidori, Fushun, Sayama-Kaori, Meiryoku, and Yabukita) are planted.

The tea tree "Okumidori", which is the basis of sencha, is a breed made by crossing "Yabukita", "Yabukita" and "Shizuoka Zairai No. 16", and it reaches its season after "Yabukita". It is characterized by its mild taste and low bitterness. It is also attracting attention as tencha (a raw material for tencha and matcha) and gyokuro. Okumidori tea tree has a large number of buds, so you can expect a large yield.

In "Fushun", which has a slightly upright tree, if the spacing between plants is 60 cm and the row spacing is changed from the customary 50 cm to 25 or 60 cm, the annual yield of fresh leaves will decrease. In the case of Fushun, when the row spacing is 50 cm, the annual fresh leaf yield decreases when the plant spacing is increased from the conventional 60 cm to 75 cm and the planting density is reduced to 80% of the conventional planting density (1481 plants/10a).

"Sayamakaori" is characterized by its strong aroma. The leaves are firmer and have a better shape than Yabukita tea. Because it contains a lot of catechins, which are tannins, the tea has a strong and astringent taste.

The plucking period of "Meiryoku" is the same as or slightly earlier than that of "Yabukita", and the tree is vigorous

and grows vigorously. Four or five years after planting, the total yield of first and second tea leaves is relatively high. The quality is the same as or slightly better than that of Yabukita. It is suitable because it is rather strong.

One of the characteristics of "Yabukita" is its strong cold resistance. It is resistant to red wilt, blue wilt, and frost damage. It is also characterized by good rooting and is highly adaptable to various soils. Another strength in terms of growth is that the roots and shoots are uniform and grow quickly, making it easy to replant. For this reason, it is highly rated by farmers as an easy-to-grow variety.

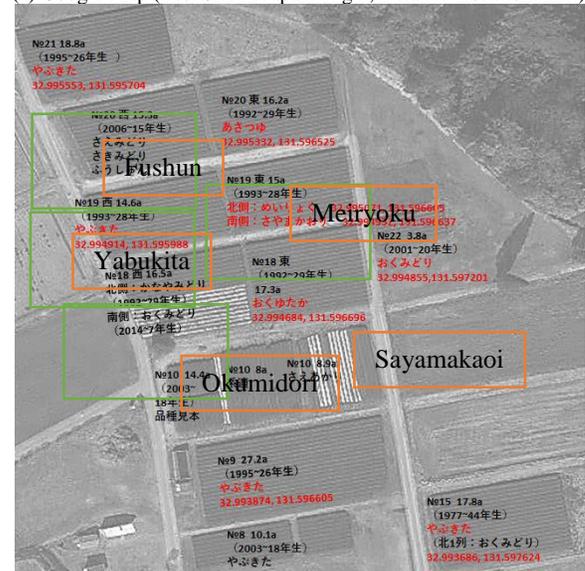

### B. Estimation of Most Appropriate Plucking Date

The most appropriate plucking date is defined as the date on when the nitrogen content in a harvested tealeaf is getting maximum and Neutral Detergent Fiber: NDF of fiber content in a harvested tealeaf is much lower. Nitrogen content is proportional to Theanine of Amino Acid which is highly correlated to the taste of tea. On the other hand, fiber content is negatively proportional to the age of tealeaf (obviously, young tealeaf is much better quality).

If harvest day is delayed, then Theanine changes to catechin (taste not so good) and fiber content is getting large. Therefore, it is important to determine the most appropriate plucking date. Through a monitor the nitrogen content and fiber content, then the most appropriate plucking date can be determined. In the proposed method, cumulative air temperature after the sprouting is used.

(b) Relations between NDF: Fiber Content and the Days after the Sprouting.

(c) Relations between Total Nitrogen Content and the Cumulative Air Temperature at the Site.

(d) Relations between Fiber Content and the Cumulative Air Temperature at the Site.

Fig. 2. Relations between Total Nitrogen Content and NDF: Fiber Content and the Days after the Sprouting as well as the Cumulative Air Temperature.

Fig.2 (a), (b) shows relations between (1) total nitrogen content and the days after the sprouting as well as (2) fiber content and the days after the sprouting. Fig.2 (c), (d) shows relations between (3) total nitrogen content and the cumulative air temperature as well as (4) fiber content and the cumulative air temperature at the fields.

### C. Relation among Cumulative Air Temperature, Solar Irradiance and PAR

In these cases, cumulative air temperature and irradiance as well as PAR after the Vernal Equinox Day is shown in Fig. 3. In Fig. 3, PAR data is downloaded through the NASA Earth Data Search site. A screenshot of the site as searching the intensive study area is shown in Fig. 4.

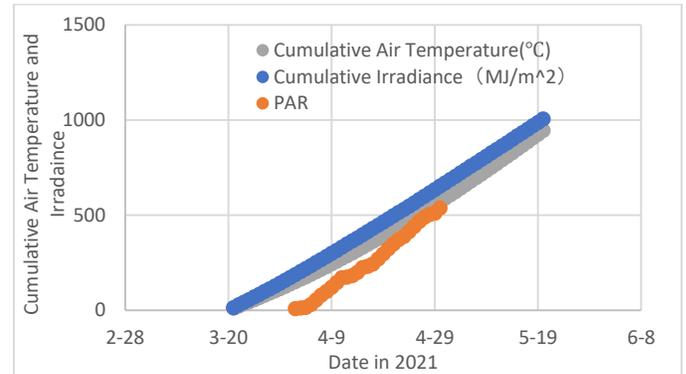

Fig. 3. Relation among Cumulative Air Temperature and Irradiance as Well as PAR after the Vernal Equinox Day.

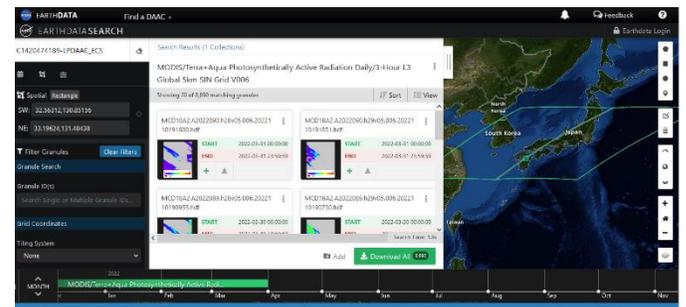

Fig. 4. NASA Earth Data Search Site.

### D. Confirmation of Uniformity of Air Temperature at the Sites

It is found that the most appropriate plucking date can be determined with cumulative air temperature. The next thing it would be better to do is confirmation of uniformity of air temperature at the sites because the temperature environment in the sites is not uniform. In order to check the uniformity, Landsat-9 TIR image which is acquired on 19 April 2021 is used. Fig. 5 shows the intensive study site of tea farm areas and thermal infrared image which is taken by Landsat-9 satellite and, false color composite image which is acquired by Landsat-9 satellite.

Table I shows the specification of Landsat-9 of TIR-1 and 2. Thermal environment can be evaluated with Landsat-9/TIR-2 of band 11 data with 100 m of spatial resolution. As a result, it is found that the temperature environment in the sites is uniform enough with 232.88 (Mean) and 1.97 (Standard Deviation).

VI. CONCLUSION

A method for estimation of most appropriate tealeaf plucking date is proposed. The method uses cumulative air temperature, Photosynthetically Active Radiation: PAR, and thermal environment. These are gathered from the remote sensing satellite data. Through a regressive analysis between the harvested tealeaf quality and the cumulative air temperature at the intensive study areas, it is found that there is a highly reliable relation between both. Thus, the tealeaves quality of theanine content can be monitored and also the plucking date can be determined maximizing the theanine content in tealeaves.

VII. FUTURE RESEARCH WORKS

Next thing it would be better to do is estimation of most appropriate harvest date with deep learning which can be applied to these estimations.

ACKNOWLEDGMENT

The authors would like to thank to Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

#### AUTHORS' PROFILE

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science on April 1990. He was a councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000. He was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is an Adjunct Professor of University of Arizona, USA since 1998. He also is Vice Chairman of the Science Commission "A" of ICSU/COSPAR since 2008 then he is now award committee member of ICSU/COSPAR. He wrote 55 books and published 620 journal papers as well as 450 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. <http://teagis.ip.is.saga-u.ac.jp/index.html>.

# Remote Monitoring Solution for Cardiovascular Diseases based on Internet of Things and PLX-DAQ Add-in

**Abstract**—Access to health remains a real problem in Africa especially for the follow up of patients with chronic diseases. Many cases of heart attack deaths are still recorded before victims can access treatment. This is due to several factors, namely the insufficient number of cardiologists, the inaccessibility of hospitals with adequate infrastructure, the carelessness and ignorance of people about their health. In response to these limitations, internet of Things, thanks to its remarkable technological contribution, allow to follow from afar and easily patient's condition. In this paper, we offer a ubiquitous surveillance solution distance from patients with cardiovascular disease in order to minimize or eliminate the risk of heart attacks. The proposed solution is based on a micro-service architecture and consists of two essential parts that are data acquisition and data transfer. It will allow the patient to access their physical data and submit them in real time to the doctor through a dedicated medical application. The doctor will then be able to analyse the data obtained and return a prescription to the patient in case of abnormality. We used the microcontroller Arduino esp8066, the heart Rate Monitor AD8232 ECG (electrocardiogram) to measure the electrical activity of the heart that can be traced as an ECG, a pulse-eater, a photoresistor LDR and an potentiometer to regulate and modify the current flow in the circuit. We also used add-in PLX-DAQ for data acquisition and Jira software for data transfer to the doctor. Our solution is inexpensive and allows people not yet suffering from cardiovascular disease to prevent it.

## I. INTRODUCTION

According to the World Health Organization, cardiovascular diseases are a group of troubles affecting the heart and blood vessels, with the most common being heart attacks and strokes. These diseases are and expected to remain the leading cause of death with a mortality rate of 31% worldwide [1] [2]. By 2030, almost 23.3 million people will die from cardiovascular disease (mainly heart disease and cerebrovascular accident) [3].

The cardiovascular morbidity and mortality burden is increasing worldwide, reaching even younger subjects in both developing and developed countries. The work of Kantako et al. reveals that, on a sample of 666 hospitalized patients, 301

were suffering from cardiovascular diseases. Considering Table I below, these authors show that cardiovascular diseases can reach subjects as soon as 15 years old [4].

The Kantako et al. studies proposed Table II, to show that cardiac insufficiency was the most frequent reason for hospitalization with 41.9% of cardiovascular diseases.

To prevent most cardiovascular diseases, behavioral risk factors such as smoking, unhealthy diet, obesity, physical inactivity, alcoholism and many others must be strategically addressed. Lifestyle change and physical effort would be one of the World Health Organization's recommendations for the prevention of cardiovascular disease [1]. Unfortunately, the precarious living conditions of populations in developing countries do not allow for easy prevention of cardiovascular diseases. Studies have shown that the symptoms of a heart attack, even a severe one, do not appear until two hours after the event. Hence the need to monitor cardiac activity and therefore to have an appropriate and low-cost sensor solution to prevent cardiovascular disease.

Usually, people with cardiovascular disease live at home and go to the doctor when they feel sick. This is because the disease manifests itself when it is at a very advanced stage, and the damage is irreversible. Most of these patients die before receiving any treatment [5]. It becomes urgent to adapt to the current sociological changes, incorporating the digital revolution that improves the way patients interact with health institutions [6]. Patients of all ages will be able to be monitored without the need to travel.

TABLE I. DISTRIBUTION OF CARDIOVASCULAR MORTALITY BY AGE GROUP [4]

Age Range	Numbers		Number	Specific mortality
	Deaths	Percentage		
[15 – 29]	3	17.65	38	7.89%
[30 – 44]	4	23.52	54	7.40%
[45 – 59]	3	17.65	87	3.44%
[60 – 74]	4	23.52	83	4.76%
75 et plus]	3	15.65	39	7.69%
<b>Total</b>	<b>17</b>	<b>100</b>	<b>301</b>	<b>31.18%</b>

TABLE II. REPARTITION OF PATIENTS WITH RISK FACTORS [4]

Reason of hospitalization	Numbers	Percentage
Hypertensive flare-up	96	31.9
Chest Pain	6	2.0
Heart insufficiency	126	41.9
Rhythm trouble	13	4.3
Stroke	58	19.3
Other	2	0.7
<b>Total</b>	<b>301</b>	<b>100.0</b>

Using Internet of Things technologies, the physical condition of patients can be monitored in a customary way and in real time wherever they are. The acquired data can be sent to remote doctors at low cost [7] [8]. These technologies can also be used to prevent these diseases.

The aim of this paper is to propose a solution that will allow subjects from 15 years old, to be followed by a doctor at a distance if they already have a cardiovascular disease, or to follow their physiological parameters to prevent any cardiovascular pathology.

In this work, the technologies of the Internet of Things are used to realize a solution dedicated to the recovery of certain physiological parameters of the person, in particular the heart rate and the number of pulsations. The data collected via a data acquisition software will be transmitted to the doctor via a dedicated platform.

The rest of this paper will proceed as follows. Related work will be discussed in Section II and Section III will illustrate the system under three aspects namely: the architecture of the proposed system, data acquisition, data transmission. In Section IV we will present the results and a discussion with a presentation of a prototype of the proposed system. Section V presents the conclusions and perspectives.

## II. RELATED WORK

All related work on smart health systems integrating the internet of Things unanimously demonstrate the efficiency and time savings in patient care. The internet of Things has become an important technology for health monitoring systems. In professional medical centers, ECG data collection is done using twelve electrodes due to their good performance in short-term calibration. Unfortunately, these devices are not laptops and patients are often forced to visit medical centers for regular checks-up. Which could be tedious and very expensive for patients [9].

Tamana Shawn et al. designed a system to frequently monitor the electrocardiogram signal collected from the patient's body using the wearable sensors and the data is stored in the database of data that can be viewed by authorized personnel [7]. This solution has been implemented so that seniors can receive accurate care without having to make frequent trips to hospitals. When a malformation is detected, an automatic email is sent to users and doctors to analyse the critical condition of patients and provide emergency health assistance.

Hasan et al. proposed an ECG monitoring system that consists of an AD8382 ECG sensor to read patient data, an Arduino Uno, an ESP8266 Wi-Fi module, and the Blynk IoT app. The proposed ECG allows the physician to monitor the patient remotely via the Blynk IoT app installed on the patient's smartphone. The monitoring process can be performed anytime and anywhere without the need to physically come to the hospital [10].

Deli and AL. proposed a platform for disease prediction cardiovascular. This platform uses an IRI compatible ECG telemetry system that acquires the signal ECG, processes it and alerts the doctor in case of emergency. Their contribution incorporates a monitoring system based on lot for ECG signal analysis. The statistical characteristics of the raw ECG signal are calculated. They have analysed the ECG signal using the QRS detection algorithm of Pan lampkins to obtain the dynamic characteristics of the ECG signal to capture the characteristics of heart rate variability. The statistical characteristics and dynamics are then applied to the classification process to classify cardiac arrhythmias. This solution allows users to check their heart condition by acquiring the ECG signal, even when they are at home. The size of the system is reduced, and requires less maintenance and operational costs [11].

A wearable health monitoring system combined with the Internet of Things (IoT) is a promising alternative to conventional health systems according to author Wu and colleagues. They proposed a small, flexible, and wearable real-time electrocardiograph (ECG) monitoring system embedded on a T-shirt. This system uses a biopotential analogy front-end chip (AFE), AD8232, to collect ECG data from subjects. The collected ECG data is transmitted via Bluetooth low energy (BLE) to an end device for real-time display. Their solution incorporates a PC graphical user interface (GUI) and smartphone application designed for real-time viewing. The power consumption of the proposed portable ECG monitoring system can be as low as 5.2 mW. Their portable system is Powered by a 240 mAh rechargeable battery and can operate for over 110 hours continuously. To extend the battery life, a flexible solar energy sensor is also integrated into this system [12].

Mishra et al. proposed and implemented a smart healthcare application using an IoT system. They used an AD8232 heart rate sensor interfaced with Arduino UNO and connected to the Cloud. Their system uses an ESP8266 wireless LAN module for data transfer [13].

Xu has proposed an Internet of Things-assisted electrocardiogram (ECG) monitoring framework with secure data transmission. The proposed solution aims to contribute to the continuous monitoring of cardiovascular health. The author analysed the ECG signal intensity for automatic classification. For the implementation of the solution, he used ECG sensors, Arduino microcontroller, Android phones, Bluetooth and a cloud server. The work also proposed Lightweight Secure IoT (LS-IoT) and Lightweight Access Control (LAC) for secure data transmission [14]. The authors do not specify the security levels of the cloud that stores the data collected by the proposed system.

Chao LI and al. monitor multiple parameters that may not be limited to single parameters physiological. These non-physiological parameters are considered because they provide information contextual services. This can facilitate remote analysis or support for contextual services. Their solution involves a ubiquitous system that can send patients' physical signs to remote medical applications in real time. Compared to single parameter monitoring systems, multi-parameter systems can provide more accurate and richer information to remote experts [5]. The solution proposed by Chao does not provide follow-up for subjects already suffering from cardiovascular disease. The doctor cannot plan the follow-up with the patients.

The work presented in this literature review, although very interesting and edifying, has some limitations. Some authors have worked on heart activity monitoring using the Internet of Things. For this purpose, they used in most cases the unique AD8232 sensor for heart rate monitoring and the Arduino microcontroller. These solutions allow patients to be followed by their respective doctors in real time via a dedicated platform. Other work has focused on multi-parameter monitoring systems. The results of these approaches offered more accuracy and help to make the best decisions on the condition of the subjects. On the other hand, the proposed works do not specify the level of security of the cloud in which the data acquired via sensors are stored. The proposed solutions are dedicated either to subjects in senior age or suffering from a cardiovascular disease.

The literature also reveals that cardiovascular diseases affect a layer of young people from the age of 15 years and that the mortality rate is higher for the age intervals of [15-29], [30-44] and [75-plus] See Table I of this paper. The mortality rate from cardiovascular disease is expected to increase by 2030 according to the WHO. This paper proposes a real-time monitoring (multi-parameter) and management system for patients of all ages with cardiovascular disease. In order to prevent the explosion of the mortality rate due to cardiovascular diseases, the proposed monitoring system will also allow people not yet affected by cardiovascular disease to monitor their activity and participate in the reduction of the mortality rate of cardiovascular diseases. The proposed monitoring system is designed at very low cost and the acquired data is stored on a platform based on the plans made by the physician.

### III. INTERNET OF THINGS (IOT) BASED HEART ACTIVITY MONITORING SYSTEM ARCHITECTURE

Detecting a heart attack encompasses several purposes. It is above all a question of making an appropriate diagnosis, so that the patient who suffers a heart attack receives treatment as soon as possible. The monitoring of cardiac activity from the ECG module makes it possible to prevent a heart attack, but also to guide subjects to improve their lifestyle to safeguard their health. To monitor the patient's cardiac activity, our solution uses heart rate sensors and the pulse sensor.

#### A. Proposed System Architecture

Our architecture (Fig. 1) includes two essential phases, which are data acquisition, and data transfer. This architecture

is designed on the general model of IoT applications composed of the detection layer, the transport layer and the application layer. Fig. 1 shows the architecture of the Internet of Things-based remote heart activity monitoring system for heart disease patients.

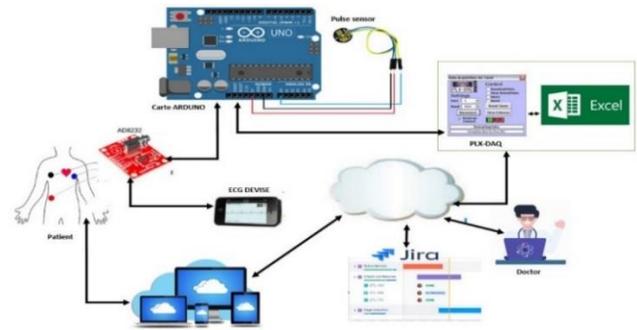

Fig. 1. System Architecture.

1) *Components of the architecture:* The proposed architecture is composed of sensors (AD8232 module, pulse sensor, potentiometer, LDR photoresistor), an Arduino board, PLX-DAQ, the ECG signal display screen and the Jira platform.

a) *AD8232 ECG sensor:* The AD8232 ECG module shown in Fig. 2 separates nine connections from the IC commonly referred to as "pins" to connect wires or header pins. It is used to determine the heart rate (heart rate or HR).

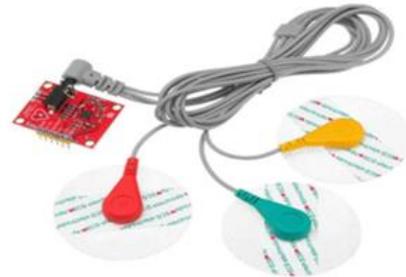

Fig. 2. AD8232 ECG.

As shown in Fig. 3, we have connected five of the nine pins of the ECG module to the Arduino Uno microcontroller. The five pins are labeled GND, 3.3v, OUTPUT, LO- and LO+. This connection collects signals from the human body which can be displayed on the screen as an ECG signal via the Arduino IDE.

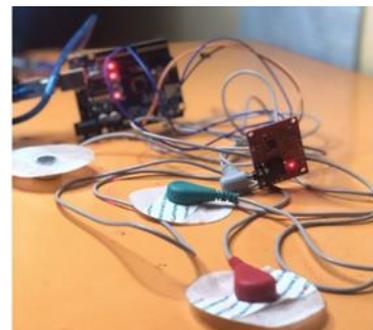

Fig. 3. Connected the Pins of the ECG Module to the Arduino.

b) *Electrocardiography ECG:* Electrocardiography (ECG) is the analysis of the electrical activity of the heart over a period. It is used to determine the heart rate, the regularity of the heartbeats, the size and position of the cavities, the existence of a possible heart attack.

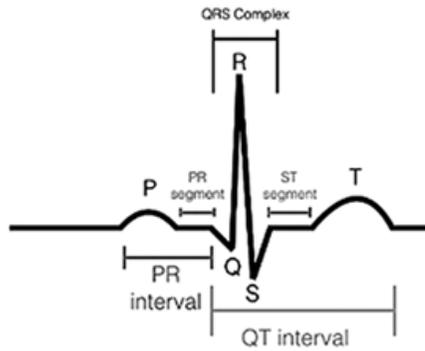

Fig. 4. ECG Signal.

The normal ECG signal is shown in Fig. 4. The ECG signal contains five characteristic peaks and valleys called P, Q, R, S, and T. The intervals of the ECG signal are the PR interval, the QT interval, and the QRS [15]. Fig. 4 illustrates a normal ECG signal

c) *Pulse sensor:* It is connected directly on the Arduino board using the Signal VCC and GND pins. The operating voltage of this sensor is +5V or +3.3V. Once the sensor is connected to the Arduino board, the code entered in the Arduino IDE and uploaded back to the board will activate the pulse sensor.

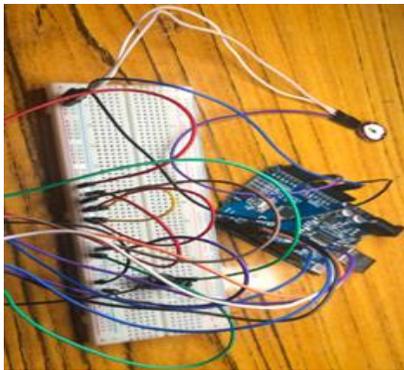

Fig. 5. Prototype Connection of the Pulse Sensor.

Fig. 5 shows a prototype connection of the pulse sensor that we have made.

d) *Arduino Uno:* The Arduino Uno in Fig. 6 is a board based on the 16 MHz ATmega328P microchip. It has 14 digital I/O pins, six analog pins, and an ICSP In-Circuit Serial Programming header. It can supply up to 5 V to the components that connect to it. The Arduino Uno board is relatively large and has the disadvantage of using a USB connector to interface with computers [16].

2) *Functioning of the architecture:* When the patient connects to the AD8232 ECG sensor and pulse sensor, the signals are picked up by the Arduino board and displayed on

the screen as a curve. Thanks to the PLX-DAQ software, a macro that only runs on Excel, the data is retrieved and stored on an Excel sheet. The patient can then save them and transfer them to the doctor via the Jira platform. The doctor receives the results, analyzes and provides feedback on the results to the patient. The patient sends his results according to the planning made by the doctor in the Jira platform.

Fig. 6. Arduino Uno.

### B. Data Acquisition with PLX-DAQ

The data acquisition part is mainly composed of sensors worn by the patients or connected to them, as shown by the architecture of the proposed system illustrated in Fig. 1. These sensors will collect the signals and transmit them to the microcontroller. The parameters to be monitored in this solution are the heart rate and the pulsation.

Data management plans typically include sections on data collection, data storage and backup, data security, data retention, data sharing and reuse [17]. It is in the sense that we used the add in PLX-DAQ confer Fig. 7, for Microsoft Excel in order to acquire up to 26 channels of data from any microcontroller. Easy spreadsheet analysis of data collected in real time will be done.

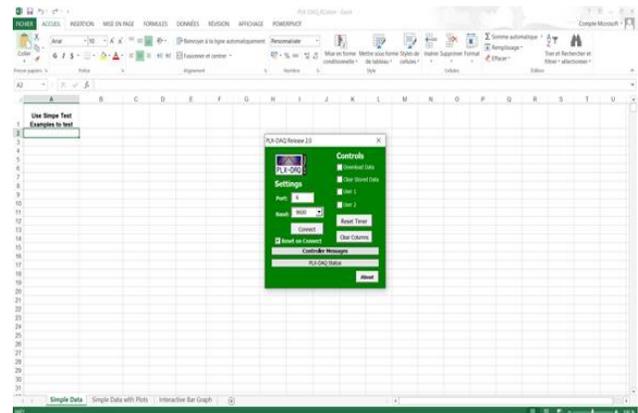

Fig. 7. PLX-DAQ.

### C. Transmission of Data Collected from the Patient to the Doctor

After collecting the data from PLX-DAQ, the patient will send it to his doctor via the Jira platform so that it can be analyzed. Indeed, the dedicated Jira platform will make work fluid and facilitate exchanges between the patient and the doctor through a single interface.

#### IV. USE CASE DIAGRAM SYSTEM

To properly express the needs of this backend and to identify the functionalities of each actor, we used the UML (Unified Modeling Language) formalism of use cases. These were developed by Ivar Jacobson long before the appearance of UML. Nevertheless, they have been integrated into this modeling language to represent the functionalities of the system from the user's point of view.

As shown in Fig. 8, these use cases allow us to structure and articulate the interactions between the actors.

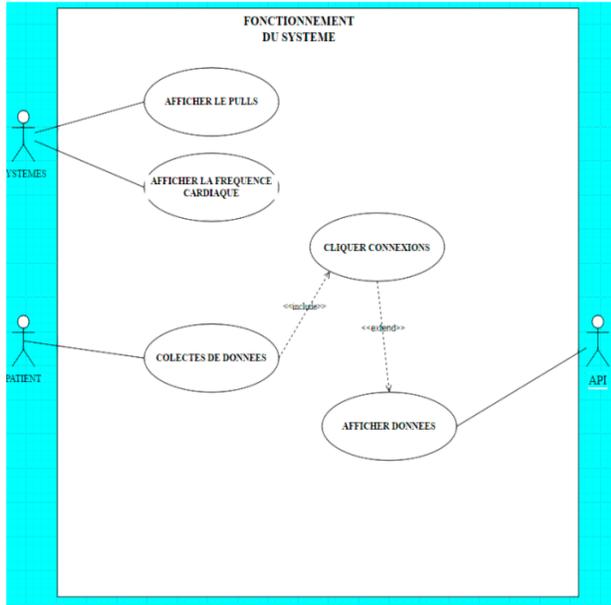

Fig. 8. The use Case of System.

We illustrate below the description of the two main use cases.

##### A. Description of the use Case to Display it Heart Rate

The Table III shows the description of the use case to display it heart rate.

TABLE III. DESCRIPTION OF THE USE CASE TO DISPLAY IT HEART RATE

Title	Show Data
Actor	Patient, System, API
Purpose	Display the patient's heart rate
Preconditions	Have a card and install Arduino IDE and the LFCSP box, having a computer, having AD8232 or Pulse sensor sensors,
Nominal scenario	1 - The patient places the sensor on him and connects to Arduino 2 - The patient executes the code already uploaded on the Arduino environment 3 - The system will display the frequency heart on an electrogram
Alternate Scenario	1-The sensor is not properly connected to the patient 2-Server unavailable 3-Error in entering the code

##### B. Description of the Data Collection use Case

The Table IV shows the description of the use case of data collection.

TABLE IV. DESCRIPTION OF THE DATA COLLECTION USE CASE

Title	Collect data
Actor	Patient, Micro-service
Purpose	Collect patient data
Preconditions	Have a card and install Arduino IDE and the LFCSP box, having a computer, having AD8232 or Pulse sensor sensors,
Nominal scenario	1 – The patient connects to PLX-DAQ 2 – The patient presses connect 3 – PLX-DAQ automatically displays the data collected 4-The patient saves the results file
Alternate Scenario	1-The data is not displayed because the sensors are incorrectly connected

#### V. RESULTS AND DISCUSSION

As mentioned above, the implementation of our solution involves two main processes which are the acquisition of the ECG signal and that of the pulse, then the transfer of data.

The ECG signal is detected using the prototype implementation shown in Fig. 9. The AD8232 ECG sensor is connected to the Arduino microprocessor.

Fig. 9. The AD8232 ECG Sensor.

With the use of the serial port, the system obtains the analog values after uploading the code to the Arduino board. The sensors are connected to a 24-year-old young man. The sensors will retrieve the data and transmit it via the microcontroller once the system is activated. The following Fig. 10 show the codes that will allow communication between different peripherals, the collection and display of information from the AD8232 ECG sensor and the pulse sensor.

The code in Fig. 10 specifically shows the connection of the AD8232 ECG and Pulse sensors. It also considers the connection between the Arduino IDE and PLX-DAQ for data acquisition. This code allows to generate the ECG signal as shown in Fig. 11.

The code in Fig. 12 only relates to the activation of the pulse sensor. It will allow the led connected to Pin 13 to turn on and off each heartbeat.

```

ECG
int AD8232 = A0;
int PulseSensor = A1;

void setup() {
  // initialize the serial communication:
  Serial.begin(9600);
  pinMode(10, INPUT);
  pinMode(11, INPUT);
  Serial.println(F("CLEARDATA"));
  Serial.println(F("LABEL,Temps,FAP,FCR"));
}

void loop() {

  int ValeurMesuree = analogRead(AD8232);
  delay(4);
  int FCR = analogRead(PulseSensor);
  Serial.print ("DATA,TIME,");
  Serial.print (ValeurMesuree);
  Serial.print (F(", "));
  Serial.println(FCR);

## VI. CONCLUSION

The damage caused by cardiovascular diseases remains spectacular. These diseases are the first cause of death in the world and reach all age groups from the 15 years old. The urgent need to minimize the mortality rate caused by these diseases consists in using the Internet of Things, in order to connect the physical world to the virtual world.

This paper proposes a cardiac activity monitoring system based on the Internet of Things and integrating the PLX-DAQ add-on module. For the design and implementation of the system, low-cost equipment's have been used. They are a computer, sensors (pulse, ECG AD8232), electrical components (potentiometer and LDR), the Arduino microcontroller for the recovery and display of information on the heart rate as well as the pulse of the subject, the JIRA software which allowed to establish the connection to facilitate the exchange of data between the actors of the system, the PLX-DAQ for the collection of these data. The results of the analysis of the data collected via the Arduino board allow the user to follow his health status and monitor his performance. In addition, the subject no longer needs to travel to health centers to be monitored. This represents a saving of time and money. The Jira platform allows the physician to plan the submission periods of the data acquired via PLX-DAQ.

In perspective, the solution will be improved by integrating more sensors to collect physiological data (temperature, blood sugar, etc.) from the subject. For emergency management, the aim will be to integrate environmental parameters to facilitate patient location in case of emergency. The security of the transferred data and the handling of the connected object will be addressed.

## ACKNOWLEDGMENT

I would like to give thanks to all people who supported in this work. Particularly to Mouhamadou Mansour SY, Mohamed SY TOUMBA, Jacques-David NGUEMA, Alioune SY and all my family members.

**Abstract**—Surveillance systems are widely used in malls, colleges, schools, shopping centers, airports, etc. This could be due to the increasing crime rate in daily life. It is a very tedious task to monitor and detect abnormal activities 24x7 from the surveillance system. So the detection of abnormal events from videos is a hugely demanding area of research. In this paper, the proposed framework is used for deep learning concepts. Here SlowFast Resnet50 has been used to extract and process the features. After that, the deep neural network has been applied to generate a class using the Softmax function. The proposed framework has been applied to the UCF-Crime dataset using Graphics Processing Unit (GPU). It includes 1900 videos with 13 classes. Our proposed algorithm is evaluated by accuracy. Our proposed algorithm works better than the existing algorithm. It achieves 47.8% more accuracy than state of art method and also achieves good accuracy compared to other approaches used for detecting abnormal activity on the UCF-Crime dataset.

**Keywords**—Accuracy; GPU (Graphics Processing Unit); SlowFast Resnet50; Softmax; UCF-Crime dataset

## I. INTRODUCTION

Abnormal activity detection is a very monotonous process for monitoring and identifying the abnormal events. In daily life, the use of surveillance cameras is increasing due to the huge crime rate. It may happen for somebody activity is suspicious activity while for others it is not. So to choose an appropriate framework for identifying suspicious activity plays a very significant role [1]. Recently surveillance system uses deep learning models to identify abnormal activities. Deep learning is very popular and one of the classes of machine learning. It is popular because of its ability to perform well on unstructured data. Deep learning uses and implements deep learning neural networks. It has good computing capability. It also provides good flexibility when it has to process a large number of features. These features have been taken from unstructured data. The Deep learning models have several layers and it passes the data through these layers. Each layer extracts the features progressively from unstructured data. These features have been passed to the next layer of the network. Low-level features have been extracted from initial layers and succeeding layers combines the features. It creates a complete form of feature representation. It addresses a variety of challenges that occur in a conventional surveillance system. It gives better performance with deep neural networks [2]. The literature study [2, 3, 4, 5, 6] summarizes the following point that inspire to use of deep learning in the surveillance systems.

- Anomaly events are irregular and unknown.
- Due to this one class of anomaly may differ from the other class of anomaly.
- The scalability of the data also plays a vital role in increasing the complexities of a system.
- Because the chances of misclassification of anomalies is too costly than the normal instances, the classes are imbalanced.
- Diversity in types of abnormalities.

## II. RELATED WORK

Abnormal activity detection can be performed in two kinds of categories. The first one is an individual activity video and the second one is a crowd activity video. Sonkar et al. [7] represent the deep learning system which provides control over the crowd. This will help to avoid suspicious activities. CNN model has been used to analyze crowd behavior. With CNN model KNN- K Nearest Neighbour is also used to calculate the position difference between two consecutive frames of an object. The motion has been analyzed using three attributes: Speed, Direction and angle. Using the thresholding technique, the event is classified. This may vary based on the application. Chaudhary et al. [8] proposed framework, in which five different features are extracted. The features are Speed, Centroid, Direction, Movement and Dimensions. After extracting features, rule based classification has been performed. This algorithm is capable of handling multiple activities which are abnormal activities. It performs successfully and gives an accuracy up to 90%. Kaminski et al. [9] proposed an unsupervised method for detecting abnormality from videos. UMN dataset has been used. They have used motion descriptors for classification, Particle filter algorithm is used. This algorithm does not require any predefined samples. The results obtained are highly efficient compared to other existing algorithms. Landi et al. [10] explored the need for spatiotemporal tubes instead of the whole frame from the surveillance video. The experimental results show that the network trained with these features gives much better performance than the ordinary way. This method is robust against different localization errors. Dubey et al. [11] focuses on minimizing false rate in abnormal activity detection.

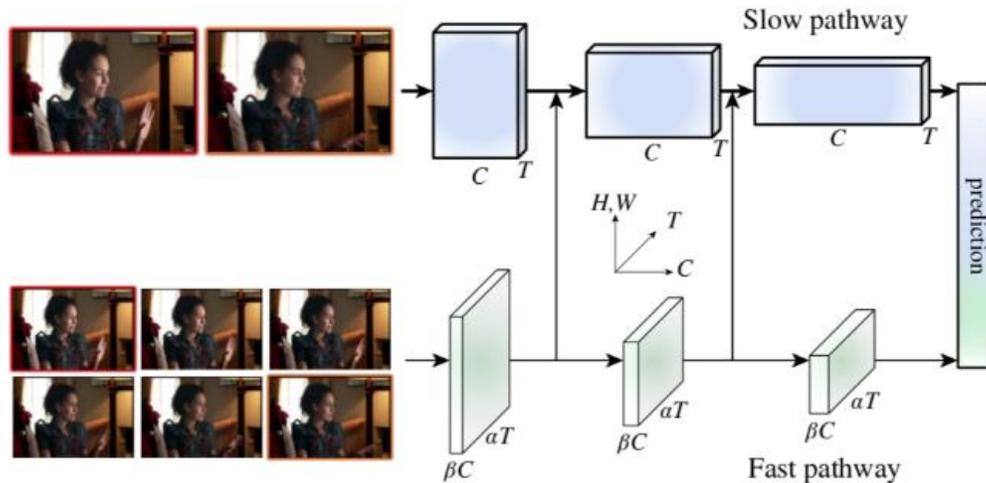

Fig. 1. Illustration of the SlowFast Network with Parameters [15].

3D Resnet has been used to extract spatio-temporal features. These features are used for deep neural networks and greatened scores. Multiple Instance Learning is used to classify the activities. The algorithm gives the best performance in the UCF-Crime dataset. Sargano et al. [12] present a novel method using CNN and a combination of SVM and KNN. In terms of accuracy, the proposed algorithm gives better performance than the existing methods. Sultani et al. [13] proposed a ranking method to classify the activities from the bag of videos. For better localization, sparsity and smoothness have been used. The results of experiments show that the proposed algorithm performs significantly higher than the other baseline algorithms.

### III. SLOWFAST RESNET – 50

Generally, with videos, the frames consist of two part: static area in frames and Dynamic area in frames. The static area cannot be changed or slowly changed though the frame has been changed while in a dynamic area, it has changed the object, background and other things. For example, during a meeting, two persons doing handshaking is dynamic and fast but the background and other objects are static. Here in this paper, SlowFast CNN [14] has been introduced for capturing abnormality. Here slow pathway is designed to capture static information from video with low frame rates and slow refreshing speed. Another pathway is the fast pathway where all dynamic information is captured with high frame rates and fast refreshing speed. The formal pathway is very light weighted. Both pathway are merged by lateral connections. SlowFast network uses the Resnet model in both pathways and runs 3D convolution operations on it. The slow pathway uses a large strides. The stride means the number of frames skipped per second. In general, it is set to 16. Approximately allowing two sampled frames per second. The fast pathway uses too smaller a stride typically eight. This allows 15 frames per second.

Fig. 1 shows the illustration of the network with parameters. The parameters used in networks are as follows [15]:

- S = Spatial.
- T = Temporal.
- C = Channel size.
- $\alpha$  = Speed ratio (Frame skipping rate).
- $\beta$  = Channel ratio.

Both the SlowFast network uses the 3D Resnet model. It captures several frames from videos and applies 3D convolution operation on them. The Slow Pathway uses a large stride, here it is 16. The Fast Pathway uses small size stride, here it uses two. As shown in Fig. 1, data from the Fast pathway faded to the Slow pathway via lateral connections. This connection allows the Slow pathway to be aware of the result of the Fast pathway. Data transformation should require as the shape of the data is different. This can be done by applying Time-strided convolution. In this, it performs 3D convolution of 5x12 kernel. Global average pooling has been one at the end of each pathway. It reduced its dimensionality of it. Now it concatenates the result of both pathways and inserts it into a fully connected classification layer [15].

### IV. PROPOSED METHOD

Fig. 2 shows the flow of the proposed algorithm. The proposed algorithm has been classified as abnormal and normal activity. Here UCF – Crime data set has been used. It is a very large dataset and it contains 1900 videos. It includes videos of normal and abnormal activities. There are 13 abnormal activities in this dataset [13]. This algorithm has been implemented with the SlowFast Resnet50 model. Resnet is a residual network that implemented identity mapping. Because of it, Resnet is able to solve vanishing gradient problem. So in the proposed algorithm Resnet has been used. This model is pre trained model. The steps of the algorithm have been mentioned below:

- 1) Take a surveillance video S for processing.
- 2) Initialize the value of the number of frames and the number of the segment.

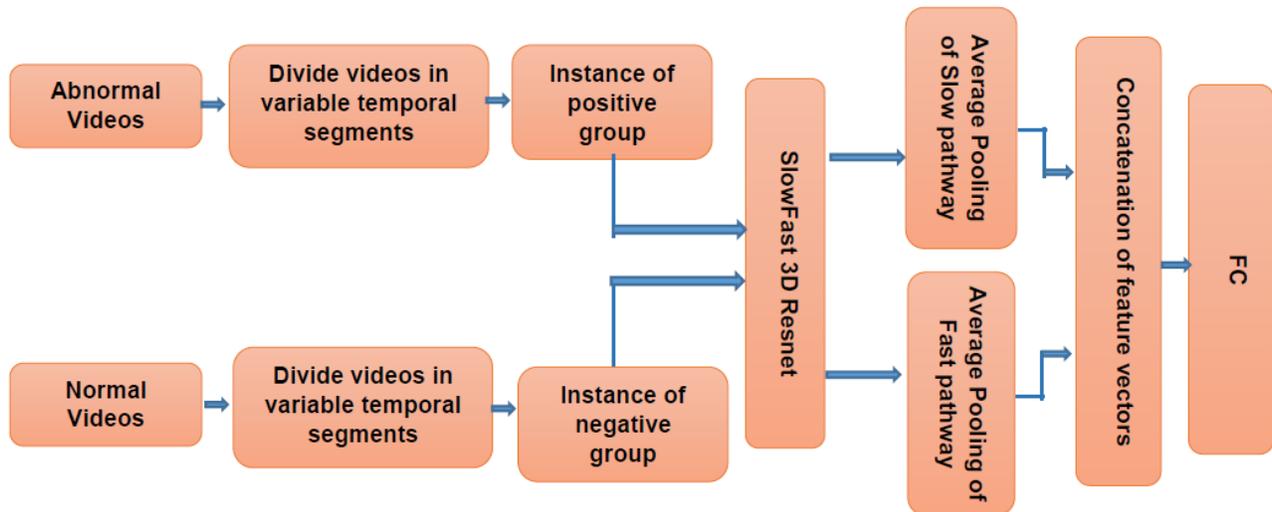

Fig. 2. Proposed Algorithm: Abnormal Activity Detection using SlowFast Resnet50 (AADSFR50).

3) Evenly divide Normal and abnormal videos into variable segments using the below formula.

$$clip = \frac{Total\_frame\_video}{I\_frame * I\_segment} \quad (1)$$

Where Total\_frame\_video is a total number of frames of the video, I\_frame is the initial value of the number of frames and I\_segment is the initial value of the segment.

4) The instance of normal and abnormal video groups has been given to SlowFast Resnet pre-trained models.

5) Data from the fast pathway is going to feed into the slow pathway network using the lateral connection.

6) Using average pooling, slow pathway feature vector has been generated.

7) Using average pooling, fast pathway feature vector has been generated.

8) Two feature vectors have been fused by performing concatenation.

9) A fused feature vector has been given to a fully connected classifier layer where the Softmax function is used to classify the activity.

## V. IMPLEMENTATION RESULTS AND DISCUSSION

UCF-Crime dataset has been used to evaluate the AADSFR50 – proposed algorithm. This dataset is widely used to research abnormal activity detection. It contains 1900 videos and 13 classes. The classes are Abuse, Arrest, Arson, Assault, Accident, Burglary, Explosion, Fighting, Robbery, Shooting, Stealing, Shoplifting, and Vandalism [13]. Google colab has been used to implement this algorithm. It provides NVIDIA Tesla K80.

Table I shows the comparison of different existing algorithms and our proposed algorithm (AADSFR50). Here as a measuring parameter Accuracy has been used. As observed

from Table I, our proposed algorithm works better than the existing algorithm.

Fig. 3 describes the pictorial information of a comparative study of existing algorithms and our proposed algorithm AADSFR50. Here the evaluation parameter taken is accuracy. Fig. 3 shows that our proposed method works better than existing algorithms. It achieves 47.8% increase in accuracy compared to state of the art method. Other approaches also have been considered. In that case also our proposed method (AADSFR50) achieves better accuracy.

Fig. 4 shows the sample of the output video that has been generated after implementing AADSFR50. Fig. 4(a) shows the true positive case where abnormal video was detected as abnormal. Fig. 4(b) shows the true negative case where normal video was detected as normal. Fig. 4(c) shows the false positive case where abnormal video was detected as normal. Fig. 4(d) shows the false negative case where normal video was detected as abnormal.

TABLE I. COMPARISON OF DIFFERENT EXISTING ALGORITHMS AND OUR PROPOSED ALGORITHM (AADSFR50)

Sr. No	Algorithm	Accuracy (%)
1	C3D[16]	23
2	TCNN[17]	28.4

Fig. 4. Implementation Results of our Proposed Method (AADSFR50) - (a) Sample of Abnormal Video Detected as Abnormal (b) Sample of Normal Video Detected as Normal (c) Sample of Abnormal Video Detected as Normal (d) Sample of Normal Video Detected as Abnormal.

## VI. CONCLUSION

Well known task has been found among researchers to detect abnormal activity from surveillance videos. Much progress has been achieved on this task but still, it is an open and interesting task for the researcher. Here in this paper, UCF crime dataset has been taken which contains challenging videos for the classification of abnormal and normal activities. SlowFast Resnet 50 has been used to perform the feature extraction. The fast pathway is used to analyze the static content and the Slow pathway is used to analyze the dynamic content of videos. Good accuracy has been achieved with the AADSF50 method compared to state of art method and other existing approaches. For state of art method 47.8% accuracy increases and with other approaches 2.34% – 52% accuracy is increased. Still, there is the scope for applying a more optimized model such as Deeper Resnet to achieve more accurate results.

# Address Pattern Recognition Flash Translation Layer for Quadruple-level cell NAND-based Smart Devices

Se Jin Kwon<sup>1</sup>

Department of AI Software  
Kangwon National University, Samcheok, South Korea

**Abstract**—The price of the solid-state drives has become a major factor in the development of flash memory technology. Major semiconductor companies are developing quadruple-level cell NAND-based SSDs for smart devices. Unfortunately, SSDs composed of quadruple-level cell (QLC) flash memory may suffer from low performance. In addition, few studies on internal page buffering mechanisms have been conducted. As a solution to these problems, an address pattern recognition flash translation layer (APR-FTL) is proposed in this study. APR-FTL gathers the data in a page unit and separates random data from sequential data. Furthermore, APR-FTL proposes address mapping algorithm which is compatible to the page buffering algorithm. Experimental results show that APR-FTL generates a lower number of write and erase operations compared to previous FTL algorithms.

**Keywords**—Memory management; nonvolatile memory; smart devices

## I. INTRODUCTION

Price has become an important factor in the development of flash memory system, as many semiconductor manufacturing companies are competing for dominance in the smart device market [1]. Some semiconductor companies have recently turned their attention to developing QLC flash memories for smart devices as a means of providing large capacity at a low price [2]. As a result, instead of applying high-performing single-level cell (SLC) or multi-level cell (MLC) technology to smart devices, major semiconductor companies are developing QLC flash memory for smart devices. However, implementing QLC flash memories on smart devices may drastically diminish device performance and durability and even generate inconsistent response times, as smart devices must generate frequent updates from temporary files and metadata [3].

Furthermore, smart devices may execute unnecessary write operations on QLC-based SSDs because of the large page size of QLC flash memory. Although the page size of SLC or MLC flash memory is only four to eight times larger than the data sector of the file system [4], the page size of QLC flash memory is predicted to be 64 to 512 sectors. Because of the large page size of QLC flash memory, there is a considerable chance that the file system may frequently command a page re-access in the flash memory. However, the number of partial programming (NOP) requirements within a page is limited to only one to avoid program-disturbing errors [5]. Therefore, QLC flash memory tends to use an internal register or page buffer to gather data in a page unit.

Well-optimized flash translation layers (FTLs) are based on SLC/MLC/TLC flash memory [6], and therefore they do not give considerable attention to their own page buffering mechanisms (PBMs). This is an issue that has yet to be fully researched. In this study, the implementation of an address pattern recognition flash translation layer is proposed. APR-FTL gathers the data sectors and rearranges them into the page size of the QLC flash memory, instead of writing data on the flash memory immediately. Furthermore, APR-FTL proposes address mapping algorithm which is compatible to the page buffering algorithm. The efficient data collection of APR-FTL provides improved performance and consistent response despite the use of low-performing QLC flash memories.

## II. RELATED WORKS

Previous PBMs can be classified into fine- and coarse-level PBMs. A fine-level PBM [7] gathers data sectors without a logical address boundary. However, this method reveals every corresponding physical sector number in DRAM. Therefore, it requires approximately 8 GB per 1 TB of flash memory. By contrast, a coarse-level PBM [8][9] gathers data using the same logical page number (LPN). Fig. 1 shows an example of a coarse-level PBM. Here, the extensive data from the write command are broken down into a unit of file system data sectors. A logical sector number (LSN) and its corresponding data are shown as (LSN, data). For simplicity, the size of a block is assumed to be four pages, where each page consists of only four sectors. Because they all belong to LPN 0, (0, A), (1, B), and (2, C) belong to a single page ( $= 0/4, = 1/4, = 2/4$ ). However, when (16, D) occurs, the data within the page buffer are sealed as a page and written to flash memory because (16, D) belongs to LPN 4 ( $= 16/4$ ). Finally, the page buffer is flushed, and data “D” are written to the emptied page buffer. Similarly, other data are gathered as a page unit. The coarse-level PBM generates six subpages, as shown in Fig. 1, although the file system issues only nine data sectors. If each page is filled with data, the coarse-level PBM generates only three pages. In Fig. 1, it is assumed that a page consists of only four subpages. However, we should note that the page size of QLC flash memory ranges from 64 to 512 sectors. There is a considerable chance that the space utilization of a QLC-NAND SSD will decrease drastically because of the frequent occurrence of subpages.

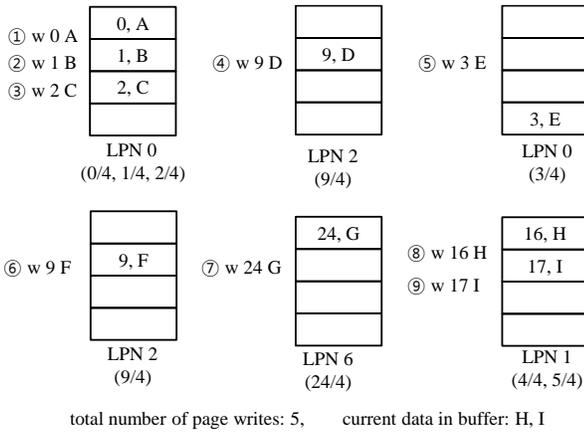

Fig. 1. Coarse-level Page Buffering Mechanism.

### III. ADDRESS PATTERN RECOGNITION FLASH TRANSLATION LAYER

#### A. Address Pattern Recognition Algorithm

Address pattern recognition algorithm (APRA) modifies previous adaptation layer [10] and provides compatible address mapping algorithm according to the experiments in Section III.B. In other words, the address pattern recognition FTL is composed of address pattern recognition algorithm and address mapping algorithm.

The QLC flash memory cannot access to a page for an additional write operation because of the restricted NOP. Therefore, the QLC flash memory requires an efficient PBM. Unfortunately, the coarse-level PBM generates five page write operations, as previously explained in Section II. We should note that the QLC flash memory consists of 8 to 16 sectors per page. Because the amount of random data tends to fill the space of only one to four sectors, it is likely that the scenario will frequently occur. As a solution for the unnecessary write operations, the address pattern recognition algorithm (APRA) has been proposed [10].

APRA is shown as Algorithm I. The main objective of APRA is to segregate the random data from the sequential data and to allow the address mapping algorithm in FTL to separately manage them [10]. When the file system issues a write command along with the LSN, APRA first checks whether (LSN, data) is sequential to the sequential buffer (Algorithm 1 line 1). If (LSN, data) is sequential to the sequential page buffer, it is considered as the sequential data, and therefore it is inserted into the sequential page buffer (Algorithm 1 line 2). On the other hand, if the incoming data's LSN already exists in the page buffers (Algorithm 1 line 3), APRA consider (LSN, data) as an update, and therefore it is inserted into the random page buffer (Algorithm 1 line 4). Finally (LSN, data) is included in the undefined buffer if (LSN, data) is not sequential pattern nor an update.

---

#### ALGORITHM I: Address Pattern Recognition

---

**Input:** logical sector number (*LSN*), data (*data*)

**Procedure:** write\_page\_buffer (*LSN*, *data*)

1: **if** (*LSN*, *data*) is sequential **then**

---

2: data\_insert(*sequential\_buffer*, *LSN*, *data*);  
 3: **else if** (*LSN*, *data*) is update **then**  
 4: data\_insert(*random\_buffer*, *LSN*, *data*);  
 5: **else**  
 6: data\_insert(*undefined\_buffer*, *LSN*, *data*);  
 13 **end if**

**Input:** page buffer (*PB*), *LSN*, *data*

**Procedure:** data\_insert (*PB*, *LSN*, *data*)

14: **if** *PB* is full **then**  
 15: Write *PB* to flash memory;  
 16: Flush *PB*;  
 17: Insert (*LSN*, *data*) into *PB*;  
 18: **else**  
 19: Insert (*LSN*, *data*) to *PB*;  
 20: **end if**

---

#### B. Address Mapping Algorithm

The page buffering layer reorganizes the data sectors at the page unit, and the address mapping layer determines the physical address of the data to be written onto the flash memory. To evaluate the performance of the PBM and APRA, previous log-block algorithms were implemented in the address mapping layer.

Log blocks are temporary buffers for physical blocks. Of previous address mapping algorithms, log-block algorithms are well known to be the most optimized FTL algorithms with respect to their DRAM requirements and performance. Previous log-block algorithms made use of variations in the associativity between the blocks and log blocks, which can be classified into block-level associativity, full associativity, and superblock-level associativity. In this study, address mapping algorithms based on block-level associativity, full associativity, and superblock-level associativity are referred to as BAST, FAST, and SAST, respectively.

### IV. PERFORMANCE EVALUATION

#### A. Experimental Setup

For this study's experiment, an FTL simulator was developed, and trace-driven simulations were conducted. The traces were retrieved from smartphones running various multimedia services and applications. The developed FTL simulator consisted of two layers: a page buffering layer and an address mapping layer. The previous PBM and APRA were implemented in the page buffering layer, and the number of pages generated by both algorithms were then monitored. It is also assumed that each page and block consist of 64 sectors and 256 pages, respectively, and that the performances of the read, write, and erase operations are 100  $\mu$ s, 1,500  $\mu$ s, and 6 ms, respectively. Furthermore, ARPA-FTL is analyzed by implementing block-level, full, superblock-level associative address mapping algorithms.

B. Performance Analysis

After PBM and APRA generates the data in the unit of a page, the address mapping layer determines the physical address within the flash memory. Fig. 2 shows the number of write and erase operations executed on BAST, FAST, and SAST. In the case of Trace A, the PBM generated approximately 1,575,200, 1,571,900, and 1,569,800 write and 358, 347, and 321 erase operations in BAST, FAST, and SAST, respectively. By contrast, APRA-FTL it executed approximately 1,546,700, 1,547,300, and 1,543,900 write and 271, 269, and 261 erase operations in BAST, FAST, and SAST,

respectively. Similarly, APRA-FTL executed fewer write and erase operations in the overall traces, as shown in Fig. 2.

As previously indicated, the number of pages transferred from the page buffering layer considerably affects the number of write and erase operations. A close observation reveals that APRA-FTL avoids numerous operations in the address mapping layer because it collects small-sized random data at the page unit. We should note that the number of write operations executed on the flash memory is higher than that of the pages themselves.

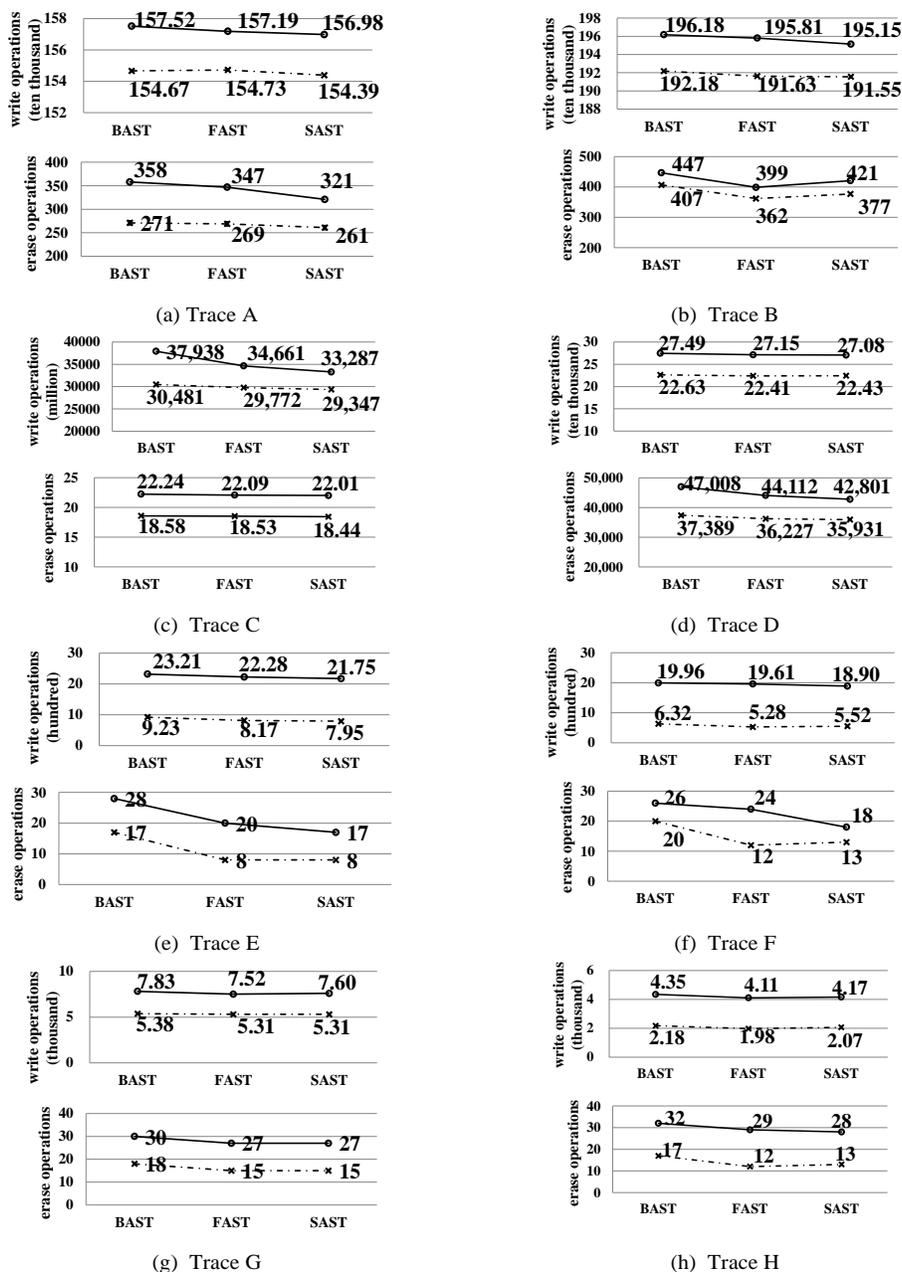

Fig. 2. Number of Write and Erase Operations.

The cause of the deviation between the number of pages and write operations might be of interest, as the page buffering layer issues a write operation to the address mapping layer whenever it gathers the data into a page unit. This is because the address mapping layer executes additional write operations internally to copy the data from an old to a new block. When a block is determined to be erased in the address mapping layer, BAST, FAST, and SAST copy the valid data from the old block to a new block and then execute an erase operation on the old data block. Therefore, the number of additional write operations for copying the data is considerably influenced by the number of erase operations. Because APRA-FTL reduces the number of erase operations by gathering random data and avoiding unnecessary write commands, it reduces the overall number of write operations as well.

## V. CONCLUSION

Major semiconductor companies are using QLC flash memory in smart devices to lower the prices of smart devices. Unfortunately, previous page buffering algorithms do not segregate random data, thus generating many unnecessary write commands in the QLC flash memory. This results in a drastic performance degradation in smart devices. Furthermore, there has not been any experiment that considers the compatibility between page buffering algorithm and address mapping algorithm. As a solution, an APRA-FTL was proposed in this study. The APRA-FTL may require additional DRAM or the use of an internal buffer. However, we showed that it accurately identifies random data and thus considerably reduces the number of write operations. From experiments conducted in this study, APRA-FTL reduced the overall number of operations. In a future study, APRA-FTL will be implemented in various wear-leveling algorithms, and additional

experiments will be conducted on the durability and power-off recovery of smart devices.

# Hybrid Deep Learning Signature based Correlation Filter for Vehicle Tracking in Presence of Clutters and Occlusion

Shobha B.S, Deepu.R

Department of Computer Science and Engineering  
ATME College of Engineering, Mysore, Mysore, India

**Abstract**—This vehicle tracking is an important task of smart traffic management. Tracking is very challenging in presence of occlusions, clutters, variation in real world lighting, scene conditions and camera vantage. Joint distribution of vehicle movement, clutter and occlusions introduces larger errors in particle tracking based approaches. This work proposes a hybrid tracker by adapting kernel and particle-based filter with aggregation signature and fusing the results of both to get the accurate estimation of target vehicle in video frames. Aggregation signature of object to be tracked is constructed using a probabilistic distribution function of lighting variation, clutters and occlusions with deep learning model in frequency domain. The work also proposed a fuzzy adaptive background modeling and subtraction algorithm to remove the backgrounds and clutters affecting the tracking performance. This hybrid tracker improves the tracking accuracy even in presence of larger disturbances in the environment. The proposed solution is able to track the objects with 3% higher precision compared to existing works even in presence of clutters.

**Keywords**—Smart traffic management; background subtraction; vehicle detection; aggregation signature; hybrid tracker

## I. INTRODUCTION

The Video surveillance based smart traffic management is the cost-effective solution for traffic monitoring and control. With the convergence of image processing and artificial intelligence, various traffic related applications like vehicle classification, congestion detection, accident detection, over-speeding detection, tracking vehicles etc. can be realized for smart traffic management. Vehicle tracing is an important application in smart traffic management for various traffic violation detections and criminal forensics.

Traditional vehicle tracking algorithms predict the vehicle location in consecutive frames based on its position in the previous frames. Some of the well-known tracking algorithms in this category are Kalman filter [1], mean shift [2], particle filter [3] and tracking learning detection [4]. Many methods have been proposed extending these approaches. Edge feature-based extension to Kalman filter [5], SIFT based extension to mean shift filter [6], integrated mean shift with particle filter [7] and long-term TLC combining detection and tracking [8] are some of the works extending traditional tracking algorithms. The traditional algorithms and its extension have many challenges in tracking due to clutters, occlusion, speed

of vehicle and lighting conditions [9]. In presence of these challenges, target vehicle localization becomes erroneous. The five important challenges considered in this work are lighting variations, object occlusion, fast movement, shape deformation and false positive. These challenges result in failure to detect and track the vehicles. Occlusion makes object detection difficult both in current frame and for updating future images. Fast movement introduces blurred effect in video frames. Clutters and occlusion jointly introduce either partial or complete deformation of the target object. False positives are introduced due to presence of multiple similar objects [10].

Based on functionality, the existing tracking methods can be divided into two classes: background modeling and foreground modeling [11]. Background modeling-based approaches uses the first frame or few initial frames to build a background model, and then compare the current frame with the background model to detect moving foreground objects, and finally review the background model. Most of the backgrounds modeling methods are supported on Bayesian filtering, Kalman and particle filters. Background modeling approaches suffer from illumination changes and dynamic background. Detailed survey on vehicle detection, recognition and tracking is provided [12]. Foreground modeling approach uses vehicle shape properties to track the vehicle. Various features like local binary pattern (LBP), histogram, Scale invariant feature transform (SIFT) etc. are used for vehicle detection but in presence of occlusions, vehicle shape distortions create higher false positives in vehicle tracking. Thus the proposed solution addresses the problem of tracking in presence of lighting variations, object occlusion, fast movement, shape deformation and false positive which affects the precision of tracking the vehicles.

In our proposed work we combine the best of both background and foreground modeling for effective vehicle tracking. The proposed solution preprocesses the video using background modeling that is adaptive to eliminate the effect of shadows, illuminations and clutters in the foreground. A novel hybrid tracker combining particle filtering with aggregation signature-based object detection is proposed for accurate tracing of object in presence of clutters and occlusion. The proposed aggregation signature is a deep learning feature of probability distribution of object in presence of clutter and occlusions in the frequency domain. The regions in the image are scored combining the results of particle filters and

aggregation signature tracking and the target vehicle is localized in the higher scored region. Following are the important contributions of this work.

- 1) Adaptive background modeling to eliminate shadows, illuminations and clutters.
- 2) A novel deep learning aggregation signature feature for occlusion and clutter distributed target object in frequency domain applying Quaternion Discrete Cosine Transform (QDCT) in frequency domain.
- 3) An integrated hybrid tracker combining particle filter with deep learning-based aggregation signature feature.

## II. LITERATURE SURVEY

The existing deep learning models for tracking of objects are detailed and the issues are presented in this section.

Many deep learning models have been proposed for tracking of vehicles. These deep learning models are used separately or in combination with particle filter for tracking the vehicles. Zhang et al. [14] proposed a method to track vehicles using recurrent convolutional neural network. Recurrent network trained with reinforcement learning predicts the future locations in the next frames. Learning is done based on continuous inter frame correlation. The approach does not consider the presence of occlusions in learning process. Shobha B S et al. [13] proposed a traffic adaptive multiple vehicle classification using deep learning which tries to address the problem of vehicle categorisation in presence of clutters and occlusion. Multiple online trackers are fused for vehicle tracking by Leang et al. [15]. Set of trackers are combined in different stages of tracking. But in presence of occlusions, the localization error is amplified. Chen et al. [16] addressed the problem of occlusions in tracking but their approach was template based and computational complexity was very high. Hua et al. [17] used deep learning to localize the patches of interest. But the accuracy of localization decreases with decrease in the visibility of patch. Speed was prediction based on localization of patches. But with error in localization patches, the speed prediction also becomes erroneous. A two-stage model to track vehicles is proposed by Liu et al. [18]. In the first stage, recurrent convolutional neural network is adapted to detect object and in the second stage, Kalman filtering is done to track vehicles. In presence of clutters and occlusions, first stage fails and due to this tracking also fails. Integrated YOLOv3 with ORB tracking is used for localization of vehicles by Song et al. [19]. Feature points needed for ORB cannot be extracted in presence of occlusions and thus this approach fails in presence of occlusions. Xu et al. [20] used faster RCNN to detect objects. Features collected from target object were classified by RCNN to detect object. But the overhead is very high in this approach and in presence of large variances in features due to occlusion, the detection fails. A particle-based filtering based on motion of particles is proposed by Fang et al. [21] to track vehicles. But the model needs to be trained for all poses of vehicle. A fully convolutional region-based detector was used to track vehicles by Dai et al. [22]. The method is faster compared to R-CNN

but it is not resilient to even a small shape distortion. A correlation filter using the activations from convolutional layer of CNN was proposed Danelljan et al. [23]. Though method was able to detect vehicles better than hand crafted features, it is very sensitive to occlusions. Ma et al. [24] model the hierarchy of convolutional layers as a pyramid representation of image and use these multiple levels of abstraction for visual tracking. The correlation between the filters at each layer and the visual appearance is adaptively learnt and the response of each layer to detect the target is analysed. The features from the detected layer are then used for object localization. In presence of occlusions, the detection layer response is varying and thus training becomes cumbersome. Various filters extending linear correlation filter for object tracking have been proposed. Works by Bolme et al. [27], Henriques et al. (2015) and Wang et al. [30] are some of the noteworthy extensions. Bolme et al. [27] extended the linear filter with sum of square error filtering. Though this extension made the approach robust against lighting, scale, pose and non-rigid transformations, the filter performance degrades in presence of clutters and occlusions. A dual correlation filter extending the linear correlation filter was proposed by Henriques et al. [26] for tracking the vehicles. The computational complexity increases exponentially with increase in the number of objects in the frames and the approach is not resilient to occlusions and clutters. A discriminant correlation filter (DCF) was proposed by Wang et al. [25]. It is an end to end light weight network architecture using Siamese network and back propagation trained to provide a heat map of object location in the frames. In presence of occlusion, the false positive is higher in this approach. Yang et al. [28] proposed a detection-based tracking framework using YOLO deep learning model. A light weight feature extraction for object using YOLO is combined along with filter template matching to localize the object. In presence of occlusions, the features have higher spatial difference compared to the region to be tracked in this method. This reduces the accuracy of tracking.

## III. HYBRID TRACKER

The architecture of the proposed hybrid technique to track vehicles is given in Fig.1 Background is subtracted from the current frames using a fuzzy adaptive background model. The target vehicle to be tracked is selected by marking a rectangular bounding region. Aggregation signature is learnt for the target vehicle. Kernel correlation filter (KCF) and Particle correlation filter (PCF) are adapted to use the aggregation signature and provide the response. The response of the KCF and PCF filter are fused with weighted Newton fusion function to get the predicted position of the target vehicle in any frame. The details of each of the process are detailed in following subsections.

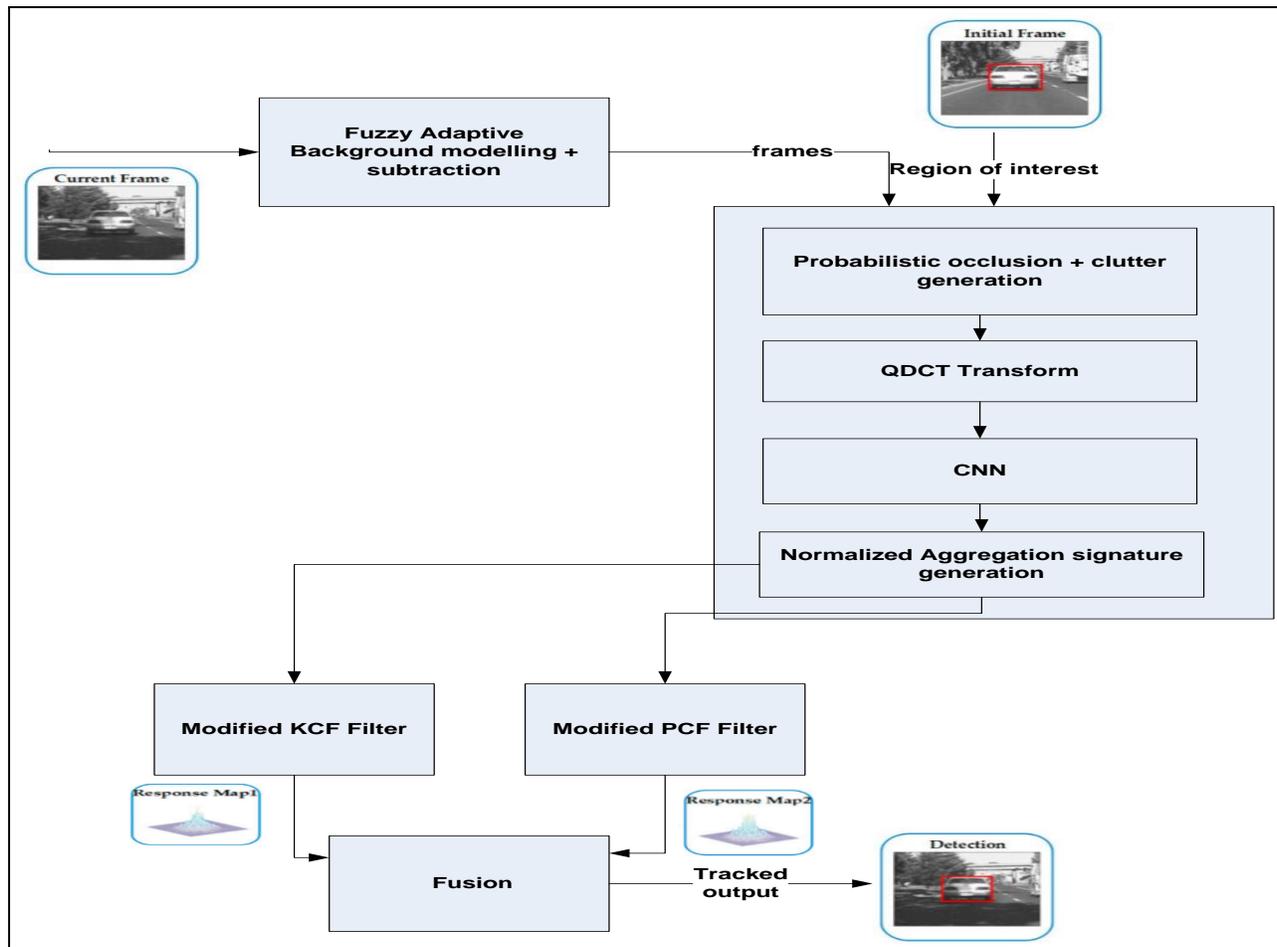

Fig. 1. Hybrid Tracking Architecture.

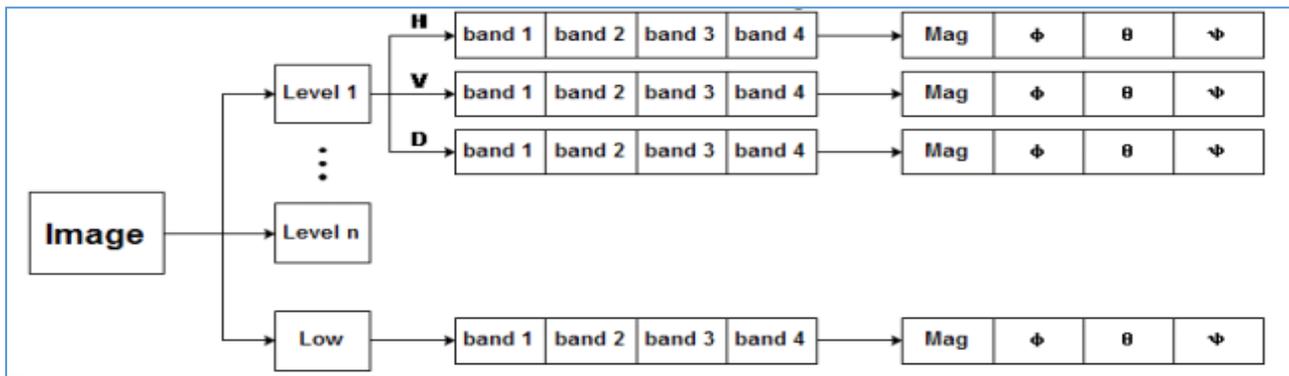

Fig. 2. QDCT Coefficients.

### A. Fuzzy Adaptive Background Modelling

A fuzzy adaptive background model is constructed from few initial frames and it is updated on every successive frames. The background for every frame is subtracted from this model. The model is designed to eliminate the impact of shadows, illuminations and clutters in the foreground. The initial model is constructed based on first  $k$  frames as

$$p_k(x) = \tilde{p}_{k-1}(x) + \frac{1}{G_k \sqrt{2\pi\sigma^2}} \exp\left(\frac{-1}{2} \left(\frac{x - x_k}{\sigma}\right)^2\right)$$

where

$$\tilde{p}_k(x) = \frac{p_k(x)}{\sum_{\sigma}^N p_k(x)} \quad (1)$$

Where,  $x_k$  is the pixel value observed at the  $k^{\text{th}}$  frame. The value of  $\tilde{p}_k$  is calculated for  $N$  frames. The parameter  $G_k$  is the learning rate whose value varies from 0 to 1. This value is adapted based on minimization of energy value between the current background and previous background. The energy ( $U$ ) of a background is calculated in spatial and temporal level as

$$U = \sum_i E_T(i) + \sum_i E_S(i) \quad (2)$$

Where  $E_T(i)$  is the temporal energy of a pixel  $i$  and  $E_S(i)$  is the spatial energy of a pixel  $i$ .

$$E_S(i) = \sum_{j \in N_i} Sim(i, j) \quad (3)$$

Where  $N_i$  is the eight pixel neighborhood of  $i$  and  $Sim$  is the similarity function between pixel  $i$  and  $j$ .

$$Sim(i, j) = \begin{cases} 1, & \text{if } |intensity_t(i) - intensity_t(j)| < D \\ -1, & \text{otherwise} \end{cases} \quad (4)$$

The temporal energy of pixel  $i$  is calculated as

$$E_t(i) = \sum_{j \in N_i} TSim(i, j) \quad (5)$$

$$TSim(i, j) = \begin{cases} 1, & \text{if } |intensity_{t+1}(i) - intensity_t(j)| < D \\ -1, & \text{otherwise} \end{cases}$$

Every time before selecting the best value of  $G_k$ , the best value from 0 to 1 is selected which leads to a small difference to  $U$ .

### B. Aggregation Signature

Most of existing trackers fail to localize the target vehicle in presence of occlusions. In this work an aggregation signature for target vehicle is created accommodating the clutter. Aggregation signature of image patch is formed from a set of probable noise occluded image patches using frequency domain deep learning model. On the image patch of the target vehicle, occlusion patches of various probabilistic distributions are added. QDCT is applied to the Noised image patches of target vehicles to get the low and high frequency components. QDCT for an image  $f(x, y)$  is calculated as.

$$(x, y) = A_n^q f(x, y) + \sum_{s=1}^n [D_{s,1}^q f(x, y) + D_{s,2}^q f(x, y) + D_{s,3}^q f(x, y)] \quad (6)$$

Where  $A_n^q f(x, y)$  and  $D_{s,1}^q f(x, y)$  are low frequency and high frequency band of the image respectively.

A low frequency part and  $n$  groups of high frequency parts are obtained after QDCT is applied on the image.

The frequency of the coefficients are as shown in Fig.2.

To reduce the dimension of the coefficients, average fusion is done on low frequency sub bands. Fusing of High frequency sub bands based on maximum value of energy of coefficients. Fusing the low frequency bands is carried by average of the coefficients pair wise between the Low frequency coefficients of two patch images. Selecting the maximum value of coefficient between the pair wise high frequency sub band is the fusion rule for fusing the high frequency sub bands.

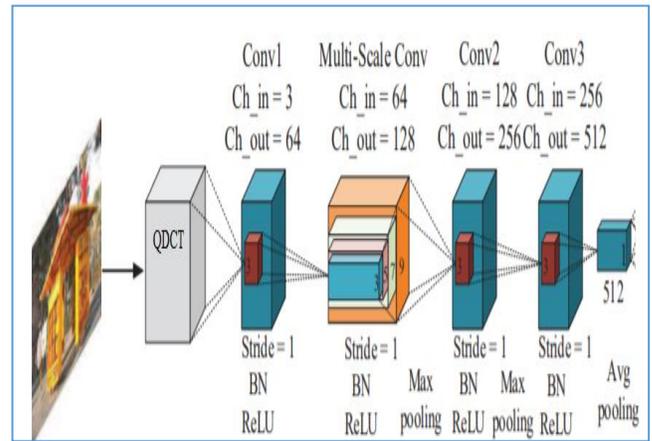

Fig. 3. Deep Learning Features Extraction.

The QDCT coefficients are given as input to a frequency domain convolutional neural network shown in Fig.3. The coefficients pass through a sequence of ReLU and max pooling layer and a final average pooling layer to provide an output of  $1 \times 512$  dimension feature vector. The CNN configuration used for feature extraction is given in Table I. An aggregation signature is constructed from the feature vectors belonging to same image patch as below:

- A unit random vector of dimension  $d$  ( $d < 512$ ) is generated  $\{r_0, r_1, \dots, r_d\}$ . A Gaussian function with mean 0 and variance 1 is used to sample each element. The  $d$  vector is put together into a matrix  $D$  of dimension  $512 \times d$ . This is generated on time at time of collecting the video as input for tracking.
- An inner product between the feature vectors  $v$  and the matrix  $D$  is done to get vector  $u = D^T v$ .
- For every vector  $u$ , following transformation function  $tf$  is applied produce the transformed feature vector  $\bar{u}$
- $tf(u) = \begin{cases} 1 & r \cdot u \geq 0 \\ 0 & r \cdot u < 0 \end{cases}$
- $\bar{u} = \{tf_{r_1}(u), tf_{r_2}(u), \dots, tf_{r_d}(u)\}$

The feature vectors belonging to same image patch is now represented as bit stream of length  $d$  called as aggregation signature of the target image patch.

The benefits of converting the features of same patch to binary bit stream of aggregation signature have two benefits of: compressed form and reduced time complexity for matching the aggregation distance between aggregation signatures. The value of  $d$  can be selected by making a compromise between the matching time and accuracy of matching. The time complexity for construction of aggregation signature is  $O(n \times 512 * d)$  where  $n$  is the number of feature vectors.

TABLE I. CNN CONFIGURATION FOR FEATURE EXTRACTION

Layer	Input	Filter	Stride	Padding	Out
MaxPool	32×32×128	2×2	2	0	16×16×128
Conv2	16×16×128	3×3	1	1	16×16×256
MaxPool	16×16×256	2×2	2	0	8×8×256
Conv3	8×8×256	3×3	1	1	8×8×512
AvgPool	8×8×512	8×8	1	0	1×1×512
FC	512×1	-	-	-	2×1

### C. Hybrid Tracking

The hybrid trackers performs vehicle tracking by fusing the results of modified KCF filter and modified PCF filter. Though KCF filter [24] is known for its effectiveness and robustness, it cannot handle the appearance variations caused due to occlusions. This is because it does not make decisions based on tracking result but utilizes the maximum response in the output response graph to localize the target and update the template. Occlusion results in tracking deviation in KCF. The modified KCF filter adds a re-detection module to the standard KCF filter. The re-detection is activated by calculating the average peak correlation energy (AC) as in [28] and comparing it historical mean.

$$AC = \frac{|F_{max} - F_{min}|^2}{\text{mean}(\sum_{w,h}(F_{w,h} - F_{min})^2)} \quad (7)$$

Target re-detection is initiated when the AC is greater than historical mean. Re-detection is done by combining sliding window and template matching procedure. Template matching is done by calculating the hamming distance between the aggregation signature between the target and the candidate regions. Template matching on entire area of image takes significant amount of time, to avoid the probable area for matching is selected using Gray model GM (1,1) approach proposed in [29]. For each of the candidate regions identified by GM(1,1), template matching with aggregation signature is done with sliding window approach to get the hamming distance matching scores for each of the candidate regions as.

$$R1 = \{ \langle C_1, h_{s1} \rangle, \langle C_2, h_{s2} \rangle, \dots, \langle C_n, h_{sn} \rangle \} \quad (8)$$

Particle filters apply Monte Carlo simulation for visual tracking [30]. A particle filter can be effective only if it can capture all the variations in state space. But this introduces a higher computation overhead. Many approaches [31-34] have been proposed to increase the capability of particle filters. But these models don't accommodate the appearance variations introduced due to occlusions. A correlation particle filter model is proposed in [35] which solves the problem of occlusions using a mixture and correlation filter. We modify the correlation particle filter algorithm proposed in [35] at the step 5 by removing the prediction step.

**Algorithm 1:** The proposed correlation particle filter tracking algorithm.

```

Input : Image Sequences and Initialization.
Output: Tracking Results  $s_t \forall t$ .
1 for each frame do
2   Generate particles using the transition model
    $p(s_t | s_{t-1})$  and re-sample them.
3   Shift particles with a mixture correlation filter
    $s_t^i \rightarrow S_{mcf}(s_t^i)$ .
4   Update particle importance weights
5   Predict target object state
6 end
    
```

Fig. 4. Correlation PCF [35].

Instead of step 5 of correlation PCF shown in Fig.4, we calculate the hamming distance for the results achieved in step 4 between aggregation signature of target and particle regions and return the result. The modified algorithm is given below.

**Algorithm: Modified PCF**

```

Input: frame ,agg_sig
Output: Candidate regions
1. Collect the current frame
2. Generate particles using the transition model
 $p(s_t | s_{t-1})$  and resample them
3. Shift particles with a KCF correlation filter
 $s_t^i \rightarrow S_{mcf}(s_t^i)$ 
4.  $R2 = \{ \}$ 
5. for each particle region r
6.  $R2 = \{ R2, (r, \text{Hamming}(r, \text{agg\_sig})) \}$ 
7. end
8. return
    
```

From the results of modified KCF (R1) and modified PCF(R2), the final target is found by fusion. Fusion is done by selecting the region with least hamming distance score in R1 and R2 and calculating the overlap of these regions. The overlap provides the target region. KCF filter is through the procedure of re-detection. The entire process flow of hybrid tracker is given in Fig. 5.

TABLE II. COMPARISON FOR DIFFERENT DISTURBANCES

Parameters/Solutions	KCF tracker	Parallel correlation filter	Combined detector-tracker	MUSTER	Proposed hybrid filter
<b>Illumination</b>					
<b>variation</b>					
Precision	0.548	0.846	0.907	0.862	0.961
SR	41.4	81	84	86	97
<b>Background</b>

#### IV. RESULTS

The performance of the proposed hybrid tracker is tested against 10 videos from OTB 100 dataset [27]. OTB dataset is the visual tracking benchmark widely used for testing the performance of object tracking algorithms. The dataset has 100 video sequences in different categories of objects, humans, vehicles etc. The video sequences have wide distribution of clutter, illumination variations and occlusions. The samples for testing are selected with presence of background clutter, illumination variation and occlusions. The performance is compared against vehicle tracking algorithms of KCF tracker [24], Parallel correlation filter [37], combined detector-tracker [26] and Multistore Tracker (MUSTER) [36]. The performance is measured in terms of precision and success rate. Precision is calculated in terms of central location error (CLE). It is calculated as the Euclidean distance with respect to the central location of tracked objects and manually labelled ground truth. Precision is computed as

$$Precision = \frac{\prod_{N} CLE < Th}{N} \quad (9)$$

Where N is the total number of frames and the Th value is set as 20 in the experiment as tracking performance evaluated for every 20 frames. Keeping a higher value, may lose the minor changes and reducing to lower value, increases computational complexity. So an optimum value of 20 was selected trial and error in the experimental setup.

Success rate is computed as

$$SR = \frac{area(R_t \cap R_{gt})}{area(R_t \cup R_{gt})} \quad (10)$$

$R_t$  is the bounding box object tracked and  $R_{gt}$  is the bounding box corresponding to the ground truth. The performance is also compared in terms of two parameters of success rate and precision for varied degrees of occlusions/clutters.

The average precision and success rate for videos are measured for various disturbances and the result is given in Table II. Both precision and success rate is higher compared to all the existing works. Comparison of precision and success rate across different solutions is shown in Fig.6 and Fig.7 respectively.

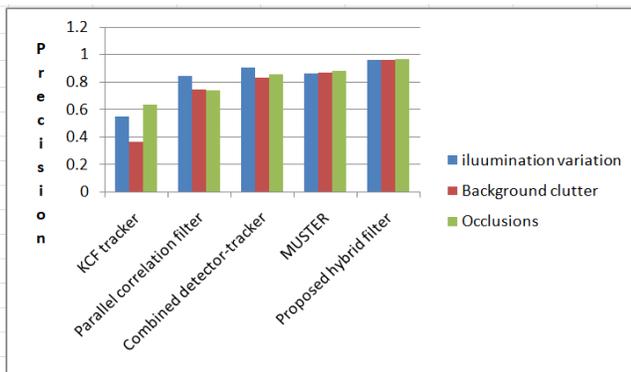

Fig. 6. Comparison of Precision Across Solutions.

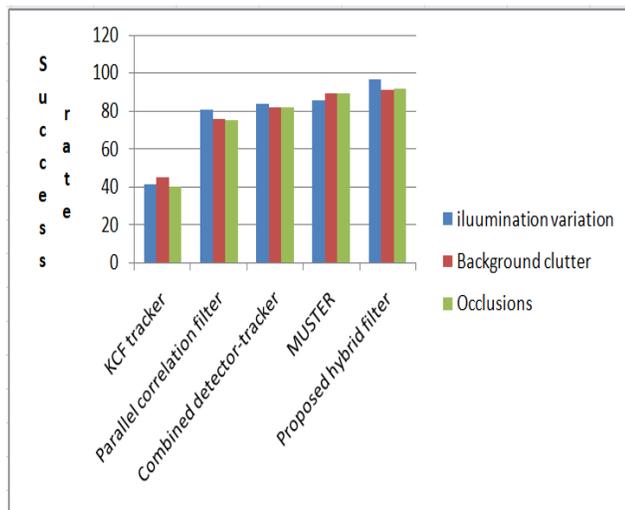

Fig. 7. Comparison of Success Rate Across Solutions.

The precision and success rate has increased in proposed solution due to use of hybrid trackers which combines the best of modified KCF and modified PCF. Also the influence of lighting variations, clutters, occlusion have been reduced due to use of novel background modeling with adaptive gain in the proposed solution.

The precision is measured for different error thresholds and the result is given in Fig. 8.

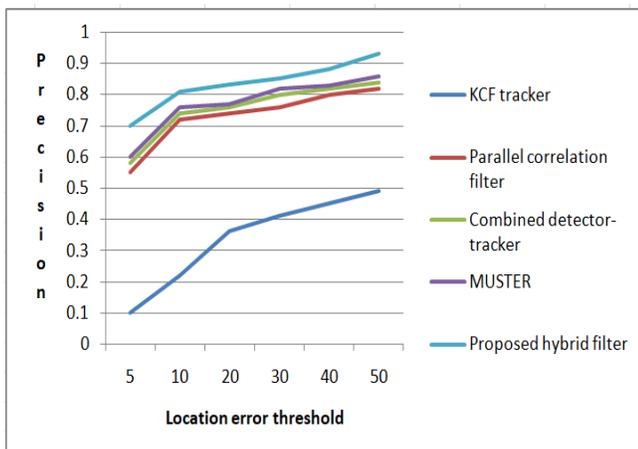

Fig. 8. Precision vs Location Error Threshold.

As location error threshold increases, the precision increases. Proposed hybrid tracker achieves highest precision among all other solutions even when location error threshold increases. Even if 50% of object is visible, the proposed solution is able to localize the vehicle accurately due to use of aggregation signature rather than exact matching. Aggregation signature is constructed with consideration for different probabilities of occlusions in the proposed solution and this helps to achieve better localization.

The success rate is measured for different overlap threshold and the result is given in Fig. 9.

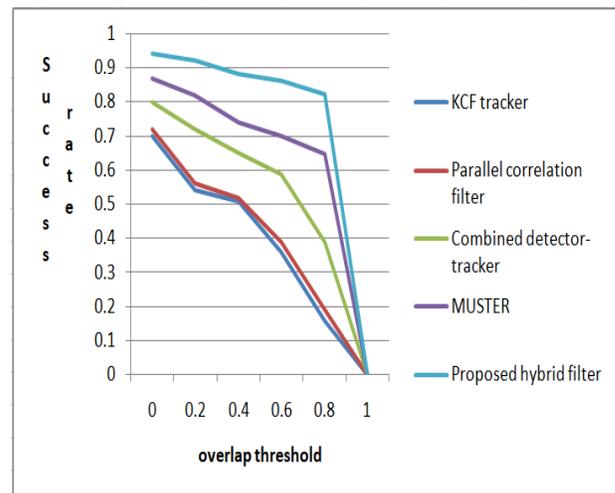

Fig. 9. Success Rate vs Overlap Threshold.

Even in presence of higher percentage of overlap, the proposed tracker is able to localize the object with higher success rate due to use of aggregation signature which already accommodates overlaps.

Video with a synthetic shape in varied percentage of occlusion is created. The performance of precision and success rate is measured with this synthetic data and the result is given in Fig.10 and Fig. 11.

Even in presence of 50% occlusion, the proposed hybrid tracker is able to achieve success rate of 0.82 and precision of 84%.

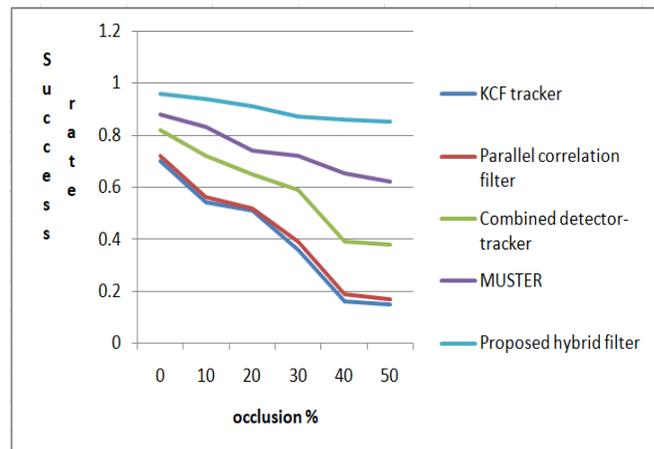

Fig. 10. Success Rate vs Occlusion %.

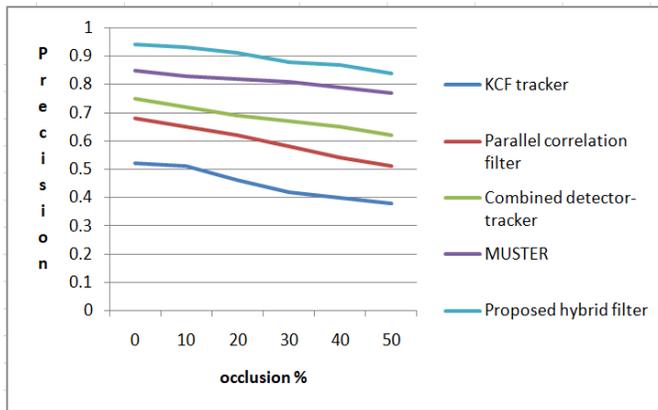

Fig. 11. Precision vs Occlusion %.

The success rate decreases as the occlusion percentage increases, but the success rate is higher in proposed solution compared to other solutions. The average success rate in proposed solution is at least 3% higher compared to others. Usage of aggregation signature-based matching within the KCF and PCF has increased the success rate in the proposed solution. The average precision in the proposed solution is at least 3% higher compared to other solutions/ Use of deep learning features with operating on image in frequency domain has increased the precision in the proposed solution.

#### A. Discussion

Through performance results, the proposed tracker is found to effectively localize the target vehicle even in presence of various degrees of occlusion and overlap. Localization accuracy has improved due to use of aggregation signature in the proposed solution. The aggregation signature is constructed considering different probabilities of occlusions and it is binary signature. Matching is realized using hamming distance. Due to this, vehicle localization accuracy has increased. Most of the existing works used in comparison used deep learning features and comparison of the features to localize the object. But in presence of occlusion, the distance match crossed the threshold and they failed to localize the object. Due to error in localization, their tracking performance too reduced. Tracking performance improved in proposed solution due to two reasons: (i) avoidance of unnecessary background objects through adaptive gain background subtraction and(ii) hybrid tracker to localize combining both kernel and particle filtering. This helped to localize object even in presence of higher overlap.

#### V. CONCLUSION

A hybrid tracking technique combining deep learning-based aggregation signature features with modified KCF & PCF is proposed in this work. Aggregation signature of target vehicle is created in frequency domain using QDCT and dimension reduced using deep learning. The proposed solution is able to achieve about 82% success rate and 86% precision in target even at 50% occlusion rate. In addition, the solution performs well against disturbances of occlusion, clutter and illumination variations. Improving the solution to work for even higher occlusion rate and various lighting conditions is in scope of future work.

**Abstract**—Slope stability has been a matter of concern for most geologists, mainly due to the fact that unstable slopes cause a greater number of accidents, which in turn reduces efficiency of mining operations. In order to reduce the probability of these slope instabilities, methods like tension crack mapping, inclinometer measurements, time domain reflectometry, borehole extensometers, piezometer, radar systems and image processing systems are deployed. These systems work efficiently for single site slope failures, but as the number of mining sites increase, dependency of one site slope failure on nearby sites also increases. Current systems are not able to capture this data, due to which the probability of accidents at open cast mines increases. In order to reduce this probability, a high efficiency internet of things (IoT) based continuous slope monitoring and control system is designed. This system assists in improving the efficiency of real-time slope monitoring via usage of a sensor array consisting of radar, reflectometer, inclinometer, piezometer and borehole extensometer. All these measurements are given to a high efficiency machine learning classifier which uses data mining, and based on its output suitable actions are taken to reduce accidents during mining. This information is dissipated to nearby mining sites in order to inform them about any inconsistencies which might occur due to the slope changes on the current site. Results were simulated using High REsolution Slope Stability Simulator (HIRESSS), and an efficiency improvement of 6% is achieved for slope analysis in open cast mines, while probability of accident reduction is increased by 35% when compared to traditional non-IoT based approach.

**Keywords**—Opencast; mining; slope; IoT; stability; machine learning; data mining

## I. INTRODUCTION

In order to design a highly efficient slope analysis model parameters like apparent dip of cutting slopes, joint dip, angle between slope aspect & joint aspect, friction angle of joint plane, cohesion of joint, joint persistence, height of slope, weight of sliding blocks, uplift force due to water pressure of joints, force due to water pressure in tension crack, etc. must be recorded and analyzed [1]. These parameters require a large variety of sensors, which must be connected in tandem in order to evaluate these values with highest possible efficiency. Depending upon these parameters, different slope stability factors are evaluated, and based on the value of these factors,

approximations are done on the stability of slope on the given opencast mining site [2]. For instance, in order to evaluate factor of safety (FoS), measurements of resting moments and disturbing moments are done, and the following equation is evaluated,

$$FoS = \frac{M_R}{M_D} \quad (1)$$

$$MR = c * \phi * R2 \quad (2)$$

$$MD = Aregion * \partial * x \quad (3)$$

Where, 'c' is a constant,  $\phi$  is the angle of measurement, 'R' is radius of measurement,

A region is area of region,  $\partial$  is weight of soil, and 'x' is distance between start point and center of slope,  $M_R$  is resting moment,  $M_D$  is disturbing moment. A high value of 'FoS' indicates that the surface has high resting moment, and low disturbing moment, which indicates that the surface is slope stable and can be used for mining operations with high efficiency. Similar measurements including shear resistance of force acting on slice, shear resistance offered by soil, etc. are also used to evaluate FoS values for opencast soil surfaces. Depending upon these values, short-term stability and long-term stability values are evaluated. Short term stability conditions include, stability of slope immediately after construction, which consists of undrained conditions and is evaluated using undrained parameters. Here, change in pore water pressure is totally dependent upon stress change. While long term stability analysis uses effective weight of soil and here changes in pore water pressure is independent of stress changes [3].

More precisely, despite the fact that this study has significantly advanced our understanding of slope stability, it is still limited by the following drawbacks of the aforementioned techniques, which prevent it from being fully resolved:

- The simulations are inaccurate. The slope stability, for instance, can be reflected by the limit equilibrium approach, but the non-uniformity of the stress distribution and the impact of deformation are not taken into consideration. Therefore, this technique cannot

accurately reflect the slope's actual level of safety and dependability.

- The safety factor's limitations are ambiguous and undefined. A slope with  $FS > 1.20$  is generally considered safe. However, in actual engineering there have been slopes that failed with  $FS > 1.2$ .
- These techniques are influenced by human subjectivity.

Throughout the course of an opencast mining operation, slope stability analysis is a crucial part of the process. A terrible social, economic, as well as a major safety catastrophe might result from a failure of slope in the vicinity of a mine being operated. The fundamental failure scenarios are extremely complex & diversified. These failure processes heavily rely on the regional geology, which is rather particular to a particular area of the rock mass. The process of developing slopes is wholly based on the field experience in recent years as well. A better strategy may be created by planning slopes safely.

The major aim of this work is to do numerical modelling for increasing the efficiency of slopes through the simulator with diverse rock qualities and slope diameters. Utilizing HIRESSS, numerical modelling is done to determine the safety factor. Every slope has different characteristics, and each step's safety factor is determined. To determine how the factor of safety alters when the bench parameters vary, these numbers are connected with them. Here our objective is to understand the different types of slope failures and the concepts of Safety.

Based on this analysis, a large number systems have been proposed over the past several years [4]. Each of these systems has its own advantages and limitations.

In the outline of this paper, the next section reviews the systems and evaluates best practices that must be used in order to improve the performance of slope stability in opencast mining conditions. This is followed by the section on the design of the proposed model, which is inspired by cutting edge IoT devices, and their interconnections for improved slope stability using a novel data mining approach. Next to this, the result analysis and comparison of the proposed model is done in order to evaluate the performance and performance gaps in existing system. Finally, this text concludes with some interesting observations about the proposed model and suggests methods to improve the same.

## II. LITERATURE REVIEW

Slope stability analysis for open cast mines is a multidomain signal processing task, wherein data from different sensors must be captured such that slopes are analyzed with high accuracy. In order to perform this task, various signal processing models are described, for instance, the work in [5] proposes a model that uses Spatio-Temporal Kriging Interpolation for improving slope stability. The model is able to perform highly accurate analysis on both open cast and open pit mines, due to efficient utilization of data interpolation. Similar models can be observed from [6, 7, 8], where Neural Networks, Gaussian processes, and 3D non-linear finite difference analysis are used. These models can be used for high performance applications like highway corridor slope analysis [9] for improving road stability.

Simpler methods like strength reduction [10], and variational calculus [11], can be used for analysing stability of slope analysis for open cast mines, National Highway (NH) development [12], and perched water conditions [13] with high efficiency. Slope stability can also be analyzed for specialized geographies like 3D geometries [14, 15], and methods like Technique for Order Preference by Similarity to Ideal Solution (TOPSIS) [16] can be used. These techniques can be extended by referring to different algorithmic models as suggested in [17], wherein Limit equilibrium method, artificial neural network, Vector sum method, Numerical simulation method and Limit analysis method are described. These methods utilize slope height & angle factors [18] while designing slope analysis models, and can be used for specialized applications like Stone Column- Supported Embankments [19]. The performance of these models can be improved via use of deep learning models as described in [20], wherein hybrid stacking ensemble method is used, which is based on finite element analysis and field data. The model is able to achieve high accuracy of slope analysis, and thereby adapt to varying structural scenarios. Various specialized methods for slope analysis can be observed from [21, 22, 23, 24, 25, 26], wherein volumetric behavior of rock salt, electromagnetic radiation mechanism of rock fracturing, uniaxial compressive strength of sandstone, influence of bedding structure, spectral induced polarization, bender element models, and pre-flawed sandstones are studied. These models assist in evaluation of slopes in open cast mines that are located near stone beds, thereby improving their scalability.

Artificial neural networks (ANN) have been applied successfully in slope stability problems (Feng, et. al 2018) [27], however they do have certain drawbacks. The restrictions are detailed below:

- Contrary to other statistical models, ANN models do not reveal the relative relevance of the individual parameters, which is a significant drawback (Samui, P. 2019) [28].
- Since the knowledge learned during training is implicitly stored in ANNs, it can be exceedingly challenging to interpret the network's general structure in a way that makes sense (Baghbani, et.al (2022)[29] has been proposed in their review. This gave rise to the phrase "black box," which many researchers use to describe the behaviour of ANNs.
- Additionally, ANN has certain intrinsic flaws such as sluggish convergence, poor generalisation, finding local minimums, and over-fitting issues.

The author's primary contribution is to provide an output utilizing several classifiers employing IoT devices and a simulator. Its result is used to determine the best course of action to decrease mining accidents. This information is shared with surrounding mining operations in order to alert them to any discrepancies that might arise as a result of the site's current slope variations. The HIgh REsolution Slope Stability Simulator (HIRESSS) was used to model the outcomes, and then it was compared to a conventional, non-IoT based technique.

Models for analysis of submerged pools [30], use of random field Gaussian methods [31], blocky structure systems [32], near-surface rock strength slope analysis [33], and reinforcement learning models [34-37] are also used for high efficiency slope analysis. It can be observed that most of these models do not define sensor placement analysis, due to which their efficiency is limited. In order to improve this efficiency, the proposed model combines various sensing elements, and defines positions for these elements in order to improve stability of slope analysis in open cast mines. The proposed model along with its analysis and comparative evaluation can be observed in the next sections.

### III. PROPOSED MACHINE LEARNING MODEL FOR IMPROVING SLOPE STABILITY ANALYSIS USING IOT

In order to improve the efficiency of slope stability analysis in open cast mines, it is mandatory that various conditions like above water table, drained, partly drained, water table 10m above toe, and water table 16m above toe must be analyzed. The significance and primary goal of this work is to put the aforementioned categorization model into practice for predicting the stability state of a soil slope.

- A weak zone in the soil profile is used to perform slope stability, which is a prevalent sort of coal mine failure in many nations.
- Practically significant numerical challenges are addressed for the simulation and investigation of the issue.
- The stability of the mine's slopes is determined by the inclination, shear strength, and water conditions in the weak zone.

The results of these conditions are given to the proposed model in order to reduce their probability of occurrence. Various IoT sensors are placed onsite in order to sense presence of these conditions, and efficient steps are taken to reduce their effect. To improve the efficiency of slope stability analysis, the following process is used, and based on the results of this process action plans are executed for improving the condition of open cast mines.

- Inputs to the model
  - Number of iterations ( $N_i$ ).
  - Number of solutions ( $N_s$ ).
  - Maximum number of sensors in the system ( $S_{max}$ ) (radar, reflectometer, inclinometer, piezometer, borehole extensometer, etc.).
  - Learning rate ( $L_r$ ).
  - Minimum advisable slope stability ( $SL_{min}$ ).
  - Maximum advisable slope stability ( $SL_{max}$ ).
- Outputs of the model
  - Estimated slope ( $SL_{es}$ ).
- Process of execution

- For each iteration in 1 to  $N_i$ 
  - For each solution in to  $N_s$
  - If the solution is marked as 'not to be changed', then skip it and go to the next solution.
  - Else, generate a new solution using the following process,
  - Select a random number of sensors from the list of available sensors =  $Sense_{sel}$ 

$$Sense_{sel} = (1, S_{max}) \quad (4)$$
  - For the selected sensors, perform random placement on the mining site, so that different sensor readings can be obtained.
  - Using these sensors, measure the slope stability from each sensor using equations 5, 6, 7, 8 and 9.

$$SS_{rader} = \frac{(ABS(H_{measured}-H_{actual}) + ABS(D_{measured}-D_{actual}))}{2 \cdot (\text{MAX}(H_{measured}, H_{actual}) + \text{MAX}(D_{measured}, D_{actual}))} \quad (5)$$

$$SS_{ref} = \frac{ABS(R_{measured}-R_{actual})}{\text{MAX}(R_{measured}, R_{actual})} \quad (6)$$

$$SS_{inc} = \frac{ABS(I_{measured}-I_{actual})}{\text{MAX}(I_{measured}, I_{actual})} \quad (7)$$

$$SS_{piez} = \frac{ABS(P_{measured}-P_{actual})}{\text{MAX}(P_{measured}, P_{actual})} \quad (8)$$

$$SS_{bh} = \frac{ABS(D_{measured}-D_{actual})}{\text{MAX}(D_{measured}, D_{actual})} \quad (9)$$

Where,  $SS_{ra}$ ,  $SS_{ref}$ ,  $SS_{inc}$ ,  $SS_{piez}$ , and  $SS_{bh}$  are slope stability values for radar, reflectometer, inclinometer, piezoelectric sensor and borehole extensometer, while H, D, R, I, and P are measured height, distance, reflectance, inclination, and soil pressure respectively.

- Based on the number of selected sensors, the value of fitness is estimated using equation 10.

$$F_i = \frac{\sum_{i=1}^{Sense_{sel}} SS_i}{Sense_{sel}} \quad (10)$$

- If the value of  $F_i$  satisfies the constraints of equation 11, then use it for processing, else generate a new solution.

$$F_i > SL_{min} \text{ and } F_i < SL_{max} \quad (11)$$

- After generation of all solutions, evaluate the fitness threshold using equation 12, wherein learning rate and other parameters are also utilized.

$$F_{th} = \sum_{i=1}^{N_s} F_i * \frac{L_r}{N_s} \quad (12)$$

- Mark all solutions as 'to be changed', where fitness is less than the threshold, while mark all other solutions as 'not to be changed'.
- At the end of last iteration, the following Table I is formed, which indicates information about each

solution, its stability, number of sensors used, and their placements.

- Select the solution with maximum fitness value, use the sensors and place them in given locations as decided by the algorithm.

Once the sensor placement is complete, then evaluate slope for the given open cast mine, and communicate this value to other locations. Generate ‘R’ random locations for deployment, and gather slope data from all these locations using the given machine learning model. Once the data is collected, then use a mode operation for find slope analysis.

$$S_{final} = MODE (|S_i|R_{i=1}) \quad (13)$$

Based on this evaluation, accuracy of slope stability, precision, recall, and fMeasure values are estimated. This estimation is done on various sites across different open cast mines, and the results are tabulated in the next section. These results are also compared with some of the reviewed models that perform highly efficient slope stability analysis in the same open cast mines.

#### IV. RESULT AND ANALYSIS

Performance evaluation of the proposed model required in depth analysis and simulations for different open cast sites. In order to perform this task, 20 different open cast mines were simulated on the High Resolution Slope Stability Simulator (HIRESSES) software, and 100 different locations were evaluated for estimation of slope stability analysis. Based on these simulation settings, accuracy of slope stability analysis (ASL) was evaluated using the following equation,

$$A_{SL} = \frac{S_c}{S_T} \quad (14)$$

Where,  $S_c$  and  $S_T$  are number of sites where slopes were correctly identified, and total number of evaluated sites respectively. We have implemented the methodologies used in [5] and [20] in our simulator and compared them with our proposed work. These results are tabulated in Table I to V, wherein accuracy of the proposed model is compared with other reference models as in Table I.

Based on this analysis it can be observed that the proposed model is 5% more effective than [5], and 6% more effective than [20] under different open mining sites. Using similar simulation settings, recall of slope stability analysis ( $P_{SL}$ ) was evaluated using the following equation,

$$P_{SL} = \frac{S_{Cl}}{S_T} \quad (15)$$

Where,  $S_{Cl}$  and  $S_T$  are number of sites where slopes were correctly identified but had lower slope values when compared with actual and total number of evaluated sites respectively. These results are tabulated in Table II, wherein Precision of the proposed model is compared with other reference models.

Based on this analysis it can be observed that the proposed model is 6% more effective than [5], and 5% more effective than [20] under different open mining sites. Using similar simulation settings, recall of slope stability analysis (RSL) was evaluated using the following equation,

$$R_{SL} = \frac{S_{CC}}{S_T} \quad (16)$$

TABLE I. ACCURACY OF SLOPE STABILITY ANALYSIS FOR DIFFERENT SITES

Where,  $S_{cc}$  and  $S_r$  are number of sites where slopes were correctly identified but had higher slope values when compared with actual, and total number of evaluated sites respectively. These results are tabulated in Table III, wherein Recall of the proposed model is compared with other reference models.

Based on this analysis it can be observed that the proposed model is 5% more effective than [5], and 4% more effective than [20] under different open mining sites. Using similar simulation settings, fMeasure of slope stability analysis ( $F_{SL}$ ) was evaluated using the following equation,

$$F_{SL} = 2 * P_{SL} * \frac{R_{SL}}{R_{SL} + R_{SL}} \quad (17)$$

These results are tabulated in Table IV, wherein FMeasure of the proposed model is compared with other reference models.

Based on this analysis it can be observed that the proposed model is 5% more effective than [5], and [20] under different open mining sites. Similarly, analysis of probability of accidents ( $P$ ) on each site was estimated using equation 18, and results were tabulated using Table V, where a major difference in accident reduction probability can be observed.

$$P_{Acc} = \frac{Accidents\ Occoured}{Total\ Accident\ Scenarios} \quad (18)$$

From this analysis, it can be observed that the proposed model is able to reduce number of accidents by over 35% when compared with reviewed models. This can also be observed from Fig. 5.

A. Simulation Results

As per our proposed work different statistical measure has been performed. A comparison study has been performed as shown in table from Table I to Table V by taking different site locations. The simulation results of the above mentioned analysis have been shown in Fig. 1 to Fig. 5. It has been found that our proposed work is comparatively showing good result in different analytical aspects.

This reduction assists in making it useful for safe and highly accurate slope estimations. The estimated slopes can be used for taking suitable actions for estimation of open cast mine accidents, and avoiding them with high efficiency.

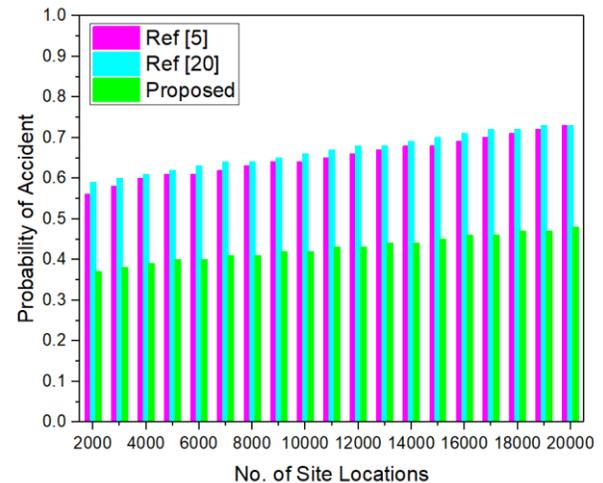

Fig. 5. Accident Probability for Different Sites.

## V. CONCLUSION AND FUTURE SCOPE

Based on the extensive result analysis, it can be observed that the proposed model is capable of improving the accuracy of slope stability analysis by 6% when compared with state-of-the-art models, while similar results are obtained for precision, recall, and F-measure values. Due to this, the number of accidents at these mines is drastically reduced, which enforces better safety measures, and thereby assists in reducing cost of mining operations. All these parameters are improved due to proper sensor placement, and improvement of stability analysis models by the machine learning model. Stochastic placement of sensors, and randomized inference of models positions from these placements further assists in identification of new placement spots on the site, thereby improving site coverage and utility. In future, researchers can improve this performance via use of deep learning models, wherein more number of sensors can be integrated in order to improve stability of slope analysis.

**Abstract**—Social network surges with multiple tweets with mixture of multiple emotions by many users when events like rape, robbery, war and murder, we use this user data to analyze user emotions between cross-events and try to predict user reactions for the next possible such event. Cross-events are a series of events that belong under the same umbrella of topics and are related to the events occurring prior to it. The proposed system solve this problem using collaborative filtering using Topical and Social context. The Text Rank Algorithm is an unsupervised algorithm used for keyword extraction. Count Vectorizer is used on preprocessed text to get the frequency of words throughout the text which is used as training data to get a probability of emotion using a logistic regression model. We incorporated social context along with topical context to account for homophily and used the Low-rank matrix factorization method for user-topic prediction. The model as an output gives a total of 8 emotions which include Shame, Disgust, Anger, Fear, Sadness, Neutral, Surprise and Joy. Finally, the model is able to predict emotions with an accuracy of 95% considering cross events.

**Keywords**—Twitter; cross events; collaborative filtering; logistic regression; social and topical context

## I. INTRODUCTION

With the advancement in technology, global news can quickly spread across the globe in a very small amount of time. Popular news spreads quickly through the internet like wildfire and all the people across the world try putting forth their opinion on social media. Social media has given rise to a platform where people can express their views on a particular topic. It has led to a formation of a community where like minded people group together. One of the most popular social media platforms to voice opinions is twitter where opinions about various global news are shared. There are over 330 million active users on twitter monthly and 145 million active users on twitter daily. There have been 1.3 billion twitter accounts created ever since twitter was launched in 2006. Thus, twitter's popularity and purpose can be a platform where a person's subjective feeling about a particular news is found in what a person tweets about it. It is a reflection of emotions a person feels towards the news and can be therefore equated. Twitter data has been used for multiple analysis because it acts as a dataset which tells us about the user. It has been used for applications like emotion detection [8], opinion tracking [9] and so on. However in our research work we have focused on a completely different domain of exploration that is to predict how a user will react to various events or sub events based on his historical tweets. Through our model we can identify the emotion a user will show if any

futuristic or hypothetical event is provided to a model. This kind of user reaction prediction can have a wide application in various domains. The government can use the data to predict the overall response on policies or it can also be used by companies to predict what a user reaction can be when a new product is launched in the market [10] [16] [17]. Additionally it can be used to model recommendations of new products [11]. To achieve this goal, we model the user-topic opinion prediction problem as a collaborative filtering task and present the topical context and social context incorporated matrix factorization method (TcScMF) framework, which includes social context and topical context as regularisation constraints. This paradigm is quite broad, and it may easily be applied to various social network setups or expanded to include other requirements. A real-world data set is gathered from Twitter, and labelled positive/negative user-topic opinions are obtained for evaluation by assessing sentiment in the observed tweets with a credible tool. We compare the proposed framework to state-of-the-art collaborative filtering methods in the trials. The experimental results show that using the TcScMF framework with social and topical context improves prediction accuracy.

A key point in our methodology is that we make use of ingenious ways to gather meaningful and clean data from twitter. One major problem that we faced while improving the accuracy of the model was sparseness of the user topic matrix. It was indeed very difficult to identify topics where the set of users are closely related to each other and have reacted to similar topics. We solve this problem by improving our data collection methodology where we first focus on identifying closely related users followed by filtering out common topics where they have reacted. This allowed us to improve the accuracy of our model by twice its original value.

Other than this, we were also keen on finalizing the ideal metric to compare users and topics in order to incorporate social and topical context. We experimented with different vector similarity measures like Cosine Similarity, Soft Cosine Similarity, Jaccard Similarity and Spearman's Rank Correlation Coefficient and we concluded that the choice of the similarity function is closely related to the type of dataset that we are working with. In our case we proceed with cosine similarity considering the size of our dataset as well as the results reflected by our model.

Last but not the least, we also expand the range of emotions that we are working with. Most data analysing techniques usually classify the given data in a binary fashion. But we incorporate a range of emotions and make sure that our model

works with this range at every stage including the loss function and the accuracy measure step. This allows our model to be robust in nature and accommodate a diverse dataset and reflect the same in the results produced.

The structure of the remaining paper is as follows. Section II is the literature survey that we undertook before working on this. It identifies the current research work and gaps in them. In Section III we talk about our method of identifying the dataset and what the dataset looks like. In Section IV we have described our model in detail. In Section V we talk about results and in Section VI what we conclude from the research work. In Section VII, we talk about the references.

## II. LITERATURE SURVEY

Nicolas Esquivel et al. [1] presents a CLSTM-NN to forecast the existence of crime events across Baltimore. Matrixes of previous criminal occurrences, in particular, are utilised as input to forecast the existence of at least single event that happens. The dataset was acquired from the Open Baltimore portal's Public Safety domain. The model performed better, with an accuracy of 0.86 utilising sequences of matrices of events that occurred over the course of seven days. The results suggest that model can learn past geographical patterns and forecast the presence of crimes in the future. The spatio-temporal resolution of forecasts is hampered by poor performance for a small percentage of crime episodes.

Yizhou Xu et al. [2] proposed to model which would predict alarm events that are due, using similar alarm patterns in flood alarm sequences. It begins by arranging the alert patterns in order of resemblance to the current alert in descending order. A Bayesian approximation is used to calculate the probabilities and confidence levels for all projected alert events. When nuisance alerts were received, they were ignored and produced no anomalies.

A method that takes into consideration the behaviours and characteristics of the user, to identify and accurately predict hot events is given by Xichan Nie, et al. [3] The similar topics on twitter are collected and segregated using semantic similarity, all this is done after applying natural language processing on the keywords extracted from these tweets. Then a relationship between the users is derived. The user information proved to be useful and gave better results on experimentation. When compared to previous models, the suggested method enhanced prediction precision by 27%, 23.5 percent accuracy, as well as 20 percent recall rate, indicating that the model efficiently anticipated hot events. Other similar methods also work on identifying "social hotspots" such as Krishna et al. [23] and Xiao et al. [19].

Alberto Rossi, et al. [4] develops an attention mechanism as well as a LSTM network - RNN method for modelling taxi driver performance and storing the semantics of famous attractions in order to anticipate a cab's next destination using spatial location from LBSNs. The datasets used were taxi paths datasets. The results show that LSTM lowers the EDS in Porto and Manhattan by 10.5 percent and 18 percent, respectively, compared to MMLP. The suggested model, like most deep-learning algorithms, lacks explainability. Because travel utility features such as journey distance, cost, and time are not accessible at the time of the prediction, the approach cannot

use them. Owing to the length limit, it may be difficult to create a precise estimation that will identify catastrophic occurrences using tweets, which may lack appropriate context and be difficult to discriminate due to word ambiguity. Song, Guizhe and Huang, Degen [5] designed a model named SentiBERT-BiLSTM-CNN which detects diaster using Tweets. To generate sentimental contextual embeddings from a Tweet the proposed pipeline uses SentiBERT, for feature extraction they used a 1D convolutional layer. The suggested model outperforms the competition in the F1 score, making it a viable model for Tweets-based diaster prediction. The CNN model gave a precision of 0.8064, BiLSTM gave 0.8571 while SentiBERT-BiLSTM-CNN gave a precision of 0.9305 making it the best model. Because specific keywords may occur in both catastrophe and non-disaster Tweets, the model's recommended accuracy can be considerably improved. However, it is difficult to successfully employ the words as additional information to help enhance the detection accuracy.

Gan, Mingxin and Xiao, Kejun [6] concluded that prior studies had failed to account for the sequential characteristics of users' click behaviour, hence the focus was on overcoming such restrictions. R-RNN is a model for understanding a user's interest from his general click history, according to the study. The Amazon Dataset was used to conduct the study. Few of the previous models are all outperformed by the recommended model, thanks to the newly introduced click behaviour patterns and the R-RNN for CTR prediction design's adopted RNN, which gathers user stats from the most recent click sequences.

Song et al. [7] suggested a semi-online Computational Offloading Model. Reinforcement learning is used to investigate user behaviour in a sophisticated action space in order to catch unknown environment information. The research proposes a dynamic edge computing simulation environment to show that user behaviour has a significant impact on system utilisation. According to their research, the mean size of offloading activities accomplished is roughly ten thousand. Large-scale Computation offloading projects could not be resolved using these strategies. This paradigm offloads compute chores based on changing contexts, although it is made up of MEC systems loosely.

A variety of media is used by different authors; C.Fu et al. [13] use micro blog user features, while Z.Zhang et al. [15] apply a situational analysis method on data from multimedia social networks. Other approach's such as M.Nyugen et al.'s hybrid generative model [12] and Chen et al.'s ensemble methodology [14] seek to combine multiple techniques to give a better result.

Through their work in [18] N Zhang et al. proposed a novel user behavior prediction model which uses automatic annotation. The model uses a combination of the Discontinuous Solving Order Sequence Mining (DVSM) behavior recognition model coupled with the LSTM based behavior prediction model. Factorization machines are applied to predict user behavior in the work of Y Wang et al. [20].

In their paper[22], Hao. et al. perform analysis on huge multi-data source of comprehensive quality. They analyse the user behavior acquisition and simulation prediction framework construction method which relies on user perception.

Hui Zhang et al.'s research[21] proposes a solution for user

prediction that concerns the single user - multiple terminal use-case. They perform weight correction that is based on adapted feedback, which is used to create a Markov model. This model can predict the user's future service states. A corresponding heavy tailed model is used to predict the duration of the service as well. Their work further integrates preference of service with the attributes of the terminal. This establishes a matching metric of services and terminal. This enables the proposal of terminal service model for recommending the best service terminal to each user.

### III. DATASET

The dataset was collected by scrapping twitter data. The data collected by us have many users who might have tweeted over multiple different topics. We used sns scrape a python package to scrape data because of it increased limits. There were multiple major events identified and under every major events many sub events were considered. For example Covid-19 was the major event and the sub events under it were lockdown, vaccination and so on. The methodology we decided to use was to identify the top most 100 influential users which solved our problem of overlapping users. After that we scrapped only their tweets from their profile about our list of subtopics. The dataset thus formed had over 10,00,000 tweets across all sub events.

### IV. PROPOSED METHODOLOGY

#### A. Keywords Extraction

A keyword extraction models goal is to automatically find a group of phrases in a tweet that best characterise the content. TextRank algorithm has been used for Keywords extraction from tweets. This algorithm is fully unsupervised.

Non-printable characters (if any) are removed from the raw input tweet before it is converted to lower case. The tokenization of the processed input text is performed using Natural Language Toolkit (NLTK) library methods. To allow the words to be lemmatized based on their Part-of-speech (POS) tags, Natural Language toolkit is used to Part-of-speech (POS) tag the input tweet. Lemmatization is used to normalise the tokenized text (mostly nouns and adjectives). Different grammatical equivalents of a word are replaced by a single fundamental lemma in lemmatization. The lemmatized text is then Part-of-speech (POS) labelled. Later on, the tags are utilised for filtering.

Any word from the lemmatized text that is not a noun, adjective, or a foreign word is regarded a stop word in this context. This is predicated on the premise that keywords are often nouns, adjectives, or gerunds. Punctuations are also included to the list of stopwords. Even after we eliminate the stop words, there may still be some exceedingly frequent nouns, adjectives, or gerunds that are poor candidates for being keywords. An external file containing a list of stopwords is loaded, and each word is added to the preceding stopwords to form the final list stopwords-plus, which is then turned into a set. Stopwords-plus are all stop words and possible phrase-delimiters combined. The contents of this collection are used to divide the lemmatized text into n-gram phrases later on. However, we simply eliminate the stop words and operate with a bag-of-words method. The stop words are then removed from

the lemmatized text. Only unique words from the processed text are stored in a set.

TextRank is a graph-based approach, which necessitates the creation of a graph. Each word in the dictionary will act as a graph vertex. The phrases in the vertices will be indicated by their index in the list. The edge connections between all vertices are stored in the weighted edge matrix. A graph is made with undirected, heavy edges. The weight of the connecting edge between the word vertex represented by index a and the word vertex represented by b is stored in weighted edge[a][b]. When weighted edge[a][b] is 0, it signifies that there is no edge or relationship between the words represented by index a and b. If the words co-occur inside a window of a defined window size in the processed text, there is a relationship between them and hence between a and b, which represents them. For each link detected between the same words in various regions of the text, we raise the value of the weighted edge[a][b] by  $(1/(\text{distance between positions of words now represented by a and b}))$ . The covered co-occurrences list which contains of a list of pairs of absolute positions in processed text of words whose co-occurrence at that location has already been checked, is managed in such a way that the same two words located in the same positions in processed text are not counted repeatedly while sliding the window one text unit at a time. All vertices start with a score of one. Because self-connections are ignored, weighted edge [a][b] are 0 initially. The total number of undirected edges associated with the vertex represented by p are stored in  $x[p]$ .

The formula for scoring a vertex represented by a is as follows:

$$s[a] = (1 - r) + r[\sum(j)((we[a][b]/x[b]) * s[b])] \quad (1)$$

In the Eq. (1), r is the damping factor and b is one of the vertices that has a relationship to a. 'we' represents weighted edge. The score is updated repeatedly until convergence is reached.

Using stopwords as delimiters, lemmatized text is partitioned into phrases. These phrases are also potential possibilities for keyphrase extraction. Then a list of unique phrases is created and removing single-word key-candidates in favour of multi-word alternatives. Candidate-key phrases are scored and a list of key phrases is compiled by listing untokenized variants of tokenized words. Phrases are graded by summing the scores of their constituents i.e. words or text-units that were ranked by the graph algorithm. Keys are ranked based on their computed scores.

#### B. Emotion Detection

For setting up the emotion detection domain of our proposed solution, we leveraged neattext python library. A data set having more than 34 thousand tweets and its corresponding emotion was used for this. Firstly, all the username and tags were removed from each individual tweet and after that removal of stopwords took place. After this step all the stopwords like 'an', 'be', 'some', 'for', 'do', 'its', 'of', 'as', etc. are removed from the tweets for optimising the emotion prediction, reducing the computation time and resources.

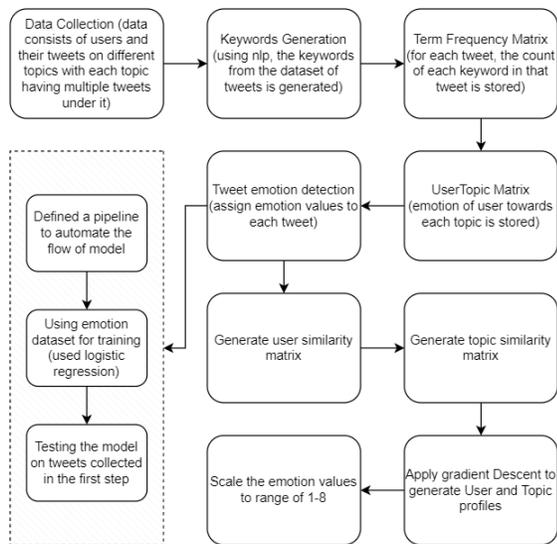

Fig. 1. Social and Topical Context System Framework.

The algorithm was trained using a dataset of 34762 tweets that included their moods. The data set is separated into training and test sets after usernames, tags, and stopwords are removed, and the model is trained on this data. Count Vectorizer is a tool that converts a text into a vector depending on the count of each word in the text. Logistic Regression is a machine learning classification algorithm which is applied to train the model precisely and predict the probability of an emotion. Finally, the web scraped twitter data set is passed to the model and emotion of each tweet is predicted.

### C. Social and Topical Context System Framework

In the above Fig. 1, the basic flow of the execution of the model is given, starting from data collection to getting the results from the trained model. The initial step is the data collection, in which data about different twitter users and the tweets of specific topics they have tweeted on, is gathered. The next step is the processing of the tweets to generate the keywords file, which is done using nlp(natural language processing) which has been described above. Then the term frequency matrix is generated following which the UserTopic matrix is generated. Emotion detection model is applied on the collected tweets, the process of which is given in detail in the 'Emotion Detection' section. After completing these steps, we then generate the similarity matrices for users and tweets and after training the model, we then scale the emotion values which we get in the result in the range of 1-8.

### D. Model Outline

The main purpose of the model is to analyse the users in a given set and predict their reactions on related events. It has been historically proven that the views of any user is influenced by the closest networks of users with similar interests as the user in question along with the similarity of the actual topic to other topics the user has already reacted upon. Although this system should be enough to deduce the reaction of a

user in any two non-related events as well, we found that solely relying on user similarity or topic similarity yielded poor results as compared to using both of them. The most effective use of the above mentioned strategy is in the case of multi-phase events which are closely related to each other. At the same time, the similarity measures used to calculate the similarity of different users and different topics also plays a key role in the preparation of the model. Inline with our previous approach, we experimented with different similarity measures, some of which are Cosine Similarity, Manhattan Distance, Jaccard Similarity, Euclidian Distance and we found that the choice of the similarity function is closely related to the type of dataset we are working with. In our original scenario where we were dealing with sparse data, we found that Cosine Similarity was very effective however, implementing the same for dense matrices proved to be computationally expensive and in such scenarios, a simple Euclidian calculation was far easier.

### E. Data Scarcity Problem and our Solution

In a quest to find similar users who reacted on similar topics, we found that such datasets are very difficult to acquire and in most cases, the data itself appeared to be biased as we would end up reading multiple accounts of the same user. Eliminating the above problem left us with a very scarce user-topic matrix where only a couple of users might have reacted on the same topic and vice versa. In order to make the user-topic matrix denser, we come up with a unique solution which is explained as follows; We first divide the user-topic matrix into different sections, essentially following a divide and conquer strategy. In the smaller subsections of the matrix, we make sure that multiple users have tweeted or reacted on the same topic and similarly, a single user has tweeted on multiple topics in the same sub-section. We found experimentally, that such local optimizations eventually lead to global patterns, and helps us develop a more robust model.

### F. Social and Topical Context Mode Framework

We follow the below mentioned algorithm which incorporates our unique approach to solve the data scarcity problem and gives an outline of the model pipeline which is explained in detail later in the paper. Table I indicates all the parameters used in designing the Social Context and Topical Context Mode Framework (ScTcMF).

### G. Example

Let say we have 4 users, User A, User B, User C and User D. We'll consider the main topic Covid and use the tweets by the users on the sub topics - 1st Dose, Omicron, Booster Dose and Lockdown.

User A (Newsweek) tweeted "Kate Middleton shares COVID vaccine photo, "hugely grateful" after 1st dose" on the sub topic 1st Dose and the emotion for the tweet was predicted to be Joy. User A tweeted "The highly mutated and contagious Omicron variant has driven the country to record the most cases in a day that any country has reported." on the sub topic Omicron and the emotion for the tweet was predicted to be Joy. User A tweeted "People struggling to get booster dose appointments could leave millions of Americans vulnerable as Omicron spreads." and the emotion for the tweet was

TABLE I. IMPORTANT PARAMETERS IN OUR MODEL

Sr. no.	Parameter	Description
1	$\alpha$	Balances the error function between front terms and the social context normalisation terms
2	$\beta$	Controls the topical context's regularisation requirement
3	$\lambda_0$	Controls the reach of regularization
4	$\lambda_1$	Controls the reach of regularization
5	A	User-Topic Opinion Matrix
6	E	Latent Representation of User
7	G	Latent Representation of Topic
8	$\ \cdot\ _F$	Frobenius norm of a matrix
9	P	Indicator Matrix
10	$\odot$	Hadamard product
11	$Q(v,w)$	Weighted number representing the similarity of two social friends' past opinions
12	$F(v)$	Set of social friends of $u(v)$
13	$Tr(\cdot)$	Matrix Trace
14	$Diag_Q$	Diagonal Matrix
15	$L_Q$	Laplacian Matrix

**Algorithm 1** Social and Topical Context Model Framework (ScTCMF)

- 1) Collect data for different kinds of events and identify sub-events of each of the events.
- 2) Identify the most active users from each of the sub-events and collect their twitter data.
- 3) Use the keywords extraction pipeline to extract important words from each and every tweet. This is further used for emotion detection.
- 4) Use the emotion detection pipeline to understand the text of the tweets and extract meaningful emotions in a range of 1-8.
- 5) Use TF-IDF to calculate the frequencies of each word of each tweet across multiple tweets of the same sub-event.
- 6) Initialize hyper-parameters like social and topical regularization factors and learning rate.
- 7) Calculate user and topic similarity using Laplace reductions and the original frequency matrix calculated previously. While doing so, choose an appropriate similarity function.
- 8) Perform stochastic gradient descent to estimate the user-topic matrix thereby predicting the user's reaction to unknown events.
- 9) Compare the result with the original matrix to retrieve the accuracy of the model. Different deviations can be used to calculate the accuracy in different scenarios.

predicted to be Disgust. User A tweeted “Xi’an residents can’t leave homes, purchasing food difficult as COVID lockdown continues” on the sub topic Lockdown and the emotion for the tweet was predicted to be Sadness.

User B (bsindia) tweeted “TOP HEADLINES — PM @narendramodi receives his 1st #Covid19vaccine dose at AIIMS; @TheOfficialSBI reduces #homeloan rates to 6.7% ; European #stocks rebound as bond markets stabilise and more...” on the sub topic 1st Dose and the emotion for the tweet was predicted to be Joy. User B tweeted “Amid surging COVID-19 cases, the Delhi Disaster Management Authority has decided to impose a weekend curfew in the national capital.” on the sub topic Omicron and the emotion for the tweet was predicted to be Anger. User B tweeted “A Delhi-based doctor said that a booster dose of Cov vaccine is a must as the protection cover of two doses declines over three to six months” on the sub topic Booster Dose and the emotion for the tweet was predicted to be Sadness. User B tweeted “#Mumbai Mayor Kishori Pednekar on Tuesday said if the daily COVID-19 cases here cross the 20,000-mark, a #lockdown will be imposed in the city as per the Union government’s rules.” on the sub topic Lockdown and the emotion for the tweet was predicted to be Anger.

User C (ChannelNewsAsia) tweeted “Duchess of Cambridge ‘hugely grateful’ for 1st vaccine dose” on the sub topic 1st Dose and the emotion for the tweet was predicted to be Joy. User C tweeted “Commentary: With Omicron threat, will returning to offices and schools bring new anxieties?” on the sub topic Omicron and the emotion for the tweet was predicted to be Joy. User C tweeted “Australia to shorten COVID-19 booster dose intervals from January” on the sub topic Booster Dose and the emotion for the tweet was predicted to be Joy. User C tweeted “Amid Omicron surge, UK PM Johnson resists another lockdown” on the sub topic Lockdown and the emotion for the tweet was predicted to be Neutral.

User D (TheQuint) tweeted “#Live — Around 90 percent adult population #vaccinated With #1stDose.” on the sub topic 1st Dose and the emotion for the tweet was predicted to be Sadness. User D tweeted “#Podcast — Given the explosive growth of #COVID cases in India, are we underplaying the threat of #Omicron and its potential impact on our fragile health care system? We discuss with @MenonBioPhysics and @RajeevJayadevan. Tune in!” on the sub topic Omicron and the emotion for the tweet was predicted to be Fear. User D tweeted “#BharatBiotech on 20 Dec, sought approval from the #DCGI for the conduction of phase-3 trials for its intranasal vaccine (BBV154), which is to be used as a booster dose.” on the sub topic Booster Dose and the emotion for the tweet was predicted to be Fear. User D tweeted “#LIVE — ‘We will have to impose #lockdown in #Mumbai if daily #COVID cases cross the 20,000-mark,’ said Mayor Kishori Pednekar.” on the sub topic Lockdown and the emotion for the tweet was predicted to be Anger.

Now we’ll take a different sub topic say “Social Distancing” and we’ll see the tweets and its emotions predicted by our model for the above users. The model predicts that User A will tweet “Many health experts are now calling on the South Korean government to reimpose social distancing measures.” on the given sub topic Social distancing and the emotion predicted by the model for the tweet was found

to be Sadness. The model predicts that User B will tweet “#Britain’s economic growth slowed more than expected in July as concern about the spread of the delta variant of #Covid-19 overshadowed the government’s decision to end most social distancing rules” on the given sub topic Social distancing and the emotion predicted by the model for the tweet was found to be Fear. The model predicts that User C will tweet “France plans tighter social distancing rules, booster ramp-up to fight COVID-19 wave” on the given sub topic Social distancing and the emotion predicted by the model for the tweet was found to be Sadness. The model predicts that User D will tweet “Amid videos of crowds flouting social distancing norms in #SarojiniNagar market surfaced, the Delhi High Court on 24 December rapped the New Delhi Municipal Council and Delhi Police for allowing illegal vendors to operate from there.” on the given sub topic Social distancing and the emotion predicted by the model for the tweet was found to be Fear.

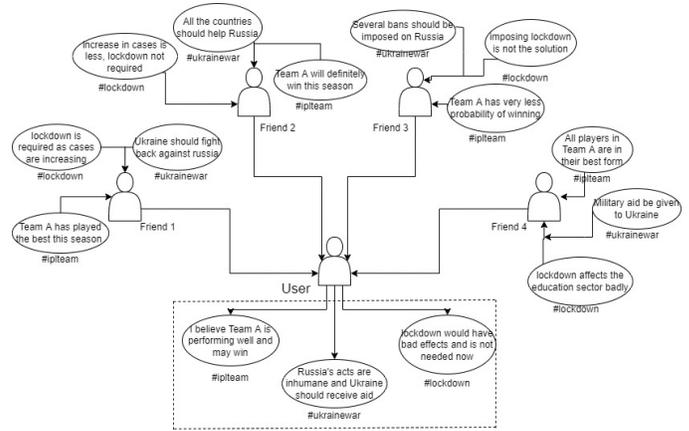

Fig. 2. Opinion Prediction.

#### H. User Topic Matrix

For user topic view prediction, a low rank matrix factorization algorithm was applied. The user-topic prediction model incorporates social and topical context mathematically. Matrix Factorization is commonly used in cutting-edge Collaborative filtering works.

In our scenario, because the user topic opinions in Twitter data is so less, the matrix A is highly scattered. Based on the assumptions that only a few factors impact the opinions, a more concise but accurate depiction is provided and goal to replicate the matrix by a multiplication of low rank factors.

$$A \approx EG^T \quad (2)$$

In Eq. (2),  $E \in \mathbb{R}^p$  and  $G \in \mathbb{R}^q$  where  $p = a * c$  where  $q = b * c$  with  $c \ll \min(a,b)$  the row vector  $E(k, :)$ ,  $1 \leq k \leq a$  and  $G(o, :)$ ,  $1 \leq o \leq b$  are the existing depictions of user  $e_k$  and topic  $g_o$ . Here R denotes Real numbers, E is the Latent Representation of user and G represents the Latent representation of Topic. By minimising the following aim, the matrix factorization technique approximates the matrix A given in Eq. (3):

$$\min_{E,G} \|A - EG^R\|_F^2 \quad (3)$$

In order to simulate the labelled viewpoints i.e. opinions we make use of matrix P  $\in \mathbb{R}^r$  where  $r = a*b$ . If  $e_k$  provided his view for  $g_o$  then we will consider the value at  $k,o$  index in the matrix P to be 1 and equal to 0 otherwise. Normalisation terms have been added to avoid overfitting.  $\lambda_0$  and  $\lambda_1$  are the control parameters. The basic low rank factorisation model is as follows illustrated by Eq. (4):

$$\min_{E,G} \|P \odot (A - EG^R)\|_F^2 + \lambda_0 \|E\|_F^2 + \lambda_1 \|G\|_F^2 \quad (4)$$

Fig. 2 illustrates the opinion prediction for user under influence. As shown, the user has four friends with different opinions on three different topics and based on the opinions the user’s opinion on these topics is impacted. Considering the topic “#Ukrainewar” the user’s friends have shown support to Ukraine in their tweets and also few tweets with support to Russia. The opinion of the user for this topic is also seen to be in favour of Ukraine. Thus the tweet of the user shows a similar emotion to that of the majority of his followers or tweets of people he/she sees.

#### I. Implementing Social Context

Homophily is a phenomenon that occurs in social networks. Forming a following connection on any social media platform typically suggests that the follower and the buddy have similar interests, and hence have more comparable perspectives on the same issue. Both users friends and followers are considered to be his social buddies. To establish the social context, we convert the directed network to undirected network. The Twitter users’ social environment may thus be represented as an undirected weighted network with a symmetric adjacency matrix Q. Social friends are more likely to have similar viewpoints on issues than non social friends. Based on the above premise, we evaluate previous opinion similarity across social friends to represent user viewpoint variety and suggest a normalisation constraint as shown below,

$$\frac{1}{2} \sum_{v=1}^a \sum_{w \in F(v)} Q(v,w) \|E(v, :) - E(w, :)\|_F^2 \quad (5)$$

In Eq. (5), F(v) indicates a group of social acquaintances and Q(v,w) is the weighted number representing the similarity of two social friends’ past opinions. Large value of Q(v,w) indicates that divergence will be less and vice versa.

Matrix form of the above equation,

$$\begin{aligned}
 X &= \frac{1}{2} \sum_{v=1}^a \sum_{w \in F(v)} Q(v, w) \|E(v, :) - E(w, :)\|_F^2 \\
 &= \frac{1}{2} \sum_{v=1}^a \sum_{w \in F(v)} \sum_{x=1}^c Q(v, w) (E(v, x) - E(w, x))^2 \\
 &= \sum_{v=1}^a \sum_{w \in F(v)} \sum_{x=1}^c Q(v, w) [E^2(i, k) - E(v, x)E(w, x)] \\
 &= \sum_{x=1}^c E^T(:, x) (Diag_Q - Q) E(:, x) \\
 &= Tr(E^R L_Q E)
 \end{aligned} \tag{6}$$

In Eq. (6),  $Diag_Q$  is the diagonal matrix,  $L_Q$  is the laplacian matrix and Tr denotes the trace of the matrix. The resulting Matrix Factorisation model which involves social context is as follows illustrated by Eq. (7),

$$\begin{aligned}
 \min_{E, G} \|P \odot (A - EG^O)\|_F^2 + \lambda_0 \|E\|_F^2 + \\
 \lambda_1 \|G\|_F^2 + \alpha Tr(E^O L_Q E)
 \end{aligned} \tag{7}$$

The regularisation parameter balances the reconstruction error between the social context regularisation term and the front terms,  $\alpha \geq 0$ . The User Opinion Similarity (UOS) is calculated by the given formula in Eq. (8),

$$UOS(e_v, e_w) = \frac{\sum_{x=1}^b A_{i_x} \cdot A_{j_x}}{\sqrt{\sum_{x=1}^b A_{v_x}^2} \sqrt{\sum_{x=1}^b A_{w_x}^2}} \tag{8}$$

A mapping is used to constrain the range of User Opinion Similarity between [0,1] where  $UOS(e_v, e_w) = (UOS(e_v, e_w) + 1)/2$  is given by Eq. (9),

$$Q(v, w) = \begin{cases} UOS(e_v, e_w), & \text{if } e_w \in F(e_v) \\ 0, & \text{otherwise} \end{cases} \tag{9}$$

### J. Implementing Topical Context

The topical context interpretation model is that consumers will supply more similar opinions to two topics that are more related in content.

$$\frac{1}{2} \sum_{v=1}^b \sum_{w=1}^b R(v, w) \|G(v, :) - G(w, :)\|_F^2 \tag{10}$$

In Eq. (10),  $G(v, w)$  represents the similarity index between the topics  $r_v$  and  $r_w$ . Greater value of  $R(v, w)$  infers that the topics  $r_v$  and  $r_w$  are very similar to each other having more similar opinions of users. On the other hand, low value of  $R(v, w)$  infers that the topic representations  $G(v, :)$  and  $G(w, :)$  have large distance between them. As per the topical context derivations mentioned earlier, we can obtain the matrix equivalent of the above equation as follows in Eq. (11):

$$\begin{aligned}
 Z &= \frac{1}{2} \sum_{v=1}^b \sum_{w=1}^b R(v, w) \|G(v, :) - G(w, :)\|_F^2 \\
 &= \sum_{x=1}^d G^R(:, x) (Diag_R - R) G(:, x) \\
 &= Tr(G^R L_R G)
 \end{aligned} \tag{11}$$

Likewise,  $Diag_R$  is a diagonal matrix and  $L_R$  is the laplacian matrix. The model with topical context regularization is given below in Eq. (12),

$$\begin{aligned}
 \min_{E, G} \|P \odot (A - EG^R)\|_F^2 + \lambda_0 \|E\|_F^2 + \\
 \lambda_1 \|G\|_F^2 + \beta Tr(G^R L_R G)
 \end{aligned} \tag{12}$$

Here, A regularisation parameter  $\beta \geq 0$  is used to adjust the regularisation requirement of topical context. After analyzing many approaches for measuring similarity using topic distribution, we chose Cosine Similarity due to its efficacy and simplicity. By using the unique terms showing up in the tweets collection as features upon removing stop words and the term frequency as a feature value, a cosine similarity between term frequency vectors could have been used to quantify the content based resemblances between similar topics. A term frequency vector  $f_{v_i}$  could be formed for each topic  $t_i$  by taking the unique terms making an appearance in the tweets gathering as features after removing stop words and the term frequency as a feature value. The similarity values in this definition vary from 0 to 1 since the word frequency cannot be negative. As a result, Topic Content Similarity was assigned (TCS).

$$TCS(r_v, r_w) = \frac{\sum_{x=1}^B f_{v_{v_x}} \cdot f_{v_{w_x}}}{\sqrt{\sum_{x=1}^B f_{v_{v_x}}^2} \sqrt{\sum_{x=1}^B f_{v_{w_x}}^2}} \tag{13}$$

In Eq. (13),  $f_{v_v}$  and  $f_{v_w}$  denote the term frequency vectors of  $r_v$  and  $r_w$  respectively, and B is the number of features in the vectors. Finally the element  $R(v, w)$  can be shown as follows in Eq. (14):

$$R(v, w) = \begin{cases} TCS(r_v, r_w), & \text{if } v \neq w \\ 0, & \text{otherwise} \end{cases} \tag{14}$$

### K. Framework with Topical and Social Context

We created and comprehended functions for social context and topical context, and then used them to describe regularisation restrictions. In this part, we develop a shared framework that incorporates both social and topical background.

This framework is used to minimize the objective function

given below in Eq. (16):

$$\begin{aligned}
 f(E, G) = & \|P \odot (A - EG^R)\|_F^2 + \lambda_0 \|E\|_F^2 + \lambda_1 \|G\|_F^2 \\
 & + \frac{\alpha}{2} \sum_{v=1}^a \sum_{w \in F(v)} Q(v, w) \|E(v, :) - E(w, :)\|_F^2 \\
 & + \frac{\beta}{2} \sum_{v=1}^a \sum_{w=1}^b R(v, w) \|G(v, :) - G(w, :)\|_F^2
 \end{aligned} \tag{15}$$

$$\begin{aligned}
 f(E, G) = & \|P \odot (A - EG^R)\|_F^2 + \lambda_0 \|E\|_F^2 + \lambda_1 \|G\|_F^2 \\
 & + \alpha \text{Tr}(E^R L_Q E) + \beta \text{Tr}(G^R L_R G)
 \end{aligned} \tag{16}$$

where  $\alpha \geq 0$  and  $\beta \geq 0$  are the social and topical normalisation parameter that can be changed to impact the findings in different ways.  $\alpha=0$  and  $\beta > 0$  infers that the framework discusses just the topical context. On the other hand  $\alpha > 0$  and  $\beta = 0$  infers that the framework discusses just the social context. When  $\alpha = 0$  and  $\beta = 0$  the method reverts to the simplest matrix factorization. In the proposed method it is suggested to keep  $\alpha > 0$  and  $\beta > 0$ .

For proper training and simplicity purpose we implement gradient descent to find the local maxima/minima and solve the objective function, thus updating  $E_{r+1}$  and  $G_{r+1}$ . The formula for which are given in Eq. (17) and Eq. (18),

$$E_{r+1} = E_r - \gamma \nabla_E f(E_r, G_r) \tag{17}$$

$$G_{r+1} = G_r - \gamma \nabla_G f(E_r, G_r) \tag{18}$$

Here the step size is  $\gamma$ ,  $\nabla_E f(E_r, G_r)$  and  $\nabla_G f(E_r, G_r)$  are gradients in step  $r+1$  which are termed as partial derivatives to E and G,

$$\begin{aligned}
 \nabla_E f(E_r, G_r) = & -2(P \odot A_r)G_r + 2P \odot (E_r G_r^R)G_r \\
 & + 2\lambda_0 E_r + 2\alpha L_Q E_r
 \end{aligned} \tag{19}$$

$$\begin{aligned}
 \nabla_G f(E_r, G_r) = & -2(P \odot A_r)^R E_r + 2(P \odot (E_r G_r^R))^R E_r \\
 & + 2\lambda_1 G_r + 2\beta L_R G_r
 \end{aligned} \tag{20}$$

## V. EXPERIMENTAL RESULTS

Our proposed model compares non zero values of the original matrix with a value of the model predicted matrix. We have considered a total of 8 emotions which include Shame, Disgust, Anger, Fear, Sadness, Neutral, Surprise and Joy and they were numbered from 1-8.

When there was no deviation i.e. we tried for an exact match of emotions we get an accuracy of 65%. If we allow the prediction model to have a deviation of +1 or -1 from the original emotion, we get an accuracy of 84%. If we allow

the prediction model to have a deviation of +2 or -2 from the original emotion, we get an accuracy of 95%.

We must note that +1 or -1 deviation should also be acceptable since many a times shame can be misjudged as disgust and vice versa. The model generated the best results when the gradient descent steps were fixed at 100. In both the original matrix factorization and the regularisation terms, the regularisation parameters are set to balance the reconstruction error. As a result,  $\alpha$  and  $\beta$  are critical in deciding how much the framework approach can benefit from the social and topical environment's regularisation limits.

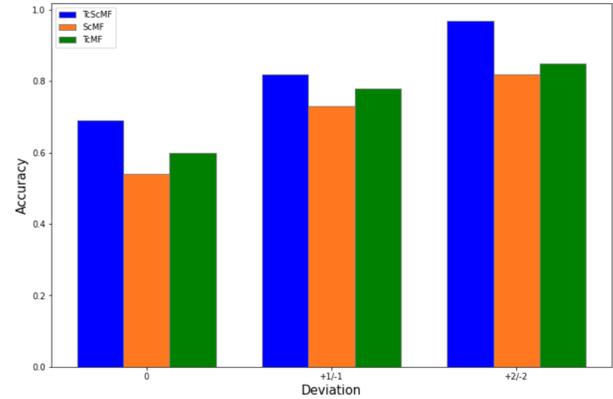

Fig. 3. Accuracy Comparison.

Fig. 3 gives a brief description of the accuracy of the model with different toleration levels. In order to calculate the accuracy of the model we first obtain a matrix that contains known values. This is because it is not necessary that every user in our original dataset or test set has reacted to every different tweet in the dataset. Hence to eliminate verifying against known data we first take a subset of the original dataset and maintain only known values in the matrix. The format of the matrix is constructed in a manner that each row represents unique users in the dataset and the columns represent unique topics. Hence each cell represents the opinions of a user on a given topic. Since our scale of emotions ranges from 1-8 we replace the value of cells with unknown values with 0. Our model is able to predict the reaction of every user on every topic, hence it returns a populated user and topic matrix whose product results in a matrix that is similar to the original user topic matrix. Once we obtain the predictions of the model, we iterate over each user and consecutively each topic and then compare the predicted value with the original value. Note that this is done only for cells whose value is not 0 in the original user topic matrix. Next we define a tolerance level which ranges from 0 to 2. This means that if a user had a reaction of 1 in the original matrix and if the model predicted 2, then we will consider this as a correct prediction only if the tolerance level is 1 or 2. This is because we assume that a tolerance level of 1 allows a deviation of 1 from the original value. Let's consider an example where we have users A and B and topics X and Y. Now user A has only reacted to topic X with an emotion of 2 and user B has reacted to topic Y with an emotion of 7. The original matrix in this case will look as follows:  $\{ \{2, 0\}, \{0, 7\} \}$ . Now let's assume that after passing our data through the model we obtain a predicted matrix which

looks like this:  $[\{3, 1\}, \{6, 7\}]$ . Now while calculating the accuracy of the model we will iterate over user A and B and in a nested for loop iterate over topics X and Y. We will first encounter the first cell (0, 0). We will consider this value since the user A had reacted to topic X in the original scenario. Now if the tolerance level is 0, the predicted and original value will have a difference of 1 which does not fall within our tolerance level/deviation allowed. Hence we will not consider this as a correct prediction. Next we will ignore cells (0, 1) and (1, 0) since their values are not known (0) in the original dataset. Moving onto cell (1, 1), we will consider this value as a correct prediction since the difference between the predicted value and original value is 0 and they are an exact match. Hence in this scenario, out of 2 known values our model was able to predict 1 value properly as per our tolerance level and hence the accuracy turns out to be  $\frac{1}{2} * 100$  which is 50%.

Fig. 3 displays the Accuracy comparison of the methods ScMF, TcMF and the ScTcMF incorporated by us. The results prove that ScTcMF: Framework with Topical and Social Context is the most efficient method. While testing our model, The values of  $\lambda_0$  and  $\lambda_1$  in the matrix factorization method was set to 1 and the values of  $\alpha$  was set to 10 and that of  $\beta$  was set to 0.01. The Learning Rate was considered to be 0.01 and Number of Steps was set to 100. The Hyper parameters were tweaked so that we could get better accuracy.

## VI. CONCLUSION

Our objective while writing this paper was to create a model and a framework that utilizes previous user reactions given a series of cross events to achieve user topic opinion prediction for future events. This was a novel idea because there are solutions that are used in predicting user emotion, but none of them explored this across cross events, which had its own set of challenges. We had to go through multiple iterations of data collection to get the right dataset which included multiple users that have tweeted on multiple topics. In this approach, we searched users on the basis of their activity across all the tweets and the top 100 among them were used as the dataset. This was crucial as a sparse matrix used for the low-rank factorization method would have resulted in poor model accuracy. Using this data, the keywords were extracted and the emotion was detected on a scale of 1 to 8 using the ScTcMF method. Finally, the results demonstrated that both social context and topical context can help improve the performance of the user-topic opinion prediction and by incorporating them we were able to get the model to the desired accuracy.
