October 2022

ISSN 2156-5570(Online)

ISSN 2158-107X(Print)

# Editorial Preface

## *From the Desk of Managing Editor...*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

**Kohei Arai**

# Editorial Board

## Editor-in-Chief

**Dr. Kohei Arai - Saga University**

*Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation*

---

## Associate Editors

**Alaa Sheta**

**Southern Connecticut State University**

*Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems*

**Domenico Ciuonzo**

**University of Naples, Federico II, Italy**

*Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things*

**Dorota Kaminska**

**Lodz University of Technology**

*Domain of Research: Artificial Intelligence, Virtual Reality*

**Elena Scutelnicu**

**"Dunarea de Jos" University of Galati**

*Domain of Research: e-Learning, e-Learning Tools, Simulation*

**In Soo Lee**

**Kyungpook National University**

*Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning*

**Krassen Stefanov**

**Professor at Sofia University St. Kliment Ohridski**

*Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design*

**Renato De Leone**

**Università di Camerino**

*Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming*

**Xiao-Zhi Gao**

**University of Eastern Finland**

*Domain of Research: Artificial Intelligence, Genetic Algorithms*

# CONTENTS

Paper 1: Hand Motion Estimation using Super-Resolution of Multipoint Surface Electromyogram by Deep Learning

Authors: Keigo FUKUSHIMA, Yoshiaki YASUMURA

PAGE 1 – 6

Paper 2: IoT-CID: A Dynamic Detection Technology for Command Injection Vulnerabilities in IoT Devices

Authors: Hao Chen, Jinxin Ma, Baojiang Cui, Junsong Fu

PAGE 7 – 14

Paper 3: English and Romanian Brain-to-Text Brain-Computer Interface Word Prediction System

Authors: Haider Abdullah Ali, Nicolae Goga, Andrei Vasileteanu, Ali M. Muslim, Khalid Abdullah Ali, Marius-Valentin Drăgoi

PAGE 15 – 23

Paper 4: Fine-grained Access Control Method for Blockchain Data Sharing based on Cloud Platform Big Data

Authors: Yu Qiu, Biying Sun, Qian Dang, Chunhui Du, Na Li

PAGE 24 – 31

Paper 5: Smart System for Emergency Traffic Recommendations : Urban Ambulance Mobility

Authors: Ayoub Charef, Zahi Jarir, Mohamed Quafafou

PAGE 32 – 44

Paper 6: A Review of Automatic Question Generation in Teaching Programming

Authors: Jawad Alshboul, Erika Baksa-Varga

PAGE 45 – 51

Paper 7: Application of Stacking Ensemble Machine in Big Data: Analyze the Determinants for Vitalization of the Multicultural Support Center

Authors: RaeHo Lee, Haewon Byeon

PAGE 52 – 57

Paper 8: Research on Precision Marketing based on Big Data Analysis and Machine Learning:Case Study of Morocco

Authors: Nouhaila El Koufi, Abdessamad Belangour, Mounir Sdiq

PAGE 58 – 63

Paper 9: A Sequence-Aware Recommendation Method based on Complex Networks

Authors: Abdullah Alhadlaq, Said Kerrache, Hatim Aboalsamh

PAGE 64 – 72

Paper 10: Mobile Applications for Cybercrime Prevention: A Comprehensive Systematic Review

Authors: Irma Huamanñahui Chipa, Javier Gamboa-Cruzado, Jimmy Ramirez Villacorta

PAGE 73 – 82

Paper 11: Evaluation of the Efficiency of the Optimization Algorithms for Transfer Learning on the Rice Leaf Disease Dataset

Authors: Luyl-Da Quach, Khang Nguyen Quoc, Anh Nguyen Quynh, Hoang Tran Ngoc

PAGE 83 – 91

**Paper 12: Associating User's Preference and Satisfaction into Quality of Experience: A Shoulder-surfing Resistant Authentication Scheme by Visual Perception**

*Authors: Juliana Mohamed, Mohd Farhan Md Fudzee, Sofia Najwa Ramli, Mohd Norasri Ismail, Muhamad Hanif*

*Jofri*

**PAGE 92 – 97**

**Paper 13: Integrating Computer-aided Argument Mapping into EFL Learners' Argumentative Writing: Evidence from Saudi Arabia**

*Authors: Nuha Abdullah Alsmari*

**PAGE 98 – 104**

**Paper 14: An Efficient Computational Method of Motif Finding in the Zika Virus Genome**

*Authors: Pushpa Susant Mahapatro, Jatinderkumar R. Saini*

**PAGE 105 – 114**

**Paper 15: Classification of Agriculture Area based on Superior Commodities in Geographic Information System**

*Authors: Lilik Sumaryanti, Rosmala Widjastuti, Firman Tempola, Heru Ismanto*

**PAGE 115 – 121**

**Paper 16: Analysis of Unsupervised Machine Learning Techniques for an Efficient Customer Segmentation using Clustering Ensemble and Spectral Clustering**

*Authors: Nouri Hicham, Sabri Karim*

**PAGE 122 – 130**

**Paper 17: Complexity of Web-based Application for Research and Community Service in Academic**

*Authors: Fitriana Fitriana, Sukarni Sukarni, Zulkifli Zulkifli*

**PAGE 131 – 135**

**Paper 18: Brain Tumor Detection using Integrated Learning Process Detection (ILPD)**

*Authors: M. Praveena, M. Kameswara Rao*

**PAGE 136 – 141**

**Paper 19: Towards Home-based Therapy: The Development of a Low-cost IoT-based Transcranial Direct Current Stimulation System**

*Authors: Ahmad O. Alokaily, Ghala Almeteb, Raghad Althabiti, Suhail S. Alshahrani*

**PAGE 142 – 146**

**Paper 20: Semi-supervised Text Annotation for Hate Speech Detection using K-Nearest Neighbors and Term Frequency-Inverse Document Frequency**

*Authors: Nur Heri Cahyana, Shoffan Saifullah, Yuli Fauziah, Agus Sasmito Aribowo, Rafal Drezewski*

**PAGE 147 – 151**

**Paper 21: Comparison of Edge Detection Algorithms for Texture Analysis on Copy-Move Forgery Detection Images**

*Authors: Bashir Idris, Lili N. Abdullah, Alfian Abdul Halim, Mohd Taufik Abdullah Selimun*

**PAGE 152 – 160**

**Paper 22: Deep Learning Model for Predicting Consumers' Interests of IoT Recommendation System**

*Authors: Talal H. Noor, Abdulqader M. Almars, El-Sayed Atlam, Ayman Noor*

**PAGE 161 – 170**

- Paper 23: A Machine Learning Model for Personalized Tariff Plan based on Customer's Behavior in the Telecom Industry**  
*Authors: Lewlisa Saha, Hrudaya Kumar Tripathy, Fatma Masmoudi, Tarek Gaber*  
**PAGE 171 – 184**
- Paper 24: A Systematic Literature Review of Deep Learning-Based Detection and Classification Methods for Bacterial Colonies**  
*Authors: Shimaa A. Nagro*  
**PAGE 185 – 202**
- Paper 25: Optimization of Multilayer Perceptron Hyperparameter in Classifying Pneumonia Disease Through X-Ray Images with Speeded-Up Robust Features Extraction Method**  
*Authors: Mutammimul Ula, Muhathir, Ilham Sahputra*  
**PAGE 203 – 210**
- Paper 26: Forecasting Covid-19 Time Series Data using the Long Short-Term Memory (LSTM)**  
*Authors: Harun Mukhtar, Reny Medikawati Taufiq, Ilham Herwinanda, Doni Winarso, Regiolina Hayami*  
**PAGE 211 – 217**
- Paper 27: Design of a Dense Layered Network Model for Epileptic Seizures Prediction with Feature Representation**  
*Authors: Summia Parveen, S. A. Siva Kumar, P. MohanRaj, Kingsly Jabakumar, R. Senthil Ganesh*  
**PAGE 218 – 223**
- Paper 28: The Effect of the Aesthetically Mobile Interfaces on Students' Learning Experience for Primary Education**  
*Authors: Nor Fatin Farzana Binti Zainuddin, Zuriana Binti Abu Bakar, Noor Maizura Binti Mohammad, Rosmayati Binti Mohamed*  
**PAGE 224 – 230**
- Paper 29: Real Time Customer Satisfaction Analysis using Facial Expressions and Headpose Estimation**  
*Authors: Nethravathi P. S, Manjula Sanjay Koti, Taramol. K.G, Soofi Anwar, Gayathri Babu J, Rajermani Thinakaran*  
**PAGE 231 – 238**
- Paper 30: An Optimized Single Layer Perceptron-based Approach for Cardiotocography Data Classification**  
*Authors: Bader Fahad Alkhamees*  
**PAGE 239 – 245**
- Paper 31: Observe-Orient-Decide-Act (OODA) for Cyber Security Education**  
*Authors: Dimas Febriyan Priambodo, Yogha Restu Pramadi, Obrina Candra Briliyant, Muhammad Hasbi, Muhammad Adi Yahya*  
**PAGE 246 – 255**
- Paper 32: Module Partition Method of Embedded Multitasking Software Based on Fuzzy Set Theory**  
*Authors: Yunpeng Gu*  
**PAGE 256 – 265**
- Paper 33: Comparison of Metaheuristic Techniques for Parcel Delivery Problem: Malaysian Case Study**  
*Authors: Shamine A/P S.Moganathan, Siti Noor Asyikin binti Mohd Razali, Aida Mustapha, Safra Liyana binti Sukiman, Rosshairy Abd Rahman, Muhammad Ammar Shafi*  
**PAGE 266 – 274**

**Paper 34: An Approach for Optimization of Features using Gorilla Troop Optimizer for Classification of Melanoma**

*Authors: Anupama Damarla, Sumathi D*

**PAGE 275 – 286**

**Paper 35: Review on Multimodal Fusion Techniques for Human Emotion Recognition**

*Authors: Ruhina Karani, Sharmishta Desai*

**PAGE 287 – 296**

**Paper 36: A Comparative Study of Predictions of Students' Performances in Offline and Online Modes using Adaptive Neuro-Fuzzy Inference System**

*Authors: Sudhindra B. Deshpande, Kiran K.Tangod, Neelkanth V.Karekar, Pandurang S.Upparmani*

**PAGE 297 – 304**

**Paper 37: Combining Innovative Technology and Context based Approaches in Teaching Software Engineering**

*Authors: Shamsul Huda, Sultan Alyahya, Lei Pan, Hmood Al-Dossari*

**PAGE 305 – 314**

**Paper 38: Modified Intrusion Detection Tree with Hybrid Deep Learning Framework based Cyber Security Intrusion Detection Model**

*Authors: Majed Alowaidi*

**PAGE 315 – 322**

**Paper 39: Performance Comparison between Meta-classifier Algorithms for Heart Disease Classification**

*Authors: Nureen Afiqah Mohd Zaini, Mohd Khalid Awang*

**PAGE 323 – 328**

**Paper 40: Detection of Severity-based Email SPAM Messages using Adaptive Threshold Driven Clustering**

*Authors: I V S Venugopal, D Lalitha Bhaskari, M N Seetaramanath*

**PAGE 329 – 339**

**Paper 41: Alz-SAENet: A Deep Sparse Autoencoder based Model for Alzheimer's Classification**

*Authors: G Nagarjuna Reddy, K Nagi Reddy*

**PAGE 340 – 348**

**Paper 42: Development of Path Loss Prediction Model using Feature Selection-Machine Learning Approach**

*Authors: Bengawan Alfaresi, Zainuddin Nawawi, Bhakti Yudho Suprpto*

**PAGE 349 – 358**

**Paper 43: Employability Prediction of Information Technology Graduates using Machine Learning Algorithms**

*Authors: Gehad ElSharkawy, Yehia Helmy, Engy Yehia*

**PAGE 359 – 367**

**Paper 44: Otsu's Thresholding for Semi-Automatic Segmentation of Breast Lesions in Digital Mammograms**

*Authors: Moustapha Mohamed Saleck, M. H. Ould Mohamed Dyla, EL Benany Mohamed Mahmoud, Mohamed Rmili*

**PAGE 368 – 375**

**Paper 45: Performance Analysis of Software Test Effort Estimation using Genetic Algorithm and Neural Network**

*Authors: Vikas Chahar, Pradeep Kumar Bhatia*

**PAGE 376 – 383**

**Paper 46: A Computer Vision System for Street Sweeper Robot**

*Authors: Ouiem Bchir, Sultana Almasoud, Lina Alyahya, Renad Aldhalaan, Lina Alsaeed, Nada Aldalbahi*

**PAGE 384 – 392**

**Paper 47: An Experimental Study with Fuzzy-Wuzzy (Partial Ratio) for Identifying the Similarity between English and French Languages for Plagiarism Detection**

*Authors: Peluru Janardhana Rao, Kunjam Nageswara Rao, Sitaratnam Gokuruboyina*

**PAGE 393 – 401**

**Paper 48: Comparing LSTM and CNN Methods in Case Study on Public Discussion about Covid-19 in Twitter**

*Authors: Fachrul Kurniawan, Yuliana Romadhoni, Laila Zahrona, Jihad Hammad*

**PAGE 402 – 409**

**Paper 49: ACT on Monte Carlo FogRA for Time-Critical Applications of IoT**

*Authors: A. S. Gowri, P. Shanthi Bala, Zion Ramdinthara, T. Siva Kumar*

**PAGE 410 – 419**

**Paper 50: Delay-Aware and Profit-Maximizing Task Migration for the Cloudlet Federation**

*Authors: Hengzhou Ye, Junhao Guo, Xinxiao Li*

**PAGE 420 – 428**

**Paper 51: Collaborative Ontology Construction Framework: An Attempt to Rationalize Effective Knowledge Dissemination**

*Authors: Kaneeka Vidanage, Noor Maizura Mohamad Noor, Rosmayati Mohemad, Zuriana Abu Bakar*

**PAGE 429 – 435**

**Paper 52: BiLSTM and Multiple Linear Regression based Sentiment Analysis Model using Polarity and Subjectivity of a Text**

*Authors: Marouane CHIHAB, Mohamed CHINY, Nabil Mabrouk, Hicham BOUSSATTA, Younes CHIHAB, Moulay Youssef HADI*

**PAGE 436 – 442**

**Paper 53: Local Texture Representation for Timber Defect Recognition based on Variation of LBP**

*Authors: Rahilda Nadhirah Norizzaty Rahiddin, Ummi Raba'ah Hashim, Lizawati Salahuddin, Kasturi Kanchymalay, Aji Prasetya Wibawa, Teo Hong Chun*

**PAGE 443 – 448**

**Paper 54: Unethical Internet Behaviour among Students in High Education Institutions: A Systematic Literature Review**

*Authors: Zakiah Ayop, Aslinda Hassan, Syarulnaziah Anawar, Nur Fadzilah Othman, Rabiah Ahmad, Nor Raihana Mohd Ali, Maslin Masrom*

**PAGE 449 – 464**

**Paper 55: Teachers' Attitudes Towards the Use of Augmented Reality Technology in Teaching Arabic in Primary School Malaysia**

*Authors: Lily Hanefarezan Asbulah, Mus'ab Sahrim, Nor Fatini Aqilah Mohd Soad, Nur Afiqah Athirah Mohd Rushdi, Muhammad Afiq Hilmi Mhd Deris*

**PAGE 465 – 474**

**Paper 56: An Algorithm for Shrinking Blood Receptacles using Retinal Internal Pictures for Clinical Characteristics Measurement**

*Authors: Aws A. Abdulsahib, Moamin A Mahmoud, Sally A. Al-Hasnawi*

**PAGE 475 – 488**

**Paper 57: Detection of Cyber-Physical Attacks using Physical Model with Nonparametric EWMA Detector**

*Authors: Joko Supriyadi, Jazi Eko Istiyanto, Agfianto Eko Putra*

**PAGE 489 – 496**

**Paper 58: Performance Evaluation of New Feature based on Ordinal Pattern Analysis for Iris Biometric Recognition**

*Authors: Sheena S, Sheena Mathew, Bindu M Krishna*

**PAGE 497 – 506**

**Paper 59: Mitigation of DDoS Attack in Cloud Computing Domain by Integrating the DCLB Algorithm with Fuzzy Logic**

*Authors: Amrutha Muralidharan Nair, R Santhosh*

**PAGE 507 – 516**

**Paper 60: Federated Learning Approach for Measuring the Response of Brain Tumors to Chemotherapy**

*Authors: Omneya Atef, Mustafa Abdul Salam, Hisham Abdelsalam*

**PAGE 517 – 524**

**Paper 61: A Fake News Detection System based on Combination of Word Embedded Techniques and Hybrid Deep Learning Model**

*Authors: Mohamed-Amine OUASSIL, Bouchaib CHERRADI, Soufiane HAMIDA, Mouaad ERRAMI, Oussama EL GANNOUR, Abdelhadi RAIHANI*

**PAGE 525 – 534**

**Paper 62: Research on Blind Obstacle Ranging based on Improved YOLOv5**

*Authors: Yongquan Xia, Yiqing Li, Jianhua Dong, Shiyu Ma*

**PAGE 535 – 542**

**Paper 63: Classification Method for Power Load Data of New Energy Grid based on Improved OTSU Algorithm**

*Authors: Xun Ma, Kai Liu, Anlei Liu, Xuchao Jia, Yong Wang*

**PAGE 543 – 552**

**Paper 64: Study on the Technical Characteristics of Badminton Players in Different Stages through Video Analysis**

*Authors: Jin Qiu*

**PAGE 553 – 558**

**Paper 65: Deep Architecture based on DenseNet-121 Model for Weather Image Recognition**

*Authors: Saleh A. Albelwi*

**PAGE 559 – 565**

**Paper 66: Research on Improved Shallow Neural Network Big Data Processing Model based on Gaussian Function**

*Authors: Lifang Fu*

**PAGE 566 – 573**

**Paper 67: Conceptual Model of Augmented Reality Mobile Application Design (ARMAD) to Enhance user Experience: An Expert Review**

*Authors: Nik Azlina Nik Ahmad, Ahmad Iqbal Hakim Suhaimi, Anitawati Mohd Lokman*

**PAGE 574 – 582**

**Paper 68: A Novel Prediction Model for Compiler Optimization with Hybrid Meta-Heuristic Optimization Algorithm**

*Authors: Sandeep U. Kadam, Sagar B. Shinde, Yogesh B. Gurav, Sunil B Dambhare, Chaitali R Shewale*

**PAGE 583 – 588**

Paper 69: A Deep Learning and Machine Learning Approach for Image Classification of Tempered Images in Digital Forensic Analysis

*Authors: Praveen Chitti, K. Prabhushetty, Shridhar Allagi*

**PAGE 589 – 593**

Paper 70: Evaluation of Land Use/Land Cover Classification based on Different Bands of Sentinel-2 Satellite Imagery using Neural Networks

*Authors: Pallavi M, Thivakaran T K, Chandankeri Ganapathi*

**PAGE 594 – 601**

Paper 71: Exponential Decay Function-Based Time-Aware Recommender System for e-Commerce Applications

*Authors: Ayat Yehia Hassan, Etimad Fadel, Nadine Akkari*

**PAGE 602 – 612**

Paper 72: A Comprehensive Assessment Framework for Evaluating Adaptive Security and Privacy Solutions for IoT e-Health Applications

*Authors: Waqas Aman, Fatima Najla Mohammed*

**PAGE 613 – 623**

Paper 73: Enhanced Jaya Algorithm for Multi-objective Optimisation Problems

*Authors: Rahaini Mohd Said, Roselina Sallehuddin, Nor Haizan Mohd Radzi, Wan Fahmn Faiz Wan Ali*

**PAGE 624 – 632**

Paper 74: Research on the Academic Early Warning Model of Distance Education based on Student Behavior Data in the Context of COVID-19

*Authors: Yi Qu, Zhiyuan Sun, Libin Liu*

**PAGE 633 – 642**

Paper 75: Dynamic Polymorphism without Inheritance: Implications for Education

*Authors: Ivaylo Donchev, Emilia Todorova*

**PAGE 643 – 649**

Paper 76: Application of Training Load Prediction Model based on Improved BP Neural Network in Sports Training of Athletes

*Authors: Lin Liu, Guannan Sheng*

**PAGE 650 – 657**

Paper 77: Analyzing Multi-stage Reverse Osmosis Desalination Using Artificial Intelligence

*Authors: Batiseba Tekle, Azmi Alazzam, Abdulwehab Ibrahim, Ghassan Malkawi, Abdulaziz Fares NajiMoqbel, Nissar Qureshi, Ahmed Hamadat, Filomento O. Corona Jr*

**PAGE 658 – 663**

Paper 78: Educational Platform based on Smartphone to Increase Students' Interaction in Classroom

*Authors: Mohamed Naser AlSubie, Omar Ben Bahri*

**PAGE 664 – 668**

Paper 79: A Novel Architecture for Community-Sustained Cultural Mapping System

*Authors: Chong Eng Tan, Sei Ping Lau, Siew Mooi Wong*

**PAGE 669 – 674**

**Paper 80: Research on Personalized Recommendation of High-Quality Academic Resources based on user Portrait**

*Authors: Jianhui Xu, Mustafa Man, Ily Amalina Ahmad Sabri, Guoyi Li, Chao Yang, Mingxue Jin*

**PAGE 675 – 683**

**Paper 81: An Inspection of Learning Management Systems on Persuasiveness of Interfaces and Persuasive Design: A Case in a Higher Learning Institution**

*Authors: Wan Nooraishya Wan Ahmad, Mohamad Hidir Mhd Salim, Ahmad Rizal Ahmad Rodzuan*

**PAGE 684 – 692**

**Paper 82: The Development of an Ontology for Information Retrieval about Ethnic Groups in Chiang Mai Province**

*Authors: Phichete Julrode, Thepchai Supnithi*

**PAGE 693 – 698**

**Paper 83: CoSiT: An Agent-based Tool for Training and Awareness to Fight the Covid-19 Spread**

*Authors: Henri-Joel Azemena, Franck-Anael K. Mbiaya, Selain K. Kasereka, Ho Tuong Vinh*

**PAGE 699 – 706**

**Paper 84: Parallel Hough Transform based on Object Dual and Pypm Library**

*Authors: Abdoulaye SERE, Moise OUEDRAOGO, Armand Kodjo ATIAMPO*

**PAGE 707 – 716**

**Paper 85: Prototyping a Mobile Application for Children with Dyscalculia in Primary Education using Augmented Reality**

*Authors: Misael Lazo-Amado, Leoncio Cueva-Ruiz, Laberiano Andrade-Arenas*

**PAGE 717 – 724**

**Paper 86: Adaptive Lane Keeping Assist for an Autonomous Vehicle based on Steering Fuzzy-PID Control in ROS**

*Authors: Hoang Tran Ngoc, Luyi-Da Quach*

**PAGE 725 – 731**

**Paper 87: Money Laundering Detection using Machine Learning and Deep Learning**

*Authors: Johrha Alotibi, Badriah Almutanni, Tahani Alsubait, Hosam Alhakami, Abdullah Baz*

**PAGE 732 – 738**

**Paper 88: Multi-Channel Speech Enhancement using a Minimum Variance Distortionless Response Beamformer based on Graph Convolutional Network**

*Authors: Nguyen Huu Binh, Duong Van Hai, Bui Tien Dat, Hoang Ngoc Chau, Nguyen Quoc Cuong*

**PAGE 739 – 747**

**Paper 89: Impact of Input Data Structure on Convolutional Neural Network Energy Prediction Model**

*Authors: Imen Toumia, Ahlem Ben Hassine*

**PAGE 748 – 757**

**Paper 90: Decode and Forward Coding Scheme for Cooperative Relay NOMA System with Cylindrical Array Transmitter**

*Authors: Samuel Tweneboah-Koduah, Emmanuel Ampoma Affum, Kingsford Sarkodie Obeng Kwakye, Owusu Agyeman Antwi*

**PAGE 758 – 767**

**Paper 91: A Decision Concept to Support House Hunting**

*Authors: Tanjim Mahmud, Dilshad Islam, Manoara Begum, Sudhakar Das, Lily Dey, Koushick Barua*

**PAGE 768 – 774**

**Paper 92: A Drone System with an Object Identification Algorithm for Tracking Dengue Disease**

*Authors: Diego Moran-Landa, Maria del Rosario Damian, Pedro Miguel Portillo Mendoza, Carlos Sotomayor-Beltran*

**PAGE 775 – 781**

**Paper 93: Analysis of the Intuitive Teleoperated System of the TxRob Multimodal Robot**

*Authors: Jeyson Carpio A, Samuel Luque C, Juan Chambi C, Jesus Talavera S*

**PAGE 782 – 788**

**Paper 94: Exploring Power Advantage of Binary Search: An Experimental Study**

*Authors: Muhammad Al-Hashimi, Naif Aljabri*

**PAGE 789 – 795**

**Paper 95: CertOracle: Enabling Long-term Self-Sovereign Certificates with Blockchain Oracles**

*Authors: Shaoxi Zou, Fa Jin, Yongdong Wu*

**PAGE 796 – 804**

**Paper 96: Evaluation of Online Machine Learning Algorithms for Electricity Theft Detection in Smart Grids**

*Authors: Ashraf Alkhrshesh, Mutaz A. B. Al-Tarawneh*

**PAGE 805 – 813**

**Paper 97: Artificial Intelligence for Automated Plant Species Identification: A Review**

*Authors: Khaoula Labrighli, Chouaib Moujahdi, Jalal El Oualidi, Laila Rhazi*

**PAGE 814 – 825**

**Paper 98: Arduino for Developing Problem-Solving and Computing Competencies in Children**

*Authors: Cristian Vidal-Silva, Claudia Jimenez-Quintana, Erika Madariaga-Garcia*

**PAGE 826 – 832**

**Paper 99: An Integrated Hardware Prototype for Monitoring Gas leaks, Fires, and Remote control via Mobile Application**

*Authors: Md. Ashiqur Rahman, Humayra Ahmed, Md. Mamun Hossain*

**PAGE 833 – 840**

**Paper 100: Performance Evaluation of Raspberry Pi as an IoT Edge Signal Processing Device for a Real-time Flash Flood Forecasting System**

*Authors: Aslinda Hassan, Haniza Nahar, Wahidah Md Shah, Azlianor Abd-Aziz, Sarah Afiqah Sahiran, Nazrulazhar Bahaman, Mohd Riduan Ahmad, Isredza Rahmi A. Hamid, Muhammad Abu Bakar Sidik*

**PAGE 841 – 848**

**Paper 101: Decentralized Payment Aggregator: Hyperledger Fabric**

*Authors: Md. Al-Amin, Khondoker Shahrina, Rubyet Hossain, Debashish Sarker, Sumya Sultana Meem*

**PAGE 849 – 857**

**Paper 102: Efficient HPC and Energy-Aware Proactive Dynamic VM Consolidation in Cloud Computing**

*Authors: Rukshanda Kamran, Ali A. El-Moursy, Amany Abdelsamea*

**PAGE 858 – 869**

**Paper 103: Triple SVM Integrated with Enhanced Random Region Segmentation for Classification of Lung Tumors**

*Authors: Sukruth Gowda M A, A Jayachandran*

**PAGE 870 – 877**

**Paper 104: Optimized Automatic Course Timetabling Service Architecture for Integration with Vendor Management Systems**

*Authors: Marwah M. Alansari*

**PAGE 878 – 890**

**Paper 105: Cryptocurrency Price Prediction using Forecasting and Sentiment Analysis**

*Authors: Shaimaa Alghamdi, Sara Alqethami, Tahani Alsubait, Hosam Alhakami*

**PAGE 891 – 900**

**Paper 106: The Multi-Objective Design of Laminated Structure with Non-Dominated Sorting Genetic Algorithm**

*Authors: Huiyao Zhang, Yuxiao Wang, Fangmeng Zeng*

**PAGE 901 – 906**

**Paper 107: From Monolith to Microservices: A Semi-Automated Approach for Legacy to Modern Architecture Transition using Static Analysis**

*Authors: Mohd Hafeez Osman, Cheikh Saadbouh, Khaironi Yatim Sharif, Novia Admodisastro, Muhammad Hadri Basri*

**PAGE 907 – 916**

**Paper 108: SDN Architecture for Smart Homes Security with Machine Learning and Deep Learning**

*Authors: Wesam Abdulrhman Alonazi, Hedi HAMD, Nesrine A. Azim, A. A. Abd El-Aziz*

**PAGE 917 – 927**

**Paper 109: Skin Melanoma Classification from Dermoscopy Images using ANU-Net Technique**

*Authors: Vankayalapati Radhika, B. Sai Chandana*

**PAGE 928 – 938**

**Paper 110: Method for Determination of Tealeaf Plucking Date with Cumulative Air Temperature: CAT and Photosynthetically Active Radiation: PAR**

*Authors: Kohei Arai, Yoshiko Hokazono*

**PAGE 939 – 944**

**Paper 111: Remote Monitoring Solution for Cardiovascular Diseases based on Internet of Things and PLX-DAQ add-in**

*Authors: Jeanne Roux NGO BILONG, Yao Gaspard Magnificat BOSSOU, Adam Ismael Paco SIE, Gervais MENDY, Cheikhane SEYED*

**PAGE 945 – 951**

**Paper 112: Anomaly Detection in Video Surveillance using SlowFast Resnet-50**

*Authors: Mahasweta Joshi, Jitendra Chaudhari*

**PAGE 952 – 956**

**Paper 113: Address Pattern Recognition Flash Translation Layer for Quadruple-level cell NAND-based Smart Devices**

*Authors: Se Jin Kwon*

**PAGE 957 – 960**

**Paper 114: Hybrid Deep Learning Signature based Correlation Filter for Vehicle Tracking in Presence of Clutters and Occlusion**

*Authors: Shobha B. S, Deepu. R*

**PAGE 961 – 969**

**Paper 115: Improving Slope Stability in Open Cast Mines via Machine Learning based IoT Framework**

# Hand Motion Estimation using Super-Resolution of Multipoint Surface Electromyogram by Deep Learning

Keigo FUKUSHIMA, Yoshiaki YASUMURA  
Graduate School of Engineering and Science  
Shibaura Institute of Technology  
Tokyo, Japan

**Abstract**—This paper proposes a method for hand motion estimation using super-resolution of multipoint surface electromyogram for prosthetic hands. In general, obtaining more EMGs (ElectroMyoGraphy) improves the accuracy of hand motion estimation, but it is costly and hard to use. Therefore, this method improves the accuracy of hand motion estimation by estimating a large number of EMG signals from a small number of EMG signals using super-resolution. This super-resolution is achieved by learning the relationship between few and many myoelectric signals using a deep neural network. Then, hand motions are estimated from the high-resolution signal using a deep neural network. Experiments using actual EMG signals show that the proposed method improves the accuracy of hand motion estimation.

**Keywords**—Hand motion estimation; super-resolution; deep neural network; prosthetic hand; electromyography

## I. INTRODUCTION

Today, many people utilize prosthetic hands in their daily lives due to accidents or congenital disabilities. Myoelectric prostheses record the electrical signals on the skin surface when muscles are moved, and the prosthetic hand moves based on these signals. This allows for intuitive movement with few restrictions on posture.

As described above, myoelectric prostheses are highly useful, but they have some problems. The prosthetic hand can be manipulated by the wearer's intention, though it is difficult for the wearer to perform all of the activities of daily living. To enable more complex hand motions, the accuracy of electromyographic analysis requires improvement. For this purpose, multipoint surface electromyography is useful [1], [2]. Multipoint surface electromyography is a measurement method of muscle movement using a grid of electrodes on the skin surface. This allows us to measure more detailed temporal and spatial myoelectric information.

Jiangcheng et al. placed 128 electrode channels on the upper arm and classified 27 gestures with 95.3% accuracy [3]. Weijie et al. also showed that a larger number of sensors results in a higher percentage of correct gestures [4]. However, increasing the number of electrodes makes mounting more difficult and electrode costs higher. The number of electrodes needs to be reduced to make it easier to use the prosthetic hand.

In order to operate a prosthetic hand with fewer electrodes, we propose a method to improve prosthetic hand motion by increasing myoelectric data with super-resolution technology. The objective of this study is to accurately estimate hand motion from fewer EMG signals. This method estimates multipoint surface electromyograms from fewer electrodes and operates the prosthetic hand more accurately based on them. For this estimation, a convolutional neural network, which is widely used in image recognition, is used for super-resolution of electromyograms and estimation of hand motions. Super-resolution is a technique to obtain a high-resolution output signal from a low-resolution input signal. This method uses deep learning to learn the relationship between low-resolution and high-resolution signals to create a higher resolution.

## II. RELATED WORKS

Since many people use prosthetic hands in their daily lives, many studies have tried to create better prosthetic hands [5]-[9]. A myoelectric prosthetic hand uses the electrical signals generated on the surface of the skin during muscle movement to operate a robotic hand. Myoelectric prosthetics are more useful than other prosthetics, but there are some problems. Myoelectric prosthetics allow some movements, but complex movements are difficult. To enable complex movements, it is necessary to measure many myoelectric signals and estimate movements from these signals.

Hudgins et al. use the multilayer perceptron to identify four forearm movements from myoelectric signals [1]. Ali et al. used a convolutional neural network to identify 10 hand motions from myoelectric signals acquired at 8000 Hz using six-channel electrodes and 0.15 seconds of myoelectric signals as input [2]. This paper shows that with the appropriate hyper parameters and network structure, it is possible to estimate with more than 80% accuracy for all movements. However, the accuracy needs to be further improved for actual use of the prosthetic hand.

Jiangcheng et al. placed 128 electrode channels on the upper arm and classified 27 gestures with 95.3% accuracy [3]. Weijie et al. also showed that the correctness rate of a gesture increases with the number of sensors [4]. Thus, increasing the number of sensors can improve the accuracy of hand motion estimation. However, increasing the number of sensors makes wearing a prosthetic hand more difficult and increases the cost of the

prosthetic hand. For this reason, a method that enables accurate hand motion estimation with fewer sensors is needed.

Therefore, this paper proposes a method that enables accurate hand estimation from fewer sensors. For accurate hand motion estimation, this method uses super-resolution to increase the number of inputs without increasing the number of sensors. This method can be as effective as using many sensors, because super-resolution can generate more input signals from fewer inputs.

### III. HAND MOTION ESTIMATION USING SUPER-RESOLUTION

#### A. Overview

Fig. 1 shows an overview of the proposed method. The inputs are multiple myoelectric signals. These signals are input to a deep neural network for super-resolution, and higher resolution signals are output. This neural network enables super-resolution by learning the relationship between signals at fewer points and those at more points. The super-resolved signals are then input to a deep neural network for hand motion estimation, and the estimation results are output. The estimated result is a class of hand motions.

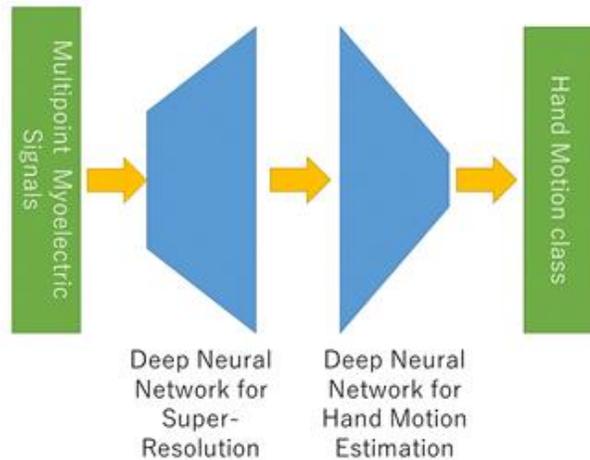

Fig. 1. Overview of the Proposed Method.

#### B. Super-Resolution for Multiple Myoelectric Signals

Super-resolution has been actively studied in the field of image processing [10]-[15]. Super-resolution in image processing generates a high-resolution image from a low-resolution image. In this study, this technique is used to obtain high-resolution myoelectric signals. Here, super-resolution uses the deep neural network shown in Fig. 2. Input is four-channel 512-sample EMG, output is 16-channel 512-sample EMG. The abbreviations in Fig. 2 mean the following.

- Conv: convolution layer

- PReLU: an activation function called parametric rectified linear unit [16].
- BN: batch normalization.
- Skip connection: a connection between two layers that passes information between them without transformation. Both skipped and un-skipped informations are available.
- Pixel Shuffler: It rearranges each pixel in the input feature map to output a high-resolution feature map [17].
- Residual block: a skip-connected block that learns a residual function by reference to the inputs of the layer, rather than learning a function that is unreferenced.

This neural network is based on SR ResNet [11]. SR ResNet keeps the height and width of the inputs the same size in the middle layer. In contrast, this method compresses the height by a quarter in the middle layer by convolution processing on the input. This is because both the height and width of the input are enlarged when using the Pixel Shuffler. By compressing the input data in advance so that the restored height is the same as the input data, it is possible to achieve more accurate super-resolution than with convolution or pooling processing. In Fig. 2, the output channel rows are replaced. This process is to make it easier to recover the original waveforms by super-resolution processing. The channel sequence is restored before input to the hand motion estimation network.

#### C. Hand Motion Estimation

Hand motion estimation uses deep neural networks. Fig. 3 shows a deep neural network for the hand motion classification. The input is a 16-channel 512-sample EMG, and the output is a label indicating the gesture. The abbreviations in Fig. 3 are the same as those used in Fig. 2. Max pool means a max pooling layer. Dropout is a method of preventing overfitting by inactivating a certain percentage of nodes while training a neural network [18]. The flatten layer converts the feature map into a one-dimensional vector. The softmax function transforms multiple output values into a sum of 1.0.

The proposed method assumes that hand motions are estimated every 0.25 seconds. A network of electromyograms with four input channels and 512 samples is also created for validation. Côté-Allard et al. [19] performed channel-by-channel convolution for hand motion estimation using multi-channel EMG. This method transforms 16 input channels with 512 sample inputs into 128 channels with a height of 64 and a width of 128 and applies convolution processing. This allows learning of numerical value changes over various times and channels by convolutional processing to achieve high accuracy.

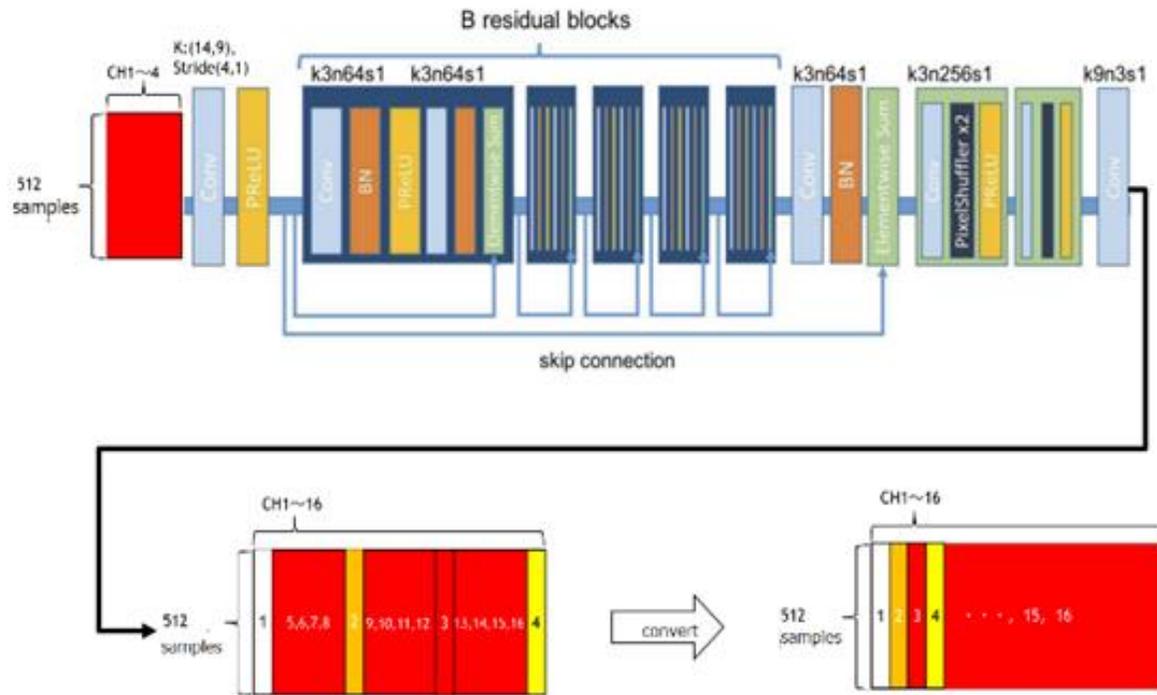

Fig. 2. Deep Neural Network for Super-Resolution.

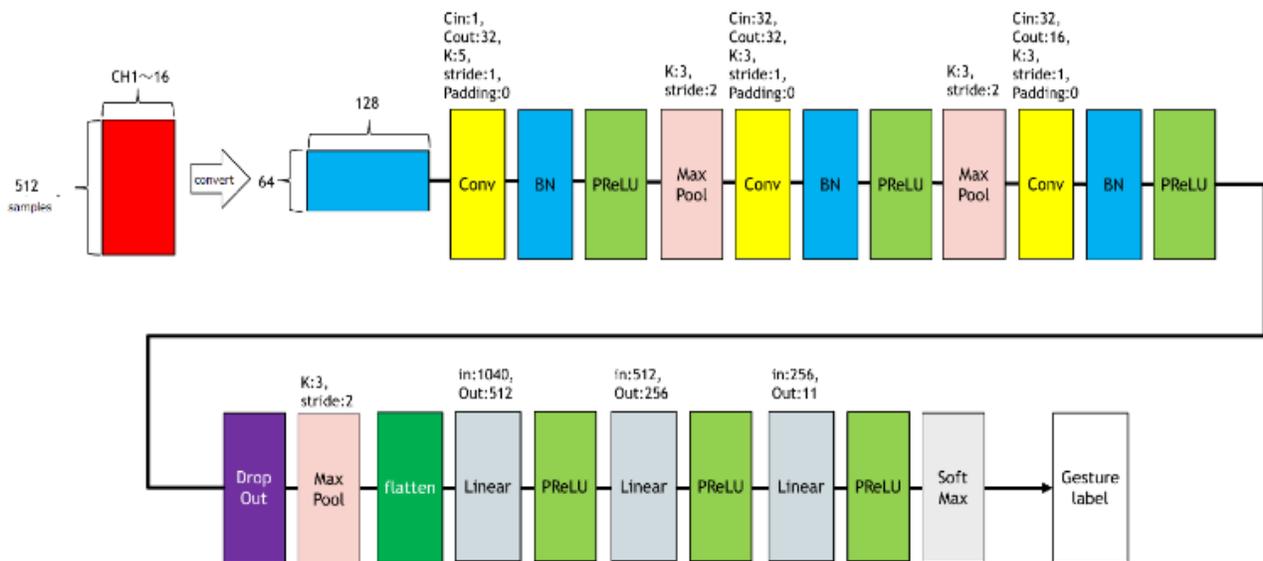

Fig. 3. Deep Neural Network for Hand Motion Estimation.

#### IV. EXPERIMENTS

This section describes evaluation experiments using actual data to evaluate the effectiveness of the proposed method.

##### A. Dataset

The dataset in this study was acquired using the following devices. Fig. 4 shows the actual device used for this experiment. This device connects a myoelectric amplifier to a microcontroller board and sends its output to a PC. The electrode is a wet disposable ECG electrode (MSGLT-04). The electrodes were placed as shown in Fig. 5, taking into

consideration the hand motions and the muscle arrangement. The reference electrode was placed at the elbow. The device was used to obtain myoelectric signals at 16 locations. This study uses the gestures in Fig. 6, as in the study by Côté-Allard et al. [19]. Each gesture is performed from a state of relaxation, and the device acquires EMG for 10 seconds during the gesture. The training data is the first nine seconds of data, and the remaining one second of data is used as the test data. To compensate for the small amount of data, the method of Lingfeng et al [20] was used. This produced 197131 training data and 16907 test data.

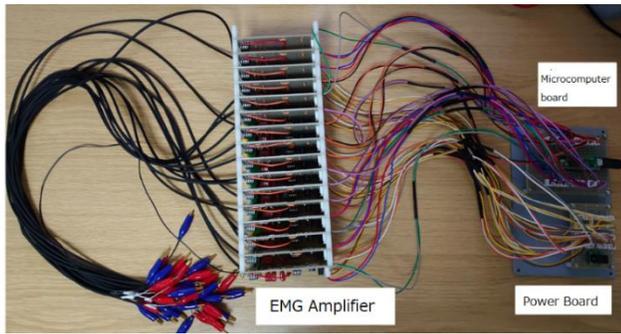

Fig. 4. EMG Measurement Device.

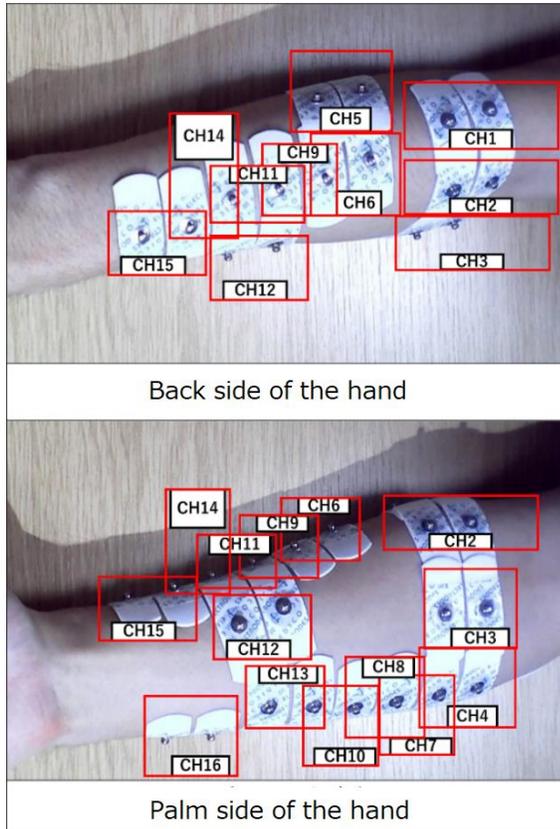

Fig. 5. Electrode Setting.

Fig. 6. Gesture Class.

### B. Experiment of Super-Resolution

Here, the effect of super-resolution of myoelectric signals is verified using actual data. In this experiment, 4-channel 512-sample, EMG is the input, and the corresponding 16-channel 512-sample EMG is the supervised data. The mean squared error (MSE) was used as the loss function. The MSE is expressed in Equation (1).

$$MSE = \frac{1}{N} \sum_{i=1}^N (y - t)^2 \quad (1)$$

N is the number of samples, and y and t are the output and supervised data, respectively. PSNR, which is also used in general image super-resolution, is used as a measure of the difference between the output and supervised data. PSNR is expressed by Equation (2). The smaller the difference between the output and supervised data, the larger the PSNR. Thus, the larger the PSNR, the better the output.

$$PSNR = 10 \log_{10} \left( \frac{1}{MSE} \right) \quad (2)$$

Using actual data, an effect of super-resolution of myoelectric signals was evaluated in an experiment. Experimental results of super-resolution learning on test data are shown in Fig. 7. Fig. 7 shows the variation of PSNR with the number of epochs. As with deep learning in general, PSNR increases as the epoch increases. This indicates that the accuracy of super-resolution improved without overfitting.

### C. Experiment of Hand Motion Estimation

Here we examine the effectiveness of hand motion estimation using super-resolution. In this experiment, a 4-channel input, a 16-channel input, and a 4-channel input increased to 16 channels by super-resolution are compared. Fig. 8 compares the experimental results for each of these inputs. As noted in previous studies, 16 channels performed better than 4 channels on all evaluation items. This means that the accuracy of hand motion estimation is improved when the number of input EMG signals is large. The proposed method using super-resolution achieved better results than the 4-channel method in all evaluation items. This is because the proposed method increases the number of inputs from 4 channels to 16 channels. However, the proposed method was not able to reach 16 channels in all indicators. It is a reasonable result because the proposed method increases the number of channels to 16 with super-resolution, but it is only an estimated value.

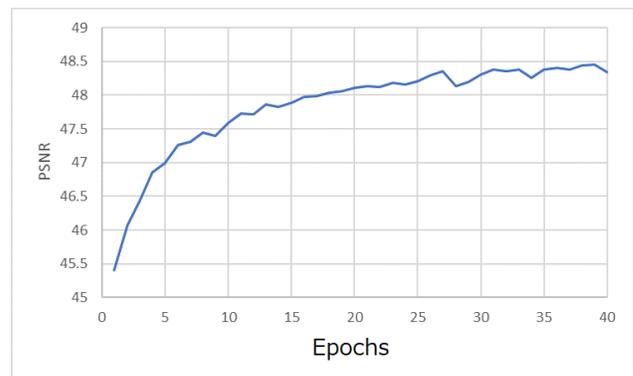

Fig. 7. PSNR for Number of Epochs.

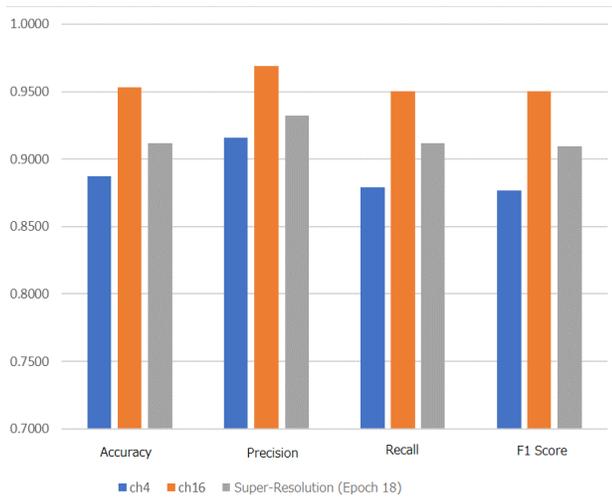

Fig. 8. Results of Hand Motion Estimation.

Based on the above experimental results, the proposed method is able to increase the accuracy of hand motion estimation even though the input is the same as the 4-channel method. This means that the knowledge acquired by the learning of super-resolution increased the accuracy of the estimation. Previous methods have increased accuracy by increasing the number of sensor inputs, however, the proposed method shows that accuracy can be increased without increasing the number of sensors.

Fig. 9 to 11 show the confusion matrices of the 4-channel, 16-channel, and proposed methods, respectively. Fig. 10 shows that the 4-channel input had more misclassifications than the other methods. For example, more of the correct label 8's were estimated as label 9, and more of the correct label 10's were estimated as label 9. The proposed method was able to classify many samples more accurately, although not as accurately as the 16-channel method. Labels 8, 9, and 10 are particularly misclassified, because these motions are close muscular motions.

The time required for hand motion estimation and super-resolution for 16907 EMGs, the test data, was 750 and 398 seconds, respectively. The time per EMG was  $(750 + 398) / 16907 \approx 0.0680$  seconds. Since the proposed method is designed to estimate hand motions every 0.25 seconds, the estimation speed is considered fast enough for practical use.

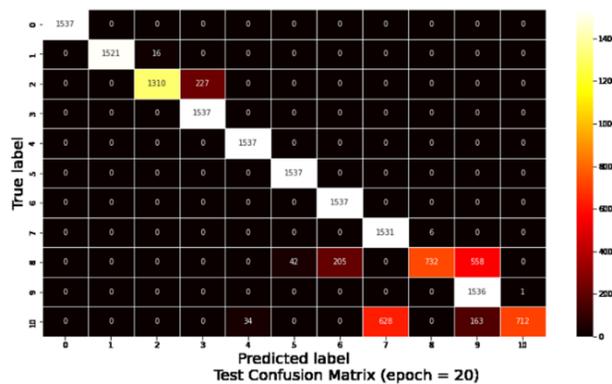

Fig. 9. Confusion Matrix of 4 Channel Input.

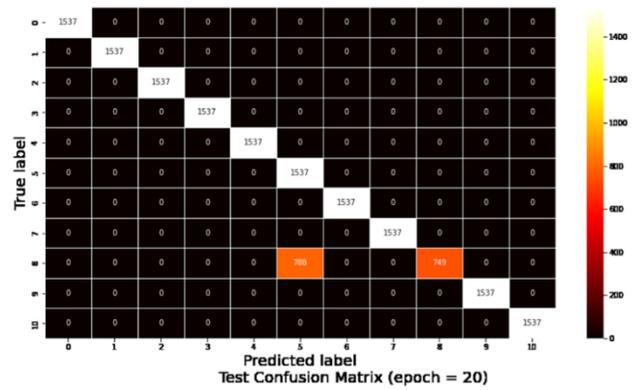

Fig. 10. Confusion Matrix of 16 Channel Input.

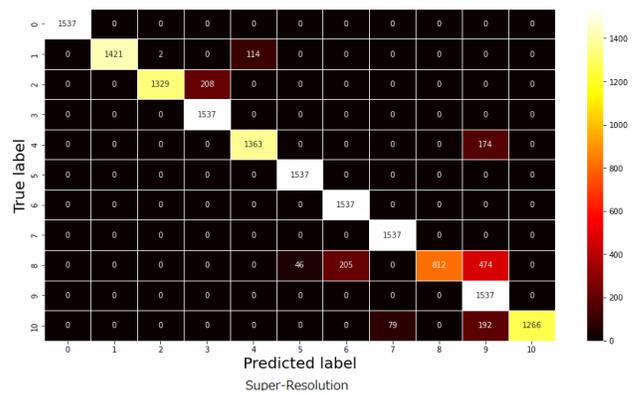

Fig. 11. Confusion Matrix of the Proposed Method.

V. CONCLUSION

In this paper, we proposed a method for estimating hand motions using super-resolution of multi-point surface electromyograms. The method uses a super-resolution network to obtain the relationship between EMGs with a small number of electrodes and those with a larger number of electrodes and estimates unknown high-resolution EMGs from new low-resolution EMGs. By inputting the estimated high-resolution EMG to the hand motion estimation network, hand motion estimation can be performed with fewer electrodes without loss of accuracy.

Hand motion estimation using super-resolution of multi-point surface EMG showed higher performance than hand motion estimation using four channels. This shows that super-resolution of electromyograms is available. This method may be used to reduce the number of electrodes in other EMG techniques as well. The accuracy was lower for gestures with the same moving muscles compared to other gestures. In this paper, the accuracy of super-resolution was evaluated using PSNR, which is used in super-resolution of general images. However, there was no relationship between the PSNR value and the results of hand motion estimation using electromyogram after super-resolution.

A future work is to reduce the number of samples per unit time of the input in super-resolution. Because this method focused on reducing the number of electrodes, the number of samples per unit time of the input was the same as that of the output. If the number of samples per unit time can be reduced,

the devices used for EMG acquisition such as microcontroller and amplifier would become less expensive.

# IoTCID: A Dynamic Detection Technology for Command Injection Vulnerabilities in IoT Devices

Hao Chen<sup>1</sup>, Jinxin Ma<sup>2</sup>, Baojiang Cui<sup>3</sup>, Junsong Fu<sup>4</sup>

School of Cyberspace Security, Beijing University of Posts and Telecommunications, Beijing, China<sup>1,3,4</sup>  
China Information Technology Security Evaluation Center, Beijing, China<sup>2</sup>

**Abstract**—The pervasiveness of IoT devices has brought us convenience as well as the risks of security vulnerabilities. However, traditional device vulnerability detection methods cannot efficiently detect command injection vulnerabilities due to heavy execution overheads or false positives and false negatives. Therefore, we propose a novel dynamic detection solution, IoTCID. First, it generates constrained models by parsing the front-end files of the IoT device, and a static binary analysis is performed towards the back-end programs to locate the interface processing function. Then, it utilizes a fuzzing method based on the feedback from Distance Function, which selects high-quality samples through various scheduling strategies. Finally, with the help of the probe code, it compares the parameter of potential risk functions with samples to confirm the command injection vulnerabilities. We implement a prototype of IoTCID and evaluate it on real-world IoT devices from three vendors and confirm six vulnerabilities. It shows that IoTCID are effective in discovering command injection vulnerabilities in IoT devices.

**Keywords**—Firmware vulnerability mining; command injection; dynamic detection

## I. INTRODUCTION

With the development of the Internet and information technologies, IoT devices are extensively used in our life [1], and attacks against IoT devices have been emerged in recent years [2]. The reason is that web interfaces are usually exposed to users to manage the devices, which contain exploitable vulnerabilities.

There are some unique features of the threats caused by vulnerabilities in IoT devices compared to which in PCs or in servers. For example, most existing security mechanism or antivirus products are not available in IoT devices due to the limit of cost and power of IoT devices, which makes it easier to perform further exploits towards certain vulnerabilities [3]. Moreover, one vulnerability may have huge influence on thousands of devices, for the devices from the same vendor usually have similar firmware [4].

Command Injection Vulnerability is one of the most effective and commonest vulnerabilities in IoT devices [14]. Attackers can exploit the target IoT devices through this vulnerability by injecting additional commands into the program. Moreover, the system commands provided by attackers are usually executed with the highest authority in IoT devices.

However, due to the complexity and the specificity of the IoT devices, existing tools cannot effectively detect Command

Injection Vulnerability. For example, Dynamic analysis tools, like fuzzing [5, 7, 9], requires valid communication formats to generate fuzzing samples and can only reach a small portion of all the provided interfaces while static analysis tools, like KARONTE [11] and SaTC [12], cannot efficiently generate interaction paradigms between the front-end files and back-end programs, leading to a lot of false positives which requires further manual check.

Therefore, to ensure the safety and reliability of IoT devices, it is urgent to develop security analysis technology towards IoT devices. In this paper, focusing on Command Injection Vulnerability, we propose a novel dynamic detection technology, IoTCID, to effectively detect command injection vulnerabilities in IoT devices.

Inspired by SaTC [12], in order to generate samples in valid communication formats and to cover interfaces as many as we can, IoTCID first performs a logic analysis to the front-end files which interact with the back-end programs to generate constrained models. It utilizes a novel scheduling strategies based on Distance Function to improve the efficiency of command injection vulnerability detection. We design and implement a prototype of IoTCID and evaluate its efficacy through a set of experiments based on real-world IoT devices and confirm six command injection vulnerabilities. It shows that IoTCID is effective in discovering command injection vulnerabilities in IoT devices.

In summary, our major contributions are as follows:

- 1) We present a dynamic detection technique towards Command Injection Vulnerabilities based on the logic analysis to front-end files and intelligent feedbacks from the back-end programs.
- 2) We design and implement a constrained model generation technique based on the logic analysis to front-end files, providing a valid format for the generation of fuzzing samples.
- 3) We design and implement scheduling strategies based on Distance Function feedback to concentrate resources on the fuzzing samples that may cover risk functions in back-end programs.

The rest of the paper is organized as follows. We first summarize related work in recent years in Section II. We then present an overview of IoTCID, and give a detailed description on design and implementation of each component of IoTCID in Section III. We demonstrate the efficacy of IoTCID through a

set of experiments and present a vulnerability detection case in Section IV. At last, Section V concludes this paper and show the future work of IoTCID.

## II. RELATED WORK

In recent security research on IoT devices, fuzzing is the most discussed technique. The general process of fuzzing is to detect the state of the testing program and guide the generation of fuzzing samples with provided feedbacks.

Chen J et al. propose and implement a generation-based firmware fuzzing method, IoTFuzzer[5], which detects vulnerabilities related to memory in IoT devices by analyzing the corresponding Android application. In view of the shortcomings of IoTFuzzer, DIANE[6] proposed a new method for generating fuzzing samples, which is based on the target fuzzing points in the APP that are located before data conversion and after input validation. However, both IoTFuzzer and DIANE conduct black-box fuzzing directly on real devices, limited to providing guidance and feedbacks based on the testing samples.

Zhang Y et al. propose SRFuzzer[7], which mutates the collected network traffic and detects the state of the fuzzing process according to the response-based monitor, routing-based monitor, and signal-based monitor. However, it would be difficult for SRFuzzer to cover the corresponding interface functions without the network traffic in advance.

FirmFuzz[8] runs the target firmware through simulation and collects payloads of different vulnerabilities for fuzzing tests. Zheng Y et al. propose FIRM-AFL[9] to enhance process simulation to fuzz the IoT firmware. However, these methods are all subject to valid inputs.

Although command injection is a common and powerful threat, related detection is less discussed in IoT security research.

Commix[10] is a tool that can automatically detect and exploit command injection vulnerability towards web applications. It sends a data packet attached with a command injection attack vector, and compares the response of the web application with the expected result to determine whether there is a command injection vulnerability. However, Commix needs to collect network traffic in advance, and it makes determine according to the response of the target. When the network delay cannot be guaranteed, there will be a certain false positive, which cannot intuitively reflect the location of the command injection vulnerability.

KARONTE[11], a static analysis framework for embedded firmware, which can detect vulnerabilities caused by its communication by modeling and tracking the interactions between binary programs. However, KARONTE cannot effectively detect command injection vulnerabilities because it does not track the data flow from input entry points to system-like functions. Aiming at the shortcomings of KARONTE, Chen L et al. propose a novel static taint technique, SaTC[12],

to effectively detect security vulnerabilities in web services provided by embedded devices. It mainly locates the communication process between front-end files and back-end programs based on the strings used in the front-end web interface, and applies targeted data flow analysis to accurately detect possible vulnerabilities. However, SaTC uses a clustering algorithm to extract the strings interacting between front-end files and back-end programs, and cannot generate an effective input model for the web interface. Besides, it requires additional manual analysis to confirm the result and eliminate false positives.

In a word, it remains problems in the use of the above detection technologies towards IoT devices. For example, the fuzzing detection technology mainly focuses on memory corruption vulnerabilities, and are subject to the input of valid format while static analysis tools may have low detection efficiency due to excessive analysis. Therefore, aiming at the command injection vulnerability of IoT devices, based on the logic analysis to front-end files and intelligent feedbacks, we propose a dynamic detection model IoTCID, which makes up for the shortcomings of the current command injection detection technology for IoT devices and improves the efficiency and accuracy of command injection vulnerability detection.

## III. METHODOLOGY

Generally, IoT devices provide user management interfaces, which are mainly composed of front-end files and back-end programs. Front-end files include HTML, Javascript while back-end programs are generally executable binary files. IoTCID is proposed based on the workflow of the front-end files and back-end programs, as Fig. 1 provides the overview of IoTCID. It first generates constrained models by parsing the front-end files of the IoT device, and then performs binary static analysis on the back-end programs to locate the interface processing function. Then, IoTCID selects high-quality fuzzing samples according to various scheduling strategies based on the feedback from Distance Function. The selected samples are given more mutation time slices and priorities, which makes concentration on the interface process functions that may exist command injection vulnerabilities. Finally, IoTCID confirms the command injection vulnerabilities combined with the fuzzing samples and the parameters of risk functions detected by the probe code.

### A. Constrained Model Generation

We propose a technology of constrained model generation based on the logic analysis to front-end files. Through syntax analysis, it generates a corresponding abstract syntax tree according to the front-end file, and extracts the variable reference chains of the abstract syntax tree as well as the variables during the interaction process between the front-end files and the back-end programs. The generated models are used as the format of the fuzzing samples, mainly including the URL, the request type, and the request keywords.

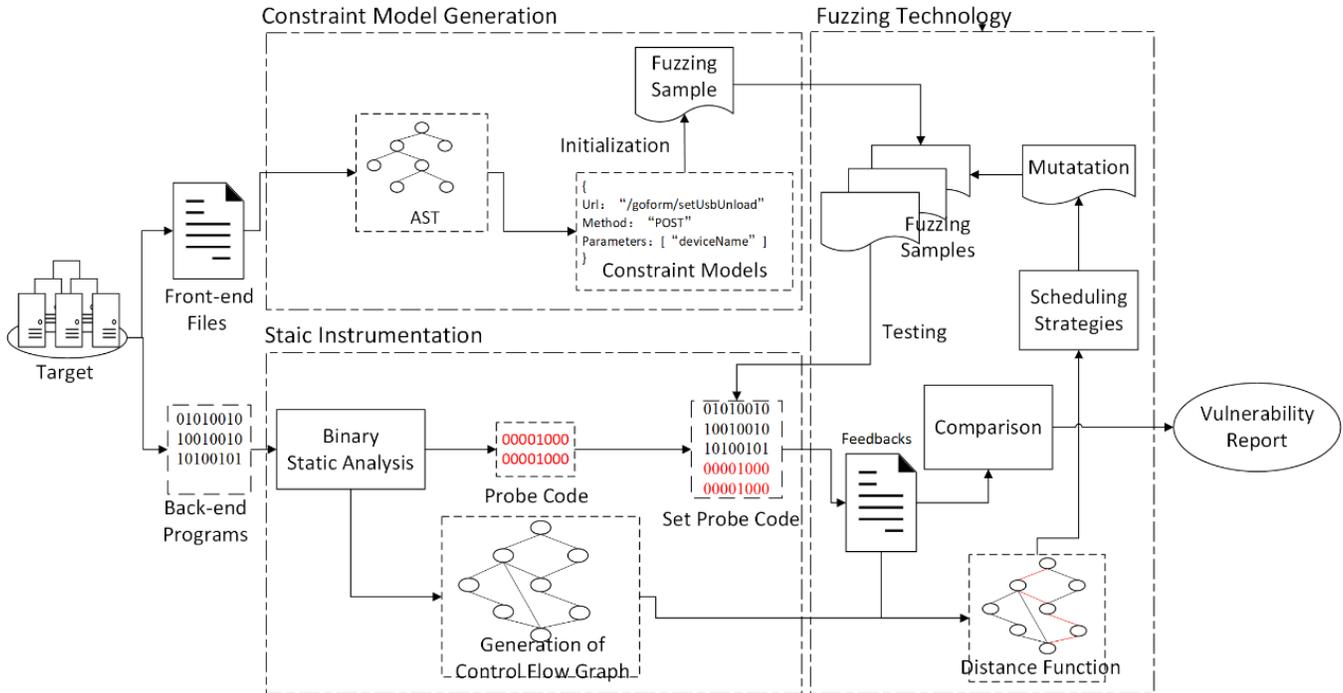

Fig. 1. Structure of IoTCID.

Algorithm 1 shows the analysis process of the function call and variable reference chain of the front-end files, where funcNode is the result of syntax analysis and varName is the parameter of the funcNode. During the analysis, there are two types of function parameters: one of which is directly passed in text value while the other is indirectly passed in variable name. For the direct one, IoTCID uses the regular expression to match and obtain the text value of the parameter. For the indirect one, the text value can be extracted through a recursive method in related function scope.

**Algorithm 1:** Analysis of Parameters during Interaction

```
Input: funcNode && varNames  
Output: Constrained models  
1. function GET_VALUE(funcNode, varName)  
2.   param ← []  
3.   if varName.type == "Literal" then  
4.     param.append(ANALYSIS(  
5.       funcNode.expression, varName));  
6.   return param  
7.   else  
8.     funcNode = FIND_PARENT(funcNode);  
9.     if funcNode == "" then  
10.      return []  
11.    end if  
12.    GET_VALUE (funcNode, varName);  
13.  end if  
14. end function
```

**B. Static Instrumentation**

IoTCID obtains the information that may trigger the command injection vulnerability function in the back-end programs through binary static analysis, and sets the probe code to obtain the performing state of the fuzzing samples. We implement a static analysis technique for back-end binary programs. It obtains information about risk functions such as

execve and system which may trigger command injection vulnerabilities. Therefore, we can record the performing paths of fuzzing samples based on binary static instrumentation technology and control flow analysis of the back-end programs.

1) *Acquisition of risk function:* The purpose of acquiring the potential dangerous function is to locate the interface in the back-end programs, which processes the requests from the front-end files according to the URL extracted in Part A, Section III, and construct its control. flow graph. We further obtain the necessary data by analyzing the header of back-end binary programs, the entry point and relevant segments. Finally, we use Capstone [13] to disassemble the code to obtain the information of the target function and related code blocks as well as building a control flow graph.

2) *Generation of probe code:* The probe code collects the performing state of fuzzing samples during the execution process and provides feedbacks to the monitor system. Based on the control flow graph of the risk functions, we set the probe code to provide information feedback of the basic blocks, including the address information and the parameters of the risk functions. The trampoline mechanism is used during the generation of probe code to make association between the set point and the risk functions, and provides the necessary environment preparation for the normal execution of the original program.

**C. Fuzzing Technology**

We apply distance function to the fuzzing technology to select high-quality fuzzing samples according to various scheduling strategies. While IoTCID is sending fuzzing samples to the back-end program for detecting command injected vulnerability, it selects high-quality one and gives them

more mutation time and priorities based on the result of measuring the feedbacks of fuzzing samples by distance function, which concentrates resources on the fuzzing samples that may cover risk functions in back-end programs, improving the efficiency of command injection vulnerability detection. Finally, combined with the parameters of risk functions and fuzzing samples, IoTCID makes checks on whether there is a suspicious point of command injection vulnerability. Obviously, the distance function and the scheduling strategies are the cores of the fuzzing technology.

1) *Distance function*: The weight of basic blocks, the edge vector of basic blocks and the distance of samples are three components of the distance function. The weight of basic blocks and the edge vector of basic blocks are calculated in the process of binary static analysis while the distance of samples calculation is calculated in the fuzzing process. Table I lists the variables and their meanings of the distance function.

We define the count of successors of Basic Block B which contain the risk functions as the weight of basic block B, as Equation (1) shows.

$$Weight_B = \begin{cases} \text{Sum}(B, \text{Func}), & \text{Func} \notin B \\ W_{Max}, & \text{Func} \in B \end{cases} \quad (1)$$

In Equation (1),  $Weight_B$  is the weight of Basic Block B while  $\text{Sum}()$  is a function that calculates the count of successors of basic block b which contain risk functions. Moreover, if the risk function is in basic block B,  $Weight_B$  is recorded as  $W_{Max}$ . After calculating the weight of related basic blocks, we infer the edge from Basic Block A to Basic Block B while Basic Block A is the predecessor of Basic Block B.

$$|Edge_{a,b}| = Weight_b \quad (2)$$

During the process of fuzzing, combined with the probe code we set before, IoTCID obtains the execution path of the fuzzing sample and calculates the function distance according to the control flow graph to evaluate the fuzzing sample with  $Score_{test}$ .

$$Score_{test} = \frac{\sum |Edge_{a,b}|}{Count_{test}} \quad (3)$$

2) *Scheduling strategy*: Therefore, towards one specific interface, we implement our scheduling strategy according to the distance function. It can be inferred that a fuzzing sample with higher  $Score_{test}$  is more likely to trigger the risk functions, so that the mutation resources should be concentrated on these high-quality fuzzing samples, improving the efficiency of command injection vulnerability detection.

Moreover, the following situations should be paid more attention on the basis of experience and practical situations. Details are shown in the control flow graph in Fig. 2.

Case 1. Supposed there is a risk function called in the basic block Target. The execution path of one fuzzing sample shows like Start->Basic Block 5->Basic Block 5->...Target-> End, where there is a loop in the path. Since the fuzzing sample can eventually traverse the basic block Target, we should avoid double counting when calculating  $Count_{test}$  and  $\sum |Edge_{a,b}|$ .

TABLE I. VARIABLES AND MEANINGS IN DISTANCE FUNCTION

Symbol	Name	Meaning
$Weight_B$	The weight of a basic block	The importance of Basic Block B in the control flow
$\overrightarrow{Edge}_{a,b}$	The edge vector of basic blocks	The edge vector from Basic Block A to Basic Block B while Basic Block A is the predecessor of Basic Block B.
$Count_{test}$	The count of edges	The count of edges traversed by the sample before triggering the target basic block
$Score_{test}$	The score of a sample	The count of valid edges traversed by the sample

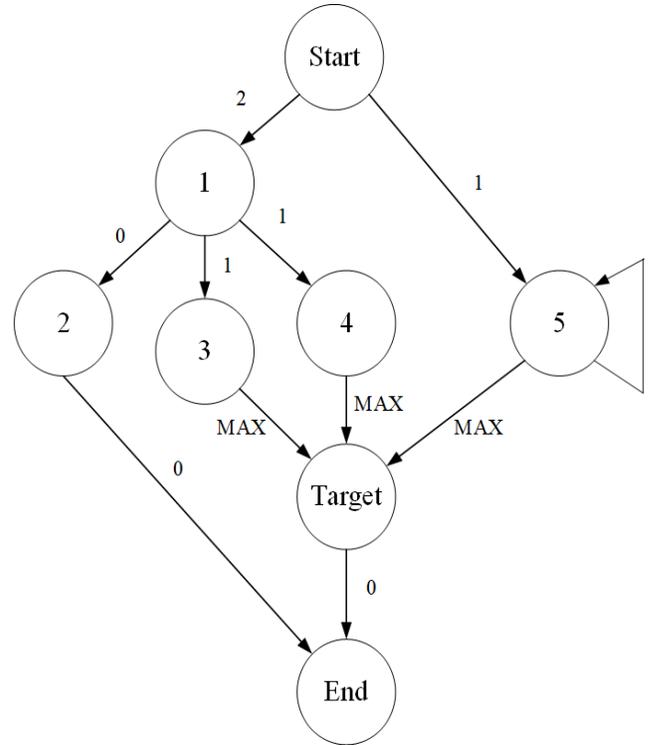

Fig. 2. The Control Flow Graph.

Case 2. Another case is that there are two fuzzing samples respectively travel through basic block 3 and basic block, and both eventually reach the basic block Target. We will find the scores of the two fuzzing samples are the same based on the above theory. However, we find there is a string concatenation functions such as `sprintf` and `strcat`, and the fuzzing sample which reaches basic block 4 should be given a higher priority under this circumstance. The reason is that the cause of command injection vulnerabilities generally originate from the back-end program that concatenates the user's input into a string which further directly works as a parameter of the risk function [14].

Considering the above situations, we propose Algorithm 2 to evaluate the quality of fuzzing samples where `sampleInfo` is the fuzzing samples and `funcGraph` is the control flow graph of function. It first traverses the basic blocks of the interfaces in the back-end program in deep first search (DFS), gathering necessary information, and then calculates  $Score_{test}$  of fuzzing samples based on their feedbacks.

---

**Algorithm 2:** Assessment of Fuzzing Samples

---

**Input:** sampleInfo && funcGraph  
**Output:** Scores of Fuzzing Samples

1. **function** ACCESSMENT(sampleInfo, funcGraph)
2. infoGraph  $\leftarrow$  DFSTraverse(funcGraph)
3. totalEdges  $\leftarrow$  makeEdges(  
sampleInfo.executionBlocks)
4. edgeCount  $\leftarrow$  0
5. edgeTotal  $\leftarrow$  0
6. **for** edge in totalEdges **do**
7.   **if** infoGraph.edge. $\overrightarrow{\text{Edge}}$   $\neq$  0 and  
sampleInfo.edge.flag  $\neq$  1 **then**
8.     edgeTotal += infoGraph.edge. $\overrightarrow{\text{Edge}}$ ;
9.     edgeCount += 1;
10.    sampleInfo.edge.flag = 1;
11.    **end if**
12. **end for**
13. **if** edgeTotal  $\geq$  MAX and  
IMPORTANT\_BLOCKS(  
sampleInfo.executionBlocks) **then**
14.    SET\_PRIORITY(sampleInfo)
15. **end if**
16. Score  $\leftarrow$  CALCULATE(  
sampleInfo, edgeTotal, edgeCount)
17. **return** Score
18. **end function**

---

Finally, according to  $Score_{test}$  of fuzzing samples, we select high-quality fuzzing samples, given higher priority and more mutation time. We further select the samples which have reached the basic block Target and confirm whether there is a command injection vulnerability by comparing its data to the parameter of risk function.

#### IV. RESULTS AND DISCUSSION

The prototype system of IoTCID consists of three subsystems including the constrained model generation subsystem, the binary static analysis subsystem, and the fuzzing subsystem. The constrained model generation subsystem implemented based on the standard HTML parsing library BeautifulSoup [15] and the standard Javascript parsing library Esprima [16] uses Algorithm 1 to extract the variables during the interaction between front-end files and back-end programs and generate the constrained models of fuzzing samples. The binary static analysis subsystem implemented based on Capstone [13] first obtains the disassembly code of back-end programs, and then establishes the control flow graph as well as sets the probe code using the trampoline mechanism. On the basis of the above two subsystems, the fuzzing subsystem initializes the fuzzing samples by LibFuzzer [17], and performs fuzzing test according to our scheduling strategies.

##### A. Preparation

We evaluate IoTCID on real-world IoT devices from three vendors, including six routers on two architectures, which are commonly used in our daily life. The target firmware can be obtained from the official website or extracted from the device based on binwalk [18].

In this paper, we design two experiments to prove the efficiency of IoTCID, one of which is the assessment of front-end files analysis while the other is the assessment of fuzzing test. Besides, we compared our tool with SaTC, the state-of-the-art static bug-hunter for IoT devices, which locates the strings

between front-end files and back-end programs based on the interaction and applies data flow analysis to detect vulnerabilities. We perform our experiments on Ubuntu 18.04LTS 64-bit operating system, with Intel Core i5-6300HQ @ 2.30GHz and 16.0 GB RAM.

##### B. Result and Discussion

Table II lists the result of the instrumentation information of target IoT devices, where  $T_1$  represents the average response time of IoT devices under normal working state while  $T_2$  represents the average response time after the static instrumentation. We get the final result after performing multiple tests to reduce the impact of fluctuations caused by the test environment. It shows that the setting of the probe codes only increases the response time by about 25%, which is an acceptable expense for the next fuzzing test.

Table III lists the analysis result of front-end files towards our target IoT devices. Among them, tURL means the total number of URL interfaces that have data interaction between the front-end files and the back-end programs. eURL means the total number of URL interfaces extracted from the front-end file by the tools. gMod means the total number of the generated constrained models. g% means the accuracy rate of the generated constrained models.

According to Table III, it can be seen according to vURL. We define TP rate (True Positive rate) and FP rate (False Positive rate) for further explanation. The TP rate means the ratio of the correct results to the actual total, which can be inferred by vURL/tURL while the FP rate means the ratio of the incorrect results to the actual total, which can be inferred by (eURL-vURL)/tURL.

As shown in the left side of Fig. 3, it can be found that, except for the X12 series, the TP rates of IoTCID and SaTC are achieving an appreciable rate, which means that both IoTCID and SaTC have correctly extracted most of the URL interfaces provided by the target IoT devices and IoTCID does a better job.

However, the FP rates are various as shown in the right side of Fig. 3. Besides a few identification errors, the main reason of the difference is that IoTCID extracts URLs in the front-end files by analyzing the calling procedures which have data interaction with the back-end programs, while SaTC extracts URLs through regular expressions and clustering algorithms directly, which causes a higher FP rate. For instance, certain URL interfaces that only provide the status of devices should not be presumed to be risks and will not be extracted by IoTCID.

TABLE II. RESULT OF STATIC INSTRUMENTATION

Vendor	Device Series	T1(ms)	T2(ms)
Tenda	AC9	3.87	4.66
	AX12	3.47	4.28
D-Link	D605L	3.94	4.64
	D816	3.81	4.68
L-Blink	X12	4.32	5.53
	X22	4.38	5.49

TABLE III. ANALYSIS RESULT OF FRONT-END FILES

Vendor	Series	tURL	IoTCID				SaTC	
			eURL	vURL	gMod	g%	eURL	vURL
Tenda	AC9	106	94	88	100	87.00	123	86
	AX12	98	102	72	108	87.04	130	71
D-Link	D605L	64	58	53	60	95.00	60	52
	D816	66	57	47	60	91.67	50	40
L-Blink	X12	114	117	101	127	74.80	25	16
	X22	114	117	101	127	74.80	25	16

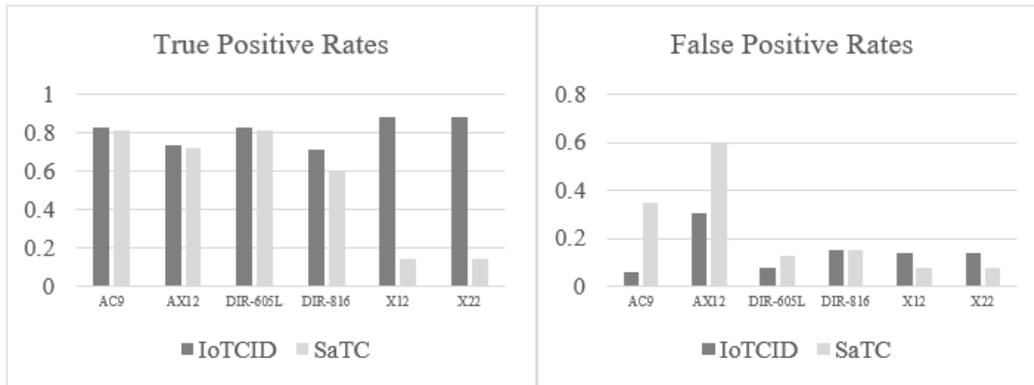

Fig. 3. TP Rates and FP Rates Comparison.

Moreover, IoTCID generates constrained models related to the extracted URLs based on the abstract syntax tree, and has a high accuracy rate in g%. In this experiment, it shows that IoTCID has a better performance in the analysis of the interactions between the front-end files and the back-end programs providing a foundation for the following command injection vulnerability detection.

As Table IV shows, the IoTCID completes all the command injection vulnerability detections towards the target IoT devices and confirms six command injection vulnerabilities, while SaTC only completes a few of them. The reason is that the implementation of SaTC is developed based on angr [19], which is limited in supporting MIPS architecture programs, and prone to cause crash during data flow analysis while IoTCID is designed based on the generation of the constrained models, and confirms whether there is a command injection vulnerability by comparing the fuzzing samples to the feedbacks of the probe code, representing a high degree of support for the detection of multi-architecture programs. Moreover, SaTC only raises alerts after completing the detection and requires further manual analysis to confirm whether the alert is reliable and the command injection vulnerability is controllable, existing certain false positives and costing additional manual analysis time. However, the detection result of IoTCID is based on the feedbacks of the executing program sent by the probe code, so it requires no more manual analysis and the accuracy of the results is guaranteed.

From the above experiments, compared with the existing command injection vulnerability detection tool SaTC towards IoT devices, IoTCID can effectively extract the constrained

models based on the analysis of the interaction between the front-end files and the back-end programs, and improve the accuracy and efficiency of detecting the command injection vulnerabilities through various scheduling strategies.

### C. Case Analysis

Taking CVE-2018-14558 as an example, when a user manages an external device, the related front-end file will generate a request (Line 5 in status\_usb.js, up side of Fig. 4) combined with the device name and send it to the back-end programs for parsing. The back-end program processes the request through the function "formsetUsbUnload", and generates a string containing the device name as the parameter of the system call. (Line 5 and 6 in httpd, low side of Fig. 4). Because the function "formsetUsbUnload" does not verify the validity of the parameter "deviceName", there exists a typical command injection vulnerability in the function "doSystemCmd", which can be exploited by attackers to execute arbitrary commands.

TABLE IV. RESULT OF VULNERABILITY DETECTION

Vendor	Series	IDs	Time (min)	
			IoTCID	SaTC
Tenda	AC9	CVE-2018-14558	4:40h	-
	AC*	CNNVD-202109-1174	4:26h	3:52h

**Abstract**—Brain-Computer Interface (BCI) can recognise the thoughts of a human through various electrophysiological signals. Electrodes (sensors) placed on the scalp are used to detect these signals, or by using electrodes implanted inside the brain. Usually, BCI can detect brain activity through different neuroimage methods, but the most preferred is Electroencephalography (EEG) because it is a non-invasive and non-critical method. BCI systems applications are very helpful in restoring functionalities to people suffering from disabilities due to different reasons. In this study, a novel brain-to-text BCI system is presented to predict the word that the subject is thinking. This brain-to-text can assist mute people or those who cannot communicate with others due to different diseases to restore some of their abilities to interact with the surrounding environment and express themselves. In addition, brain-to-text may be used in different control or entertainment applications. EMOTIV™ Insight headset has been used to collect EEG signals from the subject's brain. Feature extraction of EEG signals for BCI systems is very important to classification performance. Statistical-based feature extraction has been used in this system to extract valuable features to be used for classification. The datasets are sentences involving some commonly used words in English and Romanian languages. The results of the English language elucidated that K-Nearest neighbour (KNN) has a prediction accuracy of 86.7%, 86.1% for Support Vector Machine (SVM), and 79.2% for Linear discriminant analysis (LDA), while the Romanian language has a prediction accuracy of 96.1%, 97.1%, and 94.8% for SVM, LDA, and KNN respectively. This system is a step forward in developing advanced brain-to-text BCI prediction systems.

**Keywords**—Brain-to-text; Brain-Computer Interface (BCI); Electroencephalography (EEG); Natural Language Processing (NLP); English language; Romanian language

## I. INTRODUCTION

Communication between humans and machines is a desired concept for a long time. It was the aim of the Brain-Computer Interface (BCI). BCI can convert phonemes, binary responses, letters, and even words from brain activity [1]. BCIs can help people who have lost their ability to speak or move to restore communication with different body organs. Recently, the main coverage of BCI research is focused on restoring motor skills like, grasping, pointing, typing with a computer cursor [2], or choosing from a list of options. Other

systems may use “steady-state evoked potentials” or “Event-Related Potentials (ERPs)” to spell text out [3]. A BCI system is a collection of hardware devices and software that uses various techniques to record the brain's activity [4]. The data collected through experiments in laboratory conditions give the necessary information about the computation of neural in human beings. The response of neurons may differ between experimental and behaving in natural conditions. Thus, developing powerful decoding algorithms that can deal with the difficulties of naturalistic behaviour is important in developing real-life applications of BCIs [5].

Two approaches to language neural decoding have been used in this field: invasive decoding, based on invasive brain recording methods like Electrocorticography (ECoG); and non-invasive decoding which depends on neuroimaging technologies like EEG. Language decoding from EEG brain activity is significant in developing commonly applicable BCI systems. This technology can help people who are unable to communicate or do daily activities because of severe neuromuscular diseases or disorders. It also offers a great opportunity for neuroscientists to study brain mechanisms or activity [6].

Many years ago, researchers have predicted whether humans and machines can communicate depending on natural speech-related brain activity. In recent years, scientific research has proposed that it is possible to recognise speech from the brain's neural signals like acoustic features or one of some separate words. Expressed words can be decoded from spoken speech through brain waves ECoG recordings [5], EEG recordings, etc.

Feature extraction and classification are important procedures in each BCI model [7]. Features are extracted from a signal obtained from electrodes. Features are distinguished in frequency, time, and spatial domain. Some features of EEG may have great elective power to observe different patterns of EEG. To design and implement a well-trained model, some features with high discriminating ability are required [8].

The performance of the BCI system is mainly relying on the vector's size of the feature, which is acquired from multiple channels. In the classification of the mental tasks, the training samples' availability of features is minimal. Usually,

feature selection is used to improve the classification of mental tasks by eliminating unrelated and unnecessary features [9].

The paper describes a proposed brain-to-text system that is a simple, easy-to-implement, and cost-effective BCI system that aims to help mute or disabled people to communicate with others and electronic devices. The system may also be used for controlling purposes. The system can recognise English and Romanian languages; therefore, it is targeted individuals who can understand these languages. Considering this issue, the next sections practically describe how the brain thoughts can be translated into words starting from the literature review, the method and the techniques used in the study, and the results.

This paper is organised as follows: Section II of this study presents the literature review including background theory and related works. Section III presents the method of the research in detail. Section IV presents results and discussion, and Section V presents the conclusion and future work.

## II. LITERATURE REVIEW

### A. Background Theory

The brain of humans contains billions of connected neurons. The activity of neurons is varying according to different thoughts, where every thought generates a unique electric brain signal [10]. Brain signals can be detected using different invasive and non-invasive techniques [11]. Non-invasive techniques especially EEG, are widely used in BCI systems due to their ease of use and non-risk since it does not require a surgical invasion [12]. EEG has related to some challenges like low spatial resolution compared to invasive techniques, but it has a good temporal resolution, and may not detect a good signal due to the folding of the cortex or scalp-to-cortex distance [13]. The techniques of signal processing are required to remove the artefacts and noise from the raw EEG signals. This is performed by applying digital filters [4]. In recent years, these challenges have been highly reduced due to the development of hardware and smart software related to BCI research. The EEG signals of brain activity are detected using electrodes that measure the changes in voltage on the scalp [11].

EEG contains important data that will convert into useful information regarding responses to brain stimuli. The type of emotion and the accuracy level of the signal can be identified from the pattern of the brain waveforms. The processing of these signals can allow the control of external devices like the computer cursor, robotic arm, or wheelchairs. It also lets disabled people who have lost their ability to move or talk restore such abilities or express their emotions and thoughts. The signals of the brain can be analysed through three different steps:

- Signal Acquisition.
- Signal processing.
- Controlling.

Pre-processing step is important to convert the raw data into a useful and efficient format [14]. The obtained signal is

processed to eliminate the artefacts, noise, etc. which could improve the resulting signal. The next step is to extract features from the signal, where the feature is a special measure from a part of a signal. In feature extraction, the most important features required for classification will be extracted.

Feature extraction of EEG signals is one of the important aspects related to the system of BCI due to its important task of obtaining the correct performance of the classification stage [15] because of the complex processes inside the brain [8]. EEG signals are non-stationary, while their spectrum varies with time. These signals need different feature extraction techniques [15].

In brain signals decoding, signal processing comprises two important steps: feature extraction and feature classification [16]. The process of EEG feature extraction involving generate discriminative data features from channels that can increase the variance difference among classes [17]. The huge number of input data increases the execution time and complexity of the system. Obtaining informative features will enhance and increase the accuracy of the classification [7].

The algorithms of feature extraction must handle the signal source, which is usually complex and noisy, and detect interesting features [8]. These algorithms are used to detect the features that are strongly connected with the intent of the subject. The optimal feature set is transferred directly to the classification algorithm that associates the feature with a task to be accomplished [17]. The success of the BCI system's classification is associated with the accuracy, efficiency, and proper selection of feature extraction, thus, improving the accuracy and efficiency of the system [18]. Feature extraction depends on temporal-spatial analysis and/or time-frequency. Some of the techniques used are wavelet transform, autoregressive (AR) models, Fourier transforms (FT), and statistical properties of the signal [8].

The next step is to translate the extracted features into commands to control an external device or to do different mental tasks [8].

The final stage is the classification process which may be solved by adaptive algorithms, linear analysis, non-linear analysis, neural networks, fuzzy techniques, etc. [10]. Classification algorithms used in this work are "K-Nearest Neighbour (KNN), Support Vector Machine (SVM), and Linear Discriminant Analyser (LDA)".

### B. Related Works

The following related works introduce several solutions to the issue of BCI brain-to-text which introduced some forms of a utility function that deals with text aspects.

Shuxian Zou et al. [6] have proposed two decoding tasks, the first one is a word prediction task given a context and brain image. The second task is to generate a direct text from a given prefix and a brain image. To implement these tasks, they have proposed an approach that uses a powerful pre-trained encoder-decoder model. The model reaches 7.95% and 18.2% top1 accuracy for more than two thousand words of vocabulary on average for all task participants.

Christian Herff et al. [3], have implemented a brain-to-text system that forms single phones using “Automatic Speech Recognition (ASR)” by converting brain signals into the equivalent text representation during speaking. The results reveal that the proposed system can carry out phone error rates below 50% and word error rates as low as 25%.

G. NJayabhavani et al. [19], have proposed a BCI system to improve the typing of messages by building a mechanized system using a speller-based mechanized messenger. The smartphone, which contains a built-in speller application is connected to an EEG headset. They used wireless EEG neuroheadset-based P300 ERP for the realistic execution of the mechanized messenger. The smartphone application will be activated when a user wants to transmit a text. The obtained text is transferred after processing by the smartphone spell checker. The proposed system will let a user to text while performing other activities. In addition, the time required for typing will be much reduced. The accuracy of the system is about 98% in 16 seconds after target selection.

James W. Minett et al. [20], have analysed the performance of the P300 speller for the Chinese language’s text input. Depending on the implemented Row/Column and single character spellers, the performance of six different paradigms has been tested and compared for thirty Chinese readers. The accuracy of a single character speller is 63.3% of subjects have been capable of obtaining 80% or higher accuracy of classification for fifteen trials. Regarding the communication rate, the optimal paradigm is different from the speller of Row/Column in which stimuli are increased by changing the colour of the background. This paradigm attained 14.5 bits per minute communication rate. The input rate of this system is about 1.1 characters per minute which correspond to approximate 11,000 Chinese characters.

Kiran George et al. [21], have presented a design method to input a simple text acronym in a message through mind thoughts and natural facial expressions. They have shown that “commercially-off-the-shelf (COTS)” BCI technology as well as “Emotiv Control Panel Software Suite” can be used to translate mind thoughts and natural facial expressions into actions by pairing 12 of the most used acronyms of text. EMOTIV™ headset was used to capture the user’s Electromyography (EMG) and EEG data, while “Emotiv Control Panel Software” is used to translate the mind’s thoughts and natural facial expressions into their corresponding text acronym.

Aasim Raheel et al. [22], have presented a powerful solution for using the muscular movement of the eye to type textual content. The fast and accurate movement of the eye can be observed using EEG. They have acquired EEG signals for many users to create a content spelling framework that uses the movement of a cursor over letter sets. All analyses were carried out on datasets of many users to set the indicator in three classes using them as an assist sign for content spelling. The system’s accuracy is 70% for the right movement, 80% for the left movement, and 79% for the blink.

The literature review elucidated that the combination of BCI and machines regarding text generation is a modern and promising study direction. It was also noticed that

enhancements are required to improve writing performance while reducing the system’s complexity. In this context, this study proposes a novel system that may fulfil the gap in brain-to-text research. The system is designed to predict words that human thinks and prints them on the screen. This system can predict some common English and Romanian language words. The system can assist mute people or those who lost their ability to speak due to different reasons like genetic factors, encephalitis, brain diseases and strokes, etc. to communicate with others or machines. Most brain-to-text research or projects discussed the English language only, while the proposed system can deal with the Romanian language as well. The strengths and weaknesses of some similar projects have been analysed as shown in Table I.

### III. METHOD

To implement the proposed system, EEG data collected from a subject has been processed, feature extracted, and classified. Python programming language is used to code all the related signal processing operations and training. The training is carried out first using EEG data. EEG data are collected using EMOTIV™ Insight neuroheadset. The training model is saved after feature extraction and data classification. The prediction process is carried out through the training model by making predictions on new data received from the headset. Fig. 1 shows the basic architecture of the brain-to-text BCI system.

#### A. Signal Acquisition

To detect and collect EEG brain signals from the subject's head, EMOTIV™ Insight non-invasive neuroheadset has been used. Its 5-channel headset EEG system (see Fig. 2) contains semi-dry polymer electrodes designed for various use of BCI systems and research. EMOTIV™ Insight neuroheadset is made of lightweight materials and provides whole-brain sensing with improved advanced electronics to deliver robust and clean signals. This neuroheadset is compatible with computers and mobile devices and can be connected via Bluetooth Low Energy or a 2.4 GHz wireless dongle [23].

#### B. Data Collection

The data are recorded using EmotivPRO™. The subject whom the data was collected from is a female who is a native Romanian speaker and fluent in English. She is healthy and reported no history of neurological illness. The recorded data are divided into sentences where each sentence contains some common words. Four sentences in English, as well as four sentences in Romanian, were recorded to be trained. The subject is asked to think of some words in the English language (without speaking) separately during each time of the recording process. For example, the sentence "Boy eats home with family" has five words, each word recorded forty times. The recordings are collected using five sensors of the headset AF3, AF4, T7, T8, and Pz where the sampling rate is 128 samples per second for each channel. The recordings have been exported and saved to be used later in training. The INACTIVE case in which the headset is not worn by the subject is also recorded. The BLINK case is also considered and recorded to recognise the blinking status of the subject and to enhance training accuracy. The same procedure is applied for the remaining English sentences and the sentences in the Romanian language like "Eu merg acasa cu familia".

#### C. Feature Extraction

After data has been obtained and exported, the next step is to extract features from the collected data. The statistical features like max, min, average, median, and standard deviation are simple, easy to compute, and easy to implement. 25 features have been extracted and used in this BCI system (five features for each channel of the headset).

#### D. Classification Algorithms

Several machine learning classifiers have been tested in this study, which are SVM, KNN, and LDA. The SVM algorithm is a classifier based on statistical learning theory that is usually used for classification in BCI systems. SVM

identifies the decision boundary between the class samples [24]. The linear SVM kernel function parameter has been chosen for this work due to its high computational speed and capability to deal with multi-class issues [8]. KNN is a supervised learning algorithm which is very easy to implement. It stores all the available cases and new cases have been classified depending on a similarity measure. KNN classifies them according to the featured values' estimation, which can be done by comparing the training data with testing data [10]. The distance weight function KNN parameter has been used in this work. One of the most popular classification algorithms in BCI is LDA [25]–[27]. It classifies a set of observations into predetermined classes. The three algorithms are usually used with BCI and work well with multi-class problems and large databases.

A cross-validation procedure has been applied to evaluate and test the performance of the three algorithms. The best values of cross-validation of the three algorithms and the nearest neighbours value of KNN are practically founded as illustrated in the results section.

```
Begin
Initialise i = 0
#Set root directory of CSV files
For path, subdirectories, files in root:
  Get directoryList
  #Set path
  path_name = path+'/**/*.*.csv'
  Read CSV files
  For csvFiles in read_files:
    Extract features from all CSV files of each subdirectory
    Creating DataFrames
    Concatenate DataFrames together
  Endfor
#Update i to get new subdirectory
i=i+1
Endfor
#Divide data into attributes and labels
X = frame.drop('Word', axis=1)
y = frame['Word']
Specify training algorithm
Train the model using cross-validation
#Save the pretrained model
filename = 'final_model.sav'
End
```

Fig. 3. Training Pseudocode.

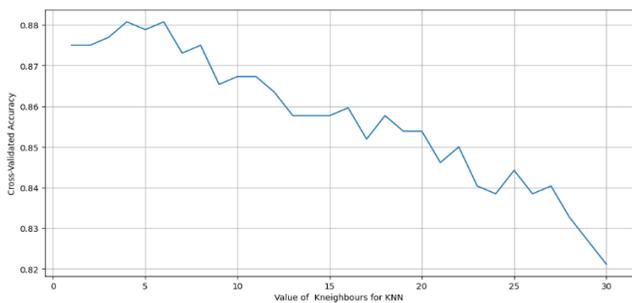

Fig. 3 shows the detailed pseudocode of the training process. As the EEG data are already collected from the subject and saved, the directory of these data must be specified to read the files and extract the feature. After specifying labels and attributes, the training starts using the three classification algorithms mentioned above through the cross-validation method.

#### IV. RESULTS AND DISCUSSION

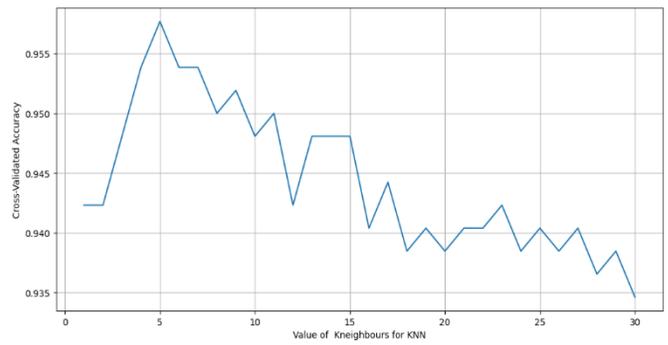

The parameters of the classification algorithms should be tuned to find the optimal hyperparameters. Specifying the optimal hyperparameters would enhance the overall performance and accuracy of the model. The “gridsearch” method has been used to find the optimal hyperparameters efficiently. The training process has done separately for each English and Romanian dataset. Table II shows the optimal hyperparameters and the configuration of each dataset for KNN, SVM, and LDA which have been found practically. The percentage of data used for training and testing can also be found in Table II, which differs according to the language and algorithm used. Fig. 4, 5, 6, and 7 show Hyperparameters graphs of KNN, SVM, and LDA. Fig. 4 elucidates that the effective values of n-neighbours are 6 and 5 for both English and Romanian datasets while the curve start dropping after six leading to low accuracy. As can be shown in Fig. 5, the effective k-fold values could be between 5 and 10 in most figures of English and Romanian datasets, where the accuracy is slightly changed. The prediction accuracy of English words is 86.7% for KNN, 86.1% for SVM, and 79.2% for LDA while the prediction accuracy of Romanian words is 96.1%, 97.1%, and 94.8% for SVM, LDA, and KNN respectively. The confusion matrices of the three algorithms for English and Romanian are shown in Fig. 8 and Fig. 9. The results of Romanian words are more accurate than in English words most probably because the subject is a native Romanian speaker.

TABLE II. KNN, SVM, AND LDA HYPERPARAMETERS SETTINGS

Algorithm	Parameters for the English dataset	Parameters for the Romanian dataset
<b>KNN</b>	Number of neighbours = 6 Weight function = distance Number of kfolds = 8	Number of neighbours = 5 Weight function = distance Number of kfolds = 10
<b>SVM</b>	Kernel type = linear Number of kfolds = 10	Kernel type = linear Number of kfolds = 9
<b>LDA</b>	Slover = svd Number of kfolds = 8	Slover = svd Number of kfolds = 7

In Table III and Table IV, True Positive Rate (TPR) or recall computes the ability of the model to detect positive samples which must be close to one for better results, and precision or “positive predictive value” is the ratio of positive samples that are correctly classified to the total number of classified positive samples where precision value must be close to one also for better results. Precision helps to find the machine learning model’s reliability to positively classify the model. It can be noticed from the Tables that the KNN is the best classification algorithm for the English dataset while LDA is the best classification algorithm for the Romanian dataset.

The system testing is conducted using the pre-trained model with real-time EEG data streamed from the subject’s brain through the headset. Fig. 10 shows different execution screenshots for English and Romanian words. The subject was asked to think of the previously trained words where the desired word should be printed on the screen. The BLINK word in the figure refers to blink status when the subject

blinks her eyes, while the red words present a misclassification status. The results may be affected by limitations like the mood of the subject, ability of focusing, or whether is he/she patient. Although some miss classifications occurred during the execution, a limited group of words have been used in this work, and the study is conducted on one person only, the system has successfully decoded thoughts which are a necessary step toward human interaction with computers or the surrounding environment through speech imagery.

TABLE III. PRECISION AND RECALL OF ENGLISH CLASSIFICATION

Classifier \ Class	KNN		SVM		LDA	
	Precision	Recall	Precision	Recall	Precision	Recall
<b>BLINK</b>	0.7	0.35	0.68	0.62	0.65	0.28

## V. CONCLUSION AND FUTURE WORK

There is always a necessity for a new natural approach to control and communicate with electronic devices and machines than the usual digital input approaches like touchscreens and buttons which may be limited to healthy people more than people with disabilities and diseases. Brain-to-text is a very modern field of research, and more research and gaps can be achieved and fulfilled in this field, especially in the medical domain. In this study, a brain-to-text BCI system is presented to mentally predict the word in English and Romanian languages. The system can help the disabled who cannot write or mute people to communicate with others or machines in writing in real-time. It will translate the neural activity into text using algorithms for feature extraction and classification. The three algorithms used in this system show promising results like high accuracy and prediction speed, especially KNN in English and SVM in Romanian.

In future work, more feature extraction and classification techniques like Fast Fourier Transform (FFT), neural networks, etc. may be used to enhance the accuracy and prediction of the system, considering increasing the collected EEG signals and samples. In addition, more languages like Arabic, which is written from right to left and its script is totally different from Latin script may be involved to target different language speakers.

# Fine-grained Access Control Method for Blockchain Data Sharing based on Cloud Platform Big Data

Yu Qiu\*, Biying Sun, Qian Dang, Chunhui Du, Na Li  
State Grid Gansu Electric Power Company Internet Division, Lanzhou, China

**Abstract**—Blockchain technology has the advantages of decentralization, de-trust, and non-tampering, which breaks through the limitations of traditional centralized technology, so it has gradually become the key technology of power data security storage and privacy protection. In the existing smart grid framework, the grid operator is a centralized key distribution organization, which is responsible for sending all the secret credentials, so it is easy to have a single point of failure, resulting in a large number of personal information losses. To solve the problems of inflexible access control in smart grid data-sharing framework and considering the limitation of multi-party cooperation among grid operators and efficiency, an attribute-based access control scheme supporting privacy preservation in smart grid is constructed in this paper. A fine-grained access control scheme supporting privacy protection is designed and extended to the smart grid system, which enables the system to achieve fine-grained access control of power data. A decryption test algorithm is added before the decryption algorithm. Finally, through performance analysis and comparison with other schemes, it is verified that the performance of this system is 7% higher than the traditional method, and the storage cost is 9.5% lower, which reflects the superiority of the system. Full optimization of the access policy is achieved. It is proved that the scheme is more efficient to implement the coordination and cooperation of multiple authorized agencies in the system initialization.

**Keywords**—Power grid data; blockchain technology; data sharing; fine-grained access control; game strategy; ciphertext key

## I. INTRODUCTION

With the wide application of big data, fog computing, and Internet of Things technology, more and more applications store a large number of users' private data in the near-end fog node for computing. This solves the problem of insufficient storage space or limited computing resources of most mobile terminals in the current Internet of Things environment. At the same time, with the rise of new network architectures such as SDN, the computing, and storage capabilities of edge network devices and core gateway devices are continuously enhanced [1]. However, because the private data of users can bring commercial value to criminals, Internet of Things devices with weak performance have become the main target of hackers [2]. To prevent the user's data from being stolen, it is necessary to authenticate all unknown devices in the environment through identity authentication and other technical means, and then grant the corresponding device access to data after passing the identity authentication. However, most of the existing identity authentication schemes ignore the user's privacy disclosure in the authentication

process, including the user's functional attributes, real identity privacy and geographical location privacy.

Power data can be used by other organizations outside the grid system, for example, to calculate costs, monitor unexpected behavior, and predict future conditions. However, the power data of a single smart meter contains private information such as household habits, which needs to be protected. Therefore, how to balance the availability and privacy of power data is a problem faced by the smart grid [3]. In addition, RTUs and power consumers want to control access from users. Users want to get different power information depending on their specific tasks. For example, maintainers and system engineers monitor the network, while costing and analysis will be performed by auditors [4]. Therefore, in the smart grid system, it is particularly important to achieve fine-grained access control of power data [5]. However, most of the existing smart grid schemes focus on information aggregation but ignore the privacy protection and access control in the process of power data sharing.

Blockchain technology is a trusted storage network composed of distributed equal nodes, consisting of tamper-proof block data and automatically executable smart contract code, which has the characteristics of tamper-proof, coordination autonomy, high security, and trust of decentralized decision-making [6]. In the research of data sharing mechanisms based on blockchain, Dai Mingjun et al. [7] promoted the storage space of blockchain through distributed storage (DS) based on network coding (NC). Yang Jiachen et al. [8] introduced encryption algorithms to solve the problem of distributed secure storage of big data. Wang Zuan et al. [9] separated the original data storage and data transactions by using a double-chain structure and combined with proxy re-encryption technology to achieve secure and reliable data sharing. In 2016, Alharbi et al. [10] proposed an efficient privacy-preserving identity-based signature (IBS) scheme for smart grid communication. In 2017, a smart grid communication model [11] was proposed by Sedaghat et al., in which the cloud proxy service center, as a trusted third party with powerful computing power, is responsible for partially decrypting the shared ciphertext to reduce the burden of authorized users. In 2019, a privacy-preserving power data aggregation scheme [12] was proposed by Liu et al., but this scheme does not consider the access control of shared data.

This paper aims to design a fine-grained access control scheme supporting privacy preservation in the cloud environment. Firstly, a fine-grained access control scheme for data sharing with a completely hidden access policy is constructed. Then, based on this, extended research on

application scenarios is carried out, and an attribute-based access control scheme supporting privacy preservation in a smart grid is constructed.

The main innovations of this paper are:

- 1) The access policy and attribute set are transformed into vectors, and the access policy is completely hidden.
- 2) An attribute-based access control scheme supporting privacy preservation in a smart grid is constructed. Combine blockchain technology to control data sharing and access.
- 3) The scheme in this paper can realize the independent work of multiple distribution network operators, realize lightweight encryption, and improve decryption efficiency.

Content and structure of this paper are as follows:

- 1) Elaborate the research direction, introduce the research background and content;
- 2) Introduce the theoretical content of the relevant basic content;
- 3) Design the security game strategy of power grid big data access control system;
- 4) Establish a shared data access scheme for power grid block chain;
- 5) Realize the attribute-based access control scheme for the power grid privacy protection;
- 6) Summarize the paper and look forward to the next step.

## II. RELATED WORK

### A. Access Control Security Model

With the rapid development of the ubiquitous power Internet of Things (IoT), various IoT intelligent terminal devices deployed in the smart grid generate a large amount of data. Although the application of cloud Internet of Things technology has effectively solved the problem of massive data collection, storage and sharing, the smart grid is faced with a huge number of intelligent terminal devices deployed in all aspects of the grid, users with a sharp increase in data and mixed personnel. Therefore, the data privacy security issues that involve posing a serious security threat [13]. These security threats are mainly manifested in:

**Data security risk:** the combination of smart grid and Internet of Things technology, and the application of various emerging technologies in the smart grid makes the system complexity of the smart grid become higher. The security risk of various types of data is increased [14]. The application of cloud Internet of Things technology effectively realizes the collection, storage, and management of terminal data, but when it interacts with users, business systems, and power grid researchers, the misoperation and illegal access will cause data leakage.

**User privacy risk:** In the smart grid, while protecting the privacy data of ordinary users, it is also necessary to prevent the leakage of grid system data. Users' personal information and power consumption data belong to users' privacy; and the important operation data of each link of the smart grid system also need to be protected [15]. In the face of distributed attacks by illegal elements, illegal access by malicious users

and illegal operations by staff, the privacy data of power grid users and systems will be threatened.

### B. Safety Requirements

According to the security threat analysis of data privacy protection in the smart grid cloud Internet of Things, effective access control methods are adopted to achieve the goal of data privacy security, and the following security requirements are considered:

- 1) **Authentication:** The identity of the user connected to the smart grid control center needs to be authenticated to prevent the user from stealing private data under false names. Data visitors must be authenticated with the control center in both directions [16].
- 2) **Data confidentiality:** When a visitor in the smart grid needs to decrypt and obtain encrypted data, its attribute set needs to meet the access policy requirements defined by the data owner, and unauthorized visitors cannot access user data.
- 3) **Anti-collision attack:** Unauthorized users cannot combine their key information to decrypt the ciphertext through the collusion of multiple users.
- 4) **Forward-backward confidentiality:** The newly authorized visitor cannot decrypt the previous ciphertext data with his own private key; the unauthorized visitor cannot decrypt the decrypted ciphertext data [17].
- 5) **Data integrity:** All kinds of private data must be encrypted before they can be transmitted between entities to avoid illegal tampering, damage and plagiarism during transmission and storage [18].

## III. POWER GRID BIG DATA ACCESS CONTROL SYSTEM

The system consists of five main bodies, as shown in Fig. 1.

**Grid Operator (GO):** As a certification center, the GO is responsible for setting up the smart grid system, distributing GIDs to users, and granting access to users. In addition, GO distributes identity keys for legitimate users.

**Multiple Distribution Operators (DGOs):** As multiple attribute authorities, each DGO is responsible for establishing its own domain, managing attributes, and distributing attribute keys to users according to the attribute set.

**Cloud storage server:** It is responsible for storing power data in the form of ciphertext. The cloud storage server does not participate in the access control and data decryption process.

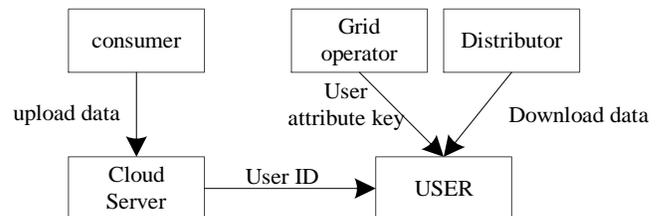

Fig. 1. Access Control System Model of Smart Grid.

Power data owners: Power data owners include RTUs and power consumers. The owner of the power data can define an access policy, use it to encrypt the power data, and upload it to the cloud storage server.

Users: Users may be maintainers, system engineers, researchers, policymakers, and auditors of power systems [19]. After the user downloads the encrypted power data from the cloud storage server, if the user wants to decrypt it, he needs to prove his identity to GO and initiate a key request to DGOs.

#### A. Fine-grained Shared Security Game Strategy

This section will elaborate the security model of the scheme based on the security game between the attacker  $A$  and the simulator  $B$ . Among them, the security game will have the following stages:

Initialization: attacker  $A$  sends fine-grained authority  $DGO_k^*$  to emulator  $B$ , and  $B$  gets the public parameter  $pp$  of the system.

Authority establishment: for each fine-grain authority, that simulator  $B$  runs an authority establishment algorithm. The public key  $PK_k$  and the private key  $SK_k$  are obtained, and then the public key  $PK_k$  is published to  $A$  [20].

Stage 1: Attacker  $A$  submits attribute vector  $\bar{y}$  and  $GID$  and initiates a user key challenge to impersonator  $B$ . Wherein the vector  $\bar{y}$  is generated by encoding the attribute set  $S'$  randomly selected by  $A$ .  $B$  runs the user key generation algorithm and replies the corresponding  $SK_{k,j}$  and  $SK_{gid}$  to  $A$ . In phase 1,  $A$  may interrogate the key within the PPT.

Challenge:  $A$  submits two messages  $M_0, M_1$  of equal length and two policy vectors  $\bar{x}_0, \bar{x}_1$  to  $B$ . Wherein, the vectors  $\bar{x}_0$  and  $\bar{x}_1$  are respectively encoded and generated by the access strategies  $W'_0$  and  $W'_1$  selected by  $A$  [21]. But it must be satisfy that neither that vector  $\bar{x}_0$  nor the vector  $\bar{x}_1$  is orthogonal  $\bar{y}$ , that is,  $(\langle \bar{x}_0, \bar{y} \rangle \neq 0) \wedge (\langle \bar{x}_1, \bar{y} \rangle \neq 0)$ . Simulator  $B$  tosses a coin to generate a random bit  $\xi \in \{0,1\}$ , and then runs the encryption algorithm to generate the corresponding ciphertext  $CT_\xi$  and sends it to attacker  $A$ .

Stage 2: As in stage 1,  $A$  then makes a user key challenge to  $B$ . But must satisfy that vector  $\bar{x}_0$ . Neither  $\bar{x}_1$  nor the vector  $\bar{y}$  is orthogonal.

Guess:  $A$  guesses  $\xi$  and gives  $\xi'$ . If  $\xi' = \xi$ , then  $A$

$$Adv_A = \left| \Pr[\xi' = \xi] - \frac{1}{2} \right|$$

wins and the winning margin is

#### B. Threshold Access Policy

The key technologies of threshold access policy encoding are divided into the following two parts:

1) The access policy  $W$  is transformed into a vector  $\bar{x}$ :

First, the power data owner defines an access policy  $W = \{t_{1,n_1}, t_{2,n_2}, \dots, t_{j,n_j}\}$ , selects  $t$  random coefficients  $a_i \in \mathbb{Z}_p$ , and sets a polynomial  $f(x)$  of order  $t-1$  as follows:

$$f(x) = a_{t-1}x^{t-1} + \dots + a_1x + a_0 \pmod{p} \quad (1)$$

Then, for each element  $t_{i,j}$  in the access policy  $W$ , the component elements of the corresponding vector  $\bar{x}$  are generated:

$$\begin{cases} x_i = \begin{cases} f(t_{i,j}) & t_{i,j} \in W \\ 0 & t_{i,j} \notin W \end{cases} : \forall i = 1, \dots, L-1 \\ x_L = -f(0) = -a_0 \end{cases} \quad (2)$$

2) Convert the attribute set  $S_k$  to a vector  $\bar{y}$ :

Let  $S = \{v_{1,n_1}, v_{2,n_2}, \dots, v_{j,n_j}\}$  and  $U_k = \{w_{1,n_1}, w_{2,n_2}, \dots, w_{j,n_j}\}$  be two attribute sets of the same length, where  $S$  represents the attribute set of the user in the system, and  $U_k$  represents the attribute set managed by the authority  $DGO_k$ . For a corresponding location that is not an attribute managed by  $U_k$ , let  $w_{i,j} = 0$ . Define  $S_k = S \cap U_k = \begin{cases} v_{i,j} & v_{i,j} = w_{i,j} \\ 0 & v_{i,j} \neq w_{i,j} \end{cases}$ . Then, calculate the value of the Lagrange polynomial  $\Delta_{v_{i,j}, S}(x)$  at  $x=0$ , where  $\Delta_{v_{i,j}, S}(x) = \prod_{k \in S, i \neq k} \frac{x - v_{k,j}}{v_{i,j} - v_{k,j}}$ . For each element  $v_{i,j}$  in the attribute set  $S_k$ , a component element of the corresponding vector  $\bar{y}$  is generated:

$$\begin{cases} y_i = \begin{cases} \Delta_{v_{i,j}, S}(0) & v_{i,j} \in S_k \\ 0 & v_{i,j} \notin S_k \end{cases} : \forall i = 1, \dots, L-1 \\ y_L = 1 \end{cases} \quad (3)$$

Attention:

$$\langle \bar{x}, \bar{y} \rangle = f(0) \Leftrightarrow t_{i,j} = v_{i,j} (i \geq t) \Leftrightarrow S \perp W \quad (4)$$

The above calculations only appear in the exponential part of the decryption phase.

#### IV. BLOCKCHAIN SHARED DATA ACCESS SCHEME

$u = \{att_1, \dots, att_L\}$  is defined as the global attribute set of the system and  $H: \{0,1\}^\lambda \times Z_p^{l+1} \rightarrow Z_p^{k+1}$  is a collision-resistant hash function. The specific construction of the attribute-based access control scheme supporting privacy protection in the smart grid is as follows:

**System initialization:** This phase consists of the following two algorithms. GO generates the whole system by running the system establishment algorithm, and DGOs generates its own domain by running the authority establishment algorithm.

**GO-Setup:** Run the group generator  $g$  to generate the bilinear group  $(p, g_1, g_2, e, G_1, G_2, G_T)$ . GO builds  $N$  authorities for the system, respectively:  $DGO_1, DGO_2, \dots, DGO_N$ , where each  $DGO_k$  manages a mutually exclusive set of attributes  $U_k = \{Att_1, Att_2, \dots, Att_{n_k}\}$ , and  $|U_k| = n_k$ . Let  $\sum_{sign} = (keygen, Sign, Verify)$  be a signature scheme. Select the random matrix  $A, B \in Z_p^{(k+1) \times k}$ ,  $P \in Z_p^{(k+1) \times (k+1)}$ , calculate  $P_1 = g_1^A, P_2 = g_2^B, X = g_1^{P^T A}$ , and return the common parameter  $pp$  as follows:

$$pp = \{G_1, G_2, G_T, e, p, g_1, g_2, P_1, P_2, X, Verify\} \quad (5)$$

**DGOS-Setup:** For any authority  $DGO_k$  in the system, select two random matrices  $U_k, W_k \in Z_p^{(k+1) \times (k+1)}$  and a random vector  $\bar{\alpha}_k \in Z_p^{k+1}$ , calculate  $V_{1,k} = g_1^{U_k^T A}, V_{2,k} = g_1^{W_k^T A}, Y_k = e(g_1, g_2)^{\bar{\alpha}_k^T A}$ , and then publish the public key  $PK_k$  of  $DGO_k$  and keep the private key  $SK_k$ .

$$PK_k = \{V_{1,k}, V_{2,k}, Y_k\}, SK_k = \{U_k, W_k, \bar{\alpha}_k\} \quad (6)$$

**Authentication and key distribution:** When a user joins the system, GO assigns a unique  $GID$  to the user. If the user wants to decrypt the ciphertext, first, the user needs to convert the attribute set  $S$  into a vector  $\bar{y} = \{y_j | j \in [1, L]\}$ , the user needs to submit the attribute set  $S$  and the attribute vector  $\bar{y}$  to request the key from GO. For the legal user who has completed the registration, GO will distribute the identity key

$SK_{gid}$  with the signature to the legal user by running the identity key generation algorithm. Next, the user needs to submit the attribute set  $S$ , the attribute vector  $\bar{y}$ , and the identity key  $SK_{gid}$  with the GO signature to request the attribute key from the DGOs. Each  $DGO_k$  then uses Verify to verify the signature. Once the verification is passed, each  $DGO_k$  generates attribute keys  $SK_{k,j}$  by running the attribute key generation algorithm and sends them to the user. This process involves the following two algorithms:

**Identity key generation (GO-KeyGen):** For the authentication center GO in the system, randomly select two vectors  $\bar{y} \in Z_p^{(k+1)}, \bar{r} \in Z_p^k$  and calculate the user identity key:

$$SK_{gid} = P_2^{\frac{\bar{r}}{u + \bar{y}}} \quad (7)$$

Where,  $u = H(GID, \bar{y})$ .

**Attribute key generation (DGOS-KeyGen):** For each authority  $DGO_k$  in the system, it is first necessary to convert the attribute set  $S_k$  into a vector  $\bar{y} = \{y_j | j \in [1, n_k], \sum_{k=1}^N n_k = L\}$ , where  $S_k = S \cap U_k$ , according to Section 4.1.5, and then calculate the user attribute key:

$$SK_{k,j} = g_2^{\bar{\alpha}_k} [(SK_{gid}^T)^{y_j} U_k^T + W_k^T]^T \quad (8)$$

**Data release:** The power data owner defines an access policy  $W$ , and converts it into a vector  $\bar{x}$ ; then, the power data  $M_p$  is encrypted by the following encryption algorithm, and the ciphertext  $CT_p$  is uploaded.

**Encrypt:** For the power data owner in the system, randomly select two vectors  $\bar{s}, \bar{s}^* \in Z_p^k$  and calculate the ciphertext  $CT_p = \{C_0, C_1, C_k, C_j^*, C_{k,j}\}$  as follows:

$$\begin{cases} C_0 = M_p \cdot \prod_{k=1}^N Y_k^{\bar{s}} = M_p \cdot e(g_1, g_2)^{\sum_{k=1}^N \bar{\alpha}_k^T \cdot A \bar{s}} \\ C_1 = P_1^{\bar{s}} \\ C_k = V_{2,k}^{\bar{s}} = g_1^{W_k^T A \bar{s}} \\ C_{k,j} = [X^{x_j} \cdot V_{1,k}]^{\bar{s}} = g_1^{(x_j P^T + U_k^T) A \bar{s}} \\ C_j^* = P_1^{\bar{s} \cdot x_j} (k \in [1, N], j \in [1, L]) \end{cases} \quad (9)$$

Data recovery: Any user can access the power data encrypted in the cloud, but only when  $S \perp W$ , the authorized user can successfully decrypt it. In order to reduce the cost of decryption, the decryption process is divided into two stages: decryption test and complete decryption. The user first runs the test algorithm to verify  $S \perp W$  or  $S \nabla W$ . If  $F(W, S) = 1$  is output, the user runs the full decryption algorithm; otherwise, the decryption is terminated. Details are as follows:

Decryption Test Phase: User calculation:

$$F(W, S) = \sum_{j=1}^{l+1} C_j^{*y_j} \quad (10)$$

Attention:  $F(W, S) = 1 \Leftrightarrow \sum_{j=1}^L x_j y_j = 0 \Leftrightarrow S \perp W$ . If output  $F(W, S) = 1$ , so, it represents  $S \perp W$ , then the user will proceed to the next stage for full decryption; otherwise, the user will terminate decryption.

Dec-Phase: Once the above test Phase is passed, it indicates  $S \perp W$ , and the user has performed the following calculations:

$$C_0 \cdot \frac{e(\prod_{k=1}^N \prod_{j=1}^L C_{k,j}^{y_j} \cdot C_k, SK_{gid})}{e(C_1, \prod_{k=1}^N \prod_{j=1}^L SK_{k,j})} = M_p \quad (11)$$

## V. ATTRIBUTE-BASED ACCESS CONTROL SCHEME FOR PRIVACY PROTECTION IN POWER GRID

System initialization Setup1 (PK, MSK):

Enter the security parameters to obtain the public key PK and the master key MSK.

Encrypt (M, PK, W) CT: Input message M, public key PK, and access policy W to get ciphertext CT.

Key GenPK, MSK, S SK: Input public key PK, master key MSK and attribute set S to get user key SK.

Decrypt CT, SK, PK M or: input ciphertext CT, user key SK and public key PK, if  $S \nabla W$ , output message M; otherwise, the algorithm aborts and outputs.

System Setup (GO-Setup): This phase is executed by GO, which inputs security parameters  $I^{\lambda}$  and obtains system public parameters  $PP$ , as well as a pair of signature and authentication keys (Sign, Verify).

DGOS-Setup: This algorithm is executed by DGOs, which inputs the subscript k of DGOk and outputs the public and private keys.

User key generation (KeyGen): includes two stages of identity key generation and attribute key generation, as follows:

1) Identity key generation phase (GO-KeyGen): This phase is executed by GO. Input the global identity GID of the user to get the identity key  $SK_{gid}$  of the user.

2) Attribute key generation phase (DGOS-KeyGen): This phase is performed by DGOs, inputting the private key  $SK_k$  and the encoding vector  $\vec{y}$  of the attribute set S, and then outputting the attribute key  $SK_{k,j}$  of the user.

Encrypt: The algorithm is run by the owner of the power data, inputting the public key  $PK_k$ , power data  $M_p$ , and the encoding vector  $\vec{x}$  of the access policy W, and outputting the power data in encrypted form  $SK_{k,j}$ .

Decrypt: This algorithm includes two phases: decryption test and full decryption, as follows:

1) Decryption Test Phase: Input the power data  $CT_p$  in encrypted form and the encoding vector  $\vec{y}$ . If  $F(W, S) = 1$ , proceed to the next phase; otherwise, the algorithm is aborted.

2) Complete Decryption Phase (Dec-Phase): Input the power data  $CT_p$  in encrypted form, the encoding vector  $\vec{y}$ , the user's attribute key  $SK_{k,j}$  and the user's identity key  $SK_{gid}$ , and output the power data  $M_p$  or  $\perp$ .

## VI. EXPERIMENTAL ANALYSIS

### A. Experimental Platform

The experimental environment builds a micro-cloud environment to simulate the big data service under the cloud platform. The server-side and client-side configurations are shown in Table I.

This paper is based on the Pairwise Cryptography Laboratory (PBC) and uses 160-bit elliptic curve groups over a 512-bit finite field, which are used to calculate the cost of the test operation and the decryption operation.

### B. Performance Analysis

In the simulation test,  $E_{G_1}$ ,  $E_{G_2}$  and  $E_{G_T}$  respectively represent the time cost of an index operation in  $G_1$ ,  $G_2$  and  $G_T$ .  $N_w$  and  $N_s$  represent the number of attributes in the access policy and user attribute set, respectively. The  $\hat{e}$  represents the time cost required to compute a bilinear function. The  $O(H)$  represents the time required to compute a hash function. The  $P_i$  indicates the number of possible values for a multivalued attribute.

1) *Theoretical analysis*: In Table II, this scheme is further compared with scheme [22-25] from four aspects of key generation cost, encryption cost, test cost and decryption cost.

TABLE I. EXPERIMENTAL PLATFORM CONFIGURATION PARAMETERS

Configurations	Type	
	Server side	Client side
CPU	Core(TM) i7-10900k4.6GHz	Core(TM) i5-10400f 4.3GHz
Memory	128G	16G
System	Windows Server LTSC Preview	Windows 11

TABLE II. PERFORMANCE COMPARISON OF SMART GRID ACCESS CONTROL SCHEMES

Plan	Types	Independent authorized agency	Decryption test	Full hiding strategy	IPE	Adaptive safety
[22]	MA-ABE	√	×	×	×	×
[23]	MA-ABE	√	×	×	×	×
[24]	MA-ABE	√	×	×	×	×
[25]	D-MA-ABE	×	×	√	√	√
The plan	MA-ABE	√	√	√	√	√

TABLE III. COMPARISON OF COMPUTATIONAL COMPLEXITY OF SMART GRID ACCESS CONTROL SCHEMES IN DIFFERENT STAGES

Plan	User key generation		Encryption			Decryption test			Fully decrypted		
	$E_{G_2}$	$O(H)$	$e$	$E_{G_1}$	$E_{G_T}$	$e$	$E_{G_1}$	$E_{G_T}$	$e$	$E_{G_2}$	$E_{G_T}$
[25]	$N_s$	$N_s$	1	$1 + N_w$	1	-	-	-	2	2	$2p_i N_s$
The plan	$N_s$	0	1	$1 + 3N_w$	1	0	$p_i N_s$	0	1	$3p_i N_s$	3

It can be seen from Table III that this scheme is more efficient than the scheme [25] in the key generation and decryption stages because of the calculation of the hash function in the scheme [25].

2) *Simulation test*: The actual performance of the present protocol and the protocol [25] will be tested. The results show that, compared with the scheme [25], the present scheme has obvious advantages in both the key distribution phase and the decryption phase. Fig. 2 shows the comparison of the storage cost of this scheme and the scheme [25] in each stage of the algorithm. In the simulation, the lengths of the elements in the bilinear groups  $G_1$ ,  $G_2$ , and  $G_T$  are set to 512 bits. Assume that there are 10 authorities in the system, that is,  $N=10$ , and specify that each authority manages five attributes.

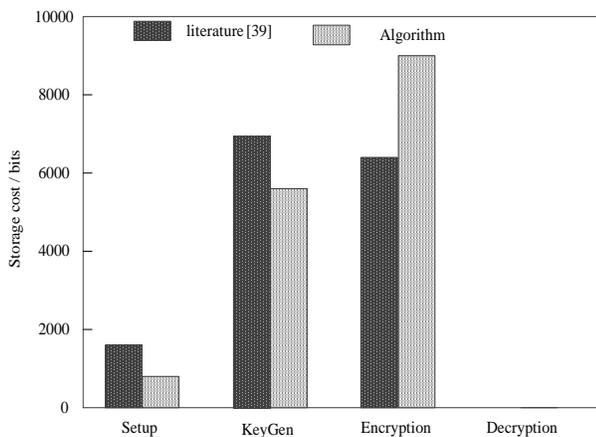

Fig. 2. Storage Cost Comparison.

It can be seen from Fig. 2 that, compared with the scheme [25], the construction of this scheme requires less space to store the public key and the secret key of the user. Fig. 3, Fig. 4 and Fig. 5 respectively show the running time comparison of the user key distribution algorithm, the encryption algorithm and the decryption algorithm in this scheme and the scheme [25].

Fig. 3 shows that the running time of the user key distribution algorithm of the two schemes increases linearly with the number of attribute sets.

As can be seen from Fig. 4, the efficiency of the encryption algorithm in this scheme is obviously low, which is a compromise for security performance.

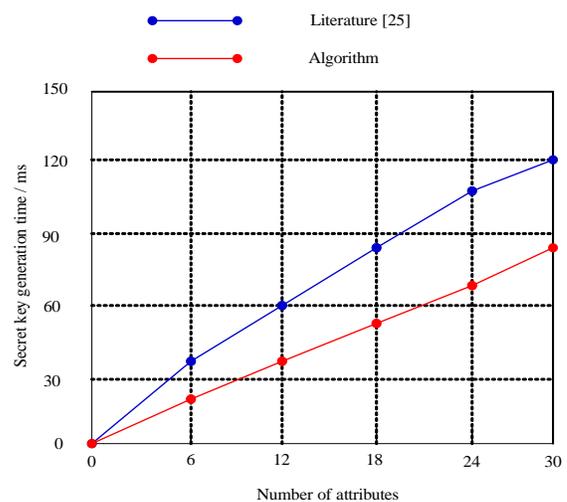

Fig. 3. Comparison of Secret Key Generation Time.

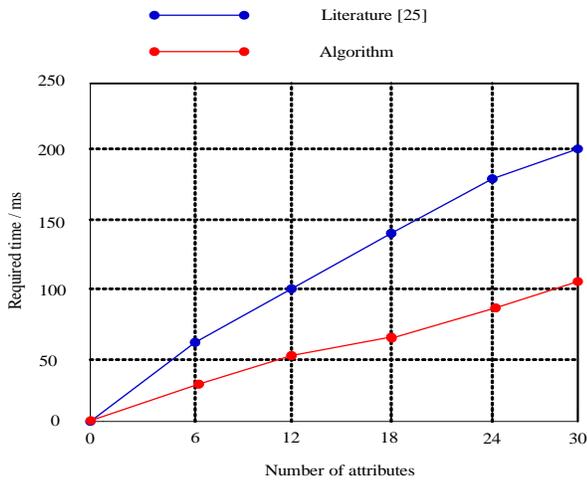

Fig. 4. Time Comparison of Encryption Algorithms.

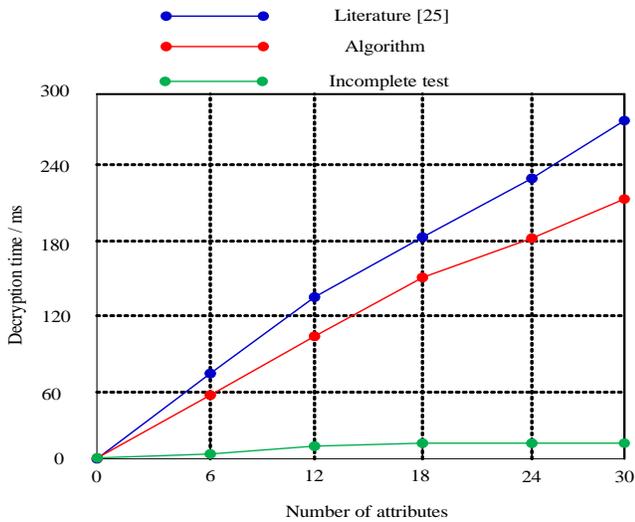

Fig. 5. Time Comparison of Decryption Algorithms.

As shown in Fig. 5, the decryption test algorithm in this scheme takes significantly less time than the full decryption algorithm. If the attribute set of the user does not satisfy the access policy, the scheme only executes the decryption test algorithm and does not need to execute the complete decryption operation. Due to the decryption test operation, the time required for successful decryption of the present scheme is much shorter than that of the scheme [25].

### C. Discussion

If the distributions of encryption and decryption are statistically similar, there is no one simulator B that can distinguish the two strategies by any advantage.

Proof: In the challenge phase, simulator B randomly selects A, to satisfy.

Then generate:

$$C_{k,j} = g_1^{(x_{b,j}P^T + U_k^T)(A\bar{s} + b^\perp \hat{s})} = g_1^{x_{b,j}P^T(A\bar{s} + b^\perp \hat{s})} \cdot g_1^{U_k^T(A\bar{s} + b^\perp \hat{s})} \quad (12)$$

Given  $g_1^A, g_1^{A\bar{s} + b^\perp \hat{s}}, g_1^{U_k^T A}, g_2^B$ , this term  $g_1^{U_k^T(A\bar{s} + b^\perp \hat{s})}$  is uniformly distributed in the group. Therefore, there is no adversary that can distinguish strategies  $Game_3$  and  $Game_4$  with any advantage.

In the strategy  $Game_4$ , in the opponent's view, the choice of  $b$  by the simulator B is statistically independent, and the opponent cannot win the strategy by any advantage.

If the K-Linear assumption holds, the privacy-preserving power data access control scheme is IND-CPA secure.

It is proved that under the k-Linear assumption, based on the proof of the above lemma, the attacker's advantage in winning the real security strategy is negligible. Therefore, the attacker cannot break the scheme in the PPT.

## VII. CONCLUSION

In this paper, a fine-grained access control scheme is proposed to support data sharing in the smart grid. The main work includes:

- 1) The decentralized attribute-based encryption scheme is extended to the smart grid system, which is based on a more flexible threshold access structure.
- 2) In order to improve the efficiency, a test phase is added before the data is completely decrypted, which avoids many unnecessary decryption operations.
- 3) Based on the k-Linear assumption, it is proved that the scheme achieves adaptive security.

Performance analysis shows that this scheme has obvious advantages compared with similar schemes.

The content of this paper can protect the privacy information of the trajectory data, and improve the availability of the data. Finally, through the experimental verification, it is proved that the proposed method not only protects the privacy information of trajectory data but also improves the availability of data.

In the next step, when the privacy budget is allocated by the special series method. Although infinitely many points can be protected, if there are too many position points in trajectory data, the smaller the privacy budget allocated to the later position points is, the larger the corresponding added random noise is. Then, the availability of the data will be reduced.

# Smart System for Emergency Traffic Recommendations: Urban Ambulance Mobility

Ayoub Charef<sup>1</sup>, Zahi Jarir<sup>2</sup>, Mohamed Quafafou<sup>3</sup>

Department of Computer Science, Faculty of Science, Cadi Ayyad University, Marrakech, Morocco<sup>1,2</sup>

Department of Computer Science, University of Aix-Marseille, Marseille, France<sup>3</sup>

**Abstract**—With the increasing evolution of advanced technologies and techniques such as the Internet of Things, Artificial Intelligence and Big Data, the traffic management systems industry has acquired new methodologies for creating advanced and intelligent services and applications for traffic management and safety. The current contribution focuses on the implementation of a path recommendation service for paramedics in emergency situations, which is one of the most critical and complex issues in traffic management for the survival of individuals involved in emergency incidents. This work mainly focused on the response time to life-threatening incidents, which is an indicator for emergency ambulance services and for recommending a fastest ambulance route. To this end, we propose a hybrid approach consisting on a local approach using machine learning techniques to predict the congestion of different sections of a map from an origin to a destination, and a global approach to suggest the fastest path to ambulance drivers in real time as they move in OpenStreetMap.

**Keywords**—*Recommendation systems; emergency urban traffic; ambulance mobility; emergency navigation services*

## I. INTRODUCTION AND MOTIVATION

Nowadays traffic congestion represents a real major issue for all societies and also an inconvenience for the townspeople because of the increase of population and vehicles in an urban zone. The level of these challenges encountered varies from one region to another depending on road infrastructure resources, road safety education, people's behavior [1], etc. Traffic blockage becomes one of the major and most difficult problems in various urban areas according to the negative effects it induces to the various actors of the road: road users, pedestrians, police officers, which in turn result in various social and economic problems according to [2]. Among these effects and by the observation that the frequency of road accidents and their effects are increasing, more and more every day [3]. Therefore, most of the ministries of equipment and transport over the world have invested in road infrastructures by installing the latest generation technologies and solutions to be able to reduce the level of stress and save the lives of citizens. Moreover, the emergency rescue research is receiving more and more attention. The most important factor in an emergency rescue is rescue timeliness, and often makes a difference between life and death [4].

However, finding an effective response to this challenge is considered as complex and tedious research topic in the literature. Despite the advances and published results of scientific contributions on this topic, this challenge remains open. This complexity is compounded when other constraints

or factors must be met, such as the inability to create emergency lanes due to narrow roads, undeveloped urban road infrastructure, etc.

In this paper the proposed approach consists of offering an emergency mobility service with the advantage of continuously recommending to ambulance drivers with the fastest way to reach the destination. The data used comes from road infrastructure sensors, Internet of Things installed in roads, etc. as well as data from previously traveled routes, such as incidents, line changes, travel time, traffic flow, etc. All these data enable us to calculate the speed interval and travel duration for every route taken by an ambulance in response to an emergency. In this contribution, this paper mainly focuses on how to reduce ambulance travel time by addressing the challenges of an efficient ambulance response. To achieve this goal, the proposed approach is twofold: 1) to analyze the mobility of emergency ambulances and identify the main factors preventing their travel, and 2) to model the fastest travel recommendation solution to improve ambulance mobility time by focusing on data collection from roadway infrastructure sensors, archived data on confirmed past travel history.

The remainder of the paper is organized as follows. Section II exposes a related work on path recommendation solutions for Emergency Medical Transportations (EMTs) in emergency states presented in the literature. Section III details the constraints to be considered when proposing an emergency path recommendation solution. Section IV describes the multilayer architecture of the proposed recommendation solution. Section V explains the multi-agents modeling approach, while data and random traffic generation used for an experimentation is exposed in section VI. Section VII presents details of the proposed hybrid approach for predicting the traffic state based on machine learning techniques, and proposing the fastest path to a destination in real-time using Dijkstra algorithm. Finally, Section VIII concludes the paper and presents some future works.

This section starts by exposing some interesting finding published in literature concerning the prediction of travel path for emergency vehicles (EV). Then it focuses on some important machine learning algorithms predicting urban traffic congestion.

## II. LITERATURE REVIEW

### A. Trajectory Prediction for Emergency Vehicles

Traffic congestion contributes greatly either indirectly or directly to both economic and health losses in countries.

According to [5], other repercussions of traffic jams include prolonged time loss, especially during peak hours, mental stress, traffic accidents, air pollution, noise, and disturbance [6]. Therefore, it is difficult for emergency vehicle services to achieve short response times during interventions without using effective advanced solutions, techniques and technologies. In the literature, several approaches have been proposed to reduce ambulance response time. This delay is mainly due to several traffic lights management, uncontrolled intersections, that creates a crowd of vehicles and thus puts ambulances on hold.

The work presented in [7] suggests a solution to make on the traffic lights for ambulance from the start position to the scene of an incident or where a patient is. However, the proposed solution is very restrictive since signalized intersections could present colossal travel delays. So the most generally taken on procedure for EV prioritization is traffic light need control. In the same context, authors in [8] propose a method of controlling traffic lights and performing the aforementioned task to allow the ambulance to cross all intersections without waiting. However, road signs remain an uncontrollable problem.

Authors in [9] propose an Android application with an Internet of Things (IoT) network model for an EV routing using Fuzzy logic-based data fusion. The data fusion approach calculates the exact congestion for a certain place by taking into account crowd inputs and sensory data. However, the suggested system requires the crowdsourced data to be assessed for trust in order to confirm the identity of the crowdsourced user. Moreover, strong communication protocols are required when using IoT in order to reduce the danger of security threats.

In other work, [10] uses radiofrequency sensors to count vehicles, which are equipped with radio frequency identification tags, to propose a dynamic traffic signal as a solution to avoid ambulance blockage. However, the proposed solution is also very restrictive since vehicles should be equipped with radio frequency identification tags.

The work in [11] proposes a unique decentralized approach to geofencing based on radio frequency and global navigation satellite system that allows emergency service vehicles to pass through intersections with the least amount of delays by giving them the right of way green signal. In the same context [12] proposed a cooperative vehicle-road scheduling method that includes a real-time route planning module and a group traffic signal management module.

The approach presented in [13] provides green indicators to help EV to pass through intersections quickly without stopping, and restores the road network to the normal situation as soon as possible by using linear programming to find the shortest green time in each phase after an EV passes the intersection. However, the proposed contribution does not take into account the dynamics the global traffic state and the impact of a scheduling strategy on the ordinary vehicles.

The authors in [14] propose an algorithm for finding the shortest or fastest path. This algorithm based on Ant Colony Optimization with Fuzzy Logic to deal with local path planning for obstacle avoidance by taking into account wind, flow air,

and dynamic obstacles. However, the weakness of this approach is that the response time of the algorithm is very slow.

In the same context, [15] and [16] proposed an ASNN-FRR (A traffic-aware neural network for fastest route recommendation) model suggesting a fastest route recommendation. This model uses two powerful predictors for  $g(\cdot)$  and  $h(\cdot)$  functions of A\* algorithm respectively, to find fastest path between two points origin-destination (OD) based on travel time estimation. However, the trajectory recommendation is given initially, the problem here is that the authors do not take into account that urban traffic changes over time.

By collecting and analyzing social media data and using new technologies of granular computing that transforms big data collections into granular information, [17] proposes a fastest path optimization model to incorporate the impact of traffic events and generate the optimal routing strategy. However, the obtained results show that the strategy is good for public transport and not for the emergency vehicles.

To help EVs such as ambulance, fire engine, and police vehicles to greatly benefit from accurate path prediction systems, [18] and [19] suggested a ventilation network model to automatically assess and determine potential escape routes. A variant of Dijkstra's algorithm is used to forecast intricate pathways between any two sites across a model. However, the proposed model uses data from the begin and not take in consideration frequent traffic changes.

The proposed approach in [4] offers a data-driven system for precisely predicting the path taken by an ambulance moving with blue lights and sirens in response to an emergency situation. This technique calculates the typical response time of an ambulance to an emergency call using historical data, and then estimates the travel time from these speeds for each route. Finally, it finds the quickest path between any beginning and finishing points using a common graph-theoretic approach based on Hidden Markov model. However, historical data can only be used to make predictions; in contrast, emergency situations need using real-time data.

The work of [20] uses the technique of multiple classifiers with maximum vote to predict the route to the destination with the highest degree of accuracy and select the best path to reach the destination as quickly as possible. Three algorithms—the artificial neural network (ANN), the k-nearest neighbors (KNN), and the support vector machine (SVM) are the foundation of this system. As classifiers, which can't foresee the quickest path between two points. By and by, the real travel season of a similar route can be exceptionally irregular at various times or simultaneously of day on various days, because of the blockages from vehicles.

### B. Traffic Congestion Prediction

Several interesting contributions focus on traffic congestion prediction problems to avoid traffic jams and minimize travel time. The objective of this subsection is to present some of them in order to highlight the most used techniques.

Table I shows the comparison of Proposed Approach with Existing works in Literature.

TABLE I. COMPARISON OF PROPOSED APPROACH WITH EXISTING MODELS

The approach suggested in [21] that the combination of a Genetic Algorithm and the Cross Entropy method for the optimization of a Parallel Hierarchical Fuzzy Rule-Based System would help to develop a synergy between exploration and exploitation to improve the system's parameters.

The authors in [22] designed an approach based on hierarchical fuzzy rule based system and genetic algorithms to build traffic congestion prediction systems from a large number of input data. However, this approach does not take into consideration many parameters that will have to be obtained in real time.

In the same context [23] and [24] estimate and predict traffic congestion in large-scale urban regions using a fuzzy comprehensive evaluation method. This method involved mapping the floating vehicle in sample points using data from its route. However, the authors focus on the traffic prediction on the roads and don't take in account the intersections where the congestion is more interesting to manage.

In the paper [25], a hybrid model of SVM and KNN is proposed as a short-term prediction technique for highway exiting traffic. However, the problem is that the traffic data are not strictly periodic. For example, in the normal day the peak

hours could vary from 4:30pm to 6:00pm, but on weekdays usually happen in afternoon. In the same context, the work presented in [26] consists in creating a multimodal Big data fusion framework for traffic congestion prediction. This work uses a highway traffic dataset to predict traffic travel times using data mining predictive and Extended Kalman filters. However, the weakness of the approach lies in the non-use in the traffic data used of certain important qualified parameters such as time and area.

The works proposed in both [27] and [28] are based on the Bayesian Network analysis approach to model the probabilistic dependency structure between causes of congestion on a particular road segment and analyzing the probability of traffic congestion given various roadway condition scenarios. However, the obtained results show that the both approaches take a lot of time for making prediction, and thereafter cannot be considered as real time solution.

In [29], offers a fusion deep learning model that takes spatial-temporal correlation into account in order to address the issue of predicting urban road traffic flow and increase prediction accuracy.

Referring to the literature, this work can summarize that the challenge of emergency traffic recommender systems is still an open problem and the proposed approaches are not complete to be used in such situations. Firstly, the majority of these evoked contributions attempt to forecast traffic flows for a specific area of the urban road network and are mainly based on the variations of the time series specific to this area. However, they must take into account the entire region, including origin and destination, as a whole. Also, the prediction response must be provided at runtime and continuously. In addition, most traffic jam prediction are for road segments and not for intersections, despite the fact that most of the time traffic jams start from intersections.

This motivates us to propose an emergency traffic recommender system combining optimal path problems and real-time congestion prediction to find the fastest route from an origin to a destination. This system is based on a flexible architecture having the advantage to collect useful information gathered from road infrastructure, traffic tracking, etc., and to process and provide real-time congestion prediction using machine learning algorithms and in particular classification algorithms. The main reason for choosing classification algorithms is that their processing time is lower than deep learning algorithms according to [30], and they also meet the goal of reaching a fastest path.

### III. RESEARCH METHODOLOGY

The objective of the current contribution is to propose an emergency traffic recommendation solution having the advantage of proposing fastest routes from an origin to a destination while avoiding as much as possible that ambulances get stuck in traffic jams during their travels. The implementation of such an emergency traffic recommendation system requires massive empirical data to build the most appropriate and fastest path for ambulance drivers. Therefore, this paper proposes a flexible architecture that has the advantage of collecting all the required data from the environment and also of processing them in real time to respond to the travel emergency.

The proposed architecture uses techniques to collect, filter, store and process the data in real-time, and machine learning algorithms to analyze and predict the fastest path in real time throughout the mobility.

To build this architecture, we started by understanding, identifying, and analyzing all parameters involved in the emergency traffic recommendation process before the modeling phase. The necessary parameters we have identified mainly belong to two main categories: static and dynamic parameters. Static parameters refer to data that do not change during the period of travel, such as infrastructure data, traffic signals, road structures, red light scheduling, etc. While the dynamic category focuses on variables whose values change over time, such as traffic trips.

Traffic congestion prediction has two essential steps of forecast model development and data collection. Each step of the process is important and, if performed incorrectly, could have an impact on the results or consequences of the next steps. After data collection, data processing assumes an imperative

part to prepare the training and testing datasets, and help to predict the traffic flow as well as an estimated traffic congestion state. In addition, proposed traffic datasets are divided into two categories: stationary data and probe data. Additional categories for fixed information includes sensor and fixed cameras. Probe data includes data collected from GPS or applications installed on vehicles, traffic parameters we have identified mainly belong to two main categories: static and dynamic parameters. Static parameters refer to data that do not change during the period of travel, such as infrastructure data, traffic signals, road structures, red light scheduling, etc. While the dynamic category focuses on variables whose values change over time, such as traffic trips, data collected by IoT connected objects, or sensors, driver behaviors, traffic flow, etc. Fig. 1 summarizes the components and parameters taken into account by the proposed architecture.

In order to propose a flexible model for emergency traffic services for the case of ambulance mobility, this paper was interested in the use of multi-agent system (MAS). That is more adapted to this case and meets our needs perfectly. Moreover, it has the ability to hold the properties of distributed systems, to meet the required coordination which consists in organizing the cooperation between the connected objects by sharing knowledge and relying on the capabilities and knowledge of each entity, and to adapt to artificial intelligence techniques. For all these reasons, in this paper, we have opted for SARL (Multi-agent programming language of system) as an agent programming language because of its robustness, the multitude of features offered, etc. the proposed architecture is shown in Fig. 2.

The Fig. 3 represent the main layers of the emergency traffic recommender system concern the multi-agent system module, a data management module represented by a NoSQL solution (mongoDB in this work), an extraction and decision module for traffic management, and a mobility services module that represents the interface of the recommendation system offering to the ambulance drivers real-time positioning information, the fastest path between a departure point and destination, etc. This last module interacts with the multi-agent system module, which through the agents, allows to manage each physical object (sensors, IoT, etc.). These agents are permanently connected to the road infrastructure. Based on the information collected from the physical infrastructure, this module is able to compose the required event or task using a coordination process and send it to the navigation services module.

The Traffic Management Extraction and Decision module provides the overall decision on the appropriate measure of mobility, fluidity in the segments and nodes to traverse to reach a destination from an origin. This decision is based on historical urban traffic states, data collected in real time by the multi-agent system. To implement the proposed solution, we propose a hybrid approach: 1) a local approach dedicated to traffic prediction based on a learning algorithm and 2) a global approach to propose the fastest path from an origin to a destination based on the output of the local approach.

The aim of the next section is to detail the proposed MAS module.

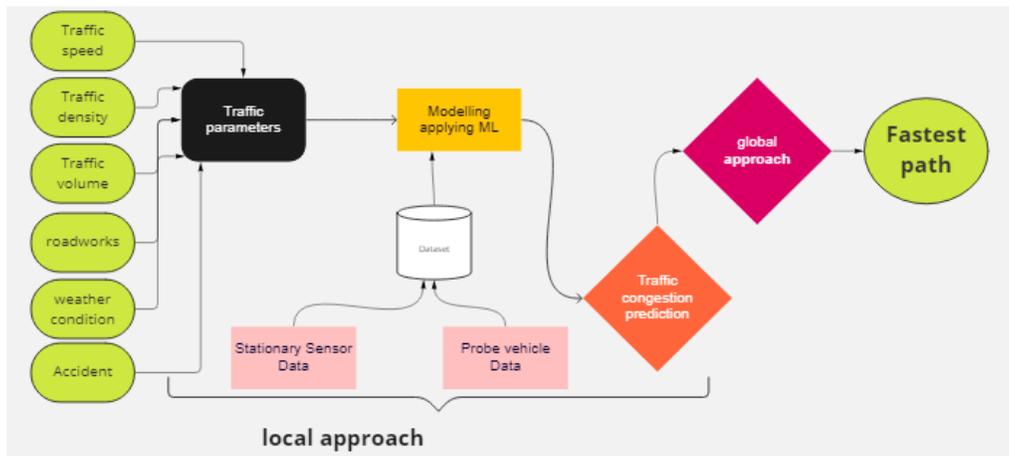

Fig. 1. The Proposed Architecture for Emergency Traffic Recommendation System.

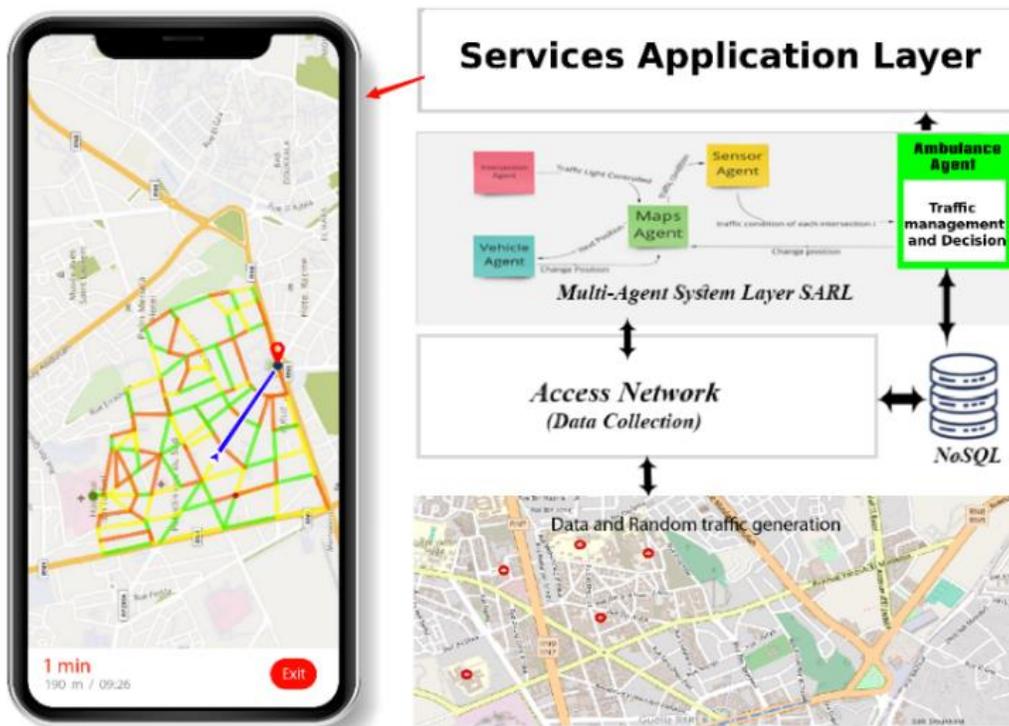

Fig. 2. An Architecture of Multi-Agent with SARL.

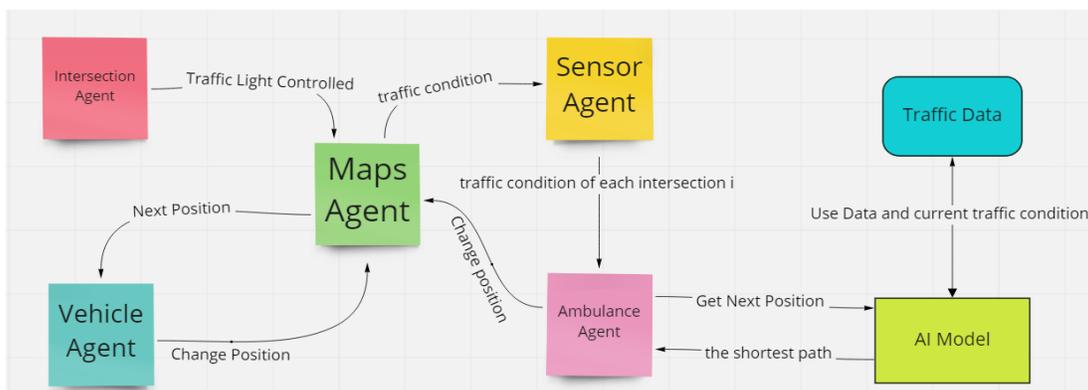

Fig. 3. The Proposed Architecture for Emergency Traffic Recommendation System.

#### IV. MULTI-AGENT SYSTEM MODELLING

To recommend the shortest time-based path in the case of an emergency from a departure point to an arrival point for an ambulance driver, the proposed approach was interested in the use of multi-agent systems, we have opted for SARL as an agent programming language that provides a set of concepts for the development of holonic systems (agents composed of other agents, with possibly new capacity) and based on events for communication between agents.

The proposed MAS contains five categories of agent:

- The maps agent, which is responsible for the simulation of traffic on the map, the input and the output of the agent vehicle, and also communicates with the other agents, for example giving the current coordinates to the ambulance agent.
- The sensor agent, responsible to collect data for each section on the map. For each section, we have two sensor agents positioned at the entry and exit of the section. The aim of this agent is to calculate the flow and the density of the vehicles on each section.
- The Intersection agent that takes control of the traffic light and priority of an intersection.
- The vehicle agent.
- The ambulance agent which represents the ambulance driver.

Table II summarizes all functions and events used to communicate between agents.

The agent ambulance needs to make a decision at each intersection from the origin to destination. So to choose the right direction it will communicate with the map agent to get its current position after that communicate with all sensor agents in each section of the road from its position to the arrival point to get the traffic condition for each section at instant T and used to predict the traffic condition at T+Δt to find uncongested road segments that will allow it to reach the arrival point.

According to fluid mechanics, the flow rate q is equal to the product of the concentration k and the velocity of the flow v, the average velocity for a traffic flow at time t and point x is defined by the ratio between the flow rate and the density such that:

$$v(x, t) = \frac{q(x,t)}{k(x,t)} \quad (1)$$

Therefore, the proposed methodology was adopted to predict the flow and density of each section on the map and then calculate the average speed as a function of time to cross each different section. The main idea of this study is to identify similar patterns from the historical data of density and flow, and as an input real time data to predict the next state of the Traffic.

TABLE II. AGENT TYPES USED IN PROPOSED MULTI-AGENT SYSTEMS

Agent	Event	Functions
Intersection	TrafficLightEvent: for each ΔT the Intersection agent send the traffic light condition to the maps agent	control the traffic light and priority of intersection
Vehicle	SendPositionEvent: for each ΔT the vehicle agent sends their position to the maps agent: to get permission to move to the next position.	move from intersection to other
Maps	After receiving the request from the vehicle agent to change their position, depending on the capacity of the red light or the priority the agent maps to verify the request, if possible it emits ChangePositionEvent: to give permission to the vehicle agent to change his position. In addition, the maps agent is able to detect every vehicle entering or leaving on section j, and it sends this information to the input sensor agent j and output sensor agent j.	simulation of traffic
Sensor	after receiving the request from the ambulance agent, it uses the information received from the maps agent to calculate the flow and density and send SendEtatTrafficEvent to respond to this request.	calculate traffic flow, density and speed
Ambulance	GetEtatTrafficEvent : send message to Sensor Agent to get (flow and density ) of each edges of maps.	is VehicleAgent with some exception (move from an origin to destination, always have a priority in intersection)

#### V. DATA AND RANDOM TRAFFIC GENERATION

To evaluate the proposed approach and given the lack of empirical data, we were interested in randomly generating data representing vehicles, on road sections and intersections, that move randomly with a constant speed. The main properties of this traffic generation are presented as follows.

- Initialization at t=0: Assign to each intersection a number of vehicles NV.
- For each intersection I at time t with the number of vehicles NVi(t), assign to each exit section of intersection I a random percentage XTi(t) % of NVi(t).
- The exit sections of an intersection I correspond to the entry sections at other intersections J1, J2, ...Jn.
- the following equations are presented by [31].
- The traffic flow is the number N of vehicles passing a period Δt at point x,

$$Q_{\Delta t}(x) = Q(x, t \rightarrow t + \Delta t) = \frac{N}{\Delta t} \quad (2)$$

- The density  $K$  is the number  $M$  of vehicles between  $x$  and  $x+\Delta x$  at time  $t$ .

$$K_{\Delta x}(t) = K(x \rightarrow x + \Delta x, t) = \frac{M}{\Delta x} \quad (3)$$

- These two equations (1) and (2) allow us to calculate the time needed to go from an intersection  $I$  to an intersection  $J$ .

An example of traffic visualization after vehicle generation is shown in Fig. 4

#### A. Data Mining

It incorporates choice interaction as information determination, pre-handling as information cleaning from missing qualities, copies, inconsistencies, and incorrect information, dimensional reduction transformation using 0–1 ranges for normalizing, and choice interaction as information determination. By using the formula below, it is very likely possible to determine data normalization.

$$V^i = \frac{v - \min_a}{\max_a - \min_a} (new\_max_a - new\_min_a) + new\_min_a \quad (4)$$

Where:

- $v_i$  = updated data following normalization.
- $V$  = normal data (without normalization).
- $new\_max_a$  = the new maximum value is 1.
- The new  $min_a$  variable's maximum value is 0.
- $max_a$  = the column's highest value.
- $min_a$  is the column's lowest value.

#### B. Algorithm for Congestion Coloring in Sections and Intersections

The upstream and downstream movements of road segments in a road network frequently have an impact on the traffic conditions of those segments. For instance, congestion frequently starts on one or more road segments and expands to other road segments over time. Fig. 5 illustrates congestion by

assigning colors to road segments; the red, yellow, and green lines represent congested, slightly congested, and uncongested road segments, respectively.

To visualize changes in congestion on a map, we propose to color the sections and intersections according to the following two rules:

Rule 1 —  $CI_j$  is the maximum capacity of the intersection  $J$ , so if the value of  $NV_j(t)$  approaches  $CI_j$  then it will have congestion. Three classes of congestion are considered by this experiment: Class 0 for  $NV_j(t) \leq CI_j/3$  (green coloring), Class 1 for  $CI_j/3 < NV_j(t) \leq 2CI_j/3$  (yellow coloring) and Class 2 for  $2CI_j/3 < NV_j(t) \leq CI_j$  (red coloring).

Rule 2 —  $CT_k$  is the maximum capacity of the section  $K$ , so if the value of  $XV_k(t)$  approaches  $CT_k$  then it will have congestion. Three classes of congestion are considered in this experiment: Class 0 for  $NV_k(t) \leq CT_k/3$  (green coloring), Class 1 for  $CT_k/3 < NV_k(t) \leq 2CT_k/3$  (yellow coloring) and Class 2 for  $2CT_k/3 < NV_k(t) \leq CT_k$  (red coloring).

The idea is to exploit the fact that traffic jams move, dissipate or form from one section to another or from one intersection to another [32]. In order to recognize these congestions and show them on a map, we are interested in the sliding window algorithm to predict the state of a section exiting an intersection  $I$  at time  $t$  based on the traffic history of the entry sections of the same intersection  $I$  at time  $t+\Delta t$ .

For a more efficient recommendation system, it is mandatory that the prediction time of the traffic parameters is as fast as possible. In other words, the faster path recommendation must be present before the ambulance arrives at the next intersection.

The data of this simulated history is stored in a MongoDB database and comes from the traffic flows (number of cars per two minute) randomly generated on 84 intersections and 300 sections on the map of the city Marrakech in Morocco. These collected data which correspond to about 1000 hours of execution of the traffic generation algorithm generated more than 30000 elements for each section.

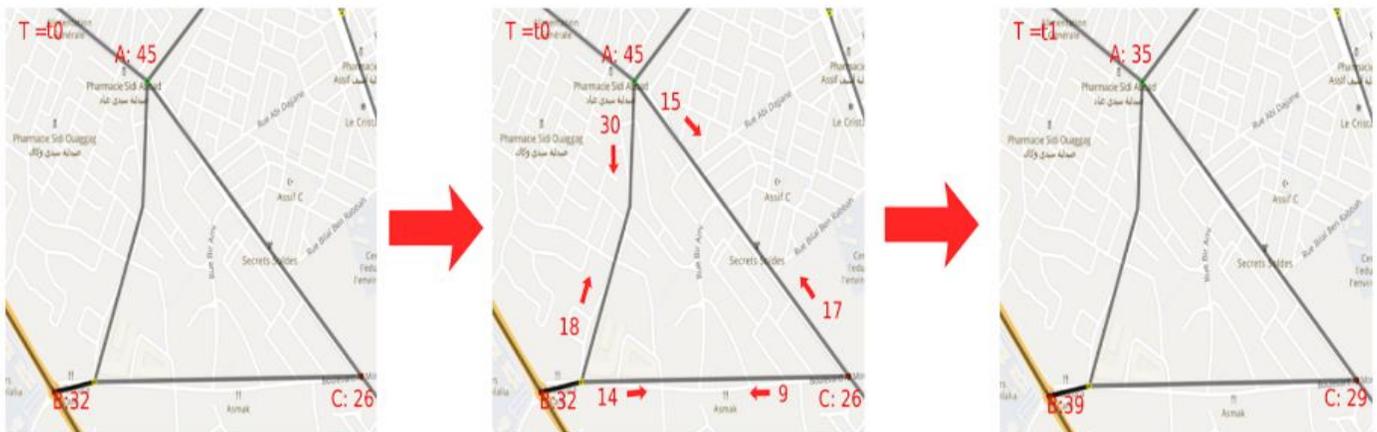

Fig. 4. Example of Traffic Generation between Intersections and Sections.

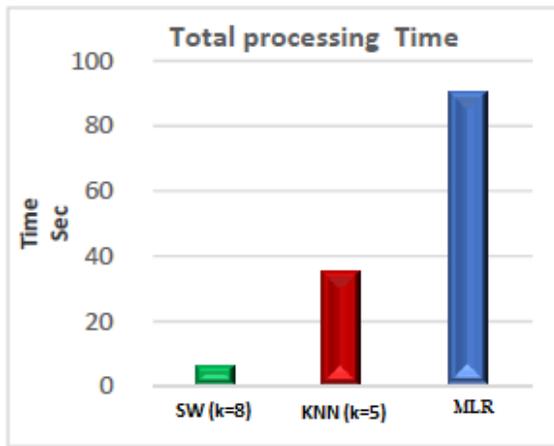

Fig. 5. The Processing Time of SW, KNN and MLR.

## VI. PROPOSED METHODOLOGY BASED ON HYBRID APPROACH

Recall that the proposed approach is based on hybrid approach: 1) a local approach dedicated to traffic prediction based on a machine learning algorithm and 2) a global approach to propose the fastest path from an origin to a destination.

### A. Local Approach: Traffic State Prediction using Machine Learning

The traffic conditions on the same road throughout time exhibit some degree of regularity and consistency. As a result, future road traffic circumstances can be reliably predicted using an accurate comparison of historical and current road traffic conditions [40] and [41].

To identify the more suitable machine learning model for the proposed local approach, this work presents in the following subsections a comparison between the sliding window model, multivariate linear regression model and K-nearest Neighbor model. So we first construct a representative high-capacity historical database. Next, we define the elements of the model, including the value of K sliding window, Finally, a similar traffic flow matching to the present actual time and the observation data from the history database are retrieved to predict the traffic flow at the next time based on the observed values of the input and the search mechanism.

1) *Sliding window algorithm*: This algorithm has the advantage to mathematically model the aforesaid defined dependencies. Therefore, it is able to make the relationship between the historical data and previous k min data to predict the future traffic conditions [42].

The reason for applying the sliding window matching is that there is always a slight variation in traffic conditions that may depend on the variation of the last few minutes and also a dependence between the traffic conditions that persist in the current day and those of previous days [33] and [35]. Therefore, the previous days of the same time are checked to find similar traffic conditions. The sliding window is a good technique to capture the variation that could correspond to the real time variation.

The algorithm is as follows:

1. The matrix "TC" of the last k min for current day's width size  $k \times i$ , i is the number of the sections of intersection I.
2. Consider the matrix "PY" of n min data of size n i.
3. From the matrix "PY," create k sliding windows, each of size  $n * i$ , as  $W_1, W_2, W_3,$  and  $W_{n-k-1}$ .
4. With the matrix "TC" as  $ED_1, ED_2, ED_3, \dots, ED_{n-k-1}$ , represent the Euclidean distance of each sliding window.
5. Select matrix  $W_i$  as:
  - $W = \text{Corresponding Matrix (Min.(ED}_i\text{))}$
  - $\forall i \in [1, n-k-1]$
6.
  - (i) Calculate the variation vector, abbreviated "VC," for the matrix "TC" of dimension  $k-1 * 1$ .
  - (ii) Calculate the variation vector for matrix "W" with dimension  $k-1 * 1$  as "VP" for WC.
  - (iii)  $M_c = \text{Mean(VC)}$
  - (iv)  $M_p = \text{Mean(VP)}$
  - (v) Estimated Variation "V" =  $(M_c + M_p)/2$
  - (vi) To determine the anticipated traffic situation in  $t + \Delta t$ , add "V" to the existing traffic condition at t.

The performance of the Sliding Window is affected by the chosen number of neighborhoods (the parameter K). Table III shows the method used to determine the K sliding windows (k=8 in this case).

---

The steps to calculate the Longest Substring k sliding windows are explained below:

- Selection of beginning data as the system's basic knowledge base.

- find the k sliding windows.
- The preparation of the training data in the form of the criteria's worth of fresh information about which the status is unknown
- Evaluation of each training set's state in accordance with predetermined rules to provide system knowledge.
- Based on each sample's training data and testing data, a distance calculation is made for each sample. the Euclidian equation:

$$d(x, y) = \sqrt{\sum_i^n (x_i - y_i)^2} \quad (5)$$

- determining the testing data's status based on the average of K samples of training data from sliding windows.

Testing results for training data 70% and testing data 30% the confusion matrix result with sliding window method can be seen in Table III.

TABLE III. SLIDING WINDOW TESTING RESULTS FOR TRAINING DATA 70% AND TESTING DATA 30%

K value	Accuracy	Precision	Recall	Classification Error	Mean squared Error
5	83.85%	83.22%	84.93%	16.15%	0.157
6	84.49%	83.75%	85.60%	15.51%	0.143
7	84.57%	84.30%	86.23%	15.43%	0.115
8	85.98%	85.69%	88.45%	14.02%	0.104
9	84.22%	85.08%	85.45%	14.78%	0.121

2) *Multivariate linear regression*: An effective way of modeling and prediction to investigate the quantitative relationship between the dependent and independent variables is to create a multivariate linear regression model utilizing historical data. Assume that there are m independent variables stated as  $X_{tj}$  ( $j = 1, \dots, m$ ), the sample size is n, and the dependent variable is expressed as  $y_t$  at t. Then, the multivariate linear regression model can be written as follows.

In case of multivariate linear regression, results are depending on multiple input values. The parameters used in the implementation are: m-row for the number of training elements (the number of vehicles in each section at time t), n-column for the number of features (the number of section and intersection).

Algorithm.2 Multivariate linear regression

---

**Input:** data set  $D = \{(x_1, y_1), (x_2, y_2) \dots (x_n, y_n)\}$  at t

**Output:**  $\theta = [w_1, w_2, \dots, w_d, b]$

- 1: Define the loss function  $J(\theta) = 1/2n \sum^n (\theta^T x_i - y_i)^2$
  - 2: Generating the randomly  $\theta^0$
  - 3: **repeat**
  - 4:  $\theta^k = \theta^{k-1} - a(\partial J(\theta) / \partial \theta)$  where  $\theta^k$  is the value of  $k^{\text{th}}$  iteration and a is the iteration Step.
  - 5: until  $J(\theta^{k+1}) - J(\theta^k) < \epsilon$
  - 6: return  $\theta$
- 

3) *KNN*: K Nearest Neighbor calculation falls under the Supervised Learning class and is utilized for grouping (most usually) and regression. It is a flexible calculation additionally utilized for ascribing missing qualities and resampling datasets. As the name (K Nearest Neighbor) proposes it thinks about K Nearest Neighbors (Data highlights) anticipate the class or continuous value for the new Data point.

KNN is a non-parametric supervised learning technique, that allows to classify the data point to a given category with the help of training set. The parameters used in the implementation are: K = 5 (after the test result), the number of vehicles of each intersection and road and the traffic states (0: free-flowing traffic/1: semi-congested/2: congested).

---

Algorithm.3 KNN

---

D: the set of learning objects.

$Z(I) = (NV_1, NV_2, \dots, NV_k, t)$  the vector of real-time values, such that  $NV_{ij}$  represents the number of vehicles in the input section j of intersection I at time, t) with j belongs to 1...k

CG is the set of traffic states (0: free-flowing traffic/1: semi-congested/2: congested)

L class used to label the objects:

(CG, the number of vehicles in the exit edge of the intersection I at time  $t + \Delta t$ )

**Input:**  $Z(I)$

**Output:**  $z = (CG, \text{number of vehicles in the edge}) \in L$ , class of z

- 1: **for** object y in D **do**
  - 2: calculate  $d(z, y)$ , the distance between z and y
  - 3: **end for**
  - 4: select N of D, the set (neighborhood) of the k nearest training objects for z.
  - 5:  $cap - max$  is the maximum capacity of the output section of the intersection I
  - 6: returns =  $\sum_{y \in N} NV(t) / cap - max$
- 

B. *Comparison between Multivariate Linear Regression, KNN and Sliding Window*

Table IV compares the performance values that sliding window, multivariate linear regression, and KNN provide in three separate simulation tests: 70:30, 50:50, and 30:70. When compared to Multivariate Linear Regression and KNN, Sliding Window's performance metrics of accuracy, precision, recall, classification error, and mean squared error yield better results. Accordingly, Sliding Window's prediction is more accurate than both of these methods.

Fig. 5 shows the comparison of the processing time of the three algorithms. The result shows that the processing time of SW, KNN and MLR is 13, 38, 87 seconds respectively.

TABLE IV. COMPARISON ANALYSIS OF SLIDING WINDOW, KNN AND MULTIVARIATE LINEAR REGRESSION

Sim Test	Method	Accuracy	Precision	Recall	Classification Error	Mean Squared Error
70:30	SW	85,98%	85,69%	88,45%	14,02%	0,104
	KNN	84,44%	84,41%	84,2%	15,56%	0,124
	MLR	77,25%	72,08%	83,03%	22,75%	0,345
30:30	SW	87,38%	88,84%	89,30%	12,62%	0,061
	KNN	87,13%	88,44%	88,56%	12,87%	0,083
	MLR	76,57%	72,21%	82,46%	23,43%	0,339
30:70	SW	81,94%	78,05%	86,07%	18,06%	0,179
	KNN	81,30%	76,89%	84,77%	18,70%	0,196
	MLR	56,13%	54,23%	66,89%	43,87%	0,463

### C. Global Approach: Prediction based on the Traffic Flow Coefficient

To determine the fastest path between a starting point and all other intersections of a graph (map), we propose as a first contribution to adapt Dijkstra's algorithm to take into account the traffic flow parameter. The value of this parameter is computed according to the real time traffic density, the traffic history, the road condition (public works, ...), etc. This value is also continuously calculated from the data collected at the moment by the road infrastructure sensors in order to find the fastest path from a starting point and to exclude the road with a high degree of congestion. Before presenting the equation (7) used to determine the time needed to cross each road, in [31] present the equations it refers to.

The density K is expressed as the number of vehicles per unit length (veh/km or veh/m).

$$k = \frac{TO}{L+l} \quad (6)$$

where TO is the occupancy rate, L is the length of the assumed vehicles and l is the length of the detection loop, tell that Q is the traffic flow.

$$Q = K \times V \quad (7)$$

Thus, the velocity v is expressed as follows.

$$V = \frac{Q}{TO} \times (L + l) \quad (8)$$

Finally, the travel time Ti for edge i is calculated as follows.

$$Ti = \frac{vi}{Di} \quad (9)$$

The algorithm 2 used follows the following steps:

1. Initialize all roads with a high degree of "infinite" congestion, in other words vehicles cannot move. Moreover, the ambulance is initially at the starting point at time T0.
2. Activate the starting point (algorithm 4 line 4)
3. Calculate the temporary travel time of all intersections adjacent to the current intersection by adding their times (algorithm 4 line 7).
4. If the calculated time of an intersection is less than the current time, update the time and set the current intersection

as the antecedent. This step is also called updating and is the central idea of Dijkstra. (algorithm 4 line 9-19)

5. Set the intersection with the minimum temporary time as active. Mark its travel time as permanent. (algorithm 4 line 10)
6. Repeat steps 3 to 5 until there are no more intersections with a permanent time, whose neighbors still have a temporary travel time.

---

#### Algorithm.4 Dijkstra

---

**Input:** current-Point: the current ambulance junction, destination, graph of time at T0 d travel time for (each section i and each node j), from the prediction Algorithm.

**Output:** path[] : the fastest path.

- 1: **while** (current- Point! = destination) **do**
  - 2: min = infinity
  - 3: **for** vertex v in Graph **do**
  - 4: time[v] =infinity // initial travel time from current-Point to vertex v is set to infinity
  - 5: previous[v] =undefined // Previous node in fastest path from current-Point
  - 6: **end for**
  - 7: time[current-Point]=0 // travel time from current-Point to current-Point
  - 8: Q = set // the set of all nodes in Graph
  - 9: **while** sum >= min **do**
  - 10: u = node // node in Q with fastest time[ ]
  - 11: remove u from Q
  - 12: **for** neighbor v of u **do** //where v has not yet been removed from Q.
  - 13: alt = time[u] + timebetween(u; v)
  - 14: **if** alt < time[v] **then**
  - 15: time[v] = alt
  - 16: previous[v] = u
  - 17: **end if**
  - 18: **end for**
  - 19: **end while**
  - 20: fastest path = previous[] // the ambulance moves to the next point
  - 21: current = Next-Point // from fastest-path
  - 22: Graph =prediction- travel - time(T0 + t) d graph of time at T0+t
  - 23: **end while**
- 

## VII. EMERGENCY TRAFFIC RECOMMENDER SYSTEM IMPLEMENTATION

To implement the proposed emergency traffic recommender system, this paper opted for the agent-oriented programming language SARL, the DBMS MongoDB, and the JavaScript language to build the emergency navigation service for paramedics based on OpenStreetMap.

Fig. 6. Update of the Recommended Path to the Destination.

Fig. 6 illustrates the different stages of movement of the two ambulances A, B. The first ambulance A (red dot) uses the proposed recommendation system to avoid congestion, while the second ambulance B (blue dot) uses classical Dijkstra's algorithm to find the fastest path between the starting point and the destination.

TABLE V. COMPARISON BETWEEN THE PERFORMANCES OF THE THREE METHODS ON DIFFERENT TIMES OF THE SIMULATION

simulation time	Method	distance	time of trips	Fastest Path time
2:00 pm	KNN	1.5 km	449 s	449 s
	MLR	1.7 km	483 s	
	SW	1.5 km	449 s	
2:40 pm	KNN	1.7 km	413 s	413 s
	MLR	1.7 km	413 s	
	SW	1.7 km	413 s	
3:00 pm	KNN	1.7 km	285 s	285 s
	MLR	1.7 km	285 s	
	SW	1.7 km	285 s	
3:20 pm	KNN	1.7 km	435 s	419 s
	MLR	1.5 km	428 s	
	SW	1.9 km	419 s	

The Table V compares the performances of congestion prediction that sliding window, multivariate linear regression, and KNN provide in different moments of the simulation. The

result shows that the Sliding Window's prediction is better than both of these methods. Sliding Window has the advantage to make the ambulance avoiding traffic congestion every time, and taking different way to destination by using the fastest way based on the distance and traffic congestion.

Based on the results obtained, we are currently working on improving the proposed equation (8) to include more detailed parameters such as road condition (public works, presence of accidents, ...), type of vehicle crowd, speed of the vehicle crowd, etc.

## VIII. CONCLUSIONS

The objective of this contribution is to propose a solution for traffic recommendation in emergency situations in order to avoid ambulances to be stuck in traffic jams at the time of trips and interventions. For this purpose, we proposed an architecture based on machine learning techniques for classification and collection of the required information to predict the fastest path to ambulances. Given the lack of empirical data, this paper proposed a random traffic generation algorithm to experiment with the recommendation solution. Based on the generated dataset, we proposed a hybrid approach composed of a local approach to visualize the state of congestion on the map of the city of Marrakech under OpenStreetMap, and a global approach to suggest the fastest path as the ambulance moves. The local approach relies on the Sliding window technique to predict the congestion of sections in three classes: congested, slightly congested and not congested sections. While the global approach implements the Dijkstra algorithm using the multi-agent system modeling language SARL.

The proposed recommendation solution predicts the fastest path for emergency situation from an origin to a destination. Since these recommendations may or may not be taken into consideration by drivers, we are currently integrating drivers experience interaction with the recommender system to build more efficient emergency traffic recommender system.

# A Review of Automatic Question Generation in Teaching Programming

Jawad Alshboul, Erika Baksa-Varga

University of Miskolc, Faculty of Mechanical Engineering and Informatics, Miskolc, Hungary

**Abstract**—Computer programming is a complex field that requires rigorous practice in programming code writing and learning skills, which can be one of the critical challenges in learning and teaching programming. The complicated nature of computer programming requires an instructor to manage its learning resources and diligently generate programming-related questions for students that need conceptual programming and procedural programming rules. In this regard, automatic question generation techniques help teachers carefully align their learning objectives with the question designs in terms of relevancy and complexity. This also helps in reducing the costs linked with the manual generation of questions and fulfills the need of supplying new questions through automatic question techniques. This paper presents a theoretical review of automatic question generation (AQG) techniques, particularly related to computer programming languages from the year 2017 till 2022. A total of 18 papers are included in this study. one of the goals is to analyze and compare the state of the field in question generation before COVID-19 and after the COVID-19 period, and to summarize the challenges and future directions in the field. In congruence to previous studies, there is little focus given in the existing literature on generating questions related to learning programming languages through different techniques. Our findings show that there is a need to further enhance experimental studies in implementing automatic question generation especially in the field of programming. Also, there is a need to implement an authoring tool that can demonstrate designing more practical evaluation metrics for students.

**Keywords**—Question generation; question generation techniques; automatic question generation; teaching programming

## I. INTRODUCTION

### A. Background

In recent years, a number of researchers have been attracted from different disciplines toward automatic question generation for educational purposes [1] [2] [3]. The researcher in [4] defined question generation as “It is an activity of automatically generating questions for different inputs like raw text through semantic illustration”. The definition shows that the generated question type can differ like being a sentence, a semantic map, or a paragraph. The educational question generation is not a new concept, but it has a long history and can be traced back to the use of logic in questions [2], [4], [5]. Cohen is the pioneer of this research area who initially proposed the content for generating questions through an open formula and used one or more unbound variables [1]. Whilst research on generating questions is carried out for a long time, using techniques for automatic question generation for teaching computer programming has raised interest only recently amongst various

research communities, because it requires inclusion of cognitive science, natural language processing and human interaction with computers. Intelligent Tutoring System (ITS) is the recently proposed computer-based teaching context to help students learn programming languages but to the best of our knowledge, computer-based applications for teaching programming are not widely implemented [2]. With rising novice computer scientists, specific questions are generated which can address knowledge gaps that were often negligible in the manual process of articulating questions [6]. In support of enhancing the metacognitive skills of students, asking students to generate questions can be a constructive process but the use of various metacognitive skills can be time-consuming and needs extended knowledge of various metacognitive strategies.

### B. Problem Statement

The success of a rule-based question generation (QG) method depends on the quantity and quality of teachers’ domain knowledge, language knowledge and the amount of time spent on it. On the other hand, data-driven techniques have recently emerged such as deep neural network-based methods that are considered a promising approach for different tasks like recognizing entities, and sentiment categorization. In particular, teaching programming skills to students require extensive motivation which cannot be an easy task from the teachers’ perspective. A key issue is, that students interact with a program that has limited, syntactic and semantic level knowledge of a programming language (for example a compiler or interpreter), while teachers know and therefore can teach also the logic of programming. This requires teachers’ knowledge of how to apply the key concepts of computer programming and teach them to students with appropriate models of Automatic Question Generation (AQQ).

The research in [7] provided a question generation method considering a generative encoder-decoder model. The researchers in [5] mentioned that although there are advances made in the neural models for automatic question generation, there is still a gap indicating a comprehensive survey on how different learning paradigms can present improvements in automatic question generation that broadens the input spectrum of instructors for teaching programming. This shows that various studies have been conducted on automatic question generation process for educational purposes, but to the best of our knowledge, there are only a few studies reporting on the state-of-the-art techniques used for automatic question generation in teaching programming languages, especially for the previous six years i.e. 2017 till 2022. Thus, the objective of this study is to review recent studies that provided different

techniques for automatic question generation with reference to various methods required for teaching programming.

This review extends the systematic review previously conducted on automatic question generation by Kurdi et al. [8] that covered literature from 2014 and up to 2019, respectively, by focusing on the domain of computer programming. The extensive amount of research that has been published since Kurdi et al, an extension of these studies is reasonable at this stage as it helps in understanding recent developments in the given field. The present article uses the previous article by Kurdi et al. [8] as a starting point and extending the review in a number of ways like additional review questions and criteria for inclusion/exclusion, which is discussed in the methodology section.

### C. Research Questions

The questions that will be addressed in this research comes as follows:

- What are the recent developments made in the techniques for automatic question generation in teaching programming?
- What is the difference in the state of the field focusing on before COVID-19 and after COVID-19 period?
- What can be the future directions based on identified gaps in the field of automatic question generation in teaching programming?

### D. Research Objectives

To address research questions the following objectives are considered for this work:

- To review recent literature on the approaches and techniques used for automatic question generation in teaching programming.
- To analyze and compare the state of the field before COVID-19 and after COVID-19 period.
- To provide summary of the challenges and future directions in the field of automatic question generation in teaching programming.

The remaining parts of the paper is structured as follows: Section II represent a literature review which will address previous work on the field. Section III describes the methodology used to conduct this review. Section IV shows the analysis and findings for the papers considered. Section V concludes the paper. Finally, Section IV describes future directions of this work.

## II. LITERATURE REVIEW

Manual question creation consumes much time and labor. The concept of question generation was envisioned back in 1960s [4]. It is generally estimated that learning scientists believe that the provision of high-quality learning questions must use the basics of language knowledge and domain knowledge and so approach the activity using “rule-based” technique [9]. The given approach used syntactic changes to transform declarative sentences into questions. For example, multiple choice questions were generated using rules of term

extraction. Next, questions were sometimes generated using over-generate-and-rank manner that helped in ranking questions [7]. The given methods were limited in their wider applications and rules were also based on a few subjects, like English language. They were not easily applied to other domains, since defining rules and procedures needed considerable efforts from expertise. The given methods are also very limited and do not offer high quality questions, thereby limiting the implementation of rule-based generators. However, entering into digital landscape required wider-scale online learning; hence, the demand for automatic question generation is also increased along with massive number of online courses available to learners. In order to address this need, various computational techniques like deep neural network-based state-of-the-art techniques were proposed [7] [6]. Du et al [4] is pioneered in providing encoder-decoder sequence learning that was later on used for automatic question generation. The given model automatically captured question-asking patterns without taking any help from hand-crafted rules, indicating supreme performance over previous rule-based methods. However, it had a major gap identified by scholars that this technique was helpful in collecting data for machine reading comprehension tasks. Notably, such datasets included a very limited number of useful questions for learning, indicating that extended research is needed to offer question generations for complex learning documents to facilitate teachers.

Assessing students’ answers manually is also a time-consuming mission. Depending on the type of the question, this action can also be automatized more or less. Question types of quizzes are generally categorized into two groups: objective questions and subjective questions. Objective means that there is only one correct answer, which can be checked automatically. The objective questions request the learners to select the correct answer from several options or offer a number of words/short sentences as options or to complete a sentence. Multiple-choice, matching, true-false, and fill-in-the-blank are examples of objective questions, and they are considered the most popular ones, since they provide automatic assessment methods due to its their unambiguous, quick and trusted evaluation process. On the other hand, the subjective questions ask for a written answer composed by the learners and such answer might be short or long. A short answer could be up to three sentences while a long answer might be as long as an essay. The subjective questions should have an increased attention by the teachers to assess learner’s deep knowledge and understanding of the topics, similarly to the traditional education system that have been employed for centuries [10].

Most researchers have focused on generating objective-type questions, automatically or semi-automatically, while limited focus has put on subjective question generation because scoring is a difficult challenge in the case of subjective assessment. Comparing the level of difficulty to generate questions and in assessing the learner’s answers, learner's assessment of the textual question types is very easy for close questions and multiple-choice questions, easy for open-close questions, and difficult for subjective questions. Recent advances in deep learning-based natural language processing (NLP) offer promising solutions in answer assessment of objective-type questions [10].

### A. Automatic Question Generation Process

In recent years, there has been an emerging interest in AQG from the text, which is explained as an activity to generate a question from a passage and optionally an answer. According to [11], AQG helps in curating question-answer datasets and improves our experience in Artificial Intelligence (AI) systems and helps in designing educational materials. But for this purpose, it is equally important for the questions to be grammatically error-free and answerable. Pertinent approaches emphasize on encoding the whole passage as the relationship is shown between them using complicated operations and then questions are generated in one single passage [12]. However, empirical studies show that if careful analysis is carried out for question generation, there are some approaches that probably miss out one or more of the essential aspects of the questions. For example, as mentioned in Table I, the question is generated by the single-pass baseline model that is grammatically correct but it does not fit to the answer [3].

TABLE I. THE PASSAGES AND THE QUESTIONS GENERATED FROM THEM USING REFNET [8]

<i>Passage 1: Functioned by Napoleon army in 1800, Warsaw was given the authority of the newly established Duchy of Warsaw</i>
<i>Questions: Baseline: What was the governor of the newly established Warsaw?</i> <i>RefNet: Who gave freedom to Warsaw?</i> <i>Reward-RefNet: Whose army was given freedom in 1800?</i>
<i>Passage 2: In order to fix the process of carbon dioxide into the sugar molecules, the enzyme called rubisco is used by chloroplasts.</i>
<i>Questions: Baseline: What is used by chloroplasts?</i> <i>RefNet: What is used by chloroplasts to fix carbon dioxide?</i> <i>Reward RefNet: What is used by chloroplasts to fix carbon dioxide into the sugar molecules?</i>

Table I shows that there is a visible scope of enhancing the general quality of the question generation process in contemporary field of teaching [6]. In the literature, scholars argue that one way is to approach this by constantly re-visiting the passage and then answer them with the goal to refine the preliminary draft by producing a better question in the second stage and then bringing further enhancements in the further stages [1][8]. This can be done using a comparison between human process of generating questions and with the computer-generated models [3]. In the examples above RefNet (Refine Network) was used as the model to evaluate the initial questions generated and then carried out a second test to generate revised questions. The Reward RefNet used explicit reward signals to attain the refined questions with two attributes: fluency and answering. This RefNet is a sequence-to-sequence model that includes two decoders called Initial and Refined decoder. According to [13], the proposed dual model helped generating the final question by revisiting the adequate parts of the input passage and preliminary draft.

### B. Automatic Question Generation in Teaching Programming

The Literature exhibited various approaches for automated generation of questions, based on the extraction of featured words given on the topic and established variations on the same question for object-focused programming quizzes. For example, [13] used programming-by-example for code snippets that was a test regulated by synthesis. Recently, the research

article [15] provided facts for generating questions for teaching programming languages. The study reported in [16] found that students are taught by teachers to produce a program but they are not fully sure about the use of their own codes as they failed to grasp basic concepts. But if students are taught using Quality License Scheme (QLS,) it can prompt them to have a deeper level of understanding of given concepts. Schulte's Block Model of Program is another model used by scholars to attain better understanding of programming that needs different levels of knowledge about the program, and its purpose. However, experts argue that such models need knowledge at different levels ranging from individual building blocks to the integration of constructs to complete deficient Research shows that we cannot evaluate how coding process works as it requires skills and debugging process and the aptitude of learners to trace code that helps them write automatically testable code [18]. It is hypothesized that writing codes in a programming language requires preceding abilities of learners to write comparable codes that can be better understood by questions about learner's code (QLCs) approach that helps in learning programming comprehensions. On the other hand, in 2019, scholars of the George Washington University created a software that produced program-tracing questions for introducing programming content to students [12]. But this system also failed as the majority of questions were not applicable due to their complex nature. Later, scholars used Turing test as the tool to determine algorithm-based questions and identify the extent to which they could be helpful for teachers to generate questions that analyze students' learning abilities [14]. But this Turing test also did not pass as it failed to identify the particular issue in the algorithm when generating questions. Later and to extend this work, the researchers in [3] proposed a system called QuizJET, as another tool for generating questions, especially for teaching Java. This QuizJET was based on template-based questions that was linked to different concepts of Java and was actively used for generating quizzes; however, the research conducted in [16] did not find any correlation between the success rates of QuizJET and students' home assignment work, because QuizJET was more focused on understanding programs while home assignments were focused on writing skills of computer programming learners. Despite all these, QuizJET was identified as a valuable source in preparing students for exams.

### III. METHODOLOGY

This study uses systematic literature review as the methodological approach to assess and understand the pertinent literature linked with research questions. From a number of approaches available in the literature for systematic review of studies, this study uses the approach provided by the researchers in [16] who provided detailed guidelines for conducting reviews. The methodological review consists of three key stages which in turn included ten sub activities. The details are showcased in Fig. 1. In the preliminary stage, the given questions were addressed; what are the key areas for which question generation is being designed; what are the different techniques and tools used for question generation process in teaching programming; what are the different modes of delivery for the creation of question generation in teaching programming; and how authors validated such techniques.

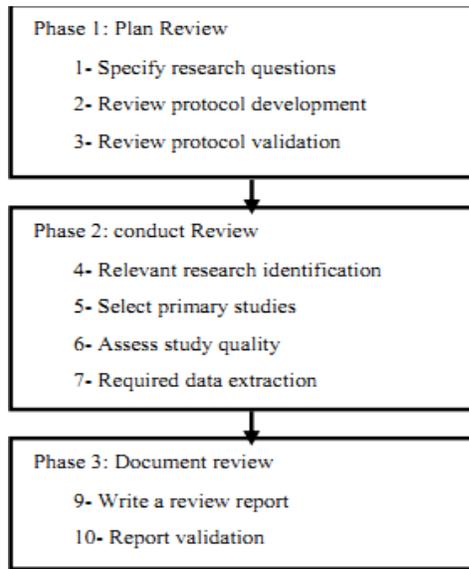

Fig. 1. Phases of Review Adopted from [16].

The questions were generated to complete the preliminary stages and then the sub-activity was carried out by reviewing protocols for the study. The review included determined time span for the published papers, and keywords along with the sources of publications to find most accurate data. The focus of research articles spanned for the last six years i.e. 2017 till 2022 and the sources were obtained from IEEE Xplorer, science direct, Google scholar, and SCOPUS. Table II shows the sources and keywords used to search the materials. Whereas Table III presents the considered papers in each year.

The search process offered a set of total 100 articles and they were then screened on the basis of their titles and abstracts. After filtration, only 18 articles were left that met the inclusion criteria of this study. In order to strengthen the search linked with the articles, backward snowballing provided by [19] was also adopted to identify the most cited articles. This step was ensured to address questions of the study in an effective manner so that no question was left unanswered. The inclusion criteria of this study are based on the research questions of this study and in the end, this study only included those articles that were accurately linked to the research questions of this study.

TABLE II. REVIEW TABLE

Year	Sources	Key words
2017-2022	IEEE Xplorer, Science direct, Google Scholar, SCOPUS	question generation techniques, teaching programming, automatic question generation techniques

TABLE III. YEAR WISE SEARCH RESULTS

Year	Number of papers
2017	4
2018	2
2019	3
2020	3
2021	5
2022	1

#### IV. RESEARCH ANALYSIS AND DISCUSSION

This study has reviewed a total of 18 papers for AQG in teaching programming in the past six years from 2017 to 2022. Older papers are excluded from the search criteria. Most of them used automated evaluation tools [4][5] [6] [14] [17] or they used automated contexts for programming languages [20] [21] [15]. It was also identified that generating feedback for the questions produced to teach programming languages are equally important. Most of the tools were used to grade student solutions but there were some that offered extended feedback and could be used to support learning process of students.

The study conducted in [21] described the attributes of the tools and identified challenges and some future directions. However, a study by [19] selected some papers and mentioned qualitative elements at the time of evaluating tools for question generation. It was also found that the majority of the studies i.e. 12 out of 18 studies lacked comprehensiveness and the scope of the tools varied immensely. Tools are mostly grouped but there is no such agreement on the naming of different groups. Eight papers discussed technical aspects of teaching tools used for programming languages.

As observed from Table IV, studies [1][3][4][5][14][21] used web-based solution to generate questions for students on the online platform. Whereas some of them proposed a theoretical framework like [7][13] [15][22] and the rest of the studies proposed it as a computer application [12] [16][19] [23] [24]. The main observation on the literature is that most of the applied applications use web-based solution to generate general questions from existing materials using different techniques like Artificial Intelligence, Machine Learning, Deep Learning, and traditional custom-made algorithms.

This review paper is different from other reviews as it focused on the dimensions of generating questions and the feedback in teaching programming tools by closely evaluating the various types of feedback provided on the techniques.

##### A. Comparison of State-of-the-Field before Covid-19 and after Covid-19

The findings of the study show that teachers require various kinds of tools and techniques when they generate new programming questions. In order to find out the state of the field before COVID-19 and after COVID-19, a review of the techniques used for generating questions by programming teachers shows that varying techniques have been employed to address certain needs of the instructors. The analysis also showed that prior to COVID-19, scholars have been involved in generating questions for teaching programming using Bayesian Network [5], ITSB tool (Delphi IDE) [2], Artificial Neural Network (ANN) based technique [13][17] [9], and ANN combined with Vortex Optimization Algorithm [7]. All these tools were either based on web-based or experimental or theoretical framework that does not exhibit strength of one technique over another technique for generating questions. Some interesting facts were revealed during the analysis. These are the following: 1) after COVID-19, the instructors valued code-writing question generation techniques like Junit that is a web-based tool and used user feedback as a validating tool. 2) Next, ITA [12], JAVA software, C programming for generating

questions, CodeTraining [15], dynamic codes [16] and PQG model [23] were employed by instructors for generating questions that were identified as the key source of positive ratings in the assessment of students during exams. 3) The analysis of articles published after COVID-19, i.e. from 2020 till 2022, valued code-tracing procedures as compared to pre-COVID-19 that seems a major difference between the two periods. 4) Before COVID-19 the focus was on supporting students in learning (finding answers for questions from long texts). Whereas after COVID-19 the focus has shifted to supporting teachers in generating online quizzes and assessing student assignments automatically. This difference also exhibits that the extensibility of tools used for generating

questions got significantly positive ratings from users as compared to pre-COVID-19 tools [23]. This finding is interesting as it identified that the models used after COVID-19 address the needs of particular users and provided only extensible questions to the instructors to be used after edits in practice. On the other hand, the analysis also shows that the automatic question generation process through code-tracing method is very limited and can generate questions when the topic is wide and it is difficult for instructor to cover all ideas when making the questions. One plausible explanation could be, that instructors now anticipate the questions to be more in line with the content they teach in the class.

TABLE IV. ANALYSIS OF ARTICLES

Year of publication	Title of the study	Domain	Aim	Tool for generating questions	Mode of delivery	Validating study
2017	[5]	Computer Science	Teaching programming language	Bayesian Network	Web-based	Experimental
2017	[2]	Computer Science	Teaching programming language	ITSB tool (Delphi IDE)	Web-based	User feedback
2017	[7]	Computer Science	Teaching programming language	Artificial Neural Network based technique & Vortex Optimization Algorithm	Theoretical framework	Experimental
2017	[13]	Computer Science	Teaching programming language	Artificial Neural Network	Theoretical framework	User feedback
2018	[4]	Computer Science	Teaching programming language	Bayesian Network	Web-based	Student feedback
2018	[18]	Computer Science	Teaching programming language	Automatic Item Generation (AIG)	test-item templates	User feedback
2019	[1]	Computer Science	Teaching programming language	ITA	Web-based	Teacher feedback
2019	[23]	Computer Science	Teaching Programming Language	SQL question Generation (DB-Learn)	Computer based application	User feedback
2021	[19]	Computer Science	Teaching programming language and question generation	Question Similarity mechanism.	Application	Teacher feedback and user response
2019	[21]	Computer Science	Teaching programming language	ITA	Web-based	Experimental
2020	[3]	Computer Science	Teaching programming language	JUnit	Web-based	User feedback
2020	[12]	Computer Science	Teaching programming language	ITA	Computer based application	Student performance
2020	[22]	Computer Science	Teaching programming language	AA	Theoretical framework	Teacher feedback
2021	[6]	Computer Science	Teaching programming language	JAVA software	Web-based	Student performance
2021	[14]	Computer Science	Teaching programming language	Java Programming Course	Web-based	Student performance
2021	[15]	Computer Science	Teaching programming language	CodeTraining	Theoretical framework	User feedback
2021	[16]	Computer Science	Teaching programming language	Dynamic codes	Computer based application	Student performance
2022	[24]	Computer Science	Teaching programming language	PQG model	Computer based application	Student performance

### B. Techniques of Automatic Question Generation in Teaching Programming

Intelligent Tutoring Systems (ITS) are mainly identified as major systems for teaching programming domain. The analysis of articles showed that there are some general ITS techniques such as the tools that use model tracing for analyzing the process followed by students to solve problems in programming languages. The authors contrasted production rules and buggy rules in [16] while other researchers in [19] used constraint-based modeling techniques that is based on three levels, logical, empirical and data-based constraints. This model has a major limitation for how to conduct loop and eliminate the chances of generating error messages that could affect teachers' ability to generate questions. This study identified theoretical and practical gaps in the literature that could be used as future direction by scholars.

Dynamic code analysis through automated testing is another technique used by [13] as the way to teach programming and then generate questions for analyzing students' abilities and knowledge skills. According to [25], this was identified as the major type of automated testing but it lacked modern techniques necessary for unit testing and property-based testing, mostly executed through pertinent test frameworks like JUnit. In order to address this limitation, the research in [19] used another technique, called basic static analysis and identified the misunderstood concepts and the inadequacy of code structures. However, recently the article [15] also concluded that Program Transformations are another language processing tool that reduces the syntactical complications and help instructors to produce same level of abstraction when designing questions. Notably, all the tools identified during the analysis of articles showed that they fall within two major categories; automated assessment (AA) and intelligent tutoring system (ITS). Automated assessment focused on the use of tools that evaluate students' abilities to solve questions with a feedback report, but ITS helps students to reach solutions with novice feedback that is helpful for teachers to generate questions [17][18].

A recent study conducted by [15] mentioned that previous meta-analysis methods have been used to recognize the factors affecting students' performance but this study is pioneered in evaluating students' computer programming skills through Educational Data mining approaches. The authors stated that there are various categorizations of algorithms for identifying student's performance studying computer programming and the most effective is to use pooled approach to estimate students' performance progress in programming as their educational domain. The authors tried to identify the probable sources of heterogeneity by using subgroup analysis and sensitivity analysis; however, a major gap is identified in defining the sources of variability as authors were unable to establish any in their cases. It is highly likely that the key reason for this colossal heterogeneity was linked with some studies that were obtained from the varying sample sizes; however, it needed further research that could help in adopting different algorithms for assessing student performance.

A study by [16] provided important contribution in generating quizzes for C programming language. The key

contribution of this study is that authors solved the programming questions and generated questions by following an entity discovery approach. It was estimated during the analysis of the question generation process that teachers and students can use them for solving quizzes and attain concepts in a better way. However, this study has a major limitation of practical knowledge related to precision and inclusion of more features like mining answers from the posts and grouping the questions into different levels of their difficulty. On the other hand, an article by [12] generated questions for teaching C programming through JAVA software application that illustrated the likelihood to produce automatic quizzes. It is estimated that if students have acquired knowledge for C programming language, students are able to learn other programming languages in a better way. This paper has a key strength to test the students' knowledge about how to define the C language functions; however, knowledge gap is identified about how students can enhance their aptitude skills for programming in other languages. This restricts the generalizability of the study on learning other programming languages. Although an article by [12] used educational software for studying JAVA language and then assessed their skills towards basics of object-focused programming. The authors provided very important contribution by generating automatic quizzes for JAVA programming through six different types of parametrized questions. This particular technique had major implication in theory as every time the test is conducted to test comprehensive skills of learners, new questions are generated. However, this article did not specify how learners can answer accurate questions based on their programming knowledge. CodeTraining is a very new approach that used an authoring tool for Gamified Programming Learning Environment; however, this particular tool lacks approaches on how teachers can create questions through the integration of different resources [25]. It is also suggested that future scholars can extend knowledge based on Gamification Programming Learning Environment by conducting experimental studies and through the use of an authoring tool that demonstrates how to design questions relevant to the course.

### V. CONCLUSION

The objectives of this study are attained by offering a picture of the existing state of teaching programming and the tools used for generating questions. We have discussed the gaps in each article and the limitations of each article that could be used as future research directions. The article also addressed the objective related to comparing state of the field situation in the pre-COVID-19 and during COVID-19 periods. During the review of the studies, various effective methods were identified to that can be helpful in generating questions. A total of 18 papers were analyzed from the year 2017 up to 2022 that were relevant to the given topic of the study. The key techniques included AA and ITS and in particular, Dynamic code analysis, JUnit tests, JAVA programming software, CodeTraining, Program Transformations, PQG model and Educational Data mining approaches. Some gaps are related to the inefficacy linked with the models and the techniques adopted by scholars for generating questions. The inability to properly evaluate students' performance and abilities is related to the quality of the data used for that evaluation. Future studies may seek to

focus on the development of techniques based on key approaches identified in this study to improve the applicability of techniques on a wider scale and in practical context. Furthermore, interested researchers can work on the identified promising research topics in question generation for educational purposes.

## VI. FUTURE RESEARCH DIRECTIONS

Based on the literature, the following points represent promising research topics for the interested researchers in question generation for educational purposes:

- Implementing question generation approaches to generate questions on programming languages topics.
- Enhancing experimental reporting, standardizing evaluation metrics, and studying and developing more practical evaluation metrics.
- Extracting informative sentences from existing sentences need to be improved.
- Generating questions from several sentences and summarizing sentences based on their relations need to be explored.

## ACKNOWLEDGMENT

The authors gratefully acknowledge the financial assistance from the Institute of Information Science, Faculty of Mechanical Engineering and Informatics, University of Miskolc.

Gimhae 50834, Republic of Korea

**Abstract**—For multicultural families to successfully promote social adaptation and achieve desirable social integration, the role of the multicultural family support center (Multi-FSC) is crucial. In addition, it's important to examine the factors that will contribute to the multicultural support center's vitality from the standpoint of the customers. In this study, machine learning models based on a single machine learning model and stacking ensemble using survey data from all multicultural families were used to examine the determinants for the utilization of multicultural family support centers for multicultural families. Additionally, based on the constructed prediction model, this study offered the foundational data for the revitalization of the multicultural support center. In this study, 281,606 adults (19 years or older), 56,273 of whom were married immigrants or naturalized citizens as of 2012, were examined. The stacking ensemble method was employed in this work to forecast the use of multicultural family support centers. In the base stage (model) of this model, logistic regression was employed, along with Classification and Regression Tree (CART), Radial Basis Function Neural Network (RBF-NN), and Random Forest (RF) model. The RBF-NN-Logit reg model had the best prediction performance, according to the study's findings (RMSE = 0.20, Ev = 0.45, and IA = 0.68). The findings of this study suggested that the prediction performance of the stacking ensemble can be improved when creating classification or prediction models using epidemiological data from a community.

**Keywords**—Stacking ensemble machine; radial basis function neural network; random forest; multicultural family support centers; prediction model

## I. INTRODUCTION

In South Korea, the number of married immigrants and foreign workers has increased rapidly since the 1990s. Consequently, South Korea has also transformed into a multicultural society starting in the 21st century. Multicultural Demographic Statistics [1] reported that the number of foreigners residing in South Korea was 1.13 million as of 2011, exceeding 2.3% of the resident registration population in South Korea. Furthermore, multicultural marriages increased by 4.0% (24,721 cases), and the proportion of multicultural marriages in total marriages in South Korea was 10.3%, up 1.1% from 2019 [1]. If current trends continue, the number of married immigrant families will exceed 2 million, accounting for 5% of the total population, by 2050 [2]. In addition, the Ministry of Education, Science and Technology [3] estimated that one out of five

citizens in their 20s will be from multicultural families and one out of three newborns will be born in multicultural families in 2030. South Korean society must prepare for measures to cope with various issues, which may arise during the paradigm shift to multiculturalism (e.g., early adaptation of marriage immigrants to South Korean society), as well as these rapid changes in the demographic structure.

As the number of multicultural families has increased, support for multicultural families has also been diversifying over the past 20 years [4]. Currently, the South Korean government has established and operated multicultural family support centers nationwide as a part of national policy for stably supporting a multicultural society [5]. The multicultural family support center (Multi-FSC) is a central management that has been operated since 2006 for the purpose of helping marriage immigrants to adapt to South Korean society quickly and supporting for stable family life of multicultural families through providing services including family education, counseling, and cultural programs for multicultural families. Twenty-one centers were established in 2006, and the number of centers increased to 201 by 2012, following the passage of the Multicultural Families Support Act (No. 8937) in 2008 [6,7].

In one aspect, as the number of multicultural family support centers was increasing, the necessity of careful management for participants was emphasized in addition to the effectiveness of services [8]. Nevertheless, studies on the Multi-FSC have focused on the results of one region or just analyzed the achievement or satisfaction of multicultural support projects [9, 10, 11, 12].

The role of Multi-FSC is very important for the successful social adaptation support and desirable social integration of multicultural families. In addition, it's important to examine the factors that will contribute to the multicultural support center's vitality from the standpoint of the customers. This study explored the predictors for the use of Multi-FSCs for multicultural families using machine learning models based on a single machine learning model and stacking ensemble using the survey data of all multicultural families. Furthermore, based on the developed prediction model, this study provided foundational data for the revitalization of the multicultural support center.

## II. MATERIALS AND METHODS

### A. Source Data

This study analyzed survey data from a national survey of multicultural families (NS-mulfam) that the Ministries of Health, Welfare and Family Affairs, Justice, and Gender Equality jointly conducted in 2017 on multicultural families living in South Korea. The purpose of the NS-nulfam was to create tailored policies by identifying the living circumstances and welfare requirements of multicultural families [13]. The general characteristics of multicultural families, employment, economic status, marriage, health, and medical care were among the survey's questions. The NS-nulfam targeted 154,333 married immigrants for its survey, all of whom were living in South Korea. A survey on married immigrants, a survey on their spouses, and a survey on their kids were all independently conducted as part of this study. The survey subjects were sampled by using the status of foreign residents in 16 cities and provinces in South Korea and the basic status data of multicultural families organized by the Ministry of Public Administration and Security. The survey was carried out from July 20 to October 31, 2017, and a separate sample design was not taken into consideration because this study used a complete enumeration. According to the Multicultural Families Support Act (No. 8937), the multicultural families used in this research were defined as either 1) families made up of marriage immigrants and South Korean citizens who became citizens by birth, acknowledgment, or naturalization, or 2) families made up of foreigners who became citizens of South Korea by acknowledgment or naturalization and South Korean citizens who became citizens by birth, acknowledgment, or naturalization. After removing 1,618 individuals who were under the age of 19 from the study, 281,606 adults (56,273 men and 225,333 females) who were married immigrants or naturalized as of 2012 were examined.

### B. Definition of Variables

The outcome (label) was defined as the use experience of a Multi-FSC (not aware of or never used it OR used it before). Features included gender, marital status (single, having a spouse, bereavement / widowed, or divorcement / divorced / separation / separated), highest education level (elementary school or below, junior high school, high school, or college or higher), occupation (regular worker, temporary worker, day-to-day worker, self-employed with employees, self-employed without employees, or unpaid family worker), age (19-29, 30-39, 40-49, 50-, 60-69, or 70 years old or older), family relationship satisfaction (not applicable, satisfactory, not satisfied or dissatisfied, or dissatisfied), relationship satisfaction with a spouse's siblings (not applicable, satisfactory, not satisfied or dissatisfied, or dissatisfied), relationship satisfaction with children (not applicable, satisfactory, not satisfied or dissatisfied, or dissatisfied), life satisfaction (good, moderate, or bad), relationship satisfaction with a spouse's parents (not applicable, satisfactory, not satisfied or dissatisfied, or dissatisfied), heritage // nationality of origin (Chinese, Korean-Chinese, Taiwanese or Hong Kong, Vietnam, Philippines, Japan, Mongolia, Uzbekistan, Russia, Thailand, Cambodia, North America, other southeast Asian countries, Western Europe, or Southern Asia), Korean

citizenship (yes or no), social discrimination experiences (yes or no), and subjective state of health (good, moderate, or bad).

### C. Base Model (Single Machine Learner): Classification and Regression Tree (CART)

One of the statistical decision classification methods, CART, uses the Gini Index to quantify impurity [14]. It is a binary split-based technique that only creates two child nodes from a parent node [14]. Advantages of CART include its ability to handle both continuous and categorical data as well as the ease with which its rules may be understood [15]. The likelihood that two randomly selected items from  $n$  elements belong to separate groups is known as the Gini coefficient [16]. The classifier and ideal classification that reduce the Gini coefficient the most are chosen as a child node once the algorithm has determined how much the Gini coefficient has decreased.

### D. Radial basis Function Neural Network (RBF-NN)

RBF-NN is a data mining modeling technique that finds hidden patterns in data by repeating learning from real data and mimicking the human brain's neural network [17, 18]. It is a nonlinear flexible model used to forecast using data with complicated structures [17,18]. The neural network is a hierarchical algorithm made of several processing components [19]. The relationship between input and output is learned while weights are repeatedly changed using historical input data and corresponding output values [19]. The neural network is made up of an input layer made up of nodes that correspond to input variables and a hidden layer (or layers) made up of numerous hidden nodes. The hidden node uses a nonlinear function to handle the linear combination of variable values given from the input layer and sends it to the output layer or another hidden layer. The coupling function for the hidden layer in this work was RBF-NN, which employs the Radial Basis function. Fig. 1 illustrates the RBF-NN idea.

### E. Random Forest (RF)

The RF algorithm randomly selects which decision trees to learn [21]. Multiple bootstrap samples are used in this technique to create a decision tree for each sample, and the results showing the highest frequency among the decision tree results are used to forecast the outcome of a new dataset [22]. In Fig. 2, the RF structure is shown.

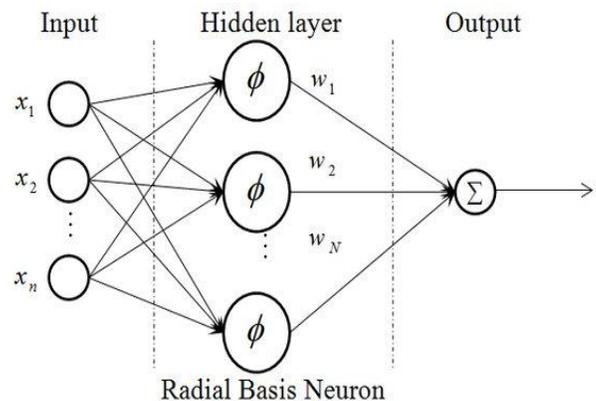

Fig. 1. Structure of the RBF-NN Modeling [20].

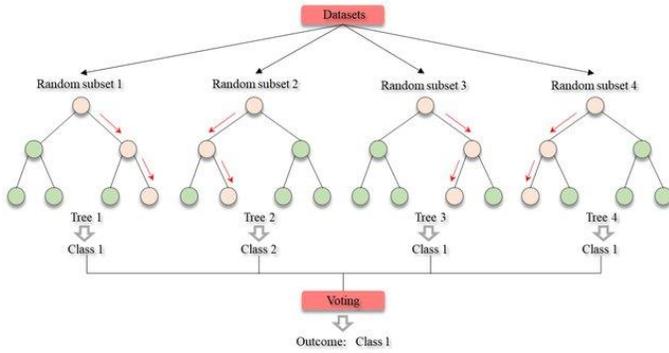

Fig. 2. Structure of the Random Forest Modeling [23].

F. Meta Model (Stacking Ensemble)

The stacking ensemble technique was used in this study to predict the use of Multi-FSCs. In recent years, stacking ensemble outperforms a single machine learning model in terms of generalization and robustness, and it has been used for classification and prediction in a variety of fields [24, 25, 26, 27, 28]. This technique generates a new model by stacking several different models [29]. It improves the final model's performance by combining the strengths of each model and supplementing the weaknesses of each model through two stages (base and meta) [29].

In the base stage (model), this model used RBF-NN, CART, and RF. In the meta stage, the model used the logistic regression algorithm (model). The regression algorithm is the most straightforward way to maximize generality and stability while increasing the reliability of the base model, and it is unlikely to overfit the training data [30]. Due to this, the regression algorithm has been employed in numerous recent publications [30, 31] as the meta model for the stacking ensemble algorithm. For the same reason, the regression algorithm for a meta model was used in this study. Fig. 3 illustrates the final stacking ensemble model's structural layout.

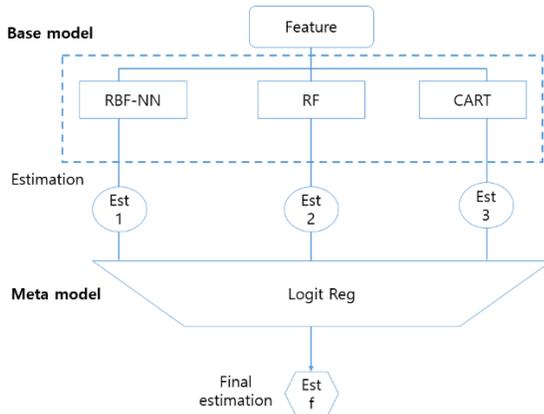

Fig. 3. Structure of the Prediction Model (Stacking Ensemble).

G. Meta Model (Stacking Ensemble)

Through the use of seven-fold cross-validation, each machine learning model was verified. With this approach, ten groups of equal size are randomly selected from the entire sample, and one group is used for validation while the other is

used for learning. Seven times are run through this procedure to ensure that the knowledge is retained. The root-mean-square error (RMSE), error variance (Ev), and index of agreement (IA) were used in this study to assess how well the developed models performed as predictors. A lower RMSE among these indices denotes a prediction model with greater accuracy, whereas a lower Ev denotes a model with greater stability. A model becomes more stable as IA gets closer to 1.

III. RESULTS

A. General Characteristics of Subjects by the Experience of using the Multi-FSC

Table I depicts the general characteristics of the research subject based on their experience with the Multi-FSC. Among the 281,606 subjects, 95,826 subjects (34.0%) had used the Multi-FSC at least once, while 185,780 subjects (66.0%) had not used the Multi-FSC. The results of chi-square test showed that the group with experience of using the Multi-FSC and the group without experience of using the Multi-FSC had significantly ( $p < 0.05$ ) different age, gender, relationship satisfaction with children, the highest level of education, family relationship satisfaction, relationship satisfaction with a spouse's parents, siblings, subjective health status, life satisfaction, occupation, nationality of origin, South Korean citizenship, and social discrimination experience.

TABLE I. GENERAL CHARACTERISTICS ACCORDING TO THE EXPERIENCE OF USING THE USING THE MULTI-FSC, N (%)

Variables	Experience of using the Multi-FSC		p
	Yes (n=95,826)	No (n=185,780)	
Age			<0.001
19-29	42,122 (55.9)	33,258 (44.1)	
30-39	32,219 (37.5)	53,794 (62.5)	
40-49	16,905 (23.8)	54,090 (76.2)

*B. A Comparison of the Prediction Performance of Models Anticipating the Utilization of the Multi-FSC*

Fig. 4 to 6 depict the prediction performance (RMSE, Ev, and IA respectively) of six machine learning models for forecasting the use of Multi-FSCs. The findings revealed that the RBF-NN-Logit reg model had the best prediction performance (RMSE=0.20, Ev=0.45, and IA=0.68).

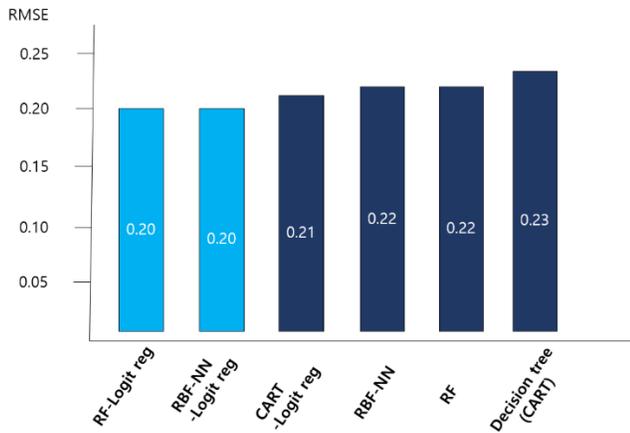

Fig. 4. Models for Machine Learning Compared using the Root-mean-Square Error.

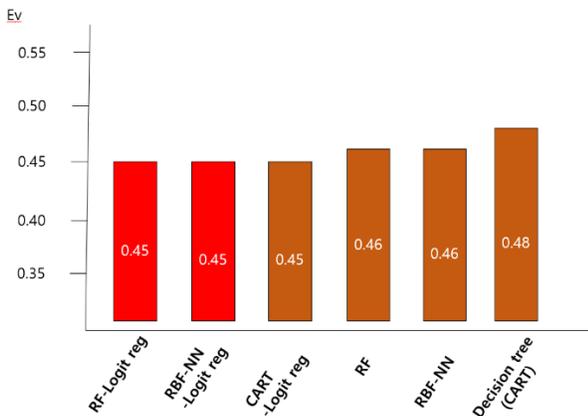

Fig. 5. Models for Machine Learning Compared using Error Variance.

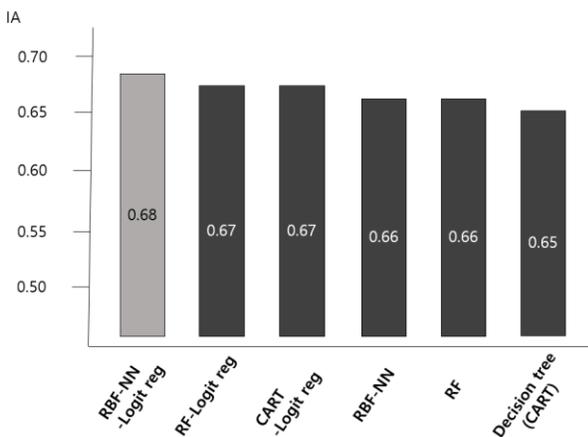

Fig. 6. Models for Machine Learning Compared using Index of Agreement.

### C. Predictors for the use of Multi-FSCs in South Korea

The normalized importance of the variables of the RBF-NN-Logit reg model, the final model, is presented in Fig. 7. The results confirmed that gender (100%), relationship satisfaction with children (93%), age (85%), country of origin (69%), relationship satisfaction with a spouse's siblings (61%), and relationship satisfaction with a spouse's parents (57%) were a

significant factor that carried a significant amount of weight in the South Korean experience of using Multi-FSCs. The gender (female) of these was the one that had the greatest impact on the final model.

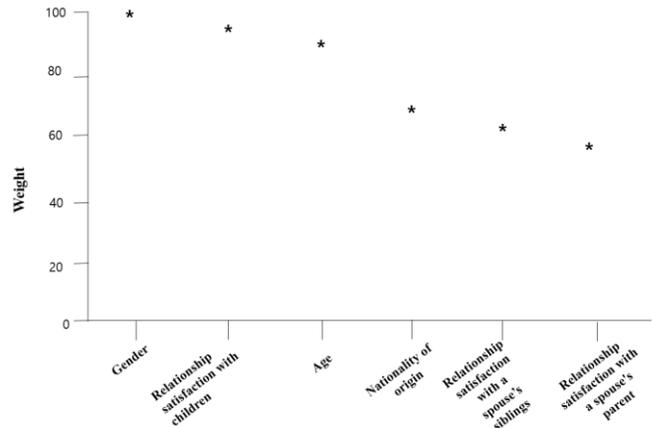

Fig. 7. Variable's Importance for use of Multi-FSCs (only top 6).

### IV. CONCLUSIONS

In our study, the RBF-NN-Logitreg model predicted gender, relationship satisfaction with children, age, country of origin, relationship satisfaction with spouse's siblings, and relationship satisfaction with spouse's parents for the application of Multi-FSC. The South Korean government can use these forecast results as policy data to further promote Multi-FSC.

Using six machine learning techniques—three base models and three stacking ensemble models—this study created prediction models for factors linked to the use of the Multi-FSC in South Korea and evaluated the effectiveness of the models. The RBF-NN-Logit reg model based on the stacking ensemble algorithm had the best prediction performance, according to the results. Given that their RMSE was 0.03 less than that of the base models, prediction models based on the stacking ensemble technique in particular demonstrated improved accuracy (single machine learning model). Furthermore, given that their EV was 0.03 higher than the EV of base models, they had better stability. The findings of this study suggested that the prediction performance of the stacking ensemble may be superior to that of the single machine learning model when developing classification or prediction models using epidemiology data from a community.

The stacking ensemble takes longer to run than the single machine learning model because its algorithm is more complex than the base model [32, 33, 34, 35, 36, 37]. Furthermore, depending on the combination of the base model and meta model, it has been reported that it is more likely to cause overfitting than a single machine learning model in some cases [32, 33, 34, 35, 36, 37]. As a result, more research is required to evaluate the prediction performance of the stacking ensemble. Future research is required to investigate the stacking ensemble model with the best performance using more diverse combinations of base models and meta models in order to find a model that can minimize overfitting while maximizing accuracy.

# Research on Precision Marketing based on Big Data Analysis and Machine Learning: Case Study of Morocco

Nouhaila El Koufi, Abdessamad Belangour, Mounir Sdiq  
Laboratory of Information Technology and Modeling (LTIM)  
Faculty of Sciences, Ben M'sik, Hassan II University, Casablanca, Morocco

**Abstract**—With the growth of the Internet industry and the informatization of services, online services and transactions have become the mainstream method used by clients and companies. How to attract potential customers and keep up with the Big Data era are the important challenges and issues for the banking sector. With the development of artificial intelligence and machine learning, it has become possible to identify potential customers and provide personalized recommendations based on transactional data to realize precision marketing in banking. The current study aims to provide a potential customer's prediction algorithm (PCPA) to predict potential clients using big data analysis and machine learning techniques. Our proposed methodology consists of five stages: data preprocessing, feature selection using Grid search algorithm, data splitting into two parts train and test set with the ratio of 80% and 20% respectively, modeling, evaluations of results using confusion matrix. According to the obtained results, the accuracy of the final model is the highest (98.9%). The dataset used in this research about banking customers has been collected from a Moroccan bank. It contains 6000 records, 14 predictor variables, and one outcome variable.

**Keywords**—Precision marketing; big data analysis; machine learning; potential customers prediction algorithm (PCPA)

## I. INTRODUCTION

After entering the 21st century, the world witnessed a rapid growth in internet technology which resulted in the development of online transactions and the change in consumer habits and consumption patterns. The traditional model of bank marketing seriously hinders the development of the bank sector due to the lack of understanding of clients' needs, inability to adapt to the modern market characteristics, and the lack of personalized recommendations for quality customers. However, Big data analysis and machine learning techniques applied in precision marketing will provide ideal results to traditional marketing. Therefore, the banking industries need to change their old marketing model toward a precision marketing model based on big data analysis, artificial intelligence (AI), and modern information technology to realize long-term development.

The advancement of big data technology has also contributed to the acceleration of transformation from traditional banking to modern and digital banking. Meanwhile, machine learning techniques and big data analysis technology play an essential role in the precision marketing of banking

services. Machine learning techniques provide the possibility to extract facts, information, and patterns about customers from the large amount of data gathered in banks [1]. Analyzing and extracting knowledge from such data can provide a decision-making foundation for banking companies.

The marketing strategy is a long-term scheme that principally studied the marketing and market environment to understand market opportunities and meet the customers' needs. It covers everything from the study of the situations confronted by enterprises marketing under current market conditions and competitions, the choice of customers, and the channel of communication between companies and clients. Whereas precision marketing refers to a marketing strategy that has a clear focus, it targets the consumers that have a great willingness to consume. Based on modern information technology, precision marketing precise the position accurately to build personalized communication between enterprises and customers so that companies can realize long-term development and maximize wealth.

Theoretically, precision marketing is a marketing strategy that aims to understand customers well and their actual needs. Practically, based on big data analysis, machine learning techniques, and modern technology, precision marketing can render the prediction reasoning nearest to customers' needs. The principle of precision marketing was first proposed back in 1999 by Lester. In 2004, the 4R rule of precision marketing was declared by Brebach and Zabin. Then, Philip Kotler gave a clear introduction to precision marketing. Jin et al. [2] have stated that companies can achieve high sales performance by adapting precision marketing.

Precision marketing can not only achieve high sales and decrease the purchase cost of customers but also help companies to build a loyal customer base. The modern bank is customer-centric. It focuses on how understanding customers' behaviors to provide clients with accurate and quality services via a digital operation technologies chain. Banks not only need to realize deals with customers but also need to maximize wealth and ensure return rates last long. Thanks to the fast development of information technologies, precision marketing realize the goal of enterprises to understand clients and provide them with the right product at the right time and via appropriate methods. Precision marketing contains four parts: target customer, right message and channel, and a good time.

The main objective of this paper is to propose a new precision marketing model based on big data analysis and machine learning techniques to identify potential customers. The rest of this paper is organized as follows: we review previous related works in the next section. In Section III, we present and discuss the proposed methodology. Section IV is reserved to illustrating and analyzing our simulation results and performance evaluation. Finally, the conclusion of our paper is in Section V.

## II. RELATED WORK

### A. Literature Review

We present a summary of what has been proposed in precision marketing based on machine learning and big data by renowned researchers. In this subsection, we have reviewed various researches related to our work.

Chiu et al. [3] have proposed an Omni-channel Chatbot that merges IOS, Android, and Web components. Based on convolutional neural networks (CNNs), the proposed chatbot can provide personalized service and precision marketing. In order to show the advantages of the new method, a case study of a shared kitchen is utilized, which can be employed for other consumer applications like personalized services and clothing selection.

Zhang et al. [4] developed a predictive model to forecast high potential luxury car buyers using car owners' and telecom users' data. They combined two machine learning algorithms, logistic regression, and neural network mining. A case study of a traffic management department and telecom operators in a medium-growth city in china is used to demonstrate the efficiency of the new model.

In [5], Xia Liu has compared the CNN model, LSTM model, LSTM attention model, and CNN + LSTM attention. As a result, the performance of the CNN + LSTM attention model and the LSTM attention model is better, with the highest overall accuracy of testing and training. The model is applied to precision marketing for obtaining precision consumer portraits'.

In [6], Xie et al. have used Hamming distance classification algorithm and BP Neural network to classify clients using purchase data to release the purpose of precision marketing. In order to solve the problem of the chosen transportation program, the related decision objectives, and location selection. Xiao et al. [7] built a precision marketing optimization strategy using neural network modeling and the fuzzy method.

In [8], Chong et al. adopted neural networking for consumer product demand prediction. In order to show the advantage of the proposed solution, an electronic data from Amazon.com was used. This data is about promotional marketing information and online reviews.

Tang et al. [9] proposed an advanced K-means clustering algorithm to provide an accurate customer division. Scholars have applied this new method in the precision marketing of ETC credit cards to precisely detect potential ETC users. To build a precision marketing device for forecasting the cumulative number of voice app users for China Mobile communications, Yan et al. [10] adopted ARIMA modeling.

The proposed method gives a reference to understanding its market demand.

The studies in precision marketing based on Big data analysis and machine learning are fewer in the banking field. The related research of machine learning in the banking sector mainly focuses on banking crisis prediction and forecasting customer churn. In [11], Jessica et al. adopted artificial neural network modeling that predicts the short-term financial distress for Spanish banking. A predictive model based on Big data analysis and crisis Index to predict the banking crisis was proposed in [12]. Zizi et al. [13] used logistic regression and neural network modeling based on financial indicators to forecast financial distress in the bank sector.

In this study, we propose a new precision marketing model based on banking big data to forecast potential target customers and realize accurate marketing of bank housing loans. The proposed PCPA algorithm is based on big data and machine learning technology. The process of PCPA consists of five steps: data selection and understanding, data cleaning and filtering, feature selection, data modeling, and results evaluation. After a comparison of various famous machine learning methods [14], we chose XGBoost as the central algorithm of PCPA. Moreover, we have preprocessed the data and extracted the significant features using the Grid search algorithm for well understanding of the data.

## III. PROPOSED WORK

### A. System Architecture

In this subsection, a pictorial representation of the whole process of PCPA is illustrated in Fig. 1. The process of PCPA consists of six phases: data selection and understanding, data cleaning and filtering, feature selection, splitting the prepared data, modeling, and results evaluation.

### B. Description of Proposed Model

1) *Data selection and understanding*: The dataset used in this study is from a Moroccan bank, Attawfiq Micro-Finance. The data consists of 6000 records and 14 variables; it contains demographic information and information about customers' behaviors. The provided data are from 2018 to 2021. For building a suitable predictive model, a selection of important information from data was established using advanced data variance analysis and analyzing attributes correlation (using Correlation matrix).

Each case from the final dataset is represented by thirteen variables used as input to the proposed model and one categorical variable that represents whether the customer has applied for a housing loan (Housing\_credit) as output. Table I represents the attributes of the data. We represent the coded of some indicators in Table II.

2) *Data cleaning and filtering*: The data cleaning and filtering stage consists of cleaning the selected data from missing values, outliers, noise, etc. This phase is eliminatory for reducing the dimensions of the dataset and reducing the time of required computation. In order to extract deeper insights, we have considered the data visualization in this methodology.

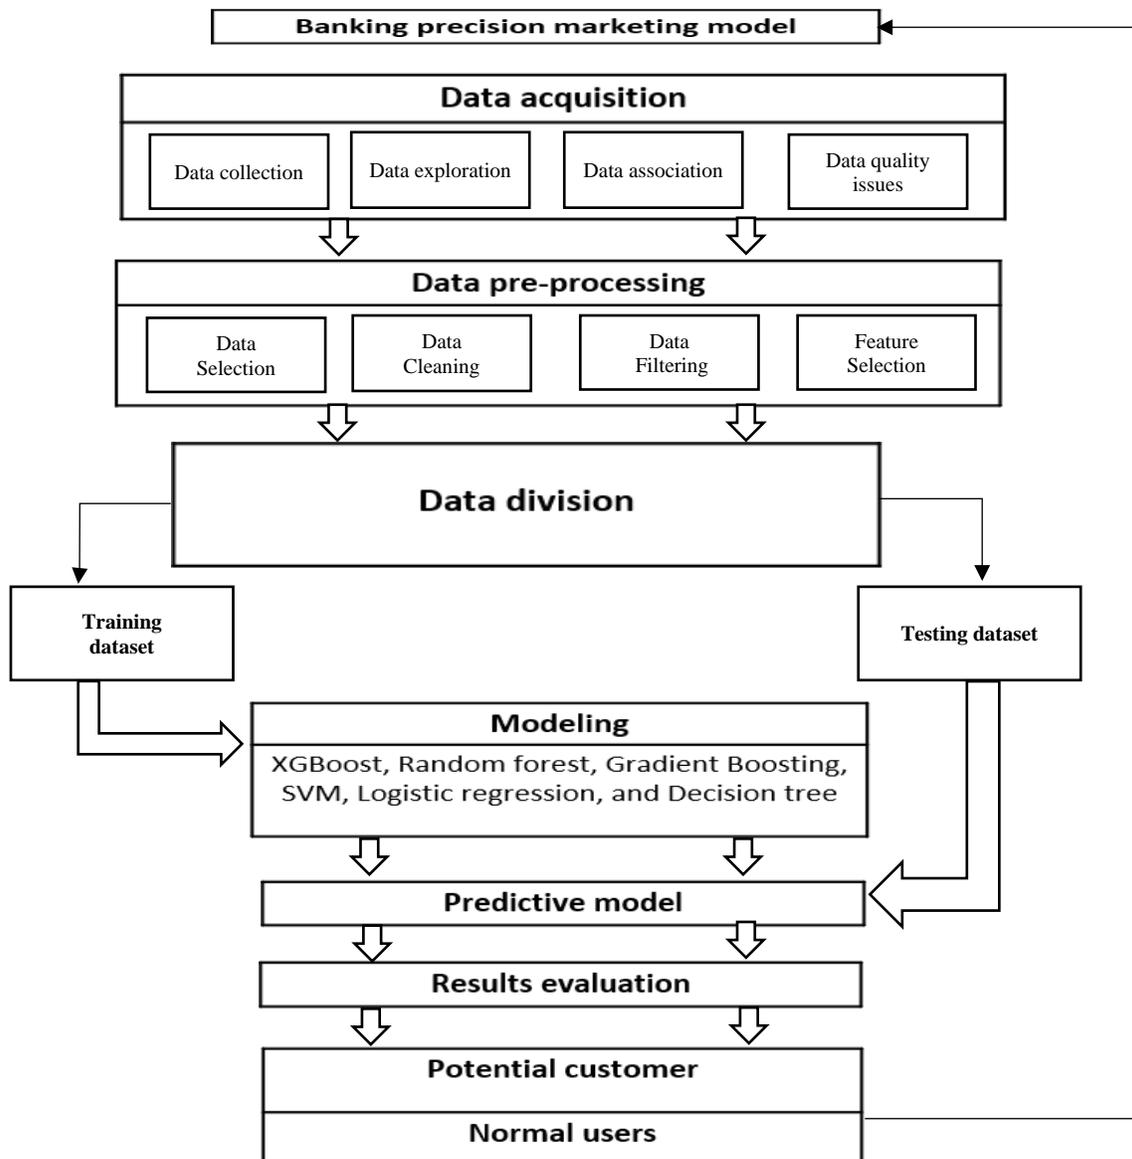

Fig. 1. PCPA Architecture.

3) *Feature selection*: The feature selection stage plays an essential role in extracting the critical features and removing the non-significant attributes from the dataset. Also, it contributes to the improvement of model performance and reduces the time of training and validation. Firstly a uni-variate selection is applied then, Grid search (GS) method is used to choose the optimal parameter.

4) *Modeling*: As we declared above, our proposed PCPA is based on machine learning techniques and big data. In this phase, we have applied five machine learning algorithms, namely, XGBoost, Random forest, Gradient Boosting, SVM, Logistic regression, and Decision tree. Then after comparison of the accuracy and performance of the five models, we choose XGBoost as the central algorithm of PCPA because it illustrates the most excellent accuracy and performance. The results of all the models are presented in Section IV.

5) *Results evaluation*:

a) *Confusion matrix*: In order to evaluate and measure the performance of the predictive models for forecasting the potential customers correctly, we have applied different metrics: namely, precision, recall, accuracy, and F-measure. The calculation of these four measures depends on information extracted using the confusion matrix. After the prediction, the confusion matrix analyzes the value of accurate and wrong predictions. In Table III, the representation of the confusion matrix is presented.

*TP*: These are the correctly predicted negative values which mean that the value of the actual class is potential, and the value of the predicted class is also potential customers.

*TN*: These are the correctly predicted negative values which mean that the value of the actual class is non-potential and the value of the predicted class is also non-potential customers.

*FP*: The number of non-potential customers, but the predictive model has forecasted them incorrectly (as potential).

*FN*: The number of potential customers, but the predictive model has forecasted them incorrectly (as non-potential).

TABLE I. CONFUSION MATRIX

	Potential	Non-Potential
Potential	TP	FN
Non-Potential	FP	TN

b) Performance indicators

Accuracy: The proportion of the number of all right predictions is known as accuracy. It is calculated by the following formula:

$$Accuracy = \frac{(TP + TN)}{(TP + FP + TN + FN)} \quad (1)$$

Precision: It is the proportion of true positives to all positives. It is calculated by the following formula:

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

Recall: It is used to calculate the real positive rate. It is calculated by the following formula:

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

F1-measure: The weighted harmonic average of precision and recall is called F1-measure.

$$F1 - measure = \frac{(2 \times Precision \times Recall)}{(Precision + Recall)} \quad (4)$$

C. PCPA Algorithm

Algorithm 1: Proposed algorithm for Potential Customers prediction

**Input:** The training dataset consisting of input features such as xi and output label y;

**Output:** Predicted labels; Potential or not potential

**Procedure;**

1. Data selection and understanding;
2. Data cleaning and filtering;
3. Feature selection using Grid search algorithm;
4. Data modeling using XGBoost, Random forest, Gradient Boosting, SVM, Logistic regression, Decision tree;
5. Results Evaluation (confusion matrix);

IV. RESULTS AND DISCUSSION

The PCPA is based on machine learning technology and big data. First, we split the data into two parts train with a proportion of 80% and a test set with a ratio of 20%. We tested the pre-processed data on various famous classification algorithms that we have chosen based on our previous study [14], such as XGBoost, Random forest, Gradient Boosting, SVM, Logistic regression, and Decision tree. Then we compared the performance of the selected machine learning methods based on performance indicators (Accuracy, Precision, Recall, F-measure, and Cross-validation score). We presented the findings in Table IV. According to the comparison of the performance of the six machine learning methods illustrated in Table IV and Fig. 2, the RF and GBDT have the highest accuracy (98, 9%). RF achieved good precision with 93, 6%, Recall of 93,5%, and an F-measure of 93,5%. Another model which illustrates good results is

XGBoost. It reached a good accuracy with 98,1%, F-measure with 90,8%, Cross-validation score of 90,1%, and highest Recall of 95,4%. Also, the SVM gave significant results, registered a good accuracy of 97, 1%, Recall of 88,7%. We can notice that the GBDT shows a better performance amount the other models in terms of Accuracy, Precision, Recall, F-

Measure, and Cross-validation score. It accomplished the highest accuracy compared to other i.e. 98, 9%, precision with 96,3%, F-measure 92,9%, Cross-validation of 94,2% with good Recall 89,7%. Hence Gradient Boosting outperforms the other ML methods used in our work. This is why, we choose Gradient Boosting as the central algorithm of PCPA.

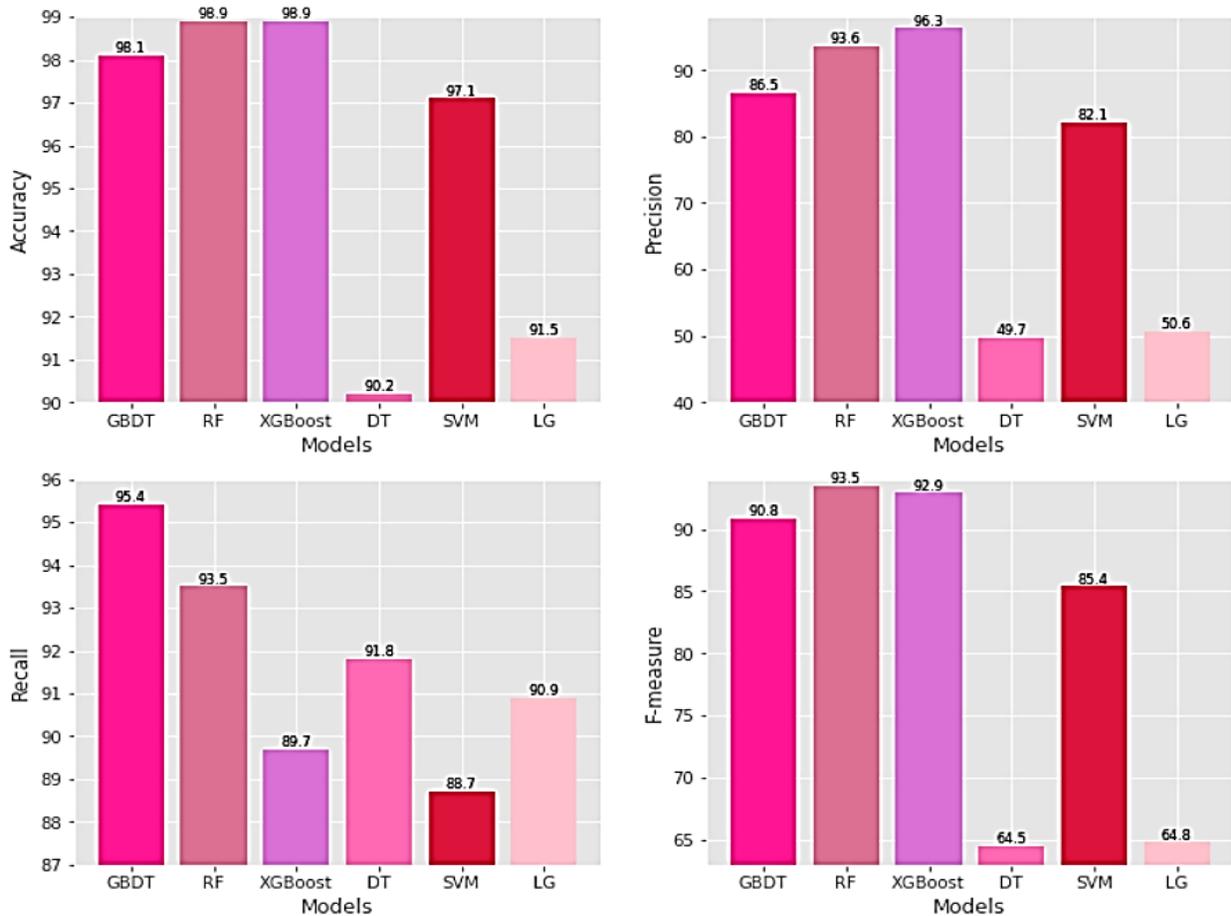

Fig. 2. Evaluation of Models on Performance Indicators (Accuracy, Recall, Precision, F-measure).

TABLE IV. COMPARISON OF MACHINE LEARNING MODELS

Model	Accuracy (%)	Precision (%)	Recall (%)	F-Measure (%)	Cross Validation (%)
<b>XGBOOST</b>	<b>98,1</b>	<b>86,5</b>	<b>95,4</b>	<b>90,8</b>	<b>90,1</b>
<b>RF</b>	<b>98,9</b>	<b>93,6</b>	<b>93,5</b>	<b>93,5</b>	<b>91,8</b>
<b>GBDT</b>	<b>98,9</b>	<b>96,3</b>	<b>89,7</b>	<b>92,9</b>	<b>94,2</b>
<b>DT</b>	<b>90,2</b>	<b>49,7</b>	<b>91,8</b>	<b>64,5</b>	<b>61,2</b>
<b>SVM</b>	<b>97,1</b>	<b>82,1</b>	<b>88,7</b>	<b>85,4</b>	<b>88,1</b>
<b>LG</b>	<b>91,5</b>	<b>50,6</b>	<b>90,9</b>	<b>64,8</b>	<b>65,3</b>

### V. CONCLUSION

In this study, we have proposed a PCPA algorithm for precision marketing based on machine learning and Big data analysis. We have used a dataset collected from Moroccan banking. Our model predicts potential housing loan customers from whole banking users. This prediction can help the marketing department to target quality customers at a low cost

and fast time. At the same time, we compared the efficiency of different famous machine learning approaches, which are: XGBoost, Random forest, Gradient Boosting, SVM, Logistic regression, and Decision tree in terms of accuracy, F-measure, recall, precision. The results illustrate that Gradient Boosting achieved better performance amount the other ML methods used in terms of accuracy, F-measure, recall, precision, and cross-validation score. Hence we choose Gradient Boosting as the central algorithm of PCPA.

# A Sequence-Aware Recommendation Method based on Complex Networks

Abdullah Alhadlaq, Said Kerrache, Hatim Aboalsamh  
College of Computer and Information Sciences,  
King Saud University, Riyadh 11543,  
Saudi Arabia

**Abstract**—Online stores and service providers rely heavily on recommendation software to guide users through the vast number of available products. Consequently, the field of recommender systems has attracted increased attention from the industry and academia alike, but despite this joint effort, the field still faces several challenges. For instance, most existing work models the recommendation problem as a matrix completion problem to predict the user preference for an item. This abstraction prevents the system from utilizing the rich information from the ordered sequence of user actions logged in online sessions. To address this limitation, researchers have recently developed a promising new breed of algorithms called sequence-aware recommender systems to predict the user's next action by utilizing the time series composed of the sequence of actions in an ongoing user session. This paper proposes a novel sequence-aware recommendation approach based on a complex network generated by the hidden metric space model, which combines node similarity and popularity to generate links. We build a network model from data and then use it to predict the user's subsequent actions. The network model provides an additional information source that improves the recommendations' accuracy. The proposed method is implemented and tested experimentally on a large dataset. The results prove that the proposed approach performs better than state-of-the-art recommendation methods.

**Keywords**—Sequence-aware recommender systems; complex networks; similarity-popularity

## I. INTRODUCTION

A recommendation system (RS) is a software tool that uses various techniques and algorithms to filter the relevant information from the vast amount of information found in an online platform based on multiple factors to provide users with item recommendations that most likely suit their preferences. RSs have been applied in various domains, including travel and hotel industries, online shopping, books, and movie recommendations [1].

Conventionally, the recommendation problem is abstracted as a matrix-completion problem where users correspond to rows, items correspond to columns, and the numerical cell values indicate the user-item ratings. The goal of matrix completion is to predict the ratings of unseen items for a given user based on historical data [2]. Although this abstraction has proved helpful in various ways, it suffers from the limitation of not utilizing the sequence of user interaction logs that are often available in real applications [3]. Moreover, conventional recommendation systems assume user profile availability and long-term historical data. However, such long-term data does not always exist for many reasons, such as the user being new to the system, having opted not to log in, or if the user is

enabling tracking countermeasures [4], [5]. For this, sequence-aware recommendation systems (SARS) have recently been developed to harness the rich information from logged users' interactions with the system. The goal is to derive predictions for subsequent user actions based on the recent series of actions in the ongoing user session, thus, bringing highly relevant and practical computational tasks to real-life applications.

Despite the ongoing efforts to improve SARS, the accuracy of recommendations remains an open challenge. Most of the existing complex models, including deep learning and matrix factorization, are outperformed by straightforward trivial approaches such as the  $k$  nearest neighbors' approach [6], [7]. One of the most promising directions to remedy this is using graph (or network) models to generate recommendations. In network-based recommenders, where nodes represent users or items and the weighted links between the nodes represent relevancy, the analysis derived from the graph structure can produce accurate predictions. Many network-based recommendation approaches have been introduced in the literature, including approaches based on real-world networks [8]–[10]. However, most approaches use networks without underlying models or established properties. Using complex network models with well-understood and proven properties can improve the quality of recommendations and constitutes a promising research direction.

Moreover, one of the most relevant recent advances in complex network modeling to the field of sequence-aware recommendation is the development of efficient navigation and routing algorithms [11], [12]. Since the interaction between the user and items in SARS can be seen as navigation in the space of items, this hints at the possibility of using complex network models to guide the recommendation process.

In this paper, we propose a novel sequence-aware recommender system approach that takes advantage of complex network models, primarily the hidden metric space model [13], to generate more accurate recommendations. The hidden metric space model is a complex network model that suggests the existence of a hidden metric space underlying any observed complex network. The distance between the nodes abstracts their similarities, whereas their degrees represent popularity [12]. Our method utilizes the rich navigation information within the large logs of sequentially ordered actions to improve recommendation accuracy. Moreover, introducing predefined model characteristics as an additional source of information enriches the model to overcome the limitations of data sparsity and limited coverage. Additionally, constructing graph models to guide the recommendations resembles a neighborhood struc-

ture that is intuitive and easy to understand and allows efficient recommendation queries. Another advantage of using graphs is the ability to interpret and visualize the recommendations, which is often a limitation in other complex methods. Finally, the resulting algorithm is trained and tested on a large public dataset and evaluated using standard performance measures to compare its performance to state-of-art methods.

The remainder of this paper is organized as follows. Section II covers background and related work. Section III describes the details of the proposed method. Section IV presents the experimental setup and performance evaluation results. Finally, Section V summarizes the work and presents future research directions.

## II. BACKGROUND AND RELATED WORK

In this section, we briefly introduce recommender systems, particularly sequence-aware recommender systems, followed by an overview of the complex networks and the hidden metric space model.

### A. Sequence-Aware Recommender Systems

The goal of sequence-aware recommender systems is to predict the evolution of the user's current session. They achieve this goal by predicting the user's next action using extracted features from historical sessions' logs tracked by the application [4]. Fig. 1 shows a schematic illustration of the recommendation process under the sequence-aware setting. The recommender system's input takes the form of an ordered set of users' logged actions (sessions). These actions consist of various user interactions towards an item, such as 'clicks', 'views', or 'purchases', or actions towards the application, such as 'searches' or 'applies filters'. The computational task of sequence-aware recommenders is mainly to process the input to build a model that attempts to identify recurring patterns

in the sequences of actions. For example, this pattern may reflect the co-occurrence of actions or their sequential ordering. Finally, the system's output is the predictions for the user's next action (or set of actions) derived from the identified pattern based on the current user session.

Although the output from traditional RS and SARS aims at the same goal: to provide an item recommendation for the users, their settings and characteristics are distinct in several ways. First, the standard input for traditional RS takes the form of user, item, and rating tuples without any information about the user's behavior or interactions with the items or the application. In contrast, the primary input for SARS is the rich sequential session data. Moreover, a standard RS takes the form of a matrix-completion problem, as illustrated in Fig. 2, in which the task is to fill the predicted ratings given by users to items based solely on the long-term observed user behavior and preferences. This formulation, however, can not accommodate the sequential input representation [2].

The problem of sequence-aware recommendation has been increasingly attracting researchers. Early research efforts proposed oversimplified model-free attempts to provide recommendations driven by data pattern mining and association rules techniques. However, since the 2010s, machine learning and time-series techniques have shifted the algorithmic approaches towards adopting more sophisticated models to tackle the problem [14]. Models such as Markov chain models [15], [16], graph-based models [17]–[19], factorization-based models [20], recurrent neural networks [21]–[23] and attention mechanisms [24] contributed to improving sequence-aware recommendation systems [6].

Several graph-based approaches for sequence-aware recommenders exist in the literature that extends the work proposed for traditional recommender systems. In these methods, the graph is often modeled as a bipartite graph having items and

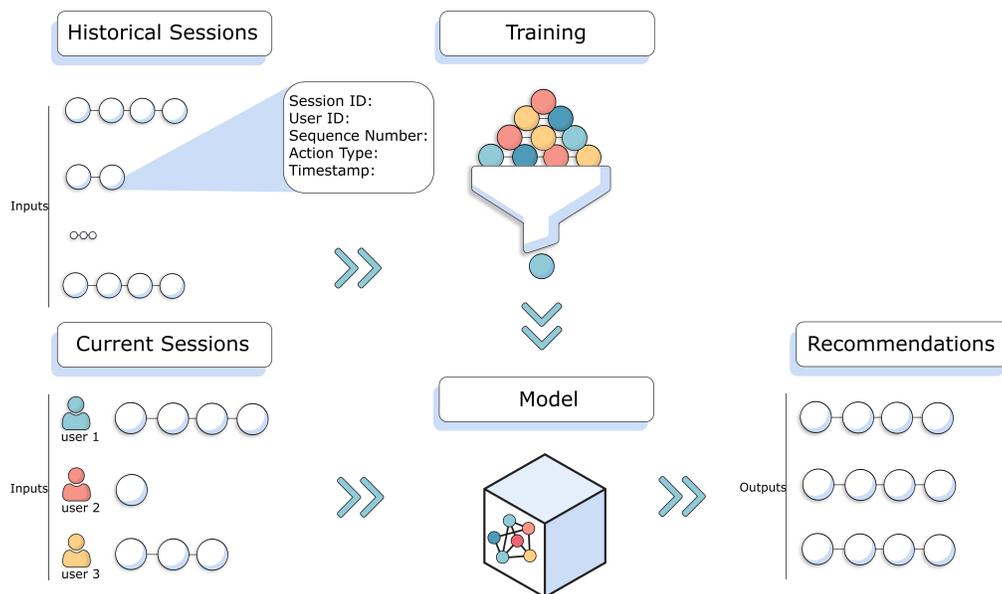

Fig. 1. A High-Level Representation of Sequence-Aware Recommender Systems Process.

User 2				
User 3				
User 4				

Fig. 2. Representation of the User-Item Matrix in Traditional Recommender Systems. The Goal of the Recommender is to Complete this Matrix.

users on separate sides. However, this poses a limitation as these approaches fail to exploit the rich information in sessions. To overcome this issue, authors in [17] proposed the session-based temporal graph (STG) method that incorporates temporal dynamics and short- and long-term preferences. The STG graph is represented as a two-sided bipartite graph (tripartite), with one side of the graph connecting users with items they have interacted with before (i.e., long-term interactions) and the other side connecting the current user session with session items (i.e., short-term interactions). The graph is then traversed to recommend items via random walk.

Similarly, the Geographical-Temporal influences Aware Graph (GTAG) method [18] uses a tripartite graph representation. However, GTAG incorporates geographical location to enhance the point of interest recommendations and traverse the resulting graph model in a breadth-first propagation manner. Both methods, however, as in all multipartite graphs models, which do not allow edges between nodes on the same side, fail to exploit information on any independent side, for example, item-to-item data. Additionally, both methods construct a simple graph without an underlying model. Conversely, the proposed method in this article relies on constructing a graph with an underlying model and established properties to guide the recommendations.

In recent years, researchers have attempted to achieve accurate recommendations by providing explicit interpretations of the challenges and tasks in the SARS and then attempting to tackle the identified challenges by designing appropriate algorithms. Quadrana et al. [3] suggest that the main tasks of sequence-aware recommender systems are adopting the recommendation context, such as the current weather or the current user location, detecting the shared and individual trends, identifying the repeated patterns in user behavior, and finally identifying the order constraints of the sequence in the session. Jannach et al. [25] state the price discounts and current offers on items as a success factor for SARS and emphasize the impact of the user's short-term intentions rather than only long-

term ones. Wang et al. [14] further focus on understanding the inner interactions within the session and the interactions between the sessions as the two key challenges to reducing the complexity of the SARS structure.

### B. Complex Networks and Hidden Metric Space Model

Complex networks refer to a class of graphs that exhibit nontrivial topological features that can be observed in real-life networked systems. Those features are not observable in simple graphs such as regular and purely random graphs but in networks resulting from complex natural phenomena such as social, biological, technological, and physical systems [26]. For example, when modeling a real-life social network, where the nodes represent the people and the edges between the nodes represent the relationships between them, the resulting graph possesses a complex network structure. Its topology reveals some fundamental complex network properties and characteristics [27], such as the small-world [28] and the scale-free properties. Scale-free networks gained significant interest within the network science community upon the publication of the Barabási and Albert model [29]. The latter generates scale-free networks with short paths and highly connected nodes as hubs and is considered one of the earliest models to capture real-life natural network properties [30].

Efforts to design network models that capture more faithfully the properties of real-life networks have continued after the work of Barabási and Albert model [29]. The hidden metric space model [13] suggests the existence of a hidden metric space underlying any scale-free complex network and contains all the nodes of the observed network. The nodes are positioned and linked in the hidden metric space based on their similarity and popularity. The distance between nodes abstracts the nodes' similarities, and their degrees reflect their popularity. Thus, the shorter the distance between nodes in the hidden metric space and the more popular they are, the higher probability of them connecting in the observed network.

One of the successful applications of the hidden metric space model is its capacity to guide the routing function in networks by greedily moving toward the node nearest to the target [31]. Unlike many complex network models, such as the small-world model or Barabási and Albert model, the hidden metric space model generates an embedding of the network, which provides a useful representation of the items for downstream applications. Furthermore, the model not only aims at capturing the network's structural properties but also describes how these properties are connected with essential functionalities. In [32], the authors propose a recommendation method for predicting user-item ratings using a hidden metric space model based on popularity and similarity. By using this complex network model, the approach is able to outperform existing methods in term of prediction accuracy. The successful use of the model in the traditional recommendation setting as demonstrated in [32] and various other domains, including developing efficient information routing algorithms [11], network modeling [12], information routing and signaling [31], link prediction [33]–[35] hints at the possibility of applying it to guide the recommendation in a SARS settings.

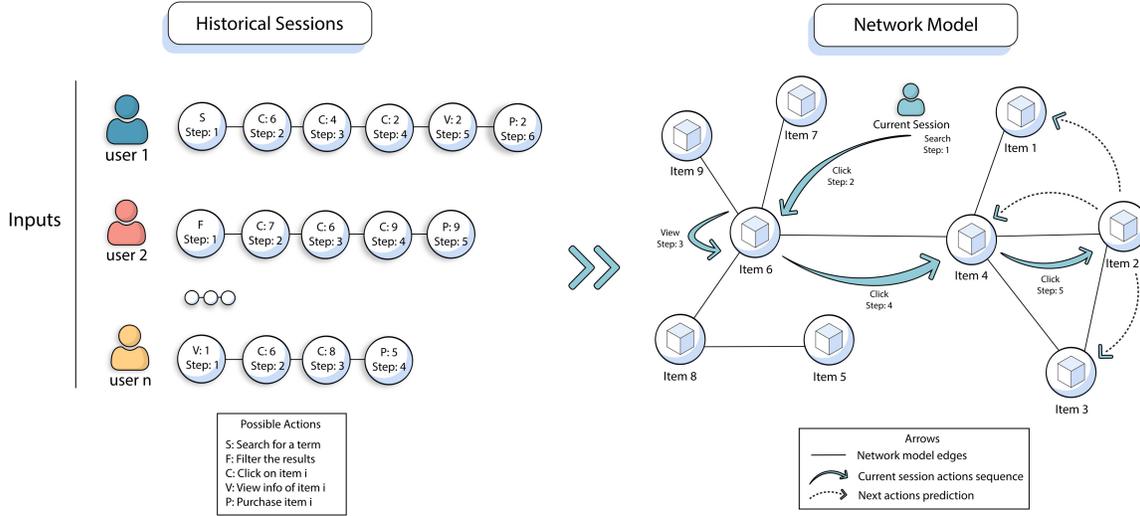

Fig. 3. Illustration of the Proposed Approach. Items are Modeled as Nodes in a Complex Network and are Connected based on Similarity and Popularity.

### III. PROPOSED METHOD

In this paper, we propose a sequence-aware recommendation method based on complex networks where items are modeled as a graph embedded in  $D$ -dimensional space with a scale-free network structure controlled by an underlying hidden metric space. Since the goal of a SARS is to predict the next click the user will perform in a session, the problem is defined as the task of ranking the most probable next item. The output of the recommender is an ordered list of items  $r \in R^*$  for each session  $s$ , where  $R^*$  is a subset of the group of all possible items permutations, and each predicted ordered list of recommendations  $r$  consists of  $i$  items of length between 0 and  $t$ . First, each item in the system  $i$  is assigned a point  $x^i$  in a  $D$ -dimensional Euclidean space:

$$x^i = (x_1^i, x_2^i, \dots, x_D^i)^T, i = 1, \dots, n, \quad (1)$$

where  $n$  denotes the number of items. The position of the items reflects their description or features. Hence, each dimension represents a latent feature or a combination of features relevant to the item. The probability  $p_{ij}$  of connection between two items nodes  $i$  and  $j$  is based on two factors, their similarity reflected by their distance and popularity (or degree) as derived from the hidden metric model:

$$p_{ij} = \left( 1 + \frac{d^2(x^i, x^j)}{\kappa_i \kappa_j} \right)^{-\alpha}, \quad (2)$$

where  $\kappa_i$  and  $\kappa_j$  denotes the hidden degree (popularity) of items  $i$  and  $j$ , respectively, and  $d^2(x^i, x^j)$  is the squared distance between them. The parameter  $\alpha > 1$  controls the weights given to distance and popularity.

According to Eq. (2), the connection probability between nodes in the generated network increases when popularity increases and decreases with the squared hidden distance (dissimilarity) increase. The reason behind this choice is that generated network will have three characteristics observed in real-life complex networks. First, a pair of popular nodes will

have a higher probability of being connected even if they are far away from each other or dissimilar. A pair of nodes with moderate average popularity will be connected if the distance is moderate, and a pair of nodes with low popularity on average will get connected if the distance is short.

As illustrated in Fig. 3, items are embedded in a  $D$ -dimensional space, where the distance between them encodes their similarity, which, combined with item popularity, results in a network model. The model can be used to compute the probability of a pair of nodes being connected and predict the next clicked item in a sequence. We need to calculate the item's popularity and similarity to construct the model. The node's degree represents its popularity and can therefore be directly calculated from the number of clicks or interactions the item has in historical sessions. Next, we assign each node a position in  $D$ -dimensional space to calculate the distances. Since we cannot readily obtain the positions of the nodes, we infer them from the history of interactive sessions. We first estimate the link probabilities directly from historical data and then use them to infer the items' positions. There are arguably many ways to estimate connection probabilities. However, the method we adopt in this work is to assume that the connection probability is proportional to the number of items co-occurrence in sessions calculated by the cosine similarity as follows:

$$p_{ij} \propto sim(i, j) = \frac{\sum_{s \in S} i_s j_s}{\sqrt{\sum_{s \in S} i_s^2} \sqrt{\sum_{s \in S} j_s^2}}, \quad (3)$$

where  $i_s$  is set to 1 if item  $i$  is present in session  $s$  and 0 otherwise. From that, we obtain the set  $P$  of all connections probabilities  $p_{ij}$  such that  $p_{ij} > 0$ . It is now possible to deduce the distance  $d_{ij}^2$  in Eq. (2) as follows:

$$d_{ij}^2 = \kappa_i \kappa_j \left( p_{ij}^{-1/\alpha} - 1 \right). \quad (4)$$

Hence, the problem of estimating the items' positions is reduced to finding coordinates  $x^i$ , such that the resulting Euclidean distances are as close as possible to the distances prescribed by Eq. (4). This problem falls into the category of nonlinear optimization problems that can be solved by minimizing an objective function that measures the difference between the computed and observed distances:

$$\sum_{p_{ij} \in P} \left( \|x^i - x^j\|_2^2 - d_{ij}^2 \right)^2, \quad (5)$$

where  $\|\cdot\|_2$  stands for the  $L_2$  norm. In order to avoid overfitting, a regularization term is added, resulting in the following objective function:

$$f(x^1, \dots, x^n) = \sum_{p_{ij} \in P} \left( \|x^i - x^j\|_2^2 - d_{ij}^2 \right)^2 + \lambda \sum_{i=1}^n \|x^i\|_2^2. \quad (6)$$

Since this objective function is not convex, only local minima can be computed. Several algorithms for local optimization exist to solve this minimization problem, and most of them require computing the gradient of the objective function:

$$\frac{\partial f}{\partial x^i} = \sum_{p_{ij}, p_{ji} \in P} 4(x^i - x^j) \left( \|x^i - x^j\|_2^2 - d_{ij}^2 \right) + 2\lambda x^i. \quad (7)$$

The proposed method's objective is to predict a list of items ordered by the likelihood that the user will click next in the active session. Once we have the item embeddings, we can use different techniques to capture the user's short-term interest in the current session to predict the next item. We propose to use the  $K$  nearest neighbors technique, where distance is measured in terms of connection probability. Thus, the method recommends the items with the highest connection probability to the most popular item the user interacted with in the active session. In other words, the method generates a list of  $t$  items ordered decreasingly by the probability of connection to the most popular item in the active session as calculated by Eq. (2).

#### IV. EXPERIMENTAL EVALUATION

This section presents the experimental framework used to evaluate the proposed method's performance. First, we present the experimental setup and describe the dataset, the dataset preparation techniques, the competing methods, the evaluation metrics, the training method, and the parameter tuning technique. Finally, we compare the overall performance results against competing methods.

##### A. Dataset Description

The dataset used in this paper is the Trivago dataset [36], [37] presented in the 2019 RecSys challenge obtainable online from a publicly available data source (<https://recsys2019data.trivago.com>). The dataset contains sequences of various users actions on the Trivago hotels booking website. It contains

981,655 users, 927,142 hotels, and 1,202,064 sessions containing a total of 19,715,327 user actions.

The dataset is pre-split into 80%-20% splits for train and test sets, respectively. The splits were used as they are in this experiment. We cleaned the dataset by removing sessions that do not lead to a hotel booking. Each session in the test set ends with a hidden hotel booking action and a list of a maximum of 25 hotels in the impressions list, and the goal is to reorder the list of impressions in decreasing order by the likelihood of user clicks.

##### B. Evaluation Criteria

The proposed approach is evaluated using the test set by applying standard metrics for the sequence-aware recommender systems evaluation. There are different evaluation techniques and accuracy measures for sequence-aware recommender methods in the literature. However, since the output of a sequence-aware recommender system typically takes the form of ordered lists, it is applicable to use standard information retrieval accuracy metrics [6] such as mean reciprocal rank (MRR) and mean average precision (MAP).

The MRR measures the place of the correct item in the predicted list. Given a test set  $S^{Test}$  containing previously unseen sessions, the MRR is defined as:

$$MRR = \frac{1}{|S^{Test}|} \sum_{s \in S^{Test}} \frac{1}{Rank_s} \quad (8)$$

where  $Rank_s$  is the place of the correct item in session  $s$ . From Eq. (8), we can see that, at most, the MRR reaches 1 if the algorithm consistently predicts the item correctly by placing it first in the list and reaches  $1/t$ , where  $t$  is the length of the recommended list when the recommender consistently predicts the item the last in the list. On the other hand, the MAP evaluates the predicted list up to a specific cut-off point  $N$ . MAP@ $N$  does not consider the order of the list. However, it checks if the correct item is present within the first  $N$  items in the list.

$$MAP@N = \frac{1}{|S^{Test}|} \sum_{s \in S^{Test}} \frac{Top(s, N)}{N} \quad (9)$$

where  $Top(s, N)$  is a function that returns 1 if the correct item for session  $s$  is in the top  $N$  items in the predicted list and returns 0 otherwise. In this experiment, we use the following values for  $N$ : 1, 3, 5, and 10.

##### C. Implementation

The experimental framework, competing methods, data preprocessing, and experimental evaluation are implemented using python with standard numerical and data manipulation libraries.

Several specialized software libraries can be used to solve the optimization problem, which is the most crucial step in our proposed method. Interior Point OPTimizer (IPOPT) [38] is a stable and well-tested advanced nonlinear programming (NLP) solver based on an interior-point filter with a line-search algorithm for large-scale nonlinear optimization. Efficient and effective linear solvers are required by IPOPT and are essential

for solving the optimization problem. Therefore, The solver MA57, part of the HSL package [39], was used in the experiment.

IPOPT NLP solver requires, at each iteration, essential information about the optimization problem in order to solve and proceed iteratively toward the solution. At each step, the following information is required, given the current values of the unknowns:

- The objective function as defined in Eq. (6).
- The gradient of the objective function (vector of first derivatives with respect to all unknowns) as defined in Eq. (7).
- The Hessian of the objective function (matrix of all second derivatives). This matrix is very large. However, the library offers the possibility of approximating the Hessian numerically. This option has been used in order to avoid large memory consumption.

#### D. Competing Methods

To assess the effectiveness of the proposed method, we compare it with a set of commonly used baselines and state-of-the-art methods:

- Random: Even though this is not a recommendation method, it provides insight into the lowest acceptable value that other methods must achieve on this dataset.
- Items Popularity (I-POP): A naive baseline predictor that consistently recommends a list of the most popular items in the training set without considering user actions or similarities. Regardless of its simplicity, it often provides a stable baseline in sequence-aware recommender systems.
- Items Click-out Popularity (IC-POP): Similar to I-POP, however, only clicked-out items are considered when determining the item's popularity.
- Items Metadata  $K$ -Nearest Neighbors (IM-KNN): An implementation of a content-based filtering method that predicts the current user's next action based on the  $k$ -most similar neighbors to the previously clicked item. The similarity between the items is determined by the cosine similarity of the item's metadata.
- Items Co-occurrence  $K$ -Nearest Neighbors (IC-KNN): An implementation of an item-based collaborative filtering method that predicts the current user's next action based on the  $k$ -most similar neighbors to the previously clicked item. The similarity between the items is determined by the number of co-occurrence between them in sessions, calculated by cosine similarity.
- Logistic Regression (LR) [36]: A method that predicts whether the item is clicked-out or not (i.e., binary classification). The method requires the extraction of specific features. We adopted the same problem formalization and feature selection as in [36].

TABLE I. PERFORMANCE RESULTS OBTAINED ON THE TRIVAGO DATASET

Method	MRR	MAP@1	MAP@3	MAP@5	MAP@10
Random	0.177	0.054	0.051	0.049	0.047
I-POP	0.262	0.116	0.091	0.078	0.061
IC-POP	0.288	0.137	0.103	0.086	0.065
IM-KNN	0.613	0.526	0.210	0.139	0.081
IC-KNN	0.620	0.523	0.215	0.145	0.084
LR	0.641	0.537	0.228	0.151	0.086
MLP	0.631	0.520	0.227	0.150	0.086
Proposed	<b>0.644</b>	<b>0.540</b>	<b>0.230</b>	<b>0.153</b>	<b>0.087</b>

- MLP Regressor (MLP): Multilayer perceptron is a neural network model that trains using backpropagation with no activation function in the output layer. We used the same features as in the LR model.

#### E. Parameters Settings and Tuning

For the proposed method, several adjustable parameters require tuning. The number of dimensions  $D$ , the regularization coefficient  $\lambda$ , and the constant  $\alpha$ . In this experiment, we used grid search to determine those parameters. The number of dimensions  $D$  is tried with  $\{5, 10, 20\}$ . The regularization  $\lambda$  is selected from the set  $\{0.1, 0.01\}$ . Finally, the constant  $\alpha$  is chosen from  $\{1, 2, 3\}$ .

An important issue when fitting our model to data is the initialization step. Since the objective function is non-convex, only local minima can be found, and consequently, the initial values of the unknowns significantly affect the quality of the solution. In particular, initialization with the same values, such as setting all coordinates to 0, causes the gradient in Eq. (7) to vanish, and the optimizer stops immediately. Hence, a random initialization is essential to avoid the trivial solution where all items are assigned the same position.

#### F. Experimental Results

Table I summarizes the results in terms of MRR and MAP. The results are also displayed in Fig. 4 for the case baseline methods and Fig. 5 for state-of-the-art methods. The results show that the proposed method produces better scores than other competing methods under all considered metrics.

As expected, popularity-based methods (I-POP and IC-POP) score weak results as they rely solely on an item's popularity and ignore the user features. In other words, those methods are expected not to achieve well as they do not produce personalized recommendations.

Interestingly, the proposed method performed better not only against KNN-based methods (IM-KNN and IC-KNN), which rely on similarity measures without requiring feature extractions, but also against feature-based methods (MLP and LR), which require considerable effort in the feature engineering process. This is particularly important given that the Trivago dataset is rich in information, which may not be true for all datasets.

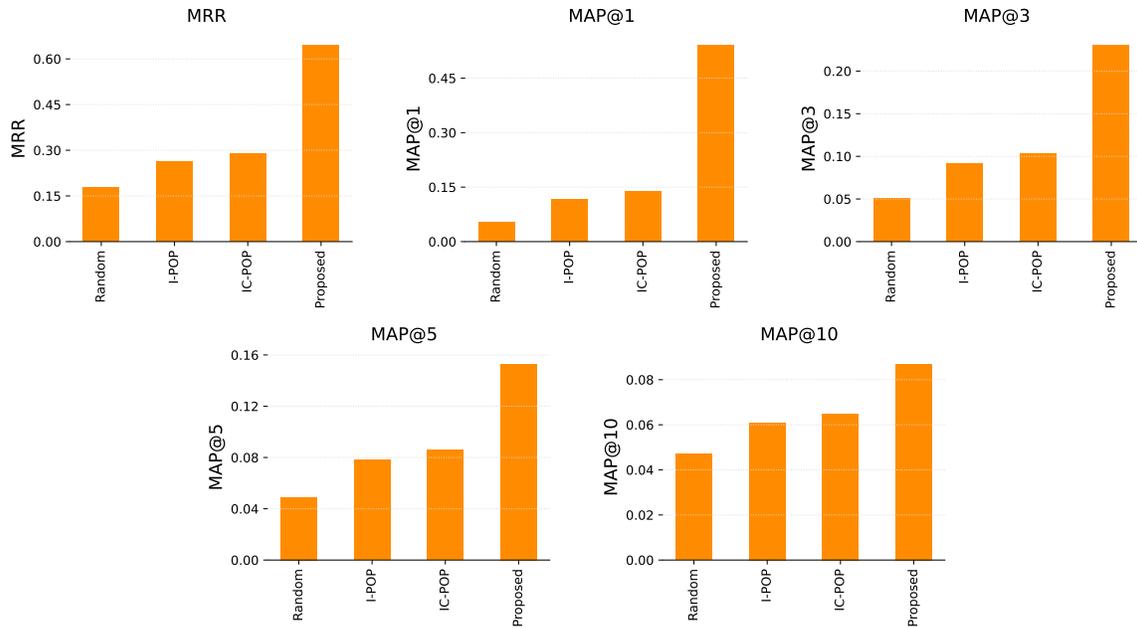

Fig. 4. Comparison of the Performance of the Proposed Approach against Baseline Methods on the Trivago Dataset.

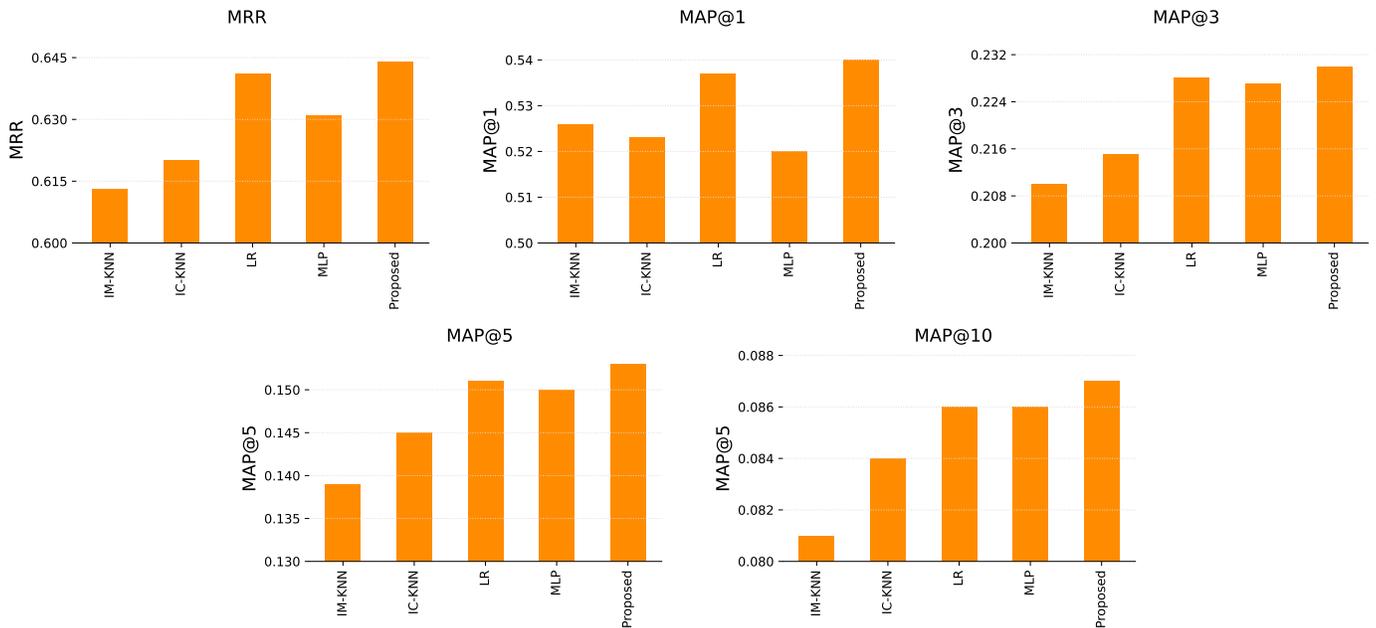

Fig. 5. Comparison of the Performance of the Proposed Approach against State-of-the-Art Methods on the Trivago Dataset.

Since the proposed approach does not involve the additional semantic information available in Trivago datasets, we expect it to perform very well on datasets with limited information (similar to KNN-based approaches) while providing better results.

## V. CONCLUSION AND FUTURE WORK

This paper demonstrates the potential of using complex networks with underlying similarity-popularity models for a sequence-aware recommendation system. The experimen-

tal results show that the proposed method performs better than state-of-the-art methods in terms of MRR and MAP. Furthermore, the proposed method does not rely on feature extraction, making it suitable for generalizing datasets with limited information while providing better results.

In future work, we propose testing the method on other datasets from various domains to confirm its generalization capacity. Moreover, additional similarity-popularity models other than the hidden metric space model can be explored. Such models range from basic similarity-popularity dot-product to

more recent and sophisticated models found in the literature. In this work, once the items are embedded, we use the  $k$ -nearest neighbors technique to capture the user's current session and predict the next item. However, it is possible to use more advanced techniques such as deep neural networks, namely the LSTM or GRU variants of recurrent neural networks, by feeding the network the user's current sequence of actions and item embeddings as input and then training it to predict the next item.

# Mobile Applications for Cybercrime Prevention: A Comprehensive Systematic Review

Irma Huamanñahui Chipa<sup>1</sup>, Javier Gamboa-Cruzado<sup>2</sup>, Jimmy Ramirez Villacorta<sup>3</sup>

Facultad de Ingeniería de Sistemas, Universidad Nacional Mayor de San Marcos, Lima, Perú<sup>1,2</sup>

Facultad de Ingeniería de Sistemas e Informática, Universidad Nacional de la Amazonía Peruana, Iquitos, Perú<sup>3</sup>

**Abstract**—Now-a-days, cybercrime, cyberattacks, cyber security, phishing and malware are taking a more notorious role in people's daily lives, not only at the international level. The great technological leaps brought with them new modalities of cybercrime, the number of victims of cybercriminals has increased considerably. The objective of this study is to determine the state of the art about Mobile Applications and their impact on Computer Crime Prevention. Therefore, it has become necessary to know what preventive measures are being taken, such as techniques for detecting computer crimes, their modalities and their classification. To close this knowledge gap, a systematic literature review (SLR), a methodology proposed by Kitchenham & Charters, was proposed to obtain the detection techniques and classification of computer crimes based on the review of 68 papers published between the years 2017 and 2022. Likewise, different tables and graphs of the selected studies are provided, which offer additional information such as the most used keywords per paper, biometric networks, among others.

**Keywords**—Computer crimes; cyberattacks; cyber security; mobile apps; phishing; machine learning; malware; systematic literature review

## I. INTRODUCTION

Due to the Covid-19 pandemic, the use of Information and Communication Technologies (ICT) has taken an enormous leap forward, especially in the less developed countries of Latin America. In the labor field, many continue to opt for teleworking, online sales have increased notoriously, in the same way computer crimes in all its forms have also been increasing. A computer crime is a crime committed through the use of electronic tools and methods, against people or organizations [1, 6]. It should also be noted that computer crimes have a tendency to become a long-term factor in the political and economic process, due to the lack of great success in counteracting them [4]. There are several types of cybercrime, for which various criteria must be used to classify them [2]. There are two categories of computer crimes: those that are computer or cell phone assisted, such as child pornography, fraud, money laundering and cyberstalking, while computer crimes that are computer-centric include hacking, phishing and website defacement [6]. As well as there are computer crimes there are also techniques to counter various computer crimes; such as Machine Learning, Data mining, Neural network, Firewall, etc. [2, 6, 8, 27,68].

Being clear about the types of cybercrime and possible techniques to counteract them, would be of great help if these in turn are disseminated to users, so that they can avoid becoming victims of cybercriminals. In 2017 cybercrime costs

amounted to approximately \$600 billion in the United States, by 2019 they increased by 118% in the first half of the year leading to huge losses and financial implications, and by 2020 the statistics increased from 71% in mobile malware and 689% in PowerShell malware [1].

Therefore, it is important to determine the types of computer crimes and techniques that help to counteract them and above all to have a dissemination plan to all users of mobile applications, who day by day perform different operations online, or simply use their cell phones to enter their social networks. There are different studies in which they apply other technologies and tools such as Machine Learning to prevent computer crimes [2, 6, 8, 27,68], as well as they also use artificial intelligence to be able to counteract computer crimes [70, 71].

Given this worrying reality, i.e., the lack of knowledge of the advances and achievements of experimental research worldwide and its impact on the prevention of computer crimes in the countless articles published, and the limited dissemination of systematic review articles on the subject will allow the international research community to close these technological and scientific gaps.

In the present study, the aim is to conduct a comprehensive systematic review of research regarding mobile applications that help prevent computer crimes. Few studies involving both variables were found, but studies found on other tools and technologies that help to counteract computer crimes are also shown.

The structure of the document is organized as follows. Section II presents the Background of the study. The research methodology is presented in Section III. Section IV presents the research results and discussions. Section V presents the conclusions and future studies. Finally, Section VI presents the acknowledgements.

## II. BACKGROUND AND RELATED WORKS

In this study, no SLR has been found that is focused on presenting how mobile applications can improve the prevention of computer crimes, however, some papers have been found that partially provide answers to the problem of computer crimes, not necessarily using mobile applications, but other technologies and some potential methods and techniques to detect computer crime threats.

The authors Al-Khater, Al-Ma'adeed, Ahmed, Sadiq & Khan [6] conducted a comprehensive literature review on

computer crime detection techniques, for this purpose they first made a classification of the types of computer crimes, then they presented the computer crime detection techniques using Statistical methods, Machine Learning, Neural Networks, Deep Learning, Fuzzy Logic Neural Network, Data Mining and other techniques. They managed to make a broad classification of computer crimes, they also analyzed numerous studies regarding the detection rates achieved and some limitations, advantages and disadvantages of each technique.

Wiafe, Nti, Nyarko, Assyne & Gulliver [70], conducted an SLR with 131 papers, which were analyzed using quantitative and qualitative methods, to minimize the knowledge gap regarding artificial intelligence methods to combat computer crimes. The study was focused on intrusion prevention and detection systems, where it was determined that the most used technique was support vector machines.

Author Jeong [71] also conducted a literature review on security threats and crimes related to Artificial Intelligence. His paper defines the term Artificial Intelligence crime and classifies it into 2 categories: Artificial Intelligence as a crime tool and Artificial Intelligence as a target crime, inspired by a taxonomy of cybercrime: Computer as a crime tool and Computer as a crime tool. Through the proposed taxonomy, foreseeable Artificial Intelligence crimes are systematically studied and related, forensic techniques are also addressed.

Weichbroth & Łysik [72], performed a RSL on a set of keywords, aiming to identify and analyze existing threats and best practices in mobile security. To obtain the results, 167 users were evaluated; the results show a high awareness of threats and their countermeasures in the mobile application domain. While recognizing the risks associated with physical and social factors, the majority of respondents stated the use of integrated methods to mitigate the negative impact of malware and social engineering scams.

Liu, Xu, Zhang, & Sun [73] conducted a systematic literature review, where they suggest that machine learning is an effective and promising way to detect Android malware. This paper presents a comprehensive survey of Machine Learning-based Android malware detection approaches, they also present the background of Android applications including Android system architecture, security mechanisms, and Android malware classification with the aim to help scholars get a complete picture of Machine Learning-based Android malware detection.

The RSL provides a comprehensive review of new threats and techniques to be able to counter cybercrime, given the new juncture of the Covid-19 pandemic, there have been huge leaps in the use of ICT and thus new cybercrime threats have also been generated. To process the information extracted from the papers, the artificial intelligence tool (RAj) developed by the author Dr. Javier Gamboa Cruzado has been used.

### III. METHODOLOGY

The review method used is based on the fundamentals and guidelines of Kitchenham & Charters [69]. The method allows the formulation of research questions, objectives, search

sources and their respective strategies, also allows the selection of studies by exclusion criteria, achieving the identification of studies, also applying quality criteria, data extraction and finally the synthesis of findings. It can be seen in Fig. 1.

#### A. Research Problems and Objectives

In the SLR conducted, the formulation of the research questions made it possible to formulate the search strategies necessary to achieve a good extraction and analysis of the data. It also made it possible to identify the research objectives, as shown in Table I.

#### B. Search Sources and Search Strategies

The libraries used to perform the research searches are: Web of Science, Scopus, ProQuest, ScienceDirect, ACM Digital Library, Wiley Online Library and Taylor & Francis Online.

The search strategy included keywords relevant to the research. As shown in Table II.

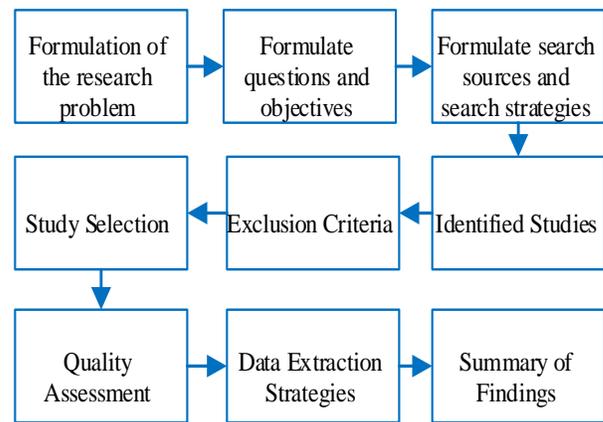

Fig. 1. Stages of Systematic Literature Review.

TABLE I. RESEARCH QUESTIONS AND OBJECTIVES

Research Question	Objective
<b>RQ1:</b> What are the most commonly used techniques in Computer Crime Prevention investigations?	To know the techniques of Computer Crime Prevention.
<b>RQ2:</b> What are the most used Keywords in Mobile Application research and Cybercrime prevention?	Determine the most used keywords in the papers on Mobile Applications and Cybercrime prevention.
<b>RQ3:</b> What are the most cited papers, by country, number of citations and by source in research on mobile applications and cybercrime prevention?	Identify the most cited papers by country, number of citations and sources in research on mobile applications and cybercrime prevention.
<b>RQ4:</b> What are the types of computer crimes in the investigations reviewed?	To know the classification of computer crimes in the investigations reviewed.
<b>RQ5:</b> Which Authors are Co-Occurring in Research on Mobile Applications and Cybercrime Prevention?	Determine the authors who frequently co-occur in research on mobile applications and cybercrime prevention.

TABLE II. SEARCH DESCRIPTORS AND THEIR SYNONYMS

Descriptor	Type of Variable
Mobile Applications/ Applications	Independent Variable
Computer Crime Prevention/ Computer Crimes	Dependent Variable

The search equations were used according to the selected sources, as shown in Table III.

TABLE III. SOURCES AND SEARCH EQUATIONS

Source	Search Equations
Web of Science	(ALL=((“mobile apps”) OR apps AND (“prevention from cybercrime”) OR cybercrime))
Scopus	(ALL (“mobile apps”) OR ALL ( apps ) AND ALL (“prevention from cybercrime”) OR ALL ( cybercrime ))
ProQuest	(“mobile apps”) OR apps AND (“prevention from cybercrime”) OR cybercrime
ScienceDirect	((“mobile apps” OR apps) AND (“prevention from cybercrime” OR cybercrime))
ACM Digital Library	[[All: “mobile apps”] OR [All: apps]] AND [[All: “prevention from cybercrime”] OR [All: cybercrime]]
Wiley Online Library	(“mobile apps” OR apps) AND (“prevention from cybercrime” OR cybercrime)
Taylor & Francis Online	[[All: “mobile apps”] OR [All: apps]] AND [[All: “prevention from cybercrime”] OR [All: cybercrime]]

C. Identified Studies

The search yielded 561,055 papers, see Fig. 2.

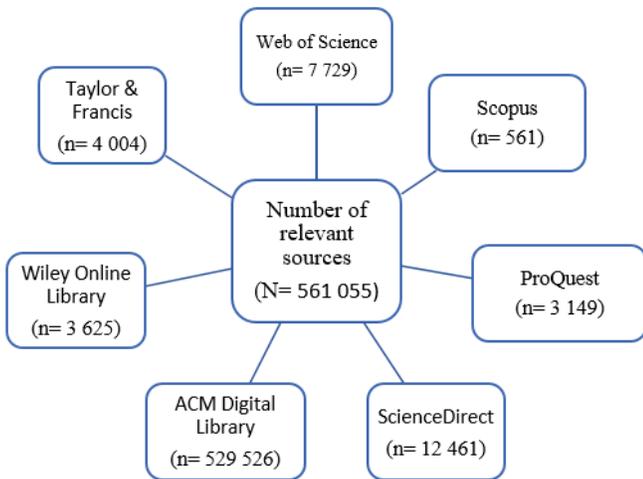

Fig. 2. Number of Studies Identified.

D. Exclusion Criteria

Six exclusion criteria (EC) were applied in order to obtain papers with more relevance to the present investigation. The EC were as follows:

- CE1: The papers are older than five years.
- CE2: The papers are not written in English.
- SG3: The full text of the paper is not available.
- SG4: The papers were not published in Conferences or peer-reviewed Journals.

SD5: The titles and keywords of the papers are not very appropriate

SD6: The proposed solution does not apply to the prevention of cybercrime.

E. Study Selection

To select the most relevant studies, exclusion criteria were applied to ensure that the papers selected were relevant to the research. Quality criteria were then applied to ensure that the papers selected provided solutions and answers to the research questions. See Fig. 3.

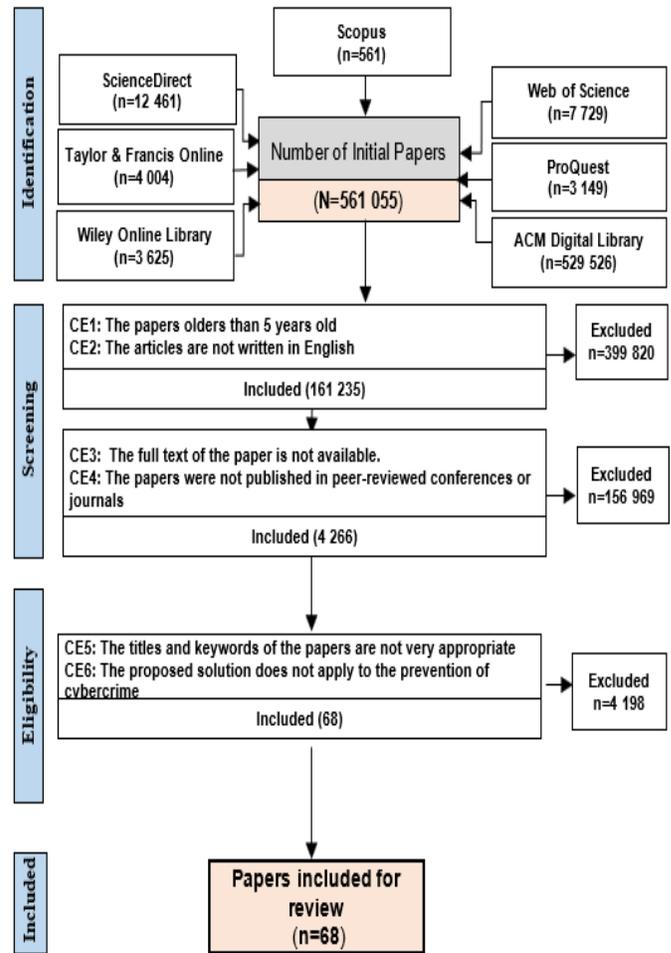

Fig. 3. PRISMA Flowchart.

F. Quality Assessment

As a final step for the selection of the papers, four quality criteria (QA) were applied, with the aim of selecting papers that are of quality for the literature review. Quality criteria used:

- QA1. Is the purpose of the research clearly explained?
- QA2. Is the research methodology clearly explained?
- QA3. Is the specific subject area used clearly defined?
- QA4. Are the results of the experiments performed clearly identified and reported?

These rules were applied to identify the final list of research papers reviewed. After the evaluation of the 4 QAs to the 68 papers, it was determined that all of them had met the quality criteria.

**G. Data Extraction Strategy**

Once the final list of papers was obtained, the necessary information was extracted to support and answer the research questions.

The information extracted from the papers were the following: Article ID, title of the paper, URL, source, Country, Number of pages, language, type of publication, authors, affiliation, number of citations, abstract, keywords, sample size.

The Mendeley tool was used to manage the papers, as shown in Fig. 4.

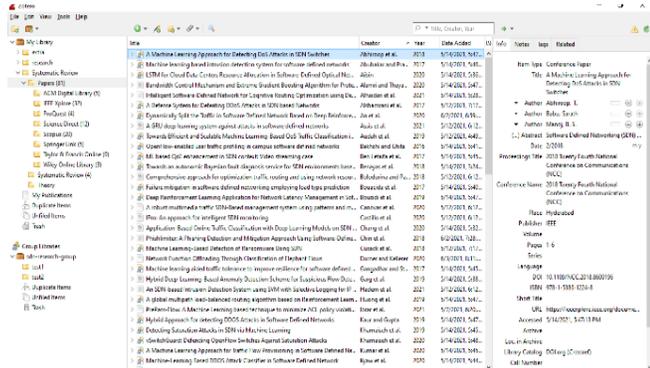

Fig. 4. Document Management with Mendeley.

**H. Summary of Findings**

The data extracted to answer the research questions were tabulated as quantitative data where an in-depth analysis of the data was performed in order to answer each research question, also allowing statistical comparisons between all findings per research question.

**IV. RESULTS AND DISCUSSION**

**A. General Description of the Studies**

The 68 papers selected were processed and the necessary information was extracted. Table IV shows the two types of publications used in the reviewed research: 66 were published in Journals and 2 in Conferences.

The authors Meneses, Silva & Colaço [74], also considered two types of publications for their research: Journal with 29% and Conference with 71%.

Other authors considered more types of publications, for example: Hijji & Alam [75], considered seven types of publications for their research of 52 documents such as: (Journals: 23.1%, Conferences / Workshops: 1.9%, White papers: 17.3%, Report articles: 19.2%, websites: 21.2%, blogs: 13.5% and News report: 3.8%).

Likewise, Cascavilla, Tamburri & Van [76], for their research considered three types of sources: Workshop, Conference and Journal.

TABLE IV. SOURCES AND SEARCH EQUATIONS

Type of Publication	N° Papers
Journal	66
Conference	2
<b>Total</b>	<b>68</b>

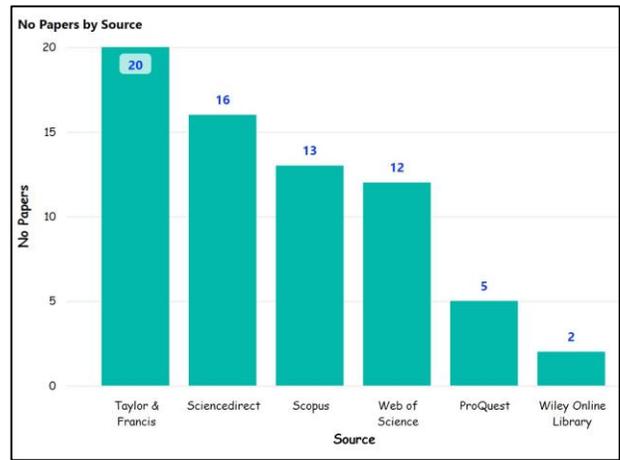

Fig. 5. Papers by Source.

Fig. 5 shows the number of articles selected by type of source, where it can be seen that Taylor & Francis contributed 20 papers, while ScienceDirect contributed 16 papers, followed by Scopus with 13 papers, Web of Science with 12 papers, ProQuest with 5 papers and Wiley Online Library with 2 papers.

For the present study, seven types of important sources were initially considered, but after applying the exclusion criteria, six types of sources were left.

Other authors such as Meneses, Silva & Colaço [74] considered five types of sources to search for the papers of their research on the detection of new fraudulent intelligences: ACM, Engineering Village, IEEE, Scopus and Web of Science.

Fig. 6 shows the 68 papers selected for SLR grouped by country. It can be seen that United Kingdom is the country that publishes the most papers, with 19 papers representing 20.88%, followed by US with 13 papers representing 14.29%.

For the authors Tandon, Kaur, Mäntymäki & Dhir [77], the country that contributed most to their research was the USA with 135 papers followed by the United Kingdom with 82 papers.

For Sonkor, & García de Soto [78], they classify the reviewed publications by country according to 3 categories: (a) Construction and Cybersecurity (USA with 42%, United Kingdom with 33%, United Arab Emirates with 17% and South Africa with 8%), (b) Construction and OT (The levels of operational technology) (USA with 20%, Germany with 16%, Hong Kong with 8%, Russia with 8% and others with 48%) and (c) OT and cybersecurity (USA with 18%, China with 12%, Singapore with 9%, United Kingdom with 9%,

Australia with 6%, Germany with 6%, Japan with 6% and others with 33%).

**B. Answers to Research Questions**

RQ1: What are the most commonly used techniques in Cybercrime Prevention investigations?

The results of the literature review found 14 computer crime detection techniques. Which are not necessarily listed in a specific order, the % obtained should be considered to determine which technique is the most applied. Table V shows the computer crime detection techniques.

The most applied techniques are Machine Learning which is found in 19 papers [6], [8], [12], [19], [26], [27], [32], [34], [46], [47], [48], [49], [50], [56], [59], [60], [63], [64] and [68] with 26.4% of the total, likewise Data Mining is found in 12 papers [6], [23], [27], [34], [47], [48], [49], [50], [54], [55], [61] and [68] with 16.7%.

The authors Al-Khater, Al-Ma'adeed, Ahmed, Sadiq & Khan [6], considered in their research that the detection techniques for computer crimes are: Statistical, Machine Learning (which is divided into Neural (Deep Learning and Fuzzy Logic Neural)), Data Mining and other techniques such as Computer Vision Techniques, Biometric Techniques, Cryptography and Forensics tools. Although the authors classified the techniques in 4 groups, there is agreement with the types of techniques mentioned.

With the authors Meneses, Silva & Colaço [74] do not agree with part of their classification of the detection techniques found, such as: Data Mining and Machine Learning.

TABLE V. COMPUTER CRIME DETECTION TECHNIQUES

Detection Techniques	Reference	Qty. (%)
Statistical	[6]	1 (1.4)
Machine Learning	[6] [8] [12] [19] [26] [27] [32] [34] [46] [47] [48] [49] [50] [56] [59] [60] [63] [64][68]	19 (26.4)
Data Mining	[6] [23][27][34][47][48][49][50][54][55] [61][68]	12 (16.7)
Neural network	[6] [26][27][49][50][56][59][68]	8 (11.1)
Deep learning	[6] [27][49][50][59][68]	6 (8.3)
Fuzzy logic neural network	[6]	1 (1.4)
Computer Vision Techniques	[6]	1 (1.4)
Biometric Techniques	[6]	1 (1.4)
Cryptography	[6][11][23][27][38][55][64]	7 (9.7)
Forensics tools	[6][61]	2 (2.8)
Proxies	[34]	1 (1.4)
Firewalls	[2][6][11][23][27][29][38][40][55] [56][62][68]	12 (16.7)
Cyber Liability Insurance	[5]	1 (1.4)

Guo, Cho, Chen, Sengupta, Hong & Mitra [79], considered as data-driven deception detection techniques: data driven, social honeypots, user profile, message content, network structure, early detection, information propagation mitigation and blockchain - based authenticity. Therefore, there is no agreement on any detection technique because the authors more focused on online social deception techniques.

The authors Bangui & Buhnova [80], in their research regarding Machine Learning techniques for intrusion detection, considered the following techniques: Neural networks with 34%, followed by SVM with 20%, Regression techniques with 10%, Learning Automata with 7%, Markov models with 7%, k-means with 7%, Naive Bayes with 7%, Decision Tree with 3%, Random Forest with 3% and K-NN with 3%. There is only agreement on some techniques since the study is more focused on Machine Learning techniques.

Based on the results shown in Table V, it can be inferred that, although the most used techniques are Machine Learning, Data Mining and Neural network, they are applied jointly and with other techniques, such as Deep learning, Fuzzy logic neural network, among others, to obtain better results in Computer Crime Prevention. In this sense, applying these techniques in different organizations and countries, would improve the performance of their computer systems, generating reliability in the organization and reducing maintenance costs.

RQ2: What are the most used Keywords in Mobile Application research and Cybercrime prevention?

Fig. 6. Papers by Country.

According to the results of the literature review, the most used keywords are: cybercrime with 23 repetitions, followed by cybersecurity with 14 repetitions. See Fig. 7 and Fig. 8.

Although the most repeated keywords are Cybercrime and Cybersecurity, it should be emphasized that the word covid-19 conceptually is not related to the research, but as a result of the current situation, it managed to increase computer crimes, and even causing the emergence of new modalities of computer crimes, due to the technological leap worldwide.

Fig. 7. Keywords Most Frequently Repeated in the Papers.

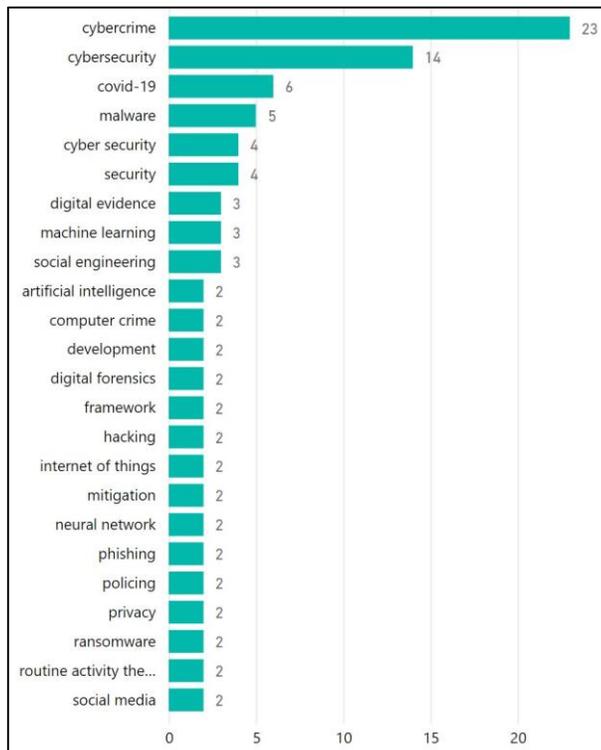

Fig. 8. Number of Keywords in the Papers.

For Tandon, Kaur, Mäntymäki & Dhir [77], in their research regarding the management of computer crimes, considers that the keyword Blockchain is the most used keyword with 311 times in the keywords per author and 138 times per paper. While the research is not closely related to cybercrime it touches on cybercrime issues in parts of the paper.

It can be emphasized that the keywords of this research should be considered in the bibliographic searches regarding Mobile Applications for the prevention of Computer Crimes. They should also be included as keywords in papers produced as a result of experimental research and systematic literature reviews.

RQ3: What are the most cited papers, by country, number of citations and by source in research on mobile applications and cybercrime prevention?

Table VI shows the list of the most cited papers by country, number of citations and source in this study. Of the 68 papers selected for the literature review, the 2 most cited papers are: paper [37] with 67 citations, which was published in ScienceDirect and its author is from United Kingdom, followed by paper [61] with 40 citations which belongs to Web of Science and its author is from Lithuania.

The papers [37, 61], are the most cited, therefore, they are the most relevant of the research. The paper [37] investigated human factors in cyber security, while the paper [61] proposed a tool based on digital evidence object models and habit attribution for computer crime investigation. No other studies with the same research question were found for comparison.

TABLE VI. MOST CITED PAPERS BY COUNTRY AND SOURCE

Ref.	No. Quotations	Country	Source
[37]	67	United Kingdom	ScienceDirect
[61]	40	Lithuania	Web of Science
[57]	39	South Africa	Taylor & Francis
[27]	37	Australia	Scopus
[16]	37	United Kingdom	Taylor & Francis
[25]	34	United Kingdom	Scopus
[44]	29	The Netherlands	Taylor & Francis
[60]	27	Canada	Scopus
[50]	24	Eswatini	ScienceDirect
[45]	24	Japan	Wiley Online L.
[32]	24	United Kingdom	ScienceDirect
[56]	18	United Kingdom	Taylor & Francis
[51]	17	Norway	Taylor & Francis
[42]	17	United Kingdom	Taylor & Francis
[11]	15	The Netherlands	Taylor & Francis
[29]	15	USA	Web of Science
[36]	13	Germany	ProQuest
[64]	11	United Kingdom	Scopus
....	....		
<b>Total</b>	<b>600</b>		

Based on what has been reported, it can be concluded that it is necessary to review in detail the papers published in the United Kingdom, Lithuania and South Africa in the experimental studies on Mobile Applications for Cybercrime prevention that will be developed in other countries and in the future.

RQ4: What are the types of computer crimes in the investigations reviewed?

The results of the literature review found 23 types of computer crimes. Which are not necessarily listed in a specific order, the % obtained should be considered to determine which computer crime is most committed by computer criminals. Table VII shows a list of the types of computer crimes.

The types of computer crimes most commonly used by criminal offenders are: Malware present in 39 papers: [1] [2] [3] [4] [5] [6] [7] [9] [12] [15] [16] [21] [22] [23] [24] [25] [26] [29] [32] [33] [34] [35] [40] [42] [43][44] [46] [47] [48] [49] [51] [55] [57] [59] [62] [63] [64] [65] and [68] and represents 14.2% of the total papers, followed by Phishing found in 31 papers [1] [2] [6] [7] [9] [14] [15] [16] [21] [22] [23] [24] [25] [26] [27] [34] [37] [39] [41] [42] [43] [44] [48] [50] [55] [56] [57] [60] [62] [64] [64] and [68] with 11.3% of the total.

The authors Hijji & Alam [75] in their classification of techniques used for cyber-attacks during the Covid-19 pandemic indicate that the type of computer crime Phishing is the most used with 35.3%, followed by Spam with 16.3%, and among the most important are Scams with 13.7%, Smishing with 12.4%, Extortion with 2.6%, cyberbullying with 2.0% and cyberstalking with 1.3%. It is agreed that Phishing is one of the most used computer crimes.

An & Kim [34], classified computer crimes differently, separating into 2 groups crime articles for services (Phishing, Brute Force attack, DDoS attack, Spamming) and crime articles for products (Drive-by download, Botnet, Exploit, Ransomware, Rootkit and Trojan) do not agree with some of the mentioned types.

For the authors Iakovakis & Xarhoulacos [81], the types of computer crimes produced during Covid-19, are: Phishing with 59%, Malware - Ransomware with 36%, Malicious Domains with 22% and new falsehoods with 14%. According to the results the study agrees that both Phishing and Malware are the most used computer crimes.

Other authors such as Wiafe, Nti, Nyarko, Assyne & Gulliver [70], considered according to publications per year the following computer crimes: Intrusion, encryption and certification, imaging and captcha, phishing, malware, traffic, DoS and others.

Karie, Kebande & Venter [82], consider that the major motivations for attacks are computer crimes with 81.7%, followed by Cyber Espionage with 12.2%, Cyber Warfare with 4.3% and Hactivism with 1.7%.

TABLE VII. MOST CITED PAPERS BY COUNTRY AND SOURCE

Type of Cybercrime	Reference	Qty. (%)
Cyber Terrorism	[6] [11] [17] [39] [41] [42]	6 (2.2)
Cyber Warfare	[3] [6] [11] [39]	4 (1.5)
Cyber Espionage	[3] [6] [11] [39]	4 (1.5)
Child Pornography	[2] [6] [9] [19] [30] [41] [50]	7 (2.5)
Cyber Bullying	[6] [10] [43]	3 (1.1)
Cyber Extortion	[23] [42]	2 (0.7)
Cyberstalking	[2] [6] [9] [28] [50] [57] [68]	7 (2.5)
Cyber Fraud / Online Fraud	[2] [6] [9] [10] [16] [22] [28] [30] [33] [43] [53] [57] [65]	13 (4.7)
Phishing	[1] [2] [6] [7] [9] [13] [14] [16] [21] [22] [23] [24] [25] [26] [27] [34] [37] [39] [41] [42] [43] [44] [48] [50] [55] [56] [57] [60] [62] [64] [68]	31 (11.3)
Denial of service Attack / DOS	[5] [6] [9] [14] [16] [25] [27] [35] [42] [43] [44] [52] [62]	13 (4.7)
SQL Injection Attack / SQL injection	[5] [6] [7] [27] [66]	5 (1.8)
Malware	[1] [2] [3] [4] [5] [6] [7] [9] [12] [15] [16] [21] [22] [23] [24] [25] [26] [29] [32] [33] [34] [35] [40] [42] [43] [44] [46] [47] [48] [49] [51] [55] [58] [59] [62] [63] [64] [65] [68]	39 (14.2)
Trojans	[6] [9] [15] [24] [34] [57] [59] [64] [68]	9 (3.3)
Identity Theft	[1] [2] [6] [8] [9] [11] [24] [28] [29] [36] [40] [41] [42] [43] [45] [46] [48] [57] [68]	19 (6.9)
Key Logger	[15] [56]	2 (0.7)
Screen Logger	[9]	1 (0.4)
Evil Twin	[9]	1 (0.4)
Botnets	[3] [6] [10] [12] [20] [23] [27] [34] [35] [43] [63][64] [65]	13 (4.7)
Social Engineering	[1] [2] [5] [6] [9] [14] [21] [23] [24] [25] [26] [27] [34] [38] [41] [42] [48] [55] [57] [62] [64] [65] [66]	23 (8.4)
Worms	[3] [6] [9] [27] [56] [57] [59]	7 (2.5)
Ransomware	[1] [5] [14] [15] [20] [21] [23] [24] [25] [27] [29] [31] [32] [34] [35] [38] [41] [43] [47] [48] [51] [55] [57] [59] [60] [64] [67]	27 (9.8)
Hacking	[2] [6] [11] [14] [15] [16] [17] [18] [19] [22] [25] [28] [30] [31] [34] [35] [39] [41] [44] [46] [47] [50] [55] [56] [57] [60] [61] [62] [63] [64]	30 (10.9)
Data breach	[5] [15] [21] [25] [27] [42] [43] [60] [68]	9 (3.3)

Likewise, Guo, Cho, Chen, Sengupta, Hong & Mitra [79], considered according to their classification five groups of computer crimes: False Information (False News, rumors, information manipulation, fake reviews), Luring (Phishing, spamming), Fake Identity (fake profile, compromised account, profile cloning attack), Crowdturfing (Crowdturfing), Human targeted attacks (human trafficking, cyberbullying, cybergrooming and cyberstalking).

On the other hand, Senarak [83] considers as a category of computer crimes to: Hacktivism, Cyber criminality, Cyber espionage, Cyber terrorism and Cyber war.

And the author Jeong [71], in his research regarding security threats, crimes and forensic analysis of artificial intelligence, the most committed computer crime is Advanced Computer as Tool Crime.

The detailed identification of types of cybercrime is expected to further accelerate the development of Mobile Applications that enable the prevention of Cybercrime in all business sectors, leading to the emergence of new businesses based on this technology and a booming economy based on data protection.

RQ5: Which Authors are Co-Occurring in Research on Mobile Applications and Cybercrime Prevention?

According to the literature review, authors E. Rutger Leukfeldt and Steve Van de Weijer present three co-occurrences (weight 3). See Fig. 9.

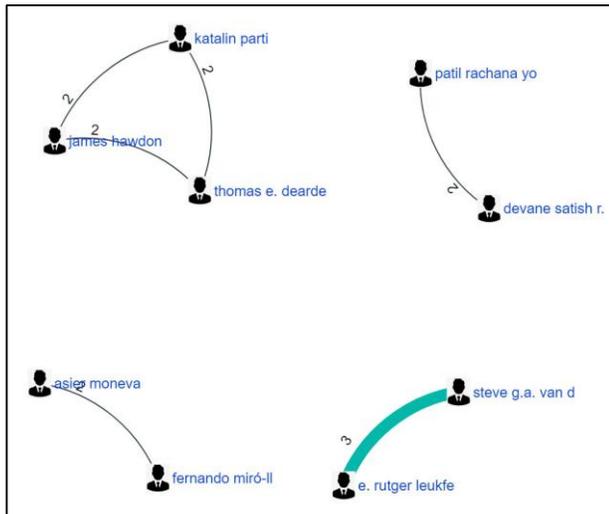

Fig. 9. Co-authorship Bibliometric Network.

While authors E. Rutger Leukfeldt and Steve Van de Weijer are presented together in three papers, it is important to mention that authors James Hawdon, Katalin Parti and Thomas Dearde are presented together in two papers.

For Tandon, Kaur, Mäntymäki & Dhir [77], the author presenting the highest co-occurrence in the selected studies is Wang X. Do not agree with the authors because the research focused more on blockchain.

## V. CONCLUSIONS AND FUTURE RESEARCH

This study has managed to identify and analyze which are the most used techniques for the detection of computer crimes, the classification of computer crimes, the most used words in the papers, the most used keywords, the most cited papers and the authors that present cooccurrence in their research based on the research questions posed and analyzed with the systematic literature review between 2017 and 2021 in several databases. The results of the review determine that the most used techniques for the detection of computer crimes are: Statical, Machine Learning, Data Mining, Neural network, Deep learning, Fuzzy logic neural network, Computer Vision Techniques, Biometric Techniques, Cryptography, Forensics tools, Network Encryption, Proxies, Firewalls and Cyber Liability Insurance. The most used technique is Machine Learning. Likewise, computer crimes were classified as follows: Cyber Terrorism, Cyber Warfare, Cyber Espionage, Child Pornography, Cyber Bullying, Cyber Extortion, Cyber Extortion, Cyberstalking, Cyber Fraud / Online Fraud / Fraud, Cyber Laundering, Phishing, Denial of service Attack, SQL Injection Attack, Malware, Unauthorized System Access, Trojans, Identity Theft, Key Logger, Screen Logger, Evil Twin, Botnets, Social Engineering, Worms, Ransomware, Hacking and Data breach. Few co-authorships were identified among the researchers and very few systematic reviews that made use of bibliometric networks; however, this did not improve the interpretation of the results. Future research should consider a larger number of articles for review and analysis.

# Evaluation of the Efficiency of the Optimization Algorithms for Transfer Learning on the Rice Leaf Disease Dataset

Luyi-Da Quach, Khang Nguyen Quoc, Anh Nguyen Quynh, Hoang Tran Ngoc  
FPT University, Cantho city, Vietnam

**Abstract**—To improve the model's efficiency, people use many different methods, including the Transfer Learning algorithm, to improve the efficiency of recognition and classification of image data. The study was carried out to combine optimization algorithms with the Transfer Learning model with MobileNet, MobileNetV2, InceptionV3, Xception, ResNet50V2, DenseNet201 models. Then, testing on rice disease data set with 13.186 images, background removed. The result obtained with high accuracy is the RMSprop algorithm, with an accuracy of 88% when combined with the Xception model, similar to the F1, Xception model, and ResNet50V2 score of 87% when combined with the Adam algorithm. This shows the effect of gradients on the Transition learning model. Research, evaluate and draw the optimal model to build a website to identify diseases on rice leaves, with the main functions including images and recording of disease identification points for better management purposes on diseased areas of rice.

**Keywords**—Optimization algorithm; transfer learning; RMSprop; rice leaf disease; Adam

## I. INTRODUCTION

Transfer learning is a popular method used for machine learning recognition problems, with the goal of reusing as a starting point for a second task. Therefore, a Transfer learning model is used to learn on a certain source task and pre-trained this model, then it is used for another model so that the new model learns on the target tasks faster. With the use of pre-trained models, Transfer learning models take a big step up from previous models in improving the accuracy of recognition model and classification based on object features.

In practical applications, Transfer learning models are quite commonly used to improve the accuracy of deep learning models. Specifically in this regard, some studies can be mentioned such as: the problem of identifying patients with Parkinson's disease [1], predicting air quality at large time resolution [2], using VGG-16 classifies retinopathy caused by diabetes [3], improving the process of sleep organization method [4], improving ad accuracy by checking clicks [5], improving the accuracy in counting the number of wheat ears [6], improving the accuracy in classifying medicinal leaves [7], classifying diseases in poultry [8], etc. In general, when using a Transfer learning model with different data sets, the accuracy of the model is also significantly improved when the accuracy increases from 5-8%. This makes an important contribution in predicting more accurately in the recognition problem. However, the Transfer learning model also cannot

get high accuracy on a number of different data sets. Therefore, the transfer learning model is interested in order to improve the accuracy of the model.

In improving, the accuracy of the Transfer learning model is also approached in various data problems. In which, there are some applied studies in improving the accuracy of Transfer learning models from input data, or combining algorithms. For the improvement of input data, these studies can be mentioned: A Stacked Denoising Autoencoder [9], Sparse Fingerprinting [10], converting High-Resource to Low-Resource Language [11], time series data augmentation [12], combine images [13], .... For the algorithm, there are studies such as Vector Segmentation [14], Kidney Segmentation [15], SURF features [16], etc. This shows that improving the accuracy of the Transfer learning model has been extremely attended in recent times, especially in the use of optimization models, in which there are some studies such as: using particle swarm optimization (PSO)[17], heuristic optimization for gesture recognition [18], approaching adaptive fine-tuning for routing through custom or pre-trained layer – called SpotTune [19], using hyper-parameters optimization to identify diseases on maize leaves [20], using Bayesian optimization to create a mixed-signal analog circuit model [21], Adam Deep Learning optimization algorithm for recognizing flower images with background [22], ....

In general, in the past time, there have been many studies to improve the accuracy of Transfer learning models, but there has been no research to evaluate the accuracy by combining Transfer learning models with optimal algorithms. advantage on the rice leaf disease dataset. The main contribution of the study is the implementation of the tasks below:

- Combining optimization algorithms with Transfer learning models on rice leaf disease dataset has no image background.
- Evaluate the optimal model after testing; aim is checking the appropriateness of the Transfer learning model and the optimization algorithm.

Finally, the study uses the Transfer learning model and the optimal algorithm with the highest accuracy to build a system. This system is used to diagnose rice diseases by imaging.

## II. TRANSFER LEARNING MODELS

In this section, the study will present six Transfer learning models used, through the introduction to get an overview of

the model. In recent years, the MobileNet model has had good results for identifying and implementing embedded and mobile systems. There are different versions of this architecture. MobileNet [23], introduced in 2017, used depth integrals and started with two singles global hyper parameters that effectively balance latency and accuracy. MobieNetV2 [24] was introduced two years later with residuals opposite the number of linear bottlenecks between classes. This model takes tight low dimensional space (bottleneck) as input which is then expanded on high dimensional space. With filtered by deep light convolution, then projected back to low dimensional space with linear convolution. MobileNetV3 [25] is the higher generation of Mobilenets which is public at the ICCV conference in 2019, this model is a config for CPUs in mobile phones with the association of hardware-aware network architecture search (NAS), and the NetAdapt algorithm enhanced through novel architecture refinements. There are two sub-models in this model, MobileNetV3-Large and MobileNetV3-Small, with high and low resource-use matching, which helps the model to promote efficiency on hardware effectively. Another model to be introduced is the network model that goes deeper and deeper, which also makes the training process more difficult and degrades the accuracy of the training rapidly. To solve this problem, in 2016, Deep

Residual Learning (ResNet) [26] implemented connection skipping and used batch normalization techniques, using Residual Block to remove the connection layer. This block allows each layer to connect its inputs to its outputs. Families in ResNet include ResNet50, ResNet101, and ResNet152 [27], corresponding to a network of 60 layers, 101 classes, and 152 classes trained on the ImageNet dataset. In 2018, similar to ResNet, the InceptionV3 model [28] is a network trained on the ImageNet dataset. It is introduced as a convolutional neural network model consisting of multiple convolution and maximal steps. DenseNet [29] further modified the model for ResNet, the purpose is that instead of aggregating the output feature maps from all previous layers, it will concatenate all feature maps sequentially instead of summarizing them. Merge output feature maps from all previous layers. DenseNet is used in three variants, DenseNet-121, DenseNet-169, and DenseNet-201. In 2020, EfficientNetB0 [30] was introduced with multiple optimizations when scaling each dimension using a fixed set of scaling factors. This approach surpasses other mod-ern models trained on the ImageNet dataset. In 2017, Xception [31] was introduced as an extension of the Inception architecture, which is intended to replace standard Inceptions with depth-separable aggregates. The architectural models used in this study is shown in Fig. 1.

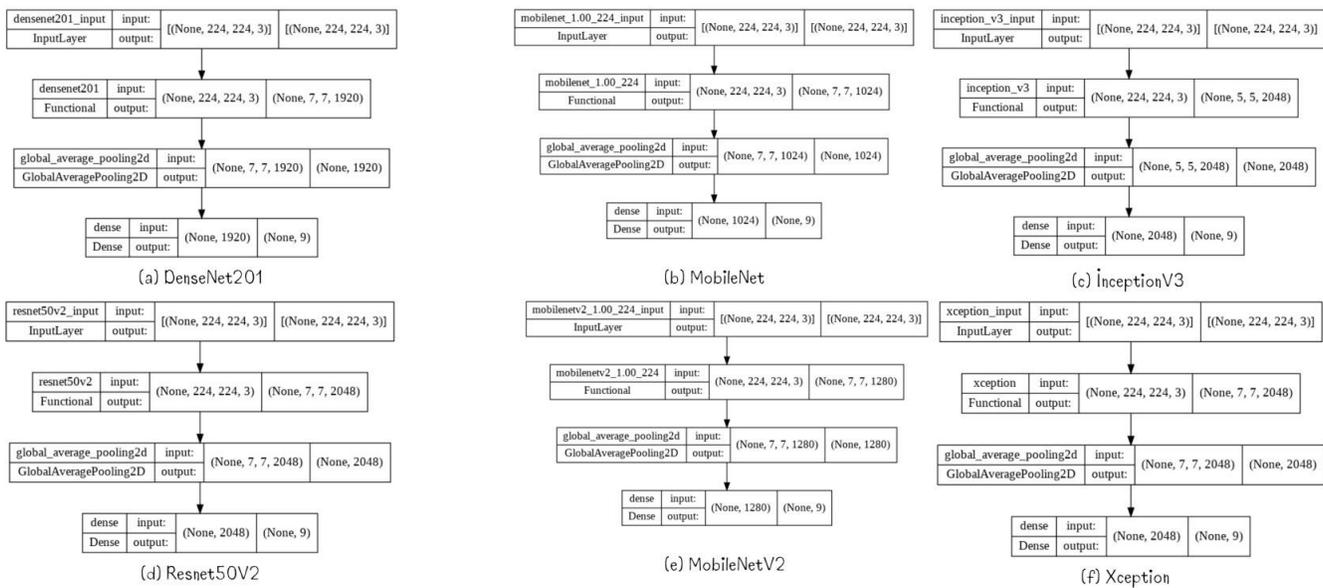

Fig. 1. The Architecture of the Models is used in the Study to Evaluate the Effectiveness of the Optimization Algorithm on Transfer Learning Models.

### III. OPTIMIZATION ALGORITHM

In this section, the study will theoretically present some optimization algorithms used in the research. The main purpose helps to correct the learning coefficient to accelerate the training, increase the accuracy with fast convergence on the Transfer learning model.

#### A. Adaptive Moment Estimation (Adam)

Adam algorithm [32] adjusts the learning rate for each weight of the neural network by calculating the first and second intervals of the slope. This makes the algorithm optimal in using the learning rate selection method based on the particular situation. Adam algorithm uses parameters  $v_t$ ,

$m_t$  to estimate of the first moment (the mean) and the second moment (the uncentered variance) of the gradients respectively;  $\beta_1, \beta_2$  is speed of movement,  $g_t$  is gradient at time t in the formula (1-4) and (5) is the Adam update rule, it is the same as in the RMSprop optimization algorithm.

$$m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t \quad (1)$$

$$v_t = \beta_2 v_{t-1} + (1 - \beta_2) g_t^2 \quad (2)$$

$$\hat{m}_t = \frac{m_t}{1 - \beta_1^t} \quad (3)$$

$$\hat{v}_t = \frac{v_t}{1 - \beta_2^t} \quad (4)$$

$$W_{t+1} = W_t - \frac{\eta}{\sqrt{v_t + \epsilon}} \cdot \hat{m}_t \quad (5)$$

### B. Adaptive Gradient Algorithm (Adagrad)

Adagrad algorithm [33] implements varying the learning rate to reduce gradients in machine learning techniques. The use of learning weights based on previous inputs to automatically adjust the learning rate to the best divisor instead of a single learning rate, which makes Adagrad better than other algorithms. In the formula (6),  $\eta$  is learning rate,  $\epsilon$  is guaranteed parameter,  $g_t$  is gradient at time  $t$ ,  $G_t$  is the diagonal matrix containing the square of the derivative of the parameter vector at  $t$ .

$$W_{t+1} = W_t - \frac{\eta}{\sqrt{G_t + \epsilon}} \cdot g_t \quad (6)$$

### C. Root Mean Squared Propagation (RMSprop)

For gradient normalization, RMSprop [34] uses the mean square of the gradient. This helps balance the step size – reduce the step for large gradients to avert Exploding Gradient and increase the step for small gradients to sidestep Vanishing Gradient. Formula (7) is used to calculate the running time parameter  $E[g^2]_t$ , and form aa rules for formula (8).

$$E[g^2]_t = 0.9E[g^2]_{t-1} + 0.1g_t^2 \quad (7)$$

$$W_{t+1} = W_t - \frac{\eta}{\sqrt{E[g^2]_t + \epsilon}} \cdot g_t \quad (8)$$

### D. Adaptive Delta (Adadelata)

Adadelata algorithm [35] allows to reduce the learning rate on each dimension of SGD. Adadelata restricts the previously accumulated gradients to a predefined size  $w$ , which makes the difference in the algorithm by not having to sum the previously squared gradients together. The sum of the gradients is defined recursively as the descending average of all previous gradients. The only variables that affect the running average  $E[t]$  at time step  $t$  are the previous average and the current gradient (9). By substituting the descending mean on the previous squared gradients for the diagonal matrix ( $G[t]$ ), in terms of parameter update vector  $\Delta\theta_t$  (10).

$$E[g^2]_t = \gamma E[g^2]_{t-1} + (1 - \gamma)g_t^2 \quad (9)$$

$$\Delta\theta_t = - \frac{\eta}{\sqrt{E[g^2]_t + \epsilon}} g_t \quad (10)$$

### E. Stochastic Gradient Descent (SGD)

Stochastic is a variant of Gradient Descent [36]. Instead of after each epoch we will update the weight (Weight) once, in each epoch with  $N$  data points we will update the weight  $N$  times. Therefore, it is usually much faster and can also be used to learn online. SGD performs frequent updates with high variance causing the objective function to fluctuate a lot with the corresponding formula with  $x(i)$  and  $y(i)$  presented for each training instance.

$$\theta = \theta - \eta \cdot \nabla_{\theta} J(\theta; x^{(i)}; y^{(i)}) \quad (11)$$

## IV. METHODOLOGY

### A. Data and Data Preparation

With the background dataset provided by the Mekong Delta Rice Institute taken by phone (Samsung SM-N770F)

with image size (1816x4032). We combed and collected additional leaf disease datasets from multiple sources including Kaggle, GitHub, and from previous related studies in Google Scholar<sup>1</sup>. This dataset contains fully captured rice leaf images from leaf roll to leaf apex, which increases the accuracy of the model and is accompanied by a more complete assessment (Fig. 2). By collecting progress, our dataset consists of 9839 images of diseased leaves of rice consisting of the eight most common diseases namely Bacteria blight, Brown spot, Hispa, Leaf scald, Leaf blast, Leaf smut, Narrow brown spot, and Tungro with the characteristics shown in Fig. 3. There are 3347 images of Healthy leaves. After gathering data, the original size of images in the dataset has various sizes. Hence, we resize it to a large size (1024 x 1024 pixels) for keeping the quality of the image and having a standard size. Besides, we split this dataset into 3 parts: training, validation, and testing with a ratio is 60:30:10 is shown in the Table I.

Since the data is enough, research used various preprocessing steps like image resizing to 224 x 224 and using the processing function of each Transfer learning model to preprocess images to train. With preprocessing dataset, the image in the dataset transforms into an array of RGB colors. The value of each element in array that was scaled to [0; 1], [-1; 1], or [0; 255] depending on each Transfer learning model is shown in Fig. 4.

### B. Evaluation Methods

Accuracy is an instance that is precisely determined from the total number of data sets. In other words, it is the correct predictions made by the model relative to the total predictions. It is given by equation (12)

$$Accuracy = \frac{TP+TN}{Total\ sample} \quad (12)$$

In which, TP (True Positive): Total number of Positive matches. TN (True Negative): Total number of Negative matches.

TABLE I. STATISTICS OF TRAINING, VALIDATION AND TESTING DATASETS FOR EACH TYPE OF RICE LEAF DISEASE

Class	Training	Validation	Test	Total
Bacteria blight	496	248	83	827
Brown spot	1,738	869	290	2,897
Hispa	1,189	594	198	1,981
Leaf blast	1,803	901	301	3,005
Leaf scald	214	107	37	358
Leaf smut	203	102	34	339
Narrow brown spot	211	105	36	352
Tungro	48	24	8	80
Healthy	2,008	1004	335	3,347
Total	7,910	3,954	1,322	13,186

<sup>1</sup> The aggregated dataset is stored at <https://github.com/raianrido/diseases-on-rice-leaf>

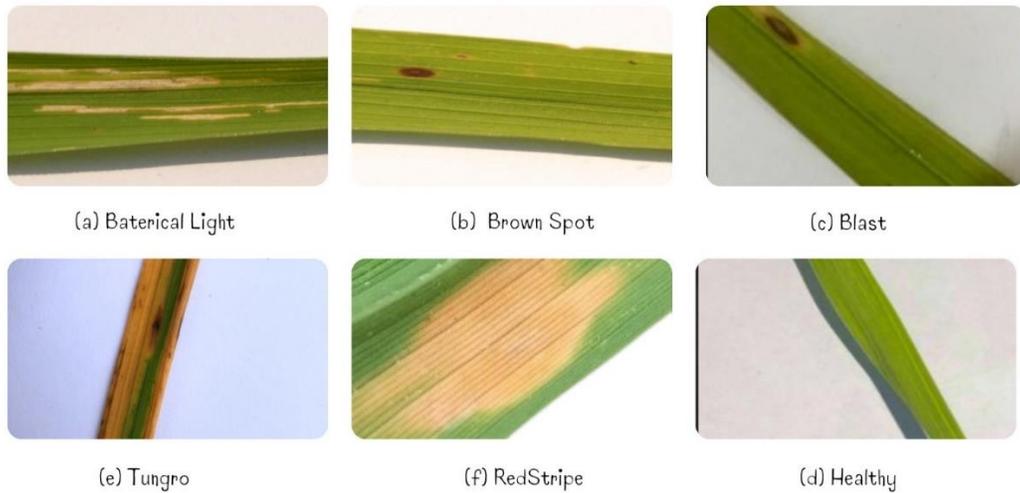

Fig. 2. Images are Collected from the Rice Institute in the Mekong Delta.

Fig. 3. Illustrated Image of Disease Data on Rice Leaf.

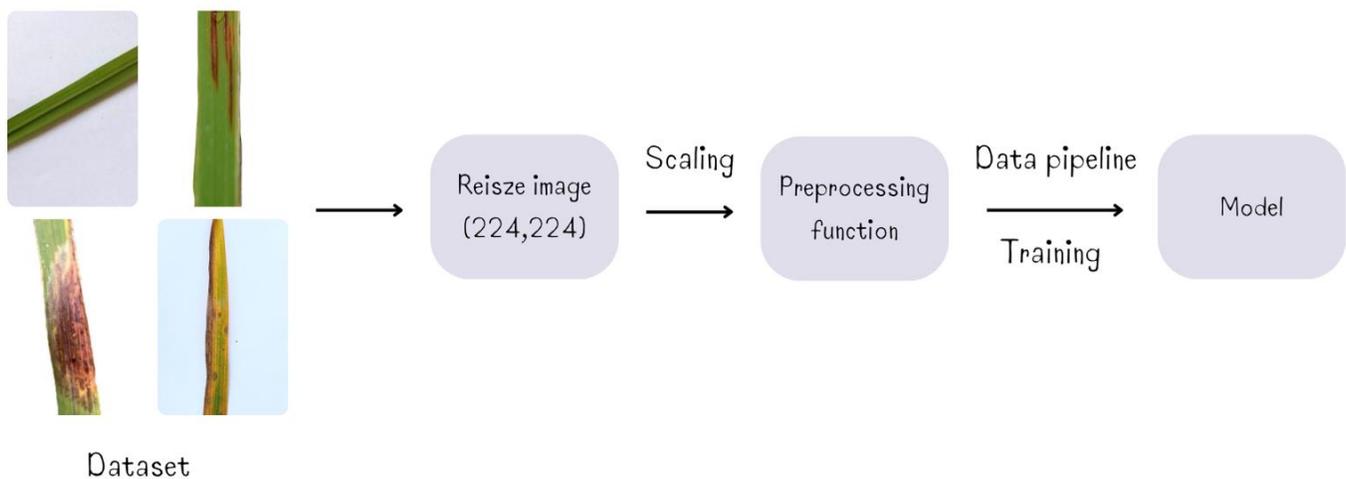

Fig. 4. Data Preparation on Rice Leaf Disease Dataset.

Loss function evaluates the effectiveness of the learning algorithm for the model on the used data set. It produces a non-negative real number representing the distinction between two quantities:  $a$ , the predicted label, and  $y$ , the correct label. This is a reward-punishment mechanism, the model will have to pay a penalty each time the prediction is wrong and the penalty is proportional to the size of the error. In any supervised math problem, the goal always includes reducing the total penalty payable. In the ideal case  $a = y$ , the loss function will return a minimum value of 0. Cross-entropy (CE) is considered as a measure of classifier performance (13).

$$CE = -\sum_i^c a_i \log(p_i) \quad (13)$$

In which,  $c$  is the number of classes,  $a_i$  the actual value,  $p_i$  is the predicted value.

The Confusion matrix gives a better view of how the data points are classified as true/false. It is the summary used to evaluate the classification model performance. The number of true and false predictions is summarized by the count values and broken down by class. When trying to increase the accuracy of the model, the recall will decrease and vice versa. The parameter F1-score reconciles the two values above.

$$F_1 - Score = \frac{2}{\frac{1}{Recall} + \frac{1}{Precision}} \quad (14)$$

$$Precision = \frac{TP}{Total\ predicted\ positive} = \frac{TP}{TP+FP} \quad (15)$$

$$Recall = \frac{TP}{Total\ actual\ positive} = \frac{TP}{TP+FN} \quad (16)$$

In which, FP (False Positive) is the total number of cases that predict the observations of the label Negative to Positive, FN (False Negative) is the total number of cases that predict the observations of the label Positive to Negative.

F1-Score is a harmonized average of Precision and Recall. It can have the lowest score of 0 (perfect precision and recall) and the highest of 1. The quality of the model in machine learning or deep learning depends on the value of the F1-Score, F1 is high which demonstrates the model is reasonable. Combining Transfer learning model and optimization algorithm.

In this research, Transfer learning will help resolve the issue by utilizing a previously trained in ImageNet dataset as the base for a new model. Transfer learning allows us to customize an already-trained model for a specific problem. Therefore, we are fine-tuning the last layer of six Transfer learning models for the classification of leaf disease consisting of MobileNet, MobileNetV2, InceptionV3, Xception, Resnet50V2, and DenseNet201. By the base layer of model architecture, whose weights were pre-trained and imagined to be frozen, the default input is 224x224 pixels for each image. Then we add the last layers global\_average\_pooling2d (None, 512) and Dense (0,9) with the activation 'SoftMax'. Before training, each model compiles one in five optimization algorithms. The proposed work offers deep learning, which

causes an increase in diseases on rice leaf classification efficiency. The research plotted the history of training processing with accuracy in the training dataset and validation dataset to evaluate the difference between each model with optimization. All optimization algorithms have a default value of a parameter such as a learning rate is 0.001. After training progress, we plotted the confusion matrix and classification report on the testing dataset to have a different view of accuracy in each class and model (Fig. 5).

### C. Results

The study is tested on the system CPU Intel Xeon X5675 3.07 GHz, RAM 24 Gbytes and graphics devices NVIDIA Quadro K2200. Experimental results on five optimization algorithms combined with six Transfer learning models on the rice leaf disease data set are presented in Table II and Fig. 6. The study evaluates the accuracy with parameters F1-Score and Accuracy. The results obtained are as follows:

- For the F1-Score evaluation, the association of the ResNet50V2 model, Xception, and Adam algorithm at 87% was the model that reached the highest results, and the lowest was 50% when combining the MobileNet model and Adadelta algorithm.
- For accuracy evaluation, the results show that the discrepancy when the highest accuracy is RMSprop algorithm applying to the Xception model is 88%, and the lowest is 49% when incorporating MobileNet and Adadelta.

### D. Application System

A website system is built based on the Xception trained model which compiles RMSprop algorithm with 88% accuracy on the test data set (Fig. 7), with main functions including:

Image recognition: When the user uploads an image at the browse button under the title Detect now and clicks submit, the image will be recognized to detect the disease and return the disease name, symptoms, treatment, and prevention measures in both English and Vietnamese.

- Report false identification and contribute to the system: This is a report function button, helping users to contribute images related to the disease when the system recognizes it wrong. Nevertheless, it will be put into the retraining system when passing the check processing by the admin. At that time, the Report screen will be divided into 3 states: pending (waiting for approval), reject (report has been processed and user information reported is not valid (false)), accept (system error, needed repair and optimization).
- Disease area map: When the user uses the system to identify the disease, the system will use the user's location (Google API) to get information and create a map of the disease. Each color of the dot corresponds to a different disease.

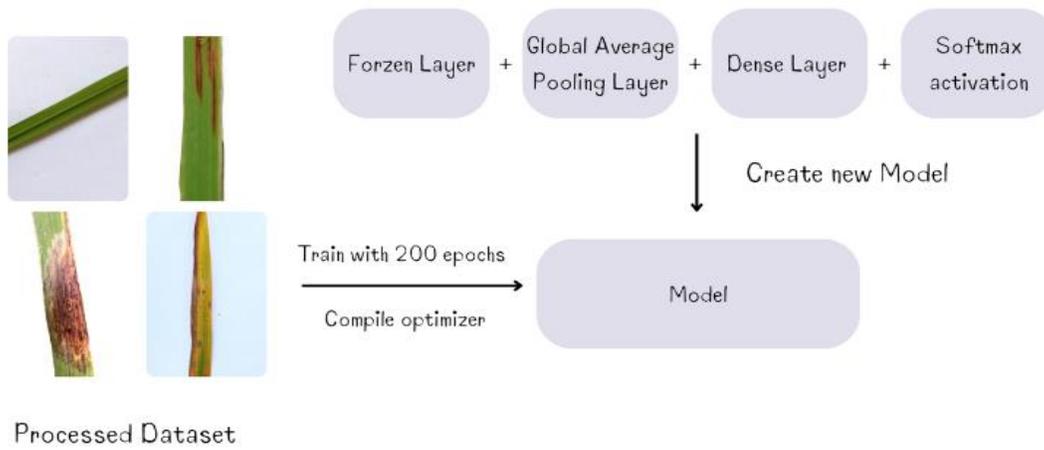

Fig. 5. Illustrating the Combining Transfer Learning Model and Optimization Algorithm.

TABLE II. RESULT TABLE OF COMBINING THE OPTIMAL ALGORITHM WITH THE TRANSFER LEARNING MODEL

Optimization Algorithms	SGD		Adam		Adagrad		Adadelta		RMSprop	
	F1-Score	Accuracy	F1-Score	Accuracy	F1-Score	Accuracy	F1-Score	Accuracy	F1-Score	Accuracy
<b>MobileNet</b>	84%	75%	86%	76%	77%	69%	50%	49%	85%	76%
<b>MobileNetV2</b>	84%	74%	83%	73%	79%	70%	53%	55%	83%	73%

V. DISCUSSION

Based on test results at Table II and Fig. 6, ResNet50V2 and Xception models combined with Adam algorithm show the efficiency of the algorithm. Analysis of the results shows that Adam algorithm performs better than other algorithms when the accuracy is always high at 87% (F1-Score) and 80% (accuracy). This is because the Adam algorithm further extends stochastic gradient descent to update the network weights during training. The Adam algorithm updates the learning rate for each individual network weight when using a random gradient descent algorithm. Therefore, the optimizers of the Adam algorithm inherit the features of the Adagrad and RMSprop algorithms. In Adam algorithm, instead of adjusting the learning rate based on the first moment (average) but in RMSprop it also uses the second moment of the gradient. In which, the cause comes from the representations of the decay rate  $\beta_1$  and  $\beta_2$  of the average of the gradients (17). Regardless, the model that compiles the Adam algorithm is still flawed by incorrectly receiving many images of healthy rice leaves, which figure shows this error.

$$m_t = \beta_1 m_t + (1 - \beta_1) \left[ \frac{\delta L}{\delta w_t} \right] v_t = \beta_2 v_{t-1} + (1 - \beta_2) \left[ \frac{\delta L}{\delta w_t} \right]^2 \quad (17)$$

However, when evaluating the accuracy of the algorithm, the optimal model RMSprop shows high efficiency when applied on six models tested on research with parameters of accuracy and F1-Score. This is because RMSprop maintains a moving average of the quadratic gradient, while adjusting the updates to the weights by this magnitude.

In the opposite direction, Adadelta shows no efficiency when combined with Transfer learning model. As proof for this, we can see the results of 5/6 models such as MobileNet, MobileNetV2, InceptionV3, Xception and ResNet50V2. But it works well on the DenseNet201 model (Fig. 8 shows diagnostic discrepancies on some data sets). This result is because the Adadelta algorithm does not use a learning rate parameter. Instead, the algorithm uses its own rate of change as a parameter to adjust the learning rate. Adadelta needs to use two state variables to store the quadratic moments of the gradient and of the change in parameters. In addition, Adadelta uses a leak average to store dynamic estimates of the required statistics. As a result, the learning rate has to be changed manually and the learning rate will decline and become smaller at some point. Therefore, after a certain number of iterations, the model will no longer be able to learn new knowledge.

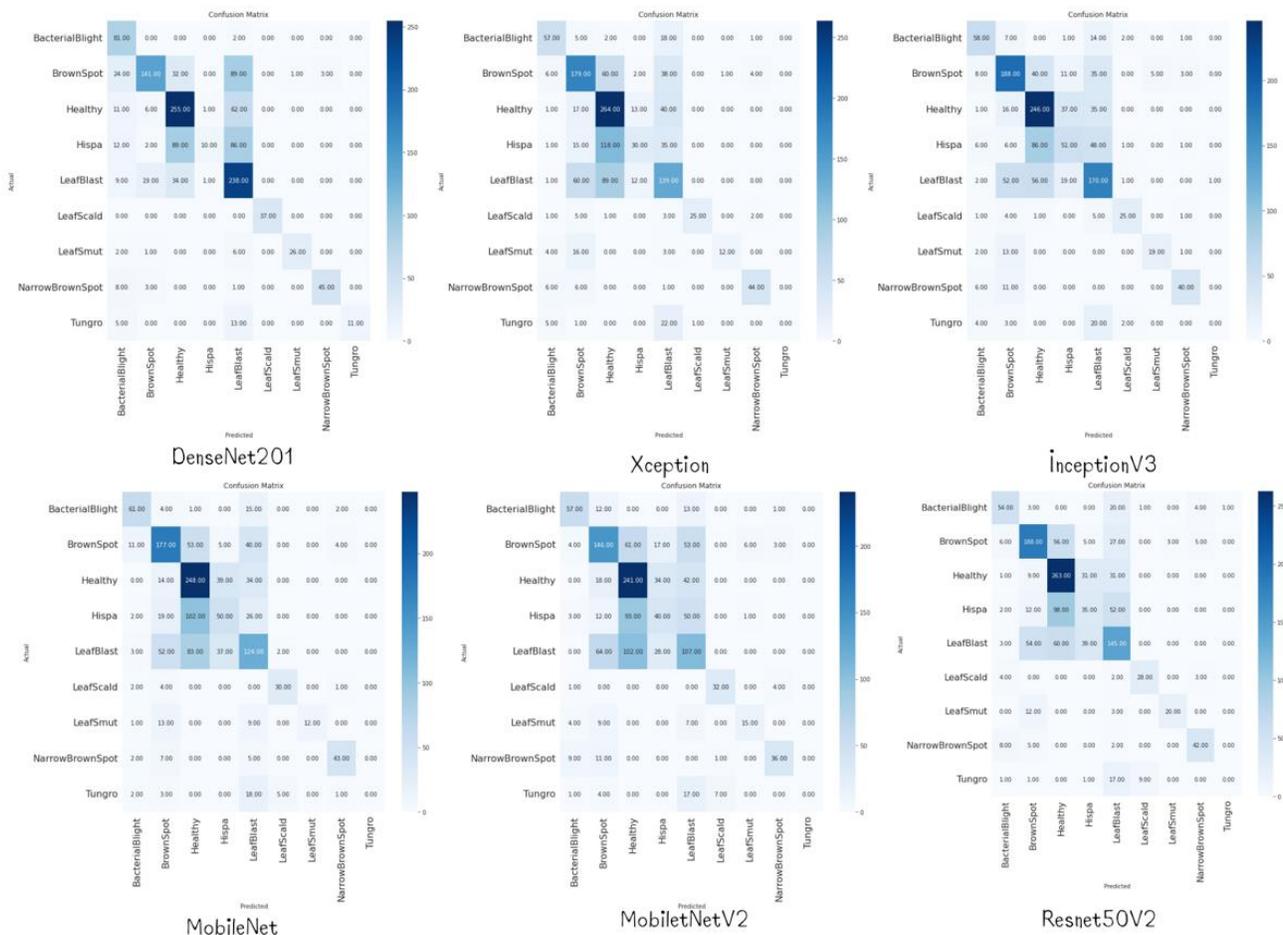

Fig. 8. Confusion Matrix of Adadelta Algorithm with Transfer Learning Models.

## VI. CONCLUSIONS

The study proposes that Adam's method is effective when combined with Transfer learning models through gradient expansion to update network parameters and reduce random gradients. This also works for the SGD and RMSprop models. Besides, the low accuracy may come from the influence of input parameters. Although the used image has eliminated the background influence of the image, the resolution parameters cannot be controlled because it is taken from many different sources, in which the data source is generated from study with higher accuracy.

## VII. FUTURE WORKS

Based on the research results, it can be seen how effective the optimization algorithms are on different Transfer learning models. However, in this study, we have not gone into detailed evaluation of the combination of models with the optimal algorithm when adjusting the learning rate. Therefore, the study opens up the research and evaluation of the changes of the parameters on the model with the optimization algorithm. Accordingly, the proposal of follow-up studies can more closely evaluate the relationship between the parameters in the optimal model, the influence of the input data set on experiment, and so on. In further research, Transfer Learning

models will be fine tuning with a more complex output structure and compile implementation with more optimization algorithms, increasing the efficiency of the model.

**Abstract**—Authentication acts as a secured method of usability concepts to certain transactions, especially for online banking transaction. Existing method is lacking in terms of usability, thus, making the goal of usability for authentication activities unsuccessful. A study has discovered some key concepts of usability in terms of Human Computer Interaction (HCI) by comparing two existing models of two different factors: environmental factors and display factors. An algorithm shows the authentication step during the online transaction activity. This paper is to prove that shoulder-surfing resistant authentication scheme that uses visual colour-blind mode-based model meets all the requirements of usability, hence, achieved the goal of usability of authentication. This study will bring forward an algorithm that examined the stated authentication scheme with the two factors, i.e environmental and display, during the authentication activity.

**Keywords**—Authentication; usability; algorithm; model

## I. INTRODUCTION

Online banking application deals with varied issues of authentication, confidentiality, integrity and non-repudiation [1]. A secured application is highly dependent on the procedures of authentication to the online banking transaction. Authentication has been widely studied for its security and trustworthiness [1][2]. A success authentication method makes users satisfy with the services.

There are several methods of authentications that can be studied from [3][4]. These methods are highly related with users' experience and interface [5][6]. Authentication method is applied to most of authentication procedures during login process to any page or application, as well as in online transaction [7][8][9]. However, most of the studies are limited to usability towards users' experience and satisfaction [10][11]. This motivates us to investigate deeply to the authentication purposes and processes.

The objectives of this research are to: 1) identify shoulder surfing attack by utilizing users' visual perception model to the authentication; 2) propose a shoulder-surfing Resistant Authentication Scheme using Visual perception colour blind mode-based model and algorithm by taking into account users' quality of experience (QoE); and 3) analyze the proposed authentication scheme against usability, accessibility performance and shoulder surfing attack to the human computer interaction (HCI). Hence, the research is significant to the authentication step during the online transaction activity due to the shoulder-surfing attack.

This study will examine the usability in terms of human computer interaction (HCI) which is based on human preference and human satisfaction of quality of experience (QoE) [12][13]. This paper will be comparing the two existing authentication model that are based on environmental and display factors, and find the possible limitation of a compatible model of graphical-based authentication to the authentication activities.

## II. LITERATURE REVIEW

There are two types of element that can give some impact readability: environmental factors and display factors [14] [15]. Regarding the surrounding environment, the users' reading experience is directly affected by ambient brightness, viewing angle, and distance. From here, the size of the visual image of an item created in the viewers' eyes is influenced by viewing distance. The users' eyesight has a strong correlation with ambient brightness. According to geometrical optics, the viewers' perception of brightness is determined by the viewing angle and distance [16]. In addition, display parameters such as resolution and colour scheme, as well as screen brightness are also among important influencing factors [17].

### A. Hybrid Keypad

Human factor is the most crucial part while handling any online activities. Human preference and satisfaction have been widely discussed from the view of usability to the authentication. The existed model of authentication is called the Hybrid keypad [18][19]. The model creates coloured-hybrid-image keypads using superimposition. The keypad is developed automatically by appearing to the screen when user requests the one-time password (OTP). Fig. 1 depicts the existing model.

Fig. 1. The Existing Model of Hybrid Keypad.

Fig. 1 shows the illustration of Hybrid keypad. From the perspective of display factors, this model confuses the actual users when they keyed in their OT, due to two or more numbers that are overlapped on the keypad. However, the limitation of this model caused by environment factors is still uncertain, as to whether adding color-complementary components can further diminish the attacker's appearance and counteract the low frequency.

### B. HideScreen

A researcher has developed HideScreen, utilizing human vision and optical system features, where users' on-screen information may be hidden from shoulder surfers [20]. That is, when the on-screen information (OSI) was viewed from outside of the specified range, HideScreen discretized the OSI into grid patterns in order to neutralize the low-frequency components, thus allowing the OSI to "blend into" the background. Fig. 2 shows the process of the grid patterns model.

The existing model, however, only allows spatial frequency by focusing on the protection of short texts and complex pictures on the screen, which is shown on soft keypad or keyboard. This limitation focuses solely on display factors. On the other hand, from the perspective of environmental factors, there have been various graphical schemes that are resistant or immune to shoulder-surfing but they have substantial usability problems, where most notably are in terms of time and effort required to log in. This paper will be discussing on the said problems. The comparison of the two factors is depicted in the Table I.

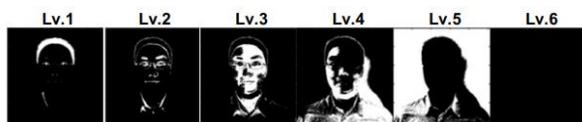

Fig. 2. The Existing Model of Grid Patterns.

TABLE I. COMPARISONS BETWEEN TWO FACTORS

Model	Environment factor	Display factor
Hybrid keypad	Adding colour-complementary components which can further diminish the attacker's appearance, and counteract the low frequency	Confusing to user due to overlapping numbers on the keypad
HideScreen	Substantial usability problems, most notably time and effort required to log in	Allows spatial frequency by focusing on the protection of short texts and complex pictures on the screen shown on soft keypad or keyboard
Shoulder-surfing resistant authentication scheme using visual colour-blind mode-based	Auto glare/auto hide which cannot be seen by shoulder surfer see from their angle	Using four colour-blind charts with eight-numbers combination

## III. PROPOSED MODEL AND ALGORITHM

Due to the problems counter from the authentication type, a proposed model has been created to encounter the authentication problem. Shoulder-surfing resistant authentication scheme that uses visual colour-blind mode-based model was proposed to address the problem of shoulder surfing attack, in order to identify any suitable authentication approach, as well as to simulate and analyse the proposed mechanism in terms of usability of HCI. The proposed model was accessible from the smartphone screen with no hybrid keypad provided to the user.

### A. Shoulder-surfing Resistant Authentication Scheme using Visual Colour-blind Mode-based Model

The model represents a set of four randomly colour-blind pictures in every session. Each picture contained two-digits number that was as similar as a TAC. Uniquely, the model enabled HideScreen or glare to the process by utilising the complex pixels of complementary Red, Green, Blue (RGB) colours of each picture whenever shoulder surfer sees to the actual user [21][22]. Users can access the proposed model from their smartphone screen. Fig. 3 illustrates the proposed authentication model.

During the transaction, users will request the one-time password (OTP) to the server. Server will react by randomly selecting four charts of colour-blind, with the combination of two number in each chart. Two matching colors were used for each chart to maintain the view of user perception. Next, the server will send the requested OTP to the users. Here, the OTP pictures will enable the auto glare or hide. The users must keyed in the OTP within 60 seconds since it will be automatically nullified after the period of time. The server will compare the keyed-in OTP with the one been sent. If the OTP is a matched, the authentication will be considered as successful, but if it is not, the users were to repeat the procedure. In addition, the proposed model can be used to all types of users including the one with colour vision deficiency.

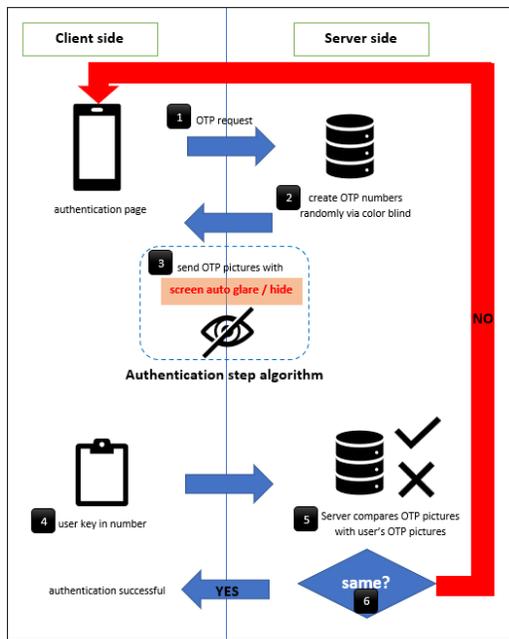

Fig. 3. Shoulder-surfing Resistant Authentication Scheme using Visual Colour-blind Mode-based Model.

### B. Shoulder-surfing Resistant Authentication Scheme using Visual Colour-blind Mode-based Algorithm

The algorithm represents the focus area of authentication step during the activity. From Fig. 4, the method started with the number of incoming requests, then sorted out based on their priority and order. Later, the server will load and announce QoE offer upon initiation. This method assumed that the provider's system that handled the incoming requests has access to this data. The number of requests that can be fulfilled within the advertised waiting time can be estimated based on the current server load. Fig. 4 depicted to the authentication step of algorithm.

Algorithm 1: Authentication Step

```

INPUT:  $B, \bar{U}, s, E$ 
OUTPUT: Settlement of ( $S_i$ )
BEGIN
1:  $B \leftarrow t_i \in \bar{U}$ 
2: FOR  $t$  DO
3:    $B \leftarrow \bar{U}, s$  read colour-blind chart
4:   Estimate  $B$  can be served within the  $E$ 
5:   FOR each  $B$  DO
6:     IF  $B$  can be served within the  $E$  THEN
7:       Authentication successful ( $B, S_i$ )
8:     ELSE
9:       Perform 'auto glare/auto hide'
10:      IF request within actual  $E$  THEN
11:        Authentication successful ( $B, S_i$ )
12:      ELSE
13:        Request  $E$  from  $s$ 
14:        Authentication successful ( $B, S_i$ )
15:        accepted by  $s$ 
16:      END IF
17:    END IF
18:  END FOR
19: END FOR
END

```

Fig. 4. Authentication Steps' Algorithm.

The programme will, then, extract the requests, their priorities, and the prospective providers server loads for each job, which was declared as the parameter to the algorithm. The authentication stage will further determine the total requests that can be fulfilled within the advertised  $E$ . Line 5 will, lastly, carry out the requests. As a result, the request for these duties will be completed. If this is not the case, the authentication step will request  $E$  from the provider in line 9 and conducted the "auto glare" or "auto hide" function. Table II depicted to the abbreviation from Algorithm 1.

TABLE II. LIST OF COMMONLY USED NOTATION

Notation	Description
$B$	Request
$\bar{U}$	OTP priority
$E$	Estimate time
$s$	Server load
$T$	Task
$t_i$	Number of tasks
$S_i$	Authentication settlement

## IV. EXPERIMENTAL SETUP

The study continued with simulation setup by using an application namely 'i-Smart Bank apps' which was developed using Android Studio and the database was supported by Firebase. This experiment was to show the authentication step during online transaction activities.

During the experiment, the users' reading experience was directly impacted by the ambient brightness, viewing angle, and distance. From here, the visual image of an item created in the viewers' eye was influenced by viewing distance. The users' eyesight has a strong correlation with ambient brightness. According to geometrical optics, the viewers' eyes perception of brightness is determined by the viewing angle and distance. Moreover, display parameters, such as resolution and colour scheme and screen brightness, are among important influencing factors.

Fig. 5(a), (b) and (c) illustrate steps involved during the authentication activities when users keyed in the one-time password. During the activity, the users will receive randomly chosen colour-blind chart with numbers to be keyed in. This activity will enable auto glare or auto hide which disallow shoulder-surfer to see what is happening to users' smartphone. Here, viewing angle and distance played an important role in determining whether the authentication will be succeeded or not. In addition, resolution and screen brightness also gave some influence to this activity.

Table III shows the measurement setup for this experiment. The relationship between luminance contrast and screen brightness will be discovered further in the study. These variables were chosen in order to test the algorithm for authentication procedures. The measurement setup testing was used to compare the algorithm step. This setup started with 10% to 100% for QoE of users' satisfaction.

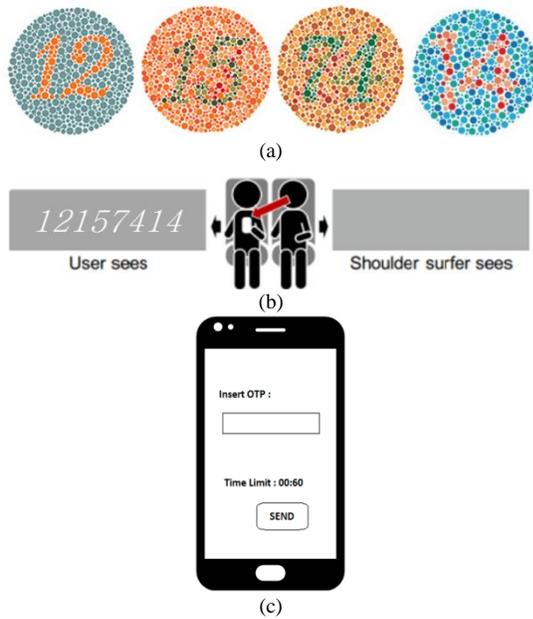

Fig. 5. Simulation Setup, (a) Example of Server Database (b) Example of Shoulder Surfing and the Effect after Applying Hide Screen or Glare (c) Example of a User Interface.

TABLE III. MEASUREMENT SETUP

Display brightness	Contrast luminance
10	0.1
20	0.2
40	0.4
60	0.6
80	0.8
100	1.0

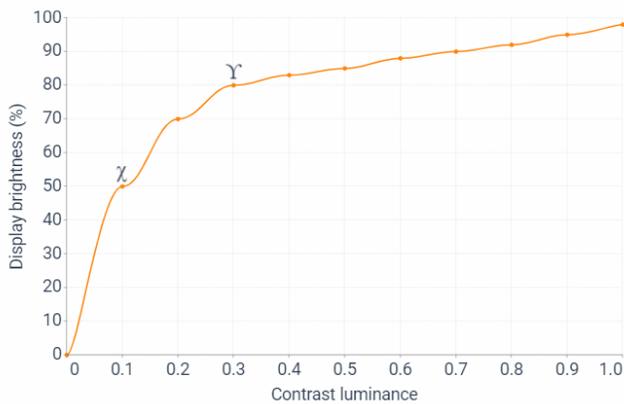

Fig. 6. Influence Trend to Human Vision (Display Brightness to Contrast Luminance).

Fig. 6 shows the contrast influence trend to human vision. From here, users' reading experience was found to be better when the contrast value is  $\gamma$ , with an improvement of 80%; but, when the contrast value is  $\chi$ , the reading experience was extremely bad, with an improvement of just 50%, substantially impairing reading.

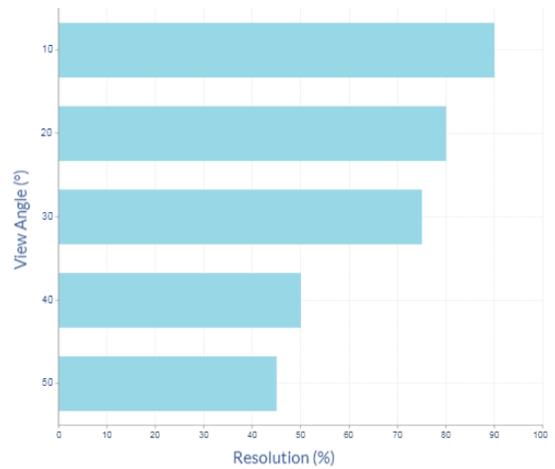

Fig. 7. Some Effect of Viewing Angle to Resolution.

Fig. 7 shows some effect of viewing angle to resolution. Users used i-Smart Bank apps at 10°, 20°, 30°, 40° and 50°, respectively while keeping the viewing distance of 20 cm, ambient brightness, and screen display content remained the same in order to verify the influence of viewing angle on the reading experience. As the viewing angle expanded, the users' relative visual performance fluctuated.

## V. RESULTS AND DISCUSSIONS

The proposed model reviewed the experimental result of viewing angle by the shoulder-surfer and the authority users. This study also compares the limitation of existing models based on two factors: environmental factors and display factors. The environmental factor will be investigated based on view angle, meanwhile the display factor will be examined based on resolution of smartphone. The result is shown in the following table.

Table IV shows the test started at 0° of view angle. This experiment continued with another three different types of view angle. Users, as shown in Table II, were asked to hold their smartphone in different view angles. Another shoulder-surfer volunteer were standing at the same distance but with different view angle. This experiment started with some contents were displayed and the shoulder-surfer were asked to read it before the actual users. The test and its results were recorded.

From Fig. 8, the resolution of shoulder-surfer was increased up to 90% at a distance of 20 cm, proving that the experiment had no appreciable effects on users or the regular use. In comparison, the resolution values from shoulder-surfer at 20 cm to 40 cm were barely above the boundary but less than 60%. However, the resolution clearly decreased below the boundary at distances greater than 60 cm. Nevertheless, shoulder-surfers seldom position themselves at an angle less than 40 degrees when standing 20 cm to 40 cm from the screen. In actuality, a shoulder surfers' viewing angle is always wide when the distance between them is modest. As a result, when resolution values from shoulder-surfer dropped as viewing distance increased, their overall reading experiences are still excellent and much exceed the minimal resolution barrier at 50% in the case of real applications.

TABLE IV. EXPERIMENTAL SETUP ENVIRONMENT

View Angle (°)	Distance (cm)	Ambient Brightness
0	20	150
20	40	300
40	60	500
60	80	800

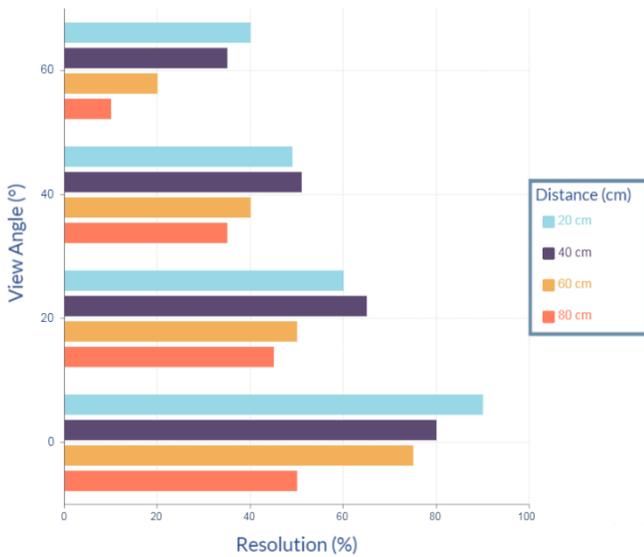

Fig. 8. Experimental Result from Resolution vs. View Angle.

The resolution values from shoulder-surfers at four viewing positions: (20 cm, 40°), (40 cm, 40°), (60 cm, 20°) and (80 cm, 20°) were close to 50% minimum boundary, while the resolution values located outside the four points area were significantly less than 50%. This suggests that a privacy space might be constructed, i.e when actual users are in a secure environment, reading is going well and the resolution value is higher than the required minimum of 50%. The shoulder-surfer will have a terrible reading experience, or may not even be able to read when they were outside of the safety zone. Furthermore, it should be emphasised that this security zone is not a permanent location. A safe zone is established provided that the farthest viewing distance for the user is 50 cm. Depending on the actual users' reading distance, which ranges from 20 cm to 80 cm, the safe zone narrows as the reading distance between the user and the screen decreases. In conclusion, the authentication procedure works well with the proposed model, and meets all requirements based on the key concepts of usability, thus, archive the users' preference and satisfaction to QoE.

## VI. CONCLUSION

This study has discovered the key concepts of usability in terms of Human Computer Interaction (HCI) by comparing two existing model models with two factors: environmental factors and display factors. Shoulder-surfing resistant authentication scheme using visual colour-blind mode-based model is proven to meet all the requirements of usability, hence, achieved the goal of usability of authentication. Hopefully, in future, the study will be able to bring forward an

algorithm by investigating the colour scheme, i.e the matching two complementary colours by the two factors of environmental factors and display factors during the authentication activity.

## ACKNOWLEDGMENT

This research was supported by Universiti Tun Hussein Onn Malaysia (UTHM) through Tier 1 (H808).

# Integrating Computer-aided Argument Mapping into EFL Learners' Argumentative Writing: Evidence from Saudi Arabia

Nuha Abdullah Alsmari

Department of English, College of Science and Humanities  
Prince Sattam bin Abdulaziz University  
Alkharj, Saudi Arabia

**Abstract**—This paper aims to examine the effects of Computer-Aided Argument Mapping (CAAM) on Saudi EFL learners' argumentative writing performance across the development of writing content and coherence and their self-regulated learning skills. A total of 40 second-year university EFL learners were purposively selected as a one-group of pre- and post-test design. Using a mixed-method approach, three research tools were utilized: pre- and post-writing tests, a Self-regulated Learning Scale (SRLS), and semi-structured interviews. Quantitative results demonstrated that EFL learners' argumentative writing performance made noteworthy gains, as manifested by the statistically significant differences between their pre- and post-test scores. Significant positive correlations were also found between the EFL learners' overall argumentative writing performance and the SRL factor subscales, indicating an increase in the self-regulation mechanism relative to planning, self-monitoring, evaluation, effort, and self-efficacy. Qualitative results indicate that the participants have positively embraced the integration of CAAM to improve their writing skills and self-regulation processes. Recommendations for implementing digital mapping to revolutionize EFL learning classrooms in this digital era are provided.

**Keywords**—Argumentative writing; argument mapping; computer-aided argument mapping; self-regulated learning; Saudi EFL learners

## I. INTRODUCTION

There is a consensus that developing effective writing competency is a challenging task, especially among EFL learners [1]. As English is used as the medium of instruction in various academic fields at higher education institutions in Saudi Arabia and numerous other EFL countries, writing has become a necessary prerequisite for foreign language learners to be successful in other fields that demand a written representation of knowledge [2]. In addition, international students are not permitted to enroll in various academic programs unless they fulfill certain requirements; one is attaining a specific level on a standardized English test (e.g., TOEFL, or IELTS). Some academic institutions impose an extra requirement that entails attaining a minimum score on the writing section, thus increasing the need to master advanced L2 writing skills to achieve success in higher education [11].

The complexity of L2 writing is inherent in the development of effective writing ability that comprises knowledge of the content and task, lexical complexity, cohesion, coherence, and fluency of ideas [7], [8]. Writing genres (such as argumentative writing and expository writing) also contribute to the inherent complexity involved in writing compositions due to the special lexicon and syntactical features as well as the structure [8]. These tasks overburden learners' cognitive loads during the learning process, creating a mental block against acquiring new information [15]. One way to support learners in managing their cognitive learning processes is to adopt certain problem-solving solutions, such as generating maps and diagrams [3], [7], [14].

Mapping or diagramming serves as a learning tool that helps facilitate comprehension when there is an abundance of data to process within a short amount of time. It encourages learners to engage in the process of developing ideas and information, as it activates the schemata necessary to organize ideas and content for writing. Learners will gain a full grasp of their thoughts and produce more developed and coherent outputs, thus stimulating their critical thinking, problem-solving [12], and self-regulation abilities [9]. As a result, they will optimize their learning performance and mental capacity. Writing is a complex skill that requires a strategic approach to accelerate EFL learners' control, confidence, and subsequent proficiency [5], [18]. Presumably, if learners are taught to map their ideas, they will be able to plan, monitor, and evaluate their progress [12].

This study was intended to examine the effects of computer-aided argument mapping (CAAM) on Saudi EFL learners' performance in argumentative writing, as well as their self-regulated learning skills.

## II. LITERATURE REVIEW

### A. Argument Mapping

Argument maps (AMs) are visual aids that facilitate the comprehension and evaluation of arguments [3]. They are organized in text-based, hierarchical representations in which propositions are displayed in color-coded boxes and linked with arrows to indicate the relationships among them [4], [17]. AMs visualize reasoning in a clear and concise fashion by diagramming the inferential construction of an argument [3]. It is a pedagogical tool that increases the opportunity for

comprehensive learning. Recent studies [3], [7], [12] have revealed the instructive benefits of AMs. For example, AMs have been adopted in language teaching methods in general [14], and in EFL writing in particular [7], [12]. According to [7], a well-constructed argument diagram enhances critical thinking skills and writing performance among EFL learners. AM stimulates EFL learners' schemata, which are essential for the development of argumentative writing.

The author [4] evaluated the effects of promoting critical thinking through AM compared to a strategy of generating themes from texts and sorting them hierarchically. Although AM training had no significant impact on students' critical thinking skills, the experimental group exceeded the no-instruction control groups on the evaluation and inductive reasoning tests. That is, after the intervention, EFL learners were able to compose more cohesive and developed writing. The study of [10] has further supported the use of AM for developing second-language learners' composition writing. The author [3] contends that "...the process of making an argument map is advantageous since it encourages students to construct and/or reconstruct their arguments with a level of clarity and thoroughness" (p. 115). Fig. 1 presents the main conventions used in AM.

Fig. 1 illustrates the major themes in an argument map. The primary premise is situated at the top. The arguments for the primary premise are represented by green boxes and connected by arrows to the primary premise. The primary premise in the figure has two arguments, 1A and 1B. Individual premises are placed inside white boxes shaded with green. Each premise is presented separately, with its own justification. Linked premises are grouped to support the conclusion. Additionally, claims with objections are marked in red. Writers designate reasons and objections using words such as "supports" and "opposes," respectively [3].

### B. Computer-Aided Argument Mapping (CAAM)

The advent of computer software has accelerated the task of creating user-friendly AMs. While AM can be taught effectively using pen and paper [7], CAAM can facilitate and speed up the mapping process efficiently, as it employs a number of programs specifically developed to enable users to quickly display arguments and reasons using cells and line diagrams [3], [17]. CAAM is an instructional system intended to promote learners' critical thinking by visually representing reasoning for any subject area [9] as well as offering a convenient workspace and a dashboard for building AMs [17]. Users can construct maps by simply inserting text into cells and then moving them to any desired location on the map using various levels of reasoning boxes. These cells can be modified, eliminated, or transferred to a different location. Although CAAM programs do not analyze or check the soundness of arguments, they help learners analyze and evaluate their arguments in a practical, visual, and professional way. According to [3], CAAM encourages students to compose arguments openly and thoroughly.

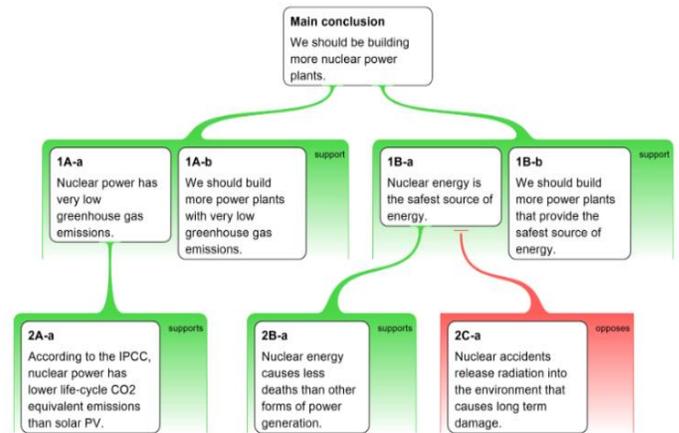

Fig. 1. Argument Mapping Demonstrating the Main Conventions.

CAAM serves as a platform that helps learners form conceptualizations by diagramming and revising reasoning clearly so that knowledge gaps and errors can be identified and reasoning can be reformulated [9], providing a better performance at argument analysis and evaluation. CAAM allows learners to access their previous essays in another panel while simultaneously accomplishing their AM in the panel, as well as helping them to be considerate of cohesion and coherence throughout the mapping process (see Fig. 2). In addition, CAAM offers learners the means for extensive problem-solving and critical thinking practice through activities with varying levels of complexity, which helps them develop these skills [6]. It enables learners to experiment practically with multiple logical structures and move the parts of an argument freely, allowing them to become more aware of the structure of their arguments, which is a prerequisite to critical thinking and self-regulation. Fig. 2 displays an excerpt of a learner's AM conducted via CAAM.

Numerous studies have demonstrated empirical evidence for the efficacy of CAAM in developing students' writing skills [3], [9], [14] and critical thinking skills [3], [12], [17]. The author [17] conducted a study using one-subject CAAM-based interventions during a three-month course and reported that courses teaching AM increased critical thinking performance. The authors [9] examined the effects of implementing CAAM to improve EFL students' self-regulated writing. After completing the self-regulation pretest in writing skills, the respondents were randomly divided into two experimental groups and a control group. The experimental groups who carried out their writing composition via CAAM software during the course of the training outperformed the control group and enhanced the self-regulation of their writing.

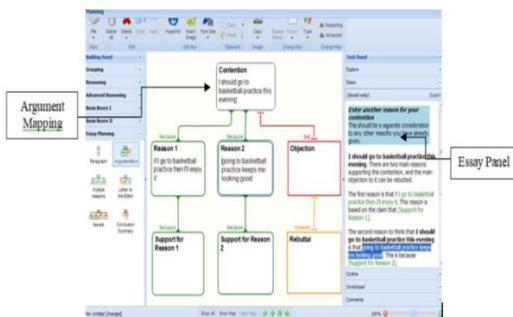

Fig. 2. Example of a Student's Argument Map (AM) Produced in CAAM.

### C. Self-Regulated Learning

A number of empirical studies [16], [13], [14], [19] have viewed SRL as a valuable new construct in the field of education. For example, the authors [16] described SRL as an active process in which learners are able to self-regulate by setting goals for their learning, monitor their learning processes, control and regulate their own thinking, and evaluate and reflect on their learning. The author's [19] view asserts that self-regulated learners actively adopt motivational, behavioral, and metacognitive approaches and dynamically engage in their learning processes.

Researchers have further revealed that learner-related factors, such as learning styles, personality traits, self-regulation, beliefs, and motivation, can substantially influence language learning progress [8], [14]. The author [16] argued that learners who self-regulate need to strategically consider how to approach a task, monitor their own progress while performing the task, assess the process and output after completing the task, review what they have accomplished and failed to accomplish, and further develop more strategies to use, which provide them more opportunities to execute tasks the next time. However, apart from understanding what areas to optimize and how to optimize them, self-regulated learners need to be stimulated to progress [19]. The authors [9] claimed that self-regulatory capacity can interact with cognitive factors since, as underscored by [14], learners who self-regulate can set goals, monitor, self-reflect, and assess their progress. The procedures involved in argument mapping are structured by planning and monitoring throughout the task, which helps raise learners' self-reflection and self-evaluation. With reflection and critical thinking, learners can maximize their self-regulated learning potential because they have fully acknowledged their role in the task.

A number of studies have been conducted that relate to teaching and learning EFL writing, such as critical writing using digital diagramming [7], descriptive writing achievement via CAAM [8], and teaching reasoning via CAAM [3]. However, to the researcher's knowledge, no study has focused on the effectiveness of CAAM in developing EFL learners' performance in argumentative writing and promoting SRLs, particularly in the Saudi EFL context. The study is significant because it contributes pertinent information to higher education institutions in EFL contexts. It is hoped that the findings will help EFL teachers gain better knowledge of language learning from the learners' perspectives and provide additional insights into the advantages of teaching English

writing with CAAM, thereby aiding EFL learners' argumentative writing skills and their ability to self-regulate their learning. Accordingly, the current study sought to answer the following research questions:

- 1) How does the CAAM intervention affect Saudi EFL learners' argumentative writing performance and self-regulated learning skills?
- 2) Is there a significant correlation between Saudi EFL learners' performance in argumentative writing composition and their ability to self-regulate their learning after the CAAM intervention?
- 3) How do Saudi EFL learners perceive the CAAM intervention?

## III. METHODOLOGY

### A. Research Design and Participants

The study employed a mixed-methods approach on a single group of pre- and post-test designs. The quantitative measures were used to explore the extent to which the integration of CAAM affected EFL learners' argumentative writing skills relative to the development of writing content and coherence, and self-regulated learning variables. The qualitative measures served to reveal how respondents perceived the experiment and the advantages relative to their argumentative writing tasks. The intervention was conducted over 11 weeks. The study sample consisted of 40 English majors at Prince Sattam bin Abdulaziz University who enrolled in the Essay Writing 2 course (3 credits), which was intended to promote EFL learners' academic writing and critical thinking.

### B. Research Instruments

Data were collected using four instruments: (1) a pre- and post-writing test, (2) a self-regulation learning scale (SRLS), and (3) semi-structured interviews. In the pre- and post-writing tests, the respondents developed an argumentative essay of at least 250 words in one hour. The topic was chosen from a list of the topics typically used for IELTS writing task 2 and aligned with topics they were studying in their Essay Writing 2 course. Prior activities, such as brainstorming, posing questions, and reading text to accelerate learners' schemata, which took an hour, were also performed. The scoring rubric evaluated four components: conclusion, premises, evidence, and counter-arguments. The topics were screened by three English lecturers at the University for their cognitive and cultural appropriateness prior to distribution.

Pre- and post-writing tests were checked for elements such as writing content and coherence, and marks were awarded based on a four-factor rubric including a conclusion, premises, evidence, and counter-arguments. "Conclusion" received 1 mark if the respondent stated the conclusion of the argument properly and zero mark if not. "Premises" received a mark that reflected the number of premises the respondent could give based on the topic. "Counter-arguments" received a mark that reflected the number of counter-arguments the respondent could include. "Evidence" received a mark that reflected the number of premises that were supported by facts. Similarly, under writing coherence, "Logical connections 1" received a

mark that reflected the number of connections between a premise and the conclusion the respondent could make. "Logical connections 2" received a mark that reflected the number of connections between premises. "Signposts" received a mark that reflected the number of signposts that were properly and correctly used, and zero marks were awarded if no signposts were used. One point was rewarded if the signposts were weak, and two points if the signposts were strong. The writing rubric was screened by three English lecturers at the University for its Cognitive Appropriateness prior to use.

The self-regulation learning scale (SRLS) was distributed before and after the intervention to assess self-regulation as a fairly constant trait across various learning settings. The scale was originally devised by [16] and comprised 46 items grouped into six categories: planning (9 items), self-monitoring (8 items), effort (10 items), reflection (5 items), evaluation (8 items), and self-efficacy (10 items). The planning, self-monitoring, effort, and self-efficacy subscales were revised and converted into a five-point Likert scale ranging from (1) strongly agree to (5) strongly disagree, and the reflection subscale ranging from (1) never, (2) rarely, (3) sometimes, (4) very often to (5) always. The subscales' reliability scores were 0.85, 0.82, 0.84, and 0.80, respectively. A pilot study was conducted to examine the reliability of the survey involving 30 participants from the same population, but who were not part of the study sample. A reliability value of 0.85 was reported.

The semi-structured interviews were carried out at the end of the intervention to gain more information about how often and when the CAAM was used, as well as how this instructional intervention aided EFL learners' argumentative writing processes across the development of writing content and coherence.

### C. Intervention

Using CAAM, participants were trained to analyze and evaluate one or more issues from multiple perspectives and eventually construct their own arguments by writing essays once a week. The intervention consisted of weekly one-hour sessions over an 11-week period and utilized three stages: planning, monitoring, and evaluation; corresponding tasks undertaken at each stage. The first session was the introduction, in which argumentative writing was presented and key concepts of CAAM were demystified, described, and discussed. The three stages were completed within the 2nd to 11th sessions.

During the planning stage, the activities included advanced organization and schema building. The teacher introduced the writing topic to be discussed and asked the participants to brainstorm and share their thoughts with their peers.

During the monitoring stage, learners constructed argument maps and were asked to share them with their peers to refine their ideas prior to writing and solve issues concerning inconsistent premises, inaccurate counter-arguments, and the like. Meanwhile, the researcher provided feedback to those who encountered difficulties during their work.

The evaluation stage was composed of submission, discovery, and reflection parts in which participants composed their essays and sent their argument maps via CAAM software to the researcher. Indirect corrective feedback was also provided to monitor the respondents' writing processes. When essays were handed back to the respondents, they had the chance to self-reflect and self-evaluate their performance as well as negotiate their written work with peers. Thus, they shared some possible solutions for issues they may encounter in the future. Finally, revising and editing checklists were also provided to help participants revise and edit their writing products.

### D. Data Analysis

Quantitative data were statistically analyzed using descriptive and inferential statistics, including means, frequency, and percentage. Paired-sample t-tests were conducted to compare the means of two sets of tests to reveal the effects of the intervention and verify whether there was a significant difference between the pre- and post-test writing tests. The Pearson correlation coefficient was also calculated to examine the relationship between the use of CAAM and respondents' argumentative writing across the development of writing content and writing coherence, as well as their SRLSs. Qualitative data were analyzed, coded, and interpreted using thematic analysis to capture the respondents' opinions and understanding of the use of CAAM to process their argument writing. Accordingly, the following themes were identified: theme 1 pertains to the benefits of using CAAM, theme 2 includes quality practice, theme 3 includes learners' perceptions of CAAM integration, and theme 4 pertains to the enhanced SRL of the respondents.

## IV. RESULTS AND DISCUSSION

### A. Quantitative Analysis

1) *EFL learners' argumentative writing performance before and after the CAAM intervention*: Results from the t-test analysis revealed that participants' argumentative writing differed significantly with respect to the development of content and coherence before and after the CAAM intervention. As shown in Table I, statistical comparisons of the overall mean scores before the intervention ( $M = 8.93$ ,  $p < .000$ ) and after the intervention ( $M = 18.36$ ,  $p < .000$ ) indicate statistically significant differences as manifested by p-values that are less than the 0.05 level of significance. That is, the performance of EFL learners' argumentative writing with respect to the development of content and coherence improved substantially after the CAAM intervention.

Table II shows the statistical differences in EFL learners' argumentative writing across the four components constituting the development of writing content (premises, conclusion, evidence, and counter-arguments) on the pre- and post-writing tests. All four components were significantly higher on the post-test scores, as manifested by p-values of less than the 0.05 level of significance. The "counter-argument" part was the most improved element ( $M = 5.61$ ), while the "conclusion" part demonstrated the least improvement ( $M = 4.35$ ).

TABLE I. PAIRED-SAMPLE T-TEST OF EFL LEARNERS' ARGUMENTATIVE WRITING PERFORMANCE ACROSS DEVELOPMENT OF WRITING CONTENT AND COHERENCE BEFORE AND AFTER CAAM INTERVENTION

Components	Pretest		Post-test		t-value	Sig. (2-tailed)
	Mean	Std	Mean	Std		
Development of writing content	6.22	1.22	12.33	1.73	-20.54	0.000
Development of writing coherence	4.11	1.15	8.96	1.11	-17.52	0.000
Overall	10.35	1.79	21.30	2.07	-19.31	0.000

TABLE II. PAIRED-SAMPLE T-TEST OF EFL LEARNERS' ARGUMENTATIVE WRITING PERFORMANCE ACROSS DEVELOPMENT OF WRITING CONTENT IN THE PRE- AND POST-WRITING TEST

Development of writing content	Pretest		Post-test		t-value	Sig. (2-tailed)
	Mean	Std	Mean	Std		
Conclusion	1.44	0.35	4.35	0.60	-6.74	0.000
Premises	1.45	0.39	5.45	0.71	-13.62	0.000
Evidence	1.63	0.30	5.50	0.96	-11.38	0.000
Counter-arguments	1.69	0.31	5.61	0.74	-16.92	0.000
Overall	6.22	1.22	21.30	2.07	-22.66	0.000

Table III provides the statistical differences of EFL learners' argumentative writing in terms of coherence on the pre- and post-tests. This component consists of three elements: (a) Logical connections 1 (referring to logical relations between the premises and the conclusion), (b) Logical connections 2 (referring to logical relations between premises), and (c) Signposts. The three components of argumentative writing differ significantly before and after the strategy intervention, as indicated by p-values of 0.000, which are less than the 0.05 level of significance. The logical connections 1 component was the most improved element ( $M = 3.01$ ) compared to the pre-test score, whereas the "logical connection 2" component was the least improved ( $M = 2.87$ ).

TABLE III. PAIRED-SAMPLE T-TEST OF EFL LEARNERS' ARGUMENTATIVE WRITING PERFORMANCE ACROSS WRITING COHERENCE IN THE PRE- AND POST-WRITING TEST

Development of Writing Coherence	Pretest		Post-test		t-value	Sig. (2-tailed)
	Mean	Std	Mean	Std		
Logical connection 1	1.67	0.58	3.01	0.82	-10.23	0.000
Logical connection 2	1.23	0.41	2.87	0.69	-8.31	0.000
Signposts	0.99	0.67	2.0	0.39	-9.11	0.000
Overall	3.89	1.04	7.88	1.11	-17.53	0.000

### B. Correlations between EFL Learners' Argumentative Writing Performance and SRL after CAAM Intervention

To confirm whether there were any correlations between EFL learners' argumentative writing performance and SRLs, the Pearson correlation was computed. Table IV indicates that SRLS is significantly correlated with the EFL learners' overall argumentative writing performance ( $r = 0.53$ ,  $p < 0.01$ ). Specifically, strong positive correlations exist between the EFL learners' overall argumentative writing performance and the planning ( $r = 0.65$ ,  $p < 0.01$ ), self-monitoring ( $r = 0.52$ ,  $p < 0.01$ ), evaluation ( $r = 0.45$ ,  $p < 0.01$ ), effort ( $r = 0.71$ ,  $p < 0.01$ ), and self-efficacy ( $r = 0.55$ ,  $p < 0.01$ ) subcategories. There was a moderate positive correlation with the reflection ( $r = 0.35$ ,  $p < 0.01$ ) subcategory. Overall, using CAAM as an instructional tool to improve argumentative writing influenced EFL learners' SRLs.

TABLE IV. CORRELATIONS BETWEEN THE EFL LEARNERS' ARGUMENTATIVE WRITING PERFORMANCE AND SRLS AFTER CAAM INTERVENTION

	SRLSs	Pearson correlation
Argumentative writing performance	Planning	0.65**
	Self-efficacy	0.55**
	Self-monitoring	0.52**
	Effort	0.71**
	Evaluation	0.45**
	Reflection	0.35**
	Overall	0.53**
** $p < 0.01$		

## V. QUALITATIVE ANALYSIS

### A. EFL Learners' Perceptions of the CAAM Intervention

Twenty-eight respondents from the study sample participated in the semi-structured interviews. The findings revealed several themes related to EFL learners' perceptions of the benefits of using CAAM to compose their argumentative writing compositions. The sub-themes cover effective visualization of arguments, reducing cognitive overload, assuring quality in practice, and activating SDLs.

When EFL learners were interviewed about the role of CAAM in processing their argumentative writing tasks, they responded that CAAM aided them in forming better visualizations of their arguments. It enabled them to construct their arguments quickly and easily, including evidence, objections, and counter-arguments, using box and line diagrams [3] with the possibility of generating, modifying, or transferring these boxes to a new position as needed. The participants exploited this CAAM feature effectively to regulate their writing performance, as one respondent noted:

*I) CAAM helped me identify complex arguments quickly. I can divide them into smaller sections. I can distinguish the support and objections of my arguments as well as my conclusion.*

Argumentative writing is often open-textured and sometimes ambiguous [3], thus, distinguishing conclusions, support, and objections requires more time and effort due to the lexical complexity of the text itself. The use of CAAM

helped participants distinguish conclusions and premises, and thereby facilitated a better flow of knowledge in the brain that avoided mental overloading, as one described:

2) CAAM allowed me to map graphically my arguments, and enabled me to interpret them correctly without overloading my mind with a lot of information.

Using CAAM offered ample opportunities for quality practice and online feedback, ensuring that the tasks were enjoyable and effective. Some respondents reported feeling motivated in constructing these activities, as they were directed gradually in using CAAM to map their arguments, which inspired them to successfully write down their arguments into text composition.

3) CAAM helps improve my writing skill because it made me practice purposefully. It also guided me throughout the process by informing us what to do next and what to avoid. I enjoyed the gradual complexity of the tasks in CAAM (R18, 78-81).

CAAM integration not only improved participants' writing output but also enhanced their self-regulation learning skills as they were inclined to plan, self-monitor, reflect on, and evaluate their learning processes. As one participant stated:

4) With CAAM, I can have an overview of my work and monitor by double checking to see if my writing content and conclusions are correct and free of mistakes and contradictions.

The use of CAAM activated brainstorming techniques, which helped participants activate prior knowledge and create new ideas that they may associate with their writing tasks. It also promoted EFL learners' self-monitoring processes by motivating them to double-check their ideas and arguments two or three times, edit their work more closely, or compare it to other arguments as these participants contended:

1) The brainstorming activity triggered my background information and helped me link to the new topic to be developed.

2) I can double-check my arguments by simply moving the elements of an argument with multiple logical structures to another position. Also, group sharing drew my attention to points of misunderstanding or not fully understood. Collaboration gave me inspiration and guidance about my arguments (R6, 98-101).

Some respondents further reported that evaluating their writing performance based on whether the arguments were correct made them more determined to keep writing and to use the right argumentative markers in the future. It also helped them trace their performances.

1) Mapping my arguments helped me examine my performance, whether or not I got the correct arguments and evidences. I also self-evaluate my work after receiving feedback from my peers. If I didn't succeed, I challenge myself to do better in the future.

Collaboration via CAAM further allowed EFL learners to reflect on their contributions, whether they successfully or unsuccessfully grasped the argument, and whether they used effective or ineffective approaches. One participant expressed her opinion regarding this:

1) CAAM gave me the chance to assess the quality of my writing performance. I also consider the views my peers suggested on my text.

## VI. CONCLUSION

The study findings revealed that Saudi EFL learners' use of CAAM accelerated their argumentative writing performance with respect to the development of content and coherence. Given the useful features of CAAM, EFL learners' reasoning skills have been enhanced substantially, which is considered a potential factor for successful argumentative writing. CAAM provided them with more enjoyable and productive experiences throughout the entire writing process, down to the final product. It offered not only a stimulating environment for writing but also served as a reliable scaffold for the writing and editing process. Through CAAMs, maps can be constructed easily and edited freely; therefore, learners can engage in many practical exercises, which consequently enable them to engage in self-regulated learning because they are able to practice different argument structures to determine which works best for them. CAAM facilitates the production of coherent paragraph texts since these mappings serve as a support tool to aid EFL learners in their English writing.

Results have also demonstrated a significant correlation between EFL learners' overall writing performance and the implementation of CAAM, as confirmed by the marked improvement in their writing output after the intervention. As for writing content, EFL learners were able to provide various premises to back up their theses and distinguish their argument conclusions as well as present supporting evidence and counter-arguments. They also demonstrated writing coherence by logically connecting their premises with their conclusions, as well as using their linguistic signposts more effectively on the writing post-tests, resulting in more coherent and cohesive essays. The study findings coincide with [8], who reported the effectiveness of implementing CAAM on descriptive and expository writing in an EFL context and found that CAAM improved coherence, cohesion, grammar, and task achievement. This study focused on how EFL learners compose the argumentative content of their writing, emphasizing the conclusion statement and how it can be reinforced with evidence and counter-arguments. It also examined the use of coherence markers to determine whether EFL learners are able to make logical relations between their premises and conclusions as well as between premises.

By using CAAM, learners develop better critical attitudes toward arguments, evaluate arguments better, and become more open-minded in their thinking processes [7]. A learner who is able to think analytically and learn independently is more likely to be purposeful, strategic, and persistent in learning [19]. Results have further revealed that the learners became more aware of their self-regulated learning, as reflected in their inclinations toward planning, self-efficacy,

self-monitoring, effort, and self-evaluation. These results are consistent with [14], who argued that the use of CAAM involves well-planned and well-monitored processes that help raise learners' self-evaluation and self-reflection. Similarly, the authors [7] claimed that if CAAM is often used, learners' critical thinking will be enhanced and self-reflection can be optimized, which may foster learners' SRL because self-regulated learners have acknowledged their role in the task.

Pedagogically speaking, the study findings have implications for EFL materials development, which contributes to learners' improvement of argumentative writing skills and a better comprehension of their self-regulated learning procedures in general and EFL writing in particular. Identifying learners' personality traits and offering them facilities to promote their performance can lead to remarkable accomplishments in EFL instruction. Likewise, the findings provide thoughtful insights into utilizing CAAM within writing courses to revolutionize EFL learning classrooms in this digital era, especially since educators are dealing with tech-savvy learners who often enjoy utilizing technological-based platforms for more effective and meaningful learning. Further research needs to be conducted on the utilization of CAAM in different disciplines to further strengthen the many benefits of CAAM.

**Abstract**—The Zika virus (ZIKV) outbreak and spread is a global health emergency declared by World Health Organization. ZIKV rapidly spread across the world, causing neurological disorders. It is gaining public and scientific consideration. ZIKV genome biology and molecular structure are better understood with published papers. Genetic regulation is better understood by finding the motif in the DNA Genome sequence. The transcription factor binding sites need to be identified to understand the genetic code. There is diversity in gene expression. Motif-finding methods work towards efficiently identifying the repeated patterns in the genome. ZIKV genome sequence is used in the study. Identifying the motif is still a difficult task. There is a low probability of identifying the binding sites. Finding all possible solutions is challenging as it requires a lot of time and has high space complexity for finding long motifs. The Greedy search technique with pseudocount finds the motif in real-time. The count matrix is computed, and the profile matrix is constructed from the genome of the Zika virus. The calculated consensus string helps in calculating the score of the motif. The Greedy motif search technique is applied in this paper to find the motifs in the Zika virus Genome. This technique is not applied earlier to find the motifs in Zika Virus. The motifs are identified using a Greedy motif search without pseudocount and with pseudocount.

**Keywords**—Consensus string; genome study; greedy search technique; motif search; pseudocount; regulatory proteins; ZIKV; Zika virus

## I. INTRODUCTION

The Zika virus (ZIKV) was first separated from a rhesus macaque in Uganda in 1947. The study of ZIKV was not given importance till 2015. In 2015, Brazil's big epidemic of ZIKV infections was linked to intensification in microcephaly cases. ZIKV can spread sexually and is known to persevere in the male and female reproductive systems. West Nile virus (WNV), Dengue virus (DENV), Yellow fever virus (YFV), and Japanese encephalitis virus (JEV) are included in the family Flaviviridae, genus Flavivirus. These are mosquito-borne pathogens. Zika virus also belongs to the same family of viruses. The ZIKV lifespan has Aedes mosquitoes and monkeys, whereas a broader range of mosquito species transmits WNV.

World Health Organization (WHO) has acknowledged the Zika virus (ZIKV) as a public health crisis worldwide. ZIKV is a flavivirus. It has its place in the family of Flaviviridae. It is spread over several parts of Africa, Southeast Asia, and the Pacific island. In August 2016, the ZIKV outburst in Brazil was the major ever recorded, with a projected 165000 doubted

cases. ZIKV is transmitted through monkeys and the Aedes genus [1]. ZIKV infection causes slight illness, headache, and rash. A recent study suggested that the virus causes neurological disorders such as Guillain-Barre syndrome. ZIKV is transmitted from mother to child and is also transmitted sexually. It has identical symptoms as compared to different arboviral diseases like DENV. Analysis based on symptoms is unpredictable for precise detection. Test center analysis is vital to obtain conclusive results. A suitable choice of molecular analysis is meaningful for routine ZIKV or flavivirus detection. No specific treatment for the infection is available. The course of injection and medicine development is extremely complicated. Anti-ZIKV vaccine development may take several years. Traditional drug development policies make the circumstances worse. Silico methods are helpful in enlightening possible vaccine candidates.

This fast rise of ZIKV cases and its consequence is severe. The disease has provoked the research community to produce interventions to battle Zika disease. The disease mechanism is presently unstated. Reviewing and analyzing ZIKV genome ecology and pathogenesis can provide awareness of ZIKV. microRNAs are also found to play a significant part in virus-related diseases and activation of the phenomenal immune response. Methodical genome-wide study of the ZIKV genome may assist in designing antiviral therapeutics. Zika virus has a 10.7 kb genome of single-stranded RNA. Multiscale examination of the genomic data produced throughout the widespread of infection and available in public databases was combined. The focus of the study was to inspect virus-related appearance at different scales [2] [3].

The research problem was understanding the regulatory mechanism of genes. This involves finding transcription factor binding sites. Identifying regulatory networks is also challenging. The objective of the research was to find the regulatory relations of genes. It is better considered with the identification of motifs. Motifs are known to have complex forms. An essential class of motifs is spaced motifs. It consists of short segments separated by nucleotides of different lengths. Locating motifs is a difficult task. Existing algorithms identify short contiguous motifs. Better algorithms identify spaced motifs with a different number of spaces in between [4]. So, this research is significant as it will help in identifying the spaced motifs with a mutation at one or more places in the genome.

In this Research paper, a literature review is conducted on various studies conducted on the Zika virus. The study is

\*Corresponding Author.

conducted on phylogenetic analysis, ZIKV circulation in different countries, RNA-protein interaction, Viral RNA targets, Host cell-binding mechanism of ZIKV, Motif finding and Genetic behaviors of ZIKV, ZIKV infection, and the role of E-protein amino acids and many other aspects of Zika virus. The count matrix and profile matrix is calculated on the dataset of the Zika virus genome with pseudocount. The Greedy motif search method is applied to the dataset, and results are tabulated with and without pseudocount.

## II. LITERATURE REVIEW

Zika virus has turned out to be a worldwide health problem as it is linked to potential congenital disabilities. The virus was revealed 70 years ago; still, the genomic construction and genetic variation are not fully known. The genome structure is compared with different other flaviviruses. Structural and functional similarity is found between the various flaviviruses' genome structures. The similarity is found in the conserved terminal structures. So, it is concluded that the Zika virus shares a high constitutional and functional similarity with other viruses of the Flavi family. It is known from the genomic comparison. Also, the prediction of motifs in viral proteins in the Zika virus with other viruses shows similarities. All Zika virus strains in America have similarities with the strains in Asia. Some conserved amino acids differentiate earlier African strains from Asian and American strains. Studies provide clues for different viruses' studies.

The Zika virus spread over more than fifty nations of the world. The evolution and spread are understood by studying the replication in the genome. Zika infection happens when an infected mosquito bites a person. It is also transmitted from one person to another person due to various reasons. ZIKV molecule needs to be studied to understand the infection in detail. It can also help in finding a solution to the problem. The neural progenitor cell growth is affected by ZIKV infection in monkeys [5] [6]. The same things happen in the case of humans. The virus damages the DNA of humans and monkeys. It also initiates DNA damage responses. The DNA damage response is then attenuated. The cycle of the growth of the virus is considered to determine the behavior of the virus during

different times of the day. The virus may behave differently during the day and during the night. A different mutation of the Zika virus is reported in America. These mutations are different from the mutations found in Asia and Africa. The Aedes Aegypti mosquito was studied with mutation, and the results were compared with the studies performed without mutation. Fitness is increased for new mutations. It increases the risk of the spread of the virus. Fitness is reduced for original mutations. Zika virus infects the immunocompetent adult. It precipitates and increases brain damage due to antiviral responses. The immune system of mice is studied. The modifications stimulated by the Zika virus were found. A significant decline in micro-organisms like Actinobacteria and Firmicutes phyla was found due to the Zika virus infection. A boost of Spirochaetes and Deferribacteres was prominent in infected mice compared to healthy mice. The modulation caused the enhancement of white blood cells. The Zika virus induced the modulation of microbiota. Birth defects are caused due to utero exposure to the Zika virus. The ill effects of this virus were not prominent in the early stages of birth. The researchers concluded that if they studied the toddlers till twenty-four months, then the effects would be clear. It was concluded that the women who became pregnant during the year 2016 were to be studied. It was the time of the outbreak of the Zika virus in America. The study was conducted on the neurodevelopment stages of toddlers from birth to twenty-four months. The behavior of the child was normal before and after birth. The activities of the body seemed to be reduced as the child started growing. The child started showing the symptoms of birth defects. The connection of birth defects to Zika virus infection was later identified. As such, no vaccine was available for the disease, and treatment of the condition was not possible. People were not aware of such an infection. A vaccine named VacDZ was produced using the dengue vaccine as a reference [7]. The immune responses are seen to the Zika virus. The vaccine seems to be showing positive results in mice infected with the Zika virus. Blood samples were collected from Brazil to study the impact and spread of the virus. The people of Brazil were impacted by three viruses: Zika, chikungunya, and dengue. The situation was challenging to handle and trace the spread of the virus [8]. The review of the literature is presented in Table I.

TABLE I. LITERATURE REVIEW

Sr. No.	Year	Ref.	Topic	Concept/ Theoretical Model	Paradigm/ Method	Context/ Setting/ Sample	Findings	Research Gap
1	2016	[2]	ZIKV circulation in America and phylogenetic analysis	ZIKV is a global public health problem. The genetic alterations and genomic structure are constantly under study.	The comparison of the genome organization of mosquito-borne diseases and the ZIKV genome was made to understand to features of the Zika virus genome. The conserved terminal structure is studied.	The similarity of structural and functional components was found between the Zika virus genome and other viruses. It was clear with sequence comparison and prediction of functional motifs.	American strains of the Zika virus form a unique clade with the Asian lineage. A sequence of preserved amino acids was identified that discriminated the Asian strains from the African strains. Studies provide an overview of the characters of the ZIKV genome.	Critical study to be conducted in the virological and epidemiological domain.
2	2018	[3]	RNA-protein interaction	RNA-protein interactions control	RaPID has usage in different applications.	A new mutant BirA has been introduced to progress the	A direct study of Protein-RNA interaction is enabled	The RNA protein connections can be further studied

			detection in living cells	cellular functionalities and diseases. Proximity-dependent protein labeling is used by RNA-protein interaction detection (RaPID).	It helps in assessing protein binding to mutant RNA motifs in human hereditary illnesses in finding potential post-transcriptional networks in breast cancer.	BirA-labelling component of RaPID.	in living cells. The timescale of interaction is as short as 1 min.	to understand more about cellular functionalities.
3	2018	[5]	small-molecule ligands in Viral RNA targets	Conserved structured motifs are contained in RNA genomes. These are attractive targets for small molecules of viral infection.	Conformational states are affected by ligand binding. These play an important role in the infection process.	HIV and Hepatitis C virus are studied. Inhibition process, RNA functions ligands are focused. The RNA targets in other viral pathogens are also studied.	The structural viral RNA motif is targeted by small molecules called ligands.	Ligand's discovery guides therapeutic opportunities. It guides the participation in key processes of infection as well as high conservation of pathogens.
4	2019	[6]	Host cell-binding mechanism of ZIKV	Two reputed binding mechanisms of inherited and emerging Zika viruses were identified. It features the envelope protein residue ASN154.	ASN 154 was visible to neuronal cells and fibroblasts to classical Zika virus protein and cell communications.	Peptides meaningfully expressed Vero cell contamination by ZIKV strains. A putative binding mechanism of ancestral African ZIKV strains and emergent Western Hemisphere strains is represented.	Western hemisphere strains may additionally be capable of utilizing PS-mediated entry to infect host cells. The region surrounding E protein ASN154 is capable of binding fibroblasts and primary neuronal cells	PS-mediated entry may be a secondary mechanism for infectivity utilized by Western Hemisphere strains.
5	2021	[4]	Motif finding and Genetic behaviors of ZIKV	The genome of ZIKV is used for the study. Circadian behavior and the appearance of genetic factors are considered.	Motif finding is done using a count matrix and profile matrix. The score of the consent string is calculated.	The Brute force method is certain to find the motif, but it will take a huge amount of time. So other techniques are to be used.	The motif finding is done using Greedy search techniques, and results are analyzed.	The score can be enhanced using other techniques, such as Gibbs Sampler.
6	2021	[9]	ZIKV infection and the role of E-protein amino acids	Learning of E-proteins in ZIKV infection, as it is the furthest proteins in the constitution of ZIKV	ZIKV uses covering proteins to bind to cell addition receptors.	Many sites are situated in an unusual position of the protein construction, such as the $\alpha$ -helix in the stem area.	Cover protein amino acids that contribute to the flavi virus initial contamination process are presented.	A detailed study of E-protein assistance can accomplish an efficient antigen strategy.
7	2021	[10]	Dengue virus whole genome of structural landscape	Protein binding domains and secondary structure is to be used for categorization	A prediction score of 85% is to be achieved with a secondary structure. The consensus secondary structure of profiles is computed. For computation, silico models are used.	Viruses of Dengue and Ebola are less structured. Viruses show structural patterns.	A correlation between the number of interaction sites with human proteins and the secondary structure of 89% is achieved in ZIKV.	Further classification of complex viruses to be done using the given approaches
8	2021	[11]	Dependent immune response genes of DENV provoke the countenance of PAF1	To establish infection, DENV disturbance of innate excepted responses is critical. DENV non-structural protein five plays a dominant part in such distress.	PAF1, LEO1, CTR9, and CDC73 are primary members of PAF1C. It helps in the immune reaction. It encourages the appearance of	Knockout of PAF1 enhances the DENV infection. NS5 atomic localization and the C-terminal area of the methyl transferase field are compulsory for its	PAF1C plays a significant role in restricting DENV reproduction.	A study can be performed on PAF1C role in dengue virus replication.

					antiviral, antimicrobial, and inflammatory responses.	communication with PAFIC.		
9	2021	[12]	Viral and molecular factors on ZIKV entry	Flavivirus are arthropod-borne pathogens for a wide range of mortality.	Around seventy viruses are contained in the genus. Different viruses present different clinical presentations even though the genomic and structural similarity is seen.	New methods to control virus infection are searched in order to control the disease.	Different steps present in the arboviruses entry process are attachment, internalization, endosomal escape, and capsid uncoating. Cellular machinery, host factor, and cellular pathways are taken over by events.	These are required as possible approaches for developing broad-spectrum antiviral drugs.
10	2021	[13]	The search for pseudoknots and three-layered associations in the genome of ZIKV RNA	The Flavivirus RNA genome covers a number of functionally significant constructions in 30 untranslated regions.	The genome sequence has diversity, and its identification is difficult. Flavivirus replication is well understood with the prediction of structure and helps in the development of antiviral strategies.	An algorithm is developed for structure design examination in the RNA sequence. Secondary constructions, pseudoknots, and triple base interactions are also identified. The structural descriptor is constructed by means of the data on preserved flavivirus 3'UTR constructions. It enclosed a variety of designs in these motifs.	The construction of a database of flavivirus 3'UTR structures is done. A total of areas identical to the overall design of exoribonuclease Xrn1-resistant RNAs in the rising collection of bug-specific flaviviruses is recognized.	Diagnostics, genotyping, mutational study, and drug design can be done with the record of flavivirus RNA.
11	2022	[14]	The common protein - Binding Motif of ZIKV and Dengue is PEX 19	ZIKV capsid (C) protein regulates peroxisomes. It causes reduced production of interferons as it interacts with protein PEX19	The usage and interaction of C interaction with PEX19 in the Zika virus are studied. The importance and usage of peroxisomes are also studied.	Peroxisomes are required for the replication of DENV. A conserved PEX19 binding motif is used for DENV and Zika virus C binding. This motif commonly occurs in cellular peroxisomal membrane proteins (PMPs).	This paper find identifies and questions how flavivirus C might downregulate peroxisomal abundance	Study to be conducted on the unknown role of peroxisomes in ZIKV.
12	2022	[15]	RNA requisite proteins used for interior Initiation of mRNA conversion	Viruses utilize the host's protein synthesis mechanism for interpreting their mRNAs. Viruses are obligate intracellular parasites.	The virus-related mRNA (vRNA) contends with the host mRNA together with ribosomes, tRNAs, and the eukaryotic translation initiation factor (eIFs) pool.	Viruses targets host eIFs, and RNA essentials reprogram cellular gene expression, guaranteeing the favored transformation of mRNAs.	vRNA IRES facilitated conversion beginning is highlighted. The role of RNA-required proteins (RBPs), other than the established conversion initiation factors, in modifying their movement is also discussed.	Accepting how the PTMs of ITAFs impact viral IRES activity also arises as a striking study domain.
13	2022	[7]	Computational method to cure ZIKV infection by the screening of phytochemicals against NS5	ZIKV study provides stimulation for new and capable anti-ZIKV agents. RNA-dependent RNA polymerase (RdRp) is found to be significant among all. It is considered a valuable drug target.	The cellular dock approach is used to reasonably screen the files of 5000 phytochemicals to find inhibitors against NS5 RdRp.	Polydatin, Dihydrogenistin, Liquiritin, Rhapontin, and Cichoriin were investigated with NS5 RdRp. The replicated complexes showed steadiness.	Natural and low price medicines are to be produced against the Zika virus	The efficiency of can be obtained by further study and research

14	2022	[8]	Tick-Borne Encephalitis Viral disease and the contribution of IFITM Proteins	A study is conducted on the Tick-borne encephalitis virus. The factors that inhibit the multiplication are Interferon-induced transmembrane proteins,	The part of IFITM proteins in the reticence of TBEV infection is studied. IFITM3 plays the important role of including analysis of useful motifs.	The role and additive action of endogenous IFITMs in TBEV dominance is confirmed.	TBEV might, to some extent, run off interferon and IFITM interceded containment throughout high-density co-culture infection.	Cell-to-cell reach may form an approach for viruses to break out from native host defenses.
----	------	-----	--	---	---	---	---	---

From the detailed literature review, it is identified that different categories of algorithms are applied to find the motif in DNA sequence. The limitations found in the previous search are that the Greedy motif search without pseudocount and with pseudocount is not applied to find motifs in the Zika virus [16]. Heuristics algorithms worked for solving combinatorial, but bit did not work for large datasets [17]. The greedy motif search algorithm is proposed to find the motif in RNA sequences [18]. A greedy mixture learning technique is proposed for finding motifs in already known motifs in real proteins by using the PRINTS datasets [19]. Time series-based data of different lengths are aligned and joined using the Greedy search technique [20]. The Greedy search algorithm is used to discover motifs in hm03r, yst04r, and yst08r. The results show that the algorithm is effective in finding motifs in the DNA sequences of hm03r, yst04r, and yst08r [21]. DNA motif discovery is made using the Greedy motif search method over the datasets - GATA1, SOX2, OCT4, STAT3, and KLF1 [22]. So, a research gap is identified that the Greedy search technique for motif finding is not applied to the genome of the Zika virus.

### III. MATERIALS AND METHODS

#### A. Data Collection: Zika virus genome

ZIKV genome structure data from openly existing catalogs are collected and used in this study. The Zika virus genome sequence is available at NCBI [23]. ZikaVirus.fasta is the file name of the dataset. Fasta is a file format; the genome sequence is stored as a nucleotide sequence. The size of the dataset is 10.7 KB.

#### B. Gene Representations

RNA is formed using DNA. RNA further gets converted into proteins. Four ribonucleotides from the RNA. These four nucleotides are namely Adenine, Cytosine, Guanine, and Uracil. DNA replaces Thymine with Uracil. Amino acid sequences of proteins are formed by RNA transcripts [9]. Proteins regulate the function of the cell. Ori is the replication for the origin of DNA, so DNA replication starts at ori. Ori has some specific properties. Biologists find it difficult to identify the position of replication. Some other complicated tasks happening inside the cell are transcription and transpiration. The transcription process replaces what happens inside the cells. Thymine (T) that occurs in DNA is getting converted into Uracil (U) during the transcription process. The amino acids sequence is formed from RNA. There are a total of twenty different amino acids in RNA [13]. Three different nucleotides form these amino acids, also called 3-mers or codons. Each combination of these 3-mers forms different amino acids following a genetic code. Due to transcription, different genes can form RNA. Different genes may transcribe at different rates. This property is also called gene expression. Due to gene expression, different cell at different parts of the body of any

living being behaves differently. Brain cells behave differently compared to skin cells. They differ in features and functionality. Cells with different variations know how to keep track of time. The variation in cell functionalities is known to occur in people infected with ZIKV. Pro-inflammatory reactions are prominent in women infected with the Zika virus.

### IV. COMPUTATION OF MOTIF IN ZIKA VIRUS GENOME

Zika virus genome nucleotide sequence has a length of 10780. The length is calculated using the program. Based on the profile matrix of the Zika virus, the probability of a string can be calculated. The regulatory motif binds to specific short DNA. It regulates the gene. The site of binding is generally the upstream region and is important to identify. A method to identify the motif is useful for gene study.

#### A. Importance of Motif

Motifs are important to identify and study. Motifs have finite lengths. These are short sequences in DNA. Sequence motifs are used to signify transcription factor binding sites. Transcription regulations are better assumed with motif sequences. Dynamic sites of enzymes and proteins are characterized by motifs. The individual instances of the motif is calculated and scored using the ideal motif. An ideal motif is not known and can only be predicted. To recognize motif, a k-mer string is selected from each string. Based on identical nucleotides, each motif is scored. A list of t strings is created. The length of the string in each list is n. a motif collection is created by selecting k-mer nucleotides from each string. A t X k motif matrix is formed. From the t X k matrix created, the nucleotides are counted and stored in an array. There are four different types of nucleotides, so four rows are created. The first row represents nucleotide A, the second row represents C, the third row represents G, and the fourth row represents T. Now in the matrix, the columns are viewed to find the nucleotide with the highest count. So for that column, the nucleotide with the highest count is represented in the uppercase letter. Different motif matrices for DNA strings if formed using different values of k. The aim is to obtain the most conserved motif matrix. The conserved matrix also means the matrix has more capital letters. The minimum score is to be obtained for the collection of k-mers.

#### B. Calculating the Count Matrix

A count matrix is formed for the Motifs. It is 4 X k matrix. It is abbreviated as count (Motifs). It is the sum of each nucleotide column-wise. The element (I, j) represents I nucleotide in jth column. The count matrix obtained is further used for the calculation in the next steps [4].

### C. Finding the Count Matrix with Pseudocount

Pseudocount is a small number that is added to zeroes. This improves the unfair scoring. This method is named Laplace's Rule of Succession. In motifs, pseudocount method, one or a small number is added to the count matrix. The different matrices are formed for calculations. These are the motif, count, and profile matrices. A count matrix of 4 X k is formed for a given matrix. This count matrix's (I, j) element represents nucleotide I of column j. Pseudocounts one is added to each element of this count matrix.

{'A': [46, 38, 40, 42, 43, 37, 34, 47, 46, 51, 42, 42, 43, 47, 39, 46, 47, 37, 40, 50, 39, 43, 41, 46, 37, 40, 43, 42, 41, 31, 37, 41, 37, 45, 41, 47, 37, 46, 41, 49, 38, 47, 42, 42, 48, 41, 45, 52, 39, 48, 42, 47, 30, 50, 42, 52, 40, 41, 40, 47, 34, 51, 53, 37, 51, 41, 46, 59, 48, 51],

### D. Framing the Profile Matrices with Pseudocount

Finding a perfect motif is a challenging task. It binds the finest to the transcription site. A motif discovery problem is solved by finding the similarity to the ideal motif. A motif similar to an ideal motif is calculated, as an ideal motif is not known. Capital letters are used to denote the most common nucleotide in each column. Motif[i][j] represent the ith row and jth column. If the matrix has more capital letters, it means the matrix is more conserved. The genome of the Zika virus is used to create different motif matrices for different values on k. The count of the small letter is noted. The sum of this count gives the score of the matrix. Then a k-mer is assumed, which will reduce the value of the score. The profile of the motif matrix is calculated. The elements of the count are divided by the number of rows. The sum of any column of the profile matrix is unity. The profile matrix for the Zika virus genome is given below.

{'A': [0.29, 0.24, 0.25, 0.27, 0.27, 0.23, 0.22, 0.3, 0.29, 0.32, 0.27, 0.27, 0.27, 0.3, 0.25, 0.29, 0.3, 0.23, 0.25, 0.32, 0.25, 0.27, 0.26, 0.29, 0.23, 0.25, 0.27, 0.27, 0.26, 0.2, 0.23, 0.26, 0.23,

### E. Calculating a Consensus String for the Genome of the Zika Virus and Score

The consensus string of the Zika virus is calculated from the genome and is given below.

AGGGGGGAGAGGGAGGAGGACGAAGGAGGTGGC  
AGATAGAGAGGAGAAGGGGGAGAGGGAGAAGAGGA  
AA. The score of the consensus string is calculated to be 7444.

## V. DISCUSSION OF RESULTS

### A. Using Profile Matrix for Calculation

Iterative algorithms use select different alternatives during each iteration. The greedy search technique selects the most attractive alternative in each iteration. The profile matrix of the Zika virus is calculated in the preceding section and is used the same. The likelihood of any string can be intended. The probability of the consensus string is also calculated.

### B. The Search of Binding Sites

The Greedy motif algorithm is implemented with pseudocount. The results of the Greedy motif search with pseudocount are summarized in Table II. The table contains values from 3-mer strings to 15-mer strings. The string with one nucleotide and two nucleotides have little significance and are hence ignored.

6	8-mer	508	443	GCTGG', 'AATGATAG', 'GACCCTAA', 'GCAGCTGG', 'GTGGATGG', 'CCGCCTG G', 'GAGGCTGG', 'TTGGCTGG', 'GACCCTGG', 'GGCCCTGG', 'CATGCTGT', 'AAAGCTGA', 'GGGGCTGG', 'GGCCCTGG', 'GTTGCTGT', 'CATGGTGG', 'AAC CCTGG', 'AGGACTGG', 'GTCTCTGG', 'GAGGATGT', 'GATCATTG', 'GAAGCTA T', 'GTGACTGG', 'AAAAGTGG', 'GAGCATGG', 'GAGTCTGT', 'GAAGCTGT', 'GAGAGTGC', 'GAATTGG', 'GTGGCTAG', 'AGGCTGG', 'CTGGCTGG', 'GAG AATGA', 'CAAAGTGG', 'CAACCTAG', 'GAGGCTGA', 'CCAAGTGG', 'GATGATA G', 'CTGGATGG', 'CATTGTGG', 'GAGACTGC', 'ACTGATGG', 'CTACCTGG', 'GAGTGTGG', 'AAGACTTG', 'CAACATGG', 'GTACATGG', 'ACACCTGG', 'GAA GCTGG', 'CATGCTGC', 'GAAGGTGG', 'GAAGAGGG', 'CACGCTGG'] 443

13	15-mer	1190	1138	GGATCCGCA', 'CTTTGACGAGAACCA', 'CTGGGATGTGGTGC', 'GGTCAGCAAAGAG TT', 'TAGGGTGCCAGACCC', 'GTTTCATCAACAAGGT', 'AGGAAAAGAGTGGGA', 'C AAGGAAAGAGAGCA', 'ATGGGAAAAGAGAA', 'CTTGAACGAGGATCA', 'GTTGAAGG GCTGGGA', 'CAGGAGGAAGGATGT', 'AATGGAGAAAAGGGCA', 'AGGAAAAGCAGTTAT , 'TTCGAGACAAGACCA', 'TATGGAGGCTGAGGA', 'ATGGCAGTCAGTGGGA', 'TGT GAAGCCAATTGA', 'CTGGGAAGAAGTTC', 'CTTCAACAAGCTCCA', 'GGCGGGGATG GAGCA', 'GTGGCAGCTCCTTTA', 'CATGGAAAAGGGAGAA', 'GTGGATTGAGGAGAA', 'TGGGAAAAGGGAA', 'ATTAATAACACAGTC', 'TTGGGTGAAGAAGGG', 'TAGTCA GCCACAGCT', 'CTGGGAAACCAAGCC', 'AGTCAAAAACCCCA', 'ATGGGAAAAGAAG GT', 'GTGGTTAGAGGAGAC', 'TGGGAAAGACCAGAG'] 1138

The results of various k-mers are tabulated. The score of the Greedy motif search without pseudocount is compared with the score of the Greedy motif with pseudocount. The score of the Greedy motif search without pseudocount and with pseudocount is calculated for string of length three to string of length fifteen. It is found that the score is less for calculations with pseudocount so these results are more promising compared to motifs obtained without pseudocount. For 15-mer string, the score is 1190 for the Greedy motif search and 1138 for the Greedy motif search with pseudocount. If the score is low means, the performance of the algorithm is good. For the fifteen nucleotides long string, a score of 1190 is obtained for the Greedy motif search without pseudocount. A score of 1138 is obtained for the Greedy motif search with pseudocount. So, the results have considerably improved by using the Greedy motif search with pseudocount.

## VI. CONCLUSION AND FUTURE WORK

The genome of ZIKV is considered for the study. In the case of an infected mother, ZIKV causes neurological disorders in babies. The causes and effects of ZIKV were not identified earlier as the symptoms of the disease are mild headache and fever. Later it was linked to reduced brain activities in babies. The diseases pass from the infected mother to the child. Medicines or vaccines for this infection are not available. This research paper studies the Zika virus genome to get more insight into the molecular structure. For a given profile matrix, the probability of every k-mer string is calculated and tabulated. The score is calculated with the Greedy motif search without

pseudocount and with pseudocount. The results are computed and tabulated. The comparison shows the results are improved with the Greedy motif search with pseudocount. The aim is to reduce the score, and it is obtained with a Greedy motif search with pseudocount. The Greedy motif search for motif finding is applied to PRINTS datasets, hm03r, yst04r, and yst08r, in earlier research. It is also applied to datasets GATA1, SOX2, OCT4, STAT3, and KLF1. It is not applied to the Zika virus to identify the motifs in the Zika virus genome. It is concluded that the Greedy motif search with pseudocount performs better than the Greedy motif search without pseudocount as it gives a score of 1138 over a score of 1190.

Department of Informatic Engineering, Universitas Khairun, Ternate, Indonesia<sup>3</sup>

**Abstract**—Research carries a classification model that combines LQ analysis and hierarchical classification using a single linkage. The classification results are a basis for mapping the potential of agriculture areas based on superior food commodities in Merauke Regency, Indonesia. LQ analysis is used to select food commodities. In contrast, the application of single linkage uses the production of three features, rice, corn, and peanuts, which have an LQ value >1, to group sub-districts based on agricultural potential. Intelligent mapping is represented by mapping the sub-districts agricultural areas according to the cluster. The classification results show that the first cluster has sixteen sub-district members, the second consists of three sub-districts, and the third cluster consists of one sub-district. Each cluster member has similarities based on the distance measurement with the smallest value using the Euclidean distance. The proposed classification model is a creative idea to map agricultural areas, which can present information on regional potential based on superior food crop commodities.

**Keywords**—Classification; agriculture; location quotient; single linkage; geographic information system

## I. INTRODUCTION

The agricultural sector is an essential source of income in the national economy in Indonesia, as evidenced by its contribution to gross domestic product. The agricultural sector's potential is the basis for developing rural economic activities through business development, namely agribusiness and agro-industry. Merauke is one of the regencies in eastern Indonesia, where most of the population depends on the agricultural sector, especially for rice commodities, and has become a food barn in Papua Province, with rice production in 2022 reaching 354192.32 tons [1]. Agriculture is a sector being the center of attention in efforts to develop and grow the economy that concerns many people's lives, not only the current generation but also the generations to come. Agricultural potential in Merauke Regency for food crops consists of various commodities, namely, rice, corn, green beans, soybeans, peanuts, cassava, and sweet potatoes [2].

The information on agriculture areas in Merauke Regency is presented by survey reports from the Central Statistics Agency or by seeking information directly to visit the place. Making it difficult for those who want to seek information on the agriculture sector's potential, do not support user mobility, and are not efficient in doing so. The agriculture sector's potential has to increase by determining the best commodity of food crops in an area to be used as information for local governments to make programs and policies [3]. The aim of

developing the best commodity is to meet the needs of local consumption in the region and to develop prospects so the production can be exported outside the region. The results of mapping agriculture areas based on superior food crop commodities can be used as a source of information for policymakers, both the government and farmers, to support the sustainability of the livelihoods of people who depend on the agrarian sector to improve their welfare. They can also be used as information for the private sector as potential investors for assisting in finding the potential of agricultural areas based on superior food crop commodities. Building agricultural businesses following strategies maximizes the available and optimally managed agriculture potential. The use of technology with the concept of intelligent agriculture [4] is a significant change in the development of the agriculture sector [5][6]. The applications for agricultural information classification analysis and agriculture production management have been developed [7], such as the classification model used to determine superior food crop clusters [8], The use of machine learning models for crop cultivation prediction [9], allows farmers to assess the cultivated types, monitor plant growth, and choose the correct harvest time [10]. System development using a classification model that combines qualitative and quantitative methods improves the relevance [11], completeness, and accuracy in finding information and increases the utilization of agricultural data information [12].

The proposed classification model for mapping agriculture areas combines two methods, Location Quotient (LQ) and Single Linkage, which aims to determine hierarchically based on regional potential. Using the LQ method to determine the regionally superior food crop commodities in Merauke Regency[13], the classification model produces the best commodity types based on the LQ value > 1. The results are then used as a feature for cluster analysis of agricultural areas using the single linkage method, so the classification accuracy is high. The proposed classification model is generated well with relevant features [14]; the classification model is trained by reducing the number of features that are the results of the LQ method analysis so that the proposed hybrid algorithm can work optimally [15]. Classification of superior food crop commodities provides essential information for mapping agricultural areas. Implementation of Hierarchical classification is widely used for data mining, and the performance of the single linkage method is suitable for handling various types of data [16]. The application of the proposed classification model produces a mapping of agriculture areas in geographic information systems [17]. The

purpose of this research is to map agricultural areas based on potential clusters of superior commodity production areas using a creative classification model that combines LQ analysis with single linkage classification methods. The results of regional mapping are dynamic, so they can be continuously updated according to the production data of food crops.

## II. METHOD

The classification model is a combination of LQ and single linkage methods. It aims to group agriculture areas based on superior food crop commodities to present cluster information on the hierarchy and map agriculture areas according to their clusters [18]. Determination of agriculture area clusters using data on the production of food crop commodities in a city and province. The stages of research methods are shown in Fig. 1, explained as follows:

### 1) Data collection

a) Data on food crop production in Merauke Regency, obtained from reports on agricultural production from the Central Statistics Agency, collected agricultural production data from 2013 to 2022.

b) Collected data on food crop production in Papua Province was based on reports of agriculture production in Papua province sourced from the Central Bureau of Statistics of Papua Province. This data is used as comparison data for the analysis of determining superior food crop commodities in the Merauke Regency.

2) Location Quotient Analysis is a step to analyze by comparing agricultural production data in Merauke Regency with production data in Papua province to determine superior food crop commodities using the LQ method analysis in Merauke Regency.

3) Hierarchical Clustering: the process of determining the clusters of agricultural areas in a hierarchical manner, which forms certain levels such as tree structures because the clustering process is carried out in stages and tiers to determine the potential of agricultural areas by sub-district category.

a) Normalization: the stage for scaling features or data used to determine clusters so that the distance between data is not too conspicuous and can produce valid clustering results.

b) Implementation of Single Linkage and Euclidean Distance: the process of grouping agricultural areas by looking for similarities between two objects /sub-districts with a minimum distance, measuring using Euclidean distance.

c) A *dendrogram* is a stage that shows a visual representation of the steps in cluster analysis that shows how clusters are formed and the value of the distance coefficient at each step.

### 4) Mapping of agricultural area

a) The district's mapping agriculture areas determine agricultural areas on a map and coordinates points.

b) Determination of the layer structure on the map is a step for following the function of presenting the information [19] for the potential of the agriculture area. In the form of

colored polygons according to the cluster category that has been formed.

The flowchart of the classification model used for mapping agricultural areas based on superior commodities combining LQ and single linkage is shown in Fig. 2.

### A. Location Quotient Analysis

Location Quotient (LQ) analysis is a method used to determine regional potential by comparing the role of a sector in a local area to a higher level [20]. The selection of superior food crop commodities can be called a basis if the LQ value is  $> 1$  by analyzing food crop production data in Merauke Regency and Papua Province. LQ value determines superior food crop commodities using the equation [21].

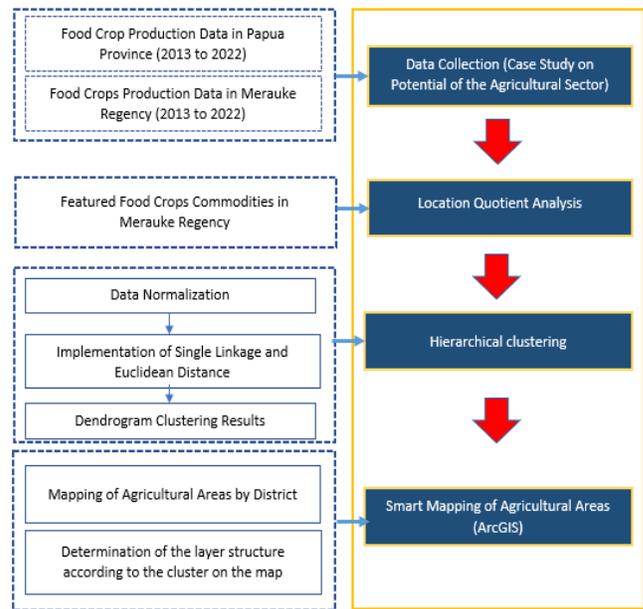

Fig. 1. Research Method Diagram.

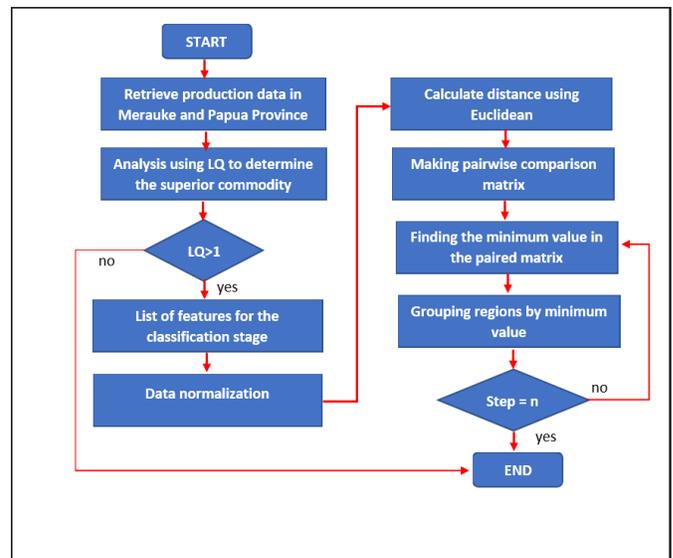

Fig. 2. Flowchart of the Proposed Classification Model.

$$LQ = \frac{\left[ \frac{C_i}{\sum_{i=1}^n C_i} \right]}{\frac{D_i}{\sum_{i=1}^n D_i}} \quad (1)$$

The determination of the LQ value depends on the C variable, which is the production of food crop commodities at the city/district level. In contrast, the D variable indicates the province. The criteria for measuring the LQ value to determine the leading food crop commodity are based on the following rules [18]: a) If LQ value >1, indicates that the commodity is a superior food crop, b) If LQ <1 or LQ = 1, it indicates that the food crop commodity is classified as not superior.

**B. Hierarchical Clustering using Single Linkage**

Cluster analysis is a statistical analysis that aims to group objects based on similar characteristics. These objects will be grouped into one or several groups (clusters) which are identical [13]. The hierarchical method is a cluster analysis that forms certain levels, such as in a tree structure, because the clustering process is carried out in stages and tiers [22].

The results of the hierarchical method analysis can be presented as a dendrogram. The dendrogram is a visual representation of the steps in cluster analysis [23]. It shows how clusters are formed and the value of the distance coefficient at each step [24]. The hierarchical method is divided based on the distance measurement technique between sets used to group objects. Distance measurement in the hierarchical approach includes a single linkage, and the grouping process begins with finding two areas with a minimum distance using the following equation [25].

$$S(v, w) = \min_{ij} \{S(v[i], w[j])\} \quad (2)$$

Measurement of the distance between objects in a single linkage based on the minimum distance, grouped in one cluster using Euclidean Distance based on the following equation [26].

$$d(v, w) = \sqrt{\sum_{i=1}^n (w_i - v_i)^2} \quad (3)$$

Where v, w are two points in Euclidean at n-place, v<sub>i</sub>, w<sub>i</sub> as vector values indicating the starting point. The use of the hierarchical method with distance measurement techniques provides a solution in its application based on the similarity size to the object's distance [27][28].

**III. RESULT AND DISCUSSION**

**A. Determination of Superior Commodities**

The selection of superior food crop commodities is an initial stage of the proposed classification method. Food crop commodities analyzed as superior commodities in Merauke Regency consist of rice, corn, soybeans, peanuts, green beans, sweet potatoes, and cassava. Location quotient analysis compares the yield of food crop production based on commodities in Merauke Regency with regional production in Papua Province. Table 1 shows a recapitulation of data on food crop production in Merauke Regency and Papua Province obtained from survey reports from the Central Statistics Agency

from 2013 to 2022. These data show that rice is a commodity that contributes the most significant production output in Merauke Regency. Determination of superior food crop commodities in Merauke Regency using the LQ method analysis is carried out by comparing the results of food crop production at the Merauke Regency level with production in the Papua province.

Table I shows the LQ calculation results for determining superior commodities based on the rules. If the LQ value >1, then based on the analysis results, it is known that there are three superior food crop commodities in Merauke Regency, namely rice, corn, and peanuts. After analyzing using the LQ method, the next step is classifying agricultural areas based on sub-districts so that regional clusters are formed. Features or data of three types of superior commodities are used as a reference in grouping districts in a set. The analysis of the LQ value uses the recapitulation data of food crop production by applying equation 1, for example:

$$LQ(Rice) = \frac{2520692,44}{2691575,59} / \frac{2670060,14}{6242813,40} = 2,19$$

TABLE I. RESULT OF LQ ANALYSIS

Commodity	Production in Merauke (Ton)	Production in Papua (Ton)	LQ
Rice	2520692,44	2670060,14	2,19
Corn	35007,42	72706,37	1,12
Soya bean	2468,11	29032,61	0,20
Cassava	73755,19	334982,60	0,51
Sweet potato	45862,00	3088929,71	0,03
Peanuts	10063,40	22732,28	1,03
Mung beans	3727,03	24369,69	0,35
Total	2691575,59	6242813,40	

**B. Clustering of Agricultural Areas using Single Linkage**

The proposed classification model maps agriculture areas with sub-district categories based on superior commodities. Implementation of a single linkage using the production data of these three types of commodities is used to determine regional clusters based on agriculture production survey data from the Central Statistics Agency of Merauke Regency in 2022, shown in Table II. The production of valid sets and normalization of data is carried out using the min-max normalization method. The mapping of agriculture areas in the Merauke Regency consists of twenty sub-districts grouped in clusters of the potential agriculture sector. Applying the single linkage method and calculating the Euclidean distance is used to classify agricultural areas using normalized data. The initial classification step is creating a symmetrical paired matrix by finding the minimum distance between regions to produce regional clusters.

The results of measuring the distance between areas of agriculture potential using the Euclidean distance[26] are shown in Table III. The use of variable  $D_i$  is used to represent the name of the agricultural district/area. The results of distance measurements are used to find the minimum value [27] between two districts to apply the classification of agriculture areas using the single linkage method. The smallest distance between two objects at the initial stage of classification is marked with red text in the table. The result of a minimum distance between the  $D_{13}$  area representing Naukenjerai and  $D_{19}$  representing Elikobel will be grouped into one cluster. For example:  $S(v,w)=\min(D_{13},D_{19})=0$ .

The next stage is to search for the minimum distance with clusters formed [22] from a combination of  $D_{13}$  and  $D_{19}$  using equation 2, shown in Table IV. Based on the search results for the minimum value, many regions have the same minimum distance, so at this stage, a merger is carried out between regions in a cluster. If a region has similar features to other regions, it shows a close hierarchical relationship to form a cluster [24], for example:  $S(D_{13},D_{19},D_1)=\min(D_{13} \rightarrow D_1, D_{19} \rightarrow D_1) = 0,02$ .

The classification step of potential agricultural areas using a single linkage is shown in Table III. The stage of finding the minimum value between the region and the process of grouping regions into specific clusters is repeated continuously until all areas become part of the cluster. The results of the analysis are that three clusters are formed. Each cluster member has similarities based on the distance measurement with the smallest value, represented through superior commodity crop production features.

C. Classification Result of Agricultural Area

Mapping the potential of agriculture areas by carrying out the intelligent mapping concept is based on the results of regional classification using hierarchical clustering, namely the single linkage method. The implementation proposed a classification model for intelligent mapping by compiling a layer structure that is categorized based on the clusters that have been formed, which consist of three. The layer representation on the map for mapping the potential of agricultural areas is shown through colored polygon images that show the boundaries of agriculture areas based on sub-district categories in Merauke Regency based on their respective clusters.

Fig. 3(a) shows the stages of classifying potential agricultural areas represented in the form of a dendrogram. Sub-districts that have the same color symbol are in one cluster. The first cluster with the blue sign has 16 sub-districts with a low potential for producing only commodities. The second cluster with the red mark has three members, and the third consists of one sub-district.

The area is in one cluster if a sub-district has the same polygon color. The mapping of agriculture areas shown in Fig. 3(b) can represent regions or sub-districts that produce the best production of superior commodities with the following information on the order of clusters:

- 1) Cluster 1 indicates that the area has a low amount of superior commodity production.
- 2) Cluster 2 can be called the central cluster. The sub-districts members of this cluster have a high number of superior commodity productions in the high category, with particular dominance on rice commodities.
- 3) Cluster 3 is the highest level, indicating that cluster members are agricultural areas producing the most increased production of superior commodities with the dominance of two types, corn, and peanuts.

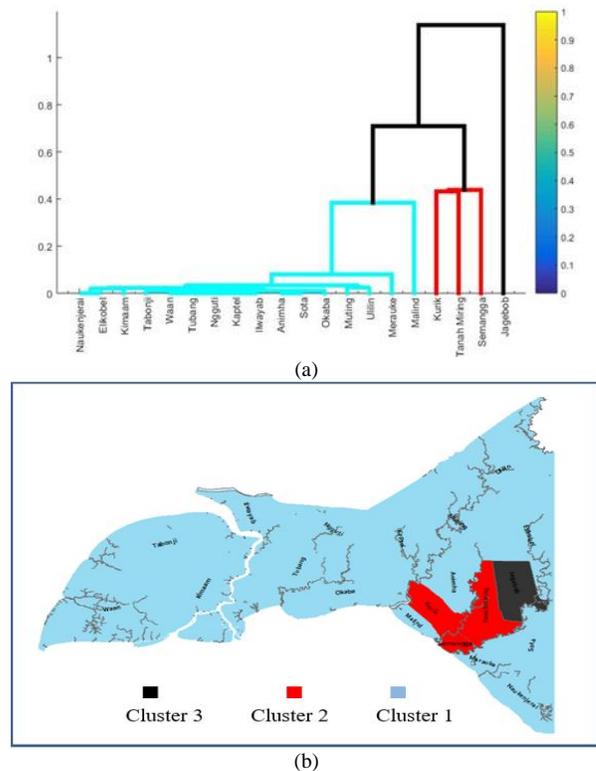

Fig. 3. (a). Dendrogram of Agricultural Area Classification using Single Linkage, (b). Implementation Classification Model for Mapping Agricultural area based on Superior Commodities.

The proposed classification method is the concept of intelligent mapping that helps map agricultural areas that provide information on superior food crop commodities so that it can become data for policymakers. The development of the agriculture industry can increase GDP income from the agriculture sector regionally and nationally, focusing on superior commodities.

#### IV. CONCLUSION

The classification model combining location quotient analysis and single linkage to group areas based on the agriculture sector's potential showed it could be used as a reference for intelligent mapping in a geographic information system. The classification stage groups sub-districts/regions in a cluster by measuring the minimum distance between two sub-districts that focus on superior commodities that can be used as information for those who need it. The sustainable agriculture industry develops prospects so it can be exported outside the region and improve the welfare of people who depend on the agriculture sector.

The stage of future research is mapping of livestock potential areas that are integrated with agricultural potential by utilizing Global Position System (GPS) technology in geographic information systems, to assist in finding potential land locations for both the agricultural and livestock sectors.

#### ACKNOWLEDGMENTS

The authors would like to thank the leadership and staff at the Ministry of Education, Culture, Research and Technology. Directorate General of Higher Education, Research and Technology, Republic of Indonesia, who has financed the implementation of this research, based on the research grant contract for fiscal year 2022, number 224/E5/PG.02.00.PT/2022 and also the contract between LPPM Universtas Musamus and researchers 169.3/UN.52.8/LT/2022.

# Analysis of Unsupervised Machine Learning Techniques for an Efficient Customer Segmentation using Clustering Ensemble and Spectral Clustering

Nouri Hicham, Sabri Karim

Research Laboratory on New Economy and Development (LARNED)  
Faculty of Legal Economic and Social Sciences AIN SEBAA, Hassan II University of Casablanca, Morocco

**Abstract**—Customer segmentation is key to a corporate decision support system. It is an important marketing technique that can target specific client categories. We create a novel consumer segmentation technique based on a clustering ensemble; in this stage, we ensemble four fundamental clustering models: DBSCAN, K-means, Mini Batch K-means, and Mean Shift, to deliver a consistent and high-quality conclusion. Then, we use spectral clustering to integrate numerous clustering findings and increase clustering quality. The new technique is more flexible with client data. Feature engineering cleans, processes, and transforms raw data into features. These traits are then used to form clusters. Adjust Rand Index (ARI), Normalized Mutual Information (NMI), Dunn's Index (DI), and Silhouette Coefficient (SC) were utilized to evaluate our model's performances with individual clustering approaches. The experimental analysis found that our model has the best ARI (70.14%), NMI (71.75), DI (75.15), and SC (72.89%). After retaining these results, we applied our model to an actual dataset obtained from Moroccan citizens via social networks and email boxes between 03/06/2022 and 19/08/2022.

**Keywords**—Machine learning; customer segmentation; marketing; clustering ensemble; spectral clustering

## I. INTRODUCTION

It is possible to win the competition in the market and enhance corporate earnings by better understanding the client's needs. Companies can develop successful marketing strategies if they are aware of the wants and needs of their target audiences. While the requirements and expectations of each customer are unique, many customers share identical or quite similar qualities. Customer segmentation is one method that may be used to put together multiple different consumers who share similar qualities. Improving the quality of the connections with your customers also requires proper consumer segmentation. Marketing intelligence is conducting information analysis to comprehend better a target market and its consumers' demographics [1], [2].

In marketing, it is common for analysts to categorize customers into comparable customer groups to understand better how to advertise to each group of customers. Therefore, segmentation is a collection of approaches that might be useful in categorizing different types of customers. Customers' existing relationships with a company are the primary focus of most direct marketing operations. The more you know about your customer's needs, desires, and

purchasing habits, the easier it is to tailor marketing programs to their needs and desires and how they buy things [3].

Marketers can determine the approach that will be most successful in communicating with each unique consumer by segmenting their customer base. Marketers can zero in on particular demographic, behavioral, and other characteristics of their target audience by conducting in-depth analyses of vast amounts of data about existing and prospective clients [4], [5].

A frequent objective in marketing is to increase the worth of each consumer (revenue and profit). To achieve success in this aspect of the marketing mix, it is vital to understand how a particular marketing action influences customers' behaviour. Regarding customer segmentation, and "action-centric" approach prioritizes the impact that marketing activities will have on a customer's lifetime value (CLV) over the value that marketing activities will have in the short term. This is in contrast to a "short-term value" approach. As a direct result, consumers ought to be divided into distinct categories according to the amount of money they will spend throughout their lifetime [6].

In this paper, we ensemble four basic clustering models (DBSCAN, K-means, MiniBatch K-means, and MeanShift) to develop a novel consumer segmentation strategy based on a clustering ensemble, which yields a more consistent and high-quality result than any of the individual clustering techniques. We then use spectral clustering to combine the findings of different clustering methods to increase the overall quality of our clustering results. After the retention of these results, we applied our model to a real dataset, which was collected from Moroccan residents using a questionnaire sent via social networks and email boxes between 03/06/2022 and 25/07/2022. As for the rest of this paper, it is structured as follows: The literature review is described in Section II, the methodology and proposed model are presented in Section III, the findings are covered in Section IV, as well as the findings, interpretations of the study and directions for future research are presented in Section V.

## II. BACKGROUND

Knowing customer behavior in today's highly competitive and ever-changing business environment is crucial. Customers must be categorized according to their demographics and the products they buy. This is an essential component of client

segmentation that enables marketers to target certain target groups more precisely with their promotional, marketing, and product development strategies. The relevance of data-driven marketing, a crucial component in client segmentation, is growing due to the growth of data sources, particularly social networks. Because of their immense size and complexity, modern databases make data-driven marketing and customer segmentation exceedingly challenging in the retail industry. Until recently, traditional cluster analysis approaches were employed on retail databases. Nevertheless, because there are so many different kinds of customers today, statistical clustering algorithms find it harder and harder to evaluate and understand what customers do [7].

In the past five years, due to the recent development of machine learning techniques and data science, many one-of-a-kind algorithms in these two fields have been developed for customer relationship management, specifically for customer segmentation. These algorithms have been developed for customer relationship management (CRM) software [8]. An integrated strategy employing the Apriori algorithm and the CRM method with associated mining is used in customer segmentation [9]. This strategy brings the benefits of both methodologies to bear in solving this challenge. For consumer segmentation, [10] utilized two primary methods: the LRFM (Length, Recency, Frequency, and Monetary) techniques and an extended model known as the LRFM-Average Item (AI) model. Both of these methods utilized LRFM techniques. The authors concluded that adding simple parameters and averages did not improve customer segmentation and did not show a significant change in results. This means that complex parameters are needed for better customer segmentation results.

As demonstrated in [11], an investigation into silent customers was carried out since silent consumers are a category of customers that a company runs the risk of quickly losing. As a result, it is essential to research the characteristics of these clients to arrive at the most appropriate business decisions. This research came up with a K-means method for customer segmentation that focused on silent customers to help the company make more money in the telecom industry.

About the Yunnan Electricity Market, an algorithm for market segmentation was developed in [12] that was primarily concerned with density-based spatial clustering of applications with noise (DBSCAN) and the K-means technique. In [13], the K-means clustering algorithm and the SPSS Software were used to construct a real-time and online system for predicting seasonal sales in annual cycles. This system integrated an important complex feature of temporal spikes in the sales of particular items, making it capable of predicting seasonal sales on annual cycles. The study [14] explains how the technique of unsupervised machine learning can be used to tackle the difficult problem of consumer segmentation by analyzing purchase data from credit cards used by African customers. The objective of [15] customer segmentation with a multi-

layer perceptron (MLP) neural network is to categorize customers into separate groups according to the characteristics of those categories.

Furthermore, in [16], The Mini Batch K-means technique is implemented to group sediment samples. The clustering result will be verified using a set of four typical evaluation indices. Using this approach, simulations show that the Sample network may be divided into three sedimentary clusters: fluvial, marine, and lacustrine. Researchers have found that experimental results on sediment particle size have an accuracy of up to 0.92254367, suggesting that this technique of studying sedimentary environment by grain size works exceptionally well and precisely. On the other hand, in [17], Using the proposed automatic selection of nearest neighbors for density gradients, it is proven to identify the number, position reliably, and form of non-elliptical clusters in multivariate data analysis and picture segmentation using mean shift.

Recent years have seen an increase in ensemble learning (EL), which has emerged as a successful teaching strategy. EL utilizes a meta-classifier to integrate the results of different classification techniques [18]. The complete training set is utilized for training the base classifiers, and the outputs of the base-level model are used as features in the learning process for the meta-classifier. Another thing to add is that EL is superior to other approaches because it combines the most accurate components of numerous machine learning to provide more accurate predictions than any algorithm in the ensemble can produce. This makes EL the method of choice [19].

### III. METHODOLOGY

This study offered a new customer segmentation strategy based on the Clustering ensemble technique. DBSCAN, K-means, MiniBatch K-Means, and MeanShift algorithm are used in the suggested method, shown in Fig. 1. The outputs are combined with a consensus function. Stacking ensemble learning allows us to use each model's structural and functional benefits while increasing overall performance. The consensus function and unsupervised machine learning models will be discussed in greater detail in the following paragraphs.

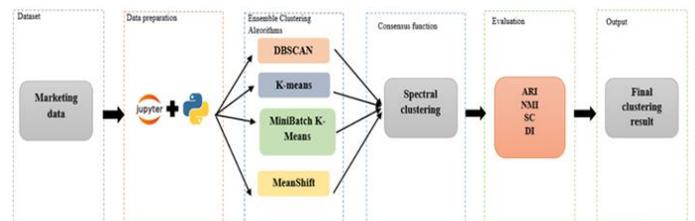

Fig. 1. The Global Architecture.

The general architecture structure is made up of the five fundamental steps listed below:

TABLE I. THE USED DATASET

Variable	Data Type	Range	Description
ID	numerical	Integer	Displays a customer's ID.
Sex	categorical	{0,1}	Customer's gender. 0=male/1=female
Marital status	categorical	{0,1}	Customer's marital status. 0=single/1=non-single
Age	numerical	Integer	The customer's age in years
Education	categorical	{0,1,2,3}	Customer's education. 1=high school, 2=college, 3=graduate
Income	numerical	Real	Customer's self-reported annual US income.
Occupation	categorical	{0,1,2}	Customer's profession. 0=unemployed/1=employee/official/2=management or self-employed
Settlement size	categorical	{0,1,2}	Customer's city size. 0=small/1=midsize/2=big

TABLE II. SOME DESCRIPTIONS OF DATASET

	ID	Sex	Marital status	Age	Education	Income	Occupation	Settlement size
count	35000	35000	35000	35000	35000	35000	35000	35000
mean	1.00	0.457	0.496500	35.909	1.038	120954.419000	0.810500	0.739000
std	5.77e+02	0.4982	0.500113	11.7194	0.599	38108.824679	0.638587	0.812533
min	1.00	00	00	18.00	0.00	35832.00	00	00

50%	1.00	00	00	33.00	1.00	115548.50	1.00	1.00
75%	1.00	1.00	1.00	42.00	1.00	138072.250	1.00	1.00
max	1.00	1.00	1.00	76.00	3.00	309364.00	2.00	2.00

#### A. Dataset

The data for this study, which involves 35,000 clients and eight different characteristics, was collected from a supermarket mall. This database includes essential customer information, such as the customer's identification number (Customer ID), annual income, gender, age, and expenditure score. In order to make sense of the marketing team and develop a suitable strategy for the situation, we need to have a solid understanding of these clients, such as who the target customers are. The full dataset description is provided in Table I and II.

1) *Data preparation*: Data selection, preprocessing, and transformation are the three stages of the process that are involved in getting data suitable for an algorithm that does machine learning [20] [21].

2) *Data selection*: At this point, we narrow down all of the data we have access to and are utilizing by selecting a subset of it to work with. Consider the data we already own, the data we do not possess, and the data we can get rid of.

3) *Data preprocessing*: The preprocessing of data is necessary because we frequently receive a large amount of raw data that machine learning algorithms cannot use. It is essential to process the raw data entirely before incorporating it into the various machine learning algorithms. In order to compile our selected data, we first formatted it, then cleaned it, and last, we took some samples from it. The data's poor quality hinders several attempts to process the data.

4) *Data transformation*: Data processing can be transformed through a series of procedures known as "data transformation." Another name for this practice is "feature engineering." The extraction of features from our data is a time-consuming process, but the benefits of machine learning

may be worth the wait. The following are the three most frequent methods in which data is altered:

Depending on the amount being measured, the properties of the pre-processed data may have been given a variety of scales. Each of the characteristics must be the same size.

- **Aggregation**: It is possible that some features can be combined to make a single feature that fits the issue that we are attempting to solve better.
- **Decomposition**: It is possible that intricate elements are easier to understand if they are broken up into chunks. Decomposing the subject into its parts may be helpful. For illustration, a feature that displays the time and date as a long string can be simplified such that it only displays the current hour of the day.

#### B. Ensemble Clustering Algorithms

The DBSCAN, K-means, MiniBatch K-means, and MeanShift basis clustering algorithms will be the topics of discussion in this article section.

- **DBSCAN**

Density-Based Clustering is a term that refers to different unsupervised learning approaches that identify different clusters in the data. These approaches are premised on the idea that a group in data space is a sector that contains a significant number of points and is partitioned into smaller regions that include a less considerable amount of points [22].

The abbreviation for a technique that uses density-based clustering as its basis is DBSCAN, which stands for Density-Based Spatial Clustering of Applications with Noise. Using large amounts of data with outlying values and noise, clusters of different shapes and sizes can be found [23].

The DBSCAN method makes use of two different parameters, which are as follows [24]:

*minPts* is the minimum amount of clustered points (also known as a threshold) that are necessary for a region to be considered dense.

*Eps()* is an abbreviation for the distance measure used to determine which points are located in close proximity to a specific point.

- K-means

Unsupervised machine learning K-means clustering may be used on a dataset to determine the data object groupings within it. There are other alternative data grouping methods, but the k-means clustering method is one of the oldest and simplest to comprehend [25]. The "K-Means algorithm" parameter "k" represents the number of data clusters. We have two ways of picking the right number of clusters: the Elbow method (which graphs random values to achieve the best k value) (see Fig. 5) and the Silhouette score approach (the value which has the greatest score will be considered as the optimal k value) (the value which has the highest score will be taken as the best k value). Using these two, we find the optimum k value is three and train the model using three [26]. According to the Euclidean distance, clustering goals are chosen which reduce the total of squares of all types in a given data set X, which contains n multi-dimensional data points.

$$d = \sum_{k=1}^k \sum_{i=1}^n \Pi(x_i - u_k) \Pi^2$$

K denotes the centers of the first K clusters,  $u_k$  is shorthand for the kth cluster center, and  $x_i$  is shorthand for the ith data point. The answer to the problem of the centroid  $u_k$  can be found as follows:

$$\begin{aligned} \frac{\delta}{\delta u_k} &= \frac{\delta y}{\delta u_k} \sum_{k=1}^k \sum_{i=1}^n (x_i - u_k)^2 \\ &= \sum_{k=1}^k \sum_{i=1}^n \frac{\delta y}{\delta u_k} (x_i - u_k)^2 \\ &= \sum_{i=1}^n 2(x_i - u_k) \end{aligned}$$

Let the second equation be zero. Then  $u_k = \frac{1}{n} \sum_{i=1}^n x_i$

- MiniBatch K-means

Clustering on enormous datasets can also be accomplished using the Mini-batch K-means clustering algorithm as an alternative to the K-means technique. It frequently outperforms the standard K-means algorithm when working with big datasets since it does not cycle over the entire dataset. This is because it does not cycle over the entire dataset. It starts by making random data batches to store them in memory. Then, for each loop, it collects a random data batch to update the clusters [27] [29].

The key benefit of mini-batch K-means is that it reduces the processing required to identify clusters. The K-means algorithm may be more to your liking, but when dealing with a big dataset, the mini-batch method is the way to go [28].

- Mean Shift algorithm

The Mean Shift Clustering Algorithm is a technique based on the centroid that is useful in various applications, including unsupervised learning. It is one of the most successful algorithms for a variety of machine learning applications, including clustering, which is one of those applications. Each individual data point is then relocated in the direction of the centroids of the region, which are determined by taking the average of all the other places. A different name for this technique is the mode-seeking algorithm. The benefit of the method is that it disperses groups of objects according to the data without automatically estimating the number of clusters depending on bandwidth. This is an advantage over competing algorithms.

### C. Consensus Function

Clustering ensemble (CE) is a method that has emerged as an essential tool for improving the overall quality of clustering solutions. This method merges the multiple clustering results obtained through DBSCAN, K-means, MiniBatch K-means, and MeanShift. This research project describes a novel approach to cluster ensembles predicated on spectral clustering. This function is the first step in the CE algorithm, and it is possible to improve the outcomes of individual clustering algorithms because it is the major step in the algorithm [30] [31]. The final consensus partition is found, which is the result of any CE technique that has been used.

### D. Evaluation

Adjust Rand Index (ARI), Normalised Mutual Information (NMI), Dunn's Index (DI), and Silhouette Coefficient (SC) were the performance indicators that we used to compare the results obtained by the proposed method with those obtained by base classifiers (DBSCAN, K-means, MiniBatch K-means, and MeanShift). This allowed us to determine whether or not the method that was proposed was effective. We applied it to the dataset that was described above.

- Adjust Rand Index (ARI)

The adjusted Rand index (ARI) is a measurement that is frequently utilized in the field of cluster analysis to determine the level of agreement that exists between two data partitions. Since the index's inception, there has been a growing amount of interest in investigating cases involving extreme agreement and disagreement under various conditions. This investigation aims to gain a deeper understanding of the index [32], [33].

The following denotes the ARI:

$$ARI = \frac{\sum_{ij} \binom{n_{ij}}{2} - \left[ \sum_i \binom{a_i}{2} \sum_j \binom{b_j}{2} \right] / \binom{n}{2}}{1/2 \left[ \sum_i \binom{a_i}{2} + \sum_j \binom{b_j}{2} \right] - \left[ \sum_i \binom{a_i}{2} \sum_j \binom{b_j}{2} \right] / \binom{n}{2}}$$

Where  $n_{ji}$ ,  $a_i$  and  $b_j$  are values from the contingency table.

- Normalised Mutual Information (NMI)

Normalized mutual information, also known as NMI, is a measurement that is frequently utilized to compare different community identification approaches. More recently, the necessity of adjusting information theory-based measures have been advocated because of the so-called selection bias problem. This problem is that these kinds of measures tend to pick clustering solutions that include more communities [34], [35]. The Mutual Information (MI) score is normalized to produce the Normalized Mutual Information (NMI), which scales the results between 0 and 1 (1 perfect correlation).

The following formula shows the NMI:

$$NMI(y, c) = \frac{2 * I(y, c)}{[H(y) + H(c)]}$$

where, 1)  $y$  = class names 2)  $c$  = group identifiers 3)  $H(\cdot)$  = Entropy 4). The formula for the amount of mutual information between  $y$  and  $c$  is  $I(y; c)$ .

- Silhouette Coefficient (SC)

A statistic that can be used to evaluate a clustering technique is called the silhouette score. The silhouette score is the sum of two separate scores, referred to as  $a$  and  $b$ . ‘ $a$ ’ indicates the average range between a sampling site and every other point that is part of the same cluster. [36] In contrast, ‘ $b$ ’ shows the typical mean distance between a sample and all other points that are part of the cluster that is the next closest to it [37]. The following formula is used to determine a sample's score for the silhouette category:

$$s = \frac{b - a}{\max(a, b)}$$

The average of the silhouette scores obtained for each sample constitutes a set's overall silhouette score. The score for the silhouette might range anywhere from -1 to +1. A silhouette score of -1 indicates that the clustering was inaccurate, whereas a score of +1 indicates that the clustering was correct and highly dense. A score of 0 for the silhouette indicates that the groups are overlapping.

- Dunn's Index(DI)

Another statistic might be employed when evaluating clustering techniques, like DI [38]. The formula for calculating DI is dividing the shortest distance between clusters by the most significant size possible. A more significant DI indicates that the clustering is done more effectively. It works under the assumption that more effective clustering results in clusters that are both closely packed and physically distinct from one another [39]. The following formula can be used to determine the value of the Dunn's Index:

$$DI = \frac{\min_{1 \leq i < j \leq n} d(i, j)}{\max_{1 \leq k \leq n} d'(k)}$$

where  $i, j$ , and  $k$  are indices for groups,  $d$  represents the distance between clusters, and  $d'$  measures the difference between clusters within the same group.

#### IV. RESULTS AND DISCUSSIONS

The following information can be found in this section: The research results of our tests assess the effectiveness of the most common diverse analytical and unsupervised techniques and offer a new customer segmentation strategy based on the Clustering ensemble technique. The suggested strategy uses the algorithms DBSCAN, K-means, MiniBatch K-means, and MeanShift.

Before beginning the presentation and discussion of the results obtained, it seems like it would be of some use to us to have a better understanding of the potential connections that exist between the many different variables that are contained within our dataset. The bivariate analysis of the relationships between the various factors is depicted in Fig. 2.

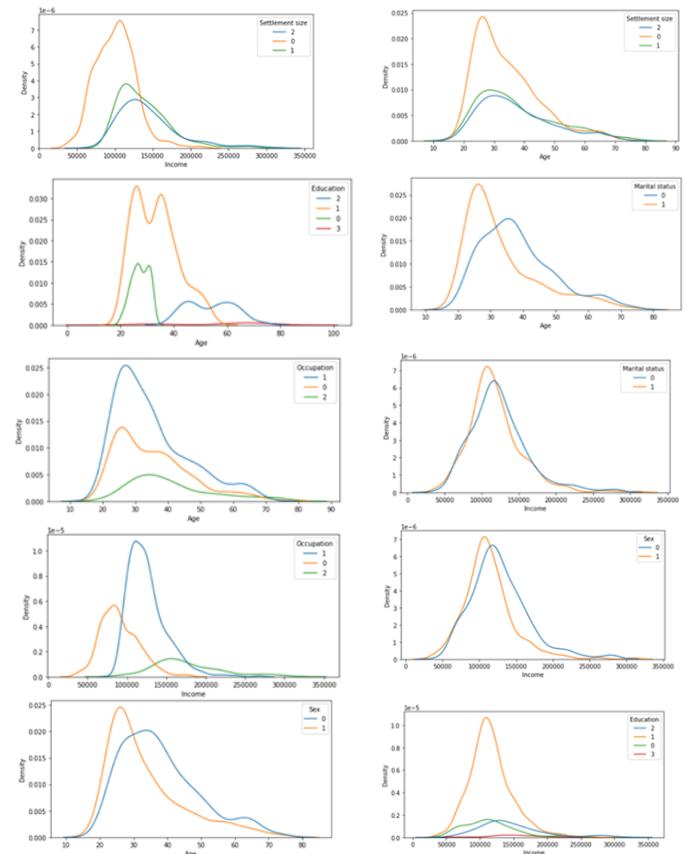

Fig. 2. Bivariate Analysis between the Various Variables.

The analysis of the data reveals several interesting correlations, including the following (Fig. 3):

- 1) People with an occupation of '0' (unemployed) are more likely to reside in smaller cities closer to the customers.
- 2) Married customers are more likely to have post-graduate or high school-level education.
- 3) Married people are more likely to reside in less populous cities.
- 4) A woman on the client list is more likely to be married than a man.

5) Males make up a larger proportion of the customer list than females. On the other hand, the dataset has a disproportionately high number of unemployed women.

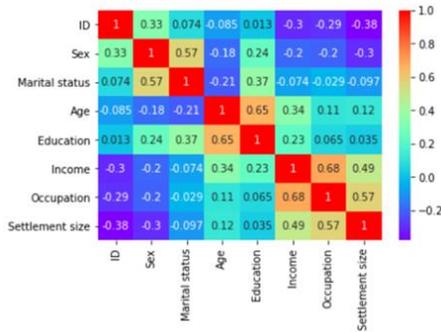

Fig. 3. Correlation between the Various Variables.

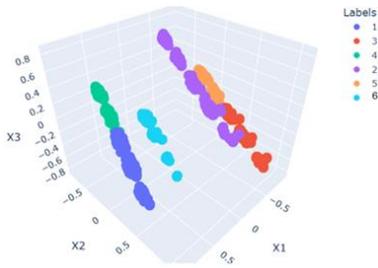

Fig. 4. Clusters Visualization.

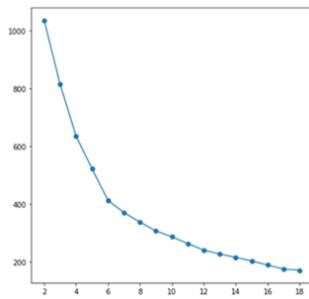

Fig. 5. Elbow Method (k=6).

To begin, we should note that the clusters are incredibly distinct from one another and that the algorithm performs the cluster separation task accurately, given that the clusters' boundaries appear pretty distinct.

In the following, we present the statistical characteristics of the different clusters generated by our model (Fig. 4).

This cluster comprises unemployed, middle-income, single men residing in small cities. As we will see later in the analysis, this also occurs in other clusters. Therefore we conclude that age and education are good cluster separators for clusters 2 and 4 in our dataset.

This cluster consists of married women with a high school diploma or higher and a moderate salary. They are either unemployed or work as employees/officials and reside in small cities. The age falls within the same range as before, so we will disregard it.

Summary statistics of Clusters 1 to 6 are shown below in Tables III to VIII.

TABLE III. SUMMARY STATISTICS OF CLUSTER 1

Cluster 3 comprises non-single females with at least a high school diploma and a high level of education and income. Large to medium-sized cities are where they reside. This cluster's distribution of Age is also identical; hence this trait does not provide any further information.

If we look at the median Age of the people in clusters 2 and 3, we obtain 28.5 and 29 years, respectively, whereas the median Age of the people in clusters 1 and 4 is significantly older (Clusters 0 and 3 have a median value of 36, while clusters 3 have a median value of 37.). However, the change is not negligible, as we can see from the next cell.

In Table VI, the cluster represented is single men with higher incomes and managerial or self-employed employment. They reside in medium to big urban centers. Education is comparable to cluster one, with the majority holding a high school diploma or less. Ages appear to fall within the same range as cluster one; hence they will not be considered.

Cluster 5 is made up of married or cohabiting men who have completed high school or higher levels of education but have a low to medium income. The vast majority of them hold jobs as employees or officials. It is important to note that this consumer base is equally represented in small, medium, and large cities; hence, we have chosen to ignore that fact in this research. Age suffers from the same issue as the other clusters, which is why it is not taken into consideration.

Cluster 6 is made up of single females of low education. The vast majority of them have completed their high school education, reside in small cities, and are either unemployed or working for someone else.

The performance of this model, which is based on clustering ensemble and spectral clustering, is presented together with its comparison to the performance of other classical models in Table VIII, which allows us to evaluate the effectiveness of our model.

As a result of the findings acquired at the ARI, NMI, SC, and DI levels, respectively, compared to other traditional models, our model demonstrates the highest level of performance across all four evaluation levels.

TABLE VI. SUMMARY STATISTICS OF CLUSTER 4

Then, we put our model to the test by applying it to an actual database collected from Moroccan residents using a questionnaire sent via social networks and email boxes between the dates of 03/06/2022 and 19/08/2022. This authentic database had 1357 individuals with eight distinguishing traits (the same as the last database). We used the programming language python and its library to manipulate and process the collected data. The results that were obtained are displayed in the figure that follows (Fig. 6).

Comparative analysis of several performance metrics for various models is shown in Table IX.

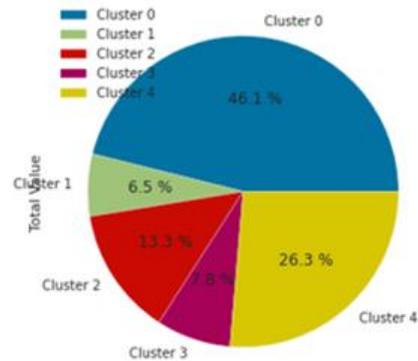

Fig. 6. Percentage of the 5 Clusters.

TABLE IX. COMPARATIVE ANALYSIS OF SEVERAL PERFORMANCE METRICS FOR VARIOUS MODELS

	DBSCAN	K-means	MiniBatch K-means	MeanShift	The proposed model
<b>ARI</b>	0.6953	0.6917	0.6252	0.6164	0.7014
<b>NMI</b>	0.7110	0.7035	0.6937	0.6839	0.7175
<b>SC</b>	0.7215	0.7172	0.6991	0.6927	0.7289
<b>DI</b>	0.7461	0.7201	0.7104	0.7063	0.7515

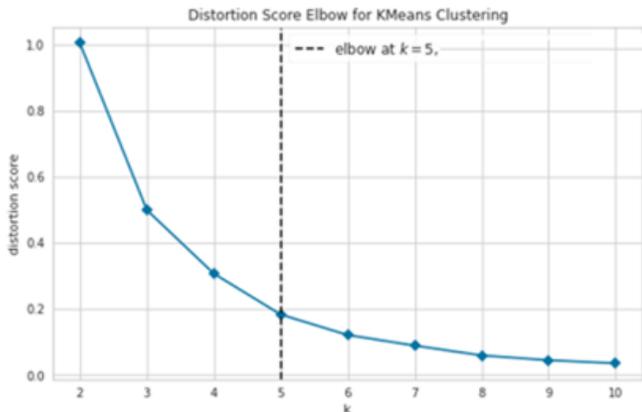

Fig. 7. Elbow Method (k=5).

We can clearly see in Fig. 7 that the elbow method reports five different clusters and that the distribution of these clusters differs from each other; however, cluster 0 has the highest percentage of 46.10%, followed by cluster 4 with a value of 26.30%, while clusters 1, 2 and 3 have a total of 27.60%.

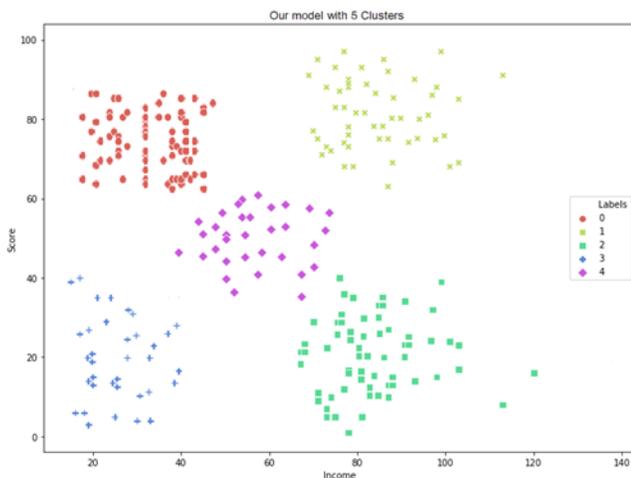

Fig. 8. Presentation of the Clusters According to our Model.

The clusters generated in this real dataset are characterized by the following (Fig. 8):

- Cluster 0 consists of middle-class single men who are highly educated and/or self-employed. We could be inclined to claim they are between twenty and forty years old.

- People in Cluster 1 are evenly split between the sexes; on average are 56 years old and have all earned at least a bachelor's degree.
- Cluster 2 consists of women who are married and have higher incomes, as well as management or self-employed employment. They have education up to a high school diploma and live in medium to large cities.
- Single people of either gender with a middle-class income and education equal to or higher than that of a high school graduate make up cluster 3. They reside in relatively tiny towns and either do not have jobs or work as employees or officials.
- Cluster 4 includes married or cohabiting women who have graduated from high school or above and have a high income. They are either employed or run their businesses. They call somewhat large to sizable cities home.

### V. CONCLUSION AND FUTURE DIRECTIONS

This paper proposes a novel clustering ensemble approach; based on a clustering ensemble; in this step, we used four essentials clustering models; DBSCAN, K-means, Mini Batch K-means, and Mean Shift, to provide a superior-conclusion, in terms of consistency and quality, to that produced by the individual clustering algorithms. After that we utilize spectral clustering to merge the multiple clustering results to improve the overall quality of clustering solutions. After the retention of these results, we applied this model to a real dataset, which was collected from Moroccan residents using a questionnaire sent via social networks and email boxes between 03/06/2022 and 19/08/2022. Therefore, the research can involve deep learning models and other performance indicators. The model can also be compared to other datasets.

**Abstract**—Research data and community service in academic environment is a very important asset that must be managed properly. They have to be applied synergically in order to obtain as quality standards of higher education. A centralized web-based application designed for research data management and community service have been applied in terms of supporting the managerial of activities. To make the application suitable for users, it is necessary to estimate the size of the software built. This study aimed at measuring the consistency of the apps based on feature point analysis method which is owned by research and community service in Indonesia. Fourteen Modification Complexity Adjustment Factor (MCAF) were used for calculating a program scale with adequate precision. The main cost is determining the quality of application sequentially, which includes measuring the weighted value of feature point components, namely, Crude Function Points (CFPs), calculating the Relative Complexity Adjustment Factor (RCAF), and estimating the Function Point (FP) by using the formula itself. The results depict that the size of application was estimated about 18381 lines using FPA methods and achieved successful estimation with 2.2 percent of deviation.

**Keywords**—Application complexity; program scale; software size; function point analysis

## I. INTRODUCTION

Research data and community service in an academic environment is a very important asset that must be managed properly. Research and community service is an essential factor of higher education in Indonesia. Both have to be applied synergically in order to obtain higher education quality standards. Some institutions have been focused on learning activities only and they neglect research and community service. The quality of their institution is not only seen from their learning quality, but also from the side of their research and community service. 16 of 24 performance indicators of higher education quality standards in Indonesia are determined by research and campus service to the community. These two factors must be considered properly [1]. Higher-education institutions have to pay more attention to the quality of their research and community service. They must be able to present data obtained from the result of their research along with provided contents, processes, assessments, facilities, infrastructure, and funds. If they able to manage all those data, then it can be said that quality of their institution is excellent [2], [3].

Research and community service are generally carried out by lecturers. A source of lecturers' work is not just research, but is a long-term work starting from the implementation of the

research, responsibility and ranging from the baseline to achievement. If management of research data and community service is not running well, so then it will become problematic for lecturers as a researcher.

In order to support this matter, we have developed a centralized web-based application for management of research data and community service which can be used by the academic community such as lecturers and students. The key features of an application consist of a machine login module, a master consumer, a textbook, and journal publishing application. Therefore, the consistency of an application needs to be evaluated in order to determine the status of the product during and after the build. Otherwise, to ensure that the application can run properly, it is necessary to measure the compatibility of the application. Software or application measurement is appraisal method consisting of size, review and adaptation to enhance software development [4]. The tool that is widely used to measure functional size of the software work product is Function Point Analysis (FPA). FPA is the software which is relocated to the production application at project implementation. FPA technique is used to analyze the functionality of the software by using Unadjusted Function Point (UFP) [5]. FPA approach calculates the size of the program in Function Point (FP) units derived from five parameters, namely: Internal Logical File (ILF), External Interface File (EIF), External Input (EI), External Output (EO) and External Inquiries (EQ) which are divided into low, medium or large classes depending on the amount of Record Entity Types (RET), Data Element Form (DET) and File Type Reference (FTR) [6].

The quality of software product is a convenience from the user's point of view that can fulfil many characteristics such as: performance, usability, robustness, and security/safety. Meanwhile a high value of maintainability, availability and reusability were tested for specific quality attribute of software project [7]. Quality software is inseparable from both program code, the suitability of data entered and generated by the software process without errors. Hence, this study aims to estimate the size of web-based application project using FPA method. Subsequently, about 72 features were used to estimate the project size. The estimated size is compared with the actual project size.

## II. RELATED WORK

In 2018 [8], the author proposed on designing and implementing a system that makes it convenient for users in analyzing software functionality size based on FP method

referring to IFPUG CPM 4.3.1 standards. The system helps users to perform FP analysis in a faster and easier way without sacrificing accuracy. Whereas, in [9], the author builds the application chat messenger fellow android user through internal operation office. Their result shows that the application can translate automatically into a different language. It also shows the application can achieve the good performance in CPU, RAM, GPU and bandwidth usage.

Furthermore, [10] performs a good estimation of size of a mobile software project using FPA method about 4235 lines. When the estimated size is compared to the actual size, the deviation gained a highly successful estimation by 1.2%. Another study by [11], aims to identify improvements proposed for FPA to make the results generated more accurate. Their paper has presented eleven additional factors for FP analysis and suggested to address FPA as considered as an outdated method given by the great diversity and complexity of currently existing technology scenarios. Bani et. al [12] confirm that Random Forests has a better Confusion Matrix and scored better in both classification accuracy, and precision measures. The results of this work verify the validity of data mining in general and the applied technique in particular for software estimation.

Recently, in [13] it was investigated that the PSO feature selection can increase the accuracy or reduce the RMSE average value to 1552,999. Their result indicates that, compared with the original regression linear model, the accuracy or error rate of software effort estimation has increased by 3.12% by applying PSO feature selection. Also, [14] reviewed the machine learning models have been introduced to handle the flaws of parametric estimation models. These models also complement the modern project development and management.

Commonly, several earlier studies have presented only one type of feature that was used. Therefore, this study uses more features which differ from prior study. We will use the function point analysis method to perform software measurements complexity for research and community service application. Another objective of this research is to measure the consistency of the apps which we hope can provide more understanding about the level of complexity application from user's point of view.

### III. RESEARCH METHOD

This research applies a Function Point Analysis (FPA) to measure the complexity of web-based application of research and services community in academic environment. It has been done after making several observations in [14]-[19], in which they also use FPA for measure software complexity.

The proposed stages include: measurement of crude function points (CFP), calculating the relative complexity adjustment factor (RCAF), and measurement function point (FP). The stages of software quality measurement are based on feature point analysis of research and community service application called E-LPPM application which is illustrated in Fig. 1.

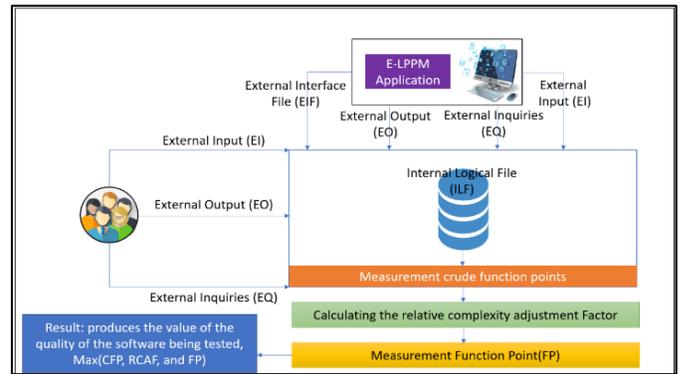

Fig. 1. Stages of Measurement Software.

Calculating the software's quality begins with the determining how to measure the success of software. It has been done with the decipherment of an application into its data and transactional functions. The data functions characterize the functionality afforded to the user by attending to their internal and external requirements in relation to the data, whereas the transactional functions explains the functionality delivered to the user in relation to processing this data by the application.

Second stage is calculating the CFP (Crude Function Points). The number of functional components of the system were first recognized and followed to calculate the complexity of quantization weight of every component including input, output, online queries, logic files, and the external interface.

The next stage is calculating the complexity of transcription factors of RCAF (Relative Complexity Adjustment Factor) for the project. RCAF is to calculate the complexity assessment of software system from several characteristics of subject. Rating scale from 0 to 5 is given to each subject that most affect the development effort required. Lastly, calculating Function Points by the formula:

$$FP = UFP \times VAF \tag{1}$$

The UFP is calculated as the complexities from parameters provided in the question where VAF is Value added Factor  $0.65 + (0.01 * TDI)$ , where TDI is Total Degree of Influence of the 14 General System Characteristics.

### IV. IMPLEMENTATION AND RESULTS

Actual total size of the application which is specified by PHP source code files is 17988 lines in 300 files. Comment line inside the code is also taken in this counting because important comments are the key as the actual code line.

#### A. Calculating Crude Function Points (CFP)

The number of functional components of the system were first recognized and followed to calculate the complexity of quantization weight of every component.

FP calculation includes five types of software system components following: 1) the number of input applications; 2) the number of output applications; 3) the number of online query applications; 4) the application related to query against the data stored; 5) the number of logical files or tables which are involved; 6) the number of external interfaces. Then given

a weighting factor to every of the above components based on its complexity.

Table I shows the User Function (UF) results for compatibility feature of External Input (EI). There are two modules with low complexity, nine modules with medium complexity, and nine modules with high complexity. The result represents that processes data or control information comes from outside by external applications. As per Table I, this EI is considered as an "Average" complexity EI.

Table II describes Internal Logical File (ILF). There are 11 rows for overall with a low complexity ILF worth 4 points, an average ILF worth 2 points, and a high worth 5 points. ILFs represent data that is stored and maintained within the boundary of the application being counted.

Meanwhile, External Interface File (EIF) listed with their complexity levels is shown in Table III. Low complexity EIF is worth 4 points, an average EIF worth 2 points and high complexity worth 5 points. EIFs represent the data that application used or referenced. This means an EIF is counted for an application in an ILF in another application. As per Table III, EIF is considered as "High".

Using the UF result and complexity of data, UFP value was calculated afterwards and depicted of 276 as shown in Table IV.

TABLE I. THE PERFORMANCE OF MODULES AND COMPLEXITY OF EXTERNAL INPUT (EI)

Excel File Publish Lecturer Journal	High

After calculating the UFP, then the Relative Complexity Adjustment Factor (RCAF) value was computed and portrayed of 46 as total degree of influence which can be seen in Table V.

Finally, the Function Point (FP) of application was calculated by multiplying the UFP to RCAF as in (2).

$$FP = 276 \times 1.11 = 306.36 \tag{2}$$

To estimate the size of application within source code line, the FP value was multiplied by 60 as reference in the [20] and [21].

$$\text{Size\_in\_LOC} = 306.36 \times 60 \cong 18381 \tag{3}$$

Size of the project was estimated about 18381 lines using the FPA method. Accomplishment of the project, the actual size was 17988 lines. The estimated size then equaled to the actual size, depicted deviation of around 2.2%. This was considered as successful estimation. Nevertheless, there might be a larger dissimilarity between the estimate and the actual size since acceptable identification of the function type was a tough process.

TABLE IV. CALCULATION OF THE UFP VALUE

Software Parameters	Level of Complexity									Total CF
	Low			Medium			High			
	Count	Weight	Point	Count	Weight	Point	Count	Weight	Point	
	A	B	C=A*B	D	E	F=D*E	G	H	I=G*H

Facilitate Change	4
Total Degree of Influence	46

As discussion matters, complexity of the identified function types was a particular matter although International Function Point Users Group (IFPUG) have been provided a broad guideline. Hence, it would be adequate to anticipate a disparity among the estimate and the actual size to a certain point.

V. CONCLUSIONS

In this report, Function Point Analysis software size estimation method was described at some point. The method was used on a web-based application developed by the author, the results were investigated. Applications developed in a web-based are commonly small in size and running properly when compared to regular software tasks like information systems. It is realized that the FPA method yields a perfect estimate for a small-scale web-based application. In extension to function point-based approach, the full data set requires to be prepared for future studies. The observation by end user can be used to make increasingly accurate estimates and classifications of web-based application. Thus, it will be of much support to the researchers' goal in the future for emerging languages and tools of programming tasks.

**Abstract**—Brain tumor detection becomes more complicated process in medical image processing. Analyzing brain tumors is very difficult task because of the unstructured shape of the tumors. Generally, tumors are of two types such as cancerous and non-cancerous. Cancerous tumors are called malignant and non-cancerous are called benign tumors. Malignant tumors are more complex to the patients if these are not detected in the early stages. Precancerous are the other types of tumors that may become cancerous if the treatment is not taken in the early stages. Machine Learning (ML) approaches are most widely used to detect complex patterns but ML has various disadvantages such as time taking process to detect brain tumors. In this paper, integrated learning process detection (ILPD) is introduced to detect the tumors in the brain and analyzes the shape and size of the tumors, and find the stage of the tumors in the given input image. To increase the tumor detection rate advanced image filters are adopted with Deep Convolutional Neural Networks (D-CNN) to improve the detection rate. A pre-trained model called VGG19 is applied to train the MRI brain images for effective detection of tumors. Two benchmark datasets are collected from Kaggle and BraTS 2019 contains MRI brain scan images. The performance of the proposed approach is analyzed by showing the accuracy, f1-score, sensitivity, dice similarity score and specificity.

**Keywords**—Machine learning (ML); deep convolutional neural network (D-CNN); brain-tumor-detection; integrated learning process detection (ILPD)

## I. INTRODUCTION

A tumor is a type of irregular tissue or cell that didn't have any shape or size [1]. Tumors will grow irregularly and can cause more damage to health if they are not detected in the early stages. These tumors may convert into cancerous or non-cancerous. Generally, the human brain is closed with a strong skull. Skull is a very small area, if it is extended this will become more complicated. Abnormal cells grow more heavily than normal cells and this may transform tumors [2]. It is very tedious to recognize tumors in the brain by using MRI images. This is based on the experience of the doctor and some methods are selected from the treatment of the patient for fast recovery. One of the tough tasks in this context is to detect the particular type of tumor in the early stages; this will help the experts treat the patient accordingly [3]. Hybrid feature extraction is one of the approaches which is used to extract the accurate features that show the huge impact on brain tumor detection [4].

Glioma is one type of brain tumor that shows severe damage to the brain. The properties of glioma are entirely different compared with other types of tumors. This consists of three types of tumors such as whole tumor (WT), tumor core (TC), and enhancing tumor (ET) [5]. Some tumors are very complicated like glioma because to reduce the impact of these tumors surgery is required. Segmentation is one of the most difficult tasks to detect tumors using MRI scan images. In MRI brain image analysis modality gives the unique and key details that belong to every piece of the tumor. The four modalities that are present in the segmentation are T1, T1c, T2, and FLAIR [6]. Multi-atlas segmentation (MAS) is the approach that segments the brain tumor images. To recover the brain image into a normal-looking image the low-rank approach is used. MAS approach is an iterative approach that recovered the image and increases the segmentation accuracy [7]. Brain tumor segmentation has many unsolved issues. Brain tumor segmentation considers every label as one unit [8]. In general, the segmentation of brain images didn't contain the tumor tissue or other anomalies [9]. In brain images, several types of segmented images are present such as gray matter and white matter. Gray matter consists of necrotic cells. White matter consists of militated axons called tracts.

In this paper, Integrated Learning Approach (ILA) is introduced to detect the tumor regions by using advanced filtering techniques and a Deep Convolutional Neural Network (D-CNN).

## II. LITERATURE SURVEY

Several authors discussed about the brain tumors detection using MRI images. In this section, various methodologies are discussed about brain tumors detection and also discussed about traditional image processing and DL approaches.

V. Shreyas et al., [10] proposed a novel approach that shows the rapid runtime compared with traditional approaches. The proposed approach Brain Tumor Segmentation (BraTS) achieved better performance by showing a dice score of 83% in the full tumor region, 75% in the core region, and 72% in the intensified tumor region. The proposed BraTS is 18 times faster than the other existing approaches. M. Ali et al., [11] introduced the two new segmentation approaches such as 3D CNN and U-Net are merged to give the better accurate results. The training is given by using the BraTS-19 challenge dataset that gives the segmentation of the brain input images. This system segments the tumor sub-regions that are used to predict the final output.

A. Kumar et al., [12] developed the ML approach to recognize tumor in brain by using the MRI images. This approach uses the Particle Swarm Optimization (PSO) for feature selection and Support Vector Machine (SVM) for classification of tumors. This approach achieved better results in classification of input images.

Zhang, D et al., [13] proposed the unique segmentation approach called a task-structured brain tumor segmentation network (TSBTS net). This approach mainly focused on predicting the tumor regions in the given dataset images. From the modality data the weights are also extracted in this approach. The proposed approach achieved better segmentation performance compared with existing approaches. Zhou C et al., [14] proposed the One-pass Multi-task Network (OM-Net) be used to solve the irrelevant issues in detecting the tumor regions. The OM-Net is the combination of segmentation and DL model that consists of shared parameters and used to learn the merged features. This is also the task specific parameters to learn preferential features. Badrinarayanan V., [15] proposed the novel deep fully segmented approach called as SegNet. SegNet is one of the decoder networks which is mapped with the low-resolution encoder that uses pixel-wise classification. Hu, K. et al., [16] proposed the novel tumor segmentation technique based on a multi-cascaded convolutional neural network (MCCNN) and fully connected conditional random fields (CRFs). This technique is a combination of MCCNN and CRFs. Each feature has its properties to detect the brain. The proposed technique finds the image patches that are extracted from axial, coronal, and sagittal used to train the three segmentation approaches. This will give the final segmented output.

### III. ROLE OF DEEP LEARNING (DL)

In recent years, CNN becomes more popular in the classification of images. Pereira S et al., [17] introduced the dynamic partition approach that uses the CNN that has a 3 x 3 core size. This approach will follow the steps such as preprocessing, training, and validation of the dataset. The dataset used to analyze the algorithm is BraTS 2015. Hao et al., [18] proposed the automatic segmentation approach that uses the U-net D-CNN. This is applied to BraTS 2015 dataset. Better segmentation is applied in this to get accurate results. Wang et al., [19] introduced the cataract network. The proposed network follows several steps for tumor segmentation. Secondly, the bounding box is implemented on tumor image, and the segmented region is shown. By using the multi-view fusion techniques the false positives are reduced. Myronenko A [20] introduced the 3D tumor segmentation approach that uses the auto-encoder to redesign the brain tumor images. The dataset is the 2018 BraTS Challenge used for result analysis. Xue F et al., [21] introduced the 3D MRI tumor segmented technique. The input uses the encoder and decoder defines several block sizes and weight loss. The training is also increased in this paper. Zhou X et al., [22] introduced 3D approach for segment the brain tumor images. To achieve high performance the 3D shuffleNetV2 as encoder, and decoder with residual blocks are used. Saman S et al., [23] introduced the active lineation model for the MRI brain tumor images with segmentation. This approach is mainly used to extract the features that belong to tumor parts in MRI. Liu et

al., [24] discussed the DL approach that learns the set of convolution and deep supervision. This technique is replaced with the feature extraction that leans with group convolution. The dataset is collected from BraTS2018 and the proposed technique detects the segmented region of an input image.

M. Rizwan et al., [25] introduced a new approach called Gaussian Convolutional Neural Network (GCNN). CNN applied two benchmark datasets to classify the multiple tumor diseases. This is mainly focused on finding the grades of the tumor. The accuracy of GCNN is 99.8% for one dataset and 97.15% for another dataset. Bhuiyan et al., [26] proposed an automated approach to finding the cancer cells present in the human brain. The proposed approach is combined with several ground-truth-level approaches giving better approaches than existing approaches. Compare with all the existing models, the proposed approach achieved the 98.6% of accuracy. Yazdan SA et al., [27-32] proposed the automated diagnostic approach called as Multi-Scale CNN (MSCNN) to classify [32-36] the brain tumors. Compare with AlexNet and ResNet the proposed MSCNN achieved the accuracy of 91.2%.

### IV. VGG 19 FOR MRI BRAIN IMAGES

Visual Geometry Group (VGG) is the CNN architecture which consists of number of layers. Transfer learning is one of the domains that reduce the training set size and computation time when deep learning models are built. This domain helps us to transfer the pre-trained learning to a new model. This is utilized in the segmentation of tumors, classifications of tumor images, etc. The proposed approach is integrated with advanced image filters with VGG-19 and Deep CNN. In this paper, VGG-19 is used as the pre-trained model which contains 19 layers. VGG19 is mainly used to recognize the brain tumors. From the ImageNet database, the training is done with huge number of predefined brain tumors and other types of brain images. Based on this pre-trained model the tumor and non tumor images are classified. The input size of brain images are converted to 224 by 224.

The VGG contains very small convolutional filters. VGG-19 contains 19 convolutional layers and three are fully connected layers (see Fig. 1).

Input: The input brain image size is 224x224. For this tumor detection, the image is cropped to the center of the image for maintaining consistency.

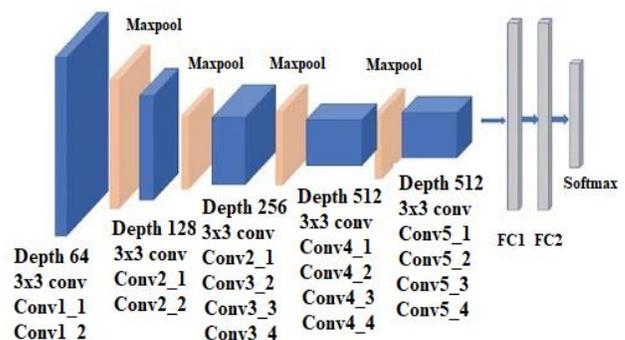

Fig. 1. Shows the Architecture of VGG19 with Total Number of Layers Present in this Process.

**Convolutional Layers:** This layer contains the minimal responsive field, i.e., 3×3, very small size catches the up/down and left/right. In this scenario, the 1x1 filters also act as the linear transformation of the input. The continuation of this is done by the ReLu function, which reduces the training time by using the AlexNet.

**Hidden Layers:** These layers used the ReLu in VGG. To reduce the memory consumption and training time ReLu is used by the VGG. This will show the huge impact on overall accuracy.

**Fully-Connected Layers:** In VGG-19 there are three fully connected layers. Among these, two layers contain 4096 and 3rd contains 1k channels and one for every class.

## V. IMAGE FILTERING AND PRE-PROCESSING OF INPUT BRAIN IMAGE

Image filtering is one of the significant tasks that will analyze the specific features of the image. There are various operations that show impact on image filtering such as smoothing and sharpening. The properties of the image filters are represented as:

$$f(a) = \alpha a + \beta \quad (1)$$

The result of the integer is rounded and fixes the range [0, 255]. The color component value (R, G, or B) is represented as x.  $\alpha$  is the contrast with the range ( $\alpha > 1$  initializes high contrast and  $0 < \alpha < 1$  low contrast). To make it easy for making changes in "brightness" and "contrast" the formula is given as:

$$f(x) = \alpha (a - 128) + 128 + b \quad (2)$$

Where b controls brightness.

More complex contrast adjustments can be done using arbitrary "curves"  $f: [0, 255] \rightarrow [0, 255]$ , which are provided by the user of the image processing software using graphical tools.

By using the linear smoothing layer the quality of the input image is improved as shown in Fig. 2. These are very good filters that can easily remove the noise from the images. By using the weighted sum of the pixels the linear filter is implemented. In every window, this weighted sum is implemented using a convolution mask. A filter that does not have the weighted sum of pixels then is considered non-linear filters.

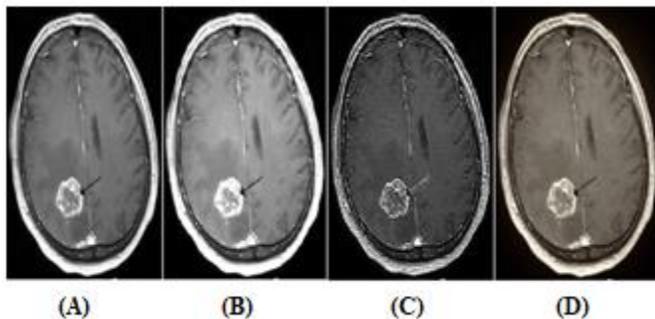

Fig. 2. (A) Input Image, (B) Filtered Image, (C) Sharpen Image and (D) Pre-Processed Image.

### A. Mean Filtering

This is one of the better filtering approaches which are used in this paper. By using the local averaging operation (LAP), the filtering approach is implemented. In this context, the pixels are replaced with all the nearest values of the input image.

$$h(a, b) = \frac{1}{M} \sum_{(k,l) \in N} f(k, l) \quad (3)$$

Where 'M' represents the total pixels in the nearest 'N'.

### B. Region based Segmentation for Finding the Statistical Information of the Input Image

Region based mathematical model is used to find the statistical information of the image. For example, the region in the image u of the image domain calculates the intensity of the mean of X with u.

$$\mu_u = \frac{1}{|X|} \int_u X(a) da \quad (4)$$

Where  $|X| = \int_u da$  (the measure of X, or the variance within X).

$$\sigma_u^2 = \frac{1}{|X|} \int_u (\mu_u - X(a))^2 da \quad (5)$$

Equation 4 and 5 combined to show the hybrid model.

$$u_t + F ||\nabla u|| = 0 \quad (6)$$

Where,  $u = u(a, t)$  initializes the level sets of curves of family C (a, t). F is used to combine the equations.

### C. Preprocessing

In this step, the input images subtracts the mean " $\mu$ " for every sample image " $i$ " and standard deviation (SD) " $\sigma$ " divides to extract " $i_0$ " output image as:

$$i_0 = \frac{i - \mu}{\sigma} \quad (7)$$

### D. Deep CNN

Deep CNN is focused on finding the important patterns from the MRI dataset. Deep CNN or CNN works better on brain MRI image classification for detecting the tumor or non-tumor images. The D-CNN takes the input image and classifies the image based on specific types such as tumor or abnormality is present or not. This classification of tumor images is based on image resolution. Image resolution mainly considers the height (h), width (w), dimension (d). For this brain image segmentation, two types of images are present such as RGB and grayscale images. RGB image contains 8 x 8 x 3 array of matrix and the grayscale image contains a 6 x 6 x 1 array of the matrix. To segment the image into two parts the threshold-based segmented approach is integrated with the input image. Based on the pixel values the segmentation is done. For every image, the pixel values are different for the tumors and background of the image. The system will set the threshold value. The threshold value is based on pixel values are between low and high. According to this, the classification is done.

### E. Non Linearity (ReLU)

**Rectified Linear Unit (ReLU):** This is utilized to analyze output and shows result as positive or zero. Positive represents the tumor is present and zero represents no tumor. In general, ReLU is very fast and easy to implement on MRI brain images. The output of the ReLU is given below.

$$f(x) = \max(0, x) \quad (8)$$

### F. Pooling Layer

This layer mainly reduces the size of the input image without losing any pixels. This layer consists of two pooling hidden layers contains five nodes at each pool and this will help the proposed algorithm to limit the iterations. MRI brain image is reduced by size and extracts only tumor affected image which is most important for classification.

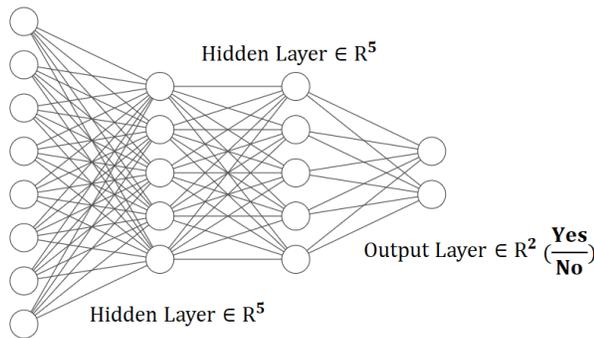

Fig. 3. The Overall Process of MRI Input Image and Output of the Image.

Fig. 3 shows the number of layers that are used to process the MRI input images. The input layer consists of eight nodes and one pooling layer consists of two hidden layers with five nodes each. Finally, the output layer shows the final output of the input image which is tumor present or not.

### VI. DATASET DESCRIPTION

Two datasets used for experimental analysis are Brain Tumor Segmentation Challenge (BraTS) 2019 [17] (see Fig. 7 and Fig. 8) and Kaggle dataset (see Fig. 5 and Fig. 6). These datasets contain two folders such as training and testing. BraTS 2019 contains 259 high and low-grade glioma patient samples. From these samples, 125 are unknown status [18]. This dataset contains five types of images namely T1, T1ce, T2, and FLAIR images as shown in the Fig. 4. The dimensions are 240 x 240 x 155 with 1mm<sup>3</sup> resolution. The algorithm shows the three-segmented regions such as deep segmented region, normal region, and light segmented region (see Tables I to III).

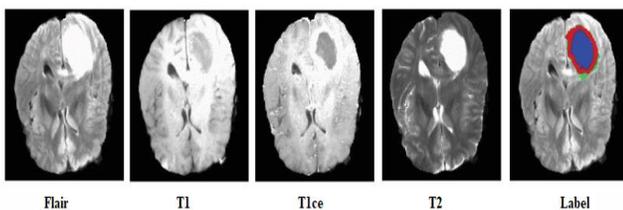

Fig. 4. Types of Images Present in Dataset.

### A. Limitations and Challenges

- Finding the accurate location of tumor becomes more challenging task.
- Finding the abnormal cells becomes more complex by using the state-of-art approaches.
- Accurate classification of tumors and cancer cells is detected using MRI scan images.
- Two types of datasets are used to diagnose the MRI scan images.

### VII. PERFORMANCE METRICS

The performance of the proposed models is analyzed by using the confusion matrix (CM). This is the advanced representation to predict the accurate prediction of diseases. This presents the actual value and predicted value of the given inputs. To count the overall values the following are the attributes used to find the accurate values.

**True Positive (TP)-**This initializes the actual value as positive (tumor identified) and the predicted value is also positive (tumor identified).

**True Negative (TN)-**This initializes the actual value as negative (No tumor) and the predicted value is also negative (No tumor).

**False Positive (FP)-**This initializes the actual value as positive (tumor identified) and the predicted value is negative (No tumor).

**False Negative (FN)-**This initializes the actual value as negative (No tumor) and the predicted value is also positive (tumor identified).

**Specificity:** This parameter mainly detects the total number of TP and FP and this parameter has more potential to predict the background region.

$$\text{Specificity} = \frac{TN}{TN+FP} \quad (9)$$

**Sensitivity** This parameter mainly detects the total number of TP and FN and this parameter has more potential to predict the segmented region.

$$\text{Sensitivity or Recall} = \frac{TP}{TP+FN} \quad (10)$$

Accuracy is one metric that measures the reliability of the classification result. The formula is give below.

$$\text{Accuracy} = \frac{TP+TN}{TP+FN+FP+TN} \quad (11)$$

**Precision:** The percentage of quality of predictions is defined as:

$$\text{Precision} = \frac{TP}{TP+FP} \quad (12)$$

TABLE I. TRAINING AND TESTING TIME (SEC) FOR TWO DATASETS

Algorithms	Training Time (Sec)	Testing Time (Sec)
EfficientNetB0 [28]	66.78	69.12

## VIII. CONCLUSION

In this paper, the ILPD is the efficient approach for finding tumors in the given MRI images. The MRI image is preprocessed and filtered by utilizing the advanced filtering approach. The classification is mainly focused on detecting the tumors or healthy images by using Integrated Learning Process Detection (ILPD). The final output consists of two neurons that belong to tumor or normal image. Two segmented images are represented by showing red and green color regions. From these images the features are extracted from last convolution layer. The ILPD focused on solving various issues in detecting brain tumors by using the segmentation approach and advanced image filters with the preprocessing method. Advanced image filters eliminate the noise from the MRI images and segment the images and represent the tumors with the green and red colors. Red represents the deep tumors and the green represents the tumors with low density. The performance of the existing and proposed approach shows the results based on the parameters. The ILPD achieved precision (99.67%), dice score (98.87), sensitivity (97.89%), specificity (99.12%), and accuracy (98.45%). The dice score shows the efficiency of the segmented image. In the future, the deeply segmented approach is used to increase the performance in terms of detecting the density of the image.

# Towards Home-based Therapy: The Development of a Low-cost IoT-based Transcranial Direct Current Stimulation System

Ahmad O. Alokaily, Ghala Almeteb, Raghad Alhabiti, Suhail S. Alshahrani  
Dept. of Biomedical Technology, College of Applied Medical Sciences  
King Saud University, Riyadh, Saudi Arabia

**Abstract**—Transcranial direct current stimulation (tDCS), a neuromodulation technique that is painless and noninvasive, has shown promising results in assisting patients suffering from brain injuries and psychiatric conditions. Recently, there has been an increased interest in home-based therapeutic applications in various areas. This study proposes a low-cost, internet of things (IoT)-based tDCS prototype that provides the basic tDCS features with internet connectivity to enable remote monitoring of the system's usage and adherence. An IoT-enabled microcontroller was programmed with C++ to supply a specific dose of direct current between the anode and cathode electrodes for a predefined duration. Each tDCS session's information was successfully synchronized with an IoT cloud server to be remotely monitored. The accuracy of the resulting stimulation currents was close to the expected values with an acceptable error range. The proposed IoT-based tDCS system has the potential to be used as a telerehabilitation approach to enhance safety and adherence to home-based noninvasive brain stimulation techniques.

**Keywords**—IoT; Internet of medical things; tDCS; home-based; brain stimulation; cloud

## I. INTRODUCTION

Neurostimulation has a long and rich history of gaining scholarly and public interest. The use of electricity in treating medical disorders was well documented in ancient times. The first documented evidence of electrical stimulation dates to ancient Greek, when Plato and Aristotle explained the torpedo fish's potential to generate therapeutic effects through its electric discharges [1, 2]. In the first century AD, Scribonius Largus reported that placing a live torpedo fish over a patient's scalp had curative effects in healing headaches and gout [2, 3]. Moreover, in the late 11th century, Ibn-Sidah suggested that torpedo fish could be used to treat epilepsy by placing them on the patients' foreheads [2, 4]. It is important to note that the electrical energy produced by electric fish is an alternating current. Nevertheless, in the 18th century, Giovanni Aldini was one of the first to use galvanism in medicinal applications, creating direct current stimulation [5, 6]. Since then, transcranial electrical stimulation has progressed from simple galvanic batteries to the most precise and advanced electronic microprocessors [1, 7].

From a biomedical engineering perspective, there are three electrical interactions between tissues and electronic systems. The first type is invasive, in which medical devices are surgically placed into the body to restore function. The second

type is minimally invasive, when medical instruments are temporarily inserted for diagnosis and short-term treatment. The last type involves noninvasive devices used for monitoring, diagnosis, and treatment [8].

Transcranial direct current stimulation (tDCS) is a noninvasive brain stimulation technique that modulates cortical excitability by transmitting a low-intensity direct current to facilitate or inhibit cortical neuronal activities [9]. This approach has been shown to be safe and painless and to induce long-lasting excitability changes [10]. The cortical excitability changes caused by tDCS are presumed to follow the long-term potentiation (LTP) and long-term depression (LTD) neuroplasticity mechanisms [11]. Two standard stimulation montages are used in tDCS protocols. First, the anodal tDCS induces an enhancement in the cortical excitability (i.e., LTP-like effect) by depolarizing the resting membrane potential. Second, the cathodal tDCS induces a reduction in cortical excitability (i.e., LTD-like effect) by hyperpolarizing the resting membrane potential [12, 13].

In the past two decades, many studies have investigated the tDCS effects and their biomarkers in neuropsychiatric, cognitive, and motor disorders. tDCS is a promising and effective therapeutic tool in several conditions such as stroke, Parkinson's disease, Alzheimer's disease, depression, and schizophrenia [14]. For instance, a tDCS study was conducted on 10 clinically depressed patients. Half of them (five patients) received a 1mA anodal stimulation for 20 minutes per day, and the other half underwent sham treatment. The study showed that the tDCS stimulation led to a significant decrease in depression symptoms in the sample group compared with the sham group, suggesting tDCS can be an effective treatment for acute major depression [15]. In addition, tDCS antidepressant effects were shown to last up to 30 days after treatment [16].

It was also reported that almost 30% of patients with schizophrenia suffer from auditory hallucinations that are refractory to medications [14]. For this reason, the treatment of hallucinations in schizophrenia was studied using tDCS. Brunelin et al. [17] investigated the effect of tDCS on 30 patients with schizophrenia randomly assigned to receive an active 2mA tDCS or sham stimulation. A significant decrease in the severity of the hallucinations was observed, suggesting that tDCS could reduce symptoms of hallucinations, and the reduction lasted for up to three months [17]. Moreover, eight sessions of anodal tDCS treatment were applied to 13 patients

diagnosed with Parkinson's disease and compared with a control group of 12 Parkinson's patients who received sham stimulation. Using 2mA for 20 minutes over three weeks led to an enhancement in the anodal tDCS stimulation group's upper extremity bradykinesia and gait [18]. Furthermore, tDCS showed promising results in enhancing cognitive performance in healthy populations [19]. For example, a study aimed to investigate the effect of tDCS on attention demonstrated a significant increase in concentration for a group who underwent 2mA tDCS when compared with those receiving 0.1mA [20].

Certain health-related events such as the global spread of COVID-19 have revealed the necessity of telehealth applications in various areas [21]. Such applications have proven to be a practical and effective approach by facilitating remote access and monitoring of healthcare services and reducing the associated contamination risks during the pandemic [21]. Furthermore, telehealth-based tDCS systems have therapeutic potential as they enable use for severely ill patients, enhance the recruitment rate in clinical studies, and optimize patients' and physicians' schedules [22].

Several investigators have developed a smart tDCS system to facilitate the in-home-based approach of tDCS. For instance, Sourav et al. [23] developed an Android application-controlled tDCS system with an adjustable headset to enhance the user's experience. This system was able to deliver a constant current of 0.1–2.5 mA and can store the session's information on external memory.

Additionally, Charvet et al. [24, 25] implemented supervision protocols of telemonitored tDCS and investigated the feasibility of monitoring and controlling the delivery of home-based tDCS sessions. The stimulation in these studies was applied using the Soterix mini-Clinical Trials tDCS device (Soterix Medical, New York, NY, USA). The tDCS sessions were monitored in real-time via the videoconferencing platform. It was concluded that telemonitored tDCS has a high compliance rate with no observed technical issues.

In this paper, a home-based tDCS device equipped with the internet of things (IoT) and controlled by a microcontroller is proposed. The internet cloud-based storage and monitoring system would be integrated with the traditional tDCS device to help healthcare providers monitor the system remotely. The main objective of the approach is to improve the patients' experience since it is a home-based device, self-administered with minimal training and cost-effective.

The remainder of this paper is organized as follows: Section II describes the main hardware components of the proposed IoT-based tDCS as well as the software structure and interface. Section III discusses the integration and validation of the proposed system. Finally, Section IV concludes the objective of this study and suggests future directions.

## II. METHODS

The proposed system consists of electrical hardware, custom-made software, and an IoT platform. The custom-made software controls the stimulation duration and intensity of the pulses, and the IoT platform registers session information on the cloud. The block diagram of the IoT-enabled home-based tDCS system is illustrated in Fig. 1.

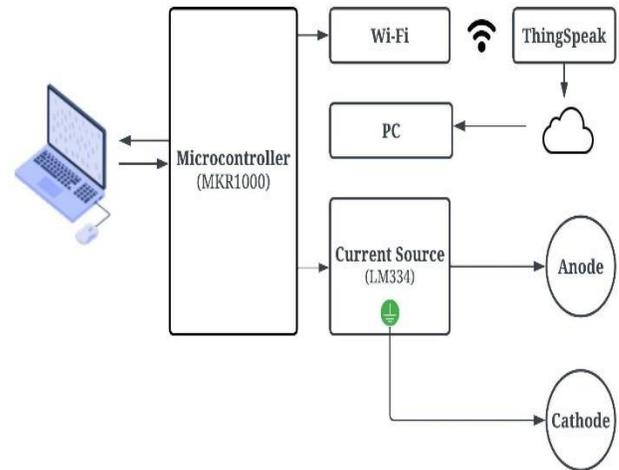

Fig. 1. Block Diagram of the Proposed IoT-based tDCS Device.

### A. Hardware

The proposed IoT-based tDCS device consists of the following main hardware components:

- **Computer:** The proposed tDCS must be connected to a personal computer (PC) or notebook to power the system and send the commands to the microcontroller through a simple and user-friendly interface.
- **Microcontroller:** A low-cost consumer-grade microcontroller with internet connectivity (Arduino MKR1000) was used to control and regulate the operation of the proposed IoT-based tDCS system.
- **Current regulators:** Four three-terminal adjustable current sources (LM334-Z; Texas Instruments, USA) that operate with a sense voltage of 64 mV were connected in a parallel configuration to provide 0.5 mA in each loop, with a maximum current of 2 mA when the microcontroller triggered all loops. The LM334-Z was connected to digital pins 2, 3, 4, and 5.
- **tDCS electrodes:** A pair of commercially available tDCS electrodes (anode and cathode) as well as electrode wires, sponges, and an elastic headband for electrode placement (TheBrainDriver, USA) were used in the testing of the current tDCS system.
- **Resistors:** Four sets of resistors with an equivalent resistance of 128  $\Omega$  were connected in a parallel configuration to ensure that each loop in the tDCS circuitry provided 0.5 mA.
- **Light-emitting diodes (LEDs):** Four green LEDs were used as visual indicators of the current intensity.

### B. Internet of Things (IoT) Platform

The ThingSpeak platform was used in the IoT-based tDCS device because it has the advantage of simplicity. A private channel was set to record, monitor, and retrieve real-time information on the stimulation duration and selected current intensity. The collected data are used for further analyses.

C. Software Architecture

The control and user interaction of the IoT-based tDCS prototype were programmed with an open-access Arduino IDE based on the C++ language. The flowchart of the system is shown in Fig. 2. A custom-made algorithm based on a switch statement to select an option from a set of defined discrete options was uploaded to the microcontroller (Arduino MKR 1000). The discrete options were constructed based on the most commonly used tDCS settings, which depend on the current intensity and stimulation duration. Thus, for this tDCS prototype, four current intensity options (low: 0.5 mA, medium: 1 mA, high: 1.5 mA, and very high: 2 mA) and three stimulation duration options (5, 10, and 20 minutes) were selected, defined, and coded to be received as a serial input entered by the user as illustrated in Table I. Based on the entered session's condition code, the microcontroller would activate all or some of the defined digital pins to supply the required current level for the selected time. Each digital pin (pins 2, 3, 4, and 5) on the microcontroller has a voltage of 3.3V when triggered, which is sufficient to supply 0.5 mA of direct current. Additionally, the operation of the IoT-based tDCS system could be terminated at any time during the session by pressing any keyboard character. Furthermore, data points were uploaded to the ThinkSpeak cloud when the session was started and at the end of each session. The recorded data points report the selected stimulation current intensity and duration of each session.

D. System Testing and Validation

The amount of current produced by the system was continuously measured using a digital multimeter (DMM) for each condition separately and compared with the expected calculated values to ensure an accurate and stable operation of the proposed IoT-based tDCS device. The stimulation duration was also recorded and confirmed with each selected state. Moreover, the real-time data synchronization accuracy between the proposed device and the ThinkSpeak cloud was validated.

TABLE I. THE TDCS STIMULATION SESSION SETTINGS

Current Intensity levels	Session Setting Code (entered by users)	Delivered Current (mA)	Session Duration (min)
Low	L05	0.5	5
	L10		10
	L20		20
Medium	M05	1	5
	M10		10
	M20		20
High	H05	1.5	5
	H10		10
	H20		20
Very High	VH05	2	5
	VH10		10
	VH20		20

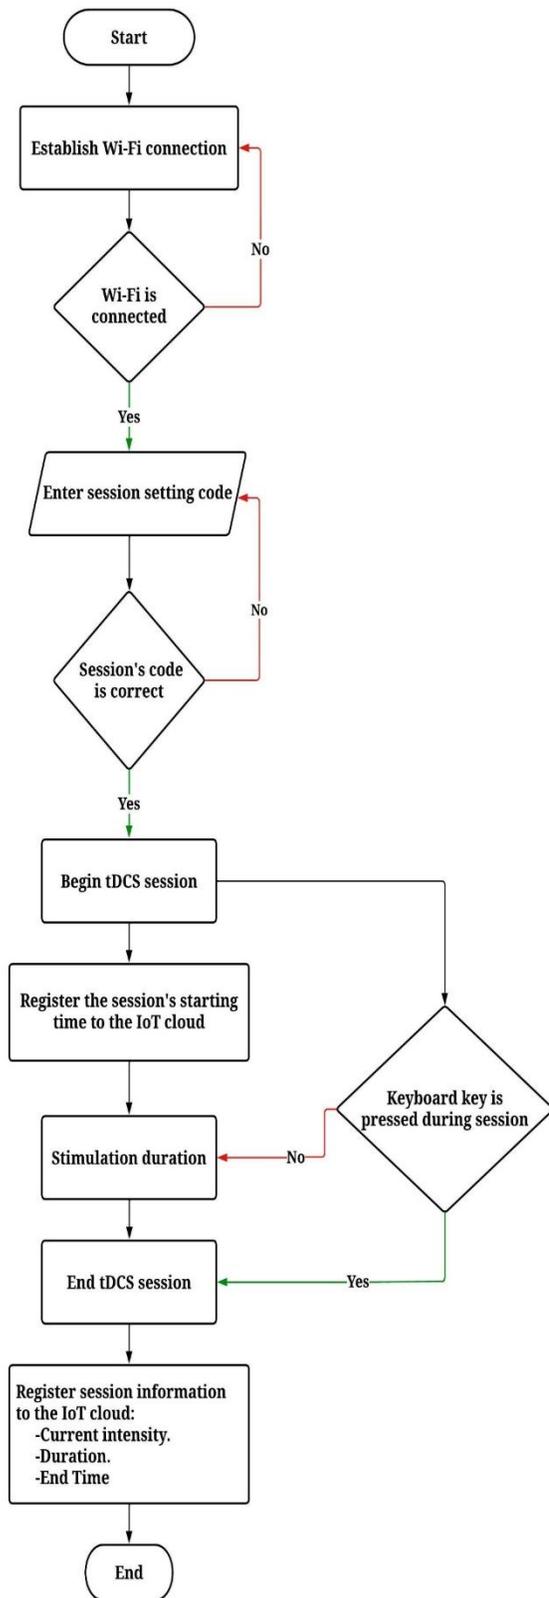

Fig. 2. Flowchart Illustrating the Operation Principle of the Proposed IoT-based tDCS Device.

### III. RESULTS AND DISCUSSION

#### A. System Integration

The IoT-based tDCS system hardware was securely placed in a compact, lightweight box (20 cm x 20cm x 9 cm), as shown in Fig. 3. The LEDs were lit up according to the selected amount of current passing between the anode and cathode.

#### B. System Validation

The IoT-based current outputs were measured using a DMM (GDM-451, GW Instek) for all current intensity settings and compared with the calculated current output. The measured currents were 0.58, 0.99, 1.6, and 2 mA for the low, medium, high, and very high settings, respectively. Furthermore, the error percentage of the output current intensity ranged from -1% to +16%, as shown in Table II. However, when the selected current was at the higher end of the system output (i.e., high and very high), the output current measured between the anode and cathode showed a minimum to 0% error compared with the expected current intensity. Compared with another study that implemented a mobile-controlled tDCS system [23], our approach has significantly lower error rates.

In addition, all the proposed tDCS current and duration settings were tested, and successful real-time information was uploaded to the private channel on the ThingSpeak platform, as shown in Fig. 4. Two recorded readings were registered on the ThingSpeak private channel as starting and ending points. The starting point was marked at 0, while the ending point was marked at the selected current intensity and duration. This provided the advantage of remote monitoring and registration of the tDCS session data, which can benefit healthcare providers.

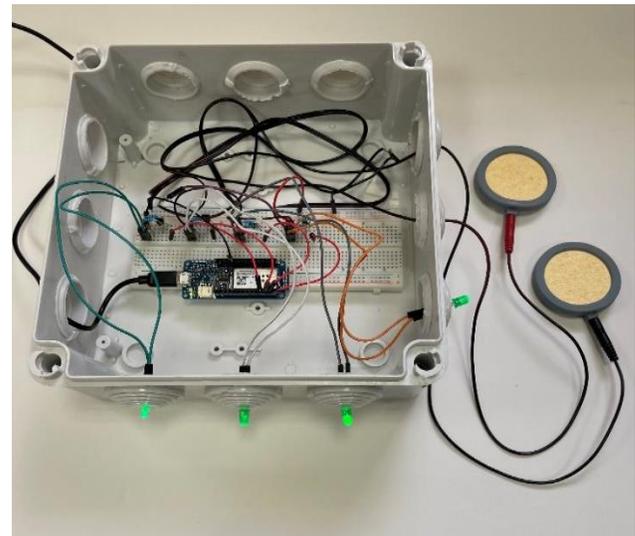

Fig. 3. Photograph of the IoT-based tDCS Device.

TABLE II. THE COMPARISON BETWEEN CALCULATED CURRENT INTENSITY AND MEASURED CURRENT INTENSITY AND THE ERROR PERCENTAGE AT DIFFERENT CURRENT INTENSITY LEVELS

Current Intensity Levels	Calculated Current Intensity (mA)	Measured Current Intensity (mA)	Error (%)
Low	0.50	0.58	+16.00%
Medium	1.00	0.99	-1.00%
High	1.50	1.60	+6.67%
Very High	2.00	2.00	0.00%

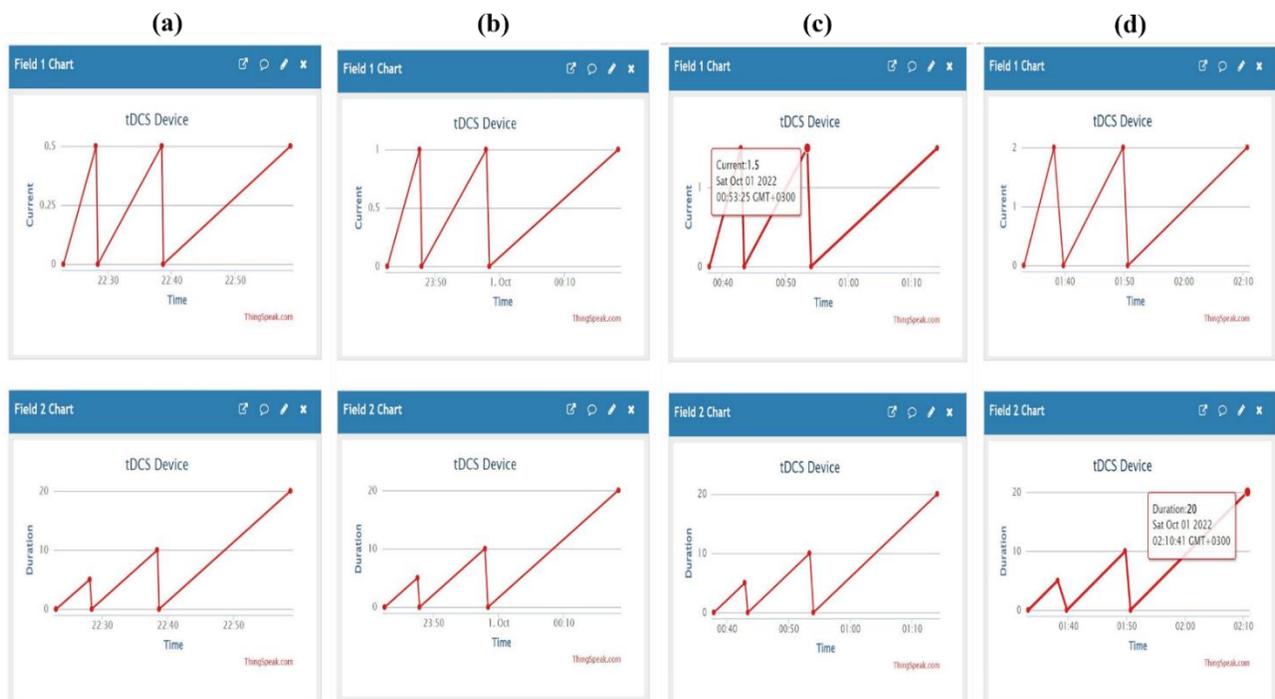

Fig. 4. The Figure Shows a Caption of the ThingSpeak Channel Information: Column (a) Exhibits Trials Taken at L05, L10, and L20 Settings. Column (b) Exhibits Trials Taken at M05, M10, and M20 Settings. Column (c) Exhibits Trials Taken at H05, H10, and H20 Settings. Column (d) Exhibits Trials Taken at VH05, VH10, and VH20 Settings.

Moreover, the proposed IoT-based tDCS system could be configured based on the subject's needs as prescribed by clinicians. Thus, the safety of delivering in-home tDCS sessions will be enhanced by ensuring that users can only apply the recommended current intensity and duration for each session.

#### IV. CONCLUSION

The present study focused on the feasibility of developing an IoT-based tDCS prototype using low-cost materials and a free-of-charge and accessible IoT platform. The use of IoT in our system could enhance the safety and adherence to home-based noninvasive research and therapy.

Future studies will be conducted to further improve the system's performance. Moreover, upon receiving the internal review board's approval, testing on human subjects will be investigated to evaluate the system's efficacy. Finally, the feasibility of a clinician remotely controlling the tDCS system over the internet will be explored.

**Abstract**—Sentiment analysis can detect hate speech using the Natural Language Processing (NLP) concept. This process requires annotation of the text in the labeling. However, when carried out by people, this process must use experts in the field of hate speech, so there is no subjectivity. In addition, if processed by humans, it will take a long time and allow errors in the annotation process for extensive data. To solve this problem, we propose an automatic annotation process with the concept of semi-supervised learning using the K-Nearest Neighbor algorithm. This process requires feature extraction of term frequency-inverse document frequency (TF-IDF) to obtain optimal results. KNN and TF-IDF were able to annotate and increase the accuracy of < 2% from the initial iteration of 57.25% to 59.68% in detecting hate speech. This process can annotate the initial dataset of 13169 with the distribution of 80:20 of training and testing data. There are 2370 labeled datasets; for testing, there are 1317 unannotated data; after preprocessing, there are 9482. The final results of the KNN and TF-IDF annotation processes have a length of 11235 for annotated data.

**Keywords**—Natural language processing; text annotation; semi-supervised learning; TF-IDF; K-NN

## I. INTRODUCTION

The concept of text mining in natural language processing is often experienced in the annotation process, including the length of the human annotation process in data labeling. This annotation process also often causes errors due to time pressure and instructions to complete it [1]. In addition, sometimes, they are not trained and skilled in annotating specific fields. Thus, it is necessary to annotate with little knowledge (data labels) from humans semi-automatically, making complete annotations with machine learning.

Text classification also includes processing, which puts documents into predetermined categories [2]. Text classification can be done for solving several cases, such as sentiment analysis [3], emotion analysis [4], and hate speech detection [5], [6].

This study discusses detecting hate speech in the text, especially in text annotation. The discussion starts with determining the hate speech category, then grouping documents into those categories and validating them. The hate speech detection process in documents uses the basic principles of sentiment analysis, starting with document preprocessing,

vectorization, modeling, and validation. There are three models in the classification of sentiment analysis (or hate speech): machine learning, lexicon, and mixed models [7]. The lexicon and mixed models need a hate speech dictionary. This study uses a machine learning approach because the lexicon of hate speech in Indonesian is not widely available. The machine learning approach is divided into three approaches: supervised, unsupervised, and semi-supervised [8]. The unsupervised approach causes hate speech categories not to be directed as needed. It all depends purely on the condition of the document features. However, in supervised and semi-supervised, researchers can direct the categorization of hate speech into two or three categories: very hate speech, low hate speech, and non-hate speech. Based on existing research, annotators generally polarize hate speech into only two categories (hate speech and non-hate speech). Human annotators can assess the presence of hate speech in a document.

The hate speech annotation process is where experts separate or provide information on documents into two categories: groups of documents containing elements of hate (hate speech) and groups of documents that do not contain elements of hate (non-hate speech). This annotation follows the ways of annotating sentiments which are generally in two polarities (positive and negative) as used in [9]–[18]. This annotation process requires an expert (human annotator) who understands the meaning of hate speech and has experience annotating opinion documents.

This study aims to use the model of semi-supervised text annotations automatically by K-Nearest Neighbor. In addition, we have not been able to determine the best vectorizer because, as in [14], we used TF-IDF. This study's results differ from [19] with increased accuracy in the model that produces hate speech annotated datasets.

## II. METHOD

### A. Similar Research on Semi-supervised Text Annotation

Typically, in semi-supervised text annotations, the annotator uses the sentiment lexicon to annotate the unlabeled data and manually revise the annotated data sample. This approach requires more time to revise the annotations [20]. AraSenCorpus in [20] is a self-learning approach to automate annotations and reduce human effort. AraSenCorpus is a semi-

supervised framework for annotating a sizeable Arabic text corpus using a small subset of manually annotated tweets and extending it from a large set of unlabeled tweets to reduce human effort in annotating. This process uses the FastText neural network and the LSTM [21] deep learning classifier to manually expand the annotated corpus and ensure the quality of the newly created corpus, respectively (Fig. 1).

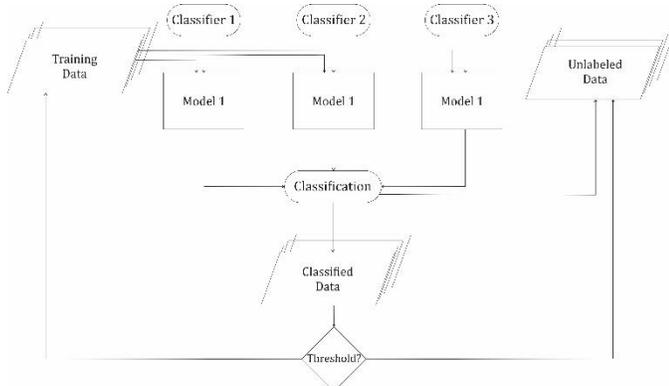

Fig. 1. AraSenCorpus Architecture [20].

This study performs a two-way (positive and negative) and three-way (positive, negative, and neutral) sentiment classification. In the case of two-way classification, AraSenCorpus improved the sentiment classification results from 80.37% to 87.4% using the 2017 SemEval dataset and from 79.77% to 85.2% using the ASTD dataset. The three-way classification gives 69.4% accuracy for the SemEval 2017 dataset, while the best system gives 63.38% using the F1-score and from 64.10% to 68.1% using the ASTD dataset. However, according to our assessment, the classification process is not determined by the type of classifier. Accuracy also depends on the vectorizer used. Another weakness is that if the iteration has been done many times and the classification results are consistently below the threshold, there is no visible solution to whether the dataset will still be included or discarded.

Another semi-supervised annotation study involved two targets: sentiment analysis and emotion analysis on an English textual review of three digital payment applications. The approach used involved supervised and unsupervised machine learning techniques. Data annotation involves three assistants from the field of Psychology. Annotators were recruited to label sentiments and emotions for 3,000 reviews. If the sentiment is neutral, the emotion is labeled neutral and excluded from the emotion analysis because no emotion can be detected from the neutral document. The machine learning algorithms are Support Vector Machine, Random Forest, and Naïve Bayes. Random Forest yielded the best accuracy for sentiment (F1 score = 73.8%; Kappa Cohen = 52.2%) and emotion (F1 score = 58.8%; Kappa Cohen = 44.7%) [22]. The architecture of the model used is shown in Fig. 2. The advantage of the approach used in [22] is that analyzing sentiment and emotion is carried out simultaneously. The downside is that the average accuracy for emotion classification based on Random Forest and SVM is around 61.3% (deficient), even though it uses a quite sophisticated algorithm. Another weakness is in the annotation process step. Sentiment and emotion annotations are carried out simultaneously so that it is prone to ambiguity in labeling

positive sentiments with negative emotions (anger, sadness, fear, disgust) or vice versa. This model also cannot anticipate if the annotation results are low in accuracy as in the AraSenCorpus Architecture (Fig. 2) [20].

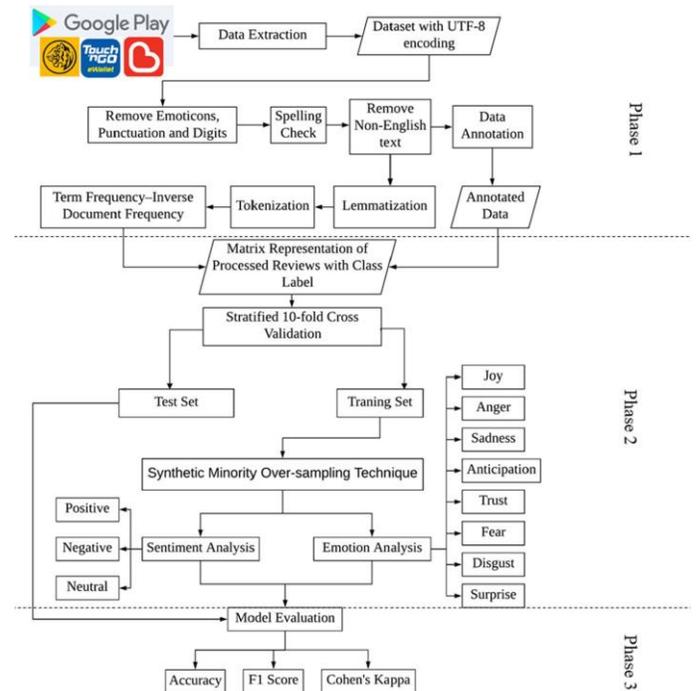

Fig. 2. Semi-Supervised Sentiment-Emotion Architecture [22].

### B. Proposed Method

The semi-supervised text annotation method for hate speech that we propose is a new method that has never been used in any research. The semi-supervised text annotation begins with reading 2000 hate-speech training data and 9000 non-annotated testing data. The flow of the semi-supervised text annotation process is shown in Fig. 3.

The semi-supervised hate speech annotation process (Fig. 3) starts from step 1, reading the DT as training data annotated as hate speech (by experts). Step 2 reads unannotated UD data. Step 3 is the text preprocessing of DT and UD. Step 4 is the meta-vectorization process. The meta-vectorization process converts the clean DT and UD datasets into four types of vectors. The first vector is VBoW, created using the Bag-Of-Word method. The second vector is VTFIDF, created using the TF-IDF method [23], [24]. Step 5 is the process of preparing training data. Step 6 is the setup of machine learning algorithms.

The algorithm involved is K-Nearest Neighbor (K-NN). Step 7 is the creation of a meta-learning model. The meta-vector and meta-learning models will produce vectorization and machine-learning approaches. The combination of machine learning will be used for the auto-annotation process. Steps 8 and 9 prepare vector datasets that have not been annotated. In step 10, it will be checked if there is still a dataset that has not been annotated then the process will continue to step 11, namely the process of annotating the dataset. The annotation process is done by predicting labels by the vector and machine

learning combinations. The prediction results are also subject to validation to determine their accuracy—the auto-annotation process results in Step 12 as a meta-labeled dataset. In Step 12, a voting process will be carried out to determine the label for each dataset record. The voting counts used the sample of the voting process for labeling decisions. There are two types of weight: the total  $W$  (weight) score of the vectorization-machine-learning model for the hate-speech polarity and the  $W$  (weight) score from the vectorized-machine-learning model for the non-hate speech polarity. In Step 13, if the polarity score of hate speech or non-hate speech exceeds the threshold, then the dataset and its annotations will be transferred to data training. If not, it will be re-annotated in the next cycle. In step 14, the data will be looping processed three times for optimization. If it is more than three times, then the rest of the Unlabeled Dataset will go to Step 15, which is manual annotation. The results of manual annotations will be combined with the training data.

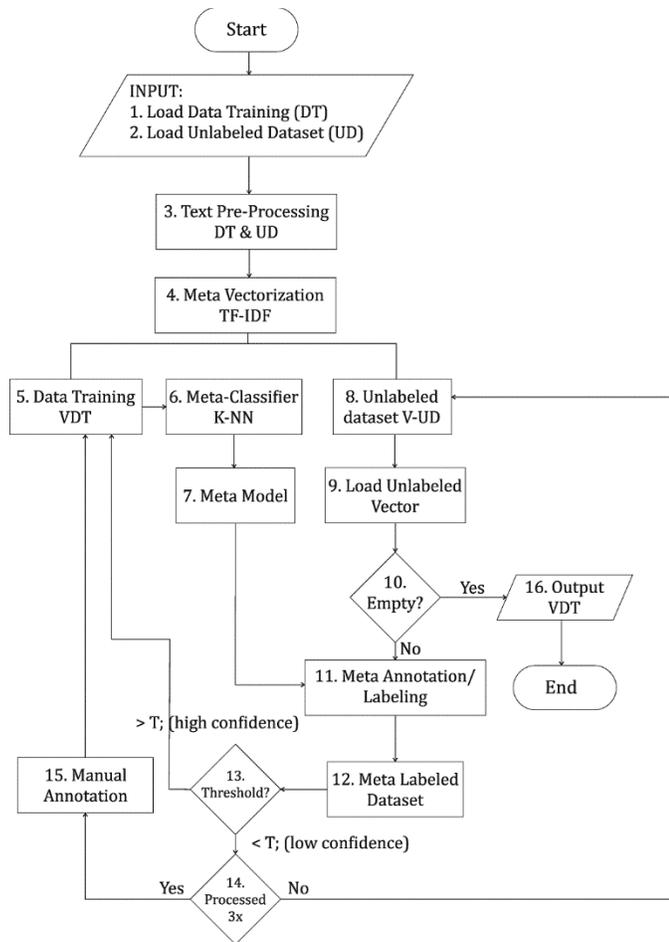

Fig. 3. Semi-Supervised Hate Speech Annotation Model (Proposed).

### III. RESULTS AND DISCUSSION

#### A. Population and Sampling

Based on the monitoring of data sources, it is known that the dataset size is dynamic, meaning that these opinions continue to grow, even though the presidential-vice presidential debate or the Covid-19 pandemic has already occurred. A new video on the official channel also appeared, followed by

viewers' opinions. So this study concludes that the population size is unknown, and it is impossible to download all comments from the YouTube repository. So the research determined that the sampling method used was purposive sampling. This purposive sampling method was chosen for the following reasons:

- 1) Our initial observations found hate speech in YouTube video comments on the topic of the 2019 Indonesian presidential debate and Covid-19. So, the data are suitable for our study.
- 2) The data from YouTube video comments are public and can be downloaded for free

The number of videos related to the presidential debate samples required refers to previous similar studies. In the process of getting the population of comments from videos, this study uses videos that meet the following criteria:

- 1) The data collection stage downloads all comments from the presidential debates one to five, each broadcast in full by two official channels. So this study downloads comments from 10 presidential debate videos and five Covid-19 news.
- 2) The data collection stage also downloads from the official channel comments from videos that do not show the whole presidential debate but are considered necessary to download because of the high number of views, more than 10,000 views, and comments above 1000 comments on exciting topics.

#### B. Data Annotation

In supervised learning, opinion data must be annotated by experts responsible for labeling hate speech on opinion data. So the data labeling process is the first step of knowledge transfer before categorization is carried out. The level of hate speech used for the labeling process is shown in Table I.

TABLE I. HATE SPEECH LEVELS IN THIS RESEARCH

No	Level	Code	Information
1.	Very Hate	VH	Hate speech that has the potential to cause dangerous social unrest
2.	Hate	H	Hate speech does not have the potential to cause harmful social unrest
3.	Non-Hate	NH	No hate speech

An annotator is an expert with expertise and knowledge following the political realm. Experts know the fields of social humanities and information technology (social media). The method of annotating opinions has also been determined. There are two experts and a team, all of which annotate hate speech, sentiment, and emotion. Steps of the annotation process:

- 1) The first expert will take around 2,000 opinions and then describe Very Hate, Hate or non-Hate.
- 2) The first expert's annotation results will be kept and not given to the second expert. Only comments from the first-choice expert are given to the second expert for hate speech annotation. The second expert does not know the first expert's annotation label. Then proceed with automatic annotation by

algorithms on data sets that experts do not annotate. This method is a semi-supervised text annotation based on meta-learning, which will automatically perform hate speech annotation, as shown in Fig. 4.

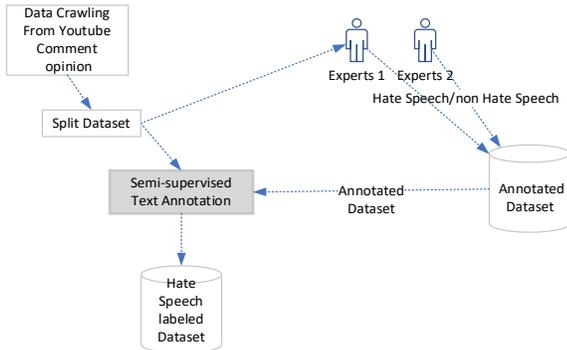

Fig. 4. Hate Speech Levels in this Research.

### C. Scenarios and the Results of Text Annotation using K-NN and TF-IDF

This study uses a scenario with the composition of training data, testing data, and threshold: 20%, 80%, and 80%. As for the training data, the initial labeling process was carried out by experts. This annotation process is tested using data, as shown in Table II. In contrast, 80% of data is testing data used to verify the accuracy of the annotation process with a data-limiting threshold of 80%.

TABLE II. SCENARIO

No	Parameters	Value	Information
1.	Threshold	80	Presents
2.	Data training annotated	2370	Length of datasets
3.	Data training un-annotated	9482	Length of datasets
4.	Data testing	1317	Length of datasets
5.	Total of datasets	13169	Length of datasets

The KNN method can perform initial training data with a sample of 20% and has an accuracy of 57.25%. After validating using TF-IDF vectorization, the best iteration is 59.68% so this method can increase the accuracy by 2.43%.

The implementation of KNN and TF-IDF with this scenario resulted in 11,235 annotated data from the total dataset processed after preprocessing of 11,852. So in this process, there are still 617 data that have not been annotated. It happens because the process still has shortcomings from the initial annotation process. In the future, the initial accuracy of the annotation will be improved to optimize the final annotation. In addition, other vectorization and classification methods will also be implemented.

### IV. CONCLUSION

The results of the presented research are the KNN and TF-IDF models of speech classifiers with semi-supervised hate speech annotations to detect hate speech on social media with low accuracy. The applied TF-IDF vectorization method increased the accuracy by 2.43%. Thus, future works will

increase by using the percentage variation of data labeling on the initial annotation (5%, 10%, 20%) and threshold (0.6, 0.7, 0.8, and 0.9). Besides, the vectorization will be improved by applying methods such as Bag-Of-Word and Word2Vec. The classification methods will be improved and compared with other methods like Random Forest (RF), Extra Tree (ET), Naïve Bayes (NB), Support Vector Machine (SVM), and Decision Tree (DT).

**Abstract**—Feature extraction in Copy-Move Forgery Detection (CMFD) is crucial to facilitate image forgery analysis. Edge detection is one of the processes to extract specific information from Copy-Move Forgery (CMF) Images. It sensitizes the amount of information in the image and filters out useless ones while preserving the important structural properties in the image. This paper compares five edge detection methods: Robert, Sobel, Prewitt (first Derivative), Laplacian, and Canny edge detectors (second Derivatives). CMFD evaluation datasets images (MICC-F220) are tested with both methods to facilitate comparison. The edge detection operators were implemented with their respective convolution masks. Robert with a 2x2 mask, The Prewitt and Sobel with a 3x3 mask, while Laplacian and canny used adjustable masks. These masks determine the quality of the detected edges. Edges reflect a great-intensity contrast that is either darker or brighter.

**Keywords**—Edge detection; first derivative; second derivatives; robert; sobel; prewitt; laplacian; canny edge detector

## I. INTRODUCTION

Image forensic analysis requires good-quality images in any orientation to accurately detect the image textural properties. A good quality image can give the best evaluation when investigating a crime scene on any query image. Therefore, the analysis of CMFD detection image texture plays a significant role in image forensics. Edge-based segmentation is one of the methods used to analyze image textures in CMFD.

Segmentation is an essential determinant for image information understanding and retrieval. It is also one of the frequent topics of discussion in the image processing and computer vision community [1]. Theoretically, image segmentation separates digital image data into a set of visually separate and identical regions based on parameters such as pixel intensity, similarity, discontinuity, cluster data, and so on [2]. The primary objective of segmentation is to clearly identify an image object from its background. Researchers have categorized segmentation into different techniques. The author [3] express segmentation as threshold techniques, edge detection techniques, region-based techniques, and connectivity-preserving relaxation methods. In [1] segmentation is seen as threshold-based, regional growth, edge, and segmentation based on clustering and weakly-supervised learning in CNN. In 2022, due to a significant improvement

over the last four decades from the traditional segmentation-based method to advance deep learning algorithms, [2] categorized segmentation algorithms into rule-driven and data-driven methods. Methods for cleaning objects that rely on one or more rules are referred to as rule-driven. Classification methods that learn features from data, such as ANN and DL, are referred to as data-driven. According to [2], several rule-based segmentation methods, such as fuzzy-based image segmentation (FBS), have been abandoned because they do not give satisfactory performance or because their lengthy computation times do not sufficiently substantiate their use. However, the reviewed literature mentioned that thresholding and edge detection methods are the most popular and applicable traditional image segmentation methods. This paper primarily focused on the edge detection-based segmentation method.

Edge detection is a method for recognizing the points or pixels in an image where the luminance varies abruptly or significantly. These points are clustered along segments of lines known as edges. Edge detection seeks to identify and locate image discontinuities. Due to the high frequency of both noise and image, edge identification becomes problematic. This paper discusses the edge detection techniques to address the choice of an edge detection method based on distinctive edge identification, noisy removal, etc.

Filtering is a method of correcting or improving the process of selecting the best keypoints in an image [4]. Edge detectors utilize filters to highlight edges while removing noise in a given image. Smoothing, sharpening, and edge enhancement are some image-filtering activities invoked using filtering methods. These activities are used interchangeably to enhance images for proper image-processing applications [5]. The filters are utilized for locating the sharp, discontinuous edges. These discontinuities cause variations in pixel intensities, which define the object's boundaries [5]. By applying filters to images, salient key points can be efficiently located for object detection.

Edges are of fundamental importance during any image-processing task. The intensity values of pixels that share a neighborhood are compared in detecting edges. The significant changes in the dense regions are located as edges. These dense areas are often difficult to trace due to the presence of noise. The presence of noise in the image affects the detection of the Edges; therefore, noise needs to be cleaned before the detection

of edges [6]. Noise reduction has been a challenge in the edge detection process, attracting the attention of many scholars in different areas of application that use images. Edge detection algorithms have been used for decades and have recently been employed in various domains because of their ability to detect and differentiate good boundaries in images.

Research has been conducted over the past decades to detect abrupt changes in image intensities (edges). Edge detection was employed in glass production for texture analysis [6], Canny Edge Detection Algorithm for Congregating Traffic Information [7], Sobel edge detector for synthetic aperture radar (SAR) detection [8], Laplacian edge detector for bladder cancer diagnosis [9], Kirsch edge detector for sharpening effect in images [10], Sobel edge detector for hardware implementation on the FPGA Nexys 4 DDR Board [11], copy-move forgery detection in digital images [12].

This paper presents an analysis of five types of edge detectors. It examines the edges by applying various edge operators and their respective filters. Five selected images in the MICC-F220 CMFD dataset are tested and compared to each other. This paper presented the related work in Section II; Section III presents the algorithms based on the first derivatives and explains the edge detector operators and their various masks. Section IV presented an algorithm based on the second Derivative, and Section V presented the result of the five operators. Finally, Section VI discussed the result, and the conclusion was depicted in Section VII.

## II. RELATED WORK

As shown in Fig. 1, an angle gradient vector indicates the intensity change at that edge pixel. The cycle spot in Fig. 1 is the corresponding gradient vector on one data point or pixel. The intensity changes from 0 to 255 in the gradient direction at that pixel. The gradient's magnitude determines the edge's strength by calculating the gradient in uniform regions; a zero vector is obtained, indicating that there are no edge pixels. In natural images, where there are rarely ideal discontinuities or uniform regions, as seen in Fig. 1, thus, the gradient magnitude is evaluated to determine whether to detect the edge pixels. Edge detection is one of the simplest and oldest image-processing procedures, it is frequently employed in recently advanced edge detection algorithms. Edge detection is a technique for detecting abrupt changes in image intensity. The use of first-order or second-order derivatives can be employed to detect those changes [13]. Edge detection methods were developed in the 1970s using small operators such as Sobel (3x3) to compute an approximation of the image's first Derivative. Edge detection involves the application of different size operators because the change in image intensity depends on the image scale. This variation in intensity can be demonstrated as a peak in Fig. 3, using gradient-based operators (first Derivative) or a sharp zero-crossing on gaussian-based operators (second Derivative), respectively.

The edge detection algorithms are divided into two distinct categories: Gradient-based (first Derivative) and Gaussian-based (second Derivative) [10]. An adaptive mask convolves the input image, resulting in a gradient image with edges recognized via the thresholding technique. To detect edges, the gradient operators (Sobel, Prewitt, and Roberts) examine the

maximum and minimum intensity values. They determine the distribution of intensity values in each pixel's neighborhood to see if it should be categorized as an edge. Sobel, Prewitt, and Roberts operators are time-consuming and cannot be deployed for real-time applications (Bhardwaj & Mittal, 2012). On the other hand, the Laplacian of Gaussian (LoG) is categorized under the Gaussian-based method (second Derivative). Gradient-based operators are filters with various kernel sizes convolved with the original input image to produce the image gradient. Zero-crossing or second-order derivative methods are other names for Gaussian-based approaches. They significantly extract sharp zero-crossing points, and zero-crossing indicates the presence of maxima (an edge) [3]. The Canny operator is well-known for its exceptional performance, as it goes through noise reduction, gradient magnitude calculation as gradient operators, thresholding to maintain firm edges while deleting weak ones, and finally, non-maximum suppression for edge thinning through Hysteresis [8], [10].

Various survey has been conducted to investigate the impact of edge detection in digital images. This can be summarized in Table I.

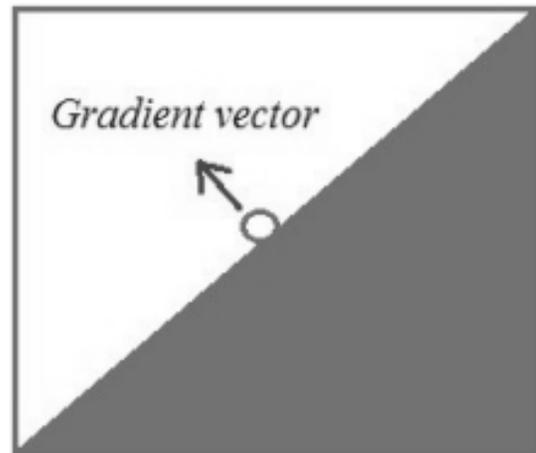

Fig. 1. Gradient Vector with Red Spot Indicating the Location of a Pixel.

### III. ALGORITHMS BASED ON FIRST DERIVATIVE (GRADIENT-BASED)

The main difference between the algorithms based on the first derivatives is the nature of the mask or filters (known as low pass filters) they applied during the computation of the derivatives. A general flow diagram for computing the First Derivative of an image is presented in Fig. 2.

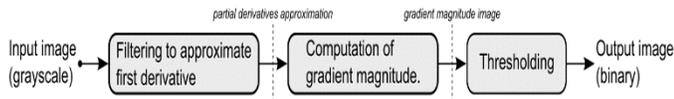

Fig. 2. Block Diagram of the First Derivative Edge Detection Algorithms [13].

The intensity variations in the magnitude and direction of an image  $f$  can be calculated using the gradient operator ( $\nabla$ ). It is a well-known tool in image processing for calculating image orientations. Let's consider a 1 D image signal to detect an edge.

#### A. Edge Detection using Gradient Operator based on 1D Image

Consider a 1D image signal with edges in Fig. 3.

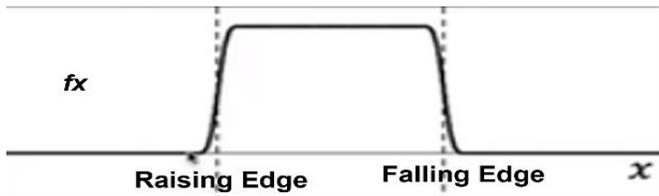

Fig. 3. Image Signal ( $f(x)$ ).

The first Derivative of the image is computed to determine the intensity changes in the above image,  $f(x)$ . Ideally, the Derivative of a continuous function represents the amount of change in the function [19]. When dealing with edges, those changes are obtained from the function. When the first Derivative of  $f$  for  $x$  is applied to the image in Fig. 3, it is transformed into the image in Fig. 4. The local extrema indicate the edges in the image. Finding the absolute value of the first Derivative obtained the two peaks (local extrema Fig. 4). The location of the peaks indicates where the edges occur, and the height of the peaks expresses the strength of the edges (local maxima Fig. 4).

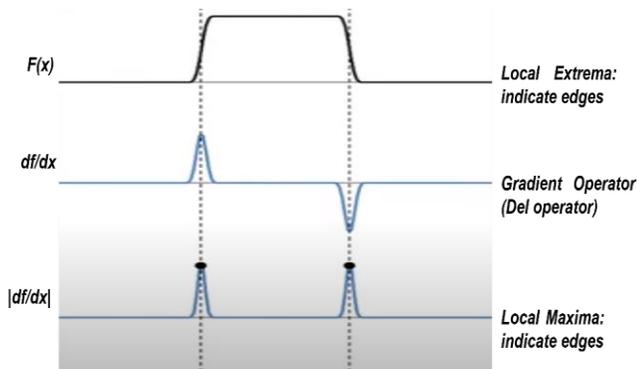

Fig. 4. First Derivative of  $f$  with Respect to  $x$ .

#### B. Edge Detection using Gradient Operator based on 2D image

When the above idea is applied to 2 D images, it is referred pure derivatives (partial Derivatives). According to calculus, a partial derivative of a 2D continuous function represents the number of changes along each dimension [19]. The gradient operator (partial Derivative) represents the most rapid change in intensity (see Fig. 5).

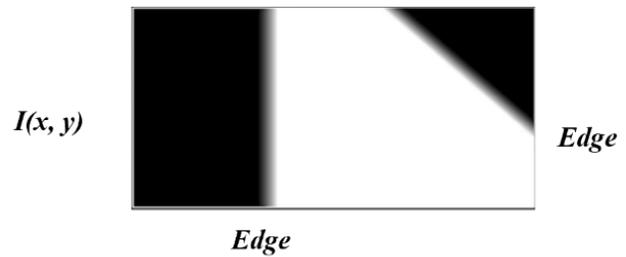

Fig. 5. Edge Detection using 2D Image.

The gradient operator is computed by:

$$\Delta I = \left[ \frac{\partial I}{\partial x} + \frac{\partial I}{\partial y} \right] \quad (1)$$

When equation (1) is applied to an image, it produces two numbers; the Derivative of the image ( $\partial I$ ) with respect to  $x$  and  $y$ . these two numbers (vectors) comprise all information needed to know about the edges. For example:

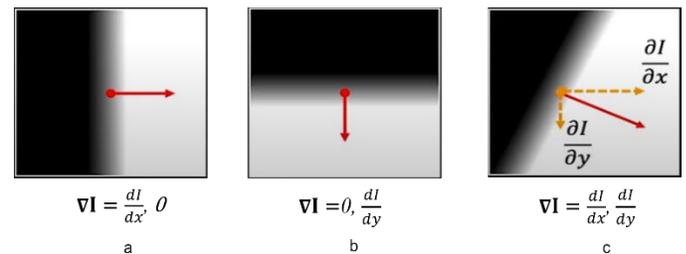

Fig. 6. Gradient Operator when Applied to an Image.

After applying the del operator, ( $\Delta I$ ), Fig. 6 produces two number vectors along each edge. Image (a) is a vertical edge with a non-zero value for the  $x$  direction and a zero value for the  $y$  component. Image (b) is a horizontal edge, with zero for the  $x$  direction and a non-zero value for the  $y$  component. Image (c) is a tilted edge and therefore has a non-zero value for both the  $x$  and  $y$  direction. From these two numbers at each pixel, we can obtain both the edge strength and the edge orientation. The magnitude equals the sum of squares of the two partial derivatives, and their square root equals 1. While the orientation of the edge is measured with respect to the horizontal axis, Eq. 3.

$$\text{Gradient Magnitude } S = \|\nabla I\| = \sqrt{\left(\frac{\partial I}{\partial x} + \frac{\partial I}{\partial y}\right)^2} \quad (2)$$

$$\text{Gradient Orientation } \theta = \tan^{-1} \left( \frac{\frac{\partial I}{\partial x}}{\frac{\partial I}{\partial y}} \right) \quad (3)$$

When Eq. 2 and Eq. 3 are applied to discrete images, we will have a finite difference approximation for the partial Derivative ( $f$ ) for  $x$  and  $y$ . To find the difference in the  $x$  and  $y$  direction, we need at least two pixels in each direction, making four pixels in Fig. 7. Assuming the physical distance between the pixels is epsilon. We obtain a finite difference in the image as in Fig. 7.

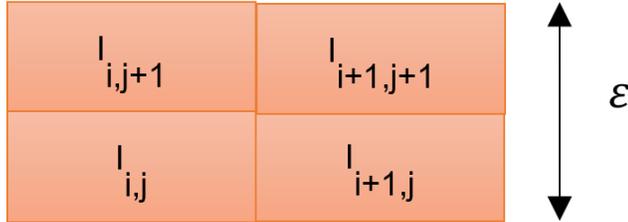

Fig. 7. Four Pixels Images in 1D Image.

$$\frac{dI}{dx} \approx \frac{1}{2\epsilon} ((I_{i+1,j+1} - I_{i,j+1}) + (I_{i+1,j} - I_{i,j})) \quad (4)$$

$$\frac{dI}{dy} \approx \frac{1}{2\epsilon} ((I_{i+1,j+1} - I_{i+1,j}) + (I_{i+1,j} - I_{i,j})) \quad (5)$$

Eq. 4 and Eq. 5 can be applied as a convolution using the filter in Eq. 6 and Eq. 7 to convolve the image for  $x$  and  $y$ . when this is done, the values obtained are enough to determine the edge magnitude and orientation.

$$\frac{dI}{dx} \sim \frac{1}{2\epsilon} \begin{pmatrix} -1 & 1 \\ -1 & 1 \end{pmatrix} \quad (6)$$

$$\frac{dI}{dy} \sim \frac{1}{2\epsilon} \begin{pmatrix} 1 & 1 \\ -1 & -1 \end{pmatrix} \quad (7)$$

With the gradient approach, a variety of gradient operators have been proposed over the last few decades [6], [20]–[23], which include Robert, Prewitt, Sobel (3x3), and larger Sobel (5x5). The Sobel operator (3x3) has been broadly used across various applications in the literature. The Derivative is found in the diagonal direction to the orthogonal direction of the convolution. The main obstacle of these operators lies mainly between the Robert operator, a small operator, and the larger Sobel. The Robert (2x2) operator with four-pixel values has a perfect localization ability for the edges but is very sensitive to noise because of the fewer pixels to revolve around. Any minor modification with any of those pixels can affect the detection accuracy. Therefore, noise sensitivity does not produce a good edge in a noisy image. On the other hand, the larger Sobel operator (5x5) has very poor localization accuracy. This is because when the operator becomes larger, determining an edge at a particular pixel can be affected by the activities happening in other larger pixels around it, affecting the edge localization. From a practical point of view, getting the orientation and magnitude does not declare an edge to be an edge. It still needs to be localized by thresholding. In this case, two standard thresholds are applied such that for a threshold  $T$ , the edge is obtained when Eq. 9 is satisfied:

$$||\nabla I(x,y)|| < T \text{ (not an edge)} \quad (8)$$

$$||\nabla I(x,y)|| > T \text{ (an edge)} \quad (9)$$

By introducing hysteresis-based thresholding, two thresholds are used ( $T_0$ ,  $T_1$ ) to obtain an edge, Eq. 11 and Eq. 12.

$$||\nabla I(x,y)|| < T_0 \text{ (not an edge)} \quad (10)$$

$$||\nabla I(x,y)|| < T_1 \text{ (an edge)} \quad (11)$$

$$T_0 \leq ||\nabla I(x,y)|| < T_1 \text{ (an edge if the neighboring pixel is an edge)} \quad (12)$$

An edge pixel is defined by two fundamental characteristics: its edge strength, which is equal to the gradient magnitude, and its edge direction, which is equal to the gradient angle. However, for a discrete function, a gradient is not defined; instead, the gradient may be defined as an ideal continuous image, which is inferred using some specific operators. These operators use a pre-determined convolution mask to detect edges.

### C. The Roberts Cross Operators

Roberts (1963) introduced the Roberts Cross operator. He clearly and concisely measures a 2-D spatial gradient on an image. As a result, high spatial frequency zones are emphasized, which typically correspond to edges. The operator's input and output are grayscale images in the most common situation. The estimated absolute magnitude of the spatial gradient of the input image at that point is represented by pixel values at each position in the output. Eq. 13 and Eq. 14 are the 2x2 convolution mask that convolves images in  $x$  and  $y$  directions ( $G_x$ ,  $G_y$ ). These masks are made such that  $G_y$  is a 90° rotation of  $G_x$  [11].

Roberts Operators Masks

$$G_x = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \quad (13)$$

$$G_y = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix} \quad (14)$$

Eq. 13 and Eq. 14 can be applied independently to the query image to obtain separate gradient components at each orientation. The absolute value of the combination of the gradient components ( $G_x$ ,  $G_y$ ) gives the magnitude at each point in Eq. 16 and the orientation of the gradient in Eq. 17.

$$|G| = \sqrt{G_x^2 + G_y^2} \quad (15)$$

Which can also be computed approximately as:

$$|G| = |G_x| + |G_y| \quad (16)$$

The angle  $\theta$  of orientation is given by:

$$\theta = \arctan \left( \frac{G_x}{G_y} \right) - \frac{3\pi}{4} \quad (17)$$

#### D. Sobel Operator

The Sobel operator introduced by [21] indicates a high-frequency spatial region. The Sobel operator is achieved through a 2D image spatial frequency measurement by converting the image into grayscale and computing the absolute approximate gradient magnitude value at each point.

The Sobel operator is convolved using a (3x3) convolution kernel. With one kernel rotated 90 degrees over the other. Eq. 18 and Eq. 19 show the Robert cross operators.

Sobel Operators Masks

$$G_x = \begin{bmatrix} 1 & 0 & -1 \\ 2 & 0 & -2 \\ 1 & 0 & -1 \end{bmatrix} \quad (18)$$

$$G_y = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix} \quad (19)$$

Sobel kernels can be used to compute separate measurements of the gradient component at each orientation, which are later combined to form the magnitude of the gradient for  $x$  and  $y$  orientations. The gradient magnitude can be computed using Eq. 20 and Eq. 21, while the orientation is computed using Eq. 22.

$$|G| = \sqrt{G_x^2 + G_y^2} \quad (20)$$

It can further be approximated by:

$$|G| = |G_x| + |G_y| \quad (21)$$

The angle of orientation is given by:

$$\theta = \arctan\left(\frac{G_x}{G_y}\right) \quad (22)$$

One of the problems of Sobel is using a gaussian smooth to reduce noise, which in turn affects the detection of a good edge. Despite this limitation, Sobel exhibits the quality of edge detection applied to solving various computer vision problems [24].

#### E. Prewitt Operator

The Prewitt operator introduced by [25] has similar properties to that of Sobel, such as convolution kernels. The kernel for the Prewitt operators are shown in Eq. 23 and Eq. 24. When applied to a noiseless and well-contrasted image, it is a computationally less expensive and faster edge detection method (Pujare et al., 2020). It is a gradient-based edge detection operator, and it has gradient features. Compared to the success of edge detection in complex images, the success of the Prewitt operator is greater than Roberts's operator [6]

$$G_x = \begin{bmatrix} 1 & 0 & -1 \\ 1 & 0 & -1 \\ 1 & 0 & -1 \end{bmatrix} \quad (23)$$

$$G_x = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ 1 & -1 & -1 \end{bmatrix} \quad (24)$$

The gradient-based operators can be determined using some pre-determined steps known as algorithms. Algorithm 1 is one

of the general algorithms used for gradient-based edge detection.

#### Algorithm 1: Gradient-based edge detection algorithm

```

1: Define x and y operators(ox and oy)
2: gx ← convolve(img, ox)
3: gy ← convolution(im,oy)

13:     detected_edges|i| ← 1
14:   else
15:     detected_edges|i| ← 0
16:   end if
17: end for
18: return detected_edges

```

#### IV. ALGORITHMS BASED ON SECOND DERIVATIVES (NON-GRADIENT-BASED)

The methods outlined in the previous discussions merely involve filtering the image with various masks without considering the edges' properties or the image's noise. The second Derivative first dealt with the noise problem before going into edge detection. It is based on the concept introduced by Haralick and Marr and Hildreth Algorithms [26], [27]. This idea brings us to the concept of the Laplacian operator.

##### A. Laplacian Operator

Pierre-Simon de Laplace first applied the Laplace operator to the study of celestial mechanics or the motion of objects in space, and it is named after him. Since then, the Laplace operator has been used to represent many phenomena, including electric potentials, heat and fluid flow diffusion equations, and quantum physics. It's also been requested in discrete space, where it's been employed in image processing and spectral clustering applications [28].

The intensity variations in the sharp zero-crossing of an image  $f$  can be calculated using the Laplacian operator ( $\nabla^2$ ). Consider a 1D signal  $f(x)$  in Fig. 8. The edge is located at the local extrema, which is the first Derivative of the signal ( $\partial f / \partial x$ ). But in the case of the second Derivative of the image (i.e., the Derivative of an image ( $\partial^2 f / \partial^2 x$ )). The zero-crossing through each peak of the signal indicates an edge. Peaks are not obtained at the edges, but a strong zeros-crossing indicates an edge (Fig. 8).

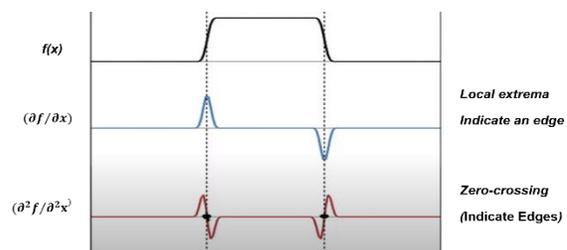

Fig. 8. Second Derivative in 1D Signal.

The zero-crossing is obtained through the Laplacian operator in Eq. 25, known as dell square operator II.

$$\nabla^2 I = \frac{\partial^2 I}{\partial x^2} + \frac{\partial^2 I}{\partial y^2} \quad (\text{D1 square II}) \quad (25)$$

When Eq. 25 is applied to an image, the edges obtained are zero-crossing in the Laplacian of the image. The Laplacian operator does not provide the direction of the edges but a sharp zero-crossing which indicates the location of the edge. In discrete images, the second Derivative is in terms of finite difference (difference of the difference). This difference requires at least three pixels (3x3), known as the 3x3 Laplacian operator. Assuming the physical distance between the pixels is epsilon. We obtain a finite difference using the 3x3 image pixels in Fig. 9.

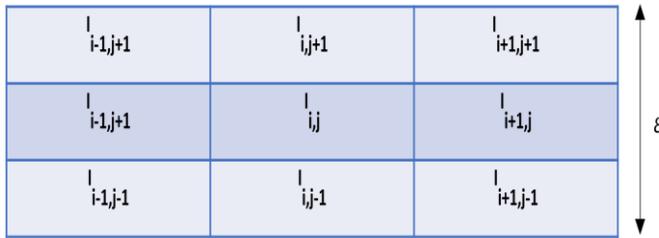

Fig. 9. 3x3 Laplacian Operator.

Fig. 9 is a 3x3 Laplacian operator called the "Del square operator II," where the epsilon (ε) denotes the distance between the pixels. It is referred to as the sum of the second Derivative of the image for x and the second Derivative of the image for y. For example, obtain an output of the Laplacian operator for the center pixel (I<sub>i+1, j</sub>) from the above 3x3 operator. Eq. 26 and Eq. 27 are derived.

$$\frac{\partial^2 I}{\partial x^2} \approx \frac{1}{\epsilon^2} (I_{i-1,j} - 2I_{i,j} + I_{i+1,j}) \quad (26)$$

$$\frac{\partial^2 I}{\partial y^2} \approx \frac{1}{\epsilon^2} (I_{i,j-1} - 2I_{i,j} + I_{i,j+1}) \quad (27)$$

$$\nabla^2 I = \frac{\partial^2 I}{\partial x^2} + \frac{\partial^2 I}{\partial y^2} \quad (28)$$

Adding Eq. 26 and Eq. 27 and the Derivative of I with respect to y formulate the convolution mask in Eq. 29:

$$\nabla^2 \approx \frac{1}{\epsilon^2} \begin{bmatrix} 0 & 1 & 0 \\ 1 & -4 & 1 \\ 0 & 1 & 0 \end{bmatrix} \quad (29)$$

The convolution mask in Eq. 29 obtained the second Derivative for x and the second Derivative for y. However, the edge can appear in any orientation. Assuming the edge appears in 450°, the epsilon in that direction (I<sub>i,j</sub>, I<sub>i+1,j+1</sub>) is not yet accounted for. This problem is peculiar to a continuous grid. However, the convolution can be modified on a discrete grid to fit all possible orientations in the image. The modified convolution, which is the most applicable Laplacian operator, is obtained in Eq. 30:

$$\nabla^2 \approx \frac{1}{6\epsilon^2} \begin{bmatrix} 1 & 4 & 1 \\ 4 & -20 & 4 \\ 1 & 4 & 1 \end{bmatrix} \quad (30)$$

One of the common algorithms used to implement the Laplacian operator for finding zero-crossing is the Marr-Hildreth algorithm [13]. This method obtains a sharp zero-crossing point by applying a convolution with a gaussian kernel and approximating the Laplacian operator with a 3x3 filter. Presented in Fig. 10 is a general flow diagram for finding zero-crossing, while Algorithm 2 is used for the implementation [13].

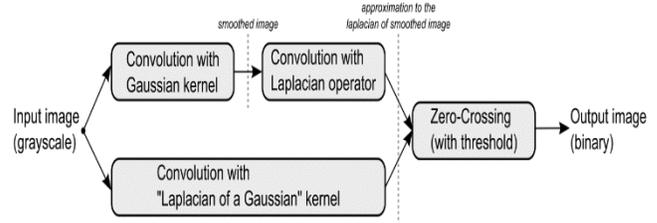

Fig. 10. Marr-Hildreth Algorithm;s Block Diagram for Finding Zero-crossing [13].

**Algorithms 2: Marr-Hildreth edge detection algorithm**

Input required: input img, sigma value σ, size of kernel k, and threshold for zero-crossing Tzc

```

1:   If kernel size then
2:     Kernel ← compute-kernel k (n,σ)
3:   imggm ← convolve (img, k)
4:   #Define Laplacian operator Laplacian L
5:   imgl ← convolve(imggs, L)
6:   else
7:     log_k ← compute_log_k(n,σ)
8:     imgl ← convolve(imggs, log_k)
9:   end if
10:  maxL ← 0
11:
12:  for pixels i in images imgl do
13:    if imgl [i] > maxl then
14:      maxL ← imgl [i]
15:    end if
16:  end for
17:  for pixels i in images imgl, except borders do
18:    for pair (pts1, pts2) of opposite neighbors
19:      of p in inlap do
20:        if (sign(imgl[pts1]) ≠
21:           sign(imgl[pts2])) and (|imgl[pts1]| > TZC then
22:           detected_edges[i] ← 1
23:         else
24:           detected_edges[i] ← 0
25:         end if
26:       end for
27:     end for
28:   return edges

```

**B. Canny Edge Detection**

The Canny Edge Detection Algorithm consists of a specific sequence of steps. Smooth the image with a Gaussian filter first. Then, compute the gradient magnitude and orientation by approximating the partial derivatives with finite-difference approximations. The gradient magnitude is then subjected to a non-maximum suppression. Then, the double threshold technique to find and connect edges [20] using Eq. 31.

$$G(x, y) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2+y^2}{2\sigma^2}} \quad (31)$$

Where  $x$  and  $y$  distance from the origin to the horizontal and vertical direction, respectively,  $\sigma$  is the Gaussian factor that determines the level of smoothing. The gradient of the smoothed array  $G(x,y)$  is employed to generate the  $x$  and  $y$  Partial Derivatives. After that, the results of  $x$  and  $y$  partial are added to obtain the normal gradient. Then non-maximum suppression is applied after determining the edge direction through the use of two thresholding in the Hysteresis [15][20].

Non-maximum suppression: Facilitate the detection of thin layered edges that produces smarter edges. The Canny edge detector employs non-maximum suppression to emphasize the local maxima as edges while suppressing all other ones along with the gradient magnitudes.

Other operators employed the use of a single threshold value to remove edges that do not meet the required edge limit. Canny uses Hysteresis with upper and lower threshold values to suppress the edge that falls below the required threshold limit. If the high threshold is  $T1$ , the low threshold is  $T2$ , and the gradient magnitude is  $GM$ , then  $GM < T1$  are dropped, and  $GM > T1$  are maintained as the edge. However, an edge that falls between  $T1$  and  $T2$ , is only maintained if it has a pixel value higher than  $T2$  [11] and is expressed it as:

$$GM < T1 = \text{drop}$$

$$GM > T1 = \text{maintain}$$

$$\text{If } T2 \leq GM < T1$$

$$GM = \text{edge if Pixel } GM > T2 \forall i \in I(x, y)$$

The canny edge detector has the advantage of intensive noise filtering than other detectors. It has three distinct attributes that differentiate it from the other detectors. Table II shows the advantages and disadvantages of various edge detection methods.

Low error rate: The detected edges are refined not to include non-edges. It also ensures that all occurring edges are not missed. This is achieved by Eq. 32.

$$SNR = \frac{\int_{-w}^w G(-x)f(x)dx}{n_0 \sqrt{\int_{-w}^w f^2(x)dx}} \quad (32)$$

Where  $f$  is the filter,  $G$  is the edge signal; the denominator is the root-mean-square (RMS) response to noise  $n(x)$  only.

Good localization ensures a minimal distance between the actual edge and the detected edge which is expressed in Eq. 33.

$$\text{Localization} = \frac{1}{\sqrt{E[X_0^2]}} = \frac{|\int_{-w}^w G'(-x)f'(x)dx|}{n_0 \sqrt{\int_{-w}^w f'^2(x)dx}} \quad (33)$$

Single response rate: Each detected edge should maintain a single response in the total edges detected. This is implicit in the first criterion but made explicit about eliminating multiple responses. The first two criteria can be minimized by setting the parameter in Eq. 34 [29].

$$f(x) = G(-x) \quad (34)$$

TABLE II. ADVANTAGES AND DISADVANTAGES OF VARIOUS EDGE DETECTION METHODS

Edge detection methods	Advantages	Disadvantages
An algorithm based on the first Derivative (Robert, Prewitt, and Sobel)	Fast and more accessible in computation Edges are detected along with their orientation.	Sensitive to noise. The inaccurate and unreliable edge detection output
An algorithm based on the second Derivative (LoG)	Due to ease in an approximation of gradient magnitude, the cross-operation detection of edges and their orientation is also simple The characteristics of all directions of the image are fixed. A wide testing area around the pixel is possible	The detection of edges and their orientation degrades the magnitude of the edges and increases the noise Malfunctioning at the corners, curves, and where the grey level intensity function varies
Canny Edge Detector	Better detection in noise conditions.	Do not require zero crossing. Difficult to specify a generic threshold value that works well across all images

## V. EXPERIMENTAL RESULT AND DISCUSSION

The edge detection methods discussed in the paper are applied to five sample images taken from the MICC-F220 CMFD evaluation dataset. The result of each algorithm is shown in Fig. 11.

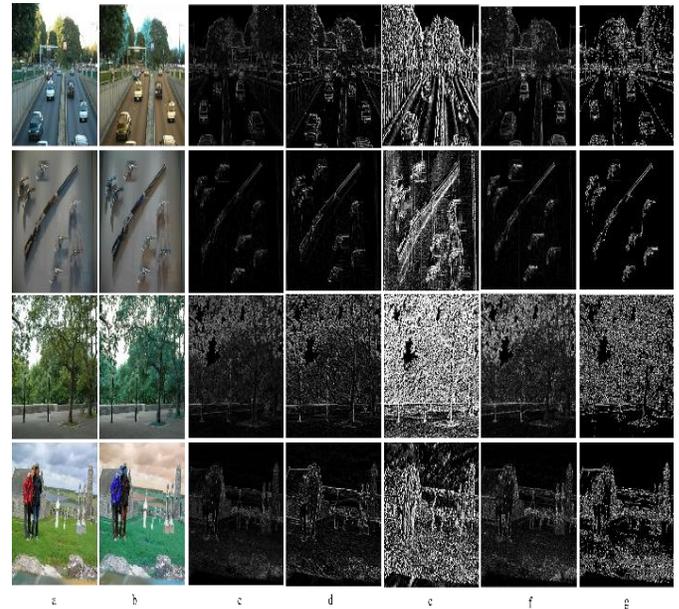

Fig. 11. Comparison of Edge Detection Algorithms using Five Sample Images from MICC-F220 Benchmark Dataset, (a) Original Image (b) Grayscale (c) Robert (d) Prewitt (e) Sobel (f) Laplacian and (g) Canny Edge Detector.

## VI. DISCUSSION

Edge detection methods play an important role in object detection. It is used primarily in the pre-processing stage before feature extraction, an essential step in CMFD. Images are converted to grayscale to reduce noise. Edge detection based on first derivatives is generally sensitive to noise and, in most cases, produces unrealistic features.

We have implemented five selected images from MICC-F220 datasets. Roberts, Sobel, Prewitt, Laplacian, and canny edge detectors have been implemented on those images. The result in Fig. 11 shows that the edges in (c, d and e) detected using Robert, Prewitt, and Sobel, are too cluttered and almost lost the important image structures. The image appeared noisy with thick layered unsmoothed edges, mainly the result in (e), the Sobel, the edges appeared two to three times the pixel thickness. Since most of those images appeared to have lost their essential edge information, the results did not show the appropriate edge structure. However, the result can still indicate the geometric parts of the images but does not reveal the thin layer edges, essential for feature extraction in CMFD.

On the other hand, edge detectors based on second derivatives, such as Laplacian and canny edge detectors, use adjustable parameters such as the size of the Gaussian filter and threshold [20]. The edges are smoothly detected on the image, and almost no noise pixels were detected while protecting the important structural properties in the images, as shown in Fig. 11 (f and g). However, the canny method produces smoother and thin edges than the Laplacian. In Fig. 11 (g), we can see a good view of the various image structures. Fewer noise pixels were detected compared to gradient-based edge detectors.

## VII. CONCLUSION

This study demonstrates that the Canny approach can produce equally acceptable edges with smooth continuous pixels and thin edges. Unlike the canny method, the Laplacian method also has better edge features compared to Robert, Prewitt, and Sobel method. These methods cannot generate a smooth and thin edge. However, the Laplacian and Canny algorithms are often susceptible to noise pixels. Sometimes it is impossible to filter a noisy image perfectly. Noisy pixels that are not eliminated will affect the outcome of edge detection. Based on our investigation, we have determined that between the Canny and other edge detection algorithms, Canny edge detection provided a superior response for CMFD images in MICC-F220 datasets.

**Abstract**—This electronic the Internet of Things (IoT) technology has contributed to several domains such as health, energy, education, transportation, industry, and other domains. However, with the increased number of IoT solutions worldwide, IoT consumers find it difficult to choose the technology that suits their needs. This article describes the design and implementation of an IoT recommendation system based on consumer interests. In particular, the knowledge-based IoT recommendation system exploits a Service Oriented Architecture (SOA) where IoT device and service providers use a registry to advertise their products. Moreover, the proposed model uses a Long Short-term Memory (LSTM) deep learning technique to predict the consumer's interest based on the consumer's data. Then the recommendation system do the mapping between the consumers and the related IoT devices based on the consumer interests. The proposed Knowledge-based IoT recommendation system has been validated using a real-world IoT dataset collected from Twitter Application Programming Interface (API) that include more than 15,791 tweets. Overall the results of our experiment are promising in terms of precision and recall. Furthermore, the proposed model achieved the highest accuracy score compared with other state-of-the-art methods.

**Keywords**—Internet of things; IoT; knowledge-based; recommendation system; service-oriented architecture; SOA; long short-term memory; LSTM; deep learning

## I. INTRODUCTION

The number of Internet of Things (IoT) devices connected to the internet is growing exponentially. According to statistics [1], the number of devices connected to the internet will keep increasing to reach 19.1 billion devices by the year 2025. IoT technology plays a vital role in improving services provided in several domains such as energy, transportation, food production, water supply, health care, education, and other crucial services [2,3,4,5]. IoT Technology has the capability of solving several issues related to smart grids, warming systems, saving water, increasing smart farms, and are considered to be the main part when it comes to smart cars.

With the accelerated growth in the number of connected IoT devices and the targeted services that the IoT devices are designed for, IoT services' consumers face an issue in choosing the appropriate IoT devices and services that suits their needs [6,7,8,9]. Therefore, novel techniques are required to help IoT services' consumers in choosing the suitable IoT devices and services that makes their life easier and their daily activities more efficient. Traditional techniques presented in the literature that involves recommendations from other

consumers or IoT devices and services reputation based on other consumers' ratings might be impractical in this case (i.e., such as collaborative filtering or content-based techniques). For example, let us say consumer  $x$  recommended IoT device  $i$  to consumer  $y$  because it's good in saving energy. However, consumer  $y$  misses IoT device  $t$  that have more features related to consumer  $y$  field which is health (i.e., consumer  $y$  is a doctor and more interested in health related gadgets and IoT devices). Knowledge-based techniques can be more beneficial especially when predicting suitable IoT devices and services based on the IoT services' consumers knowledge [10] (i.e., consumer interests are derived from her knowledge).

Consumer interest recognition is becoming an important research problem [11,12]. Consumer interest analysis is the procedure of evaluating, identifying, and understanding the interests, sentiments, qualities, attitudes, and traits of an individual. The consumer interest analysis is beneficial in identifying targeted consumers and improving consumer's service experience. Social media is a good platform for consumer interest analysis where the consumers text, photos, shares, likes, dislikes are used to understand the consumers behavior [13,14,15]. Knowledge-based techniques are used to improve the recommendation process of IoT devices for IoT services' consumers. Hence, this research focuses more on the knowledge of IoT services' consumers by analyzing their tweets from Twitter. Then based on the consumers interests profiling, the knowledge-based recommender system starts the mapping process between the IoT devices registered by IoT device and service providers and the appropriate consumers.

The purpose of this article is to present the design and implementation of a knowledge-based IoT recommendation system architecture to enhance the recommendation of IoT devices and services for users of IoT services. The knowledge-based IoT recommendation system is based on a Service Oriented Architecture (SOA) and a deep learning model to predict the consumer's interest using the consumer's data. The contribution of this work can be outlined as follows:

- 1) A knowledge-based IoT recommendation system based on SOA is designed and implemented to recommend IoT devices and services to consumers.
- 2) This study uses a deep learning model called Long Short-term Memory (LSTM) to classify IoT services' consumers based on their interests.
- 3) The knowledge-based IoT recommendation system is demonstrated using a prototype implementation and experiments using a Twitter API dataset with 15,791 tweets.

The rest of the article is organized as follows: The literature review is discussed in Section II, the design of the knowledge-based recommendation system architecture and the IoT services consumers' interest analysis are presented in Section III, the implementation and experimentation are discussed in Section IV, Section V concludes with some concluding remarks and directions for future work.

## II. LITERATURE REVIEW

Several research works have recognized the significance of recommendation systems for IoT environments and discussed different recommendation techniques including: i) content-based, ii) collaborative filtering, iii) knowledge-based, and other techniques [16,17,18,19,20]. Other researchers conducted more specific survey papers on IoT recommendation systems related to the fields of context-aware [21], trust [22], and mobile health (m-health) [23]. Some research works used a content-based technique to recommend IoT devices and services. For example, Frey et al. [24] propose a novel recommendation system that collects IoT related information into inventories from smartphones to facilitate IoT device providers in recommending new personalized IoT devices that are similar to the ones that IoT services consumers are using. In particular, the recommendation system consists of three layers including: i) data gathering from mobile device, ii) building a digital inventory, and iii) creating personalized recommendations. Unlike this research work that neglects the idea of predicting suitable IoT devices and services based on the IoT services' consumers knowledge, a knowledge-based technique is employed when predicting suitable IoT devices and services. In other words, it's more likely that the IoT services' consumers would prefer IoT devices and services that are related to their interest.

Other research works used a collaborative filtering technique to recommend IoT devices and services. For example, Forouzandeh et al. [25] propose an IoT recommendation system based on a collaborative filtering technique. In particular, the system analyzes IoT services consumers' behaviors and uses the Cosine similarity to aggregate the distance between two IoT devices or IoT services consumers. The proposed system architecture consists of three modules including IoT devices, IoT services, and IoT services consumers. Kashaf [26] presents an IoT recommendation system based on a clustering technique that overcomes traditional collaborative filtering techniques that suffer from scalability and sparsity issues. In particular, the study compares the performance of several clustering algorithms including k-means, fuzzy c-mean, single-linkage, and self-organization maps. In the evaluation of these clustering algorithms the authors used several datasets including: i) LDOS-CoMoDa (i.e., movie ratings), ii) InCarMusic (i.e., music ratings), iii) Apps in Frappe' (i.e., apps ratings), iv) POI in STS (i.e., rating of places), v) TripAdvisor (i.e., hotel ratings), vi) apple store ratings (i.e., apps ratings), and vii) drug review (i.e., patent reviews on drugs); where the performance of self-organization maps overcomes the other clustering algorithms. Unlike these research works that use collaborative filtering techniques for recommending IoT devices and services and use datasets that

are not related to IoT devices and services to evaluate their proposed approaches; A real-world IoT dataset collected from Twitter, which included 15,791 tweets, was used to evaluate our proposed approach of analyzing consumers' interests in IoT services.

Some research works used a hybrid technique to recommend IoT devices and services. For example, Bouazza et al. [27] propose an IoT recommendation system based on a hybrid technique (i.e., collaborative filtering and knowledge-based techniques). In particular, the authors propose to use collaborative filtering and ontology to recommend IoT services that suit IoT services consumers' needs. The proposed ontology namely, Social IoT (SIoT) consists of two different ontologies including social network ontology and IoT ontology. The proposed system uses SIoT ontology to identify the relationship between the IoT services consumer, IoT devices and IoT services to aggregate the IoT services consumer preferences. Moreover, the proposed system determine the top N IoT services based on other IoT services consumer ratings. Yao et al. [28] present a novel framework for recommending things of interest in IoT environments. In particular, the proposed framework is based on a probabilistic matrix factorization model. The model uses three different matrices including: i) user-user relationship matrix, ii) the thing-thing correlation matrix, and iii) the user-thing usage matrix. Unlike these research works that uses ontologies to predict the IoT services' consumers prior knowledge about IoT devices and services, our proposed approach complements these research works by using a deep learning model namely, Long Short-term Memory (LSTM), to classify IoT services' consumers based on their interest and recommend the appropriate IoT devices and services accordingly.

Knowledge-based techniques and IoT technology is used in the literature for recommendations for smart city development and education systems. For example, Xin et al. [29] propose a knowledge-based education recommendation system utilizing IoT technology. In particular, the proposed recommendation system uses an ontology of scientific papers in the field of entrepreneurship (i.e., the authors used it as an example of building an ontology for the education system) and factorization matrix to measure the relevance of users' feedback. Bokolo [30] presents a case-based reasoning recommender system for smart city development (i.e., case-based reasoning is considered as a knowledge-based technique). The main notion of the system is to build a case library which represents a prior experience in the development of smart cities and measure the similarity of the current case with the ones stored in the library. Unlike these research works that use knowledge-based techniques and IoT technology for the recommendations of smart city development and education systems, knowledge-based techniques are used in recommending appropriate IoT devices and services.

IoT technology is also utilized in the literature for context-aware recommendation systems. For example, Cha et al. [31] present an IoT platform for real-time context-aware recommendation. In particular, the architecture of the proposed IoT platform uses a geofencing technique to model the user context-aware based on the location, time and

surroundings data collected from IoT users' devices. The proposed IoT platform has been demonstrated using a tourism application. Gyrard and Shetha [32] propose a knowledge-based recommendation system that uses IoT technology for the health-context recommendations. In particular, the proposed system exploits a knowledge repository which consists of linked open datasets and ontologies to recommend alternative medicine for daily discomforts such as fever and headaches. Jabeen et al. [33] present a hybrid-based cardiovascular health recommendation system that uses IoT technology. In particular, the proposed system uses four classifiers including Multi-layer Perceptron (MLP), Support Vector Machines (SVM), Random Forest (RF), and Naive Bayes (NB) for the process of classifying cardiovascular diseases. The classifiers are capable of predicting eight types of cardiovascular diseases (e.g., Hypertension and Acute Coronary Syndrome) using a dataset of cardiovascular diseases. In addition, the proposed system uses collaborative filtering technique for community advice on treatments. Gladence et al. [34] propose a recommendation system for home automation using IoT technology. In particular, the authors use Natural Language Processing (NLP) and voice recognition to help unfortunate people to gain control over IoT devices and the propose system makes recommendations based on the users iterations with the system. Mohamed et al. [35] present a collaborative filtering recommendation system for e-commerce products that uses IoT technology. In particular, the proposed system uses data collected from IoT devices to identify user behavior and other users' feedback on products to make the recommendation of personalized e-commerce products. Unlike these research works that uses IoT technology for recommending products and other context-aware related recommendations such as health related applications, this paper focus on recommending IoT devices and services.

### III. KNOWLEDGE-BASED IOT RECOMMENDATION SYSTEM ARCHITECTURE

In this paper, a knowledge-based IoT recommendation system architecture is proposed that uses the Service Oriented Architecture (SOA) to deliver IoT devices and services' recommendations based on IoT services consumers' prior knowledge about IoT devices and services. Fig.1 depicts the architecture of our knowledge-based IoT recommendation system which consists of three different layers including: i) the IoT Device and Service Providers Layer, ii) the Knowledge-based IoT Recommendation Layer, and iii) the IoT Services Consumers Layer.

The IoT Device and Service Providers Layer. This layer consists of several IoT device and service providers where IoT devices are provided through shipping companies to IoT services consumers. IoT services are normally provided through web portals and mobile applications. The IoT device and service providers interact with Knowledge-based IoT Recommendation Layer through the IoT Device and Service Registry where they can advertise their IoT devices and services. In order to register the IoT devices and services, the

providers need to add the IoT device or service ID, description, and choose an IoT category. In this phase of our work, five different categories are identified for IoT devices and services namely Health, Energy, Education, Transportation, and Industry.

The Knowledge-based IoT Recommendation Layer. This layer consists of eight components including: i) IoT Services Consumers Identity Management (IdM), which is responsible for managing the IoT services consumers identities and require IoT services consumers to register their credentials when they attempt to use the recommender system for the first time, ii) IoT Services Consumers Tweets Collector which is responsible for collecting the IoT services consumers tweets from Twitter API (i.e., this component will be elaborated further in Section 3.1) after requesting their permission to gain access to their Twitter account, iii) Term Frequency–Inverse Document Frequency (TF-IDF) Calculator which is responsible for measuring the terms relevance in the IoT services consumers tweets (i.e., which will be explained in detail in Section 3.2.1), iv) IoT Services Consumers' Interests Analysis which is responsible for identifying the IoT services consumers' interests (i.e., prior knowledge about IoT devices and services, more details about the IoT services consumers' interests identification are presented in Section 3.2.2), v) Categorized IoT Services Consumers is responsible for storing the IoT services consumers categories based on the identified interests (i.e., whether the IoT services consumers interested in IoT devices or services related to the health, energy, education, transportation, or industry domain), vi) IoT Device and Service Registry is responsible for managing the IoT devices and services advertisements where IoT device and service providers are required to register their IoT devices and services by adding the IoT device or service ID, description, and choose an IoT category as aforementioned earlier, vii) Recommendation Handler is responsible for handling IoT device and service recommendation requests from IoT services consumers and recommendation feedbacks, and viii) Recommendation Mapper which is responsible for mapping the recommendations based on the IoT services consumers' category (i.e., based on their interests) and the IoT device and service registered in the IoT Device and Services Registry (i.e., this component will be elaborated further in Section 3.2.3).

The IoT Services Consumers Layer. This layer consists of several IoT services consumers who use IoT devices received from IoT device and service providers through shipping companies. IoT services consumers also use IoT services through web portals and mobile applications. The IoT services consumers interact with Knowledge-based IoT Recommendation Layer through the Recommendation Handler where they can request an IoT device and service recommendation and receive the recommendation feedback. In order for the IoT services consumers to start using the recommender system, they are required to register their credentials first through the IoT Services Consumers Identity Management (IdM).

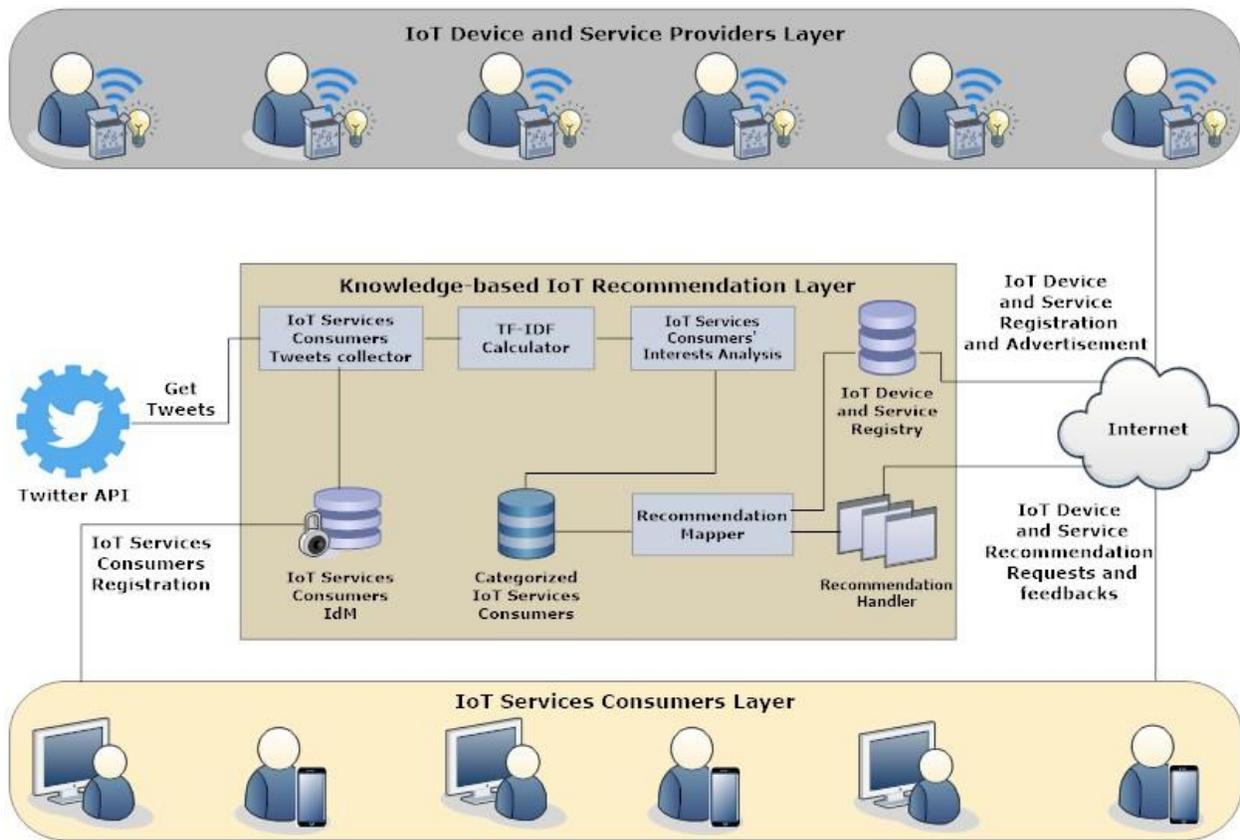

Fig. 1. A Knowledge-based IoT Recommendation System Architecture.

A. IoT Services Consumers' Tweet Collector

The IoT Services Consumers' Tweets Collector is used to get the IoT services consumers tweets based on IoT categories. According to several research works the IoT devices and services are applied in several domains including health, energy, education, transportation, and industry [16,17,18,19,20]. Thus, these application domains were used as categories for IoT service consumers' interests. Then, several keywords are used to retrieve tweets related to each IoT proposed interests' category as shown in Table I (i.e., in Section 4.2, the dataset is described in more detail). Then the IoT services consumers' tweets collector uses these keywords to collect the IoT services consumers tweets from Twitter API.

B. IoT Services Consumers' Interests Analysis

1) Term Frequency-Inverse Document Frequency (TF-IDF): Term frequency and inverse document frequency (TF-IDF) is a statistic metric used in text mining that determines how relevant a term is to a particular IoT services consumers tweet comparing with all IoT services consumers tweets. TF-IDF assigns two scores to each word in an IoT services consumers' tweets: term frequency (TF) and inverse document frequency (IDF). IDF calculates a word's inverse document frequency, whereas TF calculates the number of times a term appears in an IoT services consumers' tweets. In this paper, the TF-IDF is computed for the most frequent K vocabularies for all posts for the purpose of modeling different terms. Each

IoT services consumers tweet has a K-word dictionary reflecting the importance of each term, and the value is 0 if the term does not appear in the IoT services consumers' tweets. A matrix of  $K \times N$  can be constructed as the input of LSTM model (see Section 3.2.2) based on the corresponding K-word TF-IDF dictionary. The TF-IDF weight of that sentence is computed by multiplying the two scores [36].

TABLE I. THE IOT PROPOSED INTERESTS' CATEGORIES AND RELEVANT KEYWORDS

IoT	Keywords
Energy	Energy Consumption Energy Conservation Energy Technologies
Health	Health Technologies Wearable Technologies Digital Health Health Informatics
Industry	Industry Technologies Smart Industry Industry Solutions
Transportation	Transportation Solutions Smart Transportation Transportation Technologies
Education	Smart Classrooms Education Technology Education Automation

Where TF-IDF denotes the importance of a phrase in an IoT services consumers' tweet. The higher the TF-IDF weight score, the more significant the term in the IoT services consumers' tweets. The suggested model extracts and models different terms in our dataset using the TF-IDF measure. The following equations (1) and (2) can be used to compute TF and IDF of terms:

$$TF(t) = \frac{\text{Number of times word appear in documents}}{\text{Total number of words in documents}} \quad (1)$$

$$IDF = \log \frac{\text{Total number of documents}}{\text{Frequency of word in all documents}} \quad (2)$$

Here, the TF-IDF value is computed by making a product of the two statistics which means the weight of the words as in Equation (3):

$$TF-IDF(t) = TF(t) * IDF(t) \quad (3)$$

TF-IDF is used in this study because it provides a vector representation of the IoT services consumers tweets. The next step is to analyze the IoT services consumers' interests after computing the TF-IDF for our dataset.

2) *IoT Services consumers' interests classification using LSTM model*: The LSTM model is a powerful deep learning algorithm that produces excellent results and has been applied to several text classification tasks [37, 38, 39, 40]. Our study employs a LSTM model to learn high-level discriminative representations and to identify the IoT services consumers' interests across several categories, including education, energy, health, industry, transportation, and others. Using TF-IDF to extract input representations, the structure of LSTM is expressed in the following manner:

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (4)$$

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (5)$$

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \quad (6)$$

$$c_t = f_t \odot c_{t-1} + i_t \odot \tan h(W_c \cdot [h_{t-1}, x_t] + b_c) \quad (7)$$

$$h_t = o_t \odot \tan h(c_t) \quad (8)$$

$i_t, f_t, o_t$  and  $c_t$  are the input gate, forget gate, output gate, and cell input vector respectively. The last hidden state is  $h_{[t-1]}$ , the current input is  $x_t$ , the weighted matrix is  $W *$ , and the biases are  $b *$ . The  $\sigma$  is a logistic sigmoid function, while the  $\tan h$  function is a tangent function. The element-wise product of two vectors is  $\odot$ .

Our LSTM model has the following configurations. It uses 2000 epochs and a loss function namely mean squared logarithmic error with adam optimizer. The softmax activation function is used in all the input, hidden and output layers. The total number of tunable parameters used in the proposed model are summarized in Table II.

TABLE II. THE DESCRIPTION OF THE PROPOSED LSTM MODEL

Layer (type)	Output Shape	Param #
Embedding	(None, 25, 50)	1,647,250
Spatial Dropout1d	(None, 25, 50)	0
LSTM	(None, 124)	29,440
Dense	(None, 5)	325
Total params		1,677,015
Trainable params		1,677,015

3) *Recommendation mapper algorithm*: In the knowledge-based IoT recommendation system, we propose that the Recommendation Mapper is responsible for mapping the recommendations based on the IoT services consumers' category  $\tau(c)$  and the IoT device ( $i$ ) or IoT service ( $i$ ) that has the same IoT device and services category  $\tau(i)$  which are registered in the IoT Device and Services Registry  $R_i$ . Then the Recommendation Mapper starts the mapping process and updates the recommendation table  $\mu(c)$  and present the recommendation  $m$  to the IoT services consumers  $c$ . Algorithm 1 shows the brief process of the Recommendation Mapper.

#### IV. IMPLEMENTATION AND EXPERIMENTATION

This section describes the knowledge-based IoT recommendation system for evaluating the IoT services consumers' interest classification model collected using Twitter API. Second, we explain the dataset that we have collected using Twitter API to evaluate the IoT services consumers' interest classification model. Finally, the results of the empirical experimentation are discussed to validate the performance of the classification model for IoT services consumers' interests.

##### A. System Implementation

The implementation of the knowledge-based IoT recommendation system is developed using Flutter 3.0.2 for the mobile application's Graphical User Interfaces (GUIs) to enable IoT device and service registration and advertisement, as well as, IoT device and service recommendation requests and feedbacks. PHP 8.1.7 is used for the mobile application backend. Python 3.10.5 is used for the development of the IoT services consumers' interest classification model in the backend. MySQL 8.0.29 for the development of the database.

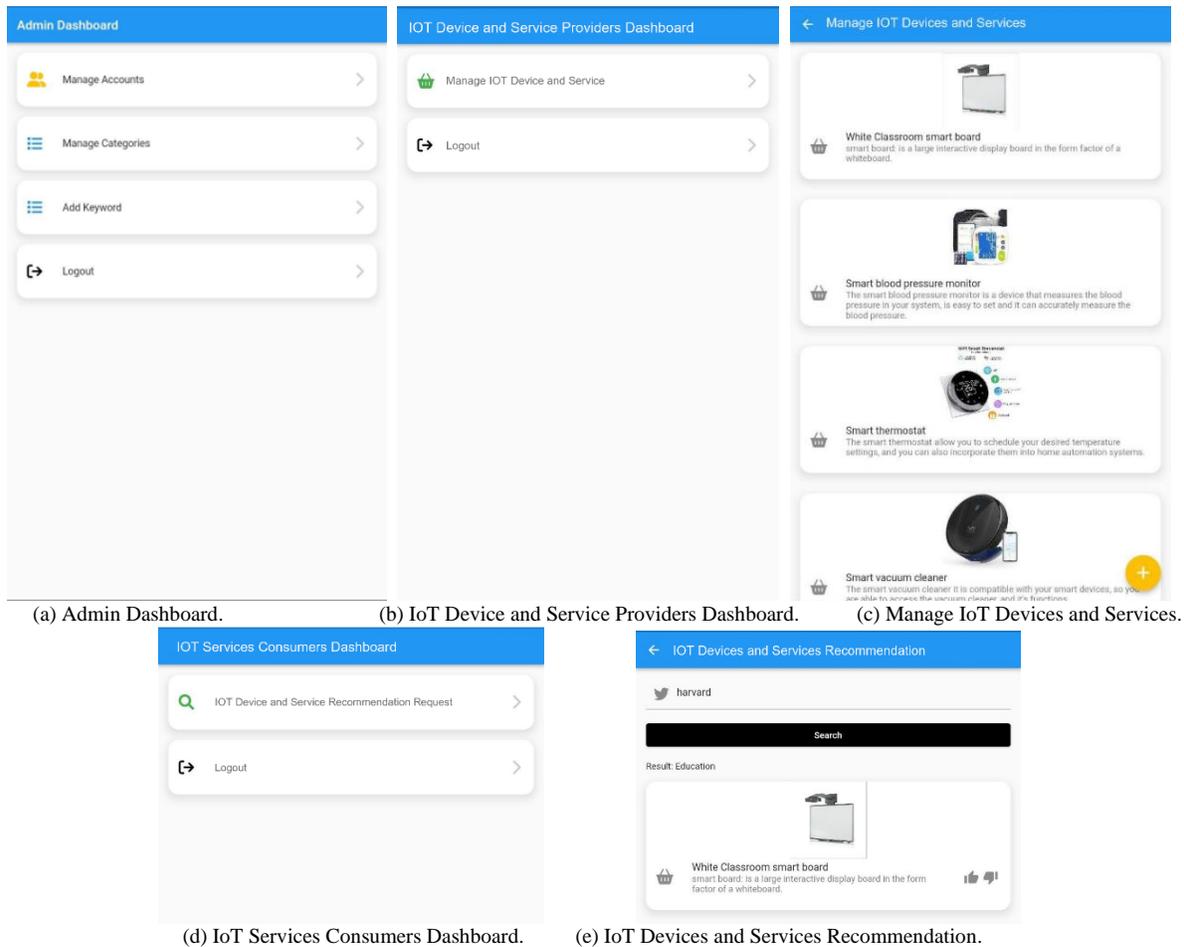

Fig. 2. Knowledge-based IoT Recommendation System's GUIs

The proposed knowledge-based IoT recommendation system uses several GUIs for the Admin, IoT device and service providers, and consumers of IoT services. Fig. 2 illustrates some of the knowledge-based IoT recommendation system GUIs. For example, Fig. 2(a) showcases the admin's dashboard where she can manage the users accounts whether they were IoT device and service providers or IoT services' consumers, manage IoT categories (i.e., as mentioned earlier, the proposed method categorized IoT devices or services into several categories including health, energy, education, transportation, and industry, where the admin can eventually add new categories as required), add keywords related to the IoT categories to enable the IoT services consumers' interests analysis. Fig. 2(b) illustrates the IoT device and service providers dashboard where they can manage their IoT device or service registration and advertisement by adding an ID, name, description, and image for each IoT device or service as shown in Fig. 2(c). Fig. 2(d) showcases the IoT services' consumers' dashboard where they can request IoT device or service recommendation after requesting their permission to gain access to their Twitter account. Fig. 2(e) illustrates the

IoT device and service recommendation to the IoT services' consumers which is based on their interests. Moreover, a like/dislike buttons are added to have some feedback from the IoT services' consumers (i.e., this will help us in calculating the True Positives (TPs), False Positives (FPs), False Negatives (FNs), True Negatives (TNs) later on).

### B. Data Description

To evaluate the performance of the IoT services consumers' interest analysis which is the core of the proposed knowledge-based IoT recommendation system, a real-world IoT dataset is collected using Twitter Application Programming Interface (API). The dataset was collected from August 2021 until October 2021. It contains around 15,791 distinct tweets and 11,421 users. Fig. 3 displays the number of tweets for each category. After that the following pre-processing was performed on the dataset: (i) lower casing all words; (ii) filtering out all stop-words non-alphabetic characters; and (iii) removing all words that occurred too rarely in the documents. Finally, the labeling process is conducted to annotate tweets for the classification task using LSTM model.

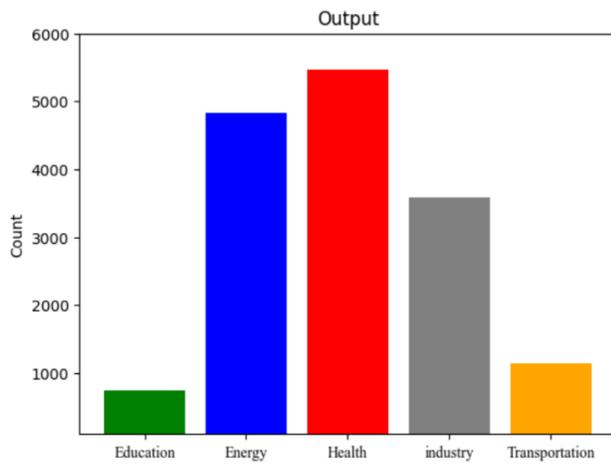

Fig. 3. Data Description.

### C. Performance Evaluations

To evaluate the IoT services consumers' classification using LSTM model, we split the dataset into training and testing datasets 70% and 30% respectively. The training dataset includes 12,632 tweets from 7,995 users and the testing dataset includes 3,426 tweets from 3,159 users whereas we divide these users into 5 groups representing the IoT services' consumers interests categories including health, energy, education, transportation, and industry. In the following Section 4.3.1, we describe the evaluation methods used to test our model's performance. We then described the comparison methods in Section 4.3.2. Section 4.4 summarizes the results of our experiments.

1) *Evaluations methods*: Several well-known evaluation metrics [40] are used including accuracy, precision, recall, and F1-score which are calculated based on the numbers of True Positives (TPs) (i.e., the IoT services consumers' interests classification model predicted positive and it is true), False Positives (FPs) (i.e., the IoT services consumers' interests classification model predicted positive and it is false), False Negatives (FNs) (i.e., the IoT services consumers' interests classification model predicted negative and it is false), True Negatives (TNs) (i.e., the IoT services consumers' interests classification model predicted negative and it is true). These evaluation metrics are calculated as follows:

$$Accuracy = \frac{TPs + TNs}{TPs + FPs + TNs + FNs} \quad (9)$$

$$Precision = \frac{TPs}{TPs + FPs} \quad (10)$$

$$Recall = \frac{TPs}{TPs + FNs} \quad (11)$$

$$F1-Score = 2 * \left( \frac{Precision * Recall}{Precision + Recall} \right) \quad (12)$$

2) *Methods for comparison*: The proposed approach was compared with three well-known models:

a) *Naive Bayes (NB)*: is a supervised machine learning method that utilizes Bayes theory to identify consumer attitudes [41, 42].

b) *Support Vector Machine (SVM)*: is a supervised machine learning algorithm that has been used for understanding consumer interests [43,44].

c) *Logistics Regression (LR)*: is another machine learning model that has been used to analyze user interests from Twitter data [45, 46].

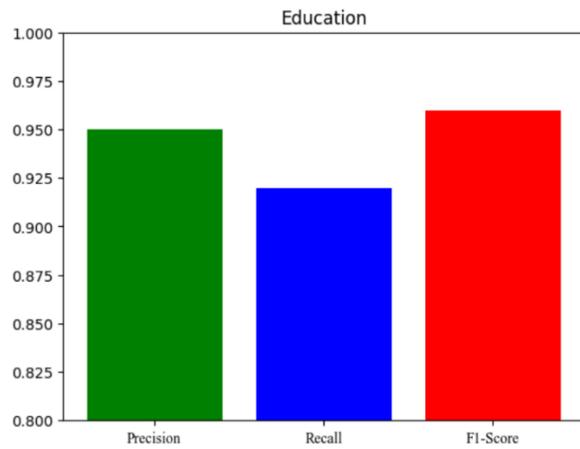

d) *Long- Term Short Memory (LSTM)*: A deep learning model that can be used to perform sentiment analysis on social.

Media [36,47,48].

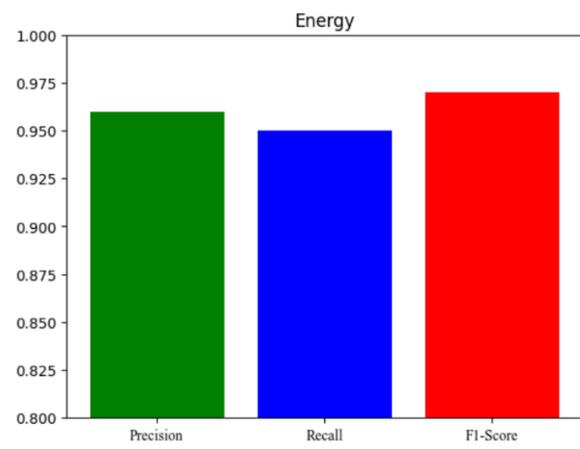

### D. Result and Discussion

The empirical experimentation is performed for the IoT services consumers' interests classification model against the five groups of the IoT services' consumers' interests where the precision, recall, and F1-Score is calculated for each category as shown in Fig. 4. The highest result in precision appeared in the health category to reach 0.96 as shown in Fig. 4(c). Fig. 4(c) shows the highest recall score of 0.95. The highest result in F1-score appeared in the education category and energy category and it is recorded at 0.95 and 0.96 respectively.

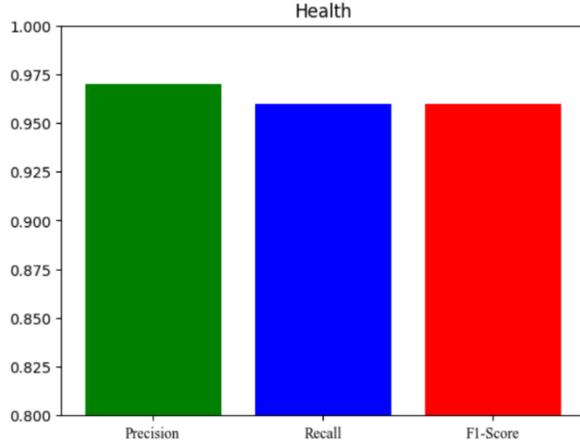

This study used several methods for conducting a comparative study. The LSTM model is compared with three well-known models: NB, SVM, and LR. These models are evaluated in terms of accuracy. Fig. 5 shows the accuracy results for our model compared with other classifiers. Compared to LSTM, SVM, and LR, Naive Bayes performed the worst with an accuracy score of 0.82. Conversely, LSTM has the highest accuracy score when compared to other methods. The LSTM achieved an accuracy of 0.96. Fig. 6 illustrates the training accuracy and validation accuracy of the proposed model. According to the results, the proposed model can identify consumers' interests from social media effectively, resulting in high accuracy in IoT devices and services recommendations. Fig. 7 illustrates the IoT services consumers' interests classification model confusion matrix. The LSTM model correctly predicted 0.96 tweets, while it mis-predicted 0.4.

## V. CONCLUSION

IoT devices connected to the internet have increased dramatically and played an important role in several domains such as health, energy, education, transportation, industry, and other domains. With this increase, IoT services' consumers find it difficult to choose the suitable IoT devices and services that solve their problems. This paper explores how consumers' knowledge about IoT services can be used to predict suitable devices and services. Therefore, a knowledge-based IoT recommendation system is introduced based on SOA to allow IoT device and service providers to register and advertise their IoT device and services and recommend IoT devices for IoT services consumers based on their interest. In particular, this paper presents an IoT services consumers' interests classification model that uses a deep learning model namely, Long Short-term Memory (LSTM), to classify IoT services' consumers based on their interest. In order to demonstrate the feasibility of our proposed approach, a real-world IoT dataset is collected from Twitter that includes more than 15,791 tweets, a prototype system is implemented, and empirical experiments were conducted. The results of the experiments on the IoT services consumers' interests classification model were promising where the overall average results in accuracy, precision, recall, and F1-score are 0.96, 0.95, 0.96, and 0.95 respectively.

In future work, the IoT recommendation system will be extended to be a hybrid recommendation system, which can be enhanced by collaborative filtering techniques. Furthermore, several IoT categories and languages such as Arabic will also be added to evaluate the accuracy of the proposed model. As part of our recommendation system, videos can also be added to explain how to use IoT devices.

**Abstract**—In the telecommunication industry, being able to predict customers' behavioral pattern to successfully design and recommend a suitable tariff plan is the ultimate target. The behavioral pattern has a vital connection with the customers' demographic background. Different researches have been done based on hypothesis testing, regression analysis, and conjoint analysis to determine the interdependencies among them and the effects on the customers' behavioral needs. This has presented us with ample scope for research using numerous classification-based techniques. This work proposes a model to predict customer's behavioral pattern by using their demographic data. This model was built after investigating various types of classification-based machine learning techniques including the traditional ones like decision tree, k-nearest neighbor, logistic regression, and artificial neural networks along with some ensemble techniques such as random forest, adaboost, gradient boosting machine, extreme gradient boosting, bagging, and stacking. They are applied to a dataset collected using a questionnaire in India. Among the traditional classifiers, decision tree gave the best result of 81% accuracy and random forest showed the best result among the ensemble learning techniques with an accuracy of 83%. The proposed model has shown a very positive outcome in predicting the customers' behavioral pattern.

**Keywords**—Customer behavior; data analytics; ensemble learning; machine learning; telecommunication industry

## I. INTRODUCTION

Telecommunication industry is one of the world's largest services providing industry and is known for having the highest number of customers. Customers are the most vital entity of any business platform, and the telecom sector is no exception to that. Bringing in new customers, understanding their needs and requirements, dividing the customers into proper groups to be able to offer the right product or service, gain their loyalty and retain them in the long term are the targets of any customer-centric business. As for the telecommunication sector, retaining customers has become a necessity to survive in the competitive market.

In [1], the authors have discussed the framework containing the development over the recent years in the Indian mobile communication sector. Over 23 years, the Indian telecom sector has seen a fundamental shift in communication modes from fixed line to mobile, making India the world's second-largest telephone market. The exponential rise of smart phones and the

Internet in 2013 marked the beginning of the era of convergence of two technologies: mobile and the Internet. In India, mobile penetration (density) has increased from 4% in 1995, when mobile telephony was first introduced, to 88.50% in 2019 (with 1165.46 million subscribers). The low density of mobile telephony in rural India remains an issue. This high mobile density in urban India is owing to higher per capita income, education, and network externality (as compared to rural India), resulting in a single user owning numerous subscriber identity modules (SIM). The Indian population's total teledensity has surged up to 90.1% as of March 2019 [2]. In this paper, authors have given a deep insight into the telecommunication industry and their relationship with their customers and how it has developed over the years. The necessity to maintain existing consumers has grown over time as the number of new entering customers decrease. The urban India had a teledensity of 159.66% in March 2019, while rural India had a teledensity of 57.5%. This demonstrates the significant differences in people's socioeconomic position based on where they live. For example, metro cities like Delhi had a teledensity of 238.57%, Kolkata had a teledensity of 165.51%, and Mumbai had a teledensity of 165.62 %, whereas the states of Bihar had a teledensity of 59.95 %, Assam had a teledensity of 68.81 %, and so on. As a result, the location is crucial in determining the demands and requirements of customers. This latter compels us to go on to the next level in customer relationship management: customer segmentation.

In the telecommunication sector, geographic location, socio-economic background, age group, gender identity, and so on have a profound impact on the selection of tariff plans by their respective customers. A significant variation in the selection of tariff plans can be observed between customers belonging to a metropolitan city to that of a rural area. Hence, this invites scope for better customer segmentation and customization of services. To address this existing generalized tariff system in the Indian telecommunication industry, our work focuses on predicting customer behavioral pattern that would lead to better-personalized tariff plans by designing a flexible tariff plan for the customers in accordance with their needs.

Keeping those aspects in the hindsight, we propose to analyze the customers' demographic data using different classification-based machine learning techniques such as decision tree, logistic regression, k-nearest neighbor, and

artificial neural network among traditional classifiers and random forest, Adaboost, extreme gradient boosting, gradient boosting machine and stacking among ensemble learning techniques. This study is used to train the model into predicting the customers' behavioral pattern in the form of call duration and data consumption. The result of the proposed model is at par with the desired outcome. With a larger amount of data the performance of the model could be improved and could be enhanced significantly.

The rest of the paper is organized as follows: Section II shows the related works in the research area. Section III discusses the machine learning techniques used in the proposed research model. Section III also provides a detailed idea about the dataset used and the methodology followed in the research. The results that are obtained by the research are detailed in Section IV, Section V highlights the discussion of the present work and the whole work has been concluded in Section VI.

## II. RELATED WORK

The Telecom sector offers services that broadcast voice, data, sound, text, video, and other signal forms. It also consists of wired and wireless activities. Nowadays, when the Internet is the dominating factor, the telecommunication industry has grown tremendously. In order to meet the increasing demand for data consumption, the telecommunication service industry needs to rise so that it can keep up with the high usage of social media platforms. Over the years, authors across the globe have worked with different datasets belonging to the telecommunication sector spanning various countries. Hence, we try in our work to analyze and assimilate a few of the previous works based on tariff plan design in the telecommunication sector. Authors in (Nkordeh et al., 2017) [3] discussed the growth of GSM in the Nigerian telecommunication industry over the period time of 2001 to 2016. They performed a detailed market analysis of the annual growth based on subscribers, revenue growth, and market penetration and how it caused the loss of subscribers. In (Shao et al., 2017) [4], the authors have performed a study which adopts MTFPI (Malmquist total factor productivity index) and data envelopment analysis to conclude that because of their high acceptance of technology developments, the telecommunication service industries had a higher rate of productivity growth. In [5] the author intended to offer a CRM optimization scheme for the telecommunications industry utilizing business intelligence (BI). In the first phase of their work, they conducted a literature survey for all available assignments in the Scopus and web of science. New concepts were introduced to the current work in its second phase and the third phase, the new approach was implemented by a Brazilian telecommunications operator. Authors in [6] used hypothesis testing to study the impact of business intelligence on CRM from the perspective of the employees of telecommunication companies in Oman. Tong et al. discussed a way of increasing customer loyalty through the use of net promoter data mining (NPS) which depended on information gained on decision tree model and k-means clustering [7]. They attempted to identify the reasons for customer loyalty and conclude the connection between the NPS and the financial performance of the customer groups. Jose et al. sought to determine the important parameters affecting the performance of the telecommunication contact

center which was vital to customer satisfaction [8]. A case study on Big Data Analytics in the incoming and external contact center was undertaken by the authors by using principal component analysis (PCA), factor analysis, regression analysis, and cross-tabulation. Bahri-Ammari and Bilgihan proposed a framework that uses hypotheses testing for examining the relationship between customer satisfaction and loyalty and customer retention [9]. In reconciling customer satisfaction among mobile telecommunication providers, Newton and Ragel reviewed the potential relational linkages concerning customer loyalty with the help of correlation and regression analysis [10]. The authors intended to detect the degree, relationships, and impact of customer satisfaction and reliability. In their article, Belwal and Amireh have been focused on the Omani telecommunications market and have evaluated the service quality of two main Omani telecom companies: Omantel and Ooredoo [11]. This was tested on customer attitudinal loyalty to see how the five SERVQUAL factors influenced it, by using a machine learning technique called structural equation modeling.

In a variety of industries, including telecom, understanding how consumers make tariff decisions is a key issue. Most telecommunication service providers assign customers with a variety of mobile plans from which they can choose one that best suits their monthly needs. As mentioned in [12] due to many service providers, the telecom business has become extremely competitive. Their study proposed an association-based rule mining technique to help telecom operators select optimal recharge combo deals that are appropriate for their clients. In another work, Gerpott and Meinert used hypotheses testing on data obtained from the German subsidiary of a large multinational MNO to analyze the degree of tariff plan misfit depending on the socio-demographic features [13].

Consumer overspending in mobile plan selections may result in higher revenues for telecom service providers. However, it could ultimately lead to less satisfied customers and are thus more prone to churn, which is a major problem for telecom service providers. As a result, enhancing customer happiness by encouraging them to make better choices is a superior long-term approach. Author in [14] studied the impact of launching of JIO on the Indian telecommunication market which led to a one-dimensional design of the tariff plans in the long term and resulted in the need for getting a better understanding of the customers' requirements. Bibim and Ramanathan tried to use conjoint analysis to determine the best combination of data, voice, and SMS for postgraduate and undergraduate students, as well as to investigate how they use it [15]. The suitable effects on customer loyalty and customer relationship management in the Indian telecommunications sector had been shown by [16] with the help of Exploratory Factor Analysis and Regression Analysis.

The most challenging issue is the difficulty to comprehend consumers' tariff options. Although customers aspire to save money by selecting a cost-cutting strategy, they are only partially focused on resolving the issue. As a result, rather than making tariff decisions based on predicted demand, they tend to simplify the process by employing cognitive shortcuts, such as heuristic thinking, which leads to systemic tariff biases. Ignoring how consumers utilize heuristic thinking can lead to

failures in consumer protection and market control policies. The authors in [17] have investigated the quality of decision making in a lab setting where consumers were presented with a limited number of mobile phone plan options. However, they have not dealt with varying degrees of tariff complexity as well as unknown usage. According to Jin et al., the goal of their study has been to check whether consumers employ a specific type of heuristic reasoning, known as salience-based decision making when choosing mobile plans and they preferred the approach of hypotheses testing [18]. Based on market segmentation theory, Shuochen et al. have introduced a matching model that links tariff packages and consumers' usage behavior (e.g., total minutes utilized, data consumption, etc.) [19]. Gerpott and Meinert have looked at the relationship between outgoing mobile voice minutes and monthly mobile internet data traffic in a sample of 11,614 residential postpaid members over 25 months, from October 2011 to October 2013 by using regression analysis [20]. Díaz examined the factors determining customer satisfaction and customer loyalty in the Peruvian mobile market [21]. Multinomial logit and the GSEM estimates have showed, based on a survey of 1259 customers, how customer satisfaction determinants can be assessed when satisfaction has been measured using ordered categorical data.

Ascarza et al. have examined the efficacy of retention campaigns with the help of a large-scale field test where recommendations for plans have been provided to some customers and not others [22]. Lee et al. have used conjoint analysis in their research to study the effects of B2B service introduction in the Korean telecommunication industry [23]. In their research, Garcia-Marioso and Suárez have examined the reasons that motivate consumers to transfer mobile operators by using logit model over data from a longitudinal survey of 4110 Spanish mobile users conducted over the period of 2015 and 2016 [24]. Xu et al. presented a system for predicting customer turnover that employed an ensemble-learning technique, including stacking models and soft voting [25]. Bachan and Gaber performed churn prediction by using decision tree, logistic regression, and support vector machine [26]. Capponi et al. used a formal economic model to investigate the incentives for businesses and to offer tailored pricing plans when customers were on the verge of quitting and their service utilization was heterogeneous [27]. Kim et al. addressed a few of the research gaps such as lack of customer support and subscription work that had been based on the benefits and rewards that result in customer subscription, subscription switching costs, and retention of customer support [28].

After analyzing various previous works, we notice that even though various machine learning techniques, alongside many non-IT-based techniques, have been used time and again by researchers to get a better understanding of the customers. These works have primarily revolved around regression analysis and hypothesis testing. To provide personalized tariff plans, many works have tried to study the customers' behavioral pattern. The authors have mostly concentrated on finding the interrelationship among the constraints by using the correlation coefficient and likelihood ratio to get a better understanding of the customers' behavior. Hence, the objective of our work is to take a different approach where irrespective of the interdependency among the constraints. It is not the focal

point of the work. A step-by-step learning approach has been considered where the pattern of different constraints and how it can impact the main governing aim has been comprehensively analyzed.

### III. MATERIALS AND METHODS

Classification falls under the supervised learning category, where the targets are also given access to the input data. Supervised learning is a type of machine learning where the output is predicted by the machines using well-labeled training data that has been used to train the machines. The term "labelled data" refers to input data that has already been assigned the appropriate output. This section accounts for a detailed description about different traditional as well as ensemble learning based classifiers used in the proposed model.

#### A. Traditional Classifiers

1) *Decision tree*: A decision tree is considered one of the few most generally used grading systems in classifying data or understanding the hidden pattern of a particular data collection. It consists of a group of nodes among which the first node is designated as the root node while the rests are known as internal and leaf nodes. The last layer of the decision tree consists of leaf nodes which usually have a predefined class target value. The primary backbone for building a decision tree is repeatedly dividing the nodes on each level based on the criteria for splitting [29]. This splitting and expanding phases last until a stopping criterion are encountered. The various criteria can be represented as follows numerically,

$$InformationGain(b_i, R) = Entropy(z, R) - \sum_{u_{i,j} \in dom(b_i)} \frac{|\sigma_{b_i=u_{i,j}R}|}{|R|} \cdot Entropy(z, \sigma_{b_i=u_{i,j}R}) \quad (1)$$

Where,

$$Entropy(z, R) = \sum_{d_j \in dom(z)} - \frac{|\sigma_{z=d_jR}|}{|R|} \cdot \log_2 \frac{|\sigma_{z=d_jR}|}{|R|} \quad (2)$$

$$Gini(z, R) = 1 - \sum_{d_j \in dom(z)} \left( \frac{|\sigma_{z=d_jR}|}{|R|} \right)^2 \quad (3)$$

Where,  $R$ = a training set;  $b_i$ = a discrete attribute;  $z$ = target attribute;  $u_{i,j}$ = values.

2) *K-Nearest Neighbor*: The KNN classifier assesses the similarity between the new system and the training process instances to classify a new process into either normal or intrusive classes. It also uses the class-label of the nearest  $k$  classes to predict the new process class. The assumption behind the procedure is that the processes of the same class are grouped into the vector space. The computation of the neighbor elements depends on the value of  $k$  which is the number of neighbors to describe the class of the data. The election of the immediate neighbors is done by majority voting. This is a straightforward solution but depends on the value of  $k$ . Euclidean distance metric can be used to calculate the distance and the mathematical representation has been shown in equation 4 [30, 31].

$$d(x, y) = \sqrt{(x_1 - y_1)^2 + \dots + (x_n - y_n)^2} \quad (4)$$

3) *Logistic regression*: Logistic regression is a sort of statistical probabilistic model of categorization. It is also used to forecast a category variable that depends on the predictor variables of one or more of them (such as client characteristics). In our problem, it is used after extensive data preprocessing on the original dataset [25]. The logistic regression uses sigmoid function and it will output the probability which will then be mapped to the two or more classes.

$$s(z) = \frac{1}{1+e^{-z}} \quad (5)$$

where,  $s(z)$  = output between 0 and 1 (probability estimate);  $z$  = input to the function;  $e$  = base of natural log.

For multiclass logistic regression, the binary classification is run multiple times, once for each class. Prediction = max (probability of the classes).

4) *Artificial neural network*: The artificial neural network (ANN) is a mathematical representation that is strongly based on the functional and structural aspects of the human nervous system. Each input of a neural network is multiplied by a weight which is then added to the sum of these weighted inputs, and the bias in the layers following the input layer. The network's last layer contains the transfer function, also known as an activation function, which helps in achieving the desired scalar output. The following is the mathematical representation of an artificial neuron:

$$O(t) = f(\sum_{i=1}^n v_i(t) \cdot I_i(t) + c) \quad (6)$$

where;  $O(t)$  is the output which is found from the neural network at a given time,  $f$  represents the activation or transfer function,  $c$  is the bias,  $I_i(t)$  and  $v_i(t)$  are the inputs and their weights respectively [32].

### B. Ensemble Learning

Ensemble learning is a collection of distinct learning machines or classifiers that work together to produce more accurate and reliable results by combining all methods. An inducer, also known as a strong learner in ensemble methods, is a learner that is randomly well correlated with the actual classification of the labeled training set. While a weak learner is related to the true classification to some extent. Boosting, bagging, and random forests are some of the new techniques that have emerged because of the ensemble learning framework. In the training of the base model, parameter values vary as well, allowing different ensemble components to offer their uniqueness to the framework. As a result, ensemble systems are incredibly versatile and efficient in real-world applications, giving them the ability to solve and approach a wide range of problems. In ensemble learning, there are various aggregation strategies; bagging is one of them, and it is employed in prediction models to reduce variance. Other strategies include: stacking which tries to reduce prediction bias, and boosting which aids in the conversion of several weak learners into an aggregated strong model [29,25]. Fig. 1 shows a generalized tree representation of the work behind ensemble learning.

1) *Random forest*: Random forest is an ensemble study that uses more than one decision-making tree for classification and regression. There is some randomness while selecting the subset and characteristics for the nodes of each tree in the random forest classifier. The Gini index is one of the criteria to divide the data into random forest. The random forest is also important for variables, which does not only contribute to the development of a precise model but also contributes to prediction [29,30]. Fig. 2 shows the tree representation of the working behind a random forest ensemble model.

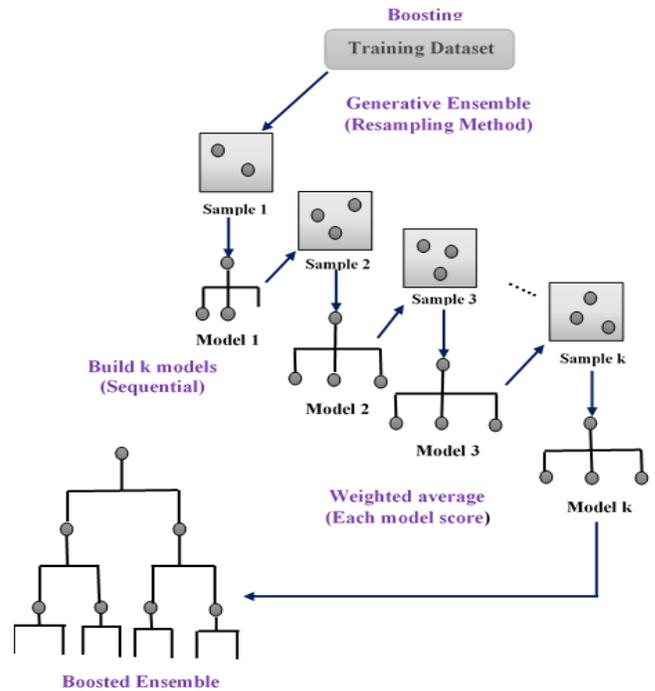

Fig. 1. Tree Representation of Ensemble Learning.

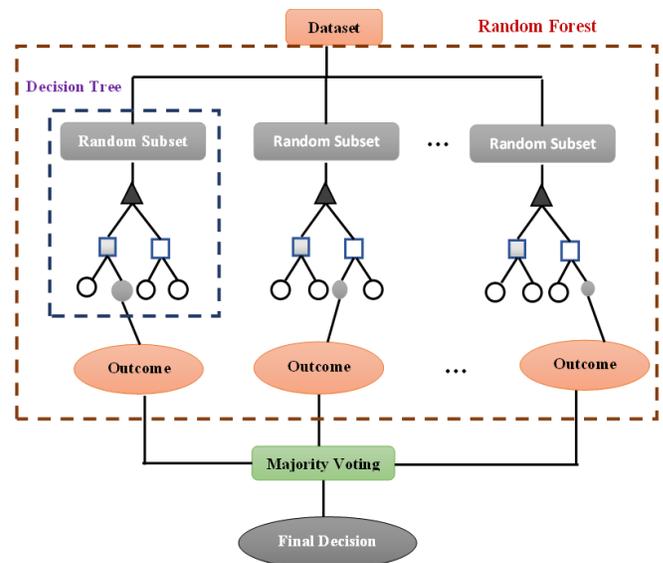

Fig. 2. Tree Representation of Random Forest.

2) *Gradient Boosting Machine (GBM)*: GBM is a frequently used machine learning approach for both regression and classification issues. It is highly effective in solving a wide variety of practical applications. The GBM approach is considered an approach for numerical optimization, which seeks to identify an additive model to minimize loss. The GBM approach builds a new decision tree (i.e., "weak learners") at each step, which will lower loss function most effectively [33, 34, 35].

$$F_M(x) = F_{M-1}(x) + \gamma_M h_M \quad (7)$$

where, M= number of iterations;  $\gamma_M$  = multiplier;  $h_M(x)$  = a base learner.

3) *Extreme Gradient Boosting (XGB)*: XGBoost is a regression tree with the same Decision Tree principles. It promotes regression and classification. This approach is an effective and scalable gradient booster (GBM) variation which is frequently used for computer vision, data mining, and other applications. The training is carried out via an "additive strategy": a tree ensemble model utilizes  $t$  additive functions to predict the output, given a molecule  $i$  using a descriptor  $x_i$  vector [36,37]. The mathematical representation of a simplified objective of XGBoost has been shown in equation 7.

$$L^{(t)} = \sum_{i=1}^n \left[ g_i f_t(x_i) + \frac{1}{2} h_i f_t^2(x_i) \right] + \Omega(f_t) \quad (8)$$

where,  $L^{(t)}$  is the objective function at iteration  $t$  and  $g_i$  and  $h_i$  are the first and second order gradient statistics of the loss function.

4) *AdaBoost*: AdaBoost is the acronym for adaptive boosting. It is a form of classification algorithm model of dichotomy which trains and combines a range of weak classifiers to fulfill the classification criteria of datasets. AdaBoost is adapted to increase the weight of a sample misclassified by the previous weak classifier and to reduce the weight of the correctly classified sample to the following weak learner. AdaBoost's instance categorization can be expressed mathematically as:

$$H(x) = \text{sign}(\sum_{t=1}^T \alpha_t \cdot M_t(x)) \quad (9)$$

where  $M_t$  represents the classifiers while  $\alpha_t$  is the individual weight of each classifier [38, 39].

5) *Bagging*: Bagging is an ensemble learning approach for improving the accuracy of other learning algorithms' predictions. An ensemble method of learning is a strategy that integrates numerous machine algorithms for the prediction that can be done with better accuracy and stability than with only a single algorithm. Bagging is very effective for decision tree, even though it may be used for various types of classification techniques. Bagging is a technique for combining numerous complex models and then averaging (in regression) or majority voting (in classification) the outputs of the different models of the same kind to create a more powerful prediction model [40, 30].

**Input:** Data set  $D = \{(x_1, y_1), (x_2, y_2), \dots, (x_m, y_m)\}$ ;  
Base learning algorithm  $L$ ; Number of base learners  $T$ .

**Process:**

1. **for**  $t = 1, \dots, T$  :
2.  $h_t = L(D, D_{bs}) // D_{bs}$  is the bootstrap distribution
3. **end**

**Output:**  $H(x) = \arg \max_{y \in Y} \sum_{t=1}^T (h_t(x) = y)$  (10)

#### IV. PROPOSED METHODOLOGY

##### A. Dataset Used

A survey in the form of a questionnaire was used to collect the data from different mobile phone users. It has been prepared after consulting with an Indian telecommunication service provider. It was designed by using google form and has been shared among different Indian telecommunication subscribers through different social media platforms, emails, and messages. The data was collected from the legal users of different Indian service providers in the form of a categorical form dataset. The questionnaire contains multiple-choice questions. The unclean dataset contains 476 user information and 88 attributes. Then, we have proceeded to the preprocessing steps which led to the formation of the final refined dataset containing 476 user information and 16 attributes. Table I shows the attribute list of the cleaned dataset and Table II shows the lists of attributes used to calculate the three target attributes obtained after the preprocessing.

TABLE I. FINAL ATTRIBUTE LIST AND THEIR DESCRIPTION

Attribute Name	Labels Assigned	Label Distribution	Description
Type of service used	<ul style="list-style-type: none"> <li>• Cellular Prepaid</li> <li>• Cellular Post-paid</li> </ul>	418 58	Connection type
Age group	<ul style="list-style-type: none"> <li>• Under 18</li> <li>• 19 – 25 Years</li> <li>• 26 – 40 Years</li> <li>• 41- 55 Years</li> <li>• 56 and above</li> </ul>	4 347 77 19 29	Customer age group
Gender	<ul style="list-style-type: none"> <li>• Male</li> <li>• Female</li> <li>• Non-Binary</li> <li>• Others</li> </ul>	309 166 0 1	Customer gender identity
Occupational status	<ul style="list-style-type: none"> <li>• Employed</li> <li>• House wife</li> <li>• Business</li> <li>• Student</li> <li>• Retired</li> </ul>	71 17 8 359 21	Customer occupational background
Income group (income per month)	<ul style="list-style-type: none"> <li>• Below Rs. 20,000</li> <li>• Rs.20,000 – 50,000</li> </ul>	47 64 28 29	Customer monthly income

	<ul style="list-style-type: none"> <li>Rs. 50,000 – 1 Lakh</li> <li>Above Rs. 1 Lakh</li> <li>Dependent</li> </ul>	308	
Education	<ul style="list-style-type: none"> <li>Non-graduate</li> <li>Graduate</li> <li>Post-graduation and above</li> </ul>	300 115 61	Customer educational background
You have been using cellular services for	<ul style="list-style-type: none"> <li>Less than 1 Year</li> <li>1 to 3 years</li> <li>More than 3 Years</li> </ul>	21 117 338	Duration for which the customer has been using the telecom service
Average expense on cellular services per month will be about	<ul style="list-style-type: none"> <li>Less than Rs. 500</li> <li>Rs. 500 – 1000</li> <li>Rs. 1001 – 3000</li> <li>More than Rs. 3000</li> </ul>	308 141 23 4	Approximate monthly expenditure on monthly recharge
Do you use internet	<ul style="list-style-type: none"> <li>Yes</li> <li>No</li> </ul>	471 5	If the customer uses internet
Preferable medium for messaging:	<ul style="list-style-type: none"> <li>SMS/ Offline messaging Platform</li> <li>Online Messaging Platform</li> </ul>	13 463	Customers' preferred medium of messaging
How frequently do you travel?	<ul style="list-style-type: none"> <li>Once a year</li> <li>Twice a year</li> <li>More than twice</li> </ul>	177 126 173	An approximate number of times the customer travels
Where do you travel the most?	<ul style="list-style-type: none"> <li>Within the country</li> <li>Outside the country</li> </ul>	444 32	Travelling preference
Do you use the same number while travelling?	<ul style="list-style-type: none"> <li>Yes</li> <li>No</li> </ul>	450 26	Preferred number used during travelling
Total time spent on call during weekdays	<ul style="list-style-type: none"> <li>1 to 3 hours</li> <li>3 hours to 5 hours</li> <li>5 hours to 10 hours</li> <li>More than 10 hours</li> </ul>	0 204 144 128	Number of hours spent on call during the weekdays and over the weekend. <b>(Target Data)</b>
Total time spent on call during weekends	<ul style="list-style-type: none"> <li>1 to 3 hours</li> <li>3 hours to 5 hours</li> <li>5 hours to 10 hours</li> <li>More than 10 hours</li> </ul>	0 172 154 150	
Total data consumptions	<ul style="list-style-type: none"> <li>Less than 500 MB</li> <li>500 MB to 1 GB</li> <li>1 GB to 3 GB</li> <li>More than 3 GB</li> </ul>	74 66 211 125	Amount of mobile data consumed. <b>(Target Data)</b>

TABLE II. TARGET ATTRIBUTES AND THEIR DETAILS

Target Attributes	Attributes used to obtain the Target Attributes	Description
Total time spent on call during weekdays	Preferable time to connect during the weekdays (Monday- Friday): [Family]	Preferred time of the day to connect over calls during the weekdays. <ul style="list-style-type: none"> <li>Morning (6am – 12 pm)</li> <li>Afternoon (12pm – 5pm)</li> <li>Evening (5pm – 10pm)</li> <li>Night (10pm – 6am)</li> </ul>
	Preferable time to connect during the weekdays (Monday- Friday): [Relatives]	
	Preferable time to connect during the weekdays (Monday- Friday): [Friends]	
	Preferable time to connect during the weekdays (Monday- Friday): [Colleague]	
	Preferable time to connect during the weekdays (Monday- Friday): [Others]	
	Time spent for total calls per day during weekdays (Monday- Friday): [Family]

From Fig. 3, it can be seen that a greater number of weekday calls ranging from three to five hours, and during the weekends a larger number of calls exceeds 10 hours. Our dataset lacks any record which ranges between one to three hours. Fig. 4 shows the count of customers based on their data consumption. As it can be seen in both graphical representations, data imbalance is an issue. However, balancing out the data doesn't have any positive effect on the model outputs. Hence, the step of data balancing was not further considered during the execution of the models.

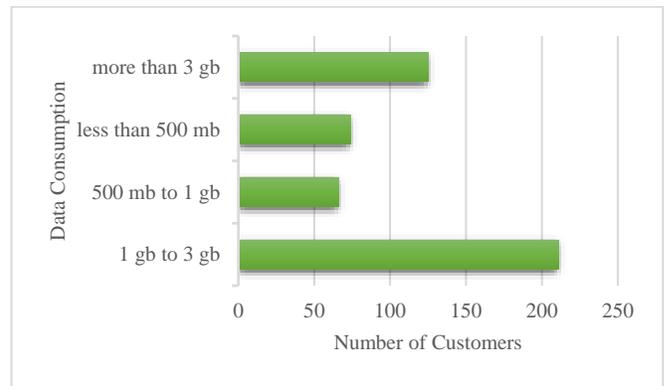

Fig. 4. Count of Customers for Each Data Consumption Range.

### B. Proposed Model

The work proposes a research model which predicts customers' behavioral data like call duration and data consumption, by analyzing their demographic data such as age, gender identity, occupation, education and so on. Different constraints have been taken into consideration to design a generalized model that would provide a better prediction. Even though the machine learning techniques that are used here are already existing and well-known, the proposed approach has not been used in the Indian telecommunication sector. Fig. 5 shows the diagrammatic approach toward the research objective in a step-by-step style.

**Step 1: Data collection.** As discussed in Section 4.1, the data has been collected using a questionnaire through a survey among regular telecom subscribers of the Indian telecom industry. After the data has been collected, it has been divided into two parts: the customer demographic data and customer behavioral data.

**Step 2: Data Preprocessing.** Since the main target is to predict the customers' call duration and data consumption, the behavioral data obtained are used to calculate target attributes as mentioned in Table II. For calculating the data consumption, depending on the browsing history using Internet, the option is replaced by an Internet data unit such as Streaming Video: 353 Mb/Hour; social media: 20 Mb/Hour; Websites: 25Mb/Hour; Chats (if both Video and Voice calls or just Video call): 100 Mb/Hour; Chat (if just voice call): 60 Mb/Hour. For situations where multiple options are selected by the users, the option having the maximum value is selected. Once the target is calculated, the attributes that are used for the purpose and all the other attributes irrelevant to the study are dropped. On the other hand, the demographic data are only cleaned by removing redundant data and null values. After completing all the preprocessing steps, the data has been encoded using one-hot encoding technique.

**Step 3: Training, Testing, and Validation.** After the preprocessing has been completed, the data have been encoded by using the one hot encoding technique and partitioned for the training and testing purpose. The split for the training and testing has been 80% and 20% respectively. As discussed in Sections 3.1 and 3.2, multiple ensemble models and traditional classifiers have been used for the prediction purpose. Other than

all the techniques discussed previously, a stacking ensemble model has been used as one of the ensemble techniques for the predictive system which has been shown in Fig. 6. The stacking model consists of two levels. Level 0 comprises four base classifiers: Decision tree (DT), Random Forest (RF), Logistic Regression (LR), k-nearest neighbor (KNN); and level one consists of LR as the meta classifier. A soft voting technique has been used to predict the final output of the stacking ensemble model. Majority voting, plurality voting, and weighted voting can be used for individual classifiers that produce clear class labels, although soft voting is typically preferred for individual classifiers that produce class probability outputs. When all the individual classifiers are treated equally, the simple soft voting approach simply averages all the individual outputs to produce the combined output, but if we combine the individual outputs by using

various weights, a weight specific to each classifier is generated, and the total output for class  $c_j$  is,

$$H^j(x) = \sum_{i=1}^T w_i h_i^j(x) \tag{11}$$

where  $w_i$  is the weight assigned to the classifier  $h_i$ .

Other used ensemble models: Random Forest, AdaBoost, XGB, GBM, and Bagging. Among these models, Random Forest has given the best accuracy of 83%. The traditional classifiers used have been Decision Tree, Logistic regression, k-Nearest Neighbor, and ANN. Table III presents the detailed tuning parameter specifications of different classifiers that are used in the research during the implementation by using Python.

### C. Performance Metrics

In this work, the proposed predictive model for customer behavior has been evaluated by using accuracy, precision, sensitivity, specificity, F1 score, and kappa analysis. The fraction of total samples properly classified by the classifier is called accuracy.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (12)$$

where TP denotes true positive, FP denotes false positive, TN denotes true negative, and FN denotes false negative. Precision is what percentage of positive forecasts were truly positive.

$$Precision = \frac{TP}{TP+FP} \quad (13)$$

The sensitivity is the fraction of all positive samples that the classifier accurately identified as positive.

$$Sensitivity = \frac{TP}{TP+FN} \quad (14)$$

Specificity is the fraction of all negative samples that have been accurately identified as negative.

$$Specificity = \frac{TN}{TN+FP} \quad (15)$$

F1 score is the combination of precision and sensitivity.

$$F1\ score = 2 \times \frac{Precision \times Sensitivity}{Precision + Sensitivity} \quad (16)$$

For qualitative items, kappa analysis is a statistical measure of inter-rater reliability.

$$k = \frac{p_o - p_e}{1 - p_e} = 1 - \frac{1 - p_o}{1 - p_e} \quad (17)$$

The kappa coefficient varies from 0 to 1 and following statements can be made,

< 0 = agreement equivalent to a chance

0.1 – 0.2 = slight agreement

0.21 – 0.40 = fair agreement

0.41 – 0.60 = moderate agreement

0.61 – 0.80 = substantial agreement

0.81 – 0.99 = almost perfect agreement.

## V. RESULTS

In this work, different classification techniques have been applied to the customers' demographic data to predict their behavioral pattern. As discussed in the previous section, the data collected has been preprocessed to calculate the target attributes: total call duration during weekdays, total call duration during the weekend, and total data consumption. After preprocessing, the desired target has been selected for the classification. In this work, few ensemble learning techniques and some traditional classifiers have been applied. K-fold cross validation has been used, as well, to validate the models, where k is been maintained at 10 irrespective of models. As shown in Tables IV and V, random forest has given the best accuracy of 83% among all the techniques applied. Apart from the performance metrics, the reliability of the model has been tested by using kappa analysis. Random Forest has shown the best result among all the classifiers that are applied with a kappa value of 0.74, which comes under the categorization of substantial agreement. When kappa analysis was performed on the ensemble models, except for the bagging technique, all models have given values within the range of 0.61 to 0.88 which signifies substantial agreement. Models that recorded accuracy of over 80% were AdaBoost, XGB, and the stacking ensemble model whose kappa values have been 0.71, 0.71, and 0.69, respectively. Among traditional classifiers, decision tree has given the best result with an accuracy of 81% and 0.71 kappa value. The other traditional classifying techniques with kappa value of substantial agreement are logistic regression and k-nearest neighbor.

Fig. 7-9 show the bar graph plot of the accuracy, specificity, and precision measures of all the classifiers that are used in this work. Fig. 10 shows the obtained F1-scores and sensitivity from all the classifiers. Concerning the specificity, it can be inferred that there is a small number of false negative samples. As kappa values have been calculated for substantiating the reliability of the proposed approach, Fig. 11 presents the bar plot of the accuracy of each classifier, as well as their corresponding kappa values and Fig. 12 shows a bar plot of the kappa values in decreasing order.

TABLE IV. PERFORMANCE OF ENSEMBLE MODELS

Classifiers	Accuracy	Precision	Sensitivity	Specificity	F1-score	Kappa
Random Forest	0.83	0.83	0.83	0.91	0.83	0.74
AdaBoost	0.81	0.82	0.81	0.90	0.81	0.71
XGB	0.81	0.82	0.81	0.90	0.81	0.71
GBM	0.78	0.77	0.78	0.89	0.78	0.66
Bagging	0.73	0.72	0.73	0.88	0.72	0.58
Stacking	0.80	0.80	0.80	0.93	0.79	0.69

TABLE V. PERFORMANCE OF TRADITIONAL CLASSIFIERS

Classifiers	Accuracy	Precision	Sensitivity	Specificity	F1-score	Kappa
Decision Tree	0.81	0.82	0.81	0.90	0.81	0.71
Logistic Regression	0.74	0.74	0.74	0.87	0.74	0.61
k-Nearest Neighbor	0.76	0.76	0.76	0.89	0.76	0.63
Artificial Neural Network	0.72	0.72	0.72	0.86	0.72	0.57

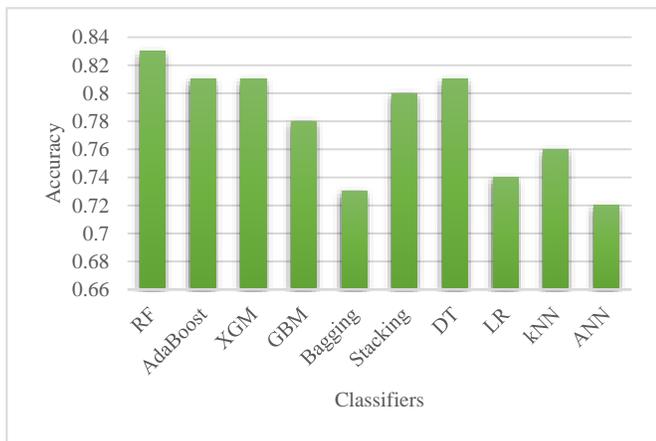

Fig. 7. Accuracy Plot of different Classifiers.

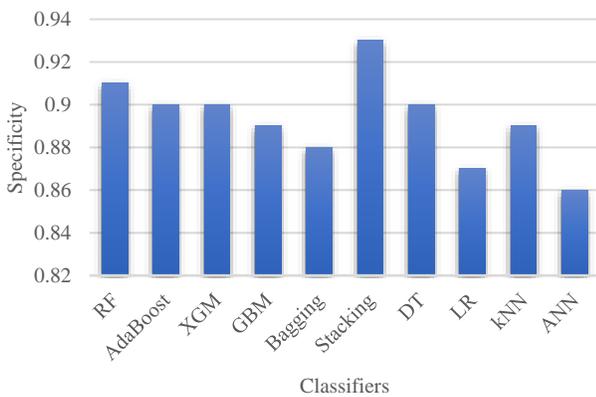

Fig. 8. Specificity Plot of different Classifiers.

Table VI shows some instances of test cases that have been used to test the classification models. It can be seen that test cases 1, 2, and 3 are predicted correctly by using all the classifiers except KNN, which has the least average success rate among all classifiers. Test case 4 is incorrectly predicted by

most of the classifiers other than bagging, stacking, and ANN. Even though the performance accuracies obtained during training of the bagging and ANN models are lower than the other classifiers, yet when applied to certain test cases they have performed better.

5	2	2	2	2	2	2	2	2	1	2	2
Average success rate (%)		80	80	80	80	100	100	80	80	60	100

## VI. DISCUSSION

Personalized tariff plans can solve a lot of problems for the Indian telecom industry. The current generalized status of the tariff, plan design has led to a lot of dissatisfaction among the customers. This can be solved by better analyzing the customers' behavioral pattern and how it varies depending on their socio-economic background. To offer a better recommendation to customers, flexible tariff plans need to be designed and hence the requirement for an effective predictive system.

In this work, a predictive system has been designed to be able to predict customers' behaviors: call duration and data consumption. Different classification models have been tested on the data obtained from the customers to get a better prediction of the customers' behavioral pattern. This can help with understanding what kind of tariff plan should be recommended and for which segment of the customers. Every customer's needs vary based on their lifestyle and background. An ideal scenario for the proposed work would be the current situation where students, teachers, and IT sector personnel has been working online which have led to a drastic increase in data consumption among these people. Therefore, the tariff plans that are recommended for these people should include higher data allocation than those who are working offline. Again, the total call duration of females who are housewives and in the age group over 56 is different from those who are working and of

the age group of 26 to 40. Thus, a desperate need for flexible tariff plans. As shown previously, this work is based on customers' age group, gender identity, educational background, occupational status, monthly income, expenditure on mobile plans, and so on to predict their behavioral pattern.

Comparing to different works of literature on customers' behavioral pattern, this work focuses on determining the feasibility and efficiency of using classification techniques on customers' demographic data to detect patterns. According to the results obtained through this work, ensemble learning techniques and ANN can be used to predict the customers' call duration and data consumption with high efficacy. Service providers can use this proposed model to predict the call duration and data consumption which can be used to design more flexible tariff plans catering to the customers' needs in a much more personalized form. This research model can also be used for customer segmentation depending on their socio-economic background, which will make it easier for recommending the right tariff plan. This can also help with customer retention since retaining the right customer is one of the major goals of any telecom service provider. Investing in the right customer can lead to higher profit for the business. As the dataset varies in all the previous works, hence a usual comparative study was not feasible for the proposed work. Therefore, Table VII only highlights the different inferences that are reached for the general goal of tariff plan design.

Tong et al., 2017	Information Gain on Decision tree Model and k mean Clustering.	Survey data from customers of telecom industry.	Accuracy of 71.24%
Jose et al., 2017	Principle Component Analysis (PCA), Factor Analysis, Regression Analysis and Cross Tabulation.	Data from Telecom contact center.	Sampling adequacy is validated with KMO test score of 0.739.
Gerpott and Meinert, 2017	Hypothesis testing	Data obtained from the German subsidiary of a large multinational MNO.	McFadden's pseudo R2 of 0.085 and coefficient of determination of 0.318.
Bibin and Ramanathan, 2018	Conjoint analysis	Survey data of students.	Result showed that better network and low cost are the main reasons for their choice of service provider.
Dubey and Srivastava, 2016	Exploratory Factor Analysis, Regression Analysis.	Customer Survey data from Indian telecommunication industry.	KMO test score of 0.833.
Jin et al., 2021	Hypothesis testing	Major telecommunication operator in China.	Probability of switching up = 0.002 Probability of switching down = 0.010
Shouchen et al., 2017	Distance method by norm method	Dataset from China telecommunication industry.	The matching result indicates that 302 676 users' current tariff package are not optimized selection and should shift their consumption suit.
Gerpott and Meinert, 2016	Regression analysis	A dataset of residential users of mobile communication services.	63.2% of sampled subscribers share a positive/ complementary relationship between the two services whereas a considerable proportion of 36.8% of subscribers substitutes call minutes by data consumption.
Diaz, 2017	Generalized Structural Equation Modelling (GSEM), Multinomial Logit	Real-life survey data from Peru.	Wald Tests shows that the estimation is statistically significant at 1%.
Lee et al., 2018	Conjoint Analysis	Real life survey data from South Korean Telecom	Conjoint analysis show that free data service provides significantly greater benefits on average than smartphone interphone and Enterprise messenger services do.
García-Mariñoso and Suárez, 2019	Logit model	Real-life survey data collected by Spanish Markets and Competition Authority.	estimated correlation coefficient 0.043, p value= 0.669
Kim et al., 2019	Statistical Analysis	Real life data from Korean company.	In the model 1, amount of the variance (R2=0.210, p < 0.001). In the model 2, amount of the variance (the increase of R2=5.6%, p < 0.001)
<b>This Work</b>	Random Forest	Survey data collected through questionnaire	Accuracy= 83%, Kappa Value= 0.74.

Most of the existing works implementing machine learning are applied on real-life customer data and the inference drawn from those works also varies based on the techniques and the used dataset. (Tong et al., 2017) have used machine learning technique of decision tree and have achieved an accuracy of 71.24%. Compared to our work, this work has produced higher accuracy. Whereas works like (Bahri-Ammari and Bilgihan, 2017; Newton and Ragel, 2017; Gerpott and Meinert, 2016) have used correlation coefficients to draw the inference for their work. In another study (Maji et al., 2017) have implemented pattern recognition by using rule-mining based apriori algorithm to study their customers. Considering the varying factors in every research study on personalizing tariff plans drawing a comprehensive comparative study seems to be not

feasible. As governing hypotheses of each problem varies greatly among each other, hence drawing a common point of inference is not reasonable enough in this kind of situation.

The major challenge that are faced throughout our work is the data collection. In the telecommunication industry, customer data involves the intricate policies of privacy and security preservation. Therefore, collecting enough data has been a huge challenge. For any data related research, the quality of the data is a major concern. In this work, the data collected from customers directly has been assumed to be accurate and thorough. But the concern regarding the accuracy of the information provided by the customers remains.

Highlights of the contributions of the present work:

- Predicts customers' behavioral pattern by analyzing their demographic data by using classification-based learning methods.
- Helps with customer segmentation which in turn will help recommending the right service to the customers.
- Contributes to designing a personalized tariff plan which will cater to the customers' requirements at a much more reasonable price.

## VII. CONCLUSION

Because of the high efficiency of classification-based learning models, the proposed model produced a higher success rate in predicting the customers' behavior. Among traditional classifiers, the decision tree has given the best result with an accuracy of 81% among other techniques. Also, the reliability of the model has been tested using kappa analysis and showed to be higher than all other investigated classifiers with a value of 0.71. While the ensemble classifier, random forest, has given the best accuracy of 83% among other techniques with kappa value of 0.74. Although the proposed work has provided satisfactory results, it has certain limitations. The major shortcoming of the work can be identified as the size of the dataset which has impacted the performance of certain classifiers to a great extent. Therefore, in future, the work can be extended by using a much larger dataset such that inherent patterns can be identified with more precision. Also, a more robust and generalized model could be designed that would work irrespective of the type of dataset.

# A Systematic Literature Review of Deep Learning-Based Detection and Classification Methods for Bacterial Colonies

Shimaa A. Nagro

College of Computing and Informatics, Saudi Electronic University, Riyadh, Saudi Arabia

**Abstract**—Deep learning is an area of machine learning that has substantial potential in various fields of study such as image processing and computer vision. A large number of studies are published annually on deep learning techniques. The focus of this paper is on bacteria detection, identification, and classification. This paper presents a systematic literature review that synthesizes the evidence related to bacteria colony identification and detection published in the year 2021. The aim is to aggregate, analyse, and summarize the evidence related to deep learning detection, identification, and classification of bacteria and bacteria colonies. The significance is that the review will help experts and technicians to understand how deep learning techniques can apply in this regard and potentially further support more accurate detection of bacteria types. A total of 38 studies are analysed. The majority of the published studies focus on supervised-learning-based convolutional neural networks. Furthermore, a large number of studies make use of laboratory-prepared datasets as compared to open-source and industrial datasets. The results also indicate a lack of tools, which is a barrier in adapting academic research in industrial settings.

**Keywords**—AI; bacterial-colonies; classification; deep learning; detection; literature review

## I. INTRODUCTION

Bacteria are unicellular microorganisms that are present on everything around us. A single drop of sea water contains at least a million cells of bacteria [1]. Knowledge of the bacterial genre is extremely important in microbiology. Accurate and quick recognition of the bacterial genre is crucial in various fields including clinical diagnosis, medicine, water and food industry, etc. [2] [3] [4].

In the traditional identification process, preparing samples requires not only substantial time but also specific equipment and costly chemicals. This step must take place before the identification process can even start. The resultant samples are observed by experts to identify features in traditional laboratory setups. Samples are also compared with standard reference images for accurate identification, which is a tedious and time-consuming task [5].

The most important feature for recognition of bacteria is shape. Bacteria can be classified into numerous categories based on its shape. Some of the prominent shapes include spiral, longitudinal, and cylindrical. Since various types of bacteria share very similar shapes, however, considering shape alone makes differentiation difficult. Therefore, other characteristics such as presence and shape of colonies and morphology are

exploited to correctly recognize bacteria. In short, identifying type of bacteria is arduous even for experienced microbiologists [5].

Image processing and computer vision techniques have revolutionized the approach to bacterial identification with the ability to process and classify large amounts of data. Yet identifying patterns to derive conclusions from complex, dynamic, and heterogeneous data created by computerized techniques is another challenge for scientists. Evolution of machine learning techniques has enabled scientists to classify, predict, and identify patterns from large amounts of data [6]. Deep learning is a subset of machine learning that has shown tremendous success in various fields including identification and classification of bacteria.

Systematic literature reviews (SLRs) aggregate, classify, and analyse state-of-the-art information from existing literature. SLRs are a type of secondary study that collects and summarizes the literature published in a particular area. The studies under review are referred to as primary studies [7].

This paper presents an SLR on deep-learning-based classification and identification of bacterial colonies. This work aggregates, analyses, and summarizes 38 studies related to deep-learning-based bacterial classification. The aim of this study is to benefit new researchers by providing organized insights from the literature. Furthermore, this SLR is also beneficial for practitioners since it highlights the latest tools, techniques, and frameworks in this area. Specifically, this paper provides the following contributions:

- Identification of the deep-learning-based bacterial classification techniques presented in the literature. This paper presents a taxonomy and classifies existing literature according to types of deep learning approach, types of learning, and tools used to perform bacterial colony classification.
- A descriptive analysis of quantitative data and a thematic analysis of qualitative data to provide insights into deep learning approaches and datasets. This paper also presents a comparative analysis to find the similarities and differences in performance evaluation metrics and tools available in existing studies.
- Insights for practitioners into the latest advancements in tools, techniques, and frameworks in the deep-learning-based classification of bacterial colonies.

- Reporting of benchmark datasets and performance evaluation metrics used to measure the performance of deep learning approaches for bacterial colony classification.

The rest of the paper is organized as follows: Section II discusses the background of various deep learning approaches in general. Section III presents the research methodology applied in this study. Section IV presents the results of this study. Finally, Section V presents a discussion followed by the conclusion.

## II. BACKGROUND

### A. A State-of-the-Art Survey on Deep Learning Theory and Architectures

Deep learning is an advanced subset of machine learning, which is now emerging in numerous traditional and new areas. Deep learning has gained tremendous attention from researchers and practitioners in recent years. In comparison with conventional techniques, deep learning has generated experimental results that show extraordinary success in different fields such as cyber security, natural language processing, image processing, biotechnology, speech recognition and translation, and robotics [8] [9] [10]. In deep learning architecture, there are quite a few intermediary layers between the input and output layers. These intermediary layers allow deep learning models to pick up patterns and perform classifications. Deep learning is a general solution that can apply to almost any field, whether new or old, and has proven successful in solving almost any kind of problem [11].

### B. Types of Deep Learning Techniques

Deep learning techniques can be classified into three categories: supervised, unsupervised, and semi-supervised learning techniques.

1) *Supervised deep learning techniques:* Supervised deep learning techniques make use of labelled input and output datasets. Examples of supervised deep learning techniques are Deep Neural Network (DNN), Convolutional Neural Network (CNN), and Recurrent Neural Network (RNN).

2) *Unsupervised deep learning techniques:* In machine learning, unsupervised deep learning techniques make use of unlabelled datasets. Clustering is an example of unsupervised deep learning. In unsupervised deep learning, learning agents identify and study indefinite relationships among input data. It promises to identify extremely intricate and nonlinear models with many free parameters. Deep unsupervised learning makes use of millions of parameters and unlabelled data. Generative Adversarial Network (GAN), Restricted Boltzmann Machine (RBM), and Auto Encoder techniques are used in unsupervised deep learning.

3) *Semi-supervised deep learning techniques:* This type of learning occurs when datasets are not completely labelled. It is a blend of unsupervised and supervised deep learning. First, the role of supervised deep learning is to identify key features from the data for which outputs are known. Then unsupervised deep learning takes place, in which less information about the data is

available, basically no information about the output. This unsupervised deep learning helps in exploiting just input data to identify other features. For instance, in a face recognition problem, supervised learning can identify that eyes are an important feature to differentiate faces from other objects. Then unsupervised learning identifies other new features such as eyebrows and noses and lips as important to identify a face in case eyes are not visible. Thus unsupervised learning improves the overall generalizability of a semi-supervised learning model [12]. Semi-supervised deep learning techniques include Deep Reinforcement Learning (DRL), GAN, and RNN.

**Deep Neural Network (DNN):** An Artificial Neural Network (ANN) has been mapped on human neurons to solve identification- and classification-related problems. A DNN is an advanced form of ANN that consists of several hidden layers between input and output layers. Each layer contributes to improving classification accuracy. The following sections discuss specialized forms of DNNs. Fig. 1 shows the architecture of a DNN.

**Convolutional Neural Network (CNN):** CNNs are a type of ANN that support recognition- and classification-related tasks. CNNs are similar to a multi-layered simple neural network, albeit with the difference that unlike in other neural networks, the layers in CNNs are stacked. A CNN works in a similar way to how humans process visuals, with the ability to process multidimensional images [11]. The basic architecture of a CNN consists of a feature extractor and a classifier. This architecture can be further distributed into three type of layers: convolutional, pooling, and fully connected layers. These layers are sandwiched between input and output layers. At the input layer, the input parameters are specified, including height, width, and depth. Odd numbered layers are for pooling, whereas even numbered layers are dedicated for convolution tasks. Convolutional layers extract and create feature maps, which are then processed through an activation function and biased to produce the final output. The function of each odd pooling layer is to reduce the dimensions of the output produced by the former convolution layer. This step is necessary because the exponential increase in dimensions make the dimensions increasingly difficult for the computer to process. Finally, the output produced by pooling and convolutional layers is given as an input to the classification layer, or the fully connected layer [13]. In the classification layer, the features are collected, and activation functions are applied. This layer is computationally expensive, so alternatives such as global and average pooling layers have been reported that reduce parameters, thereby reducing the overall complexity at this layer. Fig. 2 presents architecture of a CNN.

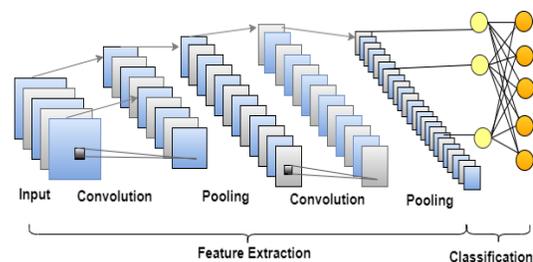

Fig. 1. Deep Neural Network.

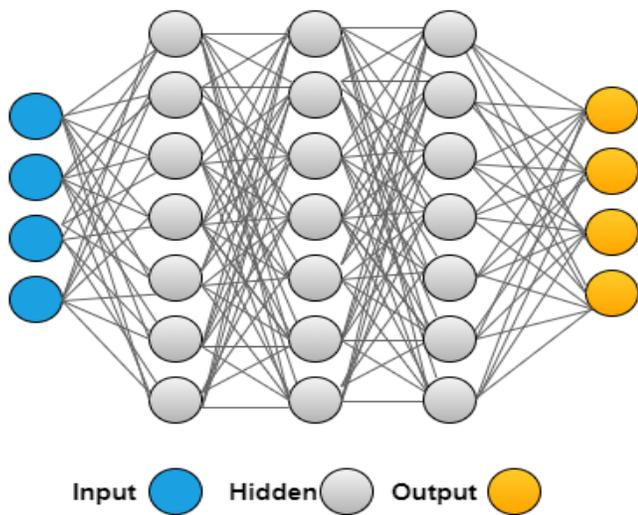

Fig. 2. Convolutional Neural Network.

Recurrent Neural Network (RNN): CNN and conventional neural networks work on fixed sized vectors as input and output, e.g., the images and probability of classes respectively. In contrast, the distinguishing quality of an RNN is that it can handle variably sized vectors. RNNs are iterative in nature, which allows them to pass on information through each iteration. RNNs can be considered as replicas of the same network. They can retain information from the past to interpret, present, and predict the future. For instance, an RNN model can retain information about previous video frames to understand the present and to predict and produce future frames. RNNs have also been used to solve natural language processing [14], text mining, time series, and financial data related problems [6]. The limitation of this neural network is that it faces a ‘vanishing gradient problem’, though this problem has been solved in the literature by the invention of Long Short-Term Memory (LSTM).

Generative Adversarial Network (GAN): A GAN involves unsupervised deep learning where the dataset is not labelled. It uses input data to generate previously unknown patterns and then uses learnt patterns to generate new but similar samples of data. GANs make use of two neural networks, i.e., a generator and a discriminator. These neural networks compete against each other in an adversarial fashion. The generator generates sample data, whereas the discriminator compares the sample with input data and determines whether the generated sample is close enough to be acceptable. The feedback is fed back to the generator, which helps it to perform better. GANs have been used to solve numerous problems in diverse fields. GANs use deep learning methods, which is why they are categorized as both semi-supervised and unsupervised learning. For instance, GANs support image, video, and voice generation. GANs are also being used in game development.

Restricted Boltzmann Machine (RBM): RBM is another example of unsupervised learning. Just like GAN, RBM is also a generative approach that generates samples based on unlabelled input data. An RBM is composed of two layers, i.e., hidden and visible. The standard Boltzmann Machine is known for its slow learning process. The training part in an RBM can be exhibited using a Boltzmann Machine, which is a two-

layered network. It makes use of randomly distributed probability-based binary pixel and feature detectors. The RBM is based on hidden variables and undirected graphs. The stochastic nature of the RBM and its slow training phase makes the overall approach computationally expensive. RBMs can be used to solve classification and dimension reduction problems.

Deep Reinforcement Learning (DRL): This learning approach learns from an unknown environment. DRL is different from other supervised and unsupervised deep learning approaches since these approaches model data while DRL models environments. DRL can be thought of as an approach that suggests actions to be performed based on a given environment. Other deep learning approaches are exploited by DRL to model data based on the environment being modelled. DRL can be applied in numerous fields to determine actions, for instance, in engineering and mathematics. In addition, it can be used for decision making in investment markets.

Deep Auto Encoder (DAE): This approach is categorized as unsupervised deep learning. Auto encoders are used for encoding input data and to learn features from it. DAE consists of two parts: the encoder and decoder. In the encoding part, input data is encoded. In the decoding part, real features are generated. DAE encoders can be thought of as stacked data-driven auto encoders and are famous for solving dimension reduction problems. However, there are a few limitations to DAE approaches. For example, they are highly sensitive to input errors and face the ‘vanishing error’ problem [11].

Transfer Learning (TL): In conventional machine learning practices, a model is designed, created, and trained to produce accurate results. Mostly weights are initialized randomly before the start of a training process. As a result, models learn slowly, adjusting the weights on each iteration to reach a certain level of accuracy. TL is different from the traditional machine learning training process. It makes use of source information to improve the learning rate of a related target model. TL is a process in which pre-trained models are used to initialize the weights of a new model. This process can greatly improve the time required by a target model to reach higher classification accuracy. Performance of TL is dependent upon the DL algorithm being used by the model. Usually the last layer of the pre-trained model is removed, and a fully connected model is attached with the number of classes in the target model. If the target model performs well as compared to a model that learnt from scratch, then this process will be considered as positive TL. However, if the target model does not benefit from pre-trained model and performance is degraded as compared to the model that learnt from scratch, then this will be considered as negative TL [15]. This learning produces the best results when there is a limited amount of training data [13].

### III. PROPOSED METHODOLOGY

This study presents an SLR by following the guidelines presented by [16] [17]. These guidelines are well accepted in the software engineering community and have been followed by a number of studies [18] [19]. Fig. 3 shows the review protocol. This review is divided into three phases. The first phase presents the plan. This phase presents the research questions that are formulated based on the objectives of this study. The second phase is divided into three parts: definition

of the search strategy with the help of keywords, formulation of inclusion and exclusion criteria for study selection, and data extraction of selected attributes to answer the research questions. Finally, the data is synthesized. In the third phase, the results are reported by answering each research question. The following sections align with the phases and steps as outlined in Table I.

**A. Research Questions**

The following research questions align with the objectives of this study.

RQ 1. What is most state of the art in the field of deep-learning-based detection and classification of bacterial colonies?

This question is further sub-divided into the following questions:

RQ 1.1 What are the techniques/deep learning models that have been used in the primary studies?

Motivation: This research question is answered by identifying the deep learning models used in each primary study, for instance, the CNN and RNN. The summarized research methodology of deep learning models presented in primary studies are reported. The reporting covers, for instance, the number of layers and steps used during the pre-processing, training, and testing phases of each study.

RQ 1.2 Which types of learning have been applied?

Motivation: This research question aims to present the types of learning used by the techniques. For instance, supervised learning, unsupervised learning, and semi-supervised learning. This is assessed by mapping each deep learning model on the taxonomy presented in Fig. 4.

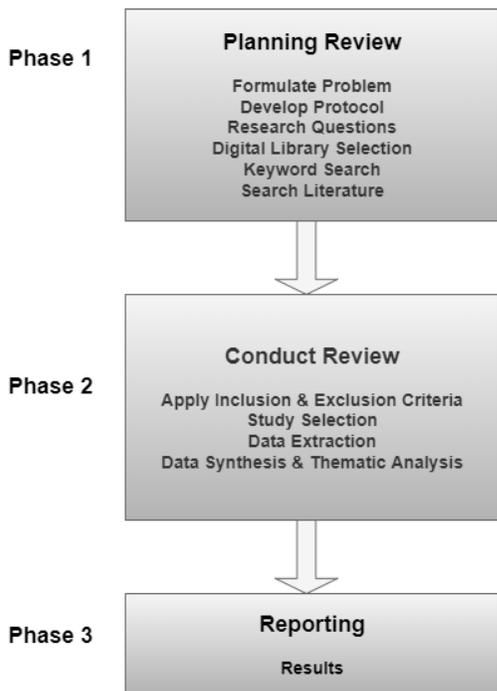

Fig. 3. Review Protocol.

TABLE I. STEPS FOLLOWED IN EACH PHASE

Phases	Steps Followed
Planning	Problem Formulation
	Protocol Development
	Research Questions
	Online Digital Library Selection
	Formulation of Query String
	Inclusion and Exclusion Criteria Definition
Conducting Review	Study Selection
	Attribute Identification
	Data Extraction
	Data Analysis
Reporting	Report Results

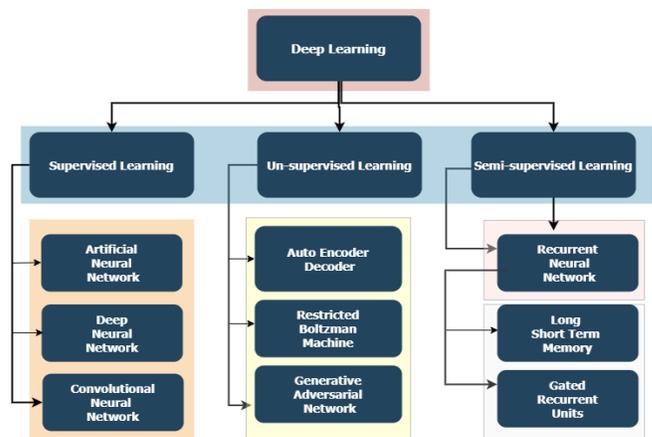

Fig. 4. Taxonomy of Deep Learning Methods.

RQ 1.3 What tools are available for deep-learning-based detection and classification of bacterial colonies?

Motivation: Availability of tools is an important concern for practitioners. To answer this research question, we aim to discover and report the tools developed and used by primary studies. The answer to this research question includes a list of tools presented and used in primary studies.

RQ 2. What type of datasets have been used for evaluation in the primary studies related to deep-learning-based detection and classification of bacterial colonies?

Motivation: The answer to this research question involves identifying the name and types of datasets used for the training and testing of deep learning models presented in primary studies. The datasets are categorized into three categories: academic, open-source, and industrial. Datasets constructed in lab environments that are not affiliated with any organization or institute are considered academic. Open-source datasets are those that are publicly available, well known, and used in similar studies. Datasets received from a specific organization that are not publicly available and solely used for the scope of a particular primary study are called industrial datasets. This research question is further divided into the following sub-questions.

### RQ 2.1 What are the characteristics of the datasets?

Motivation: This research question aims to identify the characteristics of data, such as type of sample (microscopic images, spectroscopic data, genomic data, etc.); number and size of dataset; and number of classes. The answer to this research question is a comparative analysis presented in a table listing dataset name, number of classes, type, and size.

RQ 2.2 What performance evaluation metrics do the studies use to evaluate the performance of deep-learning-based techniques for the detection and classification of bacterial colonies?

Motivation: This research question aims to investigate the performance of a deep learning model based on its ability to perform the classification accurately. To answer this research question, the evaluation data of each model were extracted for a given dataset. Different studies incorporate different metrics for performance evaluation depending on the dataset and deep learning technique used. Performance metrics can be accuracy (in percentage), Area Under the ROC Curve (AUC), precision, receiver operating curve, F1 score, sensitivity, confusion metrics, etc. The answer to this research question is a comparative analysis presented in a table providing the name of the deep learning model, dataset, and highest accuracy achieved on that dataset.

#### B. Digital Library Selection

The search was carried out using the large extensive databases shown in Table II. We searched a total of five digital databases: Google Scholar, IEEE Explore, ACM, PubMed, and Springer. We searched on the basis of keywords, titles, abstracts, and (in the case of Google Scholar) full texts to identify the relevant primary studies. These libraries provided almost complete sets of relevant studies. To complete the search process, a manual search was also conducted by looking into relevant journals and identifying articles from references of primary and secondary studies.

TABLE II. DIGITAL LIBRARIES AND URL

Digital Library	Uniform Resource Locator
Google Scholar	<a href="https://scholar.google.com">https://scholar.google.com</a>
ACM	<a href="https://dl.acm.org">https://dl.acm.org</a>
IEEE Explorer	<a href="https://ieeexplore.ieee.org">https://ieeexplore.ieee.org</a>
PubMed	<a href="https://pubmed.ncbi.nlm.nih.gov">https://pubmed.ncbi.nlm.nih.gov</a>
Springer	<a href="https://springer.com">https://springer.com</a>

#### C. Query String Formulation

By using the keywords identified in Table III, query strings were formulated. Keywords were identified based on the research questions. Synonyms and alternate terms and spellings were used to perform the advanced search. Query strings were used to perform advanced searches on the digital databases. The Boolean operator OR was used for synonyms and alternate keywords, and the operator AND was used for connecting keywords and phrases. Multiple versions of query strings were developed and executed on different databases in order to find as many relevant studies as possible.

TABLE III. QUERY STRING

Digital Library	Key Words Searched
Google Scholar	("Deep Learning" AND Bacteria*) AND (Classification OR Identification) AND Microscope* AND Image
IEEE Explore	("Document Title": Deep Learning ) AND ("Document Title": Bacteria Classification)
Springer Link	"Deep Learning" AND Bacteria AND Classification
PubMed	((Deep Learning) AND (Bacteria[Title/Abstract])) AND (Classification[Title/Abstract])
ACM	[Publication Title: deep learning] AND [Abstract: bacteria*] AND [Abstract: classification identification] AND [Publication Date: (01/01/2021 TO 12/31/2021)]

Table III presents the main query strings applied to the digital databases.

#### D. Inclusion and Exclusion Criteria

An SLR includes and excludes papers from the study pool with the help of well-defined criteria. In order to select relevant papers, a simple yet straight forward inclusion and exclusion criteria was formulated. In the first phase of study selection, studies were selected based on their titles. In the next phase, abstracts of studies were reviewed. Finally, full texts of included studies were reviewed, and any study that was not in alignment with the inclusion criteria was excluded. The inclusion and exclusion criteria are stated below:

##### 1) Inclusion Criteria

IC1: Published in the year 2021

IC2: Written in the English language

IC3: Full text of paper is available

IC4: Peer reviewed

IC5: Discusses deep learning methods to detect and classify bacterial colonies

##### 2) Exclusion Criteria

EC1: Published before 2021

EC2: Written in a language other than English

EC3: A version other than the most recent version (if multiple versions are available)

EC4: Non-peer reviewed (e.g., presentations or books)

EC5: Duplicate article

EC6: Discusses classification of other microorganisms such as viruses and other non-bacterial microorganisms

#### E. Conducting Systematic Literature Review

This section presents the study selection, data extraction, and synthesis process.

1) *Selection of primary studies:* The search across five online digital libraries retrieved a total of 310 articles. In the first pass, the titles and abstracts of all the articles were

analysed. As a result, 50 articles were selected (IC2, EC2, IC5, and EC6). In the second pass, the duplicate articles (i.e., papers appearing more than once) were removed (EC5). Furthermore, any non-peer reviewed articles such as books, magazines, lecture notes, editorials, and presentations were removed (IC4, EC4). Articles whose full text was unavailable were also excluded (IC3, EC3). A manual search was also conducted by looking into relevant journals and identifying articles from the references of primary and secondary studies. As a result, a total of 38 articles were present in the study pool. Fig. 5 shows the study selection process.

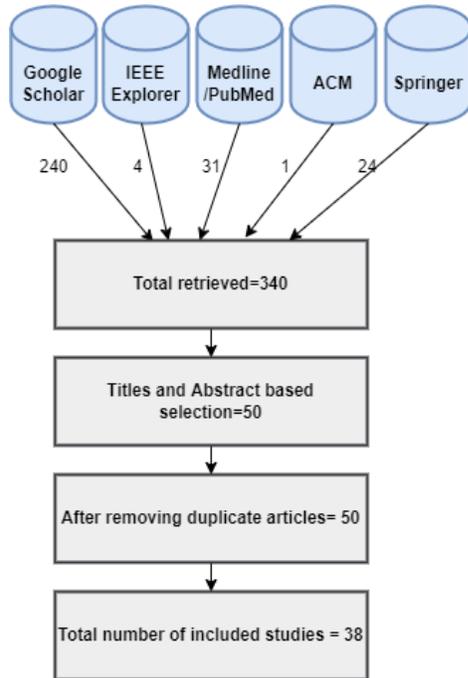

Fig. 5. Study Selection Process.

2) *Data extraction and synthesis:* The selected attributes were extracted from the primary studies and stored in a spreadsheet for analysis. We also extracted the quantitative data, such as number of datasets, size, number of classes, and accuracy, and the qualitative data, such as type of learning, type of dataset, and steps followed to develop the deep learning model. Data synthesis is a technique to summarize reported evidence from included primary studies to answer research questions. Table IV presents the data attributes extracted from each of the primary studies and maps those attributes on each respective research question. To synthesize qualitative data, a descriptive analysis was conducted, and to synthesize quantitative data, a thematic analysis was performed.

#### IV. RESULTS

This section presents the results and answers the research questions presented in section 3.1.

RQ 1. What is most state of the art in the field of deep-learning-based detection and classification of bacterial colonies?

TABLE IV. DATA ATTRIBUTES' MAPPING ON RESEARCH QUESTIONS

Data Attributes	Possible Values	Research Question
Deep Learning Model	e.g. CNN, RNN, DBN, AE	RQ 1.1
Type of Learning	Supervised Unsupervised Semi-Supervised	RQ 1.2
Tool	Tool Name	RQ 1.3
Tool Language	e.g. MATLAB, Python etc.	RQ 1.3
Tool Availability	Available Not available	RQ 1.3
Name of Dataset	e.g. DIBaS	RQ 2
Dataset Type	Academic Open source Industrial	RQ 2
No. of Classes	e.g. 3, 5	RQ 2.1
Type of data sample	Spectroscopic, microscopic, etc.	RQ 2.1
Highest Accuracy Achieved	Value in percentage	RQ 2.2
Evaluation Metrics	F1 score, precision, sensitivity, etc.	RQ 2.2

To identify what is most state of the art in deep learning approaches used for bacteria classification and identification, the information presented in Table IV was extracted and used to answer all sub questions.

RQ 1.1 What deep learning models/architectures have been used in the primary studies?

The primary studies were classified using thematic analysis, which involves identifying different patterns. A word cloud based on the extracted keywords is presented in Fig. 6. More than 75% of the primary studies are based on different architectures of CNN. Fig. 7 shows the distribution of deep learning architectures. Studies were further classified according to various CNN architectures, for example, ResNet, UNet, SqueezeNet, MobileNet, and InceptionNet. Fig. 8 shows the distribution of architectures within CNNs. A large number of primary studies incorporate ResNet architecture because it can accommodate as many as one thousand layers to achieve greater performance. The following sections discuss the research summaries of the studies categorized in each of these architectures.

1) *CNN-Based architectures:* In [20], the authors identify and classify three types of food-borne bacteria with a cytometric approach on micro-fluidic impedance. The three type of bacteria, namely 'Salmonella Enteritidis', 'Vibrio Parahaemolyticus', and 'Escherichia coli', were classified with the help of a CNN with 100% accuracy. The authors claim that this impedance-based technique can classify unlabelled data. This system can also detect pathogenic bacteria, thus it could be prolific in clinical diagnosis. Regarding the architecture of the CNN, the CNN was composed of one input layer, two convolutional layers, one fully connected layer, and one output layer. The depth of convolution was 8, and Rectified Linear Unit (ReLU) was used as an activation function. The same

In [26], the authors develop a spectra identification technique to identify the bacteria responsible for causing urinary tract infections (UTIs). A CNN was developed to perform the classification of bacterial species and their sensitivity to antibiotics. The proposed CNN model consists of four convolutional and max pooling layers. Two fully connected layers were used for classification. The results indicate that, as compared to traditional UTI bacterial identification techniques, this technique based on surface-enhanced Raman spectroscopy is faster and has an accuracy level of 96%.

In [27], the authors develop a deep learning approach to identify the geometrical characteristics of sulfate-reducing bacteria in order to avoid corrosion. They use a deep CNN model on Scanning Electron Microscopic (SEM) images. A modified watershed algorithm was used for bacterial cell segmentation before counting of the cells and identification of geometric properties such as height and width. The model takes unprocessed SEM images as input and produces geometric properties (height and width) as output. The model uses Deeplabv3+ pre-trained on ResNet50, ResNet18, and MobileNet. The results show that the proposed model can detect individual and clustered bacterial cells effectively in the presence of other objects.

In [28], the authors developed a CNN-based classifier to distinguish between two types of bacteria, i.e., MRSA and MSSA. The proposed CNN is a shallow model that takes 1D spectra as input and extracts feature maps. The model classifies spectra into two classes, so it can be considered as a binary classifier. The results indicate that the proposed approach can identify and distinguish two types of bacteria with an accuracy of 100%. In [29], the authors made use of a CNN-based model called VGG-16 for classification of bacterial colonies. Pre-trained VGG-16 was used with atrous convolution instead of a conventional CNN. The proposed model altered the standard VGG16 model by introducing additional dilated convolutional layers; the rest of its architecture was similar to original VGG-16. The performance of the proposed approach on test data was 94.8%.

In [30], the authors investigate the identification of growth paths of E.coli bacteria on non-transparent metallic mediums. Their aim was to identify multiple stages of bacterial image formation. These steps included identification of base, colony formation, bacterial dispersion, and crystallization. They incorporate a deep CNN model with four convolution layers followed by max pooling layers and a classification layer followed by a SoftMax layer. The authors in [31] attempt to develop a system to automatically calculate the number of bacterial cells in a colony in water samples. A CNN was developed to identify a specific type of bacteria called E-coli. The CNN model comprises six convolutional followed by two fully connected layers. Another deep learning model R-CNN was employed to automatically count the number of bacterial cells in a colony. This model was developed with the help of previously trained ResNet-50, hence use of TL. Classification layers of ResNet were replaced by a layer with nine neurons representing nine classes of R-CNN. The results indicate that the proposed models works significantly well with an accuracy

of 97% in automatic detection and cell counting of E-coli bacteria in colonies.

The authors in [32] use a CNN to detect bacterial cells from three-dimensional (3D) fluorescent microscopic images. The CNN is composed of 11 layers in total, distributed as follows: two convolutional layers followed by max pooling layers and two fully connected dense layers that use SoftMax function. The results indicate that the proposed approach works effectively with an accuracy of 95% and can detect bacterial cells from 3D fluorescent images.

2) *ResNet architecture*: In [33], the authors aim to identify the structural features of the G20 bacteria that are normally present on steel surfaces and cause corrosion. Data samples are SEM images. Mask Region CNN (RCNN) and Deep Convolutional Neural Network (DCNN) were used for segmentation of bacterial instance and identification of grouped bacteria respectively. The authors incorporate a previously developed platform named DeepLABv3+ for implementing deep learning architectures. RCNN is a pre-trained architecture with pre-extracted feature maps of images. Comparison was performed with deductions of experienced human experts. The results indicate that RCNN and DCNN are far faster with an accuracy of 81% as compared to manual and conventional approaches to detect bacteria from biofilms.

In [34], the authors present a CNN-based approach to classify three species of gram-positive bacteria through Whole Slide Images. Data were pre-processed to segment bacteria from background. The segmented bacteria images were then fed to a classifier, which classified them into three classes. Pre-trained ResNet was used to segment the bacteria from the background. The authors conclude that ResNet architecture can be effective in differentiating among three gram-positive bacteria with an accuracy of 81%.

In [35], the authors propose a bacilli detection approach based on deep CNN. Specifically, ResNet, SqueezeNet, and VGG-16 are used for training and testing to identify which models work best in bacilli identification. Use of pre-trained architecture indicates that the models used TL. Bacterial images were segmented from the background using K-means clustering and colouring techniques. Images were resized to 224x224x3 and fed to the model. ReLU and sigmoid activation functions were used between layers. Overall, SqueezeNet outperformed the other CNN models with an accuracy of 97%.

The authors in [36] employed five CNN-based architectures to differentiate between 33 different species of pathogenic microbes. These architectures included ResNet50, Mobile Net, ResNetv2, Inception Net, and DenseNet. All the architectures used TL, i.e., they were pre-trained to reduce the time required to achieve better performance. Fine tuning was used to vary the weights of parameters in deep and shallow layers. Shallow layers identified basic line features whereas deeper layers identified other complex features. The input to the models was a 224x224 image. Stochastic Gradient Approach was used to prevent the technique from getting stuck in local minima. MobileNet performed better than the other architectures with an accuracy of 96.8%.

In [37], the authors developed a tool called Motility-J to identify bacteria and detect surfaces that are covered with pathogenic bacteria. The authors emphasize that pathogenic bacteria develop features such as flagella to move across surfaces in order to survive in a constrained environment. The tedious task of labelling datasets was alleviated by labelling images with a semi-automatic technique. The authors used image segmentation to identify the part of image where bacteria are present from the background image and used that part as input to the model. A number of image processing techniques such as noising and erosion were used to obtain bacteria segments. A number of CNNs were used including ResNet50, ResNet101, FBNet, and EfficientNet B3 with fine tuning and TL. Fine tuning was done such that the last convolutional layer was replaced by a linear layer. All the models were trained using input images.

In [38], the authors differentiate longitudinal bacterial divisions (Fission) from horizontal and other divisions. They make use of a pre-trained CNN called ResNet with TL. Comparison was conducted of a pre-trained model with an un-trained model. The results indicate that classification accuracy for pre-trained ResNet was 99.67%, better than un-trained ResNet.

3) *UNet architecture*: In [39], the authors developed an approach for segmentation and classification of six bacterial species. They employed UNet architecture for segmenting the SEM image into foreground and background images. In the classification part, VGG16 was used to classify bacteria species before counting the number of cells. The authors kept the segmentation and classification independent so that they could learn independently and improve their individual accuracies. The results indicate that the performance of the proposed approach as compared to standard CNN was better with a classification accuracy of 95.8%.

The authors in [40] aim to identify bacteria and other harmful pathogens that contaminate the bloodstream and cause life-threatening health problems. The authors incorporated CNN-based architecture called UNet to identify the presence or absence of bacterial cells in dark field microscopic images. The authors emphasize that UNet architecture works well in image segmentation and object detection. The authors divided the architecture into four models. The first model used the concept of early stopping to prevent over fitting in case the performance on the training set does not increase even after a few iterations. The second model does not apply early stopping. The third model implements a loss function. The results indicate that the proposed UNet third model performed well with an accuracy of 96.6%.

In [41], the authors build on a previously proposed BCM3D approach. BCM3D is a combination of image processing techniques and CNN to detect, count, and segment single cell bacteria from biofilms. BCM3D2.0 addresses the challenge of segmenting bacterial cells from dense biofilms and a low signal-to-background ratio. Fluorescence microscopic images were used to train and test the new approach. The authors processed the images and created two types of transitional images for object localization and boundary detection. The proposed

approach not only creates a 3D outline of an object but also measures its distance from nearby objects. A UNet-based CNN was incorporated with two convolutional layers followed by max pooling and a linear function followed by a classifier. Another CNN was trained to determine the physiological shape of segmented objects. This CNN consisted of three convolutional layers: two average pooling layers followed by a sigmoid layer.

In [42], the authors aim to measure the number and length of bacterial cells and the overall area covered by biofilms. They claim to have solved the object segmentation problem that occurs in closely located or overlapping cells. The authors combined deep-learning-based UNet model with 'region-based ellipse fitting technique' to segment, count, and measure bacterial cell instances from biofilms. UNet architecture is an encoding decoding model where convolution and deconvolution take place on input images. The final output of the model is a logically outlined mask of bacteria cell instance where each pixel is categorized to a particular class. In the second phase, the ellipse technique was applied, in which centroids and distances were calculated and ellipses with similar angles were combined iteratively. This technique performed well with a recall of 93.6%.

4) *SqueezeNet*: The authors in [43] propose 12 CNN-based models to classify bacterial species. The proposed models have minor differences, though all were pre-trained and fine-tuned. An open-source dataset called DIBaS was used to train and test the models. Furthermore, the dataset was augmented to increase its size. Augmentation was done by cropping and zooming in multiple times. A total of 24,073 images (including the originals) were present after the augmentation. Models were trained by resizing the images to 224x224 pixels. Some architectures used in this paper are Efficient-net, SqueezeNet, Mobilenetv2, Mobilenetv3, and ShuffleNet. Almost all the architectures used pre-trained models and fine-tuned them such that the last layer was modified to 32 neurons representing the number of bacterial classes. Fine-tuning also reduced the number of parameters drastically thus enabling the models to consume less resources. Comparison of proposed models was done with other techniques with and without data augmentation. The results indicate that augmentation can have a great impact on performance of a model.

In [35], the authors propose a bacilli detection approach based on deep CNN. Specifically, SqueezeNet, ResNet, and VGG-16 are used for training and testing to identify which models work best in bacilli identification. The open-source dataset ZNSM-iDB, which has 2,000 images, was pre-processed with colouring techniques. Bacterial images were segmented from the background using K-means clustering and colouring techniques. Images were resized to 224x224x3 and fed to the model. ReLU and sigmoid activation functions were used between layers. Overall, SqueezeNet outperformed rest of the CNN models with an accuracy of 97%.

5) *Inception net*: The authors in [44] developed a classifier to identify the presence and absence of filamentous bacteria in waste water. They used pre-trained inception v3, an open-

source CNN-based architecture, to train the classifier into two classes. Inception v3 was developed by Google. It consists of 22 layers and 24 parameters. It has been trained on an image-net dataset, which is well known and large. Using a pre-trained inception net allowed the authors to use it as it was for identifying bacteria in waste water. The results indicate that the Inception v3 classifier was able to identify filamentous bacteria in abundance.

6) *Stacked auto encoder*: In [45], the authors present a DNN-based approach to differentiate between two types of bacteria: MSRA and MSSA. Stacked Auto Encoder is used to perform the training and testing of the unlabelled dataset. The authors highlight that auto encoders are good at learning complex features from unlabelled data. They stack a number of auto encoders such that the first's hidden layer will feed the second's hidden layers followed by SoftMax layers. Comparison of the proposed approach was conducted with six machine learning approaches including K nearest neighbours, Support vector machine, and decision trees. The results indicate that the proposed stacked Auto Encoder accurately detects MSSA and MSRA bacteria with an accuracy of 97.6% and AUC of 0.99.

7) *Recurrent neural network long short-term memory*: in [46], the authors aim to identify bacteria from marine water. A model based on Recurrent Neural Network (RNN) called Long Short-Term Memory (LSTM) was employed to do the task. The results were compared with a simple CNN mode with two convolutional layers and max pooling and a classification layer. The LSTM model consisted of two LSTM layers, each with 64 neurons followed by a classifier with 8 neurons representing eight marine bacterial species. Both models were trained, validated, and tested on the same data so that performances would be comparable. The results indicate that the proposed LSTM method performed better than the conventional CNN with an accuracy of 94%. Furthermore, the LSTM-based model was faster and more accurate.

The authors in [47] investigate the use of LSTM for identification and classification of food-borne bacteria. The authors make use of Hyper Spectral Microscopic Images, which were pre-processed and fed to an LSTM model as well as to three other models: PCA KNN, SCM, and LDA. The results of the LSTM model were compared with those of the three classifiers. The LSTM model is composed of several blocks, a dense layer and a SoftMax layer that contains five neurons representing five classes of bacteria. Three types of Region of Interest (ROI) were utilized to extract features of bacteria: inner cell, outer layer and boundary ROIs. The results indicate that centre ROI is a better feature to consider for bacterial classification. The proposed RNN-based LSTM model performed better than other models with an accuracy of 92.9 %.

RQ 1.2 Which types of learning have been applied?

This research question is answered by mapping each type of deep learning model on the taxonomy proposed in Fig. 3.

In [20], the authors make use of unlabelled impedance data, which means the proposed technique is unsupervised. The

authors in [26] use unlabelled Raman spectroscopy data to identify UTI-causing bacteria. The authors in [28], proposed binary classifiers using unsupervised learning. The classifiers detect two types of bacteria: MSSA and MRSA. The authors in [45] make use of stacked auto encoders for training and testing an unlabelled dataset, so we categorize this study under unsupervised learning models. The authors in [35] perform unsupervised learning as they detect bacilli-shaped bacteria from an open-source dataset of microscopic images. In [48], the authors develop a binary classifier using supervised learning. The proposed classifier classifies bacteria into two classes: harmful and benign bacteria. The authors in [49] propose a graph-based unsupervised technique called M-Lcuts that identifies numerous bacterial clusters in 3D space.

The authors in [47] make use of live spectral analysis to train an RNN-based LSTM model. The authors in [46] propose an RNN-based model called LSTM to identify bacteria from marine water. Since the authors consider the LSTM model semi-supervised, we categorize it under semi-supervised learning.

The authors in [21] collected six types of bacteria through a gram-staining method from a university in Malaysia. The dataset was annotated hence this technique can be classified as supervised learning. In [50], the authors differentiated between three strains of 'Klebsiella pneumonia' by using supervised learning'. The study [22] use a labelled dataset to detect bacterial vaginosis. The authors in [38] and [40] performed supervised learning by manually labelling the dataset into two classes. The authors in [23] performed bacteria sequence classification by using labelled barcode sequences of an open-source dataset. In [51], the authors performed supervised learning as they annotated the dataset into two classes: Escherichia coli and 'Mysococcus Xanthus'. The authors in [39], [27], and [33] used a labelled SEM-based dataset for identifying and classifying bacteria species. In [52], the authors used a labelled dataset to investigate the classification accuracies of some deep learning architectures on three types of bacteria. In [44], the authors used supervised learning and annotated microscopic images obtained from waste water. The authors in [24] used supervised learning for identification of food-borne bacteria, specifically 'Salmonella Typhimurium'. The authors in [53] make use of an annotated dataset of microscopic images to identify bacteria from images. In [25], the authors performed supervised learning as they made use of an annotated dataset composed of microscopic images. The authors in [43] proposed a supervised learning approach for quick identification of bacteria. In [54], the authors propose a supervised learning method to differentiate between different species of gram-positive bacteria through Hyper-spectral Microscopic Images. The authors in [29] performed supervised-learning-based bacterial colony classification by employing TL. The authors in [37], [31], and [41] made use of supervised learning to train models. In [36], the authors propose a fine-tuning-based supervised learning approach for pathogenic bacteria identification. Similarly, the authors in [30], [42], and [32] also made use of supervised learning techniques.

To summarize, 77% of the architectures belong to supervised learning and thus make use of annotated or labelled datasets. Furthermore, 5% of the architectures belong to semi-

supervised learning. The remaining 18% of architectures belong to unsupervised learning. Fig. 9 presents the distribution of deep learning techniques for bacterial classification using three types of learning approaches. Fig. 10 presents the distribution of techniques within unsupervised learning architectures.

RQ 1.3 What tools are available for detection and classification of deep-learning-based detection and classification of bacterial colonies?

Development of tools has important implications for practitioners. Development of automated deep learning tools allows academic research to support practitioners. It also helps novice researchers and beginners to adapt to deep learning methods by overcoming the technology barrier. Table V presents the list of available tools in the field of bacterial detection and classification in deep learning. It also presents their languages, frameworks, and usage information.

Seven deep learning tools are available for detection and classification of bacteria and their colonies. These tools perform various functions and work on different levels. Functions such as image segmentation, de-noising, cell counting, and labelling can be performed. For instance, the authors in [53] develop a tool called eHooke for automatic analysis of images to detect bacteria. In particular, spherical bacteria are targeted. An ANN was used as a deep learning model to detect this bacteria. eHooke was developed in Python. The eHooke tool is available publicly for download. ZeroCostDL4Mic was used in [52]. This tool supports different architectures like U-Net, CARE, pix2pix, StarDist, and SplineDist. Furthermore, the authors in [51] propose Mistic, which is a tool based on CNN and UNet architecture that helps in image segmentation in dense and multi-species environments. Mistic can work on numerous types of images such as two-dimensional (2D) fluorescence, bright field, and phase contrast images, and it does not depend on microscopes. It makes use of Shape Index map (SI), which can be derived from microscopic image data, so diverse types of sample data can be used for bacterial identification. A CNN-based UNet architecture is trained to identify the shapes of bacteria by extracting their features. The general workflow of Mistic is to take input of any type of image, convert that input into SI, and then segment by UNet. Mistic-Pip and Mistic-GUI are available for download. The authors in [37] developed a tool called Motility-J to identify bacteria and detect surfaces covered with pathogenic bacteria. The tedious task of labelling datasets was also improved by labelling images with semi-automatic technique. eHooke, Mistic, and MotilityJ have been used for image segmentation and classification. Interestingly, the majority of the tools have been developed using Python language. Fig. 11 presents the common frameworks reported by primary studies for development of deep learning architectures whereas Fig. 12 presents languages used by primary studies for implanting architectures. The majority of studies have used TensorFlow, PyTorch, and Keras framework and Python for implementing architectures.

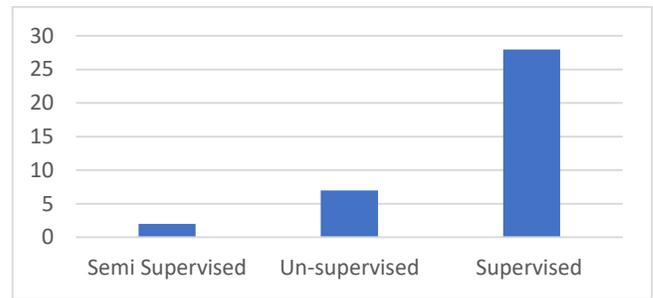

Fig. 9. Distribution of Deep Learning Techniques.

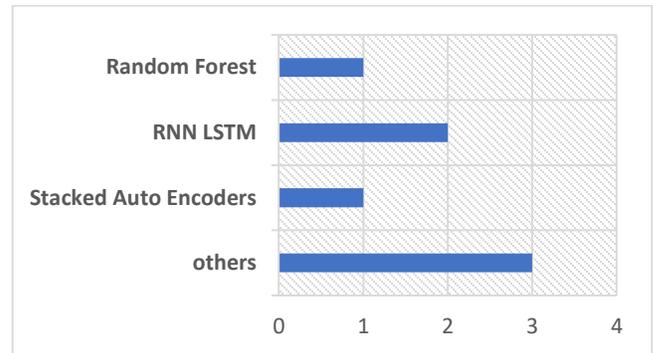

Fig. 10. Unsupervised Learning Architectures.

TABLE V. LIST OF AVAILABLE TOOLS IN BACTERIA DETECTION AND CLASSIFICATION

Ref.	Tool Name	Language	Framework	Usage
[37]	MotilityJ	Java, Python	PyTorch	Classification and segmentation
[31]	Mobile Application GUI	MATLAB	TensorFlow	Bacteria colony quantification
[38]	Anonymous	Python	PyTorch	Classification of longitudinal bacteria division
[51]	Mistic-Pip, Mistic-GUI	Python	TensorFlow	Segmentation in dense colonies
[52]	ZeroCostDL4Mic	Python	Google Colab	Image segmentation, Image de-noising, labelling for rod and spherical shape bacteria
[44]	Automated Microscopic Image Acquisition System	Python	TensorFlow	Obtaining image from waste water
[53]	eHooke	Python	eHooke	Classification, segmentation and quantification of spherical bacteria

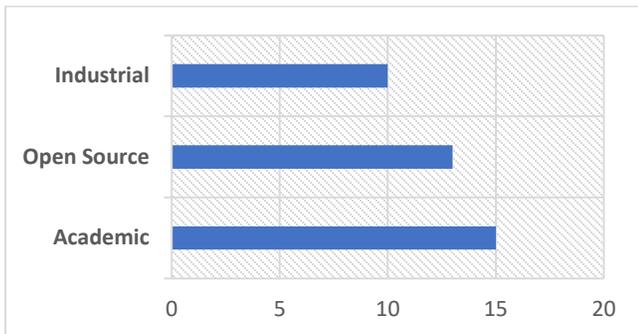

Fig. 12. Languages used to Implement Deep Learning Architectures.

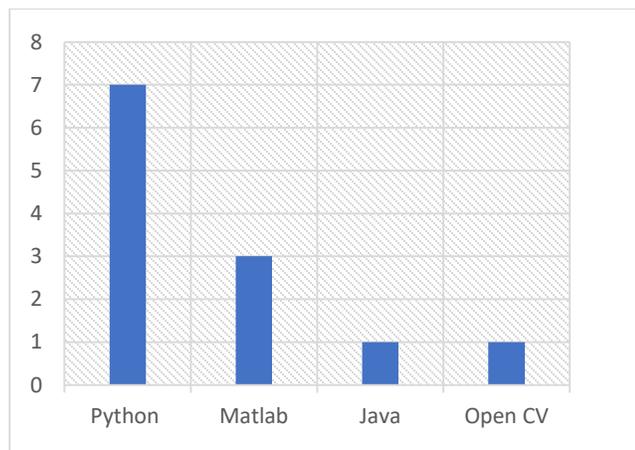

Fig. 13. Types of Datasets.

RQ 2 What type of datasets have been used for evaluation in the primary studies related to deep-learning-based detection and classification of bacterial colonies?

Fig. 13 shows the distribution of type of datasets used by the primary studies. Most of the datasets are academic. Namely, 40% (15) of the primary studies use academic datasets, meaning these datasets were constructed in lab environments and are not associated with any organization or institute. For instance, one study grew bacteria in lab settings under certain temperatures using chemical reagents [33]. Industrial datasets were used in 26% (10) of the primary studies. These datasets come from a specific organization, are not publicly available, and are solely used for the scope of that particular primary study. For instance, one study collected water samples from five domestic waste

water treatment plants in Japan [44]. Since a particular type of waste water treatment plant in Japan was targeted for sample collection, this dataset is categorized as industrial. Finally, open-source datasets were used in 34% (13) of the studies. Open-source datasets are publicly available, well known, and have been used in similar studies. For instance, one study used an open-source database called DIBaS, which is freely available and has been used in other similar studies [25].

The authors in [55] classify bacterial species in the DIBaS dataset. DIBaS is an open-source dataset with 33 classes of bacteria and other microorganisms. This dataset was augmented to increase its size and to avoid over-fitting. Images were resized as 224x224x3. Another open-source dataset of 205 images was incorporated by [48]. In this case, the dataset was divided into different ratios of training and testing data. The open-source dataset DIBaS was also used by [25] for training and testing. The dataset was reduced to 1,669 relevant microscopic images that were resized to 128x128x3. The authors in [35] used the open-source dataset ZNSM-iDB, with 2,000 images pre-processed with colouring techniques. Bacterial images were segmented from the background using K-means clustering and colouring techniques. Images were resized to 224x224x3 and fed to the model. The authors in [29] also used the DIBaS dataset for training, validating, and testing the proposed model. Since the number of relevant images in original dataset was small, data augmentation was used to increase dataset size. Augmentation was done by zooming, flipping, and cropping the original images multiple times. An open-source dataset named ‘‘Bacteria Detection with Dark-field Microscopy’’ (BDDM) used by [40] for training and testing UNet architecture. It contains 366 images of size 128x128, which were manually labelled. The authors in [36] and [43] used DIBaS for training and testing the models. The dataset was augmented to increase its size. Augmentation was done by cropping and zooming in multiple times. A total of 24,073 images (including originals) were present after augmentation. Models were trained by resizing the images to 224x224 pixels. Table VI presents list of open-source datasets in the context of primary studies.

RQ 2.1 What are the characteristics of the datasets?

TABLE VI. OPEN-SOURCE DATASETS REPORTED AND USED IN PRIMARY STUDIES

Dataset	Size	Type	Classes
16SsRNA	393	Gene barcode	3
DIBaS	3000	Microscopic images	33
2DBEST	66	SEM Images	4
BDDM	366	Dark-field Microscopic Images	2
ZNSM-iDB	800	Microscopic Images	2

In [20], the authors detect and classify three types of food-borne bacteria: ‘Salmonella Enteritidis’, ‘Vibrio Parahaemolyticus’, and ‘Escherichia coli’. An academic dataset of 600 microfluidic data was used for training the model. TL is used when there is limited availability of training data. In [21], the authors augmented an industrial dataset with random image transformations such as rotations and reflections in order to reduce the dataset’s bias and increase its size. A total of 44,985

images divided into six classes of bacteria were in the laboratory-provided datasets. Images were resized to 224x224. The authors in [50] used 610 gram-stained microscopic images of dimension 3500x5760. This dataset was provided by a hospital and prepared in a laboratory setting. Three classes were used in the dataset to distinguish between the clones of *Klebsiella pneumoniae*. The authors in [22] obtained three datasets from three different hospitals in China to automatically detect bacterial vaginosis from gram-stained microscopic images. Several data augmentation methods like scale jittering and image flipping were used to reduce sampling bias. A total of 29,095 images were used and divided into three smaller datasets. All images were resized to 1024x768. Since the datasets used by [22] and [50] were provided by hospitals, they are categorized as industrial datasets. Another study used an open-source dataset of 15,090 microscopic images to differentiate longitudinal bacterial divisions (Fission) from horizontal and other divisions [38]. This dataset was also used by [56] and [57]. In these studies, the dataset was manually labelled and divided into two types of classes, 'longitudinal' and 'other', to classify bacterial division. Apart from labelling, a number of pre-processing steps were performed on the open-source dataset, and images were resized to 128x128. The authors in [23] used the open-source dataset 16SrRNA for classifying bacterial sequences into a taxonomy. The authors concluded that performance can be enhanced by increasing the size of dataset, i.e., by including more samples in datasets. The authors in [37] addressed the tedious task of labelling datasets by labelling images with a semi-automatic technique. In this technique, images are segmented to identify the part of the image where bacteria are present from the background image, and that part is used as input for the model. A number of image-processing techniques such as noising and erosion were used to obtain bacteria segments. The dataset was augmented by applying filters, zooming, and flipping to increase its size. Models were trained using input images of two sizes. A total of 2,772 images were used for training and testing; these images are available for download. An industrial dataset of microscopic images was used to train the models. Images were resized to 100x100x3.

Fig. 14 presents the different data samples and their frequencies. Many studies have used microscopic data. Many have also used spectroscopic data samples in their datasets.

In [51], the authors used two academic datasets composed of 695 fluorescence, bright-field, and phase contrast images to train models for bacterial cells detection and classification in complex multi-cellular environments.

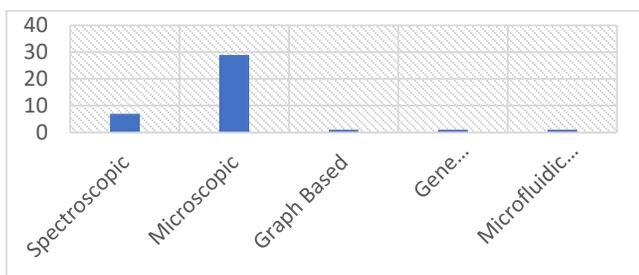

Fig. 14. Types of Data Samples.

In [52], the authors developed different datasets in order to segment three types of bacteria. Since the datasets were developed and labelled in laboratory settings, they are categorized as academic datasets. Datasets contain different types of samples such as bright field, wide field, and fluorescence images. Datasets were augmented to increase the size. These datasets are available for download. The authors in [41] prepared an academic dataset composed of fluorescence microscopic images to train and test deep learning models. The authors processed the images and created two types of transitional images for object localization and boundary detection. The augmented dataset contains 733 images. In [32], the authors detected bacterial cells from the 3D fluorescent microscopic images of an academic dataset. The authors classify the detected cells into two classes: bacteria and non-bacteria. The dataset was prepared by using 3D images of Zebrafish intestine. The image size is 10x30x30. The authors in [24] applied a number of pre-processing steps to their datasets. For instance, a magnetic field was used to convert 3D signals into 2D data. Each 5000x3000 image was divided into one hundred 500x300 images. Two datasets were used for training and verification, including an academic and an open-source dataset named 'VOC 2007'.

The authors in [39] used an academic dataset composed of SEM images. Three datasets created in a laboratory environment were used for training and testing: the first contained two types of bacteria; the second contained two different types of bacteria; and the third contained six types of bacteria, including those present in the first and second dataset. The third dataset was considered challenging because bacteria present in this dataset resemble each other in shape. Images were resized to 400x400 before being fed to UNet architecture. The authors in [58] used an open-source dataset composed of spectral data. This dataset was pre-processed and augmented before it was fed to the deep learning model. In [26], a 3000 Raman spectra from an industrial dataset was used for identification of UTI-causing bacteria. This dataset was divided for training and testing purposes. In [45], the authors used 33,951 unlabelled spectroscopic data from an academic dataset to train and test the model, which was able to differentiate between two types of bacteria: MSRA and MSSA. The authors in [46] also used spectral data from an academic dataset to classify bacteria into eight classes. In [28], an industrial dataset obtained from a hospital was used. This dataset contains 1,000 spectra from 25 different bacterial species. Data were randomly divided for training and testing purposes in 9:1.

The authors in [44] used a pre-trained Inception v3 model to identify the presence and absence of filamentous bacteria in waste water. An industrial dataset of 13,860 images was prepared in a laboratory setting by obtaining waste water samples from eight different waste water plants in Japan. In [31], the authors prepared an extensive dataset by collecting water samples from 1,301 locations. This dataset was pre-processed, and images were resized to 3228x3215.

In [34], pre-processing steps were performed to segment bacteria from the background of Whole Slide Images into three bacterial classes. Three types of industrial datasets were used to train models. A labelled dataset was used for segmentation whereas an unlabelled dataset was fed to the fine-tuned CNN

classifier. An academic dataset was used by [53], where training data comprised of around 11,000 wide-field microscopic images and around 9,000 SIM images. In each case, 10% of the images were set aside randomly and used for a test set.

One study made use of 6,900 SEM images of size 1280x960 as an academic dataset [30]. A sliding window of size 40x40 was used to scan them. In [33], the authors used SEM images as data samples for identification of structural features of G20 bacteria. An academic dataset with 66 images and two classes was divided into validation, testing, and testing data. The authors in [42] used a dataset of 290 SEM images. The data were pre-processed to remove any noise and resized to 512x512. In [27], an open-source dataset called 2DBEST composed of 66 SEM images was used to train the DCNN model. This dataset contains images of size 229x256.

In [54], the authors differentiate between different species of gram-positive bacteria through Hyper-spectral Microscopic Images of an industrial dataset. Bacteria were segmented from a 512x512 image background with the help of a binarization image-processing technique. The authors in [47] made use of a pre-processed industrial dataset of Hyper Spectral Microscopic Images to classify food-borne bacteria into five classes.

RQ 2.2 What performance evaluation metrics do the studies use to evaluate the performance of deep-learning-based techniques for the detection and classification of bacterial colonies?

Performance evaluation of bacteria detection and classification techniques involves well-known evaluation metrics. Metrics such as accuracy, F1 score, precision, and confusion matrix are commonly used to compare the performance of a newly proposed technique with previously available techniques. Apart from these metrics, criteria such as computation complexity, cost, size of dataset, and level of pre-processing activities are also used to evaluate the performance

of deep learning classifiers and extracted features. Deep learning models are inherently complex in nature. For instance, the number of layers in a CNN may increase overall computational cost and complexity.

$$Accuracy = (TP + TN)/(TP + FP + TN + FN) \quad (1)$$

$$Precision = TP/(TP + FP) \quad (2)$$

$$Recall/Sensitivity = TP/(TP + FN) \quad (3)$$

$$Specificity = TN/(TN + FP) \quad (4)$$

$$F1\ Score = (2 * Sensitivity * Precision)/(Sensitivity + Precision) \quad (5)$$

$$Dice\ Index = (2(A \cap B))/(A + B) \quad (6)$$

Equations 1–6 can calculate accuracy, precision, sensitivity, and F1-score. Here ‘TP’ stands for ‘true positive’, or the correct identification of bacteria presence. ‘TN’ stands for ‘true negative’, indicating correct identification of absent bacteria. ‘FP’ represents ‘false positive’, or the false presence of bacteria as absent, whereas ‘FN’ stands for ‘false negative’, or the incorrect identification of absent bacteria as present. Accuracy is the sum of correct identifications (both present and absent) divided by total samples. Precision is the fraction of correctly identified positive instances over all positive instances. Sensitivity is the proportion of correctly identified positive instances out of all positive instances. Specificity is calculated as correctly identified negative instances over all negative instances. The receiver operating curve (ROC) presents the true positive rate against the true negative rate and is also known as the precision-recall rate. F1-score is a statistical measure that is calculated as the geometric mean of specificity and sensitivity. Confusion matrix represents the rate of misclassified bacterial instances. Rows in the confusion matrix represent actual classes while columns represent predicted classes. The evaluation metrics used by the studies included in this review are presented in Table VII.

TABLE VII. EVALUATION METRICS USED IN PRIMARY STUDIES

## V. DISCUSSION AND IMPLICATIONS

This secondary study, an SLR, has reviewed a total of 38 primary studies. This section discusses the results and their implications.

Most of the articles reviewed focus on supervised learning techniques. Only a few papers discuss unsupervised learning techniques. More contributions to semi-supervised and unsupervised learning techniques are needed. Overall, 77% of the primary studies focus on supervised learning, 18% focus on unsupervised learning, and only 5% focus on semi-supervised learning techniques. In short, semi-supervised learning is a potential area that can be further explored for bacterial colony detection and classification. This implication is noteworthy for researchers who want to contribute in the area of deep-learning-based identification and classification of bacterial colonies. Within supervised learning, the majority of studies have focused on CNNs and their different architectures. Around 86% of the supervised learning techniques focus on different CNN architectures. ResNet (48%) and UNet (20%) dominate as compared to other CNN architectures such as SqueezeNet and AlexNet. There is a need to investigate the evidence regarding how to select a particular CNN architecture according to type and size of dataset. Such research may enable new researchers and practitioners to select the best deep learning model according to the size and type of their data.

Development of tools plays an important role in applying academic research to industrial practices. Lack of tools can be a great barrier when it comes to adopting academic research into industrial practices. Only a few tools are available publicly. The majority of the primary studies did not develop end-to-end

tools, with some providing only implementation details and others mentioning no implementation details at all. Most deep learning methods are computationally expensive, with optimization demanding an extremely large number of parameters and with memory constraints that necessitate simultaneous use of Graphics processing unit (GPUs). There is a need for stand-alone tools that can operate without technological constraints such as memory and that are accessible even to beginners or practitioners who might not possess technical understanding of architectural details.

Datasets are the fundamental entities that determine performance in deep learning methods. It was observed that 40% percent of the primary studies used academic datasets. Thus most data samples were constructed in laboratory settings. While 34% of the primary studies employed open-source datasets, only 26% used industrial datasets. Datasets created in laboratory settings under specific conditions always have an inherent bias, which is a threat to validity of results. Future research must incorporate more industrial datasets so that academic research can solve real industrial problems. Furthermore, a large number of benchmark open-source datasets must be readily available to researchers so that performance of different methods can become comparable. Hence, creating and updating of open-source datasets also needs researchers' attention.

A number of studies performed data augmentation to increase the size of datasets and reduce the bias of sampling. Images were augmented in a number of ways. For instance, the authors in [22] performed jittering and horizontal and vertical flips. Yet there is little discussion on the cost of augmentation and comparison of performance of deep learning models with

and without augmentation. It would be interesting to conduct such empirical studies and compare the cost and accuracies.

Performance evaluation of the primary studies was conducted using well-known evaluation metrics such as precision, recall, FP rate, AUC/ROC, and F1-score. Accuracy, precision, F1-score, confusion matrix, and recall were most frequently used for performance evaluation.

This study can benefit researchers and practitioners by providing them a bird's eye view as well as an in-depth analysis of existing research in the area of deep-learning-based identification and classification of bacterial colonies. Researchers can benefit from the classification of existing studies on the taxonomy of deep learning models. This study helps to identify where primary studies are lacking so that researchers can target and contribute to those areas. This study also benefits practitioners by outlining recent developments in academic research so that they can adopt those developments in the industry with confidence and evidence.

## VI. CONCLUSION AND FUTURE DIRECTIONS

This study analysed 38 articles and identified trends in most commonly used deep learning techniques, commonly used datasets, and availability of tools. The study has presented a taxonomy of deep learning techniques and mapped existing primary studies to identify the gaps in the literature. Furthermore, a thematic and descriptive analysis was conducted on qualitative and quantitative data respectively to answer the research questions and provide insights into deep learning approaches. The study reports on benchmark datasets used by deep learning approaches for bacterial colony classification. This study also presents a comparative analysis to find the similarities and differences in performance evaluation metrics used in primary studies. The results indicate that most of the articles focus on supervised learning techniques. Within supervised learning, the majority of the articles focus on CNN. Only a few used unsupervised learning techniques. Development of tools plays an important role in applying academic research to industrial practices, yet only a limited number of tools are publicly available. The results also indicate that a majority of the primary studies use academic datasets. Furthermore, accuracy, precision, F1-score, confusion matrix, and recall were the most frequently used performance evaluation metrics. This study is beneficial for researchers as it helps to identify areas where they can contribute.

In the future, more contributions towards semi-supervised and unsupervised learning techniques are needed. Future research works must incorporate more industrial datasets so that academic research can solve real industrial problems. Furthermore, there is a need for stand-alone tools that can operate without technological constraints so that beginners and practitioners can use them.

**Abstract**—Pneumonia is an illness that affects practically everyone, from children to the elderly. Pneumonia is an infectious disease caused by viruses, bacteria, or fungi that affect the lungs. It is quite difficult to recognize someone who has pneumonia. This is because pneumonia has multiple levels of classification, and so the symptoms experienced may vary. The multilayer perceptron approach will be used in this study to categorize Pneumonia and determine the level of accuracy, which will contribute to scientific development. The Multilayer Perceptron is employed as the classification method with hyperparameter learning rate and momentum, while SURF is used to extract the features in this classification. Based on the experiments that have been carried out, in general, the learning rate value is not very influential in the learning process, both at the momentum values of 0.1, 0.3, 0.5, 0.7, and 0.9. The best desirable accuracy value for momentum 0.1 is at a learning rate of 0.05. The best desirable accuracy value for momentum 0.3 is at a learning rate of 0.09. The most desirable accuracy value for momentum 0.3 is at a learning rate of 0.05 and 0.07. At a learning rate of 0.03 the highest ideal accuracy value is obtained. The best desirable accuracy value for momentum 0.9 is at a learning rate of 0.09. this research should be redone using the number of hidden layers and nodes in each hidden layer. The addition of a hidden layer, as well as variations in the number of nodes in the hidden layer, will affect computation time and yield more optimal accuracy results.

**Keywords**—Multilayer perceptron; SURF; pneumonia hyperparameter

## I. INTRODUCTION

Medical images have an important role in classifying or identifying a disease. One of the most frequently used techniques is X-ray Photo [1] [2] [3]. This technique is used by radiologists to be able to see and find out information about the patient's body condition. In addition, it has advantages, easy to use, and has a high economic value [4] [5]. A chest X-ray is used by radiographs to see the condition of the patient's chest area. The results of this chest x-ray illustrate the condition of the patient's body starting from the chest, lungs, heart, and trachea [6] [7]. Lung infections caused by bacteria, viruses, fungi, or parasites will be marked with a white-gray area. The pattern area makes it easier for doctors to identify the patient's illness, such as pneumonia [8] [9].

\*Corresponding Author.

Pneumonia is a type of acute respiratory infection (ARI) at the bottom caused by inflammation of the tissues and air sacs in the lungs by bacteria, viruses, fungi, or parasites. The air sacs are filled with fluid which can cause coughing up phlegm, fever, difficulty breathing, and chills [10] [11]. Pneumonia is an airborne disease. Elderly people aged 65 years and over are a high-risk group for pneumonia. In the elderly the pneumonia rate has a high degree of severity of disease, it can even lead to death [12] [13].

Pneumonia classification using the k-nearest neighbor method with glcm feature extraction is the topic of Wijaya's 2020 study. the findings of his study suggest that cropping an x-ray image of the lungs can improve accuracy. the greatest accuracy per class is 66.20 percent while utilizing gray level co-occurrence (glcm) feature extraction and k-nearest neighbor (knn) classification for k = 5. the maximum level of accuracy is 72.90 percent for the virus lung picture object because the gray level co-occurrence (glcm) does not indicate the proper value, the precision and recall levels tend to have the same value [14].

The CNN model in classifying CT image data sets and determining the probability of COVID-19 infection, according to Xu [15] in his study. In this work, two test models were used: one that ignored the distraction component and another that took into account the distraction effect by adding a noisy-OR bayesian function. the acquisition of classification evaluation with 79.4 % accuracy, 68.9% precision, 76.5 % recall, and 72.5 % f1-score in the initial model. While the acquisition of classification evaluation in the second model had 86.7 % accuracy, 81.3 % precision, 86.7 % recall, and 83.9 % f1-score.

Detection of COVID-19 Infection in Chest X-rays Based Deep Transfer Learning, according to Das [16], explains to circumvent the low sensitivity of RT-PCR, chest X-ray images were employed to detect and diagnose COVID-19 in this study. CT scans were favored over chest X-rays. We chose chest x-ray images since X-ray machines are less expensive than CT scan devices. Furthermore, X-rays emit less ionizing radiation than CT scans. Chest X-ray scans of COVID-19 infected patients show several unique patterns and bilateral alterations, according to the exhaustive review. Manual COVID-19 testing from chest x-ray images, on the other hand, is a difficult task. As a result,

utilizing deep learning-based methodologies, an automatic analysis of chest X-rays was performed in this article. Deep transfer learning methods were capable of training network weights on big datasets as well as fine-tuning the weights of pre-trained networks on small datasets. Using multiple performance metrics like as accuracy, f-measures, sensitivity, specificity, and kappa statistics, extensive comparison analyses have been undertaken to evaluate the performance of the suggested model. The proposed model outperforms competing models, according to comparative analyses. deep understanding Under test conditions, the VGGNet model has an accuracy of 89.30 %, F-measure 90.07 %, sensitivity 91.22 %, specificity 89.12 %, and kappa statistic 90.12 %, while in training conditions it has an accuracy of 90.32 %, F-measure 91.69 %, sensitivity 91.83 %, specificity 90.16 %, and kappa statistic 91.54 %.

Optimizing [46] the hyper-parameters of multi-layer perceptron with greedy search, in experiment using Fashion MNIST and Kuzushiji MNIST datasets, is the topic of Bae's et al [36]. The proposed algorithm shows the similar performance as compared to complete search, which means the proposed algorithm can be a potential alternative to complete search. Experiments used with variations in the learning rate [0.1; 0.05; 0.01; 0.005; 0.001] the most optimal results are at a learning rate of 0.1 and 0.001[36].

Ke [37] in his report 2021 discusses enhancement of multilayer perceptron model training accuracy through the optimization of hyperparameters: a case study of the quality prediction of injection-molded parts. In the experiment the learning rate used [0.1; 0.001; 0.0001; 0.0001; 0.00001] and the activation functions [Sigmoid, Tanh, ReLU, LeakyReLU, ELU] the most optimal accuracy results are at a learning rate of 0.1 both in the activation functions of Sigmoid, Tanh, ReLU, LeakyReLU, and ELU[37].

Kerny et al. [39] research uses deep learning model inception to determine medical conditions. Layer training was done using Adam Optimizer with a learning rate of 0.001 and stochastic gradient descent in batches of 1,000 photos each step. In all categories, training lasts 10,000 steps or 100 epochs.

A wavelet technique was included as a noise remover before the forecasting data was processed using the ANN model, according to Ekonomou [40], who found that while the ANN model produced good results when used to solve forecasting situations, more optimal results were obtained. This model demonstrates that in order to produce more accurate results, ANN still has to be expanded with different combinations and enhancements.

In his manuscript addressing the case of the Power System Topology Observability analysis, Reddy [43] also investigated the enhanced Neural Network Hopfield model; the Power System Topology Observability was then analyzed using the particle swarm optimization technique as a comparative model. According to his research, the improved Hopfield Neural Network model required the least amount of computational time when compared to the particle swarm optimization algorithm, which had a time ratio of 0.2811: 18,592 in seconds. The Hopfield model also required the fewest iterations to produce the best results. When compared to the particle swarm optimization

approach, the upgraded neural network requires less iterations which had an iterations ratio 45:189.

In his research, Alqudah [44] claimed that by integrating the deep learning model as a feature extraction process and machine learning as a classification, the CNN model had been improved from the basic Neural network model. This study examined the accuracy, sensitivity, specification, and precision of the image size input model with variations of 32x32, 64x64, 128,128,256, and achieved the best results at 64x64 image input circumstances with successive values of 80.07, 79.24, 89.55, and 78.80.

The ResNet model was used by Latif [45] in his research on pneumonia detection. The CNN model (9 layers), CNN model (10 layers), CNN model (12 layers), ResNet V1 (3 blocks), and ResNet V2 (12 blocks) were all tested in trials to get the best results. The CNN model's results took less time to accomplish than those of the ResNet model, with training times of 26.72 minutes, 28.10 minutes, 36.18 minutes, 9.09 hours, and 14.58 hours. However, with accuracy scores of 80.88, 81.24, 80.28, 87.67, and 88.67 correspondingly, the ResNet model outperforms CNN.

In the comparison of chest X-rays presenting as pneumonia versus normal, we achieved an accuracy of 92.8%, with a sensitivity of 93.2% and a specificity of 90.1%. The area under the ROC curve for detection of pneumonia from normal was 96.8%. Binary comparison of bacterial and viral pneumonia resulted in a test accuracy of 90.7%, with a sensitivity of 88.6% and a specificity of 90.9%. The area under the ROC curve for distinguishing bacterial and viral pneumonia was 94.0%.[39].

According to earlier studies, multilayer perceptron as a classification approach and speed up robust feature (SURF) as feature extraction have not been identified in X-Ray Image Classification research. The multilayer perceptron classification approach with variations in momentum and learning rates, as well as SURF as its feature extraction model, will be investigated in this study in categorizing pneumonia based on X-Ray pictures.

This work uses SURF as a feature selection and feature extraction model because surf can reduce data loss in the high-quality data extraction process [35]. Feature selection and feature extraction are difficult tasks when getting high-dimensional data [41][42][47].

## II. STUDY LITERATURE

### A. Pneumonia

Pneumonia is inflammation of the lung parenchyma where the acini are filled with inflammatory fluid with or without infiltration of inflammatory cells into the walls of the alveoli and interstitial spaces characterized by coughing accompanied by rapid breathing and/or shortness of breath in children under five [17]. Pneumonia causes inflammation of the lungs that makes breathing difficult and oxygen intake less. Pneumonia is a disease caused by microorganisms such as pneumococcus, staphylococcus, streptococcus, and viruses whose mode of transmission can be through the medium of air, saliva splashes, direct contact through the mouth, and contact with shared objects [18] [19].

Indonesia as a country located in the tropics has the potential to become an endemic area for infectious diseases which at any time can be a threat to public health. Pneumonia is the second leading cause of death for children under five in Indonesia after diarrhea. The number of pneumonia sufferers in Indonesia in 2013 ranged from 23-27% and deaths from pneumonia were 1.19% [20].

### B. Multilayer Perceptron

The Multilayer Perceptron is a variant of the original Perceptron model proposed by Rosenblatt in 1950 [21]. Neural Network Model or Neural Network is a brain computing system. This is because Neural Networks are inspired by the human brain which can provide input, process, and produce output. Neural Network can produce output because it has acquired the knowledge gained through the learning process [22] [23]. Neural Networks here have several functions, such as pattern classification, mapping patterns from input to new at output, storing patterns to be recalled, mapping similar patterns, optimizing problems, and predictions [24] [25].

Neural Network Multilayer Perceptron is a development of Neural Network Perceptron. Developed to cover the weakness of the Neural Network Perceptron, namely performing complex logic operations [26].

The perceptron algorithm, which forms the basis of the Multilayer Perceptron model, was invented by Frank Rosenblatt, funded by the United States Maritime Research Department at the Cornell Aviation Laboratory in 1957.

Multilayer Perceptron is arranged in three levels consisting of one input layer, one or more hidden layers, and one output layer. So that later the process will run from the input layer to the output layer, which there is no repetition. Neural Network architecture like this is called feedforward [27], Fig. 1.

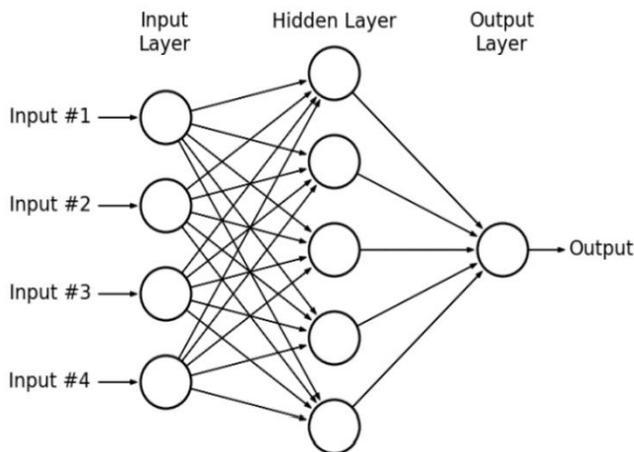

Fig. 1. Research Architecture Multilayer Perceptron.

### C. Surf

The Speed Up Robust Feature (SURF) algorithm was first published by researchers from ETH Zurich, Herbert Bay in 2006 [28]. In its development Herbert Bay was assisted by two colleagues, namely Tinne Tuytelaars and Luc Van Gool [29] [30]. The SURF algorithm can detect local features in an image reliably and quickly. This algorithm is inspired by the Scale

Invariant Feature Transform (SIFT), especially at the scale space representation stage. The SURF algorithm uses a combination of an integral image algorithm and blob detection based on the determinants of the Hessian matrix [31].

SURF is a very powerful local feature detector, which can be used in computer vision such as object recognition and 3D reconstruction [32]. One of the advantages of SURF is its processing speed, this is due in part to the use of integral images. The value of this integral image comes from the sum of the grayscale values of the image [33]. SURF is designed to extract the uniqueness and similarity of features from images. The SURF algorithm is divided into several stages, namely interest point detection and feature description [34].

## III. RESEARCH METHODS

### A. Dataset

The dataset used in this study was taken from the Kaggle dataset source which can be accessed via the following link <https://www.kaggle.com/paultimothymooney/chest-xray-pneumonia>. Consists of 5,863 X-Ray images (Jpeg) and has two categories, namely Pneumonia and Normal.

### B. Data Analysis

Biomedical images come in a wide variety of shapes and sizes. Images for a comparable pathological condition could alter significantly from person to person, and even from encounter to encounter. These discrepancies could be due to variances in illumination, marker stains (for pathological investigations), image extraction procedure, image dimension, and so on. Image preprocessing guarantees that all of the photos are in the same format and are free of noise that is irrelevant to the study.

### C. Research Architecture

This study's research architecture is based on multiple previous investigations [35][38]. A training model and a test model are included in the created model. (See Fig. 2).

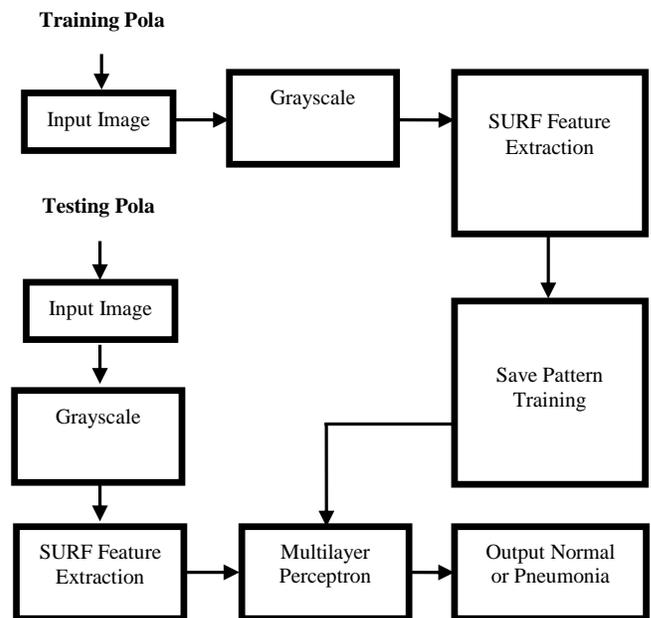

Fig. 2. Research Architecture [35] [38].

Fig. 2 shows the research steps that will be carried out with two processes, the first is the training process, namely the process of extracting data (grayscale to minimize the color space in the image from three color spaces R, G, B into one color space, namely grayscale and extracting by utilizing the SURF feature). and the data is stored as a pattern model that will be used in the testing phase, the second testing process is the process of matching the pattern model that has been trained by utilizing the Multilayer perceptron method as a classification.

#### IV. RESULTS AND DISCUSSION

##### A. Pneumonia X-Ray Sample Set

Fig. 3 shows some pneumonia samples and normal x-ray images used in this study Fig. 3.

Sample X-ray Set of Pneumonia is illustrated in Fig. 3.

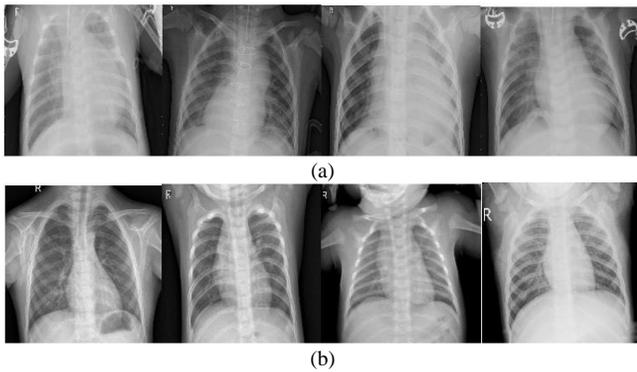

Fig. 3. Sample X-Ray Set (a) Pneumonia, (b) Normal.

##### B. Surf Detection

The results of feature SURF detection are marked with a circle on the image, Fig. 4 shows the results of feature SURF detection with 100 strongest values on the X-ray Set Pneumonia image.

##### C. Performance Measure

A confusion matrix was used to describe the performance of a classification model on a test dataset for which the true values were known. It enables the visualization of an algorithm's performance.

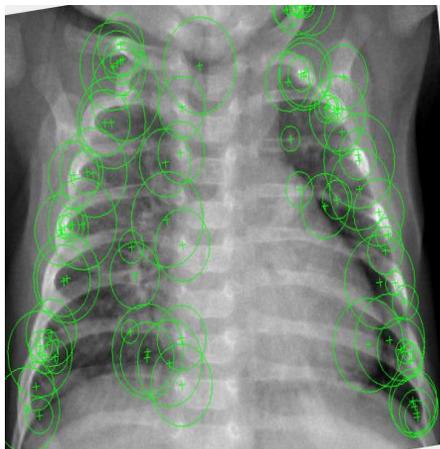

Fig. 4. Surf Detection.

A method's accuracy indicates how accurate the projected values are. Precision refers to the measurement's repeatability, or how many of the forecasts are right. The recall specifies how many right answers are found. The f1-score calculates a balanced average outcome by combining precision and recall. The equations below illustrate how to calculate these values, with TP, TN, FP, and FN standing for true positive, true negative, false positive, and false negative, respectively.

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+TN+FN} \quad (1)$$

$$\text{Precision} = \frac{TP}{TP+FP} \quad (2)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (3)$$

$$\text{F1 - Score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (4)$$

##### D. Experiment

The classification process using a multilayer perceptron was tested with variations in the learning rate [0.1; 0.3; 0.5; 0.7; 0.9; 0.01; 0.03; 0.05; 0.07; 0.09; 0.001; 0.003; 0.005; 0.007; 0.009; 0.0001; 0.0003; 0.0005; 0.0007; 0.0009;] and momentum variation [0.1; 0.3; 0.5; 0.7; 0.9] to determine the optimal level of accuracy on the multilayer perceptron in classifying Pneumonia with condition 100 epochs. The experimental results are presented in Table I, Table II, Table III, Table IV and Table V.

Based on the results of the experiments, the accuracy, precision, recall, and f1-score obtained a relatively stable value, with the lowest accuracy value being 78.4% and the highest accuracy value being 82.8%, the lowest precision value being .80.5% and the highest precision value being 82.8%, the lowest recall value being 78.4% and the highest recall value being 82.8%, the lowest f1-score being 76.4% and the highest f1-score being 82.8%.

Fig. 5 illustrates the entire experiment, from the highest classification report level to the lowest classification report level.

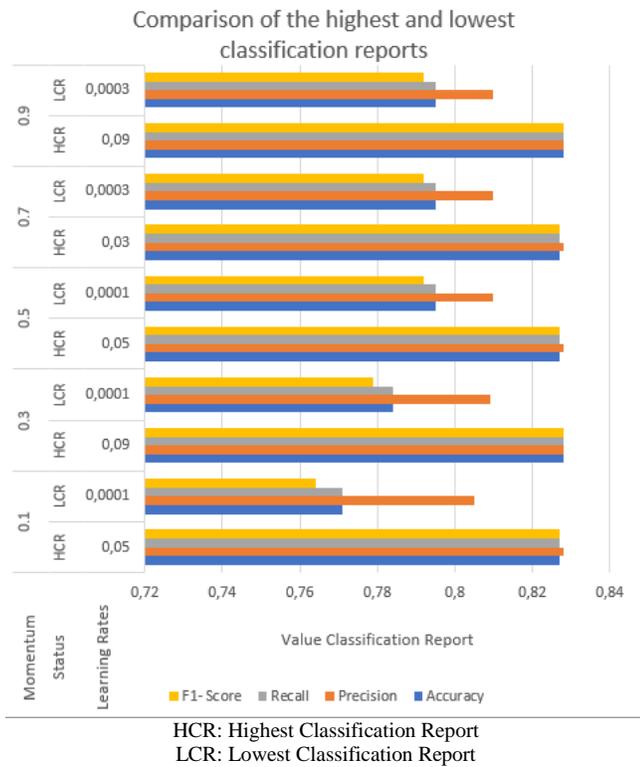

Fig. 5. Comparison of Highest and Lowest Classification Report.

### E. Discussion

The highest classification report rate was found at the momentum condition 0.3 and the learning rate 0.09, and at the momentum condition 0.9 and the learning rate 0.09, with 82.8 %, 82.8 % precision, Recall 82.8 %, and f1-score 82.8 %, based on the results of 100 experiments with variations in the momentum value and variations in the learning rate value.

Detection of COVID-19 Infection in Chest X-rays Using Deep Transfer Learning is a previous study. In training conditions, the VGGNet model has an accuracy of 90.32 %, F-measure 90.07 %, sensitivity 91.22 %, specificity 89.12 %, and kappa statistic 90.12 %, while it has an accuracy of 90.32 %, F-measure 91.69 %, sensitivity 91.83 %, specificity 90.16 %, and kappa statistic 90.54 %.

Using the bayesian noise-OR function to account for the effects of interference on the image, previous research discussed the CNN Model in classifying CT image data sets and determining the probability of COVID19. The results of the

classification report 86.7 % accuracy, 81.3 % precision, 86.7 % recall, and 83.9 % f1-score.

Deep learning and the inception have been used in previous research. To learn about medical disorders. The layers are trained using the Adam Optimizer with a learning rate of 0.001 and stochastic gradient descent in batches of 1,000 images each step. In all categories, training lasts 10,000 steps or 100 epochs. In a comparison of pneumonia to normal chest X-rays, we achieved an accuracy of 92.8 %, with a sensitivity of 93.2 % and a specificity of 90.1 %. The area under the ROC curve for pneumonia detection from normal was 96.8%.

The classification of pneumonia is covered by khairina[48]. The successes in this study are with the level of accuracy, precision, recall, and f1-score with values of 0.8067, 0.7948, 0.9237, and 0.8544 in identifying the symptoms of pneumonia by combining the K-Nearest Neighbor method with the Histogram of Oriented Gradient as a feature selection and feature extraction model.

### IV. CONCLUSION

Based on the experiments that have been carried out, in general, the learning rate value is not very influential in the learning process, both at the momentum values of 0.1, 0.3, 0.5, 0.7, and 0.9. The best desirable accuracy value for momentum 0.1 is at a learning rate of 0.05. The best desirable accuracy value for momentum 0.3 is at a learning rate of 0.09. The most desirable accuracy value for momentum 0.3 is at a learning rate of 0.05 and 0.07. At a learning rate of 0.03 the highest ideal accuracy value is obtained. The best desirable accuracy value for momentum 0.9 is at a learning rate of 0.09 this research should be redone using the number of hidden layers and nodes in each hidden layer. The addition of a hidden layer, as well as variations in the number of nodes in the hidden layer, will affect computation time and yield more optimal accuracy results.

**Abstract**—Confirmed statistical data of Covid-19 cases that have accumulated sourced from (<https://corona.riau.go.id/data-statistik/>) in Riau Province on June 7, 2021, there were 63441 cases, on June 14, 2021, it increased to 65883 cases, on June 21, 2021, it increased to 67910, and on June 28, 2021, it increased to 69830 cases. Since the beginning of this pandemic outbreak, it has been observed that the case data continues to increase every week until this July. This study predicts cases of Covid-19 time series data in Riau Province using the LSTM algorithm, with a dataset of 64 lines. Long-Short Term Memory has the ability to store memory information for patterns in the data for a long time at the same time. Tests predicting historical data for Covid-19 cases in Riau Province resulted in the lowest RMSE value in the training data, which was 8.87, and the test data, which was 13.00, in the death column. The evaluation of the best MAPE value in the training data, which is 0.23%, is in the recovered column, and the evaluation of the best MAPE value in the test data, which is 0.27%, in the positive\_number column. In the test to predict the next 30 days using the LSTM model that has been trained, it was found that the performance evaluation of the prediction results for the positive\_number column and the death column was very good, the recovery column was categorized as good, the independent\_isolation column and the care\_rs column were categorized as poor.

**Keywords**—Time series prediction; forecasting; recurrent neural network; long short-term memory

## I. INTRODUCTION

Indonesia is one of the countries hit by the Covid-19 pandemic which continues to increase every day. Covid-19 outbreak due to the coronavirus began to appear in mid-December 2019 in China, precisely in the city of Wuhan, and has spread to several countries worldwide. The World Health Organization (WHO) had declared January 30, 2020, a public health emergency. The Covid-19 pandemic entered Indonesia on March 2, 2020, it is known from existing information that there have been Indonesian citizens who have been infected. The two 64-year-old women, and their 31-year-old daughter were declared positive for Covid-19 after having contact with a Japanese citizen [1], [2].

The Riau Provincial Government made various efforts to suppress the transmission of the coronavirus, namely by providing health protocol directions, including washing hands, maintaining a distance of two meters, avoiding crowds, avoiding touching your face with your hands, and maintaining a healthy diet. This is in the spotlight with the aim of suppressing the addition of new cases and reducing the death rate. Confirmed statistical data for the accumulation of the

Covid-19 cases sourced from (<https://corona.riau.go.id/data-statistik/>), in Riau Province on June 7, 2021, as many as 63441 cases; on June 14, 2021 it increased to 65883 cases, on June 21, 2021 it increased to 67910, on June 28, 2021 it increased to 69830 cases, and so on. Since the beginning of the outbreak of this pandemic outbreak, it has been observed that case data continues to grow every week until this August [3]. Riau Province is one of the areas in Indonesia which is included in the dangerous zone.

A method is needed to estimate the number of Covid-19 cases every day with data in Riau Province. Forecasting is a technique for predicting conditions that will occur in the future based on data from the past. Predicting the Covid-19 phenomenon based on incident data with sequential time series can be done using the Machine Learning approach [4]. The predicted data in this study are classified as time series. Time series data is a series of observed data based on a certain time interval. The time-series approach explains that the model is influenced by data that occurred in the past [5]. This study makes predictions using the Long Short-Term Memory (LSTM) algorithm. LSTM can store memory information for patterns in the data for a long time simultaneously. LSTM is used for data processing, one of which is time-series data, including that carried out in research by [6] using the LSTM machine learning method, to predict the spread of Covid-19 cases in India based on the realization of prevention that have been implemented such as social restrictions and lockdowns. Then research [7] also uses the LSTM architecture, in forecasting time series data in predicting the development of Covid-19 transmission in Canada.

Based on the previous description, this study aims to predict cases of Covid-19 time series data in Riau Province, using the LSTM algorithm, by achieving the maximum level of accuracy and producing the slightest difference in values between the actual data and prediction [8]. The data sample used was obtained from public data which amounted to 64 lines of accumulated data on Covid-19 cases in Riau Province, starting from June 7, 2021, to August 9, 2021. Referring to the reference, the attributes used as input data are positive numbers, self-isolation, hospitalization, recovery, and death.

## II. LITERATURE REVIEW

Forecasting is a challenging part of time series data analysis. The dominant factors that affect the performance and accuracy of time series data analysis and the forecasting techniques used are based on the type of data and its context. Several problem domains that have dependent variables such

as seasons, economic shocks, unexpected events, and internal organizational changes that produce data also affect predictions [9]. Another review by the same author points out evaluation, and dynamic modeling is exciting fields of study with a wide variety of packages in business, economics, finance, and computer science. The reason for evaluating the collection time is to look at the observations of the time collection path and build a mode to explain the shape of the information and then predict the value of gathering time density. Due to the importance of time collection forecasting in many branches of implemented science, it is important to build robust modes with the aim of increasing forecasting accuracy [10].

Forecasting techniques are used in various case studies, such as in predicting the future affordability of Covid-2019 throughout countries by utilizing real-time information from the Johns Hopkins dashboard [11]. Indicates the accuracy of the flow of foreign tourist arrivals in the Intelligent Tourism System (ITS), using the Long Short Term Memory Neural Network (LSTM) method [12]. Forecasts the arrival of foreign tourists in the Covid-19 pandemic situation, using the LSTM artificial neural network approach [13]. Conducted a study predicting the value of financial market assets in the future with higher accuracy [14].

LSTM is a variation of RNN and has been proven to carry out proper time collection mastering due to the fact that LSTM can preserve contextual data in addition to conducting primarily based totally on sure time-collection events [15]. LSTM is a form of iterative community which has been tested to be very successful on several problems, given its capacity to differentiate between maximum current and initial instance through assigning extraordinary weights to each at the same time as forgetting reminiscences deemed imprecise to predict subsequent outputs [16]. Siami-Namini *et al.* [10], compared Deep Learning algorithms such as LSTM and traditional algorithms such as ARIMA to estimate time series data. They got the result that LSTM is better than ARIMA. More specifically, the average reduction in the error rate obtained by LSTM is between 84 - 87 percent compared to ARIMA. Dutta *et al.* [17] use machine learning to help doctors verify and predict disease growth shortly. The result of their research is that the combination of machine learning models (CNN-LSTM) outperforms other models.

By evaluating the prediction outcomes of the LSTM and AT-LSTM fashions, it may be visible that the AT-LSTM overall performance is higher due to the fact the smallest MAPE cost is obtained. MAPE is a degree of the predictive accuracy of forecasting strategies in data and is greater persuasive whilst evaluating the overall performance of fashions on one-of-a-kind facts sets, as it is now no longer most effective considering the deviation among the expected cost and the authentic cost; however additionally considers the ratio among them [18].

Comparing the LSTM and BI-LSTM forecasting models, where the BI-LSTM combines the LSTM in the incoming collection school system instead of using a single LSTM and ends up with a decreased RMSE compared to the LSTM version. The BI-LSTM version plays higher than the LSTM

version due to the fact that the BI-LSTM version has backward propagation at every time the school expects data. Therefore, the prediction version proposed using the BI-LSTM can be utilized by the public and companies for forecasting the inventory market [19]. To test the performance of the prediction engine, Root Mean Square Error (RMSE) was used. The error or difference between the objective and the obtained output price is minimized by using the RMSE price. RMSE is the rectangular root of the implication/rectangular implication of all errors. The use of RMSE may be very unusual and lead to first-degree forecasting errors of metrics for the prediction of numerical data [20].

### III. RESEARCH METHODOLOGY

The study predicts Covid-19 cases in Riau Province using the Long Short-Term Memory algorithm, carried out with data mining flow steps for forecasting as shown in Fig. 1.

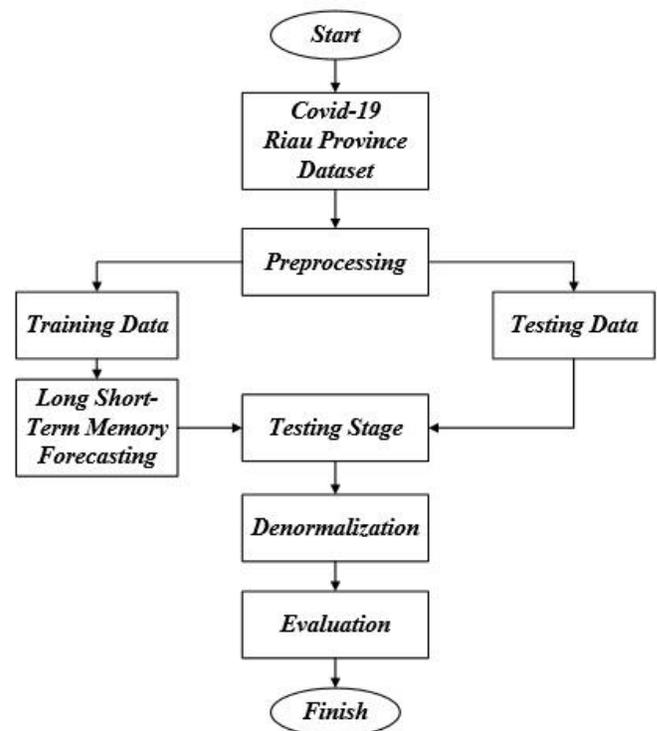

Fig. 1. Forecasting Workflow.

#### A. Dataset

The dataset being searched comes from public data obtained from the official website <https://corona.riau.go.id/data-statistik/>. This dataset is a time-series data type, containing information on Covid-19 cases in Riau Province, which is visualized in the form of a bar graph. Data collection starts from June 7, 2021, to August 9, 2021. The dataset consists of 64 rows of data manually entered in a Microsoft Excel spreadsheet and saved in .csv file format and named the file dataset\_covid19\_riau. Table I is a representation of time series data that has been accumulated, from Covid-19 cases that have occurred in Riau Province.

TABLE I. COVID-19 RIAU PROVINCE DATASET

date	total_ positive	self_ isolation	hospital_ care	recover	decease
6/7/2021	63441	4335	867	56546	1693
6/8/2021	63786	4060	837	57183	1706
6/9/2021	64188	3836	806	57827	1719
6/10/2021	64626	3836	762	58297	1731
6/11/2021	65010	3808	715	58744	1743
...	...	...	...	...	...
8/5/2021	102926	12365	1392	86375	2794
8/6/2021	105125	13416	1374	87486	2849
8/7/2021	106376	13574	1376	88526	2900
8/8/2021	107532	12783	1356	90466	2927
8/9/2021	108316	12012	1362	91963	2979

### B. Preprocessing

This time-series data processing leads to one sample of attribute data as input and output data for the future, and determines how many prediction outputs are generated. Processing of data categorized as numerical data is carried out by normalizing the min-max scale. The min-max normalization preprocessing stage is the stage of changing the value of the actual numeric data (units, tens, hundreds, thousands, and so on) to a scaled value between 0 (as the minimum value) to 1 (as the maximum value) [3]. The data normalization process for all columns is intended as data input into the LSTM forecasting engine, which accepts input values with a distance between 0 to 1. For example, the smallest value in the positive\_number column, which is 63441, is changed to 0, then the largest value 108316 is changed to 1. The other data values are converted to decimal numbers between 0 and 1. Table II is the result of normalization data in the positive\_number column.

TABLE II. DATA NORMALIZATION RESULTS

date	positive_number	data normalization
6/7/2021	63441	0
6/8/2021	63786	0.007688022
6/9/2021	64188	0.01664624
6/10/2021	64626	0.026406685
6/11/2021	65010	0.034963788
...	...	...
8/5/2021	102926	0.879888579
8/6/2021	105125	0.928891365
8/7/2021	106376	0.956768802
8/8/2021	107532	0.982529248
8/9/2021	108316	1

### C. Composition of Training Data and Test Data

The dataset is divided into two, namely training data and test data. The proportion of distribution for training data is more than for test data. The training data is intended to build a forecasting learning machine with the Long Short-Term

Memory (LSTM) algorithm, and the test data is intended for testing in predicting Covid-19 cases in Riau Province. The separation process of training data and test data is carried out with a division ratio of 85:15. As much as 85% of the total dataset, namely 54 data lines, starting from June 7, 2021, to July 30, 2021, is used for training data in order to build a forecasting engine with the LSTM algorithm. As much as 15% of the total dataset, which is 10 data lines, starting from July 31, 2021, to August 9, 2021, is used for test data in predicting the next accumulated cases of Covid-19 in Riau Province.

### D. Long Short-Term-Memory Forecasting

Build an LSTM forecasting architecture using the python hard module, then import the sequential model, LSTM layer, and dense layer. A sequential model is a model that has one input layer, several hidden layers, and one output layer. By creating a new variable, namely the model, the architecture that is built is composed of one hidden LSTM layer with 50 units of neurons or nerves that function to process input data, which in the LSTM layer also becomes an input layer with shape parameters that have been made in the previous program code. It also uses the sigmoid activation function parameter. Dense layer functions as an output that receives the input information that has been processed in the hidden layer. After that call the compile() function to configure the data training process, with adam optimization and perform a loss percentage calculation with the mean squared error, to review the information on the predicted error rate that is targeted to a minimum. The LSTM forecasting architecture can be seen in Fig. 2.

```
Model: "sequential_17"  
  
Layer (type)                Output Shape                Param #  
-----  
lstm_17 (LSTM)              (None, 50)                 10200  
-----  
dense_16 (Dense)           (None, 1)                  51  
-----  
Total params: 10,251  
Trainable params: 10,251  
Non-trainable params: 0
```

Fig. 2. LSTM Forecasting Architecture.

### E. Testing Predictions of Covid-19 Cases in Riau Province

The tests carried out were comparing and calculating the difference between the results of the actual test case data values and the test data values for the predicted accumulated Covid-19 cases. The prediction testing process is carried out with training data that has gone through the training stage. Furthermore, predictions of positive cases of Covid-19 are carried out on training data, starting from June 8, 2021, to July 29, 2021, and test data starting from August 1, 2021, until August 8, 2021.

### F. Denormalization of Actual Data and Predicted Data

After the test is complete, the prediction results on the two data are data that are still normalized. The normalized values in the training data, test data, training data prediction results, and test data prediction results are converted into actual values by a denormalization process and then display the overall

results of these actual values. The results of denormalization can be seen in Table III and Table IV.

G. Evaluation of Test Results

In proving the accuracy and performance of the LSTM forecasting engine, it is necessary to calculate the difference between the predicted data value and the actual data value, based on the results of the Covid-19 prediction test in Riau Province. First measured by calculating the level of accuracy using the calculation of Root Mean Square Error (RMSE) to find the smallest error, which can be seen in the following equation (1).

$$RMSE = \sqrt{\frac{\sum_{i=1}^N (y - \hat{y})^2}{N}} \tag{1}$$

Where N is the number of observed data,  $y_1, y_2, y_3, \dots, y_n$  is the observed value, while  $\hat{y}_1, \hat{y}_2, \hat{y}_3, \dots, \hat{y}_n$  is the predicted value.

The higher the resulting RMSE value, the lower the level of accuracy, and the lower the resulting RMSE value, the higher the level of accuracy [5]. The second measure is the Mean Absolute Percentage Error (MAPE) calculation, to determine LSTM performance evaluation in forecasting (forecasting), which can be seen in the following equation (2).

$$MAPE = \frac{100}{N} \sum_{i=1}^N \frac{|y_i - \hat{y}_i|}{y_i} \tag{2}$$

7	107532.0	107427.906250	104.093750

The use of MAPE in the evaluation of the prediction results can calculate the measurement accuracy of the actual value and the predicted value. MAPE calculates the error from the observation and prediction data, that is expressed in percent value [18]. The MAPE value criteria are shown in Table V.

TABLE V. MAPE QUALITATIVE CRITERIA [21]

MAPE Value	Interpretation
<10%	Evaluation of forecasting model capability is very good
10% - 20%	Evaluation of forecasting model capability is good
20% - 50%	Evaluation of forecasting model capability is sufficient
>50%	Evaluation of forecasting model capability is poor

Evaluation of predictions on statistics of COVID-19 instances is performed in five columns, specifically, positive\_number, independent\_isolation, hospitalization\_rs, recovered, and died. Information on the assessment effects in every column, in predicting the dataset of showed Covid-19 instances that befell in Riau Province, is offered in Table VI.

Fig. 3 shows the positive case prediction test results, the yellow line shows the actual value of the training data, which coincides with the red dotted line, which is the predicted value of the training data, with an evaluation of RMSE 246.92 and MAPE 0.24%. Then the black line shows the actual value of the test data, which coincides with the green dotted line which is the predicted value of the test data, with an evaluation of RMSE 423.85 and MAPE 0.27%.

Fig. 4 shows the results of the self-isolation case prediction test, the yellow line shows the actual value of the training data, which coincides with the red dotted line, which is the predicted value of the training data, with an evaluation of RMSE 236.41 and MAPE 4.39%. Then the black line shows the actual value of the test data, which coincides with the green dotted line which is the predicted value of the test data, with an evaluation of RMSE 815.17 and MAPE 5.36%.

Fig. 5 shows the results of the prediction test for hospitalization cases, the yellow line show the actual value of the training data, which coincides with the red dotted line which is the predicted value of the training data, with an evaluation of RMSE 33.21 and MAPE 3.61%. Then the black line shows the actual value of the test data, which coincides with the green dotted line which is the predicted value of the test data, with an evaluation of RMSE 33.03 and MAPE 2.00%.

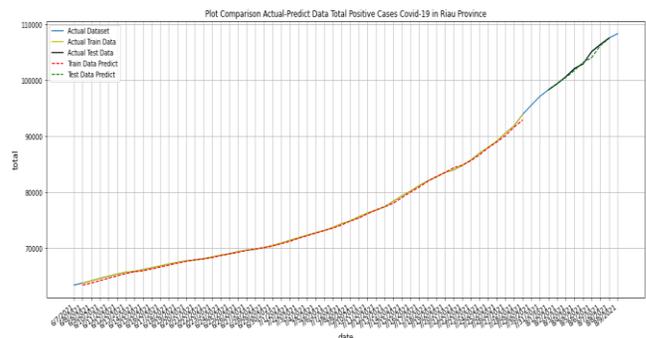

Fig. 3. Prediction Result of Positive Number.

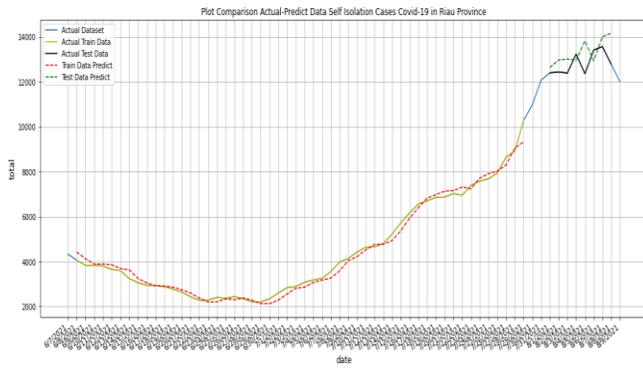

Fig. 4. Prediction Results of Isolation Cases.

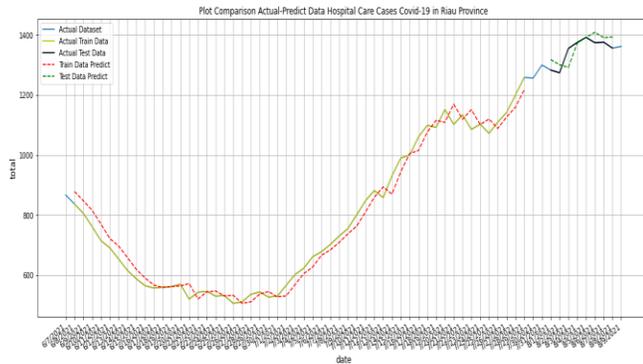

Fig. 5. Prediction Results of Hospitalization Cases.

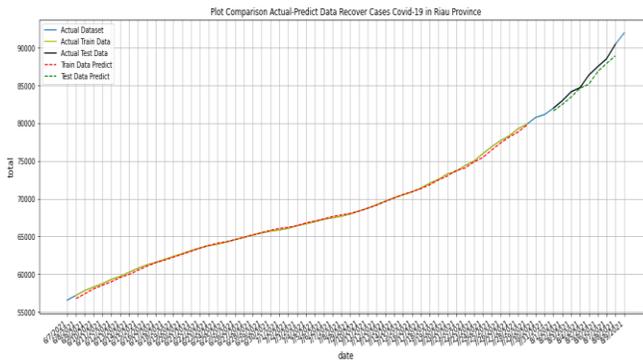

Fig. 6. Prediction Results of Healed Cases.

Fig. 6 shows the results of the prediction test for cured cases, the yellow line, show the actual value of the training data, which coincides with the red dotted line which is the predicted value of the training data, with RMSE 201.34 and MAPE 0.23% evaluation results. Then the black line shows the actual value of the test data, which coincides with the green dotted line which is the predicted value of the test data, with an evaluation of RMSE 827.57 and MAPE 0.81%.

Fig. 7 shows the death case prediction test results, the yellow line, show the actual value of the training data, which coincides with the red dotted line, which is the predicted value of the training data, with an evaluation of RMSE 7.51 and MAPE 0.32%. Then the black line shows the actual value of the test data, which coincides with the green dotted line which is the predicted value of the test data, with an evaluation of RMSE 17.85 and MAPE 0.54%.

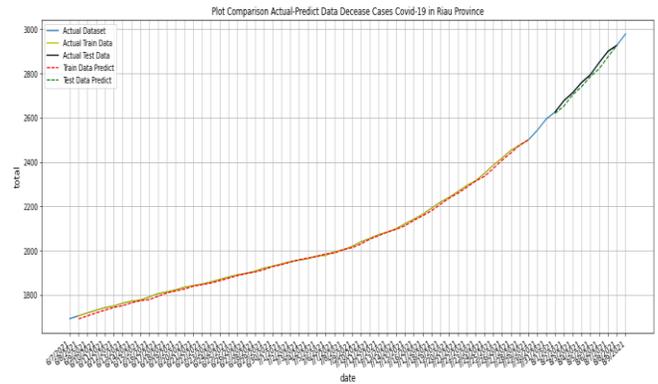

Fig. 7. Prediction Results of Death Cases.

In the graph above, it can be explained that the blue line is the overall data or dataset of Covid-19 cases that have accumulated in Riau Province. The yellow line shows the actual value of the training data, which coincides with the red dotted line which is the predicted value of the training data. Then the black line shows the actual value of the test data, which coincides with the green dotted line which is the predicted value of the test data.

TABLE VI. CONCLUSION OF EVALUATION OF HISTORICAL DATA PREDICTION TEST

No	Column Name	RMSE		MAPE		MAPE Criteria
		Actual & Prediction Training Data	Actual & Prediction Testing Data	Actual & Prediction Training Data	Actual & Prediction Testing Data	
1.	total_positive	246.92	423.85	0.24%	0.27%	Very Good
2.	self_isolation	236.41	815.17	4.39%	5.36%	Very Good
3.	hospital_care	33.21	33.03	3.61%	2.00%	Very Good
4.	recover	201.34	827.57	0.23%	0.81%	Very Good
5.	decease	7.51	17.85	0.32%	0.54%	Very Good

From Table VI, it can be seen that the column that has the lowest evaluation of the RMSE value in the training data is 7.51 and the test data is 17.85 in the death column, meaning that the actual data and the predicted data have the smallest difference in values. Then the evaluation of the best MAPE value in the training data, which is 0.23%, is in the recovered column, and the evaluation of the best MAPE value in the test data, which is 0.27%, in the positive\_number column. The MAPE value in the table above is the average MAPE value of all existing data. Overall, the implementation of the Long Short-Term Memory (LSTM) algorithm, in predicting each column of Covid-19 cases in Riau Province, resulted in excellent forecasting machine learning capabilities.

### H. Future Covid-19 Predictions

With a dataset of 64 data lines, predictions of Covid-19 cases are made for the next 30 days, using LSTM forecasting. The predicted value data obtained are then combined in tabular form with the initial dataset, and make a line graph comparing the actual data (blue line) and predictive data for 30 days in the future (red line). A composite graph between the initial dataset and the predicted results for each column.

Fig. 8 shows dataset on the number of positive cases with a blue line graph. In this case, where data is showing the number 108316, it is predicted that the number of positive cases in the next 30 days with a red line graph will be an increase which accumulated as many as 14939 cases.

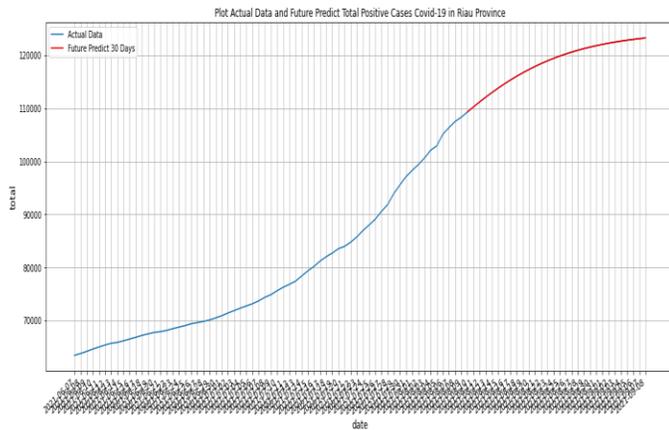

Fig. 8. 30 Days Prediction of Positive Number.

Fig. 9 shows dataset on the number of positive cases with a blue line graph. In this case, where data is showing the number 12012, it is predicted that the number of positive cases in the next 30 days with a red line graph will be an increase which accumulated as many as 11200 cases.

Fig. 10 shows dataset on the number of positive cases with a blue line graph. In this case, where data is showing the number 1362, it is predicted that the number of positive cases in the next 30 days with a red line graph will be an increase which accumulated as many as 336 cases.

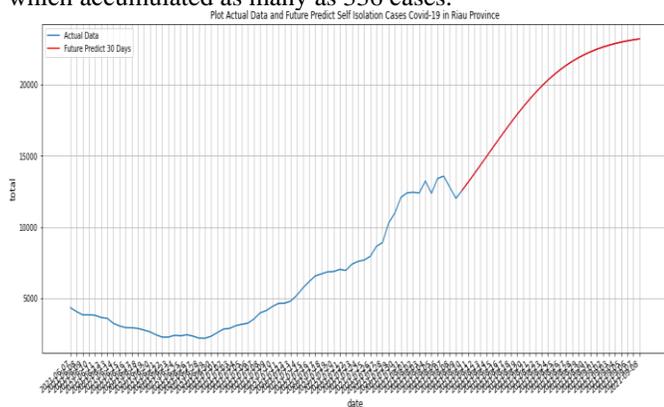

Fig. 9. 30 Days Prediction of Independent Isolation Cases.

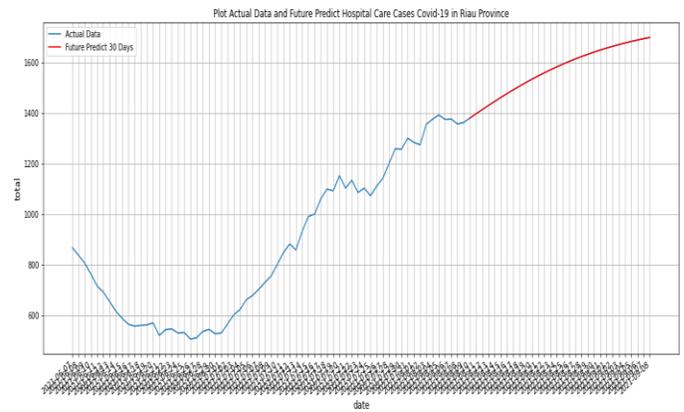

Fig. 10. Prediction of 30 Days of Hospitalization Cases.

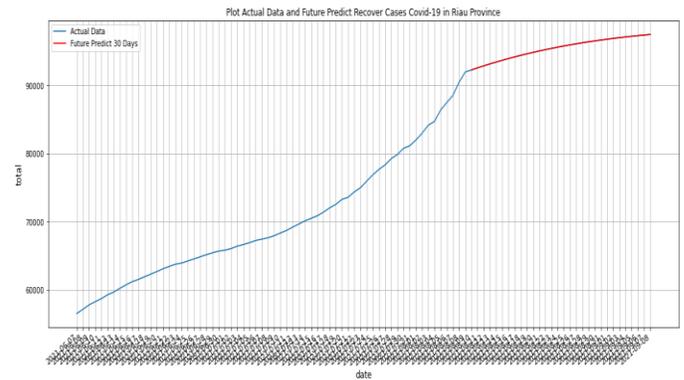

Fig. 11. Prediction of 30 Days of Cure Cases.

Fig. 11 shows dataset on the number of positive cases with a blue line graph. In this case, where data is showing the number 91963, it is predicted that the number of positive cases in the next 30 days with a red line graph will be an increase which accumulated as many as 5512 cases.

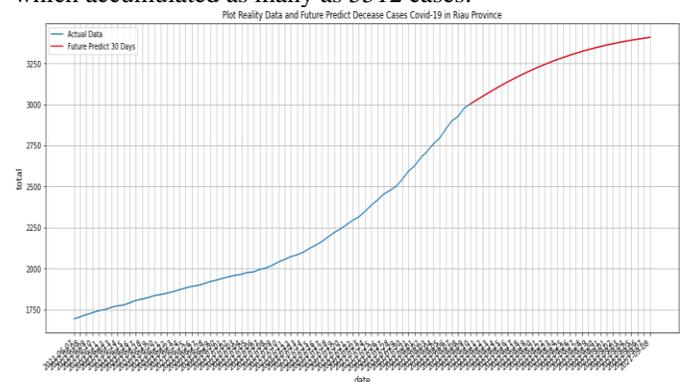

Fig. 12. Prediction of 30 Days of Death Cases.

Fig. 12 shows dataset on the number of positive cases with a blue line graph. In this case, where data is showing the number 2979, it is predicted that the number of positive cases in the next 30 days with a red line graph will be an increase which accumulated as many as 430 cases.

TABLE VII. CONCLUSION OF FUTURE PREDICTION TEST EVALUATION

No	Column Name	RMSE	MAPE	MAPE Criteria
		Reality Data & Future Predict 30 Days	Reality Data & Future Predict 30 Days	
1.	total_positive	1148.67	0.86%	Very Good
2.	self_isolation	13775.46	257.89%	Poor
3.	hospital_care	795.79	107.84%	Poor
4.	recover	13833.96	11.10%	Good
5.	decease	294.68	7.24%	Very Good

Table VII is the evaluation of the LSTM model for testing the prediction results for the next 30 days, with the real data that has been running from the initial data acquisition. The positive\_number column obtained an RMSE value of 1148.67 and a MAPE value of 0.86%, then the death column with an RMSE value of 294.68 and a MAPE value of 7.24%. LSTM's prediction performance on the two columns is categorized as very good. The cured column has a good predictive performance with an RMSE value of 13833.96 and a MAPE value of 11.10%. This column of positive\_number, recovered, and dead obtains the difference between each value in the data row and the difference in the average value which is not far away. The last two columns, namely isolation\_mandiri and care\_rs, obtained prediction performance that was categorized as poor because the MAPE value was above 50% and the RMSE value was very far, as seen from the difference in comparison between the real data values and the predicted results.

#### IV. CONCLUSION

From the results of research on forecasting that have been carried out, several conclusions can be drawn including (1) the application of the Long Short Term-Memory algorithm can be used to predict cases of time series data that have accumulated from Covid-19 in Riau Province which has occurred within a day; (2) prediction testing on a dataset consisting of 64 data lines, produces the lowest RMSE value in the training data, which is 8.87 and the test data, which is 13.00, in the death column. The evaluation of the best MAPE value in the training data, which is 0.23%, is in the recovered column, and the evaluation of the best MAPE value in the test data, which is 0.27%, is in the positive\_number column; (3) evaluation of the Long Short Term-Memory algorithm in predicting historical data on Covid-19 cases that have accumulated in Riau Province, resulting in excellent forecasting machine learning capabilities, with the MAPE value criteria below 10% in both training data and test data; in the column of positive\_number, independent\_isolation, care\_rs, recovered, and died; (4) in the test to predict the next 30 days using the LSTM model that has been trained, it was found that the performance evaluation of the prediction results for the positive\_number column and the death column was very good, the recovery column was categorized as good, the independent\_isolation column and the care\_rs column were categorized as poor.

**Abstract**—Epilepsy is a neurological disorder that influences about 60 million people all over the world. With this, about 30% of the people cannot be cured with surgery or medications. The seizure prediction in the earlier stage helps in disease prevention using therapeutic interventions. Certain studies have sensed that abnormal brain activity is observed before the initiation of seizure which is medically termed as a pre-ictal state. Various investigators intend to predict the baseline for curing the pre-ictal seizure stage; however, an effectual prediction model with higher specificity and sensitivity is still a challenging task. This work concentrates on modelling an efficient dense layered network model (DLNM) for seizure prediction using deep learning (DL) approach. The anticipated framework is composed of pre-processing, feature representation and classification with support vector based layered model (dense layered model). The anticipated model is tested for roughly about 24 subjects from CHBMIT dataset which outcomes in attaining an average accuracy of 96% respectively. The purpose of the research is to make earlier seizure prediction to reduce the mortality rate and the severity of the disease to help the human community suffering from the disease.

**Keywords**—Epilepsy seizure; pre-ictal state; deep learning; feature representation; vector model

## I. INTRODUCTION

A patient affected continuous seizures due to Epilepsy, a neurological order. This disease is afflicted on more than 1% of the world population. Medicines or surgical therapy were given to the patients afflicted by this disease [1]. In more than 40% cases, seizures cannot be manipulated with the recent models which consist of surgical procedures [2]. Hence, it is immensely vital that seizures can be treated with the help of medication by anticipating the consequent seizures before they arise. To sense brain activity, EEG signals are monitored [3].

Denoting EEG electrodes on the tissue termed intracranial EEG signals recorded these signals. The advancements in electrical signals of the internal brain are noticed by EEG recording and it is termed as scalp EEG or electrodes implantations of internal brain.

These states consist of preictal state, i.e. 30 minutes a seizure takes place. Then, Ictal state, i.e. the seizures' starting and ending are the same period and finally, post-ictal state, i.e. period after the seizure occurs [4]. The initial state gives knowledge about the starting of a seizure, which is beneficial for us; as it is the period before the seizure happens. Identifying preictal state can assist in eliminating seizures with treatment. Multiple EEG signal generation channels for interictal, preictal, and ictal states are exhibited sequentially [5]. There is a contradiction among these two states based on amplitude and frequency. It substantially enlarges in the preictal state on the contrary to interictal state. This case instigates predicting epileptic seizures successfully by categorizing interictal and preictal signals.

After digitization with a sampling rate from 200Hz to 5000Hz, EEG signals are captured with headsets and processed. These signals are clarified during the seizure onset by a neurologist on the particular software [6]. Before preictal seizure onset, the individuals' state is examined for 30 to 90 minutes. It is the next state of post-ictal state and ends before preictal state. However, interictal is the normal brain state. The aim is to accomplish preictal and interictal state classification, as mentioned previously [7]. Numerous researchers have suggested ML and DL approaches for seizures prediction. Pre-processing, features extraction and classification are included in this method. Pre-processing is terminated in the initial step to detach noise and accelerate

SNR. EEG signal filtering in the time domain with notch and bandpass Butterworth filters are added as common pre-processing methods. When enforced on EEG signals, the spatial and optimized pattern filter renders superior SNR. To preprocess EEG signals, EMD is beneficial. We can increase the SNR as it affords intrinsic mode and preserves low-frequency components. To make the proper victual in CNN, Wavelet and Fourier transform is also utilized [8]. Features are removed, and relevant features are preferred after noise removal, which affords high interclass and intra-class variance. For forecasting epileptic seizures, researchers have removed handcrafted features in both temporal and spectral features. The first four statistical moments are embraced in temporal features, PSD and spectral moments are embraced as special features [9]. After the progression of DL approaches, automatic feature extraction with CNN has also been utilized by many researchers and these features are removed based on class information. After feature selection with the CNN model, classification is executed. Various investigators utilized SVM, RF, K-NN, NB and MLP for classifications. In some cases, CNN, LSTM and RNN can also be utilized for classification, which included in deep learning classifiers [10]. However, there are some flaws over the existing models. The major limitation is the lack of prediction rather than classification. Earlier prediction helps to reduce the mortality rate and proper decision can be done to help the patients to get rid of the disease. This research focuses on modelling a dense layered network for epileptic seizure prediction and evaluates various metrics like sensitivity and specificity. The dense network model alleviates the vanishing-gradient problem, strengthen feature propagation, encourage feature reuse, and substantially reduce the number of parameters. The purpose of the research is to make earlier seizure prediction to reduce the mortality rate and the severity of the disease to help the human community suffering from the disease. The major contributions of the proposed model are:

- 1) Initially, an online available dataset known as CHBMIT is considered to perform the analysis for epileptic seizure prediction;
- 2) Fourier transform is applied for performing feature representation to enhance the quality of prediction;
- 3) Finally, a dense layered network model is proposed to perform the prediction process. The significance of the model is achieved with metrics like accuracy.

The work is provided as: Section II provides a comprehensive analysis on various prevailing approaches. The methodology is elaborated in Section III and the numerical results are discussed in Section IV. The summary is discussed in Section V.

## II. RELATED WORKS

EEG signal-processing features extraction and classification are associated with seizure prediction systems. Various ML and DL approaches are proposed by many researchers for forecasting epileptic seizures, manipulating scalp EEG signals and enrol EEG signals with electrodes placed on the patient's scalp. Many researchers in recent years have proposed prediction methods [11]. Three common steps

are embraced by all these methods, which comprise EEG signal pre-processing, extracting features from EEG signals and classification between preictal and interictal states.

During EEG signals acquisition, noise is attached, which deals with the SNR of EEG signals, consequently in poor categorization among preictal and interictal states. Various kinds of noise affect EEG signals embracing power line of 50 to 60 HZ baseline noise because of intervention of numerous electrodes and noise annex because of the electrical activity embracing eye movement and heart pulse [12]. Hence, to multiply SNR for progressive outcomes, it is excessively linked to discharge noise as pre-processing step to enlarge SNR, different pre-processing techniques are scheduled by researchers [13]. To eliminate noise, low/high pass filtering is used by author [14]. Using scalp EEG signals for seizure prediction, numerous pre-processing approaches are utilized by researchers [15]. For noise removal, Zandietal, Feietal and Myersetal have utilized Bandpass filtering. To preprocess the dataset in the frequency domain, the author has enforced FFT [16]. In pre-processing of EEG signals, Truongetal has practised short-time Fourier transform. Cause of non-stationary EEG signals, STEFT has been suggested for pre-processing. For pre-processing the signals, both EMD and WT are utilized by [17]. Based on frequency components, EMD separates signals into intrinsic mode functions. Wavelet transforms for pre-processing, Khan et al., have enforced. Using spatial and adaptive filtering, local decomposition and other methods helps in noise extraction from EEG signals [18].

Features are detached after EEG signals pre-processing to classify various seizure states. Utilizing deep learning methods, features can be divided into two ways: extracting handcrafted features is the first, and automated feature extraction is another. Handcrafted features embrace uni- and multivariate features in both the frequency and time domains. Statistical moments define variance, entropy, skewness and kurtosis, entropy, PCA and Lyapunov exponent are embraced in temporal features [19]. Spectral moments and PSD are embraced in special features. Handicraft features have been divided into various seizure prediction methods in recent days, where researchers are embraced zero-crossing intervals, BoW, spectral features in the frequency domain, spatial pattern filtering and for automated feature extraction, some studies have utilized convolutional neural networks [20] – [22]. CNN separating features separate features keeping the target classes beneath consideration with high inter –lasso's variance with the support of CNN in this method. On scalp EEG signals, feature extraction techniques in state-of-the-art seizure prediction methods [23].

Classification between preictal and interictal states is done once the features have been separated from EEG signals. For categorizing EEG signals with seizure prediction, both ML and DL approaches are utilized by researchers. Nearest neighbour, Naive Bayes, support vector machine, Gaussian mixture model, DT, and RT are added to machine learning classification methods. The deep CNN, RNN, and LSTM units are embraced in deep learning classifiers. Variation mixture models are utilized in recent studies. An extreme learning machine and certain threshold to differentiate among interictal

and precital classes are utilized for classification and are tried quietly as a classifier support vector machine by [24]. For various seizures classification, convolutional neural networks are also utilized. Currently, researches utilized classification techniques are shown in [25]. The limitations in automatic detection of interictal spikes and epileptic seizures are preferred using the deep learning approach. The major research gap is the lack of accurate prediction of the disease and the computational complexity encountered during the prediction process. Based on these issues, the proposed model intends to reduce the complexity in the prediction process and enhance the accuracy.

### III. METHODOLOGY

We used the CHBMIT dataset, freely available to the public, to apply our suggested methodology. It is a collection of 24 frontal ECG signals from patients aged 2 to 22. The section that follows gives a thorough summary of this database.

#### A. Dataset

A patient's EEG signals may be captured using electrodes placed on the forehead (scalp electrode) or by transplanting the electrical stimulation in the brain parenchyma (EEG signals). We utilized a publicly accessible collection of head EEG signals from CHBMIT (ECG recordings) from the pediatric subjects with intractable seizures. This dataset was compiled via a partnership between Children's Hospital Cambridge and Harvard and is freely accessible on Pysionet.org. It contains 22 participants, all humans, comprising 17 and 05, female and male, respectively ranging in age from 1.5 years to 19 years for females and 3 years to 22 years for males. Twenty-three microphones positioned on the scalps of people living with Epilepsy helped capture the dataset. All EDF files were turned to .mat documents using the MATLAB 'edfread' program. The sampling rate for the data was 256 Hz. MATLAB 2020a plays a substantial role in pre-processing and classification approach as the simulation environment is ease of use, it helps to make prediction faster. That participant's material has been separated into numerous files with an hour-long recording. The Preictal state in this country occurs before the onset of the ictal stage. The database is described in full in Table I.

#### B. Prediction Model

A strategy for predicting seizures begins a few seconds well before the commencement of the seizure, is described here. The suggested method's flowchart is shown in Fig. 1 and Fig. 2. We utilized the publicly available CHBMIT electroencephalographic dataset, which includes 24 people and signals collected with 23 wires and digitized at 256 Hz. The data source is freely accessible for download. "edfread" converts these outputs to mat files. Whitehead wide bandwidth removes background noise from EEG data. After noise reduction, STFT is done to boost the noise ratio and translate signals to the frequency domain. It is possible to extract several individually created univariate and multivariate characteristics in both the time and frequency domains [26]. These traits are not, however, retrieved based on the classification method to which they belong. So we used DNN to extract characteristics. As they are retrieved with the aid of

class information taken into account, these characteristics provide superior covariance variance [27]. Following DNN feature extraction, fully linked layers are swapped out for SVM. DNN extracts features whereas SVM classifies interictal & preictal segments. STFT, DNN, and SVM are briefly explained in the following subgroups.

#### C. Fourier-based Feature Analysis

Short-Time Fourier Transform (STFT) converts the time to frequency domain. Due to non-stationary characteristic of EEG data, STFT produces superior pretreatment results since it catches variations in the signals that last for a brief period. On an equally spaced interval of 30 seconds, we used STFT.

TABLE I. DATASET DESCRIPTION

Type	Scalp EEG
Subject	22
Male	5
Female	17
Channel	23
Sampling rate	256
Total seizures	198
Recordings	644

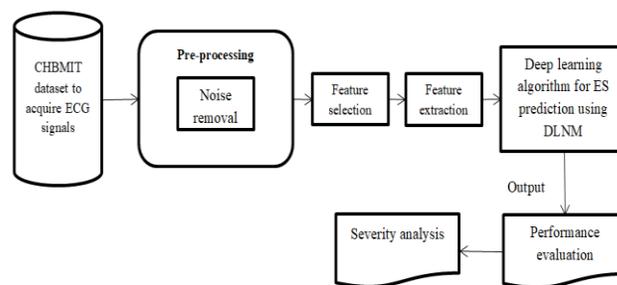

Fig. 1. Block Diagram of Proposed Model.

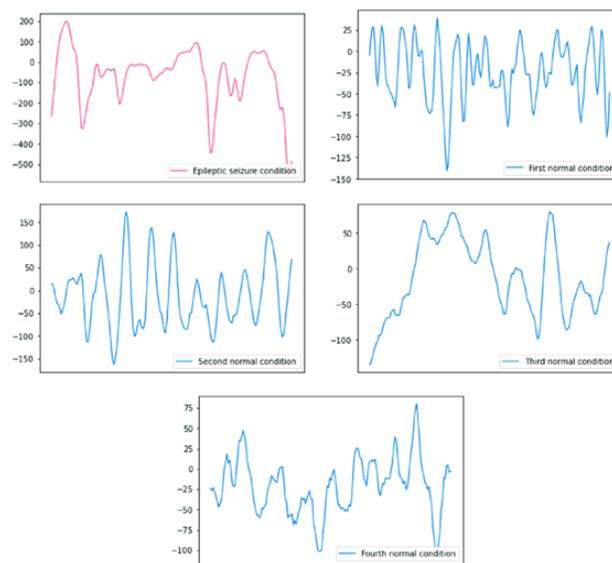

Fig. 2. Epileptic Seizure Dataset based Sample Waveforms.

### D. Dense Layered Network Model (DLNM)

This architecture is provided to make the prediction process based on the dataset class labels. The model includes three sections: input, feature representation and output layer for classification purpose. The extracted features are provided as the input to the input layer. The feature representation section helps in extracting the most influencing feature that shows major impact in triggering the disease as in Fig. 3. Finally, the output layer is to extract the outcome. DLNM is frequently employed for input and time-varying series categorization and semantic segmentation [28]. It has many layers: compression, pools, and conventional neural network-based final layers for identification. Eq. (1) & (2) display the DNN updated weights.

$$\Delta W_l(t + 1) = -\frac{x\lambda}{r} W_l - \frac{x}{n} \left( \frac{\partial C}{\partial W_l} \right) + m\Delta W_l(t) \quad (1)$$

$$\Delta B_l(t + 1) = -\frac{x}{n} \left( \frac{\partial C}{\partial B_l} \right) + m\Delta B_l(t) \quad (2)$$

Here,  $W$  stands for weighting,  $l$  for layers, and  $B$  for bias, while  $x, n, m,$  and  $t$  are regularisation parameters. The artificial neuron, which may be a gaussian, softmax, or linear transfer unit, comes after compression. Eq. (3), (4) & (5) present exponential, softmax and linear transfer unit model parameters.

$$y = \frac{1}{1+e^{-x}} \quad (3)$$

$$\sigma(z) = \frac{e^z}{\sum_{j=1}^k e^{z_j}} \quad (4)$$

$$f(x) = \max(0, x) \quad (5)$$

The mathematical notation used in this section is shown in Table II. The layer used to decrease the number of features is called the pooling layer. The two most popular pooling techniques are maximum and average. In this suggested technique, 16 filters (5\*5) were used in the convolutional layer (CL), batch normalization with 0.4 dispersion, 32 filters (3\*3) is utilized in the second CL, batch normalization, and 64 filters of 3\*3 is the third layer. In all layers, an improved activation function non-linear unit is employed. After each convolution operation, batch normalization and convolutional with 2\*2 are used. Well, after the third layer, some characteristics combine both classes. Fig. 2 depicts the DLNM used in our suggested strategy for image retrieval. In the suggested method, learnable CNN settings are 32576.

### E. Support Vectors for Classification

After extracting DLNM characteristics, we utilized SVM to classify interictal and nine-month states. Linear and non-linear SVMs are the two main categories inside which SVMs may be separated. We can discover support vectors and build a maximum margin using slope and intercept if we have feature space variables. They are known as linear SVMs. We cannot know when to use a linear barrier since data cannot be linear. SVM maps data into higher dimensional space. As a result, making it is simple to separate the data. The use of kernel functions accomplishes it. The recurrent neural network, linear, and gaussian hemispheres are a few of the

often used kernels. This study uses linear SVM to categorize preictal and nine-month states.

TABLE II. DLNM NOTATION

Symbol	Explanation
$\Delta W(t + 1)$	Revised weight
$\Delta B(t + 1)$	Revised bias
$L$	Layer number
$\Lambda$	Regularized parameter
$Y$	Activation function (sigmoid)
$\sigma(z)$	Activation function (softmax)
$f(x)$	ReLU

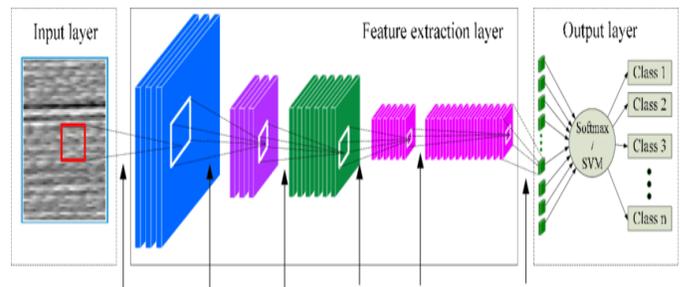

Fig. 3. Proposed DLNM.

## IV. RESULTS AND DISCUSSION

We used our suggested technique on 24 CHBMIT scalp EEG dataset individuals to classify interictal and preictal states and predict epileptic episodes. Our average sensibility is 93%, and our specificity is 91%. The strategy we suggest has a 21-minute average anticipation time. The results of our suggested technique are compared to cutting-edge seizure prediction systems. It has been shown that our suggested strategy for anticipating grand mal seizures outperforms prevailing techniques based on specificity and sensitiveness. Preictal class is a college career according to our definition. Hence a 100 % detection rate with few FPR is crucial. These ROC curves assess the effectiveness of approaches by plotting sensibility against a false positive rate. A method's performance is deemed satisfactory if positive result alarms do not rise as sensitivity increases. In terms of attaining real positive rates with few false reports, it is evident that our suggested strategy works better. As a result, it can be said that the suggested strategy accurately predicts seizures in people with Epilepsy. Here, single input is given and multiple class labels based classified outcomes of extracted as output. The outputs are related to the dataset class labels.

The extracted features are provided as the input to the DLNM. The features are identified to enhance the quality of prediction. The effectiveness of the systems is determined by comparing the classification choices made by the classification to the manual choices made with each session through one or more new born EEG specialists. The classifier's conclusion is captured by the binary classification, which has four types: true positives (TP), epochs properly identified as seizures; false positives (FP), epochs wrongly

tagged as seizures; true negatives (TN), successfully identified non-seizure epochs; and false negatives (FN).

Accuracy (Acc): It is the number of occurrences accurately identified. The formulae given below are to determine accuracy:

$$Accuracy = \frac{TP+TN}{(TP+FN+TN+FP)} \quad (6)$$

Precision (Pn): It is calculated as the ratio of accurately forecasted to total positive observations.

$$Precision = \frac{TP}{TP+FP} \quad (7)$$

Recall (Rc): The percentage of total useful content that the good stuff identifies is known as recall.

$$Recall = \frac{TP}{TP+FN} \quad (8)$$

Sensitivity (Sn): Sensitivity is the only positive metric considering all situations.

$$Sensitivity = \frac{TP}{TP+FN} * 100 \quad (9)$$

Specificity (Sp): It measures the number of correctly detected true negatives and is computed as follows:

$$Specificity = \frac{TN}{TN+FP} * 100 \quad (10)$$

F-measure: It is a harmonic average of memory and accuracy. The highest possible F grade is 1, which denotes faultless accuracy and recall.

$$F - measure = \frac{2*recall*precision}{recall+precision} \quad (11)$$

Table III depicts the comparison of the anticipated DLNM with other approaches for error computation, i.e. MAE and RMSE along with execution time. The MAE value DLNM model is 3.2 which is lesser than SVM, RF, k-NN, NB and MLP (see Table III) and the RMSE of the anticipated DLNM is 11.2 which is lesser than SVM, RF, k-NN, NB and MLP. The execution time of DLNM is 0.02 seconds lesser than SVM, RF, k-NN, NB and MLP (see Fig. 4 and Fig. 5).

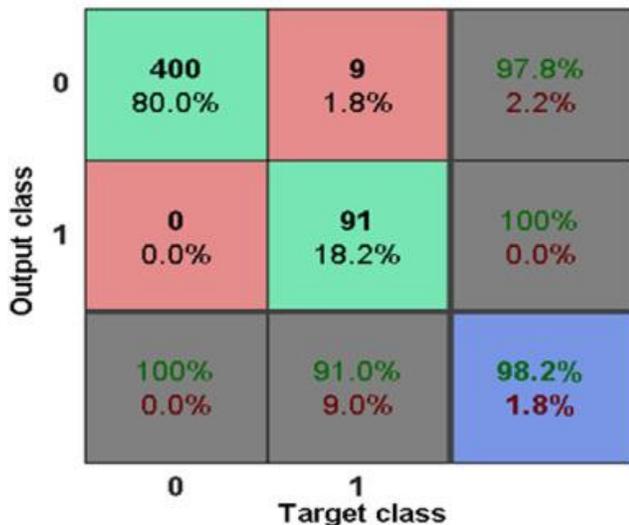

Fig. 4. Confusion Matrix.

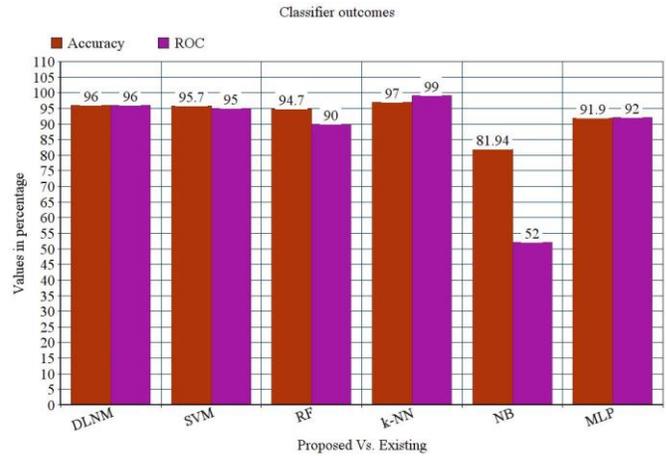

Fig. 5. Accuracy and ROC Comparison.

TABLE III. CLASSIFIER OUTCOMES

Method	Accuracy (%)	ROC	MAE	RMSE	Time (s)
DLNM	96	96	3.2	11.2	0.02
SVM	95.6	95	4.2	20.6	0.30
RF	94.7	90	5.4	22.6	10.36
k-NN	97.0	99	6.67	15.27	17.04
NB	81.9	52	29.64	38.84	3.68
MLP	91.9	92	12.8	25.5	22.05

Table III depicts the comparison of the anticipated DLNM model with various prevailing approaches like SVM, RF, k-NN, NB and MLP. DLNM's accuracy is 96% which is 0.4%, 1.3%, 14.1% and 4.1% higher than SVM, RF, NB and MLP and 1% lesser than k-NN. The recall of the anticipated model is 92% which is 7%, 3%, 5%, 6% and 8% higher than other approaches. DLNM's F-measure is 92% which is 7%, 3%, 5%, 7% and 8% superior to others. The DLNM precision is 92% which is 7%, 3%, 5%, 6% and 8% superior to others (see Fig. 6 and Fig. 7). Based on these analyses, it is proven that the anticipated DLNM model works well compared to other approaches in terms of performance indices.

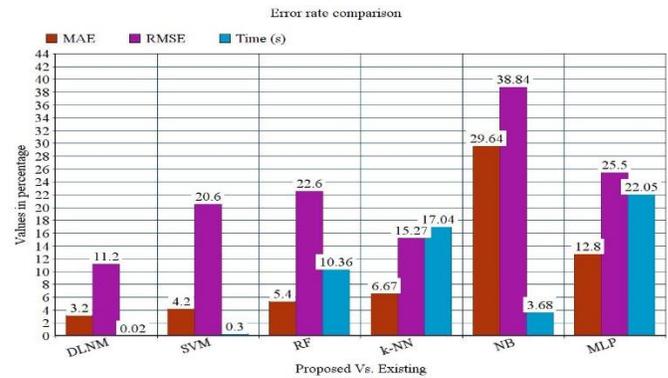

Fig. 6. Error Rate Comparison.

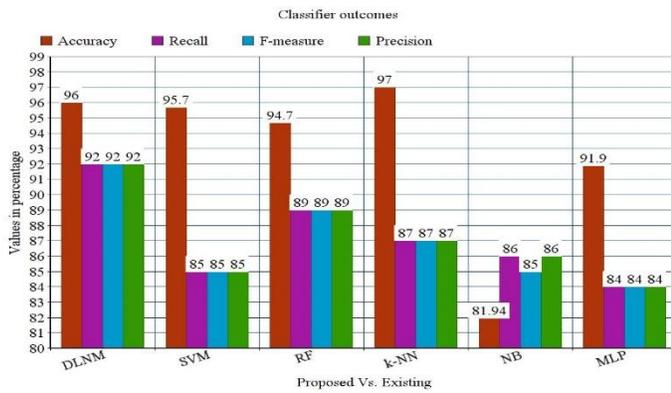

Fig. 7. Performance Metric Outcomes.

## V. CONCLUSION

This work has suggested a technique for predicting epileptic seizures with DL. Individuals with Epilepsy may lead risk-free life when an adequate event prognosis is achieved. The suggested approach combines morphological operations with DLNM and identification using a DL classifier to outperform existing approaches with prediction accuracy. The novelty of identified with the DLNM model is its ability to encourage feature reuse, reduced number of parameters and stronger feature propagation which enhances the prediction outcome. Nevertheless, there is still space for development in several areas if filtering is improved in the future to improve the signal-to-noise ratio. Deep learning algorithms for feature extraction and classifying need several parameters. Future studies may thus be done to lower the number of factors. The suggested approach offers patient-specific seizure prediction, similar to other cutting-edge approaches. Continued studies on non-patient individual epileptic seizure prediction systems are necessary.

## VI. FUTURE RESEARCH

In the future, this work is extended with multi-modal analysis and the hybrid learning approach is adopted for performing the prediction. The quality of prediction has to be improved further to make faster prediction outcomes.

**Abstract**—Mobile devices such as mobile phones are becoming more important to school students today. This is due to the COVID-19 pandemic, mostly traditional face-to-face learning has shifted to online learning such as learning via a mobile platform. Mobile learning also known as m-learning, is defined as learning in numerous situations through social and content interaction utilizing personal electronic devices. M-learning applications not only need to have efficient functions, but it also has to attract students to learn by providing an attractive interface. An aesthetic of a mobile interface is essential since it could influence the user's learning experiences, but vice versa for non-aesthetic interfaces. User experience (UX) encompasses an extensive range of outcomes of the user-device interaction, including cognitions, attitudes, beliefs, behaviour, behavioural intentions, and affect. However, this study focuses on UX in terms of learnability, satisfaction, and efficiency since most previous studies were not explicitly focused on examining these three (3) UX components. Thus, this study aims to investigate the effect of aesthetically mobile interfaces on the learnability, satisfaction, and efficiency of primary school students, specifically, for *Kelas Al-Quran and Fardu Ain (KAFA)* students. This study found that aesthetically mobile interfaces significantly affected students' learning experiences regarding learnability, satisfaction, and efficiency. In conclusion, the findings of this study could serve as guidelines for future research in the field of mobile interface design.

**Keywords**—Aesthetic; non-aesthetic; mobile interfaces; primary education

## I. INTRODUCTION

The rapid growth of technology is one of the factors that contribute to incorporating education with technology such as learning online using the mobile application. This is further encouraged by the COVID-19 pandemic, in which most traditional face-to-face learning has shifted to online learning such as learning via the mobile platform. Online learning including mobile learning requires an aesthetic interface to attract students to learning and further could assist students to focus and feel less bored when facing mobile devices for a quite long time during online learning. This is due to online learning, students do not have peers that have a physical presence and this environment could make students feel bored and lose focus.

Mobile learning (m-learning) is the use of ubiquitous portable technologies, in conjunction with mobile phone networks and wireless, to enable, enhance, assist, and expand the reach of learning and teaching [1]. In addition, define M-learning as any learning that occurs when the learner is not in a

fixed specified location or uses the learning possibilities afforded by mobile technology [2].

User interface design (UID) is the process of developing interfaces that focus on styling and connectivity. Place the user in control, reducing the user's memory load, and making the interface consistent are three (3) factors for effective user interfaces [3]. The impact of mobile devices today makes creating user interfaces crucial [4]. Designers can use various ideas to create the most efficient design interface for m-learning education that could give a beneficial user experience to learners when using mobile learning devices for learning.

This paper focuses on three (3) user experience components which are learnability, satisfaction, and efficiency. This is because most of the previous studies investigated usability theory including learnability, efficiency, memorability, errors, satisfaction, ease of use, attractiveness, easy access, a user-friendly interface, and others [5][6][7]. On the other hand, in particular, fewer studies focus on learnability, efficiency, and satisfaction [8]. Taken together, this paper focuses on the effects of aesthetically mobile learning interfaces on students' experiences which are learnability, satisfaction, and efficiency.

The paper is organised as follows. The extensive research background is explained in Section II. Next, the methodology adopted for this research is described in Section III, followed by the results and discussion in Section IV, and future works in section V. Finally, conclusion are described in Section VI.

## II. RESEARCH BACKGROUND

This part describes the main components of this study which are user interface design and user experience that consists of satisfaction, efficiency, and learnability.

### A. User Interface Design

Every technological device lately has an interface through which people can interact with the application [9]. This definition explains how an interface links the user and the content, allowing the content to adapt to the user's needs. Furthermore, the interface design is similar to a quality experience in that cognition, perception, semantics, and ergonomics must be integrated into the design process. Some operations necessitate usability testing to ensure that user interaction is supported [10].

Interface design is a crucial stage in system development because it provides an essential interaction on user experience. In addition, that interface design is linked to interaction design

because both interact to see how interfaces interact and are part of the system development process [11]. As a result, digital information is a critical area for application design interfaces. Designers can employ a variety of approaches to create the most efficient design interface for m-learning education. A graphic designer, a user interface designer, and a programmer typically work together at this stage to create interfaces for mobile applications. Table I summarises research on mobile interface design.

From Table I, it can be seen that most previous studies used various elements in mobile interface design, such as four (4) UID elements, UID patterns, UID framework, called “Mobile Web UI Transformation Framework”, design patterns and others. Although there were many studies that have been done on mobile interface design, however, a few study specifically focused on design principles for designing mobile interfaces such as proximity, balance, proportion, and others. Thus, this study applied nine (9) design principles to design m-learning application interfaces for this study which are balance, proportion, simplicity, alignment, movement, hierarchy, consistency, contrast, and proximity for the m-learning application for this study.

TABLE I. LITERATURE STUDIES ON MOBILE INTERFACES DESIGN

Author(s) name and years	The summary of the studies
Kalimullah and Sushmitha (2017)[12]	There are four (4) UID elements: mobile design guidelines, Unitarian Universalist principles, mobile health guidelines, and inclusive design guidelines.
Punchoojit and Hongwarittorn (2017)[13]	The design applied UID patterns: customization/personalisation, screen design, layout, learning potential, feedback, user control, navigation/orientation, help/support, error, interactivity, time required engagement, and readability.
Oyibo et al. (2018)[14]	Find out how the Canadian and Nigerian cultures perceive various mobile UID, which differ in terms of colours, images and layouts. The design applied a UID framework, called “Mobile Web UI Transformation Framework” or, simply, “Action-Artifact (A2) Framework”, to systematically modify the UI design of four hypothetical webpages adapted from existing websites in the market.
Braham et al., (2019)[15]	Examines user interfaces design pattern structures to support the adaptive mobile application that enable a more versatile and powerful organization of mobile interface emens, as well as their adaption to context changes and user requirements in specific scenario.
Bunian et al., (2021)[16]	Introduces visual search framework, that takes as input a UI image (wireframe, high-fidelity) and retrieves visually similar design examples.
Grandi et al., (2021)[17]	Utilizing Virtual Reality (VR) to simulate Augmented Reality (AR), that can design and evaluate the benefits of idealized User Interfaces
Börsting et al., (2022)[18]	Formulated several principles and patterns to simplify User Interfaces design for Augmented Reality (AR) applications

### B. User Experience and Mobile Design

The goal of designing user experience is to train the next generation of user experience and interactive system designers [19]. There is already much interest in creating appealing, user-friendly m-learning applications to increase end-user adoption. Table II contains some guidelines for designing user interfaces for mobile applications. These guidelines are based on user interface design criteria and sub-criteria [20] and focus on the interface design of children’s mobile educational applications: cognitive load, graphical design, learning potential, readability, engagement, learnability, and satisfaction [21].

TABLE II. USER EXPERIENCE GUIDELINES OF MOBILE DESIGN

User experience elements	Sub criteria	Guidelines
Cognitive Load	Content/ concept	i. Use appropriate language ii. Use appropriate content
Graphical Design (Efficiency)	i. Aesthetic ii. Size/Font style iii. Colours iv. Icons v. Menu vi. Buttons	i. Attractive, simple and organised, the design ii. Use proper size and font style iii. Use bright colours for children iv. Icons with the information have to be relevant v. Provide a proper touch for the screen menu vi. Provide colourful and animated buttons
Learning Potential	i. Ease to learn ii. Education value iii. Suitability	i. Ease of learning ii. Suitable for educational content iii. Suitable for all users and controlling learners.
Readability	No sub-criteria	i. Readability ease ii. Provide appropriate text, size and spacing.
Engagement	Motivation to learn	i. Endorse commitments ii. Provide interesting rewards.
Satisfaction	No sub-criteria	i. Flexibility and efficiency of use ii. Aesthetic and minimalist design
Navigation/ Orientation (Learnability)	i. Easy to navigate ii. Start screen / Main menu iii. Hierarchal menus iv. Scrolling	i. Facilitate orientation ii. Navigation facility iii. Clear and consistent navigation iv. Give clear buttons for navigation i. Provide the main navigation menu ii. Straightforward main menu or start page link i. Hierarchal menu for easy navigation i. Scrolling may be problematic for children to scroll and view when much information is present.

The user experience and sub-criteria of mobile design illustrated in Table II demonstrate that many essential criteria, such as efficiency, satisfaction, learnability, and others, could be considered when designing interfaces.

TABLE III. LITERATURE STUDIES OF USER EXPERIENCES IN MOBILE LEARNING

Author(s) name and year	The use of user experience
Ismail et al. (2010)[10]	Examine learners' students' perceptions of the satisfaction experience using Mobile learning in School of Distance Education, University Sains Malaysia (USM).
Ali et al. (2014)[7]	Investigate two (2) models, which are Model A and Model B, on mobile learning smartphone applications from the user's perspective regarding ease of use, user satisfaction, attractiveness, and learnability.
Popovic et al. (2016)[6]	The development of electronic learning is based on efficient delivery of services by using a Learning Management System (LMS) to provide all the necessary study materials, easy access, and a user-friendly interface.
Joo et al. (2016)[4]	Analyze the relationships among factors predicting online university students' ease of use, perceived usefulness, expectation-confirmation, satisfaction, continuance intention and actual usage of m-LMS.
Kumar and Chand (2019)[5]	Categorised these user experience factors into 15 major factors; attitude, intention, ease of use, enjoyment, learner interest, prior experience, usefulness, learnability, anxiety, personal, technological, social, financial, pedagogical, and readiness.

A gap in the literature refers to a user experience research problem that has not been resolved in the study area. Previous studies have found a few gaps in the literature that can be filled. According to Table III, previous research has made less attempt to specifically focus on learnability, efficiency, and satisfaction. As a result, this study will focus on learnability, efficiency, and satisfaction as user experience criteria that must be investigated. The following sub-sections will explain satisfaction, efficiency and learnability.

1) *Satisfaction*: Satisfaction is defined as the absence of discomfort and positive feelings about using a product, and it is determined by the content, user guide, and beauty application interfaces [22]. While, satisfaction is the user's level of enjoyment as a result of interacting with the social networking application in a limited context of use in terms of learning the application, using the application, conducting a specific task, finding the attributes, knowledge navigation, trying to recover from error, and completing a task anywhere and at any time [23]. Furthermore, satisfaction is defined as a pleasant feeling experienced when receiving something desired or when performing an action desired, as well as the act of fulfilling (achieving) a need or wish [24]. Satisfaction is challenging to quantify because numerous factors influence it. Many businesses use usability testing to determine customer satisfaction or ask customers to complete a survey. Satisfaction is also linked to end-user confidence, which is especially important in health care due to the need for accurate information. As a result, a health care mobile application must

be developed with caution, especially the graphical user interface elements that directly affect the user's ease of use [25].

2) *Efficiency*: According to definition of efficiency, efficiency in user's completing the task in a given context of use is expressed in actions per second [23]. Efficiency is also defined as the number of resources used to achieve users' objectives with precision and completeness [20]. Furthermore, the less time spent regulating access permissions, the more time there is to capitalise on the value of those sources.

3) *Learnability*: Some researchers said that there is little agreement on how learnability should be defined [26]. Previously, user interfaces necessitated training and new learnability techniques that allowed users to become proficient with a little trial and error quickly. The term learnability refers to how easy a product is to comprehend. Numerous authors have defined learnability, further discussing a definition applied to various forms of learning, both initial and long-term [27]. A system's learnability also implies that it should be simple to learn so the user can begin working with it quickly [22].

### III. METHODOLOGY

This part describes the research methodology used to conduct the research that contributed to the findings in this study. The Cronbach alpha is explained, including the One-way repeated measures (ANOVA). The interfaces are designed using a variety of design principles which are used stimuli of this study.

#### A. Stimuli

This study considers three (3) pages of learning, including Homepage, Introduction page, and Learning page. Overall, there are 15 mobile interfaces that applied nine (9) design principles: balance, proportion, simplicity, alignment, movement, hierarchy, consistency, contrast, and proximity. Each interface applied three (3) combinations of design principles. Table IV, Table V and Table VI illustrate three (3) design principles for the Homepage, Introduction page, and Learning page, respectively.

TABLE IV. COMBINATION OF DESIGN PRINCIPLES FOR HOMEPAGE

Interfaces	Design principle
1	Balance, Proportion, Simplicity
2	Alignment, Movement, Hierarchy
3	Balance, Consistency, Simplicity
4	Balance, Proportion, Alignment
5	Balance, Consistency, Contrast

TABLE V. COMBINATION OF DESIGN PRINCIPLES FOR INTRODUCTION PAGE

Interfaces	Design principle
6	Balance, Proportion, Simplicity
7	Balance, Contrast, Simplicity
8	Balance, Proportion, Simplicity
9	Balance, Alignment, Proximity
10	Balance, Proportion, Contrast

TABLE VI. COMBINATION OF DESIGN PRINCIPLES FOR LEARNING PAGE

Interfaces	Design principle
11	Proportion, Contrast, Consistency
12	Contrast, Proximity, Proportion
13	Balance, Consistency, Simplicity
14	Balance, Alignment, Proximity
15	Balance, Proximity, Contrast

This study was implemented for Kelas Al-Quran and Fardhu Ain (KAFA) students. KAFA is an additional subject for primary schools' students from Year 1 to Year 5 that consists of Jawi, Ibadat, Aqidah, Bahasa Arab, Adab, Penghayatan Cara Hidup Islam, Sirah dan Al-Quran. In year 5, at the end of the KAFA learning, students have to sit for an assessment test called Ujian Penilaian Kelas Kafa (UPKK). However, during the COVID-19 pandemic, KAFA class was also executed online like the other common subjects. Therefore, the KAFA subject needs to transform from a conventional learning approach to online learning, such as learning using a mobile platform. Therefore, this study will focus on the KAFA subject as content materials for this study.

B. Development of KAFA M-Learning

This prototype was created with NetBeans IDE 8.0, which supports language on development for the Java SE 87 specification and JDK 1.8 language features. It also includes a WebLogic server that supports Apache Tomcat. In contrast, a database is a collection of structured data that uses numbers as the primary key in a data relationship and uses the concept of normalisation to detail the data it requires. A database is a collection of data used by a company-owned application system and managed by a database management system [28]. Fig. 1, Fig. 2 and Fig. 3 show KAFA M-learning application interfaces for the homepage, introduction page and learning page.

C. Data Collection

KAFA M-learning application was developed for implementation of this study. The participants were required to use two (2) sets of interfaces, namely Apple and Pineapple, representing aesthetic and non-aesthetic interfaces. The participants were not informed that the Apple interface represents aesthetic interfaces and vice versa to avoid influencing them when answering questionnaires for user experience elements. In addition, the prototype and questionnaire used *Bahasa Melayu* because *Bahasa Melayu* is the national language and the main spoken language in Malay. Thus, it may affect the questionnaire feedback if using the English language.

This study involved 40 participants from primary school students. The range of the participants' ages was from 9 to 12 years. This range of participants was chosen because they were involved in KAFA class. The participants consisted of 25 females and 15 males.

Then, participants are required to answer the questionnaire to investigate the effect of aesthetic (Apple) and non-aesthetic (Pineapple) interfaces on students' experiences which are learnability, satisfaction and efficiency. The questionnaire consists of 15 questions for both interfaces. Furthermore, five

(5) questions are allocated for each user experience component. Questions 1 to 5 are learnability questions, Questions 6 to 10 are satisfaction questions, and questions 11 to 15 are efficiency questions. The questionnaire scale ranges from 1 = lowest to 5 = highest.

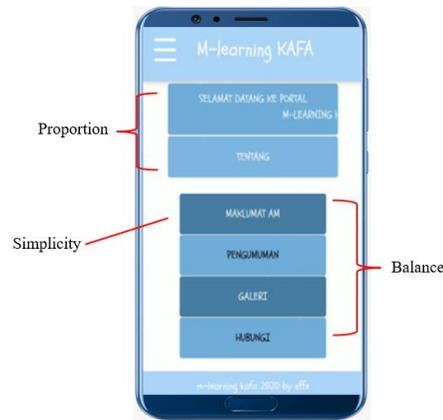

Fig. 1. KAFA M-learning Application Interfaces for Homepage.

Fig. 2. KAFA M-learning Application Interfaces for Learning Page.

Fig. 3. KAFA M-learning Application Interfaces for Introduction Page.

D. Data Analysis

Two (2) types of analysis are involved in this study which are preliminary analysis and main analysis. The Cronbach’s Alpha reliability, skewness, and kurtosis measurements were conducted for preliminary analysis. Further, the main analysis is conducted using the One-way repeated measures ANOVA test. ANOVA test has been done using Statistical Package for the Social Sciences (SPSS) 27.0. ANOVA (also known as a within-subjects ANOVA) is applied in this study to determine whether three (3) or more groups are different, where the participants are the same in each group. This study used the same group of primary school students for three (3) different user experience questionnaires: learnability, satisfaction, and efficiency.

IV. RESULTS AND DISCUSSIONS

The findings of this study are divided into two (2) categories, which are as follows:

- Preliminary results of aesthetics interfaces and non-aesthetics interfaces.
- Main results of the effect of aesthetics interfaces and non-aesthetics interfaces.

A. Preliminary Results

This section explains the preliminary results for aesthetic and non-aesthetic interfaces regarding user experience components such as learnability, satisfaction, and efficiency. Cronbach’s Alpha reliability values for aesthetic and non-aesthetic interfaces are 0.654 and 0.651, respectively, as shown in Table VII. From Table VII, it is found that, the aesthetic and non-aesthetic interface scales have acceptable internal consistency reliability, as measured by Cronbach’s Alpha greater than 0.6 [29].

Skewness and kurtosis normality tests were performed on user experience components: learnability, satisfaction, and efficiency for both aesthetic and non-aesthetic interfaces. The skewness and kurtosis normality test results for both types of interfaces are shown in Tables VIII and IX.

The skewness values of aesthetic interfaces are shown in Table VIII, which are learnability is -0.298, satisfaction is -0.782, and efficiency is -0.755.

The skewness values of non-aesthetic interfaces are shown in Table IX, which are learnability is -0.450, satisfaction is -0.917, and efficiency is -0.659.

According to the skewness results in Tables VIII and IX, aesthetic and non-aesthetic interfaces are considered an acceptable skewness value for a normally distributed set of test scores because it is very close to zero and is most likely just a chance fluctuation from zero [30]. Kurtosis values in Tables VIII and IX revealed that aesthetic and non-aesthetic interfaces are considered acceptable kurtosis values for a mesokurtic (ordinarily high) distribution because it is close to zero [30].

As a result, skewness and kurtosis for both aesthetic and non-aesthetic interfaces follow a normal distribution. Thus, the parametric test, one-way repeated measures (ANOVA), is suggested as an analytical approach in the main study.

TABLE VII. CRONBACH’S ALPHA RELIABILITY RESULTS FOR AESTHETIC AND NON-AESTHETIC INTERFACES

Aesthetic interfaces	Cronbach’s alpha values	
	Statistic	No. of items
	0.654	15
Non-Aesthetic interfaces	0.651	15

TABLE VIII. SKEWNESS AND KURTOSIS NORMALITY RESULTS OF AESTHETIC INTERFACES

User experience	Skewness		Kurtosis	
	Statistic	Std. Error	Statistic	Std. Error
Learnability	-0.298	0.374	-0.726	0.733
Satisfaction	-0.782	0.374	-0.275	0.733
Efficiency	-0.755	0.374	-0.427	0.733

TABLE IX. SKEWNESS AND KURTOSIS NORMALITY RESULTS OF NON-AESTHETIC INTERFACES

User experience	Skewness		Kurtosis	
	Statistic	Std. Error	Statistic	Std. Error
Learnability	-0.450	0.374	0.022	0.733
Satisfaction	-0.917	0.374	-0.016	0.733
Efficiency	-0.659	0.374	-0.475	0.733

B. Main Result: Effect of Aesthetic and Non-aesthetic Interfaces on user Experiences

The repeated one-way measurements: The ANOVA test was used to assess the effect of aesthetic interfaces on user experience, specifically learnability, satisfaction, and efficiency. The multivariate effects of user experience components for aesthetic interfaces are shown in Table X.

Table X depicts there were significant effects on:

- 1) Learnability, Wilks’ lambda = 0.486, F(4, 36), p < 0.0005, multivariate partial eta squared = 0.514.
- 2) Satisfaction, Wilks’ lambda = 0.187, F(4, 36), p < 0.0005, multivariate partial eta squared = 0.813.
- 3) Efficiency, Wilks’ lambda = 0.265, F(4, 36), p < 0.0005, multivariate partial eta squared = 0.735.

TABLE X. SIGNIFICANT MULTIVARIATE EFFECTS ON AESTHETIC INTERFACES

User experience components	Learnability	Satisfaction	Efficiency
Wilks' lambda	0.486	0.187	0.265
F	9.509 <sup>b</sup>	39.029 <sup>b</sup>	24.961 <sup>b</sup>
Hypothesis df	4.000	4.000	4.000
Error df	36.000	36.000	36.000
Sig.	.000	.000	.000
Partial Eta Squared	0.514	0.813	0.735

TABLE XI. SIGNIFICANT MULTIVARIATE EFFECTS ON NON-AESTHETIC INTERFACES

User experience components	Learnability	Satisfaction	Efficiency
Wilks' lambda	0.371	0.216	0.299
F	15.244 <sup>a</sup>	32.596 <sup>b</sup>	21.120 <sup>b</sup>
Hypothesis df	4.000	4.000	4.000
Error df	36.000	36.000	36.000
Sig.	.000	.000	.000
Partial Eta Squared	0.629	0.784	0.701

Table XI depicts there were significant effects on:

- 1) Learnability, Wilks' lambda = 0.371, F(4, 36), p < 0.005, multivariate partial eta squared = 0.629.
- 2) Satisfaction, Wilks' lambda = 0.216, F(4, 36), p < 0.005, multivariate partial eta squared = 0.784.
- 3) Efficiency, Wilks' lambda = 0.299, F(4, 36), p < 0.005, multivariate partial eta squared = 0.701.

The summary results of the significant effect of aesthetic and non-aesthetic interfaces on user experiences are shown in Table XI. It was found that, the p-value of aesthetic and non-aesthetic interfaces is less than 0.05, indicating a statistically significant effect [30] for the learnability, satisfaction and efficiency value for Wilks' Lambda are 0.371, 0.216, 0.299, with probability value of 0.000 (which really means p < 0.005). Therefore, both aesthetic and non-aesthetic interfaces significantly impact students' learnability, satisfaction, and efficiency.

The findings indicate that the effects of aesthetic and non-aesthetic interfaces on primary school students when using KAFA M-learning application interfaces support the hypothesis that aesthetic and non-aesthetic interfaces of mobile interfaces, have a significant impact on students' learnability, satisfaction, and efficiency. Although all multivariate tests yield the same result, Wilks' Lambda is the most frequently reported statistic. The effect is statistically significant if the Wilks' Lambda value is p < 0.0005. This study concludes that the effects of aesthetic and non-aesthetic interfaces are significant because the p-value is less than 0.005. This evidence supports the hypothesis that the similarity of aesthetic interfaces influences the primary student participants' perceptions [30].

## V. CONCLUSION

As a conclusion, the primary goal of this study is to investigate the impact of aesthetic and non-aesthetic interfaces on students' experiences of learnability, satisfaction, and efficiency. The survey was carried out with the participation of 40 primary school students. The study findings revealed that aesthetic and non-aesthetic interfaces significantly impact students' learnability, satisfaction, and efficiency.

This study also could help user interface designers by providing guidelines for designing M-learning interfaces that could create better learning experiences for primary school students in terms of learnability, efficiency, and satisfaction. This user experience is essential because M-learning applications need to have efficient functions, but it also needs

to attract students to learn by providing an attractive interface. Therefore, the UI designer can use these guidelines in the future to design an aesthetic interface for mobile learning applications.

## VI. FUTURE WORKS

It is recommended that further research might explore Analysis of covariance (ANCOVA) for data analysis. This is because ANCOVA has several techniques and models for better solutions. The formulas will help to find the results easily [31]. Besides that in other areas such as business, management, and others, user interface design also can use ANCOVA technique.

**Abstract**—One of the most exciting, innovative, and promising topics in marketing research is the quantification of customer interest. This work focuses on interest detection and provides a deep learning-based system that monitors client behaviour. By assessing head position, the recommended method assesses customer attentiveness. Customers whose heads are directed toward the promotion or the item of curiosity are identified by the system, which analyses facial expressions and records client interest. An exclusive method is recommended to recognize frontal face postures first, then splits facial components that are critical for detecting facial expressions into iconized face pictures. Mainly consumer interest monitoring will be executed. Finally, the raw facial images are combined with the iconized face image's confidence ratings to estimate facial emotions. This technique combines local part-based characteristics through holistic face data for precise facial emotion identification. The new method provides the dimension of required marketing and product findings indicate that the suggested architecture has the potential to be implemented because it is efficient and operates in real time.

**Keywords**—Customer monitoring; convolutional neural network; facial expression recognition; facial analysis; head pose estimations component; CNN Model; object localization; face boosting

## I. INTRODUCTION

The usual way is for a salesperson to study client behavior during the shopping phase or advertisement watching and then recall customer interest. However, every salesperson needs special talents for this job, and each spectator may interpret consumer behavior differently. In this aspect, only a few extraordinarily tactful and competent salespeople can have good salesperson-customer interactions [1]. According to [2], subjective emotional perception-based approaches may not always represent the human emotional state appropriately. On the other hand, automatic measurements provide a more exact and dependable result. As a result, developing non-invasive,

objective, and quantifiable measures for tracking client interest is crucial.

Human choices can be analyzed in various ways such as brain images [3]; an electroencephalogram also known as EEG [4], [5]; eye tracking [6], [7]; heart rate registration [8]; and other approaches have been a recent topic in the existing literature. Customer behavior classification [9 - 11] and customer face analysis studies have also been used in several studies [12], [13].

Estimating a client's visual focus of attention is one approach of evaluating their interest. Head posture is quantified in research on visual center of attention [14 - 16]. Recognizing consumer sentiments for advertising purposes is also a difficult and quickly growing academic area [17]. The intuitive decision-making process is substantially influenced by one's mood [17]. People who are in a good mood assume that everything is well and that they are safe in their surroundings. When they're in a poor mood, though, they believe things aren't going well and that an incident is approaching, and needing their attention [18]. Marketers must consider their customers' emotions and moods [19]. Knowing mental status of the buyer helps marketer in creating good business [19]. According to [20], annoyance, anxiety, sorrow, and disgust are all bad feelings, but happiness is a good emotion. Because it's difficult to discriminate between good and negative emotions, surprise isn't mentioned. According to [21], happy clients are positive, confident, passionate, stimulated, and thrilled.

The goal of this study is to develop a deep learning-based method for tracking client interest that relies on head-pose alignment and facial expression identification. The recommended method identifies the visual center of attention by first recognizing the human face and then analyzing the head posture orientation because the camera is an important item, the frontal faces suggest the visual center of focus. If the observed face is concentrated on the advertisement or product of interest, the algorithm begins to recognize the facial expression.

Customers' facial expressions are captured by the equipment over a period of time that may be assessed by specialists. Based on the gathered facial expressions, the system decides if the customer is in a good or poor mood. Based on the gathered data the system concludes he/she is in good or poor mood. The image can be captured by the camera and used to estimate face expression detection. As a result, determining client interest may be done non-invasively, quantitatively, and at a minimal cost. The suggested approach might be beneficial for identifying marketing campaigns and other corporate initiatives that clients would be interested in. Salespeople can also make changes to their marketing materials based on client feedback. This software could also help salespeople respond more effectively to customer emotions, leading to higher satisfaction.

The suggested study's main contributions can be stated in four points:

- 1) A system is proposed for measuring customer interest that is non-invasive, objective, and quantifiable.
- 2) Because the proposed system does not have the feature to save customer facial photos, personal privacy is protected. The system processes current client photos and does not require them to be saved for later processing. If there is a need to keep track of a customer's facial expressions, de-identified iconized face photos can be saved. Face expression data is included in iconized face photos while maintaining personal privacy.
- 3) A three-cascade Convolutional Neural Network (CNN) model is proposed which performs multiple tasks. In the third part CNN combines raw face images with iconized image confidence values. Part-based information is included in the confidence values of iconized images, whereas holistic details are included in raw face images. Improved facial expression detection is possible thanks to the combination of part-based and holistic data.
- 4) The system recognises and localises the face components that are crucial for facial expression detection in the facial component segmentation step, resulting in an ionised image. The CNN permits directed training at the facial emotion recognition stage by compelling earlier layers of the architecture to learn to identify and locate the essential face components using the confidence values of that ionized picture as input.

Consumer interest monitoring using CNN is performed for all mentioned three steps. Detecting frontal faces, classifying facial expressions, head posture estimation and facial expression detection are performed.

The next parts, which are organized as follows, give further information. The literature evaluation of current state-of-the-art methods that are relevant to the proposed methodology is summarized in Section II. Section III delves into the suggested technique, while Section IV covers the results, analysis, arguments, and inferences, while Section V wraps up the paper by summarizing some of the work's future directions.

## II. LITERATURE SURVEY

Several publications in the literature describe how to use images or videos to solve real-world problems. For video processing, speed is critical, and many frameworks are being

developed to improve it [22 - 24]. Real-world challenges include object identification [25], text detection [26], [27], facial expression recognition [28], head position estimation [15], and so on. This section looks into the work's two key components: facial expression recognition and head posture estimation.

### A. Facial Expression Recognition

Avatar animation [29]; smart environments [30 - 33]; robotics [34]; medical [35]; traffic [36], [37]; and human-computer interaction [38 - 44] are some of the applications of automated facial expression recognition. Ekman and Friesen's six universal facial expressions, namely disgust, happiness, fear, wrath, sadness, and surprise, were commonly utilised in automated facial expression detection experiments in their early research [45].

Geometric and appearance-based algorithms for facial expression recognition have been identified [46]. The features derived from positional correlations between facial components focus on geometric-based approaches [46]. Appearance-based features determine face texture [47 - 49]. Histogram of oriented gradients (HOG) [50], principal component analysis (PCA) [51], local binary pattern (LBP) operator [52], and other appearance-based methods have been used for facial emotion identification.

In the field of face expression analysis, the use of machine learning approaches specifically the deep learning is a recent trend. To extract just particular properties for expressions and examine the six essential expressions, Lopes et al. [53] used a CNN network with picture pre-processing techniques such as image rotation, face cropping, and intensity normalization. Pitaloka et al. [54] analyzed six essential sentences using a CNN. They used many data normalization techniques, scaling, face detection, cropping, and resizing algorithms. Matsugu et al. [55] recommended that CNNs be used to give a rule-based technique for detecting smiles and faces.

### B. Head Pose Estimation

Visual surveillance [56], [57]; driver attention [58], [59]; the visual focus of attention [15], [60]; and robotics [61] have all been investigated using head posture estimation appearance-based, model-based, manifold embedding, and nonlinear regression techniques are used to create head position prediction systems [62]. Appearance-based strategies compare a new head picture to a set of head posture templates to determine which viewpoint is the most related Appearance-based approaches have the drawback of only being able to predict discrete posture locations [63].

Furthermore, certain templates [63] necessitate long picture comparisons. In model-based strategies, geometric information or facial landmark locations are employed to estimate head position [63]. The amount and quality of geometric signals produced from the image determine the accuracy of model-based techniques. In manifold embedding techniques like PCA [63], dimensionality reduction strategies are used. [64] Estimated head location by projecting images into a PCA subspace and comparing the results to a collection of embedded templates. The problem with manifold embedding is that it can be modified by factors other than location and identity, such as lighting [63]. A labelled training set is used in nonlinear

regression algorithms to construct a nonlinear mapping from pictures to postures [62]. According to [62], a dataset with consistency is required to train the parameters a nonlinear regression.

CNNs [62] are a nonlinear regression technique. CNNs give better accuracy in performance for difficult head pose orientations. In [65] described a CNN technique for estimating head posture. Three CNNs make up their network, each of which corresponds to one of three head posture types: yaw, pitch, or roll. To estimate head posture, [66] used a combination of regression models and CNN-based classification. [67] estimated head posture and located landmarks using local and global data collected from a CNN. For head posture estimation, [62] employed CNN and adaptive gradient methods. The literature shows that none of the existing methods used a cascade of the best deep learning architecture in each element and explored how it works. As we already cited, there is substantial evidence that the use of cascaded CNNs has the potential to provide the most optimized and robust results. Hence, in this study, we proposed a three-cascaded CNN architecture to analyze customer satisfaction in real-time.

### III. METHODOLOGY

Each face picture is trimmed using the Viola and Jones Algorithm [68] to eliminate background information and leave just expression and head pose-specific data. The proposed technique makes use of the Viola and Jones algorithm, which allows for quick feature evaluations while also reducing the complexity of feature detection for each frame [68]. When this coordinate is included, as shown in (1), the integral image at the point x, y comprises the total of the pixels above and to the left of x, y [68].

$$jj(x, y) = \sum_{x' \leq x, y' \leq y} j(x', y') \quad (1)$$

A raw picture is  $j(x,y)$ , while an integral image is  $jj(x,y)$ . The integral image may be computed in one pass over the raw picture using (2) and (3) [68]. Where  $a(x, y)$  stands for the cumulative row total,  $a(x, -1)$  stands for zero, and  $jj(-1, y)$  stands for zero.

$$a(x, y) = a(x, y-1) + j(x, y) \quad (2)$$

$$jj(x, y) = jj(x-1, y) + a(x, y) \quad (3)$$

The recommended system's initial stage determines if the client is looking at the correct advertisement or product. The suggested approach that classifies a head in frontal versus non-frontal profile can use the coarsest level head position estimation. Non-frontal faces are ignored when frontal faces are provided to CNN-2 for facial component segmentation. At 00, 450, 900, 1300, and 1800, the CNN-1 has been taught to estimate head position (Fig. 1).

Fig. 1. Sample Image Snapshots with Different Head Pose Positions.

CNN 1: To modify the backbone network design for the pose estimation issue, we use differentiable neural architecture search (NAS). Differentiable Neural Architecture Search is what we employ (NAS). NAS is formulated as a nested optimization problem. Fig. 2 shows the complete information, including the Differentiable neural architecture search, efficient backbone, efficient head, and Cost optimization.

CNN 2: Faces such as the mouth, eye, and brow areas are separated from the rest of the image by the CNN-2. Face component segmentation is a binary classification problem using the face component and the backdrop. The original raw images and corresponding training masks are partitioned into 16 \* 16 non-overlapping blocks before moving to the training step. The majority class is assigned to blocks that contain more than 80% of the face component or backdrop pixels. The remaining mixed-class blocks are omitted during training. According to our tests, the threshold value of 80% was calculated. Fig. 3 depicts the image's construction block steps. Two channels are the output of the fully connected layer, one of which provides confidence values for facial components and the other of which contains confidence values for the backdrop. The higher component confidence value in the fully linked layer creates iconized facial images. Additionally, two channels' confidence values are passed to the CNN-3's input for guided image training and more powerful face expression identification. A movable window is used for testing, as stated in [69].

Stage	Output size	Layer	
		Small	Large
Input	256 × 256	—

Fig. 2. Neural Architecture Search Architecture.

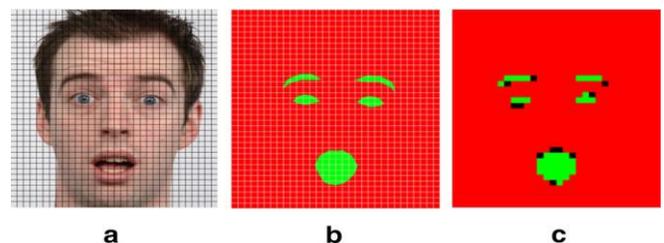

Fig. 3. Sample Image which Shows the Non Overlapping Parts. Black is the Ignored Part, Green is the Facial Component and Red is the Background in the Image C which Shows the Built and Labeled Part. Ground Truth is B and A is the Sample Divided Input Image.

CNN 3: The standard Xception model inspired this architecture. SeparableConv is the modified depthwise separable convolution, as shown in Fig. 4. SeparableConv's are considered as Inception Modules and used throughout the deep learning architecture, as can be established. All flows have residual (or shortcut/skip) connections, which ResNet first proposed.

The proposed method for consumer interest monitoring uses CNNs to complete the three learning steps. The method begins with CNN-1 detecting frontal faces. The frontal pictures are then

split using CNN-2 in order to maintain facial components such as critical and important traits of facial expression. Finally, CNN-3 uses CNN-2's fully connected layer confidence values together with raw facial photos to classify facial expressions. The proposed CNN design is shown in Fig. 5.

Fig. 5. Sample Image which shows the non-overlapping parts. Black is the ignored part, Green is the facial component and red is the background in the image C which shows the built and labeled part. Ground truth is B and A is the sample divided input image.

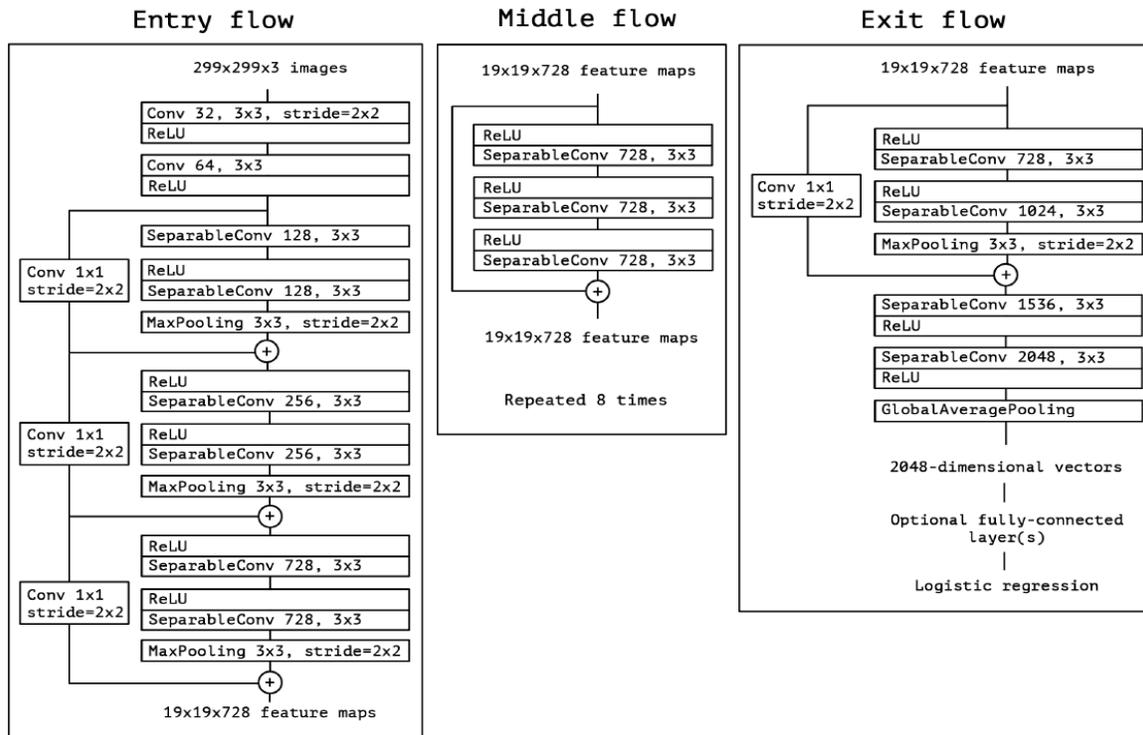

Fig. 4. Standard Exception Architecture.

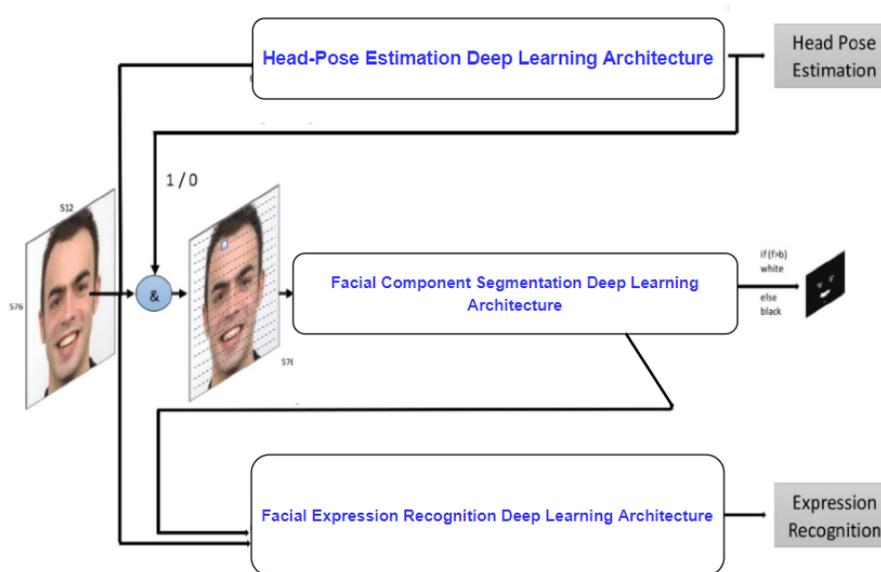

Fig. 5. Complete Work Flow of the Proposed Architecture.

IV. RESULTS AND ANALYSIS

The proposed deep learning architecture was built using the Keras library with Tensor Flow as the back-end. The Radboud Face Database (RaFD) was used to train and test the network [70].

In this work, 8040 photographs were utilised to estimate head posture, while 1206 frontal images were used to detect face expressions from RaFD (for angry, pleased, disgust, surprise, sad, and fear). The training and testing sets for head posture estimation and facial expression detection were divided into two equal halves. There are no photographs in the testing and training sets that belong to the same person. Raw facial images were used to train the algorithm in the head posture assessment phase. Although the suggested approach can distinguish between frontal and non-frontal profile head positions, it was trained to recognise five separate yaw movement angles. Table I shows the head posture estimate confusion matrix for RaFD.

Using the Karolinska Directed Emotional Face (KDEF) database, the proposed technique was also evaluated [71]. KDEF is ideal for evaluating proposed system performance since it incorporates both head posture angle and facial expression labels of the face photos. KDEF consists of 4900 pictures taken from five different angles and with seven different face expressions. 4900 shots were utilised to estimate head position, while 840 frontal images were used to recognise facial expressions. Because of the small number of images in these collections, they were divided into two groups for training (90%) and testing (10%). Table II shows the KDEF's head posture estimate confusion matrix.

Each picture was clipped to contain facial areas of the brows, eyes, and mouth in order to build learning masks for the face element segmentation approach. The Face++ toolbox (Face++ 2017) was then used to detect critical facial points. On a human face, the toolkit can recognise 83 important regions. Training masks were made at 45 key locations. Each essential point was connected to make a polygon. These polygons were used to create training masks. After that, the pictures were thresholded to create a final training set. Fig. 6 depicts the producing process. The system was trained on a 5-channel input for facial emotion recognition (comprising a 3-channel raw facial picture and 2-channel ionized face confidence values).

The system was trained on a 5-channel input for facial emotion recognition (comprising a 3- channel raw facial picture and 2-channel iconized face confidence values). Table III shows the RaFD confusion matrix for emotion recognition. When the confusion matrix is used to recalculate the accuracy of positive and negative expressions, positive expression (happy) has a 95.11 percent accuracy, while negative expression (anger, disgust, fear, and sadness) has a 92.88 percent accuracy. Table IV also includes the KDEF confusion matrix for face expression recognition.

Happy	0	0	0	98.11	0.34	1.55
Sad	5.66	0	0	0	94.34	0
Surprised	0	0	0	1.77	0	98.23

Because the RaFD database contains strange expressions, our system may experience certain mistakes. Fig. 7 depicts a visual representation of some of our mistake instances. The proposed system's performance was compared to that of previous face emotion recognition studies. The comparison's findings are shown in Table V. The results of facial expression recognition utilising 3-channel raw image, 1-channel iconized image, and 5-channel composite image for RaFD are shown in

the table below. Table VI illustrates the execution times for three different types of CNNs, as well as the overall execution time, with estimated values for one picture. The segmentation procedure takes up a significant amount of time.

The proposed pipeline is intended for photos with a resolution of 576 \* 512 pixels and discrete facial components. CNN-1 and CNN-3 use 64x64 images as inputs, while CNN-2 uses 576x512 images. As a result, it takes longer for CNN-2 to process the input pictures. Performance declines by 13% if the segmentation phase is bypassed in order to save time (85.12 percent for raw input image data vs. 95.11 percent for the data from the five channel).

The details of hyperparameters and their values are Threshold 0.005, Learning rate 0.10, Input channels 3 5 5, regularization strength of 0.0005 and the Batch-size 3. The train and test of the aligned face are regular and saturated well, but the unaligned looks are quite different. But they still saturate at the same number of epochs, but the variations can be observed in Fig. 8.

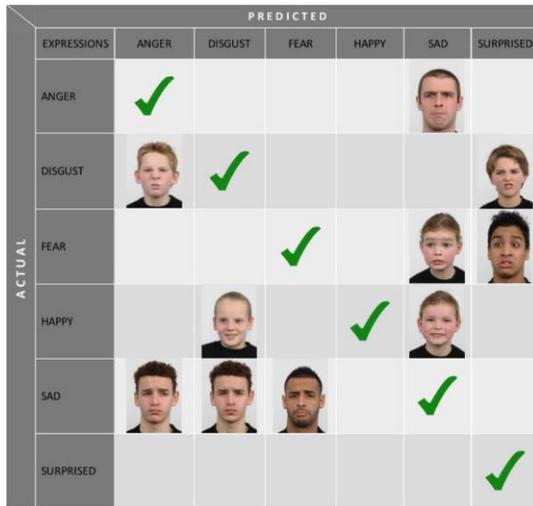

Fig. 7. Misclassification of Results and its Visualizations.

TABLE V. FACIAL EMOTION RECOGNITION OF PROPOSED METHOD WITH OTHER STUDIES ON RAFD / KDEF DATABASES

Methods	Database	Accuracy (in %)
HoG + NNE [1]	RaFD	93.75
Surf Boosting [64]	RaFD	90.64
Gabor F. + GLCM [36]	RaFD	88.41

HoG + AdaBoost [38]	KDEF	87.20

TABLE VI. EXECUTION TIME FOR CNN STRUCTURES

CNN Structures	Task	45	90	135	Time
1	Estimation of Head Pose				~0.02
2	Segmentation of Facial Component				~0.13
3	Recognition of Facial Expression				~0.80
<b>0.31 Sec. is the total execution time for one image</b>					

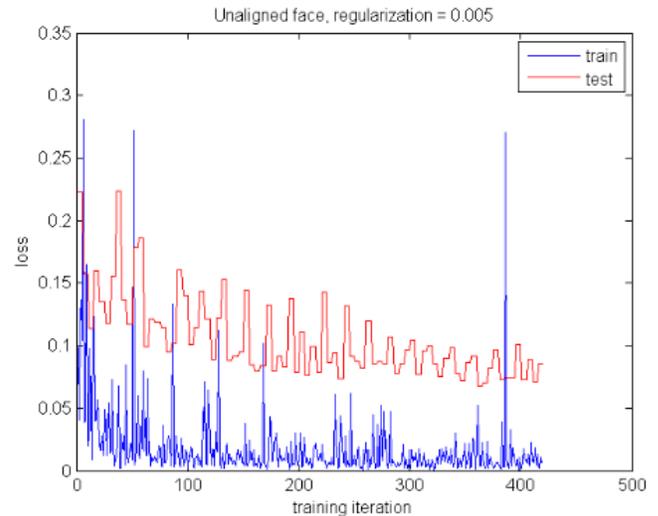

Fig. 8. Train and Test Curves of Unaligned Face Images.

## V. CONCLUSION AND FUTUTRE DIRECTIONS

A unique deep learning system for automatic head posture estimation and face emotion identification is proposed. The proposed method started with developing a noninvasive, quantifiable approach for tracking client interest. The suggested system is made up of three CNN structures in a cascade. The first CNN's task is to estimate head posture. Face segmentation was taught to the second CNN structure. Face recognition and classification were encoded into the third CNN. The latter two steps (CNN-2 and CNN-3) allow for guided picture classification and the integration of part-based and holistic data. The RaFD dataset demonstrated that head posture estimation was 99.43 percent accurate and face expression detection was 93.20 percent accurate in experimental tests. The average accuracy of positive and negative emotions is 93.99.

The proposed approach can aid in the measurement of relevant marketing and product likability as well as the quantification of the client interest. It can also be used to identify sales-boosting company initiatives. According to customer feedback, marketing efforts can alter their methods. Future direction includes the temporal analysis of the data and the optimization space used in the architecture. Track human faces and use object localization so that the system can watch and index an individual's facial expressions over time. Exploring the proposed architecture with people of different regions and cultural background and testing it on various other domains.

# An Optimized Single Layer Perceptron-based Approach for Cardiotocography Data Classification

Bader Fahad Alkhamees

Department of Information Systems, College of Computer and Information Sciences  
King Saud University, Riyadh 11543, Saudi Arabia

**Abstract**—Uterine Contractions (UC) and Fetal Heart Rate (FHR) are the most common techniques for evaluating fetal and maternal assessment during pregnancy and detecting the changes in fetal oxygenation occurred throughout labor. By monitoring the Cardiotocography (CTG) patterns, doctors can measure fetus state, accelerations, heart rate, and uterine contractions. Several computational and machine learning (ML) methods have been done on CTG recordings to improve the effectiveness of fetus analysis and aid the doctors to understand the variations in their interpretation. However, getting an optimal solution and best accuracy remains an important concern. Among the various ML approaches, artificial neural network (ANN)-based approach has achieved a high performance in several applications. In this paper, an optimized Single Layer Perceptron (SLP)-based approach is proposed to classify the CTG data accurately and predict the fetal state. The approach is able to exploit the advantages of SLP model and optimize the learning rate using a grid search method in which we can arrive at the best accuracy and converge to a local minima. The approach is evaluated on CTG dataset of University of California, Irvine (UCI). The optimized SLP model is trained and tested on the dataset using a 10-fold cross-validation technique to classify the CTG patterns as normal, suspect or pathologic. The experimental results show that the proposed approach achieved 99.20% accuracy compared with the state-of-the-art models.

**Keywords**—Cardiotocography; machine learning; artificial neural network (ANN); learning rate; grid search; 10-fold cross-validation

## I. INTRODUCTION

Nowadays, development and research have been taking place in the healthcare area, and they will continue to expand the analysis by gathering all relevant data from different devices or methods in medical domains, such as medicine, biotechnology, and biomedical [1, 2]. Electronic Fetal Monitoring (EFM) is one of the common methods used to assess fetal well-being during labor [3, 4]. During labor, the fetus is relatively inaccessible as a result, the clinician evaluations depend just on the available and indirect fetal condition measures [5]. The EFM is the most effective method in assessing the fetal status. Also, it is safety through recording maternal Uterine Pressure (UP) and FHR during labor and delivery, that is, the Cardiotocography (CTG) procedure [6]. In addition, nowadays (over 90%) of the labors are electronically monitored by using sensors in order to measure and record UC and FHR [4]. The EFM is commonly used to assess fetal well-being through labor [4]. In the past, before using the EFM the fetal heart rate was measured through the fetal stethoscope [4]. There was a disadvantage of using the stethoscope because it

was not able to detect the FHR subtle changes [6]. On the other hand, the EFM is able to overcome this problem by giving the continuous monitoring of the fetus during pregnancy and labor. The EFM has other effective roles. It is able to give minute-by-minute information on the fetus status. Also, it can note the historical information on fetal status accurately and give insight into the stresses on the fetus. The EFM consists of the Cardiotocography which is continuous recording of the fetal heart rate and the (ST) which is used to analyze the fetal electrocardiogram (FECCG) [5, 7].

The CTG is the check-up that is generally done during the last three months of pregnancy. This test is for checking the heartbeats of the baby if it has a regular rate and changeability [8]. In general, the baby's heart rate is 110 to 160 beats for each minute [9]. The Cardiotocography expression composed of: (cardio-) which means the fetal heartbeat, (-toco-) which means Uterine contractions and (-graphy) which means recording [9]. EFM enables us to detect the “at risk fetus” early for medical intervention where the delay or failure in detection of abnormal fetus in the CTG recordings can lead to fetal death or injury; which may be a brain injury [10]. In addition, some reviews on birth-related brain injury cases noted that nearly (50%) of brain-injuries refer to preventable medical errors especially the wrong FHR signal analysis [10]. For example, the recognition of the acceleration and deceleration samples in FHR signal is a fateful matter. Because it is important for the detecting of fetal intrauterine distress where there is any delay or failure in their recognition may cause a fetal injury [10].

More than half of these deaths are the result of improper diagnoses made based on FHR pattern recordings and treatments given to the fetus [11, 12]. Despite its practicality, CTG monitoring may not always be effective, especially in low-risk pregnancies. If fetal pain is incorrectly assessed, it could lead to ineffective treatments, and if fetal well-being is improperly investigated, it could leave out necessary treatments [11]. Difficulties in the interpretation of CTG records require methods for computer-assisted analysis where the computer analysis of classifying the FHR and Uterine Contraction (UC) is generally more accurate than human analysis. Classifying the fetal heart rate and fetal state from CTG patterns using computational methods will provide more accurate and less confused medical intervention decisions which provided in the appropriate time is a very important decision in the fetal life where any fault or delay could lead to fetal death or injury [10].

Using effective machine learning (ML) classification methods for classifying the CTG patterns may increase

significantly the performance of predicting the fetal state [13]. Moreover, selecting the appropriate values for the parameters of ML methods is considered as one of the factors that effect on the success of ML-based applications on the various medical data samples [13, 14]. Where, if these parameters have inappropriate values then the classification process will be more difficult during training to get optimal or near optimal solutions. The optimization of ML parameters is the process of choosing the most appropriate values on the data in order to increase the accuracy and performance of ML methods [15].

Among the different ML methods, artificial neural network (ANN) has a high capability to model the relationships between output and input data points, which are complex like data of medical field. However, optimizing Single Layer Perceptron (SLP) parameters is also critical to get a high accuracy output of the medical applications. This paper tries to reduce the risk of misclassification and its negative impact by exploiting the advantages of SLP model and learning rate optimization to arrive at the best accuracy and converge to a local minima.

This study intends to design an optimized SLP-based approach for classifying the CTG data accurately and predicting the fetal state. The developed approach selects the best value for learning rate hyper-parameter and converge to a local minima. The main contributions of this research work are itemised in the following lines.

- An accurate approach using optimized SLP model and a grid search algorithm is proposed to classify the CTG patterns as normal, suspect or pathologic.
- By using the grid search algorithm, an optimal or near-optimal value of learning rate is selected to improve learning process of SLP model, arriving at the best accuracy and converge to a local minima.
- The optimized SLP model is trained and tested on the dataset using a 10-fold cross-validation technique to achieve the diversity in learning the SLP model.
- The performance of the optimized SLP model is evaluated and compared with the recent work on the same CTG dataset.

The rest of the paper is structured as follows: Section II provides the related work of the proposed approach. Section III gives an explanation about the materials and methods of the research study. Section IV describes the experimental results with discussion and outcomes. Finally, Section V summarizes the conclusions and future work.

## II. RELATED WORK

There are a number of studies and methods that have been presented by many researchers and professionals on medical data and healthcare [16]. Data mining and machine learning techniques are one of these methods, which are applied in different stages of medical applications, including data collection, storage allocation, analytics, pre-processing, and classification or predication [17]. However, the focus of this section aims to evaluate the various classification approaches and methods used on the Cardiotocography (CTG) data

patterns. According to Grivell et al. [11], the evaluation of CTG patterns is an important diagnostic procedure, used to measure the maternity during pregnancy and detect the fetal heart rate.

Using ML, e-health software, and traditional pregnancy tests, Akbulut et al. [18] created a framework for prediction in e-health applications that can assist doctors and pregnant women in identifying congenital abnormalities. In order to process the clinical data and maternal predicting for fetal anomalies, nine binary-classification models that have been trained on 96 pregnant women in the clinical datasets were compared for performance. Decision forest models have the highest forecasting accuracy, at 89.5%, during development tests.

Huang [19] used three different machine learning techniques to analyze the CTG data in order to predict fetal distress. Employing statistical features taken from empirical mode decomposition was suggested by Krupa et al. [20]. (EMD). The sub-band decomposition's extracted features were categorized as either normal or risky. For the test data, they achieved an accuracy of 86%. Another study described a two-step analysis of fetal heart rate data that enables accurate risk prediction. Support Vector Machines (SVM), fuzzy, and multilayer perceptron are used to classify the FHR signals. Sundar et al. [21] implemented a new model that classifies the CTG data using ANN. The F-score and Recall were used to evaluate the performance. They also suggested the use of k-means clustering for CTG classification. Moreover, Ocak and Ertunc [22] used adaptive neuro-fuzzy inference systems (ANFIS) for classifying CTG data patterns. Genetic Algorithm (GA) and SVM methods have been implemented for CTG classification by Ocak [23].

In 2019, Potharaju et al. [24] examined the CTG classification using J48, Ridor, Jrip, NBStar, Kstar, and IBk. They used the SMOTE technique to balance the dataset after realizing the CTG data was inherently unbalanced. Their experimental findings show that a balanced dataset performs classification more effectively than one that is unbalanced. After choosing the top six features, they also experimented with three feature selection techniques to assess the effectiveness.

An associative classification (CBA) model has been put forth by Piri and Mohapatra [25] for the analysis of Cardiotocographic fetal evaluation. When choosing a smaller data set with the most crucial features, they also considered the significance of each feature. Zhang and Zhao's [26] developed a decision-support system for clinical fetal risk diagnosis using a cutting-edge machine learning method through pertinent features, which are extracted from the CTG recordings. Therefore, this research showed that hybrid AdaBoost and PCA were effective for classifying the CTG results and determining the fetal status. AUC, sensitivity, and specificity are just a few of the performance classification criteria that have been adopted.

Rough Neural Network has been proposed by the authors in [27] as one of the most popular data mining methods for categorizing medical data in the classification of Cardiotocography data. They timed the classification process

and measured the accuracy outcomes. The WEKA tool uses a variety of algorithms, including neural networks, decision tables, bagging, and the nearest neighbor, among others, to analyze Cardiotocographic data. In a study, Hoodbhoy et al. [28] evaluated the efficiency of using CTG data to identify high-risk fetuses using ML techniques. They developed the prediction task using XGBoost to obtain the fetal outcome specified in the classification model.

Recently, Yan and Han [29] proposed a Cost-Sensitive Stacked Generalization (CSSG) approach for re-sampling based on two layers analytics model to sample the distribution of imbalanced class in the dataset. With 17 imbalanced public data sets, the results indicated that their method performed better in classification than other ensembles and single algorithms. Brown and Mues [30] have set themselves the task of analyzing various approaches used to analyze credit score data that is unbalanced. As there are typically many more defaulted loans than there are non-defaulting observations in a portfolio, imbalanced data sets frequently occur in a loan scoring environment. The appropriateness of predictions for loan default is examined by random forests, gradient boosting, and SVM, in addition to the use of conventional classification methods such as neural networks, logistic regression, and decision making trees.

Some under-sampling methods have been studied, for example, Shang [31] in his paper introduced two kinds of sampling methods for missing data in the networks. These two methods are uniform and non-uniform random sampling. In uniform random sampling, a fraction of data sample ( $q$ ) is arranged uniformly at a random manner in the dataset. This kind of sampling is commonly used in some other work of different applications. In non-uniform random sampling, the data sample is generated by selecting the nearest neighbors data of a seed point, then, its second nearest neighbors data and so on until a fraction of data sample ( $1 - q$ ) in the entire dataset are selected.

Additionally, a popular SMOTE algorithm for cardiovascular data are examined by Rahman and Davis [32]. They also recommended a modified under-sampling technique using clusters that can produce high-quality training samples for classifier design while also balancing the data. Yen and Lee [33] utilized clusters-based under-sampling approach to choose representative data for examining the under-sampling impact on the distribution of unbalanced classes, with the goal of improving the classification accuracy for minority classes. The experimental results of the approach showed that the cluster-based approach outperformed the other under-sampling methods used in earlier studies.

To address imbalanced and limited CTG data, Piri and Mohapatra [34] have proposed a different number of re-sampling methods and two ensemble models to balance the training samples and improve the classification task. They applied several ML models such as Support vector machine (SVM), Random Forest (RF), Decision Tree (DT) K-Nearest Neighbors (KNN), Logistic Regression (LR), and Gaussian Naive Bayes (GNB). They achieved a 95% classification accuracy using RF model on the balanced dataset. From the previous studies and related work, still there is a need to

optimize the learning process and improve the accuracy of CTG data classification. In this work, an optimized SLP-based approach is proposed to classify accurately the CTG data as normal, suspect or pathologic for predicting the fetal state.

### III. MATERIALS AND METHODS

This section explains the materials and methods of the research study. It describes the dataset used for obtaining the experimental result and gives an explanation about the methods of the proposed approach. In the following subsections, the dataset, methods, and the approach will be given in more detail.

#### A. CTG Dataset

In this proposed work, the CTG dataset obtained from the UCI repository [35] is chosen for conducting the experiment of the study. It is prepared for CTG trace analysis and the discovery of fundamental attributes. The dataset contains two attributes (FHR pattern and fetal state) represent the target labels and 21 distinguished features (LB-FHR; AC; FM; UC; etc.). Because the target attribute of the study includes the normal, suspect, and pathological classes, the Fetal state attribute is used as class label to solve a three-class problem and determine the fetal health-state using the other attributes; and the FHR pattern class label is removed from the dataset. According to the fetal state target class, the number of instances in the dataset is distributed into three groups: 1655 instances for normal class, 295 instances for suspect class, and 176 instances for pathological class. The distribution of instances for the three target classes is presented in Fig. 1.

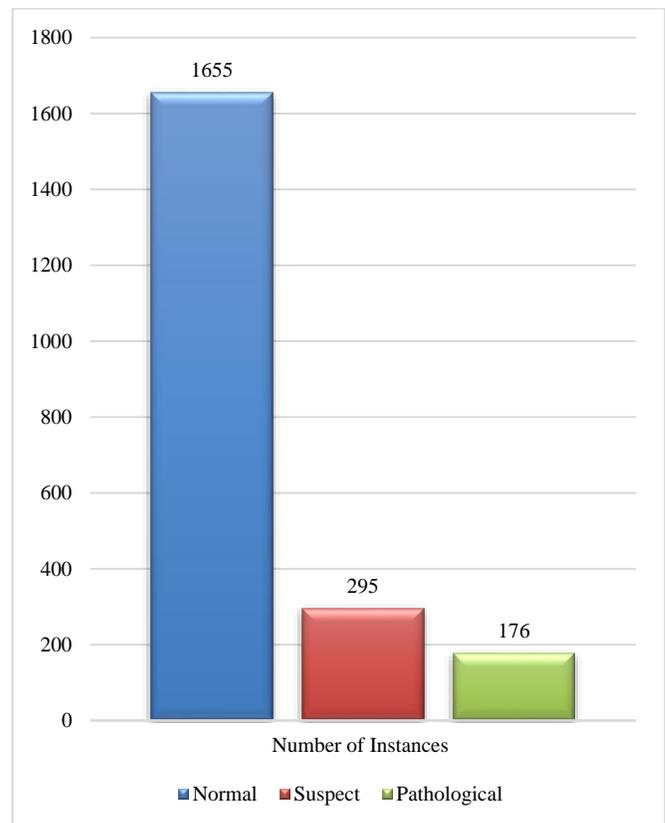

Fig. 1. The Distribution of Instances for the Three Target Classes.

TABLE I. THE ATTRIBUTES INFORMATION OF THE CTG DATASET

No.	Attribute	Description
1	LB-FHR	The baseline (beats per minute)
3	FM	The number of fetal movements for each second
2	AC	The number of accelerations for each second
5	DL	The number of light decelerations for each second
4	UC	The number of uterine contractions for each second
6	DS	The number of severe decelerations for each second
8	ASTV	The percentage of time with abnormal short term variability
7	DP	The number of prolonged decelerations for each second
9	MSTV	The mean value of short term variability
11	MLTV	The mean value of long term variability
10	ALTV	The percentage of time with abnormal long term variability
12	Width	The width of FHR histogram
14	Max	The maximum of FHR histogram
13	Min	The minimum of FHR histogram
15	Nmax	The number of histogram peaks
17	Mode	The histogram mode
16	Nzeros	The number of histogram zeros
18	Mean	The histogram mean
20	Variance	The histogram variance
19	Median	The histogram median
21	Tendency	The histogram tendency
22	CLASS	The FHR pattern class code (1 to 10)
23	NSP	The fetal state class code (N = Normal; S = Suspect; P = Pathologic)

The information of the attributes is given in Table I. As shown in Fig. 1, the number of instance for each class shows that the CTG dataset is imbalanced. Therefore, it is important to build a robust ML method to improve the performance in present of the imbalanced class problem.

### B. Single-Layer Perceptron (SLP)

Single-layer perceptron (SLP) is the first and most fundamental model of ANN. The feed-forward neural network is another name for it [36]. The threshold transfer between the nodes serves as the foundation for the SLP's operation. This is the most basic type of ANN used to solve machine learning problems with linear cases. It is a straightforward neural network with only one layer is known as a single layer perceptron [37]. There are only two layers for input and output in the single layer perceptron (See Fig. 2). The name single layer perceptron refers to the fact that it only has one layer. As opposed to a multilayer perceptron, it lacks hidden layers.

The single layer perceptron computation is the sum of the input vectors multiplied by the corresponding vector weight. The input to an activation function will be the value displayed as the output. Four components make up the perceptron: the input values or one input layer, the weights and biases, the network sum, and the activation function as seen in Fig. 3.

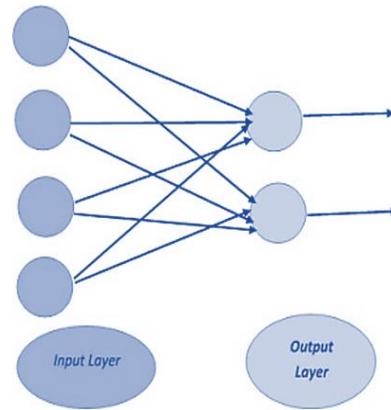

Fig. 2. Two Layers for Input and Output in the Single Layer Perceptron Classes.

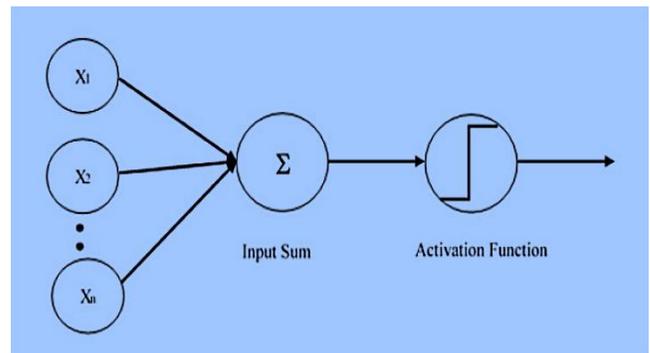

Fig. 3. The Components of Single Layer Perceptron.

### C. Grid Search Technique

A grid search or a parameter sweep, it is just a search process through a manually specified subset of the hyper-parameter space of a learning algorithm [38]. It is considered a traditional method of performing hyper-parameter optimization. A performance metric, typically determined by cross-validation on the training set or evaluation on a hold-out validation set that can guide the grid search technique. Before using grid search, it may be necessary to manually set bounds and discretize certain parameters because the parameter space of a machine learning may include real-valued or unbounded value spaces [39].

For instance, a typical classifier with a kernel function, which has a regularization constant  $C$  and a kernel hyperparameter  $\gamma$ . They can be tuned for good performance on unseen data. Since both parameters are continuous, one chooses a limited number of "reasonable" values for each in order to perform a grid search, such as:

$$C \in \{10, 100, 1000\}$$

$$\gamma \in \{0.1, 0.2, 0.5, 1.0\}$$

Then, using each pair  $(C, \gamma)$  in the Cartesian product of these two sets, grid search trains the classifier. The performance of the classifier is then assessed using a held-out validation set (or by internal cross-validation on the training set, in which case multiple classifiers are trained per pair). The settings that received the highest score during the validation process are finally returned by the grid search algorithm. The

hyper-parameter settings are typically evaluated independently of one another, allowing the grid search method to operate in parallel [39].

#### D. Proposed Approach

The proposed approach aims to build an effective and robust SLP classification model that archives a high accuracy for classifying the CTG patterns and predicting the fetal state. It contains two main phases presented in Fig. 4. The approach exploits the advantages of SLP model and optimizes the learning rate using a grid search method in which we can arrive at the best accuracy and converge to a local minima.

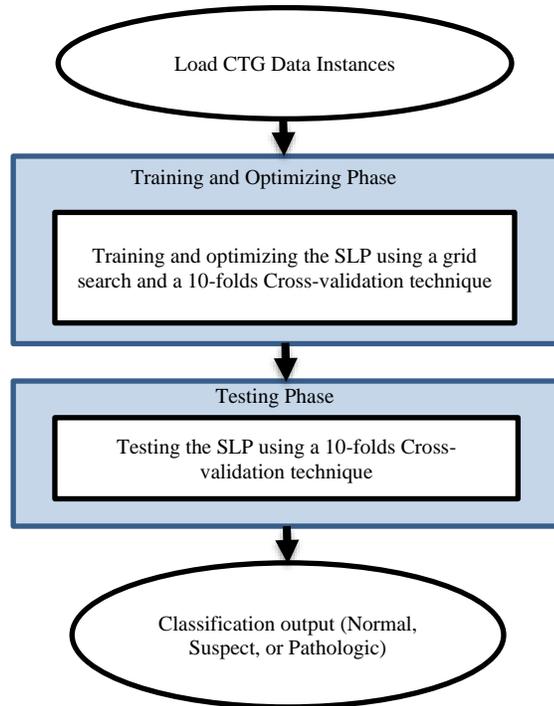

Fig. 4. Flowchart of Proposed Approach.

1) *Training and optimizing phase*: This subsection explains the training and optimizing phase of the SLP model. The training process is conducted on the CTG dataset using a 10-folds cross-validation technique. In this technique, the dataset is divided into ten subsets and the SLP model is trained using nine out of ten subsets for ten times. The remaining set each time is used in the validation process. The output of this phase is the best model from the ten trained SLP models. Then, the classification result is evaluated through the best model on the whole dataset in the testing phase. The optimizing process of the SLP model is performed to determine the optimal value of the learning rate during the training step by the grid method algorithm. The grid search method selects a set of possible values for the learning rate and evaluates the result for each value.

2) *Testing phase*: After dividing the dataset to ten subsets and training the SLP model on nine subsets, the remaining subset from the ten subsets is used for testing the trained SLP model. This procedure is repeated for ten times until all ten subsets are involved in the validation process of the trained

models. The classification result is obtained by testing the dataset on the best model of trained in the training and optimizing phase for getting the final result of the approach. The classification test result is measured using a number of evaluation metrics such as accuracy, F1-score, precision, and recall, which will be described in the experimental results section.

#### IV. EXPERIMENTAL RESULTS AND DISCUSSIONS

In this section, the performance of proposed approach is analyzed using a 10-fold cross-validation technique to classify the fetal state from CTG data instances. The experimental results are performed on a laptop with the Intel Core i7, 2.50 GHz CPU, 16GB RAM and Windows 10. The proposed approach is implemented using a WEKA data mining tool. A number of evaluation metrics such as precision, recall, F-score, and accuracy are computed from the classification outputs. These metrics are computed using the following equations:

$$Precision = \frac{TP}{(TP+FP)} \quad (1)$$

$$Recall = \frac{TP}{(TP+FN)} \quad (2)$$

$$F1-score = 2 * \left( \frac{Precision * Recall}{Precision + Recall} \right) \quad (3)$$

$$Accuracy = \frac{(TP+TN)}{(TP+FP+TN+FN)} \quad (4)$$

Where FN, FP, TN, and TP are the false negative, false positive, true negative, and true positive instances, respectively. The confusion matrix for the classification task is also used. To measure the confusion matrix, FN, FP, TN, and TP are required.

The evaluation results of the approach are also compared with the various recent existing methods and approaches designed for CTG fetal state classification. The experimental parameters of the SLP model are established in Table II.

The values of the model's parameters in Table II are selected experimentally where the learning rate is chosen to be optimized using a grid search method with 10-fold cross-validation technique. The grid search method starts the searching operation among a set of possible values, which are 0.0005, 0.001, 0.005, 0.01, 0.1, 0.15, 0.2, 0.25, and 0.3. Then, the model is trained at each value of these possible learning rate values. The best value of learning rate hyper-parameter is 0.1. Fig. 5 shows the results of accuracy at these different values of learning rate.

TABLE II. EXPERIMENTAL PARAMETERS OF PROPOSED APPROACH SLP MODEL

Parameter	Value
Hidden nodes	19
Momentum	0.2
Batch Size	100
Learning Rate	0.1
Number of Epochs	500

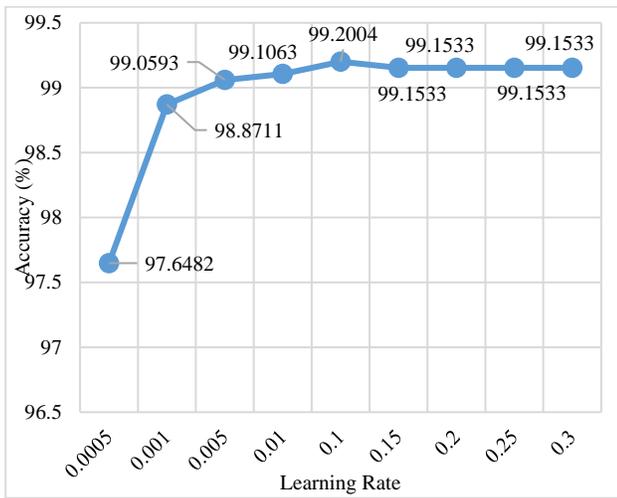

Fig. 5. Accuracies of SLP Model at different Learning Rate.

Also, Fig. 6 demonstrates the classification confusion matrix of optimized SLP model. We can see that 1649 from 1655 normal instances are classified correctly as normal class and 285 of 295 suspect instances are classified correctly as suspect class, as well as 175 of 176 pathologic instances are classified correctly as pathologic class. These classification results confirm the ability of SLP model to classify the CTG patterns in accurate manner.

		Actual Classes		
		Normal	Suspect	Pathologic
Predicted Classes	Normal	1649	6	0
	Suspect	9	285	1
	Pathologic	0	1	175

Fig. 6. Confusion Matrix of SLP Model Test Classification.

According the result of confusion matrix in Fig. 6, Table III displays the results of other evaluation metrics. It shows that the model achieves 99.2% of accuracy and 0.992 for weighted average F1-score, recall, and precision metrics.

To highlight the performance of the proposed approach, the accuracy result obtained on the dataset is compared with the other models proposed in the recent current study [34] for classifying CTG data into normal, suspect, and pathologic classes. The visualization of this comparative analysis is presented in Fig. 7.

TABLE III. RESULTS OF EVALUATION METRICS FOR SLP MODEL

Class Name	Precision	Recall	F-score
Normal	0.995	0.996	0.995
Suspect	0.976	0.966	0.971
Pathologic	0.994	0.994	0.994
Weighted Avg.	0.992	0.992	0.992
Accuracy	99.2004%		

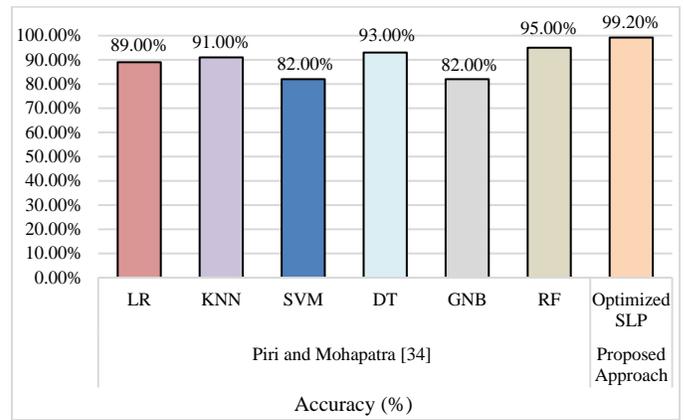

Fig. 7. Comparison Results of Accuracy for Developed SLP Model and other Models in the State-of-the Art.

From the comparison analysis, we can see that among the different models in [34], the DT and RF have the best accuracy results, which are 93% and 95%, respectively. However, the optimized SLP model has the highest accuracy (99.2%) compared with DT and RF.

## V. CONCLUSIONS AND FUTURE WORK

Fetal state detection from the CTG data using classification methods has become an important task for developing various medical applications. In this paper, an optimized SLP-based approach is introduced for improving CTG data classification and analysis. The approach is able to select an optimal learning rate value of SLP model and make the learning process converge to a local minima, achieving a best accuracy result. The experimental results of the research are conducted on CTG dataset and by using a number of evaluation metrics, such as accuracy, F1-score, precision, and recall. The optimized SLP model is trained and tested on the dataset using a 10-fold cross-validation technique to generalize the training phase of developed model. The obtained results on the test process revealed that the optimized SLP model has the highest accuracy result (99.2%) compared with the models used in the recent study of related work. According to the accuracy results of the state-of-the-art models, the accuracy of optimized SLP model is increased by 4.2%. Therefore, the SLP has the ability to classify the CTG patterns in an accurate manner. In future work, a combination of different methods and deep learning models will be explored to classify the CTG data and detect fetal heart state.

**Abstract**—A cyber range is a term to define an isolated simulation environment that can be used for cybersecurity training. As a training tool, the cyber range has a crucial role in improving the competence of its users. Isolated environmental conditions allow users to increase competence through cybersecurity training based on predetermined scenarios. There is no standard for scenario in training, most of them using common case. In this research, the cyber range is built based on the cyber range taxonomy and uses the observe-orient-decide-act (OODA) loop that has been proven for military education. The OODA loop is implemented and helps guiding each step of the attack and its handling in the built scenario. The scenario chosen is a case of data theft since data theft incidents have often occurred so that it is easier for user to understand. OODA loop for cyber range meets 16 of the 17 characteristics in the cyber range taxonomy. The final cyber range acceptance rate was 81.82%. The results of this acceptance give confidence that this new method can be used as an alternative to learning cybersecurity.

**Keywords**—Cyber security; cybersecurity education; cyber range; OODA loop; play-role scenario

## I. INTRODUCTION

There are no renowned holistic Security Operating Center standards or industry specific guidelines [1]. It has deep impact for cyber range especially for education. Lack of standardization leads to the need for solutions.

In cyber security education, one of the factors that support the success of implementing a cybersecurity curriculum [2] is the availability of isolated laboratories for learning [2]. Most isolated laboratories that are specifically used for cybersecurity learning are scenario-based. Scenarios are prepared using field experience.

From this, a big problem arises, there is no standardization in real world of SOC, so how to transfer experience in education especially in scenario for cyber range.

Observe-Orient-Decide-Act (OODA) loop is a well-known analytical framework for decision-making developed by John Boyd [3]. The method has been used in the military world long time ago and has been proven to provide experience and improvement for military students. This is inspiring to be applied in cyber security learning as well as being a standard and measuring its suitability in meeting the need for cyber security learning tools. In bigger scenario SOC is giving many

open problems described in Vielbert's paper [4]. The problem can be minimized by proper cyber security laboratories.

Several methods of building cyber ranges have been carried out previously, as summarized in the research of [5], [6], and [7] to overcome similar problems. The data presented by [6] shows that the most commonly used experimental method is the simulation method due to its ease of use.

A cyber range with data exfiltration attack simulation is built in this research that simulates a real attack case. The built cyber range is expected to be used as a learning tool to understand cyber-attacks better and apply the framework of thinking according to the OODA loop in further learning. The final results of the research were then validated with the user acceptance test (UAT) to find out whether the system built could meet the needs of cyber security learning.

## II. RELATED WORKS

### A. ISMS Role in The Improvement of Digital Forensics Related Process in SOC's

This research [8] presents similar solution for better SOC with Plan, Do, Check, Act. The purpose of this research is to provide an Information Security Management System solution that complies with ISO 27001:2013. Focus in digital forensic and not for education purpose.

### B. Design and Implementation of a Research and Education Cybersecurity Operations Center

This paper [9] show common SOC and tools inside it. This research also builds simulation with honeypot and dashboard and also implementing OODA loop in concept of SOC not in scenario build.

### C. Design and Implementation of a Research and Education Cybersecurity Operations Center

This research [10] present Action Observe Hypothesis method to build SOC. Using Questionnaire for post task, same method with user acceptance test in this research. This research focus in recap many SOCs and implemented with multi honeypot for implementation.

Novelty in this paper is the use of multiple Intrusion Detection System (IDS) with agent based and rule based also Elasticsearch, Logstash and Kibana (ELK) for dashboard. OODA loop implemented inside scenario build and detail

inside it to provide experience for student. This research is also suitable for Covid-19 learning situation which implement VPN for student and lecture for remote education and proofed with User Acceptance Test for validation with curriculum.

### III. RESEARCH METHODOLOGY

The research design refers to knowledge embodied in development, techniques, methods, models, and theory development to map out how to produce artifacts or products that meet predetermined functional requirement [11]. In this study, the research design used was Design Science Research (DSR) as seen in Fig. 1. DSR was chosen since it has the principle of “learning through development (making artifacts),” which is appropriate when applied to this research. DSR is a method of determining and conducting research with the ultimate goal of an artifact of recommendations. DSR can also be defined as a method oriented to solving specific problems to get the right solution even though the solution is not optimal.

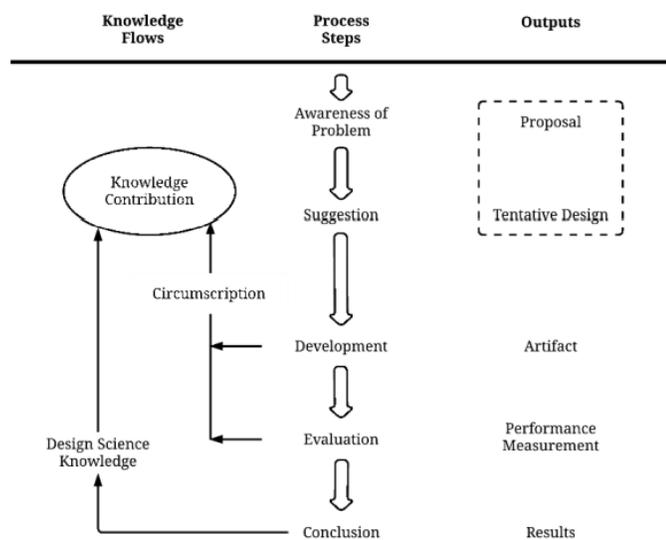

Fig. 1. DSR Process Model Cycle.

Fig. 1 shows the relationship of each process, the flow of knowledge, and the output of the DSR, which is called the DSR cycle.

#### A. Awareness of Problem

Researchers identify problems that will be raised for research or problem formulation [11]. Sources of problems can be obtained from various existing sources. The problem identification process can be carried out in various ways such as literature study, practice, and discussion or interview. Once identified, the problem must also be defined. The problem definition process be done through a literature study to state that the problem has not been resolved and the solutions offered will contribute academically. In addition, problem definition also includes determining the scope of the problem to be solved using available resources.

#### B. Suggestion

The suggestion stage contains suggestions or solutions offered by researchers to overcome the problems that have been defined at the awareness of problem stage. These

solutions can be generated based on existing research or through the thoughts and creativity of researchers in solving problems using appropriate research methods. The solution can be a new idea or combine an existing solution with something different. The result of this stage is a tentative design that describes the solution to the problems in the previous stage.

The pattern chosen to be used in the suggestion stage is modeling existing solutions and combining partial solutions. The existing solution modeling pattern is a design used to model solutions that have been used to overcome similar problems [11]. The results of the solution modeling are then developed and adapted to be a solution to the current research problems. The pattern of combining partial solution is a pattern that is used to take some concepts, ideas, or solutions from related references that can support the construction of solutions from the research conducted [11].

#### C. Development

The development stage is the stage to implement or develop a tentative design that has been made at the suggestion stage. The pattern used in the development stage is the same as the suggestion stage, namely modeling existing solutions and combining partial solutions. The explanation of the two patterns is also the same as the one at the suggestion stage. In addition, the solutions developed at the development stage are also prepared based on the tentative designs that have been made at the suggestion stage. In the development stage of this research, the cyber range is built based on the cyber range taxonomy from the research of Yamin et al. [7], attack simulation laboratory of Mahardhika research [12], and the benefits of building cyber ranges from the research of Leitner et al. [13] through a pattern of combining partial solutions while still considering the tentative designs that have been made. The combined results of the research of Yamin et al. [7] and Mahardhika [12] is used to compile a needs analysis in the design and construction of cyber ranges. In addition, the research of Grant et al. [14] also Debatty dan Mees [15] is used to create solution modeling in the form of scenarios and topology of the cyber range environment through the existing solution modeling pattern.

#### D. Evaluation

The results of the artifact implementation at the development stage are then evaluated at this stage based on predetermined functional specifications. The process carried out at the evaluation stage is to determine how well the performance of the artifact is based on the empirical method used. This stage is an opportunity to make improvements to the artifact based on the experience gained during the previous stage. This is also called the circumscription of the DSR cycle. The pattern used in the evaluation stage is demonstration. After the development stage is complete, the cyber range will be demonstrated. For validation a number of Cyber and Crypto Politechnic cadets will be asked to run the scenario that has been built according to the steps stated in the user manual for the attack simulation laboratory. After running the scenario, cadets will be asked to fill out a UAT questionnaire. UAT is needed to find out whether the cadets are able to apply the OODA loops framework during running APT attack scenarios. In addition, UAT is also used to measure whether the attack

simulation laboratory built has met the learning needs of the Cyber and Crypto Politechnic and can increase cyber situation awareness among Cyber and Crypto Politechnic cadets. Validation is done with UAT. The results of filling out the UAT questionnaire were then analyzed using a Likert measurement scale.

E. Conclusion

This is the last stage of the research cycle in DSR. The result of this stage is the solutions delivering that answer the formulation of the problem in research. In addition, the results obtained at the evaluation stage will also be presented at the conclusion stage. The process carried out at the conclusion stage is symbolized by a small arrow outwards in the DSR cycle. The purpose of the arrow is that the results of the research must be communicated or published so that they can contribute to science in the related field [16].

IV. IMPLEMENTATION

A. Design of Cyber Range

Cyber range design is done through a literature study of solutions and related research. The literature study was conducted on the research of Grant et al.[14], Debatty and Mees [15] to produce a cyber range design in the form of a tentative network infrastructure design from the cyber range and analysis of cyber range needs.

B. Tentative Design

Based on the literature study conducted on the research of Grant et al.[14], the network security infrastructure in an organization generally consists of a firewall, DMZ, servers, and workstations located in the Intranet. In addition, there is also an IDS located in the DMZ. Placing the IDS on the DMZ allows the IDS to monitor network traffic between the Intranet to the Internet, between the DMZ to the Internet and between machines within the DMZ. Network security infrastructure in organizations from the research results of Grant et al. [14] is in Fig. 2.

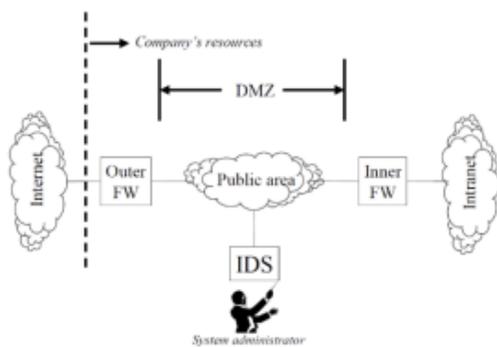

Fig. 2. Network Security Infrastructure in Organizations.

In addition to this research, a literature study was also conducted on the research of [15]. From the research of [15], obtained infrastructure for simulation of a small organization network consisting of firewall, DMZ, honeypot, vulnerable web server, internal workstation, Security Onion server for monitoring, and traffic generator. Virtual workstations are also provided for users connected to the internal network. The

design of the organization's network simulation infrastructure can be seen in Fig. 3.

From the results of a literature study conducted on [12], obtained information that the attack laboratory topology can be built on the CAN topology provided that it has two main components, network infrastructure as the target of attack and APT group [17] infrastructure. Topology design of attack simulation laboratory in [12] research can be seen in Fig. 4.

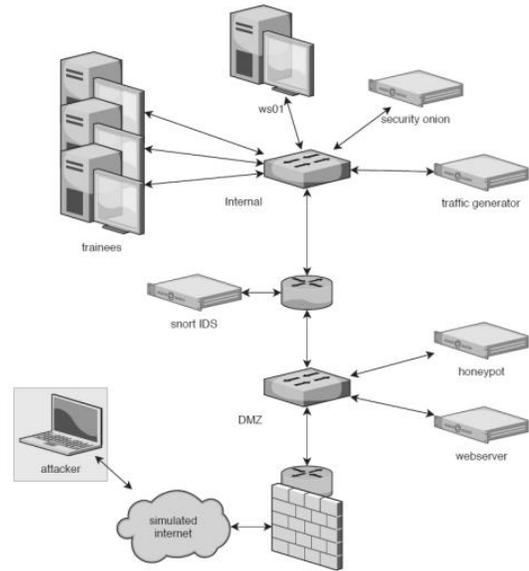

Fig. 3. Organizational Network Simulation Infrastructure.

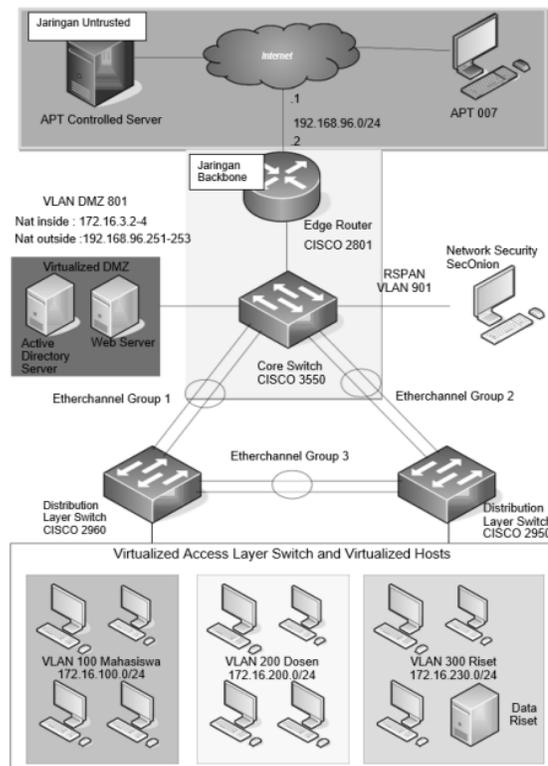

Fig. 4. Attack Simulation Laboratory Topology[12].

By utilizing the results of the literature study from previous research, a tentative design was designed as the final result of the suggestion stage in the DSR cycle as well as an initial design in the development of cyber range infrastructure. The design results of the cyber range design that have been made can be seen in Fig. 5.

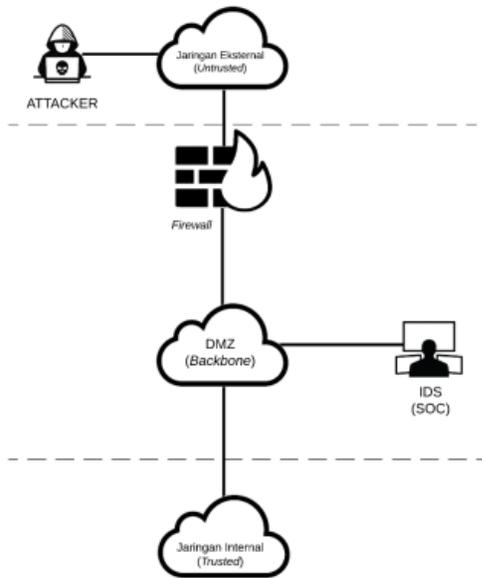

Fig. 5. Cyber Range Tentative Design.

The tentative design of cyber range divides the network into, external network (untrusted) in Table III, DMZ, backbone network, and internal network (trusted), all part was built in hardware listed in Table I and virtual machine listed in Table II. On the external network, there is an attacker's infrastructure consisting of various tools or virtual machines that aim to steal data from the internal (trusted) network seen in Table IV. Meanwhile, on the backbone and DMZ networks shown in Table V and Table VI, there is a main infrastructure to connect every device in the cyber range, firewalls, and IDSs that monitor activities in the internal network and the DMZ. On the internal network, there is an infrastructure of the target that is vulnerable to attacks from external networks seen in Fig. 6

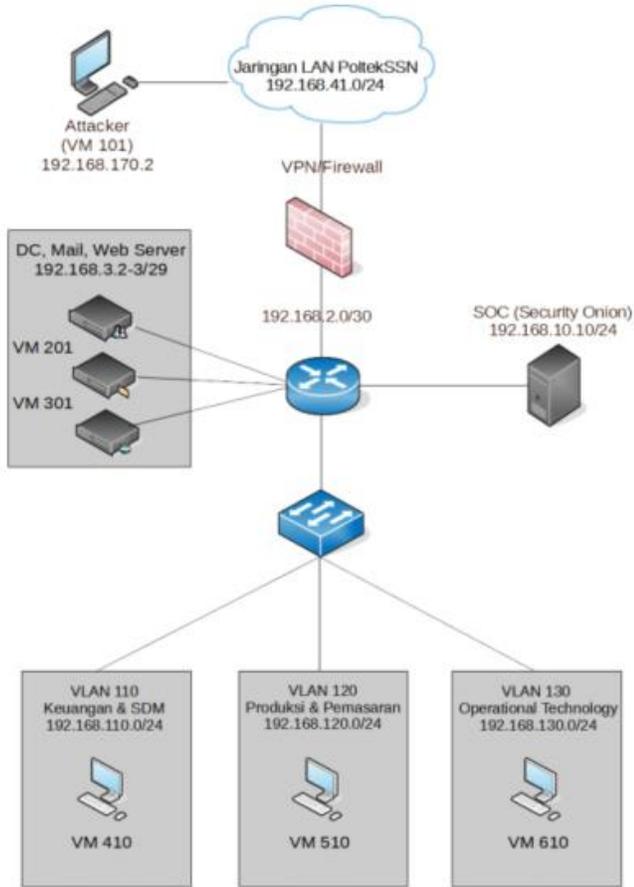

Fig. 6. Cyber Range Design.

C. Needs Analysis

Based on a survey conducted in the research of Yamin et al.[7], a system can be classified as a cyber range if it fulfills part or all of the components of the cyber range taxonomy. In the construction of cyber ranges in this study, the cyber range taxonomy is used as the basis for compiling a needs analysis of the built cyber ranges. The complete components of the cyber range taxonomy can be seen in Fig. 7.

D. Scenario

The scenario explains the objectives of the cyber range development, the environment in the form of the infrastructure used, the storyline behind the operation of the cyber range, the scenario application domain, and various tools used in the construction of the cyber range. Scenarios built-in cyber range is based on OODA loops. Every step taken by the attacker and the defender is arranged based on each stage in the OODA loop, which includes observing, orienting, deciding, and acting.

In the attack simulation scenario, initially cyber range users perform the task of the Red Team or Red APT group to attack

with the aim of stealing data. After the attack was carried out, the students carried out the task of the blue team as SOC to monitor the attacks that occurred and take action against these attacks. The stages of the data exfiltration as resesarch by F Ullah [18] carried out by Red APT based on the OODA loop are as follows:

1) *Observe*: Red APT collects information through various sources related to target. From the results of the information collected, Red APT found several names of employees from target along with their email addresses. The names include Joko Nugroho (jnugroho@cybergym.local), Aurora Rahayu (arahayu@cybergym.local), and Caraka Kurniawan (ckurniawan@cybergym.local). This information is found on the website page of example target as shown in Fig. 8.

2) *Orient*: Red APT plans to exploit the weaknesses of the employee's nature to gain access to the target system. Red APT plans to make job offers with salaries and facilities that are more attractive than those offered by target to these employees via email.

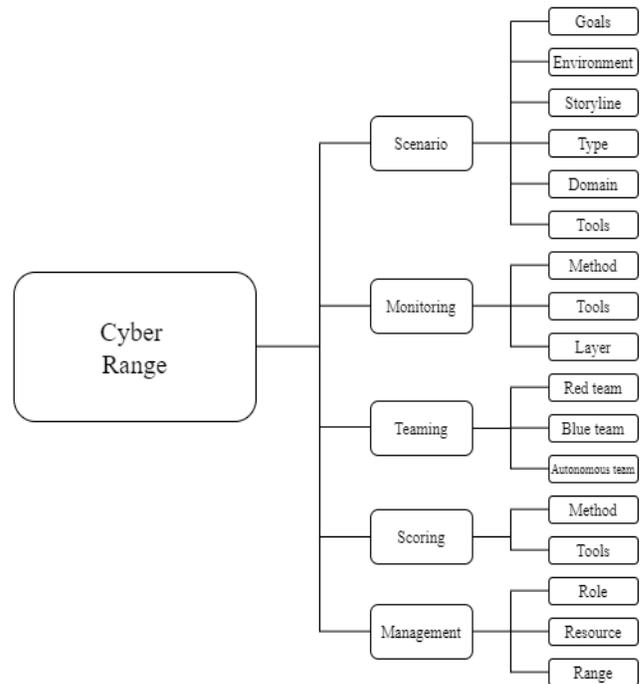

Fig. 7. Cyber Range Taxonomy

Pengalaman Kerja di PT TRINAKLIR

Joko Nugroho (jnugroho@cybergym.local), Aurora Rahayu (jnurroho@cybergym.local), Caraka Kurniawan (ckurniawan@cybergym.local)

We have created a fictional band website. Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor incididunt ut labore et dolore magna aliqua. Ut enim ad minim veniam, quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea commodo consequat. Duis aute irure dolor in reprehenderit in voluptate velit esse cillum dolore eu fugiat

Fig. 8. Example Target Website for Observing

3) *Decide*: Red APT creates a payload in the form of an executable file that contains an access trojan command. The payload contains the command to execute the CALDERA agent. Payload is disguised by giving a file icon in the form of a job offer poster and providing a file name with the suffix.jpg. Windows operating system by default does not display the extension of a file, so naming a file with a .jpg ending will give the target the illusion that the received file is an image file.

4) *Act*: Red APT sends the payload accompanied by an attractive offer sentence using an email address with the name of the Company's HRD. The payload is sent to the email addresses of the three employees of target and hopes that there are employees who are interested and open the payload file. Fig. 9 shows the view of the email containing the payload received by the target.

Open the payload file and ignore the UAC notification on the computer gave an effect to automatically install trojan. After the payload installation process is complete, a backdoor is created so that Red APT has access to the victim's computer to steal database files on the target computer in SQL format. Agent implemented show in caldera dashboard seen in Fig. 10. The file theft was carried out using data exfiltration and data staging techniques using CALDERA. Fig. 11 shows the techniques used by Red APT to carry out data theft.

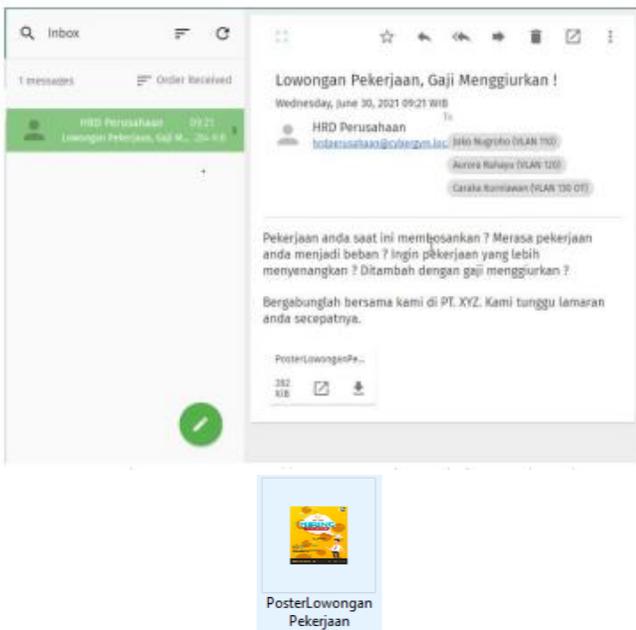

Fig. 9. Email Contains Payload.

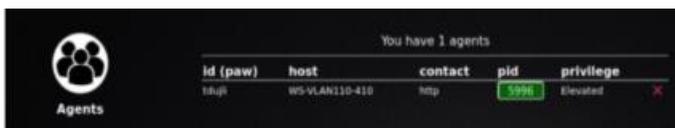

Fig. 10. Caldera Dashboard.

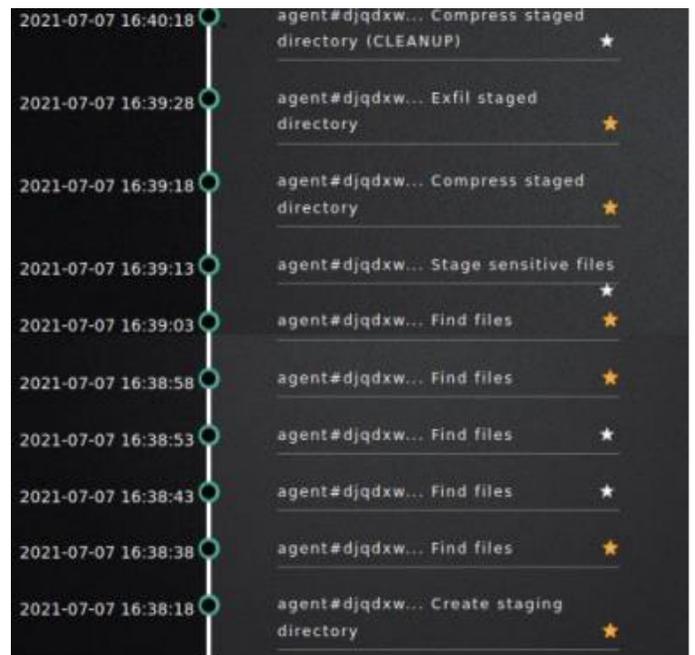

Fig. 11. Red APT Data Theft Techniques.

5) *Observe*: The OODA loop is an iteration, so after the goal of the attack, data theft is achieved, Red APT will return to the observe stage with the knowledge that has been obtained from the previous OODA iteration. In the next iteration, Red APT can explore the system to find data, information, or other vulnerabilities that can be exploited.

In future research RED team can be improved [19] by implementing automated system as Applebaum's research. Meanwhile, the OODA loop carried out by SOC defender to detect anomalies and APT. APT has been studied in [20] and [21] research. OODA loop for blue team or defender in research scenario is as follows:

1) *Observe*: SOC target or defender team checks the results of network monitoring through Security Onion to find and collect network data. Security onion is agent based for cyber-attack defense [22]. The network monitor display on Security Onion can be seen in Fig. 12.

2) *Orient*: Filter and check for alerts detected by Security Onion. From these alerts, SOC performs an analysis to find suspicious activity. At this stage, the SOC can download the .pcap file to facilitate the analysis process. Based on the results of the analysis, it was found that there is HTTP access to an unknown IP address. Fig. 13 shows an HTTP access alert from a 192.168.110.2 (VM 410) to 192.168.170.2 (VM 101).

After further inspection with PCAP file, it was suspected that there was the theft of files from one computer because there was a file that was compressed in the .zip format as shown in Fig. 14. This allegation was also strengthened by evidence in the form of an email sent to several employees of PT TRINAKLIR containing a payload.

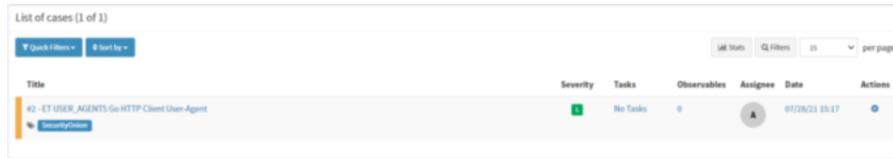

Fig. 15. Ticket Registered.

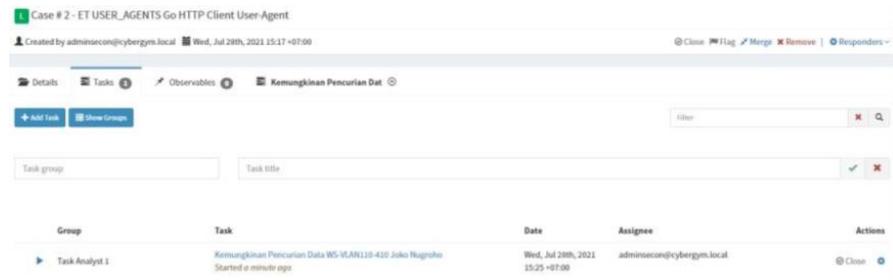

Fig. 16. Task Generated.

E. UAT Questionnaire

Evaluation of research results in the form of the cyber range is also carried out through UAT testing with respondent, 11 cybersecurity lecture (all population of cybersecurity engineering programme). Making instruments in the questionnaire aims to determine whether the features of the cyber range have met the cyber range taxonomy and can meet the needs of cyber security learning tools. The results of filling out the questionnaire were then analyzed using a Likert scale. The Likert scale is a measurement scale that aims to measure respondents' opinions on research results from very positive to very negative and in the form of words [24][25][26]. Table VII is list of questionnaire in this research.

TABLE VII. USER ACCEPTANCE TEST QUESTIONNAIRE

No	Statement	SS	S	R	TS	STS
1	The operation of the cyber range is easy for first-time users to learn					
2	The steps in the attack simulation scenario at the cyber range are in accordance with the OODA loop so that it is easy to understand and execute.					
3	Cyber range can meet cyber security learning					
4	Cyber range provides an isolated environment to execute simulated attack scenarios.					
5	All the tools in the cyber range work well.					
6	The monitoring system on the cyber range is running well.					
7	Cyber range can help cadets understand the role of the red team and blue team.					
8	The scoring method (assessment of attack simulation results) on the cyber range is running well.					
9	Cyber range management or management can be done easily					

F. UAT Questionnaire Analysis

The results of the UAT response data were then analyzed to measure the respondent's level of agreement with each statement in the UAT questionnaire using the following equation:

$$\frac{\sum(a \times b)}{c \times d} \tag{1}$$

a = total number of respondents who chose the b answer

b = score of the answer choices

c = respondent total

d = highest score

Furthermore, the results of the previous calculations are summed and recalculated to determine the level of acceptance of the cyber range that was built as a whole using the following equation:

$$\frac{\sum wx}{x \times y \times z} \times 100\% \tag{2}$$

w = total score of respondent's choice

x = total statement

y = total answer

z = highest score

Where w is score total of respondent's choice, x is total statement, y is total respondent, z is highest score.

V. RESULT AND DISCUSSION

A. Result of Reaching the Needs

The cyber range that has been built is then evaluated to find out the results of meeting the needs of the cyber range against the needs analysis that has been compiled based on the cyber range taxonomy. Based on the results of fulfilling the needs, cyber range meets 16 of 17 seen in Table VIII. Characteristics that are not fulfilled is special tools for scoring. In this cyber range, scoring is done by checking the success of the attack stages as well as ticketing with the help of Security Onion

monitoring tools, CALDERA attack automation tools and TheHive ticketing tools. The overall cyber range acceptance rate with formula 2 is 81.82%.

TABLE VIII. FULFILLMENT NEEDS RESULT

No	Req	Characteristics of Taxonomy	Fulfilled
1	Cyber range has a clear scenario development goal, namely simulating data theft attacks.	Scenario (Goals)	Yes
2	Cyber range provides an isolated environment to execute simulated attack scenarios in physical, virtual, or hybrid forms consisting of the target and attacker infrastructure.	Scenario (Environment)	Yes
3	Cyber range provides the storyline of the scenario to provide an overview of how the scenario execution process.	Scenario (Storyline)	Yes
4	Cyber range provides a static or dynamic scenario.	Scenario (Type)	Yes
5	The scenario in the cyber range is applied to a particular domain.	Scenario (Domain)	Yes
6	Cyber range can use a variety of tools to build or run a scenario.	Scenario (Tools)	Yes
7	Cyber range provides a particular method for monitoring the simulation of attacks carried out.	Monitoring (Method)	Yes
8	Cyber range provides special tools for monitoring systems.	Monitoring (Tools)	Yes
9	The monitoring system in cyber range works at the TCP/IP layer.	Monitoring (Layer)	Yes
10	Cyber range provides a red team role.	Teaming (Red team)	Yes
11	Cyber range provides a blue team role.	Teaming (Blue team)	Yes
12	Cyber range provides the role of an autonomous team.	Teaming (Autonomous team)	Yes
13	Cyber range provides a specific scoring method.	Scoring (Method)	Yes
14	Cyber range provides special tools for scoring.	Scoring (Tools)	No
15	Cyber range provides role management features.	Management (Role)	Yes
16	Cyber range provides computing resource management features	Management (Resource)	Yes
17	Cyber range provides range management features.	Management (Range)	Yes

B. UAT Questionnaire

Table IX is compilation of UAT result. Analysis results of the UAT response data with formula 1 is 405 in the Agree area seen in Fig. 17.

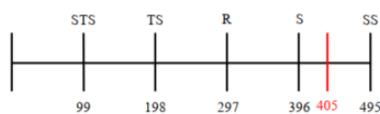

Fig. 17. Questionnaire Result.

VI. CONCLUSION

Based on meeting the needs, the cyber range meets 16 of the 17 characteristics in the cyber range taxonomy. Based on the results of the UAT questionnaire, a score of 405 was obtained in the Agree area, and the overall cyber range acceptance rate was 81.82%. This result also states that Observe-Orient-Decide-Act (OODA) for Cyber Security Education can be implemented globally.

VII. FUTURE WORKS

The scenario contained in the cyber range is only a simulation of data theft attacks. It is necessary to build a simulation with other cases to meet the learning needs of a more complete range of cybersecurity. The CALDERA agent tool can only run on Windows operating systems. It is necessary to add other similar tools so that attack simulations can be carried out on other operating systems. System performance from cyber reach has not been tested through stress tests or measured by certain methods. Cyber range performance testing and scenario and tool enhancement can be used as further research.

# Module Partition Method of Embedded Multitasking Software Based on Fuzzy Set Theory

## Embedded Multitasking Software

Yunpeng Gu<sup>1</sup>

Yangzhou Polytechnic Institute  
Art Design College, Yangzhou, 225107, China

**Abstract**—In order to improve the reliability of embedded multitask software, a module partition method based on fuzzy set theory is proposed to solve the problem of large number of software failures and high frequency of failures. Firstly, the characteristics of embedded multitask software are analyzed, and the constraint parameter distribution model is constructed. Then the reliability parameter analysis model of embedded multitask software is constructed, and the multilevel fuzzy metric structure combined with quantitative recursive analysis method is used to complete the division of embedded multitask software modules. The simulation results show that the accuracy of the proposed method exceeds 99% after the number of iterations exceeds 50. The experimental results show that the method has high reliability, high precision and high practicability.

**Keywords**—Multitasking; embedded; modular; fuzzy set theory

### I. INTRODUCTION

In the running of embedded software, the efficiency of information processing can be improved by dividing modules under multi-tasks [1, 2]. However, this method is easy to lead to software function conflicts, which will lead to software failures, and software reliability cannot be guaranteed, affecting the user experience. In the process of using embedded multitask software, the application direction of software can be combined to divide the modules, so as to improve the reliability of software application [3]. At present, some scholars have made relevant research on this. Some scholars proposed a software module division method based on the combination of genetic algorithm and particle swarm optimization, established a mathematical model of the division problem, used genetic algorithm to find a feasible solution, and used particle swarm optimization to find the optimal scheme [4]. Other scholars proposed to maintain the independence of modules by scheduling model partition [5]. However, this method does not consider the reliability of software module partition, so this paper proposes an embedded multi-task software module partition method based on fuzzy set theory. This method can improve the reliability of software module division on the basis of maintaining module independence, thereby reducing the probability of software failure and improving the customer experience. Embedded multitasking software reliability test is based on the reliability of embedded multi-tasking constraint parameter analysis

software. The embedded multitasking software reliability parameters analysis model established the embedded multitasking software module which is divided by the intelligent analysis method and embedded multitasking software module partition method based on fuzzy set theory is put forward [6]. Firstly, the constraint parameters of embedded multi-task software module partition are analyzed, and then the software compatibility and human-computer interactions are tested by using multi-layer index parameter constraint control method. Combined with the software reliability constraint index, the software reliability automatic test is realized. Finally, the simulation results show that this method is effective in improving the partition ability of embedded multitask software modules. The proposed method can effectively divide embedded multitask software modules, improve the reliability of software, and provide new ideas and ways for software improvement in the current market.

### II. RELIABILITY CONSTRAINT INDEX AND FEATURE ANALYSIS OF EMBEDDED MULTITASKING SOFTWARE

#### A. Reliability Constraint Index of Embedded Multitasking Software

In order to realize the partition of embedded multitask software modules, it is necessary to analyze the application characteristics of embedded multitask software modules. Based on the attribute, portability and importance of embedded multitask software, reliability constraint index analysis method is used to analyze the application of the software. The software reliability analysis mainly has four dimensions, namely, reliability measurement parameters, reliability parameter system, reliability measurement indicators and reliability indicator system. Among them, reliability measurement parameter refers to the mathematical attribute of quantitative description of reliability. Reliability parameter system is a set of software reliability parameters. Reliability metrics refer to the required value of a software reliability parameter. The reliability index system is the required value of all reliability parameters of a certain software. Analyze the characteristics of software module with product application. The product adaptability index distribution of embedded multitasking software is shown in Fig. 1.

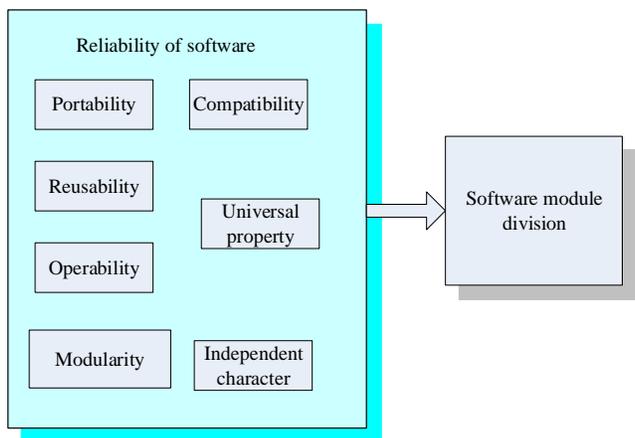

Fig. 1. Product Adaptability Index of Embedded Multitasking Software.

According to Fig. 1, the embedded multitask software modules are divided according to their quality. In combination with the operability of software applications, the adaptive feature detection model of embedded multitask software is established. In addition, the distributed algorithm [7] is used to establish the partition model of embedded multitask software modules, which improves the universality of embedded multitask software. A software quality measure is carried out by adopting a quantitative analysis method of software reliability. The reliability test of the software is mainly divided into the structural test and the object-oriented test. The complexity and the reliability distribution of the software are combined, and the embedded multi-task software module is divided into two levels. According to the above analysis, the parameter system of the secondary constraint index of the software reliability is established as shown in Fig. 2.

According to the reliability constraint parameter system of embedded multitask software shown in Fig. 2, the reliability of embedded multitask software is tested and evaluated by structure-oriented method.

The reliability of embedded multitask software refers to the probability that the software will not cause system failure within the specified time under the specified environment. Software reliability is one of the important indexes to measure software quality. It is not only related to software errors, but also related to system input and system use. Generally

speaking, the more software failures occur or the shorter event interval, the lower software reliability.

Embedded multitask software reliability test is to ensure and verify the reliability of the software. It is a kind of random test. Its main feature is to test software according to the way users actually use software. Generally, embedded multitask software reliability test is divided into software reliability growth test and software reliability verification test. If there is no requirement of reliability index and the current reliability level needs to be evaluated, there are also embedded multitask software reliability bottom test. The reliability test of embedded multitask software is different from the general software test (such as unit test, integration test, function test, performance test, boundary test, etc.) in terms of test purpose, test method, test object, etc. The comparison between embedded multitask software reliability verification test and general software test is shown in Table I.

In Fig. 2,  $t_1$ ~ $t_4$  refer to reliability, failure probability, mean time before failure and mean time between failures respectively; wherein, reliability refers to the probability of success of software to complete specified functions under specified conditions and within specified time. Failure probability refers to the probability of losing normal operation and specified functions under specified conditions and within specified time. Average time before failure refers to the mean value from the current time to the next failure time. Mean time between failures refers to the mean time interval between two successive failures. The reliability test of embedded multitask software generally uses black box test, because it is a use-oriented test, it does not need to understand the structure of the program and how to realize it. The main flow of software reliability test is shown in Fig. 3.

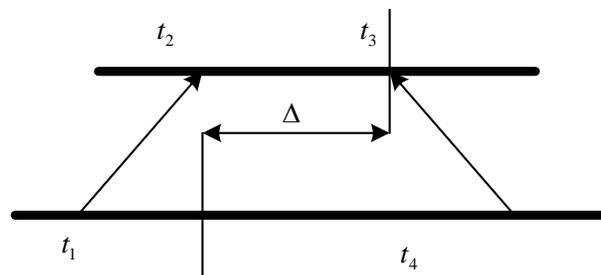

Fig. 2. Software Reliability Two-level Constraint Index Parameter System.

TABLE I. COMPARISON BETWEEN RELIABILITY VERIFICATION TEST AND GENERAL TEST OF EMBEDDED MULTITASK SOFTWARE

Item compared	Software reliability verification test	General software testing
Test purpose	Quantitative estimation of reliability level of software products	Discovery of software errors
Tester	The user usually takes part in the test	It is usually measured by the developer
Testing stage	Software acceptance phase	Trial software development stage
Test method	Random test based on software operation profile.	Testing based on requirements / structure
Test object	The final form of software products	Intermediate form of software products
Test feature	Do not eliminate software defects	Modify software errors and constantly improve software quality

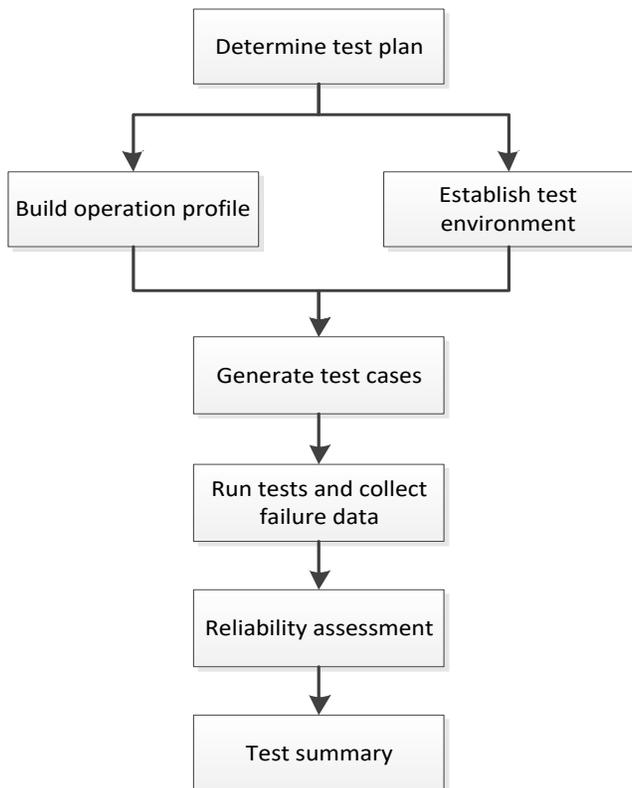

Fig. 3. Reliability Testing Process of Embedded Multitask Software.

The main idea of embedded multitask software reliability test is to test the software at random according to the statistical rules of users' actual use. At present, the use of software is usually modelled in the form of operation profile. The construction of operation section can be refined layer by layer from top to bottom. The development process of the operation profile is shown in Fig. 4.

1) The customer profile consists of independent customer type series.

Customer type is one or more customers in the group who use the system in a similar way. These customers are significantly different from other customers in the way of using the software.

The probability of occurrence needs to be determined for each customer type in the customer profile. In the case of single software customer, there is no need to establish customer profile.

2) User profile is a set of user groups and their probability of occurrence, which is usually based on the customer profile.

3) System mode profile is a set of system mode and its corresponding probability of occurrence. System patterns can be derived from software requirements or usage analysis.

4) The function profile is to decompose the functions required by the system in the system mode and determine the probability of each function.

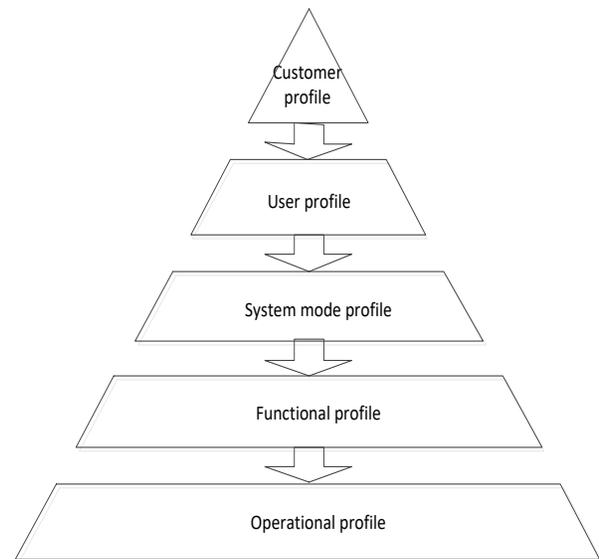

Fig. 4. Operation Profile Development Process.

The construction of function profile usually needs to get the function list according to the software development task or the software requirements document, and then combine with various situations of the operating environment, and assign the probability of occurrence for each function.

5) Operation profile is a set of operations and their probability of occurrence. The main step to determine operation profile is to list operations and determine the probability of occurrence of each operation. A function can be mapped to one or more operations, and a group of functions can also be re merged into a group of different operations, so the list of operations can be obtained according to the function profile.

The embedded multitask software reliability test environment refers to the software and hardware environment that provides test input and collects test output for the tested software. For the reliability test of real-time embedded software, we can use the test environment of full digital simulation technology, hardware in the loop simulation platform and system joint test. In order to get the real reliability test results, the reliability test should be carried out in the real environment. But in many cases, it is unrealistic to test the software reliability in real environment, so the software reliability test usually uses the semi physical simulation environment. Generally, the test environment of semi physical simulation (or full digital simulation) has the following requirements:

1) The operations involved in the operation profile can be performed in the test environment.

2) Meet the real-time requirements of the test excitation, that is, the excitation input meets the requirements of the input interface, data format and input timing of the real cross-linking environment, and the input logic of the real cross-linking environment is the same.

3) Be able to collect test result data for software reliability test analysis.

The failure data of embedded multitask software is the basis of software reliability test and evaluation. In the process of reliability test execution, it is necessary to record the actual results of each test case as required, and judge whether the use case passes according to the expected test results of each use case and the pass criteria of the use case. If not, record it. The problems found in the reliability test of embedded multitask software should be analyzed and dealt with according to the types of problems. The software problems caused by the defects of the tested embedded multitask software itself should be included in the failure of the tested software. The software problems caused by the improper design of the test environment, test methods and test cases other than the tested software should not be included in the failure of the software. In addition, the category and severity level of each embedded multitasking software problem should be described. The categories of software problems include design problems, document problems, program problems and other problems. The severity level of the problems can be described by level 4.

Reliability verification test is a kind of statistical test, which should be selected in the test planning stage. When choosing the statistical test plan, many factors should be considered, such as the type of verification index, the quality requirements of software, the maximum test time, the maximum failure number, the test cost, the trade-off between cost and time. For the verification test of product reliability using success rate, the verification test scheme of success rate is usually used. The specified success rate is the probability that a product will complete the required function or that the product will succeed in the test under the specified conditions. The observed success rate can be defined as the ratio of the number of products that have not failed to the total number of test products at the end of the test or the ratio of the number of successful tests to the total number of tests. The main parameters of the success rate verification test scheme are:

R : Success rate;

$R_0$  : Acceptable success rate;

$R_1$  : Unacceptable success rate;

d : Identification ratio of success rate  $(1-R_1)/(1-R_0)$ ;

n : Receive the required number of fixed tests;

r : Accumulated failure number;

$r_{RE}$  : Rejection failure number;

$\alpha$  : Manufacturer's risk, i.e. rejection probability when  $R=R_0$ ;

$\beta$  : User risk, i.e. the probability of reception when  $R=R_1$ .

The verification test scheme of success rate includes the truncated sequential statistical scheme and the fixed number test statistical scheme. The schematic diagram of the truncated sequential statistical scheme is shown in Fig. 5.

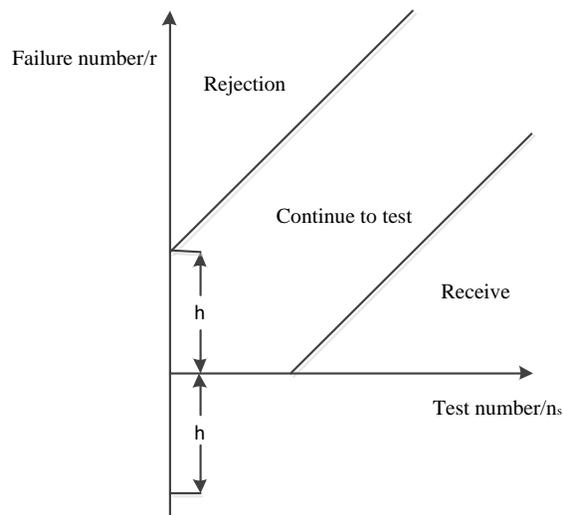

Fig. 5. Schematic Diagram of Truncated Sequential Statistical Scheme.

When  $r \leq s \cdot n_s - h$ , receive;

When  $r \geq s \cdot n_s + h$ , rejection;

When  $s \cdot n_s - h < r < s \cdot n_s + h$ , continue the test.

Sequential test to cut off line, acceptance or rejection criteria.

When  $n_s = n_t$ , when  $r < r_t$ , receive;

When  $r > r_t$ , reject;

Among them,  $n_s$  is the number of tests accumulated in the sequential test scheme,  $s$  is the slope of the receiving and rejection lines,  $h$  is the intercept of the receiving and rejection lines on the vertical line,  $n_t$  is the number of truncated tests, and  $r_t$  is the number of truncated failures.

Given  $R_0$ ,  $d$ ,  $\alpha$ ,  $\beta$ , the test number  $n$  required for receiving the judgment and the failure number  $r_{RE}$  required for making the rejection judgment can be obtained by looking up the table. The comparison between the two schemes is shown in Table II.

TABLE II. COMPARISON OF TWO STATISTICAL SCHEMES

Comparison items	Advantage	shortcoming
Truncated sequential Statistical scheme	1. The minimum number of average tests and failures required for judgment; 2. It has a certain maximum value in cumulative test number and cumulative failure number.	1. The number of failures and the cost of tested products vary greatly; 2. The maximum number of accumulated tests and failures may exceed the equivalent number of accumulated tests and failures.
Fixed number test Statistical scheme	1. The change range of failure number and cost of tested products is small; 2. The maximum number of cumulative tests is less than that of similar truncated sequential tests.	1. The average failure number and test number are large; 2. In order to make a judgment, the products with good quality and bad quality shall experience the most cumulative tests or failures.

The embedded multitask software reliability testing technology is applied to a configuration item software of an airborne weapon product. Firstly, according to the requirement documents and the actual operation of the embedded multitask software, the operation profile covering the whole working process of the software is constructed. Extract specific system execution task scenarios, design test cases for each scenario respectively, and describe the test cases in detail. Object oriented reliability testing method. The calculation formula of software package constraint index is as follows:

$$MHF = \frac{\sum_{i=1}^{TC} \sum_{m=1}^{M_d(C_i)} (1-V(M_{mi}))}{\sum_{i=1}^{TC} M_d(C_i)} \quad (1)$$

$$V(M_{mi}) = \frac{\sum_{j=1}^{TC} is\_visible(M_{mi}, C_j)}{TC - 1} \quad (2)$$

$$is\_visible(M_{mi}, C_j) = \begin{cases} 1, & \text{if } \begin{cases} j \neq i, \\ C_j \text{ may call } M_{mi} \end{cases} \\ 0, & \text{otherwise} \end{cases} \quad (3)$$

In the formula,  $TC$  is the total number of attributes distributed by embedded multitasking software, and  $M_d(C_i)$  represents the number of categories in reliability attribute category  $C_i$ .

The regression analysis of embedded multitasking software reliability measurement is carried out by using the method of multi-factor metrology [8]. Combined with the method of bottom design and top-level encapsulation, the product quality of embedded multitasking software is evaluated. Multi factor measurement is a method of measuring multiple evaluation units by using multiple indicators. Its basic idea is to convert multiple indicators into an indicator with comprehensive evaluation ability, so as to reduce calculation complexity and improve calculation efficiency and accuracy. Based on the above, the ambiguity constraint parameters of embedded multitasking software module division are obtained.

$$AHF = \frac{\sum_{i=1}^{TC} \sum_{m=1}^{A_d(C_i)} (1-V(A_{mi}))}{\sum_{i=1}^{TC} A_d(C_i)} \quad (4)$$

$$V(A_{mi}) = \frac{\sum_{j=1}^{TC} is\_visible(A_{mi}, C_j)}{TC - 1} \quad (5)$$

$$is\_visible(M_{mi}, C_j) = \begin{cases} 1, & \text{if } \begin{cases} j \neq i, \\ C_j \text{ may call } A_{mi} \end{cases} \\ 0, & \text{otherwise} \end{cases} \quad (6)$$

In the formula, the  $A_d(C_i)$  is the number of the attributes of the  $C_i$ , the constraint index parameter model divided by the embedded multi-task software module is constructed according to the analysis, and the indexes such as the correctness, the reliability, the operation efficiency, the integrity and the usability of the software are determined, and a constraint parameter index distribution model for dividing the embedded multi-task software modules is constructed [9, 10, 11].

### B. Reliability Feature Analysis of Embedded Multitasking Software

Let the reliability measurement domain of embedded multitask software be  $U$ , and  $U$  can be expressed by exact numerical value. Linear programming technology is used to analyze the reliability characteristics of embedded multitasking software, and the next year planning analysis is carried out combined with the inheritance of software reliability. The reliability characteristic analysis model of embedded software is established, and the output:  $SC_i(Ex_i, En_i, He_i)$ ,  $I = 1, 2, 3, \dots, n$ . The formula for calculating the reliability feature distribution of embedded multitasking software is as follows:

$$MHF = \frac{\sum_{i=1}^{TC} M_i(C_i)}{\sum_{i=1}^{TC} M_a(C_i)} \quad (7)$$

$$M_a(C_i) = M_d(C_i) + M_i(C_i) \quad (8)$$

Wherein,  $M_i(C_i)$  is the reliability test factor of  $C_i(i = 1, 2, \dots, n)$  class, and the reliability design of embedded multitask software is carried out with the method of fuzzy clustering analysis. The calibration model characteristics of embedded multitasking software reliability measurement are expressed as  $U \rightarrow [0, 1], \forall x \in U, x \rightarrow SC(x)$ . The reliability feature analysis of embedded software is carried out by using the method of multimodal data fusion feature analysis, and the comprehensive measurement model of software is described as follows:

$$AIF = \frac{\sum_{i=1}^{TC} A_i(C_i)}{\sum_{i=1}^{TC} A_a(C_i)} \quad (9)$$

$$A_a(C_i) = A_d(C_i) + A_i(C_i) \quad (10)$$

In the formula, the software reliability attribute class function is  $A_i(C_i)$ , and the quantitative characteristic formula of reliability test with property class  $C_i (i=1,2,\dots,n)$  is the number of attributes whose  $En_i = (Ex_i - Ex_{i-1})/3 A_d(C_i)$  is  $C_i (i=1,2,\dots,n)$ . Based on the analysis, the constraint parameter distribution model of embedded multitask software module partition is constructed, the ambiguity factor of embedded multitask scheduling and module segmentation is established, and the embedded multitasking software module is divided into embedded multitasking software modules combined with fuzzy dynamic testing method [12].

### III. OPTIMAL DESIGN OF EMBEDDED MULTITASK SOFTWARE MODULE PARTITION METHOD

#### A. Embedded Multi-task Scheduling and Module Segmentation and Ambiguity Analysis

On the basis of constructing the constraint parameter distribution model of embedded multitasking software module partition, the optimal design of embedded multitasking software module partition is carried out. In this paper, an embedded multitasking software module partition method based on fuzzy set theory is proposed [13]. Fuzzy set theory regards the object to be investigated and the fuzzy concept reflecting it as a certain fuzzy set, establishes an appropriate membership function, and analyzes the fuzzy object through the relevant operations and transformations of the fuzzy set. Based on fuzzy mathematics, fuzzy set theory studies the imprecise phenomena. The module partition of embedded multitask software is an imprecise problem, so the research is based on fuzzy set theory. Factor of embedded multi-task scheduling and module segmentation is established, and the compatibility and human-computer interactions of the software are measured by the method of multi-layer index parameter constraint control. The formula for calculating the coupling factor of embedded multi-task software module is as follows:

$$COF = \frac{\sum_{i=1}^{TC} \left( \sum_{j=1}^{TC} is\_client(C_i, C_j) \right)}{TC^2 - TC} \quad (11)$$

$$is\_client(C_c, C_s) = \begin{cases} 1 & \text{iff } C_c \Rightarrow C_s \wedge C_c \neq C_s \\ 0 & \text{otherwise} \end{cases} \quad (12)$$

In the formula,  $TC^2 - TC$  is the maximum degree of coupling of the reliability distribution of embedded multi-task software. The multi-level fuzzy metric structure model of the embedded multi-task software module is established, and the

method for combining the multi-state factor (POF) is adopted to obtain the multi-dimensional combined test index distribution set of the software to be as follows:

$$POF = \frac{\sum_{i=1}^{TC} M_o(C_i)}{\sum_{i=1}^{TC} [M_n(C_i) \times DC(C_i)]} \quad (13)$$

$$M_d(C_i) = M_n(C_i) + M_o(C_i) \quad (14)$$

The embedded multi-task software reliability measurement model is composed of five states, namely  $\lambda = (X, O, A, B, \pi)$ , where  $X = \{x_i, i=1,2,3,\dots,N\}$  is the fuzzy coupling state factor in the embedded multi-task software reliability measurement model, and the  $O = \{o_j, j=1,2,3,\dots,M\}$ .  $O$  is an embedded multi-task software safety evaluation model observation state,  $C_i (i=1,2,\dots,n)$  represents the reliability test set of embedded multi-task software, which is defined as follows:

$$\begin{aligned} \max F(X) &= (F_1(X), F_2(X), \dots, F_n(X)) \\ \text{s.t. } g_j(X) &\leq 0 \quad (j=1,2,\dots,p) \\ h_k(X) &= 0 \quad (k=1,2,\dots,p) \end{aligned} \quad (15)$$

According to the above analysis, the multi-level fuzzy measurement structure model of embedded multitask software module partition is established, and the parameter indexes such as serviceability, compatibility and portability of embedded software are analyzed by combining reliability merging and comprehensive measurement method, so as to improve the ability of embedded multitask scheduling and module segmentation and reliability measurement [14].

#### B. Embedded Multitasking Software Module Partition and Optimization Measurement

Based on the above contents, the multi-level fuzzy measurement structure model of embedded multitask software module is studied and constructed, and the number of embedded multitask software is set. However, the software module division based on this method has the problem of weak correlation between embedded multitask software. [15]. In order to solve this problem, a method is proposed to optimize the resource allocation of embedded multitask software by using association combination detection, and build an embedded multitask optimal scheduling and adaptive control model. The fuzzy membership function of embedded multi-task software is described as:

$$\begin{cases} L = \{L_1, L_2, \dots, L_q\} \\ R = \{R_1, R_2, \dots, R_p\} \end{cases} \quad (16)$$

In the above formula,  $V_k$  represents the nonlinear dynamic measurement function of software reliability. For the  $k$  software reliability attribute feature set, set up the security reliability measurement feature distribution set of embedded multitask software, map the reliability linear programming

feature set  $L_k$  of embedded multitask software to the target test set  $R_l$  by spatial programming method, and calculate the nonlinear feature quantity of software reliability measurement, which is described as follows:

$$G_{EV,q \times p} = \begin{pmatrix} G_{EV,11} & \dots & G_{EV,1p} \\ \dots & \dots & \dots \\ G_{EV,q1} & \dots & G_{EV,qp} \end{pmatrix} \quad (17)$$

Based on the comprehensive measurement model, the quantitative feature distribution set of embedded multitasking software module partition is obtained, and the principal component feature quantity of embedded multitasking software module partition is represented by  $SC (Ex, En, He)$ . According to the above analysis, the statistical analysis model of embedded multitasking software module partition is constructed, and the statistical feature distribution matrix is obtained as follows:

$$L = \begin{pmatrix} l_{11} & l_{12} & \dots & l_{kp} \\ l_{21} & l_{22} & \dots & l_{2p} \\ \dots & \dots & \dots & \dots \\ l_{q1} & l_{q2} & \dots & l_{qp} \end{pmatrix} \quad (18)$$

The embedded multitasking software module is divided by quantitative recurrent analysis, and the optimized test set function is obtained as follows:

$$V = \begin{pmatrix} v_{11} & v_{12} & \dots & v_{kp} \\ v_{21} & v_{22} & \dots & v_{2p} \\ \dots & \dots & \dots & \dots \\ v_{q1} & v_{q2} & \dots & v_{qp} \end{pmatrix} \quad (19)$$

Based on the above contents, the division of embedded multi task software modules is realized on the basis of ensuring the independence and stability of software modules. [16, 17, 18, 19].

#### IV. SIMULATION EXPERIMENT AND RESULT ANALYSIS

In order to verify the application performance of the method in the implementation of the embedded multi-task software module division, the simulation test is carried out. The reliability test environment of embedded multitask software is built by the general system test platform Geste. Among them, the general embedded software simulation test platform consists of three test hosts, two test targets, related I/O and signal conversion devices. All devices in the platform are connected by Ethernet, and the two test target computers communicate with each other in real time through the memory reflective real-time optical fiber network [20, 21]. Position diagram is shown in Fig. 6.

Software reliability can be tested by using the following definitions: the probability that software will not cause system failure under specified conditions and within specified time. This probability is a function of system input and system use, as well as a function of defects in software. The system input will determine whether existing defects will be encountered. The probability that the software will not cause system failure within the specified time, that is, the success rate of the software. Therefore, the success rate is used to verify the fixed number test statistical scheme. After analysis, it is determined that  $\alpha = 10\%$ ,  $\beta = 10\%$ ,  $R_0 = 0.9701$ ,  $R_1 = 0.91$ .

$$\text{Identification ratio } D = (1-r_1) / (1-r_0) = 3.01$$

According to  $\alpha = 10\%$ ,  $\beta = 10\%$ ,  $R_0 = 0.9701$ ,  $d = 3.01$ , the values of parameter  $n$  and  $RRE$  are obtained by looking up the table:  $n = 101$ ,  $RRE = 6$ .

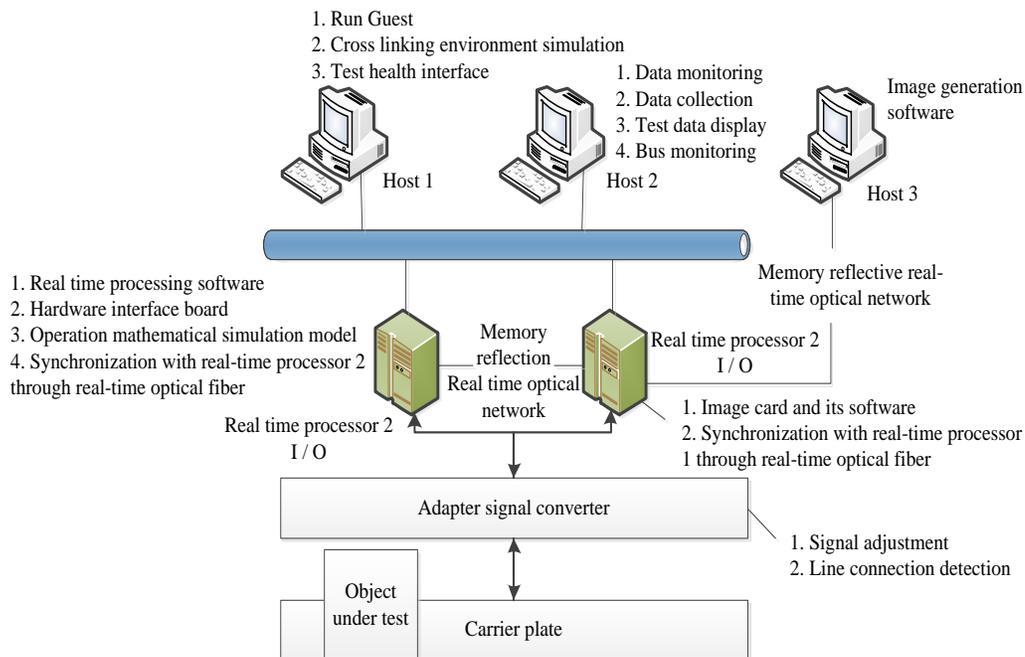

Fig. 6. General System Test Platform Geste Structure Diagram.

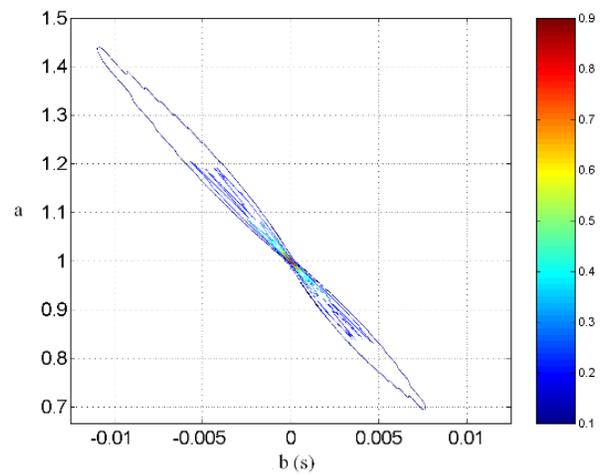

Therefore, 101 reliability test cases need to be designed for execution. If the number of software failures is less than or equal to six during the test, the software will be accepted, otherwise it will be rejected [22].

In the software reliability test, there are four failures, less than the maximum number of software failures, which meet the requirements of reliability test program. And the embedded multi-task software module is divided and analyzed in combination with the Matlab and the C ++, the distribution area of the parameter sampling of the embedded multi-task software reliability constraint index parameter is set to [0, 0.6] [0.6, 0.8] [0.8,1], and the distribution of test indicators at all levels is shown in Table III.

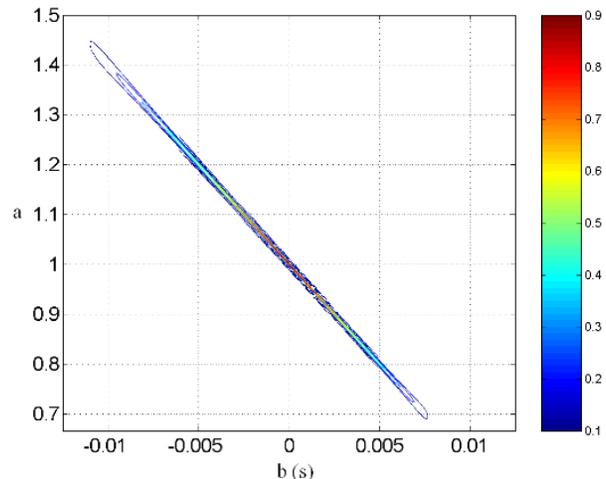

By comparing the reliability verification test of embedded multitask software with the general software test, the main process of software reliability test is designed. According to the embedded multitask software, the reliability software and hardware environment of test input and test output are provided [23]. According to the requirements document and the actual operation of the embedded multitask software, the operation section covering the whole working process of the software is constructed, and the specific system execution task scenarios are extracted. Test cases are designed for each scenario respectively, and the test cases are described in detail. The calculation formula of software package constraint index is listed, and the fuzzy constraint parameters of embedded multitask software module division are obtained [24, 25, 26, 27]. Then the fuzzy analysis of embedded multitask scheduling and module division is carried out, the embedded multitask software module is established, and the multi-level fuzzy measurement structure model is divided [28]. According to the test results of the above index parameters, the embedded multitasking software modules are divided, and the reliability test output of each software system is shown in Fig. 7.

TABLE III. DISTRIBUTION OF TEST INDICATORS AT ALL LEVELS OF EMBEDDED SOFTWARE

Primary test index	Weight	II. Test index	Test data
SC1	0.36	INDEX11	0.325
		INDEX12	0.156
		INDEX13	0.446
		INDEX14	0.332
		INDEX15	0.563
		INDEX16	0.532
		INDEX17	0.426

(a) Initial Status.

(b) Module Partition Output.

Fig. 7. Reliability Test Output of Software System.

Analysis of Fig. 3 shows that using this method can effectively achieve the embedded multi-task software module division, compare the reliability of the software, get the comparison results as shown in Fig. 8 [29].

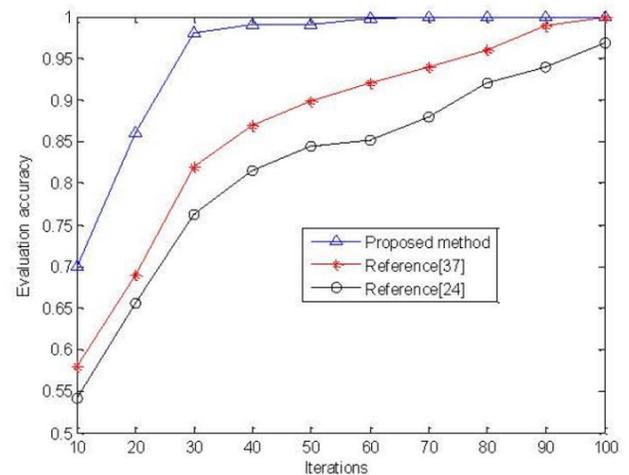

Fig. 8. Reliability Comparison Results for the Software.

In order to understand more clearly and accurately the comparison results of simulation experiments on the reliability of embedded multitask software in this paper, 10 iterations are taken and detailed data comparison is conducted according to Fig. 8 [30, 31, 32, 33]. The comparison data is shown in Table IV [34, 35, 36].

TABLE IV. RELIABILITY COMPARISON DATA OF EMBEDDED MULTITASK SOFTWARE

iterations	Proposed method Evaluation accuracy	Reference [37] Evaluation accuracy	Reference [24] Evaluation accuracy
10	0.7	0.58	0.54
20	0.86	0.82	0.65
30	0.98	0.86	0.76
40	0.99	0.88	0.81
50	0.99	0.90	0.83
60	1	0.92	0.84
70	1	0.93	0.86
80	1	0.95	0.92
90	1	0.97	0.93
100	1	1	0.96

According to Table IV and Fig. 8, when the number of iterations is 10, the accuracy of Proposed method is 0.12 higher than Reference [37], and 0.16 higher than Reference [24]; When the number of iterations is 20, the accuracy of Proposed method is 0.04 higher than Reference [37], and 0.21 higher than Reference [24]; When the number of iterations is 30, the accuracy of Proposed method is 0.12 higher than Reference [37], and 0.22 higher than Reference [24]; When the number of iterations is 40, the accuracy of Proposed method is 0.11 higher than Reference [37], and 0.18 higher than Reference [24]; When the number of iterations is 50, the accuracy of Proposed method is 0.09 higher than Reference [37], and 0.16 higher than Reference [24]; When the number of iterations is 60, the accuracy of Proposed method is 0.08 higher than Reference [37], and 0.16 higher than Reference [24]; When the number of iterations is 70, the accuracy of Proposed method is 0.07 higher than Reference [37], and 0.14 higher than Reference [24]; When the number of iterations is 80, the accuracy of Proposed method is 0.05 higher than Reference [37], and 0.08 higher than Reference [24]; When the number of iterations is 90, the accuracy of Proposed method is 0.03 higher than Reference [37], and 0.07 higher than Reference [24]; When the number of iterations is 100, the accuracy of Proposed method is the same as Reference [37], 0.04 higher than Reference [24]; It can be seen that this method improves the reliability of the software through the division of embedded multitask software modules [37, 38, 39].

## V. CONCLUSIONS

The reliability parameter analysis model of embedded multitask software is established, and the embedded multitasking software module is divided by intelligent analysis method. The embedded multitasking software module partition method based on fuzzy set theory is proposed to

construct the constraint parameter distribution model of embedded multitasking software module partition according to the correctness, reliability, running efficiency, integrity and availability of the software. The ambiguity factor of embedded multi-task scheduling and module segmentation is established, the compatibility and human-computer interactions of software are measured by multi-layer index parameter constraint control, the multi-level fuzzy metric structure model of embedded multi-task software module partition is established, and the embedded multi-task software module is divided by quantitative recurrent analysis. It is found that the embedded multitasking software module can be divided effectively by using this method, and the reliability of the software can be improved.

## VI. DISCUSSION

In order to solve the problem that the current software module partition method of embedded multitask software is easy to cause software failures and affect user experience, a module partition method of embedded multitask software based on fuzzy set theory is proposed. The basic process of the method is as follows: firstly, the characteristics of embedded multitask software are analyzed, the constraint parameter distribution model is constructed, and the interaction measurement is carried out by combining multitask scheduling and ambiguity segmentation. Then the reliability parameter analysis model of embedded multitask software is constructed, and the multilevel fuzzy metric structure combined with quantitative recursive analysis method is used to complete the division of embedded multitask software modules. In order to verify the application performance of this method in the implementation of embedded multitask software module partition, simulation tests are carried out. The results show that the accuracy of the proposed method is significantly higher than that of the other two methods when the number of iterations is the same. This is because the research builds the optimal scheduling and adaptive control model of embedded multitask software based on fuzzy membership function, which makes embedded multitask software have strong correlation, thus optimizing the reasonable allocation of resources of embedded multitask software. It can be seen that this method improves the reliability of the software through the division of embedded multi task software modules

**Abstract**—Most people preferred e-commerce ensuing the Coronavirus Disease-2019 (COVID-19) outbreak, resulting in delivery companies receiving large quantities of parcels to be delivered to clients. Hurdle emerges when delivery person needs to convey items to a large number of households in a single journey as they never face this situation before. As a result, they seek the quickest way during the trip to reduce delivery costs and time. Since the delivery challenge has been classified as an NP-hard (non-deterministic polynomial-time hard) problem, this study aims to search the shortest distance, including the runtime for the real case study located in Melaka, Malaysia. Hence, two metaheuristic approaches are compared in this study namely, Ant-Colony Optimization (ACO) and Genetic Algorithm (GA). The results show that the GA strategy outperforms the ACO technique in terms of distance, price, and runtime for moderate data sizes that is less than 90 locations.

**Keywords**—Ant-colony optimization; genetic algorithm; delivery problem; comparison; cost; runtime

## I. INTRODUCTION

Ever since the chain of Coronavirus Disease-2019 (COVID-19) infections trend up worldwide, peoples' life has been turned upside down. So, do Malaysians. When the former Prime Minister, Tan Sri Dato' Haji Muhyiddin bin Mohd Yassin imposed national lockdown through Movement Control Order (MCO), Malaysians have slowly avoided brick-and-mortar shopping and shop on e-commerce. Previously, e-commerce was a generic buzzword, however, it has become a norm these days.

COVID-19 has led to a significant spike in e-commerce and rapid digitalization in the midst of weakening economic activity in most countries. For instance, in the 2nd period of 2020, Latin America's marketplace Mercado Libre managed to sell double things per day in comparison to the same period in the previous year. In addition, African e-commerce site, Jumia recorded a spike of 50% revenues over the first half of 2020. Throughout August 2019 and August 2020, China's e-commerce percentage of sales rose from 19.4% to 24.6%. Meanwhile, the online percentage of retail sales in Kazakhstan, grew from 5% in

2019 to 9.4% in 2020. In Thailand, installations of shopping applications surged by 60% within a week in March 2020 [1].

Transport plays an essential role in every supply chain and it has an impact on logistics' efficiency and effectiveness. Transportation, inventory keeping, bureaucracy, custom fees, hazard, as well as handling and packaging costs are among six major logistics cost aspects that should have good pre-planning. Route planning is a critical issue in distribution system, and as such, it has been an important topic in logistics field. By focusing on areas such as enhanced productivity and better vehicle usage, effective routing and scheduling can result big savings. According to [2], the goal of reducing transportation costs is to reduce the number of trips.

This research article presents a case study that utilizes Asymmetric Travelling Salesman Problem (ATSP), in which a delivery service is founded to alleviate the burden of delivering items to customers' doorsteps. As a result, this delivery service will travel and organise their routes carefully to multiple locations in order to meet the needs of their consumers within a designated time frame. The primary goal of this study is to evaluate two metaheuristics approaches, namely ACO and GA, and to compare its efficiency metric of minimizing cost and time. The delivery service drivers have a plethora of options, which will allow them to seek for the shortest distance and lowest cost throughout their excursions.

The entirety throughout this paper is organised as follows: Section II highlights relevant studies on the current challenges and ways to overcome, while Section III describes the methodologies used in the study. Section IV presents the outcomes and the discussions, and Section V finishes the article with future work.

## II. LITERATURE REVIEW

### A. Logistics in Malaysia

Malaysia reported 37% of growth in e-commerce revenues by 2020. The Department of Statistics Malaysia annotated a rise in 23.1% during the first 9 months of 2021, signalling that

this pattern will remain [3]. A study by [4] indicated that e-commerce has boosted the number of buyers in both established and emerging countries, including Malaysia, Singapore, Thailand, and Pakistan since the outbreak. Most of retailers are changing their brick-and-mortar shop to e-commerce platform, as it can maintain the continuity and longevity of their business during these arduous circumstances.

Fig. 1 illustrated Malaysian’s e-commerce users from 2017 – 2025 in three different categories, namely in the past, present and forecasted data of the upcoming years [5]. The figure demonstrates a significant basis on how intra-logistics have increased during this crisis in Malaysia. This is mostly due to the rise of internet purchases for daily necessities [6].

When consumers are actively purchasing online today, the need for shipments are escalating every day. Thus, an extra demand exists during festive seasons, monthly household demands, and monthly sales organised by e-commerce platforms. The warehouse space in courier companies is quite limited to cater these high parcel volumes, resulting dumping of parcels [7][8]. When there are countless of delayed parcels to be delivered, employees must work overtime. Pos Laju riders, one of the delivery companies in Malaysia, are deemed to work on weekends to avert overburdened goods, and deliver hundreds of items every day [7]. According to the previous study [8], this circumstance is frustrating as poor coordination of logistics providers and courier services has disrupted on other activities in the company.

The following figure indicates the number of domestic courier items delivered by courier service providers in Malaysia from 2016 to 2020 (see Fig. 2) [9]. In 2020, the parcel volume distributed by the courier service providers escalate during the endemic, thus, courier companies need to be well-prepared.

Logistics are in demand ever since the COVID-19 pandemic has started. Almost all countries were having lockdowns. The only way to purchase our daily necessities were through online order and have it delivered to our doorstep. Hence, courier companies play a vital role. Planning of dispatches and navigation of vehicles are critical in supply chain operations since it influence distribution of costs and contentment of customers.

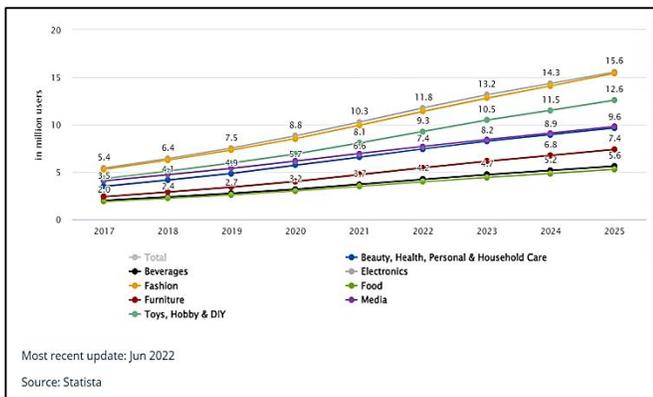

Fig. 1. Malaysian’s e-commerce users from 2017 – 2025 in different Categories [5].

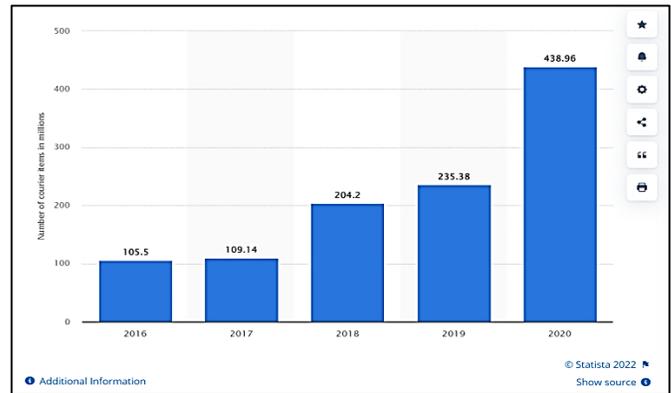

Fig. 2. The Number of Domestic Courier Items Delivered by Courier Service Providers in Malaysia from 2016 to 2020 [9].

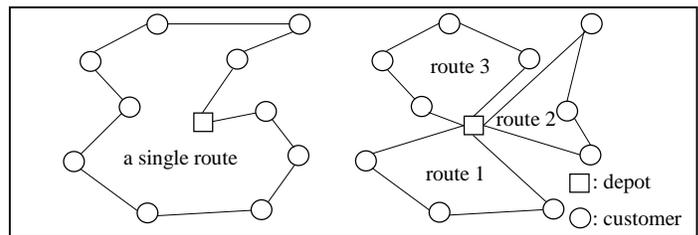

Fig. 3. The Difference between ATSP and VRP [11].

Since the distribution of goods is influenced by various factors such as the requirements of delivery providers, clients, and macro environment, Vehicle Routing Problem (VRP) is one of the most researched subjects in operational research [10]. Thus, logistics providers need to plan well if they want to use VRP or ATSP applications whenever they dispatch customers’ packages. TSP examines a single vehicle visiting numerous customer sites before heading to the depot, and it is aimed that the total journey time or vehicle distance to be as short as possible. VRP is distinct from TSP as it can generate several routes that can travel through all customer locations. The Fig. 3 below shows the difference between ATSP and VRP are shown below [11].

Despite Malaysia's economic development rate is improving, the country's logistical advances remain modest. In order to stay abreast with other South East Asian countries, Malaysia's logistics development was meticulously mapped under the Third Industrial Master Plan (IMP3) in 2006, Unfortunately, Malaysia continues to lag behind neighboring countries such as Singapore, Thailand, and Vietnam in terms of transportation, bureaucracy, and logistics. The problems occur in logistics expansion are insufficient transport infrastructure, underdeveloped transport and logistics services, as well as delayed and costly administrative practices, which contribute to major factors of Malaysia's high logistics costs [12].

### B. Algorithms in Logistics Issues

The ATSP is known as a combinatorial optimization problem in operation research and graph theory. It appears in numerous application scenarios, such as cloud computing resource deployment, efficient route search for transport, computational modelling of proteins, semiconductor

manufacturing, X-ray crystallography, school and university scheduling, as well as drone navigation [13]. There is at least one scenario in the ATSP when cost or weight on an arc is not identical in either direction of to or from a node in a travelling graph [14]. ATSP is an efficiency problem that a salesman must solve in order to visit all cities. In an ATSP situation, the distance between cities A and B is not the same as the distance between cities B and A. As a result, the salesman must identify the quickest possible route.

In a study by [15], Farmland Fertility (FF) algorithm is utilized in the experiment to solve the problem. Farming action inspires FF as a metaheuristic. FF assists farmers in obtaining high-quality plant for sale at a premium price. During the process, farmers will typically split their fields into sections by using different materials or treatments depending on the soils. The study develops an agricultural fertility algorithm to tackle ATSP by identifying parameters that influence the outcome [15].

To handle continuous optimization challenges, Social Spider Algorithm (SSA) is proposed based on spiders' information-sharing foraging approach. By retaining SSA's strengths and outstanding performance, [16] propose a novel algorithm called Discrete Social Spider Algorithm (DSSA) to solve discrete optimization problems by making some changes to the computation of Euclidean distance, construction of follow position, movement method, and fitness function. TSPLib benchmark are used to demonstrate DSSA's effectiveness, and the results are compared to six different optimization methods: Improved Bat Algorithm (IBA), GA, an Island-based Distributed Genetic Algorithm (IDGA), Evolutionary Simulated Annealing (ESA), Discrete Imperialist Competitive Algorithm (DICA), and Discrete Firefly Algorithm (DFA). DSSA surpasses other strategies in the simulation data. The experimental results suggest that the DSSA approach is superior than the existing evolutionary algorithms for solving TSP issues and it can be applied to any optimization problems such as routing problems.

ACO is a nature-inspired metaheuristic that is frequently used to develop approximations to overcome optimization problems. Even though ACO is substantially faster than precise approaches, it still can be considered sluggish when it is compared to fundamental problem-specific heuristics. Recent research has demonstrated that algorithm modifications with proper parallel implementation using multi-core CPUs and specialized accelerators can be considered to enhance speed. In this study, [17] offered Focused ACO (FACO), a unique ACO variant. One of the FACO's basic elements is a system for managing large discrepancy between a freshly produced and a previously selected solution. This technique results a more concentrated exploration process, allowing improvements and maintaining performance of existing solution. In addition, it also provides seamless interaction of problem-specific local search. A computational study based on a variety of Traveling Salesman Problem instances reveals that FACO beats state-of-the-art ACOs in tackling big TSP instances.

As for the asymmetric travelling salesman problem, [18] proposed a new GA with optimal recombination and ATSP

adaptive restarts. The crossover operator solves optimal recombination problem (ORP) using a new technique that solves the ATSP on cubic digraphs. Based on Schnabel census estimate, the researchers utilized an adaptive restart rule. A computational experiment on known benchmark examples demonstrates suggested algorithm able to produce results that are comparable to those state-of-the-art ATSP algorithms, confirming that the ORP can be utilized successfully in genetic algorithms. The study also discussed two restarting rules. The first solution employs the conventional restart rule, in which the GA is resumed as soon as the current iteration number equals double the number of iterations when the best incumbent is discovered (denoted GACL). The second strategy is based on the biometrics Schnabel census method that is combined with the maximum likelihood concept. When the population variation becomes low, novel solutions are unlikely to be identified, hence this criterion repeats the process.

Presently, there are lack of research when both methods perform their best at their own way. Hence, in this study, as for GA, it turns out to be the best when the crossover operator is removed, and subsequently the other three mutation operators, flip mutation, swap mutation, and slide mutation were added. Whereas for ACO, the best parameters were studied from various studies, and that parameter values were applied in this study. Therefore, both methods have been compared and evaluated to see which is the best to be applied in this study.

### III. METHODOLOGY

In this study, the MATLAB version R2018a software is utilized to compare the effectiveness of the algorithms to some current works. The processor Intel(R) Core (TM) i5-1035G1 CPU @ 1.00GHz has an aspect of Intel Deep Learning Boost technology for speedier artificial intelligence-based computing. Below will further discuss the methods and parameters used in this study.

#### A. Genetic Algorithm

John Holland is the pioneer to propose GA on computational difficulties of game hypothesis and case recognition. It is based on the fundamental of Darwinian advancement principles of choice, hybridization, and transformation and aims to depict developmental methods [19]. Majority of GA-phrasing comes from the realm of inherited traits [20]. It is claimed to mimic the natural progression of living creatures. Fig. 4 depicts an illustration of a GA [20].

The GA's fundamental structure can be described as follows:

1) *Start*: The process begins when a random pair of chromosomes from all best solution is identified, referred as the population.

2) *Fitness*: The fitness of each chromosome in the population is calculated using the fitness criterion. For an instance, based on a set of 5 genes, each of which would have one of the binary values 0 or 1, one must create a sequence with all 1s. Maximize the amount of 1s as much as possible.

This is an exemplar of an optimization problem. As a result, the fitness function is defined as the number of 1s in the genome. If it has five 1s, it has maximum fitness and solves the problem. If there is no 1s, it has the least fitness [21].

3) *Selection*: Two parent chromosomes are chosen from a population based on their fitness.

4) *Crossover*: Crossover on the specified parent chromosomes result a new offspring set.

5) *Mutation*: If necessary, the newly acquired progeny may also be mutated.

6) *Check*: If the specified criteria are achieved, return the optimal answer and stop.

This study applied the same approach as proposed by [22]. The crossover operator, was not included. According to [22], he does not regard the crossover operator as a necessary component of GA. The author in [22] tested different variants of the GA in terms of diverse crossover and mutation operator combinations in order to solve TSP. The crossover operator was discovered to be catastrophic as it resulted large changes to a given path and unable to impose good solution. As a result, [22] used three distinct mutation operators to generate modifications that were more important in promoting ideal results. Thus, the identical technique as described by Kirk was used in this case study. Fig. 5, Fig. 6, and Fig. 7 show three mutation operators which are elucidated in the following figures [22]:

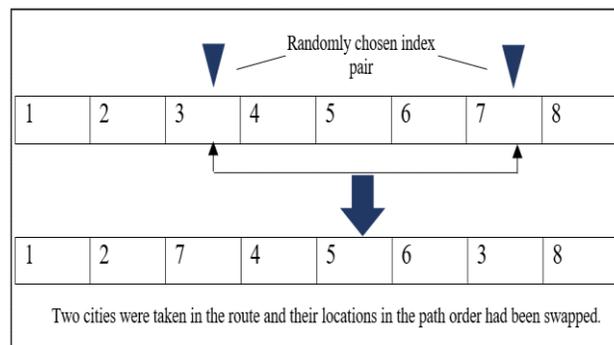

Fig. 6. Swap Mutation [22].

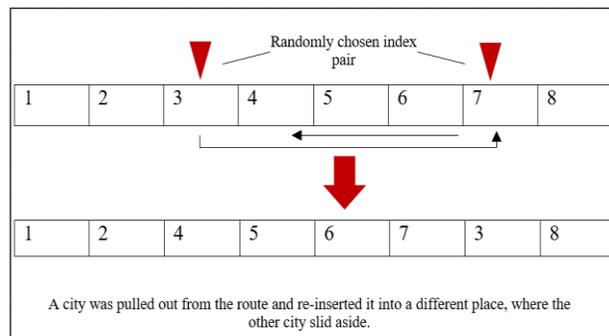

Fig. 7. Slide Mutation [22].

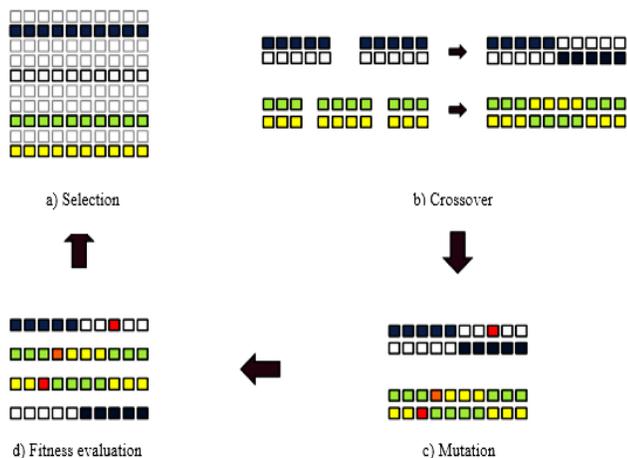

Fig. 4. Illustration of GA [20].

Fig. 8 Depicts the Flowchart of the GA.

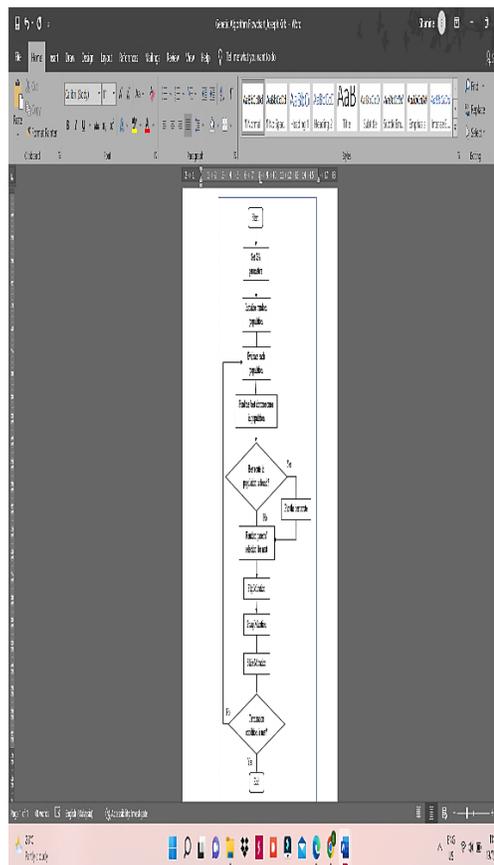

Fig. 8. Flowchart of GA [22].

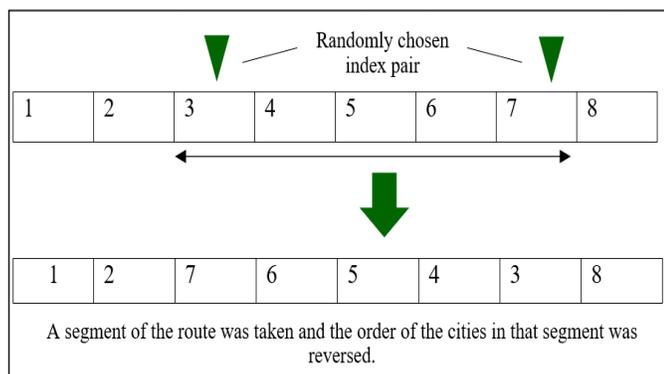

Fig. 5. Flip Mutation [22].

TABLE I. PARAMETER VALUE FOR GA

Parameter	Value
No. of Houses	10, 20, 30, 40, 50, 60, 70, 80, 90, 100
Pop. Size	10
No. of Iteration	1e4
Mutation Probability	$P_m = 1.0$

Table I shows the parameter value of GA that was used in this study. The effect of parameters in both methods play a major role in this study. Among the parameters that are vital in the GA method are population of chromosomes, number of iterations and mutation probability. The population size used is 10. As there were no previous evidence studies on the recommended population size, hence, a simulation of ten-run was done between 10 to 100 population size. It was shown that when population size of 10 was used in the study, the result showed a positive performance. The iteration 1e4, (10000) was used as, right after that, the results occurred are same.

**B. Ant-Colony Optimization**

The ACO, which is based on ant foraging behavior, was first proposed by [23]. It portrays real-life of ants' behavior to find the short routes between sources of food and their nest, an evolving habit that emerges from an ant's decision to pursue the trail pheromones released by other ants. Fig. 9 shows the basic idea behind an ant colony, with black lines denoting pheromones on every route [24].

Initially, three ants contemplate to travel via the same route to their food. Each ant follows a different course, and one ant moves quicker than the others. This ant will exude a chemical substance (pheromone) while travelling to help other ants to trail and recall their path. The pheromone trail will be stronger on the shorter way than the longer path. Subsequently, the longer road pheromone trail will fade, but the shorter path pheromone trail will become much stronger, resulting the ants to choose the shortest route. Fig. 10 shows the flowchart of ACO algorithm [25].

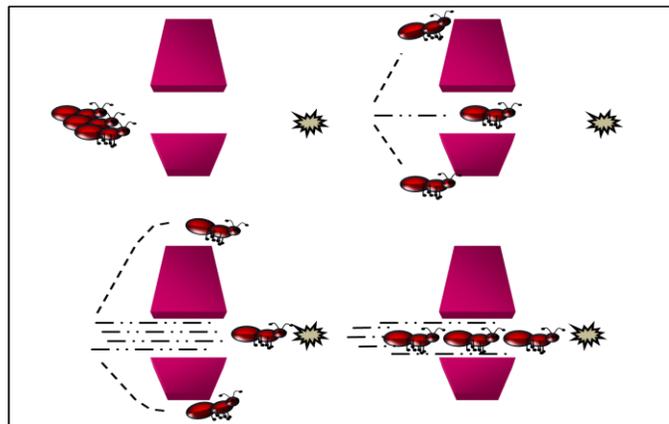

Fig. 9. ACO Behavior at Distinct Time Stamps [24].

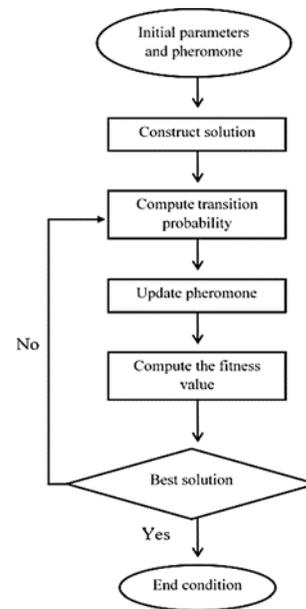

Fig. 10. Flowchart of ACO [25].

TABLE II. PARAMETER VALUE FOR ACO

Parameter	Value
No. of Houses	10, 20, 30, 40, 50, 60, 70, 80, 90, 100
No. of Ants	10
Pheromone Rate (rho)	0.15
No. of Iteration	300

Table II shows the significant parameter values of ACO that was used in this study as it affects the findings. The count of ants in this study is limited to 10. It is because, according to [31], it is suggested to assign the ants within the range of more than 6, but less than 20, for a small or medium scale TSP. Meanwhile, if the number of ants exceeds 16, it will result longer execution time when the complexity of the algorithm increases. Moreover, if the number of the ants is greater than 16, the evaporation rate of pheromone will be quicker resulting an impediment in finding the optimal solution. As a result, the number of ants is set to 10 and the rate of pheromone evaporation is determined to 0.15. This is because if the rate is lesser, there will be more pheromone and higher possibility to get the best findings. The iteration is set to 300 because if it is less, the optimum result cannot be achieved; if it is greater, simply the run time increases with the same outcome.

**C. Formulation of Costing in Mathematical Model**

The total cost of mathematical model is proposed for this study, as suggested by [26][27]. It has been employed in the pricing calculation after the distance of both approaches are obtained.

Total Cost, Z:

$$Z = \sum_{i=1}^n (LSD \times CS) \tag{1}$$

$$Z = [\sum_{i=1}^n D(L_i, L_j)]CS \tag{2}$$

$$Z = \left[ \left[ \sqrt{(x_j - x_i)^2 + (y_j - y_i)^2} \right] CS \right] \quad (3)$$

$i, j = \{1, 2, 3, \dots, n\}$

LSD = Length of the shortest path between two locations (D)

D = Distance between  $L_i$  and  $L_j$

$L_i = (x_i, y_i)$  initial point (location)

$L_j = (x_j, y_j)$  second point (location)

CS = Cost per 1 kilometer = RM0.80

#### IV. RESULTS

As a case study, we concentrated on Melaka Tengah district, which is known as one of historical capital in Malaysia. Melaka was discovered in year 1400, with an extent of 314 km<sup>2</sup>. Years after, 3 districts and 29 divisions were identified [28]. Melaka Tengah is also recognised as Malacca's most developing city. The city is divided into residential, industrial, commercial, tourist regions, and administrative areas. According to [29], while the city creates enormous economic gains, it also has a variety of socio environmental implications due to poor transportation. Hence, it is chosen as a research topic for this study. Fig. 11 depicts a map of the Melaka Tengah District [30].

Oh My Foot Delivery is a new delivery firm that is established in this area, and its delivering statistics are used in this study. As a young company, currently there is only one branch located in Melaka Tengah's district. Since the company's position is strategic and there are few residential areas nearby, it has attracted the locals' attention for its delivery service. The company begins to grow when more consumers from further away requested its delivery services. As a result, this study is implemented in order to determine the ideal delivery route. Fig. 12 depicts the MATLAB result's that resembles Google Map.

As demonstrated in Fig. 12, the MATLAB findings are similar to Google Maps; hence the recommended routes from Fig. 13 to Fig. 32 are feasible. The yellow dot on Google Maps indicates both starting and ending point for the journey. Conversely, the red dots indicate the sites in which the deliver must travel in order to deliver packages to clients.

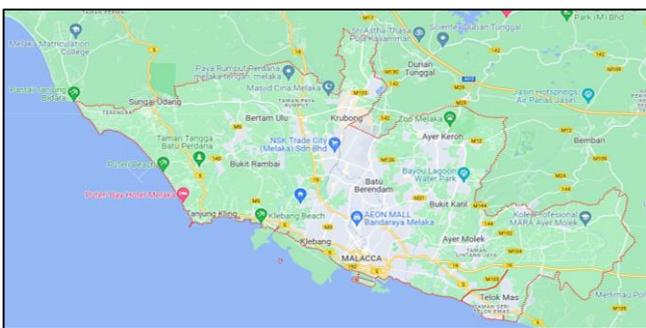

Fig. 11. Map of the Melaka Tengah District [30].

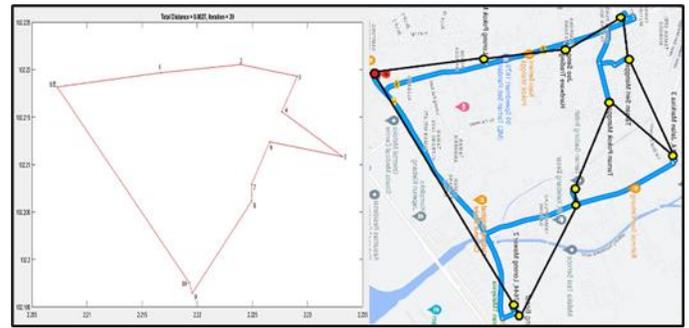

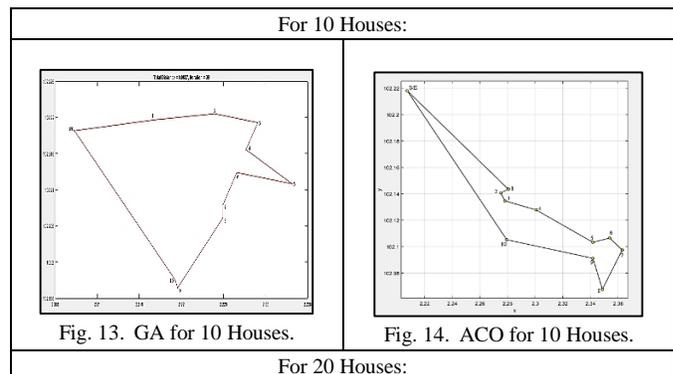

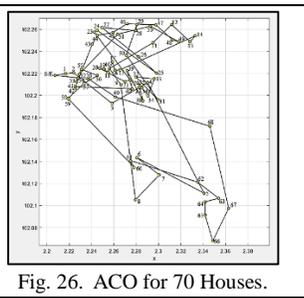

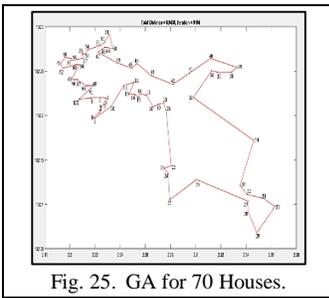

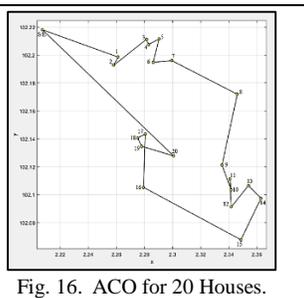

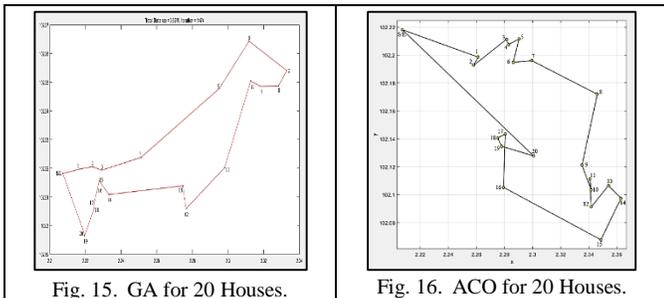

Fig. 12. The MATLAB Result's that Resembles Google Map.

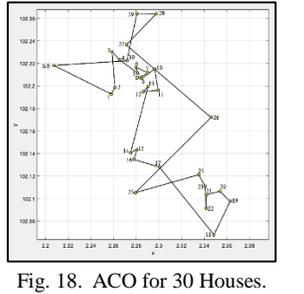

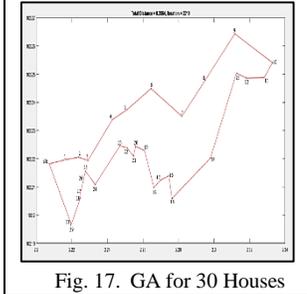

Fig. 13 to Fig. 32 show the simulated results of both GA and ACO methods where each location has been identified from its starting/ending location (S/E) until 10<sup>th</sup>, 20<sup>th</sup>, 30<sup>th</sup>, 40<sup>th</sup>, 50<sup>th</sup>, 60<sup>th</sup>, 70<sup>th</sup>, 80<sup>th</sup>, 90<sup>th</sup>, and 100<sup>th</sup> location simultaneously with its explanation. the starting and ending points are ensured in the same area (S/E). These roads are listed up to 10, 20, 30, 40, 50, 60, 70, 80, 90, and 100 houses based on insights of few riders who routinely deliver 100 sites in a trip since the pandemic. At times, these riders need to cover ten areas per trip. As a result, from the data provided by the delivery firm, a total of 10, 20, 30, 40, 50, 60, 70, 80, 90, and 100 houses are selected for this case study.

The findings of 10 houses, 20 houses, 30 houses, 40 houses, 50 houses, 60 houses, 70 houses, and 80 houses reveal that GA depicts better way than ACO due to significant reasons. When 90 and 100 points of data are assigned to test, it is discovered that the distance and cost of the ACO approach is lesser than GA. This is due to the fact when the ants choose their path, they are likely to follow the trail indicated by the preceding ant who left a strong pheromone intensity. These ants will choose a path with high probability value that has higher pheromone concentration as it will proceed to the closest desired node. Nodes with low probability values are rejected because they are too far away from the ideal node. As a result of this mechanism, the number of possible paths from one generation to the next grows rapidly, causing ACO to converge faster than GA.

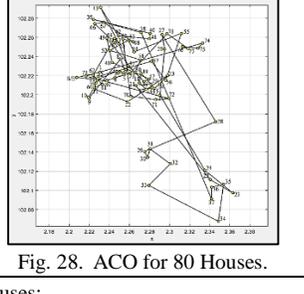

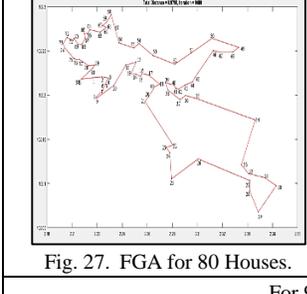

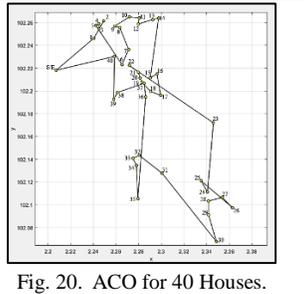

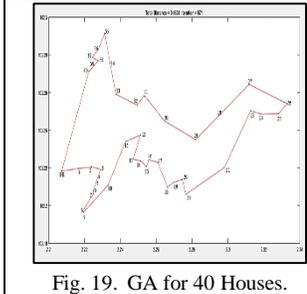

For 30 Houses:

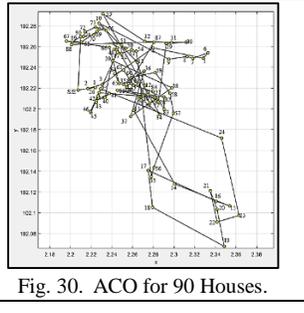

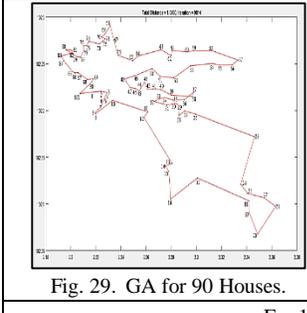

For 80 Houses:

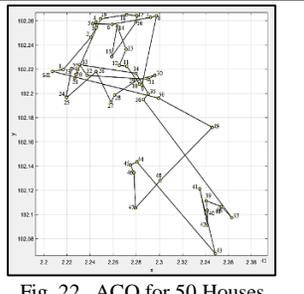

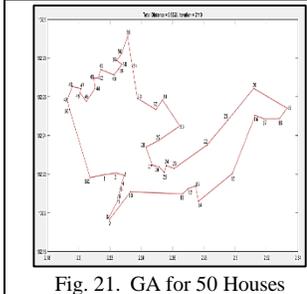

For 40 Houses:

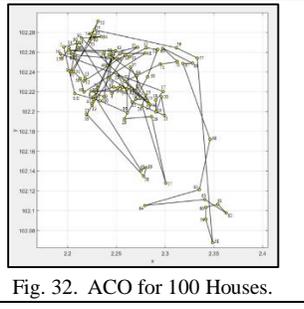

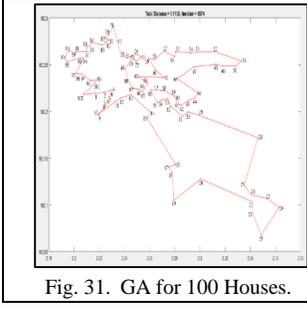

For 90 Houses:

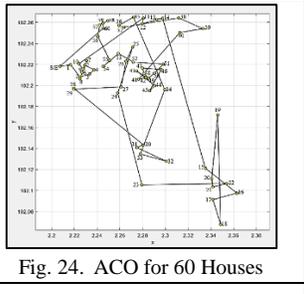

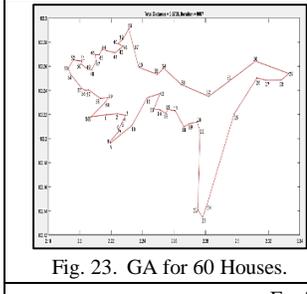

For 50 Houses:

For 100 Houses:

For 60 Houses:

For 70 Houses:

Despite the fact that the ACO's parameters are set at its best according to previous study, there are various reasons why the GA technique is the best solution, including the fact that the run time for all 10, 20, 30, 40, 50, 60, 70, 80, 90, and 100 houses is significantly lesser than the ACO. The crossover probability,  $P_c$ , is set to 0 as the deciding factor. Although crossover probability has several effects on the GA studies, it tends to be disastrous because the crossover has significant impact on the given route due to the random changes made in it which will result in longer execution time. As a result, when the chromosome population is set to 50, the crossover probability parameter,  $P_c = 0$ , the mutation probability,  $P_m = 1.0$ , and the three mutation operators are utilized, the execution time of the GA is lower than the ACO. Flip mutation, swap mutation, and slide mutation are treated as three mutation operators in the study.

The delivery firm, Oh My Foot Delivery now can use the route proposed by GA method in this study. It is because, previously the delivers need to plan their location from one place to another by calculating it one by one. So, some locations that need to be visited has been missed and the delivers need to go the locations back and forth. However, although the distance has been calculated, but the outcome routes depend on the list the deliver enters. This results in high cost that the firm need to spend as more distances need to be travelled by the delivers.

The algorithms under consideration (the GA and the ACO) are employed to identify the shortest path within the range of scenarios of 10, 20, 30, 40, 50, 60, 70, 80, 90, and 100 home counts. The findings of both methods are compared. Fig. 33 reveals that least distance can be obtained when GA is used as the ACO trend in the distance graph increased compared to the GA trend. Hence, delivery service can save more money on their fuel as well.

TABLE III. COMPARISON OF GA AND ACO

No. of Houses	GA			ACO		
	Dist. (KM)	Cost (RM)	Run Time (s)	Dist. (KM)	Cost (RM)	Run Time (s)
10	20.6	16.48	4.13	92	73.6	15.74
20	83.5	66.8	5.483	141.7	113.36	16.752
30	103.2	82.56	6.185	176.8	141.44	16.857
40	127.7	102.16	6.337	190.05	152.04	17.552
50	139.25	111.4	6.995	207.25	165.8	18.163
60	182.45	145.96	7.418	266.35	213.08	18.496
70	269.55	215.64	7.47	285.35	228.28	20.461
80	302.75	242.2	8.322	316.95	253.56	21.256
90	335.15	268.12	8.955	327.5	262	22.269
100	346.9	277.52	9.242	342.1	273.68	21.364

Table III shows the result of this study that has been summarized, following by graphs in Fig. 32, Fig. 33, and Fig. 34.

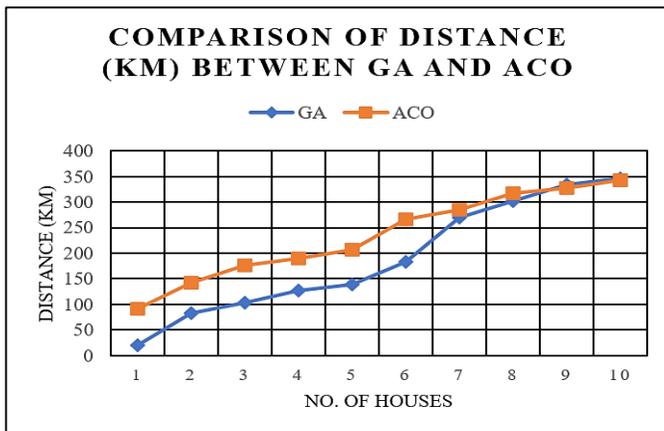

Fig. 33. Comparison of Distance (KM).

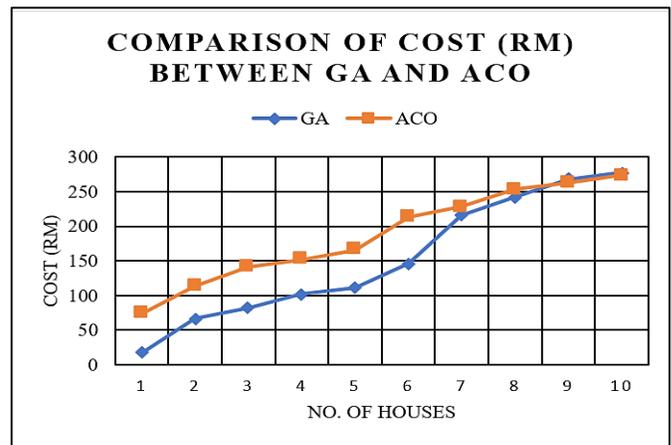

Fig. 34. Comparison of Cost (RM).

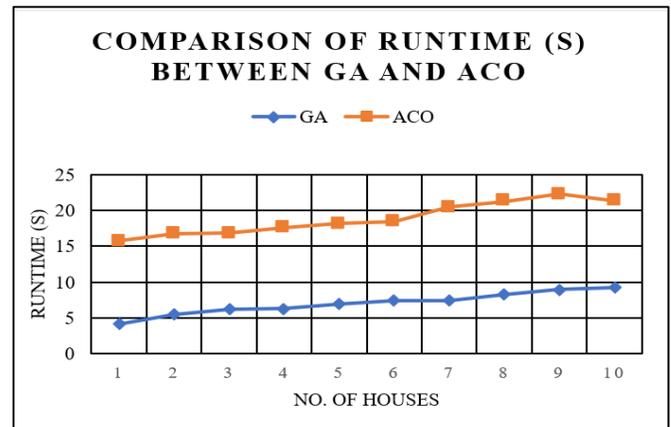

Fig. 35. Comparison of Runtime (s).

Furthermore, when the GA is applied, the graph in Fig. 34 demonstrates the lowest delivery cost which the company has to bear first, then it will be covered by the customers' delivery charge. Thus, it will be beneficial during this pandemic as both parties can save their money and profit from their delivery service. Nevertheless, when 90 and 100 dwellings are specified, the ACO algorithm scored averagely in respect of distance and cost when it is contrasted with the GA technique.

Nevertheless, the GA has yielded to be the most effective method in terms of its runtime under all conditions. It is corroborated through the graph in Fig. 35, which demonstrates a considerable difference in runtime between the GA technique and the ACO technique. From here, we can see that the objectives of this study which is to evaluate ACO and GA, and to compare their performance in terms of minimizing cost and time has been achieved. As a result, it is proven that the GA outperforms the ACO algorithm as it gives the least cost as it proposed the shortest route and minimal running time.

## V. CONCLUSION

This research aims to evaluate two metaheuristics strategies to reduce the exact distance of one trip during delivery. The appraisal methodologies used are the GA and ACO, with distance and cost of delivery as significant presenting pointers. When the GA calculation is assigned to

10, 20, 30, 40, 50, 60, 70, and 80 houses, the most minimal distances and lowest expenses are obtained, according to the exhibition correlation. Thus, when it is compared to the ACO method, the GA outperforms in terms of distances, cost, and runtime. It is also acknowledged that the ACO algorithm performs moderately in terms of distances and prices for 90 and 100 houses. Since both methods are the finest in its individual investigations, both methods and its best parameters are compared. As a result, the objective of this study is achieved.

As a recommendation of future work in this research area, the best methodology that is chosen which is GA can be used in other applications of TSP. Those applications that can be taken into account are scheduling, planning, and manufacturing of microchips. It is because, as the crossover operator has been removed from GA in this study, and it shows a positive effect in terms of runtime, it will be intriguing to know what would be the outcome of the method on other applications.

# An Approach for Optimization of Features using Gorilla Troop Optimizer for Classification of Melanoma

Anupama Damarla\*, Dr Sumathi D

SCOPE, VIT-AP University, Vijayawada, Andhra Pradesh, India

**Abstract**—The diagnosis and categorization of skin cancer, as well as the difference in skin textures and injuries, is a tough undertaking. Manually detecting skin lesions from dermoscopy images seems to be a difficult and cumbersome challenge. Recent advancements in the internet of things (IoT) and artificial intelligence for clinical applications have shown significant increase in precision and processing time. A lot of attention is given to deep learning models because they are effective at identifying cancer cells. The diagnosis and accuracy levels can be greatly increased by categorizing benign and malignant dermoscopy images. This work suggests an automated classification system based on a deep convolutional neural network (DCNN) in order to precisely perform multi-classification. The DCNN's structure was thoughtfully created by arranging a number of layers that are in charge of uniquely extracting different features from skin lesions. In this paper, we proposed a deep learning approach to tackle the three main tasks-deep extraction of features (task1) using transfer learning, selection of features (task2)-using metaheuristic algorithms such as Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and Gorilla Troop Optimization (GTO) as a feature selector, the extensive feature set is optimized, and the amount of features is reduced to within the range, and a two-level classification (task3) was proposed that are emerging in the field of skin lesion image processing. On the HAM10000 dataset, the proposed deep learning frameworks were assessed. The accuracy achieved on the dataset is 93.58 percent. The proposed method outperforms state-of-the-art (SOTA) techniques in terms of accuracy. The suggested technique is however highly scalable.

## I. INTRODUCTION

Epidermis cancer is an invasive disease produced by aberrant melanocyte cell development on the body that tends to reproduce and propagate through lymph nodes, destroying healthy tissue [1]. The ozone layer, that provides protection against UV rays [2] which is depleting causes an increase in skin cancer. On the skin's surface, damaged cells create a lesion that can either be benign or malignant. Melanoma is considered the deadliest form of skin cancer worldwide which emerged as a common disease with highest mortality [3]. Also, it is classified as cancer since it is more hazardous and life-threatening. Melanoma starts in the melanocyte cells, which seem to be brown or black in color and mimic a lesion [4]. Approximately 2500 females and 4700 males have

expired due to melanoma in 2019 [5]. Males have a higher likelihood of developing melanoma than females, according to statistics shown in Fig. 1 [6]. However, precise, reliable early detection is very important as discovered lesions have a 90.0 per cent survival rate [7].

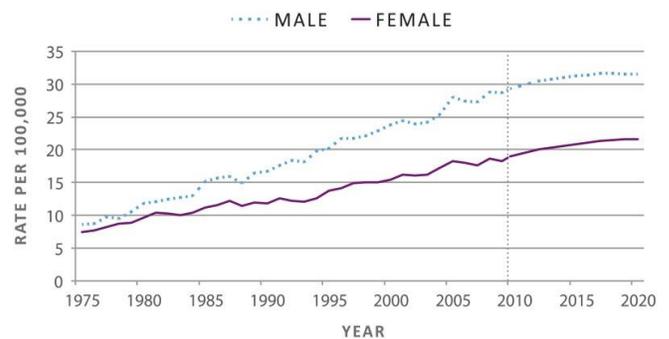

Fig. 1. Age- Adjusted Melanoma Incidence Rates from 1975-2020 [6].

## II. RELATED WORK

Although the various table text styles are provided. The formatter will need to create these components, incorporating the applicable criteria that follow.

Skin cancer detection is challenging due to the diversity in skin textures and injuries. Dermatologists therefore employ dermoscopy, a non-invasive tool, to identify skin irregularities at an initial level [8]. The foremost move in dermoscopy was applying the gel for the diseased region. After that, a magnifying tool is used to obtain a magnified image. This magnified image allows you to see the structure of the lesion region more clearly. The dermatologist's experience determines the accuracy of the detection [9]. According to a survey, the detection precision of a dermatologist might range from 75 per cent to 84 per cent [10]. Contrarily, manual dermoscopy diagnosis requires a lot of time and has a significant chance of error, including for dermatology with experience [11]. As a result, studies developed a number of computer-aided diagnostic (CAD) systems using deep CNN features [12].

The acquisition of a three primary stages of a CAD system is a skin imaging dataset, feature extraction and selection, and classification [13]. Data on skin cancer are unreliable and conventional methods are parameterized and require standard normal training data. Each lesion has a unique pattern and therefore these treatments are ineffective. Dermatologists can

\*Corresponding Author.

accurately identify malignancies with the help of deep learning methods for classifying skin. In comparison to classic feature extraction strategies, the use of epidermis lesion with deep features identification and classification has become increasingly important in recent years [14]. Deep characteristics, which were used to categorize data, are generated from the completely connected layers of a CNN model. Unlike traditional methods like hue, texture and contour, deep features encompass both local and global information about a picture. The convolutional layer extracts local information such as edge, pixel which differs immediately with adjacent pixels of an image; whereas the 1D layers (global average pooling and fully connected) gather global information such as shape descriptors, contour representations [15]. In traditional techniques, geometric information such as Histogram of Gradients, color and textures (Local Binary Patterns) are extracted independently [16].

Even though deep learning algorithms are extremely adept at processing complicated data, skin categorization remains a difficult task for several reasons:

1) As demonstrated in Fig. 2, the distribution of skin lesion classes in the current dataset is unbalanced, with more than 60% of the photos belonging to the NV: "Melanocytic nevus" class and some classes being extremely rare (less than 2%). The lesion images are classified into seven categories as shown in Table I, with number of lesions.

2) Hairlines, water bubbles, ruler marks, etc. are all examples of noisy artefacts in lesions shown in Fig. 3.

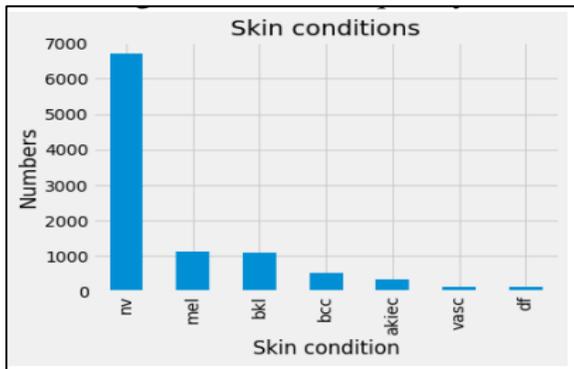

Fig. 2. Class Imbalance [52].

TABLE I. SKIN LESIONS AND INSTANCES COUNT IN HAM10K DATASET [38]

Skin Type	Instances Count
Actinic Keratosis (Akc)	326
Basal Cell Carcinoma (Bcc)	514
Dermatofibroma (Df)	116
Melanoma (Ml)	1114
Nevus (Nv)	6704
Pigmented Benign Keratosis (Bkl)	1098
Vascular Lesions (Vsc)	143
Total	10015

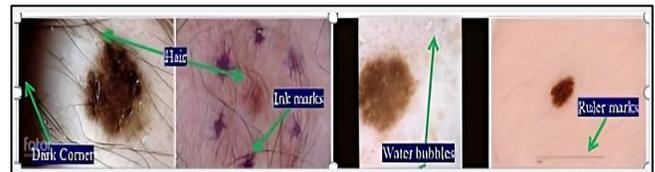

Fig. 3. A Typical Pictorial Presentation of the Skin Images in ISIC 2017 Test Dataset [17].

3) Lacerations are hard to differentiate due to significant intra class variances and inter class commonalities in terms on color, size, site and appearance.

Furthermore, there have been a few obstacles in the development of classification systems and they are provided as given below:

- Initially, there is a discrepancy in the data and there aren't many images with labels.
- Lesser complicated & lighter network designs.
- When techniques are used to categorize skin cancers that are uncommon in the training sample, a misdiagnosis is frequently the outcome.
- Millions of pixel high-resolution images frequently require extensive computing and extra training.
- The different circumstances will cause different noises to be produced (such as different imaging devices, backgrounds).

While prominent pre-trained deep learning networks are trained on diverse datasets, such as ImageNet, they are not used for skin cancer concerns in general [53]. A method for picking the best subset of features based on shape and color to build better and final categorization is required. As a result, the proposed approach shown in Fig. 4 intends to create, implements, and estimate a highly efficient deep learning-based system for malignant vs. benign categorization.

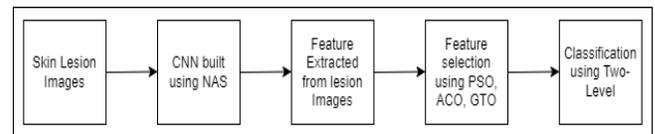

Fig. 4. Flow Structure of Whole Network.

The following is a breakdown of the remaining sections: Section II discusses the research on Neural Architecture Search and optimizers. A public dataset is used in proposed work for skin cancer detection is presented in Section III. In Section IV, a proposed method that explains the CNN, feature selection with three optimization approaches for efficiency with classification in detailed is explained. The results and discussions implemented on the dataset as well as outcomes analysis with other optimizers are seen in Section V, and finally, in Section VI, conclusions are formed.

### III. LITERATURE SURVEY

Several methodologies and procedures have been developed for categorization of skin lesions [8]. Zafar et al [18] proposed two pre-trained CNNs U-Net and ResNet called

Res-UNet for segmenting lesion boundaries and significantly improve the classification accuracy. Computer vision-based machine learning approaches were used in the developed methodologies. Machine-learning algorithms made use of supervised learning and deep learning techniques for the accurate identification, segmentation, and classification of epidermis tumors [19]. Aziz et al. [20] used deep features from a pre-trained AlexNet network, which were then classified using SVM. Their method yielded good results in terms of lesion categorization. Ren et al. [21] presented a fusion mechanism [22]. J. Zhang et al. [23] suggested a CNN for epidermis categorization that consisted of several attentions residual learning (ARL) units succeeded by global average pooling and classification layers. Yu et al. [24] developed a CNN-based design that was pre-trained on several picture resolutions. It developed a fully convolutional residual network (CRN) for segmentation and deep residual network (DRN) for classification. Majtner et al. [25] used a used local binary pattern features and hand-crafted Rsurf features for melanoma recognition system. Ahonen et al [26] uses LBP texture features for efficient facial recognition. A new method to analyze the data which were then segmented zone wise and classified using a Support Vector Machine (SVM) [27] algorithm is proposed. On the HAM10000 dataset, Sivasai et al. [32] proposed a DCNN for lesion classification based on MobileNetV2 and Long Short-Term Memory (LSTM). MobileNetV2 outperformed existing CNN models in several ways, which include reduced computational cost, tinier network size, and interoperability with smart devices. Wannipa et al [43] presented a light weight deep CNN called MobileNet for classification of skin lesions. Ahmed et al [44] presented an ensemble CNN model that combines ResNet 50 and InceptionV3 architectures to classify the seven different skin lesion types. The below Table II provides the comparative analysis.

Prior to the attention in deep learning, research on neural architecture search had been undertaken. Three factors characterize each NAS framework: search space, search strategy and performance evaluation technique [28]. NAS was created to find and develop the model that perfectly suits the dataset in use. As a result, the NAS model has a minimal set of parameters but good performance. Models suited for both small and large datasets can be found using NAS [30]. The Global search space and the Cell search space are two types of search spaces. The network-based technique investigates the entire system, whereas the cell-based approach identifies only the cells, which were subsequently stacked to address a task [29]. The count of cells in the stack is determined by the work at hand. Melanoma detection and classification using dermoscopic images, researchers used a deep learning [31] approach. Deep feature extraction was done with a deep residual network, and image encoding was done. To detect and categorize melanoma using discriminating dermoscopy images, SVM classification with chi-square was used. On the difficult ISBI 2016 dataset, the provided technique performed admirably.

Feature selection (FS) is gaining popularity which is a technique for minimizing the dimensionality of data. It reduces data intricacy by deleting superfluous contents that is

critical. This method minimizes the model's complex nature by including only the most relevant features, making it easier to interpret. By filtering out redundant data, FS approaches reduce the dimensionality of network data. As a consequence, FS is a crucial component of data preparation in medical analysis since it impacts accuracy results. Any feature selection problem could be roughly described as an optimization problem. Several Feature selection methods elicited from metaheuristics (MH) methodologies were recently been implemented. Numerous search techniques mainly inspired by nature and mimicking principles of biology, physics, ethology, or swarm intelligence, have been effectively included in metaheuristic algorithms [34]. Those were split into two categories: standard solution-based approaches and population-based approaches. Population-based algorithms have better ability than single solution-based algorithms [35]. The population-based algorithms are categorized into multiple categories: (1) Particle Swarm Intelligence algorithms (SIs), (2) Evolutionary Algorithms (EAs), (3) Natural Phenomenon algorithms (NP). Grasshopper Optimization Algorithm (GOA), Whale Optimization Algorithm (WOA), Elephant Herding Optimization (EHO), Harris Hawks Optimization (HHO), and Moth-flame Optimization (MFO) are some well-known metaheuristic algorithms [36]. The study indicates that population-based algorithms are well suited to solving real-world problems, despite the need for more objective functions [37].

The procedures outlined above follow certain automated lesion classification techniques. The Deep learning models have higher feature extraction accuracy than pre-trained models, and then applying nature-inspired metaheuristic algorithms as a new feature selection model, a latest method for binary-to-multi classification based on deep learning are the top-performing steps. The aim of maximization of accuracy degree of any subset is shown in Table III. The large number of features produces biased findings since data patterns of training set are not uniquely identifiable in testing data. The drawbacks of metaheuristic techniques get struck with the local optima rather than the global optima.

### A. Research Gap

Earlier works have been focused on various features such as shape, texture and color either by fusion or through many other techniques. Hence, the focus of this work is on performing the detection of asymmetric borders along with contrast enhancement. Therefore, this motivated us to do this work.

### B. Motivation

- The deep neural network has witnessed growth to the next generation by introducing the concept of optimized network. This idea was materialized through the concept of NasNet.
- The predominant factor is to determine a model that would be robust and intractable to seize the global solutions in this complex problem.
- Color channeling embedded with dimension has been given more attention.
- Combining these techniques will achieve high performance.

The solution strategy that does not meet the same efficiency to solve all the problems motivated to propose this method.

## IV. METHODOLOGY

The proposed method for skin cancer detection, which is provided in this part, used deep learning and nature inspired algorithms as a feature selection models that aims to improve the performance and the efficiency on selected features. Fig. 5 depicts the architecture of the suggested technique. This method has five main layers: Image acquiring and preprocessing; Extraction of features using NasNet Large;

optimizing the features using PSO, ACO, and GTO; finally, a Two-level classification.

### C. Dataset

The dermoscopic method has improved the accuracy of skin cancer diagnosis. With the help of this invasive skin imaging technique, skin lesions can be captured and the clarity of the spots is improved. In this section, the most used dataset named HAM10000 Dataset is utilized to carry out the experimental process, in this area of research. It was investigated in the HAM10000 dataset that samples belonging to minor classes can be detected by popular CNN models.

HAM10000 Dataset: The HAM10k "Human Against Machine with 10,000 Training Images" collection is most famous publicly accessible dataset, containing 10k raw dermoscopic images primarily utilized to detect pigmented epidermis Laceration. Fig. 6 depicts several types of skin cancer. Due to the low inter-class and significant intra-class variance difficulties as shown in Fig. 7 the classification of these skin types is difficult.

The dataset was split into three sections: training, validation, and test. The training set received 70 per cent of the total samples, the validation set received 10 per cent, and the test set received the remaining 20 per cent as shown in Table IV. To provide the network enough training, the percentage of samples within the train set was maintained at a higher level. The network's performance was tracked using validation data to fine-tune the settings. Finally, the network's performance was assessed using the test data.

TABLE IV. THE HAM10000 DATASET PROPORTIONS AMONG TRAIN, VALIDATION, AND TEST [39]

Category	Train Samples	Validation Samples	Test Samples	Total Samples
Malignant	3181	454	909	4544
Benign	3830	547	1094	5471
Total	7011	1001	2003	10015

#### D. Image Enhancement

During the acquisition, coding, transmission, and processing of digital images, noise is constantly present. Noise in an image is defined as an abrupt change in pixel values. Removing noise from digital images is exceedingly difficult without prior knowledge of filtering processes. Image data filtering is a standard step in almost all image processing systems. Filters are used to accomplish this. They reduce noise from the image while retaining their characteristics. The type of data and the filter's behavior determine which filters are used. Various preprocessing filtering techniques, such as mean, median, wiener, and nonlocal means filters, are used to enhance the acquired images.

The initial step in any type of medical image processing is to perform enhancement that aims to improve the quality of the original images and make the subsequent stages of operations easier. Reflections, hair follicles, epidermis lines, air bubbles, and shadows are all common artefacts in skin photographs that affect the image segmentation stage. Intensity correction, color space transformation, artefact removal, and contrast adjustment are some of the approaches that have been introduced for image enhancement. The median filter shown in (1) is a simple way to improve the quality of photographs by eliminating artefacts.

$$y[m, n] = \text{median}(x[i, j], (i, j) \in w) \quad (1)$$

where  $w$  describes the weight of neighbors and  $[m, n]$  is the median point in the image.

Median filtering is a nonlinear method for image smoothing as shown in Fig. 9. This filter can be used to

smooth skin lesion photos and remove artefacts while maintaining the lesion boundaries. The median filter mask size should really be proportional to the main image to achieve operative smoothing. The pattern of neighbors is used as the 2D window which slides pixel by pixel over the image. They extend border values outside with values at boundary. The median of all image pixels within the window will be used to replace the central pixel. The filter's principal operation is arranging all the pixel values from the window into ascending order and replacing the considered pixel with the middle pixel value. (If the neighborhood has an even pixel count, the average of two middle pixel values is used.) The pseudocode is given below:

```

for (p1=0; p1<n; p1++)
    for (p2=0; p2<n; p2++)
        if(I[p1] < I[p2])
            {
                w=I[p1]
                I[p1] = I[p2]
                I[p2] = w
            }
    
```

Moreover, the filter that has been adopted in this work may be used to smooth pictures, softening large frequency distortions like as noise, additional lines, and hair while preserving crucial information like type, texture, configuration, color and location about the lesions. In contrast to linear filters, which maintains the original image with no edge blurring? Fig. 9 depicts the results.

#### E. NasNet Large Features Extraction

With the help of the challenging image database ImageNet [37], a deep Neural Architecture Search (NAS) [36] model has been implemented on more than a millions of images. The NasNet Large requires images with an input size of 150 by 150. The Recurrent Neural Network (RNN) in NAS generates a child network with a distinct structure. The holdout method is used to train the child networks to ensure accurateness. To improve the network's architecture, the controller is updated by combining the accuracy of the child connections. Fig 8 depicts the controller structure. The controller delivers hyper parameters as tokens for forecasting feed-forward neural networks with convolutional layers. When the layer exceeds a certain value i.e. 6 normal cells, the architecture generation process is paused. Each prediction is made by a Softmax classifier, and the outcome is fed into the next phase. During the models fine-tuning procedure, it initially discards the models the last three layers and adds a new layer depending on the count of dataset classes. Transfer learning is applied to refine the model after the fine-tuning phase. Several key parameters were selected during the training process, such as the learning rate of 0.001, epochs of 20, minimum batch size of 64, and SGD for learning. Following the fine-tuning of a network on epidermis datasets, features from the average pool layer were collected and used for subsequent process, including feature selection.

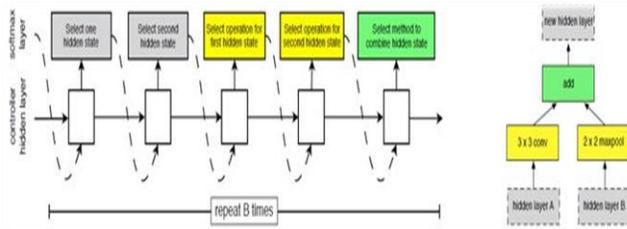

Fig. 8. Controller Architecture Model [45].

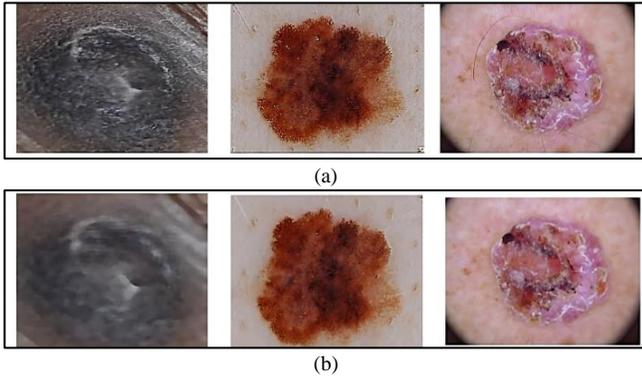

Fig. 9. (a) Original Dermoscopic Images, (b) Images after Pre-processing.

#### F. Feature Extraction using Color Space

As it is known that melanoma is typically brown, black, or tan in color, although it can also be red or pink as shown in Fig. 10. The feature extraction method focuses on obtaining information from color space. It is normalized from RGB color space using  $RGB_r$  where  $Red_r$ ,  $Green_r$ , and  $Blue_r$  are normalized color channels translated from RGB color space. The value of intensities in each pixel is represented by  $i$  and  $j$  and the dimension of skin images is stated with  $M \times N$ . There are now three color channels as shown in (2,3,4):

$$Red_r = Red_r(i, j) \quad (2)$$

$$Green_r = Red_r(i, j) - Green_r(i, j) \quad (3)$$

$$Blue_r = Red_r(i, j) - Blue_r(i, j) \quad (4)$$

Fig. 10. Appearance and Location of Melanoma.

#### G. Metaheuristic Approaches for Feature Selection

Certain metaheuristic approaches are nature-inspired and are commonly utilized in machine learning for selecting features or optimization. Numerous metaheuristic algorithms are not biologically inspired. Fong et al. [46] selected features from five datasets from the UCI repository using the

Correlation based FS, PSO and Accelerated PSO techniques. When compared to all features, Decision Tree, Naive-Bayes, SVM, and ANN classifiers have a 12.7 per cent, 1.93 per cent, 2.11 per cent, and 0.3 per cent difference in classification accuracy when just 64 per cent, 26 per cent, 26 per cent, and 64 per cent of the entire features are used. Seijas et al [47] classified the MNIST handwriting dataset with SVM Classifier using 3 metaheuristic approaches: Binary Fish School Search (BFSS), Advanced Binary Ant Colony Optimization, and Binary Particle Swarm Optimization. BFSS, ABACO, and BPSO achieve 93.36 per cent, 90.15 per cent, and 92.08 per cent classification accuracy using just 41 per cent, 22.4 per cent, and 27 per cent of the overall characteristics, respectively. Yeh and Chan [48] retrieved 277 characteristics from the MIAS database using 70 benign, 55 malignant, and 69 normal mammograms. For feature selection, they used the Genetic Algorithm (GA), ACO, SA and PSO. PSO discovered a classification accuracy of 96.9 per cent using only 189 features. Naeini et al. [49] worked on two datasets of high-resolution satellite images captured by the WorldView-2 sensors. From satellite images, a total of 173 characteristics are extracted. Particle Swarm Optimization (PSO), Genetic Algorithm (GA), Artificial-Bee-Colony (ABC), and Honey-Bee-Mating (HBM) algorithms pick Object Based Features (OBF). Their research has revealed that PSO is an inexpensive method for recognizing various entities such as trees, buildings, and roadways. Ighazran et al [50] evaluated sentiment analysis using a metaheuristic feature selection. In certain studies, multiple metaheuristic algorithms are coupled to create an advanced hybrid approach that may operate significantly better in feature selection. Arora et al [51] combined the Grey-Wolf and Crow search algorithms to create an approach. They used a total of more than 20 standard benchmark unimodal, multimodal, and fixed-dimensional multimodal mathematical functions and 21 datasets to evaluate the results of the novel hybrid approach with ten popular MH techniques for selecting of features.

1) *Contributions on this work:* The selection of the optimal features is a critical step that improves classification accuracy rate while decreasing computing time. Three metaheuristic algorithms, Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and Gorilla Troop Optimizer (GTO), are employed in this work to determine an optimum collection of features. GTO chooses an optimum feature set from among these methods to deliver the best classification accuracy of 93.58 per cent. It was discovered that color features are best for classifying skin lesions stated from section 3.4. Higher accuracy is attained in this work using less than 0.4 per cent of all the characteristics selected by the aforementioned optimizations.

#### H. Metaheuristic Algorithms

The "curse of dimensionality" refers to the challenge of using a larger collection of features, which can create noise and impede system performance. Reasons for selecting a more limited set of features quicker training, reduced difficulty of the model, and improved model precision, among other criteria like computation time, storage, etc. There are several feature selection techniques like feature ranking, feature

transformation, feature subset selection but the proposed study performs feature optimization and for this, three metaheuristic methods are used in this suggested study. These algorithms are all from the nature-inspired category. PSO, ACO and GTO are all population-based algorithms inspired by nature. To select the best technique, we used metaheuristic techniques from several types of algorithms.

1) *Particle Swarm Optimization (PSO)*: PSO emerges for an optimal outcome iteratively by conducting simultaneous searches on a population of solution candidates known as "particles" whose current particle in the search space reflects a candidate's solution [57]. PSO iteratively seeks the best outcome by travelling every particle in a manner that is a summation of the feature vector together across their individual instantaneous velocity, local best position location, and global best position location. Each particle has a social learning rate as well as an individual best-position learning rate. Every iteration, starting with a random value, the location of each particle is altered. The position of each particle is determined with the own individual best position (PBes) (as determined from the fitness function) as well as the best position of all particles in the population (GBes). Using these data, (5) and (6) are used to modify the particle's position (P) and velocity (V):

$$P(t_i + 1) = -P(t_i) + V(t_i + 1) \quad (5)$$

where

$$V(t_i + 1) = V(t_i) + a_{i1} \cdot ra_{i1} \cdot (PBes(t_i) - P(t_i)) + a_{i2} \cdot ra_{i2} \cdot (GBes(t_i) - P(t_i)) \quad (6)$$

The random number's values  $ra_{i1}$  and  $ra_{i2}$  ranges between 0 & 1 and  $a_{i1}$ ,  $a_{i2}$  are the learning rates displayed in tabular column 2. The particle's inertia value determines how much of its previous velocity is added to its current velocity. The initial inertia of the particle is its initial inertia. The change in inertia is provided by the inertia damping rate. PSO can be utilized to choose  $n_s$  features out of a maximum of  $n_T$  features. Once particles are allowed to move in  $n_T$ -dimensional space, the features corresponding to the  $n_s$  lowest components of the instantaneous position can be recognized as extracted features. It should be emphasized that the search space's axes correspond to the features, and that the selection of an axis is determined by the readings of the position vector along that axis.

2) *Ant Colony Optimization (ACO)*: To determine the shortest path from their location to the food supply and the vice versa, ants search using a metaheuristic algorithm called ACO [55] [56]. An ant will leave a trail of a specific chemical pheromone on its way of travel when it leaves its nest in search of food. The strength of the pheromone trail left by an ant's predecessor can also be determined. The term "stigmergy" refers to an indirect communication technique that chooses the quickest route from the nest location to the food location. Each way has a starting pheromone deposit level and pheromone evaporation rate. ACO can be employed to choose a series of vertices from a plot where the contours

are adaptively balanced by a property called pheromone strength. This property makes sure that an edge that is traversed more often is given more weight. A sequence is produced by the ant's movement. An ant  $i$  will select node  $j$  at a node with a probability proportional to the strength of the pheromone along the path  $i-j$  as shown in (7):

$$p_{ij} = \frac{\tau_{ij}^\alpha}{\sum_j \tau_{ij}^\alpha} \quad (7)$$

where,  $T_{ij}$  = pheromone level of a contour  $i, j$  and  $\alpha$  is a constant known as ant pheromone exponential weight. The pheromone updates with (8)

$$T_{ij} = (1 - \rho) T_{ij} + \Delta T_{ij} \quad (8)$$

where,  $\rho$  = evaporation rate &  $\Delta T_{ij}$  = deposition in the edge is illustrated in (9):

$$\Delta T_{ij} = \sum_k \frac{1}{L_k} \quad (9)$$

Here  $L_k$  signifies the value of the  $k$ th path that moves along the edges  $i, j$ . From a total of  $n_T$  features,  $n_s$  features are chosen using ACO. Also every features can be thought of as a node in a plot, with initial  $n_s$  nodes of the ACO series identifying the selected feature. The final set of features chosen is the one with the lowest cost (error of classification) shown in Fig. 12.

3) *Gorilla Troop Optimizer (GTO)*: The GTO is simple to operate and has a limited number of parameters that must be configured. There are three phases for exploration and two for exploitation. Compared to cutting-edge algorithms, GTO's key benefit is that it quickly discovers the best answer. Gorillas are symbolized as X in this algorithm, while silverbacks were being symbolized as GX.

a) *Exploration Phase*: The exploration stage is primarily used to conduct a global search of space. In GTO [41], every member can be a solution, and at each step of the optimization process, the best solution can be named the silverback gorilla. The following strategies were employed:

- 1) Transitioning to an anonymized region which searches the entire sample space.
- 2) Reducing the search area in order to strike a balance among both exploitation and exploration.
- 3) Ultimately, growing the GTO's capability to examine the region by moving forward towards a known region.

It is numerically expressed in (10,11,12,13,14,15) as:

$$GX(t+1)_i = \begin{cases} (tp - bp) \times r_1 + bp, & r < p, \\ (r_2 - C) \times X_r(t) + L_g \times H, & r \geq 0.5, \\ X(t) - L_g \times (L_g \times (X(t) - GX_r(t)) + r_3 \times (X(t) - GX_r(t))), & r < 0.5. \end{cases} \quad (10)$$

$$C = F_i \times \left(1 - \frac{t}{Max_t}\right) \quad (11)$$

$$F_i = \cos(2 \times r_4) + 1 \quad (12)$$

$$L_g = C \times 1 \quad (13)$$

$$H = Z_g \times X(t) \quad (14)$$

$$Z_g = [-C, C] \quad (15)$$

where  $tp$  = top position

$bp$  =bottom position of the variable,

$X(t)$  = present position of gorilla

$GX_r$  = Single gorilla group of a particular region

$GX(t_i + 1)$  = the candidate level of gorilla in the t+1 iteration.

$p$  = Migration parameters oscillates [0,1]

$r_1, r_2, r_3, r_4, rand, l$  = random values ranging from [0,1]

$X_r$  = Single candidate gorilla

$t_i$  = Current Iteration

$Max_t$  = Total number of Iterations

$L_g$  = used to calculate silverback gorilla

$Z_g$  = Random number ranging from [-C, C]

The fitness value of each GX solution was determined by the algorithm in the conclusion from the exploration phase, and if  $GX(t_i) < X(t)$ , the  $X(t)$  solution is swapped out for the  $GX(t_i)$  solution.

*b) Exploitation Phase:* Two approaches are employed at this point. First is Continue to track the silverback and second is compete for adult female gorillas. The approaches are chosen based on a comparison between  $C$  ((11)) and  $W$ . (initial values).

Stage 1: If  $C \geq W$ , the silverback gorilla will choose the below (16,17) for survival.

$$GX(t_i + 1) = L_g \times M \times (X(t) - X_{silverback}) + X(t) \quad (16)$$

$$M = \left( \left| \left( \frac{1}{N} \right) \sum_{i=1}^N GX_i(t) \right|^g \right)^{(1/g)}, \quad g = 2^l, \quad (17)$$

where,  $X(t)$  = gorilla position

$X_{silverback}$  = Silverback gorilla position

$GX(t_i)$  = Candidate solution at iteration  $t$

$N$  = Number of gorillas

Stage 2: If  $C < W$ , compute the (18, 19, 20, 21) i.e., competing for female mating.

$$GX(t_i) = X_{silverback} - (X_{silverback} \times Q - X(t) \times Q) \times A \quad (18)$$

$$\text{Where, } Q = 2 \times r_5 - 1 \quad (19)$$

$$A = \beta \times E, \quad (20)$$

$$E = \{N_1 rand \geq 0.5 \quad N_2 frand < 0.5\} \quad (21)$$

$r_5$  = random value [0,1]

The amount of variables generated by the GTO algorithm equals the amount of features in the dataset. All variables have a range of [0, 1] with 1 representing that the applicable

attribute is a classification selection candidate. The algorithm then computes every gorilla's fitness as shown in (22).

$$Fitness_i = \alpha \times (1 - C_i) + (1 - \alpha) \times \frac{|BX_i|}{D} \quad (22)$$

$$BX_{ij} = 1 \text{ if } X_{ij} > 0.50$$

where  $X_{ij}$  is the dimension value for search agent  $i$  at dimension  $j$  and  $\alpha$  falls within the [0,1] range, and  $C_i$  stands for the measured accuracy.  $D$  is the dimension of the input train dataset. The finest solution will be the one with the lowest fitness value. Following that, the agents will be modified utilizing the GTO algorithm stages. The updating stage was repeated until the terminal state was reached. Finally, the GTO method produces the optimal solution that includes the feature set, which is then utilized as the following step in reducing the testing dataset by deleting non-relevant characteristics. The objective value of  $GX$  is assessed at the conclusion of the exploitation stage, and if it is less than  $X(t)$ ,  $GX(t_i)$  replaces  $X(t)$  as the best solution (silverback). The accuracy is shown in Fig. 10. The resultant features are finally classified using a two-level classifier.

The parameters for these approaches are the same as those described in Table V.

TABLE V. DIFFERENT METAHEURISTIC ALGORITHM PARAMETERS

Algorithms	Parameters Settings	Values
General Settings	Population Size(N) Max num of Iterations (M) Considered Strategy	20 50(Max) Features
PSO	Acceleration Coefficients ( $C_1$ ) ( $C_2$ ) Inertia Weight (W) Num of Iterations	[0.5:2.5] [0.5:2.5] [0.2:0.9] 30
GTO	Beta( $\beta$ ) w p	3 0.8 0.03
ACO	Starting Ant Pheromone Pheromone-exponential-wt Ant Pheromone evaporation Num of Iterations Population Size(number of Ant)	1 1 0.05 30 5

### I. Two-Level Classification

For more accurate results, the final characteristics are classified using two-level classification. Given an image  $I = \{I_i\}_{i=1}^N$ , where  $I_i \in [0, 255]^3$  corresponds to one of the seven types of lesion types, the deep neural model performs a series of operations to determine the type of an image  $I \in \{1, \dots, 7\}$ . A function can be used to express these operations as shown in (23).

$$F(I, W_m) = \underset{M}{\operatorname{argmax}} y_M \quad (23)$$

where  $W_m$  is the specifications of the train neural model &  $y_m$  are the type probabilities generated by the model.

The presence of unbalanced classes in the dataset is one of the issues that arise during the training stage of any classification model. To assess and handle these scenarios, duo distinct prediction approaches for the deep learning models are proposed:

1) *Single level classifier*: Transfer learning is used to tune the weights of a neural model. This method assigns the input image to one of the two categories. In this case, the impact of unbalanced classes can be significant, necessitating the use of a preprocessing stage to optimize performance. The single level classifier's operation is as follows in (24):

$$F^P(I, W^P) = \operatorname{argmax} y_M, M \in \{1,2\} \quad (24)$$

where  $W^P$  indicates the specifications of the refined network for the two categories of epidermis lesions.

2) *Two-level classifier*: Two neural models are combined in this technique to create a two-level classifier. While the second level categorizes the other multiple classes, the first level has been trained to differentiate between the malignant melanoma class and the others. as shown in (25,26):

$$F_{c_1}(I, W_{c_1}) = \operatorname{argmax} \{y, y'\} \quad (25)$$

$$F_{c_2}(I, W_{c_2}) = \operatorname{argmax} y_M, M \in \{2, \dots, 7\} \quad (26)$$

where the refined model for two and six subclasses, respectively, is represented by  $W_{c_1}$ . The initial neuron model is transformed into a specialized model that serves as a classification model for the malignant melanoma class, which includes the binary classification on the dataset's images. Only if  $F_{c_1}(I, W_{c_1})$  fails to produce the melanoma class is the second classifier used.

## V. RESULTS AND DISCUSSIONS

This section compares the proposed optimization method to other metaheuristic feature selection algorithms in order to assess its effectiveness in identifying the best subset of features, such as the original PSO from Fig. 11, ACO from Fig. 12 and GTO shown from Fig. 13. All of these techniques are used on the HAM10000 dataset.

### A. Experiments Configuration

It is described how the experiments were set up for this study in Table VI:

TABLE VI. CONFIGURATION DETAILS

Configurations	Specification
Input Image Size	(150x150x3)
MHFS Optimizers	PSO, ACO, GTO
Dataset Split ratio	70-10-20(Tr-V-Ts)
Population Size	30
Epochs Count	50(Max)
Activation Function	Softmax
Pretrained Model	ResNet, Inception, VGG16
Losses Range	Categorical Crossentropy
Parameters optimizer Range	RMSprop, Adam, SGD
Dropout Count	[0:0.6]
Batch Size Range	[4:30]
Technologies	Tensorflow, Keras, Numpy, OpenCV, Matplotlib
Scripting Language	Python
Work Environment	Google Colab with GPU

### B. Performance Evaluation

The performance of proposed model was analyzed with the standard classification measures: Accuracy, Precision, Recall (28) and F-measure. It is well known that recall equals the ratio of relevant instances retrieved over the total number of relevant examples, precision equals the proportion of relevant instances among the retrieved instances, and accuracy equals the proportion of genuine detentions from (27, 29). By considering both precision and recall, the F-measure from (30) offers a good overall evaluation of the effectiveness of a particular approach. All metrics are ranked from [0 to 1], with 1 being the best. Below Table VII shows original deep features, Table VIII describes features from PSO, Table IX describes features from ACO, and Table X describes features from GTO extracted from metaheuristic algorithms.

Each metric is formulated as follows:

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+FN+TN} \quad (27)$$

$$\text{Recall (Sensitivity)} = \frac{TP}{TP+FN} \quad (28)$$

$$\text{Precision} = \frac{TP}{TP+FP} \quad (29)$$

$$\text{F-Measure} = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \quad (30)$$

This work yielded the following results for the suggested framework:

TABLE VII. CLASSIFICATION ACCURACY USING ORIGINALLY EXTRACTED FEATURES FOR HAM10000

Classifier	Accuracy	Recall	Precision	F-Measure
Single-Level	0.85	0.82	0.86	0.84
Two-Level	0.83	0.81	0.89	0.85

The result analysis using various metaheuristic techniques is depicted below.

TABLE VIII. CLASSIFICATION ACCURACY BASED ON PSO SELECTED FEATURES APPROACH

Classifier	Accuracy	Recall	Precision	F-Measure
Single-Level	0.85	0.83	0.87	0.8
Two-Level	0.93	0.85	0.89	0.87

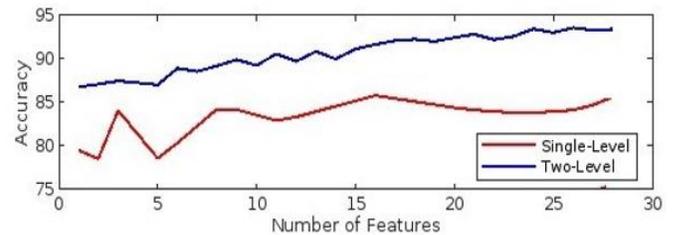

Fig. 11. PSO Selected Features vs. Accuracy.

TABLE IX. CLASSIFICATION ACCURACY BASED ON ACO SELECTED FEATURES APPROACH

Classifier	Accuracy	Recall	Precision	F-Measure
Single-Level	0.76	0.74	0.80	0.77
Two-Level	0.84	0.80	0.90	0.84

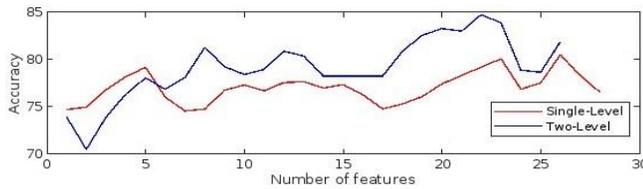

Fig. 12. ACO Selected Features vs. Accuracy.

TABLE X. CLASSIFICATION ACCURACY BASED ON GTO SELECTED FEATURES APPROACH

Classifier	Accuracy	Recall	Precision	F-Measure
Single-Level	0.89	0.84	0.90	0.87
Two-Level	0.93	0.83	0.89	0.86

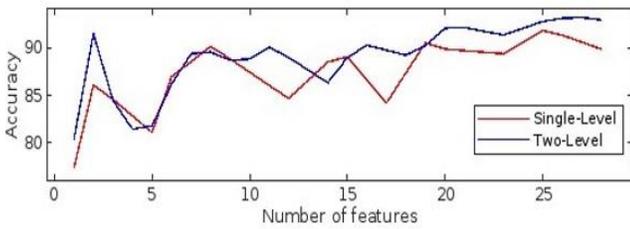

Fig. 13. GTO Selected Features vs. Accuracy.

1) *Result comparison:* The comparative assessment among various similar works using the HAM10000 dataset is shown in Table XI and Fig. 14. In comparison to other related works, the proposed work performs significantly better in terms of classification accuracy with the fewest features.

TABLE XI. COMPARISON ANALYSIS WITH OTHER STATE-OF-ART METHODS USING HAM10000 DATASET

Paper Id	Methodology	Accuracy %
[38]	PCA	89.8
[39]	Bayesian deep learning	83.59
[40]	Transfer learning	85.0
[41]	CNN	80.0
[42]	Application based CNN	78.0
[43]	MobileNet	83.2
[44]	ResNet50+InceptionV3	89.9
Proposed Work	NasNet Large	93.58

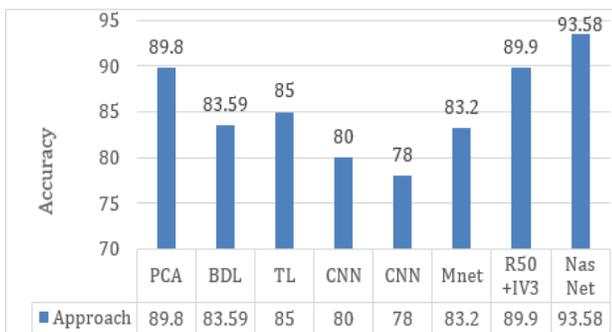

Fig. 14. Comparison of Various Deep Learning Approaches of Accuracy on HAM10000 Dataset.

## VI. CONCLUSION

The rising cost of epidermis cancer therapy throws life tough for survivors and their families. Early identification of melanoma skin cancer is critical to curing the condition. In this paper, we proposed two approaches based on domain adaptation for computer-aided diagnosis of skin cancers. We attempted to categorize the other five forms of skin illnesses in addition to the typical non-melanoma and melanoma groups. The NAS strategy and the tools offered were designed to help optimize the model and, as a result, improve research findings. Using the HAM10000 dataset, two alternative recommended models were used: a single level and a two level, the first of which clears in distinguishing between melanoma and non-melanoma images and the second with classifying benign lesions. In this study, the GTO algorithm for selecting features outperforms the PSO and ACO feature selection algorithms. The goal of this study was to provide a feature selection (FS) strategy by increasing the performance of the Gorilla Troops Optimizer (GTO). GTO feature selection algorithm selects set of optimized feature to provide deliver classification accuracy of 89.89 and 93.58. The limitation of the proposed model was computational time. Though the NasNet itself takes time to generate the desired model, feature optimization is additionally added. The aim was met due to finite computational resources within a reasonable period which is a desirable in the field of medical imaging. It is not possible to declare that the most ideal architecture was discovered, but the best-known architecture was attained.

**Funding Statement:** The authors received no specific funding for this study.

**Conflict of Interest:** The authors declare that they have no conflicts of interest.

**Availability of data and material (data transparency):** The data are publicly available at <https://challenge.isic-archive.com/data/>

Technology, MITWPU, Pune, India

**Abstract**—Emotions play an essential role in human life for planning and decision making. Emotion identification and recognition is a widely explored field in the area of artificial intelligence and affective computing as a means of empathizing with humans and thereby improving human machine interaction. Though audio visual cues are vital for recognizing human emotions, they are sometimes insufficient in identifying emotions of people who are good at hiding emotions or people suffering from Alexithymia. Considering other dimensions like Electroencephalogram (EEG) or text, along with audio visual cues can aid in improving the results in such situations. Taking advantage of the complementarity of multiple modalities normally helps capture emotions more accurately compared to single modality. However, to achieve precise and accurate results, correct fusion of these multimodal signals is solicited. This study provides a detailed review of different multimodal fusion techniques that can be used for emotion recognition. This paper proposes in-depth study of feature-level fusion, decision-level fusion and hybrid fusion techniques for identifying human emotions based on multimodal inputs and compare the results. The study concentrates on three different modalities i.e., facial images, audio and text for experimentation; at least one of which differs in temporal characteristics. The result suggests that hybrid fusion works best in combining multiple modalities which differ in time synchronicity.

**Keywords**—Feature-level fusion; decision-level fusion; hybrid fusion; artificial intelligence; EEG

## I. INTRODUCTION

Recently, emotion recognition has been explored extensively in the areas of artificial intelligence, affective computing and human computer interaction. Emotion is a psychological events generated by a person's tendency toward need, which can be broadly classified into Physiological arousal and subjective experience [1, 2]. Physiological arousal refers to the physiological responses of the human body, which can be measured by electrical signals like electrocardiogram (ECG) and electroencephalogram (EEG), whereas subjective experience is a phenomenon, which relates to individual's feelings about different emotional states. It is expressed through facial expression, audio, gestures, etc. [1, 3, 4].

Audio visual features are generally treated as vital cues for emotion recognition, but they are prone to deception, if performed deliberately. Physiological signals, on the other hand, cannot be deceived easily as they are based on internal physiological responses. Combining physiological responses

with subjective experiences leads to more accurate emotion recognition.

Although emotion recognition can be achieved through a uni-modal approach, it may not work well for certain conditions of subjective experience where the people are excellent at hiding their emotions or the input data is very noisy. Also cross culture approaches for expressiveness act as barriers to identifying emotions correctly. Multimodal approach, on the contrary, can achieve significant accuracy by combining inputs from multiple modalities [5]. However, to get precise and accurate results, correct fusion of these multimodal signals is required.

A major concern for fusing multiple modalities is deciding the level at which multimodal fusion should occur and how to achieve the fusion [6, 7]. Since different modalities differ significantly in temporal characteristics, synchronization among them plays an important role in multimodal fusion [7]. Multimodal fusion techniques are broadly classified into decision-level fusion, feature-level fusion and hybrid fusion. Decision-level fusion and feature-level fusion are the most regularly used techniques for multimodal fusion in emotion recognition.

The existing literature on review of fusing multiple modalities is either based on signals which are synchronous in time or same type of signals (e.g. Fusion of different 2D images). B. Huang et al. proposed a review of medical image fusion techniques for Computed Tomography Scan (CT), Magnetic Resonance Imaging (MRI), Positron Emission Tomography (PET) and Single-photon Emission Computed Tomography (SPECT) images which describes spatial domain fusion and transform domain fusion [8]. Chen Xiao Yu et al. published a trend of machine learning based on fusion which focused on Ensemble Learning, Transfer Learning and Federated Learning for technology and data fusion [9].

This paper reviews different multimodal fusion techniques for decision level, feature level and hybrid fusion which can be used for human emotion recognition. The study also provides comparative analysis of these techniques. The proposed work focuses on the modalities which are synchronous as well as asynchronous in time to achieve emotion recognition. For experimentation, inputs from multiple modalities like facial images, audio and text are considered.

The paper is organized as follows: Section II describes decision-level fusion and the various techniques used to

achieve it for emotion recognition. Section III is devoted to discussing feature-level fusion and the various techniques used for achieving feature-level fusion. In Section IV, Hybrid approach for multimodal fusion is discussed in detail. Section V provides experimental analysis of different fusion methods. Section VI focuses on the discussion on analyzing and comparing different fusion methods. Section VII concludes the paper.

## II. DECISION-LEVEL MULTIMODAL FUSION

Since emotion recognition works with multiple modalities, which differ from each other in various aspects, at times it becomes challenging to extract features from different and coupled modalities. Also, changes in the time synchrony of different modalities affect the dimensions which are used for emotion recognition [10]. To deal with this issue, decision-level multimodal fusion takes each modality independently for classification.

Decision-Level fusion technique first classifies the data of each modality individually and the result is combined at a later stage to achieve fusion. This fusion technique is also called late fusion as combining results occurs at a very late stage after classification. Fig. 1 shows a general framework of decision-level multimodal fusion considering audio, visual, text and EEG input for emotion recognition.

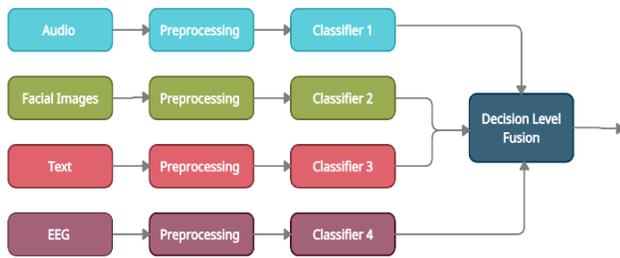

Fig. 1. General Framework of Decision-Level Fusion for Emotion Recognition.

There are various techniques of decision-level fusion that have been experimented with by researchers. This section presents each of these techniques.

### A. Support Vector Regression

Support vector regression (SVR) works on the principles of the support vector machine (SVM). The ideology behind SVR is to find the best fit line suitable for the problem at hand. The best fit line in SVR is the hyperplane that contains the maximum number of points. It uses a margin of tolerance in approximation to the SVM. SVR maps to high dimensionality to estimate a function while offering nonlinear complexity [11].

In many studies, researchers have used SVR with the RBF kernel for decision-level fusion of emotion recognition [10, 12]. Haiyang Su et al. used bidirectional long short-term memory for classifying emotions individually from audio, facial images and text along with RBF kernel SVR to achieve significant improvement in classification accuracy [10]. Mihalis A. Nicolaou et al. compared the performance of bidirectional LSTM-NN and SVR on audio, facial expression and shoulder features for predicting spontaneous effect [13].

SVR can compensate for redundant information, which makes SVR suitable for decision-level fusion required for emotion recognition but it does not perform well when the number of feature extracted are more than training samples.

### B. Blending Algorithms

Blending algorithm is a technique of ensemble machine learning that uses a metaclassifier to combine the outputs of different machine learning models.

A blending algorithm works in two layers. The first layer uses a traditional approach for training, where multiple basic classifiers are trained on the inputs from different modalities. The second layer is used for combining the outputs of the basic classifiers used in level 1. The outputs of each classifier are combined to form a new training set, which acts as an input to a higher level classifier called metaclassifier. The metaclassifier can use the ensemble learning techniques of bagging, boosting and stacking for combining the results based on the weight, bias and variances of base classifiers [14]. The role of level 1 basic classifiers is to classify the multimodal data, whereas the level 2 classifier is responsible for combining the outputs of base classifiers. Blending algorithms are found to have a better performance in the prediction.

Man Hao et al. used Convolution Neural network and support vector machine as base classifiers for speech and facial images along with the blending algorithm of metaclassifier to achieve multimodal emotion recognition and achieved 81.36% accuracy [14]. Lee et al. used ensemble learning on multimodal acoustic, lexical and discourse features using three classifiers to find negative emotions in spoken dialog [15]. Blending algorithm can be used as a decision-level fusion technique for emotion recognition owing to its improved performance for multimodal inputs. Blending algorithm is stable and less noisy.

### C. Brain Emotion Learning Models

The brain emotional learning (BEL) system takes inspiration from the biological amygdala-orbitofrontal model to emulate the high speed of the emotional learning mechanism used by the human brain [16]. The BEL model comprises four main components. Amygdala, Orbitofrontal cortex (OFC), the Thalamus and Sensory cortex. After receiving input signals in the form of emotional stimuli from the Sensory cortex & Thalamus and a reward signals from the external environment, amygdala interacts with the OFC. The OFC evaluates the response of the amygdala based on the input received from the Sensory cortex, which leads to the prevention of improper learning connections. In a nutshell, the Sensory cortex integrates the features extracted from different unimodal inputs and the amygdala and OFC works to form a decision after interacting with the memory [17, 18].

BEL models require rewards extracted from input data and are derived from monotonic reinforcement learning. BEL-based networks are efficient in predicting peak points [19]. This method can be used as a stacking ensemble method in multimodal decision fusion techniques [17]. Zeinab Farhoudi et al. used BEL as a decision-level fusion technique for multimodal audio visual features to achieve a significant

accuracy of 73.9% for emotion recognition [17]. BEL model has good decision-making capability due to its cognitive-based structure. Due to this, Brain Emotional Learning can be used at decision-level fusion for multimodal emotion recognition.

#### D. Decision Tree based Approach

A decision tree is a non-parametric supervised learning method whose internal nodes represent test and leaf nodes represent classes. Filtering is applied through the nodes to achieve the required output. A decision tree tries learning decision rules from the given input data features.

Yucel Cimtay et al. used a decision tree for fusing multimodal inputs from facial expressions, galvanic skin response (GSR) and electroencephalogram (EEG) to detect emotions where the authors emphasized more on the probability vector received from facial images-based classifier. The condition of the decision tree was set to check whether this probability vector goes below a certain threshold. The research proposes using other modalities only if the specified conditions hold true [20].

Heysem Kaya et al. used a random forest decision tree based model on audio, facial and scenic inputs extracted from videos CVs to achieve decision fusion to estimate a suitable interview variable [21].

Decision trees are suitable for decision-level fusion because of their capability of learning rules according to the requirement. The predictions made by each classifier used for unimodal inputs can be combined based on the specific conditions provided at each node by using decision trees. But, decision trees are unstable data structures and they are prone to inaccuracy.

#### E. Rule based Approach

Rule-based classifiers are types of classifiers that make the class decision using various “if-else” rules. These classifiers are used to generate a descriptive model as the rules are easily interpretable. The “if” condition is called the antecedent and the predicted class is called the consequent in rule-based classification.

Subhasmita Sahoo and A. Routray has used a rule-based approach for emotion recognition using multimodal audio and video inputs. The rules were set to give high priority to the result of the facial image classifier and low priority to the audio classifier. The results of the audio classifier were acceptable only if there was confusion in the results of the image based classifier [22].

Rule-based classification is a way to achieve decision-level fusion as they have the advantage of fuse the multimodal signal classifier’s output as per the conditions specified in the antecedent.

#### F. Dempster-Shafer Theory

The Dempster-Shafer (D-S) theory of evidence originated by Dempster [23], and formalized mathematically by Shafer [24]. D-S theory was developed as reasoning and modeling framework with epistemological uncertainty. This framework can be used to integrate multiple sources of evidence and to

agree to a combined degree of belief for different predictions. Compared to the Bayesian model, the D-S theory is an extensive approach to address uncertainty and imprecision [25]. Due to its ability to efficiently handle the uncertainty and inconsistency of multimodal data, D-S theory is widely used in data fusion, fault detection and pattern recognition [26].

The D-S theory is drawn on the concepts of allocating suitable beliefs and probabilities to hypotheses, applying the D-S rule for fusing independent inputs from different sources and arriving at the final decision of the optimal hypothesis in a workable and reasonable manner [25]. Decision-Level fusion make use D-S evidence theory to combine the outputs of each classifier used for multimodal inputs.

Xiao-Dan Zhang used D-S theory for fusing multi-modal text and image inputs after applying KNN and SVM classifiers individually on unimodal input to improve the classification results [27]. Nazmuzzaman Khan et al. claimed that D-S theory has limitations in terms of handling conflicting data. Therefore, they used an improved version of D-S theory using a distance function and evidence-weighted penalty for combining results of different sensors to achieve improved object detection [26]. S. Nemati used D-S theory for decision-level fusion in her approach of hybrid fusion for emotion recognition. The author had applied D-S theory on audio, video and textual multimodal inputs to achieve improved emotion recognition [28]. Yu-Ting Liu et al. used Weighted Fuzzy Dempster-Shafer Framework that can adjust weights of evidence, which is inconsistent for integrating the outputs of EEG and eye movement’s classifiers [25].

#### G. Decision Template Algorithm

The decision template (DT) algorithm is a simple and efficient fusion algorithm, which uses the average of decision profiles of each classifier used for training multimodal data inputs. These averages are treated as decision templates for each class. Assessing the resemblance between the decision profile and different decision templates helps provide accurate class prediction. Though the algorithm is used widely for decision fusion, it has limitations as it uses average decision profiles and does not emphasize differences in the performance of classifiers [29]. Reza Ebrahimpour et al. used a decision template algorithm for decision-level fusion of different classifiers for handwritten digit recognition [30]. Due to the limitations of the decision template algorithm, Aizhong Mi et al. proposed an improved weighted decision template algorithm that calculates the classifier’s performance using a statistical vector and allocates appropriate weights to each classifier according to the reliability of their outputs. The authors applied this improved approach to the cataract recognition system and received improved results compared to the decision template algorithm [29].

### III. FEATURE-LEVEL MULTIMODAL FUSION

Feature-level fusion is a technique, which combines the features from different layers or branches. When applied to multimodal inputs, the feature-level fusion method combines the features extracted from each modality individually using different feature fusion techniques before giving it to a classifier for classification. It is considered a ubiquitous part

of several modern network architectures. Generally, feature-level fusion is implemented using the concatenation operation, but that might not be the best choice for achieving good results.

Fig. 2 depicts a general framework for feature-level multimodal fusion considering four different modalities like facial images, audio, text and EEG for emotion recognition.

Feature-level fusion works with the idea of extracting the most discriminating features from the extracted features and removing redundant information [31, 32]. It works with the conjecture of strict time synchronicity between different modalities and performs distinctively in cases where the modalities differ considerably in temporal characteristics [31, 33]. Fusion at the feature level works best for closely connected and synchronized modalities [31].

If feature-level fusion has to be used for multimodal approaches where individual modalities differ in time synchrony, the relationship between the different feature spaces needs to be explored and the features need to be made compatible [31].

Various techniques for feature-level fusion have been explored by the researchers. This section presents those techniques in detail.

#### A. Eigen Matrix for Fusion

The German word Eigen means characteristics. The terms Eigenvalues and Eigenvectors in computation deal with determining the characteristics of a matrix. Eigenvalues and eigenvectors are used in various applications, which include Principal Component Analysis, Spectral Clustering, and detection techniques in Computer Vision, etc. Some researchers found its use in feature-level fusion of multimodal inputs, where the individual features are extracted from each modality and serialized to form an Eigen matrix. This Eigen matrix is then normalized to get the fusion Eigen matrix [30]. The formula for Eigen matrix (E) calculation is specified in equation (1).

$$E_j^{(i)} = \frac{(e_j^{(i)} - \mu_j)}{\max e_j^{(i)} - \min e_j^{(i)}} \quad (1)$$

Where  $e_j^{(i)}$  represents the  $j^{\text{th}}$  eigenvalue of  $i$  samples,  $\mu_j$  represents the mean value of the  $j^{\text{th}}$  feature, and the denominator represents the range of  $j$  features.

Jian Che et al. used an Eigen matrix for multimodal feature fusion of longitudinal tear detection of a conveyor belt where the input modalities were images and sound [34]. The authors claimed to have improved accuracy due to multimodal fusion. However, the Eigen matrix technique for feature-level fusion relies on the mean and eigenvalues of each modality to achieve fusion. Therefore, this technique may not be able to use the entire range of diversity for each modality.

#### B. Canonical Correlation Analysis

Canonical Correlation Analysis (CCA) is a method for analyzing the relationship between two multivariate sets of vectors [28, 35]. CCA is considered as an effective tool in analysis that has an ability to increase statistical power compared to univariate methods due to the use of second-order statistics [28].

CCA has an application in multimodal fusion [35]. It worked to find sets of changed variables having the maximum correlation between the two modalities [28]. CCA, when used for multimodal inputs, take linear combinations of  $X1W1$  and  $X1W1$  that maximizes the pairwise correlations of two multimodal datasets where  $X1$  &  $X2$  are two multimodal datasets and  $W1$  &  $W2$  are canonical coefficient vectors [28].

Shahla Nemati used CCA for feature-level fusion to detect multimodal emotion recognition using audio and visual modalities [28]. The features of individual modalities are first extracted using different feature extraction methods before giving it to CCA for feature-level fusion.

CCA as a method for feature-level fusion uses the concept of maximizing the pairwise correlation between the two modalities. Therefore, applying CCA on more than two modalities will require fusion at multiple levels.

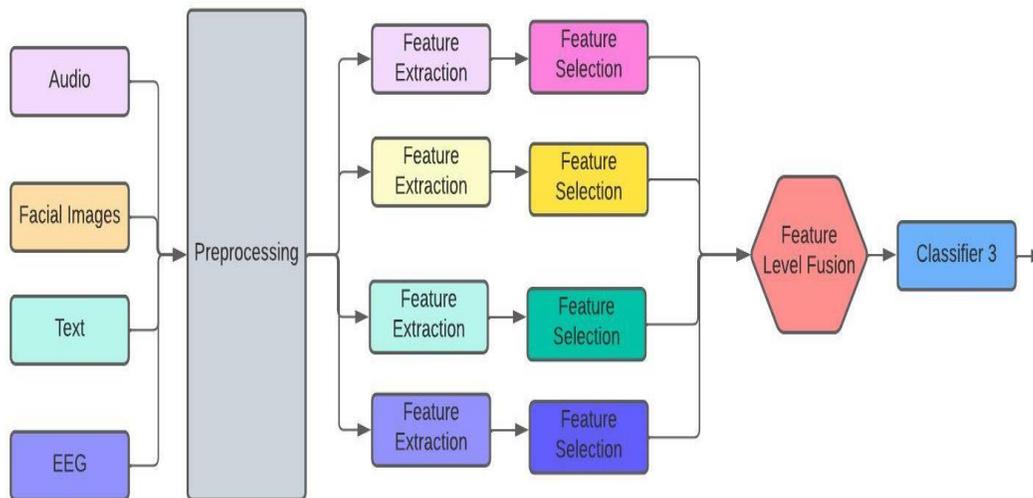

Fig. 2. General Framework for Feature-Level Fusion for Emotion Recognition.

### C. Mixture of Brain Emotional Learning Model

The mixture of brain emotional learning models (MoBEL) combines the features of Mixture of Experts neural network (MoE) and Brain Emotional Learning (BEL) model. The BEL model has a good capability of decision-making due to its cognitive-based structure and the MoE model is based on working of the associative cortex of the brain, which has the capacity to integrate information from multiple sources [17, 18]. The presence of the associative cortex improves the brain's capacity of perception of the environment [36]. Therefore, MoE has the capacity to perform better in pattern recognition.

The MoBEL model structure uses the BEL model for expert and gating networks and trains all parts of the network jointly using back-propagation. MoBEL can be used as a fusion network to integrate multimodal features. The MoBEL model is more efficient in terms of processing speed, memory consumption, and neuron numbers than the MOE [17].

Zeinab Farhoudi et al. used MoBEL as a feature-level fusion technique for multimodal audio visual features to achieve a significant accuracy of 81.7% for emotion recognition [17].

### D. Merging Features at Hidden Layer

This strategy works with the approach of inserting features of different time durations into different hidden layers of a training network [35]. This technique, though unexplored much, can tackle the problem arising due to asynchronous multimodal features. It also helps resolve the time compatibility issues of different multimodal features.

Given a network having multiple hidden layers and multimodal inputs with different time durations, short - duration features like audio are given as input to the first hidden layer. The output of the first hidden layer is combined with longer time features like visual features and given as input to the second hidden layer. The output of the second layer is then combined with longer duration features from the remaining modalities and given as the input to the third hidden layer. The process is repeated until the features are provided to the network [35].

Shizhe Chen et al. considered this approach for feature-level fusion in emotion recognition using three modalities: audio, images and EEG, wherein the authors used RNN-LSTM network for recognizing and fusing the features [35].

Though this approach can tackle the problems of asynchronous multimodal features, it depends upon the network used for training. Also, for modalities having similar duration, deciding the hidden layer at which these features need to be fused becomes an issue.

### E. Concatenation

Concatenation generally uses consolidated dimensions to achieve fusion [37]. The concatenation formula is shown in equation 2.

$$Y = x_1 \cup x_2 \cup x_3 \dots \dots \cup x_k \quad (2)$$

where  $x_k$  is a set of output feature maps for the  $k^{\text{th}}$  layer and  $Y$  represents the fusion of all features.

The main goal of concatenation is to enrich the diversity of features for better recognition ability [36]. Sanghyun lee et al. used a concatenation method in a process of multimodal feature fusion for emotion recognition based on audio, visual and textual features for emotion recognition.

Schoneveld et al. used a concatenation method for multimodal feature-level fusion for emotion recognition based on audio visual modalities [38]. The authors also claimed to have improved fusion accuracy by adding hadamard product to concatenation in attention-based approach for emotion recognition [39].

It is the most popular method for feature-level fusion. But it might not be the best choice for multimodal inputs that differ in dimensions.

## IV. HYBRID MULTIMODAL FUSION

Feature-level fusion methods require synchronization between different modalities, but it is possible to produce results even when the data from one of the modality is missing. Decision-level fusion, on the other hand, does not require synchrony between different modalities, but its capabilities cannot be exploited fully even if the data from a single modality is missing.

The hybrid fusion method tries achieving the advantages of both feature level and decision-level fusion methods by combining these approaches. The hybrid fusion approach applies feature-level fusion on some synchronous modalities and combines the result of with the remaining asynchronous modalities using decision-level fusion.

The hybrid approach works well for multimodal inputs, where some inputs assume time synchrony and some others are asynchronous in time. Fig. 3 shows the general framework of hybrid multimodal fusion for emotion recognition fusion considering four different modalities like facial images, audio, text and EEG.

Shahla Nemati used a hybrid approach for multimodal emotion recognition based on three modalities viz. audio, visual, and users' comments. The author used feature-level fusion for audio and visual features since they were synchronized. The result is then fed to a classifier for classification. A separate classifier was used for user comments because of its asynchronous nature. In the next step, decision-level fusion was used to fuse the outputs of both classifiers [28].

Zhen-zhong Lan et al. used a hybrid model for multimedia event detection based on visual, audio and textual data. The authors used five classifiers for training based on five features and feature combinations, where feature fusion was performed to combine features and the result of each classifier was combined using decision-level fusion [40].

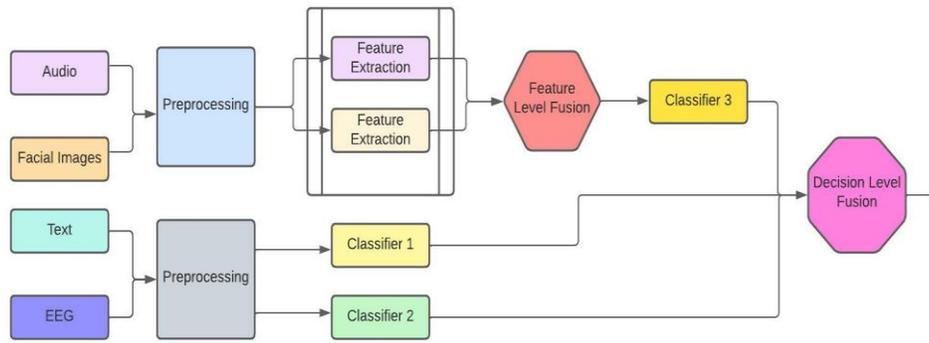

Fig. 3. General Framework for Hybrid Fusion to Emotion Recognition.

Fig. 4 depicts graphical representation of summary of different fusion methods described in review of literature.

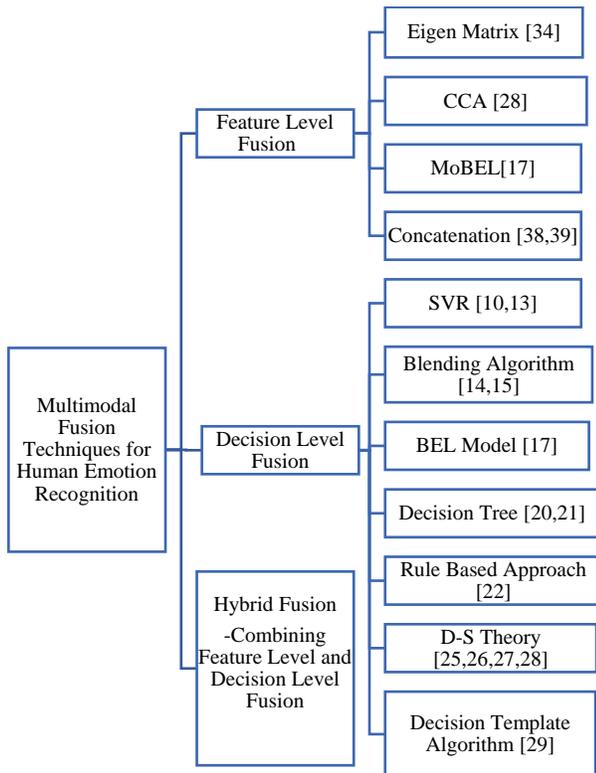

Fig. 4. Summary Diagram of Review of Literature Describing Various Fusion Methods.

### V. EXPERIMENTAL ANALYSIS

To analyze the effectiveness of decision level, feature level and hybrid fusion methods in emotion recognition, we focused on facial expression, audio and text as multimodal inputs. We have used RAVDESS dataset [41] for audio data, FER 2013 dataset curated by Pierre Luc Carrier and Aaron Courville [42] for facial images and EMOTION dataset [43] for textual data for the purpose of experimentation. The RAVDESS dataset contains 1440 sample recordings from 24 actors (12 female, 12 male), in a neutral North American accent showing 8 emotions namely calm, happy, sad, angry, fearful, surprise, and disgust [41].

The FER-2013 dataset curated by Pierre Luc Carrier and Aaron Courville contains 28,709 training examples of 48x48 pixel grayscale facial images depicting seven emotions namely angry, Disgust, Fear, Happy, Sad, Surprise and Neutral [42]. The EMOTION dataset contains Twitter messages in English having six basic emotions: anger, fear, joy, love, sadness, and surprise [43].

In order to analyze, we clustered these emotions into three categories i.e. positive, negative and neutral. Since the modalities used for experimentation were not following time synchrony, feature level fusion of text with other two modalities was impractical. For decision level fusion, we have used pre-trained models of CNN by FER and Wav2Vec.

2.0 for classifying facial expressions and audio each providing the accuracy of 59 % and 82.23% respectively and pre-trained BERT model for classifying textual data providing accuracy of 93.8%. The output of each classifier is fused using max voting ensemble algorithm. The decision level fusion is tested on annotated samples of CMU-MOSI dataset which provided accuracy of 59.09 %.

For hybrid fusion, feature level fusion is applied on features extracted from facial images and audio by concatenating them before applying random forest for classification. Feature level fusion provided accuracy of 86.6%. Textual data is classified using Pre-trained BERT model providing accuracy of 77%. The output of feature level fusion is combined with text classifier using max voting ensemble algorithm of decision level fusion. The feature level fusion is tested on annotated samples of CMU-MOSI dataset which provided accuracy of 66.67 %.

Table I describes performance analysis of individual classifier for facial images, audio and text each, feature level fusion of facial images and audio and decision level and hybrid fusion in terms of accuracy.

Fig. 5(a) shows graphical representation for the accuracy comparison of decision level and hybrid model. The decision level fusion is providing the accuracy of 59.09 % whereas feature level fusion gives the accuracy of 66.67% on annotated samples of CMU-MOSI dataset. Fig. 5(b) depicts the individual accuracy graph of facial images, text and audio respectively which provide the accuracy of 59%, 93.8% and 82.23% using CNN and BERT models. The last bar in the figure shows accuracy of 86.6% for feature level fusion of facial images and audio input.

TABLE I. PERFORMANCE ANALYSIS OF DECISION LEVEL AND HYBRID FUSION

Accuracy	Facial Images	Audio	Text
Individual Classification	0.59 (Using CNN)	0.8223 (Using CNN)	0.938 (Using BERT)
Feature Level Fusion	0.866 ( Using concatenation & Random Forest)		
Decision Level Fusion	0.5909 ( Using blending algorithm)		
Hybrid Fusion	0.6667 ( Using concatenation & blending algorithm)

## VI. DISCUSSIONS

Emotions can be classified based on the discrete theory of emotions, where the emotions are categorized into discrete classes like anger, disgust, fear, joy, sadness and surprise, or based on dimensional emotional models where emotions are classified as a two valence-arousal models or three-dimensional valence-arousal-dominance models. Facial expression - based emotions are generally classified using discrete theory whereas EEG-based emotions use dimensional models for classification. Table II summarizes different multimodal fusion approaches adopted by researchers for emotion recognition.

Although a uni-modal approach can identify emotions to a certain extent, the accuracy of emotion recognition increases with the multimodal approach. While using a multimodal approach for emotion recognition, the main hurdle lies in fusing multiple modalities that differ significantly in temporal characteristics. The feature-based fusion approach is suitable for the inputs, which are synchronous in time.

Hence, this approach may not work well for emotion recognition based on multiple modalities that differ in temporal characteristics. The Eigen matrix technique for feature-level fusion relies on the mean and eigenvalues of each modality to achieve fusion. Therefore, this technique may not be able to use the entire range of diversity for each modality. Moreover, the Eigen matrix needs to be a square matrix, which further puts restrictions on the choice of features to be considered for fusion. CCA as a method for feature-level fusion uses the concept of maximizing the pairwise correlation between the two modalities. But, a traditional CCA can handle only two modalities at a time. Therefore, applying CCA on more than two modalities will require fusion at multiple levels. MoBEL model, when used for feature-level fusion, requires less processing speed, memory consumption, and neuron numbers. Since the MoBEL model is based on brain emotional learning, to exploit it fully, expertise on cognitive-based abilities of the brain is needed. Merging the features at the hidden layer works with the concept of merging the features at different hidden layers according to the duration of features to achieve feature-level fusion. Though this approach can tackle the problems of asynchronous multimodal features, it depends upon the network used for training. Also, for modalities having similar duration, deciding the hidden layer at which these features need to be fused becomes an issue. Concatenation is the most commonly used method for feature-level fusion, but it might not be the best choice for multimodal inputs that differ in dimensions.

Decision-level fusion, on the other hand, does not require synchrony between different modalities. SVR as a method of decision-level fusion can compensate for redundant information, but it underperforms when the number of features exceeds the number of training samples. A blending algorithm works well as a decision-level fusion technique for emotion recognition owing to its improved performance for multimodal inputs. Blending model when used for decision-level fusion is stable and less noisy, but this technique has high time and space complexity. Brain emotional learning can be used at decision-level fusion owing to its good decision-making capabilities. In spite of this, expertise in cognitive-based abilities of the brain is needed to exploit this technique.

Decision trees are considered for decision-level fusion because of their capability of learning rules according to the requirement. But, decision trees are unstable data structures and they are prone to inaccuracy. Rule - based classification is a way to achieve decision-level fusion as they have the advantage of fusing the multimodal signal classifier's output as per the conditions specified in the antecedent. Nonetheless, this requires a deep understanding of the domain for deciding the conditions and demands a lot of manual work. The D-S theory is widely explored for decision-level fusion. It is based on the concepts of allocating appropriate beliefs and probabilities to hypotheses, applying the D-S rule for fusing independent items from different sources and arriving at the final decision of the optimal hypothesis in a workable and reasonable manner.

TABLE II. MULTI-PERSPECTIVE SUMMARIZATION OF MULTIMODAL FUSION METHODS

Paper	Modalities	Task	Dataset	Model	Fusion Method	Fusion Technique	Results
H. Su et al. [10]	Audio, Video and Text	Multi-level segmented decision-level fusion emotion recognition	AVEC2017	BLSTM	Decision Level	SVR	Improved CCC performance of 0.685 on arousal
Nicolaou et al. [13]	Audio and Video	Fusion of audio cues, facial expression and shoulder gesture for continuous emotion prediction	SAL	BLSTM-NN	Decision Level, Feature Level and Output Associative	SVR	Obtained COR as 0.796 & 0.642 and RMSE as 0.15& 0.21 for valence and arousal respectively
Man Hao et al. [14]	Audio and Video	Audio visual Emotion Recognition Framework	eNTERFACE	SVM and CNN	Decision Level	Blending Ensemble	Improved recognition SI accuracy of 81.36% and SD Accuracy of 78.42%
Zeinab Farhoudi and Saeed Setayeshi [17]	Audio and Video	Audio-visual Emotion recognition with the MoBEL fusion network	eNterface'05	CNN and RNN	Decision Level and Feature Level	BEL and MoBEL	Improved audio visual emotion recognition accuracy of 81.7%
Y. Cimtay et al. [20]	Facial expression GSR and EEG	Hybrid multimodal emotion recognition	LUMED-2 and DEAP	CNN	Decision Level	Decision Tree	Obtained maximum one-subject-out accuracy of 91.5% and mean accuracy of 53.8%
S. Sahoo and A. Routray [22]	Audio and Video	Audio visual Emotion Recognition	eNTERFACE'05	HMM and SVM	Decision Level	Rule Based	Obtained average recognition accuracy of 76% for males candidates and 86% for female candidates for subject-dependent cases
S. Nemati [28]	Audio, video and text	Emotion Recognition using audio, video and users' comments	DEAP	SVM and Naïve Bayes	Hybrid	CCA and D-S theory	Obtained 0.85% and 76% of accuracy and f1-measure respectively for Emotion Recognition
Liam Schoneveld et al. [39]	Audio and Video	Emotion recognition using recent advances in deep learning	RECOLA, AffectNet and Google FEC	MTCNN, VGG, LSTM	Feature Level	Concatenation	Obtained CCC of 0.740 for valence and 0.719 for arousal in RECOLA

Although it works well for non-conflicting data, it may lead to inaccuracy for data that are conflicting in nature. The decision template algorithm is also widely used for decision fusion, but it has limitations as it uses average decision profiles and does not emphasize differences in the performance of classifiers. The hybrid fusion method achieves the advantages of both feature level and decision-level fusion methods by combining these approaches. Feature-level fusion methods require synchronization between different modalities, but it is possible to produce results even when the data from one of the modality is missing. Decision-level fusion, on the other hand, does not require synchrony between different modalities, but its capabilities cannot be exploited fully even if the data from a single modality is missing.

The hybrid approach overcomes the limitations of feature and decision level based approaches by applying feature-level fusion on the synchronous modalities and combining the results of with the remaining asynchronous modalities using decision-level fusion.

Results of experimental analysis on audio, facial images and text for emotion recognition show that feature level fusion of text with other two modalities was impractical since the modalities differ in temporal characteristics. Decision-level fusion works well for fusing the modalities differing in time

synchronicity. However, Hybrid fusion works best for emotion recognition using multiple modalities which differ in time synchronicity providing the accuracy of 66.67%. These results can further be improved by taking large data samples for testing.

## VII. CONCLUSION

This paper discussed different multimodal fusion techniques for human emotion recognition. The study proposed a review of different state of art techniques for decision level, feature level and hybrid fusion to achieve multimodal emotion recognition.

The paper concentrated on using facial images, audio and text as multimodal inputs for emotion recognition. Experimental analysis of fusion methods was conducted which claimed that decision-level fusion and feature level fusion can be performed when inputs of different modalities are synchronous in time. However, when the inputs are not synchronous in time, suitable choices are decision level fusion and hybrid fusion. Hybrid fusion using concatenation and blending algorithm worked best improving accuracy by 7.6 % compared to decision level fusion. The study however had a limited test dataset. The accuracy results can be further improved if large number of annotated data samples are used for testing.

The review suggested that D-S theory is the most aggressively used method for decision-level fusion followed by rule-based and decision tree methods. Brain emotional learning is the latest approach used but it requires expertise in cognitive-based abilities of the brain. However, the blending algorithm works well for emotion recognition owing to its improved performance for multimodal inputs. For feature-level fusion, the most commonly used method is concatenation. CCA and Eigen matrix methods are also used in many applications for feature level fusion. The state of the art literature for feature fusion uses brain emotional learning but it requires expertise in cognitive-based abilities of the brain. Hybrid method is not explored much in literature. However, from experimental analysis it can be deduced that hybrid approach works best in fusing multiple modalities which differ in time synchrony. This provides a direction for the researchers to explore hybrid fusion approach on multimodal inputs.

The experimental analysis performed in this paper is based on audio, text and image inputs for emotion recognition. As a part of future work, audio-visual and physiological signals like EEG can be used to analyze different fusion techniques. Also, this paper used concatenation and meta classifier technique to evaluate effect of feature level, decision level and hybrid fusion. However, as a part of future work, there is a scope for applying different techniques of feature and decision level fusion discussed in the literature review in order to evaluate their effect on decision level, feature level and hybrid fusion.

# A Comparative Study of Predictions of Students' Performances in Offline and Online Modes using Adaptive Neuro-Fuzzy Inference System

Sudhindra B. Deshpande, Kiran K. Tangod, Neelkanth V. Karekar, Pandurang S. Upparmani  
Department of Information Science and Engineering, KLS, Gogte Institute of Technology  
Belagavi-06, Karnataka, India

**Abstract**—Predicting a student's performance can help educational institutions to support the students in improving their academic performance and providing high-quality education. Creating a model that accurately predicts a student's performance is not only difficult but challenging. Before the pandemic situation students were more accustomed to offline i.e., physical mode of learning. As covid-19 took over the world the offline mode of education was totally disturbed. This situation resulted into the new beginning towards online mode of teaching over the Internet. In this article, these two modes are analysed and compared with reference to students' academic performances. The article models a predicting academic performance of students before covid i.e., physical mode and during Covid i.e., online mode, to help the students to improve their performances. The proposed model works in two steps. First, two sets of students' previous semester end results (SEE) i.e., after offline mode and after online mode, are collected and pre-processed using normalizing the performances in order to improve the efficiency and accuracy. Secondly, Adaptive Neuro-Fuzzy Inference System (ANFIS) is applied to predict the academic result performances in both learning modes. Three membership functions gaussian (Gausmf), triangular (Trimf) and gaussian-bell (Gbellmf) of ANFIS are used to generate the fuzzy rules for the prediction process proposed in this paper.

**Keywords**—ANFIS; fuzzy systems; online learning; e-learning; classroom learning; fuzzy rules; predictions; adaptive neuro-fuzzy inference system; education technology; distance education

## I. INTRODUCTION

The Internet has made "Education" as the most exciting domains available in today's society, especially with the interconnectivity of smart and portable devices. Distance and e-Learning has grown in popularity as computer technology has advanced, networks have improved, and smartphones have become more accessible. Technology has transformed general classroom learning into e-Learning by lowering teaching costs and increasing learning efficiency while overcoming space and time constraints. A typical teaching-learning process takes place in a classroom, where a teacher uses lectures, whiteboards, slide projectors, and group discussions to communicate knowledge. To improve their learning skills, students take notes, write tests and assignments, and express doubts and questions. Students must also take tests and assessments on paper and teachers assess performance and knowledge of students in terms of marks. A variety of technological media, smart mobile devices and wireless communication have revolutionized the education system [1].

The e-Learning may happen through a variety of processes and applications such as computer-based training, digital collaborations, web-based training, and virtual classrooms [2].

Whether it is classroom learning or e-learning, one very important aspect is performance evaluation of students. Educational institutes are attempting to include student performance prediction into their educational procedures in order to help the students to improve themselves. Traditional learning modes can be enhanced to online modes by increasing portability and accessibility of mobile networks. Mobile devices can make it possible to capture the user-created content and also can serve as a powerful data collection tool [3]. Gayeski, D., & Russell, J. D. [4] have proposed that evaluations can be done in several ways. The teacher needs to make evaluations to advise students to make decisions and to write recommendations to potential employers. Data mining and machine learning techniques have been in use in HEIs to guide and improve their students' performance by using and exploring the data available in the education domain [5] [6] [7].

Artificial neural networks, Bayesian classifiers, and support vector machine algorithms are some of the techniques used to classify data [8]. Various techniques including classification, clustering, visualization, and regression have been utilized to extract hidden information from educational databases [9]. Classification is a technique for assigning data values to predetermined classes with the goal of predicting the target class for each data value [10][11].

Education data mining peruses extensive educational datasets for important data that can be analyzed deeper. Many educational activities, such as learners' performance prediction, will be supported by the smeared data, allowing teachers to identify potential knowledge about students [12][13]. The Neuro-fuzzy inference system (NFIS) has been effectively implemented in a variety of applications, including control and classification [14]. NFIS is a machine learning tool that integrates fuzzy logic reasoning with the learning capabilities of neural networks, thereby addressing the drawbacks of both neural networks and fuzzy systems when used separately [15]. A tutoring system based on Fuzzy rules [16] which implements a Fuzzy Logic inference engine that can manage different learning activities of students. A tutoring system that uses Fuzzy Logic is demonstrated to monitor the cognitive capability of each student [17].

In this article, ANFIS is applied to evaluate students' academic performance in order to assist them in improving their grades both in online and offline modes. The suggested ANFIS-based solution intelligently mixes fuzzy logic's capability reasoning with neural networks' learning abilities. The use of ANFIS for reliable student performance prediction in online and offline mode, is one of the paper's primary contributions.

## II. LITERATURE WORK

A rule mining approach is introduced for evaluating student performance based on the Association Rules [18]. To collect crucial information for the student performance evaluation, Association Rules were used to examine the student dataset. Various data mining techniques are employed to predict student performance. They discovered that the neural network technique outperformed the other data mining strategies, with a prediction accuracy of 74.8% for student performance [19]. Abu Naser et al. used the Artificial Neural Network (ANN) model to predict the performance of Engineering faculty students [20]. They used the students' course scores, number of passed credits, and cumulative grade point average as factors to evaluate the student performance, and the ANN model correctly predicted the performance of students with an accuracy of 80%. A Neuro-Fuzzy learner model was proposed to analyze errors of high school learners' by collecting data using course-related simulation tools namely vectors in mathematics and physics. The system was tested using simulated learner data with different categories of knowledge level. These learners' behaviors correspond to fuzzy values [21]. A model of feed-forward Neural Networks was also trained for error classification purposes. Barber and Sharkey employed the logistic regression method for predicting student performance based on data collected from available students' information, financial data, and learning management systems [22].

A Fuzzy learner model was discussed for student evaluation during learning activities. The procedure is to imitate a human teacher in the classroom. Fuzzy Logic is proposed to track interaction between the tutor and the students and to handle inaccurate information using the ability of Fuzzy Logic [23]. This leads to more accurate answers by students to improve the learning environment.

Xenos, M. [24] has proposed a model of the Bayesian Network to support educational tutors in making decisions under uncertain conditions. The system is implemented with 800 learners studying an informatics course. The system is designed to model learner behavior to predict the success of decision-making by tutors. Fadi R.S [25] has discussed the early stages of data mining in academics and highlighted the potential of data mining in e-Learning and suggested various data mining tools that can be beneficial for e-Learning.

## III. MOTIVATION

As the Covid-19 pandemic has affected the activities of higher education institutions (HEI) to promote the protection of teachers, staff, and students during the public health emergency. Institutions had to cancel all face-to-face lectures, including labs and other learning experiences, and determined that teachers would completely convert their courses to emergency online learning, and reduced contacts to prevent the

spread of Virus. So, to strengthen the learning community in this pandemic situation online learning has been promoted. But for the first-time online learning mode is actively used in the education. A comparative analysis is required between online and physical modes of teaching to find out how the student community is adjusting to the online mode of teaching and whether it is successful and helpful even after the Covid pandemic.

## IV. THE PROPOSED METHODOLOGY

The proposed methodology is split into four steps. First step deals with data collection and processing; in second part, students' results in the classroom mode are analyzed using ANFIS; in third part, students' results in the online mode are analyzed using ANFIS; lastly, both modes are compared for their performances to evaluate which of the teaching mode is effective in producing good results. Fig. 1 depicts the proposed methodology applied. An Adaptive Neuro-Fuzzy Inference System [26][27] is a sort of artificial neural system that depends on the Takagi– Sugeno fuzzy inference system. It incorporates both neural systems and fuzzy rationale standards; it can catch the advantages of both in a solitary structure. Its inference system compares to an arrangement of fuzzy IF-THEN rules that have learning ability to surmised nonlinear fignctions.

### A. Data Collection and Processing

The dataset used consists of 210 samples for Information science students consisting of students' scores in four core subjects and two laboratories ranging from 0 to 100. There are two sets of datasets which are collected. One set belongs to the 1st, 3rd and 5th semester students' semester end examination (SEE) results obtained through classroom learning mode and before the pandemic. Second set consists of SEE results of same students but studied in 2nd, 4th and 6th semester during the pandemic through online mode learning. The preparation of the dataset is the initial stage in the proposed approach. This stage could be crucial for reducing error throughout the learning process and obtaining more precise inputs. Equation (1) is used to normalize datasets using sample mean  $\mu$  and standard deviation  $\sigma$ .

$$X_i = \frac{x_i - \mu}{\sigma} \quad (1)$$

### B. ANFIS Architecture

“Takagi– Sugeno fuzzy inference framework” is used in ANFIS architecture which is an adaptive system that utilizes a directed learning algorithm. Fig. 2 demonstrates the architecture of ANFIS that consists of two sources of information “x” and “y”, and one yield or output “f”.

Takagi–Surgeon model follows the two variants of IF-THEN, are

$$\text{RULE 1} = \text{If 'x' is A1 and 'y' is B1 Then } f_1 = p_1x + q_1y + r_1$$

$$\text{RULE 2} = \text{If 'x' is A2 and 'y' is B2 Then } f_2 = p_2x + q_2y + r_2$$

where A1, A2, and B1, B2 are the membership elements of each info ‘x’ and ‘y’, while p1, q1, r1 and p2, q2, r2 are linear parameters to a limited extent Then (subsequent part) of Takagi– Sugeno fuzzy inference model.

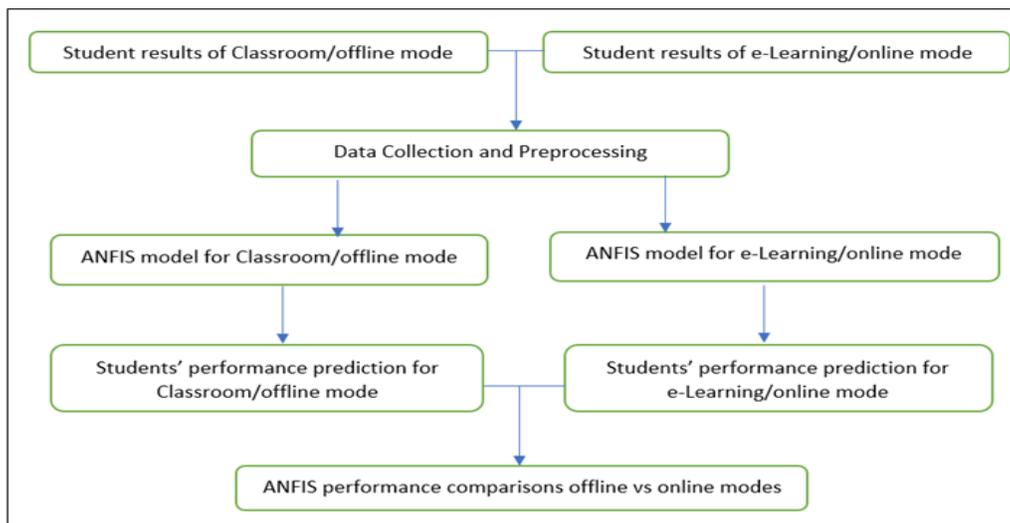

Fig. 1. Proposed Methodology of the Work Carried Out.

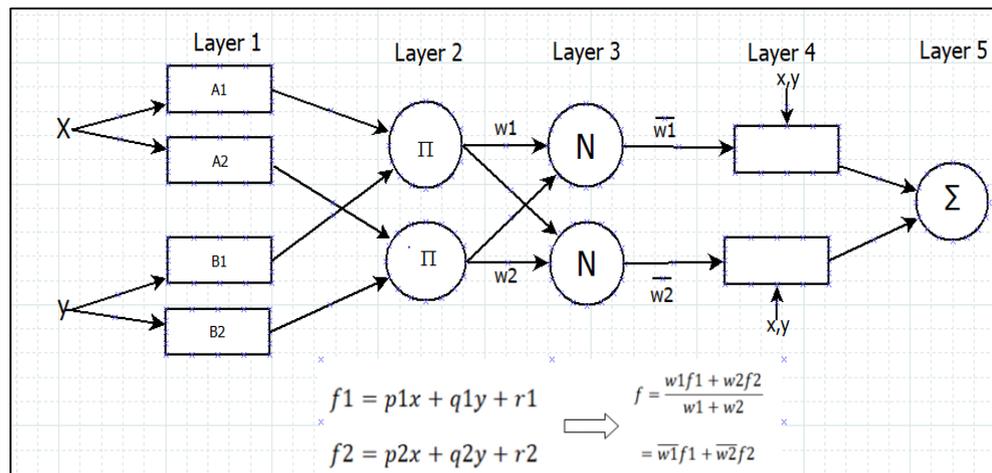

Fig. 2. ANFIS Architecture.

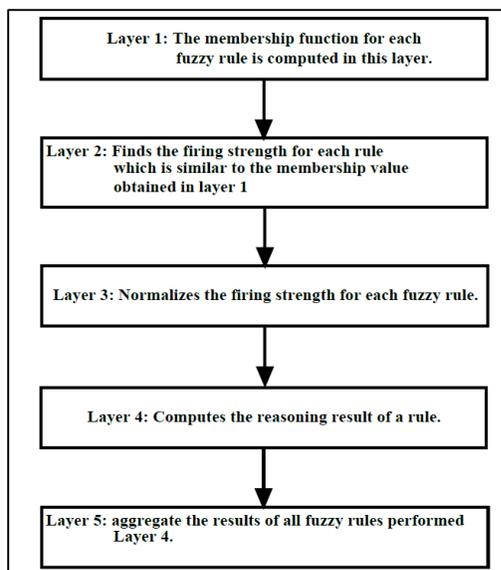

Fig. 3. ANFIS Layers and Functions.

Fig. 3 shows the functions of five layers of ANFIS. The first layer and fourth layer consist of adaptive nodes, while the remaining layers consist of fixed nodes. ANFIS tool in MATLAB provides a Grid partitioning algorithm. The algorithm generates a single-output Sugeno-type FIS by using grid partitioning on the data. `genfis1` generates a Sugeno-type FIS structure used as initial conditions (initialization of the membership function parameters) for ANFIS training. It generates input membership functions by uniformly partitioning the input variable ranges, and creates a single-output Sugeno fuzzy system. The fuzzy rule base contains one rule for each input membership function combination.

The membership function is a curve that defines how each point in the input space is mapped to a membership value (or degree of membership) between 0 and 1. They characterize fuzziness as whether the elements in fuzzy sets are discrete or continuous. The membership functions “`trimf`”, “`gaussmf`” and “`bellmf`” - are explained:

“Triangular function: defined by a lower limit  $a$ , an upper limit  $b$ , and a value  $m$ , where  $a < m < b$ , as given by equation (2).

$$\mu_A(X) = \begin{cases} 0 & x < a \\ \frac{x-a}{m-a} & a \leq x < m \\ \frac{b-x}{b-m} & m \leq x < b \\ 0 & x \geq b \end{cases} \quad (2)$$

Gaussian function: defined by a central value m and a standard deviation k > 0 as given by the equation (3).

$$\mu_A(X) = e^{-\frac{(x-m)^2}{2k^2}} \quad (3)$$

“The generalized bell function: gbellmf depends on three parameters a, b, and c given by the equation (IV) where the parameter b is usually positive and the parameter c locates the center of the curve.”

$$f(x; a, b, c) = \frac{1}{1 + \left| \frac{x-c}{a} \right|^{2b}} \quad (4)$$

The datasets are partitioned into 70 :30 i.e., 70% training data and 30% testing data. For both models of ANFIS, scores of six subjects are considered as input variables and SGPA as output variable. Three membership functions, gaussian (Gaussmf), triangular (Trimf) and gaussian-bell (Gbellmf) of ANFIS are used to generate the fuzzy rules for both the models.

### C. Performance Evaluation

The Root Mean Square Error is a metric for determining the accuracy of a student's performance prediction by comparing the actual observed data values to the ones predicted by the model. The formula in equation (5) is used to calculate the RMSE:

$$RMSE = \sqrt{\frac{\sum_{i=1}^n (X_{obs,i} - X_{model,i})^2}{n}} \quad (5)$$

## V. RESULTS AND DISCUSSIONS

Two ANFIS models using three mfs are built for the experimentation; one for classroom/offline mode of learning and second is for online mode of learning. The training data subset is used to train the ANFIS models, while the test data subset is employed to assess the trained ANFIS models' prediction accuracy. Student scores from the previous semester are taken as inputs to the ANFIS models in order to forecast student performances. The testing RMSE values for different epoch numbers will be used to designate the best ANFIS model in both learning modes. By varying the number of training epoch from 50 to 900, the performance of the three ANFIS models based on three types of membership functions (GaussMF, TriMF, and GbellMF) is examined.

### A. ANFIS for Classroom / Offline Mode

Table I displays the training and testing RMSEs for offline mode learning approach for the three types of mfs.

Fig. 4 depicts RMSE values of training and testing against the number of epochs for all the three membership functions; and trimf behaviour is found to be worst as the testing RMSE is very high with 0.877 against a very low training error of 0.025. gaussmf performs good in comparison to gbellmf and trimf with 0.334 testing RMSE.

TABLE I. TRAINING AND TESTING RMSES OF GAUSSMF, GBELLMF AND TRIME WITH DIFFERENT EPOCHS FOR OFFLINE MODE

MFs	GaussMF		GbellMF		TriMF	
	Trainin g error	Testin g error	Trainin g error	Testin g error	Trainin g error	Testin g error
50	0.73	0.792	0.78	0.898	0.037	0.987
100	0.659	0.669	0.756	0.87	0.035	0.978
150	0.61	0.77	0.698	0.866	0.035	0.971
200	0.598	0.7	0.645	0.767	0.029	0.899
250	0.245	0.566	0.388	0.689	0.02	0.859
300	0.179	0.456	0.356	0.78	0.021	0.855
350	0.171	0.423	0.355	0.789	0.028	0.889
400	0.169	0.389	0.289	0.677	0.029	0.89
450	0.168	0.389	0.219	0.654	0.032	0.929
500	0.169	0.378	0.17	0.644	0.027	0.877
600	0.168	0.378	0.169	0.655	0.027	0.876
700	0.168	0.345	0.17	0.64	0.025	0.875
800	0.168	0.336	0.17	0.64	0.027	0.875
900	0.168	0.334	0.171	0.639	0.025	0.877

Fig. 5(a) depicts the RMSE values of training for all the three-membership function. It can be observed that at 400 epoch iterations, training RMSE of gaussmf almost reaches a stable value. At 500 epoch iterations, training RMSE of gbellmf and trimf reach stable values. Further increase in the number of epochs may not yield any significant results in predictions causing overfitting of the models. Fig. 5(b) depicts that testing RMSE values of gaussmf is less than the gbellmf and trimf, meaning ANFIS-gaussmf model with least testing RMSE value of 0.334 predicts accurately. And trimf with 0.877 testing RMSE performs the worst in predictions.

### A. ANFIS for Online/e-Learning Mode

Table II displays the training and testing RMSEs for online mode learning approach for the three types of mfs of ANFIS.

Fig. 6 depicts MSE values of training and testing against the number of epochs for all the three membership functions for online mode of learning; and trimf behaviour is found to be worst as the testing RMSE is very high with 0.878 against a very low training error of 0.057. It can be observed that gaussmf and gbellmf both perform very well with 0.284 and 0.289 testing RMSEs respectively. ANFIS-gaussmf and ANFIS-gbellmf, both models perform very similar to each other in predicting the performances of students studied through online mode.

Fig. 7(a) depicts the RMSE values of training for all the three-membership function. It can be observed that at 500 epoch iterations, training RMSE of all the three mfs reach stable values. Further increase in the number of epochs may not yield any significant results in predictions causing overfitting of the models. Fig. 7(b) depicts that testing RMSE values of gaussmf and gbellmf are almost same and are very low compared trimf, meaning ANFIS-gaussmf model and ANFIS -gbellmf model predict accurately. And trimf with 0.878 testing RMSE performs the worst in predictions.

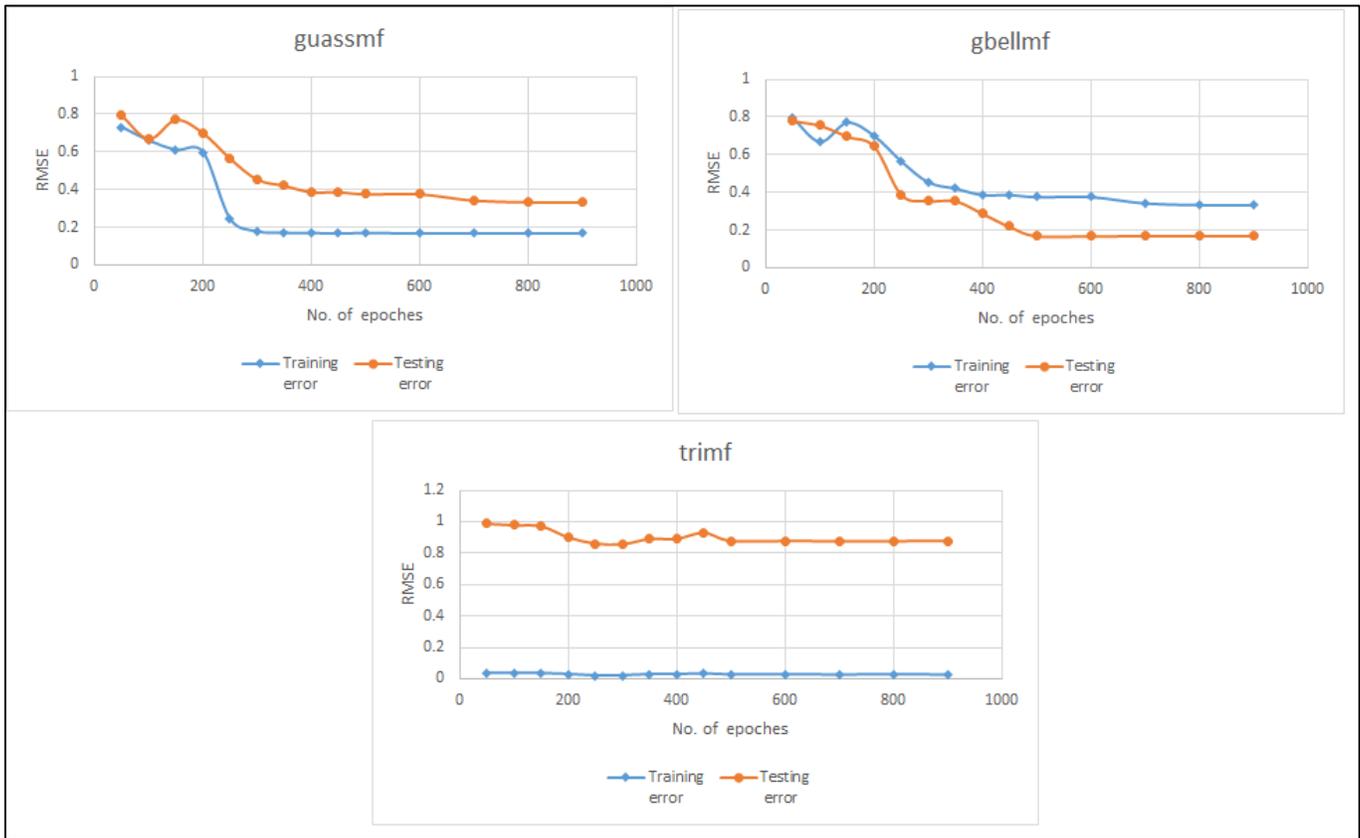

Fig. 4. Training and Testing RMSEs vs the Number of Epochs (a) Guassmf (b) Gbellmf (c) Trimf, for Offline Mode Predictions.

Fig. 5. Training RMSEs of 3 Mfs and Testing RMSEs of 3 Mfs for Offline Mode Predictions.

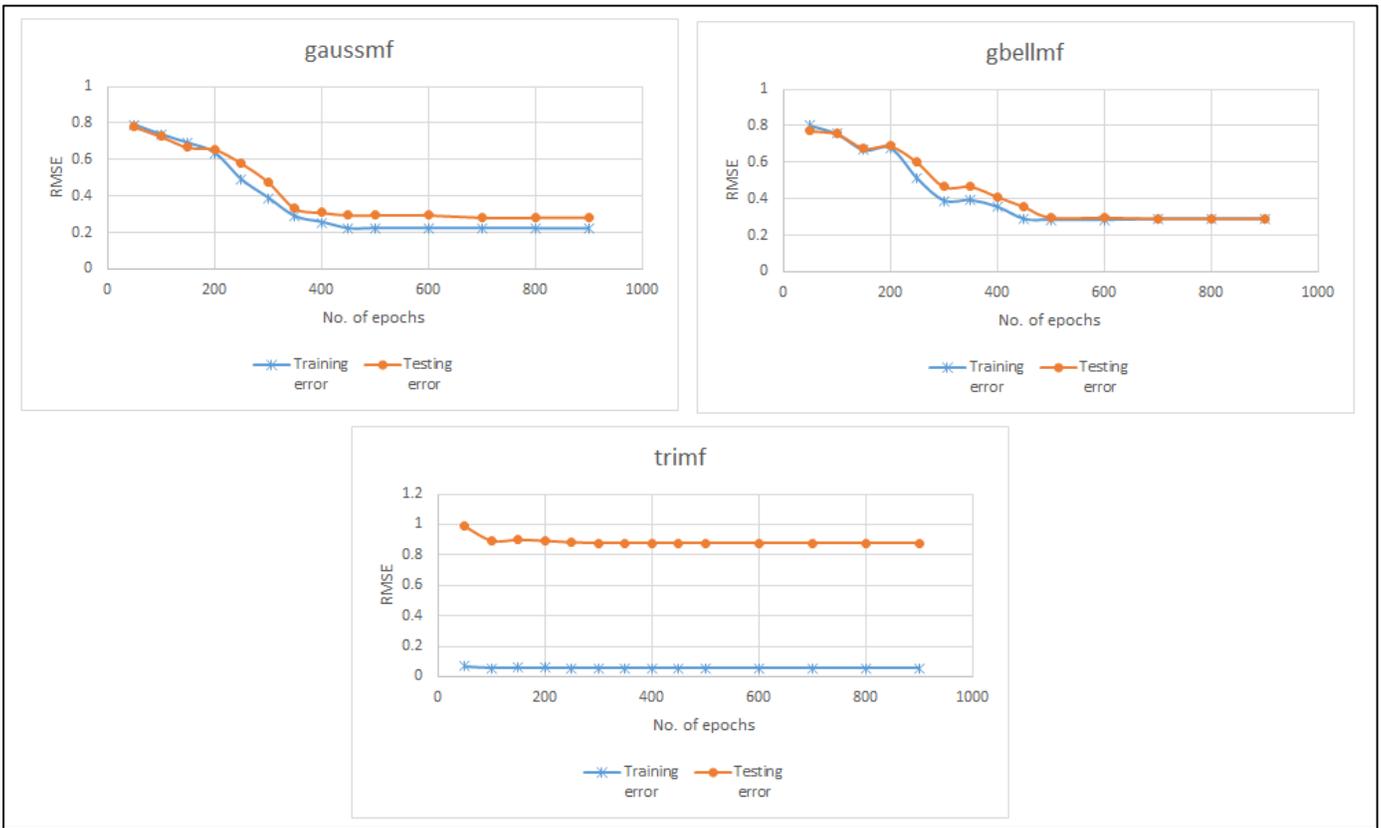

Fig. 6. Training and Testing RMSEs vs the Number of Epochs (a) Guassmf (b) Gbellmf (c) Trimf, for Online Mode Predictions.

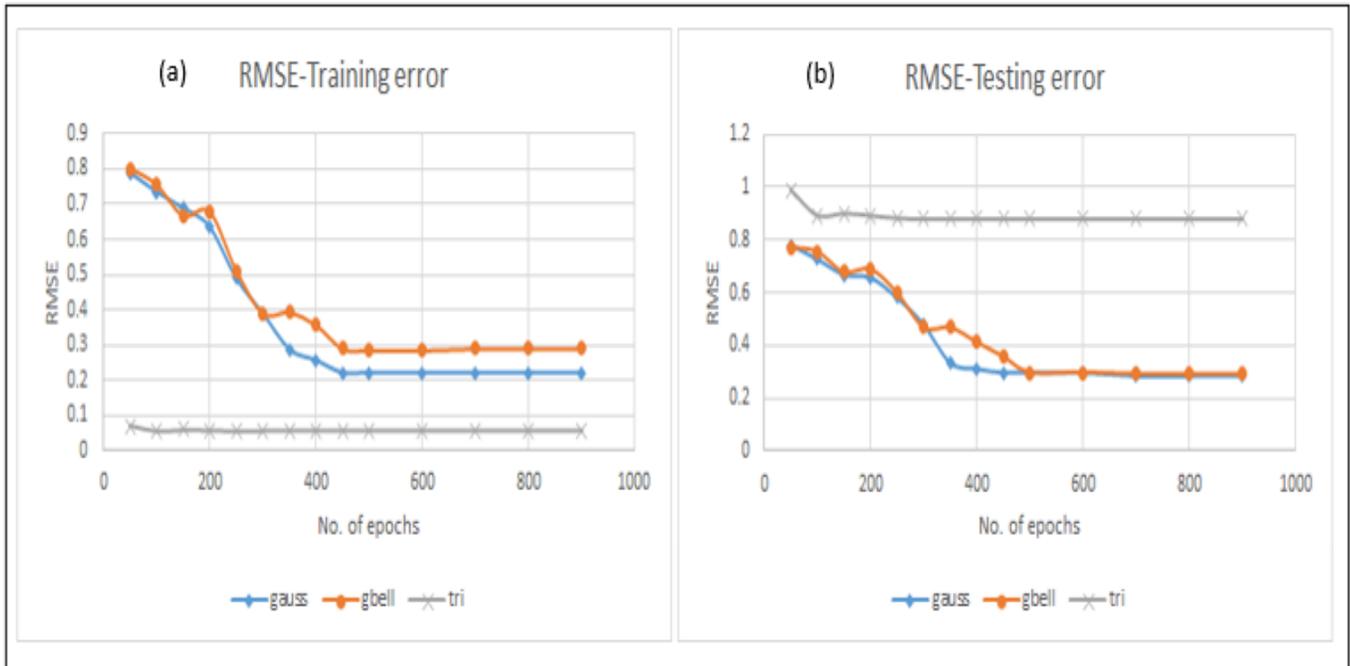

Fig. 7. Training RMSEs of 3 Mfs and Testing RMSEs of 3 Mfs for Online Mode Predictions.

TABLE II. TRAINING AND TESTING RMSES OF GAUSSMF, GBELLMF AND TRIMF WITH DIFFERENT EPOCHS FOR ONLINE MODE

MFs	GaussMF		GbellMF		TriMF	
	Trainin g error	Testin g error	Trainin g error	Testin g error	Trainin g error	Testin g error
50	0.789	0.779	0.801	0.773	0.0697	0.989
100	0.735	0.725	0.755	0.756	0.056	0.892
150	0.689	0.667	0.667	0.678	0.059	0.899
200	0.635	0.655	0.678	0.689	0.058	0.891
250	0.489	0.58	0.511	0.599	0.056	0.881
300	0.389	0.478	0.39	0.467	0.057	0.878
350	0.287	0.334	0.392	0.467	0.057	0.878
400	0.256	0.311	0.356	0.411	0.057	0.878
450	0.221	0.297	0.289	0.356	0.057	0.878
500	0.221	0.297	0.284	0.297	0.057	0.878
600	0.221	0.297	0.284	0.297	0.057	0.878
700	0.221	0.284	0.289	0.291	0.057	0.878
800	0.221	0.284	0.289	0.291	0.057	0.878
900	0.22	0.284	0.289	0.291	0.057	0.878

**B. Comparison of Offline and Online ANFIS Models**

Table III depicts training and testing RMSE of all three ANFIS mfs for epoch 900 for offline and online learning modes referring to the Tables.

TABLE III. RMSE COMPARISONS OF 3 MFS FOR OFFLINE AND ONLINE MODES

Learning Modes	MFs	GaussMF		GbellMF		TriMF	
	No. of Epochs	Train ing error	Test ing error	Train ing error	Test ing error	Train ing error	Test ing error
offline mode	900	0.168	0.334	0.171	0.639	0.025	0.877
online mode	900	0.22	0.284	0.289	0.291	0.057	0.878

Training and testing RMSE for ANFIS-gaussmf are 0.22 and 0.284; and training and testing RMSE for ANFIS-gbellmf are 0.289 and 0.291. These gaussmf and gbellmf RMSE values of online learning mode show that training and testing RMSEs are almost same without a large variation. And offline mode’s ANFIS-gaussmf testing RMSE (0.334) is larger than the online mode’s testing RMSE ANFIS-gaussmf (0.284); means predicting the performances of student results in online mode is superior and accurate compared to offline predictions.

**VI. CONCLUSION**

Before the Covid-19 students used to learn engineering subjects through physical i.e., classroom or offline mode by attending classes. At the end of semester students are assessed to check their performances by writing semester end examinations (SEE). As Covid-19 pandemic begun, these offline classes were totally suspended and e-Learning or online

mode of learning using Internet and mobile devices took over the education in a different direction. Online mode in the education domain has initiated a new paradigm shift. So, the students learned through online mode during the pandemic and also SEE were conducted after the semester end. So, there is a need to analyse and predict which mode of education (online or offline) impacted the student’s learning process and improve the learning curve by increasing the performances. This article illustrated the ANFIS approach to model and predict the students’ performances obtained through both modes of learning. Firstly, ANFIS for offline mode was built and found that ANFIS-gaussmf predictions are better. Secondly, ANFIS for online mode was built and found that ANFIS-gaussmf and gbellmf, both predicted the same and well performed. In both, ANFIS-trimf performed very worst. Finally, ANFIS-online mode performed very well compared to ANFIS-offline mode i.e., predicting the performances of student results in online mode is superior and accurate compared to offline predictions.

# Combining Innovative Technology and Context based Approaches in Teaching Software Engineering

Shamsul Huda<sup>1</sup>, Sultan Alyahya<sup>2\*</sup>, Lei Pan<sup>3</sup>, Hmood Al-Dossari<sup>4</sup>

School of IT, Deakin University, Melbourne VIC 3125, Australia<sup>1,3</sup>  
Information Systems Department, King Saud University, Riyadh 11451, Saudi Arabia<sup>2,4</sup>

**Abstract**—Sustainability in learning is very essential for a sustainable future which largely depends on education. Sustainable learning requires learners to increase and rebuild base-knowledge as the circumstances change and get more complex. This becomes very obvious particularly for information technology (IT) discipline where technology is rapidly changing and practice getting more complicated. Sustainability enables students to use their learning from formal education into practice, provide hands on experience (HOE) and help them rebuild their knowledge base in complex situations. This is also essential to achieve a high graduate outcome rate (GOR) which helps the education sector to become sustainable. In the existing policies and frameworks, institutions are moving towards more off-campus learning and less face-to-face learning. As a result, a downward trend is experienced in students' engagement across IT discipline. This affects students' ability in achieving HOE and appears to be one of the reasons of low GOR which poses a threat to the sustainability in the education sector for both stakeholder and learners' perspectives. This paper presents a combined approach of context-based teaching with incorporation of innovative technology to engage students and achieve a better HOE towards sustainability in learning. The proposed approach was adopted in a software engineering course taught at School of IT at Deakin University, Australia. Students were provided context-based teaching material and industry standard software engineering tools for practice to achieve HOE. Students evaluation and assessment results reports that proposed approach was significantly impacted positively to engage the students in classes towards improved sustainable learning.

**Keywords**—Sustainable learning and education; context-based teaching; work integrated learning; hands on experience; graduate outcome rate; positive attitude and engagement

## I. INTRODUCTION

Sustainability in our future [41] and societies is not easily achievable unless our learning and education sector is sustainable [34], [35], [39]. Therefore sustainability in learning [40] has drawn much attention from many education providers, researchers and stakeholders of sustainable development programs [34], [35], [39]. If education itself is not sustainable then achieving the factors for sustainable development and global citizenship programs is hard to be successful [34], [35]. Sustainable learning is not only limited to the retaining the knowledge [35]. But it is more towards the rebuilding of knowledge and skill-base dynamically as the circumstances change and get more complicated [35], [5]. IT discipline and related industries are facing massive technological evolution [30]. Therefore, sustainable learning is getting more essential component for IT discipline [6].

Sustainable learning requires learners to be proactively engaged in learning from past and present following a constructivist approach that enable them to relearn the knowledge, achieve more HOE and then take the new knowledge into practice for an ever-changing technological discipline [37]. From the stakeholders and business perspective, large-scale investments are also required in the education sectors for sustainability [34]. Therefore, existing policies and educational frameworks are moving towards more on extended off-campus learning and less face-to-face learning. Following the emergence of the pandemic, many institutions are also interrupted from their usual face-to-face learning and are forced to go off-campus/on-line learning [39]. It has been observed a downward tendency in students' proactive engagement which affects achieving HOE and thereby sustainability in learning.

In the information technology discipline, HOE have been explored in many studies [1], [2]. Patricia et al [1] found that more participation on hands on activities help students to achieve higher scores in a standard science-achievement test. Atanas Serbezov [2] et al. showed that students in this discipline need to understand the fundamental working principles of the field instruments' and how these can be integrated into an overall industrial systems in engineering. Literature studies [1],[2] indicate that the main objective of the universities is to provide education to the students in the fundamental areas of the engineering discipline. At the same time, universities need to extend the educational activities to make the educational programs more market oriented and relevant to the corresponding industry trend. Atanas Serbezov [2] et al. found a total of 10% increase in GOR in their quantitative study across few years while they included industry engagement as part of their learning activities.

Sustainable learning in IT discipline requires effective practice in classes to improve HOE by providing students with a real life experience aligned to the theoretical lecture classes. Therefore, many education providers are investigating and testing different ways of teaching methods including located mode practical classes, simulated laboratories, remote laboratories [3], [4] and combination of those [5], [6]. The purpose of these innovative teaching approaches is to engage students and provide HOE which make them ready for the job market after their graduation. In the IT discipline, many software/tools for practical classes are collected from open source or organized from different sources which generally are behind from the dynamic industry market [5]. In many evaluation frameworks [5], with these tools and software

\*Corresponding Author.

support for achieving the learning outcome, due to the frequency of practical classes, volume of submissions and complexity of the evaluating the assessments many practical classes are not well assessed. Students are often assessed based only on their summative assessment tasks or based on a combination of assignments and practical assessment tasks with practical assessment tasks have less fraction of total assessment marks of the subject. Therefore, students' participation has been declining in the practical classes in IT discipline across different institutions. This is a concern considering student engagement that results a cohort of technology graduates with inadequate domain knowledge which is a primary obstacle in the pathway of sustainable learning. In achieving successful learning outcome and relearn through deconstruction and reconstruction, student's attitude, motivation and engagement are important [10], [9] which are the key factors for sustainable learning. Therefore many innovative teaching approaches including context-based teaching methods, inquiry-based teaching methods and incorporation of innovation technologies in engineering and IT teaching have been adopted [11], [12]. In [13], Bennett et al. have completed a systematic review and have found that context-based teaching and incorporation of innovation technologies in teaching that worked effectively in developing positive attitude in students' learning activities.

Context-based approaches improve the learning materials and curriculum, then uses different context and applications of the theories in learning activities. Students learn how their learning outcomes can be applied in real life. Many researchers [14], [15], [16] have found that context-based approaches are useful and change students' attitude positively in achieving learning outcomes. However, context-based approaches may vary from discipline to discipline and within a particular discipline the approaches may vary over time. For example, innovation in technology for IT is very fast. This fact significantly affects the industrial market and also changes the job criteria for the graduate. Students need to be able to have a certain level of early experiences which should be achieved through their education in order to get into the job market. To achieve the learning outcomes and be up to date with the fast technological evolution, several factors need to be considered. Approaches to increase the positive attitude in learning activities and engage students into the activities is a possible direction of improvement in achieving hands on experience.

It also has been observed that applications of innovative technologies [17], [18] in teaching approaches including computer simulation, multimedia applications, online assessment process and visualization techniques have led to more positive attitude which motive students to engage and provide them enjoyment during their learning session. For ITE discipline, the use of IT tools and techniques is obvious and most of the intuitions are applying these in their teaching activities. For IT students, these approaches appear to be standard practices and may not be much motivating factor. A more motivating approach will be an approach that can give students hands on experiences (HOE) in the engineering methods and techniques, tools software in IT which will be beneficial immediately after their graduation. In this research, a combination of the above two approaches will be used which

combines context-based and incorporation of innovative technology in order to engage students, relearn knowledge from past and achieve better hands on experiences (HOE). The procedure will incorporate commercially popular tools/software in the learning activities for students' engagement and will provide related learning resources. Improvement of learning material will be done progressively and its practice will be completed in practical classes.

The rest of the paper is presented as following. Section II discusses the related work. Section III discusses proposed methodology (Materials and methods), data analysis and performance measures. Section IV presents the result of this study and last section discusses the conclusions of this study.

## II. RELATED WORK

### A. Sustainable Learning and Education (SLE) in the Current Literature

To achieve sustainability from stakeholder perspective, educational institutions are moving towards more off-campus education [33]. Therefore sustainability in learning and education is a rapidly growing research area. Jay Hays, Hayo Reinders [34] proposed a detailed curriculum for SLE and identified the expected learning outcome. They also made a conclusion on the principles of sustainable learning. Mina Chiba [34] presented a detailed review of effective teaching methods for sustainable development and global citizenship. Asmat Ara Shaikh, Anuj Kumar et.al, [36] investigated application of artificial intelligence (AI) and its sustainable impact on online learning for off-campus classes. They find that AI is useful in automated identification of gap in learning. Fatma [37] proposed a discriminant analysis technique to predict teachers view towards sustainable education. Fatma [37] concluded that criteria for curricula evaluation and students centered teaching are the key factors that identify teachers' dispositions for sustainable education. O. Polyakova and R. Galstyan-Sargsyan [38] studied tele-collaboration based sustainable education systems. They find that plurilingual competence can be developed in tele-collaboration which helps sustainable university training. Alvyra Galkiene' et al [39] has investigated modeling of the sustainable educational on a group of vulnerable learners and they find that innovative technologies such as digital tools have a positive impact on vulnerable students for sustainable education. Existing literature has a gap to understand how a better HOE can be achieved towards sustainable learning. The problem of achieving high HOE gets more complicated for off-campus students. Many research studies and practices in engineering have been accomplished to address this issue. Considering the importance of HOE in higher education, many teaching approaches have been studied in different literature [1]-[10], [11]-[16], [19] including remotely operated laboratory for off-campus students, simulated laboratory for off-campus and on-campus students, and students' placement and work integrated learning.

### B. Remotely Operated Laboratory for off-campus Students

Mihaela M. Albu et al. [3]-[4] have shown a remote operation of power engineering instruments can be used for off-campus students. In these cases [3]-[4] the authors find

that if machines constraints are properly implemented such that students cannot do any mistake beyond the normal operating conditions, then the experimental environment can be set up successfully. However, this study has shown that the approach has limitations where students cannot have full experiences of field experiences in using the power instruments for abnormal situations. In a real life situation, power instruments can go to abnormal condition frequently.

### C. Simulated Laboratory for off-campus and on-campus Students

In contrast to remote operated laboratory, simulated laboratory and simulations tools are very common approaches in IT and Engineering discipline. A simulated laboratory is an experimental environment which uses internet, information technology tools [5]-[6], programs and multimedia and networking facilities to simulate a real experimental environment. These approaches are used particularly in Engineering and IT discipline where instruments are very expensive or experiential processes are risky. For example, in IT discipline, conducting experiments for different types of targeted attack on a computer or a network, testing firewall vulnerabilities and cyber warfare in real environment is highly risky. Most classroom experiments use simulated network environment or a combination of simulated and real environment. Simulated tools are beneficial for off-campus education as well. A review [5] shows that simulations tools have many limitations. Many simulation tools [5] cannot facilitate performance analysis, available only for limited protocol, not fault-tolerant, inadequate Graphical User Interface (GUI) and have limited documentation which makes them difficult for off-campus education. A comprehensive study by Muhammad Azizur Rahman [5] on network simulation tools shows that these tools often can reach incorrect implementation solution due to lack of generalization and rigor. To overcome these and in order to provide HOE, a combination of real and simulation environment can be provided. Sushil K. Sharma et al [6] presented a case study on information security education hands on approach at Ball State University, USA for three courses where every course had 20-25 students. It is seen in this study [6] that students were highly engaged in the courses and participation in practical classes was maximum compared to other courses. This kind of real experimental environment provides students HOE and are fruitful for students' engagement as students enjoy the classes and get excited which they cannot do using simulation tools at their home environment. However authors [6] did not mention about any result whether this approach was considered for off-campus students. Literature studies [5]-[6] show that one of the difficulties for many IT courses in IT discipline is many experiments require real environment including security and hardware related subjects which are difficult to offer for the off-campus students due to inability to support for practical classes.

### D. Students' Placement and Work Integrated Learning

Students' placement and work integrated learning are also used to provide students with a real life experiences achieve HOE in engineering and IT discipline in many institutions. Work integrated learning (WIL) extends the formal university

studies with a placement in work place before they graduate. WIL can be organized at the end of program or every year or in any particular course. Particularly in engineering and medical discipline [7]-[8] this is compulsory in most of the institution's undergraduate programs. Statistical analysis and research [7]-[8] show that the approaches have been able to fill the gap of students' understanding about the theory and its application in practical work.

### E. Gamification Approach of Engaging Students and HOE

In many research studies [26]-[28] gamification has been used for educational process which was successful in engaging students that improved students' motivation towards learning and assessment activities. Gamification process in teaching is defined as the transference of game design in teaching activities to increase students' motivation in learning [28]. Often this process allows students to achieve an instant reward based on their progress in the classroom tasks [26]. In [28], the authors accomplished a study based on gamification with cohort of 97 students which demonstrated a positive impact on students' attitude and achievement. Li Ding, Chan Min Kim et al [29] used a gamification approach in online discussion forum and developed a tool named 'gEchoLu' to investigate the effect of specific game in the tool for engagement. Flipping the class model is a popular approach of engaging students in learning activities. Jingying Wang et al. [25] used a combination of flipping model and innovative technology to engage students. They find that the combined method was successful in knowledge construction and improved the transfer of new knowledge. Curtis R. Henrie, Lisa R. Halverson, Charles R. Graham [30] provides a detailed review on student engagement using innovative technology. In this review [30], they mentioned the limitations and strengths of technology mediated teaching. They [30] find that evaluation of technology-mediated teaching can provide meaningful student engagement data. In [30], it is observed that quantitative observational measures are effective at the activity level which disrupts comparatively less to the students in learning during data collection but expensive.

### F. Campus-Class-Technology (CCT) Theory in Engagement

CCT theory was proposed by Selim Gunuc [31] who explained the relationship between technology and student engagement. CCT theory describes that the value given by the student in their university life is one of the important factors for which students have the sense of belonging to a university. Then CCT theory continues a cyclic path which states that academic achievement have influence on the value for which students have the sense of belonging to a university. CCT theory [31] shows that technology is the prime factor which contribute to the student engagement. In [32] Selim Gunuc tested CCT theory with path analysis which was conducted on 332 teachers and students. It was observed that value of belonging positively impacted emotional engagement which predicted behavioral and cognitive engagement. It shows that the use of technology in class was an important factor in student engagement. Although different approaches have been adopted to engage students. In the literature, student engagement in the context of HOE was not revealed much. Therefore, achieving HOE for students still is a crucial research problem for institutions due to the dynamic job

market, changes in technologies and cost due to organize the tools/equipment for engaging students. Therefore, it is important to investigate more on student engagement and achieving HOE.

### III. MATERIALS AND METHODS

Research [11]-[13] shows that students' positive attitude and engagement affect largely not only in achieving HOE but also in accomplishing other theoretical learning activities. Therefore engagement has been active research keywords in teaching and learning domain for long time. Many approaches have been proposed including active learning [22], context-based teaching method, inquiry-based teaching method [11]-[13], flipped classroom [20], incorporation of innovation technologies in science teaching have been proposed. Flipped class room allows the students to complete their homework in lecture class time and traditional class activities are accomplished at home [20]. In this case, students watch the lecture video, read the lecture notes and additional reading at home. This is a new instructional model and it is observed that this model helps students to be engaged in the class, particularly for lecture classes. A review of different flipped models has been presented in [21]. However, if there is a downward tendency in attendance in practical classes in the current setup, then flipped model may not be a good choice. In contrast, context-based teaching approaches introduces attractive learning materials in which learning activities are designed based on the application of the theories [14]-[16] with varying context and real life examples. Several research studies [17]-[18] show use of innovative technology including visualization, simulation model of real environment, has also been useful for positive attitude of students towards learning activities. Earlier studies [13]-[16] on students' attitude shows that context-based teaching method and incorporation of innovation technologies in engineering teaching have been effective to gain positive attitude of students towards learning activities. This draws an attention for current studies to focus on these methods [14]-[16] since HOE is more related to context-based approach where learning context varies as technology changes. In addition, inclusion of innovative technology [17]-[18], [30]-[32] can attract students' attitude which can be made available in the practical classes. Based on the literature review, a hybrid model has been proposed that combines the context-based teaching and incorporation of innovative technology. In this context, the proposed approach resembles the active learning approaches [22] in the practical classes where students accomplish meaningful real-life learning activities and can think about what they are doing. However, proposed approach not only considers the meaningful activities, but also considers innovative learning tools to engage students and at the end of practical learning sessions may provide higher level of HOE.

#### A. Research Design and Procedure

The proposed methodology incorporates attractive industry-aware content and tools/ software which will cover both traditional theories and industry practices in the lecture content of the course. Then those lecture contents are made related to context-oriented practical classes where students will have the activities related to contemporary industry

practices. The assessments will also include the tasks based on the weekly practical classes. The procedure will incorporate innovative commercial software/tools in the learning activities for practical classes and will be made available for off-campus students. Context-based learning material will be delivered progressively on a weekly basis in both lecture and practical classes.

#### B. Case Study and Data Analysis

The proposed methodology considers the "Software engineering" course as a testbed as the target discipline is engineering and IT. As part of the process, new context-based learning materials have been introduced from the beginning of the trimester in the lecture class in every week. The topics have been selected through the literature study and industry practices, based on author's own industry experiences and through the consultation with industry experts. The industry consultation has been performed with a renowned software modeling expert in Sparx systems, Australia [24]. Participants are post-graduate students.

#### C. Design of Lecture-practical Content and Assessment Tasks

Summative assessment task is considered for main evaluation of students' engagement and achievement of HOE. The course has two assignments and final examination. During each week, there is an ungraded formative assessment task. For comparison of the proposed methodology, the assessment tasks have been designed such that main objective of the tasks remain same as the previous year. However, the approach of solving the assessment tasks should be based on the new industry practices and context-based teaching. In every lecture, new contents have been added which are practiced in the industry. A typical assessment task is to prepare an analysis and design report to improve an existing web application by identifying new services (epics) where services should include dynamic content update, functional processing, and navigation and over all presentation of the existing web site. The whole analysis process should include modern agile scrum approaches, target is to prepare different artifacts such as personas, a product story map backlog, use UML profile [24] to prepare content and process class models, navigational and functional models and sprint backlog for the proposed services. An example of context-based material is given below: Students need to develop a process class model from the user-interaction scenario of a web application. Students need to keep in mind that the model should be useable later stage in the navigation design and implementation of the application.

1) *Engagement fact in the lecture material:* How to integrate processes in the navigation when any user interaction requires the system to response to the users and; the processes should be visible or system's internal processes. This integration requires students to think and find the processes by investigating the user interaction scenario for the web application. In every lecture, a number of context-based facts were included in order to engage the students For example, for the above topic, students were shown an example piece of code where the processes from their process model could be used and the way practically it is done using a real

programming environment. In this case, it has been shown to the students the relationship between a Java Server Programming (JSP) technique [42] and Java Bean (JB) instantiation [42] of process classes with their design process classes. These techniques (JSP and JB) [42] are very popular in the current industry practices and students will achieve industry standard HOE through the learning process.

2) *Context-based and innovative industry practice/ activities in the practical classes:* In practical classes students had to use the most popular industry standard software engineering tool “Enterprise Architect (EA)” [24] to design the above models. For example, to relate the theory of lecture with practical, in the practical class, it also has been demonstrated how the code is generated from their design and relationship between design and generated code. That will give them ability to maintain the design and code in future.

3) *Design of assessment task:* Assessment tasks were assigned group wise and were designed so that students must follow the industry standard tool using EA. An assignment group consists of two students. In the first assignment, students have been advised to use supplied commercial

software engineering tool. In the second assignment, it was mandatory to use the provided tool (EA) [24]. In addition to this, the second assignment includes more tasks related to industry practices such as development of Unified Modeling Language (UML) profile [43] and use of the UML profile [43] in their design, development and integration of the data model in the navigational and functional design for a selected web application. An example in the assignment was related to the lecture content where students were asked to develop the analysis and design model of a web application. Students will complete different analyses including content, interaction, functional, configuration and relationship-navigation as part of the requirement analysis. Then students need to prepare different design models including content, navigation, functional, architecture, component and web application extension UML (WAE) model [44]. A part of the assignment task was to prepare the conventional analysis and design models and then integrate this with UML profiling [43]. A part of a sample design task is presented in Fig. 1, Fig. 2 and Fig. 3.

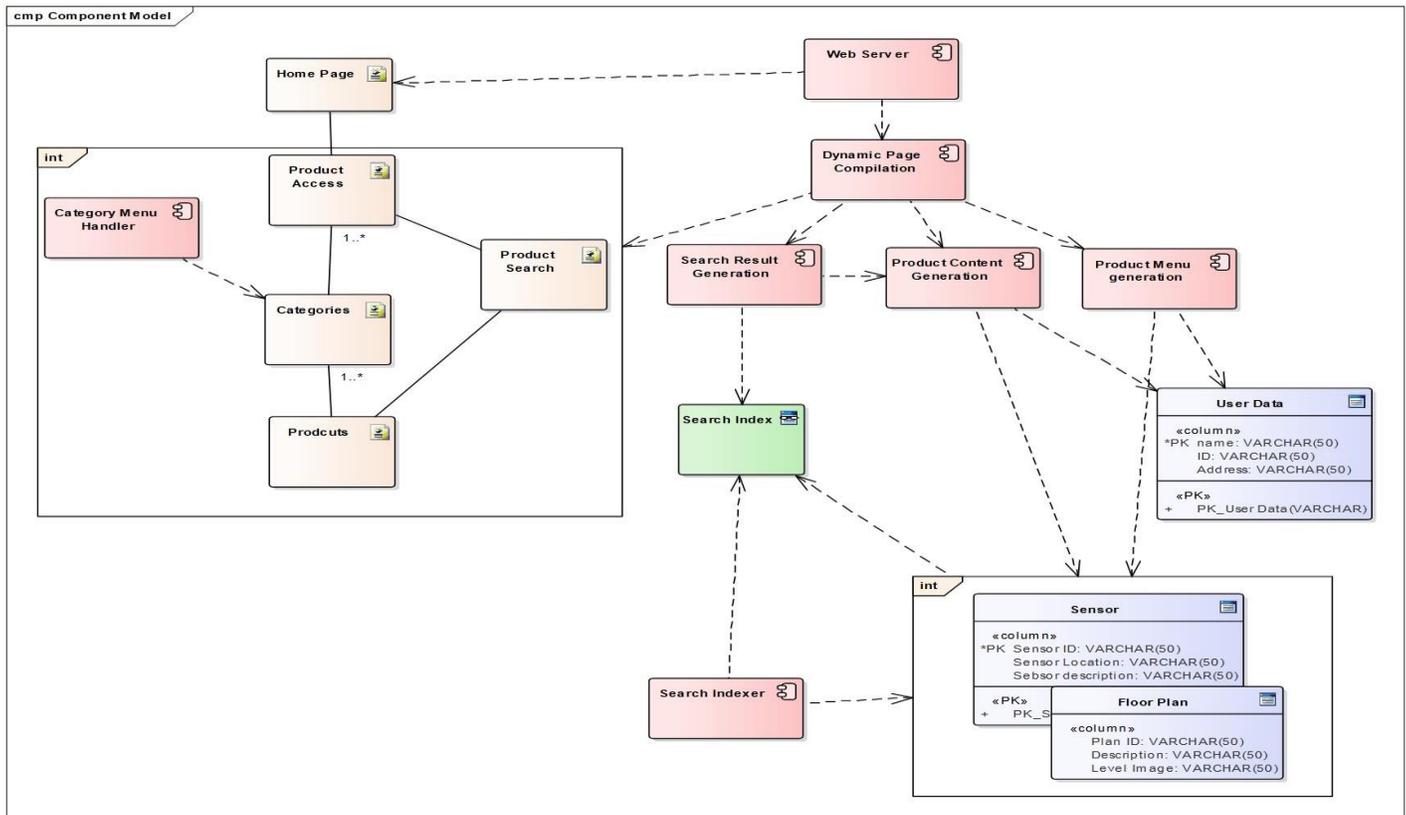

Fig. 1. A Functional Architecture of a Safe Home Web Application. The Design has been Redeveloped using EA following the Source[23].

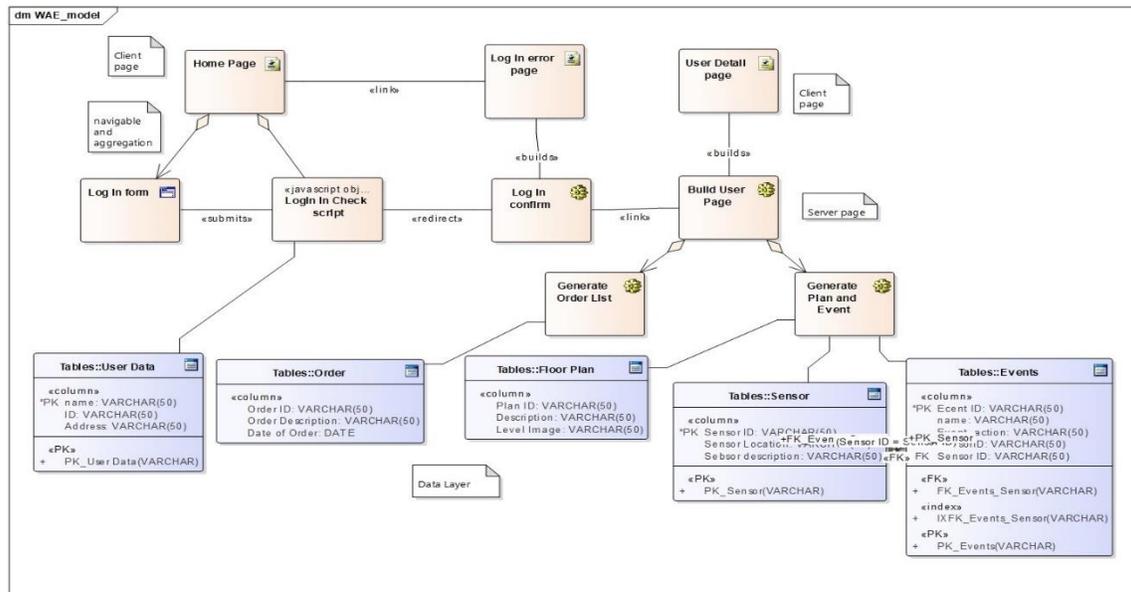

Fig. 2. A WAE Model of a Safe Home Web Application. The Design has been redeveloped by using EA According to [23].

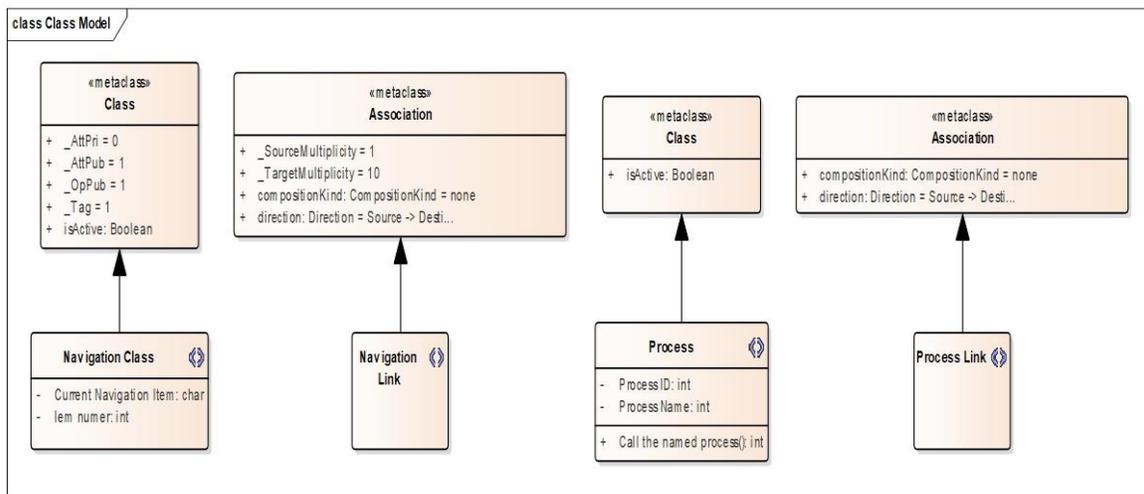

Fig. 3. A Part of a Typical UML that Student will Practice and Integrate in different Levels of their Web Application Analysis and Design.

#### IV. RESULTS AND DISCUSSION

##### A. Performance Measures

1) *Students' engagement*: An anonymous survey was conducted at week-6 of 11 week trimester and continued its participation till the end of trimester using CloudDeakin system which is an online teaching and learning system used by Deakin University. Different questions have been presented by asking whether the students were attracted and influenced in the practical and lecture classes through the delivery and teaching material. Students have also been asked whether they think the content will be helpful for them in finding a job. A sample question on assessing students' engagement has been presented as below: "Have these industry related activities using EA attracted and engaged you in the course?" Student's

answer should be in four categories "High", "Medium", "Low" and "Not at all".

2) *Importance of face to face contact*: To justify the significance of face to face contact, survey questions were introduced whether students feel comfortable with face to face teaching in practical class. A sample question is presented here: "Do you think it would be difficult if you don't come in practical class to learn the techniques of EA? (What is the level of difficulty?)" The answer should be: "Very difficult", "Difficult", "Easy" and "Very easy".

3) *Learning achievement*: This has been measured through the achieved marks of two assignments by the students and compared with earlier offer of the course.

The survey results are automatically stored in the CloudDeakin and statistical analysis has been shown in the below Tables I to Table VII.

TABLE I. QUESTIONS RELATED TO THE MEASURE MENTIONED IN ITEM-1: UML PROFILE HAS BEEN PRESENTED IN THE MATERIAL. DO YOU THINK THAT IT WILL HELP YOU LATER?

Answer	Number of Participants	Percentage
True	19	95%
false	1	5%

TABLE II. QUESTIONS RELATED TO THE MEASURE MENTIONED IN ITEM-1: UML PROFILE IS EXTENSIVELY USED IN INDUSTRIES AND ORGANIZATIONS. DO YOU THINK IT CAN BE AN ADDITIONAL INDUSTRY SKILL THAT YOU LEARNT FROM THIS COURSE?

Answer	Number of Participants	Percentage
True	19	95%
false	1	5%

TABLE III. QUESTIONS RELATED TO THE MEASURE MENTIONED IN ITEM-1: IN THIS COURSE, ENTERPRISE ARCHITECT (EA) HAS BEEN INTRODUCED FIRST TIME. MANY NEW AND INDUSTRY STANDARD OBJECT ORIENTED DESIGN TECHNIQUE USING EA HAS BEEN ADDED AND DELIVERED. HAVE THESE INDUSTRY RELATED ACTIVITIES USING EA ATTRACTED AND ENGAGED YOU IN THE COURSE?

Answer	Number of Participants	Percentage
High	8	40%
Medium	11	55%
Low	0	0%
Not at all	1	5%

TABLE IV. QUESTIONS RELATED TO THE MEASURE MENTIONED IN ITEM-1: HOW DID YOU ENJOY THE DEMONSTRATION OF PRACTICAL TASKS INCLUDING THE VIDEO AND IN CLASS DEMONSTRATION?

Answer	Number of Participants	Percentage
Very well	11	55%
Well	6	30%
Less	3	15%

TABLE V. QUESTIONS RELATED TO THE MEASURE MENTIONED IN ITEM-1: ARE YOU ENJOYING THIS COURSE SO FAR?

Answer	Number of Participants	Percentage
Very well	6	30%
Well	11	55%
Medium	1	5%
Not much	2	10%

TABLE VI. QUESTIONS RELATED TO THE MEASURE MENTIONED IN ITEM-2: DO YOU THINK IT WOULD BE DIFFICULT IF YOU DON'T COME IN PRACTICAL CLASS TO LEARN THE TECHNIQUES OF EA? (WHAT IS THE LEVEL OF DIFFICULTY?)

Answer	Number of Participants	Percentage
Very difficult	7	35%
Difficult	13	65%
Easy	0	0%
Very easy	0	0%

TABLE VII. QUESTIONS RELATED TO THE MEASURE MENTIONED IN ITEM-2: IF THIS COURSE IS OFFERED IN FULL ONLINE MODE IN WHICH THERE WILL BE NO PRACTICAL CLASS IN CAMPUS, DO YOU THINK IT WILL BE DIFFICULT FOR YOU? (WHAT IS THE LEVEL DIFFICULTY). GIVEN THAT SAME/CURRENT MATERIALS ARE PROVIDED BY ONLINE ONLY. (WHAT IS THE LEVEL OF DIFFICULTY?)

Answer	Number of Participants	Percentage
Very difficult	4	20%
Difficult	11	55%
Medium	5	25%
Easy	0	0%

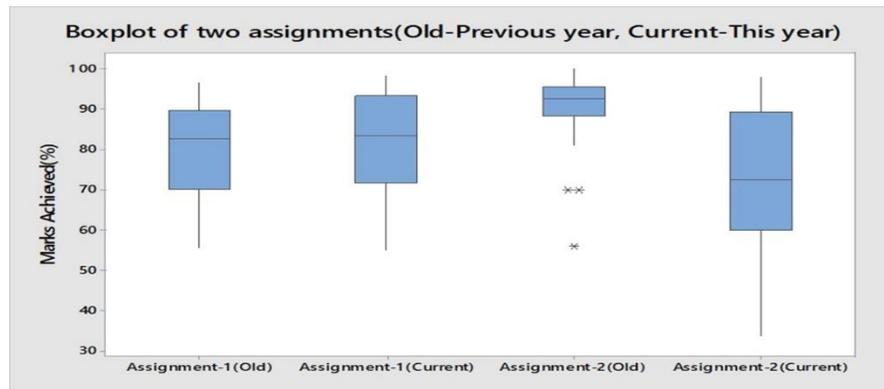

Fig. 4. Boxplot Comparison of Two Assessments' Results for this Year and Previous Year.

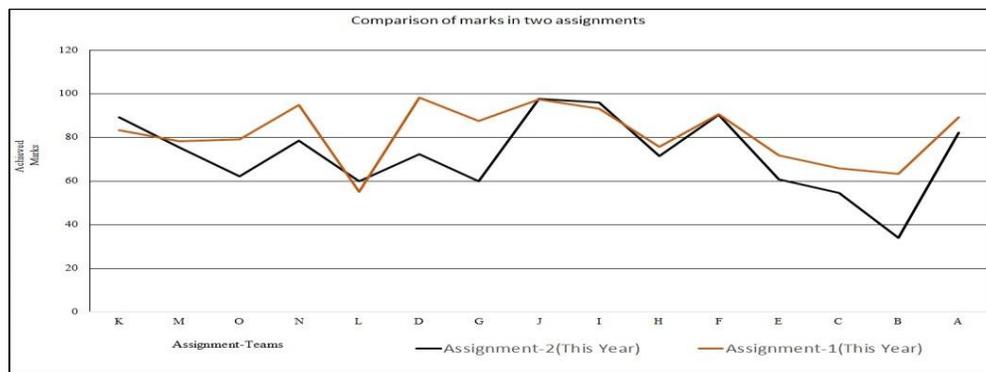

Fig. 5. Group Wise Marks for Two Assignments in this Year.

The survey results clearly show that the proposed approach has been able to engage students with a positive response rate equal to 95% for measure-1 metric within the participants. In the questions measure-2 survey results show that most of the students will face difficulties if they don't attend the practical class and fully online mode of the delivery will also be difficult for the students. To compare the performance of proposed approach for the measure-3, previous year's assessment results of the same course have been compared with this year's results. The students' personal information has been de-identified for both cases and then statistical analysis has been prepared which is presented in Fig. 4. It is observed in the results in Fig. 4 that there is a consistent distribution of marks in first and third quartile of this year's marks. In previous year, the boxplot for assignment-2 has very less gap between upper and lower extreme points with several outliers. In previous year, lower extreme of assignment-2 is also almost equal to the upper extreme point of assignment-2. This clearly shows an unbalanced distribution between the achievements. In contrast, this year boxplots of two assignments have similar patterns and wider extreme points. This shows a consistency and progressive achievement.

Fig. 5 shows that the group-wise marks follow approximately similar pattern across all the group. While in assignment-2, achieved scores are lower than assignment-1, it still follows similar pattern. The reason of lower score in assignment-2 could be explained as the increased difficulty in assessment task-2 compared to assignment-1.

## V. CONCLUSIONS

High graduate outcome rate (GOR) is one of the key objectives for a sustainable education system. Achieving a good GOR every year and continually outperform is not so easy. One of the key strategies in this pathway is to achieve sustainability in the learning itself. Equipping the learners with the environment and ways of deconstruction and reconstruction for relearning from past are the key factors to achieve high standard hands on experience (HOE) and thereby sustainability for learning. Among many hurdles to achieve the HOE, one of the most important challenges is to keep students proactively engaged in learning in a blended learning model with off-campus students. In this study, a combination of teaching strategies has been proposed including the context-based teaching and incorporation of innovative technologies to achieve sustainability in the learning and education (SLE). A case study is accomplished where software engineering course was considered as a test bed to justify the performance of proposed approach. In the proposed approach, particularly, high standard industry focused teaching material and commercially popular software engineering tools have been introduced to keep the students engaged and being tuned in the course, thereby achieve more sustainability in learning. The statistical analysis of the results of the case study proves the significance of the proposed approach. However, there are limitations in the proposed approach which can be expanded in a future work. 100% engagement was not possible which can be achieved by applying minor assessment on a weekly basis or a milestone task-based minor assessment in the course and then comparing the learning outcome with the proposed

approach in this study. Other strategies such as a combination of flipped classroom model and innovative tools can also be investigated.

# Modified Intrusion Detection Tree with Hybrid Deep Learning Framework based Cyber Security Intrusion Detection Model

Majed Alowaidi

Department of Information Technology, College of Computer and Information Sciences  
Majmaah University, Majmaah, 11952, Saudi Arabia

**Abstract**—In modern era, the most pressing issue facing modern society is protection against cyberattacks on networks. The frequency of cyber-attacks in the present world makes the problem of providing feasible security to the computer system from potential risks important and crucial. Network security cannot be effectively monitored and protected without the use of intrusion detection systems (IDSs). DLTs (Deep learning methods) and MLTs (machine learning techniques) are being employed in information security domains for effectively building IDSs. These IDSs are capable of automatically and timely identifying harmful attacks. IntruDTree (Intrusion Detection Tree), a security model based on MLTs that detects attacks effectively, is shown in the existing research effort. This model, however, suffers from an overfitting problem, which occurs when the learning method perfectly matches the training data but fails to generalize to new data. To address the issue, this study introduces the MIntruDTree-HDL (Modified IntruDTree with Hybrid Deep Learning) framework, which improves the performance and prediction of the IDSs. The MIntruDTree-HDL framework predicts and classifies harmful cyber assaults in the network using an M-IntruDtree (Modified IDS Tree) with CRNNs (convolution recurrent neural networks). To rank the key characteristics, first create a modified tree-based generalized IDSs M-IntruDTree. CNNs (convolution neural networks) then use convolution to collect local information, while the RNNs (recurrent neural networks) capture temporal features to increase IDS performance and prediction. This model is not only accurate in predicting unknown test scenarios, but it also results in reduced computational costs due to its dimensionality reductions. The efficacy of the suggested MIntruDTree-HDL schemes was benchmarked on cybersecurity datasets in terms of precisions, recalls, fscores, accuracies, and ROC. The simulation results show that the proposed MIntruDTree-HDL outperforms current IDS approaches, with a high rate of malicious attack detection accuracy.

**Keywords**—Cybersecurity; IntruDTree model; convolution recurrent neural network (CRNN); MIntruDTree-HDL; deep learning

## I. INTRODUCTION

The Internet is increasing being intertwined with social lives and revolutionising the way people learn or work, but is also getting exposed to serious security lapses [1] and identifying serious and new threats is a critical issue that must be addressed immediately. Cybersecurity is term used to represent technologies and processes designed to protect computers, networks, programmes from unknown attacks or

unauthorised accesses or alterations or destructions of data. The term information security is also used interchangeably with cybersecurity where the former recognizes human functions in security processes while the latter adds extra dimensions in focusing on possible targets [2]. However, since, it focuses on ethical components of society it has important ramifications. Techniques need to protect data in all forms including its processing, transmissions physical/virtual storages in information technologies by setting up higher security levels achieved in adopting professional measures associated with security [3]. Cybersecurity is thus prevention measures from unwanted accesses, usage, disclosures, or modifications of data using computer systems or networks.

Network security systems [4] are made up of two parts namely security systems and computers where Firewalls, antivirus software, and IDSs are all included in the overall picture. External and internal invasions are examples of security breaches. IDSs aid in the detection, determination, and identification of any illegal system activities executed by attackers [5]. Because of their ability to identify zero-day threats, they are enticing. Another benefit is that typical activity profiles can be customized based on the characteristics of systems or applications or networks which makes it difficult for attackers to execute operations unnoticed [6]. Additionally, the data that anomaly-based approaches identify (new assaults) may be leveraged to develop abuse detection signatures. Because previously undiscovered system actions might be classified as anomalies, the fundamental downside of these techniques is their generation of higher false alarms [7]. AIDSs (Anomaly based IDSs), on the other hand, evaluates network activities for trends, automatically construct data-driven models that profile usual behaviours and detect deviations in case of irregularities. The primary advantage of AIDSs over signature based IDSs are their ability to trace previously undisclosed vulnerabilities or cyber-threats [8]. However, treating previously undetected system actions as anomalies may also produce higher false alarms where MLTs can be employed to handle these issues.

Traditional MLTs fall into shallow learning groups as they do not adequately address attack classifications in real world network applications as they concentrate lesser on feature engineering or feature selections. Multi-classification attack detection tasks become less accurate as dataset sizes grow [9]. As a result, DLTs have lately been proposed as a way to improve the intelligence of IDSs, despite the lack of research

to compare such MLTs to publically available datasets [10]. These issues were the base motivation for this work which proposes a hybrid IDSs based on CNNs with evaluations of its efficacy [11].

The remainder of the research is structured as follows: The second section examines some of the most modern strategies for identifying cyber threats. The proposed technique is presented in Section III. Section IV summarises the findings and discusses them. The limitations are highlighted in Section V. The conclusion and future efforts are discussed in Section VI.

## II. RELATED WORK

IDSs generally identify malicious activities on networks while monitoring them for analyzing or discovering security risks. Several cybersecurity studies have been conducted with the aim of identifying or preventing cyber-attacks or security breaches. This section details about studies related to strategies for avoiding cyber-attacks.

Martnez Torres et al. [12] pioneered the use of MLTs in cybersecurity, defining several kinds of models based on (1) structures (network based/non-network based), (2) learning methods (supervised/unsupervised), and (3) complexities. Their descriptions were useful for further researchers on usage of MLTs in cybersecurity. Yin et al [13] proposed DLTs for IDSs where RNNs were used. The scheme called RNN-IDS showed that it was suited for building highly accurate classifications were in experimental results, and that their performances in binary/multi-class classifications surpassed performances of traditional MLTs. Kim et al. [14] also suggested DLT based IDSs which was tested on KDD Cup 1999 datasets. The scheme used LSTMs (Long Short Term Memories) with RNNs to learn. The study's results confirmed the success of DLT based IDSs in detecting malicious activities on networks. Al-Qatf et al [15] suggested IDSs based on STL (self-taught learning) frameworks and successful DLTs where the study's suggested method learnt features and reduced dimensionalities for minimizing training/testing execution times while enhancing prediction accuracies of assaults by SVMs (support vector machines). The study's suggested STL-IDSs technique improvised network IDSs while also introducing novel IDSs.

Khan et al. [16] proposed a pattern recognition technique for anticipating Denial of service (DoS) assaults with a higher prediction level. The method through DoS attacks is detected. DoS attacks are extremely serious assault that puts an organization's IT resources at risk by flooding them with fake messages or numerous requests from unauthorised users. Lekha et al [17] offered a broad overview of DMTs (Data Mining techniques) and cyber crimes in banking applications. According to the study, K-Means clustering, Influenced Association Classifiers, and J48 Prediction Trees combinations enabled complete, integrated, and precise cyber crime predictions in the banking sector. Law enforcements need to be strong to combat and prevent terrorism. Mitchell et al [18] developed probabilistic models based on stochastic Petri nets to identify behaviour of malicious nodes in CPSs (cyber physical systems) and IDRSs (intrusion detection and response systems) and thus respond to these real time

malicious events. Three different mechanisms for time-based IDSs were presented by Zimmer et al [19] where execution of illegitimate instructions in real-time CPSs were specifically identified using static timing analyses. Li et al [20] used CNNs with gated recurrent units for their suggested novel IDSs based on DLTs for industrial CPSs. The study used integrated learning in their architecture by allowing multiple industrial CPSs to work together and thus develop comprehensive new models of IDSs. Dutta et al. [21] established robust anomaly detections using semi-supervised MLTs that traced real time assaults. The proposed scheme applied DNNs (deep neural networks) using reconstruction errors for its detections. Their tests on the SWaT dataset show its efficacy by achieving AUC value of 0.9275 and better than other known anomaly detection algorithms. Sarker et al [22] introduced IntruDTree (Intrusion Detection Tree) security model based on MLTs that first examined the importance of security factors before constructing trees from fundamental features for generalizing IDSs. To evaluate performances of their resultant security models, the study compared findings of IntruDTrees with many classical MLTs including NBs (Naive Bayes), LRs (Logistic regressions), SVMs and KNNs (k-nearest neighbours).

IntruDTree did a reasonable job of detecting attempts at intrusion; but, it had issues with overfitting while it was learning, and it was unable to generalize what it had learnt so that it could apply it to new data. As a consequence of this, the goal of this effort is to improve classifier performances while at the same time recognizing cyber intrusions in real time. It increases the learning rates of IDSs, which in turn leads to an effective improvement in the performances and predictions of the system.

## III. PROPOSED METHODOLOGY

MIIntruDTree-HDL framework is suggested in this research work for predicting and classifying harmful cyberattacks in networks. The ranking of important features are done by constructing trees in IntruDTree framework. The performances of predictions are enhanced by CNN's convolutions which gather local information, while RNNs acquire temporal aspects. On the completion of the tree from training data, tests are used to validate the suggested framework. The proposed framework reduces computational complexities by reducing feature dimensionalities resulting in minimizing over fits of data and thus lays the base for improved prediction accuracies of unknown test cases. The contributions of this study can be summarized as:

- IDSs based on MLTs are presented emphasizing the importance of high dimensional security features.
- Proposing IntruDTree framework for ranking of security features based on their importance and subsequently uses them to build generalized trees encompassing chosen features.
- Increasing predictive performances of IDSs by using CNNs for collect local information and RNNs for capturing temporal features.
- Testing the IntruDTree framework for evaluating its performances.

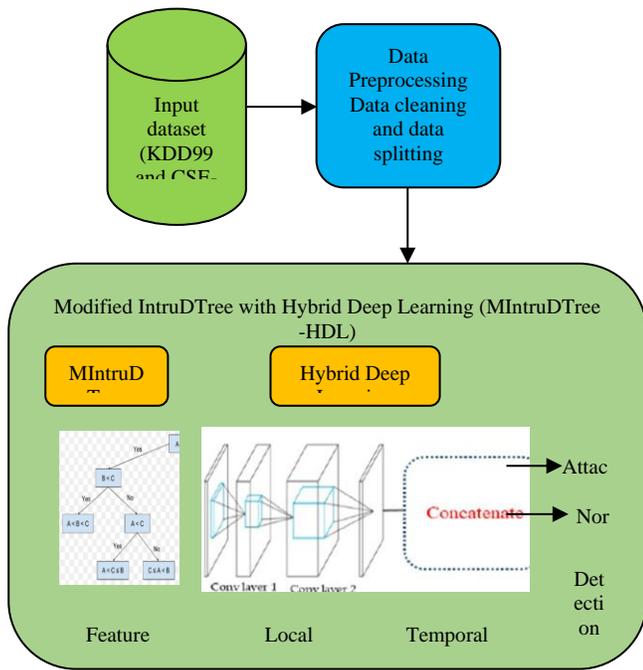

Fig. 1. The Suggested Methodology of this Research Work.

The experiment results of the suggested IntruDTree framework shows that it outperforms prior schemes in its detection previously unseen test cases of cyber intrusions. Fig. 1 depicts the suggested methodology.

A. Materials and Methods

The suggested IntruDTree framework is presented where security datasets are processed using a multitude of steps. Raw data is pre-processed, feature’s relevance are assessed and ranked for building generalized trees. The stages of the proposed methodology are detailed below in this section.

B. Exploring Security Dataset

Security datasets contain collections of data records which include many securities related information that can be used for constructing data-driven IDSs for cyber security. Understanding raw cybersecurity data and security event patterns are critical for detecting malicious irregularities or behaviors [22]. This work used intrusion detection dataset from Kaggle (largest machine learning and data science community) with two types of classes namely normal and anomalous. The dataset had 41 features with 3 qualitative features (protocol type, service, f delay). The other features were quantitative. The dataset’s security aspects are listed in Table I. The dataset had 25,000 examples obtained from simulated military network intrusion settings where US Air Force local area networks were modelled including TCP/IP dumps of data from networks. Networks were in parallel to cyber environments and subjected to a wide range of cyber-attacks or anomalies.

Encoding of features: As previously detailed, dataset had both numeric and notional values of security issues. Though most features were numerically valued, nominally values also existed (protocol type, service, f delay along with classes [anomaly, normal]). All nominal values were translated into

vectors for fitting them into MLTs where "Label Encoding" was used though most studies had used "One Hot Encoding". The values of tcp, udp, icmp, udp, icmp were label encoded for converting them into vectors.

TABLE I. FEATURES AND THEIR DATA TYPES

Feature name	Value Type	Feature Name	Value Type
dst_host_srv_count	Integer	Same_srv_rate	Float
flag	Nominal	dst_host_same_srv_rate	Float
srv_error_rate	Float	dst_host_srv_error_rate	Float
protocol_type	Float	count	Integer
dst_host_same_src_port_rate	Nominal	logged_in	Integer
error_rate	Float	dst_host_srv_diff_host_rate	Float
dst_host_srv_rerro_rate	Float	src_bytes	Integer
srv_error_rate	Float	service	Nominal
dst_host_count	Float	dst_host_error_rate	Float
srv_count	Integer	dst_host_diff_srv_rate	Float
seror_rate	Integer	wrpmg_fragment	Integer
srvidf_host_rate	Float	num_compromised	Integer
hot	Integer	dst_bytes	Integer
duration	Integer	diff_srv_rate	Float
root_shell	Integer	is_guest_login	Integer
urgent	Integer	land	Integer
su_attempted	Integer	num_failed_logins	Integer
num_file_creation	Integer	num_root	Integer
num_access_files	Integer	num_shells	Integer
is_host_login	Integer	num_outbound_cmds	Integer

Table I displays unique data distributions of outlined security methods. This work prepared raw datasets from above-mentioned features for its proposed IDSs based on DLTs. Processes and ranks of security features were based on and targeted DLT requirements and data patterns were constructed for ensuring anomalies and intrusions could be traced by intelligent cyber security services.

C. Preparation of Data from Raw Security Data: Data Preparations Include Encoding Feature and Scaling them According to Parameters of Intrusion Datasets

Feature scaling: Data normalizations are also called feature scaling in data pre-processing. Security feature may have a range of values and need to be scaled or normalized to acceptable ranges. This study used Standard Scaler to equalize security characteristics with mean values of 0 and standard deviations of 1. Subsequently, these normalized values were further analyzed while building the security model.

D. Determining Feature Importance and Ranking

On completion of investigations and preparations, relevance scores of security features were obtained and ranked based on their importance and to choose critical features for future processing. Their values varied between 0 and 1 where

0 indicates that the model's output has no relation to the feature, whereas a value of 1 shows that the model's output has a direct relationship with the feature. Thus, the "purity" of attributes were determined. Gini Indices are well-known measures for assessing node's impurity in statistics and data mining that generally judge frequency of random elements. It is the probability of mistakenly categorizing a randomly selected element in a security dataset based on class distribution of the dataset. In binary splits, Gini Indices of nodes  $n$  can be expressed as

$$I_{G(n)} = 1 - \sum_{i=1}^c p_i^2 \quad (1)$$

$$\Delta I_{G(n_p)} = I_{G(n_p)} - p_l I_{G(n_l)} - p_r I_{G(n_r)} \quad (2)$$

where  $p_i$  is the likelihood of elements being categorized as belonging to certain security classes and  $p_l$  and  $p_r$  are percentages of examples in nodes  $n_p$  allocated to child nodes  $n_l$  and  $n_r$ , respectively. Hence, Gini impurity equations determine feature's decreases of impurity. Greater ability of attributes to eliminate impurities improves its significance. Security features are sorted based on their computed importance and after evaluating the features, this work selects top  $n$  security features based on their relevance score values in order to develop effective tree-based security models by employing the  $n$  features selected.

#### E. Design of M-IntruDTree (Modified IntruDTree)

The chosen security characteristics are used to build trees for taking decisions by the intelligent data-driven IDS. In this model, all features of the dataset are not chosen instead only security features are chosen based on their relevance scores and ranks. A root is formed first, followed by the construction of connected branches of the tree in which the training dataset is divided into smaller sub-groups. This model properly matches the training data, however fails on generalizations of test data. Models memorizing training data noises tend to miss important patterns as over fits occur. DTs (Decision Trees) perform well on training data, but fail on unknown test data and hence to effectively over the issue of over fits, this study uses I-RLRs (Inductive Rule Learning Rates). Gini Indices are used to identify root node attribute in each level and gradually the tree is built with lower Gini values resulting in adding required counts of branches encompassing internal/leaf nodes with corresponding arcs or connecting edges. Labels on internal nodes are based on defined or selected security criteria while node's leaves are labelled with security features which can be one of the two: anomaly or normal. Fig. 2 displays multi-level trees with terminals or node's leaves with defined labels. This work's IntruDTree concentrates on achieving two main objectives which are reducing dimensionality of features based on their evaluated ranks or relevance and generating multiple-level trees from chosen critical features. Fig. 3 displays IntruDtree's considered IDS features like  $f$  latency, services, durations, and logged in.

- I-RERs (Inductive Re-substitution Error Rate): The fundamental idea underlying I-RERs is that instead of writing complete concept descriptions first and then trimming them, individual phrases are cut as soon as they are written which ensures the algorithm can eliminate training instances like trimming even before

learning subsequent phrases and preventing these examples from influencing success of learning clauses. Algorithm 1 depicts pseudo-code of this approach. Traditionally current collection of training examples is separated into growths (generally 2/3) and pruned (typically 1/3). However, due to the growth of collections, only one line is learned. In greedy approaches, literals from phrases are removed till deletions which can diminish validity of sentences are maintained on pruning sets. These sets are then used to derive clauses where prediction accuracy of trimmed clauses fall below empty clauses (i.e., clause with body fail), clauses are removed from concept descriptions, and I-RERs return learnt clauses. As a result, accuracy of trimmed phrases on pruning sets also serve as stopping criteria. The asymptotic complexity of I-RERs is  $O(n \log^2 n)$ , where  $n$  is the size of the training set. The cost of adding one clause in RERs is  $O(n \log n)$ , since the cost of picking sentences is  $\Theta(\log n)$  literals. As a consequence,  $O(n)$  instances are tested against fixed sets of criteria. I-RERs consider cutting every literal in phrases. Resulting in evaluating  $(\log n)$  literals on  $(n)$  samples in pruning sets at most  $O(\log n)$  times until the last phrase is discovered. hence, eliminating one clause costs  $O(n \log^2 n)$ . If I-RERs finish with identified constant sizes, the overall cost is also  $O(n \log^2 n)$  which is far less expensive than creating over fits determined by  $(n^2 \log n)$  under the same assumptions. For efficiency of computing costs, nodes must contain few values.

- $R(t)$ , re-substitution error rates at nodes  $(t)$  and done only once.
- $R(Tt)$ , re-substitution error rates at branch emerging from nodes  $(t)$  can be modified since  $Tt$  varies on pruning.
- $|Tt|$ , leaf node counts on branches from nodes  $(t)$  and may change on pruning.

To calculate re-substitution error rates  $R(t)$ , data points in each class that arrive at node  $t$  are divided by the data point counts in each class that arrive at node  $t$ . Assuming the fraction of points in classes are utilized to build class priors, then  $R(t)$  can be computed. After pruning, both re-substitution error rates of branches coming out of node  $t$  and the leaf nodes counts on the branch coming out of node  $t$  fluctuate. These variables will need to be adjusted because the leaf nodes counts would have dropped after pruning. To be more specific, all values for branch's ancestor nodes must be changed where  $R(Tt)$  and  $|Tt|$  may be computed using a recursive process.

Counts of leaf nodes in branches of nodes  $(t)$  are determined using bottom up sweeps of constructed trees. These leaf nodes counts are equal to the sum of counts of leaf nodes on the right child nodes and counts of leaf nodes on the left child nodes. The leaf node counts for child nodes are determined before determining the counts of parent nodes in bottom up sweep operations. The values of  $R(Tt)$  are also equal to the sum of two child node values of  $(t)$ . These three values are the base for determining ratio  $g(t)$  and identifying

weakest connections. The new is the comparable ratio at the weakest connection  $\alpha$  which guarantees that sequences of  $\alpha$  are obtained in pruning are strictly increasing. When there are many weakest links, for example, if  $g_k(t_k) = g_k((t')_k)$ , then define:

$$T_{(k+1)} = T_k - T_{(t_k)} - T_{((t')_k)} \quad (3)$$

Branch nodes can be nested or share nodes where pruning procedure resulting in sequence of nested sub-trees can be:

$$T1 > T2 > T3 > \dots > t1 \quad (4)$$

Algorithm 1 describes the general procedure for constructing an IntruDTree. Given a training intrusion dataset,  $DS = \{X1, X2, \dots, X_m\}$ , where  $m$  denotes the amount of the data.  $n$ -dimensional characteristics are used to represent each instance. The training data is also divided into various cyber-attack classes. CA stands for fnormal and anomalyg. An IntruDTree, a rule-based classification tree connected with DS, is the result. Fig. 2 depicts single feature's rules, when flag's value is RSTR, it implies anomalous. Multi-aspect rules for flag values can be SF implies ftb service and duration value of four implies anomalous. By traversing the resulting IntruDTree, multiple rules for security can be retrieved based on which the final outcome would result in normal or abnormal.

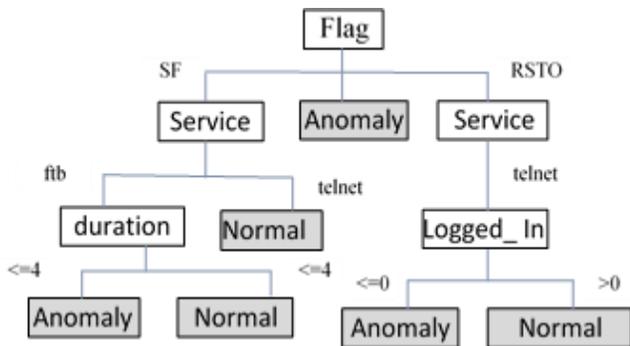

Fig. 2. M-IntruDTree Built from Features.

#### F. Hybrid Deep Learning Model

With a data processing architecture, hybrid deep learning focuses on tackling actual ID challenges. By combining a CNN and an RNN model, hybrid deep learning reduces these issues [23]. The main structure of the HDL that occurs here is the source of the experiment. Fig. 1 shows the suggested model in further detail. A CNN contains two main components, according to the HDL: (i) a feature extractor; and (ii) a classifier. Convolution and pooling layers are the two layers that make up the feature extractor. The feature map, which is the extracted result, is used as the input to the classification's second component. In this method, CNN gains a thorough understanding of the local characteristics. However, it has a flaw in that it ignores the temporal relationship between significant traits. After the CNN layers, recurrent layers were added to capture both spatial and temporal data more effectively. This method effectively handled the disappearing and inflating gradient difficulties, enhancing the capacity to record and learn from variable extent sequences and spatial and temporal correlations. In the

HDL model, CNNs are hybridized as RNNs, and inputs are initially processed by CNNs, after which the outputs are relayed via recurrent layers to form sequences at time steps, allowing capture of both spatial and temporal characteristics. As with AIDS, the bulk of traffic is categorized based on its behavior, which should not be biased or conflicting with the IP address, hence the IP address characteristics were also eliminated. Training sets were utilized for training while validation sets were used for fast prototype evaluations while training and testing sets evaluated the final model. Moreover, it was noticed that the dataset had too many instances of typical network's traffic, which can impact classifications the model.

---

#### Algorithm 1. Pseudocode of MIntruDTree

---

**Data:** Dataset:  $D = X_1, X_2, \dots, X_m$  // Occurrences of  $X_i$  have features and CIs (cyber Intrusions) class information

**Result:** MIntruDTree

```

1 Procedure MIntruDTree (D, features_list, CIs);
2 //generate feature significance scores
3  $imp\_score \leftarrow compute\_score\ features\_list$ 
4 //Choose significant features
5  $imp\_features\_list \leftarrow ChosenFeatures(\ features\_list, imp\_score, n)$ 
6 TreeGens(D,  $imp\_features\_list$ , CIs)
7  $N \leftarrow createNodes()$  //create tree's root node
8 if all instances in D belong to the same class of CIs then
9 return N as leaf node labelled with class CI.
10 end
11 if  $imp\_features\_list$  is null then
12 return N as leaf node labeled with majority class of D; // majority votes
13 end
14 identify features with highest precedence feature  $F_{split}$  for dividing and assigning  $F_{split}$  to node N.
15 for each feature's value  $val \in F_{split}$  do
16 create subset  $D_{sub}$  of D with val.
17 if  $D_{sub} \neq \emptyset$  then
18 attach node returned by TreeGens( $D_{sub}$ , { $imp\_features\_list - F_{split}$ }, CIs)) to node N;
19 end
20 // Inductive re-substitution error rates
21 calculate  $R(T_t)$  and  $|T_t|$ 
22 modify nested subtrees  $T1 > T2 > T3 > \dots > t1$ 
23 attach leaves labeled with majority class of D to node N;
24 end
25 return N

```

---

#### IV. RESULTS AND DISCUSSION

The experimental outcomes of this work are briefly discussed and reported in this section. First, we'll set up our tests to assess the suggested MIntruDTree-HDL cyber security model, and then we'll talk about the outcomes. This project uses the KDD99 and CSE-CIC-DS2018 datasets and is written in Java. These datasets are chosen based on a range of characteristics, including the amount of samples, attributes, and classifications. To compute various performance measures, TPs (true positives), FPs (false positives), TNs (true negatives), and FNs (false negatives) are measured. Precision, defined as the proportion of relevant retrieved instances, was the original performance metric. The second performance

parameter was recall, which was defined as the percentage of relevant instances. Despite their usually contradicting character, the assessments of accuracy and recall are both critical in evaluating the efficiency of a prediction approach. As a result, these two measures may be combined with equal weights to form the F-measure, which is a single metric. The last performance criterion was the accuracy measure, which was defined as the fraction of correctly predicted occurrences compared to all anticipated instances.

Precisions are defined as proportions of accurately identified positive observations against all predicted positive observations.

$$\text{Precision} = \text{TP}/(\text{TP}+\text{FP}) \tag{5}$$

The ratio of accurately detected positive observations to total observations are termed recalls.

$$\text{Recall} = \text{TP}/(\text{TP}+\text{FN}) \tag{6}$$

F-measures can be defined as weighted averages of Precisions and Recalls and hence they consider FPs and FNs.

$$\text{F1 Score} = 2 * (\text{Recall} * \text{Precision}) / (\text{Recall} + \text{Precision}) \tag{7}$$

Accuracies are computed in terms of positives and negatives as shown below:

$$\text{Accuracy} = (\text{TP}+\text{TN})/(\text{TP}+\text{TN}+\text{FP}+\text{FN}) \tag{8}$$

This work selected features that satisfies threshold values of  $t = 0.02$  which resulted in the selection of 14 features based on importance scores of Table II.

Fig. 3 illustrates precision comparison values between the proposed and existing method for detecting the cyber-attacks. Therefore, the results verify that the ranking the features using M-IntruDTree can be effective in extracting the given data. Thus the proposed model has the number of useful features does not affect the performance of the jointly learnt features transformation very much. From the given two dataset, KDD99 has high detection rate than the other CSE-CIC-DS dataset.

TABLE II. KDD99 DATASET'S TOP RANKED FEATURES WITH THEIR IMPORTANCE SCORES

Ranking	Security Feature Name	Importance Score
01	src_bytes	0.258093
02	dst_bytes	0.129825
03	flag	0.073396
04	dst_host_same_srv_rate	0.059504
05	dst_host_srv_count	0.053630
06	dst_host_diff_srv_rate	0.046281
07	diff_srv_rate	0.041144
08	count	0.040548
09	same_srv_rate	0.036620
10	protocol_type	0.31650
11	dst_host_same_src_port_rate	0.025566
12	service	0.023904
13	serror_rate	0.023188
14	logged_in	0.020901

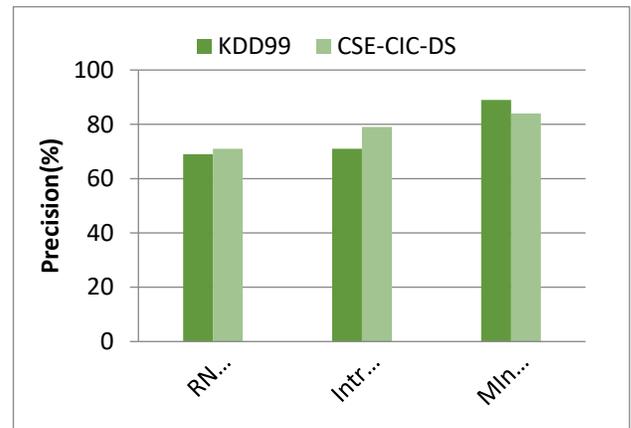

Fig. 3. Precision Comparison Results between the Proposed and Existing Method for Detecting the Cyber.

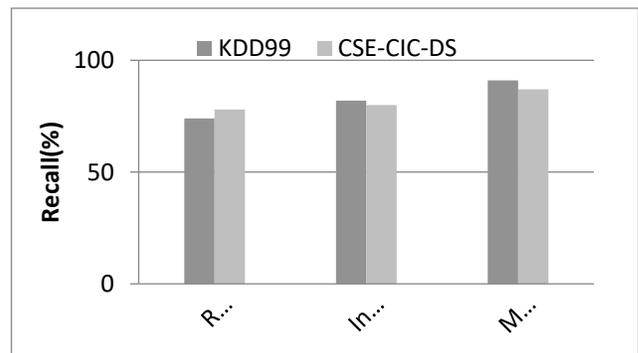

Fig. 4. Comparative Recall Values of the Proposed and Existing Methods for Detecting Cyber Attacks.

Fig. 4 illustrates recall comparisons between the proposed and existing method for detecting the cyber-attacks. Thus the results show that the proposed method gives the high recall results of 91% whereas the existing technique has less recall results such as IntruDTree method metric has 82%, and the RNN-IDSs method metric has 74% for KDD99 data. On the other hand, proposed method gives the high recall results of 87% whereas the existing technique has less recall results such as IntruDTree method metric has 80%, and the RNN-IDSs method metric has 78% for CSE-CIC-DS. Fig. 5 depicts F-measure comparative values of the proposed and existing methods for identifying cyber assaults.

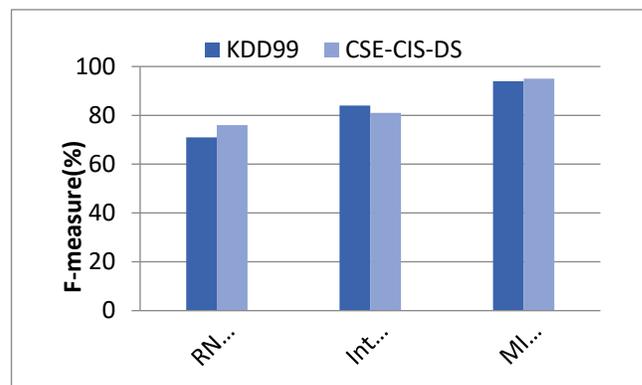

Fig. 5. F-measure Comparative Values of the Proposed and Existing Methods for Identifying Cyber Assaults.

The findings show that the suggested MIntruDTree outperforms existing attack detection strategies in terms of F-measure values.

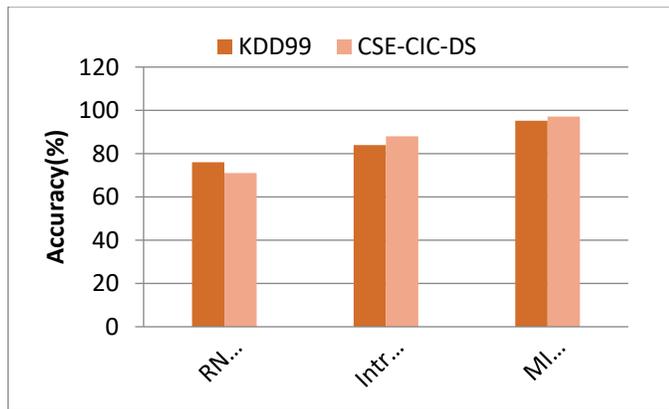

Fig. 6. Comparative Accuracies of Proposed and Existing Methods in Detecting Cyber Attacks.

Fig. 6 depicts the accuracy comparison findings between the proposed and current methods for detecting cyber assaults. In addition, the suggested method's average accuracy of classification rates (in per cent) is shown in comparison to other approaches employing IntruDTree and RNN-IDSs across ten separate runs. As the results show, the suggested technique has greater detection accuracies than previous methods in most circumstances. Furthermore, the rank of feature extraction algorithms is presented based on the detection accuracy attained for a specific dataset. The findings show that the suggested MIntruDTree-HDL approach ranked top when compared to other methods.

#### V. LIMITATIONS

IDSs also have certain limitations hence this work integrates two techniques for overcoming shortcomings of IDSs where the suggested method benefits by taking advantage of the used approaches. The MIntruDTree-HDL framework is presented to improve learning rates of IDSs and thus effectively enhance its performances and predictions.

#### VI. CONCLUSION

A modified IDSs tree (MIntruDTree) and a Hybrid Deep Learning (HDL) security model are discussed in this work where important security factors were first prioritized, and subsequently tree-based generalized IDSs were created based on the essential characteristics that were chosen. This was done to ensure that the security model was effective in terms of prediction accuracy for unknown test conditions, as well as efficient by reducing the computational cost of generating the future MIntruDTree-like model by processing fewer features. Following the CNN layers, we added recurrent layers to better capture both spatial and temporal data. We hoped to overcome the vanishing and growing gradient problems with our strategy, improving the ability to collect spatial and temporal correlations and learn effectively from them. The primary motivation for developing IDSs based on DLT categorization. The suggested IDSs aid in the reduction of computing complexity and improve the accuracy and DRs of IDSs. Known classification metrics were used to evaluate both

traditional MLTs and DLTs (DRs, Accuracies, Precisions, Recalls, and F1-scores). The results of the simulations reveal that the proposed MIntruDTree with HDL may successfully calcify harmful attack events. In the KDD99 dataset, the total accuracy of normal and other forms of assaults is approximately 95.24 per cent, while in the CSE-CIC-IDS2018 data, it's around 97.12 per cent. On the basis of the results of the simulation, we can conclude that it is possible to develop an effective security solution against harmful attacks by utilizing a MIntruDTree-based hybrid distributed ledger technology (DLT). This methodology is improved further to include additional deep learning methods and a feature extraction strategy if there are different identification problems in actual datasets currently being used. This is done in preparation for the possibility that these problems may exist.

#### ACKNOWLEDGMENT

Dr Majed Alowaidi would like to thank the Deanship of Scientific Research at Majmaah University for supporting this work under Project No. R-2022-284.

# Performance Comparison between Meta-classifier Algorithms for Heart Disease Classification

Nureen Afifah Mohd Zaini, Mohd Khalid Awang

Faculty of Informatics and Computing, Universiti Sultan Zainal Abidin, 22000 Tembil, Terengganu, Malaysia

**Abstract**—The rise in heart disease among the general population is alarming. This is because cardiovascular disease is the leading cause of death, and several studies have been conducted to assist cardiologists in identifying the primary cause of heart disease. The classification accuracy of single classifiers utilised in most recent studies to predict heart disease is quite low. The accuracy of classification can be enhanced by integrating the output of multiple classifiers in an ensemble technique. Even though they can deliver the best classification accuracy, the existing ensemble approaches that integrate all classifiers are quite resource-intensive. This study thus proposes a stacking ensemble that selects the optimal subset of classifiers to produce meta-classifiers. In addition, the research compares the effectiveness of several meta-classifiers to further enhance classification. There are ten types of algorithms, including logistic regression (LR), support vector classifier (SVC), random forest (RF), extra tree classifier (ETC), naïve bayes (NB), extreme gradient boosting (XGB), decision tree (DT), k-nearest neighbor (KNN), multilayer perceptron (MLP), and stochastic gradient descent (SGD) are used as a base classifier. The construction of the meta-classifier utilised three different algorithms consisting of LR, MLP, and SVC. The prediction results from the base classifier are then used as input for the stacking ensemble. The study demonstrates that using a stacking ensemble performs better than any other single algorithm in the base classifier. The meta-classifier of logistic regression yielded 90.16% results which is better than any base classifiers. In conclusion, we could assume that the ensemble stacking approach can be considered an additional means of achieving better accuracy and has improved the performance of the classification.

## I. INTRODUCTION

According to research published by the World Health Organization (WHO), heart disease has been one of the leading causes of death worldwide. It is estimated to have reached 17.5 million in 2012, 17.9 million in 2016, and 22.2 million by 2030 [1]. Heart disease is very dangerous as it can be a silent killer to a patient. The individual must be alert to the main symptom of heart disease. The usual symptoms of heart disease risk factors include tobacco use, alcohol consumption, physical activity, fruit and vegetable consumption, hypertension, and obesity [2]. Providing high-quality care at affordable rates is a significant problem for the healthcare industry, and accurate diagnoses are the hallmarks of high-quality care [3]. Data mining is an interdisciplinary subject of computer science and statistic whose overall objective is to extract information from a dataset and transform the data into a usable structure [3], [4].

Using magnetic resonance imaging (MRI) and CT angiography to diagnose heart disease is highly complex. The equipment is bulky and prohibitively expensive for most individuals [5]. This research proposes a technique that can reduce the time and effort required for a specialist to diagnose cardiac problems in patients. The study of how to build compelling multi-classifier ensembles has been one of the most studied, and in most cases, ensemble techniques perform better than single classifiers [6]. The approach presented in this paper uses the stacking ensemble method to enhance the accuracy of heart disease prediction. This method is used to improve the overall accuracy of predictions, as the combination of models provides a collaboratively general solid model [7].

The single classifier approach is used most of the time in heart disease prediction research. The accuracy of classification may be improved by combining the results of many different classifiers using a method known as ensemble classification. Despite having the best classification accuracy, current ensemble approaches that include all classifiers are very resource-intensive. In order to create meta-classifiers, the stacking ensemble utilized in this study finds the best subset of classifiers. The study also looks at how effective various meta-classifiers are in improving classification.

Section II of this paper presents a review of related literature. Section III covers the research methodology that intricates the details of datasets and machine learning techniques. The overall results of the experiment are then presented in Section IV. Finally, a conclusion is presented in Section V.

## II. LITERATURE REVIEW

### A. Data Mining

Data mining is a cognitive method that identifies hidden approach patterns in massive datasets [8]. The effectiveness of data mining depends heavily on the method employed, and the feature is chosen since there are duplications and inconsistencies in healthcare industry medical datasets [9]. Data mining can be applied to improve disease risk assessment, intervention design, and monitoring of chronic conditions [10]. Hence, a reduction in patient admissions and insurance claims is possible.

Data mining is seen as critical yet challenging work that must be completed precisely and efficiently, especially in the healthcare environment. Comparison of different types of classification in machine learning has the potential to provide

high classification accuracy. Prediction accuracy may vary depending on the learning technique used [11].

The classification, which is one type of data mining activity, is crucial since it has the ability to classify such as identify the two categories whether the patient diagnoses with heart disease or non-heart disease. Several usual symptoms can be linked to detect heart disease, but not all are accurate. On the other hand, machine learning, a subset of artificial intelligence, is widely used in renowned research and can be utilised in the healthcare industry to overcome this issue. In return, it can help an expert to detect the disease and suggest an appropriate action to be taken.

### B. Ensemble Method

A single classifier, such as Neural Network or Decision Tree, has been widely used in heart disease classification, but the performance of such algorithms is still lacking and need to be improved. Meanwhile, compared to a single classifier, the accuracy of ensemble methods such as stacking is significantly greater. Ensemble method approaches frequently increase predictive performance and this is due to various factors. Overfitting avoidance, computational advantage, and representation are the main factors why the ensemble method is able to improve predictive performance [12], [13]. To distinguish the main factors of the ensemble method, the following description provides examples of both:

1) Overfitting avoidance: Overfitting happens when the classifiers are tightly matched to the training data and thus lose the capacity to generalise to the test data. As a result, the performance of classification in the test set is inferior to the training set [14].

2) Computational advantage: Individual learners who undertake local searches may become mired in local optimality. By merging several learners, the ensemble method reduces the likelihood of achieving a local minimum [12].

3) Class imbalance: When there is a class imbalance in training data, learners will often overclassify the majority group because of its higher prior probability. Consequently, occurrences belonging to the minority group are more frequently misclassified than instances belonging to the majority group [15].

4) Curse of dimensionality: For high-dimension datasets, dimensionality reduction is performed prior to applying the algorithm in order to minimise the impacts of the curse of dimensionality. The more features of the dataset, the more challenges are produced for the algorithm used [16].

This study purposely proves the concept of learning and making decisions is not new to humans. As a human, we employ this concept on a regular basis to make significant decisions, such as seeking advice from multiple experts or consulting with multiple physicians before undergoing major medical treatment [17].

### C. Ensemble Stacking

Boosting, bagging, and stacking are the three most prominent ensemble learning approaches in machine learning. Ensemble techniques have been utilised in the current study to

improve heart disease prediction classification accuracy. When weak learners are combined with meta-learners in tandem, a more accurate prediction can be made.

Stacking often accounts for a variety of weak learners [18]. Stacking architecture improves the accuracy of classification over a single classifier as it uses various ways to solve classification problems [19]. Stacking is a learning strategy that uses a meta-classifier to integrate the results of numerous basic classifiers learnt on the same dataset. Each algorithm has its own set of benefits and drawbacks. By merging the classifiers, the outcome may be enhanced.

### D. Classification Algorithm in Data Mining

There are two main data mining approaches which are descriptive and predictive. These approaches uncover a hidden pattern in the vast data [20]. Classification can be categorised as supervised machine learning, in which we must train the data. Functional representations include decision trees, logistic regression, naïve bayes, extreme gradient boosting, k-nearest neighbor, extra tree classifier, multilayer perceptron, stochastic gradient classifier, random forest, and support vector machine.

A health management system is often used inside the healthcare setting to keep track of the large amounts of data pertaining to patients and the treatment they get. Such knowledge is useful, particularly if we put it to use in real-world situations. The majority of the medical database consists of discrete data. Thus, making decisions based on discrete facts becomes complex and difficult. Machine Learning which is a subset of data mining, handles large scale well-formatted datasets efficiently [21].

Numerous strategies for predicting heart disease are proposed, each of which employs a unique set of techniques and algorithms. Gaining great service at an affordable price remains the prime and challenging problem for healthcare organisations [22]. This study aims to help the specialist in the detection of heart disease in patients in the early stages.

### E. Data Mining in Heart Disease Prediction

The use of data mining is an effort to meet the urgent need to extract relevant knowledge buried in clinical data, specifically to design a solution capable of predicting the presence or absence of heart disease using data mining [23]. In predicting heart disease, several data mining techniques such as regression, clustering, association rule, and classification algorithms consists of naïve bayes, decision tree, random forest, and k-nearest neighbor to categorise various heart disease [24].

According to [25], accuracy and receiver operating characteristics (ROC) are compared. The researcher obtained 303 records with 14 sets of variables and divided the data into training and testing. ROC plot is the most used for evaluating classifier performance. It is based on specificity and sensitivity, which are specificity measures of the negative part, and sensitivity is based on the positive part. Four machine learning algorithms, consisting of logistic regression, random forest, stochastic gradient boosting and support vector machine, are tested for this research. As a result, a comparison between the accuracy and ROC of the model prediction shows

that logistic regression is the highest prediction, with an accuracy of 87.00%.

The research by [26] used Gini index and prediction models. Neural network and Gini index are tested, and the results performed that Gini index results with the most remarkable precision. A decision tree is used to predict the accuracy and sensitivity of coronary illness. Voting methods are known to produce a more precise decision tree. The decision tree makes up of these critical elements, which are the decision hub and edge or branch. The decision hub determines the test features, while the edge or chapter compares to one of the possible quality esteems and denotes one of the property findings. The class to which the question belongs is contained in a leaf, also known as an answer hub.

The author of the study [27] compared the classifier using principal component analysis (PCA) and without PCA. The authors experimented with five types of algorithms for the research. Decision tree, logistic regression, support vector machine, multilayer perceptron, and naïve bayes are tested. Logistic regression achieved the highest with 86.00% without PCA, and random forest achieved the highest with a PCA of 84.00% accuracy. The following areas of interest have seen the most application of PCA, such as classification, data clustering, and dimension reduction.

The study by [28] used a dataset from UCI and proposed four classifiers for the research. Naïve bayes, decision trees, support vector machines, and k-nearest neighbour are tested. According to the researcher, naïve bayes achieves the highest accuracy with 88.67%. Naïve bayes is a straightforward algorithm to implement. Besides, this algorithm also can be categorised as space efficient and fast to train. The author claims that knowledge discovery is essential to handling a large dataset for the identification of heart disease. Managing a massive dataset for heart disease detection and finding the relevant information to forecast a heart attack in its early stages based on patient indicators is challenging.

In 2020, [29] analysed the detection of heart disease using these six algorithms: artificial neural network (ANN), logistic regression, k-nearest neighbour, support vector machine, decision tree, and naïve bayes. The researchers also stated the standard state-of-the-art features selection algorithms consisting of Relief, MRMR, LASSO, and Local-learning-based-features selection (LLBFS) are used to select the features. The researcher also proposes fast conditional mutual information (FCMIM) features selection algorithms for feature selection. LOSO technique (Leave-one-subject-out) cross-validation is applied to select the best hyper-parameter for the best model selection. The best accuracy achieved is SVM with the proposed feature selection algorithm (FCMIM) of 92.37%, which is very good compared to the previously proposed method.

Based on the above discussion, there are two approaches to heart disease prediction: single classifier and meta-classifier. Most of the heart disease prediction research uses the single classifier approach. Existing ensemble methods that incorporate all classifiers are highly resource-intensive, notwithstanding their ability to provide the highest classification accuracy. This paper thus presents a stacking

ensemble that picks the optimum subset of classifiers in order to generate meta-classifiers. In addition, the study examines the efficacy of many meta-classifiers to improve classification. The following section will describe our proposed stacking ensemble in detail.

### III. METHODOLOGY

This study is based on the UCI dataset of people with cardiac disease. There are 303 records and 13 attributes in total, which are divided into training and test sets [33]. Table I explains the dataset features for the heart-disease patients.

TABLE I. DESCRIPTION OF ATTRIBUTES DATASET FEATURES

No	Feature Name	Type of data	Data Description
1	X <sub>1</sub> = age	Numeric	The age of the patients
2	X <sub>2</sub> =sex	Nominal	Female, male
3	X <sub>3</sub> = cp	Nominal	Chest pain type Value 0 = Typical angina Value 1 = Atypical angina Value 2 = non-anginal pain Value 3 = asymptomatic
4	X <sub>4</sub> = trestbps	Numeric	Resting blood pressure
5	X <sub>5</sub> =Chol	Numeric	Serum cholesterol
6	X <sub>6</sub> = Fbs	Nominal	Fasting blood sugar
7	X <sub>7</sub> =restecg	Nominal	Resting electrocardiographic
8	X <sub>8</sub> =thalach	Numeric	Max heart rate
9	X <sub>9</sub> = exang	Nominal	Exercise-induced angina
10	X <sub>10</sub> =oldpeak	Nominal	ST depression induced by exercise relative to the rest
11	X <sub>11</sub> =Slope	Nominal	The slope of peak exercise
12	X <sub>12</sub> =Ca	Nominal	Number of major vessels
13	X <sub>13</sub> = Thal	Nominal	The heart status
14	Y = Target	Nominal	Diagnosis of heart disease

#### A. Proposed Stacking Ensemble

Fig. 1 is a framework on how our proposed meta-classifier is designed, and Table I explains the details of the dataset. The goal of the research is to choose the optimal subset of base classifiers for creating the meta-classifier. Further, the best combination of base classifiers and meta-classifiers is determined by comparing several meta-classifier learning algorithms. The proposed stacking model is described in more detail below:

- 1) Split the data into training and test set.
- 2) Develop base classifiers based on ten different learning algorithms.
  - a) Train and test the base classifiers.
  - b) Rank the base classifiers based on the accuracy of prediction performance.
- 3) Develop meta-classifier based on three different learning algorithms.
  - a) Select the optimum number of base classifiers (2, 4, 5, 7 and 10).
  - b) Test the performance of the meta-classifiers.

4) The final model of ensemble stacking is obtained from the combination of the optimum subset of base classifiers and the meta-classifier algorithm.

From the UCI dataset, 13 attributes and ten base classifiers are utilised, as shown in Fig. 1. The output from the level-1 base classifiers is then applied to the level-2 meta-classifier and followed by the selection of optimal subset of base classifiers. Finally the model is evaluated using three distinct meta-classifiers learning algorithms.

### B. Level-1 base Classifiers Construction

The base model classifier is stimulated by certain training data and generates different predictions. The main stage of developing the ensemble technique is to populate the database with a group of base classifiers. As a result, each of the base models will produce its own set of predictions. Base classifiers for this research are created using ten different learning algorithms. Listed below are the selected algorithms:

- 1)  $C_1 = \text{LogisticRegression}()$
- 2)  $C_2 = \text{KNeighborsClassifier}()$
- 3)  $C_3 = \text{DecisionTreeClassifier}()$
- 4)  $C_4 = \text{RandomForestClassifier}()$
- 5)  $C_5 = \text{GaussianNB}()$
- 6)  $C_6 = \text{XGBoostClassifier}()$
- 7)  $C_7 = \text{SVC}()$
- 8)  $C_8 = \text{MLPClassifier}()$
- 9)  $C_9 = \text{SGDClassifier}()$
- 10)  $C_{10} = \text{ExtraTreesClassifier}()$

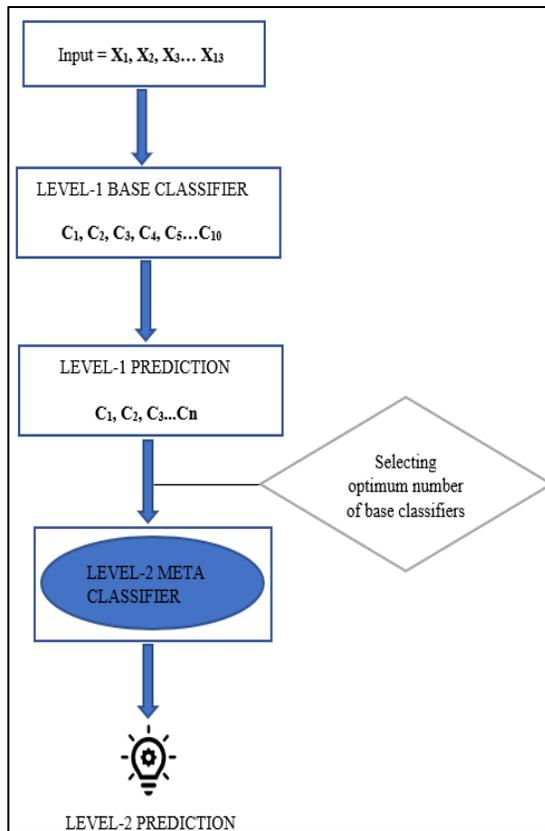

Fig. 1. Proposed Ensemble Stacking for Heart Disease Classification.

### C. Level-2 Meta-classifiers Construction

Results obtained from the base classifier are then tested for the ensemble stacking method. Three different learning algorithms are tested with different subset of base classifiers. Meta-learning encompasses a wide range of activities, such as observing the performance of different machine learning models about learning tasks, learning from metadata, and performing a faster learning process for new tasks. A few learning algorithms' classification performances will be evaluated to select optimal meta-model classification. The selected learning algorithms are described below:

- 1) Meta-Classifer using Logistic Regression ()
- 2) Meta-Classifer using Support Vector Machine ()
- 3) Meta-Classifer using Multi-Layer Perceptron ()

Based on their performance, the study has ranked the base classifiers. Five alternative subsets, including 2, 4, 5, 7, and 10 classifiers, were examined using various combinations of the base classifiers. The subset of 5 classifiers is selected as input to the meta-classifier based on the experiments since it outperforms other combinations. There are three types of learning algorithms considered in this study. First, the meta-model is based on Logistic Regression. The second is based on a Support Vector Machine classifier, and the third is based on a Multilayer Perceptron. The performance of each learning algorithm is compared using performance measurements, as discussed in the next section.

### D. Performance Measurement

Performance measurement is crucial to data mining evaluation. Several indicators, including accuracy, precision, recall, and F1-score, are used to evaluate the prediction rate and determine the validity of the models [30]. In this research, accuracy is chosen compared to the area under the curve (AUC) because of the percentage obtained. Precision is an upbeat class in which the model is predicted correctly or correctly outputs supplied by the model. The following formula can be used to compute as below [31]:

$$\text{Precision} = \text{TP} / (\text{TP} + \text{FP}) \quad (1)$$

Recall must be high as possible and can be concluded as how the model is predicted correctly. Below is how it can be computed [31]:

$$\text{Recall} = \text{TP} / (\text{TP} + \text{FN}) \quad (2)$$

A model with low precision, high recall, or high precision, low recall is hard to compare. To solve the problem, F-score can be used. This score allows for assessing both recall and precision simultaneously. The following formula can be used to compute [32]:

$$\text{F-Measure} = 2 * \text{Recall} * \text{Precision} / (\text{Recall} + \text{Precision}) \quad (3)$$

## IV. RESULTS AND DISCUSSION

The accuracy of heart disease classification will be discussed in this chapter and the findings of a series of experiments undertaken to validate the classification accuracy performance. The outcomes of this study are compared and analysed depending on the algorithm used to test the performance of the proposed strategy.

The performance measures include receiver operating characteristic area under the curve (ROC AUC), precision, recall, and F1 measure. Table II shows the classification's average performance based on precision, accuracy, recall, AUC, and F1 measure.

Table II shows the experimented results for base classifiers based on the accuracy, precision, recall, and F1-score. We have tested and compared ten base models' classifiers, logistic regression, random forest, k-nearest neighbour, decision tree, naïve bayes, support vector machine, extreme gradient boosting, multilayer perceptron, stochastic gradient descent, and extra tree classifier. The best model is MLP, with an accuracy of 88.52%, precision of 86.48%, recall of 94.11%, F1-score of 90.14%, and AUC of 87.79%. While when compared with the decision tree, the accuracy achieved is 72.13%, which is the lowest amongst others, with the precision of 79.31%, recall of 67.64%, F1-score of 73.01%, and AUC of 72.71%.

Table III shows that logistic regression, support vector classifier and multilayer perceptron are chosen as the meta-classifiers. These three meta-classifiers are then experimented with using the subset of base-classifiers. The combination of the base classifier is in the group of two, four, five, seven, and ten classifiers. The formation of the subset is based on the accuracy performance of each of the base classifiers. The base classifiers are ranked according to their prediction performance. Logistic regression is recorded as the best algorithm, tested on a subset of five base classifiers with an accuracy of 90.16%. SVC and MLP achieved 83.60% and 88.52% using the five classifiers.

TABLE II. DETAILS OF PERFORMANCE MEASURE OF THE CLASSIFICATION FOR THE BASE MODEL

Base Model	Accuracy	Precision	Recall	F1-score	AUC
Logistic Regression	85.24%	83.78%	91.17%	87.32%	84.47%
Random Forest	83.60%	85.29%	85.29%	85.29%	83.38%
KNN	81.96%	82.85%	85.29%	84.05%	81.53%
Decision Tree	72.13%	79.31%	67.64%	73.01%	72.71%
Naïve Bayes	85.24%	83.78%	91.17%	87.32%	84.47%
SVC	86.88%	84.21%	94.11%	88.88%	85.94%
XGB	85.24%	85.71%	88.23%	86.95%	84.85%
MLP	88.52%	86.48%	94.11%	90.14%	87.79%
SGD Classifier	83.60%	80.00%	94.11%	86.48%	82.24%
Extra Tree Classifier	86.88%	88.23%	88.23%	88.23%	86.71%

TABLE III. SUMMARY OF META-MODEL ACCURACY USING A DIFFERENT SUBSET OF CLASSIFIERS

Meta-Model Classifiers	Subset of 2	Subset of 4	Subset of 5	Subset of 7	Subset of 10
Logistic Regression	86.88%	88.52%	90.16%	86.88%	83.60%
SVC	86.88%	85.24%	83.60%	83.60%	83.60%
MLP	86.88%	88.52%	88.52%	86.88%	86.88%

Based on the experiment, the subset of two base classifiers, LR, SVC, and MLP achieved the same accuracy of 86.88%. LR and MLP resulted in the same accuracy of 88.52% using a subset of four classifiers, and SVC achieved 85.24%. For a subset of seven classifiers, again, LR and MLP achieved the same accuracy of 86.88%, and SVC achieved 83.60% of accuracy. This experiment also experimented using a subset of ten classifiers. The accuracy achieved for LR and SVC is 83.60%, and MLP attained an accuracy of 86.88%.

As a result, the ensemble technique showed that the best accuracy was achieved utilising a subset of five classifiers using logistic regression as meta-model classifiers. The presumption is accurate when comparing LR to SVC and MLP. This study shows that both the utilisation of large subsets and a limited number of subsets is undesirable. According to the experiments, it's crucial to identify the best subset of base classifiers before building the meta-classifiers in ensemble stacking since doing so could enhance classification performance while also making efficient use of the available resources.

## V. CONCLUSION

In conclusion, many people might prevent chronic heart disease attacks with early detection of heart disease. Most research uses a single classifier for prediction, yet the outcome is still unsatisfactory. While compared to utilising a single base classifier, the accuracy performance of heart disease in this research has improved when employing the meta-classifier, such as stacking for the ensemble technique.

Meta-classifier of the Logistic Regression algorithm and a combination of five subsets of base classifiers has achieved the highest accuracy compared to others, with 90.16% accuracy. The subset of base classifiers consists of support vector machine (SVM), multilayer perceptron (MLP), extra tree classifier (ETC), naïve bayes (NB) and extreme gradient boosting (XGB). This study can be proposed to the specialist for the future improvement of heart disease prediction and can be used for medical purposes. The use of ensemble methods such as stacking can enhance the prediction of accuracy.

**Abstract**—The classification of emails is one crucial part of the email filtering process, as emails have become one of the key methods of communication. The process for identifying safe or unsafe emails is complex due to the diversified use of the language. Nonetheless, most of the parallel research outcomes have demonstrated significant benchmarks in identifying email spam. However, the standard processes can only identify the emails as spam or ham. Henceforth, a detailed classification of the emails has not been achieved. Thus, this work proposes a novel method for the identification of the emails into various classes using the proposed deep clustering process with the help of the ranking of words into severity. The proposed work demonstrates nearly 99.4% accuracy in detecting and classifying the emails into a total of five classes.

**Keywords**—BoW collection; web crawler; email text extraction; subsetting method; email class detection; ranking method

## I. INTRODUCTION

The increase of email communication and people getting higher focus on the email-based communications have opened the door for hackers to target more and more people to be trapped using spam emails.

Email spam prevention remains a difficulty due to attackers using novel ways that evade current spam filters, as noted by H. V. Bathala et al. [1]. An email filter that can detect zero-day attacks is essential. The standard approach offers a method that not only examines the email's body content but also the phishing URLs and spam pictures attached to it. Machine Learning techniques are used to categorise the emails, and a systematic procedure is provided to detect spams. The existing machine learning models are selected using the lazyPredict library. When tested with standard data sets, these smart filters are effective at detecting spam and guarding against zero-day threats. For URL phishing detection, the Stacking classifier performs better with an accuracy of 0.97. In contrast, the perceptron classifier, which has an accuracy of 0.97, is the best at spotting spam email. Other algorithms' results are also included.

M. Hina and colleagues [2] stress the relevance of the detection procedure in their study since email has been used for a long time as a safe and trustworthy method for communication. Email's importance has grown because of the proliferation of quick and secure communication methods. Email management has become more difficult due to the tremendous growth of email data. Until now, emails have been categorised and sorted by sender, size, and date of origin. But there is a need to identify and categorise emails based on their

content. There have been a variety of methods used in the past to classify emails as either spam or non-spam based on their content. A multi-label email categorization system is proposed in the standard approach. Forensic studies of huge email data have been suggested to use an efficient categorization system (e.g., a disc image of an email server). An investigator using this technique would have an advantage when looking into crimes using email. It was shown that Logistic Regression outperforms Naive Bayes, Stochastic Gradient Descent, Random Forest and Support Vector Machines in a comparison of machine learning algorithms. Using benchmark data sets, logistic regression was shown to be the most accurate, with a 91.9 percent accuracy rate for bi-gram features. The similar recommendations can also be observed in the work by Naser et al. [21].

M. K. Islam et al. [3] have shown that email communication is crucial in many aspects of daily life, notably in the workplace. Spam email filtering is critical, especially considering its pervasiveness. Sending massive amounts of undesired communications through electronic means known as spam email, or junk email, constitutes this kind of spam. Due to hazardous frauds or malware hosting sites or viruses attached to the message, most spam emails are not only bothersome but also destructive. In standard measures, the researchers have uncovered the characteristics that set spam apart from other types of email. Including the pooled dataset, the researchers have used four machine learning models and two deep learning models. In addition, the researchers have searched the spam email collection for crucial terms that appear regularly. The researchers have may use this information to identify spam emails for the safety of the employees and the community.

However, the standard mechanism for detection of the spam emails is highly influenced by the use or choice of languages. Hence, many of the standard emails with valid text and information are also often marked as spams causing confusions. Thus, this work decides to solve this problem with deeper classification of the email using proposed machine learning method.

## II. FOUNDATIONAL STRATEGY FOR EMAIL CLASSIFICATION

After setting the context in the previous section of this work, in this section of the work, the foundational strategy for email classification is discussed.

Assuming that the total text or the collection of the email texts is  $LT[]$  and each email set is  $T[]$ . Thus, for  $n$  number of emails in the total collection can be formulated as,

$$LT[] = \langle T[0], T[1], T[2], \dots, T[n] \rangle \quad (1)$$

Further, each and every email corpus is collection of sender details, receiver details, subject and the actual email text. This can be formulated as,

$$T[] = \langle \text{Sender}, \text{Receiver}, \text{Subject}, \text{Text} \rangle \quad (2)$$

Furthermore, the set of words, which will decide the nature of the email, or popularly called bag or words, denoted as  $BOW[]$ , also must be populated. Assuming the number of elements in  $BOW[]$  are  $m$  and each word is denoted as  $W_x$ , thus, this can be formulated as,

$$BOW[] = \langle W_1, W_2, \dots, W_m \rangle \quad (3)$$

As per the foundational strategy, the frequency of any word from the  $BOW[]$  set must be cross checked in the email text and the frequency of the word must be recorded. This can be formulated as,

$$Fq\{W_x\} = \frac{\phi\{W_x \prec T[i]\{Text\}\}}{\phi\{T[i]\}} \quad (4)$$

Where,  $W_x$  is the frequency calculated using the function  $Fq\{\}$  and  $\phi$  is the function for extracting the count of the searching word.

Furthermore, the same frequency of the word,  $Fq\{W'_x\}$ , must be identified in all the text available in the dataset, that is,  $LT[]$ .

This can be formulated as,

$$Fq\{W'_x\} = \frac{\phi\{W_x \prec LT[]\{T[i].Text\}\}}{\phi\{LT[]\}} \quad (5)$$

During the final phase of the analysis, the document frequency is found to be higher than the dataset word frequency, then the email can be identified as spam or in case the document level frequency is less, then the email can be marked as ham. As, formulated below,

$$T[i]\{True | False\} : Fq\{W_x\} > Fq\{W'_x\} \quad (6)$$

Thus, this is the foundational process for identification of spam or ham in the email corpuses.

This understanding of the foundational method will help in critically analyzing the recent research outcomes in the next section.

### III. PARALLEL RECENT RESEARCH OUTCOMES

After having the foundational understanding of the traditional methods for detection of the spams, in this section of the work, the parallel recent research outcomes are discussed.

Spam, according to a study by C. Bansal et al. [4], is the most talked about topic on the Internet today. When you transmit spam, it's simple for spammers to do so. Thousands of spam emails flood inboxes. Files, contacts, and other sensitive information are stolen from the devices by spammers. Even with the most cutting-edge equipment, it's still challenging. Here, the researchers have used a computerised neural network to demonstrate how the researchers have may invert the frequency of Term Frequency documents (TFIDF). The confusion matrix, accuracy, and precision are used to compare the outcomes. The researchers have noticed a propensity to utilise Kaggle data sets with a lower mix of spammy emails and actual emails to evaluate the applicability of ANN. TFIDF-based TFIDF ANN yields a positive return of 97.58%, according to the outputs.

Email communication has become one of the most cost-effective and efficient methods for official and corporate users because of the widespread availability of internet connections. Every day, hundreds of millions of spam emails are sent and received. Spam detection is necessary to safeguard the privacy of people or organisations. Handling large datasets in machine learning is time- and space-consuming in Spam detection. Features must be selected to exclude those that aren't significant to reduce the time and space complexity. The suggested aim in this work is to reduce the time complexity, the space complexity, and the accuracy of the feature selection approach. Both global and local optimization strategies are used in the proposed feature selection method, which combines the chi2 select best method with the Tree-based feature selection method. Four distinct classifiers are put to the test in a series of experiments. According to the results of S. Sharma et al. [5], the suggested concept performs well on precision, memory, and accuracy efficiency tests.

According to A. Karim et al. [6], an intelligent and automated anti-spam framework is required due to the explosive proliferation of spam email and the inherent destructive dynamic inside such assaults on a variety of social, personal, and commercial activities. A growing number of attacks, including virus propagation and identity theft, as well as sensitive data theft, monetary and reputational harm, are taking place. There are now several solutions that don't take into consideration the wide variety of features available in email. Artificial Intelligence, particularly unsupervised machine learning, is preferred approach. Unsupervised learning is being investigated in this study to see whether it can be used to group spam and ham emails. The researchers have wanted to create an unsupervised framework that relies only on unsupervised methods and a clustering strategy that use various techniques, principally the email body and the subject header, to do this. An entirely new binary dataset of 22,000 spam and ham emails was used for the clustering (reduced from eleven to ten after the feature reduction). In this research, seven of the ten features were developed specifically to reflect important analytical email properties from several angles. With five algorithms tested, OPTICS provided the best clustering with a 0.26 percent greater average effectiveness than DBSCAN, its closest competitor. OPTICS and DBSCAN had a combined accuracy of 75.76 percent on average.

Spam e-mail has several detrimental effects, including increased communications overload and cybercrime, as shown by the study of S. A. A. Ghaleb et al. [7]. Spam email has become a key weapon for assaults such as cross-site scripting, malware infection, phishing, and cross-site request forgery, etc., which is the most dangerous feature of spam email. The effectiveness of earlier methods of discovery has been weakened by adaptive unsolicited spam. Using a series of six distinct forms of the extended Grasshopper Optimization Algorithm (EGOAs), this study presents a novel Spam Detection System (SDS) architecture, which is studied and integrated with a Multilayer Perceptron (MLP) for advanced spam email detection. Neural Network (NN) models are created as a result of combining MLP and EGOAs in this context (EGOAMLPs). In this study, EGOAs are used to train the MLP to distinguish between spam and non-spam emails. SpamBase, SpamAssassin, and the UK-2011 Webspam benchmark datasets are used to test these models. A kind of spam email is shown to be useful in identifying the models' efficacy. A comparison of the accuracy, detection rate, and false alarm rate for the EGOAs-trained MLP model indicated that it outperformed the other optimization strategies in this study.

For business reasons, email is the most common way of official communication. Despite the popularity of alternative forms of communication, email continues to grow in popularity. Automated email management is critical in today's world, as the number of emails continues to rise. More than half of all emails are considered spam. This proves that spams are a waste of time and resources for email users, since they provide no relevant information. Understanding the various spam email categorization strategies and their mechanisms is essential for spammers to carry out their illicit actions through spam emails. The study primarily focuses on the machine learning methods used to classify spam. The research also includes a complete evaluation and analysis of research done on various machine learning methods and email properties utilised in various Machine Learning methodologies. Future scholars may find it interesting to know about the issues that M. RAZA et al. [8] describe in their work on spam categorization.

Every day, new technologies and tools are created and made available to the public. Every day, new software and websites are being developed because of technological advancements. As the quantity of software products grows, so does the number of people who use them. As R. Al-Haddad et al. [9] point out, hackers and bad persons will take advantage of this opportunity to commit fraud, hack, or fool, particularly naive users. Email has long been the preferred method of communication in a variety of settings, including academia, business, and the arts. Because so many businesses depend on email to communicate with consumers and with other businesses, fraudsters and phishers devote more time and resources to sending fraudulent emails. As spam and scam emails grow increasingly common, hackers are constantly tweaking their emails to make them seem more authentic. In this study, four machine learning algorithms are used to distinguish between real and fraudulent emails. The studies make use of classifiers such as Decision Tree, Random Forest,

Nave Bayes, and Support Vector Machine. A fresh collection of 11926 emails, 5183 of which are classified as spam and the remainder as regular (ham) emails, is used to test these classification techniques. The findings reveal that SVM performs best when the attained accuracy is more than 98%.

Many organisations and people have found it more convenient to communicate through e-mail. Spammers use this technique to send unsolicited emails to make money, as shown by the study of S. Gibson et al. [10]. Machine learning algorithms that are improved using bio-inspired methodologies will be shown in this article to identify spam emails. A literature study is conducted to investigate the most effective strategies for analysing various datasets to get high-quality findings. On seven separate email datasets, along with feature extraction and pre-processing, substantial research was done to develop machine learning models utilising Nave Bayes, Support Vector Machine, Random Forest, Decision Tree and Multi-Layer Perceptron. Particle Swarm Optimization (PSO) and Genetic Algorithm (GA) were used to improve the classifiers' performance. Overall, Naive Bayes plus Genetic Algorithm outperformed all other methods. Various machine learning and bio-inspired models are also compared to determine which is the most appropriate model.

I. Saha et al. [11] recently shown that under the COVID-19 pandemic, individuals are obliged to adopt a 'work from home' strategy. Nowadays, the Internet serves as an excellent medium for social contact. People's utter reliance on digital platforms puts them up to scammers. It is illegal to employ phishing to get the login credentials of other people on websites like online banking, internet business, e-commerce and even online classrooms and digital markets. Phishers create bogus websites that seem just like the real thing and then send out spam emails to entice unsuspecting victims. When a spam recipient clicks on a link to one of the bogus websites, the phishing scammers steal the user's login credentials. Researchers have developed a wide range of techniques, including blacklists, whitelists, and antivirus software, to identify phishing websites. Defending against cyberattacks is a never-ending challenge for attackers. Phishing websites may now be detected using a data-driven methodology that employs deep learning. Phishing websites are predicted using a feed-forward neural network known as a multilayer perceptron. The data was gathered from Kaggle and consists of 10,000 websites worth of data. There is a total of 10 of them. Accuracy rates for training and testing of the proposed model are 95 percent and 93 percent, respectively.

The rapid rise in the number of internet users has resulted in an increase in email spam, as N. Kumar et al. [12] report. Illegal and unethical practises, such as phishing and fraud, are taking advantage of them. Sending spam emails with dangerous links is a certain way to bring down your system and get your data. Spammers may easily set up a bogus profile and email account, and they target those who aren't aware of the scams. There is a pressing need to identify spam mails that are fraudulent, and this project will do so using machine learning techniques. The work will discuss machine learning algorithms and apply each algorithm to data sets, and then the best algorithm for email spam detection with the best precision and accuracy will be selected.

Spam emails are becoming more widely used in criminal operations such as identity theft, virus propagation, financial loss, and harm to a company's image, among other things, as their effectiveness and diversity expand. These unlawful activities put the privacy of countless individuals and organisations at risk. Numerous studies have attempted to resolve the problem, but none have been successful. The researchers have felt an intelligent and automated approach is the best strategy for dealing with the problems at hand. There have been just a few research on the use of entirely unsupervised frameworks and algorithms to solve the challenge to far. The researchers have plan to provide an anti-spam framework that depends entirely on unsupervised techniques using a multi-algorithm clustering approach to study and examine the possibilities. The first component of the system is examined in detail in this article, focusing on the domain and header information provided in email headers. In this work, a new way of feature reduction employing an ensemble of 'unsupervised' feature selection algorithms was also explored. It was necessary to employ a dataset of 100,000 unique spam and junk email records as the data source. The following are some of the most important findings: 1) Of the six clustering algorithms employed, Spectral and K-means performed well, but OPTICS predicted the best clustering with an average of 3.5% greater efficiency than Spectral and K-means, which were confirmed by a variety of validation techniques. Second, the performance of BIRCH, HDBSCAN, and K-modes was insufficient. As shown in the work of A. Karim et al. [13], the suggested feature reduction framework fulfilled its target with great confidence, and the average balanced accuracy for the optimal three techniques is 94.91 percent.

Phishing e-mails, commonly known as spam, including spear phishing or spam-borne malware have become an increasingly significant issue in recent years, prompting the development of effective, intelligent anti-spam email filters, according to A. Karim et al. [14]. For the identification of clever spam emails, the researchers have thought this survey study on artificial intelligence and machine learning may assist design effective countermeasures. Four components of the email's structure that may be exploited for intelligent analysis were explored in the work: There are MTAs (Mail Transfer Agents) in the heads of emails that offer information about the email's origin, destination, and the number of reroutes it has made along the way. In the SMTP Envelope, the originating source and destination domains and users' identifications are included. (C) The first component of SMTP Data, which includes information such as the sender, recipient, date, and topic. (D) The email body and any attachments are included in this section of the SMTP data. Publications describing each approach were selected, reviewed, and summarised based on the number of relevant papers. The work reveals interesting results, difficulties, and research issues. Research on theoretical and empirical aspects of intelligent spam email identification is now possible thanks to this extensive survey.

There is a lot of evidence, according to M. Gupta et al. [15], that the usage of Short Message Service (SMS) on mobile phones has expanded to such an extent that the devices

are occasionally inundated with spam SMS. Additionally, spam communications might cause a user to lose confidential information. Spam emails may be effectively filtered using a variety of content-based machine learning algorithms. Text messages may be classified as either spam or ham based on certain stylistic characteristics. Text message spam detection may be considerably affected by the inclusion of well-known terms, phrases, and acronyms. Based on their accuracy, precision, recall, and CAP Curve, the study compares several classification approaches on various datasets gathered from prior research. Traditional machine learning approaches have been compared to deep learning methods.

Email is the most favoured means of transferring information over the Internet. Detecting spam is one of the most daunting tasks for email users. Detection and filtering methods may help with this. Support Vector Machine (SVM) methods may play a critical role in spam identification. Using the KFCM technique, the researchers have suggested the usage of a weighted SVM for spam detection. Various classes have different weights, which is reflected in the weight variables. The increase in weight value reduces the amount of email that is incorrectly classified. In accordance with Vishagini et al., the researchers have assessed the effect of spam detection using SVM, WSVM with KPCM, and WSVM with KFCM. [16].

Hacking and malicious email communications are becoming more severe security issues, according to S. Chawathe et al. [17]. Detection of malicious email by automated or semi-automatic means is a critical weapon in the fight against such email threats. For this aim, the work reports use fuzzy rules to categorise email. Using a real dataset, researchers test the performance of a classifier based on fuzzy rules against that of classifiers using crisp rules and decision trees. The usability and editability of the classifiers generated by these approaches are also examined.

If you've ever received an e-mail that you didn't want, you've received spam. Spam email filters are becoming more and more necessary for email users because of the ever-increasing number of spam emails they must deal with. With ever-increasing email volumes, spam classifiers are becoming more ill-equipped to manage them and to identify and detect new spam emails with high performance. It's difficult to classify spam because of the large number of characteristics. An essential part of keyword content categorization is selecting features that are among the most common and successful approaches for reducing feature complexity. As a result, any unnecessary or redundant features that would slow down the system will be removed. Meta-heuristic optimization is the process of selecting the best answer from a set of feasible alternatives while keeping in mind the study's primary goal: performance. Other issues include a lack of clarity in regard to the impact of optimization feature selection on prior work's prominent classifier algorithms, such as K-nearest Neighbor, Naive Bayesian, and Support Vector Machine. So, the goal of this study is to increase feature selection accuracy by using a hybrid Water Cycle and Simulated Annealing approach to optimise findings and assess the suggested Spam Detection method. For this study, the researchers followed a five-step approach to conducting their research. The suggested

spam categorization was put to the test using cross-validation on seven different datasets. Meta-heuristic water cycle feature selection (WCFS) was used as a feature selection method in conjunction with Simulated Annealing, as shown by the findings. The hybridization interleaved hybridization surpassed other feature selection algorithms, such as Harmony Search, Genetic Algorithm, and Particle Swarm, with an accuracy of 96.3 percent. On the other hand, the SVM outperformed other classifier algorithms with an f-measurement of 96.3 percent. As indicated by G. Al-Rawashdeh et al. [18], the number of features using interleaved water cycles and Simulated Annealing has lowered by more than half.

In both personal and professional settings, email is a go-to method for exchanging information. Even though electronic communications, mobile apps, and social networks have become more common, e-mails have remained a vital form of communication. There are several reasons why automated email management is necessary, including spam classification, phishing classification, and multifilter categorization, among others, as the number of vital e-mails grows. All articles on email classification from 2006 to 2016 were analysed using the methodological decision analysis in five areas, including e-mail classification application areas, data sets used for each area of classification, feature space used for each application area, and e-mail classification techniques and performance measures [19].

According to research by W. Z. Khan et al. [20], the issue of email spam has expanded dramatically in the last several years. It's not only a hassle for users; individuals who fall prey to scammers and other assaults suffer as well. Due to the increasing complexity of email spamming methods, which are moving from classic spamming (direct spamming) to more scalable, elusive, and indirect botnets for spreading email spam messages, spamming tactics are becoming more and more complicated. Spamming botnets employ a variety of sources and architectures to churn out enormous amounts of spam through email. There are thorough chronicles of spambots, which meticulously document the sequence of events and significant developments in these spambot networks' evolution. It also seeks to provide a complete review of the various email spamming botnet detection strategies that have been presented in the literature. According to both their nature and technique of detection, as well as a thorough comparison between their strengths and weaknesses, the researchers have sought to classify them. In addition, the researchers have provided an in-depth look at the effectiveness of various methods. Finally, the researchers have look at the future trends and problems in identifying email spamming botnets.

Clearly the global increase of the attacks as showcased in the work by Naser et al. [22] is demanding this research.

Henceforth, in the next section of the work, the persistent bottlenecks of the parallel research outcomes are formulated.

#### IV. PROBLEM FORMULATION

After realizing the recent improvements over the standard methods for identification of the email types and classifying

the emails into spam or ham emails, in this section of the work, the persistent research problems are identified and discussed in this section of the work.

Firstly, the during the classification of the emails, the emails are either classified as ham, that is safe email or spam, that is unsafe emails. However, the resent research outcomes demonstrate that, identification of the email sub classifications are also important for deploying the current email filters.

According to the Eq. 6, the emails are only been classified as spam or ham. Thus, this problem must be addressed.

Secondly, considering the time complexity of the process, the deployment of such email filtering frameworks is highly complex.

Assuming that the total time complexity of the existing process is T. This can be formulated in the light of Eq. 1 and 3 as,

$$T = n.n * m.m \quad (7)$$

Thus, this can be re-written as,

$$T = n^2 * m^2 \quad (8)$$

Assuming that,  $n \approx m$ , T can be considered to be as,

$$T(n) = O(n^4) \quad (9)$$

Clearly, this is significantly high and for a large BOW[] set, the complexity can be astronomical.

Hence, this problem must also be solved.

The solutions to these two problems are proposed in the next section of this work.

#### V. PROPOSED SOLUTION: MATHEMATICAL MODELS

After the detailed analysis of the parallel recent research progress and analysis of the persistent problems in the research, in this section, the proposed strategy is furnished using the mathematical models.

In the light of the Eq. 3, the BOW[] set is expected to contain multiple words, which are expected to contain all the words pertaining towards the suspected emails. It is convenient to convert the BOW[] set into a ranked sets, where the words are ranked in highest to lowest in terms of more risky to less risky. Thus, this can be formulated as:

$$R - BOW[] = \{BOW[], R[]\} \quad (1)$$

Where R[] is the associated rank set and R-BOW[] is the total set with words and the associated ranks.

Further, the threshold for each word in the BOW[] set must be calculated and the rank associated set, R-TH[x] must be formulated as:

$$R - TH[x] = \{Fq(W_x), R[X]\} \quad (11)$$

And,

$$R - TH[x] = \frac{\phi\{W_x \prec T[i]\{Text\}\}}{\phi\{T[i]\}}$$

Again, the global ranks,  $RG-TH[x]$  for each word must be calculated for the total dataset as:

$$RG-TH[x] = \{Fq(W'_x), R[X]\} \\ = \frac{\phi\{W_x \prec LT[]\{T[i].Text\}\}}{\phi\{LT[]\}} \quad (12)$$

Finally, the emails must be classified in terms of various classes as,

$$T[i]\{class\} : R-TH[] :: RG-TH[] \quad (13)$$

Henceforth, it is natural to realize that, due to inclusion of the ranks for detecting the class of the email, the proposed method does not only reduce the time complexity to  $O(n^2)$ , rather also provides deeper classifications of the emails.

Further, based on the proposed mathematical models, in the next section of the work, the proposed algorithm is furnished.

## VI. PROPOSED ALGORITHMS

After the detailed analysis of the proposed strategy in the previous section of this work, in this section the proposed algorithms are furnished.

Firstly, the BoW Collection Process using Web Crawler algorithms is furnished.

---

**Algorithm - I:** BoW Collection Process using Web Crawler (BCP-WC) Algorithm

---

**Input:**

U[] as set of URLs for crawling

---

**Output:**

BOW[] set as Bag or Words

---

**Process:**

- Step - 1. For each element in the U[] list as U[i]
- Extract the list of words from the U[i] as W[j]
  - If W[j] is noted as negative word
  - Then, BOW[k]=W[j]
  - Else, Continue
- Step - 2. Return BOW[]
- 

Even the most powerful search engines are only able to cover a small amount of the Internet's publicly accessible content. An investigation in 2009 found that even the most well-known search engines only index 40 to 70 percent of the searchable Web. A 1999 research by Steve Lawrence and Lee Giles found that no search engine had indexed more than 16% of the Internet at the time. Considering that a crawler gets just a small portion of the web pages, it's critical that the sites it downloads include the most relevant content.

Web pages must be prioritised based on a metric of importance. A page's significance can be gauged by a variety of factors, including the quality of its content, the number of links pointing to it, and even the URL itself (the latter is the case of vertical search engines restricted to a single top-level

domain, or search engines restricted to a fixed Web site). As the whole set of Web sites cannot be known during crawling, creating an effective selection policy is made more complex.

Crawling scheduling policies were initially studied by Junghoo Cho and colleagues. They used a 180,000-page crawl from the stanford.edu domain and a variety of crawling algorithms to generate their data. To see which measures ranked highest in terms of breadth, backlink count, and partial PageRank, researchers used a variety of techniques. According to one of the findings, the best technique for crawlers looking to download pages with high Pagerank early in the crawling process is the partial Pagerank strategy. However, these findings only apply to a single field of study. Cho also completed a PhD in web crawling at Stanford University.

Secondly, the Email Text Extraction using Subsetting Method algorithm is furnished.

---

**Algorithm - II:** Email Text Extraction using Subsetting Method (ETE-SM) Algorithm

---

**Input:**

LT[] set as collection of emails

---

**Output:**

T[] set as collection of texts from all emails

---

**Process:**

- Step - 1. For each element in the LT[] set as LT[i]
- Separate LT[i] into subsets using tags
  - If LT[i].tag == body
  - Then, T[j] = LT[i].Text
- Step - 2. Return T[]
- 

Spammer infections may have a feature that looks for email addresses on the computer's hard drive and/or network connections. These scanners unearth email addresses that have never been made public online or in Whois. Mail traffic destined for other computers on the shared network segment can be intercepted by a hacked machine on that segment. The spammer receives the harvested addresses back through the virus-created bot-net. Additionally, the addresses may be supplemented with additional data and then cross-referenced in order to obtain financial and personal information about the individuals.

As part of the "e-pending" method of direct-marketing database appending, email addresses are added. Prospect lists are typically obtained by direct marketers from a variety of sources, including subscriptions to magazines and customer lists. Direct marketers can send targeted spam email by scanning the Internet and other resources for email addresses that match the names and street addresses in their database. As with most spammer "targeting," this is not exact; consumers have claimed, for example, receiving requests to mortgage their property at a specific street location — with the address plainly being a business address containing mail stop and office number. Users have experienced similar experiences.

Thirdly, the Email Class Detection using Ranking Method algorithm is furnished.

---

**Algorithm - III:** Email Class Detection using Ranking Method (ECD-RM) Algorithm

---

**Input:**

BOW[] set as Bag or Words

T[][] set as collection of texts from all emails

**Output:**

Class of Email as {SPAM - Chain Letters, SPAM - Ads, SPAM - Spoofing, SPAM - Malware, Very positive}

---

**Process:**

- Step - 1. For each text in the list BOW[] as BOW[i]
- I. Build the ranking set as R-BOW[i] using Eq. 10
  - II. Calculate the word threshold as R-TH[i] using Eq. 11
  - III. Calculate the global threshold as RG-TH[i] using Eq. 12
- Step - 2. For each word in the email list as T[][] as T[n][m]
- I. Calculate the word ranks of T[n][m] using Eq. 13
  - II. If T[n][m].Rank == top 40%
  - III. Then, mark T[n][m] as SPAM - Chain Letters
  - IV. If T[n][m].Rank == top 30%
  - V. Then, mark T[n][m] as SPAM - Ads
  - VI. If T[n][m].Rank == top 20%
  - VII. Then, mark T[n][m] as SPAM - Spoofing
  - VIII. If T[n][m].Rank == top 10%
  - IX. Then, mark T[n][m] as SPAM - Malware
  - X. If T[n][m].Rank == top 90%
  - XI. Then, mark T[n][m] as Very positive
- Step - 3. Return class of email
- 

For the purpose of sending their messages, spammers may commit fraud. These "disposable" accounts are typically created by spammers using fake names, addresses, phone numbers and other contact details. To pay for these accounts, they frequently make use of stolen or fake credit card numbers. As the host ISPs uncover and shut down each account, they can rapidly move on to the next.

They may go to tremendous efforts in order to hide the origin of their message. Large corporations may outsource the transmission of their messages to another firm in order to deflect criticism or email blocking to a third party. Others use email faking techniques (much easier than IP address spoofing). Because the email protocol (SMTP) does not require any authentication by default, spammers can send messages that appear to come from any email address they want to use. This can be avoided by requiring the usage of SMTP-AUTH, which allows the specific account from which an email originates to be positively identified.

Due to the fact that receiving mail servers record genuine connections from the final mail server, it is impossible for a sender to spoof email delivery chains (the 'Received' header). Spammers use forged delivery headers to fool legitimate servers into believing that an email has already passed through several of their own.

For legitimate email users, spoofing can have catastrophic implications. In addition to clogging up their email inboxes with "undeliverable" emails and loads of spam, they can be incorrectly classified as a spammer. As a result, they may receive a barrage of angry emails from spam victims, as well as the threat of having their Internet service terminated for spamming.

Further, in the next section, the obtained results from the algorithms are furnished.

## VII. RESULTS AND DISCUSSIONS

The obtained results from the proposed algorithms are highly satisfactory and are discussed in this section of the work.

Firstly, the dataset analysis is furnished here (Table I).

TABLE I. DATASET CHARACTERISTICS

Parameter	Value
Number of Samples	1929
Spam Emails	1543
HAM Emails	386
Minimum Length of Email Text	111
Mean Length of Email Text	231
Maximum Length of Email Text	334
Missing Words	22279
Unique Words	325287

It is natural to realize that the dataset demonstrates highly unique characteristics to be considered for testing on the proposed algorithms.

The results are also visualized graphically here (Fig. 1).

Secondly, as proposed in the mathematical models and during the algorithm design, the work summarizes the email in terms of overall scores. The details of the assumption of the scores and correlated email classes are furnished here (Table II).

Thirdly, the email classification results are showcased (Table III). The actual tests were carried out on a total of 1923 itemsets, however in this literature only 20 samples are furnished.

The obtained results are also visualized graphically here (Fig. 2).

Further, based on the ranking and matching of the email contents with various classes, the emails are finally classified in five pre-defined classes (Table IV).

Further, the results are visualized graphically here (Fig. 3).

Fourthly, the time complexity analysis of the proposed algorithms is furnished here (Table V).

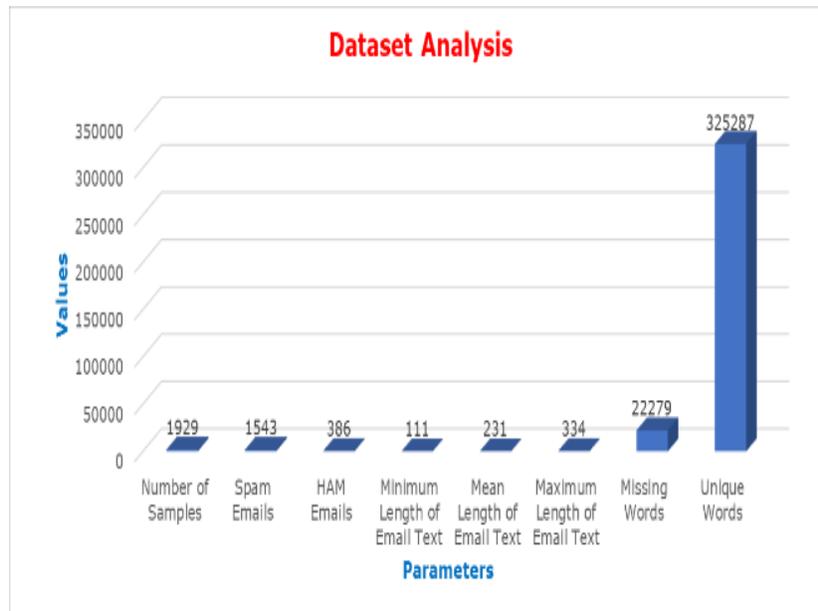

Fig. 1. Dataset Analysis.

TABLE II. EMAIL CLASS AND RANKING MAPPING

Over All Rank	Email Class
0	SPAM - Malware
1	SPAM - Spoofing
2	SPAM - Chain Letters
3	SPAM - Ads
4	Very positive

TABLE III. EMAIL CLASSIFICATION RESULTS

Email Seq. #	No. of Words	Strong - HAM	HAM	Neutral	SPAM	Strong - SPAM
1	37968	0%	17%	82%	1%	0%

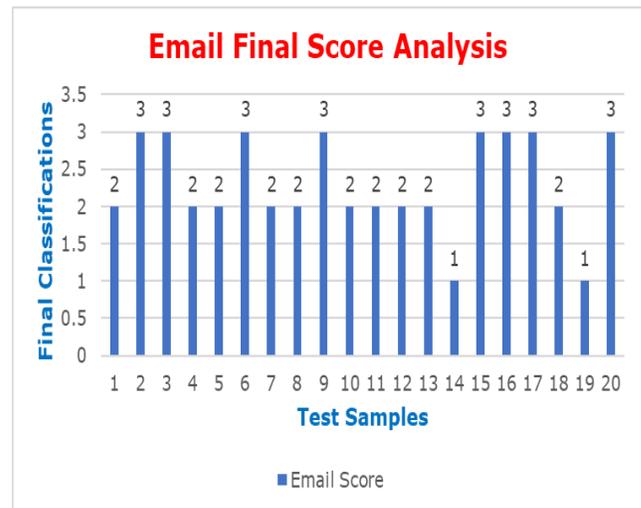

Fig. 3. Email Final Classification Analysis.

It is significant to observe that the time taken to process the complete email and further classify these emails are significantly low. The results are also visualized graphically here (Fig. 4).

Finally, the accuracy analysis results are furnished here (Table VI).

The mean accuracy of proposed system is nearly 99.42%.

Henceforth, in the next section of this work, the proposed strategy is compared with other parallel research outcomes.

TABLE V. EMAIL CLASSIFICATION TIME COMPLEXITY

Email Seq. #	Detected Email Type	No. of Words	Time (ns)
1	SPAM - Chain Letters	37968	164.4
2	SPAM - Ads	1420	6.1
3	SPAM - Ads	4333	18.8
4	SPAM - Chain Letters	2513	10.9
5	SPAM - Chain Letters	2264	9.8
6	SPAM - Ads	278	1.2
7	SPAM - Chain Letters	8207	35.5
8	SPAM - Chain Letters	3361	14.6

Trial Seq #	Number of Samples	Accuracy (%)
1	412	98.943
2	425	99.224
3	468	99.637
4	488	99.997
5	136	99.344

### VIII. COMPARATIVE ANALYSIS

In order to achieve the understanding, that the proposed system can outperform the other parallel research outcomes, it is important that the proposed system performances are compared with the parallel research results. Henceforth, the comparative analysis reports are furnished here (Table VII).

TABLE VII. COMPARATIVE ANALYSIS

Author & Year	Proposed Method	Model Complexity	Accuracy (%)
H. V. Bathala et al. [1], 2021	Filtering	$O(n^4)$	96.23
M. Hina et al. [2], 2021	Classification	$O(n^4)$	97.12
M. K. Islam et al. [3], 2021	Word Extraction	$O(n^4)$	97.68
C. Bansal et al. [4], 2021	Hybrid	$O(n^4)$	97.58
S. Sharma et al. [5], 2021	Hybrid	$O(n^4)$	98.32
Proposed Method, 2022	Classification, Ranking, Word Extraction and Deep Clstering	$O(n^2)$	99.42

Further, in the next section of the work, the research conclusion is presented.

### IX. RESEARCH CONCLUSION

It's important to categorise emails because they've become one of the most common methods of communication. Because of the wide variety of ways people speak, determining whether an email is safe or not is a difficult task. There have been significant benchmarks established in email spam detection in most of the parallel studies, however. Even so, the standard spam-detection mechanism is heavily influenced by the languages used or chosen. As a result, many standard emails with legitimate text and information are incorrectly labelled as spam. In this way, the proposed machine learning method is used to solve the problem of email classification at a deeper level. Emails can only be categorised as spam or ham by the standard processes. As a result, a precise classification of the emails has thus far failed. As a result, this work proposes a novel method for classifying emails based on their severity using the proposed deep clustering process. With a 99.4 percent accuracy rate, the proposed work can detect and classify emails into a total of five categories.

**Abstract**—Precise identification of Alzheimer's Disease (AD) is vital in health care, especially at an early stage, since recognizing the likelihood of incidence and progression allows patients to adopt preventive measures before irreparable brain damage occurs. Magnetic Resonance Imaging is an effective and common clinical strategy to diagnose AD due to its structural details. We built an advanced deep sparse autoencoder-based architecture, named Alz-SAENet for the identification of diseased from typical control subjects using MRI volumes. We focused on a novel optimal feature extraction procedure using the combination of a 3D Convolutional Neural Network (CNN) and deep sparse autoencoder (SAE). Optimal features derived from the bottleneck layer of the hyper-tuned SAE network are subsequently passed via a deep neural network (DNN). This approach results in the improved four-way categorization of AD-prone 3D MRI brain images that prove the capability of this network in AD prognosis to adopt preventive measures. This model is further evaluated using ADNI and Kaggle data and achieved 98.9% and 98.215% accuracy and showed a tremendous response in distinguishing the MRI volumes that are in a transitional phase of AD.

**Keywords**—Alzheimer's disease; MRI; CNN; sparse autoencoder; DNN; mild cognitive impairment

## I. INTRODUCTION

Alzheimer's Disease (AD) is the most predominantly reported dementia observed in elder people more than 60 years old. Late-onset effects of AD are most often seen in the mid-60s, whereas early-onset effects appear between the 30s and the mid-60s. Because of the world's aging population, it is anticipated that around 640 million individuals will be impacted by AD by the year 2050. Each year, more than 10 million fresh dementia cases are diagnosed worldwide, implying one fresh patient for every 3.2 seconds [1]. This situation leads to imposing significant impact on patients' and caretakers' daily living routines, physical and emotional states, and the economy. Early diagnosis is the only solution to find suitable medication that prevents additional damage to the cognitive ability of a patient.

Both the Mini Mental State Examination (MMSE) and the Clinical Dementia Rating (CDR) parameters are commonly used to estimate the severity of AD. Magnetic Resonance Images (MRI) are shown to be the most effective imaging biomarker [2, 3] in clinical assessment for analysing and getting a conclusion about the stage of dementia due to their ability in reflecting the structural details of human brain. In

practise, several computer-aided diagnostic tools that employ machine learning methodologies [4, 5, 6, and 7] such as Support Vector Machine (SVM), K-Nearest Neighbor (KNN), and ensemble methods [8], are suggested, developed and widely implemented using MRI to assist the medical practitioners community.

Due to the rapid advancement of Artificial Intelligence algorithms in diagnosis procedures, the deep learning techniques have been able to categorise, extract high level features, and will also aid in the right diagnosis of AD patients in short span of time. The potential for gratifying feedback from using deep learning algorithms in medical imaging prompted several investigators to emphasize the approach when tackling research difficulties and concerns [9, 10, and 11]. Convolutional Neural Network (CNN) [35] changed the complete picture of pattern recognition especially in AD diagnosis [12] with their capability in extraction of latent features from various objects by fine tuning its hyper parameters using optimizers. Sparse autoencoder (SAE), another architecture of deep learning model has shown exceptional performance in a wide range of unsupervised applications due to their ability in utilizing the sparsity in information bottleneck [13, 14, 15, and 16]. It excels in learning useful feature representations in very complex and large datasets, making it a possible solution to handle the difficulties of AD prediction.

In this research paper, a 3-stage neural network model that combines 3D CNN, SAE, and Deep Neural Network (DNN) is presented. Before feeding MRI volumes into this network, the first MRI volumes are pre-processed and converted into 2D slices in a series. In this research work, only 40 medial slices covering the hippocampal portion were considered so that MRI volume consists of AD symptoms. After pre-processing, convolutional layers in CNN are trained to extract the latent features from MRI data. SAE in the next stage reduces the feature dimension so that only dominant features are incorporated into DNN [17] in the third stage to classify the subjects into AD subcategories namely AD, low and stable Mild Cognitive Impairment (ls-MCI), progressive Mild Cognitive Impairment (p-MCI), and Cognitive Normal (CN). In contrast to earlier approaches, the proposed Alz-SAENet exhibits good accuracy, and fast convergence by leveraging the convolutional layer's potential in CNN and the SAE sparsity.

The key contributions of this work are:

- Alz-SAENet is developed for robust 4-way classification for AD diagnosis.
- For early diagnosis, this model can be utilized since classifying MCI stages were more concentrated.

The rest of this research article is organized as follows: literature is studied and challenges were drawn in Section II. Datasets and design of Alz-SAENet are discussed systematically in Section III. Experimental remarks and discussions are provided and Section IV. Finally, Section V summarized the work and future enhancement of this work.

## II. LITERATURE REVIEW

### A. Related Works

Jha et al. [18] developed a deep architecture that comprises SAE, scale conjugate gradient, stacked autoencoders, and finally one SoftMax layer for effective classification of AD subjects. When compared to other renowned investigations, this approach demonstrated a significant improvement in diagnosis, yielding an adequate and reliable accuracy of 91.6%.

Jabason et al. [19] described a novel technique to handle the missing data patterns in Alzheimer's diagnostic methods by leveraging the benefits of sparse autoencoder. It is a stacked sparse autoencoder that assign the missing data patterns with values and to select the discriminative features for supporting 3-way Alzheimer's disease diagnosis. The proposed model has attained 95.90% diagnostic accuracy over ADNI dataset by imputing the missing data patterns.

Soliman et al. [20] proposed an enhanced sparse autoencoder base CNN for 3-way Alzheimer's prediction. The authors tuned the hyperparameters of CNN and SAE thoroughly using the Adam optimizer and obtained 87.8% diagnostic accuracy over ADNI datasets. This diagnostic accuracy is attained not only due to the structure of the network and also with the pre-processing phase. Further improvement of diagnostic accuracy is a bit challenging matter.

Venugopalan et al. [21] implemented a deep learning (DL) model for analyzing multimodal data for the 3-way classification of AD. They used Stacked Denoising Autoencoders (SDAE) for feature extraction from multimodal data that comprise both clinical and genetic data and 3D-CNNs are employed for the categorization of MR volumetric data. This model outperformed almost all shallow architectures in terms of key evaluation metrics.

Zhu et al. [22] presented a sparse regression approach that utilizes a novel feature selection algorithm that considers task-wise relations amongst the clinical labels and neuroimaging features and 'self-representation' relations. Authors performed both binary and multiclass classification and this procedure outstripped all the conventional methods by improving the accuracy by an average of 4.5%.

Yagis et al. [23] focused on the end-to-end development of an AD detection technique that integrates supervised prediction with unsupervised representation using convolutional autoencoders. To capture hidden representations

in structural MRI slices, a 2D convolutional autoencoder is built. Testing the network over OASIS repository data, it is revealed that their model beats several competing classifiers with 74.66% accuracy when employing a single slice.

Lin et al. [24] employed CNN to extract discriminative features from MRI volumetric image data. The authors concentrated on some specific subjects in the transition period from MCI to AD. They attained 79.9% accuracy with their model by a solid balance between specificity and sensitivity.

Basheera et al. [25] demonstrated an innovative method to extract the grey matter from the brain voxels, and CNN is employed for AD classification. The authors resliced 18,017 voxels from 1820 MRI volumes that were retrieved from the ADNI repository. With the support of their enhanced Independent Component Analysis (ICA), they extracted hidden structural features from pre-processed voxels. With this hybrid method, authors achieved 90.47% accuracy in the 3-way classification of AD, MCI, and CN subjects. Slow convergence and moderate diagnostic accuracy are challenges here.

Akramifard et al. [26] designed and developed a hybrid method that combines Autoencoder and SVM for Alzheimer's diagnosis using multimodal datasets including MMSE, MRI, PET, CSF, and personal information. An autoencoder is designed to inputting the missing data. PCA is employed for reducing data dimension. Finally, the SVM algorithm is utilized for classification. During the evaluation, their algorithm yielded 95.57% accuracy for multimodal data whereas for only MRI it produced 84.46% diagnostic accuracy. Although the algorithm performance is superior, processing such limited datasets in all phases is a challenging task.

Almughim et al. [27] developed ASD-SAENet, a deep sparse network for distinguishing autism spectrum disorder (ASD) patients from typical control subjects. The authors proposed and implemented an SAE, that proposed an optimized feature extraction procedure for Autism patients' classification. These features are subsequently loaded into a DNN for accurate classification of ASD-prone fMRI brain voxels. Based on both the restored data error and the classifier error, this model is trained to extract optimal hidden details. The model is evaluated over 1,035 Autism Brain Imaging Data Exchange (ABIDE) datasets, and 17 research centers and achieved 70.8% accuracy and 79.1% specificity.

### B. Review

Detailed literature analysis is tabulated in Table I. Although the existing literature has many advantages, they are suffering from certain issues viz. number of AD stages, convergence, feature selection, overfitting, and hyperparameters tuning. These challenges to be addressed with productive outcomes by developing a novel network. From overall existing works, it is very clear that 3D CNN will holistically extract MRI latent features and converge quickly. The feature vector obtained from CNN would have huge redundant details that may not affect the classifier overall performance. In second stage, the sparsity of SAE aids in the mapping of low-level features from high-dimensional features while preventing overfitting due to its sample size. Finally, a

DNN is employed for the classification of subjects into four AD categories viz. CN, ls-MCI, p-MCI, and AD. With the

hyperparameters tuning, SAE can avoid overfitting by minimizing its cost function and with quick convergence.

TABLE I. LITERATURE DEEP ANALYSIS

Authors	Data	Methodology	Features	Challenges
Jha et al. [18]	OASIS	SAE	Diagnostic accuracy is obtained as 91.6% over very small datasets.	Diagnostic accuracy is low.
Jabason et al. [19]	ADNI	SAE	Imputation of missing data patterns is employed. 3-way classification is performed.	Accuracy is moderate. Early diagnosis is not precise.
Soliman et al. [20]	ADNI	SAE+CNN	Differentiates healthy controls from AD subjects. 3-way classification is performed.	Suffers from classifying MCI subjects. Less accuracy 87.8%.
Venugopalan et al. [21]	ADNI	3D CNN+ stacked DAE	3-way classification is performed. Multimodal data is used as biomarker for training.	Suffers from limited dataset sizes. Takes long running time. Early diagnosis is a bit tough.
Almuqhim et al. [27]	ADNI	SAE+DNN	Authors designed a network named ASD-SAENet to diagnose Autism Spectrum Disorder. Evaluated their model on ABIDE dataset and 70.8% accuracy is achieved.	Very low accuracy i.e. 70.8%. Features were not extracted separately in this network.
Basheera et al. [25]	ADNI	CNN+ICA	An enhanced Independent Component Analysis is employed for segmentation. For classification, CNN is utilised.	Multiclass classification accuracy is 90.47%. Diagnostic accuracy is moderate. Converging slowly.
Zhu et al. [22]	ADNI	SVM	A novel feature selection approach is employed using task specific relations. Binary and Multiclass classification is performed.	Deep learning could be used to improve the analysis. Diagnostic Accuracy is less.
Yagis et al. [23]	OASIS	2D CAE	Integrated supervised prediction with unsupervised representations using CAE. Single slice of MRI is used in diagnosis.	3D volumetric latent features were not extracted. Diagnostic accuracy is also less i.e 74.66%.
Akramifard et al. [26]	ADNI	CNN+SAE	2D CNN and 3D CNN both were employed. 3-way classification with 89.47% accuracy is obtained.	Tuned hyper-parameters could further enhance these findings.
Dongren et al [8]	ADNI	Ensemble methods	Authors presented a hierarchical grouping process in feature selection method. Binary and 4-way classification both were performed.	Deep learning architectures may improve accuracy further. Diagnostic accuracy is very poor i.e., 54.375%.
Vu et al [32]	ADNI	CNN+SAE	A novel classification model is presented in a multimodality fusion of MRI and PET. 91.14% accuracy is obtained using MRI-PET.	Instead of random, authors could select a specific patch. Overall, system converge very slowly.
Yang et al.	OASIS	SVM+ICA	Machine learning is employed so it is compulsory to specify ROI. 3-way AD diagnosis is employed.	classification accuracy is still not optimal due to various factors. Age and gender are not considered.
Lin et al. [24]	ADNI	CNN	This model is centric about MCI to AD conversion subjects. This approach achieved an accuracy of 79.9%.	AD progression was not analyzed. Diagnostic accuracy is moderate.

### III. NETWORK DESIGN AND DEVELOPMENT

This research work seeks to properly diagnose AD stages while using less processing power and storage space. To achieve these goals, 3D CNN along with SAE is presented for obtaining high-level dominant features related to multi-class AD from MRI neuroimage intensities. As shown in Fig. 1, unprocessed MRI volumes are thoroughly scaled, resized, and segmented properly before being directed into the hyperparameters tuned CNN followed by SAE to extract latent features. The low dimensional features from the bottleneck layer of SAE are subsequently loaded into a deep neural network (DNN) which results in the enhanced diagnosis of brain voxels more prone to AD.

#### A. Dataset

From the ADNI repository, 1120 unprocessed MRI volumes of 460 people of various ages and genders were obtained. We employed 1.5-Tesla, T1-weighted, MRI volumes from the patient community [28] that included patients

ranging in age from 55 to 70 and of different genders. The configuration of the MRI dataset utilized to implement this research is displayed in Table II. In the entire dataset, 351 CN, 230 ls-MCI, 234 p-MCI, and 305 AD subject volumes were meticulously gathered to orient the study effort toward the AD prognosis. Furthermore, 6400 samples of MRI slices were retrieved from the Kaggle repository and utilized for evaluating the proposed network. In all 6400 samples, 3200 CN subjects, 2240 ls-MCI subjects, 896 p-MCI subjects, and 64 AD subjects MRI slices are selected to validate the network capability in classifying the MCI subcategories.

TABLE II. ADNI DATASET CONFIGURATION [28]

Parameters	CN	p-MCI	ls-MCI	AD
Age	55	60	58	62
Gender	60% male	40% male	50% male	30% male
MMSE	29	24	26	21
CDR	0	0.5	0.3	0.5-1

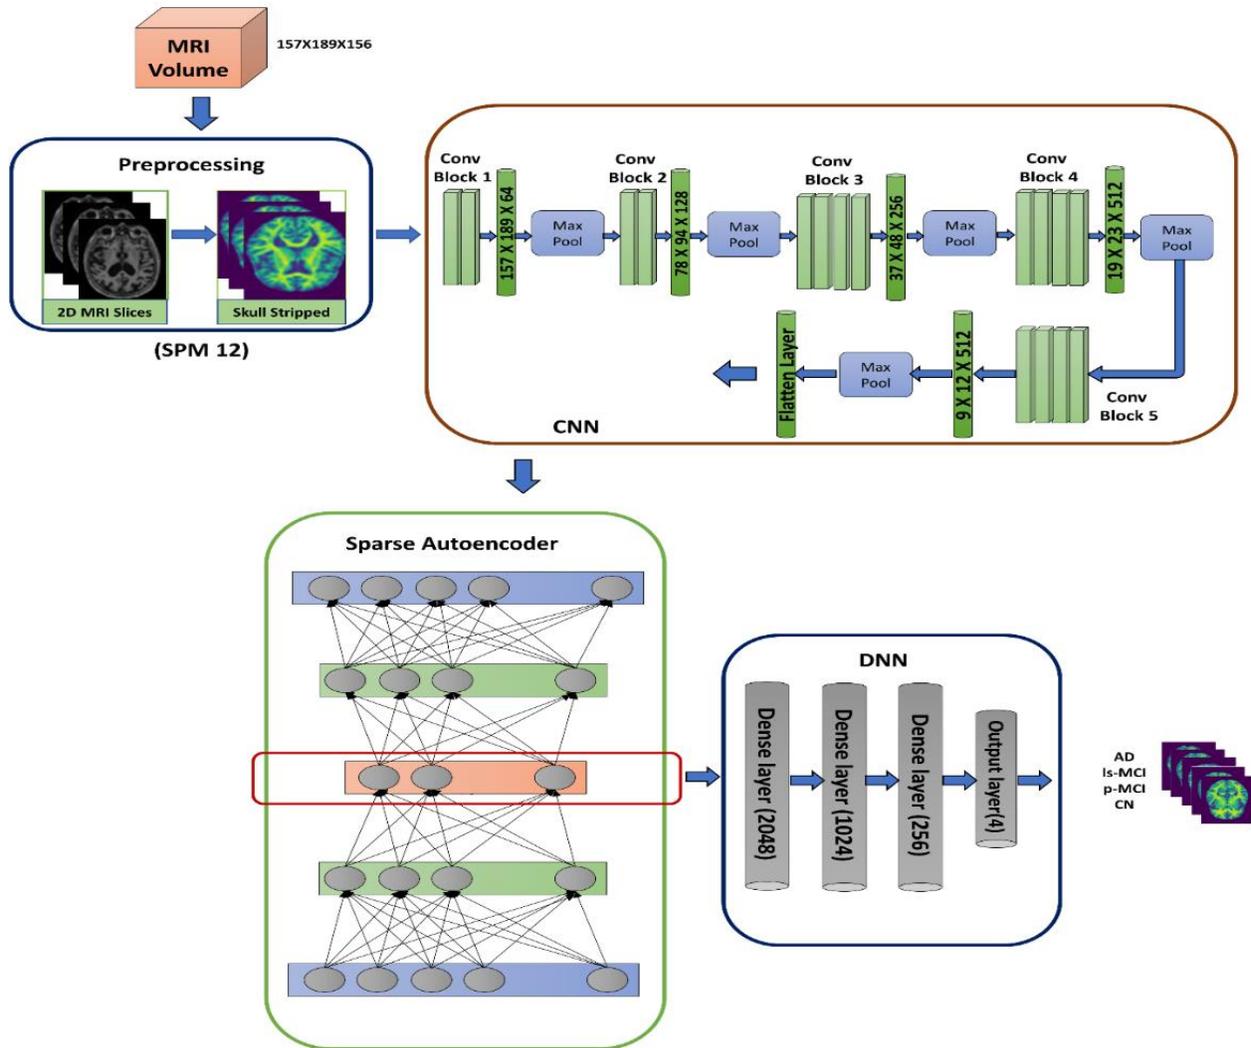

Fig. 1. Alz-SAENet Architecture.

### B. Preprocessing

Generally, the raw MRI data are stored in NifTi (.nii) format after retrieving from the ADNI repository. These NifTi files were further pre-processed utilizing the provision of the SPM12 package [29] installed under default settings. This stage pipeline is very much responsible for the removal of non-brain tissues and registering it into Montreal Neurological Institute (MNI) space. After pre-processing, the registered volumes are smoothed and scaled such that all volumes are

with the same dimension of  $157 \times 189 \times 156$  and sliced to generate  $1.5 \times 1.5 \times 1.5 \text{mm}^3$  voxels. Further, the MRI volumetric data is normalized voxel by voxel such that all intensities in the voxel fall in the 0 to 1 range for additional processing by retaining the disease features. For this investigation, only 40 medial MRI slices were considered such that they replicate AD progression clearly via hippocampal lesions to enable the network to distinguish the AD subjects. Sagittal plane views of pre-processed MRI volume for a sample are shown in Fig. 2.

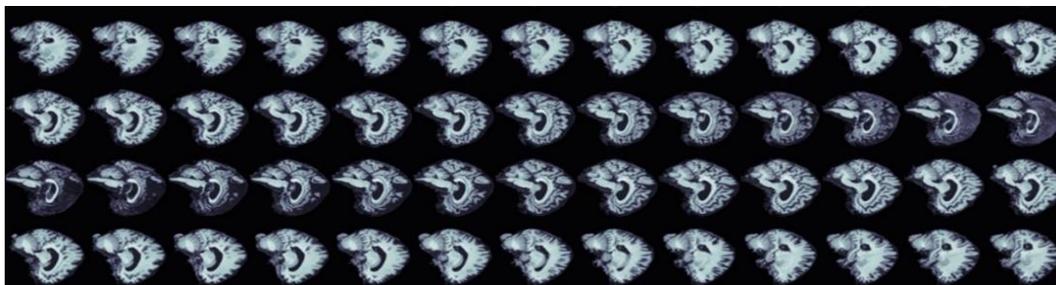

Fig. 2. Pre-processed Medial Sagittal Planes of Brain MRI.

### C. 3D CNN

Generally, CNN models consist of convolutional layers, batch normalization layers, pooling layers, and fully connected layers in sequential and backpropagation algorithm is used to learn latent features from MRI slices. Advanced architectures follow more complicated topologies for extracting features in complex applications where highly correlated data is present. In this work, we focused on a sequential model inspired by VGG 19 architecture [30], i.e., one popular version of Visual Geometric Group. VGG19 is a deep CNN that has been trained on millions of images with complex classification tasks.

This architecture consists of five blocks, amongst the very first two blocks comprise two convolutional layers preceded by a pooling layer each, and the last three blocks have four convolutional layers preceded by a pooling layer with a filter size of 2x2x2. In this method, all pretrained layers are frozen, and the output of the last convolution block is considered a discriminative feature of the MRI volume. This feature map is flattened using a flattening layer before being sent to a sparse encoder. All layers, dimensions, and several parameters for training the VGG19 network employed in this work for one MRI slice were tabulated in Table III.

### D. Sparse Autoencoder

A sparse autoencoder [31, 32] is merely an autoencoder with a sparsity penalty as a training benchmark. This autoencoder is used to draw more valuable insights from MRI with reasonable dimensionality. In addition, the bias applied at the encoder and decoder forces the AE to restore the input more accurately by avoiding overfitting.

Let  $s_i$  is the  $i^{\text{th}}$  input among the given training samples ( $s_1, s_2, \dots, s_N$ ). Then, the designed SAE is accomplished to restore the input  $s_i$  maximum similar to the estimated function  $h_{w,b}(x^i)$ . The cost function of SAE consists of three very important factors, viz., Mean squared error (MSE), Weight Decay (WD) and Sparsity [33]. The mean squared error for all  $N$  training samples and weight decay is mathematically expressed as in eq. (1) and eq. (2).

$$MSE = \frac{1}{N} \sum_{i=1}^N \frac{1}{2} \|h_{w,b}(x^i) - y^i\|^2 \quad (1)$$

$$WD = \frac{\lambda}{2} \sum_{l=1}^{n_l-1} \sum_{i=1}^{s_l} \sum_{j=1}^{s_{l+1}} (w_{ji}^l)^2 \quad (2)$$

This weight decay eq. (2) helps to avoid overfitting. Overfitting may result from a small value of  $\lambda$ , whereas underfitting may result from a big value of  $\lambda$ . To choose lambda for the term's best match, we, therefore, carried out a number of empirical studies.

TABLE III. LAYERS AND FEATURE MAPS OF 3D CNN

Block	Layer	Dimension	Parameters
	Input	[(None, 157, 189, 3)]	0
1	conv1 (Conv)	(None, 157, 189, 64)	1792
	conv2 (Conv)	(None, 157, 189, 64)	36928
	pool (MaxPooling)	(None, 78, 94, 64)	0
2	conv1 (Conv)	(None, 78, 94, 128)	73856
	conv2 (Conv)	(None, 78, 94, 128)	147584
	pool (MaxPooling)	(None, 39, 47, 128)	0
3	conv1 (Conv)	(None, 39, 47, 256)	295168
	conv2 (Conv)	(None, 39, 47, 256)	590080
	conv3 (Conv)	(None, 39, 47, 256)	590080
	conv4 (Conv)	(None, 39, 47, 256)	590080
	pool (MaxPooling)	(None, 19, 23, 256)	0
4	conv1 (Conv)	(None, 19, 23, 512)	1180160
	conv2 (Conv)	(None, 19, 23, 512)	2359808
	conv3 (Conv)	(None, 19, 23, 512)	2359808
	conv4 (Conv)	(None, 19, 23, 512)	2359808
	pool (MaxPooling)	(None, 9, 11, 512)	0
5	conv1 (Conv)	(None, 9, 11, 1024)	2359808
	conv2 (Conv)	(None, 9, 11, 1024)	2359808
	conv3 (Conv)	(None, 9, 11, 1024)	2359808
	conv4 (Conv)	(None, 9, 11, 1024)	2359808
	pool(MaxPooling)	(None, 4, 5, 1024)	0

Sparsity is the last term of the cost function that help to avoid overfitting by generating the activation for hidden neurons of the SAE to avoid overfitting. The eq. (3) is the average activated value of hidden layer, where ‘a’ is the ReLU activation function.

$$\hat{p}_j = \frac{1}{N} \sum_{i=1}^N [a_j^2(x^i)] \quad (3)$$

The sparsity is calculated so that  $\hat{p}_j=p$  constraint is satisfied, where p is the sparsity parameter. The deviation of  $\hat{p}_j$  from p help the network to activate and deactivate neurons in the hidden layer. KL divergence is used to define the parameter as in eq. (4).

$$\sum_{j=1}^{s_l} KL(p||\hat{p}_j) = \sum_{j=1}^{s_l} [p \log\left(\frac{p}{\hat{p}_j}\right) + (1-p) \log\left(\frac{1-p}{1-\hat{p}_j}\right)] \quad (4)$$

By combining the three terms, the cost function of the SAE  $J_{SAE}$  is defined as shown in eq. (5).

$$J_{SAE} = \frac{1}{N} \sum_{i=1}^N \frac{1}{2} \|h_{w,b}(x^i) - y^i\|^2 + \frac{\lambda}{2} \sum_{l=1}^{n_l-1} \sum_{i=1}^{s_l} \sum_{j=1}^{s_{l+1}} (w_{ji}^l)^2 + \beta \sum_{j=1}^{s_l} KL(p||\hat{p}_j) \quad (5)$$

Here  $\beta$  is the sparse penalty.

The primary goal of the Sparse Autoencoder [34] in this investigation is to reduce the dimensionality of 55,296 features obtained from 3D CNN. The SAE bottleneck layer provides more dominant insights, i.e., features that can be employed in classification. The bottleneck layer size is 2048 hidden units. Output from bottleneck generally has very limited number of features i.e. 2048 elements in the vector. These features are subsequently passed through DNN in final stage for classification purpose.

#### E. DNN

DNN is an artificial neural network with several hidden layers for solving complex classification problems. All these layers are dense, and the role of DNN here is in the final phase for classifying the latent features obtained from SAE. This DNN comprises two hidden layers, one input and output layer, with sizes 2048, 1024, 256, and 4, respectively. A SoftMax layer is generally employed as an output layer to estimate the incoming feature vector’s four possible classes, i.e., CN, p-MCI, ls-MCI, and AD. A dropout layer is also used between two dense layers to avoid overfitting. Finally, cross-entropy is used for determining the classifier cost function, and the weight decay term is added.

### IV. RESULTS AND INVESTIGATIONS

Concurrent training of the SAE and the DNN improved feature extraction while optimizing the classifier’s decision. The training was completed in 50 epochs with 16 batch size.

Sparse penalty, weight decay and sparsity parameter p were initialized 2, 0.0001, and 0.05, respectively. In last 20 epochs, DNN was fine-tuned, and parameters updated to minimize the cost function while the SAE parameters were frozen.

All the experimentations described in this paper were carried out in the Google Colab platform using python scripting with the support of 1X Tesla K80 GPU. To run our deep learning network, the Tensorflow Keras library is employed. To demonstrate the generalizability of the network in AD diagnosis, Alz-SAENet is examined by applying ADNI dataset and the Kaggle dataset in two scenarios.

In the first scenario, the proposed Alz-SAENet architecture is trained over 80% of the whole 1120 MRI volumes of the ADNI dataset that consists of MRI volumes with uniform dimensions of 157\*189\*156. After rigorous training, the network is tested using the remaining MRI volumes among the dataset acquired. The test results were assessed in terms of diagnostic accuracy, network sensitivity, precision, specificity, Negative Predictive Value (NPV), False Positive Rate (FPR), F1-Score, False Negative Rate (FNR), False Discovery Rate (FDR), and Mathew Correlation Coefficient (MCC). All these parameters are evaluated and listed in Table IV. AD vs CN classification over the ADNI dataset is 99.54% accurate and 100% sensitive, and produce MCC is 89.93%. p-MCI vs ls-MCI classification that facilitates early diagnosis of AD yields 98.56% accuracy, 100% sensitivity and 96.64% MCC. p-MCI vs AD classification is 97.90% accurate, 100% sensitive and 92.10% correlated data. CN vs ls-MCI classification that facilitates early diagnosis of AD yields 97.71% accuracy, 98.15% sensitivity and 95.24% MCC. However, Multiclass diagnosis produced 98.9% accuracy, 97.5% sensitivity and 94.25% MCC. These results demonstrate that Alz-SAENet has significantly classified AD stages, especially for the transitional period between ls-MCI and p-MCI, with an accuracy of 98.56%. The graphical representation is also depicted in Fig. 3.

In the second scenario, the proposed model was evaluated using another repository, i.e. Kaggle, to prove the generalization ability of this network over the unseen data during training. 6400 sample MRI medial slices belonging to four AD classes were acquired from the repository and evaluated in this model. Unlike in the first scenario, the evaluation metrics accuracy, precision, sensitivity, and F1-Score were only obtained and tabulated in Table V. The bar chart for these evaluation metrics is also shown in Fig. 4. AD vs CN classification yields 98.62% accuracy, 92% sensitivity and 98% precision. p-MCI vs ls-MCI diagnosis also attained 98.37% accuracy, 97% sensitivity, and 98% precision. This network produced 98.215% accuracy, 92.25% sensitivity, and 82.25% precision in multiclass classification.

TABLE IV. ALZ-SAENET PERFORMANCE OVER ADNI DATASET

Classification	Accuracy	F1-Score	Sensitivity	Specificity	Precision	NPV	MCC
AD vs CN	0.9954	0.8966	1	0.9953	0.8125	1	0.8993
p-MCI vs ls-MCI	0.9856	0.9761	1	0.9797	0.9534	1	0.9664
p-MCI vs AD	0.9790	0.9450	1	0.9821	0.9452	1	0.9210
ls-MCI vs CN	0.9771	0.9807	0.9815	0.9707	0.9799	0.9729	0.9524
Multiclass	0.989		0.975		0.915		0.9425

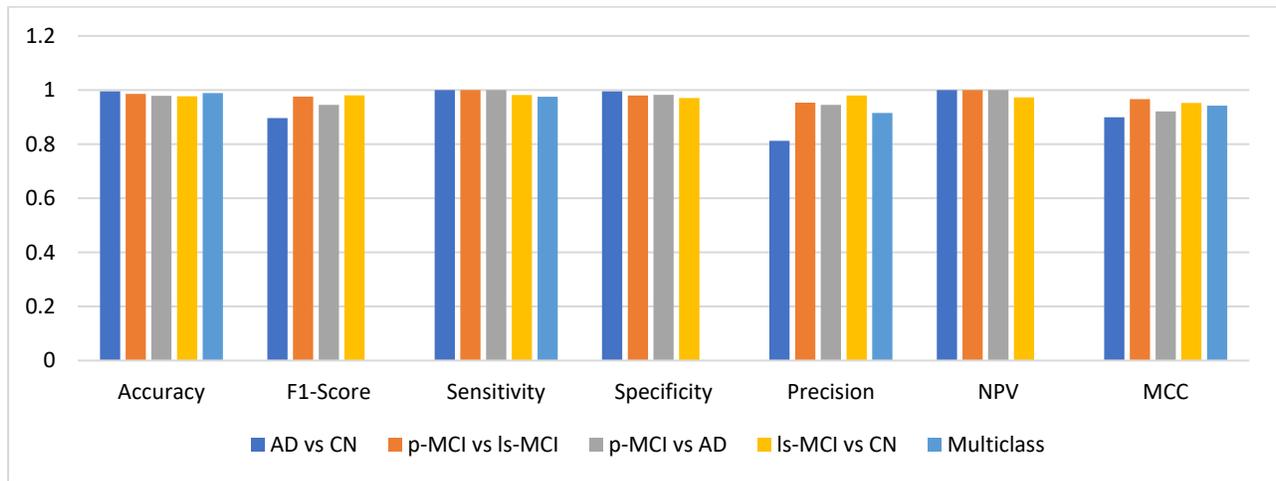

Fig. 3. Graphical Presentation of Alz-SAENet Performance over ADNI Data.

TABLE V. ALZ-SAENET PERFORMANCE OVER KAGGLE DATASET

Classification	Accuracy	F1-Score	Sensitivity	Precision
AD vs CN	0.9862	0.95	0.92	0.98
p-MCI vs ls-MCI	0.9837	0.98	0.97	0.98
p-MCI vs AD	0.9759	0.98	0.97	0.98
ls-MCI vs CN	0.9828	0.49	0.81	0.35
Multiclass	0.98215	0.85	0.9225	0.8225

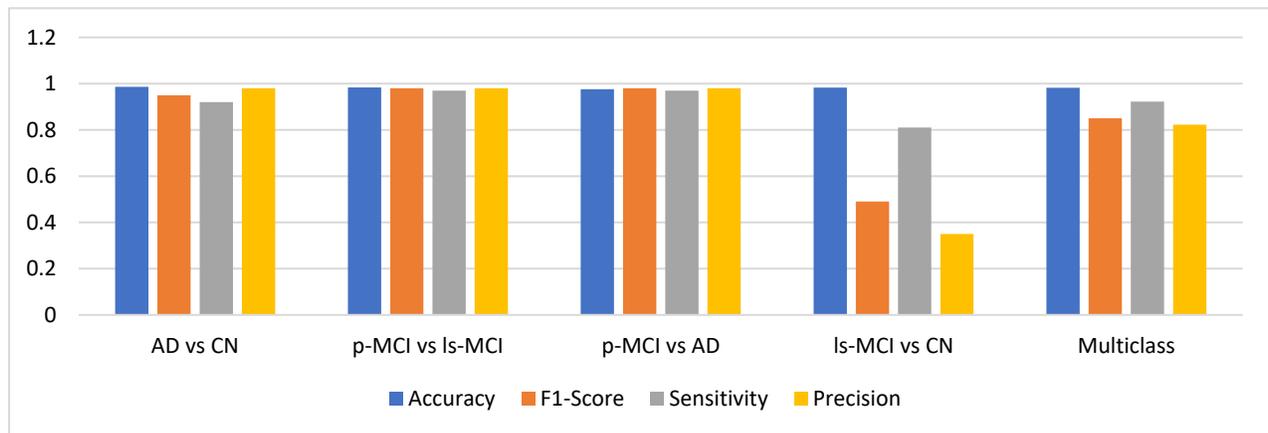

Fig. 4. Graphical view of Alz-SAENet Performance over Kaggle Data.

The results obtained in second scenario reveal that the network has shown good generalizability among the datasets which never seen during training. The model did not overfit due to the unbalanced datasets appeared in training process. This was happened because the SAE hyperparameters are tuned systematically so that its cost function gets minimized as the weight updation is in progress. With this support, the network can reliable outcomes even in non-supportive environments.

Attained results demonstrate that the proposed model, i.e., Alz-SAENet has greater generalizability in classifying the unseen data during the training process. The deep learning techniques from literature [9], [20], [25], and [26] are suffered

from different challenges in terms of convergence speed, overfitting, and hyperparameters tuning to obtain optimal performance from their networks. The results of Alz-SAENet have revealed that it has attained almost all those objectives by leveraging the benefits of Sparse autoencoder by minimizing the cost function.

The proposed model exhibited very poor performance over ADNI data in attaining precision, f1-score, and MCC for classifying AD and CN subjects. When applied to Kaggle data, it has not produced inadequate performance in terms of f1-score, sensitivity, precision, etc. for ls-MCI vs CN classification.

TABLE VI. COMPARISON OF ALZ-SAENET WITH LITERATURE REPORTED

Author	Modality	Datasets	Classifier	Subjects	Classification Metrics		
					Accuracy (%)	Precision (%)	Recall (%)
Soliman et al. [20]	MRI	ADNI	SAE+CNN	Multiclass	87.8	91%	88%
Akramifard et al. [26]	MRI	ADNI	Autoencoder + PCA + SVM	AD vs MCI MCI vs CN AD vs CN	66.84 66.97 84.46	-	48.70 78.94 81.87
Basheera et al. [25]	MRI	ADNI	CNN+ICA	Multiclass AD vs MCI MCI vs CN AD vs CN	86.7 96.2 98.0 100	89.6 93.0 96.0 100	86.61 100 100 100
Alz-SAENet	MRI	ADNI, Kaggle	3D CNN+SAE +DNN	AD vs CN CN vs ls-MCI AD vs p-MCI ls-MCI vs p-MCI Multiclass	99.54 97.71 97.90 98.56 98.90	81.25 97.99 94.52 95.34 91.5	100 98.15 100 100 97.5

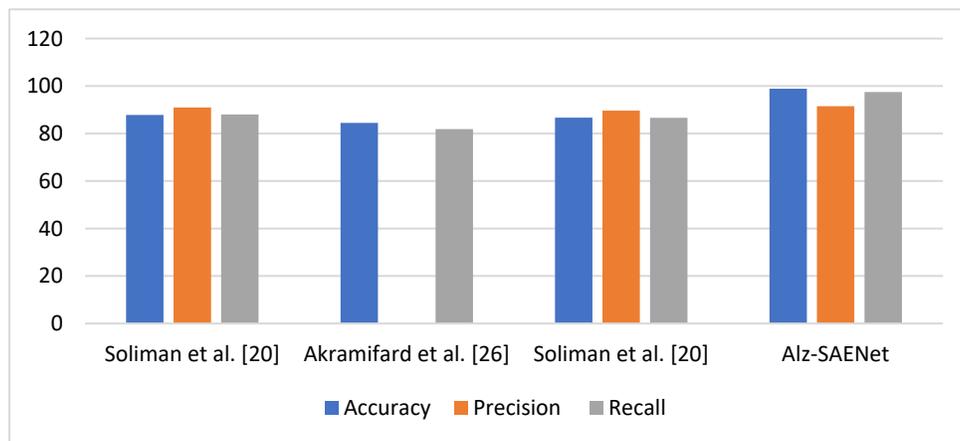

Fig. 5. Comparison of Alz-SAENet with Literature Reported.

The outcomes of the Alz-SAENet, i.e. integrated version of 3D CNN, SAE, and DNN illustrate that the performance of AD diagnosis is enhanced with the support of features that has learned and fine-tuning of hyperparameters of SAE during training. The model performs well on the test data, which is an important indicator of its generalizability, given that the model has never seen the data before. In addition, the proposed approach is also compared with recent literature in deep learning domain on ADNI data. This comparison is evidently shown in Table VI, and the proposed network outperformed all those methods focused by the literature deep analysis in Section II in terms of key parameters accuracy, precision, recall, etc. The same comparison is also depicted in Fig. 5.

## V. CONCLUSION

In this paper, we built a novel deep sparse autoencoder-based learning model named Alz-SAENet for classifying brain MRI volumes that exhibit severe AD symptoms to cognitive normal. This network utilized 3D CNN, SAE, and DNN components that assisted in understanding the neurobiological foundations of the AD brain in a better way. 3D CNN extracted 55,296 latent features from MRI volume. These features were flattened and their dimension was reduced through SAE via bottleneck layer and fed to DNN for classifying them into four stages of AD. During testing, this

network gave an accuracy of 98.9% over the ADNI dataset and 98.215% over the Kaggle data. These results demonstrated that Alz-SAENet outscored all the state-of-the-art approaches that worked on AD classification. In the future, we test the architecture over real-world data along with metadata to improve the generalizability, efficiency, and efficacy of early diagnosis of AD. Furthermore, the results obtained for ls-MCI and CN classification over the Kaggle dataset are needed to be enhanced.

# Development of Path Loss Prediction Model using Feature Selection-Machine Learning Approach

## Improvement of Path Loss Prediction Accuracy in Mixed Land-water Case

**Abstract**—Wireless network planning requires accurate coverage predictions to get good quality. The path loss accurate model requires a flexible model for each area including land and water. The purpose of this research is to develop a Cost-Hatta model that can be applied to the mixed land-water area. The approach used of this research is the three methods of feature selection of machine learning. The first stage of the research was the collection of field data. The measurement data included system, weather, and geographical parameters. The next stage was feature selection to obtain the best composition of features for the development of the model. The feature selection methods used were Univariate FS, Genetic Algorithm (GA), and Particle Swarm Optimization (PSO). After obtaining the best features from each method, the next stage was to form a model using four machine learning algorithms, namely Random Forest Regression (RF), Deep Neural Network (DNN), K-Nearest Neighbor Regression (KNN), and Support Vector Regression (SVR). The results of the improvements to the path loss prediction model were tested using the evaluation parameters of Root Mean Square Error (RMSE), Mean Square Error (MSE), and Mean Absolute Percentage Error (MAPE). The results of the testing showed that the improved Cost-Hatta model using the proposed Univariate-RF combination produced a very small RMSE value of 1.52. This indicates that the proposed model framework is highly suitable to be used in a mixed land-water area.

**Keywords**—Path loss; feature selection; machine learning; mixed land-water; Cost-Hatta

### I. INTRODUCTION

Path loss prediction is of great importance in the planning and optimization of coverage in wireless networks [1]. Path loss is used to predict the strength of the signal received by the user. The accuracy of path loss prediction plays an important role in determining the quality of a network design [2]. The complexity of environmental characteristics influences the level of complexity in the prediction of received signal strength. In the propagation process, electromagnetic waves undergo a number of treatments caused by various environmental and weather factors that are present around the propagation media. Some of the nearby objects can affect the treatment of electromagnetic wave propagation [3]. The electromagnetic wave treatments that occur include diffraction, refraction, and reflection [4], [5]. These treatments cause fluctuations in the signal power of the receiver due to a weakening in the power of the electromagnetic signal. This signal attenuation is the result of power loss that arises during

the electromagnetic wave propagation process in wireless networks. Electromagnetic wave propagation is extremely important in wireless communication systems [6].

Indonesia is an archipelago and has at least 5,590 main rivers and 65,017 tributaries spread across several islands in Indonesia, where the main rivers, watersheds (DAS) in Indonesia reach 1,512,466 square kilometers. People who live in watersheds use water transportation in carrying out the economic activities. The current problem is that there is no path loss prediction model that can be used for water areas, thus, current modeling is not accurate if it is used to plan networks in water areas, especially for areas that are passed by water transportation. Therefore it needs predictive modeling of path loss that can be flexibly used in land and water areas.

Research on the modeling of path loss prediction continues to be carried out to obtain high accuracy predictions in various area conditions. A number of researchers have studied path loss prediction in various kinds of conditions using different variables. Future challenges include the development of high speed wireless telecommunication technology with low latency. Accurate path loss prediction has a strong impact on good quality, low latency, and high throughput.

Conventional prediction models developed in the past include empirical and deterministic modeling. Empirical modeling is based on measurements and direct observation in the field. Empirical models provide a statistical picture of the connection between the dependent variables of path loss and a number of measured parameters, specifically frequency, transmitter height, receiver height, and distance between transmitter and receiver [7]. Empirical models are quick and easy to be implemented but have a low level of accuracy, which presents a challenge in empirical model development. Empirical models include Okumura-Hatta, Cost231-Hatta, the ECC model and the Ericsson model [8], [9]. Empirical modeling is the most frequently used type of modeling in planning and optimization systems of wireless networks of telecommunication vendors.

Machine learning is a method of learning about a data set which is used to create a model that can perform a particular task [7]. Machine learning carries out a study of data by learning with the use of algorithms and statistics. Machine learning can be divided into three types, namely supervised learning, unsupervised learning, and reinforcement learning.

\*Corresponding Author.

The algorithm of supervised learning can be further divided into two types, namely regression and classification. Based on the research data that exists, the modeling used in path loss prediction falls into the category of supervised learning regression. Regression is characterized by input and output data types in the form of numeric data. Examples of regression types include Support Vector Regression (SVR), Random Forest (RF), Artificial Neural Network (ANN), and K-Nearest Neighbor (KNN). The advantage of machine learning is its high level of accuracy compared with empirical methods [10].

## II. RELATED WORK

The focus of the following literature review is the various types of research field, feature variables, and feature selection methods used in the development of path loss prediction models. A number of researchers have developed path loss prediction models using machine learning in various kinds of area condition. These include a study by [11] on indoor building types using an Artificial Neural Network (ANN) model. The research of [12] and [13] also studies path loss prediction with several machine learning models in suburban areas, while [14], [6], and [15] investigate different area types, namely rural, suburban, and urban. Various other research has been developed in different places with a special measuring field, such as the research of [16] which focuses on a vegetation area, and [17], which focuses on the study of path loss prediction in the indoor area of an aircraft cabin. Other studies, such as those by [18], [19], and [20], use an unmanned aerial vehicle (UAV), while the research of [21] focuses on a mixed city-river area. Only a small number of studies have been carried out on path loss prediction in a mixed city-river area. This indicates that there is still room for development of research on path loss prediction in a mixed city-river area.

The types and numbers of input features used in the development of path loss prediction models are highly varied. Research in [22], [23] uses a single input feature, namely distance between the transmitter (TX) and receiver (RX). In addition to using the TX-RX distance feature, the research of [1] includes the feature of frequency as an additional input feature, while [7] also uses two features, with the addition of onboard GPS sensors. The study by [24] uses the feature of TX-RX distance and adds the features of PCC downlink throughput and PDCP downlink throughput as parameters of the input feature. User position based on longitude and latitude is also used as an input parameter, amongst others in the research of [17], to study the indoor area of an aircraft cabin. Longitude and latitude are also used in the research of [11] and [25] to study an outdoor location. In addition to using system parameters, some studies also use environmental parameters as input features. The research of [26], [15] uses the environmental parameters of humidity, temperature, and dew point as input feature parameters. In order to obtain results with a maximum degree of accuracy, some studies use a more complex combination of parameters in accordance with the focus of the characteristics of the research field. The research of [27], [28] uses six input parameters such as longitude, latitude, elevation, altitude, clutter height, and TX-RX distance. This shows that the types and numbers of

features can still be developed to match the specific object of the research field.

From the point of view of feature selection process, it is evident that feature selection is still rarely used in most studies. This is because the number of features used in the modeling is relatively small so there is no need to use a feature selection method. In the research of [12], PCA is used to reduce the number of data features and to simplify appropriate modeling. In addition, some research recommends Opportunities for Further Research that are related to types and development of feature selection methods. The research of [7] recommends the use of a feature selection method for further research on path loss prediction, while [16] also recommends further research on the development of feature selection methods. The purpose of including feature selection is to minimize the possibility of eliminating features that are important and relevant to the prediction model.

Main contribution of this research are proposes development of a path loss prediction model for a land-river area by varying the input parameters derived from system parameters and environmental parameters. The second contribution of this research are this model research combine an empirical model with a machine learning model by using three method features selection approach, namely Univariate, GA and PSO combined with the use of four Machine learning models namely Random Forest (RF), Support Vector Regression (SVR), K-Nearest Neighbor (KNN), and Deep Neural Network (DNN) where from the literature study has never been done before.

## III. MATERIAL AND METHOD

This section is divided into a number of stages: measurement, data processing, delta path loss empirical model calculation, feature selection, and modeling.

Fig. 1 shows the stages carried out in this study starting from the measurement stage then the data processing stage, followed by the best feature selection stage using three approaches methods namely Univariate, GA and PSO. The data with the best features are processed and modeled using four types of machine learning models, namely Random Forest (RF), Support Vector Regression (SVR), KNN Regressor and Deep Neural Network (DNN). The four models produced will be evaluated and obtained as the best model based on the level accuracy of RMSE.

### A. Measurement Location

The collection of the research data was carried out in the city of Palembang, Indonesia, which is located at 2°59'27.99"S 104°45'24.24"E. The city of Palembang covers an area of 400.61 km<sup>2</sup>, with an average altitude of 8 meters above sea level. Measurements were taken at Ultra High Frequency (UHF) on a 4G LTE 1800 MHz and 2100 MHz network. The data consisted of a number of input features which were divided into two groups, namely system parameters and environmental parameters.

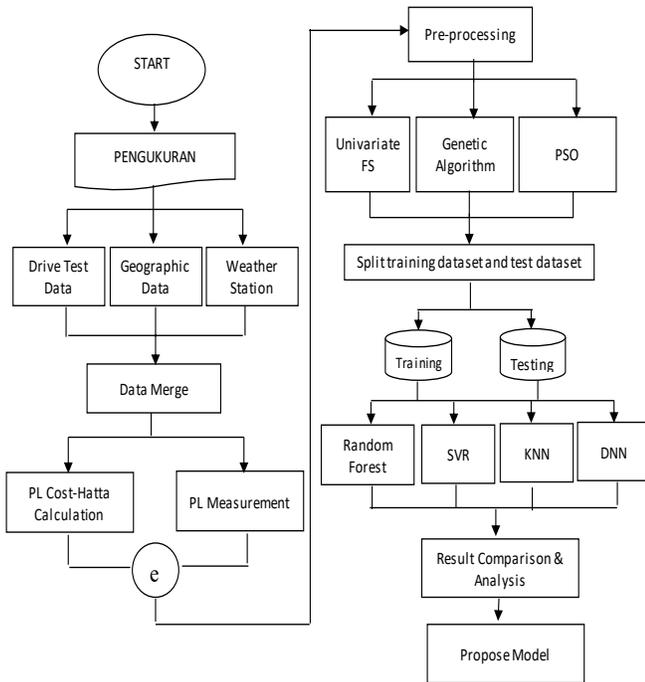

Fig. 1. Research Flow Chart Process.

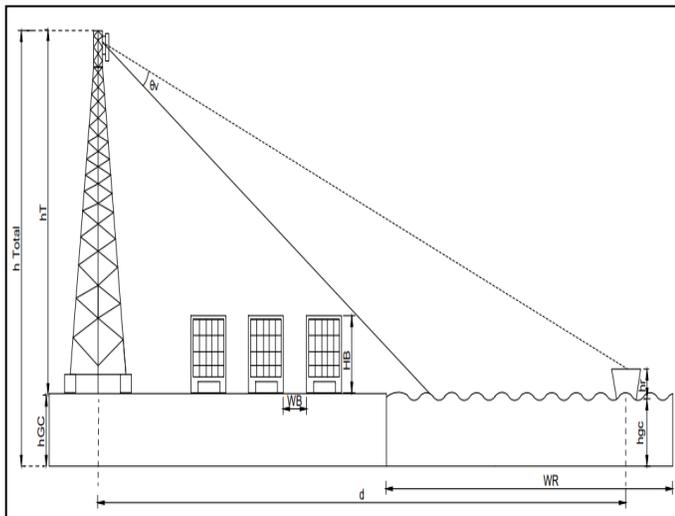

Fig. 2. Measurement Methodology.

Fig. 2 shows the data collection methods for several system parameters such as TX-RX distance, frequency, transmitter height, receiver height, river width, distance between buildings, building height, difference between TX-RX height, distance between transmitter and river border, distance between ship users and river border. The environmental parameters consisted of two segments, namely geographical parameters and weather parameters. The geographical parameters used in this research were slope contour and building density, while the four weather parameters were barometric pressure, temperature, humidity, and dew point.

The data collection was conducted using three measurement methods to obtain the various input and output parameters. A war driving measurement method was used to obtain values of path loss and system parameters. Fig. 3 shows the route taken at the measurement of path loss along the river with a distance of 13 km. The tools used for the war driving measurements were GPS and Dongle which were attached to a laptop. The war driving measurements used two handsets Samsung S5 as receiver, both of which were connected to the laptop. The handsets were locked at the two 4G LTE frequencies. The war driving methodology was used in dedicated conditions or conditions where the handsets were in active (download) mode. At the same time, the weather station tools located at Sriwijaya University took measurements of the weather parameters throughout the data collection. The geographical parameters were obtained based on the geographical maps which were processed using QGIS.

Fig. 3. Selected Route and Building Map on Google Earth for Data Collection.

### B. Data Processing

The data processing stage began with the preparation of data from the results of the measurements collected in each of the measurement stages to obtain a number of variables that could be used to create a framework for a model of path loss prediction. The data preparation stage started by processing the data. The results of the war driving measurements in the form of logfiles were treated with time based binning (in seconds) and exported in the form of excel files. The parameter used as path loss value was PUCCH Path Loss. The data of the users' location with the longitude and latitude positions of the data collection were also obtained from this data processing stage. The vertical angle, horizontal angle, and TX-RX distance parameters were calculated based on the angle and position of the BTS transmitter in relation to the user. The distances between the transmitter and river border, and user and river border were calculated based on the straight line intersection of the signal transmission and the river border, which was processed using QGIS.

The geographical parameters of slope contour, building density and distance between buildings were processed using Arcgis. The slope contour was obtained by determining the

difference between the elevation height at the transmitter point and the elevation height at four other points, specifically, 0.25%, 0.5%, and 0.75% of the TX-RX distance, and the difference between the elevation height of the transmitter point (TX) and the elevation height of the receiver point (RX). The average of these values was calculated to find the slope contour value. The building density was found by calculating the number of buildings that were crossed on a straight line between TX-RX, using the intersection on Arcgis. Fig. 4 show a building map was obtained from google earth and converted with Arcgis to find the building points. The distances between buildings were found by calculating the distance between TX-river border (on land) divided by the area of buildings crossed using the intersection on QGIS.

Fig. 4. Building Distribution Map using Arcgis.

Measurements were taken at the weather station to collect weather data about barometric pressure, temperature, humidity, and dew point, which were used as input parameters. The data from the results of the measurements in these three stages were combined to obtain a number of input and output variables.

### C. Model Cost-Hatta

The next stage was to find the delta value of the difference between path loss from the result of the measurements and path loss from the result of empirical calculations. The empirical model used in this research was the Cost231-Hatta model. This Cost-Hatta model is a combination of the Cost-231 model and the Hatta model. It can be used to calculate a number of factors, including TX-RX distance, frequency, transmitter height, and receiver height. The Cost-Hatta model is suitable for use in urban areas with a frequency range between 500 MHz – 2000 MHz [29][30]. The formula of the

Cost-Hatta model is shown below:

$$Lu \text{ (dB)} = 46.3 + 33.9 \times \log(f) - 13.82 \times \log(h_{te}) - a(h_{re}) + (44.9 - 6.55 \times \log(h_t)) \times \log(d) + CM \quad (1)$$

For urban area:

$$a(h_{re}) = 3.2 \times ((\log(11.75 \times h_{re}))^2) - 4.97 \quad (2)$$

For Sub Urban dan Rural:

$$a(h_{re}) = (1.1 \times \log(f) - 0.7) \times h_{re} - (1.56 \times \log(f) - 0.8) \quad (3)$$

CM: 0 dB for medium size towns and suburban areas

CM: 3 dB for downtown areas

Where  $f$  is frequency (MHz);  $h_{te}$  is height of BTS transmitter antenna (m);  $h_{re}$  is height of receiver antenna (m);  $d$  is distance between transmitter-receiver (m). The result of the delta calculation of the the difference in path loss was used as an output variable in the modeling.

### D. Feature Selection Dan Modelling

The next stage was the process of selecting the features that would be used in the process of developing the model. Feature selection is an important stage in machine learning modelling [31]. This research used three models of feature selection, namely Univariate Feature Selection, Genetic Algorithm, and Particle Swarm Optimization (PSO). The features selected from the three methods were then tested and compared using machine learning.

The Univariate method is a filter method. This kind of method makes an evaluation of every feature in relation to the output variables, then ranks the input features to determine the best features. The Univariate method uses the application of statistical calculations to assign the ranking of each feature. The main criteria used in the Univariate method for the selection of variables are statistical ranking technique and ranking order. After obtaining the ranking results, the next step in this research was to evaluate the number of best features based on the highest ranking, using the “MLPRegressor” model. The python script used was SelectKBest.

The next feature selection method used was Genetic Algorithm. The way this method works is to look for the most suitable composition of features, with the aim of achieving the best prediction accuracy. The Genetic Algorithm method is a search technique based on principles that arise as a result of the inspiration of genetic and evolutionary mechanisms found in a natural system and population of living organisms [32]. In a Genetic Algorithm, every individual in the population represents a candidate solution to the designated problem. The Genetic Algorithm changes a population of individuals by using several genetic functions such as selection, crossover, and mutation [33][34]. Genetic Algorithm is a wrapper method which evaluates every composition of parameter features using machine learning performance as the criteria of evaluation. The genetic algorithm approach is acceptable for various types of solving solutions such as optjimization and calls for scheduling[35].

PSO is based on the idea of the social and cooperative behavior of various species to fulfil their food needs, in this case existing in a multidimensional search space [36][37]. The PSO algorithm consists of a number of main parameters that are used by particles to determine the direction and steps that are then used to determine subsequent movement, in  $P_{best}$  and  $G_{best}$ [36][38]. The position of every particle represents a solution that has a particular fitness value. Particles have their own memory in which they store their best position, referred

to as personal best or *Pbest*[39]. These particles are evaluated in terms of a particular optimization function to identify their compatibility value and ability to hold the best solution. Every particle determines its next position in the search space based on the function of velocity, which calculates the best position of a particle and the best particle position in a population (*Gbest*). These particles will move at each iteration to a different position until they reach an optimal position [40].

After obtaining the best feature composition, the next step of the research was the modeling phase with machine learning. This research used four machine learning algorithms in the modeling process, namely Multi-Layer Perceptron (MLP), Random Forest, Support Vector Regression (SVR), and K-Nearest Neighbor. In the modeling stage, the prediction model was developed by studying how closely the data of the selected input features correlated with the results of the measurement output data.

*E. Evaluation and Deployment*

The final step was to evaluate the results of the machine learning modeling using an evaluation matrix. This evaluation parameter was used to observe the best accuracy level of the various machine learning models that had been developed. The path loss prediction model is a regression model in which the performance level of the model is calculated by comparing the prediction value with the actual value. The evaluation matrix used in this research included 3 parameters, namely RMSE, MSE, and MAPERMSE is the root of the Mean Square Error which is the evaluation parameter of the regression case.

$$RMSE = \sqrt{\frac{1}{N} \sum_{j=1}^N (y_j - \hat{y}_j)^2} \tag{4}$$

MAE is the average of absolute value of the difference between the actual value and the predicted value. MAE measures the average error between predictions and actual values.

$$MAE = \frac{1}{N} \sum_{j=1}^N |y_j - \hat{y}_j| \tag{5}$$

MAPE (Mean absolute Percentage Error) is the average value of the percentage error error between the actual value and the predicted value.

$$MAPE = \frac{1}{N} \sum_{j=1}^N \left( \frac{y_j - \hat{y}_j}{y_j} \right) \times 100\% \tag{6}$$

$y_j$  is the measured path loss,  $\hat{y}_j$  is the predicted path loss, and N is the number of samples.

IV. RESULT AND DISCUSSION

The preliminary data in this research included a total of 18 candidate variables that consisted of system parameters and environmental parameters. The environmental parameters were divided into two segments, namely geographical parameters and weather parameters. In The first step was to make calculations using the Cost-Hatta model, which is an empirical model. Only four parameter variables were used in this model, namely distance, frequency, height of TX and height of RX. These data were used to determine the value of calculated path loss and to find the delta value of the

difference between the measured path loss and calculated path loss.

The next step was to analyze the selection of the best variables from the 18 candidate variables using the stage of feature selection, as shown in Table I.

TABLE I. CANDIDATE VARIABLE

Variable Name	Variable Description	Level
Distance	Distance between transmitter (TX) and receiver (RX)	meters
Frequency	Frequency used in signal transmission	MHz
Height TX	Transmitter antenna height + altitude location	meters
Height RX	Receiver antenna height + altitude location	meters
Vertical angle	The angle difference between the vertical direction of the antenna and the vertical direction of the receiver	degree
Horizontal angle	The angle difference between the horizontal azimuth of the antenna and the horizontal direction of the receiver	degree
Width of River	River Width	meters
Height of Building	Surrounding building height	meters
Distance between Building	Distance between surrounding buildings	meters
Distance_TX to Border (Land)	Distance between transmitter (TX) and river border / distance on land	meters
Distance Border to User (Water)	The distance between the river border and the user / distance on the waters	meters
Delta Height of TX-RX	The difference between the height of the transmitting antenna and the receiving antenna	meters
Slope Contour	The angle between the horizontal plane and the direction of the contour of the ground	degree
Building Density	The building density between tranceiver and receiver	-
Barometric Pressure	Barometric pressure at the time of measurement	hPa
Temperature	Air temperature at the time of measurement	°C
Humidity	Air humidity at the time of measurement	%
Dew Point	Dew Point Value at the time of measurement	°C

A. Result of Empirical Model by using Cost-Hatta

In the preliminary stage, the path loss value was calculated using the Cost-Hatta empirical model. In the existing models, the Okumura-Hatta models are divided according to type of area, whether urban, suburban, or rural. The results of the Cost-Hatta model calculations were compared with the path loss value from the results of the measurements collected in order to obtain the evaluation parameter value.

TABLE II. EVALUATION PERFORMANCE OF COST-HATTA MODEL

Model	Area	Evaluation		
		RMSE	MAE	MAPE
Cost-Hatta	Urban	31.643	27.114	18.554
	Sub-Urban	25.832	21.319	15.375
	Rural	25.832	21.319	15.375

Table II shows that the Cost-Hatta calculation of urban area had an RMSE value of 27.114 while the suburban/rural

area calculation had an RMSE value of 21.319. This result shows that the calculation model with Cost-Hatta in a suburban area had a higher level of accuracy than the calculation value in an urban area. This indicates that the measurement value in a mixed land-water area was more compatible with the calculation in a suburban area. However, the RMSE value still showed an inadequate level of accuracy because it exceeded the limit of an RMSE value, which should be less than 10. Therefore, there is a need to improve the model of the Cost-Hatta formula by modeling path loss error using machine learning. Path loss error is the difference between the path loss result from the Cost-Hatta calculation and the path loss value from the measurement result. The path loss error value obtained was used as an output variable in the process of prediction improvement.

**B. Results of Feature Selection Process**

The first step in the process of developing the path loss prediction model was the feature selection process. The feature selection process used three methods to obtain the best composition of features. The composition of features produced by these three methods is as follows:

1) *Univariate feature selection:* The Univariate method was used to select the features with the highest level of correlation. The type of score function used was Mutual Information Regression. The next step was to provide alternative feature combinations based on the different degrees of correlation. The first feature selection method is by using Univariate FS. The score function used is mutual info regression. Univariate feature selection works by selecting the best features based on univariate statistical tests.

Fig. 5 shows that based on metode Univariate FS, frequency has the highest ranking. This indicates that the frequency value had the strongest correlation with the path loss variable, followed by TX-RX distance, border to user distance (water), and distance between buildings (m). This research shows that frequency and distance variables, including TX-RX distance, border to user distance (water), and distance between buildings, play an extremely important role in path loss prediction. The features with the weakest correlation were the parameters of RX vertical angle from TX main beam and building height. The RX vertical angle from main beam variable did not have a significant effect because the measurements were carried out in the NLOS area, so there were many measurement factors that influenced this parameter, such as blockage from buildings and other nearby objects. The building height parameter also had no significant influence because the collection of building data only took into account the height of buildings in the area of the user location point but did not take into account all the buildings between the BTS transmitter location and the receiver location.

Some of these candidate features were modeled simply and evaluated using a machine learning classifier in the form of Random Forest Regression. Table III shows that the best feature combination was achieved by combining the best 17 features, with an RMSE value of 3.07. The combination of these 17 features eliminated the variable with the lowest correlation level to output, which was the RX vertical angle from main beam variable.

TABLE III. CANDIDATE VARIABLE OF UNIVARIATE FEATURE SELECTION

Number of Variables	MAE	MSE	RMSE
1	10.59	171.99	13.11
2	9.13	138.71	11.78
3	9.11	137.15	11.71
4	9.11	140.95	11.87
5	6.68	94.48	9.72
6	6.87	97.13	9.86
7	6.71	93.52	9.67
8	6.74	95.75	9.79
9	6.68	91.89	9.59
10	6.87	98.30	9.91
11	6.53	89.96	9.48
12	6.34	85.27	9.23
13	6.58	88.15	9.39
14	6.62	91.12	9.55
15	6.66	92.65	9.63
16	2.30	10.89	3.30
17	2.18	9.41	3.07
18	2.25	10.38	3.22

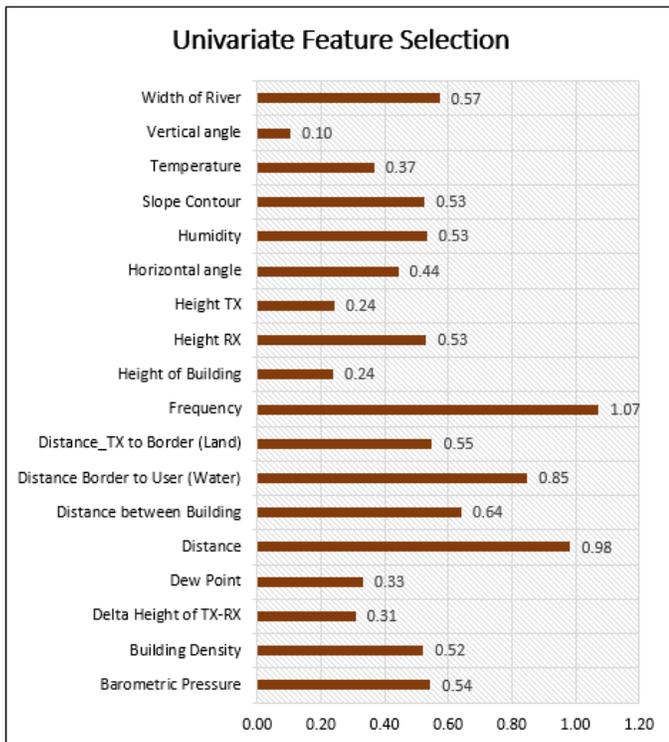

Fig. 5. Value of Mutual Information Univariate for Path Loss Prediction.

2) *Genetic algorithm feature selection:* The Genetic Algorithm feature searches for the best feature composition by performing an evaluation of every feature combination using a classifier with machine learning. The classifier used in this

research was Random Forest Regression. This research searched for the best composition by altering the values of the parameter settings on the Genetic Algorithm. The population values were changed between 20, 50, and 80. The crossover % values were changed between 0.5, 0.7, and 0.9, and the mutation % values were varied between 0.3, 0.5, and 0.7.

TABLE IV. CANDIDATE VARIABLE OF GENETIC ALGORITHM

Max Iteration	Population	%Crossover	%Mutation	Selected Variable	RMSE
20	20	0.5	0.3	[3,6,8,13,15,16,18]	9.870

Table IV shows that the best composition of variables achieved was using the variable numbers [2, 3, 4, 5, 9, 10, 11, 15, 18]. These variables are frequency, TX height, RX height, RX vertical angle from TX main beam, distance between buildings, barometric pressure, temperature, slope contour, and border to user distance (water). The parameters selected in the Genetic Algorithm showed quite a marked difference with the Univariate FS. The RX vertical angle from TX main beam and distance between buildings, which had a low correlation with output, were included in the selected parameter composition, as was the TX-RX distance parameter. This was because the GA method did not take into consideration the correlation level between the input and output variables but performed a combination search with the mutation and crossover between the variables.

3) Particle Swarm Optimization (PSO) feature selection: PSO is also a wrapper method, which searches for the best

composition by evaluating every possibility for each candidate combination using machine learning, searching for the best accuracy based on the results of the evaluation. This research carried out a number of trials by altering the values of the PSO parameter settings. Particle number, weighting, and C1/C2 values were changed to obtain the best accuracy value from the selected variables. The number of particles was varied with the values of 40, 70, and 100, while the W and C1/C2 values were varied with the values of 0.2, 0.5, and 0.8.

TABLE V. CANDIDATE VARIABLE OF PARTICLE SWARM OPTIMIZATION

Max Iteration	Particle	W	C1/C2	Selected Variable	Score Error
100	40	0.2	0.2	[1,2,3,4,5,6,8,9,10,11,12,13,4,16,17]	2.433
100	40	0.5	0.2	[2,3,5,6,7,8,11,13,4,15,16,17,18]	2.423

100	100	0.5	0.2	[2,3,4,5,6,9,12,13,4,15,16,17,18]	2.420
100	100	0.8	0.2	[1,2,3,5,6,7,8,9,10,12,13,4,15,16,17,18]	2.413
100	100	0.2	0.5	[1,2,3,4,6,7,9,4,15,16,17,18]	2.423
100	100	0.5	0.5	[1,2,3,4,5,6,7,8,9,11,12,13,4,16,17,18]	2.414
100	100	0.8	0.5	[1,2,3,4,6,7,8,9,10,11,13,4,15,16,17,18]	2.417
100	100	0.2	0.8	[2,3,4,5,6,9,10,12,13,4,15,16,17,18]	2.417
100	100	0.5	0.8	[1,2,3,4,5,6,7,8,9,10,11,12,13,4,15,16,17,18]	2.411
100	100	0.8	0.8	[2,3,4,5,6,7,8,9,11,12,13,4,15,16,17,18]	2.413

Table V shows that the best composition of variables was the composition of variables [2, 3, 4, 6, 7, 9, 10, 11, 12, 13,

14, 15, 16, 17, 18]. The variables eliminated from the selected variables were TX-RX distance, RX vertical angle to mainbeam, and building height. This was the same as the Univariate results, where the parameters of RX vertical angle to mainbeam and building height, which had a low correlation, were not included in the selected variables. However, what was significantly different was the parameter of TX-RX distance, which had a sufficiently high level of correlation but was not included in the selected variables in PSO. As in the case of GA, PSO did not take into account the level of correlation between the input and output variables, but carried out a combination search with a particular method. In PSO, the search uses a swarm technique, which is a search based on the history of the best values, whether Pbest or Gbest.

C. Machine Learning Evaluation

In this research, four machine learning models were used to improve path loss prediction. The results of the evaluation parameters using four machine learning model are presented.

Table VI shows the evaluation of combination parameters to the feature selection methods with machine learning models. These results indicate that the best feature selection in DNN modeling is the Univariate method with an RMSE value of 4.49. These results are also shown in the KNN Regressor and Random Forest modeling where the smallest RMSE value uses the Univariate feature selection method where the RMSE values are 3.75 and 1.52 respectively, while the feature selection method using the GA method has the lowest accuracy rate for the use of the three types of algorithms. The SVR modeling shows different results, namely the best feature selection using GA, while the selection feature with the largest RMSE uses Univariate.

Table VII shows the best combination of feature selection methodology and machine learning. In the improvement of the Cost-Hatta model using Univariate-Random Forest, it has the smallest level of accuracy, namely the RMSE value of 1.52, MAE of 1.09 and MAPE of 14.08. The second accuracy value is model improvement using Univariate-KNN with a RMSE value of 3.75, an MAE value of 2.76 and a MAPE value of 35.75. On the third device, using univariate-DNN with an RMSE value of 4.49, an MAE value of 3.31 and a MAPE value of 308.8. While the worst value of accuracy improvement is by using GA-SVR. The value of the level of accuracy in the model is RMSE of 17.09, MAE value of 13.9 and MAPE value of 592.29.

The results of the Cost-Hatta model improvement using a machine learning approach can be seen in Fig. 6. The graph shows that the increasing accuracy using univariate-RF was the highest in RMSE accuracy, which is around 94.12%, followed by Univariate-KNN Regression and Univariate-DNN where the increase values are 85.48% and 82.67%, respectively. The lowest RMSE accuracy increase value is in the GA-SVR combination, with an accuracy increase of 33.84% from the Cost-Hatta RMSE value of 25,832 to 1.52.

TABLE VI. EVALUATION PERFORMANCE OF FEATURE SELECTION – MACHINE LEARNING MODEL

Model	FS	RMSE	MAE	MAPE
DNN	GA	5.58	4.15	720.57
	PSO	5.18	3.86	705.96
	Univariate	4.49	3.31	308.80
KNN Regressor	GA	4.61	3.24	148.09
	PSO	3.88	2.80	89.56
	Univariate	3.75	2.76	35.75
Random Forest Regressor	GA	1.76	1.22	105.79
	PSO	1.58	1.12	36.54
	Univariate	1.52	1.09	14.08
SV Regressor	GA	17.09	13.90	592.29
	PSO	18.08	14.65	634.28
	Univariate	18.21	14.74	252.81

TABLE VII. COMPARISON OF COST-HATTA MODEL WITH MACHINE LEARNING MODIFICATION MODEL

Model	Evaluation		
	RMSE	MAE	MAPE
Cost-Hatta	25.832	21.319	15.375
Cost-Hatta - Univ-DNN	4.49	3.31	308.8
Cost-Hatta-Univ-KNN	3.75	2.76	35.75
Cost-Hatta-Univ-RF	1.52	1.09	14.08
Cost-Hatta-GA-SVR	17.09	13.9	592.29

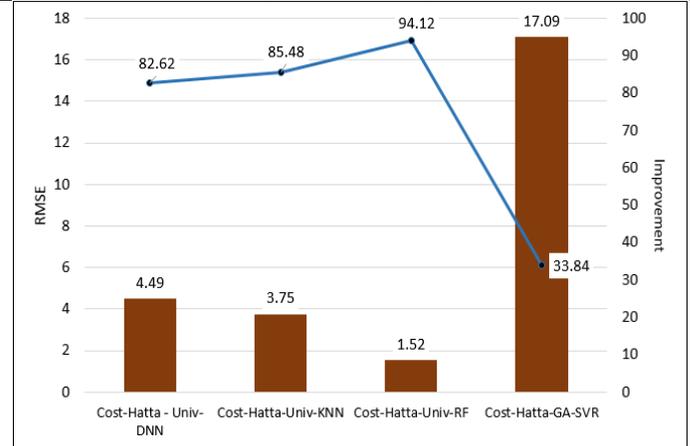

Fig. 6. Improvement Percentage of Machine Learning Model Approachment.

V. CONCLUSIONS

The determination of the features in the modeling will determine the accuracy of the path loss prediction. The condition of different signal propagation area causes the complexity of the various parameters needed in predicting path loss modeling, especially in mixed land-water areas. System parameters and environmental parameters have an influence on the path loss value. The feature selection method approach is needed to choose the best combination of

parameters in the construction of the prediction model. Improvements to the Cost-Hatta model with the feature-selection and machine learning approach resulted in a significant improvement in accuracy. The combination of the Univariate-RF model is the best combination with an increase in accuracy of 94.12% from the previous RMSE Cost-Hatta value. This indicates that the proposed model framework is highly suitable to be used in a mixed land-water area.

## VI. FUTURE WORK

In the next research, some suggestion to increase path loss prediction accuracy especially in mixed land water area:

1) Hyper-parameter optimization of machine learning models can be carried out. Metaheuristic methods such as Genetic Algorithm and Particle Swarm Optimization can be used in determining the composition of hyper-parameters to get the best accuracy value.

2) Expand measurement data to get a more varied sample value, especially for weather parameters.

## ACKNOWLEDGMENT

The first author is a doctoral student at the Faculty of Engineering Science, Universitas Sriwijaya. The authors would like to thank Universitas Sriwijaya for their support in carrying out this research.

# Employability Prediction of Information Technology Graduates using Machine Learning Algorithms

Gehad ElSharkawy, Yehia Helmy, Engy Yehia

Dept. Business Information Systems

Faculty of Commerce and Business Administration, Helwan University, Cairo, Egypt

**Abstract**—The ability to predict graduates' employability to match labor market demands is crucial for any educational institution aiming to enhance students' performance and learning process as graduates' employability is the metric of success for any higher education institution (HEI). Especially information technology (IT) graduates, due to the evolving demand for IT professionals increased in the current era. Job mismatch and unemployment remain major challenges and issues for educational institutions due to the various factors that influence graduates' employability to match labor market needs. Therefore, this paper aims to introduce a predictive model using machine learning (ML) algorithms to predict information technology graduates' employability to match the labor market demands. Five machine learning classification algorithms were applied named Decision tree (DT), Gaussian Naïve Bayes (Gaussian NB), Logistic Regression (LR), Random Forest (RF), and Support Vector Machine (SVM). The dataset used in this study is collected based on a survey given to IT graduates and employers. The performance of the study is evaluated in terms of accuracy, precision, recall, and f1 score. The results showed that DT achieved the highest accuracy, and the second highest accuracy was achieved by LR and SVM.

**Keywords**—Machine learning; IT graduates; higher education; employability; labor market

## I. INTRODUCTION

Due to the dynamically changing job market and the rapid advancements in technology. The growing demand for Information Technology (IT) professionals is one of the highest demands all over the world [1]. Human capital is one of the most important economic assets of production and is considered the main pillar for raising the standard of living and developing human resources on which countries depend in strategic planning to achieve sustainable development, as human capital represents the workforce that engages in all service, production, and consumer activities in society. As a result, higher education institutions (HEIs) produce an increasing number of graduates each year. The mismatch between the higher education outputs and the labor market demands is considered one of the major threats to economic growth which causes high unemployment rate and misplacement problems among higher education graduates in Egypt. The mismatch is due to poor collaboration between the labor market and HEIs. This lack of communication results in the wrong kind of workforce, thus errors in its production are costly [2]–[4]. Thereby, to avoid this mismatch, the HEIs have to ensure the graduates' employability.

Machine learning (ML) techniques can be used to predict the employability signals of IT graduates and identify the most significant factors affecting their employability as early as possible so appropriate actions can be taken to enhance their employability in order to equip them with the appropriate knowledge and skills before they enter the dynamic job market.

There is increasing interest in applying machine learning in higher education, according to certain prior studies to predict the graduates' employability but still, the use of automated machine learning to predict students' employability in its initial stage, ML is a subset of artificial intelligence (AI) in which computers analyze large datasets to learn patterns that will make predictions for new data, in contrast to traditional computer methodologies. In traditional reasoning, algorithms are a set of explicitly defined instructions that computers use to describe or solve problems [5], [6]. As a result, in the hiring process, graduates with experience are in high demand due to high productivity and low training cost than those who did not have any experience. HEIs must undergo frequent evaluations to provide future IT graduates with the demanded skills as it is considered the main factor to produce this workforce [7].

The earlier studies have shown a great interest in examining the mismatch between HEIs output and labor market demands. By applying different ML algorithms. However, these studies focused on one or a few features only. As a result, the two main research questions of this study are:

RQ1) What are the most significant features that affect graduates' competitive advantage to match labor market demands?

RQ2) what are the best machine learning algorithms for employability prediction of IT graduates?

The objective of this study is to develop a prediction ML model for graduates' employability status (predict whether the IT graduate is most likely to be qualified or not qualified to match labor market demands), and for better utilization of the collected dataset which can greatly help understand the extent to which IT graduates were prepared for the highly technical IT careers to enter the workforce.

The findings of this study will help:

- Reduce the gap between labor market demands and HEIs.

- Improve the IT graduates' qualifications to match labor market demands.
- Provide valuable insights for guiding HEIs to make better long-term plans for producing graduates who are knowledgeable and skilled through prediction of their employability status.
- Contribute significantly to the placement process for employers.
- Decrease the high unemployment rate of IT graduates.

The rest of this paper is organized as follows: Section II presents various relevant works in the field of employability prediction. Section III describes the proposed methodology in detail. Section IV shows the results of the used algorithms and the discussion of the analysis of the used features. Section V presents the conclusions of this study with some limitations and improvements.

## II. RELATED WORK

In recent years, many researchers attempted to use machine learning in higher education to enhance graduate's features and curricula to support employability [8]. To discuss the contribution of ML in continuous quality improvement. We focused on some of the previous works that used different machine learning techniques such as Artificial Neural Network (ANN), Decision Tree (DT), K-Nearest Neighbor (KNN), Gaussian Naïve Bayes (Gaussian NB), Logistic Regression (LR), Neural Network (NN), Random Forest (RF), Naïve Bayes (NB) and Support Vector Machine (SVM).

In [9], the author predicted which students are most likely to get work after graduation by using data analytics and machine learning techniques such as SVM, LR, ANN, DT, and discriminant analysis. Also, the features used are hard skills, demographics features, extra/co-curricular activities, and internships the data were obtained from student surveys and institutional databases. The SVM classification algorithm achieved an accuracy of 87.26%.

The authors in [10] aimed to identify the most significant factors affecting graduate employability by using three classification algorithms DT, ANN, and SVM. The features used in this research are hard skills, soft skills, demographic features, extra/co-curricular activities, university features, and internships the research data were collected from institutional databases. The SVM algorithm shows 66.096% accuracy.

A web-based application is developed by [11] through applied machine learning algorithms DT, NB, and NN to predict the sustainability of IT students' skills for recruitment mainly hard skills and soft skills, the collected data were from student and recruiter surveys, the NB achieved the highest

accuracy of 69%. In another research [12], supervised machine learning techniques such as LR, DT, RF, KNN, and SVM were used to predict high school students' employability for part-time jobs with local businesses the hard skills, demographic features, and extra/co-curricular activities features were used and collected from student surveys. The LR algorithm achieved an accuracy of 93%.

The authors in [13] analyzed the data from education institutions to predict the students' employability and determine the factors affecting their employability by using hard skills, soft skills, demographic features, extra/co-curricular activities, and university features then applied four ML algorithms which are DT, Gaussian NB, SVM, and KNN. The results achieved an accuracy of 98% by DT and SVM.

Furthermore, a student employability prediction system was developed by [14] using SVM, DT, RF, KNN, and LR algorithms to predict the students' employability, Institutional databases were obtained, and the hard skills, soft skills, and demographic features were used. The results of this research achieved an accuracy of 91% by the SVM algorithm. In [14], the authors identified the most predictive attributes through hard skills, soft skills, and demographic features to determine why students are most likely to get employed using graduates surveys and institutional databases, the applied and compared three methods are SVM, RF, and DT. The SVM achieved the highest accuracy of 91.22%.

The authors in [15] investigated the impact of various institution features on graduate employability using the hyperbox-based machine learning model which achieved 78% accuracy. A hybrid model was proposed by [16] for student employability prediction through a deep belief network and Softmax regression (DBN-SR) the dataset obtained from student surveys and the hard skills, soft skills, demographic features, and university features were used as the adopted features the results achieved high accuracy with 98%.

In [17] predicted the students' employability based on technical skills the institution databases were collected and the following algorithms were applied SVM, LR, DT, RF, AdaBoost, and NB, the highest accuracy achieved is 70% by the RF algorithm. Finally, the authors in [18] developed a model using various machine learning methods DT, RF, NN, and Gaussian NB to forecast candidate hiring by employing different statistical measures on feature selection such as hard skills, demographic features, and professional experience, the highest accuracy was achieved by Gaussian NB with 99%. Table I depicts and summarizes the relevant studies according to their adopted features, dataset sources, ML models, output features, and accuracy of the best-adapted model to answer RQ1.

TABLE I. COMPARISON OF RELATED STUDIES

Reference	Year	Adopted features categories	Dataset sources	ML model	Output features	Accuracy

### III. METHODOLOGY

In this section, we will discuss the methodology of our study, the machine learning algorithms applied, and the evaluation metrics used in this study. Fig. 1 highlights the research methodology: i) Data collection; ii) applying data preprocessing; iii) Splitting the dataset into two sets, a train set to train the model and a test set to evaluate the model; iv) building our model by applying five ML classification algorithms; v) evaluating the model; vi) outcome the proposed model to predict the qualified IT graduate to meet labor market demands. To answer RQ1: What are the most significant features that affect graduates' competitive advantage to match labor market demands? we followed the methodology steps as shown below.

#### A. Data Source

The dataset used in this research was obtained based on a survey given to IT graduates and employers in Egypt. We created an online survey with pertinent questions and then distribute it to IT graduates including (Computers & Artificial intelligence, Business information systems, Software Engineering, and Management information systems) and several IT companies from different sectors to get the desired findings. A brief description of each feature selected, and its value is described in Table II. We classified them into four categories (Trainings, Soft skills, Hard skills, and In-demand skills) each category has the most-related features, and the values (0,1) of the first three categories indicated that "0" means the graduate does not been trained or given a specific course during their study years in the college. While "1" means the graduate has been trained or given a specific course in those skills. In the fourth category, the value (0-7) means how many courses or trainings the graduate received from those fields to be qualified for the industry requirements.

#### B. Data Preprocessing

Data preparation is a critical stage while creating a machine learning model as it is difficult for a machine to read

the raw datasets to produce the expected results [19]. So, data preprocessing make data suitable for a machine learning model. First, we eliminate noise, missing values and make the data consistent. Then, we apply feature selection to identify the relevant features to allow classifiers to reach the optimal performance which has a greater impact on IT graduates' employability to match the labor market demands. Finally, we Split the dataset into two sets (80%) for training to train the model and (20%) for testing to test the accuracy of the model and enhance the performance of our machine learning models.

#### C. Prediction Models

Five different binary classification algorithms are used to predict the IT graduates' employability using the collected dataset. Because it categorizes new observations into one of two classes. The binary class in our dataset has two values (0) for a not qualified graduate that does not match labor market demands, and (1) for a qualified graduate. The number of records used in this study is 296. We used the following libraries Scikit Learn, Pandas, NumPy, Matplotlib, and Seaborn of the Python programming language. The five classification algorithms are:

Decision Tree Algorithm: is a supervised learning technique equivalent to a series of IF-THEN statements built a structure of branches and nodes based on the evidence obtained for each feature during the method learning process [10]. DT algorithm generates decision trees from training data to solve classification and regression problems. In our proposed model, the Gini method was used to create split points by finding a decision rule that produces the greatest decrease in impurity at a node.

$$G(t)=1-\sum_{i=1}^c p_i^2 \quad (1)$$

where  $G(t)$  is the Gini impurity at node  $t$  and  $p_i$  is the proportion of observations of class  $c$  at node  $t$ . Recursively, this decision-making process is carried out until all leaf nodes are pure or a certain cutoff is achieved.

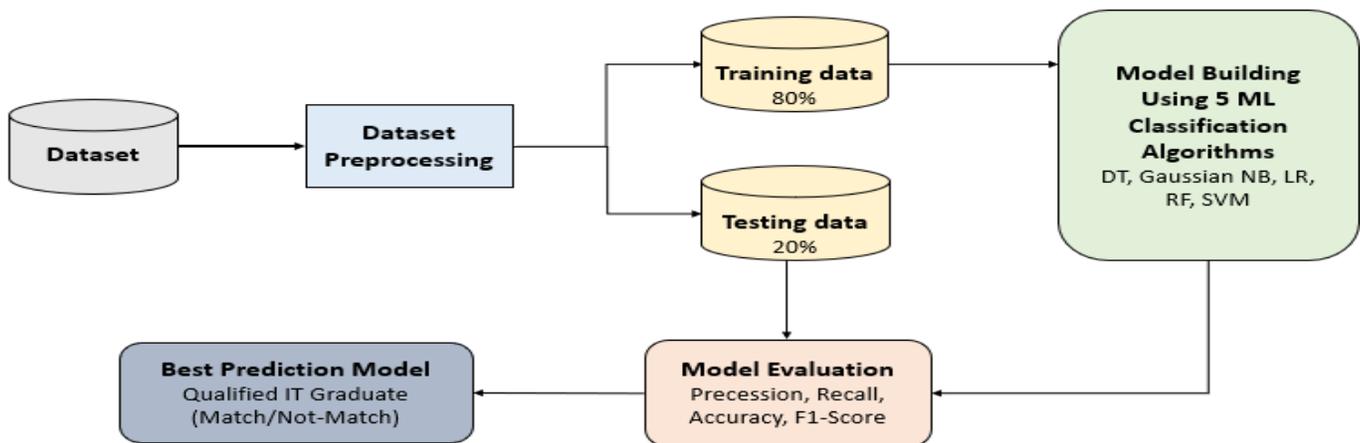

Fig. 1. The Research Methodology.

TABLE II. DESCRIPTION OF DATA FEATURES

Category	Feature	Values	Description
Trainings	Internship	(0,1)	A professional learning experience that provides meaningful work experience related to a student's field of study or career interest for a limited period of time.
	Summer training		A period spent in a reputable company to gain relevant skills and experience in a particular field is usually conducted during July and August of each year.
	Workshops		A period of discussion in which people work on a particular subject by discussing it or doing activities relating to it.
	Co-curricular activities		The activities and learning experiences that take place in the university along with the academic curriculum by students to enhance their skills.
Soft skills	Problem-solving	(0,1)	The act of defining a problem; finding the cause of the problem; identifying, prioritizing, and selecting alternatives for a solution; and implementing a solution.
	Creative thinking		The ability to generate new solutions to problems.
	Time management		The process of planning and organizing how much time to spend on specific activities.
	English proficiency		The ability to use and understand spoken and written English.
Hard skills	Data security	(0,1)	The practice of protecting digital information.
	Network security		The practice of protecting networks and data.
In-demand skills	Data Analytics	(0-7)	The student's knowledge and experience gained in those fields are based on their years of studies at the university through curricula and practical applications of them.
	Artificial Intelligence (AI)		
	Internet of Things (IoT)		
	Machine Learning (ML)		
	Cybersecurity		
	Data Science		
	Cloud Computing		

Gaussian Naïve Bayes (Gaussian NB) algorithm: is a variant of Naive Bayes it is a probabilistic machine learning algorithm used for many classification functions and is based on the Bayes theorem and has a strong assumption that predictors should be independent of each other [13]. The likelihood of the features in our proposed model is assumed to be Gaussian:

$$P(x_i|y) = \frac{1}{\sqrt{2\pi\sigma_y^2}} \exp\left(-\frac{(x_i - \mu_y)^2}{2\sigma_y^2}\right) \quad (2)$$

Where the parameters  $\sigma_y$  and  $\mu_y$  are estimated using maximum likelihood.

1) *Random forest algorithm*: is a supervised learning algorithm. It can be used both for classification and regression. This model first generates a forest of random trees. The aim of voting to merge random trees in a forest is to eliminate the most predicted tree. If a dataset contains  $x$  features, it first chooses a random feature known as  $y$ . The algorithm then attempts to merge trees based on the expected outcome and voting procedure [20]. We used the Gini method as mentioned in (1).

2) *Logistic Regression (LR) algorithm*: A LR uses regression analysis, in this method a class variable that is binary classified is required for the logistic regression model [17]. Similarly, the target column named the employability class in this dataset holds two types of binary numbers "0" for a not-qualified IT graduate who has no chance of being employable to meet labor market demands, and "1" for the IT graduate who has been predicted to be qualified and match

labor market requirements. In our proposed model, a linear model is included in a logistic function as follows:

$$P(y_i=1|X) = \frac{1}{1+e^{-(\beta_0+\beta_1x)}} \quad (3)$$

where  $P(y_i = 1 | X)$  is the probability of the  $i$ th observation's target value,  $y_i$ , being class 1,  $X$  is the training data,  $\beta_0$  and  $\beta_1$  are the parameters to be learned, and  $e$  is Euler's number. The logistic function's goal is to interpret its output as a probability by limiting its value to a range between 0 and 1.

3) *Support Vector Machine algorithm (SVM)*: in SVM the classes in the dataset should be pre-defined in this model. It works by using predefined classes to classify the objects in the given dataset. It categorizes transactions by allocating one or more classes in order to increase performance accuracy [21]. We used the linear SVC (Linear Support Vector Classification).

#### D. Model Evaluation

To evaluate the model effectiveness, a confusion matrix with true positive (TP), false positive (FP), true negative (TN), and false negative (FN) for predicted data is formed. The performance of the study is measured with respect to the accuracy, precision, recall, and F1 score. A brief description of each is described below:

**Accuracy**: It is a common metric for evaluating classifier performance. It computes the ratio of correctly classified instances to the total number of instances [8]. Its formula is as follows:

$$\text{Accuracy} = \frac{TP+TN}{TP+FP+TN+FN} \quad (4)$$

Precision: is the ratio of true positive instances divided by the total number of instances predicted as positive [22].

$$\text{Precision} = \frac{TP}{TP+FP} \quad (5)$$

Recall: is given as the ratio of relevant instances that are retrieved [22].

$$\text{Recall} = \frac{TP}{TP+FN} \quad (6)$$

F1 score: it is the combination of both precision and recall used to get the average value of them [20].

$$\text{F1 score} = 2 * \frac{\text{precision} * \text{recall}}{\text{precision} + \text{recall}} \quad (7)$$

#### IV. RESULTS AND DISCUSSION

After data pre-processing, according to the methodology used, out of the total 296 graduates collected, 80% of the data was used as a training dataset, and 20% was kept as a test dataset. The findings related to this study are presented as follows. Fig. 2 shows the correlation matrix for the used features.

The distribution of the employability class (qualified and not qualified) graduates used in this study is illustrated in Fig. 3 the value 0 represents the number of not qualified graduates while 1 represents the number of qualified graduates. From the figure, it may be shown that most involved samples are “not qualified” graduates (82%) than the “qualified” graduates (18%).

In Fig. 4, we present the participants’ distribution in terms of the features that represent the trainings taken during the graduates’ years of study. According to the internship, a total of 11 participants were trained and qualified. Furthermore, 15 participants referred to this training although they were not qualified. A total of 12 participants were trained and qualified because of the summer training. Moreover, the 105 participants referred to this training even though they were not qualified. According to the co-curricular activities, a total of 41 participants were trained and qualified. Whereas 168 participants referred to this training given the fact that they were not qualified. Lastly, 37 people were trained and qualified during the workshops. And 82 participants referred to this training despite the reality that they were not qualified.

Fig. 5 illustrates the participants’ distribution in terms of the features that represent the soft skills the graduates have

been trained or during their years of study. As stated by the problem-solving skills a total of 39 participants were trained and qualified. As well as a number of 110 participants referred to this skill although they were not qualified. Referring to creative thinking skills, a total of 33 participants were trained and qualified. Also, a number of 74 participants referred to this skill although they were not qualified. Based on time management skills, a total of 37 participants were trained and qualified. Moreover, a number of 107 participants referred to this skill although they were not qualified. According to English proficiency skills, a total of 43 participants were trained and qualified. In addition, a number of 102 participants referred to this skill although they were not qualified.

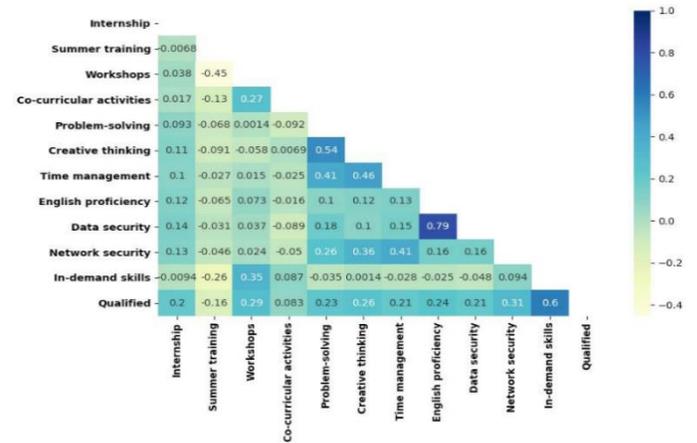

Fig. 2. Correlation Matrix of Selected Features.

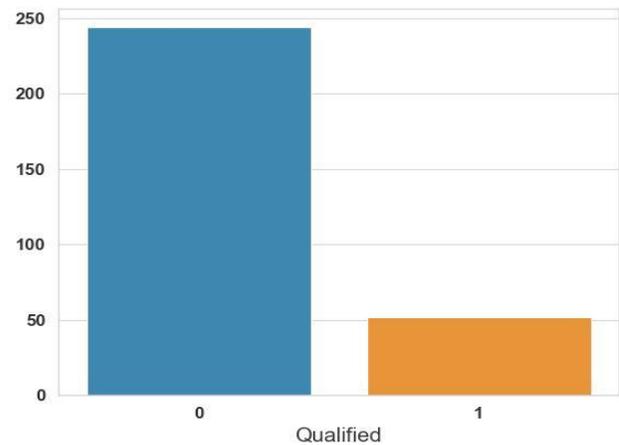

Fig. 3. Count of Employability Class (Qualified/Not Qualified).

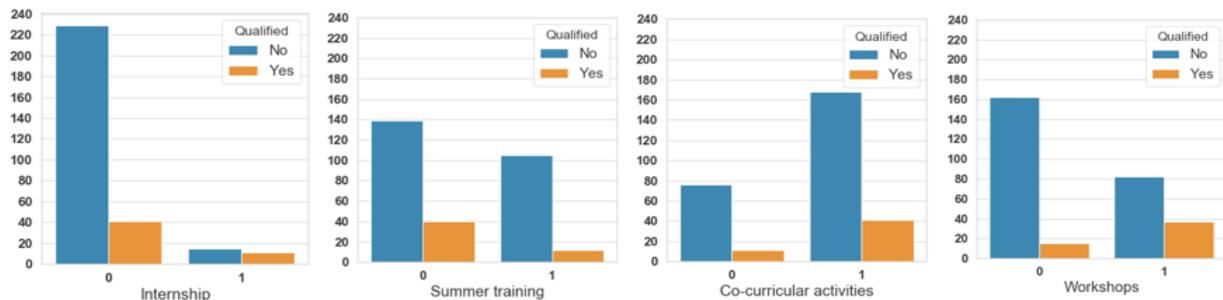

Fig. 4. Respondents’ Distribution in Terms of Trainings.

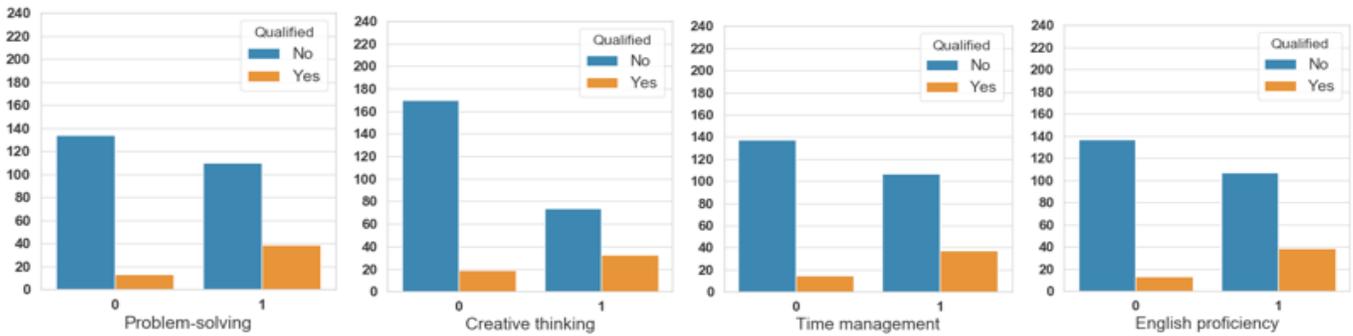

Fig. 5. Respondents' Distribution in Terms of Soft Skills.

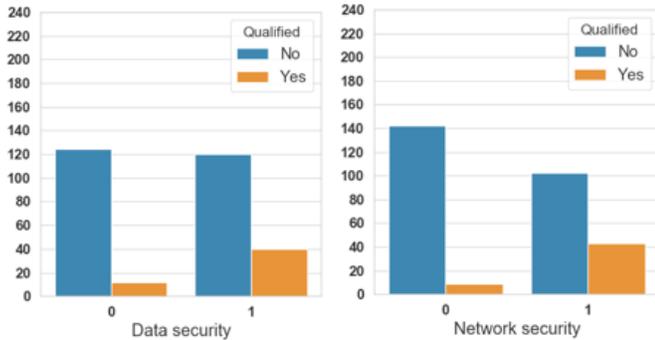

Fig. 6. Respondents' Distribution in Terms of Hard Skills.

Fig. 6 depicts the participants' distribution in terms of the features that represent the hard skills the graduates have been trained on during their years of study. According to the data security skills, a total of 39 participants were trained and qualified. Furthermore, a number of 107 participants referred to this skill although they were not qualified. A total of 40 participants were trained and qualified in network security skills, whereas a number of 120 participants referred to this skill although they were not qualified.

Fig. 7 demonstrates the participants' distribution in terms of the features that represent the in-demand skills required by the industry from the employers' perspectives of the graduates who have been trained on or given a specific course during their years of study. The 0 value means a total of 2 participants did not take any of those skills and were qualified to match labor market requirements whereas 114 participants did not take any of them and found themselves not qualified to be employable. Based on value 7, a total of 7 participants took the seven demanded skills, and they were qualified. Therefore, there are no participants who took those seven skills who were not qualified.

We applied five machine learning classification algorithms for predicting IT graduates' employability. The confusion matrix for each model is illustrated in Table III. Fig. 8 shows the outcome prediction.

Table III reveals that the DT model predicts the highest number of true positives (52 out of 59 test samples) among the five models. Furthermore, LR and SVM models predict the highest number of true negatives (13 among 59 test samples). The lowest number of false positives (0 out of 59 samples) is achieved by DT, RF, and SVM, respectively. The DT,

Gaussian NB, and LR obtained the lowest number of false negatives (0 among 59).

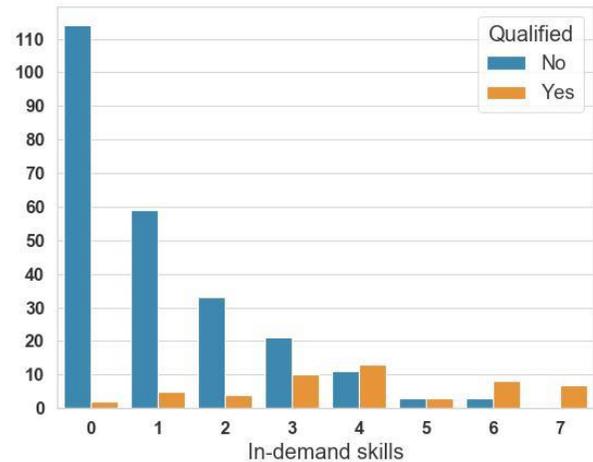

Fig. 7. Respondents' Distribution in Terms of in-demand Skills.

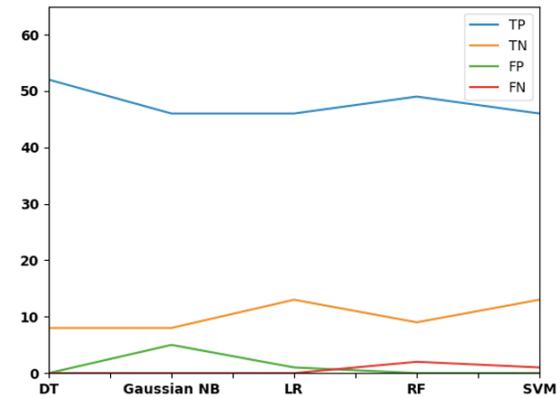

Fig. 8. Confusion Matrix for the Five Machine Learning Models.

TABLE III. CONFUSION MATRIX FOR THE MACHINE LEARNING CLASSIFICATION MODELS

	DT	Gaussian NB	LR	RF	SVM
TP	52	46	46	49	46
TN	8	9	13	9	13
FP	0	5	1	0	0
FN	0	0	0	2	1

The model performance for the employability target class in the form of a confusion matrix is presented in Table IV. In this table, the Match Class “1” means the graduates have chances of being employable and matching the labor market demands. On the other side, Not Match Class “0” denotes the graduates having no chance of being employable, the values of the row illustrating the prediction computed for both classes. As a result, the class precision, recall, and f1 score values are computed and displayed in the table. The class recall and precision values can be used to determine the classifier's overall accuracy. According to the table values, the DT classifier has the highest precision and recall, while the Gaussian NB classifier has the lowest.

The performance of the study was evaluated in terms of accuracy, precision, recall, and F1 score. The calculated performance measures are shown in Fig. 9 and Table V.

RQ2: what are the best machine learning algorithms for employability prediction of IT graduates?

Fig. 9 and Table V indicate that DT outperformed all other machine learning algorithms with a maximum accuracy of 100%, while LR and SVM achieved the second highest accuracy of 98%. DT outperformed by precision, recall, and F1 score of 100%. The second highest F1 score is achieved by LR and SVM at 98%. The second highest precision is achieved by SVM, and the second highest recall is achieved by LR. Most of the techniques have an F1 score higher than 93%, which is comparatively better.

TABLE IV. EVALUATION OF EMPLOYABILITY CLASS (QUALIFIED / NOT QUALIFIED)

Decision Tree Algorithm			
	Precision	Recall	F1 score
Match (1)	1	1	1
Not Match (0)	1	1	1
Gaussian Naive Bayes Algorithm			
	Precision	Recall	F1 score
Match (1)	0.64	1	0.78
Not Match (0)	1	0.9	0.95
Logistic Regression Algorithm			
	Precision	Recall	F1 score
Match (1)	0.93	1	0.96
Not Match (0)	1	0.98	0.99
Random Forest Algorithm			
	Precision	Recall	F1 score
Match (1)	1	0.82	0.9
Not Match (0)	0.96	1	0.98
Support Vector Machine Algorithm			
	Precision	Recall	F1 score
Match (1)	1	0.93	0.96
Not Match (0)	0.98	1	0.99

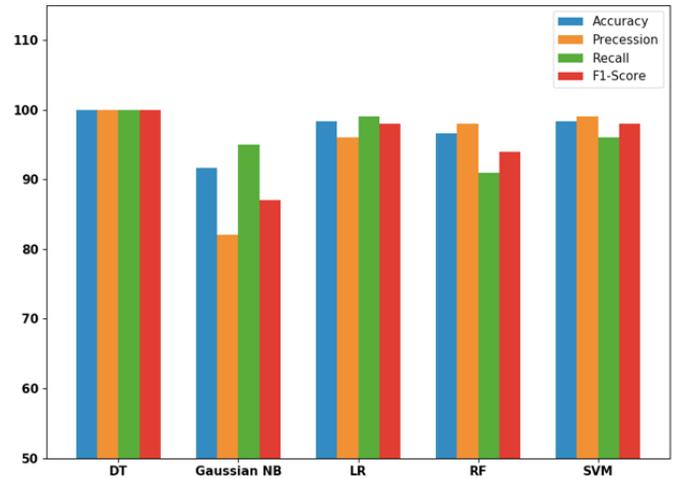

Fig. 9. Performance Measurement using Five Machine Learning Algorithms.

TABLE V. PERFORMANCE EVALUATION OF THE FIVE MACHINE LEARNING ALGORITHMS

	DT	Gaussian NB	LR	RF	SVM
Accuracy	1	0.92	0.98	0.97	0.98
Precision	1	0.82	0.96	0.98	0.99
Recall	1	0.95	0.99	0.91	0.96
F1 score	1	0.87	0.98	0.94	0.98

## V. CONCLUSION

The number of information technology graduates produced by higher education institutions has been increasing every year. To overcome their unemployment situation and the mismatch between HEIs outputs and the labor market demands, there is a need for a model that can predict IT graduates' employability to match labor market requirements using machine learning techniques. Therefore, this paper proposed, discussed, and implemented five machine learning classification algorithms namely DT, Gaussian NB, LR, RF, and SVM.

This study achieved high accuracy than earlier works. The highest accuracy is achieved by DT with 100% and the second highest accuracy is achieved by LR and SVM with 98%, whereas the lowest accuracy with 92% achieved by Gaussian NB. The small size of the dataset is the main limitation of this study. From the study, we can conclude that machine learning techniques can predict IT graduates' employability with high accuracy.

The proposed model can be useful and helpful for higher education institutions to make better long-term plans for producing graduates who are knowledgeable, skilled, and fulfill the labor market needs. The findings of the features analysis indicated that moderating the curriculum to include the demanded skills required by industry and improving the teaching and learning methods by offering more training that would produce quality graduates in the following years. Also, the proposed model will be helpful for employers to contribute significantly to the placement process.

For further research, the size of the used dataset can be expanded, and various ML algorithms can be used to get better performance.

**Abstract**—In Maghreb countries, breast cancer considered one of the leading causes of mortality between females. A screening mammogram is a method of taking low energy level x-ray images of the human breast to identify the early symptoms of breast cancer. The shape and contour of the lesion in digitized mammograms are two effective features that allow the radiologists to distinguish between benign and malignant tumors. We propose in this paper a new approach based on Otsu's thresholding method for semi-automatic extraction of lesion boundaries from mammogram images. This approach attempts to find the best threshold value where the weighted variance between the lesion and normal tissue pixels is the least. In the first step, the median filter is used for removing noise within the region of interest (ROI). In the second step, a global threshold decrement was started in order to get the proper range of pixels in which the breast lesion could be segmented by Otsu's thresholding method with high accuracy. The technique of mathematical morphology, especially opening operation is used in this work for removing small objects from the ROI while preserving the shape and size of larger objects that represent the tumors. We evaluated our proposal using 21 images obtained from Mini-MIAS database. Experimental results show that our proposal achieves better results than many previously explored methods.

**Keywords**—Tumor detection; lesion segmentation; mammogram images; Otsu's thresholding

## I. INTRODUCTION

According to the statistics published in 2020 by World Health Organization (WHO) [1] Breast cancer is classified as one of the most common cancer and a leading cause of deaths among women worldwide. The study given by WHO show that 2.3 million women about the world were subjected to diagnosis of breast cancer in 2020, and almost 29.1% of this rate died out (685 000 deaths globally). Mortality rates for breast cancer are increasing at fast and no way to treat this disease yet except early detection that can help in increasing the survival rate. Different modalities of medical imaging

have been used as screening tools for detecting and diagnosis of breast cancer, such as mammography, ultrasound, magnetic resonance imaging (MRI), nuclear medicine imaging, optical imaging, and breast microwave imaging [2]. Mammography is considered as one of the most commonly used tests for detecting breast cancer at early stages [3], it can often help find breast cancer early and reveal different abnormalities before any symptoms appear. The shape and contour of mass represent one of the most important information in analyze of mammograms. Breast mass segmentation has a key role in determining the nature of lesion since the mass having regular shapes have a high probability of being benign and the mass having irregular shapes have a high probability of being malignant. There are many challenges to detect mass contour in mammograms due to several factor including: normal breast tissues seemed to be similar to lesions, low contrast, fuzzy nature of the boundaries, complicated structured background.

In the present study, we introduce a new approach for breast masses segmentation in mammographic images, in this approach we apply Otsu's method in appropriate range of pixels limited by the maximum value of intensity and an optimal threshold where the output of Ostu is made up of two clusters one of them represents the lesion with high contour accuracy. Our proposal is titled semiautomatic because the regions of interest (ROI) are selected manually by expert breast radiologist.

The scheme proposed in this study combines the median filter, Otsu's thresholding and mathematical morphology (opening operation). The remainder of this paper is organized as follows: Section II presents related state-of-the-art works; Section III presents the proposed exploration scheme of breast lesion boundaries from digital mammograms. Section IV shows the experimental results. In Section V we discuss about the results. Finally, the conclusions of this work are presented in Section VI.

## II. RELATED WORK

The success of lesion contour detection is directly associated with the choice of the measures and methods. Various approaches have been proposed in the literature for mass segmentation in mammographic images. N.Soliman et al. [4] developed a framework for processing of mammogram images, in their work the authors have used 2D median filter to remove digitization noise from images and morphological operations to remove artifacts, they have used also a fuzzy enhancement technique for contrast enhancement and Otsu's multiple thresholding method for mammogram segmentation. Wessam M. Salama et al. [5] proposed a new framework for breast cancer image segmentation and classification. InceptionV3, DenseNet121, ResNet50, VGG16 and MobileNetV2 models are utilized to classify Mammographic Image, then the modified segmentation of the U-Net model is used for the segmentation process. V. Punithavathi et al. [6] proposed an approach based on Optimized Kernel Fuzzy Clustering Algorithm (OKFCA) to determine the cancer portions in mammogram images, After applying the Hybrid Denoising Filter (HDF) Algorithm in preprocessing, the proposed OKFCA is carried out to find out the cancer segment of mammogram image. J. Anitha et al. [7] presented a new approach based on the global adaptive thresholding to locate the suspicious regions in mammogram images. This optimal global threshold (Dual Stage Adaptive Thresholding (DuSAT)) is selected adaptively by maximizing between-class standard deviation, calculated from the gray level of the preprocessed image through the histogram peak analysis (HPA) of the entire image. Damian Valdés-Santiago et al [8] proposed two algorithms for mass boundaries extraction from mammogram images : a lesion segmentation approach based on a Fuzzy C-means modification using image histogram, and a selection criteria to choose candidate lesions that will serve as input to a classifier based on a binary decision tree. H Azary et al. [9] proposed a semi-supervised technique for mass segmentation in mammogram images in which the authors extracted the pixel information such as : the static, gray level run length matrix features and Fisher discriminant analysis (FDA) to use it in the process of classification. After that, they used a co-training algorithm based on support vector machine and Bayes classifiers for tumor segmentation. In [10] Mohammed Y. Kamil et al. applied two algorithms of the clustering approach were applied to three images from Mini-MIAS Database for determining the boundaries of the tumor. the first is the K-means method and the second is the C-means method, in addition, the lazy snapping algorithm is applied to improve the performance of segmentation of suspect area. The results showed that the second algorithm of clustering is better than the first algorithm in terms of accuracy. In [11] M. Ramli et al. suggested a hybrid method of tumor boundary detection in mammogram images. After noise suppression by using median filter method, the Contrast-Limited Adaptive Histogram Equalization (CLAHE) technique have used for image contrast enhancement. in the first stage of segmentation, the watershed transform technique is applied to extract the original region of interest (ROI), and then, the authors employed the region growing algorithm in determining the tumor's boundaries. R. S. C. Boss, et al. [12] extracted 14 Haralick texture features from mammogram

image using GrayLevel Co-occurrence Matrix (GLCM) for different angles with distance  $d = 1$ . Fuzzy c-means and K-means algorithms are used to classify texture features in order to segment the region of interests (ROI) for further classification. T.Sadad et al. [13] employed the cascading of Fuzzy C-Means (FCM), morphological operations and region-growing (RG) method for extracting the tumor located in mammograms, the Local Binary Pattern Gray-Level Co-occurrence Matrix (LBP-GLCM) and Local Phase Quantization (LPQ) are also been used for feature extraction. S. S. Ittannavar et al. [14] developed a new multiobjective optimization technique for breast lesions segmentation in mammogram images. The developed model contains three phases: image collection from Digital Database for Screening Mammography (DDSM) and Mammographic Image Analysis Society (MIAS), image enhancing using Contrast-Limited Adaptive Histogram Equalization (CLAHE) techniques, and finally electromagnetism-like (EML) optimization technique is used to detect noncancer and cancer portions on mammograms. In [15] S.H Suradi et al. used Fuzzy Anisotropic Diffusion Histogram Equalization Contrast Adaptive Limited to enhance the breast lesions by reducing the image noise. Then, a Multilevel Otsu Thresholding is applied to detect breast lesions using the e region of interest tool at different intensity levels. T.L.V.N.Swetha et al. [16] developed an approach based on tow combined methods for tumor edges detection, the first is Hybrid image segmentation based on fast sweeping algorithm and dual front evolution with laplacian or gradient, the second is Otsu's thresholding with 10 threshold levels. A.K.Khan et al. [17] proposed an approach based on improved Otsu method and discrete wavelet transform (DWT) for breast lesion detection in mammograms, in their work the adaptive median filtering and adaptive histogram equalization were used in preprocessing step. In [18] M.M.Saleck et al. developed a semi-automatic segmentation of breast masses on mammogram images using the algorithm of Fuzzy C-Means where the number of clusters is known in advance without estimation, the authors play on the set of pixels that subject to clustering by decrement global threshold to obtain the best results of segmentation. The major disadvantage of this approach is the long execution time that it takes, the present work overcome this drawback by providing another approach based on Otsu's thresholding with less execution time.

## III. MATERIALS AND METHODS

In this part of paper, we explain the techniques that were used in this study for the detection of lesions boundaries on a mammogram. The methodology comprises the following stages: Image preprocessing. Starts the process of decrement a global threshold and applying Otsu method in each step of decrement operation on the set of selected pixels (input\_pixels) that exist between the maximum intensity value and the global threshold. Identify the best value of global threshold for determining the optimal segmentation by applying morphological opening to suppress undesirable objects.

Fig. 1 shows a schematic diagram of the proposed method.

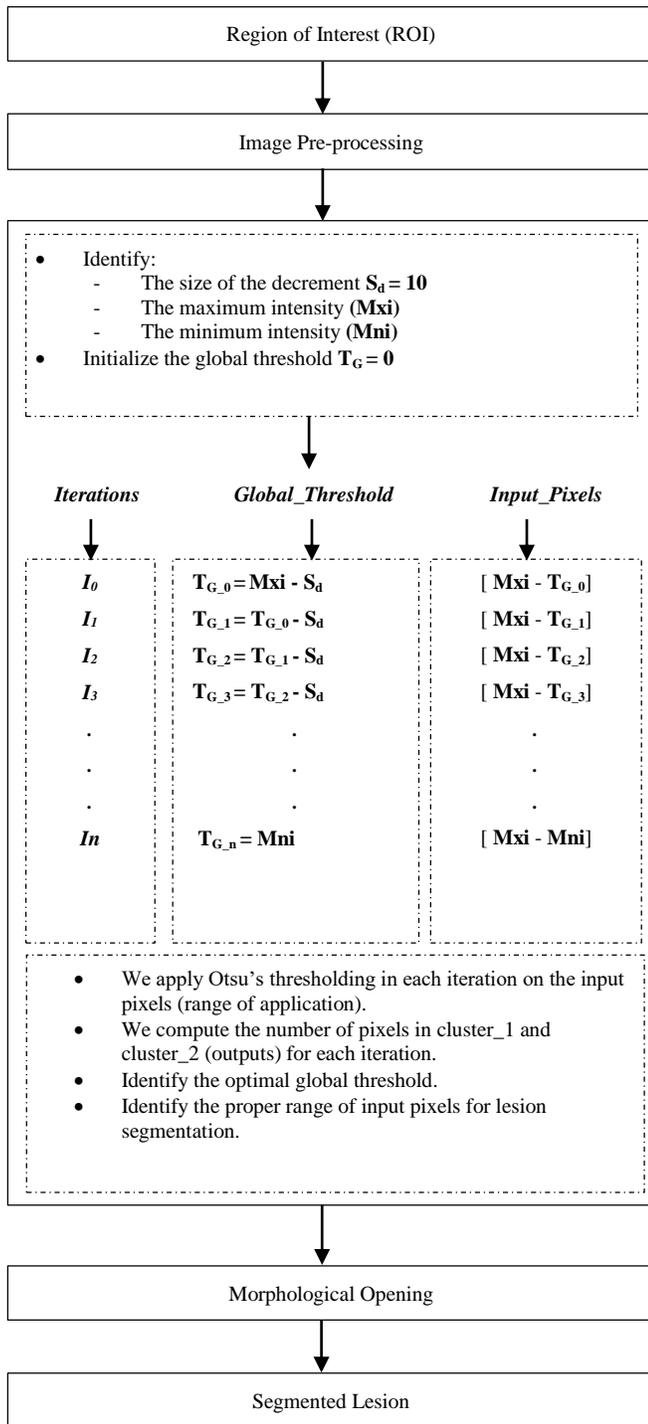

Fig. 1. Block Diagram of the Proposed Method.

### A. Region of Intersect Selection

The breast mammography images used to test our proposed methods were extracted from the Mammographic Image Analysis Mini-Mammographic Database (Mini-MIAS) [19]. The dataset includes 322 digital mammograms, the size of each mammogram from the database was reduced to become  $1024 \times 1024$ , with 8-bits grey scale level and a spatial resolution of 200-micron pixel edge. The ground truth (GT) of these mammograms have been manually extracted by a

radiologist and all abnormalities have been identified and classified. The Region of Interest (ROI) represent the place where abnormalities are identified. In this paper, we use the region of interest with a size of  $174 \times 174$  pixels, the value 174 is chosen in consultation with the radiologist because it is the radius of the largest mass present in the database [20].

### B. Image Pre-processing

Preprocessing steps are very necessary and should be applied before any image-processing technique to ensure a high level of accuracy without any influences from background [21]. Digital mammograms are medical images that are difficult to be interpreted due to the dynamics of intensity and noise appears in images provided by different patients. The basic enhancement required in digital mammograms is denoising [22]. A median filter is a nonlinear filtering technique, it is very effective at removing impulse noise, pepper noise and Gaussian noise. Its strength lies in its ability to keep the sharpness of the image at the time of enhancement. Potency of median filter depends on the size of window [23]. In this work, we applied a median filter with a simple sliding-window of size  $3 \times 3$  in order to provide smart result in proposed algorithms.

### C. Morphological Operations

Morphological Operations is the set of image processing operations that follows the goal of eliminating all the imperfections and maintaining image structure. These techniques include opening operation which is a process that applies erosion on an input image and then dilates the eroded image using the same kernel in both operations. The morphological opening could be used for removing small objects and thin lines in the segmentation results. In this work, we apply morphological opening to retain only the biggest region that represents the tumor with accuracy.

### D. Breast Mass Segmentation by Otsu's Thresholding

Otsu's segmentation is a non-parametric and unsupervised technique proposed by Nobuyuki Otsu [24]. It is an automatic threshold selection method that maximizes the between-class variance in order to segment the image into classes using optimum threshold values. To threshold a given image presented in  $L$  gray levels,  $[0, 1, 2, \dots, L - 1]$  into two classes  $C_1$  and  $C_2$ , we select a threshold  $k$ ,  $0 < k < L - 1$ . Where the range  $[0, k]$  represent the intensity of pixels for the first class ( $C_1$ ), while the second class ( $C_2$ ) is presented by the pixels that have intensity values within the range  $[k + 1, L - 1]$ .

$P_1(k)$ , represent the probability that a pixel is assigned to first class ( $C_1$ ).

$$P_1(k) = \sum_{i=0}^k P_i \quad (1)$$

$P_2(k)$ , represent the probability that a pixel is assigned to second class ( $C_2$ ).

$$P_2(k) = \sum_{i=k+1}^{L-1} P_i \quad (2)$$

The mean intensity values of classes  $C_1$  and  $C_2$  are defined as:

$$m_1(k) = \sum_{i=0}^k \frac{i P_i}{P_1(k)} \quad (3)$$

$$m_2(k) = \sum_{i=k+1}^{L-1} \frac{i P_i}{P_2(k)} \quad (4)$$

Otsu method tries to minimize the weighted within-class variance defined as:

$$\sigma_\omega^2(k) = m_1(k)\sigma_1^2(k) + m_2(k)\sigma_2^2(k) \quad (5)$$

The variances for classes  $C_1$  and  $C_2$  are defined as:

$$\sigma_1^2(k) = \sum_{i=0}^k [i - m_1(k)]^2 \frac{i P_i}{P_1(k)} \quad (6)$$

$$\sigma_2^2(k) = \sum_{i=k+1}^{L-1} [i - m_2(k)]^2 \frac{i P_i}{P_2(k)} \quad (7)$$

It's difficult to extract the boundaries of masses from mammogram images by using the classic Otsu thresholding technique only except in rare cases, due to the low difference between normal and abnormal tissue in mammograms. Fig. 2 shows the result of segmentation by using the classic Otsu thresholding.

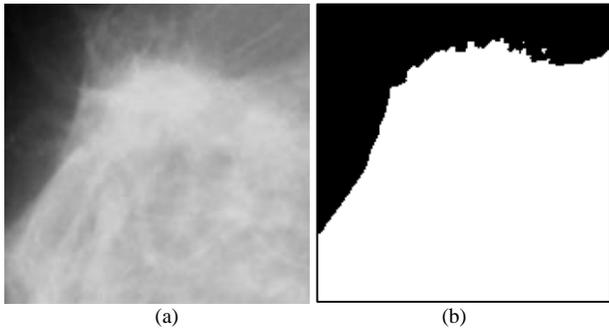

Fig. 2. Lesion Segmentation using Classic Otsu's Thresholding: (a) Original Image (mdb\_95 from MIAS). (b) Result of Segmentation (mdb\_95).

The fuzzy nature of the mammographic images and the low contrast due to masses obscuration by tissue overlap make the automatic process of lesion boundaries extraction very difficult. To overcome this limitation, we propose in this paper a new approach based on Otsu thresholding where the sets of pixels that will subject to clustering by Otsu thresholding are limited by two parameters:

- The first limit (upper limit) of the range of pixels is the maximum value of intensity, because the suspicious lesions in mammogram image having a high-intensity values compared to other regions.
- The second limit (lower limit) of the range is a global threshold, where all pixels in the ROI with intensities below this threshold value are turned off (will not be subject to process of thresholding by Otsu method).

To threshold a given set of pixels within the range  $[Mxi - T_G]$  into clusters  $C_1$  and  $C_2$  by Otsu's thresholding where:

- $Mxi$  is the maximum of intensity in the ROI.
- $T_G$  is a global threshold.

We select a threshold  $k$ ,  $T_G < K < L - 1$ , where:

- $[T_G, K]$  represent the intensity of pixels for the first cluster  $C_1$ .
- $[K + 1, Mxi - 1]$  represent the intensity of pixels for the second cluster  $C_2$ .
- $P_1(k)$ , represent the probability that a pixel is assigned to first class ( $C_1$ ).

$$P_1(k) = \sum_{i=T_G}^k P_i \quad (8)$$

- $P_2(k)$ , represent the probability that a pixel is assigned to second class ( $C_2$ ).

$$P_2(k) = \sum_{i=k+1}^{Mxi-1} P_i \quad (9)$$

- The mean intensity values of  $C_1$  and  $C_2$  are defined as:

$$m_1(k) = \sum_{i=T_G}^k \frac{i P_i}{P_1(k)} \quad (10)$$

$$m_2(k) = \sum_{i=k+1}^{Mxi-1} \frac{i P_i}{P_2(k)} \quad (11)$$

- The variances for classes  $C_1$  and  $C_2$  are defined as:

$$\sigma_1^2(k) = \sum_{i=T_G}^k [i - m_1(k)]^2 \frac{i P_i}{P_1(k)} \quad (12)$$

$$\sigma_2^2(k) = \sum_{i=k+1}^{Mxi-1} [i - m_2(k)]^2 \frac{i P_i}{P_2(k)} \quad (13)$$

Run through the full range of  $k$  values  $[T_G - Mxi]$  and pick the value that minimizes  $\sigma_\omega^2(k)$  defined in eq. (5).

In this approach, we start the decrement of the global threshold ( $T_G$ ) from the maximum intensity ( $Mxi$ ) in ROI until the minimum value of intensity ( $Mni$ ) in ROI with a step size  $S_d = 10$ . Choosing a small decrement step size leads to very slow execution time, however, takes a large decrement step value effects on the segmentation accuracy. To balance between these two points and after many tests, we have deduced that  $S_d = 10$  is the optimal value of the decrement step.

Fig. 3 shows the original images from MIAS. Fig. 4 represents the application of the proposed Otsu method on different sets of pixels where each one of these sets exists within a range limited by the maximum intensity and global threshold.

The optimal global threshold (the second limit of the range of input-pixels) is getting by tracking the changes in the number of pixels that belong to each output-cluster during the process of increase in the set of pixels that subject to clustering by Otsu's thresholding. Tables I and II shows the evolution in the number of pixels that belongs to cluster\_1 and cluster\_2 at each iteration  $t_i$ , also the different values of global thresholds and Otsu thresholds for mdb\_10 and mdb\_134.

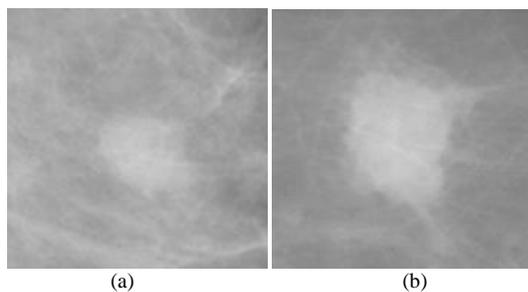

Fig. 3. Original Images: (a) mdb\_10 from MIAS (Max Intensity = 206, Min Intensity = 118). (b) mdb\_134 from MIAS (Max Intensity = 208, Min Intensity = 119).

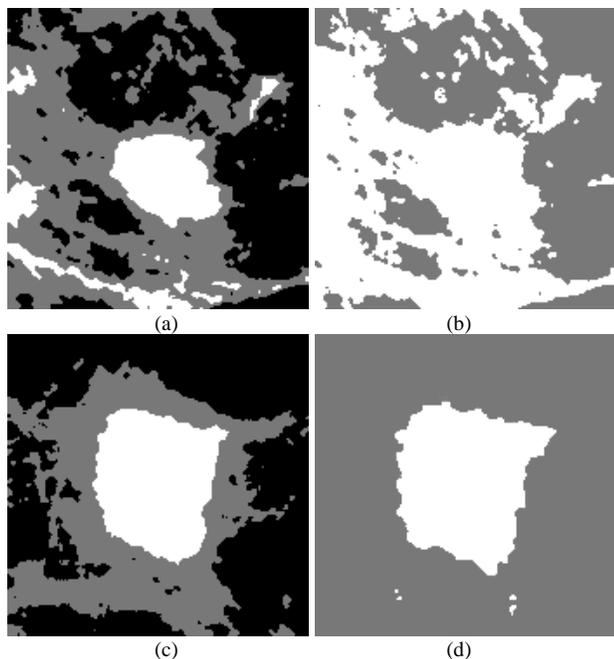

Fig. 4. Application of the Proposed Otsu Method in different Ranges of Pixels. (a) (b): mdb\_10 from MIAS. (c) (d): mdb\_134 from MIAS. White: Cluster\_1. Dark Gray: Cluster\_2. Black: Outside the Range (Not Subject to otsu thresholding).

The evolution curves in the following figures (Fig. 5 and Fig. 6) illustrates the changes in the number of pixels of clusters that happen at each iteration  $t_i$ .

TABLE I. EVOLUTION OF THE NUMBER OF PIXELS IN CLUSTER 1 AND CLUSTER 2 FOR IMAGE MDB 10 FROM MIAS

Image: mdb_10 from MIAS Database				
The maximum value of intensity (Mxi) = 206				
The minimum value of intensity (Mni) = 118				
Range of pixels	Number of pixels in cluster_1	Number of pixels in cluster_2	Global threshold ( $T_G$ )	Otsu threshold

Nbr of pixels

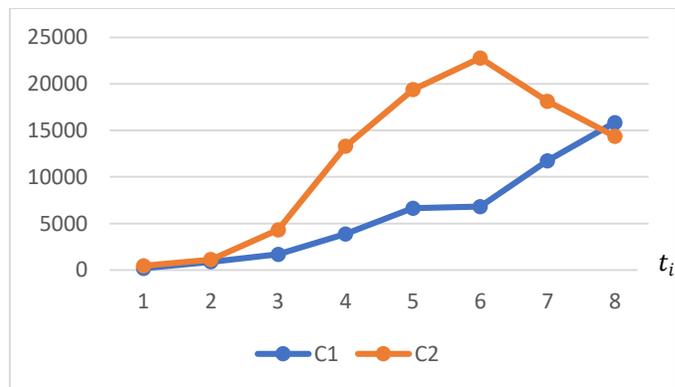

Fig. 5. Evolution of Cluster 1 and Cluster 2 for mdb 10.

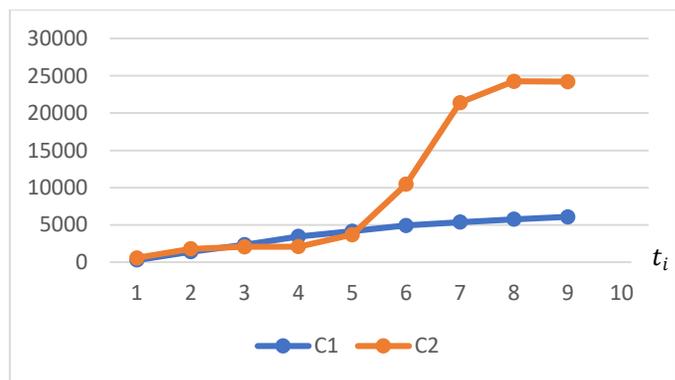

Fig. 6. Evolution of Cluster 1 and Cluster 2 for mdb 134.

After tracing the evolutionary changes in the number of pixels for both clusters (C1 and C2) on 22 images tested in this study, we can distinguish two different sorts of results:

- The first one represents the majority of the cases; this one is characterized by an increase in the number of pixels of cluster 1 and cluster 2 followed by an abrupt decrease in cluster 2. The optimal global threshold for this kind of case is the value that happens an abrupt decrease in cluster 2. Ex: Fig. 5 (mdb 10) the best value of the global threshold is  $T_G = 146$  at iteration  $t=6$ , therefore, the appropriate range of pixels that allow us to get two clusters where the cluster 1 represent the lesion with accuracy in this example is [206 - 146].
- The second is characterized by an increase continues in cluster 2, those cases are rare. The optimal global threshold for this kind is the minimum value of intensity (Mni) in the region of interest (ROI). Ex: Fig. 6 (mdb 134) the best value of the global threshold is the minimum intensity  $T_G = 119$ .

After finding the suitable range of pixels that can generate high accuracy of lesion boundaries after applying the proposed Otsu method, we apply morphological operations to remove all defects and preserve the region having the highest intensity in cluster 1 that represents the lesion.

#### IV. EXPERIMENTAL RESULTS

In this section, we present the experimental results for breast mass segmentation in mammogram images using the proposed method. A testing data set of 21 images taken from mini-MIAS database of mammograms were used in this study to test and evaluate the performance of the proposed approach. Three experienced radiologists have intervened for delineating manually the lesions margins. The obtained results in Fig. 7 shows that lesion border extracted by the proposed algorithm approximately follows the lesion contour marked by the radiologists.

To evaluate the efficiency of the proposed algorithm, four performance evaluation metrics were adopted in this paper, such as: overlap, sensitivity, specificity and accuracy [25].

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \times 100 \quad (14)$$

$$\text{Overlap} = \frac{TP}{TP+FP+FN} \times 100 \quad (15)$$

$$\text{Sensitivity} = \frac{TP}{TP+FN} \times 100 \quad (16)$$

$$\text{Specificity} = \frac{TN}{FP+FN} \times 100 \quad (17)$$

Table III displays the results of metrics of lesion segmentation obtained for measurement the performance of the proposed approach. Table IV presents the comparison with other techniques.

The proposed method is implemented on Python 3.9.5, Pycharm community edition 2021.2.2. The computer used in this work is Dell PC with Processor Intel(R) Core (TM) i5-5300U CPU 2.30GHz (4 CPUs), and 8G Ram.

The average processing time required for completing the process of segmentation using the proposed algorithm is 1.91 s, the runtime time for this approach is less 2 times than the segmentation of breast lesions using Fuzzy c-means algorithm proposed in [18] (Fig. 8).

TABLE III. PERFORMANCE RESULTS OF SEGMENTATION

Number of lesions	21 images from mini-MIAS			
	Accuracy	Overlap	Sensitivity	Specificity
22	95.06 %	80.92 %	97.16 %	73.41 %

TABLE IV. COMPARISON WITH OTHER TECHNIQUES

Methods	Overlap	Accuracy	Sensitivity	Specificity
Proposed method	80.92 %	95.06 %	96.16 %	73.41 %
Watershed and region growing : [26]	80.3 %	91.5 %	91 %	94.35 %
Fuzzy c-means and K-means : [10]	--	91.18 %	--	--
Deep learning : [27]	--	98 %	--	--
Region growing : [28]	79 %	91 %	83 %	97 %

### V. DISCUSSION

This study presents a new approach for extracting masses from ROI of digital mammogram images, aiming to assist the radiologist in the identification of the lesion. This approach is based on increasing the set of pixels that subject to clustering by decrement a global thresholding. This processing allows to test the different values of global thresholds in order to obtain the best value. The aim is to select as input the meaningful pixels that can produce in output a clearly delineated lesion after applying Otsu thresholding and morphological operations. In comparing the results of segmentation for mdb\_95 from Mini-MIAS database using classic Otsu thresholding illustrated in Fig. 2 and the results of segmentation for the same image showed in Fig. 7(f), we can deduce the efficiency of the proposed method. The strength of this method lies in its ability to eliminate the set of pixels that can have negative effects on the process of segmentation by choosing a suitable global threshold. The run-time of the proposed algorithm is considerably less than the execution time for the proposed method in [18]. This speed of execution compared to fuzzy c-means is due to the simplicity of the Otsu method in terms of algorithm complexity.

### VI. CONCLUSION

Breast cancer is the most common type of cancer among women around the world and is the second leading of death after prostate and lung cancer. We aim behind our researches, to develop new methods for helping the radiologists in diagnostic of breast cancer. In this study, we propose a new approach for breast lesion boundary segmentation for a given region of interest (ROI) in mammographic images. The proposed algorithm is an extended version of classical Otsu's technique with additional capability to dynamically change the number of input-pixels that subject to thresholding in order to get the proper set of pixels which can produce as output a segmented lesion with high accuracy. The results obtained in this work show the proposed algorithm outperforms many other methods of breast masses segmentation in performance and that it is faster than the fuzzy c-means technique.

# Performance Analysis of Software Test Effort Estimation using Genetic Algorithm and Neural Network

Vikas Chahar, Prof. Pradeep Kumar Bhatia  
G. J. University of Science and Technology, Hisar, Haryana, India

**Abstract**—In present scenario, the software companies are frequently involving software test effort estimation to allocate the resources efficiently during the software development process. Different machine learning models are developed to estimate the total effort that would be required before the software product could be delivered. These computational models are used to use the past data to estimate the efforts. In the current studies, test effort estimation for software is predicted using the Genetic algorithm and Neural Network. The attributes are selected using the Genetic algorithm and similarity measure between the attribute values has been computed using the Cosine Similarity measure. The simulation experiments were done using the PROMISE and Kaggle repository and implementation was done using the MATLAB software. The performance metrics namely, precision, recall, and accuracy are computed to evaluate against the existing techniques. The accuracy of the proposed model is 91.3% and results are improved by 8.9% in comparison to existing technique and comparison has been made for superiority to predict the test effort for software development.

**Keywords**—Test effort estimation; software testing; machine learning; computational intelligence; neural network

## I. INTRODUCTION

The success of a software project mainly depends on the determination of effort for software development [1]. The cost of the software can be computed by determining the efforts for the development of software. Software engineering is the study of techniques, quantifiable approach, software maintenance, and quantifiable approach during the development phase: application of engineering for software testing. The software testing plays a very significant role and accounts almost 50% for the total development in effort estimation.

Software testing allows the evaluation of attributes or system capability in determining the requirements to meet the desired results [2]. Software testing is mainly categorized as static and dynamic testing. In the former testing phase, testing has been done without executing the project and it is related to prevention of defects [3]. The documentation estimation is cheap and code assessment is provided in addition. Moreover, it also includes checklist, estimation of variety of errors, operated in the initial phase, and completion of 100% coverage of statement within less time. In the later testing phase, dynamic testing is very expensive, testing has been done during the execution of the project and it is related to fixing the defects [4]. The bugs estimation and assessment of bottleneck is provided whenever this phase is operated later or in the last phase of the

project. Moreover, it also includes test cases, fixing the variety of errors, and completion of 50% coverage of statement. The primary motive of testing the software is to eliminate the bugs and improve the software security and other aspects such as performance, user satisfaction level, and experience. Furthermore, test effort estimation is necessary for the test process and plays a crucial role in the operation of software development life cycle. Software effort estimation allows the organization to provide or allocate the necessary resources accordingly. The best testing deal not only improves the overall quality but also enhances the customer satisfaction level. In a competitive market, there is a need to determine the highly reliable software effort estimates. In the software project development phase, the accurate estimation allows the success of the project [5]. Further, the cost of the software is estimated using the software effort required for the development of the software. In the literature, there were large number of techniques proposed to predict the software effort accurately. The estimation of software effort is helpful for the allocation of resources in a proper manner. The estimation of software effort in terms of month and day per person, duration of the project is very difficult to predict the project cost. It is crucial to negotiate with the customer by estimating the cost and effort in an accurate manner.

### A. Computational Intelligence Techniques for Software Effort Estimation

Inaccurate prediction of software effort and cost usually results in huge financial loss and even in the failure of the project. However, there are number of techniques developed in the past such as expert judgement, machine learning techniques, fuzzy technique, and regression analysis [6]–[8] to minimize the instances of inaccurate prediction. Most of these techniques were based on the algorithmic models such as COCOMO and analogy-based estimation of effort techniques. The analogy techniques generally include the use of different characteristics such as size, interfaces, and effort of new project is estimated by determining the details of project of similar type. Furthermore, there are different techniques designed for different datasets as no single technique is applicable for all the datasets. In this process, programming language, development technique, programmer experience, tools etc. play a significant role in governing the software effort estimate. For instance, soft computing models are used to deal with computational problems and metaheuristic techniques are used to resolve the complex optimization issues [9], [10]. The evolution of neural network, fuzzy logic, support vector machine, optimization

technique, machine learning, chaotic theory, etc. fall under the category of computational intelligence models as shown in Fig. 1 [11].

Computational techniques proved fruitful results in predicting the attributes of software quality. In the past year, the computational models were developed and applied in software engineering to solve the different problems such as determining the prediction of change in software, prediction of stakeholder satisfaction, and estimation of reliability for component-based software projects. The estimation of test effort is generally performed by using the templates of Work Breakdown Structure (WBS) that fragments the project into sub-tasks. The analysis of each task during the testing phase allows the determination of defects and underlying errors. The project requirements are designed, and testing phase has been analyzed thoroughly to avoid any defect. This required a detailed overview of the project prototype and analyzing each task by coordinating with the stakeholders. This generally takes around 1.5-2 weeks to perform test effort estimation. However, employing the machine learning techniques for effort estimation eases the process in a fast manner and it is generally computed by determining the overall time to the total inputs given for the completion of the project. The proposed technique introduces the novel method by integrating the machine learning with genetic algorithm for the effort estimation of software testing. The contributions of the proposed work are summarized as follows: -

- Machine learning techniques are integrated for estimation of software effort.
- A novel combination of Genetic algorithm with Machine Learning is used to predict the software effort.
- Two datasets are employed to evaluate the computational strengths of the designed work.

The rest of the paper is organized as Section II that illustrates the related work, Section III that describes the research methodology including the different datasets and discusses the technique used for software test effort estimation. Section IV illustrates the results and finally concluded in Section V.

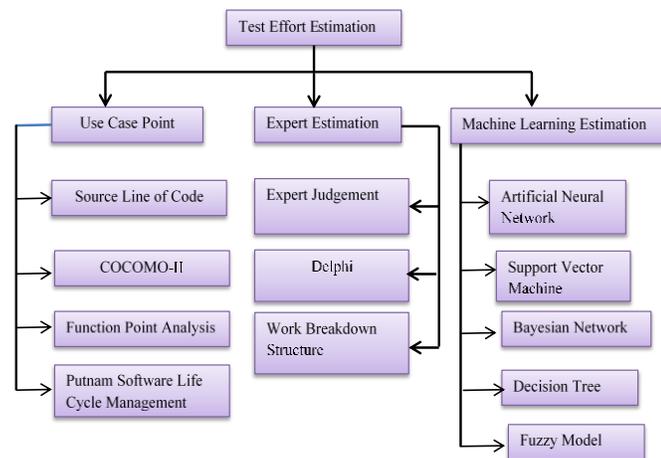

Fig. 1. Test Effort Estimation Models.

## II. RELATED WORK

The estimation of effort involved in the software development is a crucial activity for monitoring the project cost, time, and quality as well as for the software development life cycle. As a result, proper estimating was crucial to the success of projects and to lowering risks. Software effort estimation has drawn a lot of research interest recently and has become a problem for the software industry. Many academics and industry professionals have suggested statistical and machine learning-based approaches for estimating software effort over the past 20 years.

Saljoughinejad and Khatibi, 2018 had taken advantage of three metaheuristic techniques to enhance the effort accuracy estimations associated with the COCOMO model. The concept of metaheuristics mainly focused on the detailed analysis of the involved cost drivers involved in the effort estimation. The study had reflected that the integration of techniques such as PSO, Invasive Weed Optimization and GA had significantly improved the accuracy measures associated with estimations. However, despite of better performance, the work was unable to meet the desired level due to instability issues [12].

Nassif et al. 2019 compared the three different fuzzy models to estimate the software effort. The authors designed the models and conduct the regression analysis to evaluate the performance of the proposed system. The evaluation of the proposed regression fuzzy logic was measured by measuring the criteria such as standardized accuracy, effect size, and relative error. The authors used the ISBSG dataset, and it was estimated that different projects have similar size with better productivity ratio. The mean for effort dataset 1 was 883.5 and effort dataset 4 was 706 with a standard deviation of about 1194 with a skewness of about 5.8. Further, Scott Knott test was performed to determine the validity and best performance achieved using the Suzzeno fuzzy model [7].

Ghatasheh et al. 2019, evolutionary algorithms called the Firefly Algorithm was presented for optimising the parameters of three COCOMO-based models. The authors used the NASA dataset in which 30% data was tested and 60% data was trained to acquire the adequate objectives. The proposed model and two additional models that was suggested in the literature as expansions of the fundamental COCOMO model. The evaluation results using the Firefly algorithm show better accuracy. The limitation of the study was instability issues, prediction model; dataset type was affected by size [13].

Chhabra and Singh 2020 had proposed integration of non-algorithmic modelling for software effort estimation based on soft computing approaches. In the process, they had integrated genetic algorithm followed by fuzzy logic and utilized the COCOMO dataset for the evaluation of the designed work architecture. It has been observed that due to improved selection owing to the GA fitness function a 25% reduction has been observed in Mean Magnitude of Relative Error. This high improvement was mainly due to increased stability of GA in optimizing the fuzzy model that improved the overall prediction accuracy for the effort estimation [14].

Öztürk et al. 2021, a feed forward DNN algorithm (FFDNN) was put forth in this article. Finding hyperparameter was done using a binary-search-based technique in the algorithm. In the experiment using two performance parameters, FFDNN performs better than five comparative algorithms. The study's findings indicate that: 1) Using conventional techniques like grid and random search significantly lengthens tuning time. Instead, sophisticated parameter search techniques that was compatible with the structure of regression methods should be developed; 2) SEE performance was improved when the associated hyperparameter search technique was designed in accordance with the key principles of selected deep learning approach; and 3) Deep learning models outperform tree-based regression techniques like CART DE8 in terms of CPU time. The drawback of the study was that tuning time need to plan along with pruning of network [11].

Karimi and Gandomani 2021 This research introduces a new fuzzy inference technique and the differential evolution (DE) algorithm. To estimate software development labor, more precisely, this approach is capable of providing a more accurate estimate for software projects than earlier efforts using the COCOMO model. The suggested approach outperformed existing optimization algorithms derived from genetic, stochastic, conceptual, and Neuro-fuzzy technique, and could increase accuracy using the proposed technique up to 7%. The limitation of the study was assessment criteria and convergence rate, still a challenge for the accurate software effort estimation [15].

Zakaria et al. 2021 had integrated PSO as a swarm intelligence technique to optimize the existing COCOMO II. The optimized set was then fed to different machine learning techniques to evaluate their strength for the prediction of effort using NASA dataset. The machine learning techniques integrated were, Linear Regression (LR), SVM and Random Forest (RF). The simulation analysis had shown that SVM had outperformed the other machine learning techniques in terms of MMRE, accuracy and p-value computed for each of the implemented combination [16].

López-Martín 2022 proposed software testing effort estimation using the machine learning models. The authors investigate the effort of software testing using the datasets stored in the repository. The project selection was entirely based on the rating of data quality, development type, platform, programming language, sizing method, and level of resources for projects. Further, the authors investigate the performance of five machine learning models for software effort estimation using the COCOMO model. The prediction accuracy was computed for different ML techniques such as Neural Network, Decision Tree, Genetic algorithm, SVM and Case based reasoning. The limitation of the study was that software effort estimation depends upon the certain factors such as quality expectations, developer experience, tools and many other that are not sufficient to consider for accurate prediction of software effort estimation [6].

### III. RESEARCH METHODOLOGY

The proposed methodology is divided into two parts in which first part Implementation using the Genetic algorithm has

been done and Machine Learning model such as Neural Network toolbox in MATLAB was used for the classification of test effort estimation. The dataset used in this study for implementation are illustrated in the later sections.

#### A. Dataset

There are several free datasets that were used in the literature such as Kaggle, COCOMO NASA-I, COCOMO NASA-II, Kaggle, and PROMISE [17], [18]. Out of these, Kaggle and Promise datasets have been used in this study. These are further divided into five datasets namely KC1, PC3, PC4, MW1, and CM1 that support these datasets [19]. The PROMISE repository was used to extract the attributes. The dataset is an open source data set and is freely available online [20]. The dataset contains the attributes that are extracted after the operations performed through Object Oriented Programming Architecture (OOPA). As for example, RELY is an attribute that illustrates the reliability of a software and in the similar fashion, RES represents the reusability of the software component. Based on these attribute values, the overall computation effort is also provided. The dataset does not have independent attribute as they have been computed via OOPA. The data retrieval was estimated using the KC1 classes and further defect was analyzed. This study incorporates the Kaggle and PROMISE database datasets that includes different attributes such as KC1, CM1, MW1, PC3, and PC4. The datasets was stored and further assisted for implementation in the MATLAB software. Although, Kaggle and Promise data repository includes the different data, but extraction of relevant data is particularly important before the implementation. Therefore, Cosine similarity technique was applied to extract the data as per requirement for test effort estimation during the software development life cycle.

#### B. Genetic Algorithm for the Selection of Relevant Attributes

In this study, the relevant attributes have been selected using the Genetic Algorithm which is a heuristic technique employed to avoid the challenges of modelling and optimization techniques. The main features of the GA are to utilize the features of crossover operator and execute the operations to obtain the candidate solutions. The operation steps are graphically illustrated using Fig. 2. The Genetic Algorithm has been applied by considering the following steps: -

- 1) *Start*: The random population is generated considering the n-chromosomes for best solution of the problem. The random population is generated which is of n chromosomes.
- 2) *Fitness*: The fitness function  $f(a)$  is evaluated that corresponds to the chromosome (a) in the generated population.
- 3) *New Population*: The new population is initialized by repeating the following steps until the optimal solution is attained.

- *Selection*: The selection has been done by considering the fitness function of two chromosomes and then higher fitness leads to the selection of chromosomes with more possibility.
- *Crossover*: When the probability of crossover crosses then new offspring attained. If there is no crossover, then offspring is a duplicate of parent.

- Mutation: The mutation probability is attained when the new offspring mutates at each position in the population.
  - Accepting: The new offspring has been placed with respect to new population.
- 4) *Replace*: The generated population is utilized considering the aim to execute the new solution.
- 5) *Test*: The best solution has been returned after the current population attained.
- 6) *Loop*: Return to second step.

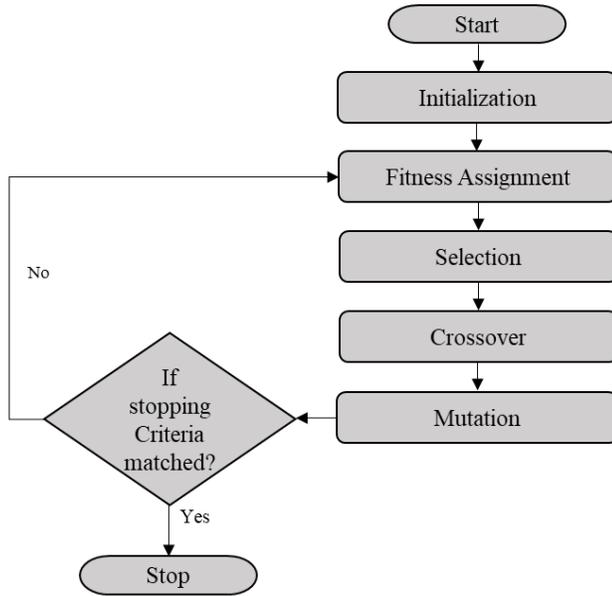

Fig. 2. Operation of GA.

After the operation of GA, further cosine similarity technique has been applied for the selection of similar attributes.

### C. Cosine Similarity

Cosine similarity is a technique in which similarity of two documents computed to determine the correlation between the vectors. The information is represented in the vector form that makes the process easier to eliminate the irrelevant data. Furthermore, the angle between the vectors is determined as the cosine angles between the attributes. Cosine similarity is one of the most important similarity measures used for different applications such as clustering, effort estimation, etc. and also used to retrieve essential information. The cosine similarity between two attribute vectors  $\vec{V}_m$  and  $\vec{V}_n$  is given by;

$$CosSim(\vec{V}_m \text{ and } \vec{V}_n) = \frac{\vec{V}_m \cdot \vec{V}_n}{|\vec{V}_m| \times |\vec{V}_n|} \quad (1)$$

Here,  $\vec{V}_m$  and  $\vec{V}_n$  are the n number of dimensional vectors in each term set of  $V = \{V_1, V_2, V_3 \dots \dots \dots V_n\}$ . Every dimension in the term set includes weight, which is positive, and therefore, the cosine similarity is positive and can be bounded between  $\{0,1\}$ .

A significant feature of cosine similarity is that it is the independent of its attribute for different set efforts in days or months. For example, integrating two effort values of different days require to obtain a novel attribute value, the cosine similarity between  $Att'$  and  $Att$  is 1, which indicates that the test effort attributes can be considered identical and can be stored for further processing.

### ALGORITHM 2: Cosine Similarity for effort estimation

Input:  $data_{files}$

Output:  $Cosine\ Similarity_{dataset}$

1. *Function*:  $Cosine\ Similarity_{dataset} = FunctionCosine\ Similarity_{dataset}(data_{records})$
2.  $Cosine\ Similarity_{dataset_{relation}} = [ ]$ ;/
3. *Similarity Index calculation using empty array*
4.  $For\ s = 0\ to\ data_{records}.count / Totalno.\ of\ data_{records}$

After the extraction of data for software test effort estimation, the data is processed to select the attribute values using the Genetic Algorithm and classification was done later using the Neural Network.

### D. Effort Estimation using the Computational Intelligence Models

After the extraction of similar attributes, Neural Network has been applied that contain processing elements that are connected using some weights. It attempts to depict the biological nervous system as per both architectures including information processing logics. This network needs to train first by applying an appropriate learning algorithm for the prediction of weights which are interconnected. After training of weight test signals are classified. The neural network's class used basically for task of classification is called the multilayer perceptron network. The ordinal measures of Neural Networks are as follows (Table I).

TABLE I. ORDINAL MEASURES OF NEURAL NETWORKS

Propagation Architecture	Software test effort estimation
Neuron Count	5-25
Nature of propagation	Progressive
Propagation behaviour model	Levenberg
Root node validation	Mean Squared Error (MSE)
Validation parameters	a) Total number of epochs b) Gradient c) Count of fails in the validation
Cross validation	Linear Regression
Regression equation	$z = ax + b$ (eq hh) Where x is a multi-objective fitness function defined by sigmoid function of neural networks

The neural network propagation is designed using Neural Network toolbox of MATLAB and it is a propagation-based model and hence the number of hidden layers has been varied to check the performance of the network.

#### ALGORITHM 6: Test effort estimation using the Neural Network (NN)

**Input:** Optimized feature (T)

**Output:** Test Effort Estimation Results

1) **Initialization of NN parameters**

$E \rightarrow$  Simulation or Epochs for NN

$N \rightarrow$  Neurons Count

Performance Measure  $\rightarrow$  Accuracy, Precision, Recall, and F-measure

Techniques  $\rightarrow$  Levenberg Marquardt

Data Division  $\rightarrow$  Random

2) **For I = 1  $\rightarrow$  T**

3) **If (T matches with 1<sup>st</sup> feature category)**

4) Group (1) = Features of training data according to the 1<sup>st</sup> category

5) **Else if (T matches with 2<sup>nd</sup> feature category)**

6) Group (2) = Features of training data according to the 2<sup>nd</sup> category

7) **Else**

8) Group (3) = Extra properties of training data

9) **End-if**

10) **End-for**

11) Initialize the NN using Training data and Group

12) Net = patternet (T, Group, N)

13) Set the training parameters and train the system

14) Net = Train (Net, Training data, Group)

**Testing Phase:**

15) Current Data = Feature of current efforts in dataset

16) Output = simulate (Net, Current Data)

17) **If Output is valid**

18) **Test Effort Estimation  $\rightarrow$  Accurate**

19) **Else**

20) **Test Effort Estimation  $\rightarrow$  Inaccurate**

21) **End-if**

22) **Return:** Prediction as an output

Since the NN architecture used multiple hidden layers, therefore the input data is filtered many times and hence chances of providing better results are increased. In this research, the performance of NN is examined and cross-validation outcomes are evaluated.

#### IV. RESULTS AND DISCUSSION

The performance is evaluated by dividing the total dataset using the separation mechanism of training dataset to testing dataset ratio.

##### A. Statistical Analysis

The results have been computed using the 70:30, 80:20, and 90:10 ratio analysis. The results obtained using the implemented methodology in which four different performance metrics has been computed as illustrated below: -

$$Precision = \frac{True_{positive\ rate}}{True_{positive\ rate} + False_{positive\ rate}}$$

$$Recall = \frac{True_{positive\ rate}}{True_{positive\ rate} + False_{negative\ rate}}$$

$$F - measure = 2 * \frac{Precision * Recall}{Precision + Recall}$$

$$Accuracy = \frac{True_{positive} + True_{negative}}{True_{positive} + True_{negative} + False_{positive} + False_{negative}}$$

The evaluation has been done to determine the superiority of the proposed approach and labelled dataset has been used which is pre-defined and specific to determine the required outcomes.

Table II shows the Recall, Precision, F-measure, and Accuracy computed using the 70:30 dataset distribution ratio. It is generalized that with increase in the number of projects the recall of the proposed model also gets improved. The proposed model shows a recall of about 0.90% for 80 projects. It is seen that Precision and Recall show 0.9% and 0.91% respectively for 20 projects and 0.90% and 90% for F-measure and Accuracy respectively using the GA and NN. The proposed results for 70:30 analyses are robust and improvised using the Genetic Algorithm in conjunction with NN.

Table III shows the analysis of performance metric computed using the 80:20 ratios. It is generalized that with increase in the number of projects the performance of the proposed model also gets enhanced. The proposed model shows a recall of about 0.93 for 300 projects and F-measure of about 0.92. It is seen that average Precision and Recall show 0.9% and 0.91% respectively and 0.91% and 91% for F-measure and Accuracy respectively using the GA and NN. The proposed

results for 80:20 analyses are robust and improvised using the Genetic Algorithm in conjunction with NN.

1000	0.950231	0.953727	0.951976	92.80485

Table IV shows the analysis of performance metric computed using the 90:10 ratio. It is generalized that with increase in the number of projects the performance of the proposed model also gets improved. The proposed model shows a recall of about 0.94 for 300 projects precision is 0.92 with F-measure of about 0.94. It is seen that average Precision and Recall show 0.92% and 0.91% respectively and 0.91% and 91.3% for F-measure and Accuracy respectively using the GA and NN. The proposed results for 90:10 analysis are robust and improvised using the Genetic Algorithm in conjunction with NN.

Table V shows the comparison of recall analysis with the existing techniques. It is seen that recall for Attri et al. 2019 and without GA show 0.81 and 0.77 respectively for 20 projects. The proposed model exhibited a recall of 0.94 when analysed for 200 projects. Similarly, recall for 1000 projects increases to 0.95 and using Attri et al. work and GA is 0.93 and 0.82 respectively. The overall recall using the proposed approach is 0.92 and 0.86 using the Attri et al. 2019. Thus, the proposed outperformed the existing techniques due to the use of Genetic algorithm and Neural Network.

TABLE V. COMPARATIVE ANALYSIS OF RECALL AGAINST ATTRI ET AL. WORK

Number of Projects	Recall Proposed	Recall Without GA	Recall Attri et al. 2019
10	0.875412	0.77543345	0.81661566

1000	0.950231	0.82961745	0.93788335

TABLE VI. COMPARATIVE ANALYSIS OF PRECISION AGAINST ATTRI ET AL. WORK

Number of Projects	Precision Proposed	Precision without GA	Precision Attri et al. 2019
10	0.909543	0.824474	0.8453636
20	0.910089	0.8320093	0.8518202
30	0.910635	0.8395446	0.8582768
40	0.91118	0.8470799	0.8647334
50	0.911726	0.8546152	0.87119
60	0.912271	0.8621505	0.8776466
70	0.912817	0.8696858	0.8841032
80	0.913363	0.8772211	0.8905598
90	0.913908	0.8847564	0.8970164
100	0.914454	0.8922917	0.897473
200	0.920999	0.892827	0.9039296
300	0.927545	0.9003623	0.9103862
400	0.934091	0.9078976	0.9168428
500	0.940636	0.9154329	0.9232994
700	0.947182	0.9229682	0.929756
1000	0.953727	0.9305035	0.9362126

Table VI shows the comparison of precision analysis with the existing techniques. The precision for Attri et al. 2019 and without GA 0.86 and 0.84 for 40 projects. Similarly, precision for 1000 projects the recall value increases to 0.95 for proposed work and Atri et al. work and GA is 0.93. The overall precision using the proposed estimation model is 0.92 and using Attri et al. is 0.89. Thus, an improved performance is exhibited by the proposed work using Genetic algorithm and Neural Network.

TABLE VII. COMPARATIVE ANALYSIS OF F-MEASURE AGAINST ATTRI ET AL. WORK

Number of Projects	F-measure Proposed	F-measure without GA	F-measure Attri et al. 2019
10	0.892151182	0.799202127	0.830740998
20	0.896683196	0.80301799	0.835100588
30	0.901180958	0.806805868	0.839384987
40	0.905644474	0.815973231	0.843741665
50	0.910075216	0.819748813	0.847977383
60	0.914472674	0.823497386	0.852319047
70	0.918838317	0.827219343	0.857654582
80	0.923172111	0.830915072	0.861658862
90	0.927473993	0.834584952	0.866264719
100	0.928363848	0.838229357	0.879716109
200	0.932337179	0.842134687	0.895649385
300	0.936295462	0.84914163	0.907123771
400	0.940238375	0.856148552	0.915425994
500	0.944165606	0.863155454	0.924707115
700	0.948078351	0.870162335	0.929605736
1000	0.95197579	0.877169198	0.93704723

Table VII shows the comparison of F-measure analysis with the existing techniques. The analysis results show that there is an increase in F-measure with increase in project count. It is seen that F-measure for Attri et al. 2019 and without GA is 0.87 and 0.83 for 100 projects. Further, it is observed that the F-measure for 1000 projects shows a rise and increases to 0.95 and Attri et al. and GA is 0.87. The overall average F-measure using the proposed approach is 0.92 and 0.88 using the Attri et al. 2019 which shows that the proposed work outperformed the Attri et al work.

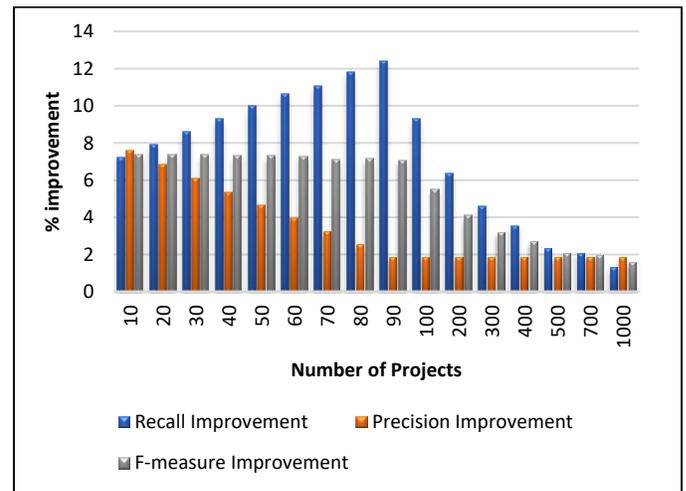

Fig. 3. Improvement Analysis of the Proposed Work over Attri et al. Work.

The observed performance in terms of precision, recall and f-measure values of both proposed and the existing work of Attri et al. are further analyzed to identify the extent of improvement exhibited by the proposed work. The individual % improvement for each of the parameters is individually computed and plotted in Fig. 3 for graphical illustration. It is concluded that despite of the variable % improvement observed

in each of the case, the overall analysis depicts the outperformance of the proposed work.

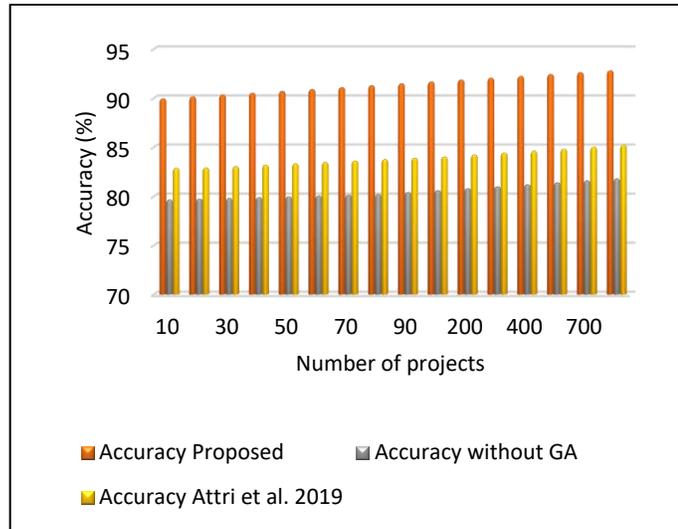

Fig. 4. Comparative Analysis for Accuracy.

Fig. 4 shows the comparison analysis for Accuracy analysis using the proposed and existing techniques. The analysis results show that there is an increase in Accuracy with increase in project count. It is seen that average Accuracy for Attri et al. 2019 and without GA is 84% and 81%. However, the proposed model shows Accuracy of about 91.3. The proposed technique has been improved by 8.9% in comparison to without GA and Attri et al. 2019. Thus, the proposed outperforms the existing work due to the integration of Genetic algorithm and Neural Network.

## V. CONCLUSION

In the present work, machine learning based algorithms such as Neural Network, Genetic Algorithm and their attributes selection have been analyzed for the prediction of software effort. Software testing allows the evaluation of attributes or system capability in determining the requirements to meet the desired results. The primary motive of testing the software is to eliminate the bugs and improve the software security and other aspects such as performance, user satisfaction level, and experience. The study is based on the development of computational intelligence models to deal with the different complex problems. The implementation using the PROMISE and Kaggle dataset has been done and machine learning models such as Genetic algorithm and Neural Network used for implementation. The results of the proposed technique are promising. The accuracy of the proposed model is 91.3% and results are improved by 8.9% in comparison to existing technique. In future, an attempt has been made to improve the accuracy using the other computational techniques such as Fuzzy logic.

# A Computer Vision System for Street Sweeper Robot

Ouiem Bchir, Sultana Almasoud, Lina Alyahya, Renad Aldhalaan, Lina Alsaeed, Nada Aldalbahi

Department of Computer Science, College of Computer and Information Sciences  
King Saud University, Riyadh, Saudi Arabia

**Abstract**—With the spread of Covid-19, more people wear personal protective equipment such as gloves and masks. However, they are littering them all over streets, parking lots and parks. This impacts the environment and damages especially the marine ecosystem. Thus, this waste should not be discarded in the environment. Moreover, it should not be recycled with other plastic materials. Actually, they have to be separated from regular trash collection. Furthermore, littering gloves and masks yields more workload for street cleaners and presents potential harm for them. In this paper, we design a computer vision system for a street sweeper robot that picks up the masks and gloves and disposes them safely in garbage containers. This system relies on Deep Learning techniques for object recognition. In particular, three Deep Learning models will be investigated. They are: You Only Look Once (YOLO) model, Faster Region based Convolutional Neural Network (Faster R-CNN) and DeepLab v3+. The experiment results showed that YOLO is the most suitable approach to design the proposed system. Thus, the performance of the proposed system is 0.94 as F1 measure, 0.79 as IoU, 0.94 as mAP, and 0.41 s as Time to process one image.

**Keywords**—Covid-19; street sweeper robot; personal protective equipment (PPE); computer vision; deep learning

## I. INTRODUCTION

In 2019, the Covid-19 pandemic started. It began to spread widely in early 2020, and was classified pandemic by the World Health Organization on March 11, 2020 when the number of infected cases reached 118,319 cases [1]. Since the infection may be spread by a person's sneezing, coughing, spitting and breathing, most countries' governments have imposed wearing face masks in public places and gatherings. In addition, supermarkets impose the use of gloves as well. This led to a significant increase in the use of face masks and gloves. As a consequence, globally, people are using and disposing of approximately 129 billion face masks and 65 billion gloves every single month during Covid-19 pandemic [2]. Unfortunately, many people are throwing these masks and gloves everywhere such as streets, parking lots, gardens and sidewalks. As a result, they will end up in the ocean through sewer systems creating a new form of pollution. In fact, they will shatter into micro plastics and will be contaminated by dangerous chemicals. Moreover, littering gloves and masks lead to a heavier workload for street cleaners. Furthermore, masks and gloves waste are dangerous for the cleaners' health since they are potentially infected. The same problem encountered by street waste workers, is also faced by recycling waste workers. In addition, Personal Protective Equipment (PPE) cannot be sorted with other material in the recycling centers [3]. In fact, they are thin and easily broken and can block and break down the sorting machine. Therefore, PPE waste materials have to be placed in separate sealed bags or

safely tight garbage containers. Nowadays, it is common to incorporate specialized robots to support workers. These machines lessen the workload since they are able to perform repetitive and simple tasks efficiently. In particular, a street sweeper robot would alleviate the burden of the waste and recycling workers by picking gloves and masks and storing them in sealed containers. In order to make the robots intelligent and aware of their surrounding environment, integrating sensors with robotics is needed. Specifically, computer vision systems that capture images of the scene surrounding the robot and recognize their content, provide the robot with useful information and an understanding of the scene. In particular, the computer vision system of the street sweeper robot would localize masks and gloves. Typically, suitable visual descriptors should be extracted from the captured images in order to segment the image into several objects. Then, another set of features is extracted from each object in order to recognize it using a classifier. Nevertheless, choosing the suitable feature for the segmentation and the recognition task is not straightforward. In fact, it is one of the main difficulties faced by computer vision systems. Recently, the use of Deep Learning (DL) models alleviated this problem by learning suitable features while training the model. The main goal of this paper is to design and implement a computer vision system for a street sweeper robot that recognizes masks and gloves. This system relies on Deep Learning techniques to recognize objects based on their visual properties. For this purpose, we intend to compare three approaches: You Only Look Once (YOLO) model [4], Faster-Region based Convolutional Neural Network (Faster R-CNN) [5], and DeepLab v3+ [6].

## II. BACKGROUND

Object recognition is a field of computer vision which localize and categorize objects in images or video frames. It has been employed in many applications such as tumor recognition in medical images [7], face recognition [8], robot navigation [9], self-driving vehicles [10], etc. Generally, object recognition approaches can be either based on conventional machine learning and image processing techniques or based on Deep Learning approaches. In conventional approaches, a selected set of visual descriptors is extracted from the image for the purpose of segmenting the image into meaningful parts. Then, from the object of interest, another selected feature is extracted and conveyed to a classifier to decide on the class of the object.

Alternatively, object recognition Deep Learning approaches are based on CNN. In fact, they use the conventional layers to 1) automatically learn and extract suitable visual descriptors, and to 2) learn the location of the object. Region Conventional

Neural Networks (R-CNN) models are a well-known family for object recognition. It includes R-CNN [11], Fast R-CNN [12], and Faster R-CNN [5]. Each one of these approaches is an improvement of the previous one. R-CNN is based on a region proposal algorithm called "Selective search". It selects 2000 regions from the image. From each region, visual descriptors are automatically extracted using convolutional layers. Finally, each region is classified using one versus all SVM [13] classifier. In order to enhance the time complexity of the model, Fast R-CNN is proposed. Instead of extracting the visual descriptors from the 2000 regions, visual descriptors are extracted from the whole image first. Then, a Region of Interest (ROI) pooling layer is used to pool the visual descriptors of the region of interest from the final feature map. A SoftMax layer finally classifies this region. An extension to R-CNN [11] and Fast R-CNN [12] is Faster R-CNN [5]. It replaces the "Selective search" algorithm by a Region Proposal Network (RPN). In fact, instead of unnecessarily extracting a fixed number of regions that can be empty or include only a part of the object, Faster R-CNN [5] learns the location of the region to be proposed through the use of a small CNN called RPN. These region-based approaches provide two outputs. These are the bounding boxes coordinate that fits the object of Interest and the class of the object.

Instead of using a region proposal module, Single Shot Detectors (SSDs), use a set of predefined anchor points. From each anchor point, a predefined number of bounding boxes are defined. Then, these models learn if the bounding box contains an object or not, predict the offset of the box so it fits tightly the object, and compute the class probability of each object. Finally, the potential recognized objects are pruned to avoid duplicated recognition. There are various SSDs approaches. They differ in the way of defining the anchors. The most well-known SSD model is YOLO [4].

Another way of semantically understanding the scene is through semantic segmentation. The latter is inextricably related to object recognition. However, it differs in that it does not predict the class and the bounding box of the object, but it learns the pixels that form the object [14]. In fact, semantic segmentation entails assigning a semantic category to each pixel in the input picture.

Recent advances in the field of Deep Learning boosted the semantic segmentation research [15]. In fact, the automatic learning of the features through the convolution layers has improved the performance of semantic segmentation approaches. Nevertheless, CNN cannot be used as it is for semantic segmentation. In fact, max pooling and striding that are suitable for feature reduction, induce low feature resolution [16]. Moreover, since objects may be represented with different scales, standard CNN models need to be trained with different scales of the same object [17]. Furthermore, CNN models discard the location information [18]. Therefore, specific Deep Learning architectures for semantic segmentation have been proposed in the literature. Among these approaches, DeepLab v3+ [6] is a well-known Deep Learning approach for semantic segmentation which has been proven to be effective in many applications [19].

### III. RELATED WORKS

Due to the Covid-19 pandemic and the need to check if people are wearing the required personal protective equipment (PPE), several masks and gloves recognition systems based on Deep Learning have been reported in the literature [20] [21] [22] [23] [24]. However, no existing work addressed the problem of recognizing masks and gloves thrown in the street. Alternatively, two works based on Deep Learning tackled the problem of recognizing different types of wastes littered in the street [25] [26].

#### A. Detection of Masks and Gloves Worn by People

The authors in [20] used two Deep Learning models, YOLO (You Only Look Once) [4] and Single-Shot multibox Detector (SSD) MobileNet [27], for the detection and proper wearing of face masks and gloves. First, the model splits the input image into an  $S \times S$  grid. After that, the grid containing the center of the ground truth bounding box of an object is activated for the detection. Finally, each grid is responsible for predicting the confidence scores of a number of bounding boxes. The MobileNet architecture has been used as a feature extractor in the SSD MobileNet based approach after combining normal convolution and depthwise convolution. The proposed recognition system considers five categories. Namely, it recognizes if the people are wearing masks, not wearing masks, wearing gloves, not wearing gloves, and if they are not properly wearing the masks. The two Deep Learning models were investigated using a dataset containing 8250 photos collected from the internet. The experimental result showed that the proposed system reached an accuracy of 90.6% when using YOLO [4], and an accuracy of 85.5% when using SSD MobileNet [28].

Similarly, the approach in [21] used two Deep Learning models ResNet-50 [29] and YOLOv2 [30]. Nevertheless, they first used ResNet-50 to extract the visual feature. Then, they used YOLOv2 to recognize facial masks. For the assessment of the proposed approach, two medical face masks datasets, Medical Masks dataset (MMD) [31] and Face Mask dataset (FMD) [32] were merged into a single dataset. These datasets have been augmented before being fed to Resnet-50. It achieved a precision of 81%.

The authors in [22] proposed a Deep Learning approach in order to recognize whether or not people are wearing PPE. More specifically, they adopted the YOLOv4 [33] model. The model has backbone, neck and head parts. In the backbone part, CSPDarknet53 is used as a feature extractor model. In the neck section, Spatial Pyramid Pooling (SPP) and Path Aggregation Network (PAN) are employed. Modified PAN has been used for instance segmentation. For the modification of PAN, they used the concatenation operation instead of the addition operation. The SPP is used to perform max pooling over a feature map. The head part was kept the same as it was in YOLOv3. Four categories have been considered which are, wearing a mask, not wearing a mask, wearing a face shield, and wearing gloves. The authors put together a dataset that includes both collected and captured photos. They collected their own dataset to assess the performance of the system. They obtained a precision of 78% and a recall of 80%.

The study in [23] proposed a mask and face recognition system based on YOLOv3 [34]. First, the videos are recorded using digital cameras. After being processed, they are conveyed to YOLOv3. The latter detects faces and masks. The proposed system was trained on a set of 6,000 photos containing surgical masks which are selected from the MAFA dataset [35]. The experimental results showed that the proposed system achieved an accuracy of 84% in recognizing masks and an accuracy of 96% in recognizing faces. The authors in [24] adopted the VGG-16 [36] Deep Learning model to determine whether or not a person is wearing a facemask and checks if the people in a region are observing physical distance. The model is trained using collected data containing 20,000 images. The input image's height and width are set to 224 pixels. Moreover, data augmentation is employed by applying rotation, rescaling, shifting, and zooming operations. It achieved an accuracy of 97%.

### B. General Waste Littered in the Street

The authors in [25] proposed a computer vision system for waste littering quantification. The proposed system is based on a Deep Learning model to localize and classify different types of wastes. They employ the OverFeat-GoogLeNet [37] Deep Learning model. It is an adaptation of the OverFeat model [38] which uses GoogLeNet [39] model as backbone deep network model. The authors collected their own dataset using a high-resolution camera placed on the top of a vehicle to take pictures of wastes on the streets and sidewalks. The performance of the system on the 18,676 collected images is 77.35% for the precision and 60% for the recall. Alternatively, the authors in [26] proposed a robot system that is able to pick up garbage from the grass independently. The computer vision part of the robot aims at recognizing general waste using ResNet-34 [29] and SegNet [40] Deep Learning models. The input image is first segmented using SegNet. The latter is a Deep Learning model designed for segmentation. It is based on a decoder-encoder model where the input image is first down-sampled to learn the visual descriptor, then the obtained visual descriptor is up-sampled to recover the input image resolution. After that, the segmented objects are conveyed to ResNet [29] in order to categorize the waste. In fact, the system considers six categories. Specifically, five classes are used for the waste and one class for non-waste. The system is trained on 40k training pictures and tested on 7k testing pictures. Moreover, they collected 750 more pictures representing non-waste for testing. Experiments have shown that the accuracy of littered waste recognition reached up to 95%.

## IV. SYSTEM FOR STREET SWEEPER ROBOT

In order to design a computer vision system that recognizes masks and gloves, we intend to compare the performance of the three approaches: YOLO [4], Faster R-CNN [5], and DeepLab v3+ [6]. First, we need to train the three considered models. In order to train the YOLO [4] model, we feed its input with images representing littered gloves and masks. The labels of these images are also provided to the recognition system to ensure the training. The labels consist of the corresponding categories of the considered objects (gloves and masks), and their surrounding boxes' information, namely, the upper left corner coordinates, the width and height of the box. Similarly,

Faster R-CNN [5] is trained in the same way since it uses the same type of labels. Alternatively, DeepLab v3+ [6] employs a different type of labels. In fact, since it is a segmentation approach, the label of each pixel should be provided. More specifically, the captured images with littered masks and gloves are conveyed to the input of DeepLab v3+ [6]. Moreover, their corresponding masks images are provided to the networks. They consist of the same image where the pixels corresponding to each object are manually colored with a different color.

Using YOLO [4], the masks and gloves will be recognized and localized. The obtained results will be assessed to measure the performance of the YOLO [4] based system in terms of the Average Precision per class, Mean Average Precision, IoU, F1 measure and Time to process one image. Similarly, the same procedure will be used for the Faster R-CNN [5] based system. And for the DeepLab v3+ [6] based system, the obtained results will be assessed in terms of the IoU, F1 measure and Time to process one image. In fact, AP and mAP are not defined in the case of semantic segmentation.

When the performances of the three systems are computed, we compare between them in order to conclude on the best system to be considered. We should mention we prioritize the recognition performance over the time one. However, in case the recognition performance is similar or slightly different, we select the faster model. The selected approach among the three considered ones will be adopted as illustrated in Fig. 1.

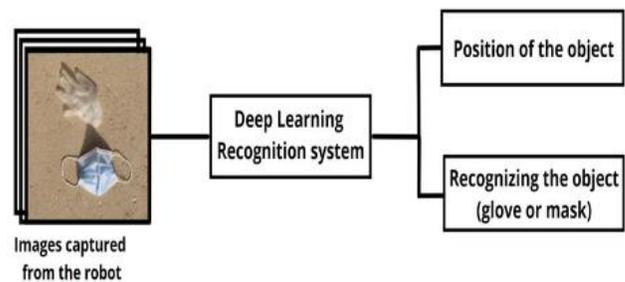

Fig. 1. Proposed System Architecture.

## V. EXPERIMENTS

A dataset of 1500 images containing masks and/or gloves is collected. They are captured using a digital camera and have a size of 224 X 224 pixels. Different backgrounds such as grass, stones, and Asphalt concrete with various angles for shooting and different lighting are considered. Moreover, the masks and gloves in the collected dataset differ in terms of number, color, material, and design. Furthermore, these masks and gloves can be twisted, knotted, or choppy. Two Ground Truth labels are considered. The first one consists of labelling the pixels which belong to the gloves, the masks, and to the background. More specifically, for each image in the dataset, the pixels corresponding to the gloves are colored with green, those corresponding to the masks are colored with blue, and all remaining pixels are colored in black. The coloration is done manually. This first type of Ground Truth will be used with DeepLab v3+ [6] which requires pixel wise labelling. Fig. 2 shows a sample image and the corresponding pixel wise labelling as required by DeepLab v3+ [6].

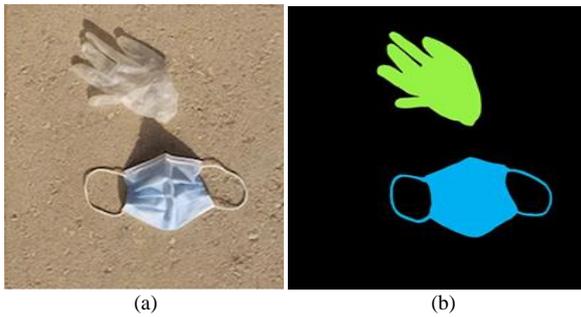

Fig. 2. Sample Pixel Wise Labelled Image. (a) The Sample Image, (b) The Corresponding Ground Truth Required by DeepLab v3+.

Alternatively, for YOLO [4] and Faster R-CNN [5] a different type of Ground Truth labelling is required. In fact, these two approaches, require the bounding boxes coordinates of each object of interest and its corresponding class (mask or glove) with respect to each considered image. The coordinates of the bounding box consist of the upper left coordinates, the width and the height of the rectangle surrounding tightly the object. Fig. 3 depicts sample images and the corresponding bounding boxes of the object of interest.

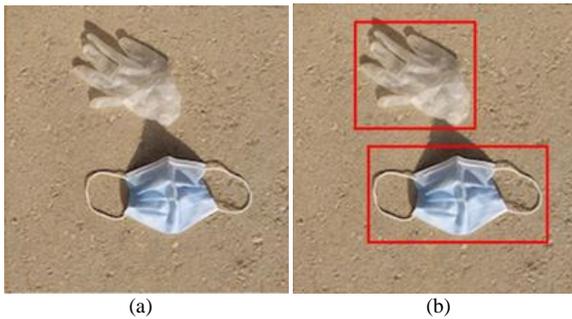

Fig. 3. Sample Labelled Image with Bounding Boxes. (a) The Sample Image, (b) The Corresponding Bounding Boxes Required by YOLO and Faster R-CNN.

### A. Experiment 1

This experiment aims at assessing the performance of YOLOv4 [33] to recognize masks and gloves. For this purpose, we want to figure out the best hyper-parameter configuration for YOLOv4 [33]. As such, YOLOv4 model was trained using different values of the learning rate, the momentum and the number of batches. The learning rate is the most crucial hyper-parameter. In fact, a too small value may result in a long training process, whereas a too large value may result in overshooting the global minimum. Table I shows the five considered configurations. In order to determine the best model, the performance results on the validation set of each configuration are reported. They are the IoU, F1 measure, AP, mAP, and Time to process one image.

Fig. 4 shows the performance measures of YOLOv4 [33] model. As shown in Fig. 4, the best performance is obtained when using configuration 3, and the worst performance is obtained when using configuration 4. In fact, the learning rate in configuration 3 is set to 0.001 while the learning rate in configuration 4 is set to 0.1. Thus, the learning rate of 0.1 yielded the overshoot of the optimal model. Moreover, when the number of batches is large, the performance is better. This

due to the fact that the prediction error used to update the weights is computed using a larger number of images at each batch. The obtained results are 0.95 as F1 measure, 0.8072 as IoU, and 0.963632 as mAP using the considered configuration. We should note that configuration 4 performed better in terms of the time to process one image. However, we prioritize the recognition performance over the time one. Moreover, the difference is not significant, we prioritize the recognition performance. Using configuration 3, the results of the validation, and testing are reported in Table II. As shown, there is no significant performance drop when using the test set. Therefore, we can assume that the learned model is not over-fitted.

In order to illustrate the result obtained by the YOLOv4 [33] model, three sample results are depicted in Fig. 5. In Fig. 5(a), Fig. 5(c), and Fig. 5(e), the images fed to the YOLO model are displayed. Moreover, in Fig. 5(b), Fig. 5(d), and Fig. 5(f), the obtained results are shown. More specifically, the bounding box surrounding the object of interest along with the confidence score are displayed. As shown, even if the gloves or masks are folded, or overlap with another object, YOLOv4 [33] model is able to recognize them with a high confidence score.

TABLE I. YOLOV4 [33] HYPER-PARAMETER CONFIGURATIONS

	Learning rate	Momentum	Number of batches
Configuration 1	0.001	0.949	64
Configuration 2	0.01	0.95	128
Configuration 3	0.001	0.949	256
Configuration 4	0.1	0.99	128
Configuration 5	0.001	0.949	8

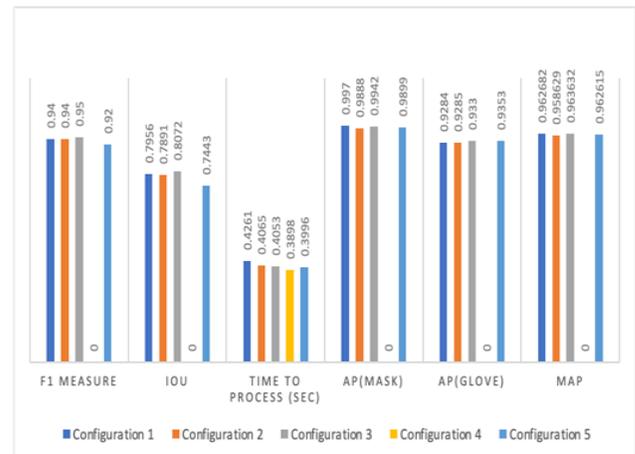

Fig. 4. YOLOv4 [33] Performance Results.

TABLE II. PERFORMANCE OF YOLOV4 [33] MODEL ON THE VALIDATION AND TEST DATASETS

	F1 Measure	IoU	Time to process (in sec)	AP (Mask)	AP (Glove)	mAP
Validation Set	0.95	0.81	0.41	0.99	0.93	0.96
Test Set	0.94	0.79	0.41	0.98	0.90	0.94

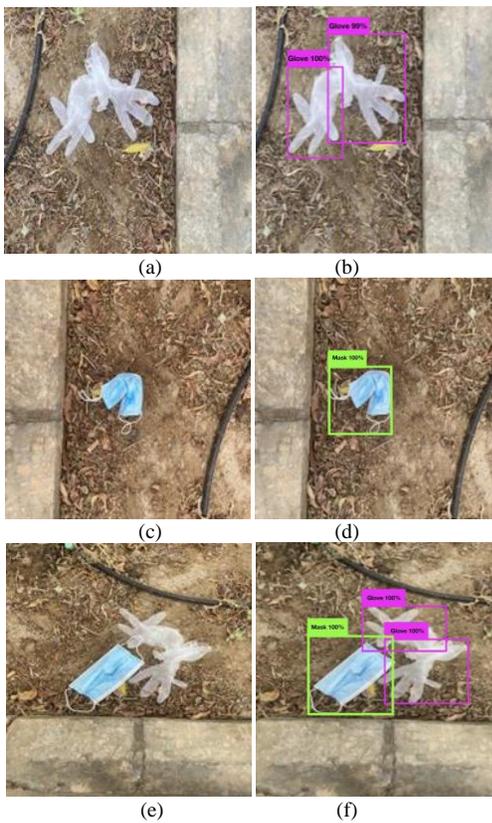

Fig. 5. Three Sample Results Illustrating the Result Obtained when using YOLOv4 [33] Model. (a) Sample Image 1, (b) The Output of Sample Image 1, (c) Sample Image 2, (d) The Output of Sample Image 2, (e) Sample Image 3, (f) The Output of Sample Image 3.

**B. Experiment 2**

In this experiment, we evaluate the performance of Faster R-CNN [5]. In this regard, the hyper-parameters are tuned using the validation set. Table III shows the five considered configurations.

Fig. 6 shows the performance measures of Faster R-CNN [5] on the validation set with respect to each considered configuration. As shown in Fig. 6, the best result is obtained using configuration 3. Specifically, the hyper-parameters are set to 0.0001 for the learning rate, 0.96 for the momentum and 690 for the number of batches. We should mention that configuration 5 gave slightly better AP with respect to the Mask class, but not with respect to the Glove class. However, in terms of mAP configuration 3 is better. The corresponding performance results are 0.5665 as F1 measure, 0.7337 as IoU, and 0.4350 as mAP. Table IV reports Faster R-CNN performance on both the validation and test sets. As shown, the performance of the test set is not significantly worse than the performance of the validation set, and thus the overfitting assumption is discarded.

Fig. 7 displays three sample results of the Faster R-CNN model. The images conveyed to Faster R-CNN model are displayed in the Fig. 7(a), Fig. 7(c), and Fig. 7(e), respectively. The corresponding output results are shown in Fig. 7(b), Fig. 7(d), and Fig. 7(f), respectively. As shown in Fig. 7, the bounding box surrounding the object of interest along with the

confidence score are depicted. We can notice that Faster R-CNN is able to recognize the withdrawn gloves and masks. Nevertheless, for some cases such the illustrative example displayed in Fig. 7(d), the confidence score is not high. This can be due to the fact the mask is folded.

**C. Experiment 3**

In order to detect masks and gloves using semantic segmentation, we tuned the hyper-parameters for DeepLab v3+ [6]. In this regard, we trained DeepLab v3+ [6] using ResNet-50 [29] as backbone. Then, using the validation set, we evaluated the model with respect to five considered configurations. In particular, the learning rate, momentum and number of batches were tuned. These five configurations are reported in Table V.

TABLE III. FASTER R-CNN [5] HYPER-PARAMETER CONFIGURATIONS

	Learning rate	Momentum	Number of batches
Configuration 1	0.001	0.96	690
Configuration 2	0.001	0.94	690
Configuration 3	0.0001	0.96	690
Configuration 4	0.00001	0.96	690
Configuration 5	0.0001	0.94	690

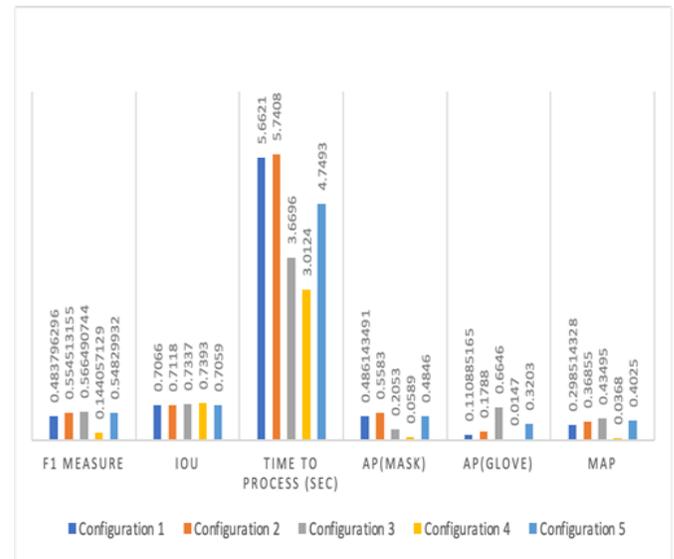

Fig. 6. Faster R-CNN [5] Performance Results.

TABLE IV. PERFORMANCE OF FASTER R-CNN [5] MODEL ON THE VALIDATION AND TEST DATASETS

	F1 Measure	IoU	Time to process (in sec)	AP (Mask)	AP (Glove)	mAP
Validation Set	0.57	0.73	3.67	0.21	0.66	0.43
Test Set	0.50	0.74	3.69	0.21	0.45	0.33

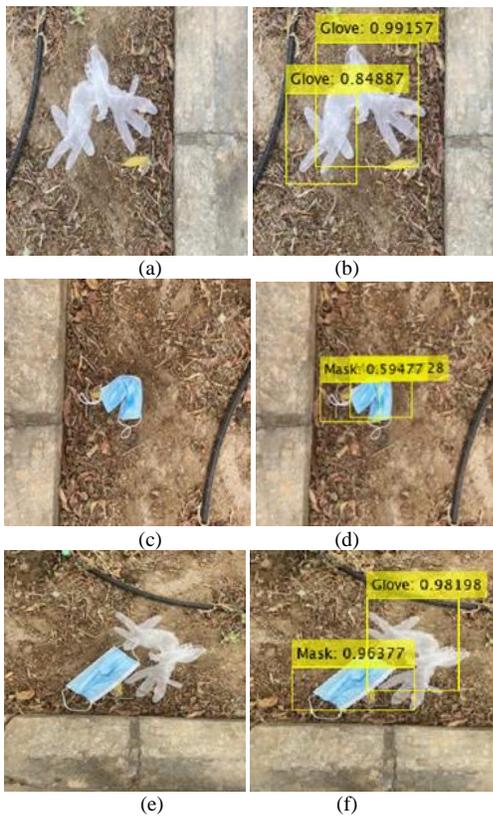

Fig. 7. Three Sample Results Illustrating the Result Obtained using Faster R-CNN Model. (a) Sample Image 1, (b) The Output of Sample Image 1, (c) Sample Image 2, (d) The Output of Sample Image 2, (e) Sample Image 3, (f) The Output of Sample Image 3.

TABLE V. DEEPLAB V3+ [6] HYPER-PARAMETER CONFIGURATIONS

	Learning rate	Momentum	Number of batches
Configuration 1	0.001	0.95	690
Configuration 2	0.01	0.97	690
Configuration 3	0.1	0.99	345
Configuration 4	0.001	0.96	171
Configuration 5	0.001	0.99	690

Fig. 8 displays the performance measures of the system when using DeepLab v3+ [6] semantic segmentation approach with ResNet-50 [29] as backbone. We should notice that contrary to the previous two experiments, only F1 measure, IoU and Time to process are considered. In fact, Average precision performance measure is not defined for segmentation approaches. As shown in Fig. 8, using configuration 1, a learning rate of 0.001, momentum of 0.95 and number of batches of 690, yielded the best performance result with an IoU of 0.9762, and F1 measure of 0.98. In fact, configuration 1 is characterized by a small learning rate avoiding missing the global minimum of the error rate, a large batch size enhancing the error computation, and a relatively smaller momentum (percentage of previous iteration gradients to be considered). Alternatively, a large learning rate of 0.1 (configuration 3) gave the worst result. This can be explained by an under-fitting situation where the model fails to find the global minimum and converges early since the learning step is too large.

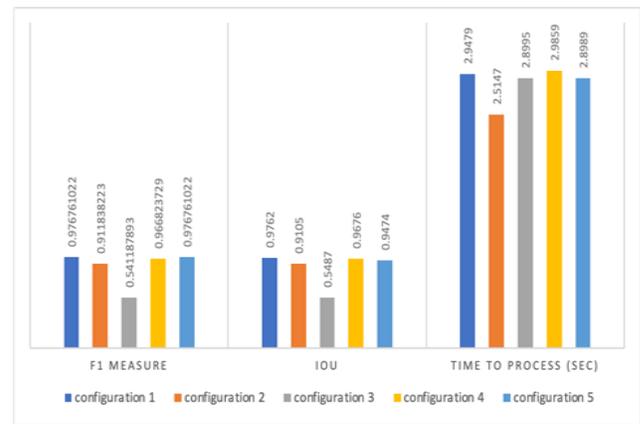

Fig. 8. DeepLab v3+ [6] Performance Results.

Using configuration 1, we evaluated the performance of DeepLab v3+ on the test images. Table VI depicts the performance results of both the validation and the test sets. As reported, there is no drop in the performance when using the test set compared with the performance of the validation set. Therefore, we can conclude that the learned model is not over-fitted.

TABLE VI. PERFORMANCE OF DEEPLAB V3+ [6] MODEL ON THE VALIDATION AND TEST DATASETS

	F1 Measure	IoU	Time to process (in sec)
Validation Set	0.98	0.98	2.95
Test Set	0.99	0.98	3.01

Fig. 9 displays three sample results of DeepLab v3+ model. The input images are shown in Fig. 9(a), Fig. 9(c), and Fig. 9(e), while the corresponding segmented images are depicted in Fig. 9(b), Fig. 9(d), and Fig. 9(f), respectively. In the segmented images, the pixels recognized as masks by DeepLab v3+ are colored in blue, those recognized as gloves with green, and all remaining pixels belonging to the background in black. We can notice that DeepLab v3+ is able to recognize the pixels belonging to withdrawn gloves and masks in different backgrounds, and for various colors of the gloves and the masks.

#### D. Discussion

Fig. 10 compares the performances of YOLOv4 [33] and Faster R-CNN [5] in terms of AP and mAP. We should notice that AP and mAP aren't defined for semantic segmentation approaches such as DeepLabv3+ [6]. As shown Fig. 10, YOLOv4 outperforms Faster R-CNN in recognizing both gloves and masks. This is also confirmed by the mAP. In fact, it is higher for YOLOv4 than Faster R-CNN. This can be explained by the fact that YOLO uses a single end-to-end network while Faster R-CNN uses two networks. Therefore, this can reduce the error. Moreover, Faster R-CNN is a region based approach where the classification is performed on the selected region only; whereas YOLO employs the whole image to predict the location and class of the object of interest. Thus, YOLO accesses more contextual information and predicts less false positives of the background. Furthermore, since YOLO has one object rule that makes it predict a single object per cell, it encourages the spatial diversity of the detected objects.

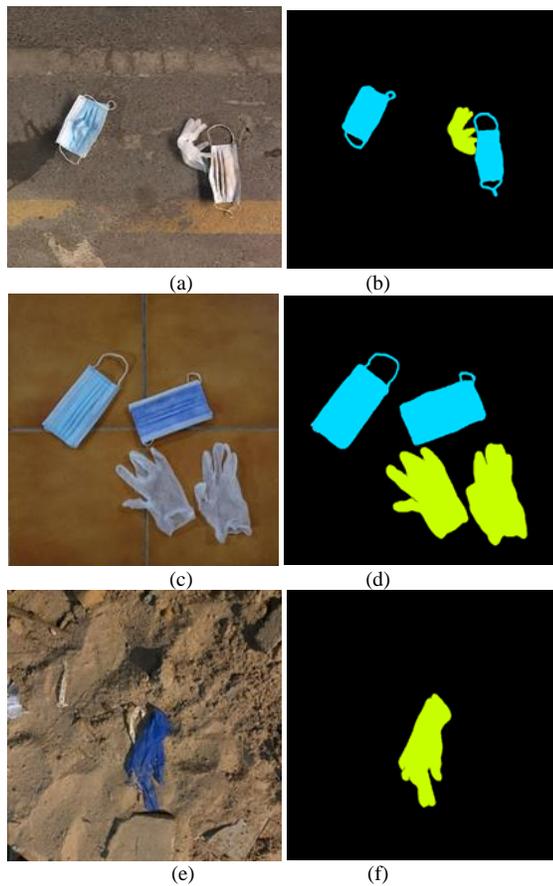

Fig. 9. Three Sample Results Illustrating the Result Obtained when using DeepLab v3+ Model. (a) Sample Image 1, (b) The Output of Sample Image 1, (c) Sample Image 2, (d) The Output of Sample Image 2, (e) Sample Image 3, (f) The Output of Sample Image 3.

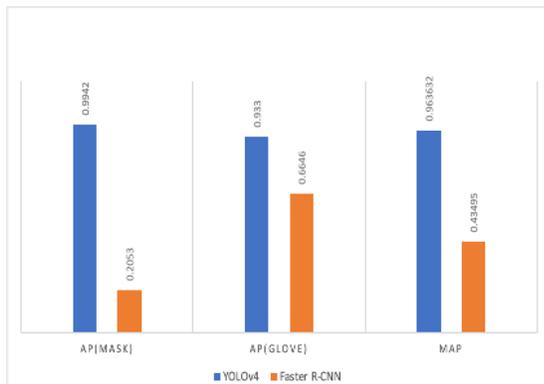

Fig. 10. Performance Comparison of YOLOv4[33], and Faster R-CNN [5] in Terms of AP, and mAP.

Fig. 11 compares the performance of YOLOv4 [33], Faster R-CNN [5], and DeepLab v3+ [6] in terms of F1 measure, IoU, and Time to process one image. As depicted, DeepLab v3+ is better in localizing masks and gloves with an IoU equal to 0.98, compared to an IoU equal to 0.81 for YOLOv4, and 0.73 for Faster R-CNN. This is an expected result since semantic segmentation is a more powerful approach for localizing the object of interest since it works at the pixel level, and not the bounding box like YOLOv4 and Faster R-CNN. Moreover,

DeepLab v3+ is slightly outperforming YOLOv4 and Faster R-CNN according to the F1 measure which combines both the localization and the classification performances of the object of interest. Nevertheless, in terms of processing time, YOLOv4 highly outperforms the other approaches with a time to process one image equal 0.41 s against 3.7 s for Faster R-CNN and 2.95 s for DeepLab v3+. Since the F1 measure difference between YOLOv4 and DeepLab v3+ is not significant while the difference in terms of processing time is large in favor of DeepLab v3+, we choose the YOLOv4 model to design the proposed approach.

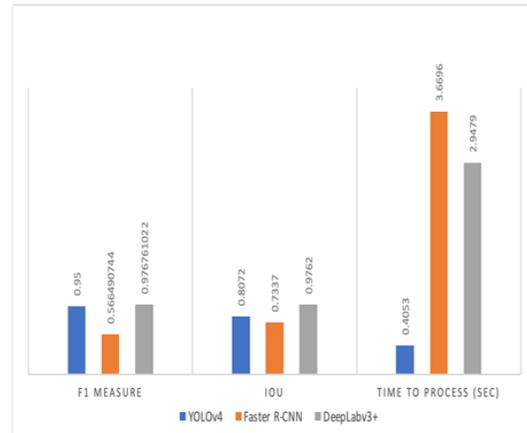

Fig. 11. Performance Comparison of YOLOv4, Faster R-CNN, and DeepLab v3+ in Terms of F1 Measure, IoU, and Time to Process One Image.

In attempt to further enhance the performance of the selected model (YOLOv4), we employed data augmentation. In other words, additional images are considered to train the model. These images are obtained by modifying existing images using rotation, cropping, blurring and adding brightness. The augmented dataset consists of 2073 images, Fig. 12 shows sample images from the augmented dataset. Table VII depicts the performance of YOLOv4 when using data augmentation and without using it. We noticed that using the augmented dataset shows a slight improvement to the results in terms of F1 measure, IoU, AP, mAP.

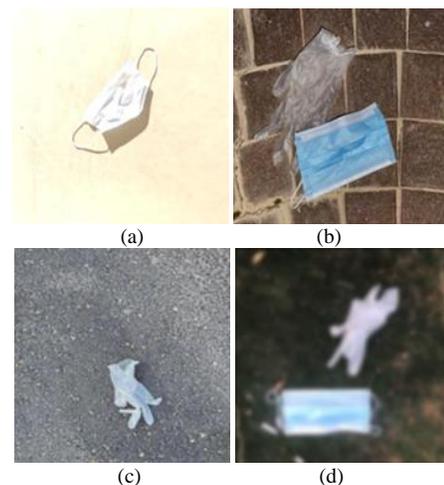

Fig. 12. Sample Images Obtained after the Data Augmentation. (a) Brightened Image, (b) Rotated Image, (c) Cropped Image, and (d) Blurred Image.

TABLE VII. PERFORMANCE COMPARISON OF YOLOV4 [33] WHEN USING DATA AUGMENTATION AND WITHOUT USING IT

	<b>F1 Measure</b>	<b>IoU</b>	<b>Time to process (in sec)</b>	<b>AP (Mask)</b>	<b>AP (Glove)</b>	<b>mAP</b>
Test results with augmented data	0.95	0.81	0.49	0.99	0.94	0.97
Test results without augmented data	0.94	0.79	0.41	0.982	0.901	0.94

### E. Conclusion and Future Works

In this paper, we propose to design and implement a computer vision system of a street sweeper robot that recognizes masks and gloves for the purpose of picking them and disposing them in securely tight garbage bags. The proposed system is based on a Deep Learning object recognition approach.

After investigating the related works and studying the related background, we proposed an effective approach to automatically recognize facial masks and gloves which have been littered in the environment. For these purposes, three Deep Learning approaches are compared. These are YOLO, Faster R-CNN and DeepLab v3+. YOLOv4 is selected as the most suitable model for detecting littered gloves and masks. As future works, we propose to investigate emerging deep learning recognition and semantic segmentation approaches. In fact, pattern recognition field is an active field of research with continuous advancement.

**Abstract**—With the rapid growth of digital libraries and language translation tools, it is easy to translate text documents from one language to other, which results in cross-language plagiarism. It is more challenging to identify plagiarism among documents in different languages. The main aim of this paper is to translate the French documents into English to detect plagiarism and to extract bilingual lexicons. The parallel corpus is used to compare multilingual text, a collection of similar sentences and sentences that complement each other. A comparative study is presented in this paper, the sentences similarity in bilingual content is found out by using the proposed Fuzzy-Wuzzy (Partial Ratio) based string similarity technique and three various techniques like Levenshtein Distance, Spacy and Fuzzy-Wuzzy (Ratio) similarity techniques in the literature. The string similarity method based on Fuzzy-Wuzzy (Partial Ratio) outperforms in terms of accuracy compared to Spacy, and Fuzzy-Wuzzy (Ratio) techniques for identifying language similarity.

**Keywords**—Plagiarism; natural language processing; string similarity; levenshtein distance; fuzzy-wuzzy

## I. INTRODUCTION

The ability of machines to understand the human language carried by Natural Language Processing is a crucial component of Artificial Intelligence. Search engines' arrival leads to several natural language processing advancements to retrieve the text from electronic documents with string comparison. The machines can recognize and extract patterns from text data by applying several text similarity and information retrieval techniques using NLP. Their meaning identified the closeness between two text words by the NLP technique called Text Similarity.

Natural Language Processing (NLP) in Artificial Intelligence is an important field. NLP plays a vital role in the comprehension of human language by computers. NLP uses different text similarity techniques and the combination that enables machines to create and extract patterns from those text data. The proximity of two text pieces is found out using the text similarity method, which is one of the essential NLP methods. Data needs to be translated in a numerical format to carry out machine learning tasks. TF-IDF, Word2vec and Bag of Words are the different word embedding techniques used for text data encoding. The essential steps in the text-similarity are: Text planning, Feature extraction, Vector similarity and Decision function.

## A. WordNet

In English, a large database of nouns, adjectives, verbs and adverbs are grouped into a collection of synonyms. WordNet that includes the link between words in over 200 languages is a lexical database. Synonyms are interlinked with lexical and semantic relations. The structure of the WordNet makes it a helpful tool for NLP. Based on their meanings, the words in WordNet are clustered as a thesaurus cursorily resembles them. Words in the network are close to each other as the definitions of words are precisely defined by WordNet. A synonym is a crucial relation in the midst of words in WordNet.

## B. NLTK

The nltk.corpus package in python defines a collection of corpus reader classes that are used to access the contents of different set of corpora. A machine that can understand the meaning of a text needs analysis which is the fundamental idea of NLP.

## C. Stop Words

The meaningless words that are designed to be ignored by the search engine to increase the database space or the processing time are stop words. nltk.corpus package in python has a list of stop words in 16 various languages.

1) *Research statement*: The content in French language can be converted into English using conversion tools which cannot be identified in plagiarism detection. The main aim of the research is to find out the copying content in a document after translating French document into English.

2) *Research objectives*: To find the accuracy by conducting an experimental study with Fuzzy-Wuzzy (Partial Ratio) for identifying the similarity between languages.

3) *Research significance*: In recent years the attention in copying the content from various sources increased while writing a new document which is an offence. There are so many plagiarism tools available in the market for checking the originality of the content. Although the tools are working efficiently for the originality checking but still there is a problem that if we copy the content from one language and using converter tools, we can convert that content into English. In such cases it is not possible for the tools to identify the

similarity between the sentences exactly leads to a less similarity index.

## II. RELATED WORK

To find and compare cross-language articles on a specific subject, a measure of similarity is required. The basis for this estimation could be bilingual dictionaries or digital techniques, for example, latent semantic indexing (LSI) [16]. To find similar Arabic/English documents in two ways, LSI is used [1]. Monolingual: the first way is to translate the English article into Arab and then map it into space in the Arabic language LSI [10]. The second method is cross-lingual. The paper then compares LSI methods on various parallel and analog English-Arabic companies with a dictionary-based approach [8-9, 11, 13-14]. The cross-language LSI framework displays the results.

String similarity search is used in many real-life applications, like data cleaning, spell checking, fuzzy keyword search or DNA sequence comparison. Given a set of large string and a query string, the problem of string similarity search is to discover all strings in the string set that are identical to the query string efficiently [12]. Similarity is defined by using similarities measures like edit distance or Hamming distance. State Set Index (SSI) is presented as an effective solution to this work's search problem. SSI is interpreted as a finite automaton of non-determinism. SSI introduces a modern state labeling method that makes the index extremely space efficient. In addition, space usage by SSI can be traded against search time. On various sets of individual names with up to 170 million strings from a social network, they measured SSI and compared it to other state-of-the-art approaches. They show that SSI is substantially faster in most cases than other methods and needs less index space.

To retrieve math formulae from the text, three separate assessments were analyzed, in specific, Sequence Matcher, string matching algorithms, Levenshtein, and Fuzzy-Wuzzy. There are four types of Fuzzy-Wuzzy, two versions of which are found to be useful for the retrieval of Math formulae. The retrieval time of partial ratio-based Fuzzy-Wuzzy is less than the ratio-based Fuzzy-Wuzzy [2-7, 15]. They found Fuzzy-Wuzzy outperforms than Levenshtein distance and Sequence matcher techniques in terms of retrieval time and accuracy through their observations.

## III. PROPOSED TECHNIQUE

In the proposed technique, French and English documents are first loaded and then stop words and special characters are removed from them. The preprocessed documents are then converted into a list of words. French synonyms are found for each word in the French list of words using NLP and then find the corresponding English synonyms for each French word. English synonyms are found for each word in the English list of words using NLP. Now prepare the final lists list1 and list2

which have all the English synonyms of French list and English synonyms of English list. String similarity between both these final lists is computed using Spacy, Levenshtein Distance, Fuzzy-Wuzzy (Ratio) and Fuzzy-Wuzzy (Partial Ratio) techniques by taking a Threshold as shown in Fig. 1. Compare List1 with List2 and remove all the words that have a match in List2. For the leftover words check semantic closeness and if it satisfies the threshold remove the words. Likewise perform for all words until we get final leftover list.

The similarity between documents is identified with the formula:

$$100 - \left( \frac{\text{finalLeftOverEnglishListLength}}{\text{OriginalEnglishLength}} \right) * 100$$

The presented techniques are discussed below.

### A. Spacy

The Spacy technique predicts how two objects are identical by comparing the objects. For flagging replicas, the similarity prediction is helpful. Context-Sensitive tensors and Word vectors are the two approaches to find the relation between the terms assisted by Spacy. Two values 0 and 1 are used to define the spectrum of similarities. The value 1 means that the two sentences are identical, and the value 0 means that the sentences are not similar. In certain instances, they still have a high similarity meaning, even though they have no standard terms. One of the essential steps in NLP is text pre-processing to remove high similarity between unmatched sentences.

### B. Levenshtein Distance

The fields in which Levenshtein distance is used are computer science, computational linguistics, bioinformatics, molecular biology, and DNA analysis. The similitude between objective string and source string is evaluated by using Levenshtein Distance. In everyday life, the Levenshtein distance is commonly used. In speech recognition and plagiarism detection, Levenshtein distance is primarily used.

### C. Fuzzy-Wuzzy

Fuzzy string matching often described as precise string matching to find a string that almost matches a particular pattern. Applications of Fuzzy String Matching include spell checking, detection of text reuse, spam filtering, and matching DNA sequences in the bioinformatics domain. The string similarity is checked by the Fuzzy-Wuzzy library between two terms or phrases and gives a value between 0 and 1. If the ratio is nearer to 1, the terms are well-matched. If the ratio is closer to 0, the terms are unrelated to each other. The two common fuzzy matches supported by Fuzzy-Wuzzy are suitable for finding the languages close to each other. Pure Levenshtein Distance-based matching is used in Fuzzy-Wuzzy (Ratio) technique and in Fuzzy-Wuzzy (Partial Ratio) technique matching is done based on best substrings.

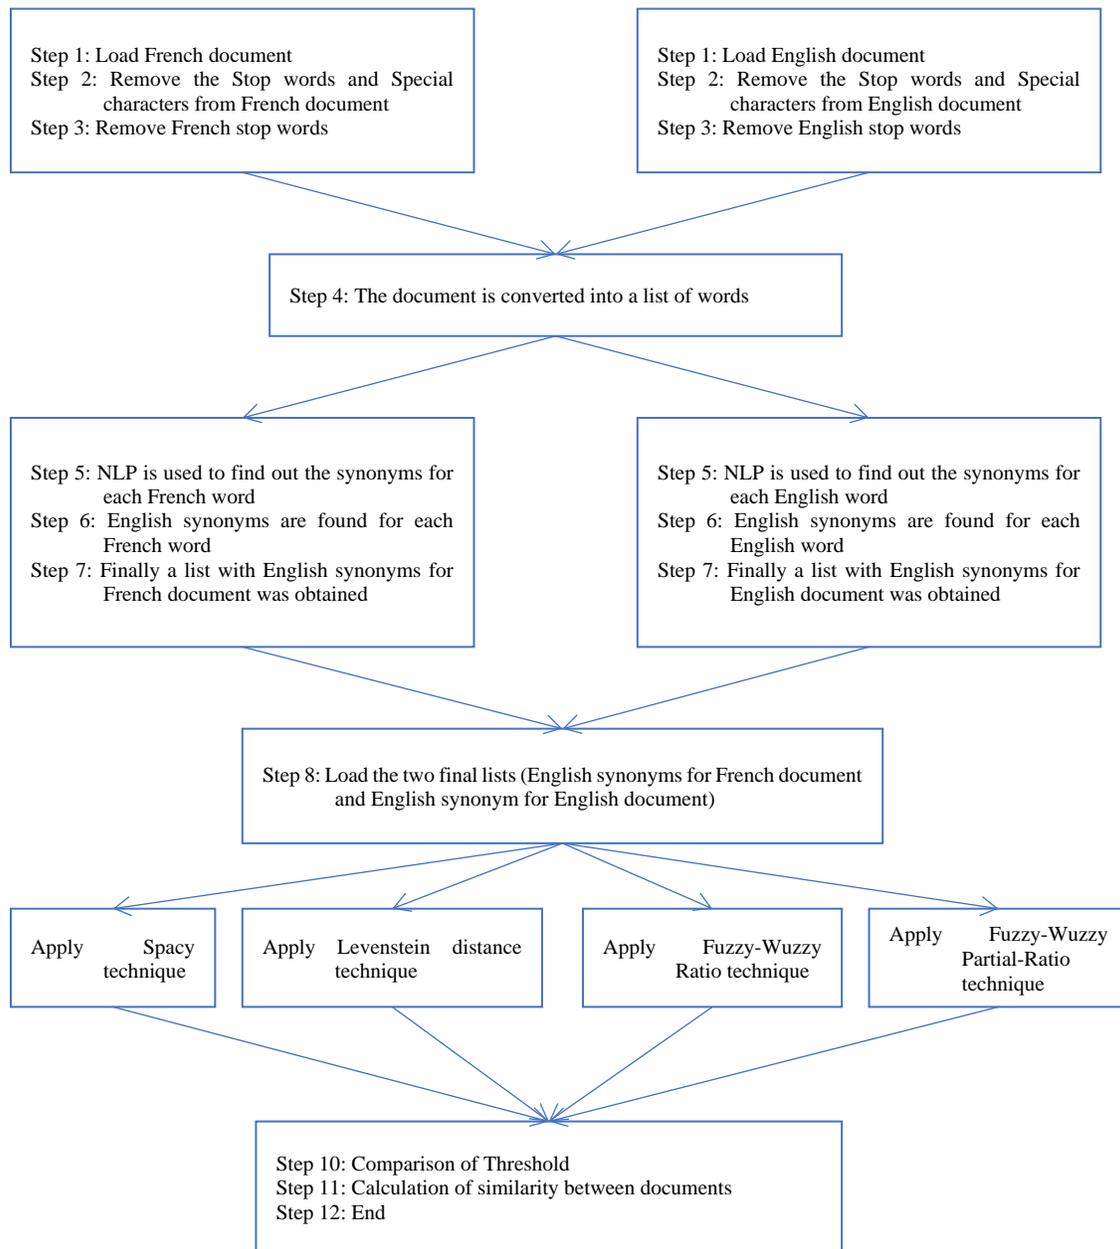

Fig. 1. Flow Diagram of the Presented String Similarity Methods.

#### IV. RESULTS

The comparison between the proposed and the literature methods is presented in terms of the metric accuracy. The similarity between the languages English and French is calculated by using the accuracy and based on that the presented techniques are compared. The proposed method's competence is presented with three kinds of mappings like one-to-one, one-to-many, and many-to-many between French documents and English documents.

From the results, the results obtainable with proposed Levenshtein Distance is much appropriate for string similarity. The tests carried out on nearly 200 documents; out of the proposed methods Fuzzy-Wuzzy (Partial Ratio) approach listed accuracy values in the range of 99 to 100 percent.

Table I and II represent accuracy with the Spacy, Levenshtein distance, Fuzzy-Wuzzy (Ratio) and Fuzzy-Wuzzy (Partial Ratio) techniques on 16 samples which are one-to-one mappings of French and English documents. In one-to-one mapping, there are four different ways in which the documents are being compared. 1) French Document + English document 2) French document rewrite + English document 3) French document + English document rewrite 4) French document rewrite + English document rewrite. It is observed from the tables that the accuracy ranges from 90.19 to 95.12 for Spacy technique, ranges from 94.63 to 100 for Levenshtein distance, ranges from 82.35 to 97.05 for Fuzzy-Wuzzy (Ratio) technique and ranges from 99.47 to 100 for Fuzzy-Wuzzy (Partial Ratio) technique.

TABLE I. MEASURING ACCURACY IN BETWEEN ENGLISH - FRENCH ONE-TO-ONE DOCUMENTS USING THE PRESENTED TECHNIQUES

Samples	Datasets	Spacy	Levenshtein Distance	Fuzzy- Wuzzy (Ratio)	Fuzzy- Wuzzy (Partial Ratio)
Sample 1	French document + English document	90.76	98.23	94.7	100
	English document + French document re-write	90.87	98.23	94.7	100
	English document re-write + French document	92.88	97.32	88.23	100
	English document re-write+ French document re-write	92.99	97.32	93	100
Sample 2	French document + English document	91.5	98.13	95.79	100
	English document + French document re-write	91.2	98.59	95.32	100
	English document re-write + French document	94.01	98.69	91.17	100
	English document re-write+ French document re-write	93.78	99.13	95.65	100
Sample 3	French document + English document	91.72	99.31	96.9	100
	English document + French document re-write	91.48	99.31	96.56	100
	English document re-write + French document	93.39	98.12	97.05	100
	English document re-write+ French document re-write	93.22	98.12	96.25	100
Sample 4	French document + English document	92.86	96.76	93.23	100
	English document + French document re-write	93.07	96.47	93.23	100
	English document re-write + French document	94.69	98.13	91.17	100
	English document re-write+ French document re-write	94.95	97.86	95.2	100
Sample 5	French document + English document	92.56	96.24	92.22	100
	English document + French document re-write	92.3	94.63	89.81	100
	English document re-write + French document	93.99	97.28	85.29	100
	English document re-write+ French document re-write	93.78	96.79	93.82	100
Sample 6	French document + English document	92.44	97.16	92.3	99.59
	English document + French document re-write	92.94	97.16	91.49	99.59
	English document re-write + French document	93.93	97.31	85.29	99.61
	English document re-write+ French document re-write	94.51	97.31	91.95	99.61

TABLE II. MEASURING ACCURACY IN BETWEEN ENGLISH-FRENCH ONE-TO-ONE DOCUMENTS USING THE PRESENTED TECHNIQUES

Samples	Datasets	Spacy	Levenshtein distance	Fuzzy- Wuzzy (Ratio)	Fuzzy-Wuzzy (Partial Ratio)
Sample 7	French document + English document	91.73	94.8	89.96	100
	English document + French document re-write	91.45	95.15	88.92	100
	English document re-write + French document	93.35	96.01	85.29	100
	English document re-write+ French document re-write	93.15	96.67	92.3	100
Sample8	French document + English document	90.73	97.55	93.7	100
	English document + French document re-write	90.76	97.9	92.65	100

Table III and IV represent accuracy with the Spacy, Levenshtein distance, Fuzzy-Wuzzy (Ratio) and Fuzzy-Wuzzy (Partial Ratio) techniques for one-to-many mappings of French and English documents. It is observed from the tables that the accuracy ranges from 90.24 to 95.11 for Spacy technique, ranges from 92.76 to 99.13 for Levenshtein distance, ranges from 80.96 to 95.79 for Fuzzy-Wuzzy (Ratio) technique and ranges from 97.64 to 100 for Fuzzy-Wuzzy (Partial Ratio) technique.

TABLE V. COMPARISON OF ACCURACY BETWEEN PRESENTED METHODS FOR ENGLISH-FRENCH MANY-TO-MANY DOCUMENTS WITH FRENCH [1 6] AND DIFFERENT ENGLISH PAIRS

French pair Samples	English pair Samples	Spacy	Levenshtein Distance	Fuzzy-Wuzzy (Ratio)	Fuzzy-Wuzzy (Partial Ratio)
[1 6]	[1 8]	91.4	97.53	92.80	100
[1 6]	[3 10]	90.4	97.50	89.88	100
[1 6]	[2 6]	92.89	95.32	93.41	99.72
[1 6]	[4 7]	92.46	96.39	93.45	100
[1 6]	[3 7]	92.21	97.10	93.01	100
[1 6]	[1 8]	89.54	97.18	90.45	100
[1 6]	[5 9]	90.4	97.50	89.88	100
[1 6]	[4 6]	92.59	95.46	90.78	99.81
[1 6]	[3 9]	91.89	94.02	92.44	100

Table V represents accuracy with the presented techniques for many-to-many mappings of [1, 6] French documents and different English documents. It is observed from the table that the accuracy ranges from 89.54 to 92.89 for Spacy technique, ranges from 94.02 to 97.53 for Levenshtein Distance, ranges from 89.88 to 93.45 for Fuzzy-Wuzzy (Ratio) technique and ranges from 99.72 to 100 for Fuzzy-Wuzzy (Partial Ratio) technique.

Table VI represents accuracy with the presented techniques for many-to-many mappings of [3, 10] French documents and different English documents. It is observed from the table that the accuracy ranges from 89.46 to 98.65 for Spacy technique, ranges from 95.71 to 97.86 for Levenshtein Distance, ranges from 90.45 to 100 for Fuzzy-Wuzzy (Ratio) technique and ranges from 99.25 to 100 for Fuzzy-Wuzzy (Partial Ratio) technique.

Table VII represents accuracy with the presented techniques for many-to-many mappings of [5, 7] French documents and different English documents. It is observed from the table that the accuracy ranges from 89.56 to 94.76 for Spacy technique,

ranges from 96.45 to 98.82 for Levenshtein distance, ranges from 90.66 to 93.47 for Fuzzy-Wuzzy (Ratio) technique and ranges from 99.82 to 100 for Fuzzy-Wuzzy (Partial Ratio) technique.

Table VIII represents the accuracy with the presented techniques for many-to-many mappings of [4, 6] French documents and different English documents. It is observed from the table that the accuracy ranges from 88.94 to 95.05 for Spacy technique, ranges from 95.11 to 98.24 for Levenshtein distance, ranges from 89.20 to 93.56 for Fuzzy-Wuzzy (Ratio) technique and ranges from 99.12 to 100 for Fuzzy-Wuzzy (Partial Ratio) technique.

TABLE VI. COMPARISON OF ACCURACY BETWEEN PRESENTED METHODS FOR ENGLISH-FRENCH MANY-TO-MANY DOCUMENTS WITH FRENCH [3 10] AND DIFFERENT ENGLISH PAIRS

French pair Samples	English pair Samples	Spacy	Levenshtein Distance	Fuzzy-Wuzzy (Ratio)	Fuzzy-Wuzzy (Partial Ratio)
[3 10]	[1 9]	92.71	97.72	93.16	100
[3 10]	[3 6]	90.45	97.63	91.21	99.81
[3 10]	[2 6]	92.55	96.16	92.95	99.77
[3 10]	[4 7]	89.46	97.45	90.45	99.25
[3 10]	[2 8]	92.47	95.86	92.45	99.67
[3 10]	[2 9]	92.71	95.74	93.68	99.64
[3 10]	[5 10]	93.14	95.71	93.66	100
[3 10]	[2 7]	92.48	95.97	92.31	99.64
[3 10]	[2 10]	98.65	97.86	95.66	100

TABLE VII. COMPARISON OF ACCURACY BETWEEN PRESENTED METHODS FOR ENGLISH-FRENCH MANY-TO-MANY DOCUMENTS WITH FRENCH [5 7] AND DIFFERENT ENGLISH PAIRS

French pair Samples	English pair Samples	Spacy	Levenshtein Distance	Fuzzy-Wuzzy (Ratio)	Fuzzy-Wuzzy (Partial Ratio)
[5 7]	[3 9]	92.64	98.60	93.29	99.82
[5 7]	[2 9]	93.11	98.82	93.47	100
[5 7]	[2 8]	92.87	98.66	93.22	100

[5 7]	[1 7]	89.56	97.62	90.66	100
[5 7]	[5 9]	94.76	98.55	91.89	99.83

TABLE VIII. COMPARISON OF ACCURACY BETWEEN PRESENTED METHODS FOR ENGLISH-FRENCH MANY-TO-MANY DOCUMENTS WITH FRENCH [4 6] AND DIFFERENT ENGLISH PAIRS

French pair Samples	English pair Samples	Spacy	Levenshtein Distance	Fuzzy-Wuzzy (Ratio)	Fuzzy-Wuzzy (Partial Ratio)
[4 6]	[3 6]	92.89	95.11	93.42	99.24
[4 6]	[3 8]	92.79	96.23	93.29	99.56
[4 6]	[1 7]	93.06	98.12	91.68	100
[4 6]	[4 6]	95.05	97.46	91.02	99.63
[4 6]	[2 8]	92.88	95.54	93.22	99.12
[4 6]	[1 8]	91.64	98.24	91.87	100
[4 6]	[5 10]	90.21	96.77	90.90	99.41
[4 6]	[5 6]	88.94	96.12	89.20	99.39
[4 6]	[2 6]	93.45	96.51	93.56	99.57

TABLE IX. COMPARISON OF ACCURACY BETWEEN PRESENTED METHODS

Technique	One-One Mapping	One-Many Mapping	Many-Many Mapping
Spacy Similarity	90.19-95.12	90.24-95.11	88.94-98.65
Levenshtein Distance	94.63-100	92.76-99.13	95.11-98.82
Fuzzy-Wuzzy (Ratio)	82.35-97.05	80.96-95.79	89.20-95.66
Fuzzy-Wuzzy (Partial-Ratio)	99.47-100	97.64-100	99.12-100

Table IX represents the overall accuracy of the presented techniques with three kinds of mappings like one-one, one-many and many-many between French documents and English documents. Out of all the presented techniques Fuzzy-Wuzzy (Partial Ratio) technique outperformed all the remaining techniques with accuracy ranging from 99.12 to 100.

Table X presents the time taken to find the similarity between languages like English and French. The time calculation was accomplished on various documents of different sizes from 3KB to 50 KB with all the techniques discussed in this article. From the table, it is clear that the Spacy method identifies the similarity between English and French languages in less time than the other techniques in the literature.

Fig. 2 illustrates the data from Table I with eight samples of French and English documents with one-to-one mapping. The graph shows that the string similarity measure values of Spacy and Fuzzy-Wuzzy (Ratio) techniques are less than the Levenshtein Distance and Fuzzy-Wuzzy (Partial Ratio) techniques. It also shows that Fuzzy-Wuzzy (Partial Ratio) technique outperforms the remaining presented techniques.

Fig. 3 illustrates the data from Table III which contains one-to-many mapping of French and English documents. It shows that the accuracy of Fuzzy-Wuzzy (Partial Ratio) technique is more than the accuracy of remaining presented techniques.

TABLE X. TIME REQUIRED TO FIND THE SIMILARITY BETWEEN ENGLISH AND FRENCH DOCUMENTS

Sample Size	Spacy	Levenshtein Distance	Fuzzy-Wuzzy (Ratio)	Fuzzy-Wuzzy (Partial Ratio)
3 KB	5	8	6	5
6 KB	8	14	12	9
9 KB	10	19	14	14
12 KB	13	23	19	18
15 KB	16	28	23	22
18 KB	19	36	27	26
24 KB	26	47	38	37
27 KB	30	52	43	43
30 KB	33	58	47	46
36 KB	38	70	56	55
39 KB	41	75	61	61
42 KB	43	79	67	65
45 KB	46	84	72	71
50 KB	50	92	86	84

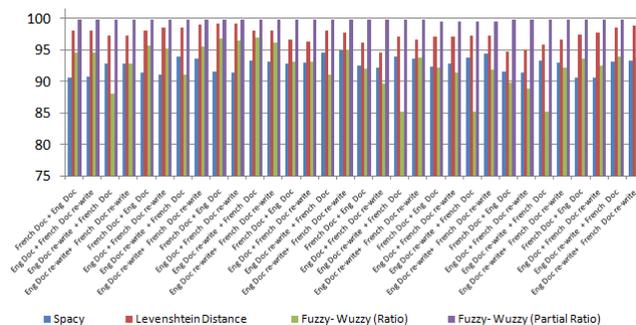

Fig. 2. Measuring Accuracy with Fuzzy-Wuzzy, Spacy Similarity and Levenshtein Distance in between French-English One-one Mapping.

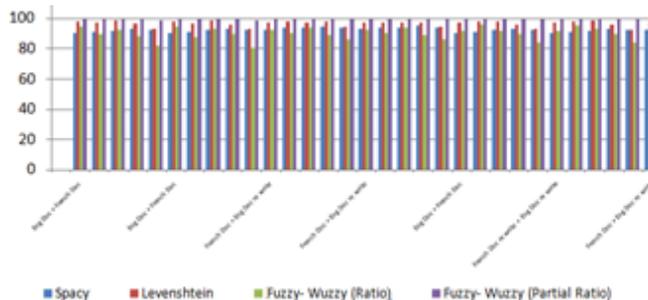

Fig. 3. Measuring Accuracy with Fuzzy-Wuzzy, Spacy Similarity and Levenshtein Distance in between French-English one-many Mapping.

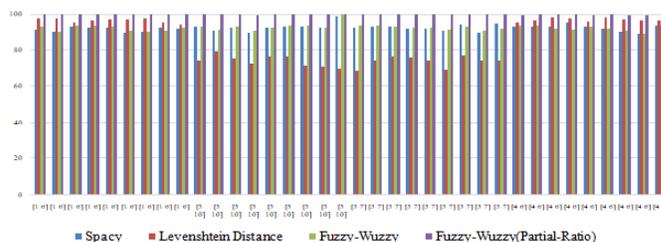

Fig. 4. Measuring Accuracy with Fuzzy-Wuzzy, Spacy Similarity and Levenshtein Distance in between French-English many-many Mapping.

Fig. 4 illustrates the data from Table V to VIII which contains many-to-many mappings of [1, 6], [3, 10], [5, 7] and [4, 6] French Documents and different English documents. It shows that the accuracy of Fuzzy-Wuzzy (Partial Ratio) technique is more than the accuracy of remaining presented techniques.

## V. CONCLUSION

In this paper, the cross-language plagiarism detection between French and English documents is discussed. Some string similarity techniques such as Fuzzy-Wuzzy (Ratio), Fuzzy-Wuzzy (Partial Ratio), Spacy similarity, and Levenshtein distance are used to retrieve the similarity of sentences and words in multilingual content. Accuracy is the criterion used in comparing the output of the presented techniques. More methods need to be identified to find a similarity between languages with improved precision. The Fuzzy-Wuzzy (Partial Ratio) accuracy is more significant than Fuzzy-Wuzzy (Ratio), Levenshtein distance, and Spacy similarity, but time required to find the similarity is substantial with Spacy compared to other techniques.

**Abstract**—This study compares two Deep Learning model methods, which include the Long Short-Term Memory (LSTM) method and the Convolution Neural Network (CNN) method. The aim of the comparison is to discover the performance of two different fundamental deep learning approaches which are based on convolutional theory (CNN) and deal with the vanishing gradient problem (LSTM). The purpose of this study is to compare the accuracy of the two methods using a dataset of 4169 obtained by crawling social media using the Twitter API. The Tweets data we've obtained are based on a specific hashtag keyword, namely "covid-19 pandemic". This study attempts to assess the sentiment of all tweets about the Covid-19 viral epidemic to determine whether tweets about Covid-19 contain positive or negative thoughts. Before classification, the Preprocessing and Word Embedding steps are completed, and this study has determined that the epoch used is 20 and the hidden layer is 64. Following the classification process, this study concludes that the two methods are appropriate for classifying public conversation sentences against Covid-19. According to this study, the LSTM method is superior, with an accuracy of 83.3%, a precision of 85.6%, a recall of 90.6%, and an f1-score of 88.5%. While the CNN method achieved an accuracy of 81%, precision of 71.7%, recall of 72%, and f1-score of 72%.

**Keywords**—COVID-19; LSTM; CNN; sentiment analysis

## I. INTRODUCTION

Social media is an online platform through which the community interacts broadly and openly, and it can also be used to disseminate information. Twitter is one of the most popular social networking platforms [1]. With 18.45 million users, Indonesia ranks fifth among countries with the most active engagement on Twitter [2]. The information regarding the Covid-19 pandemic is what is being discussed now.

The Covid-19 pandemic has resulted in the implementation of all regulations and limitations in numerous nations, including Indonesia [3]. As a result, many people express their opinions about Covid-19 on social media; therefore, this discussion or community response can be classified to determine the sentiment of the statement; after determining the classification in the sentence, accuracy calculations can be produced; and the method is required so that classification is carried out structurally.

For measuring categorization accuracy, there are two methods available: Machine Learning [4] and Deep Learning [5]. There are multiple algorithms that can be applied to both models. Deep Learning is a model based on the human brain's

artificial neural network; this model is an implementation of the modern Machine Learning model [6]. Deep Learning is a generic sort of learning that can handle issues in all domains, including categorization [7]; it has been defined as such. The Long Short-Term Memory (LSTM) technique [8] and the Convolution Neural Network (CNN) algorithm [9] can be employed for this categorization within this deep learning system. In the mode of deep learning with several levels (layers), the layers are the input layer, the hidden layer, and the output layer [10]. Before executing calculations using the Deep learning model of conversational sentence categorization. However, the preprocessing procedure must be executed to ensure that the input is first processed using natural language processing (NLP) [11]. NLP is a computerized technology that explains the function of software or hardware that analyzes spoken or written language in a computer system [12]. The primary objective of NLP is to have a computer system that truly understands natural language as closely as possible to humans [13]. In this study, two approaches, LSTM and CNN, will be utilized to compare the accuracy of findings.

Schmid Huber and Hoch Reiter introduced LSTM in 1997 [14]. LSTM is a method derived from the development of the Recurrent Neural Network (RNN) architecture. LSTM handles vanishing gradients by adding a memory cell that can hold information for an extended period [15].

CNN is a multilayer neural network type feed-forward network with two or more deep layers that has good performance in applications involving image data, including computer vision categorization data gathering [16] and NLP [17] with the results obtained being excellent. CNN is not significantly distinct from a typical neural network, which consists of neurons with weight, bias, and activation functions. CNN eliminates the need to do multiple steps on the neural network because it calculates the output using convolution operations on the input layer. Each layer has a distinct filter and mixes the convolution operation's results [18].

In this comparative research of the LSTM and CNN methods on the classification of community dialogues regarding Covid-19 with case studies on Twitter social media. It is intended that the conversations and reactions regarding Covid-19 conducted by the community on social media can be utilized by the Indonesian government to enhance regulations during the pandemic.

## II. RESEARCH METHOD

This study employed an experimental approach, which involved running several tests on the Deep Learning model with the LSTM and CNN techniques considering the following relevant studies.

### A. Relevant Studies

In this relevant studies section, it was employed to assemble data pertinent to the study at hand, which will then serve as a basis for further study, comparison, and information gathering. Comparison of relevant studies can be seen in Table I. According to Table I, researchers reviewed five related publications between 2015 and 2021. In comparison to naïve bayes, support vector machines, decision trees, and random forests, the LSTM and Gated Recurrent Units (GRU) methods achieve the highest level of accuracy with a value of 99.9%. LSTM, CNN, and GRU are all neural network examples.

TABLE I. COMPARISON OF RELEVANT STUDIES

Title	Publication Year	Method	Findings
<i>Sentiment Analysis Twitter Bahasa Indonesia Berbasis Word2vec Menggunakan Deep Convolutional Neural Network (Sentiment Analysis Twitter Indonesian Based on Word2vec Using Deep Convolutional Neural Network)</i>	2020 [19]	CNN	In this study, 999 Indonesian tweets were used taken from the social media Twitter. The results of experiments that have been carried out with the Deep Convolutional Neural Network algorithm acquired the highest accuracy value of 76.40%.
<i>Penerapan Convolutional Long Short-Term Memory untuk Klasifikasi Teks Berita Bahasa Indonesia (Application of Convolutional Long Short-Term Memory for Classification of Indonesian News Texts)</i>	2021 [20]	CNN and LSTM	This study aims to analyze the combination of two deep learning methods: CNN and LSTM (C-LSTM). The result of this combination acquired a better performance compared to CNN and LSTM.
<i>Algoritma LSTM-CNN untuk Sentimen Klasifikasi dengan</i>	2021 [21]	LSTM-CNN	Classification using LSTM, LSTM-CNN, CNN-LSTM methods

Title	Publication Year	Method	Findings
<i>Word2vec pada Media Online (LSTM-CNN Algorithm for Sentiment Classification with Word2vec on Online Media)</i>			with the dataset used was Indonesian article title data taken from the Detik Finance website resulting in testing the LSTM, LSTM-CNN, CNN-LSTM methods obtained accuracy results of, 62%, 65% and 74%.
<i>Komparasi Algoritma Machine Learning Dan Deep Learning Untuk Named Entity Recognition: Studi Kasus Data Kebencanaan (Comparison of Machine Learning and Deep Learning Algorithms for Named Entity Recognition: A Case Study of Disaster Data)</i>	2020 [22]	Naive Bayes, Support Vector Machines, Decision Tree, Dan random Forest. LSTM, CNN, GRU.	In this study, the highest accuracy machine learning model was obtained in the random forest method with an accuracy value of 0.98%, in the Deep Learning method there were LSTM and GRU methods with an accuracy value of 0.99%.
<i>A C-LSTM Neural Network for Text Classification</i>	2015 [23]	LSTM, Bi LSTM, C-LSTM	The study stated that by using the combined method of CNN and LSTM to obtain a high accuracy value with an accuracy value of 94.6%

### B. Experimental Design

In order to conduct research in a more systematic manner, we designed the experiment as depicted in Fig. 1. From Fig. 1 we compared the LSTM and CNN in general. In the following subsections, the specifics of Fig. 1 will be described.

- Data Crawling

Data crawling is a dataset that refers to conversation sentences originating from Twitter [24] with the hashtag "covid-19 pandemic". Data retrieval method utilizes the mining address provided by the social media platforms mentioned above. The data obtained 9,643 tweets from September 2020 to September 2022, tweet data will be used for two years during the covid-19 pandemic.

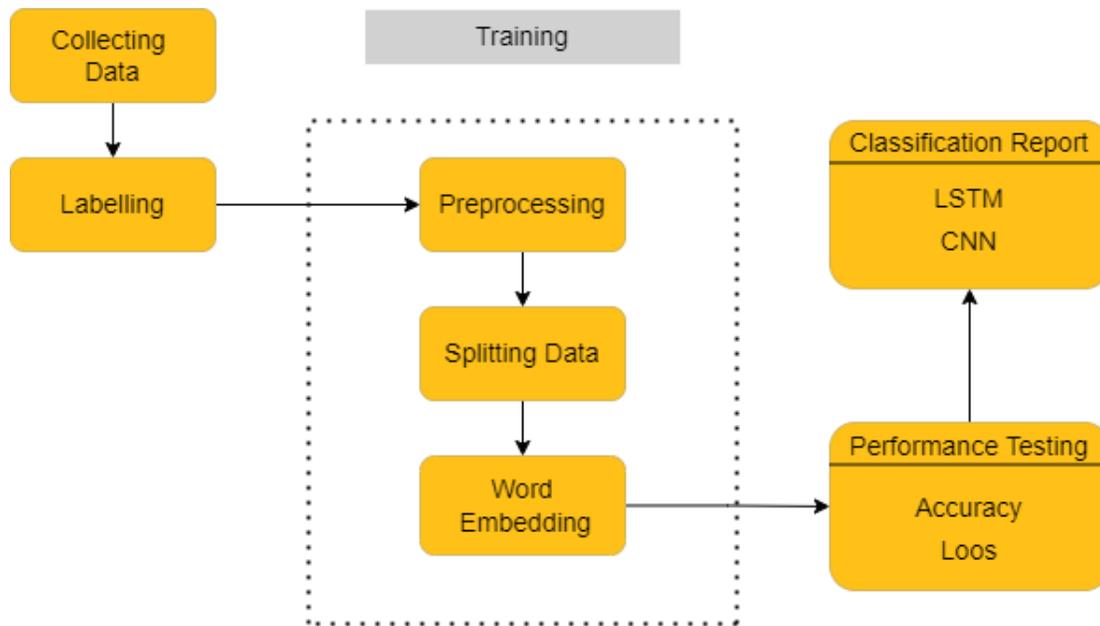

Fig. 1. Experimental Design.

- Data Labelling

In this study, data was labeled manually by language experts who already understand whether a sentence is included in a negative or positive sentence. We give a table (Table II), which contains two columns: tweet and label. The tweet column consists of the tweet status, which is collected from Twitter. The second column is an empty label. The expert should write a specific category of sentiment: negative and positive. Even though the neutral category can improve the overall accuracy, in this research we do not neutral label because it tends to be ambiguity or uncertainty. Uncertainty leads to confusion which may harm the efficiency of the decision [25]. This data labeling was done after crawling the data while the data was still intact therefore sentiment could be identified in the sentence. An example of labeled data can be found in Table II. From Table II, we obtain tweets with labels that have been validated by specialists.

TABLE II. DATA LABELLING

Tweet	Label
Kondisi ekonomi orang tua dan keluarga tengah sulit saat pandemi COVID 19, mahasiswa Unsri menuntut keringanan UKT. <a href="https://t.co/WwQ1pDJTrx">https://t.co/WwQ1pDJTrx</a>	Negative

- Text Preprocessing

Text preprocessing is used to improve the model's efficiency and accuracy by reducing unmodeled variations [26]. The selection of appropriate pre-processing methods or a combination of pre-processing methods can affect the performance of the analysis, and improper use of pre-processing techniques can reduce the model's performance [27]. The research underwent four stages during preprocessing, which are as follows:

1) *Cleaning*: Cleaning is a process of removing or eliminating unnecessary words, links, characters, emoticons, and any punctuation which has no relevance to the tweets. Punctuations, for instance (!'#\$%&'[]\*+,-./:;<=>?@[^\_`{}~), and character symbols or commonly known as emoticons such as (😊😭😂🤔) must be removed. In addition, in this research, the links within the tweet such as [28] mention symbol (@), hashtag (#), retweet symbol (RT), and unnecessary space and enter were removed.

2) *Case folding*: Case Folding is a stage in preprocessing that functions to convert capital letters into lowercase letters.

3) *Tokenizing*: Tokenizing is the process of breaking a document into units of words [8]. This process is used to get a word that will be processed at the next stage.

4) *Stemming*: Stemming is the process of transforming the words contained in the dataset into root words. In Indonesian text, the process of removing affixes in a word. Both affixes at the beginning of words (prefixes), affixes in the middle or insertions (infixes), affixes at the end of sentences (suffixes), or combination affixes from prefixes and suffixes (confixes) were altered. The illustration of stemming preprocessing can be seen in Table III. From table III it is known that there are words that were changed before stemming and already stemming.

TABLE III. STEMMING PREPROCESSING

Tweet	Process
Kerjasama ekonomi Indonesia-Australia ditengah pandemi COVID-19https://t.co/Zk3DpyiCYi	Before Preprocessing
“kerjasama” “ekonomi” “indonesia” “australia” “tengah” “pandemi” “covid”	After Preprocessing

At this stage, it generates a ready-to-use dataset is 2,835 tweets as depicted by the graph in Fig. 2. From Fig. 2 the dataset contains 1,892 tweets of positive sentiment and 943 tweets of negative sentiment.

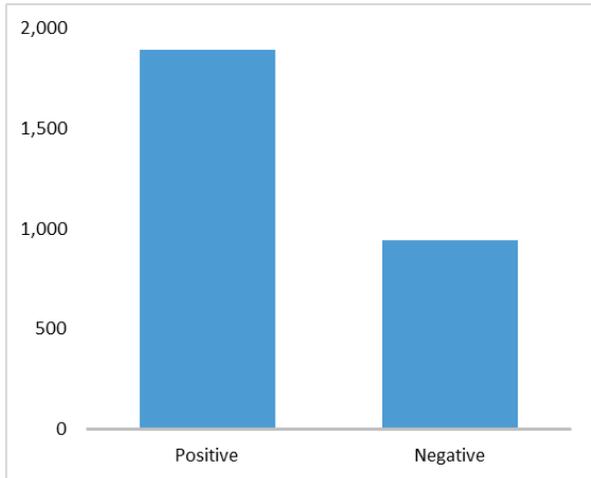

Fig. 2. Dataset Graphic.

- Data Splitting

Splitting data is a type of data sharing that occurs after the data has been processed. Data will split into two or more subsets. Data separation generally divides data into two portions, the first of which is used for test data and the second for training the model. This research divides the data into 80% of the training data and 20% of the testing data.

- Word Embedding

Word embedding is a method of creating a modified vector of word representation types that allows words with similar meanings to have similar representations [29]. In this study, two types of word embedding are used:

1) *Term Frequency-Inverse Document Frequency (TF-IDF)*: This TF-IDF method is an algorithm for merging two methods. Which include the concept of the frequency of occurrence of terms in a document and the inverse frequency containing the word [30]. Term Frequency (*tf*) provides the frequency of a word in each corpus document as in (1). Inverse Data Frequency (*idf*): used to calculate the weight of uncommon terms over the entire corpus of documents. A high *idf* score is assigned to words that appear seldom in the corpus as in (2). Combining these two (*tf* and *idf*) yields the TF-IDF score (*w*) for a word in a corpus document. It is the result of the subsequent in (3). Where  $tf_{i,j}$  represents the number of occurrences of *i* in *j*, *j* represents the number of documents containing *i* and *N* represents the total number of documents.

$$tf_{i,j} = \frac{n_{i,j}}{\sum_k n_{i,j}} \quad (1)$$

$$idf(w) = \log \frac{N}{df_t} \quad (2)$$

$$w_{i,j} = tf_{i,j} \times \log \left( \frac{N}{df_i} \right) \quad (3)$$

2) *Embedding Layer*: The embedding layer requires that data first pass through the pre-processing stage, after which the sentence is broken down into word units. The word is then assigned a vector value or weight that is seeded with a small random number [31]. The Embedding Layer is a word embedding method used in the CNN algorithm, the results of which are then processed using the CNN model.

- Classification

1) *LSTM*: By entering input values derived from word weighting or TF-IDF, the LSTM method can classify draft sentences. The LSTM network structure is presented in Fig. 3 [32]. As depicted in Fig. 3, the LSTM algorithm is composed of a neural network and multiple distinct memory blocks called cells. The data gathered by the LSTM method is then stored by the cell, and memory modification is performed by a component known as a gate. In the LSTM algorithm, there are three types of gates: forgate gate, input gate, and output gate.

The initial process of the LSTM in finding the forgate gate was by multiplying the weight with the input value and adding the bias after which the sigmoid activation was carried out with (4).

$$f_1 = \sigma(W_f x_1 + U_f h_{t-1} + b_f) \quad (4)$$

The next step was to store the value of the forgate gate and calculate the input gate and candidate cell state. The input gate and candidate cell state equations are as follows (5) and (6).

$$i_1 = \sigma(W_i x_1 + U_i h_{t-1} + b_i) \quad (5)$$

$$C'_1 = \tanh(W_c x_1 + U_c h_{t-1} + b_c) \quad (6)$$

Then after that, it can compute the value of the cell gates, which was obtained by combining the values of the forgate gate and the input gate. The output gate and hidden layer values could then be obtained in (7) to (9).

$$C_1 = (f_1 * C_{t-1} + i_1 * C'_1) \quad (7)$$

$$o_1 = \sigma(W_o x_1 + U_o h_{t-1} + b_o) \quad (8)$$

$$h_1 = o_1 * \tanh(C_1) \quad (9)$$

In this research, the parameter settings of the LSTM that was utilized included a variety of various hidden layers, specifically 2, 8, 16, 32, and 64, with each layer including a total of 50 neuronal connections. Utilizing a sigmoid activation function, a loss function of the binary crossentropy type, the optimizer adam, a batch size of 32, and an epoch of 20. The employment of a variety of different hidden layer number scenarios has the purpose of determining the influence that the number of hidden layers utilized has on the accuracy as well as the loss that occurs as a result of using those hidden layers.

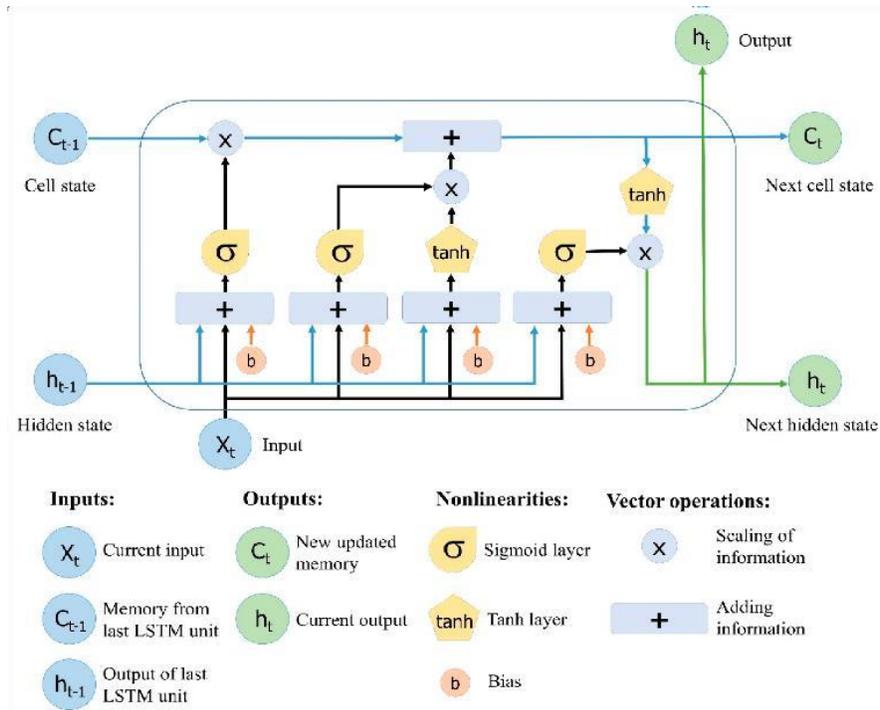

Fig. 3. LSTM Structure.

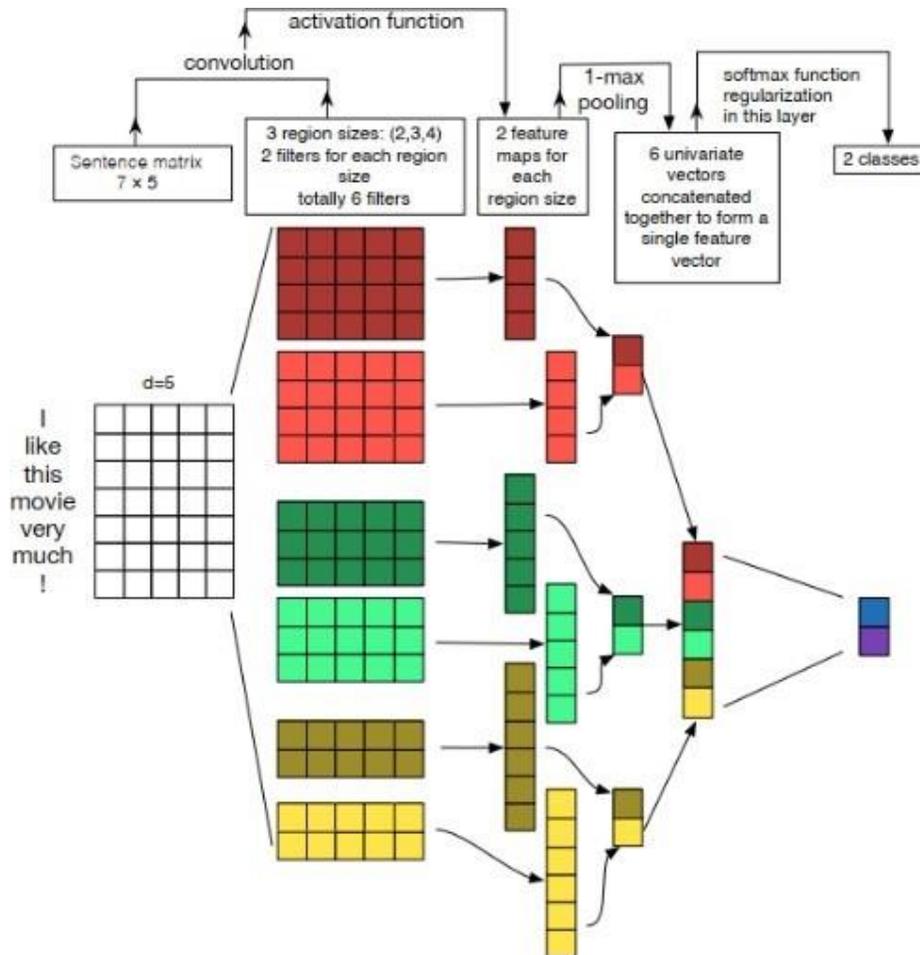

Fig. 4. CNN Model Architecture.

2) *CNN*: The input to a CNN for sentiment analysis tasks is a sentence or document represented as a matrix. The architecture of the CNN for sentiment analysis is depicted in Fig. 4 [33]. Fig. 4 describes the architecture of the CNN that will be used. This particular CNN will have one convolutional layer, and its size will be 2x2, and it will have 100 kernels. After each convolutional layer comes a maxpool layer with a size of 2 x 2, then a fully connected layer with 50 neurons in each hidden layers, and finally, a softmax layer with two neurons to represent the sentiment class comes at the end (Positive and Negative). In addition, the parameter settings used by CNN consist of the use of 20 epochs, the activation function of the Rectified Linear Unit (ReLU), the adam type optimizer, the loss function MSE, and the batch size 32. And there are scenarios using the number of hidden layers consisting of 2, 8, 16, 32, and 64.

Each row in the matrix in the Convolutional Neural Network is a token, usually a word, or it can be a character in the form of a vector that is written into a function in (10).

$$x_1:n = x_1 \oplus x_2 \oplus \dots \oplus n \tag{10}$$

The  $\oplus$  operator is a concatenation operator and is used to combine words that have been converted into vectors into a matrix form followed by the activation function of the linear unit rectifier. The feature function is written in (11).

$$c_i = \max(0, w \cdot x_i: i + h_{-1}) \tag{11}$$

Each filter convolutes the sentence matrix  $\{x_1:h, 2: h_{+1}, \dots, 1:n\}$  and produces feature-maps with  $\epsilon \mathbb{R}^n - h_{+1}$ . The feature map function is written in (12).

$$c = [c_1, c_2, \dots, c_n - h_{+1}] \tag{12}$$

Pooling on the feature map is used to continue the training process [34]. MaxPooling is the pooling method used, and it takes the maximum value of  $\hat{c} = \max\{c\}$  as a feature based on a filter that aims to get the most important features that represent other features for each feature map. The features derived from the pooling results are employed in the classification process at the fully connected layer.

### III. RESULTS AND DISCUSSION

The implementation was carried out by comparing the Long Short-Term Memory (LSTM) and Convolution Neural Network (CNN) methods. With the hidden layer values used for experiments to determine the highest accuracy value in training and the lowest loss value in training, as well as the hidden layer value used for training. It has been determined that (2, 8, 16, 32, and 64). Both methods use an epoch value of 20 in their implementation after determining the hidden layer changes. Table IV and Table V compares the results of the accuracy and loss values in the training that was performed. Table IV shows that the LSTM method generates the highest accuracy value of 99.84% for the hidden layer value of 64 and a loss value of 0.034% for the hidden layer value of 64. The results are presented in the following Fig. 5. It differs from the CNN method, which achieves the highest level of accuracy at the hidden layer value of 64, with an accuracy value of 99.24% and a loss value of 3.95 %. In this instance, the outcome is depicted by the graph in Fig. 6.

TABLE IV. TRAINING ACCURATION

A Number of Hidden Layers	LSTM	CNN
2	99.68%	96.07%
8	99.74%	98.79%
16	99.69%	98.99%
32	99.71%	98.89%
64	99.84%	99.24%

TABLE V. LOSS TRAINING

A Number of Hidden Layers	LSTM	CNN
2	0.096%	13.57%
8	0.062%	5.23%
16	0.066%	2.76%
32	0.054%	5.41%
64	0.034%	3.95%

Fig. 5 is an LSTM graph illustrating the increase in training accuracy. Which indicates that the greater the epoch used, the higher the accuracy value, and if the accuracy value is high, the loss value will decrease. However, this is not always the case, the accuracy value is not always high when the epoch is high, as data and methods also influence the increase in accuracy.

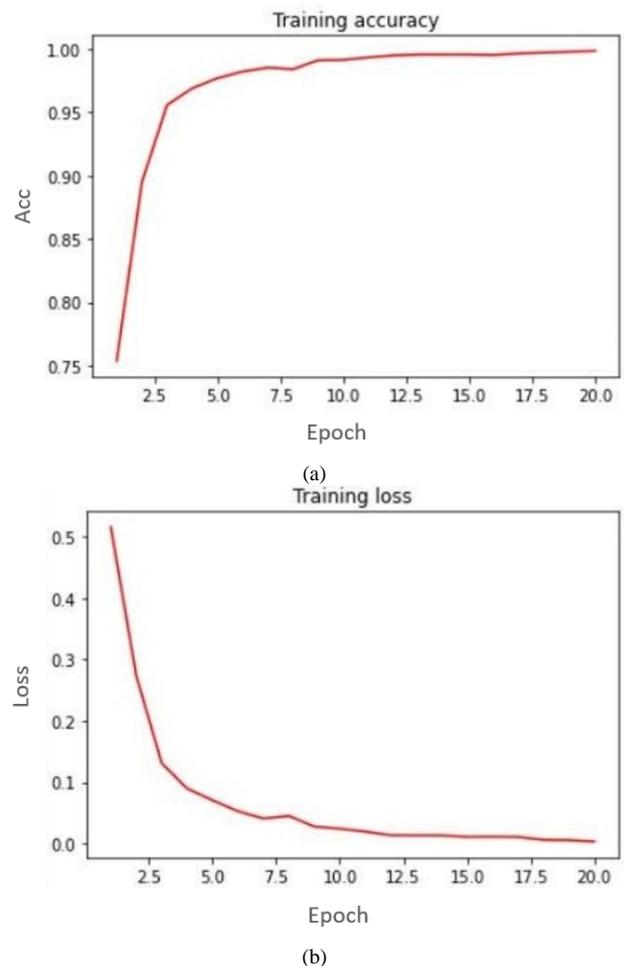

Fig. 5. LSTM Method: (a) Accuracy (b) Loss Graphs.

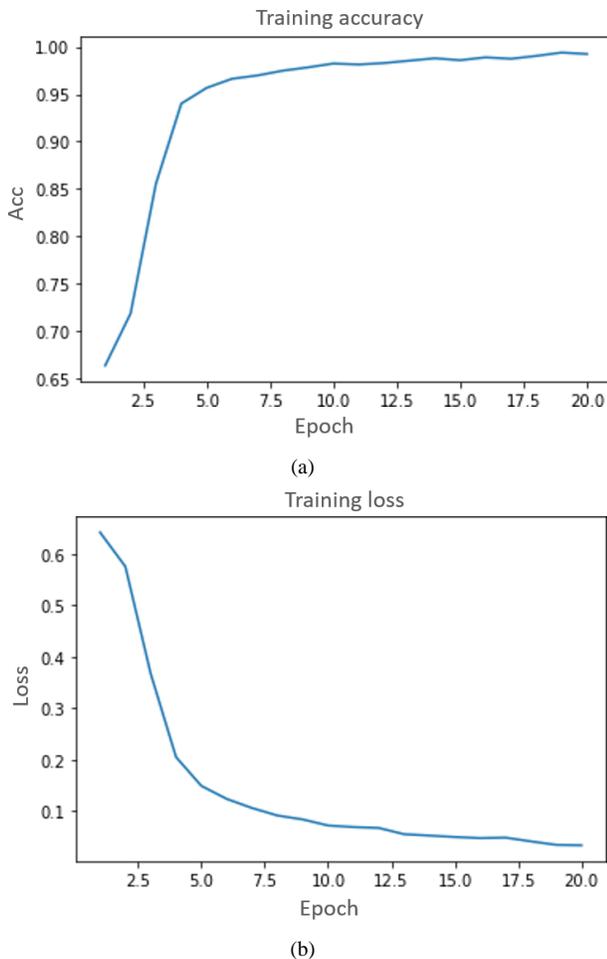

Fig. 6. CNN Method: (a) Accuracy (b) Loss Graphs.

Fig. 6 depicts a graph of the accuracy and loss of the CNN method which demonstrates that as the number of epochs used increases, so does the accuracy of the results. However, a large number of epochs does not guarantee that the accuracy obtained is also large; it is also affected by a number of other factors, such as the number of datasets and methods employed.

The 64th hidden layer will be used in the LSTM and CNN methods for this study. After obtaining the highest accuracy value during training and the lowest loss value during training, the researcher will use a confusion matrix to determine the final accuracy value for both methods. The following is an LSTM confusion matrix as can be seen in Table VI and CNN confusion matrix in Table VII. According to Table VI, the confusion matrix LSTM contains 504 true positive (TP) data, 145 true negative (TN) data, 78 false positive (FP) data, and 52 false negative (FN) data. CNN data from Table VII, TP 203, TN 487, FP 80, and FN 81 for confusion matrix.

TABLE VI. LSTM CONFUSION MATRIX

	Actually Positive	Actually Negative
Predicted Positive	504	78
Predicted Negative	52	145

TABLE VII. CNN CONFUSION MATRIX

	Actually Positive	Actually Negative
Predicted Positive	203	80
Predicted Negative	81	487

After obtaining the table confusion matrix with both methods, the performance values accuracy, precision, recall, and f1-score are reported in Table VIII. It is clear from Table VIII that both LSTM and CNN have good evaluation ratings, which means that they can be utilized for the classification of conversation sentences on Twitter relating to the Covid-19 Pandemic. The accuracy achieved by LSTM is the highest, coming up at 83.30%, whereas CNN only achieves 81.00%. Therefore, one can conclude from this research that the performance of LSTM is superior to that of CNN when it comes to analyzing people's feelings towards the COVID-19 pandemic.

TABLE VIII. VALUES ACCURACY, PRECISION, RECALL AND F1-SCORE

Method	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
LSTM	83.30%	86.50%	90.64%	88.50%
CNN	81.00%	71.73%	71.47%	72.00%

#### IV. CONCLUSION

A comparison of research that has been done using datasets from social media as many as 2,835 and distribution of data by 80% of training data and 20% of testing data states that the hidden layer and epoch determine the accuracy value, with a hidden layer of 64 and an epoch of 20, the highest training accuracy value is 99.84% and the loss value is 0.034% in the LSTM met. After calculating the accuracy and loss values in training, the LSTM method achieves an accuracy value of 83.30%, precision of 86.50%, recall of 90.64%, and f1-score of 88.50% while the CNN method achieved an accuracy of 81.00%, precision of 71.73%, recall of 71.47%, and f1-score of 72.00%. This states that the LSTM method outperforms CNN in terms of performance measurement, and that both methods can be used to classify conversation sentences about the Covid-19 Pandemic on Twitter.

Many aspects were left for future investigation due to time and computational process. It would be interesting to study the following topic: a) determining whether Twitter is a more dependable source of information than Facebook, WeChat, and Instagram. Nonetheless, it is of the utmost importance to investigate other social media platforms in terms of sentiment analysis to compare. b) This research application is useful for the Coronavirus health issue and can also be adopted as a model for identifying sentiment emotion in future cases of a similar nature.

#### ACKNOWLEDGMENT

I want to extend a special thank you to my team for this research, which have helped to make this experience motivating to finish all the writing in this paper.

**Abstract**—The need for instantaneous processing for Internet of Things (IoT) has led to the notion of fog computing where computation is performed at the proximity of the data source. Though fog computing reduces the latency and bandwidth bottlenecks, the scarcity of fog nodes hampers its efficiency. Also, due to the heterogeneity and stochastic behavior of IoT, traditional resource allocation technique does not suffice the time-sensitiveness of the applications. Therefore, adopting Artificial Intelligence (AI) based Reinforcement Learning approach that has the ability to self-learn and adapt to the dynamic environment is sought. The purpose of the work is to propose an Auto Centric Threshold (ACT) enabled Monte Carlo FogRA system that maximizes the utilization of Fog’s limited resources with minimum termination time for time-critical IoT requests. FogRA is devised as a Reinforcement Learning (RL) problem, that obtains optimal solutions through continuous interaction with the uncertain environment. Experimental results show that the optimal value achieved by the proposed system is increased by 41% more than the baseline adaptive RA model. The efficiency of FogRA is evaluated under different performance metrics.

**Keywords**—Cloud; edge; fog; Internet of Things (IoT); Reinforcement Learning (RL)

## I. INTRODUCTION

The evolution of smart devices has led to the proliferation of the Internet of Things (IoT), thus making the world, a better-connected place for wireless communication and high-speed applications. The “Little Data, Big Stream” notion of IoT is mostly about time-sensitive applications [1]. The number of connected devices per capita is anticipated to be 01 trillion devices by 2025. This massive usage of IoT will generate mobile data services of 150 zettabytes by 2025 which corresponds to 5-7 times of IP traffic today [2]. The immense amount of mobile data can be processed instantaneously, only if the computing facility is available near the data source.

Ultra-low latency, energy efficiency, distributed processing, and storage are a few of the expectations of IoT applications. So far, the cloud was tailored to tackle these demands. But, in reality, the remotely located cloud causes delay and hinders the QoS requirements of the IoT requests [3]. By the time the data from IoT is transmitted to the centralized cloud, the inevitability to act on it might be gone, which cost lives. Disastrous management, Industrial IoT, and real-time aeronautical cum nuclear reactions are some of the time-critical IoT applications where the response delay of even nanoseconds makes a huge difference [4]. Hence, a fog computing paradigm that addresses time-critical applications in its proximity is recommended.

Fog computing is a distributed paradigm where the processing nodes are dispersed geographically near the data source. The proximal distribution of the processing elements promises ultra-low latency for time-critical applications [5]. IoT requires a Resource Allocation (RA) mechanism that prioritizes time-critical tasks over others. Also, a sufficient amount of fog resources may not be available, as and when required. Hence, allocation of compute nodes to the incoming IoT requests, in a resource-constrained fog environment is challenging [6]. The RA mechanism has to adopt an optimal strategy to make a sequence of smart decisions [7]. Although evolutionary algorithms, dynamic programming, and policy gradient are commonly used to derive optimal policy, these techniques require prior knowledge of the model [8]. But, the proposed work FogRA is a sequential decision-making problem in a model-free environment.

The environment involves IoT devices whose behaviour is stochastic and hence the dynamics of the model are not known. In such a case, Reinforcement Learning (RL) is sought to solve the FogRA problem for two reasons. First, RL is a machine learning, trial and error methodology that can self-learn and adapt through continuous interaction in an uncertain environment. Second, by its origin in Markov Decision Process (MDP), RL is a sequential decision theory that generates high-quality decisions in the long term [9].

Monte Carlo (MC), MC-Exploring Starts (MC-ES), and On-Policy Monte Carlo Control (OMC) are variants of RL algorithms that compute optimal policy. They are the straightforward methods that do not bootstrap and eliminate the curse of dimensionality problem [8]. They compute the optimal value by averaging the samples obtained through various iterations and derive the optimal policy from it.

Studies reveal that the existing RA works focused more on the development of frameworks that reduced latency and increased the quality of service [10]. The works carried out using feed-forward NN, MINLP, and other optimization techniques also obtained better outcomes [11]. But these techniques were heuristic-based and time-consuming. Q-learning algorithm of RL was mostly used to devise RA strategy. The combination of RL algorithms with queuing theory and neural networks too proved more efficient but involved cost overhead.

Moreover, the earlier works addressed intra-dependent and parallel tasks, while focus on time-critical applications was hardly found. Further, the earlier RL-based RA works were mostly proactive, in the sense that they depend on history for

prediction and hence mostly model-based [12]. But, the proposed work allocates the fog resources on demand. The reactive technique does not require any dynamics of the model. The availability of the scarce fog resources, and the heterogenous latency requirement of IoT describes the uncertain behavior of the environment. Allocation of fog's limited resources and prioritizing the time-critical requests are highly challenging that need attention. The proposed work is about designing an efficient FogRA system that handles the challenges of model-free stochastic environment at ease.

The proposed work employs ACT enabled MC approach to construct the FogRA system for time-critical IoT applications. The FogRA system involves a smart agent that finds the optimal policy to allocate the fog's limited resources to the time-critical requests. The significance of the work is perceived by its usage in the modern network environment and its potential for the fog computing paradigm. The main contribution of the intended work is summarized as follows:

- A Reinforcement Learning (RL) based FogRA system is developed in which the Fog nodes are used as computing resources, to process incoming requests.
- In the pursuit of maximizing fog utilization, the Fog Controller Agent (FCA) undergoes learning to allocate its resources to time-critical application requests.
- The ACT-enabled FogRA system is proposed using Monte Carlo (MC), MC-Exploring Starts (MC-ES), and On-Policy Monte Carlo Control (OMC).
- The proposed system is compared with an existing Adaptive RA system to evaluate its performance.
- Result demonstrates that the optimal long-term reward achieved by ACT-enabled FogRA is 41% more than the existing RA model.

The rest of the article is structured as follows: Section II discusses the background knowledge that substantiates FogRA as an RL problem. An overview of the RL approach and the formulation of FogRA as an MDP are briefly discussed in this section. The system model of the proposed work is elaborated in Section III. The experimental results are evaluated and analyzed in Section IV, and Section V concludes the paper with prospects for the future.

## II. REINFORCEMENT LEARNING BACKGROUND

### A. Resource Allocation as RL Problem

As mobile apps go more and more 24/7, online solutions that deliver instantaneous decisions are highly sought. The time-critical IoT requests demand response with almost negligible delay [13]. To achieve delay-less response, fog nodes that reside near the edge devices are used as computing elements. But the distributed nature of fog creates a scarcity of its resources. This makes the allocation of fog resources tedious, hence is considered an essential problem to be dealt with [14]. Due to the limited resources, not all the requests are served in the fog layer. It has to be constantly monitored whether the incoming request is time-critical or not. Prioritizing the time-critical applications to be served in the fog delivers prompt service with negligible and tolerable delay [15].

The FogRA comprises a Fog Controller Agent (FCA) that allocates the available fog resources to the most time-critical tasks. Through continuous interaction with the environment, the agent derives the optimal policy through which it decides whether to allocate the fog resource or not. The problem that involves learning and decision-making as a continuous process is defined as the RL problem [16]. As the allocation of fog resources to IoT requests need constant learning, and decision making, FogRA is considered an RL problem.

RL problem consists of the agent and the environment as the two main components as shown in Fig. 1. An agent is a learner and decision-maker. The environment is the entity with which the agent interacts [17]. Markov Decision Process (MDP) is used to articulate the interaction between the agent and the environment in terms of states, actions, and rewards, MDP is the mathematical framework to define how the environment behaves in response to the agent's action. The Markov process is a memoryless random process [8]. It states that the future is independent of the past given its present. Any environment in which the current state is sufficient to determine the next state, irrespective of its previous states (history) is said to possess the Markov property. Thus, MDP eliminates the need to preserve the value of past states thereby reducing the memory cost considerably.

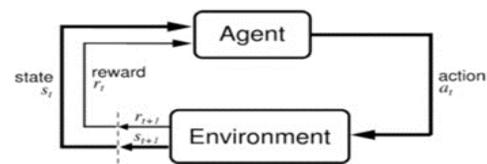

Fig. 1. Agent-Environment Interaction in RL [8].

The agent observes the environment's state ( $s_t \in S$ ) and performs one of the actions ( $a_t \in A(s)$ ) at each time step ( $t$ ) of the interaction. The agent's activity results in a reward ( $r_{t+1} \in R$ ) and a transition to the following state ( $s_{t+1}$ ). Hence a sequence of trajectory  $s_0, a_0, r_1, s_1, a_1, r_2, s_2, a_2, r_3, \dots$  is observed [18]. The crucial constraint on the agent is that it operates in an uncertain environment.

In most problems, the agent is not guided about the action that it has to carry out, instead, by trial and error, it learns the right action. The agent likely acts differently in a state for the first time, rather than after visiting the same state many times [19]. With experience, the agent learns the consequence of its action on that state. The consequence of an action influences not only the immediate reward but the next state and its subsequent rewards.

RL is a computational approach to designing a goal-directed learning agent that interacts with an uncertain environment [20]. In the Long-term, the agent seeks to maximize the cumulative payoff. At every time step ( $t$ ), the agent receives a reward in the form of a scalar value which is either positive or negative. A positive value specifies how good the current action is, whereas a negative value indicates the penalty for the wrong action. The sum of the rewards starting from time 't' until the termination time 'T' is defined as returns ( $G_t$ ). Thus, returns is

the metric that the agent aims to maximize in the long run. The definition of returns varies depending upon whether the task taken into consideration is episodic or continuous.

In Episodic tasks, the interaction between the agent and the environment breaks once the terminal state is reached [8]. The next episode starts in a state independent of the previous one ended. Tasks in episodes of this kind are called episodic tasks. Returns ( $G_t$ ) for the episodic tasks starting from time 't' is expressed as the sum of undiscounted rewards as shown in equation (1).

$$G_t = r_{t+1} + r_{t+2} + r_{t+2} + r_{t+3} + \dots \dots \dots r_T \quad (1)$$

where  $r_{t+1}$  is the reward obtained at time-step (t+1) as an effect of the action ( $a_t$ ) taken at time-step (t) on the state ( $s_t$ ). The Time of termination (T), varies from episode to episode. The FogRA problem considered in the work is episodic. Each episode ends when all the fog resources are allocated to the incoming requests. Then the system is reset with the maximum number of fog nodes for the next episode.

On the other hand, for the tasks with continuous states, the interaction between the agent and the environment does not break, but rather continues without any terminal state [8]. Such tasks that do not have an identifiable terminal state are called continuous tasks. The rewards obtained at each time-step of continuous task accumulate to a big value that becomes uncountable. Also, the immediate reward got is more valuable than the one obtained in the future [21]. Hence, the value of the future reward is discounted by a factor of gamma ( $\gamma$ ).

The value of gamma ranges from 0 to 1. When  $\gamma=0$ , the agent is myopic and concerned about maximizing the immediate reward, whereas  $\gamma=1$  specifies that the agent gives more importance to the future reward. The literature study shows that values between 0.2 and 0.8 were found to be optimal in many scenarios [15]. Thus, returns ( $G_t$ ) for the continuous tasks starting from time 't' is expressed as the sum of discounted rewards as shown in equation (2).

$$G_t = r_{t+1} + \gamma^1 r_{t+2} + \gamma^2 r_{t+2} + \gamma^3 r_{t+3} + \dots \dots \dots \quad (2)$$

where G is the reward gained at time-step (t+1) as feedback of the action ( $a_t$ ) taken at time-step (t) on the state ( $s_t$ ). The FogRA problem in the work is evaluated as an episodic task, with an initial and terminal state.

The concepts of Value function and Policy play a major role in implementing RL methodology [8]. The value function is the sum of all rewards that are expected in the future from every subsequent state. While the reward signal defines what is beneficial in the immediate sense, the value function signifies what is beneficial in the long run. In short, the reward is the immediate feedback for the current action, whereas the value function is the long-term estimation of rewards [18]. The goal of the agent is to maximize the long-term rewards in the form of the value function. Also, there is no value function without reward. As the iteration proceeds, the actions made by the agent are based on the value function.

The state value function  $V(s)$  given by the equation (3), is the expectation of the returns ( $G_t$ ) at the time 't' from the state s. It is the sum of immediate reward ( $r_{t+1}$ ) and the discounted

value of the next state  $V(s_{t+1})$  estimated iteratively, following the sequence of observation, starting from the state.

$$V(s) = \mathbb{E}[G_t | s_t = s] = \mathbb{E}[r_{t+1} + \gamma V(s_{t+1}) | s_t = s] \quad (3)$$

The value of a state is expressed as a function of expectation because future states are stochastic. Similarly, the action-value function ( $Q(s, a)$ ) given by equation (4), is the expectation on the Returns ( $G_t$ ) for the action 'a', taken at time t, in the state 's'.

$$Q(s, a) = \mathbb{E}[G_t | s_t = s, a_t = a] = \mathbb{E}[r_{t+1} + \gamma Q[s_{t+1}, a_t | s_t = s, a_t = a]] \quad (4)$$

The value obtained by these value functions helps the agent to decide the best action at a particular instant of time. Hence it is essential to know the value of the state and state-action pair. Identifying the best action for a state is termed as policy. Policies are the rules or the strategy the agent adopts to maximize the return in the long run [22]. Policies determine the optimal action that the agent has to adopt to achieve its goal.

The value of a state  $V(s)$  following the policy ( $\pi$ ) is written as  $V_\pi(s)$ . Consequently, the value of taking action 'a' in state 's' and following the policy ( $\pi$ ) thereafter is denoted as  $Q_\pi(s, a)$ . The agent looks for a policy that delivers maximum value for the state rather than the highest immediate reward. Unlikely, it is difficult to determine the state value  $V(s)$ , compared to the reward. Because rewards are the instantaneous feedback from the environment while value functions are long-run values that are estimated iteratively until the value converges with an optimal policy [15]. The value of the state resulting after convergence is the optimal value through which an optimal policy is derived. The agent uses the optimal policy to take the best action thereafter.

The Bellman Optimality equation is one of the methods to find the optimal value function [8]. The optimal value function  $V^*(s)$  is one which yields the highest returns compared to all other value functions.  $V^*(s)$  is expressed as a value function obtained by taking maximum over the policy ( $\pi$ ) as given in the equation (5).

$$V^*(s) = \max_\pi V_\pi(s) \quad (5)$$

where  $V^*(s)$  signifies the maximum quantity of long-term returns that is obtained from the system. Optimal policies also share optimal state-action value pairs  $Q^*(s, a)$ . The Bellman Optimality equation for  $Q^*$  is given by equation (6), which states that the optimal state action-value function is the one that is the maximum of all action functions following the policy  $\pi$ .

$$Q^*(s, a) = \max_\pi Q_\pi(s, a) \quad (6)$$

The goal of the RL problem is to find the optimal policy that yields the highest returns in the long run. A policy  $\pi$  is better than another policy  $\pi'$  if the value of a state obtained by following policy  $\pi$  is greater than the value of the state obtained by the following policy  $\pi'$  i.e.,  $V_\pi(s) \geq V_{\pi'}(s)$ . The optimal policy is derived by taking the maximum over the policy ' $\pi$ ' under the state 's' of the value function as given in equation (7).

$$\pi^* = \operatorname{argmax}_\pi V_\pi(s), \forall s \quad (7)$$

Computation of optimal policy involves iterative estimation of the value function. RL is a method for the efficient estimation of value functions and optimal policy. As the FogRA problem taken into account is model-free, Monte Carlo (MC), MC Exploring Starts (MC-ES), and On-Policy Monte Carlo Controls methodologies are employed to compute the optimal policy.

### B. Monte Carlo Approach

Monte Carlo (MC) is a model-free RL algorithm that learns by averaging the samples drawn from the observation [15]. It learns to derive the policy in an environment where transition probabilities and reward distribution are not known [8]. Hence, the proposed FogRA problem adopts the Monte Carlo method to estimate the optimal policy. An episode is generated starting from an initial state till the terminal state. The trajectory of an episode in the MC algorithm is shown in Fig. 2.

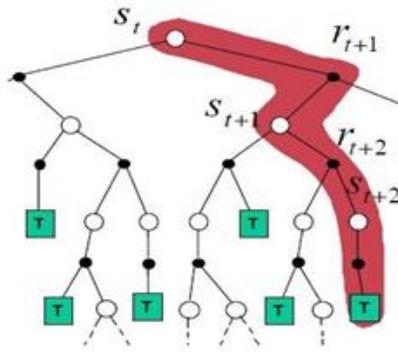

Fig. 2. Back-up Diagram for Monte Carlo Approach [8].

At any instant of time ‘ $t$ ’ the agent observes the state ‘ $s_t$ ’ chooses an action ‘ $a_t$ ’, transits to a new state  $s_{t+1}$ , and gains a reward ‘ $r_{t+1}$ ’. Returns  $G_t$  is computed for every episode. Then the value of the state  $V(s)$  is estimated by averaging the returns. This process is repeated till  $V(s)$  converges for all states and thus obtains the optimal value  $V^*(s)$  for every state. Then the optimal policy is derived for each state using the equation (7).

Given some experience (samples), FCA estimates the value of states following policy  $V_\pi(s)$ , for all the non-terminal states  $s_t$  that occur in the trajectory. The agent waits until the returns  $G_t$  following the visit is known, then use the returns as a target to update  $V_\pi(S_t)$  as given in equation (8).

$$V_\pi(S_t) \leftarrow V_\pi(S_t) + \alpha[G_t - V_\pi(S_t)] \quad (8)$$

where  $G_t$ , is the actual returns following the time ‘ $t$ ’, and ‘ $\alpha$ ’ is the step size at which the agent learns. Alpha ‘ $\alpha$ ’ is the learning rate hyperparameter. It balances the weight that has been observed in the recent past with the weight of the newly observed target. Equation (8) is also called Exponential Recency Weighted Average (ERWA), which estimates the incremental moving average by giving more weight to the immediate reward [18]. It very much suits a non-stationary environment like FogRA in which the action and the reward undergo continuous learning.

### C. Monte Carlo Exploring Starts (MC-ES)

Monte Carlo (MC) estimates the optimal value function  $V(s)$  for all states appearing in the episode. It simply looks ahead and chooses the action that leads to the best combination of reward and the next state, which means it does not consider the choice of actions in the state. Another issue is that MC works better when the state space is known in advance. Hence, finding  $Q(s, a)$  through MC-ES is the best way, as it considers the choice of actions across all the states and finds the optimal policy by maximizing the action value that produces high returns in the long run [23].

The difference is that the existing adaptive RA model used the MC approach to estimate the value of state ‘ $V(s)$ ’, while the MC-ES uses the state-action value pair ‘ $Q(s, a)$ ’ to improve the policy. The change in the algorithm is that, the returns ‘ $G_t$ ’ is computed as  $G_t(s, a)$  rather than  $G_t(s)$ . Hence, MC-ES evaluates  $Q(s, a)$  for all state-action pairs as given in equation (9).

$$Q(s_t, a_t) \leftarrow Q(s_t, a_t) + \alpha[G_t(s, a) - Q(s_t, a_t)] \quad (9)$$

Then the optimal policy  $\pi^*(a/s)$  is derived by choosing the action with maximum action value for each state  $s_t \in S$  as given by the equation (10).

$$\pi^*(a/s) \leftarrow \operatorname{argmax}_a Q(s, a) \quad (10)$$

### D. On Policy Monte Carlo Control (OMC)

The estimation of state-action value function  $Q(s, a)$  in MC-ES give rise to two issues. First, it increases the state space from  $S$  to  $(S \times A)$  leading to memory and time complexity [8]. Secondly, the agent might not be able to explore all state-action pairs, if it acts too greedy towards the policy from the start. Hence, the value of  $Q(s, a)$  and the policy obtained through MC-ES, cannot be optimal without a proper balance of exploration and exploitation [23]. Instead, the On-policy Monte Carlo Controls (OMC) estimates the optimal policy through the epsilon ( $\epsilon$ ) greedy approach. The agent picks a random action at epsilon ( $\epsilon$ ) times and acts greedy during the period  $(1 - \epsilon)$  times thus balancing the explore-exploit instability [24]. The Epsilon is a value chosen between zero and one by trial and error, and it is problem-dependent.

## III. THE PROPOSED WORK

### A. System Model

The FogRA system comprises IoT devices and Fog nodes as its core components. The fog nodes reside between the IoT devices and the cloud. These fog nodes are equipped with computing cum network functionality to process incoming requests. FogRA is modeled as an RL problem, where a fog node act as the Fog Controller Agent (FCA). Monitoring the number of fog nodes utilized, observing the time criticality of the incoming request, and then deciding to act accordingly is the prime process of FCA. The fog nodes and the requests from the IoT devices at the edge network make up the environment. The agent-environment interaction of the RL-based FogRA system is portrayed in Fig. 3.

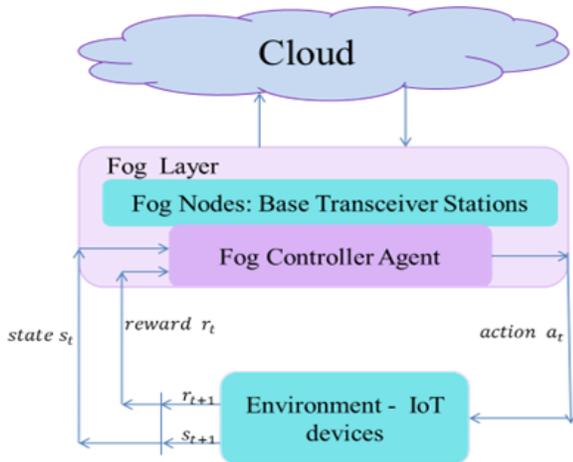

Fig. 3. The FogRA System.

At any instant of time, the time-criticality of the incoming request and the number of utilized fog nodes define the state ( $s_t$ ). The FCA's decision either to accept the request in fog or decline it forms the action. As a consequence of the action taken, the FCA receives either a positive or negative reward as feedback. The heterogeneity of time-criticality from the IoT and the fog's limited resources make the environment stochastic.

The objective of the ACT-enabled FogRA system is to allocate the fog's limited resources to the time-critical applications within a short time. In the pursuit of the objective, the system maximizes the accepted requests, rewards, and value of state-action pairs which is termed Fog Utilization ( $U_{Fog}$ ). Fog's limited resource forms the constraint of the resource allocation problem. The objective of the FogRA system is expressed as a multi-objective optimization problem as given in the equation (11).

$$\text{Maximize } U_{Fog} = \sum_{t=0}^T N_{accept} + \sum_{t=0}^T rwd_{accept} + VF_{opt}$$

$$\text{and Minimize } F_{converge} = \sum_{t=0}^T \mathbb{1}_{Time to obtain VF_{opt}}$$

$$\text{s. t. c } \sum_{t=0}^T N_{accept} = N_{max} \quad (11)$$

where, ' $T$ ' is the terminal time-step of each episode.  $N_{accept}$  refers to the number of requests accepted by the Fog layer,  $rwd_{accept}$  symbolizes the amount of reward received for allocating fog node,  $VF_{opt}$  represents the optimal value achieved and  $N_{max}$  signifies the number of fog nodes present in the fog layer.  $F_{converge}$  refers to the finish time by which all states converge to their optimal value. Hence, the work concentrates on maximizing Fog Utilization and minimizing the convergence time.

FogRA is modeled as MDP to define the mathematical framework of the RL problem. The fog nodes are defined as a set of states in the Markov model, and at each time step, it is in one of the states ( $s_0, s_1, s_2, s_3, \dots, s_n$ ). At any instant of time  $t = 1, 2, \dots, T$ , the state is represented by  $s_t$ . To achieve the objective, the FCA undergoes learning to choose the best action in a current state.

## B. Problem Definition

The Fog Controller Agent (FCA) perceives the state of the environment by constant interaction with it. With the continuous stream of application requests, the FCA takes RA decisions regularly. As the current action taken by the FCA, influences the next state and in turn possibility of future actions and rewards, the FogRA problem is formulated as MDP. The MDP to allocate fog nodes for the time-critical IoT requests is defined as  $MDP_{FogRA} = \{S, A, P, R, \gamma\}$  where,

- $S = \{(m, n_t, c_t) / m=10, \text{ and } 0 \leq n \leq N_{max} \text{ and } 1 \leq c \leq C\}$  is the set of possible states of the MDP. At any instant of time, the state of the fog node is expressed as  $\{s_0, s_1, s_2, s_3, \dots, s_t \in S\}$  in which,

$m \in \mathbb{N}$  defines the number of applications considered in the work.

$n_t \in \mathbb{N}$  is the number of fog nodes utilized at any instant of time ' $t$ ' bounded by  $N_{max}$ .

$c_t \in \mathbb{N}$  is the time criticality of the incoming request at any instant of time ' $t$ '. It is a random number in the range.

of one and ten with  $C = 10$  as the highest priority.

- $A = \{a \in \{\text{'accept'}, \text{'decline'}\}\}$  is the action set where 'accept' denotes allocation of fog node, and 'decline' indicates refusal of fog node.
- $P = S \times A \times S \rightarrow [0,1]$  is the probability of transition  $P(s'|s, a)$  to a new state  $s'$  from state ' $s$ ' when action ' $a$ ' is taken.
- $R = S \times A \rightarrow \mathbb{N}$  denotes the expected reward when the environment is in state ' $s$ ' and action ' $a$ ' is taken.
- $\gamma \rightarrow 0 < \gamma < 1$  is the discount factor that computes the present value of the expected future reward.

Allocation of fog resources to the IoT application requests depends on the number of available resources and the time criticality of the incoming request. The state of the MDP at any instant of time ( $t$ ) as defined in equation (12),

$$s_t = m \cdot n_t + c_t \quad (12)$$

where  $n_t \in \{0, 1, 2, 3, \dots, N_{max}\}$  is the number of fog nodes utilized/allocated. The current state is based on the number of utilized fog nodes, and the time-criticality of the successive task. The time criticality of the service request arriving at time ' $t$ ' is denoted by " $c_t$ ". It is obtained based on the latency requirement of the incoming request presented in Table I. " $c_t$ " is calibrated by a ten-point scale ranging between 1 and 10, with 10 being the highest priority. Starting with ten applications ( $m$ ), the total number of states encountered is  $m(N_{max}) + C$ . The next state  $s_{t+1}$  depends on the current state and the action taken, thereby reflecting the Markov property.

TABLE I. LATENCY TIME-CRITICALITY MAPPING

Applications	Latency Requirement in ms	Time Criticality "c <sub>t</sub> "
Tactile Internet	<=5	10
Industrial IoT	6-20	9
Smart Vehicles	21-100	8

Video Conference between Patient-Doctor	301-400	3
Web browsing	401-450	2
Automated Notifications	>=10 secs	1

When the fog node is in one of the possible states  $s_t \in S = \{1, 2, 3, \dots, C(N_{max} + 1)\}$ , the agent either accepts the incoming task or declines it. Thus, 'A' is the set of actions {accept, decline} where the action 'accept' denotes allocation of a fog resource and 'decline' indicates forwarding the request without allocation of a fog resource. The action chosen is based on the sum of the immediate reward and the value of the possible next state as given in equation (13).

$$action = \begin{cases} \text{accept in fog, if } [rta_{immediate} + \gamma V^*(s_{accept})] > [rtd_{immediate} + \gamma V^*(s_{decline})] \\ \text{decline, otherwise} \end{cases} \quad (13)$$

where the immediate reward is based on the time criticality and intended action as described in the reward system.  $rta_{immediate}$  and  $rtd_{immediate}$  describes the reward obtained on acceptance and declination respectively. The value of a state denotes the quantity of goodness for the agent to remain in that state. It is determined by its immediate reward and the discounted value of the next possible state. The value of the terminal states is zero.

Similarly, the action from the current state in terms of the state-action pair  $Q(s, a)$  is given in equation (14). The choice of the equation for action selection depends on whether the algorithm is MC, MC-ES, or OMC respectively.

$$action = \begin{cases} \text{accept in fog, if } (rta_{immediate} + \gamma Q^*[s, \text{accept}]) > (rtd_{immediate} + \gamma Q^*[s, \text{decline}]) \\ \text{decline, otherwise} \end{cases} \quad (14)$$

An effective reward system influences the learning ability of an agent. With the right reward as the feedback, the FCA learns better and fast. In FogRA the reward is defined as a function of time criticality, priority threshold, and action taken as shown in Table II. Every incoming request is associated with a time-criticality value ( $c_t$ ) which is appended in an array. Then the median of the array value is computed in every episode to obtain the Priority threshold ( $pth_t$ ) at the time 't'. Considering the chance of uneven distribution of  $c_t$  values, FogRA chooses the median as the measure of central tendency.

TABLE II. REWARD SYSTEM

Action taken	Time-Criticality	Reward
accept	$c_t \geq pth_t$	$pth_t$
decline	$c_t \geq pth_t$	$-pth_t$
accept	$c_t < pth_t$	$-pth_t/2$
decline	$c_t < pth_t$	$pth_t/2$

At any instant of time, if the time-criticality of the arrived request ( $c_t$ ) is greater than the priority threshold ( $pth_t$ ), then the request is considered to be of high priority. Accepting such a request indicates the right action of the agent. Hence, the agent is encouraged with a positive value of the priority threshold as a reward. Declining the high priority request indicates a wrong action, for which the agent is rewarded with a negative value of  $pth_t$ . On the other hand, a time-criticality value less than that of the priority threshold indicates the less time-sensitiveness of the incoming request. Accepting the less time-sensitive task is considered a wrong action anyway, hence the agent is rewarded with  $(-pth_t/2)$ . Otherwise, the agent is rewarded with  $(pth_t/2)$  for declining the less time-sensitive request. Thus, the reward obtained at time 't' depends on the priority threshold computed at that time step.

The probability of state transition (P) and reward distribution (R) describes the dynamics of the environment. When the dynamics of the environment are known, the optimal policy is directly obtained through Dynamic Programming (DP) [8]. Also, DP is bound to fixed values of P, R, and policy  $\pi$ . But, the FogRA environment considered in the work is neither stationary nor policy deterministic. With  $m(N_{max}) + C$  number of states and 2 actions per state, the problem of computing the transition probability for all states grows exponentially and cumbersome rather than solving the RA problem itself. Hence, Monte Carlo (MC) method that learns the optimal policy without P and R is sought. Hence, the proposed work does not consider the distribution parameters and employs MC to derive the optimal policy.

### C. ACT enabled MC for FogRA

Time criticality ( $c_t$ ) of an incoming request is defined in the range of one to ten, with ten designated as the highest priority. As Fog resources are limited, only those requests whose time criticality value is greater than the priority threshold is given importance to get processed in fog nodes. But, fixing a suitable priority threshold ( $pth_t$ ) at every time step is not a trivial task in FogRA whose environment is stochastic and non-stationary. An increased  $pth_t$  value leads to poor performance of the FCA, in which the number of accepted requests becomes less than the decline. A decrease in the  $pth_t$  results in the allocation of fog nodes to non-time-critical applications, which conflicts with the objective of the system. Hence the work suggests Auto Centric Threshold (ACT) that self-generates the threshold at every time step. The incoming time criticality ( $c_t$ ) is appended in an array. Then, the priority threshold ( $pth_t$ ) is computed as the median of the time criticality ( $c_t$ ) values stored in the array at every time step.

Initially, the FogRA system allocates the fog resource with the priority threshold computed at time  $t=0$ . As the episode proceeds, the FCA learns the best policy in which only those requests with a critical value greater than the recently computed priority threshold are allocated the fog resource. The algorithm to learn the optimal policy by the ACT-enabled MC for the FogRA is given in Algorithm 1.

**Algorithm 1:** ACT MonteCarlo

```

Initialize  $V(s) = 0 \forall S$ 
Initialize return  $(s)$  // an empty list to save returns of all state in every iteration
1. Read  $N_{max}$  // no-of-fog-nodes
2. For episode count = 1, 2, 3, .....do
3.   While utilized fog node  $\leq N_{max}$ 
4.     Read latency requirement of the incoming request
5.     Obtain the time-criticality " $c_t$ " of the incoming request from Table 1
6.     Obtain the state using equation (12)
7.     Compute the Priority-Threshold ( $pth_t$ )
8.      $rta = \text{get\_reward}(\text{'accept'}, c_t, pth_t)$ 
9.      $rtd = \text{get\_reward}(\text{'decline'}, c_t, pth_t)$ 
10.    Take action on the incoming task based on the equation (13)
11.     $\text{get\_reward}(\text{action}, c_t, pth_t)$ 
12.    Append the reward in the rewards list
13.    increment the utilized_fog_node by one
14.  Compute the returns  $G_t$  for all states appearing in the episode till the terminal state
15.   $V(s) \leftarrow$  incremental average based on the equation (8)
16.  If  $V(s)$  converges for all states then
17.     $V^*(s) \leftarrow V(s)$  for all states
18.    Break
19.  Endif
20. Endfor
21. Use the optimal state value  $V^*(s)$  to update the optimal action in equation (13)

```

The FogRA system is implemented as an episodic task. Once a task arrives, based on its latency requirement, the time-criticality is obtained from the latency time-criticality mapping table. The value of states  $V(s)$  is initialized with Zero for all states. Based on equation (13), FCA decides whether to accept the request in the fog or decline it. By continuous interaction with the environment, the FCA updates the state value of all states and derives the optimal policy for every state.

Given the episode, generated by following the policy  $\pi$  (ie., action taken based on equation (13)), the ACT-enabled MC optimal policy algorithm evaluates  $V_\pi(S_t)$  for all the non-terminal states  $S_t$  occurring in that episode. The returns  $G_t$  is computed as the sum of undiscounted rewards starting from the initial state till the terminal state of the episode. The returns of every state are used as the target to update the value of the respective state  $V_\pi(S_t)$  as given in equation (8). Episodes are generated as long as the state values converge for all states. Once state value converges, the optimal policy is obtained based on equation (7).

**IV. EXPERIMENTAL ANALYSIS AND DISCUSSION**

The MDP for FogRA system adopts the definition of state from adaptive resource allocation but differs in certain aspects [15]. First, the proposed work obtains the time-criticality value ( $c_t$ ) from the Latency Time-criticality mapping Table I, which maps the preference level of the IoT request with its criticality value. Secondly, as the proposed MDP is episodic, the returns are computed with undiscounted rewards. Thirdly, priority threshold is computed by a self-generated Auto Centric Threshold (ACT) method which suits more for the stochastic nature of the IoT environment. Finally, unlike constant value-based rewards, the novel reward system acts in coherence with the priority threshold and provides the best incentive for the agent to learn better and faster.

The experiment is implemented in python Spyder. The simulation was conducted for the latency generated at random. Then the priority level of the request is obtained from the

latency-time criticality mapping Table I. The simulation parameter and their corresponding values are maintained as given in the Table III.

TABLE III. SIMULATION PARAMETERS

Parameter	Description	Values
$\alpha$	Learning Rate	0.02
$pth_t$	Priority Threshold	Median of the time-criticality values
$\epsilon$	Probability of Random Action	0.2
$\gamma$	Discount Factor	0.6
$C$	Highest Priority level	10
$N_{max}$	Max.number of Fog Nodes	15

This section analyses the experimental results obtained through MC, MC-ES, and OMC to evaluate the performance of FCA. The work considers ten IoT applications, hence the value of 'm' is set to 10 in the work. With the number of fog nodes  $N_{max}$  as 15, and the maximum time criticality value  $C$  as 10, the MDP leads to  $m(N_{max}) + C$  possible states, which are given by  $s_t \in S = \{1,2,3, \dots, m(N_{max}) + C\}$ . Initially, at the time  $t=0$ , all fog nodes are available, so the number of occupied fog nodes  $n_t$  remains zero in the equation (12) with the possible initial state as  $s_0 \in \{1,2,3 \dots C\}$ . The MDP terminates at time T when all the fog nodes are occupied, ie.,  $n_t = N_{max}$  with the possible terminal states as  $s_T \in \{CN_{max} + 1, CN_{max} + 2, CN_{max} + 3 \dots \dots C(N_{max} + 1)\}$ . Hence, the proposed work is experimented with 160 states, with  $\{1, 2, 3, \dots, 10\}$  as one of the possible initial states and  $\{151,152,153, \dots, 160\}$  as one of the terminal states.

**A. Adaptive MC vs ACT MC**

First, the performance of FogRA is evaluated with the adaptive MC and the proposed ACT-based MC model. Fig. 4 reflects the value of a few states estimated by the Adaptive MC algorithm in the earlier work [15]. The adaptive model converges after 10000 episodes resulting in the optimal state value 16. Fig. 5 shows that the ACT-based MC derives an optimal state value of 17.5 which is 9.375 % more than the Adaptive MC. The metrics observed in the implementation of Adaptive and ACT-based MC are tabulated in Table IV.

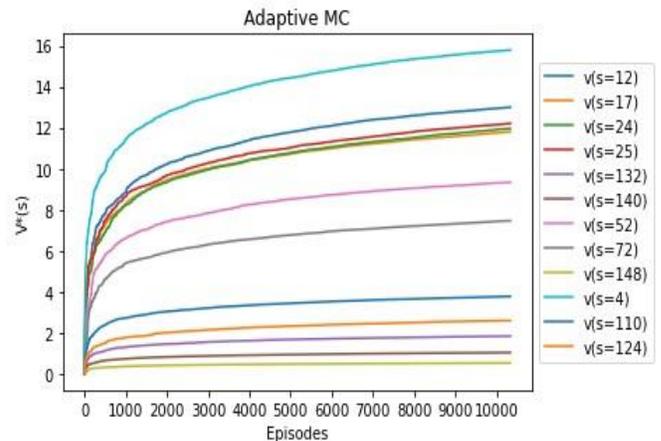

Fig. 4. Optimal State Value in Adaptive RA.

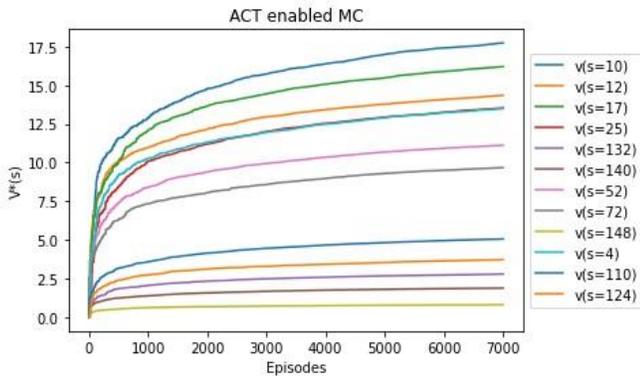

Fig. 5. Optimal State Value with ACT-MC.

The estimation of  $V^*(s)$  obtained by the MC algorithm fits more for the model-based MDP. As FogRA is a model-free system, the exploration-oriented ACT MC-ES (Monte Carlo Exploring Starts), is implemented to compare its results with the Adaptive model.

### B. Adaptive MC-ES vs ACT MC-ES

The FogRA system is then evaluated in MC-ES for both the Adaptive and ACT model. The ACT-based MC-ES algorithm estimates  $Q(s, a)$  rather than  $V(s)$ . Hence, the state space increases from  $s$  to  $(s \times a)$ , and the action selection depends on equation (14). Fig. 6 and Fig. 7 show the convergence of optimal action-value  $Q^*(state, accept)$  and  $Q^*(state, decline)$  in Adaptive RA for twelve states chosen at random.

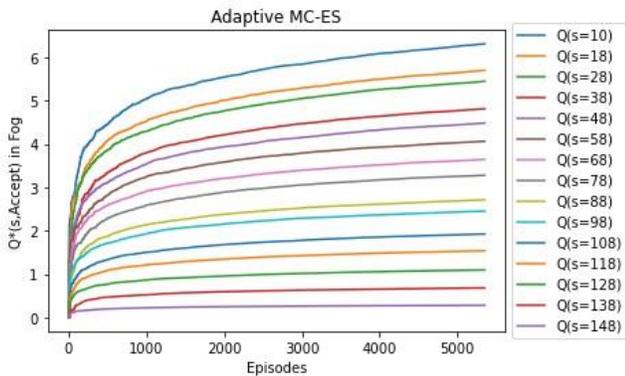

Fig. 6.  $Q^*(s, \text{Accept})$  for Adaptive MC-ES.

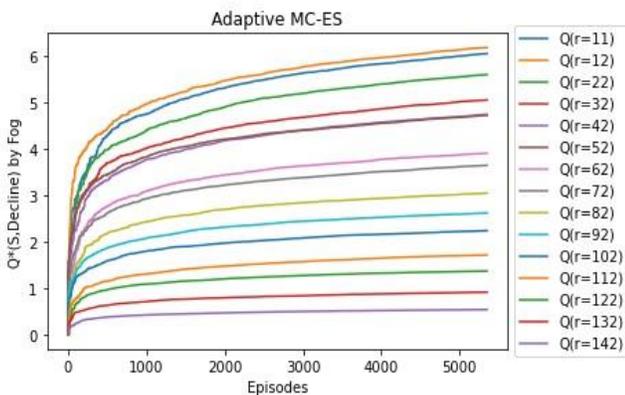

Fig. 7.  $Q^*(s, \text{Decline})$  for Adaptive MC-ES.

Unlike the Adaptive approach, the values obtained by ACT-based MC-ES in Fig. 8 and Fig. 9 show improved optimal values comparatively. The estimated  $Q^*(s, a)$  value in the Adaptive approach is lesser than the ACT model. The reason behind the poor  $Q^*(s, a)$  value is that the Adaptive MC-ES is not able to explore widely in an episodic environment with a limited number of fog nodes.

Table IV shows the improved value from 16 in the MC model to 18.7025 in ACT-based MC-ES. The increase in the percentage of 16.8906% indicates the robustness of the ACT-enabled FogRA over the Adaptive system even in an environment with scarce resources. Still, the improvement is not considered favourable as the action selection process of MC-ES is greedy without enough exploration. Hence, the ACT-based FogRA System is tuned towards a balanced mix of exploration and exploitation in the OMC approach.

### C. Adaptive OMC vs ACT OMC

The OMC algorithm estimates the value of state-action pair  $Q(s, a)$ , but the action based on equation (14) is decided only after a balanced trial of exploration and exploitation. FCA controls the level of exploration and exploitation based on a  $\epsilon$ -greedy policy and is hence named as On-Policy Monte Carlo Control (OMC). The agent explores such that a random action is picked epsilon times and the greedy action based on equation (14) is picked for the  $(1 - \epsilon)$  times. In this case, epsilon ( $\epsilon$ ) is chosen as a small positive number of 0.2 after trial and error. Fig. 10 and Fig. 11 show the convergence of optimal action value  $Q^*(state, accept)$  and  $Q^*(state, decline)$  for twelve states chosen at random using an Adaptive approach.

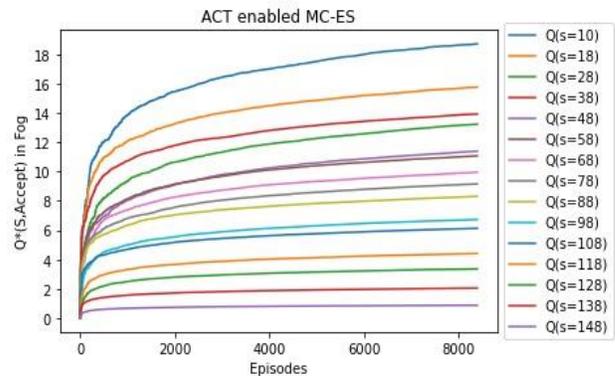

Fig. 8.  $Q^*(s, \text{Accept})$  for ACT MC-ES.

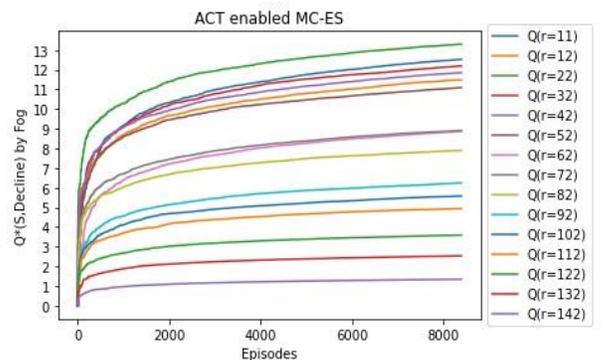

Fig. 9.  $Q^*(s, \text{Decline})$  for ACT MC-ES.

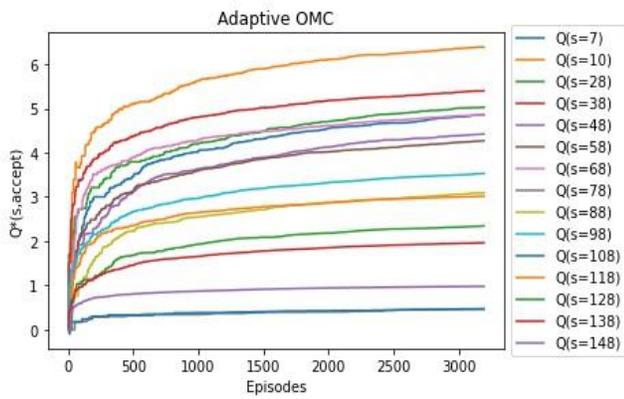

Fig. 10.  $Q^*(s, \text{Accept})$  for Adaptive OMC.

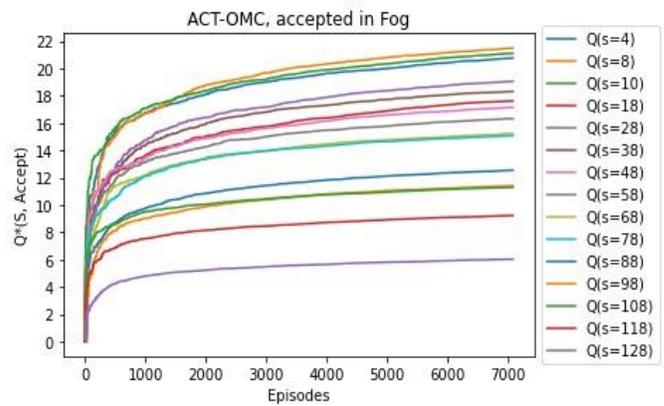

Fig. 12.  $Q^*(s, \text{Accept})$  for ACT OMC.

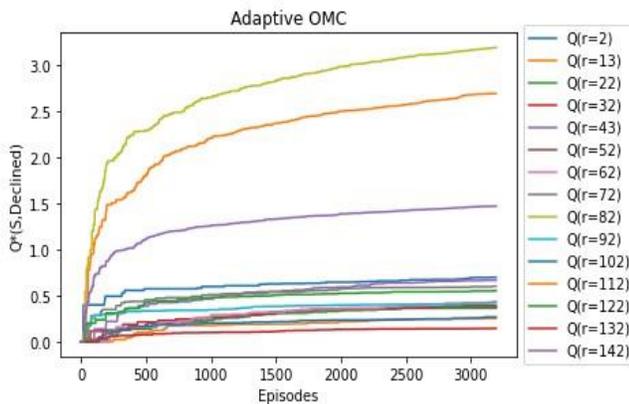

Fig. 11.  $Q^*(s, \text{Decline})$  for Adaptive OMC.

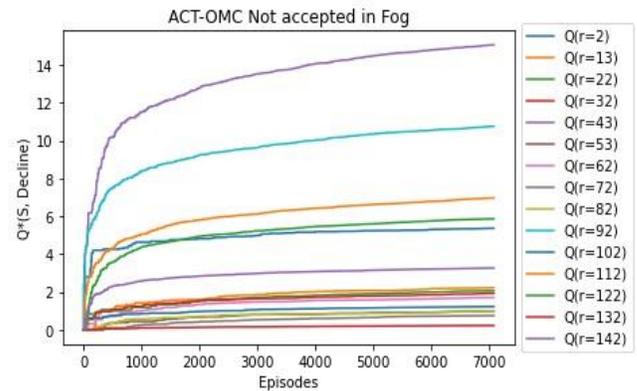

Fig. 13.  $Q^*(s, \text{Decline})$  for ACT OMC.

Despite its balanced explore-exploit strategy, the adaptive OMC terminates fast, resulting in minimal  $Q^*(s, a)$  value. It expresses the inability of the adaptive system for exploration. Whereas the ACT enabled OMC outperforms its counterpart by improved  $Q^*(s, a)$  with minimal termination time in Fig. 12 and Fig. 13. The numerical results obtained during execution are tabulated in Table IV.

The optimal state-action value estimated by ACT-based OMC is increased by 41% more than the Adaptive MC. Thus, the ACT-based OMC surpasses other methods by maximizing long-term returns. The high value of the long-term returns with minimum termination time denotes that the FCA has learned the best policy at a fast rate, thanks to the smart learning ability of the ACT-based On Policy Monte Carlo Control.

TABLE IV. PERFORMANCE EVALUATION

Model	Time in ms	Total no. requests accepted	Total no. requests declined	% requests accepted	% requests declined	Total accepted rewards	Total declined rewards	% accepted rewards	% declined rewards	% penalised episode	% successful episode	V(s), q(s,accept), q(s,decline)

## V. CONCLUSION AND FUTURE WORKS

In this work, an RL-based ACT-enabled FogRA system is implemented for time-critical applications of IoT. The proposed system instantaneously decides whether to allocate fog resources or not, based on the time-criticality of the incoming request and the availability of fog resources. In the pursuit to derive the optimal policy, the algorithm trains the FCA to learn better decision-making. The RA problem is executed for the incoming requests both on the Adaptive and ACT-enabled FogRA systems. Results show that the ACT-enabled FogRA system prioritizes time-critical applications to allocate fog nodes. Also, utilization of fog resources is maximized in terms of the percentage of requests accepted by fog, rewards obtained and optimal value achieved. The performance assessment of the ACT-enabled FogRA system exhibits an improved optimal state-action value by 41% more than the Adaptive model. In future work, the FogRA system is planned for continuous tasks with the auto-scaling feature of fog resources. Also, it is planned to extend the work as RL enabled Energy Efficient FogRA system that minimizes the energy cost with maximized performance.

Guilin University of Technology, Guilin, China

**Abstract**—As the result of Open Edge Computing (OEC) project, cloudlet embodies the middle layer of edge computing architecture. Due to the close deployment to the user side, responding to user requests through cloudlet can reduce delay, improve security, and reduce bandwidth occupancy. In order to improve the quality of user experience, more and more cloudlets need to be deployed, which makes the deployment and management costs of Cloudlet service Providers (CLP) significantly increased. Therefore, the cloudlet federation appears as a new paradigm that can reduce the cost of cloudlet deployment and management by sharing cloudlet resources among CLPs. Facing the cloudlet federation scenario, more attention still needs to be paid to the heterogeneity of resource prices, the balance of benefits among CLPs, and the more complex delay computation when exploring task migration strategies. For delay-sensitive and delay-tolerance tasks, a delay-aware and profit-maximizing task migration strategy is proposed considering the relationship between the delay and the quotation of different tasks, as well as the dynamic pricing mechanism when resources are shared among CLPs. Experimental results show that the proposed algorithm outperforms the baseline algorithm in terms of revenue and response delay.

**Keywords**—Cloudlet federation; task migration; delay-aware; dynamic pricing; profit-maximizing; edge computing

## I. INTRODUCTION

With the development of intelligent Mobile Devices (MD), a large number of computation-intensive and delay-sensitive mobile applications keep emerging [1]. To address the resource constraints of mobile devices, tasks are offloaded to remote cloud centers in traditional cloud computing [2][3], but it is followed by the problem of high response delay [4]. This makes it difficult for requirements of delay-sensitive task to be satisfied [5].

To overcome these problems, Mobile Edge Computing (MEC) [6] is proposed and regarded as a promising technology by developing servers at the edge of networks. The proximity of the MEC to the user allows the user to access and use resources with lower response latency. Cloudlets are small cloud at the edge of network and typically deployed in a distributed manner to provide storage and computing resource to MD.

Compared to existing cloud computing, MEC still suffers from constrained resources. A Cloudlet service Provider (CLP) has to deploy more and more proprietary edge devices to meet the needs of its users, resulting in increasing costs to deploy and manage edge devices. Therefore, [7] proposes the edge

federation architecture, which improves the flexibility of resource utilization and reduces the deployment and management costs by seamlessly integrating the edge resources of each CLP. When cloudlets act as edge devices, a cloudlet federation architecture is formed.

Since MD is not uniformly distributed in edge computing systems, some clouds are heavily loaded while others are lightly loaded. Task migration is the principal method used to resolve load imbalance between cloudlets [8-11]. Although many studies have been conducted on cloudlet-based load migration strategies, they have one or more shortcomings: they do not take into account the heterogeneity of resource prices, authentication delays between cloudlet resources of different CLPs, or the impact of service delays on task quotes.

This paper focuses on the task migration problem in the cloudlet federation scenario. Two types of user requests are considered: delay-sensitive and delay-tolerant, and their quotation delay curves are designed respectively. Considering the heterogeneity of resource prices among CLPs, a delay-aware and profit-maximizing task migration strategy is proposed. Our main contributions are as follows:

- For delay-sensitive and delay-tolerant tasks, a delay model and a price model are constructed by taking into account the differences in resource prices of different CLPs.
- A distributed Delay-aware and Profit-maximizing Task Migration (DPTM) algorithm is designed to schedule tasks, which tries to minimize latency and maximize profit.
- A series of experiments are conducted to verify the necessity of considering the cloudlet federation and the advantages of our method in terms of revenue and response delay.

The rest of this article is organized as follows. Section II demonstrates the related work on the task migration in different scenarios. Section III introduces the system model. In Section IV, a task scheduling algorithm considering both profit and delay is proposed. In Section V, we conduct the extensive experiments to evaluate the proposed method and gives the discussion. Finally, Section VI concludes this paper and gives the future works.

## II. RELATED WORK

We review the related works about task migration and schedule in the multi-cloudlet scenario and the edge federation scenario respectively.

### A. Task Migration in Multi-cloudlets Scenario

The existing works about task migration in the multi-cloudlets scenarios focus on minimizing delay and energy consumption. The authors in [12] propose an application-aware cloudlet adaption and VM selection framework has been devised for balancing the load in a multi-cloudlet environment. The authors in [13] propose a novel Multi-layer Latency Aware Workload Assignment Strategy (MLAWAS) to allocate the workload of E-Transport applications into optimal computing nodes. In [14] user mobility and task deadline are taken into account when task migration is optimized. Three variants of this problem are analyzed, and a group migration algorithm with known user trajectories is designed. In [15], a heuristic Task Migration Computing Offloading (TMCO) scheme is proposed for the challenges brought by complex network environment and end-user mobility, which can dynamically select the appropriate location to offload tasks for mobile users within the deadline. In [16], for collaborative vehicle edge computing group environment, a computational task migration problem is defined to balance the load and minimize the migration cost, and reinforcement learning algorithm is adopted to solve this problem.

The above researches are based on multi-cloudlet scenarios to optimize the delay and energy consumption of task migrating. However, the traditional multi-cloudlet scenario has the problem of limited resources, and a smaller number of resources are available for task migration. Different from the multi-cloudlet scenario, in the cloudlet federation, the cloudlet resource prices of different CLPs may be different, there are more options for task migration, and the delay computation is more complex.

### B. Task Migration in Edge Federation Scenario

Some studies have explored task migration strategies in the context of edge federation or cloudlet federation. The authors in [17] design a task migration strategy for multiple edge servers in mobile networks to minimize the overall service time and develop an intelligent task migration scheme using deep reinforcement learning and Q-learning technology. In [18], the authors propose a latency minimization model to provide higher efficient service provisioning in horizontal edge federation and propose a two-phase iterative approach, which alternately determines optimal task dispatching and computation resource allocation. In order to simultaneously meet the SLA requirements of IoT (Internet of Thing) devices and edge service providers, the authors in [19] design an intelligent request service provisioning system based on reinforcement learning as part of a smart edge orchestrator in the edge federation. Considering the delay and capacity constraints, [20] proposes an optimization model to minimize the total energy cost and the energy efficient offloading ratio of edge nodes.

The above studies either ignore the role of the remote cloud, or do not consider the heterogeneity of resource prices, or do not consider the impact of task delay on user quotation. In our

work, tasks can be migrated to the CLP's own cloudlet, the cloudlet of federate CLP, or the remote cloud. We consider two different types of tasks, time-sensitive and time-tolerance, and consider that their delays have different effects on user quotation. We attempt to optimize the profit and delay of the whole federation.

## III. SYSTEM MODEL

In this section, we keep our focus on the cloudlet federation framework, communication and computation models.

### A. Cloudlet Federation Framework

Compared with the cloudlet, the cloud usually has sufficient resources and is quite far away from the user. For simplicity, the cloud platform owned by each CLP is not distinguished. Therefore, as shown in Fig. 1, we consider that a cloudlet federation contains a cloud and several CLPs. Each CLP has its own cloudlet servers, and each has a set of users that need to be served. The resource of a cloudlet server is provided in the form of a virtual machine (VM) instance. Let's assume that a VM instance performs only one task at a time.

We assume each CLP has a server as the Federated Cloudlet Manager (FCLM) to provide service and resource interactions. The status of the cloudlet servers is collected by the FCLM, such as available capacity, resource utilization, and cost. Meanwhile, CLPs can communicate with each other through FCLMs and exchange their collected information. When a CLP receives a task from a terminal user, it decides where to offload the task. This could be its own cloudlet, one of the federated cloudlets, or the cloud.

### B. Task Requests from Terminal Users

Similar to works in mobile cloud computing [21] and mobile edge computing [22], the quasi-static scenario is considered, where the mobile users remain unchanged during migration. To simplify, we use task or request instead of task request without causing confusion.

Two types of task requests are considered: delay tolerance (DT) and delay sensitive (DS). For a DS task, CLP should minimize its delay while a certain amount of revenue is guaranteed. For a DT task, the priority is profit maximization.

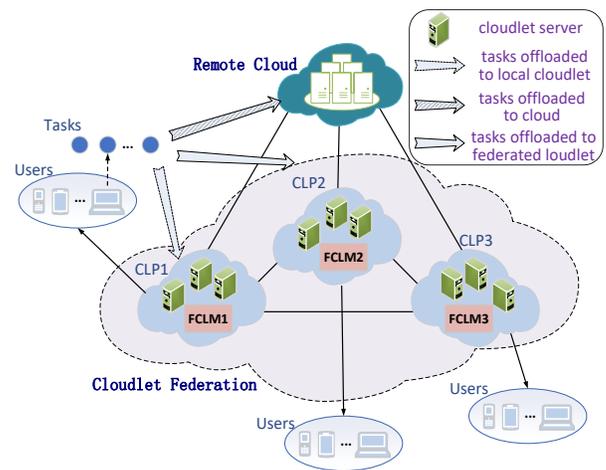

Fig. 1. Cloudlet Federation Architecture.

Regardless of the type of task, we believe that the response delay will affect the user's willingness to pay. In general, the shorter the delay, the higher the user is willing to pay.
