# Editorial Preface

## *From the Desk of Managing Editor...*

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

**Thank you for Sharing Wisdom!**

# Editorial Board

## Editor-in-Chief

**Dr. Kohei Arai - Saga University**

*Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation*

---

## Associate Editors

**Alaa Sheta**

**Southern Connecticut State University**

*Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems*

**Domenico Ciuonzo**

**University of Naples, Federico II, Italy**

*Domain of Research: Artificial Intelligence, Communication, Security, Big Data, Cloud Computing, Computer Networks, Internet of Things*

**Doroła Kaminska**

**Lodz University of Technology**

*Domain of Research: Artificial Intelligence, Virtual Reality*

**Elena Scutelnicu**

**"Dunarea de Jos" University of Galati**

*Domain of Research: e-Learning, e-Learning Tools, Simulation*

**In Soo Lee**

**Kyungpook National University**

*Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning*

**Krassen Stefanov**

**Professor at Sofia University St. Kliment Ohridski**

*Domain of Research: e-Learning, Agents and Multi-agent Systems, Artificial Intelligence, e-Learning Tools, Educational Systems Design*

**Renato De Leone**

**Università di Camerino**

*Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming*

**Xiao-Zhi Gao**

**University of Eastern Finland**

*Domain of Research: Artificial Intelligence, Genetic Algorithms*

# CONTENTS

Paper 1: CISE: Community Engagement of CEB Cloud Ecosystem in Box

*Authors: Benjamin Garlington*

PAGE 1 – 15

Paper 2: BEAM: A Network Topology Framework to Detect Weak Signals

*Authors: Hiba Abou Jamra, Marinette Savonnet, Eric Leclercq*

PAGE 16 – 27

Paper 3: Soft-sensor of Carbon Content in Fly Ash based on LightGBM

*Authors: Liu Junping, Luo Hairui, Huang Xiangguo, Peng Tao, Zhu Qiang, Hu XinRong, He Ruhan*

PAGE 28 – 33

Paper 4: Research on Intelligent Natural Language Texts Classification

*Authors: Chen Xiao Yu, Zhang Xiao Min*

PAGE 34 – 40

Paper 5: Image Analysis of Heat-Affected Zone of Laser-Cut Heat-Resistant Paper using Otsu Thresholding Technique

*Authors: Shalida Mohd Rosnan, Kong Peifu, Toshiharu Enomae, Nakagawa-Izumi Akiko*

PAGE 41 – 48

Paper 6: Hadoop as a Service: Integration of a Company's Heterogeneous Data to a Remote Hadoop Infrastructure

*Authors: Yordan Kalmukov, Milko Marinov*

PAGE 49 – 55

Paper 7: Method for Estimation of Oleic Acid Content in Soy Plants using Green Band Data of Sentinel-2/MSI

*Authors: Kohei Arai, Yoshitomo Hideshima, Yuuhi Iwaki, Ryota Ito*

PAGE 56 – 63

Paper 8: Portable ECG Monitoring System

*Authors: Zhadyra N. Alimbayeva, Chingiz A. Alimbayev, Nurlan A. Bayanbay, Kassymbek A. Ozhikenov, Oleg N. Bodin, Yerkat B. Mukazhanov*

PAGE 64 – 76

Paper 9: Development of an IoT Device for Measurement of Respiratory Rate in COVID-19 Patients

*Authors: Jean Pierre Tincopa, Paulo Vela-Anton, Cender U. Quispe-Juli, Anthony Arostegui*

PAGE 77 – 82

Paper 10: Design and Implementation of Teaching Assistant System for Mechanical Course based on Mobile AR Technology

*Authors: Jinglei Qu, Bingxin Ma, Lulu Zheng, Yuhui Kang*

PAGE 83 – 90

Paper 11: Extended Max-Occurrence with Normalized Non-Occurrence as MONO Term Weighting Modification to Improve Text Classification

*Authors: Cristopher C. Abalorio, Ariel M. Sison, Ruji P. Medina, Gleen A. Dalaorao*

PAGE 91 – 97

Paper 12: Assessing Digital Readiness of Small Medium Enterprises: Intelligent Dashboard Decision Support System

Authors: Okfalisa, Mahyarni, Wresni Angraini, Saktioto, B. Pranggono

PAGE 98 – 108

Paper 13: A Novel IoT Architecture for Seamless IoT Integration into University Systems

Authors: Wafa Altwoyan, Ibrahim S. Alsukayti

PAGE 109 – 116

Paper 14: Software Defined Network based Load Balancing for Network Performance Evaluation

Authors: Omran M. A. Alssaheli, Z. Zainal Abidin, N. A. Zakaria, Z. Abal Abas

PAGE 117 – 124

Paper 15: An Efficient Productive Feature Selection and Document Clustering (PFS-DocC) Model for Document Clustering

Authors: Perumal Pitchandi

PAGE 125 – 133

Paper 16: Smart Elevator Obstruction Detection System using Image Classification

Authors: Preethi Chandirasekeran, Shridevi S

PAGE 134 – 141

Paper 17: The SMILE, A Cyber Pedagogy based Learning Management System Models

Authors: Paula Dewanti, I Made Candiasa, I Made Tegeh, I Gde Wawan Sudatha

PAGE 142 – 153

Paper 18: Location-based Mobile Application for Blood Donor Search

Authors: Orlando Iparraguirre-Villanueva, Fernando Sierra-Linan, Michael Cabanillas-Carbonell

PAGE 154 – 161

Paper 19: Soil Nutrients Prediction and Optimal Fertilizer Recommendation for Sustainable Cultivation of Groundnut Crop using Enhanced-1DCNN DLM

Authors: Sivasankaran S, K. Jagan Mohan, G. Mohammed Nazer

PAGE 162 – 171

Paper 20: Performance Evaluation of Different Supervised Machine Learning Algorithms in Predicting Linear Accelerator Multileaf Collimator Positioning's Accuracy Problem

Authors: Hamed S. El-Ghety, Ismail Emam, AbdelMagid M. Ali

PAGE 172 – 176

Paper 21: Collaborative Course Assignment Problem to Minimize Unserved Classes and Optimize Education Quality

Authors: Purba Daru Kusuma, Ratna Astuti Nugrahaeni

PAGE 177 – 185

Paper 22: A Novel Morphological Analysis based Approach for Dynamic Detection of Inflected Gujarati Idioms

Authors: Jatin C. Modh, Jatinderkumar R. Saini, Ketan Kotecha

PAGE 186 – 193

Paper 23: Towards Employee Perceived Satisfaction in using Citrix Workspace Technology

Authors: Bandar Ali Al Fehaidi, Muhammad Asif Khan

PAGE 194 – 201

**Paper 24: Bearing Fault Detection based on Internet of Things using Convolutional Neural Network**

*Authors: Sovon Chakraborty, F. M. Javed Mehedi Shamrat, Rasel Ahammad, Md. Masum Billah, Moumita Kabir, Md Rabbani Hosen*

**PAGE 202 – 210**

**Paper 25: Three Layer Authentications with a Spiral Block Mapping to Prove Authenticity in Medical Images**

*Authors: Ferda Ernawan, Afrig Aminuddin, Danakorn Nincarean, Mohd Faizal Ab Razak, Ahmad Firdaus*

**PAGE 211 – 223**

**Paper 26: Assessing Node Trustworthiness through Adaptive Trust Threshold for Secure Routing in Mobile Ad Hoc Networks**

*Authors: M Venkata Krishna Reddy, P. V. S. Srinivas, M. Chandra Mohan*

**PAGE 224 – 231**

**Paper 27: An Ontology Model for Medical Tourism Supply Chain Knowledge Representation**

*Authors: Worawit Janchai, Abdelaziz Bouras, Veeraporn Siddoo*

**PAGE 232 – 240**

**Paper 28: Stochastic Marine Predator Algorithm with Multiple Candidates**

*Authors: Purba Daru Kusuma, Ratna Astuti Nugrahaeni*

**PAGE 241 – 251**

**Paper 29: A Novel High-Speed Key Transmission Technique to Avoid Fiddling Movements in e-Commerce**

*Authors: A. B. Hajira Be, R. Balasubramanian*

**PAGE 252 – 259**

**Paper 30: Machine Learning Algorithms for Document Classification: Comparative Analysis**

*Authors: Faizur Rashid, Suleiman M. A. Gargaare, Abdulkadir H. Aden, Afendi Abdi*

**PAGE 260 – 265**

**Paper 31: A Novel Evolving Sentimental Bag-of-Words Approach for Feature Extraction to Detect Misinformation**

*Authors: Yashoda Barve, Jatinderkumar R. Saini, Kaushika Pal, Ketan Kotecha*

**PAGE 266 – 275**

**Paper 32: Data Security Awareness in Online Learning**

*Authors: Rosilah Hassan, Wahiza Wahi, Nurul Halimatul Asmak Ismail, Samer Adnan Bani Awwad*

**PAGE 276 – 282**

**Paper 33: KP-USE: An Unsupervised Approach for Key-Phrases Extraction from Documents**

*Authors: Lahbib Ajallouda, Fatima Zahra Fagroud, Ahmed Zellou, Elhabib Ben Lahmar*

**PAGE 283 – 289**

**Paper 34: Design of a Multiloop Controller for a Nonlinear Process**

*Authors: S Anbu, M Senthilkumar, T S Muruges*

**PAGE 290 – 299**

**Paper 35: License Plates Detection and Recognition with Multi-Exposure Images**

*Authors: Seong-O Shim, Romil Imtiaz, Asif Siddiq, Ishthiaq Rasool Khan*

**PAGE 300 – 305**

- Paper 36: An Urban Water Infrastructure Management System Design with Storm Water Intervention for Smart Cities**  
*Authors: Edward B. Panganiban, Rafael J. Padre, Melanie A. Baguio, Oliver B. Francisco, Orlando F. Balderama*  
**PAGE 306 – 313**
- Paper 37: Sentiment Analysis on Amazon Product Reviews using the Recurrent Neural Network (RNN)**  
*Authors: Roobaea Alroobaea*  
**PAGE 314 – 318**
- Paper 38: Arabic Sign Language Recognition using Lightweight CNN-based Architecture**  
*Authors: Batool Yahya AlKhuraym, Mohamed Maher Ben Ismail, Ouiem Bchir*  
**PAGE 319 – 328**
- Paper 39: Review of Industry Workpiece Classification and Defect Detection using Deep Learning**  
*Authors: Changxing Chen, Azween Abdullah, S. H. Kok, D. T. K. Tien*  
**PAGE 329 – 340**
- Paper 40: Enterprise Architecture for Smart Enterprise System**  
*Authors: Meuthia Rachmaniah, Arif Imam Suroso, Muhamad Syukur, Irman Hermadi*  
**PAGE 341 – 350**
- Paper 41: Virtual Reality Application for Pain Management: User Requirements**  
*Authors: Ioan Alexandru Bratosin, Ionel Bujorel Pavaloiu, Nicolae Goga, Andreea Iuliana Luca*  
**PAGE 351 – 356**
- Paper 42: Integration of Convolutional Neural Networks and Recurrent Neural Networks for Foliar Disease Classification in Apple Trees**  
*Authors: Disha Garg, Mansaf Alam*  
**PAGE 357 – 367**
- Paper 43: Modern City Issues, Management and the Critical Role of Information and Communication Technology**  
*Authors: Qasim Hamakhurshid Hamamurad, Normal Mat Jusoh, Uznir Ujang*  
**PAGE 368 – 373**
- Paper 44: A Novel Framework for Sanskrit-Gujarati Symbolic Machine Translation System**  
*Authors: Jaideepsinh K. Raulji, Jatinderkumar R. Saini, Kaushika Pal, Ketan Kotecha*  
**PAGE 374 – 380**
- Paper 45: Detection and Analysis of Oil Spill using Image Processing**  
*Authors: Myssar Jabbar Hammood AL-BATTBOOTTI, Nicolae GOGA, Iuliana MARIN*  
**PAGE 381 – 387**
- Paper 46: Smart Information Retrieval using Query Transformation based on Ontology and Semantic-Association**  
*Authors: Ram Kumar, S. C. Sharma*  
**PAGE 388 – 394**
- Paper 47: Characters Segmentation from Arabic Handwritten Document Images: Hybrid Approach**  
*Authors: Omar Ali Boraik, M. Ravikumar, Mufeed Ahmed Naji Saif*  
**PAGE 395 – 403**
- Paper 48: Machine Learning for Exhibition Recommendation in a Museum's Virtual Tour Application**  
*Authors: Shinta Puspasari, Ermatita, Zulkardi*  
**PAGE 404 – 412**

**Paper 49: Classification of Osteoporosis in the Lumbar Vertebrae using L2 Regularized Neural Network based on PHOG Features**

*Authors: Kavita Avinash Patil, K. V. Mahendra Prashanth, A Ramalingaiah*

**PAGE 413 – 423**

**Paper 50: Deep Learning Approach for Spoken Digit Recognition in Gujarati Language**

*Authors: Jinal H. Tailor, Rajnish Rakholia, Jatinderkumar R. Saini, Ketan Kotecha*

**PAGE 424 – 429**

**Paper 51: Tweet Credibility Detection for COVID-19 Tweets using Text and User Content Features**

*Authors: Vaishali Vaibhav Hirlekar, Arun Kumar*

**PAGE 430 – 439**

**Paper 52: Integration of Ensemble Variant CNN with Architecture Modified LSTM for Distracted Driver Detection**

*Authors: Zakaria Boucetta, Abdelaziz El Fazziki, Mohamed El Adnani*

**PAGE 440 – 458**

**Paper 53: A Review of the Integration of Cyber-Physical System and Internet of Things**

*Authors: Ramesh Sneka Nandhini, Ramanathan Lakshmanan*

**PAGE 459 – 465**

**Paper 54: Is Deep Learning on Tabular Data Enough? An Assessment**

*Authors: Sheikh Amir Fayaz, Majid Zaman, Sameer Kaul, Muheet Ahmed Butt*

**PAGE 466 – 473**

**Paper 55: Smart Home Automation by Internet-of-Things Edge Computing Platform**

*Authors: Zubair Sharif, Low Tang Jung, Muhammad Ayaz, Mazlaini Yahya, Dodo Khan*

**PAGE 474 – 484**

**Paper 56: An Integrated Approach to Research Paper and Expertise Recommendation in Academic Research**

*Authors: Charles N. Mabude, Iyabo O. Awoyelu, Bodunde O. Akinyemi, Ganiyu A. Aderounmu*

**PAGE 485 – 495**

**Paper 57: Organizational Architecture and Service Delivery Re-Alignment based on ITIL and TOGAF: Case Study of the Provincial Development Bank**

*Authors: Asti Amalia Nur Fajrillah, Muharman Lubis, Irmayanti Syam*

**PAGE 496 – 508**

**Paper 58: A Lasso-based Collaborative Filtering Recommendation Model**

*Authors: Hiep Xuan Huynh, Vien Quang Dam, Long Van Nguyen, Nghia Quoc Phan*

**PAGE 509 – 514**

**Paper 59: Face Age Estimation using Shortcut Identity Connection of Convolutional Neural Network**

*Authors: Shohel Pramanik, Hadi Affendy Bin Dahlan*

**PAGE 515 – 521**

**Paper 60: Framework to Deploy Containers using Kubernetes and CI/CD Pipeline**

*Authors: Manish Kumar Abhishek, D. Rajeswara Rao, K. Subrahmanyam*

**PAGE 522 – 526**

**Paper 61: Adaptive Generation-based Approaches of Oversampling using Different Sets of Base and Nearest Neighbor's Instances**

*Authors: Hatem S Y Nabus, Aida Ali, Shafaatunnur Hassan, Siti Mariyam Shamsuddin, Ismail B Mustapha, Faisal Saeed*

**PAGE 527 – 534**

**Paper 62: Social Group Optimization-based New Routing Approach for WMN's**

*Authors: Bhanu Sharma, Amar Singh*

**PAGE 535 – 540**

**Paper 63: A New Combination Approach to CPU Scheduling based on Priority and Round-Robin Algorithms for Assigning a Priority to a Process and Eliminating Starvation**

*Authors: Hussain Mohammad Abu-Dalbouh*

**PAGE 541 – 546**

**Paper 64: Balancing a Practical Inverted Pendulum Model Employing Novel Meta-Heuristic Optimization-based Fuzzy Logic Controllers**

*Authors: Dao-Thi Mai-Phuong, Pham Van-Hung, Nguyen Ngoc-Khoat, Pham Van-Minh*

**PAGE 547 – 553**

**Paper 65: Application of Affective Computing in the Analysis of Advertising Jingles in the Political Context**

*Authors: Gabriel Elias Chanchi Golondrino, Manuel Alejandro Ospina Alarcon, Luz Marina Sierra Martínez*

**PAGE 554 – 561**

**Paper 66: An Intelligent Approach based on the Combination of the Discrete Wavelet Transform, Delta Delta MFCC for Parkinson's Disease Diagnosis**

*Authors: BOUALOULOU Nouhaila, BELHOSSINE DRISSI Taoufiq, NSIRI Benayad*

**PAGE 562 – 571**

**Paper 67: Efficient Intrusion Detection System for IoT Environment**

*Authors: Rehab Hosny Mohamed, Faried Ali Mosa, Rowayda A. Sadek*

**PAGE 572 – 578**

**Paper 68: Augmented System for Food Crops Production in Agricultural Supply Chain using Blockchain Technology**

*Authors: Dayana D. S, Kalpana G*

**PAGE 579 – 589**

**Paper 69: A Comprehensive Analysis of Blockchain-based Cryptocurrency Mining Impact on Energy Consumption**

*Authors: Md Rafiqul Islam, Muhammad Mahbubur Rashid, Mohammed Aatur Rahman, Muslim Har Sani Bin Mohamad, Abd Halim Bin Embong*

**PAGE 590 – 598**

**Paper 70: Bridge Pillar Defect Detection using Close Range Thermography Imagery**

*Authors: Abd Wahid Rasib, Muhammad Latifi Mohd Yaacob, Nurul Hawani Idris, Khairulazhar Zainuddin, Rozilawati Dollah, Norbazlan Mohd Yusof, Norisam Abd Rahaman, Shahrin Ahmad, Norhadi A. Hamid, Abdul Manaf Mhapo*

**PAGE 599 – 606**

**Paper 71: Learning Effectiveness of Virtual Land Surveying Simulator for Blended Open Distance Learning Amid Covid-19 Pandemic**

*Authors: Yeap Chu Im, Muhammad Norhadri Bin Mohd Hilmi, Tan Cheng Peng, Azrina Jamal, Noor Halizah binti Abdullah, Suzi Iryanti Fadilah*

**PAGE 607 – 615**

Paper 72: Fusion of Statistical Reasoning for Healing Highly Corrupted Image

Authors: Golam Moktader Daiyan, Leiting Chen, Chuan Zho, Golam Moktader Nayeem

PAGE 616 – 628

Paper 73: Framework of Infotainment using Predictive Scheme for Traffic Management in Internet-of-Vehicle

Authors: Reshma S, Chetanaprakash

PAGE 629 – 638

Paper 74: Internet of Things (IoT) Application for Management in Automotive Parts Manufacturing

Authors: Apiwat Krommuang, Opal Suwunnamek

PAGE 639 – 650

Paper 75: Investigation of Hybrid Feature Selection Techniques for Autism Classification using EEG Signals

Authors: S. Thirumal, J. Thangakumar

PAGE 651 – 659

Paper 76: An Optimized Hybrid Fuzzy Weighted k-Nearest Neighbor with the Presence of Data Imbalance

Authors: Soha A. Bahanshal, Rebhi S. Baraka, Bayong Kim, Vaibhav Verdhan

PAGE 660 – 665

Paper 77: SPKP: A Web-based Application System for Managing Mental Health in Higher Institution

Authors: Mohamad Fadli Zolkipli, Zahidah Mohamad Said, Massudi Mahmuddin

PAGE 666 – 675

Paper 78: Breast Cancer Classification using Decision Tree Algorithms

Authors: Omar Tarawneh, Mohammed Otair, Moath Husni, Hayfa.Y. Abuaddous, Monther Tarawneh, Malek A Almomani

PAGE 676 – 680

Paper 79: Development and Validation of e-Books during the Post-Pandemic to Improve Attitude towards Environmental Care in Case of Indonesia

Authors: Anggraeni Mashinta Sulistyani, Zuhdan Kun Prasetyo, Farida Hanum, Rizki Noor Prasetyono

PAGE 681 – 688

Paper 80: A Two-Stage Assessment Approach for QoS in Internet of Things based on Fuzzy Logic

Authors: Mutasim Elsadig Adam, Yasir Abdalgadir Ahmed Hamid

PAGE 689 – 696

Paper 81: Design and Usability Study of Hypertension Management Guideline Mobile Application with Hypertension and Non-hypertension Patients

Authors: Nor Azman Ismail, Nor Atiqah Mohd Fuaad, Muhammad Syahmi Zulkifli, Farhat Embarak, Nur Zuhairah Afiqah Husni, Su Elya Mohamed, Puteri Syaza Kamarina Megat Mohd Zainon

PAGE 697 – 702

Paper 82: A CNN based Approach for Handwritten Character Identification of Telugu Guninthalu using Various Optimizers

Authors: B. Soujanya, Suresh Chittineni, T. Sitamahalakshmi, G. Srinivas

PAGE 703 – 710

Paper 83: Information Security Enhancement by Increasing Randomness of Stream Ciphers in GSM

Authors: Ram Prakash Prajapat, Rajesh Bhadada, Arjun Choudhary

PAGE 711 – 717

**Paper 84: Plant Disease Detection using AI based VGG-16 Model**

*Authors: Anwar Abdullah Alatawi, Shahd Maadi Alomani, Najd Ibrahim Alhawiti, Muhammad Ayaz*

**PAGE 718 – 727**

**Paper 85: Analysis of Factors Influencing the COVID-19 Mortality Rate in Indonesia using Zero Inflated Negative Binomial Model**

*Authors: Maria Susan Anggreainy, Abdullah M. Ilyasu, Hanif Musyaffa, Florence Helena Kansil*

**PAGE 728 – 734**

**Paper 86: Automatic Healthy Sperm Head Detection using Deep Learning**

*Authors: Ahmad Abdelaziz Mashaal, Mohamed A. A. Eldosoky, Lamia Nabil Mahdy, Kadry Ali Ezzat*

**PAGE 735 – 742**

**Paper 87: RTL Design and Testing Methodology for UHF RFID Passive Tag Baseband-Processor**

*Authors: Syfaul Fuada, Aris Agung Pribadi, Trio Adiono, Tengku Ahmad Madya*

**PAGE 743 – 753**

**Paper 88: IAGA: Interference Aware Genetic Algorithm based VM Allocation Policy for Cloud Systems**

*Authors: Tarannum Alimahmad Bloch, Sridaran Rajagopal, Prashanth C. Ranga*

**PAGE 754 – 765**

**Paper 89: A Hybrid Deep Learning Approach for Freezing of Gait Prediction in Patients with Parkinson's Disease**

*Authors: Hadeer El-ziaat, Nashwa El-Bendary, Ramadan Moawad*

**PAGE 766 – 776**

**Paper 90: Emotions Classification from Speech with Deep Learning**

*Authors: Andry Chowanda, Yohan Muliono*

**PAGE 777 – 781**

**Paper 91: A Comprehensive Overview on Biometric Authentication Systems using Artificial Intelligence Techniques**

*Authors: Shoroog Albalawi, Lama Alshahrani, Nouf Albalawi, Reem Kilabi, Aaeshah Alhakamy*

**PAGE 782 – 791**

**Paper 92: Protecting User Preference in Ranked Queries**

*Authors: Rong Tang, Xinyu Yu*

**PAGE 792 – 799**

**Paper 93: Towards Security Awareness of Mobile Applications using Semantic-based Sentiment Analysis**

*Authors: Ahmed Alzhrani, Abdulmjeed Alatawi, Bandar Alsharari, Umar Albalawi, Mohammed Mustafa*

**PAGE 800 – 809**

**Paper 94: Deep Multi View Spatio Temporal Spectral Feature Embedding on Skeletal Sign Language Videos for Recognition**

*Authors: SK. Ashraf Ali, M. V. D. Prasad, P. Praveen Kumar, P. V. V. Kishore*

**PAGE 810 – 819**

**Paper 95: Human Activity Recognition in Car Workshop**

*Authors: Omar Magdy, Ayman Atia*

**PAGE 820 – 825**

**Paper 96: BMP: Toward a Broker-less and Microservice Platform for Internet of Thing**

*Authors: Lam Nguyen Tran Thanh, Khoi Le Quoc, The Anh Nguyen, Huong Hoang Luong, Hong Khanh Vo, Tuan Dao Anh, Hy Nguyen Vuong Khang, Khoi Nguyen Huynh Tuan, Hieu Le Van, Nghia Huynh Huu, Khoa Tran Dang, Kiem Huynh Gia*

**PAGE 826 – 834**

**Paper 97: CNN-LSTM Based Approach for Dos Attacks Detection in Wireless Sensor Networks**

*Authors: Salim Salmi, Lahcen Oughdir*

**PAGE 835 – 842**

**Paper 98: A Deep Transfer Learning Approach to Enhance Network Intrusion Detection Capabilities for Cyber Security**

*Authors: Abhijit Das, Pramod*

**PAGE 843 – 855**

**Paper 99: Design and Development of an Efficient Network Intrusion Detection System using Ensemble Machine Learning Techniques for Wifi Environments**

*Authors: Abhijit Das, Pramod*

**PAGE 856 – 866**

**Paper 100: Deep Reinforcement Learning based Ensemble Model for Intrusion Detection System**

*Authors: Abhijit Das, Pramod*

**PAGE 867 – 878**

**Paper 101: An Enhanced Predictive Approach for Students' Performance**

*Authors: Mohamed Farouk Yacoub, Huda Amin Maghawry, Nivin A Helal, Sebastian Ventura, Tarek F. Gharib*

**PAGE 879 – 883**

**Paper 102: A Comparative Performance of Optimizers and Tuning of Neural Networks for Spoof Detection Framework**

*Authors: Ankita Chadha, Azween Abdullah, Lorita Angeline*

**PAGE 884 – 890**

**Paper 103: Hybrid Deep Learning Approach for Sentiment Classification of Malayalam Tweets**

*Authors: Soumya S, Pramod K V*

**PAGE 891 – 899**

**Paper 104: IoDEP: Towards an IoT-Data Analysis and Event Processing Architecture for Business Process Incident Management**

*Authors: Abir Ismaili-Alaoui, Karim Baina, Khalid Benali*

**PAGE 900 – 915**

**Paper 105: Route Planning using Wireless Sensor Network for Garbage Collection in COVID-19 Pandemic**

*Authors: Javier E. Ramirez, Caleb M. Santiago, Angelica Kamiyama*

**PAGE 916 – 924**

**Paper 106: Empirical Analysis of Learning-based Malware Detection Methods using Image Visualization**

*Authors: Abdullah Sheneamer, Essa Alhazmi, James Henrydoss*

**PAGE 925 – 936**

**Paper 107: Eye-movement Analysis and Prediction using Deep Learning Techniques and Kalman Filter**

*Authors: Sameer Rafee, Xu Yun, Zhang Jian Xin, Zaid Yemeni*

**PAGE 937 – 949**

**Paper 108: Independent Channel Residual Convolutional Network for Gunshot Detection**

*Authors: Jakub Bajzik, Jiri Prinosil, Roman Jarina, Jiri Mekyska*

**PAGE 950 – 958**

**Paper 109: Improving Intrusion Detection for Imbalanced Network Traffic using Generative Deep Learning**

*Authors: Amani A. Alqarni, El-Sayed M. El-Alfy*

**PAGE 959 – 967**

**Paper 110: A Machine Learning Model for the Diagnosis of Coffee Diseases**

*Authors: Fredy Martinez, Holman Montiel, Fernando Martinez*

**PAGE 968 – 974**

**Paper 111: Deep Learning-based Hybrid Model for Efficient Anomaly Detection**

*Authors: Frances Osamor, Briana Wellman*

**PAGE 975 – 979**

**Paper 112: An Ensemble Deep Learning Approach for Emotion Detection in Arabic Tweets**

*Authors: Alaa Mansy, Sherine Rady, Tarek Gharib*

**PAGE 980 – 990**

**Paper 113: Chatbots for the Detection of Covid-19: A Systematic Review of the Literature**

*Authors: Antony Albites-Tapia, Javier Gamboa-Cruzado, Junior Almeyda-Ortiz, Alberto Moreno Lázaro*

**PAGE 991 – 998**

**Paper 114: An Enhanced Genetic Algorithm (EGA)-based Multi-Hop Path for Energy Efficient in Wireless Sensor Network (WSN)**

# CISE: Community Engagement of CEB Cloud Ecosystem in Box

Dr. Benjamin Garlington

Ph.D. Candidate, University of Arkansas at Little Rock, USA

**Abstract**—The explosion of digital and observational data is having a profound effect on the nature of scientific inquiry, requiring new approaches to manipulating and analyzing large and complex data and increasing the need for collaborative solid research teams to address these challenges. These data, along with the availability of computational resources and recent advances in artificial intelligence, machine learning software tools, and methods, can enable unprecedented science and innovation. Unfortunately, these software tools and techniques are not uniformly accessible to all communities, mainly scientists and engineers at Minority Serving Institutions (MSI). Cloud computing resources are natural channels to enhance these institutions' research productivity. However, utilizing cloud computing resources for research effectively requires a significant investment in time and effort, awkward manipulation of data sets, and deployment of cloud-based applications workflows that support analysis and visualization tools.

**Keywords**—*Collaboration; outreach; engagement; narrowcasting; conceptual; methodological; storage-as-a-service; software-as-a-service; data-as-a-service; infrastructure-as-a-service; platform-as-a-service; cloud-ecosystem; minority serving institutions (MSI)*

## I. INTRODUCTION

The current structure of the STEM education research enterprise highly favors individuals who can spend nearly full time on research and so take an idea from inception to publication at a competitive pace. This model is great for individuals at R1 institutions, while new scholars at smaller or less connected institutions cannot leverage communal connection to information supported by new cyberinfrastructure. The last two decades' research data has become a major defining force for America of its economic, social, and national importance. Over the last two decades, scientists within all sectors of STEM have witnessed an explosive rise of data ecosystems as a research tool, and universities are utilizing these infrastructures and their associated applications as an integral part of scientific discovery. The most commonly use tool is cloud computing environments; these ecosystems have emerged as a central tool in the scientific evolution of U.S. STEM rebirth. Additionally, the U.S. has become aware of the urgent need to educate a workforce in all sectors of STEM to take full advantage of these shared resource to ensure that the U.S. remains competitive in STEM research and scientific innovation [1]-[5]. Complicating this task is the diversity of research data that is being placed in such environments. This data is heterogeneous, and the volumes are unprecedented in

scale and complexity. It represents the next frontier for innovation, competition, and productivity in research [19].

Therefore, primary intellectual thrust of our research will come from a vision of providing a holistic pathway integrating multiple stakeholders, data sources, and training models to address both immediate and long-term data needs for researchers at MSIs utilizing cloud environments as their primary medium for research. Our project develops a service-oriented resource that assistances diverse communicate, navigate, connect, and inform the research activities of these communities. As a result, the Cloud Ecosystem in a Box (CEB) hub will have a transformational effect for these institutions to by enhancing and propelling research among minority communities and groups currently underserved.

The focus of our particular aspect of CEB will be around engagement that creates a theoretical framework of a network of practice[8], in which individuals can leverage a knowledge portal or hub to facilitates the diffusion of knowledge among a rather loosely coupled and often disconnected community [9]-[11], in certain disciplines i.e. (1) Cloud computing, (2) Nanoscience, (3) Bioinformatic, and (4) Cybersecurity.

Engaging these institutions with multi-disciplines, puts emphasis on data-enabled areas of research that can be achieved within the hub, which is a pivotal area of research in information science that examines how engagement within the context of educational activities can broaden and enhance community engagement with information sources or data.

## II. PROBLEM

Across the US, research has been broad and only been characterized through individual contributions in each field as separate entities with no single solution [1]. Tier1 research institutions and Universities greatly compensated, have the advantage in high caliber research, so primary data and secondary data mitigate and escalate to and from these campuses. Meanwhile low-income Minority Serving Institutions (MSI) that only make up 10% [1] of US institutions do not have the knowledge, capacity nor the funds to deliver top-tier data to research on, nor do they have the resources to properly engage training. Around half of MSI students have no inclination of cloud resources or what cloud resources can provide according to the results of the initial survey. Majority of Minority Serving Institutions (MSI) have no forefront knowledge of future endeavors on transitioning to cloud services provided by CEB.

Therefore, a grant has been funded through the National Science Foundation's (NSF) Directorate for Computer and Information Science and Engineering (CISE) to create an on-ramp to allocate resources for specific community domains. A funded EAGER Cloud-Ecosystem in a Box (CEB)(award:1842679) project serving the principal interface for providers in the CISE research community, the education community, and the public cloud community to contribute support from corporate partners by leveraging the Cloud Ecosystem in a Box (CEB). This grant extends cloud services to complement existing resources centered around completely different computational faucets of research. These recommendations were made at the NSF Cloud for Everyone (NSFC4E) workshop (award:1663794) also recommendations made at Enabling Computer and Information Science and Engineering Research and Education in the Cloud (ECISE-REC) workshop(award:818650).

Researchers all over the United States are over-exerted due to the volume of data being computed and stored over the vast cloud movement of processed data and crowd-sourced learning. This data has increased the number of activities to be hosted in particular with, Minority Serving Institutions (MSI), in which, these facilities has resulted in a great number of domain specific publications. In addition to the volume of this unorganized data, new findings are growing at an exponential rate and it has become more time consuming for researchers to draw conclusions within this area of collection of big data due to the lack of addressing engagement.

#### A. Dissertation Statement

Minority Serving Institutions (MSI) should have access to services such as building a cloud-based community to enhance research and infrastructure connected together. By using these engagement techniques, we can increase cloud-driven resources by 20%. Measuring analytic collaborations by building state of the art research and educational cloud ecosystems that leverage advance practices and training within a computational sphere.

#### B. Research Area Problem

How a Hub (CEB) that is an on-ramp onto cloud resources (via AWS, Google, Microsoft, Oracle) could serve Minority Serving Institutions (MSI) community needs and user needs.

With the focus of my research exerting towards Community Engagement by (1)building state of the art research and educational cloud ecosystem (CEB) that leverage advance practices and training within a computational sphere with Cloud providers, and (2)systematically engaging in response time and success of the CEB, plans are put into effect of a more precise nature to establish a mentoring network between Minority Serving Institutions (MSI), through contributing community/user-based needs respectively.

Also maintaining the CEB by being a beacon/liaison for community toolsets to train Minority Serving Institutions (MSI) for cloud-based learning in Cloud *Collaboration* through the life cycles (Phases) of the CEB. This enables superior cloud resources from corporate partners to be at the forefront of separate cloud research tools for a broader research area instead of local centralized research, to

accelerate innovation through user-defined computational cloud research while also addressing retention and scalable marketing.

### III. LITERATURE REVIEW

This literature review is designed to share similar work corresponding to cloud services provided through an ecosystem like the CEB. It will also compare complexities and pedagogies tied into the various levels of expanding cloud services to areas never incorporated. It will serve as a benchmark for new advancements within cloud services by aiding in filling gaps within the discipline and administering techniques for measuring success through the CEB expounding on the measurement of outreach, engagement, cloud ecosystems. I would like to start this literature review with XSEDE (Extreme Science and Engineering Discovery Environment) cloud services, because it is the closest infrastructure related to the CEB that I am most familiar with, also I have extensive expertise within this particular pedological area of cloud resources. I was reluctant enough to be a part of the services provided by XSEDE at the University of Arkansas at Pine Bluff where I practiced as the Campus Champion. My role expanded across a variety of activities such as helping institution researchers, educators and scholars with their computing needs. As the Campus Champion, I was engaged in high-end data intensive research focusing on large scale, high performance computing, distributed high throughput computing environments, visualization and data analysis systems, large-memory systems, data storage, and cloud systems. In addition, I attended/chaperoned the Supercomputing convention.

1) *In the paper "XSEDE: Accelerating Scientific Discovery"*, cloud resources are characterized as a co-existence between multiple cyberinfrastructure communities of scholars, scientists, engineers and researchers to form one ecosystem that addresses the most important and challenging problems [2]. XSEDE's realm of computational technologies and resources divulge in a process that is critical to the success of researchers. These digital services are accessed at a fraction of the cost that they ordinarily would, due to the outsourcing of their complexity to XSEDE. These advanced digital services make up different attributes of technology like supercomputers, storage systems, visualization systems, collections of data, networks and software. The paper emphasizes the motivation to integrate these computational services into a more general form as [2] "judiciously distributed but architecturally and functionally integrated from two arguments": First, the movement of scientific progress within multiple disciplines, which enables a combination of services and resources. Second, that top-tier digital resources are more capable by leveraging multiple smaller institutions, and not being centralized fully at a single institution. XSEDE, as an ecosystem of its on, has an ongoing interface for help-desk support, initiating allocations, and services for sharing other computing digital resources. XSEDE implements tools, policies, and methods that exist with top-tier facilities,

campuses, and government institutions as the beginning process for a national e-science infrastructure ecosystem. [3].

2) *The paper "open-source cloud management platforms and hypervisor technologies: A Review and Comparison"*, suggest further implantation of cloud-based solutions and measuring performance in an infrastructural environment [4]. It introduces cloud infrastructure and hypervisor technologies as a means to architect effective cloud solutions, also the need for continues emerging of new tools and technologies used to fit the needs of infrastructure ecosystems. Something very important within cloud infrastructure is what Cloud Framework should be implemented according to needs of the Cloud Service Provider. Software-as-a-Service (SaaS), Infrastructure-as-a-Service (IaaS) and Platform-as-a-Service (PaaS). It goes into intense discussion about Cloud Management Platforms used to deploy virtual machines and how a major consideration for the success of any cloud platform involves the activity and support of the development community behind the project. Hypervisors are introduced as a special operation system that hosts multiple Virtual Machines on a physical machine that allows simultaneous execution of entire operation system instances at the same time. The paper shows how when you combine several virtual machines onto a single physical server it provides on-demand computing to users in real-time. Discussion took place regarding identifying the best cloud technology through different studies, but in today's infrastructure needs it is enough to sustain several open-source cloud computing platforms that addresses difficulties in cloud environment [4].

3) *In the paper "DH Box: A Virtual Computer Lab in the Cloud"*, it outlines how instruction in Digital Humanities (DH) became more efficient since the creation of the DH Box [3]. Challenges within the classroom before the DH Box consisted hardware and software resources and installment/configure of DH tools running of multiple devices. Run-ins with IT departments played a major part in the attrition of facilitating the classroom and he states that on most campuses, computers were on complete lockdown. The author wanted to develop a portable, reproducible, and approachable way to get people interested in DH, up and running with DH tools with the creation of the DH Box starting out on a Raspberry Pi then graduating to the cloud. From local installs on user hardware to a web application that would be accessible remotely with the infrastructure that consists of a sign-in, front-in website, a back-end that listens for request, takes data and initiates the launch of a script, then the launch script itself, and a simple user menu. The DH Box had cut down on class time devoted to preparing technology, shifting the focus away from maintenance and configuration and toward learning and exploration where students were able to access DH tools from their own devices of their choosing [3].

4) *"STEM Outreach: A Literature Review and Definition"* is a paper that introduces a pragmatic definition of STEM outreach using a heuristic contextual framework [5]. Without

expounding on the ontological results used to complete the definition, this paper concludes the definition as:

"The act of delivering STEM content outside of the traditional student/teacher relationship to STEM stakeholders (students, parents, teachers...) in order to support and increase the understanding, awareness and interest in STEM disciplines."

Outreach delivery methods within this paper include Lecture, Active learning/Inquiry Based learning, Problem Based learning, Workshops and Training Events, and Camps and Events. Examining the College (Undergraduate through Doctoral) target area we see how college students can be both the target audience for STEM outreach programs and also to outreach efforts for younger age groups. Through an extended conference/camp where groups of target criteria can emerge educational support, we see an increasing number of providers and more program support. College students get enhanced networking and more exposure to a particular field of study.

5) *In the journal "CARES: Mentoring through University Outreach"*, characterizes a study which utilizes surveys, campus visits, interviews, and observations for a minority serving middle school [6]. These attributes are at the core of outreach, and within this study proves results to show reluctant change and improvement. The participants were students of the forementioned middle school was paired with a mentor selected and matched by race/ethnicity. The findings in this article articulate three major themes. First, the Cares act increased student's aspirations to attend college by providing access to information that expanded the realms of knowledge and exposed new thoughts and the idea that learning is fun. There are 4 categories that the article demonstrates within the first theme that constitute them for increasing the willingness for higher education: Exposure to new options and ideas, increased sense of purpose, feelings of acceptance and connection with mentors, and recognition of encouragement from mentors. Second, mentors experienced personal growth and benefits from their involvement in the Cares act. This second theme has influenced testimonies from the mentors themselves. All acknowledged the benefits, ranging from rejuvenation and increased motivation to growth in their skills and a sense of emotional satisfaction from seeing their influence on students' futures. Thirdly, the outreach from mentors to the students had decreased the negative socialization that characterized the educational experiences. School policy dictated that education was punitive and boring in which it discouraged them from considering higher education as an option. This outreach shows researchable mitigations in the inequities between the differences of white middleclass students and those of poor African American and Latino students. The policies and procedures within this middle school was evaluated because of the CARES act and staff and faculty came to see how the discipline policy discouraged students.

6) In the journal “*Outreach, Engagement, and the Changing Culture of the University*” the author narrates that in order to change the culture of an organization there has to be a noticeable crisis [7]. A recognized need for higher education to keep pace of an ever-developing societal change takes a forward standpoint pertaining to the culture of education. Outreach and Engagement are characterized by a reaching out from the university to the people and organizations a university serves, also the exchange between the university and its constituents. The author states that engagement is both outreach and in reach into the university by way of extending scholarly creativity to enhance cultural changes inside and out.

7) In the journal “*Outreach initiatives in academic libraries, 2009-2011*”, the purpose of outreach with academic libraries is reprimanded with budget cuts declining, also outreach is still on the rise [8]. This particular study represents comparing outreach initiatives through librarians to a particular project conducted by the author. The approach taken was sending a survey to academic librarians that influenced higher learning with outreach, marketing, and promotion. There were successful outreach initiatives in all categories and only a small response rate reflects the target audience. The findings of the survey conveyed a wide range of initiatives involving outreach that target funding. The authors project exceeded the cost of all other initiatives. Certain limitations identified survey flaws and the implications was just a small reach to the targeted audience. A modified survey to the academic library system involved in outreach and engagement is therefore included for future research. The practical implications hardly coexist with budget restraints, because many higher education programs across the nation have inserted outreach into public services positions. The value this type of outreach brings to the table produces limited research about successful initiatives within the spectrum of the timeline. Outreach from academic librarians will be inspired in the collected project outreach takes to create projects with limited funding.

8) In the paper “*Pre-university Outreach: Encouraging Students to Consider Engineering Careers*” outreach is discussed by activities being affected in educating students about the challenges and rewards of engineering careers [9]. It discusses the impact of certain programs motivating students to consider engineering educational pathways and career pathways. Originally the program was for female students partaking in a summer day camp. It now includes hands-on activities directly to the classroom presented as a co-ed program. There were multiple workshops ranging multiple years that combined males and females, then ranged with the classifications of each individual. The surveys portray a ripple effect with the percentages of K-12 knowledge awareness of engineering. It represents a convergence of STEM intelligence over the years that outreach becomes more and more successful. Proof of the before and after evaluations of student’s knowledge of engineering. The questionnaires and

evaluations give direct awareness for essential tools about the engineering profession at the pre-university level. It is still in its early stages to tell the increases in expansion of engineering enrollment, but the numbers don’t lie about having a positive impact on women in the field.

Whitney Bouk general manager of enterprise at Box said quote: “Future success for students and educators will be dependent on how well we integrate technology into our modern learning environments, Box helps schools to teach, conduct research and run their operations more creatively and effectively, while also giving students new ways to connect and learn. With our growing network of education partners, we are enabling students and teachers to take ownership of education [10]”.

Matthew Self Box VP for Platform Engineering said quote: “We’re transitioning from a world where the enterprise, and all of your enterprise content, are within the confines of your network and with applications you control, to this world where you have the cloud, all these different applications and all these different devices, with their content scattered all over the cloud. What Box is introducing is a solution... that will bring all of that content to a single place. By using Box OneCloud, we can leverage all of the applications that businesses want to use to run their business and store the data in a single place [11]”.

Liz Herbert, an analyst at Forrester Research said quote: “An interconnected network of add-on applications vendors, consultants and partners centered on an anchor cloud provider — and the benefits of a cloud computing ecosystem are outlined. It’s a way for organizations to balance agility and speed with control [12].

#### IV. METHODOLOGY

##### A. Initial Survey

1) *Stage/Plans of adoption for research topics:* The cloud computing technology fields provided in this question include Private/Internal Cloud, Storage-as-a-Services Only, Infrastructure-as-a-Services, Platform-as-a-Services, and Software-as-a-Service. The results show a top-down approach from the majority results to less inclined results based on answers given, also the same given the sub results of each category. The percentage equated for each category is calculated as the mean, and the sub results are the actual percentages articulated in the summary.

a) *Have no plans to use any of the Cloud Computing Services- 41.33%:* This first category ranks top priority among Minority Serving Institutions (MSI) survey results schematic. 41.33% Say they have no plans to use any cloud services. This tells me that research could be non-existent in almost half of the Minority Serving Institutions (MSI) participating in this survey. Having no plans to utilize cloud resources is a sure-fire reason why outreach should be manifested as a key component to the growth of desired infrastructure to move the cloud services via existing cloud resources to new communities.

- 50% Have no plans to use Infrastructure-as-a-Service.
- 43.33% Have no plans to use Private/Internal Cloud.
- 43.33% Have no plans to use Platform-as-a-Service.
- 40 % Have no plans to use Software-as-a-Service.
- 30% Have no plans to use Storage-as-a-Service.

Minority Serving Institutions (MSI) deemed Storage-as-a-Service more of a priority within this spectrum of down-top results. Which means Storage-as-a-Service is a more important field based on the results.

*b) Using in Production- 18.66 %:* This next category is the next top priority among Minority Serving Institutions (MSI) survey results schematic. 18.66 % Say that these stages/plans of adoption will be used in Production. Within this stage, the design, simulation, production, test, and maintenance of a product provides the whole lifecycle of the concept called cloud manufacturing. It provides a new paradigm developed from existing models under the support of cloud computing consisting of integrated and inter-connected virtualized resources for intelligent and on-demand use of services to provide solutions during the lifecycle of manufacturing [13].

- 33.33% Storage-as-a-Service will be used in Production.
- 23.33% Private/Internal Cloud ranks will be used in Production.
- 13.33% Infrastructure-as-a-Service will be used in Production.
- 13.33% Platform-as-a-Service will be used in Production.
- 10% Software-as-a-Service will be used in Production.

Again, Minority Serving Institutions (MSI) deemed Storage-as-a-Service more of a priority within this spectrum of results in Production.

*c) Using for Development and Testing only- 8.67%:* The third top category 8.67 % Say that these stages/plans of adoption are used for Development and Testing Only. It can be very costly and time-consuming to build the infrastructure for testing in a local environment. Scaling up resources when needed without investing in the infrastructure is what is utilized with cloud-based software development [14].

- 13.33% use Storage-as-a-Service.
- 10.00% use Private/Internal Cloud.
- 6.67 % use Infrastructure-as-a-Service.
- 6.67 % use Platform-as-a-Service.
- 6.67 % use Software-as-a-Service.

Once again Minority Serving Institutions (MSI) deemed Storage-as-a-Service more of a priority within this spectrum of results for The Development and Testing only Category.

*d) Plan to use but not sure when- 18%:* 18% Say that these stages/plans of adoption are Planned to be utilized but not sure when.

- 30% Plan to use Software-as-a-Service but not sure when.
- 20 % Plan to use Platform-as-a-Service but not sure when.
- 16.67% Plan to use Infrastructure-as-a-Service but not sure when.
- 13.33% Plan to use Storage-as-a-Service but not sure when.
- 10% Plan to use Private/Internal Cloud but not sure when.

Minority Serving Institutions (MSI) ability to looked forward and distinguished to use Software-as-a-Service as a priority. Maybe this survey is pushing researchers, students, and the public to recognize where resources are needed, and Software-as-a-Service holds grounds for future endeavors.

*e) Plan to use within: 3-6 months- 6.67%:* 6.67 % Say that these stages/plans of adoption are being Planned to be used within 3-6 months

- 6.67% Private/Internal Cloud.
- 6.67% Storage-as-a-Service.
- 6.67% Infrastructure-as-a-Service.
- 6.67% Platform-as-a-Service.
- 6.67% Software-as-a-Service.

*f) Plan to use within: 3 months- 3.33%:* 3.33% Say that these stages/plans of adoption are being Planned to be used within 3 months

- 3.33% Private/Internal Cloud.
- 3.33% Storage-as-a-Service.
- 3.33% Infrastructure-as-a-Service.
- 3.33% Platform-as-a-Service.
- 3.33% Software-as-a-Service.

*g) Plan to use within: 6-18 months- 3.33%:* 3.33% Say that these stages/plans of adoption are being Planned to be used within 6-18 months

- 3.33% Private/Internal Cloud.
- 0% Storage-as-a-Service.
- 3.33% Infrastructure-as-a-Service.
- 6.67% Platform-as-a-Service.
- 3.33% Software-as-a-Service.

*2) Applications planned to deploy over a 12-month period:* This question makes a relevant claim for CEB Cloud Services. Getting to know what Minority Serving Institutions

(MSI) plan to do as a whole can help mitigate activities involved in computing by transferring from a local machine location to cloud services online. We need to know what Minority Serving Institutions (MSI) have already done, that way we have cloud resources available on-top of already existing local resources.

- 29.87 % Say that Research Activities would be planned to be deployed over a 12-month period.
- 19.48% Say that Collaboration would be planned to be deployed over a 12-month period.
- 16.88% Say that Office productivity (e.g., Google Docs, Zoho) would be planned to be deployed over a 12-month period.
- 11.69% Say that Testing/QA/Staging would be planned to be deployed over a 12-month period.
- 7.79% Say that Web 2.0/Social Networking would be planned to be deployed over a 12-month period.
- 7.79% Say that Other(unspecified) would be planned to be deployed over a 12-month period.
- 3.90% Say that Monitoring/Application Performance Management would be planned to be deployed over a 12-month period.
- 2.60% Say that Security/Compliance would be planned to be deployed over a 12-month period.

3) *The Initial adoption of cloud computing within MSI was done by:* It is important for students or researchers to know the initial adoption of cloud computing in their institution. This is a question to see how literate the research community is with these services among their institutions. We find out how to distinguish as a whole among Minority Serving Institutions (MSI) where the discrepancies are, when it comes to cloud computing Literacy and direction.

- 29.17% Are not sure how the initial adoption of cloud computing was done on their campus.
- 25.00% Say Faculty for file sharing (i.e., Dropbox, OneDrive, Box.com).
- 16.67% Say A CIO/Senior IT Exec decision.
- 16.67% Say A departmental project.
- 12.50% Say A development team.
- 0% Say Cloud Infrastructure is not used at my institution.
- 0% Say other.

4) *Current State of Adoption (12-month plans):* This is a follow up question from the previous survey question The Initial adoption of cloud computing within Minority Serving Institutions (MSI). By understanding the initial adoption of cloud computing on your campus, you can give an interpretation of the current state of adoption or a 12-month

plan. Here we are interested in a 12 month plan due to the existence of cloud computing resources available via contingent on the results of this survey.

- 52.94% Says the adoption of cloud research remains the same.
- 29.41% Says the adoption of cloud research not sure.
- 11.76% Says the adoption of cloud research includes additional applications within the same department.
- 5.88% Says the adoption of cloud research includes additional applications across departments.
- 0% Says the adoption of cloud research Organizational-wide mandate to adopt cloud computing.
- 0% Says the adoption of cloud research other.

5) *How many employees work at each institution?:* This question is important because it gives focus on underrepresented Minority Serving Institutions (MSI). The idea of minority-serving institutions Minority Serving Institutions (MSI) having adequate high caliber research opportunities, or state-of-the-art facilities to collaborate research have been researched for years but minimally implemented. The caliber of research for Minority Serving Institutions (MSI) should be fundamentally congruent with resources and funds equal to or of greater depth with tier 1 institutions. The higher the funds and resources allocated; the higher caliber of research accomplished.

- 41.18% Of Minority Serving Institutions (MSI) employee 500-1000.
- 35.29% Of Minority Serving Institutions (MSI) employee 100-500.
- 11.76% Of Minority Serving Institutions (MSI) employee 5001-10000.
- 11.76% Of Minority Serving Institutions (MSI) employee more than 10000.
- 0% Of Minority Serving Institutions (MSI) employee 1001-5000.

6) *Mission critical applications for research:* This question gives momentum to cloud computing and is the catalyst that drives cloud resources. There are projects that require sophisticated resources for big data. With this type of adaptation researchers can use this process to integrate research-oriented cloud ecosystems that operationalize funded research projects concepts within Minority Serving Institutions (MSI).

- 47.37% Say they do not consider cloud computing mission critical for their research.
- 28.95% Say they do consider cloud computing mission critical for their research.

- 23.68% Say they are unsure to consider cloud computing mission critical for their research.

## B. Defining User Communities and User Desires

### 1) Define User Communities

a) *Cloud Computing*: *Cloud Computing* itself encompasses services rendered through the CEB to all the communities as services over a secured network purely online. On-demand services provided are HPC, storage, networking, analytics, databases, software, and AI delivered for faster innovation of particular research to achieve coherence and economies of scale [13]. Thus, *cloud Computing* drastically enhances the economic scale of research, and resources become flexible because the delivery mechanism encapsulates the services provided by overlapping platforms. The services provided are Infrastructure-As-a-Service (IaaS), Platform-As-a-Service (PaaS), Software-As-a-Service (SaaS), and Storage-As-a-Service (STaaS). These services overlap each other for full transparency of chosen delivery methods based on user domains.

b) *Nanoscience*: The study of extremely small things, the manipulation of materials on an atomic or molecular level to build microscopic devices. The Nanoscience community recognizes support of simulation programs in the cloud as to mitigate away from locally running software. The research tools and methods needed are aimed at fabrication methods and measurement tools along ways of measurement in regard to the characterization, design and synthesis within the ecosystems in place with goals responsible for commercialization of nanotechnology [15].

c) *Bioinformatics*: Bioinformatics is an interdisciplinary field entailed of Computer Science, Biology, Information Engineering, and Mathematical Science/Statistics that analyzes the interpretations of various data types. The role of *Bioinformatics* in cloud research extends to computation counterparts of analyzing and interpreting data. Large amounts of CPU time for tasks carried out in decomposed parallel development require users to work intermittently and facilitate continuous integration. This platform requires analysis to come to the data and to which the datasets expand in size.

d) *Cybersecurity*: *Cybersecurity* research is studying the defense of cloud systems from online attackers for the preservation of integrity, confidentiality, and availability of information in the cloud. These attacks take many forms i.e., Malware, Virus, Trojans, Spyware, Ransomware, Adware, Botnets, etc. Through *Cybersecurity* roles played in the cloud, there lies architecture built on top of layers spread across computing paradigms that hold different defenses on separate platforms. The technology used within this research entails of tools for protection from three main entity endpoint devices like: local/cloud/hybrid computers, routers, and smart devices. Also, technology used include, DNS filtering, antivirus software, malware protection, next-generation firewalls, and email [16]. As increased digitalization of human activities increase to improve lives by transferring data to the cloud, this increases vulnerability to being attached within the cloud.

### 2) Define User Desires

a) *Storage-As-a-Service (STaaS)*: Reported in the survey results MSI students who had somewhat of a degree of cloud computing or knowledge base on their institution says *Storage-as-a-Service* is what is needed at the current state. This is a top priority on the existence of the CEB resources being allocated through the NSF grant to get the CEB Hub off the ground. Research suggest that storage is a top priority in the cloud for small and medium businesses, universities, and organizations outside of the CEB so there are resources already available to help transition from local computing to cloud computing. They are extremely scalable pay as you go system and easy to manage and maintain.

b) *Software-As-a-Service (SaaS)*: This is the second service that serves the needs of Minority Serving Institutions (MSI) within a 12-month level plan to transition to cloud resources. A way to license hosted software for an extended period of time without purchasing or require a pay-as-you-go per user subscription of actual usage. *Software-As-a-Service* is an infrastructure that is most popular/common service over the internet. It correlates everything covertly that (*Paas*), (*Iaas*), and (*STaas*) is made up of infrastructurally which makes it more mature and to some extent more standardized or tailored software providers [17].

c) *Platform-As-a-Service (PaaS)*: Survey conveys Minority Serving Institutions (MSI) plan to use *Platform-As-a-Service* within 6 to 18 months as predominant adoption plan for cloud research. It allows complementary software resources as a development and deployment environment to capitalize on this infrastructure as a set of tools to build on-top of CEB resources. Within the time frame *Software-As-a-Service* will pick up off the ground, and top-tier research can be authenticated with training and collaboration.

## C. Understanding Firebase as a Backend Service

1) *Firestore Authentication Services*: Firestore backend services connected to the CEB authenticate users using username and password, phone numbers and federated identity, linking users accounts to social media providers into a single account on Firestore. Identification processes take an exhausting amount of time with traditional backend development, and Firestore takes that process out so you can focus on your users and not the sign-in infrastructure to support them. By knowing the identity of the user and creating an Authorization state we can customized an experience and keep their data secure, and we give them a choice of presenting login to the user. Either we can build our own interface or take advantage of Google opensource user interface (UI).

a) *Firestore Authentication SDK*: The identity of our users is crucial for the data to be securely saved in the cloud for a personalized experience across all devices. In order to accomplish this, Firestore Authentication tightly augments with other Firestore services leveraging standards of years of trial and error in the making of google services so it can be easily concatenated with a custom backend.

- Email and password-based Authentication – Create and Manage users through email and password sign-in. Password reset emails.
- Federated identity provider integration - (Google/Facebook/Twitter/GitHub/Apple/Microsoft/Yahoo).
- Phone number Authentication – SMS messages to phones.
- Custom auth system integration – Existing sign-in system to gain access to Firebase Realtime Database/Services.
- Anonymous Authentication - Create temporary anonymous account. If the user later chooses to sign up, you can upgrade to a regular account so the user can continue where they left off.

2) *Firebase database system*: Firebase's Cloud-Based Database query-based retrieve, sort, and filter data system supports real-time data syncing with no servers to deploy or maintain, it has real-time updates, and pay-as-you-go infrastructure. This is a NoSQL scalable infrastructure to store and sync data for server/client development. Firebase database systems carry mobile-first, real-time SDKs (software development kits) also in support of on-site storage for programs offline. Firebase offers two Database systems: (1) *Realtime Database* and (1) *Cloud Firestore*.

a) *Realtime Database*: Data is stored as JSON and managed as real-time instances that automatically receive updates within rich applications allowing secure access to the database. It provides a flexible language called the Firebase Realtime Database Security Rules which is an expression-based language used to define how your data access I/O, also defines how it can be structured. When paired with Firebase Authentication you can set up who has direct access to the communities and what services are provided through each community. This simple database system is set up for quick execution unlike an original legacy relational database in that it is set up for the whole user experience serving users of communities building real-time experiences without compromising on responsiveness.

b) *Cloud Firestore*: Like Firebases Realtime Database which allow for low-latency solutions for user devices requiring synced states across multiple mobile app platforms in real-time. Cloud Firestore builds on top Realtime Database software to create new, and more scaled data model offering rich, faster, and scalable queries that are further implemented based on the data. Following NoSQL pattern of database design, you store the data that support many different types, from simple strings and numbers to complex objects, in fields that are then stored in collections called containers that you can organize the build queries from. Querying in *Cloud Firestore* is expressive, flexible, and efficient. It creates shallow queries from documents without retrieving the entire collection, or subcollections. You are able to sort, limit, and filter into your queries to paginate your analysis in real time,

also you are able to protect access to sufficient credentials through Firebase Authentication.

3) *Firebase storage*: Storage, sync, upload and backup time capsule, and key configurations for Macs, Windows, etc. and different mobile devices, which makes them immediately available, so you can have easier ways to collaborate. Firebase cloud services allow to share important files without the hassle of attachments, but instead gives a link option to download in order to preview, you can set passwords and expiration dates for added security. Having access to be able to preview files before downloading is a perk with the iCloud system for the exception, that, in order to edit them, you will have to download the attachments then upload back to Firebase. Also, the cloud services have the ability to save the latest version of any paper, so you can have the latest document available every time while the older versions are also saved for reference. It gives flexibility to share folders and files with colleagues or the ability to set permissions for security. Basically, having private and public sharing at the same time. As with other familiar services, Firebase can create new documents, but has the ability to assign tasks which stops the need for data task management teams.

4) *Firebase machine learning*: Machine Learning is a small section of AI which incoherently focuses on training algorithms for data analysis that automates analytical model building. A process where tasks can be created without human interference specifying every step of an algorithm. This is where computers learn on their own from represented data where there are no fully satisfactory algorithms to accomplish a task. Firebase recognizes the need for cloud-based processing, the real-time capabilities of standalone devices, or the flexibility of ML resources geared toward cloud-based or mobile-optimized devices. Cloud-based devices include services like text recognition, landmark recognition, and image labeling application programming interfaces, perform inference in the cloud so they require more computational power for HPC, also require more memory so they can perform with greater accuracy and precision. Mobile devices include services for custom model deployment by uploading to the firebase server creating on-demand capabilities, and AutoML Vision Edge that is an app to help create custom image classification models with user-friendly web interfaces. These services are suitable for real-time and low-latency applications provided by optimized to run on mobile devices that don't require a network connection and runs very quickly. Video processing is best suited for processing frames of video in real-time. Firebase makes it simple with a service called the mobile SDK package to provide insights about the data provided.

a) *Firebase Predictions*: Firebase Predictions leverage ML analytics data, creating behavior influenced clusters of users so you can make research decisions based on predicted behavior rather than historic behavior. Firebase Predictions is consolidated with other ML resources mentioned above for cloud-based or mobile-device customized user experiences so

you can adjust the frequency of ads. You can increase retention by re-engaging a user who has predicted to opt-out of Firebase by sending a one-time campaign or automate sending messages for certain groups predicted to not return. Firebase also gives you the option to create your own predictions by creating a cluster based on prediction of any event defined in the analytics data in the near future. All this data is easily transferred to Google's *BigQuery* for further analysis for pushed into third party services.

b) *Natural Language Processing (NLP) / Natural Language Understanding (NLU)*: Natural Language Processing reluctantly is concerned with finding the interactions between human language computers by analyzing large amounts of language data and processing the contents for the contextual nuances then extracting information and insights from the data then organizing the documents by categorizing them under the pretenses of linguistics. Text recognition applies to automating data entry like credit cards, business cards, and receipts. Also extracting text from pictures for translating documents and increasing accessibility. It is optimized for both photos and documents, recognizes text in hundreds of different languages. Firebase Language Identification is used to determine the language of user provided text, which naturally does not come with any uniform language information of a string of text. The capabilities of text translation are limited for casual and simple translations using dynamic storage for downloading and on-device requirements by managing language packets. Firebases Smart Reply API automatically replies to messages by generating multiple reply suggestions based on the context of strings of sentences through a conversation. This API is intended for just normal conversations. It does this by comparing the messages against a list of sensitive topics, then the model provides up to three suggested responses dependent on a sufficient level of confidence.

## V. PRELIMINARY RESULTS

We started out addressing engagement of the CEB by (1) Defining User Communities, and (2) Define user desires based on survey result outcomes. The communities we are building are created from pain points within Minority Serving Institutions (MSI). We will continue address engagement of MSI's by measuring analytics of the CEB through response time through the retention/life cycle.

The results of the survey question Stage/Plans of adoption conclusively show that the overwhelming majority of Minority Serving Institutions (MSI) participating in this initial survey rule that cloud resources are novel. Meaning there is an unfamiliarity of resources beyond each institutions' limits on education. Based on this initial survey results, Storage-as-a-Service is a top priority when utilizing these cloud computing resources for the majority of Minority Serving Institutions (MSI) independently for the immediate moment. Next, Software-as-a-Service and Platform-as-a-Service is considered a priority for the future growth of the majority of Minority Serving Institutions (MSI) independently.

The adoption of infrastructural cloud services Cloud Ecosystem in a Box (CEB) across multiple campuses is integrated through a wide network that not only recognizes the need of increased viable research activities, but dedicated research in the classroom as well. Research Activities is ranked the most important at 29.87% to be utilized within the 12-month time frame. Collaboration, which according to the Survey Outcomes, holds 19.48% will also be an immediate undertaking within Minority Serving Institutions (MSI).

For the initial adoption of cloud computing on an MSI campus, here we intercept the knowledge gap and proceed to fill in the necessary timestamp that accrues when Cloud Computing education is not congruent with Minority Serving Institutions (MSI). There is a 29.17% majority of students that are not sure how the initial adoption of cloud computing was done on their campus. Next, we see that 25% of Minority Serving Institutions (MSI) say the initial adoption of cloud computing was done on their campus by Faculty for file sharing, 16.67 % say a CIO/Senior IT Executive decision, 16.67% also say a department project, and 12.50% say a Development Team. Here we see a portion of Minority Serving Institutions (MSI) collaboration on each individual campus. With the numbers being so low in comparison, we see the discrepancy with not only a shortcoming in cloud resources but an existence of ignorance (lacking knowledge or awareness) on each individual campus as well.

The results are conclusive with The Initial adoption of cloud computing within Minority Serving Institutions (MSI) when we see there is a knowledge gap of more than a 4<sup>th</sup> of students that are not sure how the initial adoption of cloud computing was done on their campus. As a result, we see 52.94% of Minority Serving Institutions (MSI) say the adoption of cloud research remains the same, and 29.41% says they are not sure. As stated previously in The Initial adoption of cloud computing within Minority Serving Institutions (MSI) conclusions, outreach should be manifested as a key component to the growth of desired infrastructure to move the cloud services via existing cloud resources to new communities.

The majority of our small MSI' 41.18% make up 500-1000 employees. The other majority of 35.29% make up 100-500 employees. Due to this underrepresented institution research sector which consist of mainly teaching institutions, both small and large [1], outreach should be attainable to sustain and utilize these resources by establishing a mentoring network to embody a relationship between mentor and student bodies with the boundaries set within each sector.

47.37% Say they do not consider cloud computing mission critical for their research. In response to nearly half of Minority Serving Institutions (MSI) response that they do not consider cloud computing mission critical for their research, again there is a trend and a consistency within these survey results that points to an education relapse of cloud computing. Previous research regarding this particular domain not only fails to address the logistics of how to properly incorporate an ecosystem, but to share, analyze, and draw insights from mined data.

1) *Storage-as-a-Service*: Transferring data from a local machine to the cloud can be reluctantly smooth, given the proper guidance and planning. Training as a top priority for outreach will be mandated to take steps to reduce any risks involved. The first thing that needs to happen before any research group starts to transfer, is to have a viable back up stored on a local machine. Reason is you don't know of any (1) security risks, (2) network connection interruptions, or (3) improper file organization. During transferring of data your files are pretty much in limbo or left in the hacker's world. Interruptions related to the network that has the network connection or the strength of the network can play a part in the loss of data. After the successful transfer of data from local to the cloud, you may find your data all in disarray. There are ways to find and organize your data, but keep in mind that keeping a backup will enable you to locate the right ones immediately. Next, research needs to be taken place on who will be a suitable cloud service provider.

CEB Cloud storage allows for offline availability and synchronizing/sharing of files on all API's providing universal access to any and all types of data stored within the CEB Hub. It provides a service layer on top of the storage services already allocated by storing all the data and metadata from the users and provides access from different faucets (i.e., FUSE access, WebDAV, XROOTD, Synchronization client, Web access, Mobile devices). How this is done is by an internal database that keeps track of the migration status for all the users of the system through home directory services. The goal is to consolidate storage solutions (i.e., Batch System, Windows Terminal Servers, Personal computers, Small/Private Experiments) into one service that can be accessed from any API, "incognito" the CEB Hub [18].

2) *Software-As-a-Service*: How Minority Serving Institutions (MSI) migrate Software-As-a-Service within this 12-month period depends on research capitalization. Collaboration supports the CEB design to support many different users safely and securely with unlimited scalability to support changing research. Coordinated efforts within communities makes the foundation become the anchor for a rich partner ecosystem.

What CEB offers with *Software-As-a-Service* within this 12-month period are resources on many levels of platforms to designated API's. The CEB resources for the communities maintain software that is delivered remotely by providers. The CEB offers ecosystem integrators that use their reputation to convince critical as-a-Service Minority Serving Institutions (MSI) solutions especially in response to security concerns.

3) *Platform-As-a-Service*: The move to Platform-As-a-Service among Minority Serving Institutions (MSI) will increasingly evolve Big Data correspondence with scalable software delivered in the cloud with pay as you go investment. PaaS is a cloud-based environment for coding and deploying applications that make coding for developers and IT professionals much more efficient. The type of Platform-As-a-Service the CEB offers is called an open-cloud PaaS where

it's not tied to a product or operating environment. It allows Minority Serving Institutions (MSI) to use a completely different platform therefore providing flexibility [19].

#### A. Cloud Ecosystem Design Infrastructure

1) *Ecosystem life cycle*: The best way to tackle our approach to gather access to cloud services is from a system engineering prospective, less from a developer perspective because the CEB Hub or onramp being built is a system with multiple interacting components performing functions that cannot be achieved by one component alone [20]. Therefore, we move forward with steps toward understanding and improving this multi-component faucet by designing and managing this complex system over its life cycles [21].

2) *Bird's eye view*: This lifecycle map is a user experience birds-eye view of an ecosystem approach to services rendered through the CEB. This diagram is taken from a source that expounds upon user experience/needs and world-class architecture in system design. This is the first step we must take to fully recognize what users of the CEB need and how to fully engage with them, also recognize future viability of emerging answers to questions and understanding of a cloud Ecosystem. The red circles represent the typical stages a user moves through when engaging with resources tailored to them specifically. The first five stages (Aware, Interest, Research, Consider, Purchase) represent from "prospect" to "user", then continuing until the user becomes aware of new services, capabilities, upgrades, and communities of the system their using [21].

"By looking at clusters, we can begin to see which stages are more important than others on a personal basis. We can look at the time required to move between stages as another element of the user experience, and again we may discover different users (Returning/Expert user or New-User) require different amount of time to transition from one stage to another [21]." Here we discover how the user interacts with specific elements of transition to uncover opportunities such as journey mapping to improving user experience leading to loyalty and returning research.

#### B. Pedagogy

1) *What is behind the CEB*: The pedagogy behind the CEB is a cloud service enabled by a complex system of unrelated independent components that work together to form a Symbian relationship of hardware and software integrated with consultants, cloud engineers, cloud customers and partners. In the center of this cloud service is a public provider (*Firebase*) that creates easy access for business or higher education to collaborate and share information with colleagues and clients. It offers storage, sync, upload and backup time capsule, and key configurations for Macs, Windows, etc. and different mobile devices, which makes them immediately available, so you can have easier ways to collaborate. *Firebase* cloud services allow to share important files without the hassle of attachments, but instead gives a link option to download in order to preview, you can set passwords and expiration dates

for added security. Having access to be able to preview files before downloading is a perk with the Firebase Cloud system for the exception, that, in order to edit them, you will have to download the attachments then upload back to *Firebase*. Also, the cloud services have the ability to save the latest version of any paper, so you can have the latest document available every time while the older versions are also saved for reference. It gives flexibility to share folders and files with colleagues or the ability to set permissions for security; basically, having private and public sharing at the same time. As with other familiar services, *Firebase* can create new documents, but has the ability to assign tasks which stops the need for data task management teams. The CEB will provide researchers with tools like RStudio, Jupyter notebooks, Linux OS, Windows, and other applications that enable Research Infrastructure within the CEB hub.

2) *Research infrastructure*: The service model platform used in this particular CEB cloud framework is utilizing the Infrastructure-as-a-Service (IaaS) model. [4] In this type of architecture, the cloud provider (Firebase) manages IT infrastructures such as storage, high performance computing power, data warehousing, security, server and networking resources, database access, big data computing environments, monitoring/manageability, and more by way of our providers (via AWS, Google, Microsoft, Oracle). There is a way to address this through the way of a hypervisor (CEB), which is a (user friendly) virtual machine monitor that host multiple VM's on a physical machine. This type of monitor allows simultaneous incorporation of different types of operation systems at the same time and provide instances of the diverse machines to users on demand [4]. With the Hub (CEB) portal activated, we see the CEB as an Infrastructure Provision cloud model. This means that the Minority Serving Institutions (MSI) utilize the cloud using the technology as a provisioning tool to supply on-demand virtualized resources. [4] The cloud model used in this project examines different types of characteristics customized for the various needs of our Minority Serving Institutions (MSI).

3) *Data mining*: Data mining refers to predictive analytics, a field of study recognized in Machine Learning that focuses on exploring data through unsupervised learning to discover previously unknown properties (Entity Resolution) in the data. When dealing with high volume big data projects, the successful implementation of the CEB life cycle become more difficult when dealing with issues related to *Data Governance*. [22] That is why resolving real issues related to the cloud services offered through CEB should identify the highest impact failures that can occur, then using work processes, risk management, and optimization methods to such services. [23].

a) *Primary/Secondary data*: Using the CEB, resources will be available for designing and populating secondary data resources that researchers can use to integrate already existing data with primary data. With this type of adaptation researchers can use this process to integrate research-oriented cloud ecosystems that operationalize funded research projects

concepts within Minority Serving Institutions (MSI). Using the CEB will solve many challenges, mainly the challenge of meta-synthesis where scholars understand how different forms of evidence, variables, and analysis fit together to formulate a plan so the researchers can identify a specific research question, search for, collect, and combine evidence so the research question can be enhanced and to identify which variables from separate data sets may be made comparable to one another.

b) *Descriptive metadata*: Our descriptive metadata will support numerous STEM researchers' efforts to identify and obtain data for comparative analysis across states/countries fit for compiling details on appropriate data sources, institutional locations and contact information for acquiring this data. The web based descriptive metadata will have the advantage of advanced cloud hypervisor capabilities with the CEB central hub (BOX) allowing researchers to upload further details based on their own use of data resources.

### C. Research Focus

1) *Collaboration and outreach*: Cloud resources enable Collaboration at its highest level, and the CEB will address the cons of cloud computing through Collaboration, by expanding on how access to real-time engagement tools offer strategies of deployment. The benefits of Cloud Collaboration exist within each community and are exercised within each group working on a particular research project also within the maintenance and management of the CEB. As you scale back from a bird's-eye view to see the logistics and the institutional boundaries, questions arise on how Outreach is attainable also how retention is manifested. Most existing national and international data are not designed to focus on the relationships between social groups relevant to our work, but through the CEB's community/user-based discussions will rethink the use of these measures. Therefore, Outreach should be manifested as a key component to the growth of desired infrastructure to move the cloud services via existing cloud resources to new communities.

2) *Measuring analytics*: Firebase Cloud Messaging offers different ways and ranges of messaging options and capabilities allowing you to send notification messages that are displayed to the user or data messages to determine what happens in your application code used by the client application. Notification messaging is used for user re-engagement and retention. Firebase Cloud Messaging targeting is very versatile, you can distribute messages in three separate ways: to single devices, groups of devices, to user devices subscribed to their different communities by either Message delivery reports, or Notification funnel analysis. You can export your analysis to Google's BigQuery Database infrastructure for further analysis. Firebase Cloud Messaging also makes messaging available through client applications by sending back to your server over its batter-efficient channel set up from settings for relevant engaging messages, targeted messages by community, and flexible custom alert. This helps you engage your applications active users by sending them

targeted messages encouraging them to use more of the application features for exploration and discovery.

Mailchimp is a cloud-based marketing automation platform designed for email campaign for a targeted audience. It offers Automated email creation and sending, it is easy to use, it has built in statistics and has a style guide and knowledge base. It is a tool that manages your mailing list for you, and also allows you to create your own custom email templates.

Social Media will be used at a level of networking and outreach to target our particular MSI groups through awareness.

The Backend Functionality configures a serverless framework in response to triggers or HTTPS requests that automatically run in the background. After you write and execute the function it immediately begins to manage as it is triggered.

#### D. Front-End Web Development

1) *Becoming a member*: In order for a user to become a member into the CEB portal, you have to get Authentication credentials from the backend set within the Authentication methods noted in the backend text. The credentials are then passed to the Firebase Authentication services, once verified there is a callback response to the client. Once Authenticated by the backend services of Firebase, you can manipulate access to storage, computing power, processing, etc. by modifying the rules set within Realtime Database Services and Storage Security Rules within the Firebase infrastructure.

2) *Log In*: Users login through the CEB Log in portal either by username and password or by a federated identity, once users are Authenticated through Firebase, the users are placed in their respective communities through the Oauth state, then the community helps them move their research into cloud ecosystem. Firebase backend services connected to the CEB authenticate users using username and password or federated identity, linking users accounts to social media providers into a single account on Firebase.

3) *OAUTH*: In order for firebase to know which community the logged in user has chosen, there is a script located within the Oauth state that pulls from the database. The Oauth function is also in charge of maintaining state for each user. It fires back at the backend services of firebase so that the user maintains state.

4) *Database*: At this point the Realtime Database is being used due to the small amount of prototyped user engagement, also its low-latency solution for synced states. This type of database is persisted locally, and able to allocate real-time events offline giving the end user a responsive experience. When online services are regained and the connection is secure, the changes made will merge any conflicts automatically that occurred while the client was offline.

## VI. SCOPE AND TIMELINE (12-MONTHS)

### Deliverable 1: Feb 2022

T1: Design methodology to deliver identifying quantitative and qualitative data-driven research and resources to the CEB community.

T2: Measuring data mining using message streams elements, the best tools to engage with them are channels tailored for each group.

- o Sentiment Analysis

### Deliverable 2: April 2022

T1: Identify content management strategies that best suits this unique community based on user feedback from each group.

T2: Local CEB members and lead correspondence officers will take the lead to develop policy procedures to work with campuses on sustaining CEB's computational research activities and resources for the long term.

- o Science Gateways

### Deliverable 3: June 2022

T1: Developing a funding strategy for new research hosted in the cloud ecosystem is a top priority for the longevity of the program.

T2: Design branding strategy, user guidelines, and content policies for the ecosystem.

- o Code of Conduct

### Deliverable 4: Aug 2022

T1: Finalize the CEB Community Groups based on user feedback from survey. Then tailor the users back into their communities.

T2: Test Beta version resources and functionalities

### Deliverable 5: Oct 2022

T1: Expanding the first wave of users in the MSI community

T2: Identify outreach opportunities to educate

### Deliverable 6: Dec 2022

T1: Promote CEB to the second wave of users in the MSI community.

T2: Consolidate a mentoring network between institutions, corporate partners, and certification organizations to enhance student-mentor relationships throughout the CEB ecosystem

- o Certifications from Providers

## VII. IMPLICATIONS

### A. Where are we now

1) *Conceptual*: The conceptual contribution conveys focus towards ideas and communication about CEB. Participants from different disciplines and backgrounds within the sphere of different communities: (1) Cloud computing, (2) Nanoscience, (3) Bioinformatic, and (4) Cybersecurity, focused on Minority Serving Institutions (MSI) discussing proposing these research communities to build new research and educational practices to advance leveraging cloud provider ecosystems. These discussions emphasized computational collaboration concepts and introduced new research techniques to using these cloud provider ecosystems. Also, these discussions served to identify critical points of commonality or identify entity resolution within the data in already existing primary data and archived these details in the descriptive metadata to create a sustainable commodity for researchers all around the world, in particular resource challenged institutions Minority Serving Institutions (MSI).

a) *Existing Initiative (Existing)*: Existing Initiative involved public talks, blogs on current topics and publishing in magazine outlets. Meetings convened inviting researchers, policy practitioners and non-profit members, cloud providers. The meetings focused on adapting and refining core ideas within CEB. Participants from different disciplines, and institutions will identify relevant research themes within projects with emphasis on articulating meta-level concepts that are robust and meaningful across national contexts. The first part of this project for year 1 we relied on participants from different disciplines to focus on establishing core ideas within CEB through a virtual meeting broadcasted in real-time via EVO. This meeting emphasized computational concepts on a national level by adapting and refining core ideas within CEB. The main goal of the first part was to showcase the work done and to introduce the community and new research techniques using cloud ecosystems. Within this portion of the project, we developed the conceptual framework for research migration into cloud ecosystems, to include a searchable web-based metadata for quantitative and qualitative data for participating institutions, including primary data from ongoing research specifically designed for researchers to operationalize data-oriented research concepts at these institutions.

b) *Education (Current year 2020-2021)*: Education included classroom innovations, service-learning pedagogies, and graduate webinars to bring together researchers between annual meetings. We invited researchers and postdoctoral students to share their experiences and present individual research activities on both public/private cloud environments. The goal was to both showcase the work done, but also to introduce the community to each other and new research techniques using cloud ecosystems. Provided self-contained learning modules for national certifications, nanodegree programs around cloud computing/cybersecurity resources such as, Cloud Platform-as-a-Service, Cloud Security and

Data Protection, and the practical tools used to store, and process access these systems.

2) *Methodological*: The *methodological* contribution conveys focus on survey result conclusions for user-based needs pertaining to mined research tools that will be mapped as a research Data-as-a-Service (DaaS) Data that already exists with emphasis on data-enabled areas of research by reaching out to corporate partners. This was the pivot point to which educational activities are broadened and enlightened through Data-as-a-Service (DaaS) rather primary or secondary, that have a case-based level on a national scale.

a) *Networking (Current year 2020-2021)*: *Networking* Video archives of talks, working papers, call for participation in conferences, links to social media, newsletter updates, the descriptive metadata, elaboration of our in-common research design and shared educational resources. All presentation materials are broadcasted in real-time via EVO. Participants are tasked with identifying quantitative and qualitative data-driven research that exist for participating campuses to be leveraged in the new ecosystems. The PIs in collaboration with the core committee members designed and deployed a Hubzero portal (CEB) on Open Educational Resources Commons (OER) to highlight innovative intellectual, methodological elements associated with project activities. This Hubzero portal (CEB) serves as enduring library of unique content, while facilitating collaboration for the MSI audience around deploying research on the cloud. Also, establishing a mentoring network between institutions, corporate partners and certification bodies to foster student-mentor relationships within and across institutional boundaries.

b) *Publishing activities (Current year 2020-2021)*: The second part of this project for year 1 constituted identifying quantitative and qualitative data that exist for participating campuses discussed in part one. The key innovation here is methodological in nature for the sheer qualitative case-based data sets and national-level secondary data sets relevant to the CEB. The combined conceptual and methodological work makes the logic keen to realizing the intellectual merit that goes into the CEB, not to mention the intellectual innovations. During this second part we developed an extensible research design for robust mixed-methods research associated with leveraging these ecosystems for (1) bioinformatics, (2) cloud computing, (3) nanoscience, and (4) cybersecurity. Developing the Hubzero portal (CEB) served as a resource for experiential-based learning in cloud ecosystems around cyber infrastructure.

3) *Bring it Home*: Using the CEB, these Minority Serving Institutions (MSI) will begin to engage computationally and collaboratively within the cloud community it serves. With addressing the methods within this study and an expected scope of future goals, Visualization and Data Analysis System will increasing become more aware within these institutions and faculty will begin to gain value and be better prepared using CEB cloud resources. High Performance and Distributed

high Throughput Computing will no longer be accepted into research only for R1 institutions. The CEB will restructure the way research is conducted and will encompass the minority research community, NSF funded ecosystems, and industry partners creating a triple convergence.

Through marketing the CEB, this is the first step to being proactive in outreach for the continuation of services rendered through the CEB. The first plan of action that was already preceded is to target Minority Serving Institutions (MSI) by developing a list of users based on NSF awards on their respective research areas of communities. Then the idea was to narrow this list by geographical location then send out a survey to measure the interest and needs of each community based on gender and demographics. Results from the survey helped us understand the dynamic within each dialect of data-driven research within each respective community of Minority Serving Institutions (MSI). Continuation of marketing throughout the life cycles of the CEB merits different styles of advertising and finding ways to target an indecisive audience. [24].

The CEB will provide at a national level the infrastructure for training program platforms by reinforcing the conceptual framework for research migration into the cloud ecosystems. It will be a direct centralized portal to provide users with: (1) applications to enable them to operate at real-time intervals within parallel computing power, (2) educational material such as links, mailing list, repositories, and YouTube channels pertaining to each Minority Serving Institutions (MSI) research to extend MSI networking through social media engagement, (3) Tools that enable data-driven research: programming interfaces, operating systems over hypervisor VM's, and a liaison/beacon for training.

Cloud services within each of these communities provides stable software platforms Infrastructure-As-a-Service (IaaS), Platform-As-a-Service (PaaS), Software-As-a-Service (SaaS), and Storage-As-a-Service (STaaS) with an associated larger community of providers ((via... AWS, Oracle Academy, Microsoft Azure, Google)) who can provide support and solutions specific to a researchers' domain, using these research specific public cloud providers that make up their own ecosystems [25].

### B. Next Steps

Building the Communities will be incorporated in the CEB website as tools connected to the cloud providers provided cloud messaging, message bird, trigger emails functions, chat, storage, and machine learning. Upon success of the creation of a conceptual framework to incorporate searchable web-based metadata for computational research, and the developing of a Hubzero portal CEB that will be the center of ongoing research in learning cloud systems communities: (1) Cloud computing, (2) Nanoscience, (3) Bioinformatic, and (4) Cybersecurity. Broadening the scope and intellectual impact of the CEB will be established to build other branches of research. This research includes primary data from current research participating institutions, providing self-contained learning modules like Cloud Platform-as-a-Service, Cloud

Security and Data Protection. These include public initiative, education, publishing activities and networking.

Measuring and understanding engagement on any platform is a complex undertaking that requires understanding multiple interconnecting ecosystems. To ensure the project was manageable in the timeframe of our funding, we initially created a survey instrument to select researchers at MSI, that are interested in migrating their research into cloud environments. This will allow us to design discipline level guides to facilitate this movement. In particular to measure engagement, we will capture the following elements, (1) user driven streams from each group i.e. nanoscience, cybersecurity, cloud computing and bioinformatics. (2) The project will be able to store publicly broadcasted messages, which are directed from users, particularly group followers; (3) The project will be able to determine the geographical location of the messages recorded; (4) The project will be able to retrieve user histories to aid in the fabrication of conversation instances; (5) The project will be able to extract all pertinent information from a tweet to aid computational processes; (6) The project will be able 'created\_at' stamp which is a more mathematically friendly timestamp of the format MM/DD/YYYY ##:##:##, this will provide context when the message was created; (7) The project will be able to determine the participation of each user involved in a given conversation with a user group; (8) The project will be able to directly query a NOSQL database to keep all data structured and organized by individual user and research groups.

# BEAM: A Network Topology Framework to Detect Weak Signals

Hiba Abou Jamra, Marinette Savonnet, Éric Leclercq  
Computer Science Department - EA 7534  
University of Burgundy

**Abstract**—In these days, strategic decision making and immediate action are becoming a complex task for companies and policymakers, since the environment is subject to emerging changes that might include unknown factors. When facing these challenges, companies are exposed to opportunities for growth, but also to threats. Therefore, they seek to explore and analyze large amounts of data to detect emerging changes, or so-called weak signals, that can help maintaining their competitive advantages and shaping up their future operational environments. But due to the increasing volume of daily produced data, scalable and automated computer-aided systems are needed to explore and extract these weak signals. To overcome the automation and scalability challenges, and capture early signs of change in a big data environment, we propose a framework for weak signals detection relying on the network topology. It is implemented under the Cocktail project framework whose goal is to create a real-time observatory of trends, innovations and weak signals circulating in the discourses of the food and health sectors on Twitter. This method analyses quantitatively the network local structure using the graphlets (particular type of motifs) to find weak signals. It provides accordingly qualitative elements that contextualise the identified signals, which will allow business experts to interpret and evaluate their dynamics to determine which ones may have a relevant future. After testing this method on different types of networks (we present two of them in this paper), we proved that it is able to detect weak signals and provides a quantifiable signature that allows better decision making.

**Keywords**—Weak signals; network analysis; network topology; graphlets

## I. INTRODUCTION

In recent years, we have noticed an increasing demand to anticipate emerging issues or so-called weak signals, which could help making strategic decisions for future opportunities or threats. In a complex and dynamic world where information circulates rapidly, companies must monitor their environment, in order to adapt and anticipate the market. Monitoring the environment is important in detecting and acting on weak signals, just as it is important to pay attention to transmitted signals at the periphery of the companies' activities without being distracted by the mass of available information. Let's take the example of a soft drink manufacturer who competes with manufacturers of water and new types of beverages instead of traditional colas. The solution to mitigate the risks consists in broadening one's field of vision and thinking by analyzing different sources, such as social networks, blogs and specialized newspapers where one's competitors and customers can express themselves. The information produced by social networks allows decision-makers to have a peripheral and

broader vision, and constitutes a source for finding weak signals announcing future threats or opportunities for the company [1], [2]. However, identifying these weak signals usually hidden amidst a large amount of noisy and strong information, and interpreting them when events are not known in advance, becomes a complex problem for researchers [3].

As early as 1975, Ansoff was among the first researchers exploring the field of weak signals. Afterwards in [4], he explained that a weak signal contains partial information available at the time a response is needed. This information must be completed before the signal becomes strong and has an impact on the company. Thus, the identification of a weak signal may announce a future event, its nature (opportunity or threat), its potential impact and the delay before it occurs. The process of carrying out these steps has been described by Ansoff as a graduated response by amplifying weak signals in relation to the level of information. Hiltunen [5] introduced the concept of future sign in which she defined the weak signal using a three-dimensional model: signal, event and interpretation. She aimed to describe a weak signal using the criteria of its visibility, diffusion and amplification. Other terms and definitions qualifying weak signals by author and field of research, are given in Table I.

TABLE I. DIFFERENT TERMS FROM THE LITERATURE TO DEFINE A WEAK SIGNAL, CLASSIFIED BY FIELDS OF RESEARCH

Author	Field of research	Description and terms
Godet (1994)[6]	Economy, strategic prospecting	A factor of a big change hardly perceptible at present; Component of a strong trend in the future.
Coffman (1997)[7]	Business management studies	Initiator of an important event, of a future trend; Signal beyond perception, or within perception but unrecognizable.
Hiltunen (2010)[8]	Event-related future studies	Early information or first symptoms of an emerging event; The emerging event itself.
Welz (2012)[3]	Social media, innovation management	Incomplete and imprecise information that is often not perceived; Evidence of strong discontinuities of present trajectory.

We hereby choose as definition for a weak signal:

*Weak signals are information that provide an indication of upcoming or emerging events that may have significant implications. The information provided is often imprecise, ambiguous and incomplete.*

We propose a method called BEAM<sup>1</sup> to detect weak signals and to help business experts in their interpretation. Although this method can be applied on different data sets, we implemented it under the context of Cocktail project to help companies to monitor their image on social networks (especially on Twitter), by detecting weak signals that might be a source of future threats or opportunities. Moreover, we provide a description of weak signal dimensions based on Hiltunen's model. The first two dimensions are translated by the signal support which is a graph built from the data of the study corpus, and a phenomenon/cause<sup>2</sup> which is a precursor of the event. For example, a tweet issued on April 14, 2021 by the official account of Game of Thrones television series, announces a potential remaking of the final season diffused earlier in 2019. The account tweeted "Winter is coming", just as it had done in previous years to announce a new season. Two hours later on the same day, the account again tweeted a video remembering a character's journey in the show. We can consider these tweets as the cause that triggered the weak signals announcing a new (or a remake) season of this show. The third dimension, interpretation, that we use in BEAM, depends on the competencies of experts or decision makers to give meaning to the detected weak signals.

Most weak signal detection approaches study the emergence of keywords using text-mining techniques. Other approaches look to identify the time points at which a behavior of change occurs, so they tend to extract interesting patterns from time series data. Another problem rises is that the data sources used to explore weak signals contain large volumes, which makes their processing and analysis a costly and time-consuming task, so that traditional methods often fail to unveil some of the strategic hidden information. Therefore, it is crucial to adapt a maximum of automation in the detection process. In our proposed approach, we do not consider these techniques neither those that are event detection-based.

Our method relies on the network topology since it allows to explore the local structure of the network and helps finding patterns that can constitute a quantifiable property of the weak signal. Our contributions are the following: 1) we automate the task of weak signals detection, and 2) we provide complementary elements that will help business experts in the interpretation of the detected signals, so that they finally judge their usefulness in a strategic decision or action.

The rest of this paper is organized as follows. Section II presents some of the related works of weak signals detection. We introduce the main steps of our method BEAM in Section III. Section IV presents two use cases and their results and Section V presents some limitations and a discussion. Finally, we conclude the paper and discuss some directions for future work in Section VI.

## II. RELATED WORK

In this section, we provide a synthetic description of some major works on weak signal detection, classified according to their detection techniques. Three main categories can be

identified: 1) methods based on keyword mapping; 2) methods based on topic modeling; and 3) methods based on network motifs.

The first work is due to Yoon [9] who proposed a quantitative method based on text mining with keyword analysis to identify topics as weak signals in the field of solar panels. The method relies in the search of keywords having a low frequency of occurrence which reflects the visibility of the signal, and a high and increasing rate corresponding to its diffusion. The developed method proposes two metrics: the degree of visibility (DoV) represents the frequency of the keywords in the set of documents, the degree of diffusion (DoD) represents the frequency of the documents. A keyword with a low DoV and a low DoD is considered as a weak signal. He used these metrics to build the Keywords Emergence Map (KEM) and the Keywords Issue Map (KIM). However, Lee and Park [10] then Krigsholm and Riekkinen [11] raise two pitfalls: 1) the problem of uncertainty when the same keyword is at the limit of several quadrants or appears in different quadrants for both maps; 2) the problem of interpretation that occurs when there are several meanings for a given keyword. In addition, keywords related to weak signals are, in general, isolated terms and the absence of relationships and context limits the information in further interpretation. Griol-Barres et al. [12], [13] use a third measure, the degree of transmission (DoT) to assess the importance of keywords. DoT takes into account the documents' h-index where keywords appear. Kim and Lee's approach [14] is based on "document/keywords" matrices. A weak signal is seen as a rare or unusual keyword (outliers) and it is not related to existing topics (cohesion). Analyses are implemented with the Local Outlier Factor (LOF) algorithm [15].

The main interest of using topic modeling techniques is to infer topics from a corpus of documents. In [16], Maitre et al. used Latent Dirichlet Allocation (LDA) with Word2Vec to detect a topic related to a weak signal. For these authors, a weak signal is characterized by a small number of words per document, present in few documents, and unrelated to other topics. Other works have also focused on the detection of weak signals using dynamic LDA as in [17] and [18].

Some researchers have been interested in identifying specific patterns in the networks, called motifs, which could be considered as precursors of events. Baiesi [19] presented a method that studies the correlations between graphs from earthquakes, using tools on network theory. He found that simple patterns such as triangles are an interesting type of major event precursors because they were found in all three studied earthquakes. Kwon et al. [20] use Minimum Spanning Tree (MST) and apply betweenness centrality on the graphs. They consider that a weak signal appears as the node with the lowest centrality score. Moreover, Kim et al. [21] propose the NEST model that collects information from expert networks worldwide. They applied clustering, pattern recognition, and cross-impact analysis using a Bayesian network.

Others considered that weak signals can characterize real-world events, therefore the authors in [22] used tweets frequency and sentiment analysis in an attempt to detect weak signals, using tweets collected during the London riots in 2011. Another study using keyword and sentiment analysis was discussed in [23], where the authors proposed a model

<sup>1</sup>BEAM: a ray or shaft of light beams from the searchlights, a collection of nearly parallel rays (such as X-rays) or a stream of particles (such as electrons), a constant directional radio signal transmitted for the guidance of pilots.

<sup>2</sup>phenomenon = observed fact, normal or surprising event

for predicting a movie performance after its release, using the tweets frequency rates and sentiment analysis.

In contrast to the above studies, our work considers the diffusion and amplification of the signal as important criteria in the detection process (as seen in [5]). In addition, when dealing with social data, it is difficult to apply topic modeling and LDA techniques. Social data consists of short texts (for example 280 characters at most in a tweet), and often contains abbreviations and spelling errors. Moreover, as opposed to these works, our method is not limited to user-generated content analysis but considers a multi-dimensional approach consisting of various data analysis and visualization methods - both quantitative (detection) and qualitative (interpretation). Therefore, we rely on the works related to the identification of specific patterns from the network, since they support our hypothesis that graphlets, which are network particular patterns, can be weak signals.

### III. PROPOSED FRAMEWORK

Our goal is to provide a weak signal signature; this signature is a quantifiable property of signals that is characteristic of a weak signal [24]. We want to detect weak signals from social network data particularly, that can be represented as an interaction graph between entities. Therefore, the proposed method is based on a topological analysis of the network, in which we have chosen the graphlets as an operational description of weak signals. Indeed, graphlets present characteristics generally associated with weak signals. According to [25] and [26] they are:

- fragmentary and not very visible because they are small sub-graphs;
- meaningless, in fact considering only a sub-graph of at most 5 nodes does not mean much in the mass of data produced by social networks;
- interpretable by business experts by means of their predefined shapes and orbits.

We assume that graphlets allow to automate the task of detecting weak signals in a large volume of data while leaving room for interpretation by experts, thus eliminating the black box effect that a fully automated method could have.

Our method is based on a standard data processing pipeline that includes data collection and exploration, before the detection of weak signals, as illustrated in Fig. 1 and detailed in the rest of this section. In the first step, we prepare the collected raw data, and build the study corpus which is then divided into snapshots of the same duration, for a more refined study. In the second step, we examine the data of the study corpus by applying algorithms and measures for network topology analysis for each snapshot. Then, we identify precursors using different filtering and selection methods. A precursor is an observable and clear fact present in an organization's operational process and caused by existing factors in the process [27]. In the last two steps, we define criteria to qualify the identified precursors as weak signals, and provide contextual elements to interpret them.

#### A. Raw Data Preparation

BEAM applies to all data types that can be modeled in the form of a graph. For example, we can find such data on the platform <https://www.data.gouv.fr/fr/> which makes available French public data. Data from social networks like Twitter and Facebook can be modeled as a labelled graph. However, their semantics is complex because the relations are multiple and context dependent. For example, thanks to a graph we can represent relationships between individuals that can be reciprocal or not, hostile or favorable. Specialized forums and scientific blogs like StackOverflow or MathOverflow can also be modeled as a graph representing interactions between entities.

TABLE II. EXAMPLE OF INTERACTIONS BETWEEN ENTITIES

$u$	$v$	$t$	$i$
1	2	1643207148	RT
1	2	1643207149	Q
2	3	1643207149	RT
1	3	1643207150	RT
2	1	1643207150	Q
2	3	1643207150	F
2	4	1643207150	R

BEAM takes as input data a list of interactions where each row represents a four-component tuple of the form  $(u, v, t, i)$ , where  $u$  and  $v$  are the identifiers of the entities in contact (e.g., accounts of Twitter users, or two hashtags that are in the same tweet),  $t$  determines the time at which the interaction took place. The time can take different formats such as a string or a timestamp epoch<sup>3</sup>, etc. The  $i$  component represents the type of interaction. For example, Twitter has often been modeled as a graph in which the nodes represent users (or hashtags and urls), and the edges represent different types of interactions that exist between the nodes, like a user retweeting (RT), quoting (Q), replying (R), or following (F) another user, or the co-occurrence of hashtags. As well as replies or mentions on other users' Facebook posts, questions and answers on a scientific forum, etc. Table II shows an example of interactions. If several interactions took place at the same time, we find several rows with the same value on the  $t$  component in the interaction list. In this table, the first two rows represent interactions between entities 1 and 2 at two different dates ( $t = 1643207148$  and  $t = 1643207149$ ) with two different types of interactions. The last four rows of the list represent four existing interactions between different pairs of entities for the same time ( $t = 1643207150$ ) with different types of interactions.

In the following, we describe the first three phases of the data preparation step.

1) *Raw Data Cleansing and Filtering*: The global corpus is composed of the raw list of interactions before being processed and filtered. Based on the raw list and the context of the study, it is possible to reduce the data in this corpus by specifying criteria to select only the data that matches the chosen criteria, such as filtering tweets containing hashtags about a topic of interest or some interactions of interest  $i$ . Several existing interactions (sometimes having different types) between the same pair of entities at the same time, are grouped together.

<sup>3</sup>Number of seconds elapsed since January 1, 1970 at 00:00; e.g. "26/01/2022 15:25:48" corresponds to timestamp 1643207148.

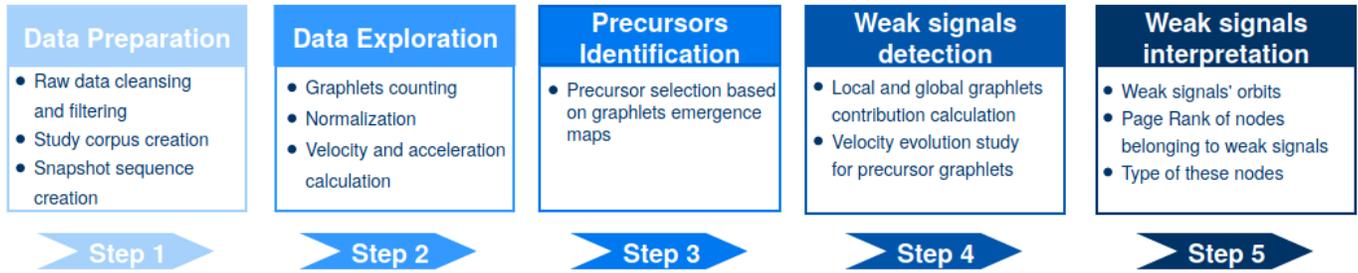

Fig. 1. The Main Steps of our Method BEAM.

This phase is important because the detection of weak signals only makes sense in a well-defined context, and the quality of the filtered data determines the reliability of the decision-making process.

2) *Creation of the Study Corpus*: Once the data has been filtered according to the chosen criteria, it is transformed into a new set that corresponds to the study corpus. Generally, the study corpus comprises a smaller volume of data than the global corpus. When we do a posteriori weak signals detection, the end of the study period must be determined.

3) *Snapshot Sequence Creation*: The interaction data can be represented in the form of a graph  $G(V, E)$  where  $V$  is the set of entities and  $E \in V \times V$  is the set of edges modeling the relationship between the pairs of entities, if  $(u, v) \in E$  then the nodes  $u$  and  $v$  are linked together. Temporal interactions between a set of nodes over the time on a period  $T = [\alpha, \beta]$  can be formulated by:

$$\mathfrak{X} = \{(u, v, t) \mid t \in T \text{ and } u, v \in V\},$$

such that  $(u, v, t) \in \mathfrak{X}$  indicates that  $u$  interacts with  $v$  at time  $t$ , these data can be ordered over time  $t$ . Temporal interactions do not admit a unique representation: some researchers study them using augmented graphs that integrate temporal information, others still, study them as link streams, others still with a temporal sequence of static graphs [28]. The link stream view was formally defined by Latapy et al. [29]: a link stream  $L = (T, V, E)$  is defined by a time interval  $T \subset \mathbb{R}$ , a set of nodes  $V$ , and a set of edges  $E \subseteq V \times V \times T$ , where  $(u, v, t) \in E$ , denotes that the nodes  $u$  and  $v$  have interacted at time  $t$ . The augmented graph view represents temporal interactions within a finite set  $\mathfrak{X}$ , in the form of a single graph. A graph is created in which a node is a pair  $(v, t)$ , with  $t \in T$  and  $v \in V$ , and in which the node  $(u, t_i)$  is related to the node  $(v, t_j)$  if they interact, i.e. if  $t_i = t_j = t$  and  $(u, v, t) \in \mathfrak{X}$ , or if they are contiguous in time, i.e. if  $u = v$  and  $t_j > t_i$  [30]. A second representation is to put temporality on the links.

The representation that we adopted to analyze the temporal interactions is a sequence of  $s \in \mathbb{N}$  static graphs:  $\mathfrak{S} = \{S^i \mid i \in \{1, \dots, s\}\}$  where  $S^i$  called snapshot  $i$ , is the undirected and unweighted graph (see top part of Fig. 3) containing all the interactions that occurred between times  $t_i = \alpha + i\Delta t$  and  $t_{i+1} = \alpha + (i+1)\Delta t$ ,  $\Delta t$  is a constant duration for all snapshots representing one day, one hour, 30 minutes, 10 minutes, etc. The aim of  $\Delta t$  is to connect nodes as a function of time, such that two consecutive snapshots  $S^t$  and  $S^{t+1}$  are

$\Delta t$ -adjacent. Note that we have grouped the interactions in a time window.

Formally,

$$S^i = (V_i, E_i) \begin{cases} V_i = \{u_i \mid (u_i, v_i, t) \in \mathfrak{X} \text{ and } t \in [t_i, t_{i+1}[] \cup \\ \{v_i \mid (u_i, v_i, t) \in \mathfrak{X} \text{ and } t \in [t_i, t_{i+1}[} \\ E_i = \{(u_i, v_i) \mid (u_i, v_i, t) \in \mathfrak{X}, t \in [t_i, t_{i+1}[ \\ \text{and } u_i, v_i \in V_i\} \end{cases}$$

Where  $u_i, v_i$  are the nodes  $u$  and  $v$  in the snapshot  $S^i$ .

## B. Data Exploration

In the following, we explain our BEAM method for finding a quantifiable property of weak signals based on graphlets.

1) *Graphlets*: Graphlets were first introduced by [31]. A graphlet is a connected induced<sup>4</sup> non-isomorphic<sup>5</sup> subgraph (2 to 5 nodes) chosen among the nodes of a large graph. There are 30 different graphlets ranging from  $G_0$  to  $G_{29}$ <sup>6</sup>. An essential element in the context of graphlets are the orbits [25]. They represent the positions (or roles) occupied by the nodes of these subgraphs. There are 73 different positions (from  $O_0$  to  $O_{72}$ ) for the 30 graphlets. The graphlets up to 4 nodes are presented in Fig. 2, with their corresponding orbits numbered from 0 to 14; in a same graphlet, the orbits having a same color are exchangeable.

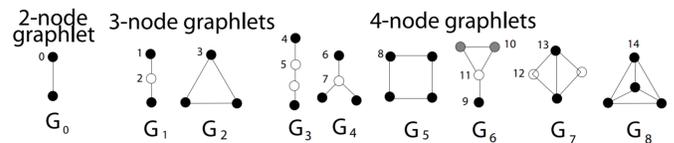

Fig. 2. Representation of the First 9 Graphlets Going from 2 to 4 Nodes.

There are several algorithms for enumerating graphlets and orbits in a graph [32]. In order to choose the most appropriate

<sup>4</sup>In graph theory, an induced subgraph is a subset of the nodes and **all** their connecting edges of an original graph.

<sup>5</sup>In graph theory, an isomorphism of two graphs  $G$  and  $H$  is a correspondence between the node sets of  $G$  and  $H$ , such that if any two nodes are adjacent in  $G$ , they are adjacent in  $H$ . Graphlets are non-isomorphic because they do not have the same form.

<sup>6</sup>In this article, we use the term graphlet for each type out of 30, however it does not represent its occurrence.

algorithm to count graphlets and orbits in the studied graph structures, we defined four criteria:

- 1) the exact enumeration of graphlets;
- 2) the enumeration of the orbits;
- 3) an acceptable complexity;
- 4) the availability of the source code.

The first criterion ensures the completeness of the graphlets. The second one ensures the interpretability of the results by studying the shape and role of the nodes in the graphlets. Orca satisfies our requirements. It was proposed by Hočevar and Demšar in 2014 [33], which is an exact enumeration algorithm. It counts graphlets up to 5 nodes and enumerates the orbits. It uses an analytical approach based on a matrix representation and works by setting up a system of linear equations per node of the input graph that relates different frequencies of orbits. Its source code is available at: [https://rdr.io/github/alan-turing-institute/network-comparison/src/R/orca\\_interface.R](https://rdr.io/github/alan-turing-institute/network-comparison/src/R/orca_interface.R)

With Orca, we count the number of graphlets for each snapshot. Each snapshot  $S^t$  is then represented as a vector of thirty elements  $(G_0^t, G_1^t, G_{29}^t)$ , where  $G_x^t$  is the number of the graphlet  $G_x$  in the snapshot  $S^t$ .

2) *Normalization*: We apply a normalization procedure on the number of graphlets in order to reduce their values to a particular magnitude. The normalized values are used in the subsequent calculations. This step is of great importance because it should not cover the weak signals but make them comparable to others. The chosen procedure is the one proposed by D. Goldin and P. Kanellakis [34] in which they study the similarity between two queries in a temporal database. A query returns a sequence  $X$  of real numbers  $(x_1, \dots, x_n)$ . Two reals  $a, b$  define a transformation  $T_{a,b}$  on  $X$  by relating each  $x_i$  with  $a \times x_i + b$ .  $\bar{X}$  represents the normal form of  $X$ , calculated by:

$$\bar{X} = T_{\sigma, \mu}^{-1}(X) = T_{\frac{1}{\sigma}, -\frac{\mu}{\sigma}}(X)$$

Where  $\mu(\bar{X}) = 0$  and  $\sigma(\bar{X}) = 1$ ,  $\mu$  being the mean and  $\sigma$  the standard deviation.

Applying this normalization procedure for each snapshot  $S^t$  where  $s$  is the number of snapshots, each component  $G_x^t$  of its vector with  $x \in \{0, \dots, 29\}$  is therefore normalized by:

$$\bar{G}_x^t = \frac{G_x^t - \mu(G_x)}{\sigma(G_x)}$$

with  $\mu(G_x)$  the mean of each graphlet  $G_x$  for all snapshots, given by:

$$\mu(G_x) = \frac{1}{s} \sum_{t=1}^s G_x^t$$

and  $\sigma(G_x)$ , the standard deviation, calculated by:

$$\sigma(G_x) = \sqrt{\frac{\sum_{t=1}^s (G_x^t - \mu(G_x))^2}{s - 1}}$$

3) *Estimation of the Signal Reinforcement: Diffusion and Amplification*: Velocity and acceleration evolution are quantitative features that allow us to evaluate the diffusion and amplification of the signal. We use these measures to identify event precursors among the graphlets.

From the obtained normalized values, the evolution of all  $\bar{G}_x^t$  components is studied via their velocity and their acceleration. Our objective is to highlight the graphlets which emerge before others. For each snapshot and each graphlet  $G_x$ , we compute its velocity as the difference between the normalized value of the graphlet in snapshot  $S^{t+1}$  and the normalized value of the same graphlet at snapshot  $S^t$ . As for the acceleration, it is also calculated in the same way by making the difference between the velocities.

We therefore acquire a numerical matrix representing for each snapshot, the normalized value of the graphlets  $\bar{G}_x^t$ , their velocity  $\bar{V}_x^t$ , and their acceleration  $\bar{A}_x^t$ . This matrix is presented in the Table III which illustrates an example of the values of some graphlets per snapshot. Note that the velocities can only be computed from snapshot  $S^2$ , and the accelerations from snapshot  $S^3$ .

TABLE III. EXAMPLE OF NORMALIZED VALUES OF GRAPHLETS, THEIR VELOCITY AND ACCELERATION FOR THE SNAPSHOTS OF THE STUDY PERIOD

Snapshot	Graphlet	$\bar{G}_x^t$	$\bar{V}_x^t$	$\bar{A}_x^t$
$S^1$	$G_1$	-0.952	NA	NA
$S^1$	$G_2$	-0.222	NA	NA
$S^2$	$G_1$	-0.666	-0.121	NA
$S^2$	$G_2$	0.456	0.678	NA
$S^3$	$G_1$	-0.786	0.938	1.059
$S^3$	$G_2$	0.758	0.302	-0.376
$S^4$	$G_1$	0.152	0.975	0.037
$S^4$	$G_2$	0.758	-0.315	-0.617
...	...	...	...	...
$S^s$	$G_{29}$	0.503	0.129	0.225

Fig. 3 summarizes the results obtained from the topological characteristics of the graphs for precursor discovery.

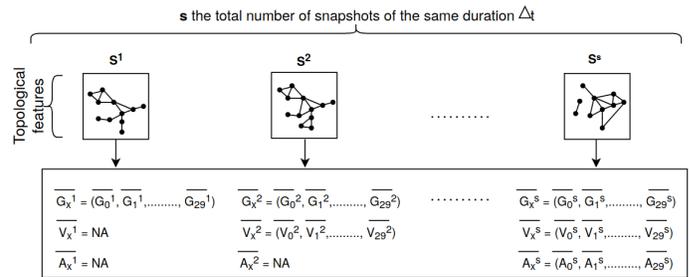

Fig. 3. Representation of the Calculation of Graphlets, Velocities and Accelerations for the Snapshots of the Study.

### C. Precursors Identification

First, we present the principles of precursor identification and then its implementation set up. To identify precursors, we rely on Hiltunen's approach in which she considers two types of precursors: early information and first symptoms. The first type represents new information that appears suddenly, such as the announcement of a new product or invention. The

second type represents a remarkable change that is difficult to interpret.

We have illustrated this representation in Fig. 4 where we consider four zones/quadrants. The "noise" area corresponds to graphlets with very small or negligible velocities and accelerations. The three remaining areas correspond to graphlets with 1) high velocity and low acceleration i.e. Q4, 2) low velocity and high acceleration i.e. Q1, 3) high values for both criteria i.e. Q2. If a graphlet is located in the areas Q1 and Q4 of the figure, we consider it as early information, whereas if it is located in the Q2 area, we consider it as first symptoms because the values of its velocity and acceleration are much higher. The graphlets located in these three zones are precursors of events because they are observable and clear facts or remarkable by their velocities and/or accelerations. The graphlets located in the noise zone are not considered as event precursors, because they represent unclear information which appears randomly but is not meaningful.

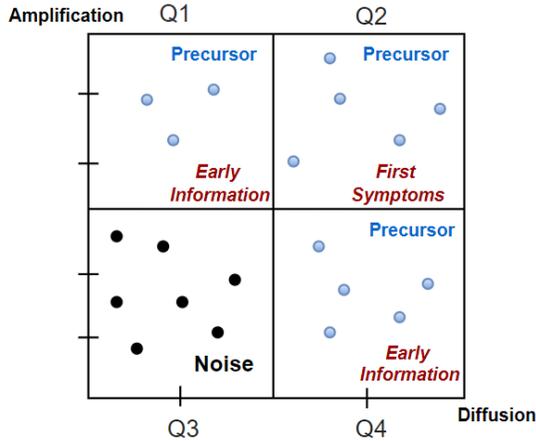

Fig. 4. Structure of the Graphlets' Emergence Map for a Particular Snapshot  $S^t$ .

Our aim here is to propose a division into graphlet emergence zones in the form of the four quadrants, not necessarily of equal size, as presented above. We propose two solutions:

- 1) **Slicing with respect to a top  $k$ :** The first possibility consists for each of the  $s$  snapshots  $S^t$  in
  - ranking their velocities  $\overline{V}_0^t, \overline{V}_1^t, \overline{V}_2^t, \dots, \overline{V}_{29}^t$  in ascending order;
  - setting a top  $k$  value for which the  $k$  graphlets have the highest velocities.

Similarly, we set a top  $k$  for the graphlet acceleration criterion.

- 2) **Slicing with respect to a threshold  $\mu$ :** The second possibility consists in setting a threshold for each of the  $s$  snapshots  $S^t$  equal for example to the average of the velocities and in selecting the velocities greater than or equal to this value,  $\overline{V}^t \geq \mu(\overline{V}^t)$ . A similar division is made for the accelerations.

For a snapshot  $S^t$ , we create an emergence map that represents on the x-axis the velocity values, and on the y-axis the acceleration values. The structure of this map is based on the representation of the signals as seen in Fig. 4, where

we place the graphlets in the four quadrants of the map. The division into quadrants depends on the choice of one of the two slicing methods presented above.

#### D. Identification of Weak Signals

The aim of this step is to qualify the graphlets as weak signals. We want to keep the True Positives and introduce the True Negatives as weak signals. False Negatives are graphlets that are neither precursors nor weak signals, and False Positives are graphlets that have been identified as precursors, but are not weak signals, they should be eliminated at the end of this step. The Table IV qualifies the results obtained by BEAM and estimates them.

TABLE IV. QUALIFICATION OF THE RESULTS OBTAINED BY BEAM

	Weak signal	$\neg$ Weak signal (noise, strong signal)
Precursor	True positive	False positive
$\neg$ Precursor	True negative	False negative

To qualify graphlets as weak signals, our BEAM method relies on:

- 1) Graphlets contribution in weak signals;
- 2) Evolution of the signal's diffusion.

The first measure aims to detect the weak signals at a certain time  $t$ , and the second one confirms or denies the detected signals, for an interval of time following  $t$ .

1) **Contribution Ratio Calculation:** We look in this phase to measure the contribution of a graphlet according to all graphlets to verify whether they are weak signals or not. The qualification criterion here is a ratio calculation. We propose two calculations: a local ratio that takes into account only the current time window, and a global ratio that takes into account all the studied windows. The number of graphlets in the chosen time window  $t$  is divided by the total number of graphlets for this time window:

$$R_{Local}(G_x) = \frac{G_x^t}{T_{Local}(G)}$$

Where  $T_{Local}(G) = \sum_{x=0}^{29} G_x^t$ .

The total number of a graphlet in the set of studied snapshots is divided by the total number of graphlets for all this set of snapshots, as follows:

$$R_{Global}(G_x) = \frac{\sum_{t=1}^s G_x^t}{T_{Global}(G)}$$

Where  $T_{Global}(G) = \sum_{t=1}^s (\sum_{x=0}^{29} G_x^t)$ , with  $s$  the number of processed time windows.

The resulting ratios  $R_{Local}(G_x)$ ,  $R_{Global}(G_x)$  are ranked in ascending order to qualify graphlets as weak signals if they are at the top of the list; the other graphlets are eliminated. This calculation is related to the **rareness characteristic** of weak signals since it selects the weakest ratios. Finally, at the end of these different analyses, we can provide per snapshot  $S^t$  a signature of the weak signal as a vector of at most 29 components:  $(G_x^t, \dots, G_y^t)$  with  $x, y \in \{0, \dots, 29\}$ .

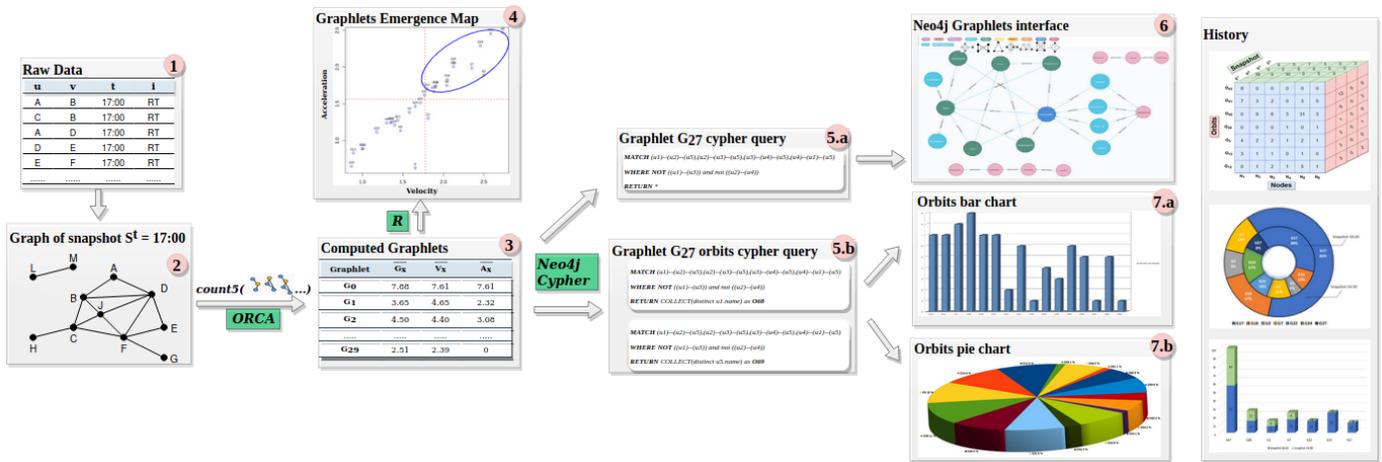

Fig. 5. BEAM user Interface for a Particular Snapshot. On the Right a Historical Panel for All Snapshots.

2) *Evolution of Graphlet Velocities:* The aim here is to propose a visual support to the identification of weak signals that can be carried out in parallel with the creation of emergence maps. This support consists in monitoring the evolution of the graphlet velocities over the time. To do this, we build a heatmap to visualize the evolution of the values of this criterion over a window of snapshots surrounding  $S^t$  :  $[S^{t-1}, S^{t+3}]$ . For example, if a graphlet  $G_x$  is found among the precursors in  $S^t$ , and if its velocity decreases in  $S^{t+1}$  and this decrease remains in  $S^{t+2}$ , then we consider that it is a false alarm thus we will not qualify it as a weak signal. On the contrary, the graphlets whose velocity increases in the studied interval, are True Positives and qualified as weak signals. Similarly, those that were not identified among the precursors but their speed increases, are True Negatives.

### E. Interpretation of Weak Signals

Searching for relevant data for important event anticipation has several challenges including the complexity of detection and interpretation. At first sight, weak signals are fragmented pieces of information, so hard to be interpreted. However, if they were combined with context or additional elements, the interpretation task may become clearer and more relevant. Hiltunen [5] considers that the interpretation dimension means the information user’s understanding of the future signal.

Our aim in this step is to make sense of the identified weak signals to help business experts in better and useful decision making. Several works tried to address this dimension like Lee and Park [10] who employed keyword clustering and topic selection based on keyword co-occurrences, or J. Kim [14] who proposed to observe the rarity and the paradigm unrelatedness of weak signals. In BEAM, we consider elements characterizing the nodes like their name, their type, as well as their role, etc. The role of a node can be characterized by its orbit, or its position in the graphlets. We therefore take advantage of this criterion to identify the central, cross or internal nodes roles. With Orca, we can also count how many times a node is playing these roles. BEAM also provides to business experts different visualizations that may help interpreting the identified signals, as shown in Fig. 5. This figure illustrates

an example of one snapshot being studied by an expert, where parts 1 and 2 represent the raw interactions data at this snapshot, and the corresponding generated graph. Once Orca is executed, it allows the user to fetch all computed graphlets (their normalized number, their velocity and their acceleration) shown in part 3, and allows him to spot the precursor graphlets on the emergence map (part 4). In parts 5.a and 5.b, the expert may look further for a particular precursor graphlet using the Neo4j Cypher queries implemented in BEAM. Consequently, he has two visualization options, either 1) with a view that highlights the precursor graphlet (here  $G_{27}$  for example) in the initial graph, as in part 6, or 2) with a chart view representing the number of nodes in each of the precursors’ orbits (including  $G_{27}$ ), as shown in the bar and pie charts (parts 7.a and 7.b). At the right of this figure, there is a historical panel that allows the user to go back to a visited visualization, or to visualize the data based on a sequence of snapshots (in the form of a data cube, a clustered bar, or pie chart).

## IV. EMPIRICAL CASE STUDY

In order to evaluate the proposed method, we performed experiments on different datasets. We will describe in this section the empirical studies carried out on the Game of Thrones Twitter network (GOT), and a sensor network holding interactions between elementary school students. The purpose behind these studies is to 1) ensure the robustness of the method by verifying that weak signals are detected prior to a certain event (GOT), but are not detected when the event is already foreseen and punctual (elementary school); and 2) confirm its reproducibility through 6 episodes of GOT.

### A. Game of Thrones Dataset

With long-tail streaming, HBO has pegged the last season of GOT as averaging around 44.2 million viewers per episode. The final season of GOT has upset many viewers because of changes in writers, shortening the season (this last one had only six episodes diffused once per week), and a surprising turn of events. This is why the fan club was more into criticizing this final season. It was released on April 14 2019, and ended on May 19 2019. The episodes were diffused live at 9 p.m.

American time, and the collected data corresponds to the tweets published at the same timestamp. The original data sample including all episodes of the season, has a total number of 46 481 705 tweets including 34 094 365 retweets.

1) *Study Corpus*: We describe the study carried on the first episode with a period limited to 14-04-2019 from 1 p.m. to 7 p.m. The graph represents 223 383 retweets between 189 741 users corresponding to audience, journalists, media, etc. This graph is divided into a sequence of snapshots with a duration  $\Delta t$  equal to 10 minutes.

2) *Precursors and Weak Signals*: For each snapshot, we counted the number of 5-node graphlets and normalized them, then computed their corresponding velocity and acceleration. In the following, we will present only the obtained results for the snapshot of 5 p.m. Fig. 6 illustrates the graphlets' emergence map of 5 p.m built based on these criteria. The 13 graphlets that are circled in red are selected as precursors, since they belong to one of the aforementioned zones Q1, Q2 or Q4. The remaining graphlets are considered noise being positioned in the Q3 zone.

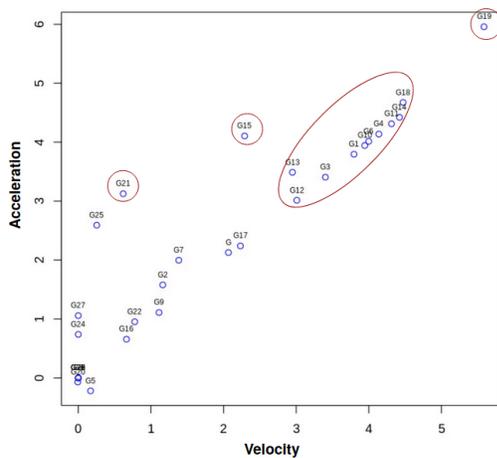

Fig. 6. Precursors Selected Among the Graphlets in the Snapshot of 5 p.m.

emergence map of 5 p.m built based on these criteria. The 13 graphlets that are circled in red are selected as precursors, since they belong to one of the aforementioned zones Q1, Q2 or Q4. The remaining graphlets are considered noise being positioned in the Q3 zone.

Once the precursors are selected, the next step is to check their relevance by identifying the false positives, preserving the true positives and adding the true negatives. For this, we first calculated the local and the global contributions of the graphlets for each snapshot, and ranked the resulted ratios in ascending order. For the 5 p.m. snapshot, we selected the top 5 graphlets according to the ranked ratios, that are respectively  $G_{21}$ ,  $G_{15}$ ,  $G_{13}$ ,  $G_{12}$  and  $G_3$ . We moved next to confirm the obtained contribution ratios, by analyzing the evolution of graphlets' velocities in the snapshots surrounding 5 p.m.

We monitored the evolution of graphlets (precursor ones in particular) velocities during an interval of snapshots going from 4:50 to 5:30 p.m., as shows the Fig. 7. The x-axis of the heatmap in this figure represents the different snapshots, and the y-axis represents some of the precursor graphlets. The legend on the right of the figure represents the graphlets velocity values between -2 and +5. The blue colors in the heatmap are the graphlets  $G_x$  such that  $\overline{V}_x^t \geq +5$ , and the red colors are those such that  $\overline{V}_x^t < 0$ . For example, when considering the 5:00 p.m. snapshot, the graphlet  $G_{19}$  shows

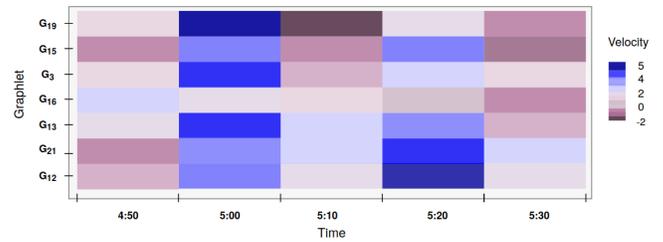

Fig. 7. Velocity Evolution of Some Precursors in the Snapshots Around 5 p.m.

a significant increase in velocity up to +5, and in the next snapshot, it decreases rapidly to -2. Another evolution is the one of  $G_{16}$ , that shows continuous decrease in its velocity for all snapshots. We revised the global contributions of these graphlets and noticed that they have higher ratios than the top 5 mentioned above. These results are therefore consistent, and indicate that these graphlets are false alarms. As for the remaining graphlets, we see that they show a significant rise in their velocities at 5 p.m., followed by a minor decrease at 5:10 p.m., then another rise at 5:20 p.m. The decreases at 5:30 p.m. do not affect the analysis results, because it is enough to observe one remarkable rise after the current snapshot (i.e. 5 p.m.). These last results are consistent with those obtained from the contribution calculation, hence we qualify the top 5 graphlets from the list as weak signals. Table V illustrates the five qualified weak signals, their shape and their global contribution.

TABLE V. TOP 5 GRAPHLETS QUALIFIED AS WEAK SIGNALS FOR THE SNAPSHOT OF 5 P.M.

Graphlet	$G_{21}$	$G_{15}$	$G_{13}$	$G_{12}$	$G_3$
Graphlet shape					
Graphlet global contribution	0.0009	0.0174	0.0235	0.0260	0.0283

3) *Weak Signals Interpretation*: Our objective here is to help in the interpretation of identified weak signals, by providing contextual elements like user accounts. We first start by calculating the number of orbits (nodes positions) of graphlets with Orca, then analyze these positions in weak signal graphlets. This is an important task because it can help explaining the users' role in assessing and supporting this final season.

Table VI illustrates an extract of the obtained results from this step at the 5 p.m. snapshot. The accounts @dcucomics, @jonatas\_maia12 and @9GAG appear mostly in a peripheral position in graphlet  $G_3$  ( $O_4$ ). The remaining accounts in this table occupy a central position ( $O_5$ ). The third and fourth columns of the table represent respectively the different node types (from comic accounts, to online platforms or journalists), and their corresponding ranks after executing the PageRank algorithm on 7000 users. We note that the official accounts of the series are communicating more than the others since they occupy the most central positions. In addition, the account @TylerIAm has a you-tube channel and diffuses live broadcasts from 12 to 3 p.m., so from his PageRank we can

see that he retweeted very much about GOT two hours after the broadcast.

TABLE VI. EXTRACT OF IMPORTANT NODES BELONGING TO  $G_3$  ORBITS, AND THEIR PAGE RANK FOR THE SNAPSHOT OF 5 P.M.

Graphlet-Orbit	Account	Account type	PageRank
O4 	@dcucomics	DC universe (fictional universe produced by Warner Bros) fan account	27
	@jonatas_maia12	Product designer	61
	@9GAG	Online platform, viral and funny videos	248
O5 	@GameofThrones	Official account of GOT	1
	@Thrones_Memes	GOT memes account	3
	@TylerIAm	Journalist	4
	@LordSnow	Got character (John Snow)	12

We then conducted a refined analysis on the account @TylerIAm using the Neo4j Cypher queries implemented in BEAM. Here we went from a graphlet type to 4 graphlet instances, and displayed the users linked to this account on a  $G_3$  instance. As shows Fig. 8, @Woodlawnwonder, a blogger, occupies the other central position of  $G_3$ , and the peripheral positions are occupied by the remaining accounts. We considered the instance containing @joestudz18, an artist and concept illustrator, as well as @holy\_schnitt who is a social media star. We assume that the blogger account activity for example, should be monitored by business experts.

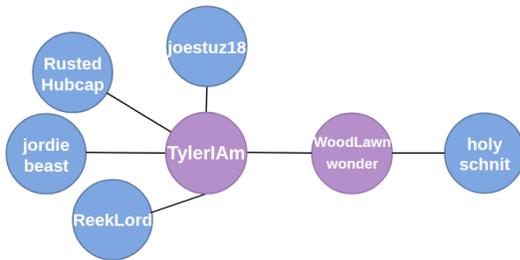

Fig. 8. Important Accounts Occupying Orbits of an Instance of  $G_3$  in the Snapshot of 5 p.m.

We also noticed an interesting fact about nodes appearing in  $G_{15}$  . These nodes belong to accounts located in Brazil, including a comic and digital creator @cleytu, an entertainer @fabwiano, the Brazilian version of HBO channel @HBO\_Brasil, and a journalist @LethyciaDias\_, etc. We then executed the Louvain algorithm for the whole episode (where all snapshots are combined). We noticed that all these users belong to the same community. We therefore allow business experts to give their final assessment regarding these results and the type/location of the users, since the shape of this graphlet can put into evidence an important social structure [26].

We performed the same experiment on the retweets published on the remaining 5 episodes of GOT, to test the reproducibility of our method. The results obtained showed that the weak signal graphlets are detected few hours before

the episode is broadcast. Moreover, we noticed that the same graphlets are found in several episodes as weak signals.

According to the results of our study, the official GOT accounts (@GameofThrones, @ThronesMemes and @LordSnow) communicated supporting information (they were motivating the audience to watch GOT, and highlighting the crucial role of the character Jon Snow). Therefore, the weak signals carried by these accounts can be opportunities, which is important that they emerge to verify if the speech is well perceived. On the other hand the comic accounts @dcucomics and @9GAG can be threats because they can make fun of GOT or even divert its image, so they must be watched to mitigate their negative impact on the audience.

### B. Elementary School Interactions Dataset

We conducted another experiment on students interactions in an elementary school in Lyon, France, on two consecutive days in October 2009 [35]. The school day runs from 8:30 a.m. to 5:30 p.m., with a lunch break between 12:00 p.m. and 2:00 p.m., and two 20-25 minute breaks at around 10:30 a.m. and 3:30 p.m. that take place in a common playground. Two students are considered to be interacting if they are within 3 to 5 feet of each other for at least 20 seconds.

Through this experiment, we aimed to:

- 1) verify that no weak signal is found when the events are known (as the breaks are scheduled at specific times, without particular triggers, ...);
- 2) verify that the error rate is reduced, i.e. that the false positives are eliminated by our method.

1) *Study Corpus*: The raw data file was downloaded from the official site<sup>7</sup>. We divided the corpus into snapshots of 10 minutes duration each, and choose to work with five snapshots that correspond to the times before the lunch break (from 11:20 a.m. to 12 p.m.) of the first school day.

2) *Precursors and Weak Signals*: We focused our analysis on the snapshot of 11:40 a.m. and we were able to spot precursors on the corresponding graphlets' emergence map. Thereafter, we evaluated the located precursors using the graphlets contribution ratios, as well as their velocity evolution. The velocities heatmap showed that for this particular snapshot, the graphlets reach high values, but then decrease rapidly in the next snapshot (11:50 a.m.) and continue to decay until the last snapshot. This decrease supports the hypothesis that the identified precursors at this snapshot were false alarms, hence shall not be qualified to weak signals. Although we did not expose weak signals from this experiment, the dataset is a ground truth example on which we relied to confirm the method's objectives.

### C. Results Validation: Cross-Correlation

This is a supplementary step that aims to validate the discovery of weak signals by studying the relation between them and a potential event<sup>8</sup>. In this step, we observe the data no more as a sequence of graphs, but instead as time series.

<sup>7</sup><http://www.sociopatterns.org/datasets/primary-school-temporal-network-data/>

<sup>8</sup>We consider an event as a situation in which the number of interactions reaches its maximum value.

A time series  $X$  is created from the number of interactions selected between all pairs of nodes. It is a sequence of  $n$  elements  $X = (x_i)_{1 \leq i \leq n} = (x_1, x_2, \dots, x_n)$ .

We rely on the Cross-correlation to validate the intrinsic properties of BEAM by studying the relation between the graphlets weak signals and the original time series of interactions (built from the raw data). Cross-correlation<sup>9</sup> is a linear measure of similarities between two time series  $X$  and  $Y$ , which helps evaluate the relation between these series over time [36]. An offset/lag  $h$  is associated with this measure, knowing that if  $h < 0$  then  $X$  could predict  $Y$ , and if  $h > 0$  then  $Y$  could predict  $X$ .

We applied this function on the GOT dataset, by first building the time series corresponding to the users' retweets, then building a time series for each one of the 30 graphlets. From the obtained results, we noticed that the graphlets that were qualified as weak signals (see Table V), presented positive correlations (between 0.5 and 0.7) with the initial series with a lag of 10 or 20 minutes ( $\Delta t = 10$  minutes). Fig. 9 illustrates the correlogram of graphlet  $G_{13}$  with the initial retweets series. The graphlets identified as false alarms in the previous steps of the method, like  $G_{16}$  and  $G_{19}$  for instance, did not present correlations.

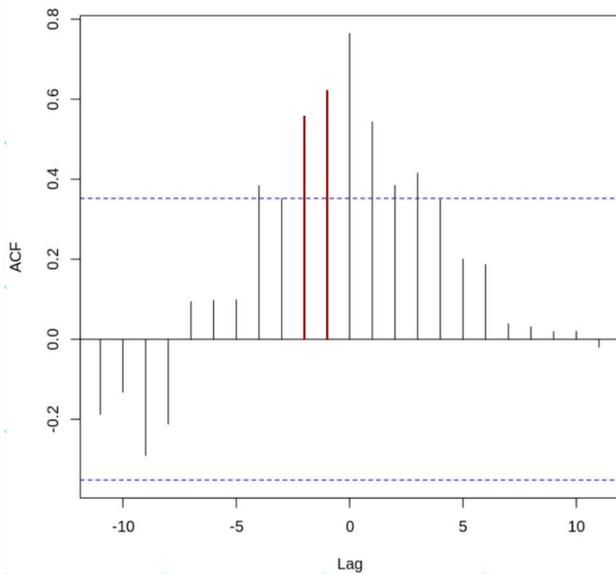

Fig. 9. Positive Correlation with Negative Lags of 10 and 20 Min Between  $G_{13}$  and the Retweets Time Series (GOT Dataset.)

We executed the Cross-correlation on the elementary students interactions dataset, and from the obtained correlograms, we did not find any negative-lag correlation between the initial time series and the precursor graphlets. These results confirm that when the event is already planned and punctual, there are no weak signals that can announce the occurrence of such event, hence the detection phenomena corresponds in this case to false positives that we were able to identify.

## V. LIMITATIONS AND DISCUSSION

Several works relied on different techniques to detect future weak signals. After applying BEAM on several data sets, the findings have been quite consistent in establishing that this method is able to detect weak signals prior to an important event. Using BEAM, the business expert does not spend time anymore to choose selection filters, prepare data and extract remarkable information for analysis. Instead, he relies on the previously detected information and assesses if it should be qualified as future weak signals or not.

However, BEAM still presents some limitations related to: 1) The constitution of study corpus. 2) The snapshots duration  $\Delta t$ . 3) The division of graphlets' emergence maps. 4) The interpretation of the detected signal through its recognition.

These limitations are related to filters that hinder the analysis of weak signals and constitute barriers to their interpretation. These barriers were discussed by Ansoff [4] who suggested that weak signals must pass three filters 1) the monitoring (surveillance), 2) the mentality and 3) the power filter, before potentially triggering an action or a decision. The monitoring filter corresponds to the capacity of the weak signal to be detected or discovered, in the midst of all other perceived information, by one or more actors within the organization. The mentality filter refers to the capacity of the signal to be recognized, after being detected, as relevant information with regard to the examined situation. Finally, the power filter refers to decision-making once the signal has been detected and its relevance recognized. The people in charge in the organization can decide for example not to make this signal a priority, despite the underlying risk.

Limits 1, 2 and 3 of BEAM are related to the monitoring filter. The first one results from an irrelevant choice of keywords, accounts or hashtags (in case of Twitter data) during the creation of the study corpus. It can be resolved by adding a feedback loop in BEAM, to allow business experts to return to the first step and modify the selection criteria, if the interpreted signals are not significant for them. Regarding the second one, the duration of snapshots  $\Delta t$  should be well-chosen for an expert to analyze the detected signals and provide his decision. To do so, we performed an experiment to measure the time in which a tweet becomes viral (i.e. when it reaches the highest number of its retweets). This limitation is also depending on the number of tweets in the studied snapshots, if it is high,  $\Delta t$  should be limited otherwise increased. The third limitation relates to the choice of the top  $k$  or the threshold that divides the graphlets' emergence maps for the precursors selection. This one was resolved with the contribution calculation with which graphlets are added or removed from the list of weak signals based on their ratio. The fourth limitation is related to the mentality and power filters, thus cannot be resolved within BEAM, since it is up to the business expert to provide his final interpretation and decision regarding the detected signals.

## VI. CONCLUSION

In this article, we presented our method BEAM whose objective is to help business experts to detect and interpret the identified weak signals in order to enable them to make decisions and plan future strategies. First, we find graphlets in a graph of interactions between entities, which represent clear

<sup>9</sup>implemented with the R package *tseries*: <https://www.rdocumentation.org/packages/tseries/versions/0.1-2/topics/ccf>

and observable facts, quantifiable using measures of diffusion and amplification that characterize them as precursors. We examine the contribution of graphlets to eliminate false alarms (False Positives) and qualify True Positives and True Negatives as weak signals. Once these signals are identified, the shapes of the graphlets and their orbits help the business experts in their interpretation. In BEAM, we have chosen graphlets as an operational description to give a signature of the weak signal, this choice allows an automation of the detection task while enabling a final judgment by the business experts for a better decision making.

Next, new experiments will be performed on other types and larger networks to resolve the remaining limitations of the method. In further research, we would like to explore if graphlets can be used to indicate phase transitions of an information emergence between transition points. This will help in analyzing the weak signal amplification process. BEAM combines data analysis and visualization tools to guide business experts in detecting and interpreting weak signals, and offers a great potential for decision-making in most business organizations. Moreover, the detection of weak signals offers promising leads for innovation.

**Abstract**—The soft-sensor method of carbon content in fly ash is to predict and calculate the carbon content of boiler fly ash by modeling the distributed control system (DCS) data of thermal power stations. A novel data-driven soft-sensor model that combines data pre-processing, feature engineering and hyperparameter optimization for application in the carbon content of fly ash is presented. First, extract steady-state data by data mining technology. Second, twenty characteristics that may affect the carbon content in fly ash are identified as variables by feature engineering. Third, a LightGBM prediction model that captures the relation between the carbon content in fly ash and various DCS parameters is established and improves the prediction accuracy by the Bayesian optimization (BO) algorithm. Finally, to verify the prediction accuracy of the proposed model, a case study is carried out using the data of a coal-fired boiler in China. Results show that the proposed method yielded the best prediction accuracy and closely approximates the non-linear relationships between variables.

**Keywords**—LightGBM; carbon content; fly ash; soft-sensor; feature engineering; Bayesian optimization

## I. INTRODUCTION

The unburned carbon content in fly ash reflects the combustion efficiency of a coal-fired boiler. The combustion condition of coal can be better evaluated by analyzing the unburned carbon content in fly ash [1]. Real-time monitoring of carbon content in fly ash helps keep the carbon content in fly ash within a reasonable range, thus reducing the cost of power generation and improving the economy of generating units.

Currently, the methods for detecting the carbon content of fly ash are divided into two categories: physical measurement methods and soft-sensor methods. Physical methods commonly include the loss-on-ignition method [2], Laser-induced breakdown spectroscopy [3], microwave absorption method. [4] etc. Physical solutions are not widely available due to technical or cost reasons [5-6]. Machine learning methods have been widely used in human life, industrial production and power generation [7-9]. Distributed control system (DCS) is a computer control system for centralised management and decentralised control of the production process [10]. The distributed control system contains many sensors, which record the information of system operation. By analyzing this information, we can predict the operation status of the system [11]. The soft-sense method organically combines the production process knowledge through mechanism analysis,

which can quickly and accurately reflect the carbon content in fly ash under different working conditions, and has a high economy.

Currently, there are three main problems with soft-sensor methods for the carbon content in fly ash:

1) The boiler combustion process is a multivariable variable, nonlinear and highly coupling thermal process [12]. For example, the DCS records variables such as air volume, air pressure, and air temperature for each coal mill outlet. These variables are highly correlated with boiler combustion prediction modeling, resulting in a certain amount of variable redundancy, affecting the model estimation accuracy, and increasing the computational complexity. Therefore, it is necessary to apply feature engineering to reduce the impact caused by redundant variables.

2) Most current research tests have limited data and working conditions. They do not effectively represent the complete operational status of the boiler.

3) The accuracy of these algorithms is limited.

## II. RELATED WORK

Zhou et al [13]. established an artificial neural networks (ANN)-based soft-sensor model for the carbon content in the fly ash of a 300MW utility tangentially firing coal burned boiler and verified the validity of the model by multi-state thermal experiments. Wang et al [14]. proposed building a prediction model with support vector regression(SVR) for carbon content in fly ash and showed through experiments that the carbon content in fly ash model using SVR has reliable generalization and is suitable for online modeling. In machine learning, finding appropriate data processing methods, such as removing noise data and extracting suitable features, will help to improve the accuracy of prediction [15]. To address these issues, Zhu et al [16] performed a sensitivity analysis of the related features for the carbon content in fly ash, using the Garson algorithm for variables selection before modeling. Wang [12] collects the factors influencing the carbon content in fly ash constitute the initial variables, and the optimal variables are selected by the random forest-based variable selection method. The machine learning model contains many super parameters, such as penalty, learning rate and loss function. A suitable combination can effectively improve the

prediction accuracy of the model [17]. Feng [18] improves the model generalization ability by using the genetic algorithm to optimize the values of each neural network parameter. Peng [19] proposed an adaptive perturbation quantum particle swarm optimization algorithm (AQPSO) with a support vector machine to jointly predict the carbon content in fly ash and improve the prediction accuracy of the SVR model by ADQPSO.

LightGBM [20] is an ensemble learning algorithm, Developed by Microsoft in 2017. It is an advanced implementation of the distributed gradient boosting decision tree (GBDT) framework. The GBDT [21] algorithm is the core of LightGBM, which iteratively sums weak estimators to generate robust estimators by computing the negative gradient of the loss function. Lightgbm integrates GOSS (Gradient-based One-Side Sampling) algorithm and EFB (Exclusive Feature Bundling) algorithm based on GBDT. GOSS algorithm can lead to a more accurate gain estimation than uniformly random sampling, and the EFB algorithm provides a nearly lossless approach to reduce the number of effective features [20]. LightGBM algorithm extensively applied in many regression problems [22-23].

Hyperparameters play a valid role in the accuracy of regression prediction algorithms. In practice, it is necessary to continuously adjust the hyperparameters, train the model under different sets of hyperparameters, and determine the best hyperparameters by comparing the model's performance. Therefore, finding the appropriate hyper-parameters has become a critical issue in machine learning [24].

Bayesian optimization (BO) is a very effective global optimization algorithm. BO is very suitable for solving highly complex optimization problems. Their objective functions could not be expressed, or the functions are non-convex, multimodal, and computational expensive [25]. BO can actively select appropriate evaluation points according to the relevant results of the current unknown function to avoid unnecessary sampling. At the same time, Bayesian optimization can use historical search information to improve

search efficiency. [26]. BO has achieved better results than other hyperparameter tuning methods in the Black-Box Optimization Challenge 2020 [27].

### III. PROPOSED WORK

In this study, a new soft-sensor method for measuring the carbon content of fly ash is proposed by analyzing and experimenting with a total of 3,272,872 DCS data from an electric boiler from October 23 to November 30, 2020. The method combines data mining, feature engineering, LightGBM, and BO algorithm. A flowchart of the applied methodology is proposed in Fig.1. By comparing with other feature selection methods, and prediction models, experiments show that the prediction results of the presented approach are closer to the actual working conditions of the carbon content of fly ash, which improves the soft-sensor accuracy and ensures the reliability and accuracy of the soft-sensor method.

The data processing part is the operation of apparent outlier removal and re-sampling of the acquired DCS data.

#### A. Apparent Outlier Removal

First, the raw data was examined, and remove the data are outside the reasonable range. For example, the actual load recorded by the DCS has some invalid data at the beginning due to plant shutdown, etc. As shown in Figure 2, the data in the red area are unreasonable. By removing apparent outliers, the natural distribution of the variables can be captured.

The load changes drastically since thermal power units need to adjust the power generation capacity according to the grid load during operation. The thermal power units are constantly changing the working conditions, such as steady-transition-steady. This will result in a miss correlation between data. This effect can be minimized by data-resampling the data in an appropriate period. In this study, the datasets were re-sampled into 6-minute intervals. The actual load's scatter plot, before and after re-sampling, is shown in Fig.3, Fig.4. The re-sampled data is smoother and more similar to regular operation, as is shown in Fig.4.

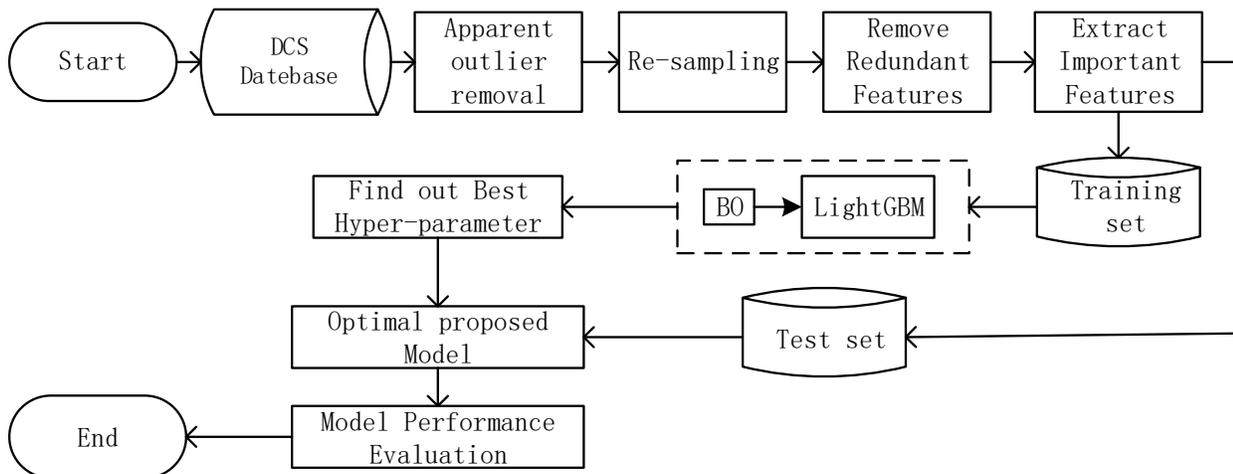

Fig. 1. Methodology Flowchart.

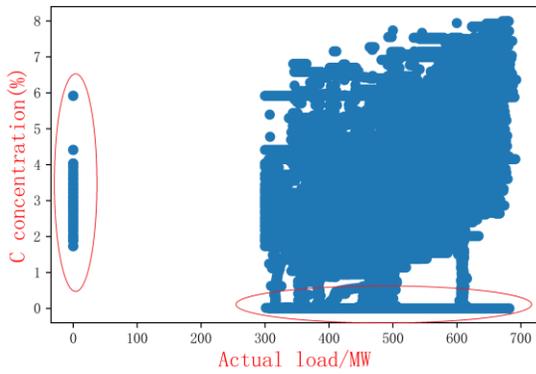

Fig. 2. Raw Load Data Scatter Plot.

**B. Data Re-sampling**

Feature engineering [28] is scoring each potential feature based on specific feature selection metrics and selecting representative variables from a given dataset to improve the final prediction. Feature engineering is crucial in the model design, as irrelevant or redundant data features will harm the model's performance. By reducing the number of variables, noisy and irrelevant data are removed, and the algorithm can run fast as the number of variables is reduced. There are generally three feature selection methods: filter method based on statistical information, wrapper method, and embedded method [29]. This study uses the correlation matrix (based on the filter method) and wrapper method to deal with variables.

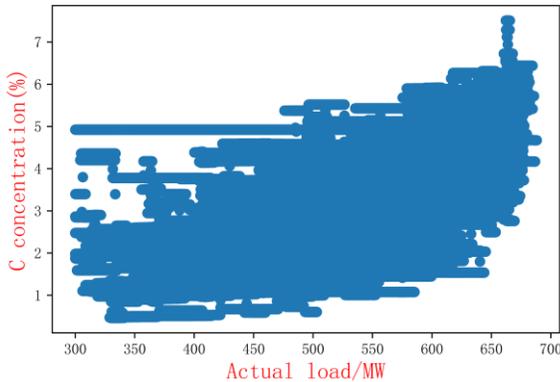

Fig. 3. Scatter Plot before Re-sampling.

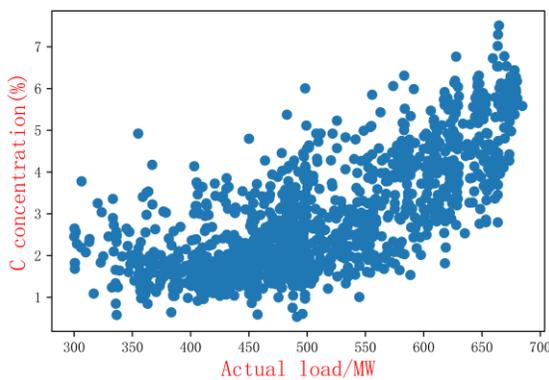

Fig. 4. Scatter Plot after Re-sampling.

According to the characteristics of multivariable variables, nonlinear and highly coupling thermal process, Firstly, the features with strong coupling are found through the correlation matrix, and the variables with low correlation with the carbon content of fly ash are eliminated. The essential variables are further extracted by the wrapper method to reduce the computational complexity of the model.

**C. Remove Redundant Features**

The correlation matrix (CM) is a table that is constructed to quantify the dependence between variables, as shown in equation (1), and the correlation coefficient indicates the positive or inverse relationship between the target variables [30]. The correlation matrix identifies and deletes redundant features in the dataset. Fig.5 shows one of the generated correlation matrices, which presents the correlation between the six features, The features from top to bottom are 'air temperature', 'air volume', 'steam temperature', 'steam temperature 2', 'air temperature 2', and 'air pressure'. If the correlation coefficient between the two variables is more significant than 0.95, they are compared with the carbon content in fly ash, and the variable with the smaller correlation coefficient is removed. For Fig.5, the features 'air temperature', 'air volume', and 'steam temperature' were removed. In this way, the number of 71 DCS variables was reduced to 45.

$$r = \frac{\sum (x_i - x_{ave})(y_i - y_{ave})}{\sqrt{\sum (x_i - x_{ave})^2 \sum (y_i - y_{ave})^2}} \tag{1}$$

where  $r$  is the correlation coefficient,  $x_i$  is value of feature  $x$ ,  $y_i$  is value of feature  $y$ ,  $x_{ave}$  is mean value of the feature  $x$ ,  $y_{ave}$  is mean value of the feature  $y$ .

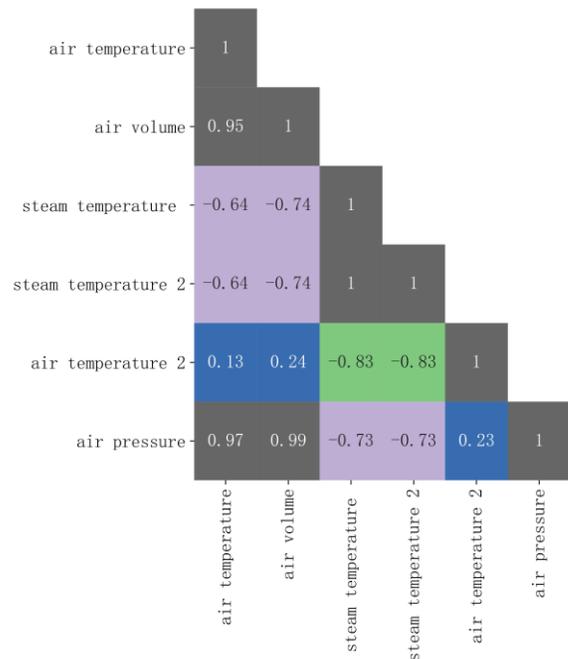

Fig. 5. Part of the Correlation Matrix.

D. Extract Important Features

The wrapper method is a feature selection method according to a specific prediction model, and this method uses recursive feature elimination (RFE). It is a greedy optimization algorithm that selects the best feature subset by repeated iteration. For the last step, the 45 variables selected by the correlation matrix are then used to determine the best performing 20 variables by the wrapper method.

E. Establishment of the Prediction Model

Before modeling, we will process features through correlation matrix and wrapper method, eliminate variables with highly coupling through correlation matrix, and select essential features subset by wrapper method, to reduce the computational complexity and further improve the expressiveness of the model.

LightGBM has many hyperparameters, and a reasonable choice of hyperparameters can improve prediction. While using the lighthGBM model to predict the carbon content of fly ash, the BO algorithm is used to continuously adjust the hyperparameters of the lighthGBM model to improve the prediction accuracy of the model. The process of generating the optimal model BO\_LightGBM is shown in Fig.6. During the model satisfaction assessment, cross-validation is set 5, the evaluation function is a root mean squared error.

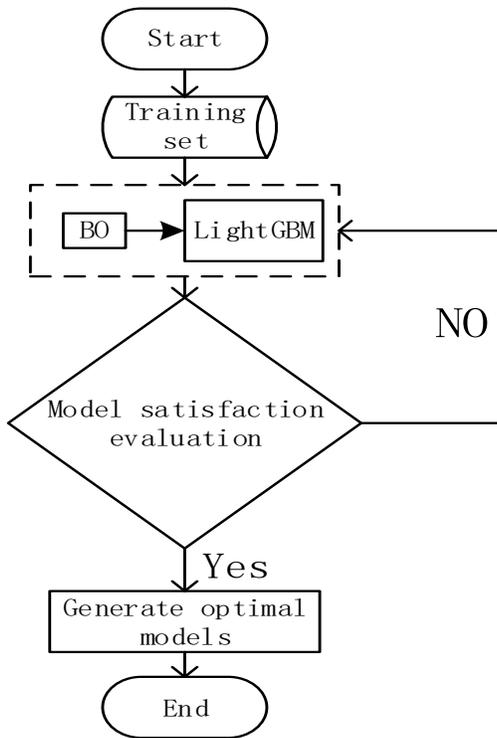

Fig. 6. Hyperparameter Tuning Flow Chart.

IV. VALIDATION AND RESULTS

A. Performance Metrics

The regression evaluation indexes in regression analysis have mean squared error (MSE), root mean squared error (RMSE), mean absolute percentage error (MAPE), and

coefficient of determination( $R^2$ ).  $RMSE = \sqrt{MSE}$ , In this study, RMSE, MAPE, and  $R^2$  were selected as performance metrics, and these indices can be calculated as Eq. (3)(4)(5).  $R^2$  is adapted to measure the approximation degree of the data to the prediction value, the closer  $R^2$  is to 1, the better the fitting effect of the model. The smaller MSE, MAPE means the more accurate the prediction.

$$RMSE = \sqrt{\frac{1}{m} \sum_{i=1}^m (y_i - \hat{y}_i)^2} \tag{3}$$

$$MAPE = \frac{1}{m} \sum_{i=1}^m \left| \frac{y_i - \hat{y}_i}{\hat{y}_i} \right| \times 100\% \tag{4}$$

$$R^2 = 1 - \frac{\sum_{i=1}^m (y_i - \hat{y}_i)^2}{\sum_{i=1}^m (y_i - \bar{y}_i)^2} \tag{5}$$

where  $y_i$  are the actual values,  $\hat{y}_i$  are the predicted values, and  $\bar{y}_i$  is the mean of  $y_i$  ( $i=1,2,\dots, n$ ).

B. Performance Comparison of Feature Processing Methods

Methods frequently used in feature processing are Random Forest (RF) [31] and Pearson correlation coefficient (PCC) [32]. The experiment compares the method proposed in this paper with RF and PCC. The optimal 20 features of the three methods are modeled for prediction while ensuring that the selected data are consistent with the boiler's steady-state operating conditions. In this process, the correlation matrix eliminates the features with high correlation, retains 45 features with low coupling, and then uses the packaging method to retain 20 features. The processed results of each of the three methods are used as input to the LightGBM model. The experimental results are listed in Table I.

The random forest method model is less effective, as shown in Table I. The model treated with PCC outperformed the RF. After using the correlation matrix to process the features, the  $R^2$ , MAPE, and RMSE were significantly optimized, and after further processing of features by wrapper method, the  $R^2$  was improved to 0.822, MAPE was reduced to 16.5%, and RMSE was reduced to 0.509. It is proved that the fitting effect of the model using the method proposed in this paper is further enhanced, and the error is further reduced, which effectively solves the problem of high correlation and strong coupling between variables.

TABLE I. PREDICTION RESULTS AFTER FEATURE PROCESSING

Method	$R^2$	MAPE	RMSE
RF	0.71	19.22%	0.644
PCC	0.78	17.47%	0.573
CM	0.814	16.69%	0.523
CM+Wrapper	0.822	16.50%	0.509

### C. Comparison of Model Prediction Performance

To validate the superiority of the proposed method, three methods, including LM-Garson-BP [16] AQPSO-SVR [19] FPA-RF [12], the three latest methods are compared as benchmarks.

- LM-Garson-BP: The LM-Garson-BP methods used sensitivity analysis to select the feature variables and then used BP neural networks for predictive modeling and genetic algorithms to optimize the connection weights, number of neurons, and number of hidden layers.
- AQPSO-SVR: The AQPSO-SVR method first adds adaptive perturbation to the quantum particle swarm optimization (QPSO) algorithm and uses this improved algorithm to find the optimal hyper-parameters of the support vector regression (SVR).
- FPA-RF: The FPA-RF method first uses the random forest method to filter features, then uses the random forest as a prediction model and uses the flower pollination (FPA) algorithm to optimize the hyperparameters of the random forest.

MAPE, RMSE, and  $R^2$  are selected as evaluation indexes. The experimental results are shown in Table II, and the prediction comparison results are listed in Fig. 7 and Fig. 8.

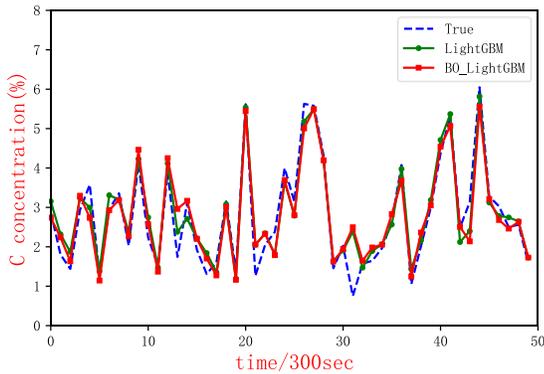

Fig. 7. Prediction Comparison of LightGBM Model and BO\_LightGBM.

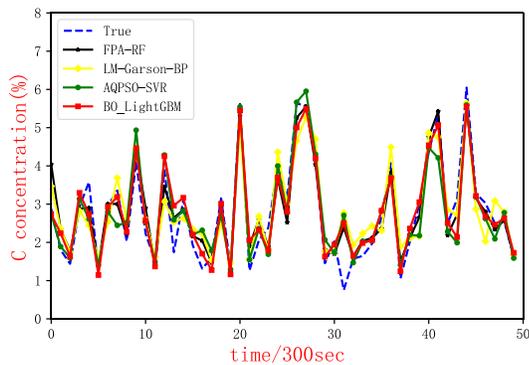

Fig. 8. Prediction Comparison of different Combined Models.

TABLE II. PREDICTION RESULTS OF DIFFERENT MODELS

Model	$R^2$	MAPE	RMSE
LM-Garson-BP [16]	0.722	19.69%	0.658
AQPSO-SVR [19]	0.786	18.22%	0.560
FPA-RF [12]	0.696	19.37%	0.652
LightGBM	0.822	16.50%	0.509
BO_LightGBM	0.831	16.02%	0.494

Table II shows the performance comparison between the proposed method and other methods. The obtained results are representative. The method proposed in this paper achieves the lowest MAPE, RMSE, and the highest  $R^2$ . The method in this paper reduces RMSE by 2.9%~24.9% and MAPE by 2.9%~18.6% compared with the above methods, indicating a further reduction of errors and improvement of measurement accuracy. The  $R^2$  was improved by 1.1%~15.1%, indicating that the prediction curves were better fitted and the method in this paper was more accurate and reliable. Specifically, LM-Garson-BP, AQPSO-SVR, and FPA-RF all use heuristic algorithms for hyperparameter tuning and combine with regression models for prediction, which improves the prediction accuracy of the corresponding models to some extent.

From the perspective of hyper-parameter tuning, The BO algorithm can find the next evaluation position based on the information obtained for the unknown objective function when facing a complex optimization problem with hyperparameter tuning that is non-convex, multimodal, and computational, to reach the optimal solution the fastest [25]. The BO algorithm avoids the issues of ineffective use of iterative feedback information and the slow search speed of the algorithm. From the perspective of the prediction model, the LightGBM algorithm objective function adopts the second-order Taylor expansion, which can fully learn the model, add regular terms, reduce the complexity of the model, prevent overfitting, support parallel and distributed computing, and effectively improve the prediction accuracy. Therefore, the prediction results are better compared to the four models compared.

### V. CONCLUSION

In this study, a data-driven approach integrating various machine learning algorithms and data mining techniques is used for the first time to analyze the relationship between the carbon content of fly ash and various operating parameters of boilers. This method has practical significance for guiding boiler production; collecting data for 37 days of complete working conditions and comparing our feature processing method with the PCC method, the RF method. The performance of the model is compared with LM-Garson-BP, AQPSO-SVR, and FPA-RF models. The results demonstrate that the method used in this paper exhibits better prediction results.

In future work, consider combining DCS data and coal type characteristics to improve accuracy by more data information. In addition, due to the high correlation between DCS data and time, it is worthwhile to study more deeply how to mine

valuable information from these unstructured time series data and find the intrinsic correlation between the time series data.

**Abstract**—Natural language texts widely exist in many aspects of social life, and classification is of great significance to its efficient use and normalized preservation. Manual texts classification has the problems such as labor intensive, experience dependent and error prone, therefore, the research on intelligent classification of natural language texts has great social value. In recent years, machine learning technology has developed rapidly, and related researchers have carried out a lot of works on the texts classification based on machine learning, the research methods show the characteristic of diversification. This paper summarizes and compares the texts classification methods mainly from three aspects, including technical routes, text vectorization methods and classification information processing methods, in order to provide references for further research and explore the development direction of the texts classification.

**Keywords**—Machine learning; natural language texts; text vectorization; classification information processing

## I. INTRODUCTION

Intelligent classification of natural language texts has many application scenarios in social life, and related research has important social value. In recent years, the research of natural language texts classification based on machine learning has received a lot of attention. Researchers tried to develop corresponding intelligent texts classification methods for different types of natural language texts, and obtained many valuable research results. The research objects involved the fields of government affairs, justice, energy and electricity, transportation, medical care and health, agriculture, science and technology, intellectual property, business, etc. The factors affecting the applicability of texts classification methods mainly include two points; firstly, the differences in the characteristics of different types of texts may affect the applicability of classification methods; secondly, the possible limitations of the training data used in model training might limit its applicability to other data of the same type.

From the perspective of technical route, the appropriate technical routes for different texts classifications are usually different due to the differences in text types and text samples. In general, the technical routes usually involve data collection, data preprocessing, text vectorization, classification information processing, classification and other links. In relevant research reports, through comparative analysis, the technical routes which were finally adopted and achieved good results were different in the links and the basic technical

methods involved. For example, for Chinese texts, it is usually necessary to add word segmentation link before text vectorization; in some classification scenarios, the classification effect could be optimized by adding feature selection or feature extraction link to reduce dimensionality before text vectorization; in the classification information processing, there are also widely differences in the appropriate information processing levels for different types of text data.

From the perspective of specific technical method, the applicability of technical method to text types has the characteristics of difference and diversity. A method may have different applicability when targeting different types of texts. Zhu F. P. et al. has achieved good classification results in the classification of news texts in the shipbuilding industry using the method based on SVM [1]; Zhao M. et al. compared the classification effects of LSTM, SVM, and CNN methods in the classification of dietary health texts, the results showed that LSTM had the best effect in the corresponding scenario, which was better than SVM [2]. The same type of texts may be classified effectively based on different types of methods, though there might be some differences in the classification accuracy. For example, Bao X. et al. compared the classification effects of the multi-instance learning method, SVM and KNN in the classification of patent texts, and the results showed that the multi-instance learning method could achieve good classification results [3]; Wen C. D, et al. used the BIGRU method in the classification of patent texts, and also achieved good results [4].

Natural language texts classification methods usually include two core parts, one is the text vectorization method, and the other is the classification information processing method. Text vectorization refers to the representation of natural language text in the form of vectors for further data processing, the technical methods used in related research include word frequency-based methods, distributed static word vector-based methods, and distributed dynamic word vector-based methods and so on. The technical methods based on word frequency express text in the form of vector mainly by counting the frequency of word appearing in the text, the principle is relatively simple and the implementation is relatively convenient, but the context-related information could not be preserved in the text vectorization; the distributed word vector methods, which understand and represent words based on context information, could effectively retain context-related information in text vectorization; the distributed dynamic word vector methods are different from the static methods, the main

Funding Project: Beijing Information Science & Technology University-Computer School- Scientific Research Business Work Funds (5029923412).

difference is that the distributed dynamic word vector methods could distinguish the polysemy of a word in different contexts. Classification information processing is the process of further processing for the information in the vectors to obtain more accurate classification prediction information after texts are represented in the form of vectors. The technical methods involved in current related research include classical machine learning methods such as SVM, NB, the methods based on signal type of neural network, the methods based on vertical combination of multiple types of neural networks, the methods combining attention mechanism, the methods based on ensemble learning strategies, etc. In general, the methods used in current natural language texts classification research usually involve the combination of a variety of basic technologies, and with the continuous development of the basic technology and the breadth and depth of the texts classification research, the basic technologies and the combination strategies are becoming more and more diverse.

This paper analyzes and compares the research methods of natural language texts classification based on machine learning from three aspects: technical routes, text vectorization methods, and classification information processing methods. On the one hand, it is expected to provide reference support for subsequent related research and application, and on the other hand, it is expected to explore the technical development direction of this field based on the analysis of high-level research reports in recent years.

## II. TECHNICAL ROUTE OF INTELLIGENT NATURAL LANGUAGE TEXTS CLASSIFICATION

The links involved in natural language texts classification include data acquisition, data preprocessing, splitting into words (for Chinese), text vectorization, feature selection, feature extraction and dimensionality reduction, classification information processing and classification. Among them, data preprocessing, splitting into words (for Chinese), text vectorization, classification information processing and classification are usually necessary links.

Natural language texts classification modeling involves multi-link collaboration. Data acquisition methods mainly include crawling data from internet, internal data and public data sets; data preprocessing mainly includes data desensitization, deduplication, removing invalid data, removing incomplete data, completing incomplete data, etc.; the link of splitting into words is usually based on jieba, and if it is combined with a thesaurus based on professional fields, better result might could be achieved; the methods commonly used in text vectorization mainly include BERT, word2vec, and TD-IDF; feature selection can reduce the vector dimension, the methods commonly used include chi-square test, removal of low-frequency words, etc.; the use of feature extraction and dimensionality reduction may improve the classification effect, related methods include PCA, etc.; classification information processing is used to find out the connection between the text content and the classification to which it belongs, related methods mainly include neural-based methods, ensemble learning-based methods in which, different types of technologies could be used in combination; in order to obtain

classification results, the softmax technical method was commonly used.

The differences and diversity exist in the technical routes of the machine learning texts classification for different types of texts or different datasets. We summarize a technical route based on the commonality summary and difference supplement, which covers the main links involved in the texts classification, and in a specific study, the technical route could be used as a basis for further applicability deletion or adjustment, the technical route is shown in Fig. 1.

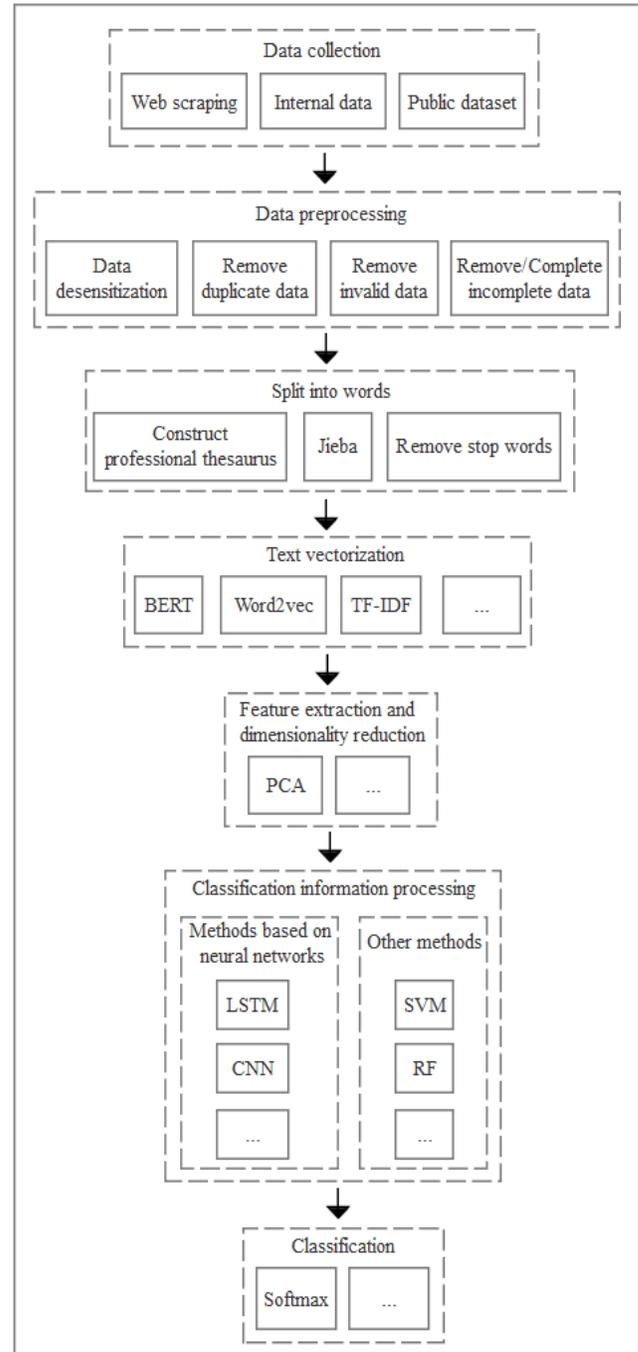

Fig. 1. The Technical Route of Texts Classification Research.

### III. TEXT VECTORIZATION METHODS

Text vectorization is one of the core links of natural language texts classification. After preprocessing, text data usually needs to be expressed in vector form firstly, and then classification information processing would be operated. Text vectorization methods could be mainly divided into four categories: methods based on distributed dynamic word vectors, methods based on distributed static word vectors, methods based on topic and methods based on word frequency, as shown in Table I.

The technical methods based on word frequency include one-hot, TF-IDF, etc. One-hot is the simplest text vectorization technical method, whose basic principle is to use an N-dimensional vector to represent text based on the size of thesaurus, the N is the number of the words in the thesaurus, for a piece of text data, each dimension value of the N-dimensional vector corresponds to a word in the thesaurus, and the value range of the dimension variables is 0 or 1, if the word corresponding to a dimension variable appears in a piece of text data, its corresponding value would be 1, and if it does not appear, the corresponding value would be 0; one-hot is simple in principle and convenient in implementation, which also has many shortcomings, for example, when the scale of thesaurus is relatively large, the dimension of the vector will also be expanded accordingly, which is not conducive for data processing and classification. One-hot could be understood as the simplest word frequency-based text vectorization technical method, furthermore, TF-IDF is a kind of some more complex text vectorization technical method based on word frequency, compared to other technical methods, TF-IDF still has the characteristics of simple principle and convenient implementation, which is widely used in current text vectorization. Text vectorization methods based on word frequency could often achieve good application results in texts classification, which also have some important disadvantages, including: (1) the extraction of text features would ignore contextual information, (2) the position information where the word appears would be lost in text vectorization, etc.

The text vectorization methods based on distributed word vector have received extensive attention in recent years. The basic principle of distributed word vector method is to understand and represent word based on the context, therefore, compared with the methods based on word frequency, it could effectively solve the problem of the loss of contextual information in the vectorized representation of text. The context-based text vectorization methods could usually more effectively extract the classification information from text data, thereby improving the classification effect, and in different methods of this type, there are also differences in the scope of the context used, based on which the technical methods could be divided into partial text information-based methods and all text information-based methods; relatively, all text information-based methods usually have the advantages in relational information extraction.

Distributed word vector methods include distributed dynamic word vector methods and distributed static word vector methods. Distributed static word vector methods understand and represent words based on context, however, it cannot solve the problem of polysemy, that is, the same word may have different meanings in different contexts, in the text vectorization based on static word vector, a word could only have one representation, so it is impossible to distinguish the different interpretations of a word in different contexts. The main difference between the distributed dynamic word vector methods and the distributed static word vector methods is that the dynamic methods could distinguish the different interpretations of a word.

Topic-based text vectorization methods are another type of commonly used methods in natural language texts classification, including LDA (latent Dirichlet allocation), improved LDA, etc. The basic principle of LDA-based texts classification methods is to firstly extract topic information based on the texts, and then implement texts classification based on the topic information.

TABLE I. TEXT VECTORIZATION METHODS

No.	Category	Method	Using Examples	References
1	Distributed dynamic word vectors	BERT (bidirectional encoder representations from transformers)	Social e-commerce text, power grid equipment defect text	[5], [6]
		ALBERT	Patent text (ALBERT VS Word2vec, global vectors for word representation)	[4]
2	Distributed static word vectors	Word2vec	Railway signal equipment breakdown short text, healthy diet text (Word2vec VS term frequency-inverse document frequency, bag-of-words model), rice knowledge text (Word2vec VS one-hot, term frequency-inverse document frequency, hashing), ultra-short commodity text, news text	[7], [2], [8], [9], [10]
		CLW2V (character level Word2Vec)	Railway text (CLW2V VS term frequency-inverse document frequency, Word2vec)	[11]
		Fasttext	Coal mine accident case text	[12]
3	Topic	LDA (latent Dirichlet allocation)	Patent text	[13]
		MULCHI-labeled LDA (improved LDA)	Science and technology video text	[14]
4	Word frequency	Bag-of-words model	Hypertension medical record text	[15]
		TF-IDF (term frequency-inverse document frequency)	People's congress report text, cultural tourism text	[16], [17]

In summary, the methods used in text vectorization have developed from simpler methods such as ont-hot and word frequency-based methods, to the methods based on static word vectors, and then to the methods based on dynamic word vectors. Zhao M. et al. compared the text vectorization methods of word2vec, TD-IDF, and bag-of-words in their research on dietary health texts classification, and the research results showed that word2vec had the best effect in corresponding scenario [2]; Wen Ch. D. et al. compared ALBERT, word2vec, and glove text vectorization methods in their research on patent texts classification, and the results showed that the ALBERT method had the best effect [4].

Text vectorization is the basis of natural language texts classification, with the development of related technologies and the extensive and in-depth development of related research, the development of the text vectorization methods could be used in texts classification currently presents two trends, firstly, new technical methods emerge in an endless stream, the new technical methods could usually better retain classification-

related information in text vectorization transformation, thereby providing a good foundation for accurate classification; secondly, in the classification of different types of texts, the applicable text vectorization methods reflect the diversified development trend, the emergence of new technical methods has enriched the options, and different technical methods have different characteristics and applicability, increasing the diversity of text vectorization technical methods.

#### IV. CLASSIFICATION INFORMATION PROCESSING METHOD

Classification information processing is another core link of natural language texts classification. After the text data is represented in the form of vector, the including classification information needs to be extracted or processed to realize texts classification. The methods mainly include neural network methods, attention machine combined methods, ensemble learning methods, active learning methods and other methods, as shown in Table II.

TABLE II. CLASSIFICATION INFORMATION PROCESSING METHODS

No.	Category	Method	Using Examples	References
1	Neural network	LSTM (long-short term memory network)	Eating healthy text (LSTM VS SVM, CNN)	[2]
		BILSTM (bidirectional LSTM)	Electricity audit text	[18]
		CNN (convolutional neural network)	Electrical equipment defect text	[19]
		MCNN (multi-pooling convolutional neural network)	Short railway signal equipment failure text	[7]
		CCNN (combined CNN)	News text	[10]
		CNN-SVM (CNN-support vector machines)	Nursing adverse event text	[20]
		CRNN (improved convolutional recurrent neural network)	Police text	[21]
		MNN (multilayer neural network)	Government website mailbox text (MNN VS naive Bayes, random forest, decision tree)	[22]
		BIGRU (bidirectional gated recurrent unit)	Patent text	[4]
		Method based on DCNN (deep CNN)	Rice knowledge text (DCNN VS BILSTM, attention-BIGRU, RCNN, DPCNN)	[8]
2	Attention machine	BILSTM-attention	Power grid equipment failure text, railway traffic accident text, commodity text	[23], [24], [25]
		CNN-NLSTM-attention (method based on CNN, nested long-short term memory network and attention mechanism)	News text	[26]
		LS-GRU (an improved GRU deep learning framework)	Medical text (LS-GRU VS BIGRU, LSTM, GRU)	[27]
		ERNIE (enhanced representation from knowledge integration)	People's congress report text	[16]
3	Active learning	SVD-CNN combined with improved active learning (CNN based on singular value decomposition algorithm combined with improved active learning)	Barrage text	[28]
4	Ensemble learning	Beam search ensemble	Short medical text	[29]
5	Other methods	NB (naive Bayes)	Cultural tourism text, agricultural text	[17], [30]
		SVM (support vector machines)	Hypertension medical record text, ship industry news text	[15], [1]
		Deep random forest	Super short commodity text (deep random forest VS k-nearest-neighbor, decision tree)	[9]
		Method based on multi-instance learning framework	Patent text (multi-instance learning VS support vector machines, k-nearest-neighbor)	[3]

Neural networks are widely used in the classification information processing in natural language texts classification, including classical neural networks, improved neural networks for specific classification problems and the combined neural networks formed by stacking different types of neural networks. There are two main advantages of the neural network methods applied to the classification information processing. On one hand, the neural network methods could usually extract the deep internal correlation information between text content and category with high quality through black-box information processing, compared with the traditional methods such as NB and SVM, neural network methods could commonly analyze classification information deeply, and thus achieve better texts classification result. On the other hand, the neural network methods have the advantage of being more flexible, in dealing with practical classification problems, the applicability could take classic neural network models (such as CNN, RNN, etc.) as basis to make suitability adjustment, and better classification results could be achieved by constructing improved neural network models to better adapt to text characteristics; different types of neural networks could also be combined vertically, using the combined neural network for texts classification information processing could realize multi-level classification information processing and possibly achieve more effective classification information extraction; neural networks could be well combined with attention mechanism to improve the processing effect for classification information, this kind of methods have attracted wide attention in related research in recent years, which could often effectively improve the classification effect of natural language texts, the combination with attention mechanism further increases the flexibility and applicability of neural network methods. In general, the advantages of deep extraction of classification information and flexibility make the neural network methods the most usable basic methods in the classification information processing of natural language texts.

Except the neural network methods, classical machine learning methods such as RF and SVM still play an important role in natural language texts classification information processing, the advantages of traditional machine learning methods are mainly that they are more convenient to implement and the principles are relatively simple, at the same time, although different types of methods have general differences in information extraction capabilities, the diversity of natural language text characteristics makes traditional machine learning methods could also be more suitable for some specific classification scenarios, which could also possibly obtain better classification results.

Ensemble learning method is an important kind of methods suitable for the classification information processing of natural language texts, the basic principle of ensemble learning is to use different basic technologies to independently train multiple models, and combine the outputs of multiple independent models through a certain strategy to obtain the final classification output. The basic technical methods used in ensemble learning could be traditional machine learning

methods such as NB, or relatively complex neural network methods such as BILSTM; ensemble learning could comprehensively apply the advantages and applicability of various types of machine learning technologies to improve the effect of texts classification. In the classification scene with diverse text features, based on ensemble learning strategy, to select different types of machine learning technologies reasonably as the basic methods could improve the applicability of the overall model and achieve high-quality texts classification result.

In summary, the methods used in the classification information processing have developed from basic methods such as NB, SVM, etc., to the methods based on neural networks, and then to attention combined methods, etc. Zhao M. et al. compared LSTM, SVM methods in the classification of diet and health texts, the results showed that LSTM has the best effect in corresponding scene [2]; Liu Y. et al. combined convolutional neural network (CNN), nested long short-term memory network (NLSTM) and attention mechanism in the study of news texts classification, and achieved good results using the CNN-NLSTM-Attention method [26]. In addition, the ensemble learning method could effectively combine the advantages of multiple classification models to improve the classification accuracy, which has received more attention in recent years [29]. Relevant theories and methods are becoming more and more abundant, further research and application could start from the texts characteristics to refer to research reports of the same type of texts for method selection or the basis for optimization, so as to efficiently and accurately implement texts classification modeling.

## V. TEXT TYPES

Natural language texts classification commonly involves multiple links, in each link, the relevant basic technical methods have different applicability in different classification problems, and the main reason is the diversification of natural language text features; in texts classification research, the application could take the text types as a basis, and refer to existing related research reports to select technical methods or build a basis for the further improvement.

In order to provide convenient reference for subsequent relevant researchers, we have sorted up the research reports cited in this paper according to the text types of their research objects, which involves the fields of energy and environment, justice, government affairs, transportation, medical care and health, agriculture, science and technology, commerce and so on, as shown in Table III. This paper conduct analysis and research mainly from the perspectives of the technical routes of natural language texts classification and the main technical methods suitable for the core links, which does not comprehensively cover the text types already involved in natural language texts classification research, it is expected that subsequent researchers could make quick reference based on the text types table organized in this article or take it as a basis for further improvement.

TABLE III. TEXT TYPES OF NATURAL LANGUAGE TEXTS CLASSIFICATION

Field	Text type	References

## VI. CONCLUSION AND OUTLOOK

In general, the research on natural language texts classification received a lot of attention in recent years, and the research reports involved many important aspects of social life, including intellectual property, government affairs, justice, energy and electricity, transportation, medical care and health, agriculture, science and technology, commerce and so on, which constructed a favorable foundation for further research and applications. In terms of texts classification methods, the methods show diversification, and different methods commonly have different characteristics and applicability differences, which are closely related to text characteristics; follow-up research could take text characteristics as the basis to select and further improve classification methods.

The core links in natural language texts classification include text vectorization and classification information processing, in recent years, the theories and technologies in these both two aspects have made great progress; the text vectorization methods have developed from the basic methods such as the methods based on word frequency to the methods based on distributed static word vectors, and then to the methods based on distributed dynamic word vectors; the classification information processing methods have developed from the methods based on a signal technology such as SVM, CNN or RNN to the methods based on vertical integration of multiple technologies and the methods based on ensemble learning. The emergence of new theories and technologies provide more options for subsequent texts classification research, and also constructed more advantageous basis for

further development of related theories and technologies; and at the same time, due to the diversification of text characteristics, the development trend of texts classification methods could still be diverse development.

In terms of similar studies comparison, the text classification modeling based on machine learning has received extensive attention in recent years, and at the same time, researchers have carried out some review and summary works. The relevant researches mainly summarized and analyzed from the aspects of research progress and development trends, and there are few systematic analyses for the links involved in text classification. This paper systematically analyzed the links involved in natural language text classification research, and summarized main research methods based on the core links. It's expected that this paper could efficiently provide reference for subsequent related research.

**Abstract**—Since ancient times, natural fibers have been essential in paper production and packaging fabrication. However, beauty-marring carbonization, or a heat-affected zone (HAZ) generated during the laser cutting process of paper materials led to an intriguing discussion on the possibility of reducing this defect zone. Thus, paper loaded with aluminum hydroxide [Al(OH)<sub>3</sub>] (AH) was prepared and tested with laser cutting. There were two input parameters of laser processing: the ratio of laser power to a maximum and the cutting speed. The study discussed the HAZ area of the paper with AH loaded at 0–40% on a dry pulp basis. The HAZ area was measured through image processing software. The Otsu thresholding technique (OTT) was applied to HAZ area determinations. The results from the image analysis signified that the smallest HAZ area was successfully achieved on samples with AH loaded at 40%. The optimal condition for the sample with 40% AH loaded was 60% power ratio and 20 mm/s in cutting speed. Based on the results, the cutting speed was the most significant parameter to produce the smallest HAZ area; therefore, the laser processing parameters were optimized to achieve a minimum HAZ area, and it was possible to reduce its dark color appearance of the material surfaces. Based on this study, it was found that the application of the Otsu thresholding technique was of significance to the HAZ area determination and reduction of the time consumption for the image analysis.

**Keywords**—Heat-affected zone; image analysis; image processing; laser cutting; thresholding

## I. INTRODUCTION

The digital image may be described as the two-dimensional function which refers to  $f(x, y)$ . To make it easy to understand, pairs of  $x$  and  $y$  are plane or spatial coordinates, and the amplitude of function  $f$  at any coordinates of  $x, y$  is called gray level or scale. Thus, when  $x, y$ , and  $f$  are all finite, we call the function  $f$  a digital image. The digital image processing is performed with a computer [1] its techniques has been widely thriven and they are now used for all kinds of tasks in various areas such as image recognition technology along with computer vision and thresholding techniques [2]. Image analysis is an area related with image processing and the extraction of useful information from an image is beneficial to various fields ranging from computer vision applications to

medical bioimaging analyses. Vision is the most advanced human senses; however, our vision is limited to the visual band of the electromagnetic spectrum. Thus, imaging machines such as electron microscopy, and computer-generated images used to operate on images [1]. Thus, digital image processing and analysis so popular nowadays and encompasses a varied field of applications. There is almost no technical area that is not impacted by the digital image processing. In our case, it is crucial to extract useful information from images that can help determine the HAZ and improve the laser cutting process. In the laser cutting process, image processing techniques and image analysis are helpful for HAZ determination.

The laser cutting process has recently become a fascinating element in paper-based product fabrication. This is because of the wide range of applications from cutting to engraving [3], perforating, and designing complex geometrics [3]–[8]. Moreover, due to the growing personal needs as well as product quality and high productivity, it is convenient to apply laser cutting technology. However, carbonization and heat-affected zone (HAZ) seem to lead to an intriguing discussion on whether reducing the HAZ in the laser cutting process is possible. Laser cutting is an efficient method for cutting materials as it can be operated readily. Through understanding, high-quality cutting optimal parameters can be obtained. Even though laser cutting has been applied since the 1990s for cutting, perforating, and creasing paper materials, unfortunately, only a few works in literature have been discussed using the laser process of paper products. The mechanisms of laser cutting for paper or other wood-based materials are a thermochemical decomposition [8][9] involving vaporization, meaning the paper material reacts to heat generated by laser beam irradiation and evaporates from the surface.

The study of laser cutting quality focused on two laser processing output which are HAZ and kerf of the cuts. However, in this study, only the HAZ output will be discussed. To analyze the HAZ quality, image analysis needed to determine the optimal setting of the laser process. Over the years, image processing and image analysis studies in the laser cutting has been grown [10] [11]. Even there was various image processing techniques reported in the literatures, this

study focused on the Otsu thresholding. In computer vision and image processing, Otsu thresholding technique (OTT) which is named after Nobuyuki Otsu, is performed to obtain automatic image thresholding. It is a simple form of algorithm. The algorithm returns a single threshold intensity that can separate pixels into two regions: foreground and background [12]–[14].

This paper is of significance on the study of HAZ and the laser cutting field. By analyzing the HAZ images and determining its HAZ area, the determination of laser cuts can be done faster and cost effectively. The use of digital image analysis has been widely thrived in laser cutting studies [15][16]. However, the literatures only reported the HAZ measurement values by measuring the mean HAZ width without any further discussion on how to determine the HAZ area. Thus, this study aimed to explore and investigate the image processing and image analysis of HAZ using ImageJ global thresholding techniques. This study reported the image processing technique and image analysis used to improve HAZ image analysis that beneficial to the laser cutting field.

## II. LITERATURE REVIEW

In the laser cutting, especially during the heating and vaporizing processes, the paper material absorbed heat energy, carbonized, and produced a HAZ. Thus, when laser cutting is performed, the process of material degradation will cut cellulose molecular chains to its shorter elements comprised of small chains of polysaccharides, carbon dioxide, carbon, and water vapor [17] [18].

Paper materials are used in packaging development because they are environmentally friendly materials because of no carbon emission and play roles as alternatives to petroleum-based plastics for packaging. The application of paper-based packaging has become widespread in alignment with a campaign to zero single-use plastics consumption and goals. For understanding the application of paper in packaging and its fabrication using laser cutting, the nature of paper must be understood first. A natural and renewable resource like plant fibers is eco-friendly, low cost, and has soft features and properties [19]. The composition of plant fibers is mainly cellulose, hemicellulose, and lignin. These three components determine the plant fiber properties. Plant fibers are a significant raw material that influences the thermal properties of paper. Some paper products, such as heat-resistance label paper and heat-resistance release paper, require fiber with high thermal stability [20]. In the thermal analysis conducted by Soares et al. 2001 [21][4], the pyrolysis of hemicellulose and cellulose readily happened. It has been reported that the loss of hemicellulose occurred between 220°C and 315°C, while that of cellulose occurred between 250°C and 400°C. However, lignin degrades at a wide temperature range from 160°C to 900°C, meaning it is more difficult to decompose. Consequently, plant fibers have poor heat-resistance, and its decomposition begins at 220°C, limiting its application at high temperatures. The mechanism of laser cutting for paper or other wood-based materials is a thermochemical decomposition process [18]. The cutting mechanism is vaporizing, which means the paper material will react to the laser beam and evaporate when the heat of the laser beam reaches the surface. Thus, when laser cutting is performed, the

process of material degradation will reduce cellulose from large cellulose molecules to its small elements, which are small chained of hydrocarbon, carbon dioxide, carbon, and water vapor [9]. Recently, natural fiber has become essential in paper-based product fabrication and laser cutting applications.

Aluminum hydroxide  $[Al(OH)_3]$  (AH) is known as a green inorganic flame-retardant [22] and has been applied as a heat-resistance compound used in flame retardant systems [23] for years. For instance, AH is used in the making of heat-resistance and flame-retardant papers [20]. Many methods have been proposed to modify the paper with AH. One of them was a placement of AH on the surfaces and inside walls of fibers. By implementing the method, AH was successfully distributed evenly on the inside and surfaces [24]. During exposure to high temperatures, AH starts to decompose while absorbing heat sourced from the radiant energy of the laser and eliminating water. Then the emitted water molecules absorb heat to evaporate and decrease the temperature around the HAZ. This mechanism leads to the improvement of the thermal properties of the modified fibers and paper. Based on the Yang, F. et al. study [24], the paper samples modified with AH content succeeded in resisting the heat by determining its thermal properties using the thermal gravimetric analysis (TGA). However, their study did not link with the application of laser irradiation process or discussed any thermal process [16].

Generally, the basic mechanisms of laser cutting are exceptionally easy to understand. Infrared light contained in a high-intensity beam is generated by a laser [25]. The beam focuses onto a material surface through a lens. The focused beam functions to heat the material and caused it to melt in case of plastics and vaporized [17]. Then, the molten material will be ejected from the area by pressurized gas. The schematic of laser cutting can be seen in Fig. 2. This study also discussed the effects of various combinations of laser power ratio and cutting speed on the area of HAZ. The samples with different contents of AH loaded were tested. The laser cutting process has been applied to them, including the control sample (without AH loaded) to determine whether it resists the heat and reduces the HAZ production during the laser cutting process. The laser cutting process has been applied to them, including the control sample (without AH loaded) to determine whether it resists the heat and reduces the HAZ production during the laser cutting process.

Based on the literature, in determining the optimal setting of HAZ, the cutting speed should be maximized to prevent excessive heat transfer depending on this parameter [26]. It also highlighted that laser power variations show less impact, and cutting speeds show more impact on HAZ. Furthermore, based on previous literature studies, the quality of a cut can be obtained by determining one of the outputs which is HAZ [27]. The significant reason that those two parameters were chosen has been discussed in literatures [4][5][8]. In this study, laboratory-made paper sheets loaded with AH were cut using  $CO_2$  laser processes at different laser power ratios and various cutting speeds. These processed samples were micrographed with a focus on the HAZ to analyze it using image processing software ImageJ [28]. Even though many methods were presented in the literature using various software tools, ImageJ

was chosen because it is the most popular open-source software provided with a detailed manual and tutorials [22].

In image processing, there is no general agreement among authors regarding when and where the image processing stops. Also, in other related areas such as image analysis and computer vision, and when it starts. However, it is important to highlight that in image processing there are types of computerized processes involved; segmentation, classification (recognition) of individual objects, extracted edges and contours [1]. Image segmentation refers to the algorithms class that can partition the image into different pixel groups or segments. In that case, image thresholding is the best and simplest image segmentation as it partitions the image into two pixels groups which are foreground and background [29].

Thresholding is an essential application, especially in any field of study that relies on image detection, inspection, and classification. The thresholding performance depends on the object-background difference in gray level, noise, and the size and position of the object [30]. The process of selecting the optimal thresholding algorithm is the most important step in image processing and analysis. Image processing has been applied in many fields with computers to process digital images through basic operations or advanced algorithms. Thus, we can extract various information from the original images through image processing and analysis. However, the manual threshold process was not preferable in the image analysis for its several limitations. Especially with a high possibility of high bias while performing the image processing [31]. It is also time-consuming to perform a manual threshold for analyzing many images. Therefore, the most crucial part of binarization is identifying the best threshold algorithms and comparing them with a least-biased comparison [23] [24].

There are 16 universal thresholding algorithms offered by ImageJ, which are Huang, Huang2, Intermodes, IsoData, Li, Mean, MinError(1), Moments, Otsu, Percentile, RenyiEntropy, Shanbhag, Triangle, and Yen. However, this study focused on the Otsu thresholding technique (OTT) based on its advantages in terms of simplicity, robustness, and the most widely applied thresholding algorithm [30] [32]. Apart from those reasons, we mainly chose OTT because we focused on determining the HAZ by identifying the optimal thresholding that is highly capable of detecting the area and edge of HAZ. In our case, HAZ images need optimal thresholding to avoid erroneous detection of an edge, dark pixels in the background, and an excessive number of pixels for the edge [33]. Therefore, in our case, OTT was the best option because of its performance in detecting edges and the HAZ area properly. The equation and demonstration of OTT application has been discussed in literature [33]. The OTT is based on the histogram of grayscale images, the main idea is to maximize the between-class variance (foreground and background region) in the histogram. By using OTT, we get the best threshold value that maximizes the variance of HAZ area and background.

OTT was proposed by Nobuyuki Otsu [12] in 1975. Since then, Otsu's technique has become the most widely used in image thresholding algorithms. The concept of OTT can be simplified into the following steps: (1) processing the input image, (2) obtaining image histogram (pixels distribution), (3)

computing the threshold value ( $t$ ), and (4) replacing the pixels obtained from the image by partitioning white and black regions. One of the advantages of OTT is its simplicity in calculating the threshold values because it only involves single-dimensional intensity data; therefore, the process helps in reducing the time for computational processing. OTT is useful in performing image segmentation because it involves a simple mathematical expression in its algorithm. Thus, it requires less computational time compared to other thresholding techniques. Owing to the advantages, the improvement of OTT has been discussed in Kalathiya et al. study [34]. The OTT (iterative and custom approaches) modified by them are also demonstrated in their study.

Over the years, the scientific community has explored the thresholding techniques in image processing. Apparently, Otsu technique appeared as the most prominent for this purpose. ImageJ Otsu global thresholding algorithms is an implementation of the OTT [12]. The histogram is classified into two classes and the inter-class variance is minimized. The Otsu thresholding can be found in ImageJ software under Auto Threshold options. Gonzalez and Woods have been discussed the Otsu method in depth in the literature. The Otsu's algorithm summarized as; (1) computation of the normalized histogram of the input image, (2) computation of the cumulative sums, (3) computation of the cumulative means, (4) computation of the global mean, (5) computation of the between-class variance term, (6) Obtaining the Otsu threshold and (7) computation of the global variance [1].

However, our study mainly focuses on applying the OTT for extracting HAZ. Although many studies in the literature have discussed the characteristics of HAZ generated in a laser cutting process, most of the recent literature mentioned more about the use of image processing to measure the HAZ area without any further discussion on how it is done. Therefore, this study is useful for the laser cutting process field of study in terms of image detection and analysis. Through this kind of study, HAZ can be easily determined, optimizing the laser process and its relations to input parameters, and minimizing the HAZ can be achieved.

### III. MATERIALS AND METHODS

#### A. Paper Sheet Preparation

The material used in the experiments was laboratory sheets prepared from pulp fibers and loaded with AH to reinforce heat resistance. The fiber materials used were commercially available hardwood pulp (Eucalyptus species). AH in the special grade was purchased from Fujifilm Wako Chemicals, Osaka, Japan. Alkyl ketene dimer (AKD) (AD1608, Seiko PMC Corporation, Tokyo, Japan) as a sizing agent and polyamine polyamide epichlorohydrin (PAE) (WS4030, Seiko PMC Corporation) as a cationic polymer for retaining the size. To prepare laboratory sheets, a 1.0% AKD emulsion was first prepared by weighing 1 g of AKD emulsion stock solution (25% solids) and diluting it 25 times. Next, a 1% cationic polymer solution was prepared likewise from the PAE stock solution (25% solids). A total of 27 g of air-dried hardwood pulp was weighed and disintegrated in 1.6 L of water using a disintegrator specified in the ISO standard for 5 min and poured into a sieve for drainage. Then, the pulp was squeezed

to 10% solids and beaten to 5000 times on a PFI mill. The pulp beating process swells pulp fibers, and therefore improves fiber flexibility and mechanical strength[35]. Next, the beaten pulp slurry was diluted to 1.6 L of water and disintegrated at 3000 rpm with the disintegrator for 1 min. Then, the suspension was diluted to 11.25 L of water, and 7.5 ml of sizing agent (1.0 % AKD) was added and stirred for 1 min, followed by adding AH (10%, 20%, and 40%) and 7.5, 15, and 30 mL of retention aid solution (PAE), respectively for sample B, C, and D as shown in Table I. It was then mixed for 1 more min. AKD works as a sizing agent, and PAE works as a retention aid when the pulp is mixed with the AH component. Paper sheets with a targeted basis of about 100 g/m<sup>2</sup> were prepared using a standard sheet former (ISO 5269-1:2005), pressed with the hydraulic press at 0.34 MPa, set between metal rings, and stored in a controlled environment (23°C) for restraint air drying.

TABLE I. THE COMPOSITION OF SOLUTION

Sample	Composition of solution for hand sheet paper making		
	AH to dry pulp mass ratio (%)	AKD (mL)	PAE (mL)
A	0	0	7
B	10	7.5	7.5
C	20	7.5	15
D	40	7.5	30

**B. Laser Processing Setup**

The experiments were conducted with a CO<sub>2</sub> laser cutting machine (PODEA 20W ZERO Corsa, PODEA Co. Ltd, Saitama, Japan) with a maximum output power of 20 W with a spatial resolution of 1000 dpi. A schematic of a laser beam head and cutting mechanism is shown in Fig. 1. The vector cutting speed is 20 mm/s at a maximum. One straight cut, each of 5 mm in length (Fig. 2a and 2b), was performed for each experimental run. Then, the results of the laser cuts were evaluated in terms of the HAZ area.

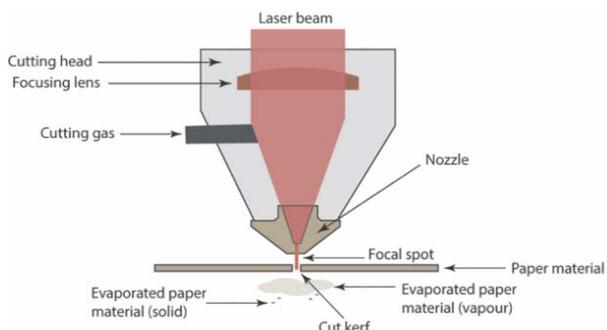

Fig. 1. A Schematic of a Laser Beam Head and Cutting Mechanism.

**C. Cutting Parameter Choice**

There were two laser parameters chosen: (1) laser power ratio expressed in percentage and (2) cutting speed (mm/s). The laser power ratio was chosen from 20%, 40%, 60%, 80%, and 100% to the maximum and the cutting speed was chosen from 4, 8, 12, 16, and 20 mm/s. The process parameters were performed for each paper condition. The laser cuts with the smallest areas of HAZ were chosen for optimization [16].

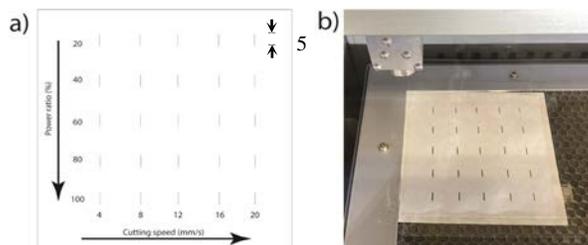

Fig. 2. (a) Illustration of Laser Cut Design (b) Laser Cutting Process.

**D. Scanning Electron Microscopy (SEM) and Optical Microscopy**

SEM images of heat resistance paper samples were taken using Hitachi Tabletop Microscopes (TM4000Plus). An industrial stereo microscope OLYMPUS SZX10 (Olympus Corporation, Tokyo, Japan) was used to observe the boundary of HAZ. First, optical images were captured using a digital single-lens reflex camera (EOS Kiss X8i, Canon Inc., Tokyo, Japan). Then, the image processing and analysis were performed using ImageJ software to identify and measure the HAZ area by performing binarization and thresholding algorithms.

**E. Image Segmentation and HAZ Area Measurement**

The identification of the area and edges of HAZ followed the procedure in Table II. First, original HAZ images were converted to the grayscale format via the RGB format. Next, image segmentation was performed with the thresholding values (*t*) determined using OTT.

TABLE II. THE IMAGE PROCESSING AND IMAGEJ COMMANDS

Image Processing	ImageJ Commands
Grayscale conversion	Image > Type > 8 bit
Thresholding	Image > Auto (global) Threshold > Select method (All 16 global threshold methods have been tested and optimal thresholding selected.)
Particles analysis	Analyze > Analyze particles

#### IV. RESULT AND DISCUSSION

##### A. Scanning Electron Microscopy (SEM) and Optical Microscopy

Samples were coated with platinum (Pt) using a spatter before observation with Hitachi Tabletop Microscopes (TM4000Plus). Fig. 3a-d shows the SEM images of the laboratory sheets with and without AH. Fig. 3a shows no particles in Sample A with no AH loaded. Obviously, AH particles are observed to be distributed increasingly in order of increasing AH dose from Samples B (10%), then C (20%) until D (40%).

Fig. 4 shows a HAZ area clearly. The clear definition of HAZ can be defined and referred to the dark burn area that clearly visible under the optical microscope. By analyzing the image, we can determine the HAZ area for each laser process parameter and setting. Each image resulted from the various setting of the laser power ratio percentage and cutting speed can be studied through image processing and image analysis.

##### B. Image Segmentation

Among the results of image segmentation available with ImageJ for the HAZ images, OTT outperformed the other 15 methods (Fig. 5) in terms of sensitivity and accuracy in detecting the intended areas in the foreground from the background obviously even by visual comparison to the original image. The OTT algorithm is one of the most used methods in binarization [31] [36]. The OTT algorithm refers to the bi-modal image histogram. We focused on OTT not just because it is used widely in many computers vision applications but also because its performance on image segmentation was by far the highest. In this case, the pixels of a HAZ became the foreground. The purpose of thresholding was to separate the HAZ as the foreground from the background. All pixels of a HAZ with intensity lower than a threshold value are considered as the background. After the binarization process, the HAZ area was identified and measured. Based on these values, HAZ was studied for each batch of samples (A to D in Table I). In the field of laser process study, it is crucial to determine and understand the HAZ. Moreover, it is important to understand the HAZ area and its correlation with the laser process parameters. Through this process, accurate extraction of HAZ has become possible using the image analysis data. The results showed the smallest values of HAZ area achieved in the condition of optimal laser process parameters for each sample (Table III).

As digital image processing is an important tool to analyze the HAZ images. The main step used to perform image analysis in digital image processing through the flowchart is shown in Fig. 6. The process of OTT started with the acquisition of data image, then followed by image segmentation through the Otsu technique. Image segmentation is an essential step in digital image processing to partition the HAZ image into foreground and background regions. In general, there are three segmentation techniques that used in image segmentation which classified as edge-based segmentation, region-based segmentation, and special theory-based segmentation [37]. In our study, we used region-based segmentation using OTT.

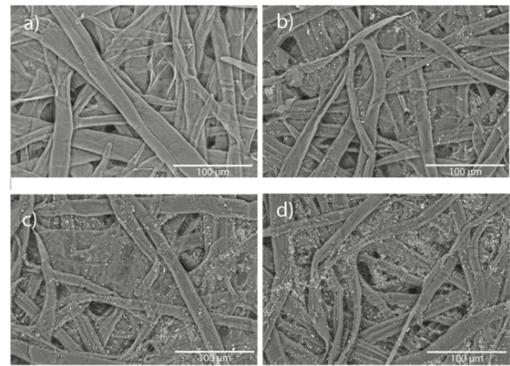

Fig. 3. The Micrographs of the Paper Surface with Different Conditions, (a) Sample A—Control (without Additives), (b) Sample B—10% of AH Loading, (c) Sample C—20% of AH Loading, (d) Sample D—40% of AH Loading.

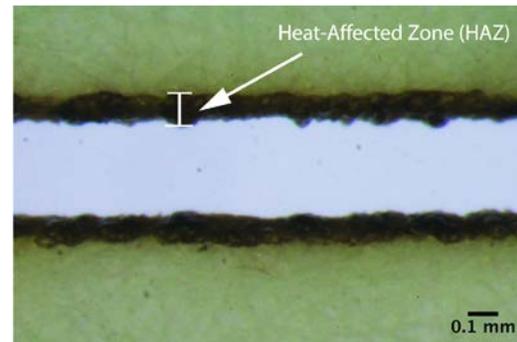

Fig. 4. HAZ Observed through an Optical Microscope.

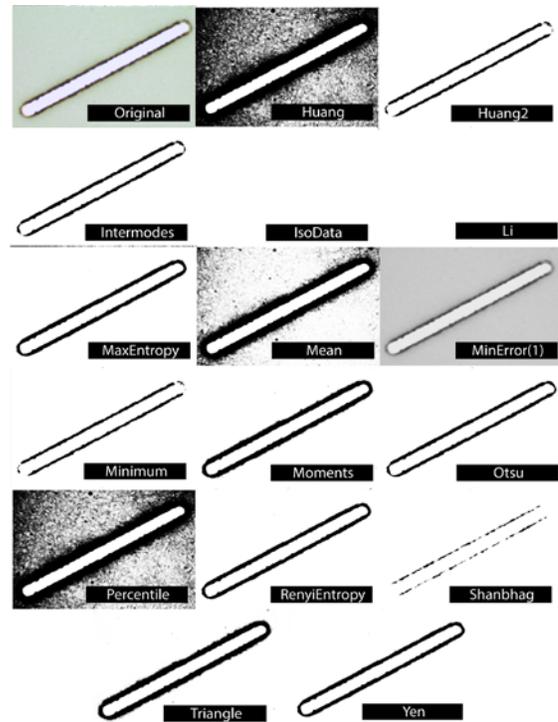

Fig. 5. Original Image and Threshold Images using 16 ImageJ Global Thresholding Techniques.

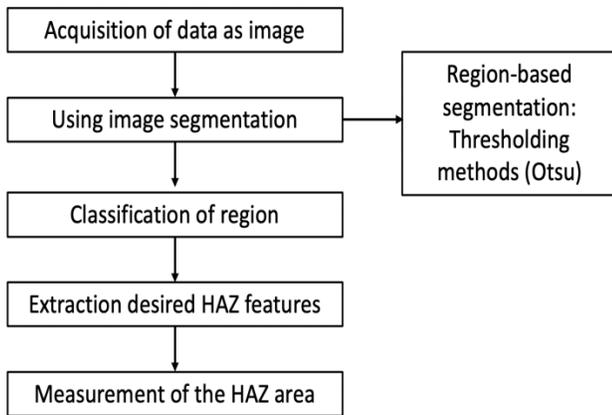

Fig. 6. Main Steps used in Image Analysis in Digital Image Processing.

Meanwhile, Fig. 7 shows some of the overlay images of threshold images on top of original images. The threshold images segmented successfully and unsuccessfully using various thresholding techniques. Fig. 7a shows the grayscale of the HAZ (ground-truth image) and red threshold refers to the detected threshold of HAZ using the mentioned techniques. Fig. 7b shows the successful segmentation of the HAZ using OTT. Fig. 7c and 7d show the unsuccessful segmentation using Shanbhag and Triangle thresholding technique. The criteria that we used to determine the OTT performance by observed the images of original grayscale and threshold images were overlaid on top of each other, and OTT was the best option and optimal thresholding based on its sensitivity in detecting the HAZ area. The OTT-treated image overlapped perfectly with the HAZ.

### C. Criteria for Selection of Thresholds

The proposed method makes use some thresholds in HAZ detection for showing the comparison between Otsu and other two examples which are Shanbag and Triangle. As mentioned earlier in Fig. 5, all ImageJ global thresholding performed in identifying the optimal thresholding for the HAZ detection. Thus, in Fig. 7 we overlapped each detected threshold images on top of the original grayscale image. The result of Fig. 7b shown the OTT successfully overlapped accurately compared to the Fig. 7c and 7d which is represent the Shanbag and Triangle technique respectively. However, for another alternative, the detected threshold value of HAZ can be measured or assessed using P-Tile as suggested by Samopa, F. and Akira, A. (2009) and Neogi, N., Dushmana, K.M., and Pranab K. Dutta (2017) [38][39]. However, the challenges are when it is not applicable when the object area ratio is unknown.

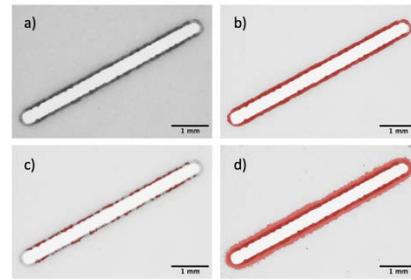

Fig. 7. Some Image Segmentation Results using Different Thresholding Techniques: (a) Original Grayscale Image, (b) Successful Segmentation using OTT, (c) Unsuccessful Segmentation using Shanbhag, and (d) Unsuccessful Segmentation using Triangle.

### D. HAZ Analysis

Fig. 8 shows the HAZ area based on various cutting speeds and laser power ratios for Sample A. The low values of HAZ obtained through an optimal laser power ratio of 80% and cutting speed of 20 mm/s gave the optimum desired output of HAZ with the 0.705 mm<sup>2</sup>. Secondly, the results of Sample B (Fig. 9) showed that the optimal process obtained the smallest HAZ (0.690 mm<sup>2</sup>) through 60% and 100% with a cutting speed of 20 mm/s. However, by considering the power consumption, 60% was preferred compared to the 100% ratio. Thirdly, the results of Sample C (Fig. 10) demonstrated that the highest cutting speed was significant in the smallest area of HAZ. The smallest area value with 0.755 mm<sup>2</sup> was achieved through the highest cutting speed (20 mm/s) and combined with a 100% power ratio. Lastly, the results of Sample D (Fig. 11) showed that the combination of a 60% power ratio with a cutting speed of 20 mm/s successfully obtained the smallest HAZ with 0.629 mm<sup>2</sup>. Based on the 100 laser cuts that had been performed, it demonstrated that the modified paper with a different composition of aluminum hydroxide showed resistance to the heat and produced a smaller area compared to the control sample. The smallest area of HAZ obtained through Sample D loaded with the largest amount of AH. The optimal laser process condition of each sample is highlighted in Table III.

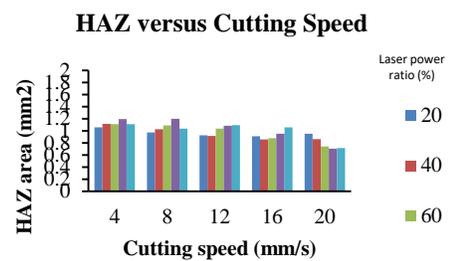

Fig. 8. HAZ Area Compared at Different Laser Power Ratios and Different Cutting Speeds for Laboratory Paper Sheets with no AH.

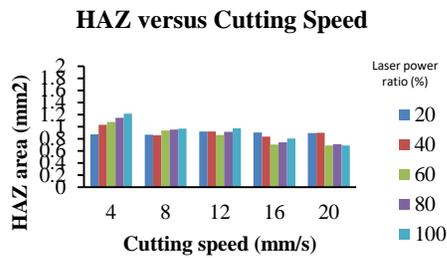

Fig. 9. HAZ Area Compared at Different Laser Power Ratios and Different Cutting Speeds for Laboratory Paper Sheets with 10% AH.

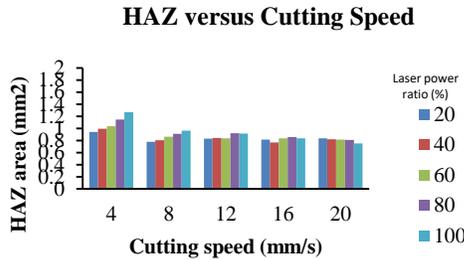

Fig. 10. HAZ Area Compared at Different Laser Power Ratios and Different Cutting Speeds for Laboratory Paper Sheets with 20% AH.

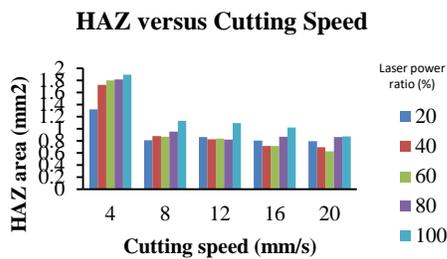

Fig. 11. HAZ Area Compared at Different Laser Power Ratios and Different Cutting Speeds for Laboratory Paper Sheets with 40% AH.

TABLE III. LABORATORY SHEET THICKNESS AND OPTIMAL LASER PROCESS CONDITION FOR EACH SAMPLE

Sample	Thickness (µm)	HAZ area at minimum (mm <sup>2</sup> )	Optimal condition
A	140	0.705	80 % power ratio and 20 mm/s cutting speed
B	148	0.609	60 % power ratio and 20 mm/s cutting speed
C	150	0.755	100 % power ratio and 20 mm/s cutting speed
D	183	0.629	60% power ratio and 20 mm/s cutting speed

## V. CONCLUSION

In the laser cutting process of paper materials for packaging applications, blackening generation of a HAZ by pulp fiber carbonization mars beauty. However, the characterization and

evaluation of HAZ lead to an intriguing discussion on the possibility of reducing this defect zone. Thus, laboratory paper sheets loaded with aluminum hydroxide (AH) were prepared because we highlighted the effect of AH to stabilize heat resistance and carbonization prevention. Laboratory paper sheets with four different amounts of AH loaded were processed by laser cutting. All the HAZ were captured with an optical microscope. The HAZ area was measured by image processing through OTT available with ImageJ. The image segmentation based on OTT permitted to accurately measure the HAZ area. Also, an optimal combination of the laser power ratio and cutting speed providing a minimum of the HAZ area was pursued. We have found that the laboratory paper sheets with the largest amount of AH loaded produced the smallest area of HAZ by a combination of a laser power ratio of 60% and a laser cutting speed of 20 mm/s. Our future work will possibly focus on depth discussion on the other image processing techniques that can be applied in laser cutting image analysis such Gonzalez & Woods technique, and other ImageJ global thresholding techniques.

## ACKNOWLEDGMENT

The authors gratefully acknowledge the Japanese Society of Printing Science and Technology (JSPST) for the printing technology research incentive. Also, special thanks to Open Facility, Research Facility Centre for Science and Technology, the University of Tsukuba for allowing the authors to use the equipment. Shalida Mohd Rosnan wants to acknowledge the Japanese Government Monbukagakusho (MEXT) Scholarship under the Special Program on Transworld Professional Human Resources Development Program on Food Security and Natural Resources Management (TPHRD).

# Hadoop as a Service: Integration of a Company's Heterogeneous Data to a Remote Hadoop Infrastructure

Yordan Kalmukov, Milko Marinov

Department of Computer Systems and Technologies, University of Ruse, Ruse, Bulgaria

**Abstract**—Data analysis is very important for the development of any business today. It helps to identify organizational bottlenecks, optimize business processes, foresee customers' demands and behavior, and provides summarized data that could help reducing costs and increase profits. Having this information when designing new products or services highly increases the chances of their success, and thus provides an additional competitive advantage over other businesses. However, having a single data analyst with a computer is far from enough in the era of big data. There are powerful data analytical software tools, but they are either expensive or hard to deploy and require multiple high-performance servers to run. Buying expensive hardware and software, and hiring highly-qualified IT experts, is not affordable for all companies, especially for smaller ones and start-ups. Therefore, this article proposes an architecture for integration of a company's heterogeneous data (stored within a database of any type, or in the file system) to a remote Hadoop cluster, providing powerful data analytical services on demand. This is an affordable and cost-effective cloud-based solution, suitable for a company of any size. Businesses are not required to buy any hardware or software, but use the data analytical services on demand, paying a small processing fee per request or by subscription.

**Keywords**—Hadoop integration; data analytical tools; heterogeneous data integration; Hadoop distributed file system (HDFS); HBase; hive

## I. INTRODUCTION

Data acquisition and analysis are very important for the development of any business today. They help to better understand the underlying business processes and allow their subsequent optimization and reorganization. The analysis of the collected data provides the company the ability to identify dependencies among processes, objects and subjects; to optimize resource planning; to analyze consumers' needs and behavior; to foresee customers' actions and demand; and many others. All these analyses give a significant competitive advantage to the company over the other competitors, since it can easily detect trends or bottlenecks and identify ineffective processes to optimize.

For all this to happen, however, the company must have the necessary computer hardware, software and the human resources to do the analysis. In case of processing large volumes of data, having a computer and an expert in the field is far from enough. Manual analysis of big data by a single person is practically impossible. Instead, automated,

computer-based tools should be applied in order to analyze big data efficiently and effectively. However, these tools are quite expensive and not every company can afford to buy them, especially start-ups. There are free tools either, some of them very powerful, but not that user-friendly, requiring highly-qualified programmers and IT administrators to deploy and configure them.

A set of powerful data analytical tools is provided by the Hadoop ecosystem [1],[2]. They are built on top of the Hadoop Distributed File System (HDFS). Most of them are distributed as open source applications developed and maintained by community of enthusiast professionals, under the auspices of the Apache Software Foundation. The tools are quite powerful, but as distributed computing applications they should be installed and configured on multiple servers. So, a company that wishes to build its own data analytics infrastructure should buy multiple high-performance servers and hire IT experts to deploy and configure the entire cluster.

Although there are third party installation and management wizards, for example Cloudera Manager, installation of Hadoop services is far from trivial and easy. There are many dependencies that should be considered in advance. For example, since all services run on top of HDFS, if the HDFS itself is not properly installed and configured, the installation of the data analytics tools may fail. The biggest problem is that in case of failure, a subsequent reinstallation is not an option at all, since there are many files left in the server's filesystem from the previous installation. A subsequent reinstallation will just make things messier. Installation and deployment should be done by really qualified and experienced IT experts. Their wages however could be even higher than the money spent for dozens of high-performance servers. As a result, installation and maintenance of own Hadoop infrastructure could be quite expensive and not affordable for small and medium size enterprises, especially for start-up companies.

Fortunately, there is a cost-effective, more flexible and easier way to use Hadoop ecosystem's data analytics tools than building a company's own Hadoop infrastructure. The cloud computing model can help a lot here. An experienced IT company, a service provider, could build the entire Hadoop infrastructure on its own servers, and then offers all the Hadoop's data analytics tools to other companies as services for rental. The idea could be named "Hadoop as a Service (HaaS)".

How could an external organization/company take advantage of the data analytics resources of the service provider? By integrating its data to the Hadoop cluster of the service provider. And this could be done at much lower cost for the external company than if it had to build its own infrastructure for data analysis. During integration however, it should be taken into account that both the Hadoop infrastructure and the company's database are already existing systems. Not just existing systems, but heterogeneous systems. The latter is very important and implies that some intermediate layer should be developed and deployed on top of the Hadoop cluster that will allow external applications/users to communicate with it regardless of their own architecture and implementation technologies. Furthermore, there is another key requirement as well – together with the data integration, the service provider should support data separation. Data separation means that data shared by one company should be invisible and inaccessible to all other companies working with the cluster. That is a key requirement from any business – to prevent illegal industrial espionage and stealing of sensitive data. In this sense, probably the most reliable, flexible and appropriate integration strategy is by implementing a service-oriented architecture (SOA). According to it, the service provides should deploy a wrapping web service (soap-based or rest-based) on top of the entire Hadoop cluster that will allow external authorized users (could be applications or people) to load and analyze data within the cluster.

The aim of this article is to propose an architecture for integration of a company's heterogeneous data (stored within a database of any type, or in the filesystem) to a remote Hadoop cluster, providing data analytical services on demand. Such integration will give the company (business organization) an affordable, cost-effective, access to powerful big data analytical tools as the ones included in the Hadoop Ecosystem. The paper is structured as follows: Section 2 reviews some previous work done by other researchers. Section 3 proposes architecture for integration of a company's data to a remote Hadoop cluster accessible as a service. Finally, Section 4 ends the article with a conclusion, outlining the usefulness of the proposed solution.

## II. RELATED WORK

Big data management has introduced some challenges (maintaining heterogeneous data, large data volumes and increased data throughput) for applications, related to data processing. Currently NoSQL databases are proposed to address these challenges by offering horizontal scalability, high availability and data storage without using fixed schemas. NoSQL databases, however, do not have a standard query language, which makes developers' life harder. On the other hand, the traditional relational databases and the SQL language are very popular for processing and storage critical data, but not suitable for large volumes of data.

As a result, multiple approaches have been proposed to define, process and store large volumes of relational data in NoSQL databases by using similar to SQL interfaces. They all focus on both scalability and availability. Schreiner et al. present a comparative analysis [3] of these approaches based

on their architectural solutions. The authors motivate their research with the fact that the use of generalized architectural solutions is a proper strategy for relational-based applications, which could be used to move/migrate relational data to NoSQL databases. One of the approaches for that is to propose a way to access NoSQL databases by SQL-like commands. Suggested methods, however, convert the relational data model to a single NoSQL data model and sometimes directly to a specific NoSQL database management system (DBMS). Schreiner et. al. present a canonical approach, called SQLToKeyNoSQL [4], which converts relational schemas and SQL commands to equivalent schemas and data access methods for any NoSQL DBMS, based on the key-value data model, the document data model, and the column-oriented data model. The authors propose architecture of a layer, focusing on strategies for data transformation and mapping.

The analysis of the relational and the non-relational databases leads to the conclusion that these data storage and processing systems are to some extent complementary. Unfortunately, the complementary behavior has a negative effect on the integration possibilities, both in terms of data model and data processing. In terms of performance, it may be useful to rely on multi-lingualism, multi-model approach or multi-step modeling, or even to transform the SQL schema into a NoSQL model and then to migrate the data. Another option is to integrate relational and non-relational databases by the help of a third-party data model. This option is discussed by Pokorný in [5]. Together with that, the author presents some new methods for designing such integrated database architectures. He also discusses that it is not possible to simply apply traditional approaches for integration of relational and non-relational DBMSs, due to the complementary nature of these two types of databases. The author reviews multiple methods for integration of these heterogeneous databases. The heterogeneity itself leads to a new set of problems. NoSQL databases are flexible, but their data design also requires specific modeling solutions that affect their performance in the integrated architectures.

Integration of data stored in heterogeneous systems is a quite challenging task as well and very difficult to solve. Vathy-Fogarassy and Huguák propose a new data integration methodology [6] in order to provide personalized data queries to multiple relational and NoSQL database management systems. Their solution does not support joins and aggregation of data from multiple sources, but it just collects and migrates data from/to the different individual sources. The method is based on a metamodel approach and covers the heterogeneity of the source systems in terms of their structure, semantic and syntactic features.

Due to the complex management of organizations, the corporate applications could contain a vast number of tables with multiple relationships and constraints among them. Organizations are currently still using relational databases, but the NoSQL systems are constantly increasing their market share due to their excellent performance and high availability. So, more and more migration tools will be needed to migrate relational to non-relational data models. The database schema is important not just for the relational databases, but for the

NoSQL systems as well, since it could provide better query execution. Although the NoSQL databases do not explicitly require database schemas, maintaining such information is important for activities such as data integration, data validation and operational compatibility. Frozza et. al. suggest in [7] a process to automatically extract schemas of NoSQL databases relying on the column-oriented data model. The authors use JSON as a canonical data representation format and test their approach by extracting schemas from HBase. Dai discusses a transformation technique [8] that is capable of transforming database schemas, and translate and optimize queries. Other approaches to design and transform schemas could be found in [9],[10].

Processing and storage of large data volumes by using conventional techniques is not possible. Nowadays, organizations should target their development to non-relational (NoSQL) systems since they support more flexible data models. It is a great challenge for business organizations to transform their existing relational data to NoSQL data models, especially when having in mind the heterogeneity and the complexity of their data. Furthermore, big data management faces an additional challenge – data cleaning and flushing. Ramzan et al. suggest a solution that supports two modules [11] – data transformation module and data cleaning module. The first phase transforms the relational database to a NoSQL database by applying an appropriate transformation model. Then the second phase provides data cleaning, aiming to improve data quality and prepare them for further (big data) analyses.

Most data model transformation methods target a single (specific) NoSQL model and provide a little or no support for transformation's personalization. Kuszera et al. present an approach [12] for transforming relational to NoSQL databases that supports the document-oriented and the column-oriented data models. Their method uses as an input a set of directed acyclic graphs (DAGs) that represent the targeted NoSQL model. DAGs are used to generate data transformation commands. The approach supports different relations' cardinality and the transformation commands could be personalized. The authors developed a tool that interprets the input DAGs and supports multiple transformation strategies.

Since big data processing applications, based on Cloud Computing become more and more popular, many existing systems will upscale their services in order to support the increasing volumes of data. Liao et al. propose a data transformation system [13] that provides hybrid architecture, including both relational and NoSQL databases. It supports simultaneous query processing and data transformation, and data synchronization. The authors focused their work on the transformation speed and the diversity of the data.

Modern applications that process different data formats often use several types of databases, and the need to migrate data between them is common. Although there are multiple methods to perform data model conversion, the process of choosing the ideal data structuring for specific application requirements is not a trivial task. Kuszera et al. describes an approach for converting relational databases to NoSQL ones, consisting of multiple steps [14] for defining, evaluating and

comparing alternative NoSQL schemas (data structuring), before migrating the data.

### III. ARCHITECTURE FOR INTEGRATING A COMPANY'S HETEROGENEOUS DATA TO AN EXISTING REMOTE HADOOP INFRASTRUCTURE

The existing approaches, reviewed in the related work, offer an integration of a relational database management system to a non-relational one with a specific target data model. This is important for companies to move their data from an old relational database management system to a modern, flexible NoSQL one, supporting data models suitable for big data processing. However, this data model transformation does not provide any data analytics at all. It just transforms the existing data. In contrast, the architecture proposed here allows integration of any type of data to an existing Hadoop infrastructure, providing powerful data analytical tools.

In order to make the most of the data analytical capabilities of the Hadoop Ecosystem, the company should be able to share not only its database, but also files whose content could be analyzed as well. So, integration is needed on multiple levels:

- Integration with the Hadoop Distributed File System (HDFS).
- Integration with the real-time column-oriented database management system HBase.
- Integration with the Hive service and obtaining aggregated analyses of it.

Integration with HDFS allows the company to share data exported from any type of database managements systems (DBMSs) – relational or NoSQL. Data could be exported in the form of CSV (comma separated values) data files or in other format. Once loaded in HDFS, these files could be later imported in any Hadoop's data analytics service. This approach provides very high level of flexibility and abstraction from the specific DBMS, and allows integration of any type of data to the Hadoop cluster. Integration could be implemented by using HDFS's REST API, called WebHDFS. There is other alternative as well – through the HDFS client distributed together with Hadoop, but the WebHDFS provides higher flexibility.

If it is needed the company's data to be stored in real time within the Hadoop infrastructure, then an integration with the column-oriented database management system HBase [15],[16] is necessary. It could be done through:

- The HBase's REST API.
- Thrift Server.

There is a third way as well – by storing data in files and loading them in HDFS, but it is not suitable for real-time operations.

The HBase's REST API provides an easy access to HBase, and since communication is done over the HTTP protocol, the client could be implemented in any programming language.

The problem however is that both the RESTAPI and the Thrift Server do not provide any access control by default. If a user knows the namespaces and the tables' names of another user, then the first one could easily steal the data of the second user. A possible solution of that is to use the Kerberos authentication protocol [1]. An alternative solution is to develop a wrapping web service around the HBase's REST API (or the Thrift Server) that should handle user authentication and perform access control.

Another useful integration is with the Hive service [1],[2]. Hive is not a database, but just a query engine that allows searching and retrieving data from different data stores by using a language that is almost identical to SQL. It is called HQL – Hive query language. The key point here is that data could be retrieved and analyzed from different data stores. Actually, HQL runs over temporarily virtual tables that could be built from multiple sources – HBase, ordinary files from HDFS and other sources. This is the highest strength of Hive – it allows using SQL to search and process data from files. Usually, files which are mapped as virtual tables are csv and tab-delimited data files, but could be also MS Excel or other sources of structured or semi-structured data. So, Hive could be used to perform data aggregation and analyses of: real database data; system log files; application log files; accounting data files; csv and MS Excel spreadsheets; and many others sources of data. Within the real world, such data files are generated as often as data stored within a database. Furthermore, Hive supports the Hadoop's MapReduce framework, meaning that the HQL queries could be distributed among multiple servers and run in parallel, which allows analysis to be performed on very large amounts of data.

Fig. 1 presents a conceptual architecture for a company's data integration (database and filesystem) to an existing Hadoop cluster. It implies design and development of just two new modules (applications) – “the integration middleware / wrapping service” from the service provider's side and the “Customer's data integration tool” from the client's side. All other components (except DBeaver) are existing services provided by Hadoop or “built-in” applications in the Hadoop Ecosystem.

Modules marked in peach color are the main Hadoop services - HDFS, HBase, Hive and Hue [1],[2]. Modules marked in white within the cluster are accompanying application programming interfaces (APIs) that allows third party applications to interact with the Hadoop services (the modules in peach). These APIs are not directly built-in within the main Hadoop services, but implemented as separate (external) applications, which however are usually distributed together with the services. The easiest way to install all of them is by installing Cloudera Manager that deploys the Cloudera Distributed Hadoop (CDH).

Cloudera Manager offers a user-friendly, comprehensive interface for installation and management of the entire Hadoop Ecosystem. It could be used to start, configure and stop individual services in the cluster. However, if services are installed as stand-alone applications, then the APIs should be started from a command-line interface and configured through xml files.

DBeaver is a database client, in general, that could connect to multiple relational and non-relational DBMS, and to some services (including Hive) from the Hadoop Ecosystem as well. It provides a graphical user interface to execute SQL queries (and not only) and visualize the results. It can be used directly by end users, without any skills in system administration and programming.

The company's database could be of any type – relational, non-relational, or even file-based. Its data are retrieved based on the database type and then packed within the necessary data structures, which are sent to the “Integration Middleware” for further processing and storing within the cluster.

The two custom and important modules are “Integration Middleware / Wrapping Service” and “Customer's data integration tool”. They are the ones, which are directly responsible for data integration. In contrast to the others, they do not exist in advanced, but should be designed and implemented entirely for the purpose of integration.

1) “*Customer's data integration tool*”: provides a graphical user interface (GUI) that allows the company to manage the data it wants to integrate (including to choose what exactly to share) with the Hadoop cluster, and also to render/visualize the received results. This module exactly extracts the data from the local database and packs them in suitable data structures (usually JSON objects) that are later send to the “Integration Middleware / Wrapping Service”. The module should work with any type of database management systems (relational or non-relational) and pack the data in similar manner, regardless of their type. The customer's data integration tool should allow browsing not only the local database, but the local filesystem as well. User should be able to browse, select and upload files to the remote HDFS filesystem for further processing and analysis by Hadoop's data analytics services.

2) “*Integration Middleware / Wrapping Service (API)*”: implements data integration on the service provider's side. It works as a wrapping service around the entire Hadoop cluster. The customer's data integration tool works with this module only, not directly with the Hadoop services or APIs. In this sense “Integration Middleware / Wrapping Service” *serves as a mediator* between the company (the client) and the WebHDFS API, HBase API and the Thrift Interface. But why such a mediation service is needed? Because all the three interfaces do not provide any user authentication and access control. For HBase, for example, if one user knows the namespaces and table names of another user, then the first one could steal the data of the second one. Similar apply to the Thrift interface as well – all connections to HBase are done through the same socket without any authentication. All users have access to everything, by default. And that is a big problem. No company will share its data if they become publicly available and easily accessible to competitors. To solve this problem the Kerberos authentication service could be installed and configured, or to implement a wrapping service around the APIs to perform user authentication and

access control. The latter could be easily integrated in this module and perform a flexible, custom access control.

The second important task of this module is to convert the data from their source model (relational or whatever) to column-oriented one, suitable for loading in HBase. This is the module that is solely responsible for data conversion. They arrive from the “Customer’s data integration tool” packed as JSON objects, then they should be converted to suitable model and loaded to HBase through the API or the Thrift Interface.

3) *Conversion of source data models to the column-oriented data model suitable for HBase:* As already mentioned, conversion from a source data model to a target data model is important for data integration from heterogeneous systems. Research in data models transformation has intensified a lot during the last years –

multiple approaches have been proposed, as seen from the related work section. Most of them apply the relational model as a source model, since there are many legacy data storage systems currently in use that relies mainly on the relational model.

In contrast to the traditional relational databases, which are strictly normalized and should meet the requirements of the 3-rd and the BCNF normal form, almost all NoSQL data stores are actually not normalized at all – data could be grouped and replicated in order to increase the read speed. Although the NoSQL databases also maintain some consistency, there may be inconsistencies in the data for a short period of time after performing an operation. As a result, the NoSQL databases are mainly suitable for OLAP systems, but not for OLTP systems, where support of the ACID properties is mandatory.

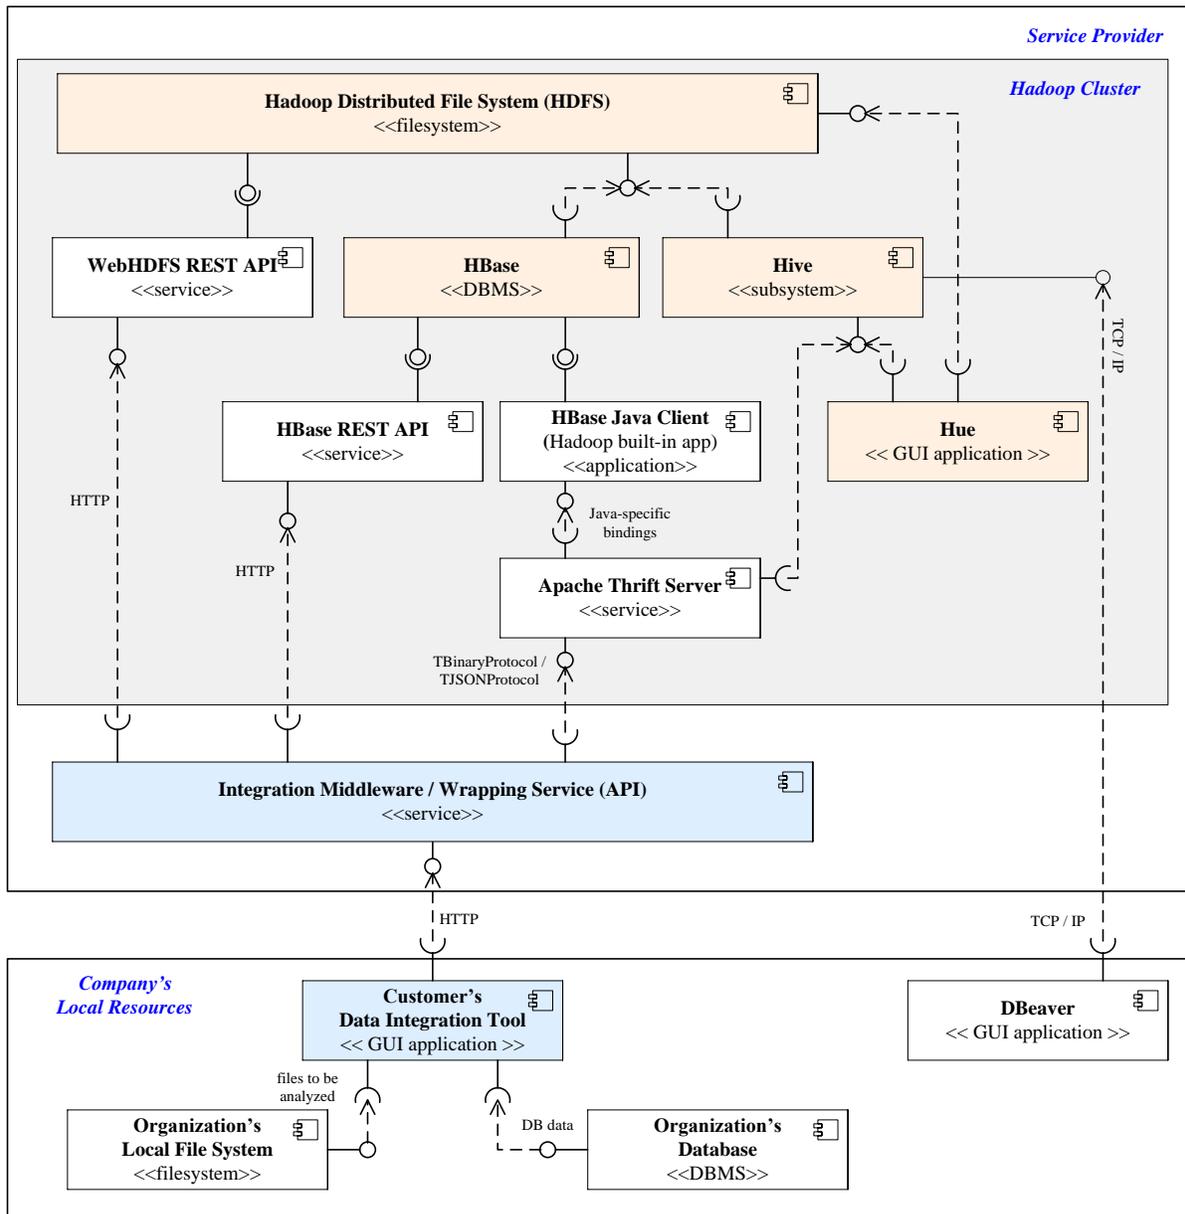

Fig. 1. Architecture for Integration of a Company’s Database and Filesystem to Hadoop Infrastructure.

Any data model could be transformed to any non-relational model by applying the methods and algorithms described in [17],[18],[19],[20]. Since this article is related to data integration with an existing Hadoop cluster, the target model here is the column-oriented data model, used by Apache HBase [15],[16]. Here is an intuitive heuristic approach for transforming the relational data model to a column-oriented one:

1) Grouping all related data in a single column family. These are data that should be read/written from/into the database at once. These are the tables' records (rows) in the relational databases. Actually, the column-oriented schema could be easily extracted from the relational schema, since the latter provides more than enough information about attributes' relationships. Every table in the relational database becomes a table in the column-oriented database, and the primary keys of the former are used as row keys in the latter. All attributes within the relational table are group together in a single column family, in order to guarantee that they will be stored and read together.

2) Convert the relationships between tables in the relational schema to "relationships" in the column-oriented schema. There are three types (cardinalities) of relationships in the relational schema: one-to-one; one-to-many; and many-to-many. They will be reviewed separately since the conversion is done in different way:

a) *One-to-one*. This is intuitive – a column with a foreign key is treated is an ordinary column and could be grouped together with other columns, based on rule 1.

b) *One-to-many*. In the column-oriented data model, this relationship is actually implemented in the "opposite way" in comparison to the relational model. In the latter, the foreign keys (multiple values) are placed at the side of "many" of the relationship, since the database should meet 1-st and 2-nd normal form. However, in the column-oriented model, multiple values could be grouped together in a single column family. So, to create a one-to-many relationship, a new column family should be created at the side of "one", which could keep multiple values, pointing to the keys at the side of "many". In other words, in the column-oriented model, all the foreign keys are kept at the side of "one".

c) *Many-to-many*. Implementing this relationship is even easier in the column-oriented data model. In the relational model, many-to-many relationships are created by the help of a third (called "connection") table that keeps and combines the foreign keys of the other two tables. However, in the column-oriented model, a single column family can contain multiple values. So, to create a many-to-many relationship, a new column family needs to be created at each table, containing the values of the row keys of the other table. There is no need of a third table at all.

In the relational model, the relational database management system (RDBMS) guarantees data integrity and relationships integrity. However, in the column-oriented data model, this is not the case, so the application itself, which uses

the data, should be designed to check, maintain and validate data integrity. This responsibility is moved from the DBMS to the software developer. As a result, it is possible to have data inconsistencies for a short period of time, until the next read.

#### IV. CONCLUSION

Data analysis is very important for the development of business organizations. It helps them to identify organizational bottlenecks, optimize business processes and increase efficiency and profits. In the era of big data, their analysis could not be done manually. There are powerful data analytical software tools, but they are either expensive or hard to deploy and requires multiple high-performance servers to run. Buying expensive hardware and software, and hiring high-qualified IT experts, is not affordable for all companies, especially for smaller ones and start-ups.

The architecture proposed in this article allows integration of a company's heterogeneous data (both database and filesystem) to a remote Hadoop infrastructure, providing powerful data analytical services on demand. This is an affordable and cost-effective cloud-based solution, suitable for any type company, from start-ups to large-size companies. Businesses are not required to buy any (expensive) hardware or software, but use the data analytical services on demand, paying a small processing fee per request or by subscription. The architecture could be easily implemented by developing just two data integration modules – an integration middleware or a wrapping service around the Hadoop data analytics services, at the service provider's side; and a graphical user interface (GUI) to work with the integration middleware, at the company's side.

The major difference between the proposed architecture and the existing approaches, reviewed in the related work, is that they offer an integration of a relational database management system to a non-relational one with a specific target data model. Instead, our architectural approach provides integration of data of any type (including relational, non-relational and even ordinary text files) to an existing Hadoop cluster. The purpose of this integration is to provide companies with cost-effective and easy to use access to the Hadoop's data analytical tools, not to permanently convert their data to other data models.

Since the proposed architecture will be very useful to the business organizations, providing them an easy access to powerful data analytical tools, and is fairly easy to deploy in the same time, our next goal is to implement it and prove its real usefulness and effectiveness. In general, it allows integration of any type of data to an existing Hadoop infrastructure. However, for this to happen, the source data model should be recognized and data should be parsed properly before sending them to the "Integration Middleware" module. For that reason, we plan to introduce data type documents (DTDs) that contain a formal definition of the source data models and the relevant parsers for these DTDs. Then the integration of a new, even custom, source data model will be quite easy – just by uploading the associated DTD. The use of DTDs highly increase flexibility of the proposed approach and allows integration of virtually any type of data.

**Abstract**—A method for estimation of oleic acid content in soy plants using green band data of Sentinel-2/MSI: Multi Spectral Imager is proposed. Conventionally, vitality of agricultural plants is estimated with NDVI: Normalized Difference Vegetation Index. Spatial resolution of Near Infrared: NIR band of Sentinel-2/MSI for calculation of NDVI, however, is 20 m. Therefore, a method for estimation of vitality with only green band data of Sentinel-2/MSI is proposed here. Through regressive analysis with the satellite data as well as drone mounted NDVI camera data together with component analysis data by gas chromatography, it is found the correlation between NDVI and green band data of the optical sensor (MSI) onboard Sentinel-2 as well as the component analysis data. It is also found that the new variety of soy plant, Saga University brand: HO1 contains about 50% much oleic acid in comparison to the conventional variety of soy plant, Fukuyutaka.

**Keywords**—Oleic acid; NDVI (normalized difference vegetation index); regressive analysis; soy plant; Multi Spectral Imager: MSI

## I. INTRODUCTION

Oleic acid is a type of unsaturated fatty acid and is a monovalent unsaturated fatty acid. It is abundant in animal fats, vegetable oils, and nuts and seeds. Since it reduces only bad cholesterol without reducing good cholesterol, it helps prevent lifestyle-related diseases such as arteriosclerosis and heart disease. In addition, it is resistant to heat and is difficult to oxidize, suppresses fatty acids peroxide that may cause carcinogenesis, regulates gastric acid secretion, and activates intestinal motility.

In addition to amino acids, meat contains various health ingredients. Examples include "heme iron," which has an anemia-preventing effect, and "conjugated linoleic acid," which has anti-cancer effects, body fat reduction, and arteriosclerosis-preventing effects. Among them, "oleic acid", which is one of the fatty acids, is expected to have a preventive effect on lifestyle-related diseases.

Oleic acid, which is abundant in beef and pork, has the function of maintaining proper cholesterol in the blood. Cholesterol includes bad (LDL) cholesterol and good (HDL) cholesterol. Bad cholesterol causes arteriosclerosis, heart disease, and high blood pressure, but good cholesterol has a function to prevent arteriosclerosis. Oleic acid is said to have the effect of reducing only bad cholesterol without reducing this good cholesterol.

Another characteristic of oleic acid is that it is not easily oxidized. In general, when fat is oxidized, it binds to active

oxygen in the body and damages DNA, causing cancer, arteriosclerosis, heart disease, brain disease, diabetes, and so on. Oleic acid has the effect of preventing cancer and lifestyle-related diseases.

The main varieties of Saga Prefecture are cultivated as standard, and the crops of the year are estimated by analyzing the growth reaction in climate change, and they are used as materials for soybean production guidance.

The new varieties were cultivated by Saga University, a national university corporation, and the application for cultivar registration was announced in 2019. The variety name is "Saga University HO1", which has a high oleic acid content, and "Fukuyutaka" has a high content of 80%, while 20% of the total fatty acid. In recent years, there have been requests from actual consumers and producers to expand cultivation in the midst of regional specialization, and there are voices in the Takeo / Kishima area requesting the establishment of technology for stable production. Therefore, the purpose is to obtain knowledge about the basic cultivation characteristics of this variety.

"High oleic acid soybean (Saga University HO1)" has a flowering period of 2 to 3 days and a maturity period of about 1 day earlier than "Fukuyutaka". The length of the main stem is a little short, and the height of the lowermost pod node is about 3 cm lower. The number of main stem nodes and the number of branches is about the same. There are many pods. Yieldability is considered to be about the same. Grains tend to be slightly flat and small in grain shape.

Relating to soy plant monitoring and content estimation in soy, there are the following papers.

Prediction of Isoflavone Content in Soybeans with Sentinel-2 Optical Sensor Data by Means of Regressive Analysis [1], and Soybean Quality Estimation with Sentinel-2 of Optical Sensor Data [2]. On the other hand, Sentinel-2 data analysis method related papers, there are the following papers.

Flooding and oil spill disaster relief using Sentinel of remote sensing satellite data [3], Sea breeze damage estimation method using Sentinel of remote sensing satellite data [4], ACIX-Aqua: A global assessment of atmospheric correction methods for Landsat-8 and Sentinel-2 over lakes, rivers, and coastal waters [5], Method for Most Appropriate Plucking Date Determination based on the Elapsed Days after Sprouting with NIR Reflection from Sentinel-2 Data [6], Prediction of

Isoflavone Content in beans with Sentinel-2 Optical Sensor Data by Means of Regressive Analysis [7].

Furthermore, agricultural plantation related research works, there are the following papers.

Regressive analysis on leaf nitrogen content and near infrared reflectance and its application to agricultural farm monitoring with helicopter mounted near infrared camera [8], Effect of sensitivity improvement of visible to near infrared digital cameras on NDVI measurement in particular for agricultural field monitoring [9], Smartphone image based agricultural product quality and harvest amount prediction method [10], A computer aided system for tropical leaf medicinal plant identification [11], Product amount and quality monitoring in agricultural fields with remote sensing satellite and radio-control helicopter [12], Intelligent System for Agricultural Field Monitoring [13], Multi-level observation system for agricultural field monitoring [14], Multi-Layer Observation for Agricultural (Tea and Rice) Field Monitoring [15], Bigdata Platform for agricultural field monitoring and environmental monitoring [16].

Prediction of isoflavone content in beans with Sentinel-2 optical sensor data by means of regressive analysis is made [17]. Meanwhile, method for most appropriate plucking date determination based on the elapsed days after sprouting with NIR reflection from Sentinel-2 data is proposed and validated [18].

The purpose of this study is to establish a method for estimation of oleic acid content in soy plants using NDVI derived from optical sensor (MSI) onboard Sentinel-2 satellite. Traditionally, it is used to use drone mounted NDVI data for the estimation. It does cost. It cannot be used for the windy condition. Turns out, Sentinel-2/MSI data can be accessible from the ESA web site freely even for windy condition, it cannot be used for cloudy and rainy conditions, though. In terms of spatial resolution of drone mounted NDVI camera, it is fine about a couple of cm depending on altitude of the drone. On the other hand, spatial resolution of Sentinel-2/MSI is 10 m for visible bands and is 20 m for Near Infrared: NIR band. Therefore, spatial resolution of NDVI which is derived with visible and NIR is 20 m. It is not good enough for Japanese soy plantation fields. In order to estimate NDVI with 10 m of spatial resolution using Sentinel-2/MSI optical sensor data, green band data derived from visible band of Sentinel-2/MSI is used in the proposed method. Through regressive analysis with the satellite data as well as drone mounted NDVI camera data together with component analysis data by gas chromatography, it is found the correlation between NDVI and green band data of the optical sensor (MSI) onboard Sentinel-2 as well as the component analysis data. It is also found that the new variety of soy plant, Saga University brand: HO1 contains about 50% much oleic acid in comparison to the conventional variety of soy plant, Fukuyutaka.

The next section describes the proposed method. Then experiments with drone mounted NDVI data and Sentinel-2/MSI of green band data together with component analysis data by gas chromatography followed by concluding remarks and future research work.

## II. PROPOSED METHOD

A method for estimation of oleic acid content in soy plants using NDVI derived from optical sensor onboard Sentinel-2 satellite is proposed. Table I shows Sentinel-2 fast track service compliance to land user requirements. Every 10 days, Sentinel-2 observes the same location of Earth's surface.

Major specification of Multispectral Imager: MSI is as follows, MSI covering 13 spectral bands (443–2190 nm), with a swath width of 290 km and a spatial resolution of 10 m (four visible and near-infrared bands), 20 m (six red edge and shortwave infrared bands) and 60 m (three atmospheric correction bands).

MSI spatial resolution versus wavelength: Sentinel-2's span of 13 spectral bands, from the visible and the near-infrared to the shortwave infrared at different spatial resolutions ranging from 10 to 60 m on the ground, takes land monitoring to an unprecedented level. Table II shows MSI spectral band specification. Green band in the MSI spectral bands can be used for estimation of oleic acid containing soybeans in living soy plantations.

The spatial resolution of Sentinel-2 is 10 m for visible bands and is 20 m for Near Infrared: NIR band (865 nm). Therefore, spatial resolution of NDVI which is derived with visible and NIR is 20 m. It is not good enough for Japanese soy plantation fields. To estimate NDVI with 10 m of spatial resolution using Sentinel-2 optical sensor data, green band data derived from visible band of Sentinel-2 is used in the proposed method.

TABLE I. SENTINEL-2 FAST TRACK SERVICE COMPLIANCE TO LAND USER REQUIREMENTS

Fast Track Service (Land Monitoring Core Services)	Compliance of the Sentinel-2 system
Geographic coverage	All land areas/islands covered (except Antarctica)
Geometrical revisit	5 days revisit cloud free fully in line with vegetation changes
Spectral sampling	Unique set of measurement/calibration bands
Service continuity	Sentinel-2A launch in 2014: the mission complements the SPOT and Landsat missions.
Spatial resolution	< 1 ha MMU (Minimum Mapping Unit) fully achievable with 10 m
Acquisition strategy	Systematic push-broom acquisitions, plus lateral mode capability for emergency events monitoring
Fast Track Service (Emergency Response Core Service)	Compliance of the Sentinel-2 system
Spatial resolution down to 5 m	Reference/damage assessment maps limited to the 10m SSD (Spatial Sampling Distance)
Accessibility/timeliness down to 6 hrs offline & 24hrs in NRT	Fully compliant (retrieval of already archived reference data in < 6 hrs, and delivery of data after request in NRT in 3 hrs for L1c)

TABLE II. MSI SPECTRAL BAND SPECIFICATION

Spectral bands (center wavelength in nm/SSD in m)	Mission objective	Measurement or calibration
B1 (443/20/60), B2 (490/65/10) & B12 (2190/180/20)	Aerosol correction	Calibration bands
B8 (842/115/10), B8a (865/20/20), B9 (940/20/60)	Water vapor correction	
B10 (1375/20/60)	Circus detection	
B2 (490/65/10), B3 (560/35/10), B4 (665/30/10), B5 (705/15/20), B6 (740/15/20), B7 (775/20/20), B8 (842/115/10), B8a (865/20/20), B11 (1610/90/20), B12(2190/180/20)	Land cover classification, Leaf chlorophyll content, leaf water content, LAI, fAPAR, snow/ice/cloud, mineral detection.	Land measurement bands

### III. EXPERIMENT

#### A. Intensive Study Area

Intensive study area is situated at the Saga Prefectural Agriculture Research Institute: SPARI which is situated at 33°13'11.5" North, 130°18'39.6" East as shown in Fig. 1. Fig. 1(a) shows the intensive study area in Japan while Fig. 1(b) shows the soy plantation areas for the new variety of soy (Saga University originated HO1) and for the conventional variety of soy (Fukuyutaka). Both soy plantation areas are indicated in red and white rectangles in Fig. 1.

(a) Intensive Study site in Japan (Red Circle).

(b) Red Rectangle: Conventional Fukuyutaka, White Rectangle: New Variety of HO1.

Fig. 1. Intensive Study Area.

The online services provided by Amazon for web operators and developers are called AWS (Amazon Web Services). Among them, a large amount of data taken by Sentinel-2 is stored in Amazon's cloud storage called Amazon S3 (Amazon Simple Storage Service), and his AWS service that provides the data taken by Sentinel-2 is Sentinel- It's called 2 on AWS. Users can now download satellite imagery data via Amazon S3 storage. Amazon publishes a huge amount of geospatial data in a project called Earth on AWS, including not only satellite images, but also terrain tiles, SpaceNet machine learning training data, next-generation weather radar (NEXRAD) weather data, and more. It also provides a variety of geospatial data and is accessible to anyone. With a paid service, you can analyze this huge amount of data on the cloud, so there is no need to download data for analysis or perform troublesome preprocessing, and it is a larger project than before. It can be realized in a shorter period of time.

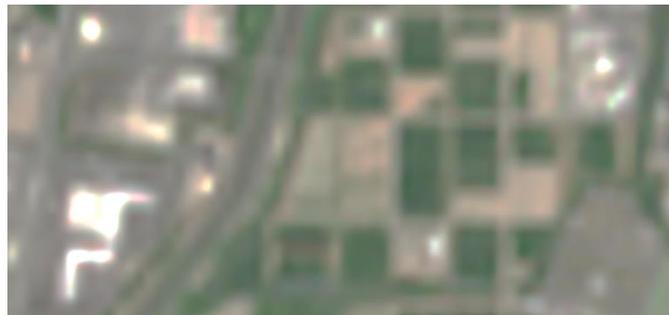

Download satellite images of where you need them. Access the Sentinel Image browser. The search screen is displayed. Specify the period to search for the image and the amount of clouds, display the area where you want to download the image, and click the [Submit] button to display the detailed information and preview of the image, the amount of clouds, the date and time when the image was acquired, the product level, etc. can be confirmed. Select the image you want to use from the search result field and click the link button. Then it can be gotten a link to the image, click AWS path (link above). After that, Launch ArcGIS Pro (or ArcMap) and add the downloaded data from the Project window (in the case of ArcMap, add it from the Catalog window). This time, we will synthesize a multi-spectral band, so add B02.jp2 to B04.jp2. Since it is added for each band, it does not look natural as it is. Next, composite each band to synthesize the true color. Click the Raster Function button on the Analysis tab to bring up the Raster Function window. Expand Data Management and click the Composite icon. Click the Raster pull-down button under Composite Properties to add each band. Add all the bands, sort them by B04, B03, B02 from the top, and click the Create New Layer button. A "Composite" layer has been added to the Content window to composite the true color multiband image.

### B. Acquired Drone Mounted NDVI Camera Data and Sentinel-2/MSI Imagery Data of Sentinel-2

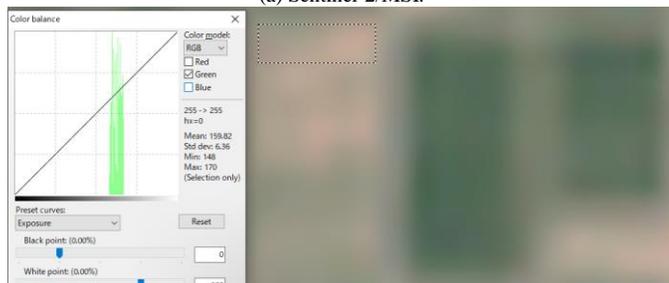

Examples of the drone mounted NDVI camera data and Sentinel-2/MSI imagery data which are acquired on 29 July 2021 and on 30 July 2021, respectively are shown in Fig. 2. Fig. 2(a) shows Sentinel-2/MSI image which is acquired on 30 July 2021 while Fig. 2(b) shows the histogram of the green band data of the Fukuyutaka field of the Sentinel-2/MSI image. On the other hand, Fig. 2(c) shows the histogram of the green band data of the HO1 field of the Sentinel-2/MSI image. Meanwhile, Fig. 2(d) shows the natural color image of drone mounted NDVI camera data which is acquired on 29 July 2021 while Fig. 2(e) shows the histogram of the NDVI image of drone mounted NDVI camera data of the Fukuyutaka. On the other hand, Fig. 2(f) shows the histogram of the NDVI image of drone mounted NDVI camera data of the HO1.

### C. Relation between Sentinel-2/MSI and Drone Mounted NDVI Camera Data

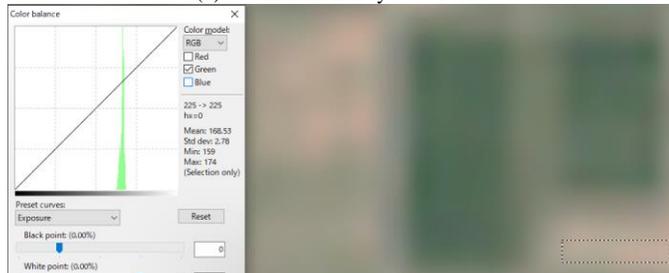

The trend of the means of the Sentinel-2/MSI data of the Fukuyutaka and the Saga University originated HO1 of new variety of soy fields is shown in Fig. 3(a) while Fig. 3(b) shows both trends of Sentinel-2/MSI and drone mounted NDVI camera data of the same soy fields. Although mean and standard deviation are different each other, trends are almost same. Therefore, the green band data of the Sentinel-2/MSI can be used for growing process analysis of soy fields.

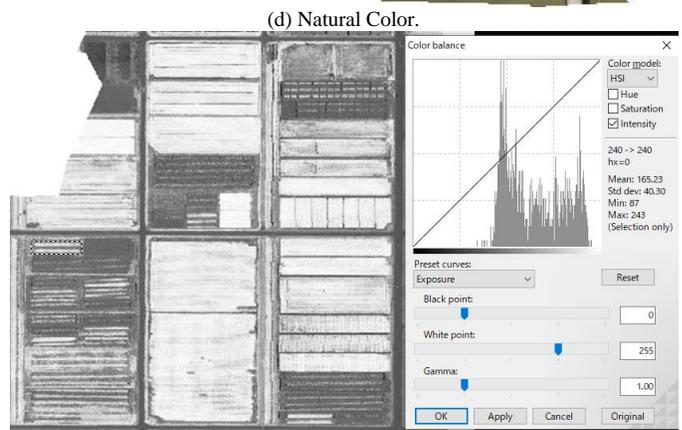

(a) Sentinel-2/MSI.

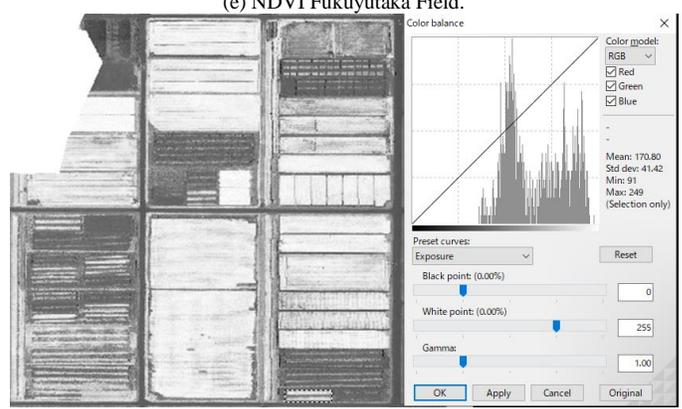

(b) Green Band Fukuyutaka Field.

(c) Green Band HO1 Field.

(d) Natural Color.

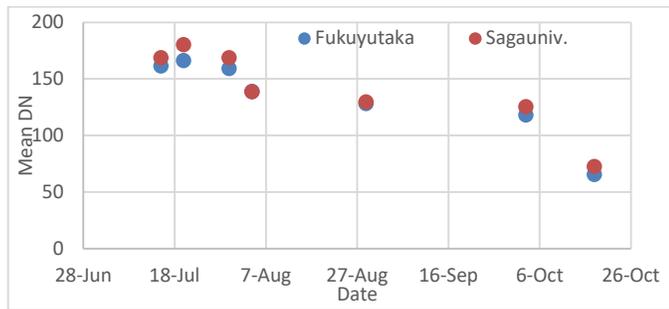

(e) NDVI Fukuyutaka Field.

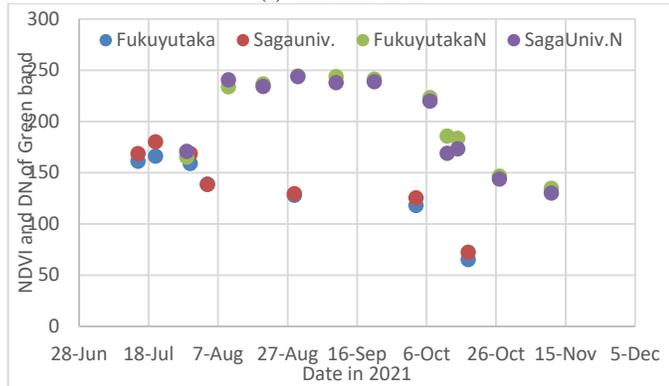

(f) NDVI HO1.

Fig. 2. Examples of the Drone Mounted NDVI Camera Data and Sentinel-2/MSI Imagery Data which are Acquired on 29 July 2021 and on 30 July 2021, respectively.

(a) Sentinel-2/MSI.

(b) Both Sentinel-2/MSI and Drone Mounted NDVI Camera.

Fig. 3. Relation between Sentinel-2/MSI and Drone Mounted NDVI Camera Data: The Trend of the means of the Sentinel-2/MSI Data of the Fukuyutaka and the Saga University Originated HO1 of New Variety of Soy Fields.

#### D. Experiment Procedure

Field experiments are conducted as follows:

Tillage overview:

- 1) Field: C4-10 (previous crop: wheat, previous summer crop: paddy rice).
- 2) Test variety: High oleic acid soybean "Saga University HO1" (Control: "Fukuyutaka")
- 3) Sowing method: After plowing and leveling, hand-sown 4 seeds per plant → 2 tailoring (Hirataka ridge)
- 4) Weeding: After sowing and before budding) Laxar granules 4kg / 10a (Growth period) Weeding as appropriate
- 5) Fertilization: No fertilization

Composition of test plot is as follows:

Ward sowing period Planting style:

- 1) Early sowing practice zone Late June 75 cm between rows \* 20 cm between stocks \* 2 (13.3 / m<sup>2</sup>)
- 2) Early sowing sparsely planted area Late June Joma 75 cm \* Strain 30 cm \* 2 (8.9 shares / m<sup>2</sup>)
- 3) Conventional sowing area Mid-July 75 cm between rows \* 20 cm between stocks \* 2 (13.3 / m<sup>2</sup>)
- 4) Control area (Fukuyutaka) Mid-July 75 cm between rows \* 20 cm between stocks \* 2 (13.3 / m<sup>2</sup>)

Survey items are as follows:

Understanding the growth stage (budding stage, flowering stage, pod setting stage, grain enlargement stage, yellow leaf stage, leaf fall stage, maturity stage).

Seedling survey is as follows:

- 1) Yield survey (grain weight, stem weight, 100 grain weight, particle size composition).
- 2) Decomposition survey (main stem length, number of main stem nodes, bottom pod height, number of branches, number of pods, number of grains).
- 3) Quality survey (inspection grade, protein content).

#### E. Relation between Sentinel-2/MSI Derived NDVI and Green Band Data

Relation between Sentinel-2/MSI derived NDVI and green band data is investigated. If the relation between Sentinel-2/MSI derived NDVI and the green band data is high, then vegetation vitality can be estimated with green band only. Fig. 4(a) shows Sentinel-2/MSI derived NDVI while Fig. 4(b) shows green band data of the intensive study area acquired on July 30 2021.

(a) NDVI.

(b) Green Band.

Fig. 4. Comparison between Sentinel-2/MSI Derived NDVI and Green Band Data of the Intensive Study Area Acquired on July 30 2021.

The correlation coefficient between both is more than 0.95. Therefore, it is concluded that vegetation vitality can be estimated with green band only.

#### F. Comparisons among the Several Band Combinations of Sentinel-2/MSI Data

Fig. 5(a) to (d) show the following several band combinations of Sentinel-2/MSI imagery data.

- a) Natural Color.
- b) False Color.
- c) R: Band 8, G: Band 3, B: Band 4 and.
- d) NDVI.

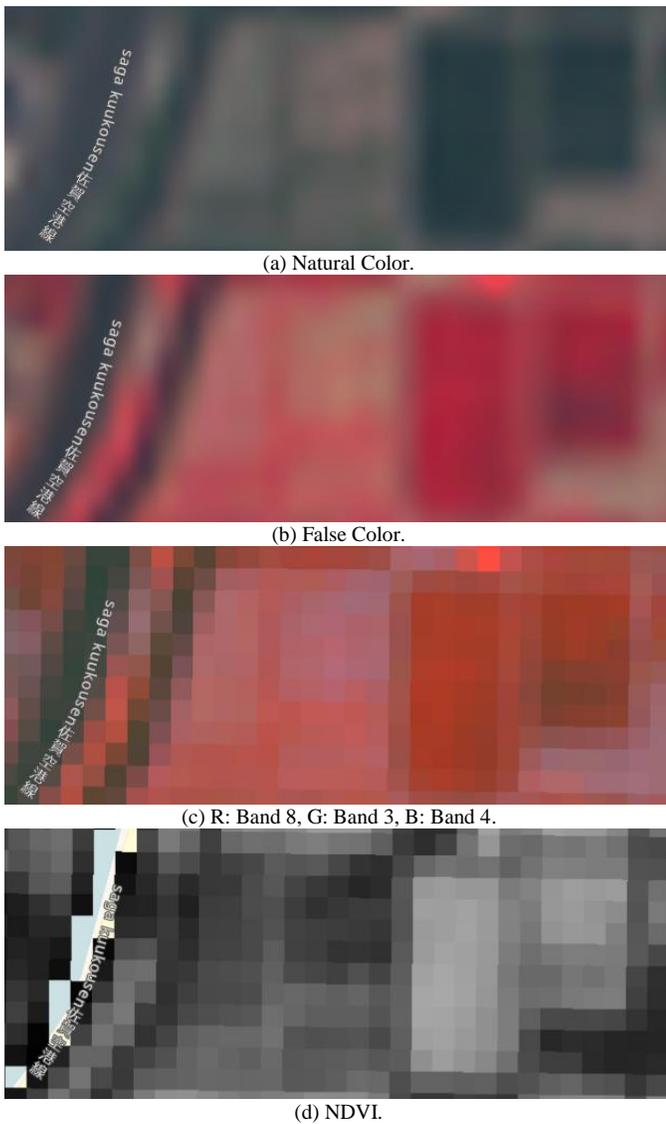

Fig. 5. Several Band Combinations of Sentinel-2/MSI Imagery Data.

Fig.6 shows the relation between the NDVI (Fig. 5(d)) and the green band data (Fig. 4(b)). Correlation coefficient between both is 0.977 and the NDVI is estimated with the green band data with regressive equation in Fig. 6 with  $R^2$  value of 0.954.

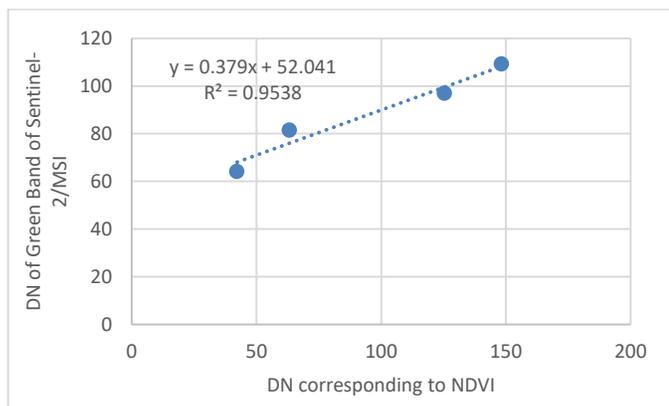

Fig. 6. Correlation between NDVI and Green Band Data.

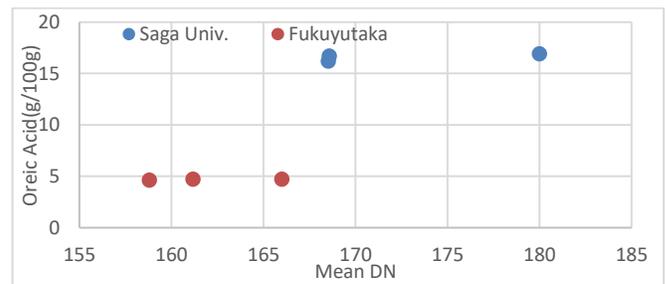

Through a comparison between Fig. 4(b) and Fig. 5(d), it is confirmed that vegetation vitality can be estimated with green band only.

### G. Experimental Results

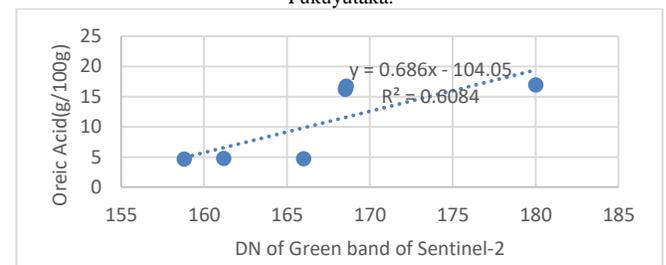

Oleic acid content in the harvested soybeans is measured with gas chromatography. Fig. 7(a) shows the results from the gas chromatography measurements for Saga University originated HO1 and conventional Fukuyutaka against mean of digital Number: DN of the Sentinel-2/MSI of the green band data for each test site. On the other hand, Fig. 7(b) shows the relation between oleic acid content and mean of the green band data derived from Sentinel-2/MSI. It is found that the  $R^2$  value of the relation between oleic acid content and mean of the green band data derived from Sentinel-2/MSI is much more than 0.6. Therefore, it can be said that it is possible to estimate oleic acid content by using the mean of the green band data derived from Sentinel-2/MSI.

The relationship between sowing time, number of repetitions and amount of oleic acid) for Fukuyutaka is shown in Fig. 8 while effect of n-piece stands on Saga University originated HO1 variety (sown on June 28) is shown in Fig. 9, respectively. In this connection, the number of iterations is defined as follows:

For those with a small number of iterations, the number of iterations had to be reduced because the field was small. The difference in the number of iterations is meaningless.

(a) Relation between Oleic Acid Content and mean of DN of the Green Band Data of Sentinel-2/MSI for the Saga University Originated HO1 and Fukuyutaka.

(b) Relation between Oleic Acid Content and Mean of the Green Band Data Derived from Sentinel-2/MSI.

Fig. 7. Relation between Oleic Acid Content and Mean of the Green Band Data Derived from Sentinel-2/MSI.

On the other hand, the number of tailoring is defined as follows:

To be exact, it was "difference between strains (difference in planting density)" rather than the number of tailored plants. The correct treatment for "Saga University originated HO1" is

that the seeding on June 30 is 30 cm (13.3 seeds / m<sup>2</sup>) and the seeds are 20 cm (8.9 seeds / m<sup>2</sup>), and the seeding on July 13 is 20 cm between the stocks. Regarding the planting density, we have set two styles that can be handled by mechanical sowing at the site in order to examine the appropriate planting density that enables stable production.

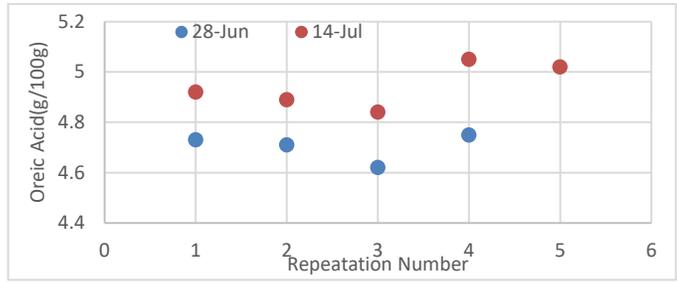

Fig. 8. Relationship between Sowing Time, Number of Repetitions and Amount of Oleic Acid) for Fukuyutaka.

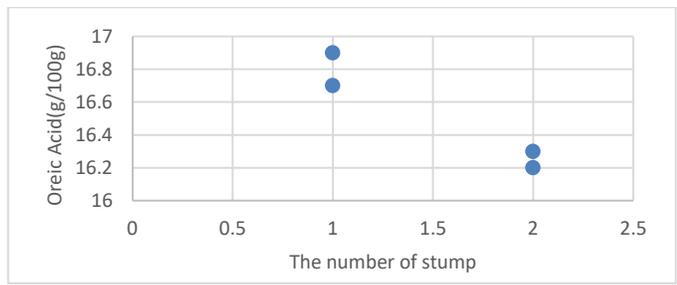

Fig. 9. Effect of n-piece Stands on Saga University Originated HO1 Variety (Sown on June 28).

Meanwhile, regressive analysis for estimation of harvest number of soybeans is made. Fig. 10 shows the result. It is found that harvest amount can be predicted with DN of green band data of Sentinel-2/MSI data about three months before the harvest with R<sup>2</sup> value of 0.965.

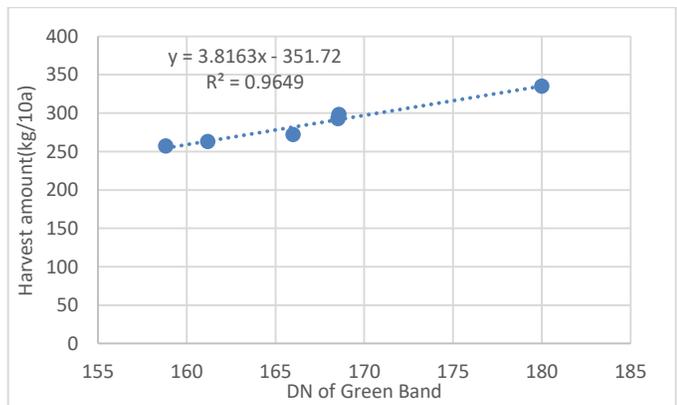

Fig. 10. Harvest Amount Prediction with Green Band Data of Sentinel-2/MSI.

#### IV. CONCLUSION

A method for estimation of oleic acid content in soy plants using NDVI derived from optical sensor onboard Sentinel-2 satellite is proposed. Through regressive analysis with the satellite data as well as drone mounted NDVI camera data together with component analysis data by gas chromatography, it is found the correlation between NDVI and green band data

of the optical sensor (MSI) onboard Sentinel-2 as well as the component analysis data. It is also found that the new variety of soy plant, Saga University brand: HO1 contains about 50% much oleic acid in comparison to the conventional variety of soy plant, Fukuyutaka.

It is found that the R<sup>2</sup> value of the relation between oleic acid content and mean of the green band data derived from Sentinel-2/MSI is much more than 0.6. Therefore, it can be said that it is possible to estimate oleic acid content by using the mean of the green band data derived from Sentinel-2/MSI.

The limitation of the proposed method is caused by the observation frequency of fine Sentinel-2/MSI data. The revisit cycle of Sentinel-2 satellite is 10 days. It is not possible to get fine data when the weather condition is not fine (cloudy and rainy).

#### V. FUTURE REAERSCH WORK

Next thing we would like to do is estimation of most appropriate harvest date with Sentinel-2/MSI data. Also, deep learning is applied to these estimations.

#### ACKNOWLEDGMENT

The authors would like to thank to Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda for their valuable discussions.

**Abstract**—The number of patients with cardiovascular diseases (CVD) is rapidly increasing in the world. Many CVDs are likely to manifest their symptoms some time prior to the onset of any adverse or catastrophic events, and early detection of cardiac abnormalities is incredibly important. To reduce the risks of life-threatening arrhythmia, it is necessary to develop and introduce portable systems for monitoring the state of the heart in conditions of free activity. This paper presents the second generation (prototype) of a portable cardiac analyzer and the developed system for non-invasive cardiac diagnostics. The portable cardiac analyzer mainly consists of an ADC for taking an electrocardiosignal (ECS) and an STM32L151xD microcontroller. To record operational data on current ECS, a block of non-volatile high-speed memory MRAM is connected to the microcontroller. A communication unit is based on the universal combo module SIM868 from SIMCOM, which supports data exchange in GSM/GPRS networks. The developed ECG monitoring system allows making decisions at different levels (cardiac analyzer, server, doctor), as well as exchanging information necessary to ensure an effective diagnostic and treatment process. We evaluated the performances of the developed system. The signal-to-noise ratio of the output signal (P waves, QRS complexes and T waves) are clearly readable.

## I. INTRODUCTION

Over the past ten years, the incidence rate of cardiovascular diseases in Kazakhstan has increased by 1.7 times. The data collected by scientists shows a four-fold increase in hospitalization due to chronic heart failure (CHF) compared with a period of 20 years ago. Of the 13 million adults in Kazakhstan 350 000 citizens are diagnosed with CHF [1]. The problem of combating cardiovascular diseases (CVD) among the population is gaining national importance due to high morbidity, a high level of disability and mortality from CVD, long-term, often lifelong, drug treatment, as well as its high cost, dictates the need to pay increasing attention to early primary prevention these diseases.

One of the areas of CVD diagnostics, which has become relevant due to rapid technological progress, is monitoring the state of the heart in conditions of free activity. Modern technologies have made it possible to develop miniature wearable devices for recording the functional parameters of a person operating in free activity conditions. The use of such

devices required a deeper and more detailed study of the means and algorithms for processing the electrocardiosignal.

This work is a continuation of our previous work [2], in which we are provided the initial experimental results of the device for diagnosing heart conditions. During the initial layout of the first test version, a microcontroller in a TQFP-100 package and an 8-channel ADC were selected. However, after manufacturing the first version of the mobile ECG device and optimizing the circuit diagram, it became clear that a microcontroller in a TQFP-64 package and four ADC input channels were enough for the device. Therefore, the version of the microcontroller in the TQFP-64 package and the 4-channel version of the ADC were used in the development of the second generation of the ECG device.

In this prototype of the device, a proprietary communication unit was developed; it was implemented on the SIM868 universal combo module from SIMCOM, which supports data exchange in GSM / GPRS cellular networks, reception of location data and exact time signals from navigation satellites (GNSS).

The advantage of the developed hardware platform of a portable ECG device over existing similar solutions is that the platform included many technological solutions that allow development and modernization of the software part of the device without changing the hardware of the platform. A photo of the manufactured sample of the device is shown in Fig. 1.

Fig. 1. Photo of a Prototype Portable ECG Device.

Software for a mobile application has been developed to receive a signal from the recording device, performing its preliminary processing, diagnosing life-threatening cardiac arrhythmias, notifying the patient about the diagnostic results and transmitting data to the application server.

The main features of the system in comparison with existing are:

- work in conditions of free activity;
- performing a preliminary ECG analysis;
- automatic diagnosis of life-threatening arrhythmias;
- call an ambulance;
- storing ECS entries locally and on a remote server; and
- ability to integrate with the medical information system.

Our paper is organized as follows. Section 2 presents the state of the art. Section 3 describes of development of circuitry and printed circuit board of the ECG device. Section 4 details the software implementation of the system. Section 5 yields the discussion and future work directions. Finally, Section 6 outlines the main conclusions.

## II. LITERATURE REVIEW

We reviewed portable systems and wearable devices designed to detect or predict cardiovascular diseases over the past 2-3 years, since the achievements in this area until 2019 were given in our previous publication [2].

The paper [3] presents a portable, wearable, low-power non-contact ECG monitoring device that helps in the early detection of cardiovascular diseases. The device is placed in a shirt pocket, from where it will transmit data via Bluetooth Low Energy (BLE) to the user's mobile phone. The device mainly consists of three non-contact electrodes for sensing the cardio signal, an AD8233 AFE chip for extracting the ECG signal, and a CC2650 microcontroller for reading, filtering and transmitting them. A study [4] described and evaluated a new transducer design and system for the "invisible" ECG. Designed in the shape of a toilet seat, it provides device-free femoral ECG data, bringing a new approach to automated comprehensive health monitoring systems. To record ECG signals on the toilet seat, a special sensor was developed, as well as polymer dry electrodes with different textures. A new wearable ECG measurement system [5] based on smart clothes consists of three subsystems, including smart clothes, a smartphone and a PC terminal. Three textile ECG electrodes are woven into the fabric of the smart clothes, and the smart clothes can transmit the received ECG signals to a smartphone via Bluetooth. The ECG signals are then sent by the smartphone to the PC terminal via WiFi, cellular network or the Internet. Also, the smart bracelet [6] VITAL-ECG, developed by the Neuronica Lab of the Polytechnic University of Turin, allows to record basic vital parameters such as heart rate and ECG, SpO<sub>2</sub>, skin temperature and humidity. The developed mobile system [7] made to improve the ability to manage patients' cardiovascular diseases, as well as reduce the workload of doctors, includes both hardware and cloud software devices based on the latest advances in Internet of

Things (IoT) and artificial intelligence (AI) technologies. A small hardware device has been developed to collect high quality electrocardiogram (ECG) data from the human body. A new cloud service based on deep learning will be deployed to automatically detect cardiovascular diseases. Twenty types of diagnostic items are supported, including sinus rhythm, tachycardia, and bradycardia. A study [8] explored the feasibility of multi-lead ECG recording using dry capacitive electrodes with a specially designed portable device to explore the feasibility of a wearable ECG device with electrodes embedded in clothing.

The main disadvantage of these devices from ECG devices with conventional wet electrodes is low signal accuracy.

The study [9] investigates the AliveCor portable device for recording and measuring the QTc interval on a 6-lead ECG. Automated QTc data from the 12-lead ECG for each patient (n = 13) were compared with the mean QTc value calculated from the corresponding AliveCor record of each patient. AliveCor underestimates QTc - 92% of the time, AliveCor calculated QTc as lower than their respective 12-lead QTc readings. AMAZFIT ® [10], a new wearable electrocardiogram (ECG) recording system, is used to measure, collect and store adult single-lead heart curves. The aim of the study was to evaluate the accuracy of AMAZFIT ® for diagnosing arrhythmia in elderly patients. The study has some limitations. First, the sample size was relatively small, especially the cohort of patients with arrhythmias without arrhythmias. Secondly, we only measured heart rate in very stable patients when immobile. Indonesian scientists have developed a portable and inexpensive Holter system [11] for recording an ECG signal during the day. The motherboard consists of a preamplifier, a bandpass filter, a notch filter, a summing amplifier, an Arduino microcontroller, an SD memory card, and a Bluetooth transmitter. The ECG signal is taken from the body based on a standard LEAD II measurement. At the stage of the laboratory sample and is large in size.

Software [12] was developed using MATLAB for QRS detection based on a combination of simple unweighted moving averages. In particular, the main elements of ECG signal processing are moving average cascades (MAC). Our algorithm improves the QRS complex by selecting a MAC from a set of MAC derivatives that are inherently noise-tolerant. Adaptive digital filtering is applied [13] to eliminate any interfering noise that may occur in a typical home environment while minimizing processing time. The accuracy of ECG and EMG signal coverage is evaluated using Bland-Altman analysis by comparison with a reference instrument for collecting physiological signals. The method proposed in [14] first extracts sequences of first-order differential RR intervals (Delta RRI) from segmented ECG data, and then performs a polar coordinate transformation on a Delta RRI Poincaré plot to obtain a phase distribution. Two features, distribution width Dw and mean distribution height Dh, are extracted from the phase distribution to classify episodes of arrhythmia and episodes without arrhythmia.

The model proposed in [15] is presented as a three-level model for analyzing ECG signals, which can potentially be adopted in portable and wearable real-time monitoring devices

and it is designed, implemented and modeled the proposed CNN network using Matlab. The author in [16] proposed a classification model with low computational cost to reliably detect arrhythmia episodes in ECG signals by using signal RR intervals and injecting them into an artificial neural network (ANN) for classification to compensate for the lack of computational complexity in traditional wearable ECG monitoring devices. In [17] there is presented a deep learning algorithm for determining high-quality intervals on single-lead ECG recordings obtained from patients with paroxysmal arrhythmia. The study [18] uses a new implementation of a 1D Convolutional Neural Network (CNN) integrated with a validation model to reduce false positives. This CNN architecture consists of an encoder block and a corresponding decoder block, followed by a sampling classification layer to construct a one-dimensional R-peak segmentation map from the input ECG signal. All experiments in these papers are based on simulation software. To increase the practical value of the proposed algorithms, it is necessary to implement monitoring systems in a real platform.

The review shows that devices and systems that allow detecting dangerous cardiac arrhythmias in real time and preventing fatal outcomes have not yet been developed. Improving our non-invasive heart monitoring system remains an urgent scientific and technical task.

### III. DEVELOPMENT OF THE HARDWARE OF A PORTABLE CARDIOANALYZER

#### A. Development of a Functional Diagram of a Portable Mobile Cardioanalyzer

Fig. 2 shows a detailed functional block diagram of the developed portable mobile ECG device.

The main element of a portable ECG device is a microcontroller. The ADC for ECS recording is connected to the microcontroller via a serial data link. The ADC must be independently powered to minimize noise passing through the power lines from the microcontroller and other digital components of the system.

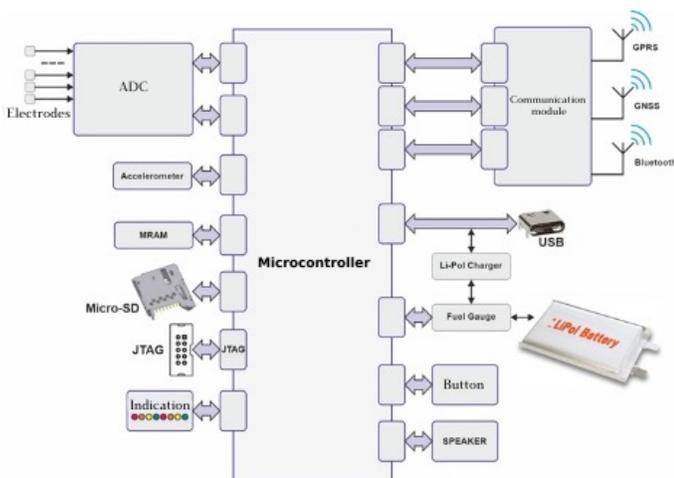

Fig. 2. Functional Block Diagram of the Cardioanalyzer.

To record operational data on current ECS, a block of non-volatile high-speed memory MRAM is connected to the

microcontroller. For further accumulation and long-term storage of ECG data, an external drive is connected to the microcontroller in the form of a MicroSD Flash memory reader, into which a Flash card with non-volatile memory up to 32 GB can be inserted.

The ECG device is equipped with a MEMS accelerometer that detects falls, and immobility of patient.

The portable ECG device is powered from an external power source. The charger ensures that the lithium polymer battery is properly charged and then disconnected in accordance with battery regulations. In accordance with the requirements of portable stand-alone devices, the portable ECG device is equipped with a power button controller, which provides manual control of power supply. Also, the power supply system of the portable ECG device is equipped with a device that determines the remaining battery charge, with the ability to transfer and record data on the current value of the battery charge to the microcontroller.

For communication with the ambulance service, as well as for the rapid transmission of ECS data to the server of the medical information system (MIS), the portable ECG device is equipped with a GPRS communication module. In the case of ECG data transmission via an external mobile phone, the portable cardiac analyzer is equipped with a Bluetooth module. The heart analyzer is also equipped with a GNSS satellite navigation module to determine the exact location of the patient.

The system of visual control of the operation of a portable mobile ECG device is made on two three-color and one single-color LEDs. One LED provides visualization of the charger's operation and indicates the "External power connection", "Battery charging" and "Battery charging complete" modes. The second three-color LED is connected directly to the microcontroller and is controlled by software. A single-color LED is connected to the GPRS module and signals the Internet connection modes and data exchange with the server.

#### B. Development of an Electrical Circuit Diagram of a Portable Mobile Cardioanalyzer

The development of a portable mobile ECG device begins with the development of a block diagram of the device, which is followed by the development of a circuit diagram. The block diagram of the device was worked out to the level of interaction of individual blocks. To form a common circuit diagram, it is necessary to work out each individual block, develop a circuit diagram for each block and combine them on a common diagram.

1) *Processor module:* The processor module is built on a modern low-power STM32L151xD microcontroller. To ensure normal operation of the microcontroller, an external 20 MHz crystal is required; a power supervisor chip to provide a RESET signal at initial power-up, a clock crystal at 32.768 kHz, an SWD connector for programming, and the provision of decoupling capacitors on all power lines in accordance with the technical documentation at this time. Microcontroller when developing a mobile cardiac analyzer, a microcontroller in a TQFP-64 package was used (Fig. 3).

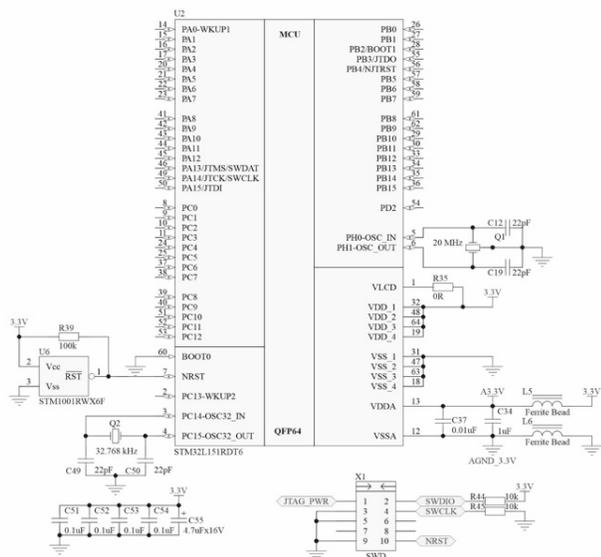

Fig. 3. Schematic Diagram of the Processor Module.

2) *ADC module:* The ADC module is based on a 4-channel 24-bit Front-End module (FEM) ADS1298 (manufactured by Texas Instruments). The module is functionally complete and is connected to the processor module via a serial synchronous SPI interface. An external 2.048 MHz reference oscillator is required to ensure normal operation of the ADC. This frequency is generated by the microcontroller and fed to the ADS1298 via the MCO line. On each input channel of the ADC (4 channels), protection lines are formed, consisting of two low-frequency RC filters and a diode assembly. Protection lines are used to filter high-frequency signals, eliminate reverse polarity and input overvoltage. This ADC construction option is shown in Fig. 4.

3) *RAM block:* The RAM block is built on non-volatile MRAM memory MR25H40 with a memory organization of 512Kx8. Access to non-volatile memory is carried out via a serial synchronous SPI interface. The MRAM connection option is shown in Fig. 5.

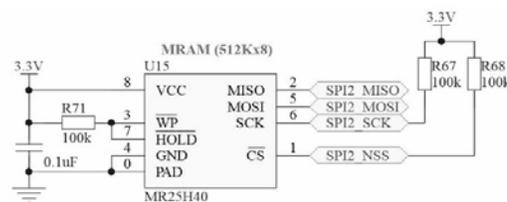

Fig. 5. Schematic Diagram of the RAM Block.

4) *Persistent memory block:* To ensure non-volatile storage of large amounts of data, a replaceable microSD solid-state drive with a memory capacity of up to 32 gigabytes is used. To use an external drive in a portable ECG device, a microSD cardholder is used, which is connected to the microcontroller via a special SDIO bus. The MRAM connection option is shown in Fig. 6.

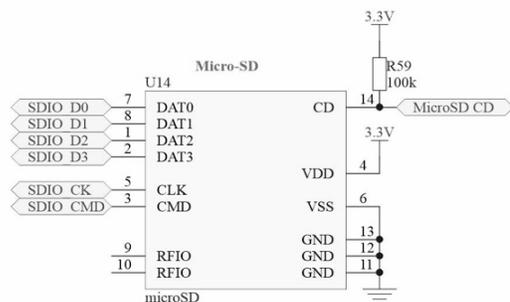

Fig. 6. Schematic Diagram of a Block of Permanent Memory.

5) *Block for determining accelerations:* The acceleration detection unit is built on a MEMS accelerometer that registers shocks, falls and a stationary state. As an accelerometer, a LIS3DH 3-axis MEMS accelerometer chip in an LGA-16 package from ST Microelectronics was used. The MEMS accelerometer is connected to the microcontroller via the I2C serial interface. Also, the accelerometer has 2 interrupt outputs INT1 and INT2, through which it is possible to wake up and wake up the microcontroller from sleep in case of sharp shocks and falls. The accelerometer connection option is shown in Fig. 7.

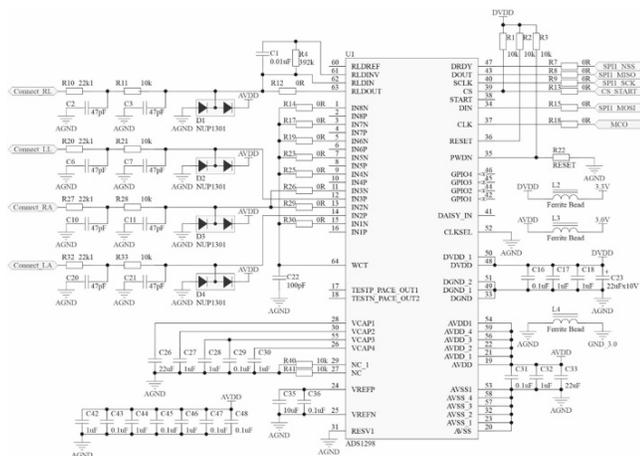

Fig. 4. Schematic Diagram of the ADC Module.

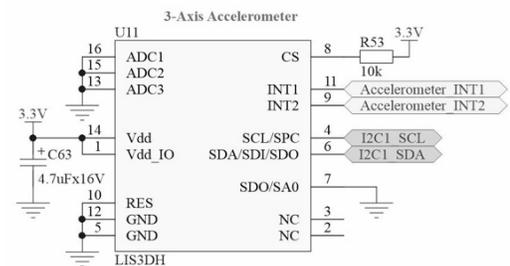

Fig. 7. Schematic Diagram of the Block for Determining Accelerations.

6) *Communication block:* A communication unit was developed based on the universal combo module SIM868 from SIMCOM, which supports data exchange in GSM / GPRS cellular networks, reception of location data and exact time signals from navigation satellites (GNSS). The SIM868

uses a Serial Port Interface (SPI) to communicate with the microcontroller. Because since the SIM868 module and the microcontroller have different supply voltages, a signal level converter on the ADG3308 chip from Analog Devices was used to ensure compatibility. To connect a telephone microSIM card module, we used a cardholder model MOLEX 503960-0696, which is additionally protected from static electricity by a quad suppressor SMF05C for the lines going to the SIM868 module. 3 antennas are connected to the SIM868 module: GPRS, GNSS and Bluetooth. Additional matching of these antennas with the module is performed on RLC components, which is shown in Fig. 8.

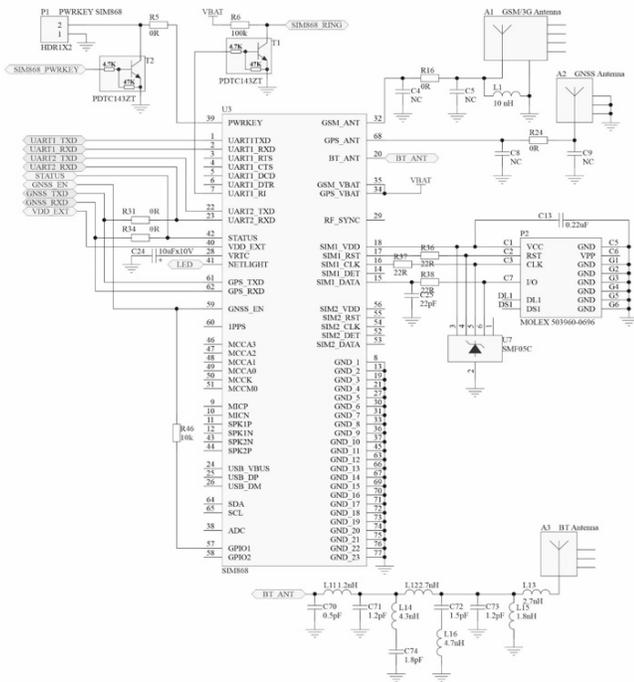

Fig. 8. Schematic Diagram of the Communication Block.

7) *Battery charge control unit:* A battery is required for the portable mobile cardiac analyzer to operate in standalone mode. When choosing a battery, the main criteria were:

- large capacity.
- minimum thickness.
- dimensions are as close as possible to the size of the printed circuit board.

A Li-POL battery in the form of a prism with a size of 90x53x4.4mm fully meets these criteria. Since such a battery requires a charging block, the BQ24070 chip from Texas Instruments was used in the design of this block. This chip is a specialized module for charging a Li-POL battery in 1S format, i.e. with a maximum voltage when charging no more than 4.3V. The BQ24070 can support up to 2A lithium polymer battery charging while supporting external power supply up to 16V. The microcircuit ensures the correct process of charging the battery in accordance with the technical documentation for lithium polymer batteries. The microcircuit ensures the transfer

of data on the status of the charge / discharge process to the microcontroller and in parallel this status is displayed on the LED indicator. The circuitry of the developed battery charge control unit is shown in Fig. 9.

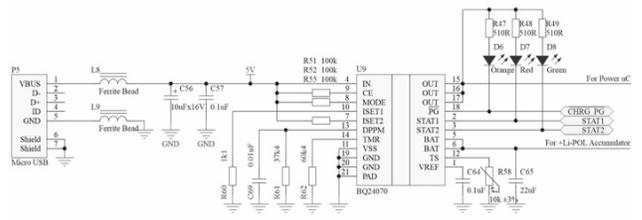

Fig. 9. Schematic Diagram of the Battery Charge Control Unit.

8) *Block for determining the residual battery charge:* To determine the exact value of the residual battery charge, circuitry was developed based on the MAX17043 chip from MAXIM. This microcircuit determines the level of residual charge and transmits data via a two-wire I2C interface. The circuitry of the developed battery charge control unit is shown in Fig. 10.

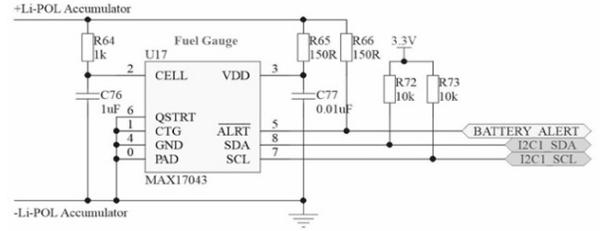

Fig. 10. Schematic Diagram of the Block for Determining the Residual Battery Charge.

9) *Overcharge/overdischarge protection block:* When operating a Li-POL battery, strict observance of the charge / discharge modes is required. It is necessary to limit the current and voltage at the end of the charge cycle to prevent overcharging and failure of the battery. It is also required to completely disconnect the load from the battery when the battery is discharged and the voltage drops below the minimum for Li-POL batteries. These modes are provided by the DW01A chip manufactured by H&M Semiconductor. The microcircuit protects the battery from overcharging / overdischarging by controlling the load with power N-MOSFET transistors in the lower arm. The developed scheme of the battery protection unit is shown in Fig. 11.

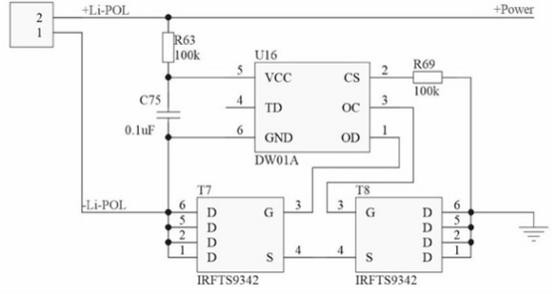

Fig. 11. Schematic Diagram of the Battery Protection Unit.

10) *Indication and notification block*: The indication of a portable mobile ECG device is represented by three LEDs that determine the charge mode in the battery charge control unit; one LED providing indication of the operation of the radio channel in the communication module; three LEDs connected to the microcontroller and providing indication for various program modes. Also, the microcontroller, using a transistor key, controls the warning system built on a piezoceramic sound emitter. This circuitry is shown in Fig. 12.

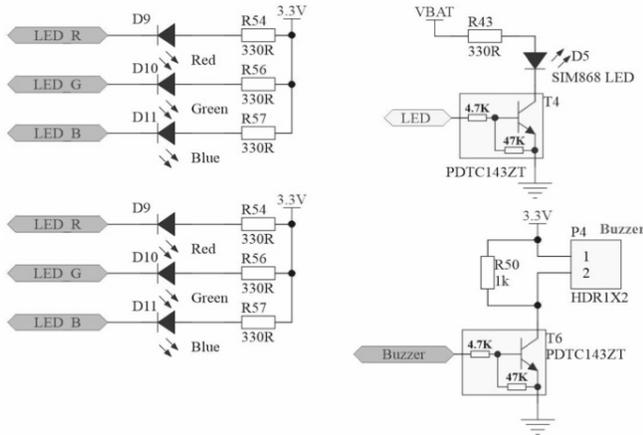

Fig. 12. Schematic Diagram of the Indication and Notification Block.

### C. Development of the Printed Circuit Board (PCB) of a Portable Mobile Cardio Analyzer

When developing a portable ECG device, a list of 215 components in 85 positions (nominal values) was used. The design complexity of the device is quite high, because a large number of components are used.

It is determined that the printed circuit board will be multilayer. Based on the design criteria for multilayer printed circuit boards, the number of individual layers allocated for power supply and the complexity of the circuitry, the number of layers in the designed PCB was determined - 6 layers. SMT components were mounted on one side of the PCB.

When arranging the components, the total area of all components and the estimated overall dimensions of the PCB were determined. After the final arrangement of the components and the multilayer tracing, the final dimensions of the PCB were determined. The size of the software was 120 x 60mm. For visual representation of the PCB and for the subsequent design of the hull solution, 3D models of the PCB with installed components were generated on an accurate scale. See Fig. 13.

1) *Defining a conductor as a transmission line*: When tracing the printed circuit board, it was revealed that it was necessary to connect the chip antennas to the radio transmitting module. Since the operating frequencies of the antennas lie within 1.8 ... 2.48 GHz, it is necessary to analyze and determine whether the strip line is an inhomogeneous transmission line, since when designing high-speed devices, various kinds of reflections and signal distortions occur. In

order for the signal to retain its integrity, it is necessary to develop transmission lines with a given wave impedance in the form of conductors of a certain width on a printed circuit board. Signal transmission without distortion is possible along a transmission line with a given wave impedance from the source to the signal receiver.

The electrical length of the printed conductor depends on the minimum wavelength of the transmitted signal and, accordingly, on the rise time of this signal. If the copper conductor on the PCB is too long in relation to the rising edge, then the conductor should be designed as a transmission line to prevent distortion. A copper conductor on a PCB is a transmission line if its electrical length on the PCB is more than 1/3 of the rise time. That is, the conductor is electrically long. Signal propagation velocity  $V_p$  is the speed at which an electrical signal travels along a copper conductor on a printed circuit board. The speed is calculated by the formula.

$$V_p = \frac{c}{\sqrt{\epsilon_r}} \quad (1)$$

where  $c$  - is the speed of light,

$\epsilon_r$  - is the dielectric constant of the printed circuit board material.

Since we are using the widespread FR-4 material with a dielectric constant of 4.0 in the project, the signal propagation speed will be equal to:

$$V_p = \frac{c}{\sqrt{\epsilon_r}} = \frac{299,792,58}{\sqrt{4}} \text{ mm/ns} = 149.89 \text{ mm/ns},$$

The length of the printed conductor  $L_r$  is calculated according to the rule of 1/3 signal rise time:

$$L_r \geq \left(\frac{t_r}{3}\right) * V_p, \quad (2)$$

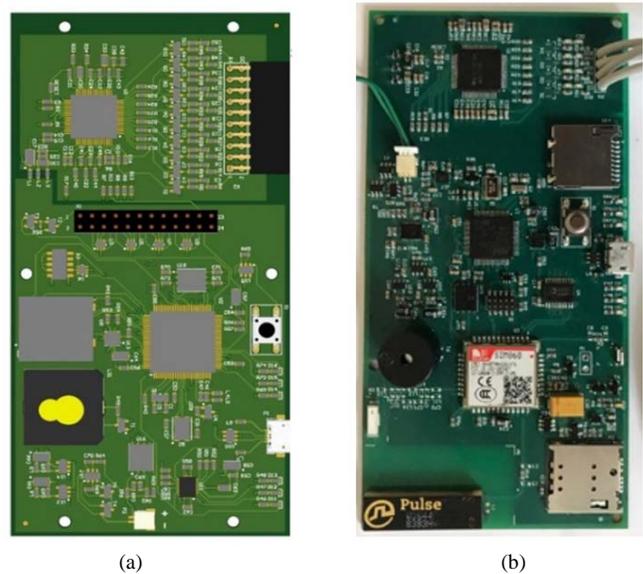

Fig. 13. 3D Model (a) and Fabricated Sample (b) PCB with Installed Components.

where  $L_r$  – conductor length,

$T_r$  - signal rise time, *ns*.

Thus, the printed conductor should be considered as a transmission line when we use FR-4 material, with the following length:

$$L_r \geq T_r * 49.96mm, \quad (3)$$

Thus, if  $T_r=1$  *ns*, then:

$$L_r \approx 50 \text{ mm},$$

That is, it turns out that under the above conditions for frequencies of 2.48 GHz, a printed conductor having a length of 20 mm or more must be considered as a transmission line, which requires additional matching.

Calculation of the wave impedance of a microstrip transmission line.

The total impedance (impedance) of the transmission line from the radio module to the antenna must be 50 ohms, because the GSM/GNSS module has antenna terminals designed to work with antennas with a characteristic impedance of 50 ohms.

The transmission line that connects the module and the antenna must be matched, i.e. should have a wave impedance of 50 ohms.

If the transmission line has a different impedance, then the electromagnetic wave propagating along the copper conductor of the printed circuit board will be partially reflected at the boundary of media with different wave impedances (if the transmission line is homogeneous, reflection will occur at the junctions with the module and with the antenna). This can lead, at best, to a decrease in the sensitivity and output power of the device, and at worst, to failure of the output stage of the module.

When designing a printed circuit board, we define and design the transmission line between the module and the antenna as a microstrip line. The impedance of a microstrip transmission line depends on the ratio of the dielectric thickness between the microstrip and the return conductor, as well as the width of the signal conductor. As long as this ratio is constant, the wave impedance of the microstrip line will also be constant. With a proportional change in these parameters, the wave impedance of the transmission line remains unchanged.

The microstrip line configuration is shown in Fig. 14.

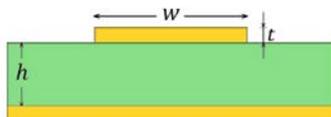

Fig. 14. Cross Section of a Microstrip Line.

The microstrip is a non-uniform transmission line because not all of the field lines between the strip conductor and the ground plane pass through the substrate. Therefore, a wave propagating along a microstrip conductor is a "quasi - T-wave".

The effective permittivity  $\epsilon_{\text{eff}}$  is less than the permittivity of the substrate, since the field outside the substrate of the return current is also taken into account.

#### IV. DEVELOPMENT OF THE SOFTWARE PART OF THE CARDIODIAGNOSTIC SYSTEM

Currently, wired connections between individual devices in medical systems are being replaced by wireless technologies for information transfer, and a number of factors must be taken into account: the distance between devices and the ability to move them, the transfer rate and amount of information transmitted, power consumption, the possibility of encryption, the level of interference, etc. Consider the communication protocols between the components of the heart monitoring system.

The portable ECG device contains its own communication unit based on the universal combo module SIM868 from SIMCOM, which supports data exchange in GSM / GPRS cellular networks, reception of location data and exact time signals from navigation satellites (GNSS). The SIM868 uses a Serial Port Interface (SPI) to communicate with the microcontroller. Because since the SIM868 module and the microcontroller have different supply voltages, a signal level converter on the ADG3308 chip from Analog Devices was used to ensure compatibility.

In accordance with the functions of the entire system and its individual parts, the structure of the software for the non-invasive heart monitoring system was developed (Fig. 15).

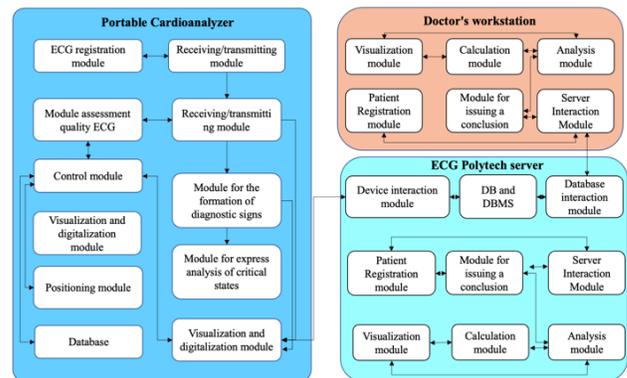

Fig. 15. Structure of the Cardiodiagnostic System.

The software of the non-invasive heart monitoring system consists of the software of a portable ECG device, a server, and a doctor's workstation. The server part (highlighted in blue in Fig. 14) includes a device interaction module, a database (DB) and a database management system (DBMS), a database interaction module.

In accordance with the three-level model, the following operating modes are possible during the operation of the heart monitoring system: "autonomous" - all tasks for processing and analyzing ECG are performed on a portable ECG device; "device -server" – ECG processing and analysis tasks are distributed between the device and the server; "cardiac analyzer-server-doctor" - all tasks for processing heart monitoring information are assigned to the doctor's workstation, and the server is used only for data storage. The

levels of the decision hierarchy, the corresponding modes of operation, analysis options and decisions made at various levels are shown in Table I.

TABLE I. LEVELS OF THE DECISION HIERARCHY OF THE CARDIODIAGNOSTIC SYSTEM

Hierarc hy levels	Operating modes	Analysis option	Decisions made
Lower	Autonomous	Automatic express analysis of ECG	Suitability of the ECG for analysis, the presence of a critical situation
Average	Cardioanalyz er-server	Automatic differentiated analysis of a critical situation	The need for a detailed medical analysis, the presence of a connection with the doctor's workstation.
Highest	Cardioanalyz er-server-doctor	Detailed medical analysis by a cardiologist	Calling an ambulance, making recommendations.

Actions and decisions that are not highlighted in color are implemented by a portable cardiac analyzer, those highlighted in yellow are implemented by the server, highlighted in blue are the doctor's workstation.

Thus, the developed system structure, software structure, decision-making model, as well as methods, algorithms and structural solutions make it possible to implement a system of non-invasive heart monitoring in accordance with the formulated requirements.

A. User Model, Linking a Specific Portable Cardiac Analyzer to a Specific user

Django comes with a default user model with fields like username, passwords and email, however in some cases these fields may not be enough for us to extend the "User" model or create our own user model. In this case, we will be extending the user model because we need a way to differentiate users.

To determine the device, we generated a unique "id" for each device and associated it with a specific user, so when transferring data, we also pass the "id" of the device. Fig. 16 shows a list of potential patients linked to the system via ID codes.

On the script (Appendix 1, A), using the Socket library, we create a socket to receive data from the device. To do this, you need to specify the server address and the number of maximum handles that can be opened at a time. Since this code was used for testing, the maximum number of descriptors is 30.

Next, we have to write a listener function and a signal handler, or as you can also call it, data packets (Appendix 1, B). The listener first of all looks at the address of the transmitted data, if they are addressed to our IP, we receive the data. Now we have to transfer our data further for processing and, if necessary, for storage in our database under a specific user.

If we run our socket script, at the output we will see data already converted to numbers in the server console. Using the hexlify() function, we converted the bytes first to hex, then by decoding with the decode() function to the String type (as shown in Fig. 17 and 18).

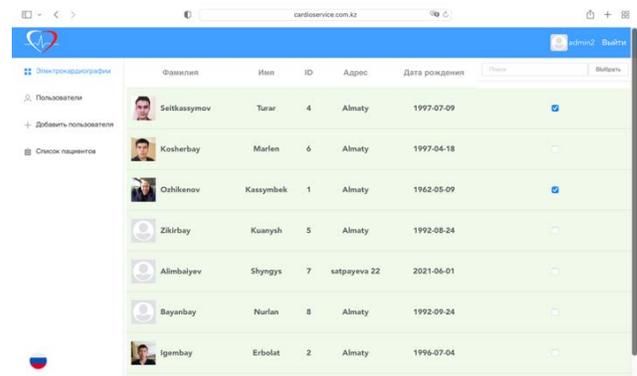

Fig. 16. User Registration in the System.

Fig. 17. Initial Data Type (Bytes).

b'\x80\x00\x00\x80\x00\x00\x80\x00\x00\x80\x00\x00\x7f\xff\xff\x7f\xff\xff\x80\x00\x00\x80\x00\x00\x80\x00\x00\x80\x00\x00' – here we assigned the first 8 bytes to identify the device itself, as well as to transfer the user id, date and time of data transfer.

Fig. 18. After Conversion (Type – List<String>).

But it is still impossible to use this data, because here we have a lot of data distorted during transmission or processing, noise and duplicated data. At the stage of processing the received data, we used the POST method. This method ensures secure data transfer. Next, using cropping, select the data area in which the transmission data and id are recorded for identification. A further goal is to filter the data in the packet body. The principle of noise trimming is used here, we determine the upper and lower threshold of the received data and trim the data accordingly. That is, all noise exceeding this threshold will be suppressed. After filtering, having determined the user id, we sort the data by the date and time of receipt and send it to the database for storage.

In our project, to receive and transmit data, we use a programming interface - a socket, which allows us to always accurately determine the state of a person and ensures immediate data exchange. In vue.js, sockets are quite mature and are constantly being improved. To use sockets, it is enough to refer to the web socket initialization function WebSocket(). The first attribute is the address directed to our server. It is worth paying attention to the explicit indication of the id of the patient whose data we want to see.

When running this script, we can observe the calculations aimed at the "@arction/lcjs" library, which is designed to visualize graphs. When drawing graphs, this library uses graph theory, which allows us to effectively arrange the received data in the form of integers. Thanks to this, the user can visually observe the pacemaker in real time (Fig. 19).

Fig. 19. Real-time ECG Visualization.

An important point in our system is the definition of dangerous cardiac arrhythmias. The key value in determining dangerous cardiac arrhythmias is - heart rate. To calculate the heart rate value, it is necessary that our device receives an ECG within 60 seconds, this will be enough. Knowing the formula for determining heart rate in advance, we rewrote the formula into a similar function, the syntax of which is written below:

$$heart\ rate = \frac{60}{R-R}, \quad (4)$$

where 60 is the number of seconds in a minute, R-R is the duration of the interval, expressed in seconds.

Formula for calculating heart rate written in the JavaScript programming language is given below:

```
if (self.seconds >= 60) {  
self.chss = parseInt(len / 360);  
self.rr = 60 / parseInt(len / 360);
```

It is also important to calculate the RR value (the distance between two signal amplitudes, that is, heartbeats). Having obtained these values, we can easily determine two extremely dangerous diagnoses: "Sinus bradycardia" and "Sinus tachycardia". To be more precise, with a very rare heart rate, less than 45 beats/sec, "Sinus bradycardia" is detected, and if more than 100 beats/sec, then "Sinus tachycardia". Code to visualize the conclusion is given in Appendix 1, C.

When we finally calculated the values needed for the conclusion, the user can see the final diagnosis of his condition (Fig. 20).

Fig. 20. Visualization of Diagnostic Result.

## V. DISCUSSION

The ECG monitoring system is an example of the practical implementation of the developed portable device and the method of noise-resistant ECG processing for patients with free activity. The basis for the creation of ECG monitoring system is modern information and communication technologies and patent-protected methods developed by the authors, algorithms, structural, circuit and software solutions.

The main features of the device in comparison with existing are:

- work in conditions of free activity;
- performing a preliminary ECG analysis;
- automatic diagnosis of life-threatening arrhythmias;
- call an ambulance;
- storing ECS entries locally and on a remote server;
- ability to integrate with the medical information system

The introduction of a ECG monitoring system in medical practice requires additional clinical trials and can serve as the basis for successful competition with leading foreign companies working in this field.

Currently, on the basis of the Satbayev University, ten sets of a portable ECG device have been designed and preclinical tests of the system are being conducted.

The developed system does not allow diagnosing more complex heart diseases, such as myocardial infarction. Currently, the authors are trying to develop a method of neural network analysis of ECG for diagnosing myocardial infarction and improving the accuracy of determining the location of myocardial damage, in particular, identifying the stages of myocardial infarction and the depth of myocardial damage.

## VI. CONCLUSION

A mobile intelligent heart monitoring system has been developed that provides a three-level ECG analysis: automatic express ECG analysis (mode: "Autonomous"), automatic differentiated ECG analysis ("device -server" mode), detailed medical analysis using a cardiologist's workstation ("device -server" mode). doctor server). Based on the formulated requirements, a detailed functional block diagram of the device was developed and built. According to the developed functional block diagram, an analysis was carried out, criteria

for selecting components were developed, and an element base was selected for designing a hardware platform for a portable mobile ECG device. After selecting the element base, an electrical circuit diagram of a portable mobile ECG device was designed. Particular attention was paid to the functional composition of the device and its reduced power consumption. Based on the developed electrical circuit diagram, the printed circuit board of the device was designed.

Software for a mobile application has been developed for receiving a signal from an ECG recording device, performing its preliminary processing, diagnosing life-threatening cardiac arrhythmias, notifying the patient about the diagnostic results, and transmitting data to the application server.

We evaluated the performances of the developed system. The signal-to-noise ratio of the output signal is favorable, and all the features needed for a clinical evaluation (P waves, QRS complexes and T waves) are clearly readable.

The current model of a portable information-measuring system for monitoring the heart in conditions of free activity is being tested in the city hospital of JSC "Central Clinical Hospital" in Almaty.

#### ACKNOWLEDGMENT

The current model of a portable monitoring system was developed on the basis of Satbayev University under the grant program of the Science Fund of the Republic of Kazakhstan. Project №0281-18-“Portable ECG device”.

**Abstract**—During the COVID-19 pandemic, patients who required face-to-face attention and tested positive, even showing signs of high risk, were forced to isolate themselves in their own homes immediately without adequate medical monitoring. Continuous remote monitoring of their vital signs would have helped to avoid subsequent hospitalization caused by the progression of the virus. Using deterministic design methods, a system to measure respiratory rate through impedance pneumography was proposed, amplifying microvolt signals to read and process data with a microcontroller. An embedded algorithm was designed to measure inspiration and expiration time. The values captured were sent via WiFi to a server, for posterior evaluation by the clinician. The key findings of this study are as follows (1) a respiratory-rate remote monitoring system was developed, displaying values calculated from impedance pneumography signals, (2) the correlation of the respiratory rate values from a patient during exercising and resting time, measured by a physician and by the device, was 0.96. (3) when analyzing separately the data obtained by the resting test and the exercise test, the performance of the device presented an average error percentage of -5.36% and +1.97%, respectively. As a conclusion, this device has practical applications for acute and chronic respiratory diseases, where respiratory rate is an indicator of the progression of these conditions.

**Keywords**—Covid-19; respiration rate; internet of things; vital signs; hardware

## I. INTRODUCTION

At the beginning of the COVID-19 pandemic, 80% of patients were mild cases, meaning they required outpatient care [1]. However, unmonitored patients quickly developed acute respiratory reactions often overlooked by physicians [2]. Constant follow-up on a high number of patients is a challenging task for public healthcare due to the shortage of human resources, as well as the lack of equipment or technology intended for this purpose, especially in low- and middle-income countries.

The traditional way of measuring vital signs requires face-to-face evaluation at a distance of less than one meter, contrary to the preventive measures established to reduce the spread of COVID-19. Due to this, healthcare professionals on the frontline were forced to use personal protective equipment (PPE), while still being exposed to a high rate of contagion, which according to initial estimates represented 10-20% of all

diagnoses from each nation [3]. Moreover, the direct consequences of the frequent use of PPE -such as eczema and blisters-, as well as the social stigma of healthcare professionals, considered “agents of contagion”, should not be ignored. This scenario was seen in cities like Italy, Brazil, and Peru, where healthcare systems collapsed due to the high demand for outpatient care for cases of COVID-19 [4,5].

To address some of these challenges, the utilization of the Internet of Things (IoT) remains a promising solution. The Internet of Things (IoT) is based on establishing a connection between the Internet and electronic devices to achieve certain goals. IoT applications are increasingly implemented in different areas such as medical care settings as are the case with wearables, agricultural monitoring, or even transportation to control traffic [6].

Following on these applications, the Internet of Medical Things (IoMT) has gained wide adoption lately due to its multiple advantageous features, such as facilitating disease and drug management, improving treatment methods and patient experience, and reducing clinical expenses of various kinds. These systems require adequate attributes for effective performance: security, adaptability, real-time measurement, intelligent decision-making technologies, and compliance with information management regulations [7].

Respiratory rate is a prognostic factor that could be crucial for early respiratory risk detection [2]. Its consistent and reliable monitoring would allow for a more effective control of the patient's progress for timely care. The proposed solution is a hardware-based system using Internet of Medical Things (IoMT) technology, capable of capturing respiratory rate measurements through impedance pneumography, which is a technique based on the direct relation between the volume variations in the lungs and the electrical impedance from the electrodes located in separated areas of the chest.

## II. LITERATURE REVIEW

In 2018, thirteen medical subfields have benefited from the development of IoMT applications, with neurological, cardiovascular and mental diseases having the greatest presence of this type of solution. Chronic diseases impose enormous costs on the healthcare system. In that manner, IoMT applications for patients suffering these conditions are expected to increase, particularly for those in need of

rehabilitation. 22% of IoMT applications are commonly used to monitor, manage, and treat cardiovascular disease [8]. The findings indicate that IoMT applications have hardly been developed and implemented for diseases with a high mortality rate, such as chronic respiratory infections [8]. One example of this is Whoop [9], a wrist fitness tracker that collects patient data for an analysis of the change in the patient's respiratory system to prevent respiratory episodes.

However, some devices have been utilized in other medical fields. For instance, Sarmah et. al. [10] developed a system which consists of monitoring patients with IoT hardware in conjunction with a deep neural network to aid in the diagnosis of heart disease. Additionally, Dese et al. [11] developed LVital, a device for monitoring vital signs of pregnant women including blood pressure, heart rate, and body temperature. The device has the notable benefit of monitoring maternal vital signs and is appropriate for those located in low-resource environments.

In the context of the pandemic, IoMT initiatives emerged to combat COVID-19. Ashraf et. al. [12] reported the monitoring of a set of physiological parameters (temperature, heart rate and respiratory rate) embedded in a wearable to map people with this infection. Similarly, Amachi-Choque et. al. [13] developed an IoT system that measures heart rate, blood oxygen saturation and body temperature of patients with preliminary diagnosis of coronavirus, and then transmits data via WiFi to an IoT platform. The technology establishes the different levels of severity of the signs using a web-based system, in which the physician visualizes statistics and graphs of the different signals, sending alerts to an email or a smartphone.

The background above indicates the extensive interest in monitoring physiological parameters remotely, even more so with the endemization of COVID-19 in the following years. In this study, a device focused on respiratory rate, a vital sign of great relevance to the progression of the coronavirus infection, is proposed. This parameter is paramount to provide early warning of any respiratory episode arising, in the course from moderate to severe phase, which can result in dire consequences for the patient when not treated at an initial stage. This solution helps to ease the workflow in healthcare systems, aiming to reduce the rate of hospitalization in the Intensive Care Units (ICU) due to acute respiratory complications.

### III. DESIGN AND DEVELOPMENT

For the development of this electronic device, the project was divided into the following stages using the deterministic design method:

#### A. Establishment of Functional and Non-Functional Requirements

Functional requirements are understood as those operational aspects that the solution must perform throughout its execution. Meanwhile, Non-functional requirements are those qualities of the device that are observable at the time of its execution. The established requirements are:

Functional requirements (FR):

- The device must be able to read the electric potential difference through electrodes placed on the chest.
- The device must amplify analog signals to the microvolt level.
- The device must have the capacity to convert analog values read into digital ones.
- The device must transmit the processed data to a server.

Non-Functional requirements (NFR):

- The device must have a shape that allows its placement in the patient's body.
- The device must have an on and off switch.
- The device must have indicators of operating modes.

#### B. Selection of Electronic Components

Once the functionalities that the device will have been established, the electronic components were determined, being the main ones those mentioned below:

1) *ADS1292R*: It is a 24-bit multi-channel analog-to-digital converter (ADC) with a built-in programmable gain amplifier (PGA) that incorporates all the features commonly required in low power [14] portable medical devices. For this work, the ProtoCentral module that contains this integrated circuit was used (Fig. 1).

Fig. 1. ProtoCentral ADS1292R Module.

2) *ESP32-WROOM-32*: It is a powerful module containing a microcontroller with Wi-Fi and Bluetooth communication capabilities that are used in a wide variety of applications, ranging from low-power sensor networks to speech encoding. [15].

3) *XC6203*: A highly accurate, low-power, 3-terminal positive voltage regulator, providing up to 400 mA current with a significantly small dropout voltage [16]. In this design, the 3.3 V output version was used.

4) *Li-Po 522040*: A rechargeable lithium polymer battery with a capacity of 360 mAh (Fig. 2).

Fig. 2. 3.7 V LiPo Battery.

5) *RGB Led*: A LED with the ability to change color based on the 3 channels (red, blue and green) that will allow us to indicate the different phases of operation of the device.

### C. Circuit Schematic Design

For the power stage of the circuit, the XC6203 voltage regulator was used, which converts the LiPo battery voltage from 3.7 volts ( $V_{in}$ ) to 3.3 volts ( $V_{33}$ ) (Fig. 3). The datasheet of the regulator also indicates that both the input and the output must have 1  $\mu\text{F}$  ceramic coupling capacitors. In addition, the output must have a 10  $\mu\text{F}$  electrolytic capacitor. In this case, a tantalum capacitor is being used.

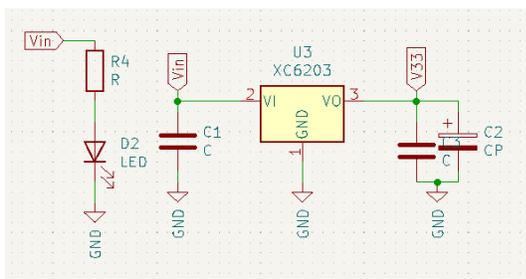

Fig. 3. Circuit Power Stage with Voltage Regulator XC6203.

Once a voltage of 3.3 V is obtained, this will be the stable level for all other active components. The communication between the ESP32 and the ADS1292R module is through the SPI protocol that uses the following pins: MISO, MOSI, SCK, CS, VCC and GND. Additionally, they have control pins (DRDY, START and PWRDST). 3 GPIOs were used to control the colors displayed by the RGB LED (Fig. 4).

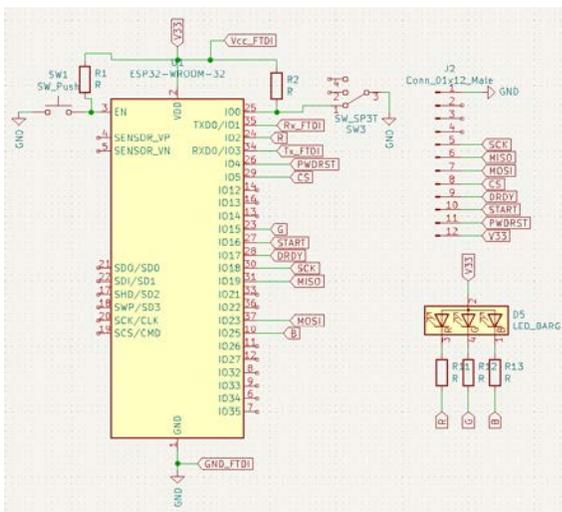

Fig. 4. Connection between ESP32 and ADS1292R Module.

Seeking to optimize the physical size of the device, a custom printed circuit board (PCB) was designed with the previously described circuits including a port to program the microcontroller with an FTDI module. On and off buttons were added as well (Fig. 5).

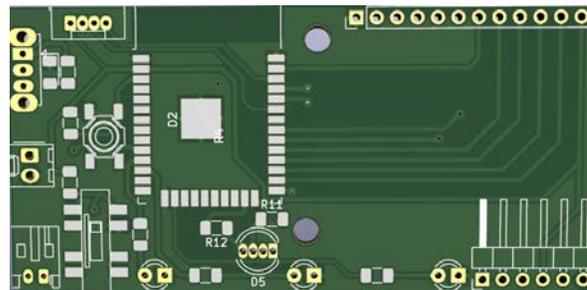

Fig. 5. Custom Printed Circuit Board (PCB).

To give the device wearable characteristics that make it comfortable on the body, an enclosure was designed to be 3D-printed using PLA-type filament. The bracelet-shaped device can be worn on the arm with an elastic band with Velcro patches (Fig. 6).

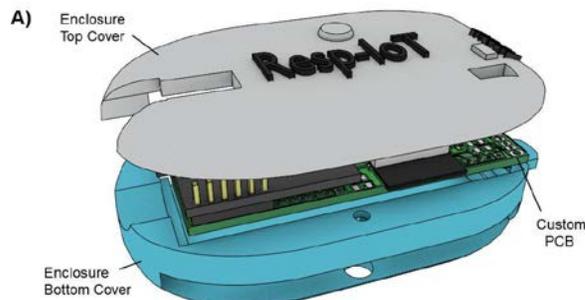

Fig. 6. Enclosure to Protect the Circuit. (A) 3D Design Rendering of the Enclosure. (B) PCB Placed Inside the 3D Printed Enclosure.

### D. Respiratory Rate Measurement Algorithm

The first step in the script is to initialize the data acquisition and communication modules when the value obtained from the electric potential difference of the electrodes (previously amplified by the ADS1292R) is obtained. This signal presented high levels of noise; therefore, it was essential to use a filter to stabilize it and prepare it to be processed. The value obtained is stored in a memory space and an average of the last 10 values is made with a separation of 10 ms. This amount of time between each reading was chosen because 100 ms is less than the duration that an

inspiration or expiration phase could have, so it does not affect the real-time reading of the sensor. This average value will allow the detection of increasing or decreasing values. The range of values indicates whether it is in the patient's inspiration or expiration phase (Fig. 7).

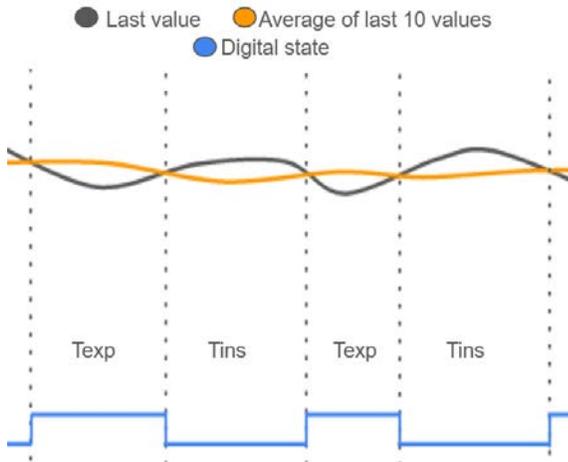

Fig. 7. Inspiratory and Expiratory Phases of the Patient.

The human respiratory cycle is defined as the time interval between the start of inspiration ( $T_{ins}$ ) and the end of expiration time ( $T_{exp}$ ). To calculate the duration of the breathing cycle ( $T_c$ ), the inspiration and expiration phases are timed. The duration time of both phases are added to obtain the cycle time as follows:

$$T_c = T_{ins} + T_{exp} \text{ (seconds)}$$

Once the  $T_c$  is calculated, in order to know how many breaths per minute (BpM) the patient performs, the conversion is calculated with the following formula:

$$BpM = 60/T_c \text{ (breaths/min)}$$

When the breaths per minute is obtained, the data is verified, as it has limit values that establish that it cannot be greater than 30 cycles/min and not less than 5 cycles/min. When the value obtained is not within that range, the algorithm redirects to the reading of the electrical potential obtained by the electrodes to start the whole process once again. If the value is valid, it is stored and sent via WiFi to the server. The flow of the algorithm can be seen in Fig. 8.

For each of the stages of the algorithm (Fig. 9), the RGB LED lights up a different color indicating the user if the reading is being captured correctly. The color legend is as follows.

**E. Experimental Setup**

To evaluate the performance of the device, multiple tests were carried out on real patients, comparing the value obtained by the device with values measured by a doctor using a stethoscope. For this purpose, the diaphragm of the device was placed on the chest wall, so that it does not rest on any structure. Then, the number of breaths in 60 seconds was quantified. For this pilot, five healthy patients were recruited, taking measurements in two different scenarios: total rest and after physical effort.

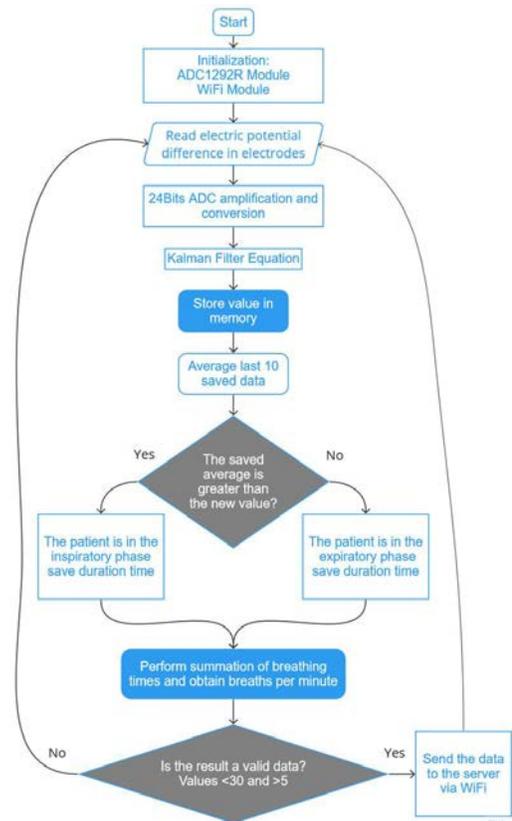

Fig. 8. Flowchart of the Algorithm for the Calculation of Breaths per Minute.

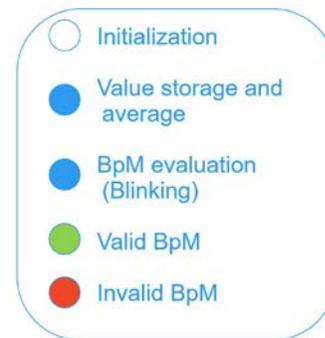

Fig. 9. Color Legend According to Script Execution Stage.

The device is placed on each patient's arm, secured with Velcro to reduce the risk of falls or impacts due to detachment (Fig. 10).

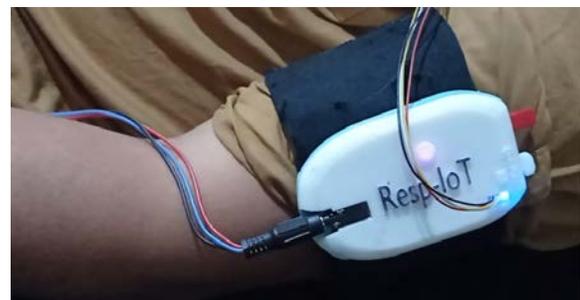

Fig. 10. Device Placed on the Patient.

Fig. 11. Electrodes Placed on the Patient.

Once the device was fixed, the electrodes were placed on the upper part of the patient's chest (Fig. 11). For the tests at rest, measurements were made for a total of two minutes, both by the doctor and the device. For the next test, the patient was instructed to do exercises such as planks or jogging for a total of five minutes with the device on, immediately after which the device was turned on and the doctor began with the quantification of breaths.

#### IV. RESULTS AND DISCUSSION

The results of the tests can be seen in Table I. When separately analyzing the data obtained by the resting test and the exercise test, the performance of the device presents an average error percentage of -5.36% and +1.97%, respectively. For small values, it shows a tendency to overestimate the number of breaths per minute. Meanwhile for high respiratory rate, the measurement tends to be slightly below the real one. When considering both tests, it has an average error value of -1.70%, meaning that the accuracy of the device is approximately 98.3%.

A comparison was performed using the values obtained by the device and by the doctor from both contexts (resting and exercising) as shown in Fig. 12. A correlation coefficient of 0.96 was obtained.

Numerous initiatives have sought to measure the respiratory rate through electronic devices. Adapting sensors to masks could be one strategy, as was demonstrated by Huang et. al. [17]. By using a temperature sensor, the device presented an insignificant error according to its results. However, its precision was evaluated by contrasting its performance with an uncalibrated belt-shaped device that measures thoracic diameter variation.

A similar design is presented by Güder et. al. [18], who introduced a carbon-electrode based paper sensor that varies its conductivity along with the different respiratory phases. To validate its performance, an analysis of the breathing cycles per minute between a light and vigorous exercise session was conducted without selecting a gold standard. Moreover, the sensor electrodes were prone to breaking if the paper was folded, which complicated the process of putting on and taking off the mask.

Different projects have tried to measure respiration rate through chemical sensors that can be mounted on the skin [19] and flexible electronic skins [20], showing promising results. However, it presented an uncomfortable user experience, as the sensors should be placed on the space near the mouth and

under the nose. Min et. al. [21] reported a device for respiratory rate measurement analogous to the proposed design. Despite calculating the lung's volume variation, it used a textile-based capacitive respiration sensor, comparing its performance to a nasal thermocouple. The strap surrounding the entire torso demonstrated a precision comparable to the proposed device ( $R^2 = 0.98$ ).

Finally, Pegan et. al. [22] used a wrinkled platinum strain sensor, placed on a part of the chest with a flexible PCB, obtaining a similarity of 95% when compared to a spirometer, which is reliable up to 1000 cycles. Among the advantages of this device is the ability to measure respiratory rate based on the volume of the rib cage, without wrapping the entire torso or causing discomfort near the mouth or nose. One of the disadvantages is the short electrode life cycle, needing to change the electrode each five measurements, and adding conductive gel to improve the quality of the signal.

TABLE I. COMPARISON OF VALUES OBTAINED BY THE DEVICE AND BY PHYSICIAN DURING THE RESPIRATORY RATE TEST

Test	Patient ID	Device	Physician	%Error
Rest	1	9,49	10	5,10
	2	11,43	11,5	0,61
	3	9,4	9	-4,44
	4	8,7	8	-8,75
	5	12,53	10,5	-19,33
Exercise	1	17,4	20	13,00
	2	23,59	24	1,71
	3	19,72	20,5	3,80
	4	26,1	25	-4,40
	5	21,9	21	-4,29
			<b>Average % Error</b>	<b>-1,70</b>

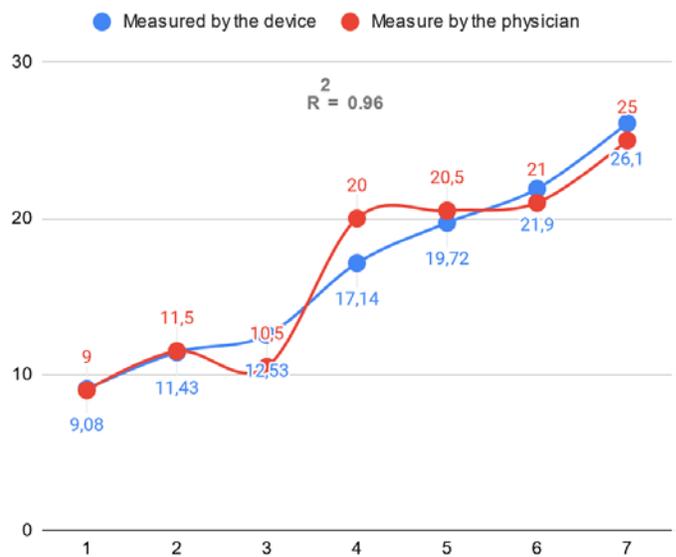

Fig. 12. Relationship between BpM Measured by the Device and by the Physician.

Among the factors that can generate an error in the reading of the proposed device, if the person using it constantly moves or continues to speak, it can generate misreading. It is recommended that patients remain in a state of rest for at least three minutes.

## V. CONCLUSION AND FUTURE WORK

In this work, an IoT device was developed and tested for remote and continuous monitoring of vital signs related to COVID-19, able to display respiratory rate measurements by calculating the electric potential difference from ECG electrodes located on the chest. The device was calibrated against a visual count performed by a trained healthcare professional in a patient while resting and exercising, demonstrating an accuracy of 96%.

As future work, this device will be tested on a wider population, and at extreme values, through randomized clinical trials with ICU patients and distinct respiratory conditions. It also needs to be calibrated by a metrology laboratory, following ISO standards for measurement management, before being tested in healthcare facilities. As COVID-19 becomes an endemic disease, this device will fill the need for monitoring from conditions like COPD or asthma.

The creation of an open database of respiratory rate values related to mild and severe COVID-19 patients would be of great impact for further research about this disease. Additionally, it will allow the development of machine learning models that anticipate the appearance of a chronic respiratory episode that may aggravate the patient's condition.

## ACKNOWLEDGMENT

This project was developed with funding provided by the Royal Academy of Engineering (United Kingdom) through the "Engineering X Pandemic Preparedness" scheme.

**Abstract**—Augmented reality technology has become a hot spot in many fields because of its unique real-time interaction and the ability to add virtual objects in 3D video space. To enable students better understand and master traditional mechanical courses and solve the limitations of the courseware teaching method, a teaching assistant system based on Vuforia platform is designed and developed by combining augmented reality technology with existing teaching methods. On the smartphone application side, the 3D model of parts can be displayed by scanning mechanical engineering drawings, which can rotate, zoom, and section view the model. It realizes 3D visualization and interactive operation of 2D drawings in textbooks and achieves the purpose of image, diversity and efficient teaching. The results show that this method can not only promote the cognition of spatial relations based on visualization, but also create a situational learning environment based on experience, which can effectively improve the learning effect of courses and enhance students' interest and enthusiasm in learning.

## I. INTRODUCTION

The rapid development of the new generation information technology has promoted the diversification of teaching resources. Improving teaching quality and learning efficiency is the basic requirement of modern education [1]. As an important factor to improve teaching quality and learning efficiency, teaching resources have attracted more and more attention [2-3]. The traditional teaching methods of the plane textbooks have obvious limitations. At present, some innovations have been made to the teaching media, such as using 2D codes and other methods to link to assistant resources on web pages. However, this form is generally not well accepted by students, and it is necessary to find a way to solve this problem that is more attuned to the needs and habits of today's students. The courses of mechanical specialty mainly study mechanical parts, mechanisms, mechanical transmission and other related contents, which have the characteristics of many knowledge points, many concepts and difficulty in understanding [4-5]. However, students seldom have the opportunity to contact related equipment and parts during their school years, which brings certain difficulties to students' learning. Even if students search through the Internet, the existing teaching resources do not have many 3D solid models

related to textbooks, so students need to have a strong sense of space.

Augmented Reality (AR) register 3D information in a real environment [6-7]. It superimposes computer-generated virtual information into the real world so that virtual enhanced information and real scene information coexist, complement, and superimpose with each other, thus strengthening users' senses and cognition of reality [8]. With the development of mobile technology, the popularity of smart phones and tablet computers has provided a solid material foundation for the wide application of mobile AR technology in many fields, showing great potential in military, medical visualization, education, construction machinery, book design and so on [9-11]. Based on the teaching needs of mechanical discipline and the purpose of improving the current teaching methods, this paper designs a teaching assisted learning system based on mobile AR technology.

In order to explore the influence of mobile AR technology on mechanical teaching effect and to expand and supplement digital teaching means, in this study, an AR assisted teaching system is designed first, and a teaching experiment is designed around AR system, which is verified and analyzed from three aspects: software function, teaching effect and influence on teaching. The results of this study can be used as a reference for teaching researchers using augmented reality.

## II. LITERATURE REVIEW

### A. Augmented Reality

AR is developed from virtual reality [12]. It realizes the effective combination of the real world and computer-generated virtual objects. By superimposing the computer-generated virtual objects on the real scene in real time, users can feel the real and virtual scene information at the same time, so as to realize the combination of virtual and real. AR technology has been applied in many fields, such as aerospace, military, education, medical treatment, video games, manufacturing and so on.

AR technology has three main characteristics: it combines the real and the virtual, it interacts in real-time, and can be executed in three dimensions [13]. The core of AR technology is the rapid recognition and spatial positioning technology. At present, the mainstream AR recognition applications are

mainly Google's ARCore, Apple's ARKit and Qualcomm's Vuforia. The comparison of the three development engines is shown in Table I.

TABLE I. COMPARISON OF COMMON AR DEVELOPMENT ENGINES

Development engine	Functions	Operation platform
ARCore	Motion tracking, environment understanding, light perception	Android
ARKit	Multiple face tracking, motion capture, and real-time augmented reality	IOS
Vuforia	Image recognition based on natural feature points, extended tracking, model target	IOS & Android

Mobile AR is a branch of AR technology. Traditional AR systems mostly take wearable external devices as the carrier, which is difficult to carry and difficult to maintain. Due to the continuous development and update of mobile terminal devices, mobile terminals have powerful processors, high-definition cameras and convenient touch screen operation [14]. These functions provide a convenient platform for the development of AR systems for mobile devices. On the basis of inheriting the key technologies and core problems of traditional augmented display technology, mobile AR technology combines the portability and mobility of mobile devices, greatly promotes the development of mobile AR applications, and makes the application field broader and the interaction means more humanized.

### B. Augmented Reality in Education

This interactive means based on the real world and enhanced by virtual data provides a new teaching method for educators, which has a strong guiding significance for the abstract content teaching. Through AR technology, learners can enter an environment that is highly simulated with reality and dynamically learn in vision and interaction.

At present, the application of AR technology in the field of education is gradually expanding. Colleges and educational institutions are committed to promoting the deep integration of information technology with higher education and vocational education. AR technology will bring a positive impact on teaching content, models and learning methods [15].

AR technology can create an intelligent learning environment to adapt the educational content to students' personalized learning. To improve students' practical skills, based on emphasizing the theoretical knowledge in textbooks, AR technology is used to show the relevant knowledge in an information-based 3D way. Literature [16] research shows that adopting AR technology assisted teaching can improve students' learning efficiency and information understanding ability. Literature [17] uses AR technology in creative design courses to improve the learning motivation and creativity of students. Literature [18] developed an AR mobile application for engineering students, and the statistical data indicate that the application positively affects learning. An interactive teaching system based on mobile AR technology is designed and implemented, the case study shows that stimulate students' spatial imagination and learning interest [19]. [20-23] show that AR helps students improve their skills and knowledge in physics, biology, mathematics, art and architectural topics. A

large number of empirical studies show that augmented reality technology has great potential and application prospects in learning support and teaching.

### C. Advantages of using Augmented Reality in Education

1) *Rich interactive means to create mobile learning environment:* AR emphasizes the combination of virtual and real, superimposing virtual objects on the real world, which is a supplement to the real world. It allows users to see the real world. For some abstract cognitive knowledge, AR can transform it into specific situations. Different knowledge can shape different situations, so that students can obtain learning knowledge more directly.

Traditional teaching methods are generally divided into two links: classroom teaching and after-school practice. When students encounter difficulties, they often have to understand and digest them by themselves which is also difficult to solve problems in time. Moreover, AR can realize mobile learning and break the restrictions of teaching conditions. Even if not in class, students can immerse themselves in the learning situation again through mobile AR technology. It solves the blind area of understanding caused by the unclear expression of some teachers [24]. Through electronic devices and books, students can learn anytime and anywhere, realizing seamless and continuous mobile learning.

2) *Stimulate learning interest and reduce cognitive difficulty:* In many university basic courses, there are some knowledge that is difficult to describe in words. For example, engineering drawing of mechanical major and some courses of other majors that require students to carry out spatial imagination. For some students whose space imagination is not strong enough, this undoubtedly hinders their learning. For some students with strong space imagination, even if they can imagine most of them, some details are still unimaginable, which will make students feel frustrated without timely answers. AR technology can directly and vividly express the abstract things in three-dimensional form. Through the combination of virtual and real, it is more conducive to students' understanding and memory, improves students' autonomy and reduces the requirements for learners' cognitive transfer ability. This interactive way greatly improves students' learning participation, meets students' curiosity, and makes learning simple and natural.

3) *Deepen immersive learning and strengthen knowledge cognition:* In the classroom, teachers should reflect the application scene of knowledge as realistically as possible and be related to the social practice scene of human beings. Mobile AR technology organically combines virtual and real, which makes the cognitive scene closer to the effect carried out outdoors. Compared with traditional teaching resources, the biggest advantage of AR teaching is reflected in the constructed immersive learning environment [25-26]. The three-dimensional immersion teaching created by AR enhances learners' sense of experience, enables students to learn more quickly, further deepen their cognition of knowledge and achieve in-depth learning.

In the existing literature, some researchers have noted the limitations of AR in the field of education. Traditional AR systems are mostly based on wearable external devices, which are difficult to carry and maintain. Without a well-designed student interface and guidance, AR technology can be too complex to use. The various devices that provide AR applications can cause other technical problems. In this paper, mobile AR is used as the technical support to develop the teaching assistance system for engineering drawing courses. Mobile devices such as mobile phones and tablet computers are used to design and develop the teaching assistance system. Teachers can quickly deploy AR content, which is simple, stable and has high platform support.

### III. PROPOSED TEACHING ASSISTANT SYSTEM

#### A. Overall Design

The teaching assistant system based on mobile AR technology is mainly used to assist teaching. Its purpose is to strengthen students' imagination of 3D graphics and improve students' thinking conversion ability between 3D space and 2D plane. The system consists of three modules: information input module, fusion display module and information interaction module, as shown in Fig. 1.

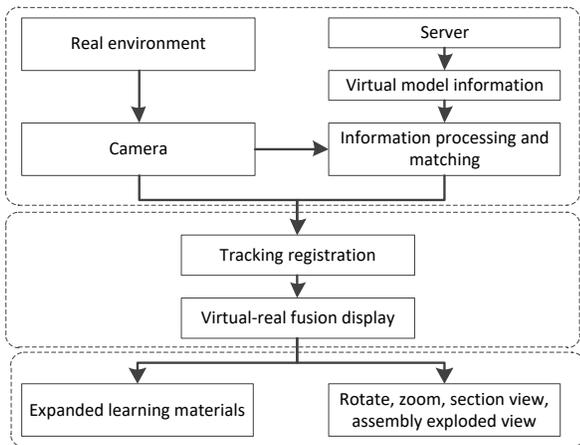

Fig. 1. Overall Design of the Proposed System.

The information input module collects the feature point information of engineering drawings in the real environment through the camera, then processes and matches them to obtain the virtual model information on the server side. The fusion display module tracks the real-world position of virtual model in real-time according to the matching and identified information from information input module, and performs superposition fusion display of real and virtual information. In the human-computer interaction module, the user interacts with the teaching assistant system through interface touch control and can perform operations such as rotation, zooming, section view of parts and explosion diagram display of assembly parts. At the same time, the user can view relevant parts introduction, network reference materials and other expanded information.

#### B. Development Environment

The system uses Unity3D as the development platform, builds 3D models through SolidWorks software, and uses AR technology to realize the interaction between touch instructions

and the 3D model nested in the screen through Vuforia AR Toolkit. The software running system is Android. The specific development platform and tools are shown in Table II.

TABLE II. DEVELOPMENT PLATFORM AND TOOLS

Tools	Functions
Unity3D	Rendering Interaction and Software Development Platform
Android NDK	Data Communication between Android and Unity3D
Vuforia SDK	Software Development Toolkit
XAMMP	Database
SolidWorks	3D modeling
Deep Exploration 6.3	3D model format conversion

#### C. Development Process

The implementation of the system mainly includes three steps: Creating a database; Objective management; Resource integration and publishing. The system implementation flow is shown in Fig. 2.

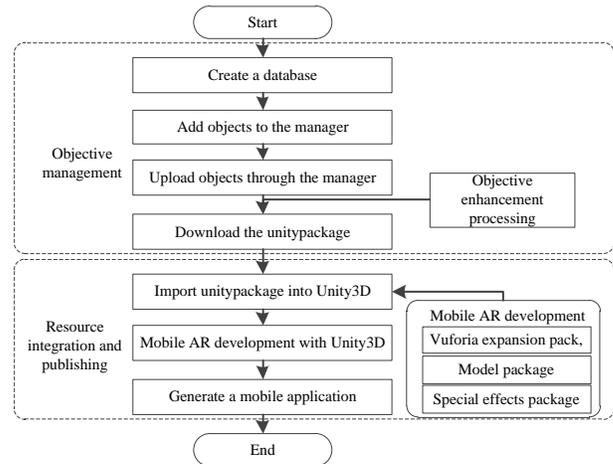

Fig. 2. System Implementation Flow.

- 1) Create a database.
- 2) Objective management. Create a 3D model, add and upload identification point data, model data, references and other data to the objective manager.
- 3) Target enhancement processing. Improve the recognition effect through data enhancement.
- 4) Setup of the development platform. Importing Vuforia AR Toolkit, model package and special effects package into Unity3D, and setting a series of initial values such as camera direction and lighting system.
- 5) Unity3D mobile AR development. Write Unity3D camera identification code and C# script for model controlled interaction.
- 6) Generate mobile application. The Unity3D project is exported as an Android project. The secondary development of mobile APP is carried out in Android Studio include complete the UI design, cache management module and communication module.

#### D. Implementation of Key System Functions

1) *Fusion display function:* The 3D modeling software SolidWorks is used to model the display parts. Because of the different recognition formats of each software, the SolidWorks 3D model is converted into .fbx file through DeepExploration software and imported into Unity3D software. Register on Vuforia website, create a cloud database and manage markers. In this system, pictures are used as markers, and the recognized objects of image target are set as 3D models of parts. The image implementation mechanism of Vuforia is completed by detecting the matching of natural feature points on the image. The feature point data of the picture or the image in the target manager is collected and then stored in the database. When the application runs, the feature points of the image are detected in real-time and the feature points of the picture stored in the data center are matched. After identifying the corresponding results, adjust the model size, position and light illumination with the predefined configuration, and then display them on the screen. The recognition effect of the display function is shown in Fig. 3.

2) *Rotate, zoom and section function:* The zoom is realized by the localScale() function. Firstly, the initial positions oPos1 and oPos2 of the fingers are recorded. When at least one finger moves on the screen, the real-time positions tPos1 and tPos2 of the fingers are checked. Finally, the model is enlarged or reduced by comparing the distance between the starting and ending positions where the fingers stay. The effect of model scaling is shown in Fig. 4, where the aperture represents the finger movement path.

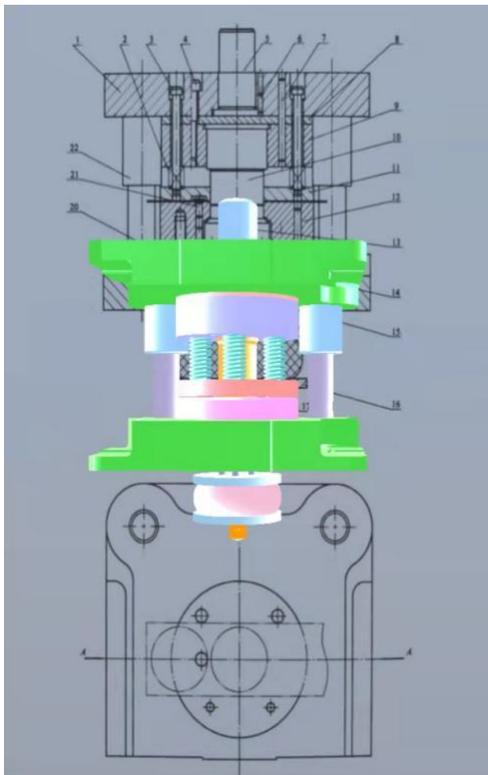

Fig. 3. The Recognition Effect of the Display Function.

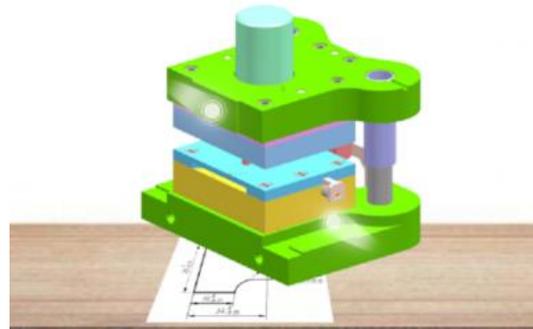

Fig. 4. Model Scaling Implementation Effect.

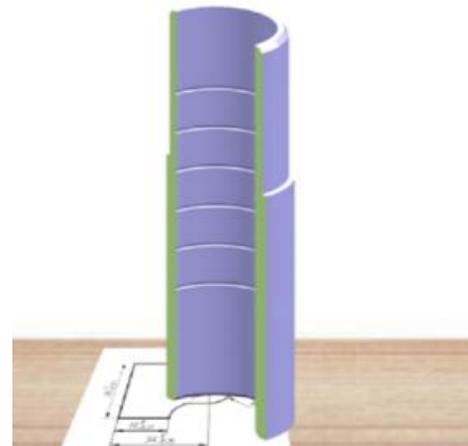

Fig. 5. Section View Effect.

Since section display cannot be directly carried out in Unity3D, it is necessary to set "true/false button assembly" to convert the overall model to the section model by establishing another parallel and independent section 3D model. The effect achieved in section view is shown in Fig. 5.

#### IV. EXPERIMENTAL DESIGN

In order to verify the influence of the AR teaching assistant system on the teaching effect of mechanical drawing course, 154 undergraduates from Henan Institute of technology were selected as research participants. According to the large class teaching, 154 students were divided into experimental class and control class. The control class adopts the traditional teaching mode. First, the students are required to preview the knowledge before class. During the teaching process, the teachers teach the knowledge through books and PPT, and answer the questions raised by the students. Smart phones are not allowed to be used in the course of class. The experimental class adopts the AR teaching assistant system to carry out teaching activities. The specific steps are knowledge Preview - Teacher Explanation - Deep Learning - Question Answering - Opinion Feedback. First of all, students preview around the knowledge points arranged by teachers in advance. When encountering unimaginable models, they can deepen their understanding with the help of AR teaching assistant system. Teachers use teaching strategies that match technology and content to teach. Then, students enter the deep learning link.

Through the four links of cognition, construction, transfer and Application, students can independently understand knowledge, and then solve problems, explain the problems that students haven't digested. Finally, students put forward the deficiencies in the teaching link, so as to promote better teaching improvement next time.

In order to better understand the effect of AR teaching assistant system in the process of mechanical drawing teaching, the teaching effect is analyzed by score analysis and questionnaire survey. At the end of the semester, the teaching effect is judged by analyzing the results of the two classes. Each student in the experimental class is required to fill in a questionnaire. From the two dimensions of learning cognition and product experience, the questionnaire sets up five aspects: exploratory learning, learning interest, User satisfaction, resources abundant degree and students' willingness to use. The questionnaire settings are shown in Table III.

TABLE III. CURRICULUM SATISFACTION QUESTIONNAIRE

Category	Questionnaire
Learning cognition	1. Using AR teaching assistant system in the classroom is more conducive to exploratory learning
	2. Using AR teaching assistant system can improve the interest in learning engineering drawing
User experience	3. The function of AR teaching assistant system meets the teaching requirements
	4. AR teaching assistant system is abundant in teaching resources
	5. I am willing to use AR teaching assistant system to assist learning

## V. EXPERIMENT AND RESULT ANALYSIS

### A. Practical Application of AR Teaching Assistant System

Through AR technology, image recognition and stereo presentation methods, this system displays stereo effects through 3D modeling, directly converts the plan into 3D objects, and enhances the interactivity in the learning process.

Taking the mechanical drawing course as an example, the application scenario of this system is introduced. Students scan the engineering drawings by opening the App on the mobile phone, and the 3D model of the displayed part is fused on the screen, as shown in Fig. 6. After the mobile phone screen is loaded with the 3D model, even if the camera is moved to other positions, the 3D model can still stay and be displayed, as shown in Fig. 7. On the mobile phone screen, students can rotate, zoom, and section model through gestures. Through 3D display from various angles, students can be helped to analyze and understand the correlation between 2D engineering drawings and 3D entities model, thus improving the learning effect.

In the process of classroom theoretical teaching, by setting specific identification pictures, the virtual 3D model is superimposed on the real teaching scene, and various parts and mechanisms are presented in front of students. Let the students observe the movement process of the 3D structure or principle of the mechanism from a close and all-around angle to deepen their understanding of the textbook knowledge.

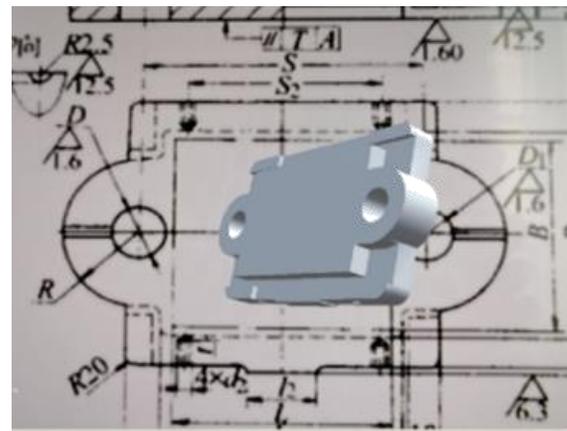

Fig. 6. Scan Drawings to Obtain 3D Models.

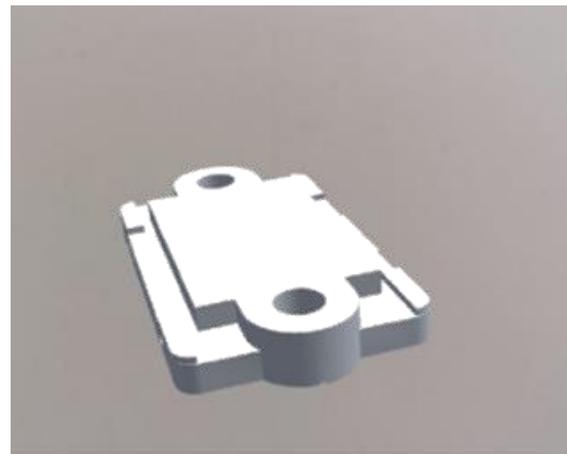

Fig. 7. Effect of Removing Background Drawing.

### B. Teaching Effectiveness Analysis

The teaching effect of mechanical drawing course in the spring semester of 2020-2021 school year is shown in Table IV. There are 78 people in the control class and 76 people in the experimental class. The control class adopts the traditional paper teaching mode, while the experimental class adopts the AR assisted teaching system. Comparing the final examination results of the two classes, the average score of the experimental class is 84.24, and the pass rate is 100%, which is better than that of the control class. The Standard deviation of the experimental class is 9.17, which is less than 15.31 of the control class, indicating that the distribution of students' score is more concentrated. Through the statistical analysis of teaching effect, it can be concluded that after using AR assisted teaching, the results of students in the experimental class are better than those in the control class. Through the questionnaire survey, we know the students' recognition of AR assisted teaching, and most students are satisfied. Most of the gains of students focus on the enhancement of autonomous learning ability, the deepening of classroom participation, the solid mastery of knowledge, the improvement of problem-solving ability and so on. From students' feedback, it can be found that students have high recognition of AR assisted teaching mode.

TABLE IV. TEACHING EFFECT OF AR ASSISTED TEACHING

Index Group	Fractional segment (Grade)					Average score	Pass rate	Standard deviation
	[100-90]	(90-80]	(80-70]	(70-60]	(60-0]			
Experimental Class (76 students)	27 35.5%	27 35.5%	16 35.5%	6 35.5%	0 0%	84.24	100%	9.17
Control Class (78 students)	5 6.4%	22 28.2%	25 32.1%	13 16.7%	13 16.7%	72.35	83.33%	15.31

TABLE V. DATA ANALYSIS OF CURRICULUM SATISFACTION QUESTIONNAIRE

Questionnaire Evaluation	Very satisfied	Generally satisfied	Dissatisfied	Very dissatisfied
1. Using AR teaching assistant system in the classroom is more conducive to exploratory learning	42	21	8	5
2. Using AR teaching assistant system can improve the interest in learning engineering drawing	40	24	10	2
3. The function of AR teaching assistant system meets the teaching requirements	44	24	7	1
4. AR teaching assistant system is abundant in teaching resources	34	25	13	4
5. I am willing to use AR teaching assistant system to assist learning	46	22	8	0

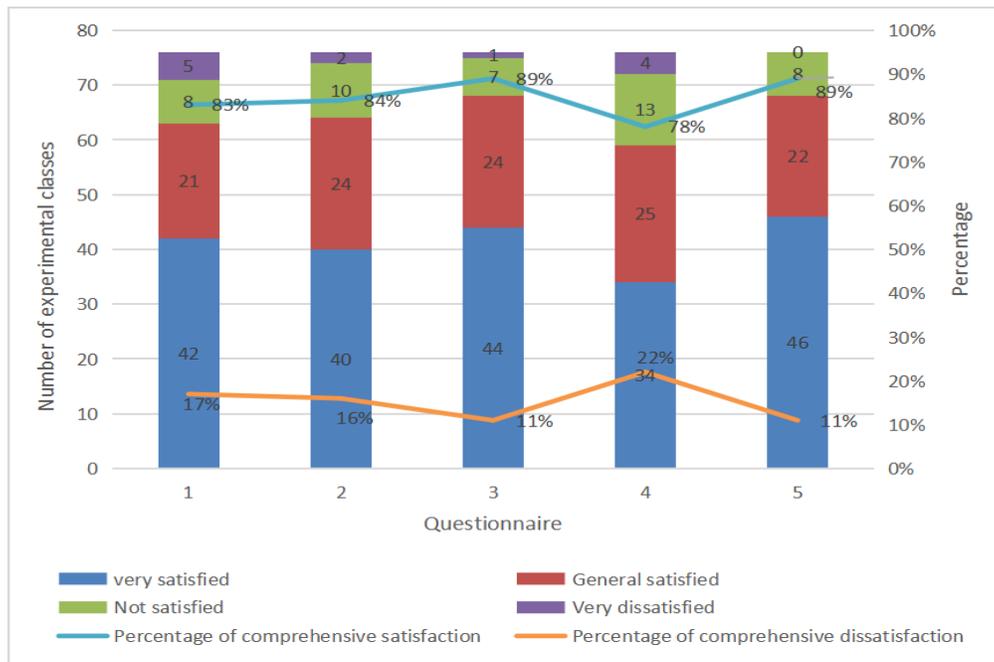

Fig. 8. Questionnaire Statistical Analysis Results.

After the examination, a questionnaire was distributed to the students in the experimental class. See Table III for questions 1-5 in the questionnaire. For the five questions in the questionnaire, students can choose four grades: very satisfied, generally satisfied, dissatisfied and very dissatisfied. A total of 76 questionnaires were distributed, and 76 were recovered, with a recovery rate of 100%. After inspection and verification, 76 valid questionnaires were found, with an effective rate of 100%. The statistical results of the questionnaire are shown in Table V. In terms of improving exploratory learning ability, 42 students expressed very satisfied and 21 students were generally satisfied, while only 8 and 5 students chose dissatisfied and very dissatisfied respectively. It shows that students agree that AR teaching assistant system can improve

their exploratory learning ability. Similarly, it has been highly evaluated in improving learning interest, satisfaction with the system and usability. However, the richness of software models is slightly lower. Some students believe that the models and resources in courseware and after-school exercises need to be further improved. For more intuitive data analysis, convert the table into a chart, add the very satisfied and generally satisfied people to calculate the comprehensive satisfaction percentage, add the dissatisfied and very dissatisfied people to obtain the comprehensive dissatisfaction percentage, and draw the questionnaire statistical analysis results chart as shown in Fig. 8. It is obvious from Fig. 8 that the AR teaching assistant system has been recognized by most of the students in the experimental class.

In the process of questionnaire survey, the author also interviewed the teachers. The instructor said that most students had not been exposed to AR before the experiment, but thanks to the popularity of smart electronic devices such as smart phones, students' information literacy was relatively high, so the installation and use of teaching assistance system were relatively smooth. By using the assistant learning system, students can understand knowledge more easily, their interest and confidence in learning have been improved, the frequency and efficiency of classroom teaching interaction have become higher, and the teaching quality has been significantly improved compared with the traditional teaching mode.

### C. Influence of AR on Engineering Drawing Teaching

Contemporary college students have many new characteristics. As a generation growing up in the digital environment, they can skillfully use electronic products and have a strong curiosity about new things. As a popular field in recent years, AR technology is introduced into teaching to create mobile learning environment and more opportunities for autonomous learning for students. It will also arouse students' interest, make students understand knowledge more easily and learn happily.

Integrating AR technology into some courses with higher learning difficulties will make students' learning easier and make the classroom more efficient. From another point of view, it will also reduce teachers' teaching pressure and make teachers easy to teach. The setting of every model and scene in augmented reality is carefully considered by teachers, which has certain demonstration, typicality and guidance. Students can study anytime and anywhere, reducing the disadvantages of being unable to concentrate on their study caused by external conditions. Compared with traditional learning methods, under the same time investment cost, students using AR technology assisted learning can immerse themselves in deep learning faster, so as to achieve better learning effect.

In the future, AR assisted instruction technology can be further extended to the process of experimental teaching. Due to the lack of experimental resources, colleges and universities have limited laboratory opening time, places and number of experiments which leads to the unsatisfactory effect of students' hands-on operation. Some mechanical equipment is expensive and dangerous, so it cannot be carried out in reality. Using AR technology can carry out some experiments that cannot be realized or dangerous in the real environment to solve this problem. AR technology is used to convert the required experimental equipment and instruments into digital models, import and create a virtual database, and realize virtual simulation experiment operation, which can provide students with a more flexible experimental environment and course arrangement while reducing consumables and maintenance costs. Moreover, through virtual operation, students can more accurately understand the experimental principle and content, and carry out design experiments to realize the differentiated cultivation of students, so as to implement the educational concept of "student-centered".

## VI. CONCLUSION

AR technology can realize the superposition and supplement of virtual enhancement information and real scene information, which provides a new way for the current mechanical course teaching and development. In view of the strong practicality of mechanical courses, the traditional teaching method is too simple, and it is difficult for students to establish stereoscopic impression. A mechanical course teaching assistant system based on mobile AR technology is designed and developed. Through the integration of AR technology and traditional paper teaching materials, the 3D visualization and interactive operation of parts and mechanisms in teaching materials are realized to achieve the purpose of diversity and efficient course teaching.

According to the experimental results and questionnaire analysis, the proposed system has a beneficial impact on students' learning effect and learning motivation. The academic performance of the experimental class is significantly higher than that of the control class. Because the AR based teaching method is more likely to improve students' attention and interest, the questionnaire results show that students are more satisfied with the AR teaching method and expect to have a more functional and perfect software system. The above results show that introducing AR technology into mechanical course can make up for students' lack of practical exercise. Through the combination of AR technology and mechanical course teaching, students can better understand and master the principle of mechanical structure, manufacturing and assembly process, use and operation, and promote the cognition of spatial relationships based on visualization. This teaching method can stimulate students' learning enthusiasm and improve innovative ability and engineering consciousness.

Information technology has a revolutionary influence on the development of education, has become a new wave of educational reform, and provides new ideas for the further development of teaching and learning. This paper is a practical exploration of the application of AR in the field of education. The mobile learning mode based on AR technology has the advantages of interactivity, mobility and sharing that traditional learning does not have. The auxiliary mobile learning platform based on AR technology still has a lot of development space. In the next step, it can be studied and developed in multi-disciplinary and interactive functions.

## ACKNOWLEDGMENT

This research was supported by Key Scientific and Technological Project of Henan Province (222102210189, 212102210324, 202102210286), Industry-university Cooperative Education Program of Ministry of Education, (202002029035), Key Scientific Research Projects of the Higher Education Institutions of Henan Province (22B460004), Educational Reform and Practice project of Henan Institute of Technology (2021-YB024) and Doctoral Fund of Henan Institute of Technology (KY1750).

**Abstract**—The increased volume of data due to advancements in the internet and relevant technology makes text classification of text documents a popular demand. Providing better representations of the feature vector by setting appropriate term weight values using supervised term weighting schemes improves classification performance in classifying text documents. A state-of-the-art term weighting scheme MONO with variants TF-MONO and SRTF-MONO improves text classification considering the values of non-occurrences. However, the MONO strategy suffers setbacks in weighting terms with non-uniformity values in its term's interclass distinguishing power. In this study, extended max-occurrence with normalized non-occurrence (EMONO) with variants TF-EMONO and SRTF-EMONO are proposed where EMO value is determined as MO interclass extensions as improvements to address its problematic weighting behavior of MONO as it neglected the utilization of the occurrence of the classes with short-distance document frequency in non-uniformity values. The proposed schemes' classification performance is compared with the MONO variants on the Reuters-21578 dataset with the KNN classifier. Chi-square-max was used to conduct experiments in different feature sizes using micro-F1 and macro-F1. The results of the experiments explicitly showed that the proposed EMONO outperforms the variants of MONO strategy in all feature sizes with an EMO parameter value of 2 sets number of classes in MO extension. However, the SRTF-EMONO showed better performance with Micro-F1 scores of 94.85% and 95.19% for smallest to largest feature size, respectively. Moreover, this study also emphasized the significance of interclass document frequency values in improving text classification aside from non-occurrence values in term weighting schemes.

**Keywords**—Extended MO; normalized NO; text classification; term weighting scheme

## I. INTRODUCTION

As the volume of data has dramatically increased in the digital environment due to rapid advances in the internet and developing technology, many researchers focus on the data organization, data retrieval, and data mining. One widely used technology mentioned above is text classification [1]. Text classification (TC) labels text documents with categories from predefined classes according to their content. Spam SMS and email filtering [2][3][4], author recognition [5][6], classification in clinical text and medical documents [7][8][9],

sentiment analysis [10][11], and short text classification[12] [13][14] are topics in research under the different subdomains category of TC in literature.

In TC, modeling in the feature vector space used Bag-Of-Words (BOW) [14], which extracts unique words representing the text document in the collection. The machine learning algorithm assigns documents to predefined classes. The VSM numerical feature vector represents each document with significant weights thru Term Weighting Scheme (TWS). TWS plays a vital role as it directly affects the classifying performance and simplifies the classifier's jobs. Three factors comprise the TWS for TC: term frequency factor (TFF), collection frequency factor (CFF), and length normalization factor (LNF). The TFF refers to the ratio of the number a term occurs [15][16][17], while the CFF [1] refers to the ratio of the information of the specific term to each document in a text collection. The LNF is used to normalize text collection containing different document lengths. TWS is categorized into two: supervised (STWS) and unsupervised (UTWS) Term Weighting Scheme [18][19]. STWS includes the class information in the weighting process, while UTWS ignores class information in setting weights to terms. Currently, STWS is preferred to use as it outperforms previous weighting strategies [20]. Its latest state-of-the-art is the SRTF-MONO, a variant of the MONO strategy [21] that added value to the non-occurrence of a term in stressing weights.

However, the MONO strategy suffers setbacks in weighting terms with non-uniformity of values in its class document frequency such as (1) a case of giving equal values to  $MONO_{Local}$  leads to equal  $MONO_{Global}$  weights containing different max-occurrence and non-occurrence; (2) the occurrences of interclass distinguishing power of a term proven in literature [22] [23] to give good term weighting ability leading successful classifying performance is neglected as it focused more class' document frequency for non-occurrence members.

The motivation of this study is to address the issue of MONO in its problematic weighting behavior to terms. In generating max-occurrence, the standard MONO formula neglects the utilization of the occurrence of the classes with short-distance document frequency in non-uniformity values.

These occurrences are the concentration of values representing the interclass distinguishing power essential in improving classification performance in STWS. The top classes with higher class occurrences could affect the belongingness of a document and should not be treated as non-occurrences. Thus, this study aims to enhance MONO by extending the max-occurrence group to cater to succeeding classes with higher document frequency values to set its real class distinguishing power of a term; and employing normalization to the non-occurrences to address the imbalanced distribution of the document frequency of classes.

The remaining parts of the paper are ordered as follows. The literature review that introduces several TWS and examines the state-of-the-art MONO strategy is presented in Section 2. The enhancement and required data, techniques, and evaluation are presented in Section 3. In Section 4, we present the results and discussion of the study. Finally, in Section 6, we conclude and recommend developing this study in text classification subdomains.

## II. LITERATURE REVIEW

### A. Schemes on Assigning Weights to Terms

First, Term Frequency – Inverse Document Frequency (TF-IDF), a TWS, topped the list in chronological order on research related to assigning weights to terms [24]. The IDF is one of the pioneering strategies in setting weights to terms adapted from the studies in the area of information retrieval used in text classification task proposed by Karen Spärck Jones, implied that the assigning of weights to terms should take place under the collection frequency factor (IDF) to utilize the terms effectively. This collection frequency factor is adapted to join with term frequency (TF). As an improvement in TWS for TC, Deisy et al. modified the IDF called MIDF and successfully outperformed Weighted IDF and TF-IDF [25]. The results revealed computation of MIDF is characteristically easier, and there was an improved TC performance compared with the other term weighting schemes. Sabbah et al. proposed several TWS as TF-IDF's modification (mTFmIDF, mTF, TFmIDF, and mTFIDF) which are developed with improved results than standard TF, TF-IDF, and Entropy. They also substantiated the importance of employing ELM, NB, SVM, and KNN classifiers with popular text corpora. In another study, Debole and Sebastiani proposed several term weighting strategies, namely TF-GR, TF-IG, and TF-CHI, based on feature selection methods named Gain Ratio, Information Gain, and Chi-Square [26]. The study commenced the idea of adding the class information in weighting to terms in TC, which was later called supervised term weighting schemes (STWS). The strategy improved the classifying performance compared to the previously mentioned and traditional TWS.

A novel collection frequency factor under the STWS category, introduced by Lan et al., namely TF-RF based on relevance frequency [27]. TF-RF focused terms in its terms' class distribution considering the positive and negative ratio. This new TWS showed an improved performance than Binary, TF, and TF-IDF (unsupervised TWS) and TF-IG, TF-CHI2, and TF-LogOR (supervised TWS). Another term weighting method derived from TF-RF, namely LogTFRFmax strategy

proposed by Xuan and Le Quang for TC [28]. They showed that TF-RF's classification accuracy could be increased by combining reduced TF values with RF. Liu et al. introduced a TWS intended for unbalanced text datasets, namely TF-PB [29]. TF-PB is derived using the term's interclass and intraclass distribution. They showed that classification accuracy could be increased by utilizing information on a term's inner-class distribution from unbalanced text datasets. Log-TFTRR introduced by Ko is derived from class distribution by using the negative and positive class probabilities of terms [30]. Log TF-TRR showed better performance than (TF-CHI, TF-RF) over the use collection of text data such as Korean UseNet, Reuters-21578, and 20-News groups.

A study called Positive Impact Factor (PIF) introduced by Emmanuel et al. showed better TC performance concerning computing time and classification accuracy upon experiments on Classic3 text collection [31]. Altınçay and Erenel investigated previously proposed and most-used TWS for TC [32]. They discovered that the ratios and term occurrence probabilities are the reasons for relative performance differences in giving weights to terms. A new collection frequency factor introduced by Altınçay and Erenel in another study derived from the logarithm of term frequencies [33]. They showed that the lesser term frequency values bore better classification performance combined with their proposed term weighting scheme. They also indicated that the distribution of TF in the collection of the text suggests the usable form of the TF factor.

Another related study, a proposed method by Cai et al. in tagging systems wherein it modeled the resource along with the user's profile, indicating the utilization of normalized form of term frequency [34]. Badawi and Altınçay introduced another study implemented for binary text classification using a termset weighting strategy [35]. They wanted to prove using the bag-of-words approach as an effective method. They showed that their process produces document vectors successful for TC. Later, they introduced new cardinality statistic-based TWS [36]. Two collection frequency factors integrated with Bag-of-Words (BOW) were used in this new term weighting strategy. They emphasized the success of text classification performances in setting weights to terms generated by the standard BOW approach can be increased with n-term setting its values to  $n = 2, 3, 4$ .

In another study, a term weighting scheme adapted from information of the term's document was introduced by Ren and Sohrab. [37]. They showed that TF-IDF-ICSDF outperforms five previous TWS (TF-CC, TF-IDF, TF-PB, TF-OR, and TF-RF) on 20 Newsgroups, RCV1-v2, and Reuters-21578 with Centroid, SVM, and NB classifiers. Escalante et al. used genetic programming to improve TWS [38]. They stated that genetic programming aims to acquire which combination of units makes greater discriminative TWS. They showed that genetic programming generated superior classification results than latest and popular strategy on assigning weight to terms. A new collection frequency factor for TWS introduced by Chen et al. named Inverse Gravity Moment (IGM) adapted from a statistical model [22]. IGM has two variants, namely TF-IGM and SRTF-IGM. They

stated that the adequate distinguishing power is taken from the information of the interclass distribution of the documents. They showed that IGM performed better classification than the 5 TWS (RF, CHI2, Prob, ICSDf, IDF) using KNN and SVM classification algorithm on the popular text corpora (20-Newsgroups, TanCorp, and Reuters-21578). Dogan et al. improved the IGM by reorganizing the IGM formula to address similar values given to different term weights [23]. The improvement in the IGM provides better classification results than the standard IGM. Sabbah et al. implemented a hybridized term weighting strategy for terrorism activity detection in texts [39] by creating a set of features from the combination of small feature subsets taken from TF, IDF, TF-IDF, Entropy, and Glasgow TWS. They also indicated that the successful text classification could be improved by utilizing small sets of features representing the most significant terms inside the text.

With all the previous and successfully introduced supervised TWS, the concept is always the involvement of the available class information. In contrast, another collection frequency factor STWS presented by Dogan et al., called max-occurrence and non-occurrence (MONO) [21], added the value of non-occurrence or the absence of a term in the distribution of terms in the documents on each class upon stressing weights. MONO comes with two variants, TF and SRTF (the squared root of TF). SRTF-MONO variant outperforms the classification performance of the previous STW using the news dataset.

#### B. Assigning Weight to Terms using MONO Strategy

The standard MONO term weighting scheme [21] according to Dogan et al:

1) Assume that the document frequency  $df$  of a term  $t_i$  or  $df_{t_i}$  from the  $j$  classes of a text collection is shown in (1). The  $df_{t_i}$  collection is sorted in descending order. The head of the left has the highest value, and the tail in the right has the lowest as shown in (2).

2) The sorted  $df_{t_i}$  is divided into two groups; one has the highest class  $df_{t_i}$  values and the other for the rest of the classes. Groups are categorized into two the max-occurrence (MO) ratio group and the non-occurrence (NO) ratio group as shown in (3).

3)  $MO_{t_i}$  value, corresponds the ratio between total document frequencies and the total number of documents available on the class with maximum occurring  $t_i$ . After calculating the  $MO_{t_i}$  value, the  $NO_{t_i}$  value is calculated as shown in (4).  $NO_{t_i}$  value is calculated on classes excluded from  $MO_{t_i}$  calculation. The value is computed from the ratio between the quantity of document frequencies and the total number of the documents of the class within the NO ratio group.

4) In order to obtain the  $MONO_{Local}$  weights of a term the MO and NO is multiplied as shown in (5).

5) Finally,  $MONO_{Global}$  weight of term  $t_i$  is calculated as shown in (6). In the aforementioned equation in (6),  $\alpha$  parameter is presented. The purpose of  $\alpha$  is to set balance to

weights to global values in the weighting stage where values ranges from 5.0 to 9.0 and 7.0 as its default.

6) The two TWS based upon  $MONO_{Global}$  collection frequency factor are shown in (7). The  $SRTF(t_i, d_k)$  is squared root of  $TF$  values of the term  $t_i$  in text document  $d_k$ .

$$df_{t_1} = \{d_{i1}, d_{i2}, d_{i3}, d_{i2}, \dots, d_{ij-1}, d_{ij}\} \quad (1)$$

$$sorted\_df_{t_1} = \{d_{i3}, d_{i1}, d_{i4}, \dots, d_{ij}, d_{ij-1}\} \quad (2)$$

$$sorted\_df_{t_i} = \begin{cases} C_{t_i-max} \\ \overline{d_{i3}} \\ eq \end{cases} | \overline{d_{i1}, d_{i4}, \dots, d_{ij}, d_{ij-1}} = \begin{cases} MO \\ \overline{d_{i3}} \\ eq \end{cases} | \overline{d_{i1}, d_{i4}, \dots, d_{ij}, d_{ij-1}} \quad (3)$$

$$MO_{t_i} = \frac{D_{t_{i1-max}}}{D_{total}(t_{i-max})} \quad NO_{t_i} = \frac{D_{\bar{t}_i}}{D_{total}(\bar{t}_i)} \quad (4)$$

$$MONO_{Local}(t_i) = \left[ \frac{MO_{t_i}}{D_{total}(t_{i-max})} \right] * \left[ \frac{NO_{t_i}}{D_{total}(\bar{t}_i)} \right] \quad (5)$$

$$MONO_{Global}(t_i) = [1 + \alpha * MONO_{Local}(t_i)] \quad (6)$$

$$TF - MONO = TF(t_i, d_k) * [MONO_{Global}(t_i)]$$

$$SRTF - MONO = SRTF(t_i, d_k) * [MONO_{Global}(t_i)] \quad (7)$$

#### C. Empirical Observations of Issues in MONO Local and Global Weights

This subsection illustrates empirical observations on weighting terms using standard MONO strategy.

Assume that there exist three terms ( $t_4, t_5, t_6$ ) where the frequencies of its documents in four classes are {100, 60, 0, 0}, {200, 40, 10, 10}, and {100, 55, 5, 0} respectively. Then, assume that the entire documents of each class are uneven, which are 200, 300, 400, and 500, respectively. The standard  $MONO_{Local}$  and  $MONO_{Global}$  produced similar values in this scenario.

Supervised TWS considers intraclass and interclass distinguishing essential factors in specifying weights to terms [40]. Intraclass within a specific class, while interclass in multiple classes. MO represents intra-class and NO as the interclass. However, the existing interclass is not utilized because NO neglects actual interclass existence values and obtains non-existence. Class information improves classification [27], such as TF-CHI [26] [41] considers the term's intraclass distribution. Moreover, the used of interclass [22][23] outperforms the previous TWS in classification performance. Terms ( $t_4-t_6$ ) using MONO ignore interclass occurrence as it selects one member of a MO group and the rest to NO group even to other classes containing higher class-document frequency. It failed to fully represent the distinguishing power of a term as it assigns equal scores, as shown in Table I in its weights.

TABLE I. RESULTS OF THE CASE SCENARIO

Terms	Document Frequencies	No. of documents in every class	MO	NO	MONO Local	MONO Global
$t_4$	(100, 60, 0, 0)	(200, 300, 400, 500)	0.5	0.95	0.475	4.325
$t_5$	(100, 40, 10, 10)	(200, 300, 400, 500)	0.5	0.95	0.475	4.325
$t_6$	(100, 55, 5, 0)	(200, 300, 400, 500)	0.5	0.95	0.475	4.325

### III. METHODOLOGY

The enhancement of MONO strategy is categorized into two major processes. The extended max-occurrence and non-occurrence normalization is shown in Fig. 1.

MO computation selects only a single class with the highest document frequency values, previously shown in (3). In the modification, extended max-occurrence (EMO) is proposed to cater to interclass occurrence values essential for supervised term weighting schemes. EMO refers to the number of class members of the MO group comprising the ratio of the number of documents in a class where the term mostly occurs and its total number of documents in that class. In the  $j$  classes in (1), assume that  $EMO = 2$  where  $1 < EMO < d_{ij-1}$  then MO group covers  $d_{i3}$  and  $d_{i1}$  representing

$$NO_{t_{i1}} = \frac{NO_{t_{i1}}}{D_{total}(t_{i1})} * 100 \quad NO_{t_{i2}} = \frac{NO_{t_{i2}}}{D_{total}(t_{i2})} * 100$$

$$EMONO_{Local}(t_i) = EMO_{t_i} * Normalized\_NO_{t_i}$$

$$TF - EMONO = TF(t_i, d_k) * [EMONO_{Global}(t_i)]$$

ratios as shown in (8),  $EMO_{t_i}$  calculates the new value of the weight of a term as shown in (9). In non-occurrence normalization, the original NO formula in (4) is modified. As the EMO is extended, NO members are reduced. With  $EMO = 2$  then each NO member is individually calculated in percentage and normalized as shown in (10). The rest of the formulas for assigning weight to a term using the EMONO is shown in (11) for local weights and (12) for global weights on different variants.

$$sorted\_df_{t_i} = \left\{ \overbrace{d_{i3}, d_{i1}}^{MO} \mid \overbrace{d_{i4}, d_{i5}, \dots, d_{ij}, d_{ij-1}}^{NO} \right\} \quad (8)$$

$$EMO_{t_i} = \frac{MO_{t_{i1}} + MO_{t_{i2}}}{D_{total}(MO_{t_{i1}} + MO_{t_{i2}})} \quad (9)$$

$$Normalized\_NO_{t_i} = \frac{NO_{t_{i1}} + NO_{t_{i2}}}{200} \quad (10)$$

$$EMONO_{Global}(t_i) = [1 + \alpha * EMONO_{Local}(t_i)] \quad (11)$$

$$SRTF - EMONO = SRTF(t_i, d_k) * [EMONO_{Global}(t_i)] \quad (12)$$

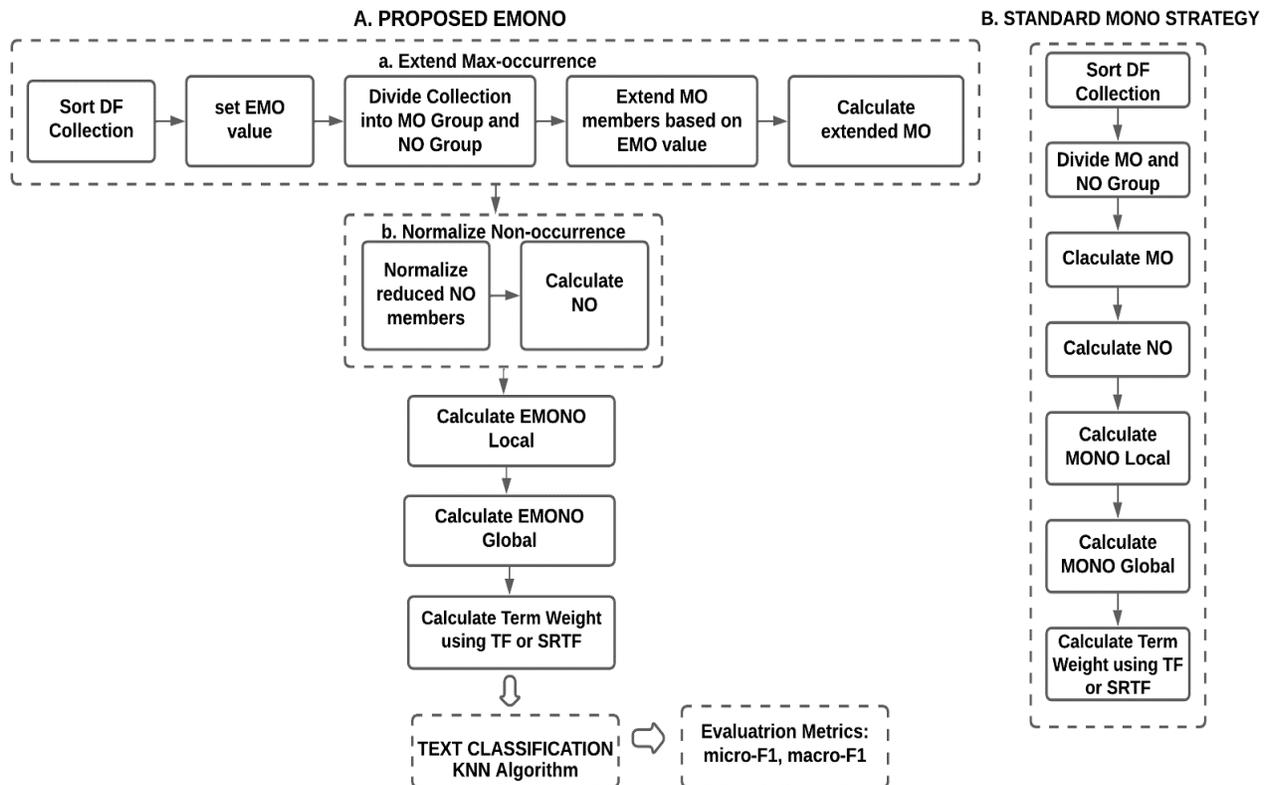

Fig. 1. Framework of the Study.

A. Dataset

Reuters-21578 is the benchmark dataset utilized in this study. It is one of the most popular unbalanced datasets preferred for text classification. Training and testing of data are taken from the Reuters-ModApte split, which is its segmentation for the experiments' training and testing. Due to removing the multi-labeled from the reading text in this dataset, the texts 'wheat' and 'corn' classes are emptied. There are a total of 7,215 documents with eight categories: earn (3735), acq (2124), money-fx (354), grain (45), crude (259), trade (332), interest (211), and ship (155).

B. Pre-Processing

In preparing the dataset, the following are the preprocessing methods [21] applied to the documents: conversion to lowercases, removing stop-words, alphabetic tokenization, Porter Stemming [42], and eliminating of seldom occurring terms (retain words occur more than one time).

C. Feature Selection

A feature selection method is preferred to manifest the proposed improvements' performance in a text classification dealing with high dimensionality. A standard statistical metric named chi-square max is used to obtain a selected number of features for this experiment. The total number for observations is 7,215 and the highest feature extracted is 9,237. The term weighting schemes are tested with top terms sorted in descending order and scored using the employed feature selection method {1000, 2000, 3000, 4000, 5000, 6000, 7000, 8000, 9000, and 9237} terms scored and sorted.

D. Learning Algorithm

The well-known and most used classification algorithm K-Nearest Neighbor (KNN) is employed in this study to classify documents from the benchmark Reuters-21578 dataset. Aside from its simplicity, it is generally utilized for performing text classification in literature [43][44].

E. Performance Evaluation

The text classification performance of this study was evaluated using micro-F1 and macro-F1 scores. Precision and Recall in (13) used to derived F1 scores preferred to use for uneven distribution of documents in the classes of multiclass text classification as shown in (14).

$$Precision_{c_k} = \frac{TP_{c_k}}{TP_{c_k} + FP_{c_k}} \quad Recall_{c_k} = \frac{TP_{c_k}}{TP_{c_k} + FN_{c_k}}$$

$$F1_{c_k} = \frac{2 * Precision_{c_k} * Recall_{c_k}}{Precision_{c_k} + Recall_{c_k}} \quad (13)$$

$$Micro - F1 = \frac{2 * \sum_k^c TP_{c_k}}{2 * \sum_k^c TP_{c_k} + \sum_k^c FP_{c_k} + \sum_k^c FN_{c_k}}$$

$$Macro - F1 = \frac{1}{c} \sum_{k=1}^c F1_{c_k} \quad (14)$$

IV. RESULT AND DISCUSSION

The results of the performance of the MONO and the proposed modification were analyzed in this section, along with the use of the classification algorithm KNN on Reuters-21578 corpus with all alpha values set to 6.0. The boldface values correspond to the highest F1 values in each micro and macro score. Table II shows the new local, and global weights generated using the proposed EMONO on case scenario with problematic weights mentioned in Table II.

Table III shows the classification performance of the proposed EMONO combined with term frequency on 1,000 and 9237 feature sizes. As EMO value implies the number of classes in MO extension, in 1000 features, EMO values 2, 3, and 4 have 0.927815207 as the highest scores for micro-F1, and only in the EMO value of 2 has 0.880240879 as the highest value for macro-F1. The proposed EMONO combined with the squared root of TF's EMO value of 2 has the highest obtained scores for micro-F1 and macro F1 with 0.948508181 and 0.893171284, respectively. In TF-EMONO 9237 features, the EMO value of 3 got the maximum micro-F1 score of 0.918671800 as the highest score, and the EMO value of 2 has 0.860379651 as the highest value for macro-F1. On the other hand, the classification performance of the proposed EMONO combined with the squared root of term frequency EMO value of 4 has the highest obtained scores of 0.957170356 and 0.909860837 micro-F1 to macro-F1, respectively.

The comparative results of the classification performance of the original MONO and proposed EMONO combined with TF and squared root of TF with 2 as the successful EMO value is shown in Table IV. The table shows that EMONO combined with both TF and SRTF have greater values than the original MONO strategy in micro-F1 and macro-F1. It is explicit that the proposed EMONO generally outperformed the original MONO strategy in all indicated feature sizes shown in the table.

Fig. 2 shows the classification performance of micro-F1 and macro-F1 in plot graph. The overall performance of the proposed EMONO is superior when combined with TF and squared root of TF explicitly shown in the plot graph.

TABLE II. EMONO WEIGHTS ON ISSUES IN LOCAL AND GLOBAL WEIGHTS

Terms	Document Frequencies	No. of documents in every class	Extended MO	Normalized NO	EMONO Local	EMONO Global
t <sub>4</sub>	(100, 60, 0, 0)	(200, 300, 400, 500)	0.32	1	0.32	3.24
t <sub>5</sub>	(100, 40, 10, 10)	(200, 300, 400, 500)	0.28	0.9775	0.2737	2.9159
t <sub>6</sub>	(100, 55, 5, 0)	(200, 300, 400, 500)	0.31	0.99375	0.3080625	3.1564375

## V. CONCLUSION AND RECOMMENDATION

In this study, behavior on how the original MONO strategy assigned a weight to terms was comprehensively analyzed. Two new variants of the EMONO, namely TF-EMONO and SRTF-EMONO, are proposed. The MONO modifications employed in the study are the EMO parameter's utilization and the normalization of the non-occurrences. EMO parameter sets classes to cover in generating max-occurrence extension, and the normalization is utilized for class imbalance. The results of the experiments explicitly showed that the proposed improvement outperforms the variants of the original MONO strategy in all feature sizes with an EMO parameter value of 2

sets number of classes in MO extension. Even though there are feature sizes in which EMONO has a slight increase of micro-F1 and macro-F1, the increase is consistent and gradual in all features with a selected EMO value. However, the SRTF-EMONO showed better performance with Micro-F1 scores of 94.85% and 95.19% for smallest to largest feature size. It can be stated that the proposed EMONO term weighting scheme is superior in classification performance to the original MONO strategy. It is recommended that the proposed EMONO be implemented in text classification. It is also suggested to utilize it in other text classification subdomains.

**Abstract**—The implication of the Covid-19 global pandemic is driving the transition of SMEs' business towards digitalization. However, despite the use of the digital platform, many SMEs are unable to survive. Therefore, this study included a focus on Decision Support System (DSS)-based dashboard model as a new feature in assessing SMEs' digitalization readiness. The twenty-four criteria appraisals are regarded in this sense as two views of business and Information Technology (IT) dimensions which include the Fuzzy-Analytical Hierarchy Process Method (F-AHP) for the weighting measurement and Objective Matrix (OMAX) for the performance mapping analysis, and both are embedded in the Business Intelligent (BI) dashboard development. In Riau Province, Indonesia, a total of 118 SMEs were interested in this study and fact thus revealed the general performance of SMEs as rated at an "Average" level of index value 4.95 with comprehensive parameters for index contribution viz., 3.79, 3.84, 7.75, 4.68, 4.32, and 5.43 for Business Activity (BA), Transaction (TC), Marketing (MC), Management (MG), Micro Environment (MI) and Macro Environment (MA) respectively. Furthermore, the dashboard prepares a tracking and analysis system with the graphical diagram extracted from each criteria hierarchy's root cause to sub-criteria. The DSS dashboard's information and knowledge have been developed into a promotional framework for stakeholders relevant to a digital business's success and sustainability performance initiatives.

**Keywords**—Decision support system; digital readiness; fuzzy analytical hierarchy process; business intelligent dashboard; objective matrix

## I. INTRODUCTION

Indonesia and other developing countries provide a historical and significant scale investment of SMEs that

influenced the country's economy, both in numbers of companies, the gross value-added, and the absorption of employees. The transformation of the manufacturing industry in the digital age has led to the development of SMEs that are leading the way in integrating creative technology utilization and digital platforms for product marketing, business transactions, as well as a wide range of quality investment services from top to bottom business [1]. Furthermore, the leverage of the digital business model of performance in SMEs has been seen to have the effect of enhancing overall cross-industry equipment, lowering inventory, workers' productivity, reducing logistical costs, boosting productivity, reducing production times, and rising sales, and cutting costs [2]. The Ministry of Co-operatives, Small and Medium-sized Enterprises, and the Ministry of Communication, Information Technology, and e-commerce actors launched a program entitled Eight million SMEs Go Online, aiming to foster this digital transformation by creating social and community awareness [3]. Here, several marketplaces and e-commerce sites in Indonesia, such as Lazada, Shopee, MatahariMall.com, BliBli.com, Bukalapak, Tokopedia, and Blanja.com, the founders of successful online companies, are comprised in this program. However, due to the lack of engagement and interest from SMEs and the suffering for the very principle of information exchange by active leaders, the program did not live up to expectations, and therefore, the digital revolution struggles to work.

Previous studies indicated that SMEs' common obstacles and demand in the revolution stage include human resources and capitalization, competition, marketing strategy, innovation, government actions, preparedness for the state, market demand

potential, innovation and creativity, exports, companies' resistance, and survival, knowledge of local business, women empowerment, internet and digitalization, currency conversion, manufacturing, trade, and infrastructure [4]. Despite the negative impacts on SMEs' growth globally, especially in Indonesia, it still offers attractive prospects. Furthermore, the Covid-19 virus outbreak has devastated countries' economies and has forced the digital revolution to accelerate fully. The number of SMEs influenced by this has attempted to make flexible and digitalize their market growth model to survive. However, digitalization's success requires full reinforcement from external and internal parties due to the high risk of investment. Peillon and Dubruc (2019) have identified various stumbling blocks to SMEs' digitalization, including technological hurdles to the accessible entrance of technology and artificial intelligence in promoting the quality and delivery of their business practices and services [5]. Besides this, technological capital and infrastructure adoption are difficult to enforce due to a lack of fund.

Furthermore, it affects essential changes in operational areas such as core business practices, commodities, procedures, organizational structures, managerial concepts, emerging capabilities and skills in management innovation, cultural shock, and analysis of company performance [5] and [6]. More importantly, customers revisiting and stored information becomes a huge burden to reach due to their protection and privacy breaches [7]. In a nutshell, this failure detection encourages further analysis of SMEs' readiness towards the digital business's success and sustenance.

Therefore, this study aims at analyzing SMEs' readiness in the vicinity of digitalization by incorporating ideas and perspective from governments, investors, the marketplace, and SMEs industries through the opportunities for creating a model-driven DSS dashboard. The application of F-AHP and OMAX enriched the DSS dashboard analysis as an information tracking system to assess the degree and parameters of the performance index. Furthermore, this intelligent business tool struggles with the new situation in Indonesia with current challenges and digital transformation issues in the future. The increasing sense of complexity and confusion in decision-making encourages the need for a forecasting process to assist decision-making, planning, analysis, and evaluation. Since model-driven DSS comprises mathematical simulation, the parameters are manipulated and optimized by investigating product analysis's sensitivity to assist in decision making [8]. This dashboard offers a wide range of digital readiness assessment options, thus providing a service as a new performance measurement tool.

## II. LITERATURE REVIEW

Understanding this performance measurement dashboard provides the contribution into the ultimate digital solution as well as market plan, business model, and technology penetration. Many researchers viewed and developed e-readiness tools and approaches from different viewpoints, environments, experiences, people, and objectives [9], and unfortunately, the gap between the concept and performance of e-readiness is inevitable [10]. For example, Beacon [11] and Verdict [12] are unable to guide the organization into

recovering and identifying the priority concerns for success, and currently, the General Practitioner Information System (GPIS) and New IT/IS Capability Evaluation (NICE) mechanism are missing out on the involvement of stakeholders rather than recruiting technology consultants for a thorough market review [13]. The Building Information Modeling (BIM) Maturity Matrix is a restrictive tool applicable only to its organizational context and hard to customize. Furthermore, Technology Readiness Levels as company maturity index tool deteriorates in meeting the demands of SMEs sector, and simultaneously, Lou et al. (2019) released an e-readiness construction (ERiC) framework as a promising sustainable instrument for assessing the extent of organizational precaution to shield and bring about a competitive digital economy. Like the previous one, the ERiC framework is explicitly deployed for the United Kingdom Construction Industry (CI) and case studies [14].

Meanwhile, the deployment of performance measurement tool in environmental quality assessment management is undergoing a significant transformation with the model-driven DSS, including Charkha and Jaju (2020) with the establishment of an Analytical Hierarchical Process (AHP)-DSS for determining the performance of the supply chain in the textile industry [15]. Govindan et al. (2020) created a practical decision support system based on physicians' knowledge and expertise complemented by a fuzzy inference system to control the supply chain demand [16].

Preliminary studies on SMEs such as Doltsinis et al. (2020) have been attempting to introduce additional information on the TOPSIS-DSS to repurpose manufacturing systems products [17]. A DSS-based fuzzy credit risk evaluation is recently carried out by Chang et al. (2020) using a logistic regression classifier [18]. Furthermore, the finding revealed no consideration of SME e-readiness with the growth of DSS above. There is a limitation in the DSS approaches that encourage a wide variety of crises to benefit from this paradigm's flexible solutions. In addition, Pandey et al. (2020) reviewed a range of challenges in adopting the DSS tool, including the organizations unable to set appropriate metrics to measure market impact, insufficient information about SMEs context measurement, and lack of oversight accountability executive management [19].

Furthermore, it is crucial to create a comprehensive performance as well as an appropriate metrics system as a framework to support the next generation decision concerning critical organizational goals in the e-readiness of the SME industry. A DSS should have an in-depth research identity of the analytical attribute such as a business intelligence dashboard model to simplify the operational phase of DSS and human cognitive capacities by incorporating graphical user interfaces to attract management engagement. A dashboard feature leads to higher task performance, reduces situation awareness, and nourishing a potential out-of-the-loop problem. In a nutshell, its adoption in this study offers the management decision-makers interactive analytical knowledge and will indeed be able to actively recognize the vulnerabilities SMEs face towards effective and sustained digitalization. In addition, the involvement of multi stakeholders' perspectives on digital DSS evaluation provides them with monitoring and

surveillance platforms to ensure SME e-readiness achievement and successful acquirement.

### III. METHODOLOGY

This study is developed by describing diversity as an instrument that examines SMEs’ digital readiness through documentary research and interviews. Here, scholars asked four academicians from the reference sectors of economics and technology in both domains for their views on proposed digital preparation tools. Government officials and key actors represent the views of true collaborative partners in the creation of SME e-readiness including the Ministry of cooperatives and, SMEs, the Ministry of Communication and Information Technology in the central region of Java, Riau, investors from a telecommunication company, and central banks, marketplaces (Tokopedia and blanja.com), conventional and digital SMEs companies leading the process of ideas for establishing requirements. An unbiased online interview addresses concerns and issues related to digital adoption, Covid-19 results, SMEs’ e-readiness, and factors affecting digitalization as well. For this reason, the suggested digital readiness evaluation criteria are summarized in Table I.

Next, the topography and technology practice against economic views has developed a conceptual framework that encompasses BA-IT Culture, Education, Financial Resources, and BA-IT Infrastructure for BA construction. TC is enrolled in TC-IT Culture, Education, Financial Resources, and TC-IT Infrastructure. MC-IT Culture, Education, Financial Resources, and MC-IT Infrastructure for MC. MG-IT Culture, Education, Financial Resources, and MG-IT Infrastructure for MG. MI-IT Culture, Education, Financial Resources, and MI-IT Infrastructure for MI. Finally, the ME is reviewed from ME-IT Culture, Education, Financial Resources, and ME-IT Infrastructure. This proposed framework grows into a foundation for designing the instruments. In this sense, two sorts of questionnaires are delivered to capture the respondents’ information and knowledge concerning SMEs’ evaluation. The first review is meant for decision-makers to assign the priority to each criterion and sub-criteria. The questionnaire fits the fuzzy AHP format of a one to nine scale, one just as equally important, three for moderately important, five for strongly important, seven for very strongly important, and nine for extremely important [25]. A panel discussion invited a community of decision-makers from four academies, five government officials, two managers of the central bank and marketplace, three investors, and three representatives from both digital and traditional SMEs to eliminate the language barriers and intervention in interpreting the questionnaires and thus, the weight of the criterion is defined.

Meanwhile, the second review has been conducted as a digital readiness assessment tool, and the questionnaire investigates the level of consensus amongst SME players on the nature of their SMEs’ criteria and sub-criteria. As key players in SMEs business, the respondents are constrained to owner, service, management, operation, marketing, and production team. In this regard, 24 questions with five Linkert-scale were submitted to 118 SMEs in Riau Province and limited to SMEs food companies. The companies were considered as one of Indonesia’s government focuses on

creative business development, and they have a low significant impact on the spread of Covid-19 in Indonesia SMEs. Thus, it tends to increase the demand due to panic buying and social distance restrictions.

TABLE I. SMEs E-READINESS CRITERIA

Economic Perceives		
No.	Criteria	Reference
1	Business activities (BA) - BA is highlighted by production, distribution, and consumer protection activities.	[2] [20]
2	Transaction (TC) is spelled out as market practices on automated data collection and distribution of innovative manufacturing systems and resources from the text, sounds, and visual images.	[21] [22]
3	Marketing (MC) is reflected as ideas, products, services, technology, and refining ideas to fulfill the market demand, to determine and satisfy the needs and target market aspirations.	[23] [24]
4	Management (MG) is the motivation of SMEs to plan, govern, organize, control, maintain, and sustain the business.	[18]
5	Micro Environment (MI) is defined as internal factors that directly or do not affect the digital readiness of an SME, such as the stakeholder perceptions, marketing systems, productivity, management, operational functions, technology adoption, the market demands, policy/strategy/vision, pricing, and licensing.	[18] [2]
6	Macro Environment (ME) is characterized as external influencing factors of SMEs, viz. demographic, economic, technology, environmental, political, government support, cultural, and a broader competitor landscape.	[11] [12]
Technological Perceives		
1	IT-Culture is defined as social culture, awareness, knowledge, creativity, attitude, and behavior to emotionally adapt to digitalization, satisfaction, trust, and confidence.	[11][14] [8]
2	IT-Education is specified as the readiness to cultivate hard and soft skills for digital technology adoption, knowledge sharing capability, creativity, and innovation.	[11][14] [8]
3	IT-Financial Resources is set up as SMEs’ financial asset readiness in terms of loans or capital assistance, grants, and resources supported programs through training, seminars, and exhibitions.	[5]
4	IT-Infrastructure is characterized as SMEs’ readiness concerning the IT infrastructure, hardware, and software to bolster digitalization, time access, and its utilization.	[6]

Furthermore, Covid-19 offers SME food companies a chance to expand through digital transformation and adoption to lower social business interaction. The DSS dashboard system is then applied as a business intelligent model-driven DSS to automate this study's mechanism, starting with acquiring expert knowledge and team research and ending with a comprehensive review of the e-readiness assessment in survey two. Adopting a hybrid F-AHP and OMAX approach enhanced this DSS dashboard's capability as an intelligent decision-making tool for SMEs' e-readiness testing. The application is developed using Hypertext Preprocessor (PHP) and PHPMyAdmin for programming languages and MySQL databases. Blackbox and User Acceptance Testing (UAT) are designed to monitor end-users performance and compliance alongside application development.

#### A. F-AHP

One of the tests performed on the model-driven DSS is multi-criteria decision making (MCDM), and it has used careful analysis of decision-making processes such as AHP, Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS), Weighted Product (WP), Simple Additive Weighting (SAW), Multi-objective optimization based on ratio analysis (MOORA). Among the above approaches, AHP is one of the most widely encountered performance tests of model-driven DSS as a single or hybrid AHP. It is a robust and practical scientific procedure that minimizes terrible decision-making [26].

Furthermore, it optimally advances the amount and contribution of what-if scenarios and their granularity to the consistency of proposed alternatives [27]. In other words, it provides a powerful cascading multi-criteria decision-making tool for aggregate and objective purposes. Tariq et al. (2020) studied its capability to render the classification of unbiased and confidential parameters and aggregate the specified versatility by relative calculation [28], while Okfalisa et al. (2018) and Okfalisa et al. (2021) successfully gave its application approach to encourage and track the organization's output through the set priority values for Key Performance Indicators (KPIs) [29 and 30]. AHP attempts the preferences more than one of the amazing series selected from one to nine range for scaling based on the perceptions made by the decision-makers [31].

Nonetheless, decision-making practices and rational thinking are hard to pinpoint into a constraint scale and produce victory over language problems in translating the decisions. Furthermore, the persistent matrices for criteria don't launch completely, and information disaster occurs when good and bad scores compensate [32]. In addition, the number of criteria and alternatives used in the measurement also affects the AHP's difficulties.

In a nutshell, the F-AHP emerges as a revolutionary approach in facing the disadvantages of AHP by emphasizing the decision-making uncertainty, the fuzziness of human reasoning style, and linguistics terms issues [33]. Furthermore, it's triangular fuzzy is sufficient in altering the algebraic language of decision-makers to the level of significance of criteria [34 and 20]. It is chosen as an intuitive model since this study captures the respondents' knowledge through natural

language, to deploy the weighting criteria and alternatives for digital readiness assessment. It also offers a reasonably stable mechanism to reduce the problems defined by the weighting factors. Its integration with OMAX develops into a new task and progress in this study to increase the revelation of F-AHP for digital readiness analysis. Subsequent studies have tried to link MADM, such as AHP, with OMAX [29 and 21]. However, it is not currently able to discover F-AHP convergence for OMAX. This assimilation of fuzzy logic and OMAX appears as a new contingency in performance measurement analysis.

The employment of Dashboard DSS-based F-AHP in this study follows the formula below [30].

- It follows the AHP modeling method to determine the comparison matrix and calculate the consistent values ( $CR \leq 0.1$ ) of the criteria and sub-criteria parameters.
- It then converts the AHP comparison matrix's value into the F-AHP value with the Triangular Fuzzy Number (TFN) scale. TFN is a trapezoidal fuzzy number that is widespread in F-AHP studies. It provides a linear mathematical formula to measure the criteria and alternatives with fuzzy triangular numbers that are denoted in simple parameters.
- To calculate Fuzzy Synthesis's value ( $S_i$ ) where  $M$  is defined as TFN number,  $m$  for the numbers of criteria,  $i$  and  $j$  as row and column of the matrix, and  $p$  as the value of variables defined in  $l$ ,  $m$ , and  $u$  values.

$$S_i = -1 \sum_{j=1}^m M_{gi}^j x [\sum_{i=1}^n \sum_{j=1}^m M_{gi}^j] \quad (1)$$

- To determine the vector value ( $V$ ),  $M_2 = (l_2, m_2, u_2) \geq M_1 = (l_1, m_1, u_1)$  are defined as a vector value.

$$V(M_2 \geq M_1) = \sup [\min (\pi M_1 (x)), \min (\pi M_2 (y))] \quad (2)$$

$$V(M_2 \geq M_1) = \begin{cases} 1 & \text{if } m_2 \geq m_1 \\ 0 & \text{if } l_1 \geq u_2 \\ \frac{l_1 - u_2}{(m_2 - u_2) - (m_1 - l_1)} & \end{cases} \quad (3)$$

- To calculate De-fuzzification Ordinary Value ( $d'$ ).

For  $k = 1, 2, n; k \neq I$ , we obtain the vector weight value:

$$W' = (d'(A_1), d'(A_2), \dots, d'(A_n)) T \quad (4)$$

- To multiple the normalization value of fuzzy vector weights ( $W$ ) by the following formula.

$$Sd(A_n) = \frac{d'}{\sum_{i=1}^n d(A_n)} \quad (5)$$

$$W = (d(A_1), d(A_2), \dots, d(A_n)) T \quad (6)$$

- Where  $W$  is a non-fuzzy number.
- It is ending with the calculation of the final weight of recommendation.

#### B. OMAX (Scoring)

OMAX is a device scoring tool based on the default KPI outcomes by keeping the matrix in a single measure, and it

allows the data interpretation to be relatively simple, easy to understand, flexible, and supports the units' normalization from different measurement specifications. A test system with OMAX balances each indicator's value scale and, as a result, each parameter's similar objective level is accomplished and compared to determine its position [21]. The previous studies observed on OMAX, including Paduloh and Hardi (2020) that measured the company productivity based on the automotive paint industry's KPIs [22] and, Margareta et al. (2020) integrated OMAX and AHP to measure the Green Warehouse KPIs [23]. The above studies have clarified how OMAX and AHP allow optimum achievement of performance assessment. Therefore, this study aimed to explore future OMAX values through its conjunction with the latest F-AHP levy to assess SMEs' digital readiness.

Here, OMAX as the operating system works by the proportion of each KPIs or criteria based on the total of the intermediate value divided into three levels viz highest, middle, and lowest level complemented by the traffic light system method as depicted in Fig. 1.

Part A in Fig. 1 describes the parameters influencing the efficiency and performance of the KPI, while Part B quantifies the degree of performance from the highest (10) to the lowest (0) by considering class and interval interpolation values.

$$\Delta X_{L-H} = \frac{Y_H - Y_L}{X_H - X_L} \quad (7)$$

The interval between high and low levels is the numbers at high levels, YL as numbers at low levels, XH as variables for the highest levels, and XL as variables for the lowest levels. Part C exemplifies the value analysis of KPIs that is outlined by the following formula.

$$value = level \times weight \quad (8)$$

Meanwhile, the index variable shows the initialization of criteria as the ultimate measures of efficiency. The OMAX traffic light system remarks the KPIs were levelling with three colors: green, yellow, and red. The green rates the scale level ranged from 6 to 10, where a good category is rated from 6 to 7, the very good type is enumerated by 8, and the excellent class is racked up from 9 to 10. The yellow color warned the measurement condition far from reaching the goal and scored from 2 to 5. It prescribes the level values 2 to 3 as bad category and the values 4 to 5 as the average order. The red color indicates the below-targeted achievement, thus requiring immediate improvement, and in this case, the OMAX curves are 0 to 1, with 0 indicating the rating class and 1 the terrible section. This traffic light system approach has been successfully solved in many labelling cases. Furthermore, it is found that the traffic light system is consistent, reduces confusion, and wastes time in determining the performance of KPIs, and as a result, it boosts the labelling criteria's efficiency in digital readiness assessment.

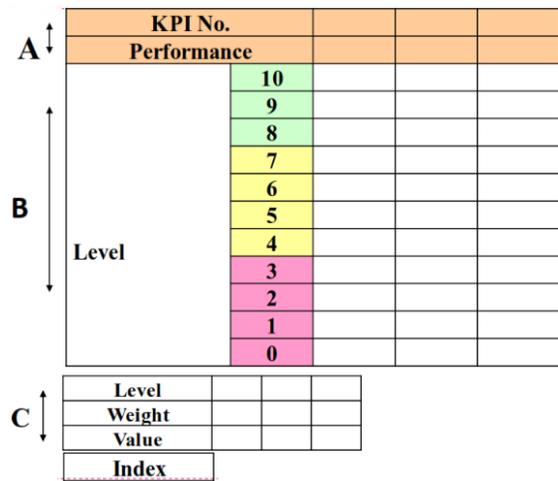

Fig. 1. OMAX Method Assessment Scheme [42].

#### IV. RESULT

##### A. KPIs Weighting Analysis – F-AHP

F-AHP resolves a questionnaire and appraises the significant weight values of SMEs' digital readiness parameters following Equation (1) to (6), and Table II is obtained in this sense. Initially, the AHP computing of comparison matrices and consistent values has led to the reasonableness and consistency of SMEs' entire digital readiness assessment parameters with the values 0.10, 0.08, 1.24, and 6.51 for CI, CR, Ratio Index (RI), and "λ maks" respectively. Hence, the parameter weighting values rank the criteria in Transaction (TC) of 0.29, Marketing (MC) and Micro Environment (MI) of 0.22, Management (MG) of 0.15, Macro Environment (MA) of 0.07, and Business Activity (BA) of 0.05, respectively. Next, the fuzzy synthesis values resulting from the operation performed on TFN are defined by Table II. Furthermore, from equations (4) to (6), Table II has elucidated the removal of fuzziness from the values of the ordinary and fuzzy vector weights (w). Thus, it attributes the summary of the priority weight value of the indicator and sub-indicators with the transaction (TC) as the most significant indicator (0.30) followed by Marketing (MC) and Micro Environment (MI) to a vector value of 0.24, Management (MG) provides 0.20, Macro Environment (MA), and Business Activity (BA) correspond to the vector values of 0.03 and 0.02, respectively. Furthermore, the weighted analysis reveals that TC-Education contributes to the weight values at 0.54, as the main sub-indicators of the transaction (TC). TC-Financial Resource, TC-Technical Infrastructure, and TC- Culture determines the vector values of 0.33, 0.13, and 0.08, respectively. Therefore, the priority indicators and sub-indicators for the SMEs digitization assessment model are established between SMEs and their stakeholders. This model as a performance measurement instrument is recommended as an aid for further analysis.

TABLE II. THE RECAPITULATION OF F-AHP PRIORITY FOR SMES DIGITAL READINESS VARIABLES AND SUB-VARIABLES

Variable	W	Si			Sub Variable	Si		
		L	M	U		L	M	U

**B. OMAX-Labeling Analysis**

The OMAX labelling emphasized the second survey analysis that delivered 118 questionnaires for food industrial SMEs in Riau Province. It rated SMEs’ degree of performance hinged on the F-AHP estimation weight values and following the Equations (7) and (8). As a result, Table III revealed the recapitulation of SMEs’ readiness at Riau Province. Furthermore, the survey found that the highest criteria value for SMEs’ digital readiness in Riau is Marketing (MC) with “Good” (7.75) and an “Average” for the entire MC sub-criteria. It then was followed by Macro Environment (MA) for index level of “Average” (5.34), Management (MG) for the index degree of “Average” (4.68), Micro Environment (MI) with index “Average” (4.32), Transaction (TC) with the category of “Bad” (3.84), and Business Activity (BA) with the class of “Bad” (3.78), respectively. Besides, Table III further describes the calculation performance analysis for each sub-criterion.

Fig. 2 and Table IV display the comprehensive evaluation of SMEs’ digital readiness in the Riau province. In Fig. 2, out of the 118 SMEs in Riau Province, their performance was 42.37%, 36.44%, 11.86%, 5.08%, and 4.24% at the “Average”

level, “Bad” degree, “Good,” “Very Good,” and at “Excellent” group respectively. The thorough levelling index of 118 SMEs for BA, TC, MC, MG, MI, and MA parameters is illustrated in Table IV. The root cause analysis is then addressed according to each sub-criterion indication. Thus, the stakeholders are advised in taking curative action.

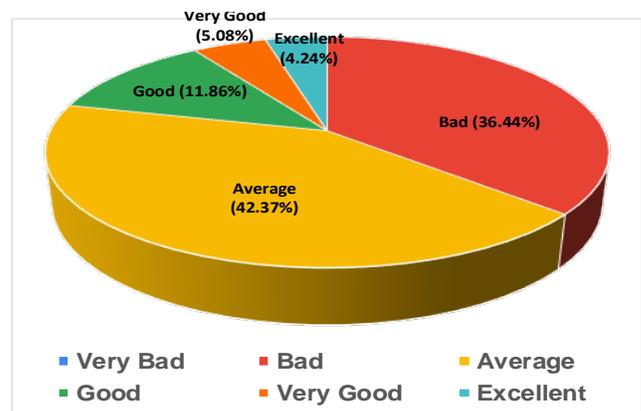

Fig. 2. The Percentage of SMEs Digital Readiness at Riau Province.

TABLE III. THE RECAPITULATION OF OMAX FOR SMES DIGITAL READINESS IN RIAU PROVINCE

Variable	Sub-Variable	Achievement	OMAX Level	Performance Value	OMAX Category	Index
BA	BA-Culture	58.47	3	0.18	Bad	3.78 (Bad)
	BA-Education	60.17	3	1.29	Bad	
	BA-Financial Resources	55.30	3	1.29	Bad	
	BA-Technical Infrastructure	62.50	3	1.02	Bad	
TC	TC-Culture	62.5	3	0.24	Bad	3.84 (Bad)
	TC-Education	58.90	3	1.62	Bad	
	TC-Financial Resources	58.26	3	0.99	Bad	
	TC-Technical Infrastructure	61.02	3	0.99	Bad	
MC	MC-Culture	69.70	5	2.15	Average	7.75 (Good)
	MC-Education	65.47	4	1.88	Average	
	MC-Financial Resources	65.04	4	1.88	Average	
	MC-Technical Infrastructure	65.25	4	1.84	Average	
MG	MG-Culture	66.74	4	1.32	Average	4.68 (Average)
	MG-Education	62.92	3	0.99	Bad	
	MG-Financial Resources	60.81	3	1.38	Bad	
	MG-Technical Infrastructure	61.86	3	0.99	Bad	
MI	MI-Culture	58.48	3	1.17	Bad	4.32 (Average)
	MI-Education	65.04	4	1.44	Average	
	MI-Financial Resources	58.48	3	0.27	Bad	
	MI-Technical Infrastructure	64.62	4	1.44	Average	
MA	MA-Culture	66.95	4	1.32	Average	5.34 (Average)
	MA-Education	65.25	4	1.8	Average	
	MA-Financial Resources	58.26	3	1.11	Bad	
	MA-Technical Infrastructure	62.92	3	1.11	Bad	

TABLE IV. THE ASSESSMENT INDEX OF SMES DIGITAL READINESS AT RIAU PROVINCE

SMEs No.	Index	Category	SMEs No.	Index	Category	SMEs No.	Index	Category	SMEs No.	Index	Category
SME1	2.36	Bad	SME10	3.14	Bad	SME19	3.81	Bad	SME28	3.64	Bad
SME2	6.94	Good	SME11	6.66	Good	SME20	2.63	Bad	SME29	4.6	Average
SME3	3.64	Bad	SME12	4.46	Average	SME21	5.28	Average	SME30	8.82	Very Good
SME4	5	Average	SME13	2.59	bad	SME22	7.34	Good	SME31	4.87	Average
SME5	6.56	Good	SME14	2.87	bad	SME23	8.1	Very Good	SME32	3.35	Bad

SME9	3.25	Bad	SME18	3.14	Bad	SME27	5	Average	SME118	5.26	Average

C. Dashboard System Development

Fig. 3 shows the SMEs Readiness Assessment Dashboard application architecture and design setup. It is designed according to the approach and components of the DSS framework and also eligible for two key players, which include; users derived from decision-makers comprising researchers, government engagement, the central bank, marketplaces managers, investors, and also participants designated for the end-users from 118 SMEs in the province of

Riau. This application is designed to provide stakeholders with an integrated and interactive platform to rack up the weight on F-AHP and make predictions for SME digital readiness predictions. Here, two questionnaire mechanisms are built through this application. It provides an exact word, video, and text formatted to eliminate gaps when performing the job. The system interfaces are equipped with the information and knowledge activities, so focusing on the outcome of analyzes and tracking of the SMEs readiness assessment as well as

scoring issues. Finally, the assessment analytical report is performed by the system as intelligent recommendations in tackling the problems identification for the stakeholders and SMEs actors as well. Fig. 4 explains the general SMEs analysis report as outcome report generate that exhibiting the performance achievement of indicators and constructs in terms of BA, TC, MC, MG, MA, and MI. Besides, the index performance percentage is also displayed as resume index of the whole SMEs in Riau Province. The graphical performance of indicators and constructs informs the SMEs achievement and provide the recommendation on how to bring about the optimal fulfillment. Fig. 5 is public OMAX calculation page in disclosing the SMEs mapping performance calculation within 10 leveling indexes into overall performance calculation. Fig. 6 resolves the performance calculation index for one SME case study namely Kebab Frozen. This page describes the graphic performance for indicators and constructs, OMAX calculation, and overall performance analysis whether this SME in good, bad, or average leveling index. Lastly, Fig. 7 expounds the mapping performance of SMEs in Riau Province based on the google map location. The rules' foundation is based on the result of DSS analysis and displayed as user interface results.

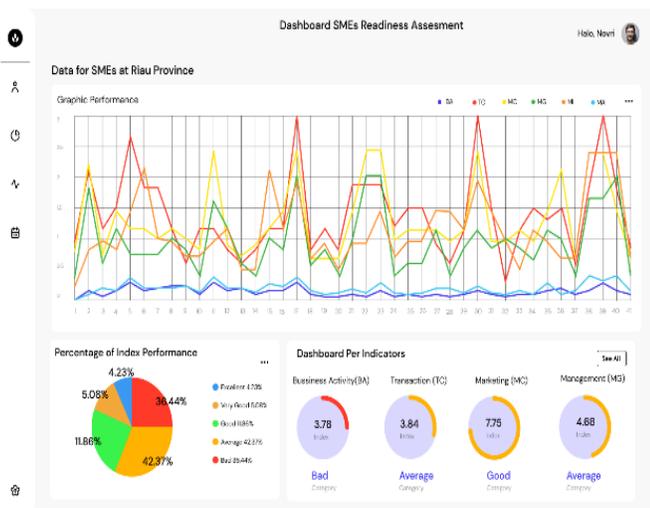

Fig. 4. General SMEs Scoring.

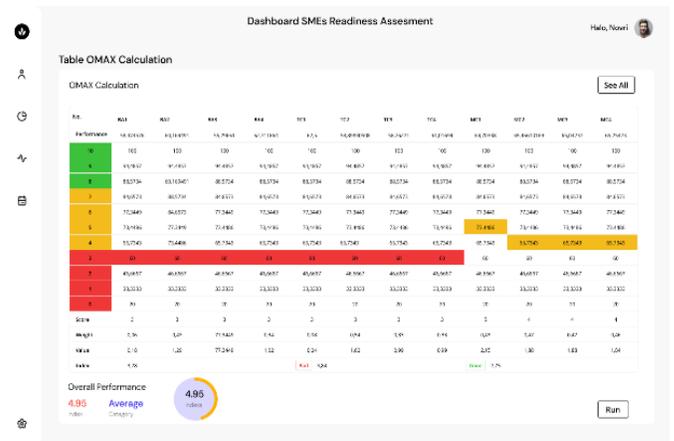

Fig. 5. General SMEs OMAX Calculation.

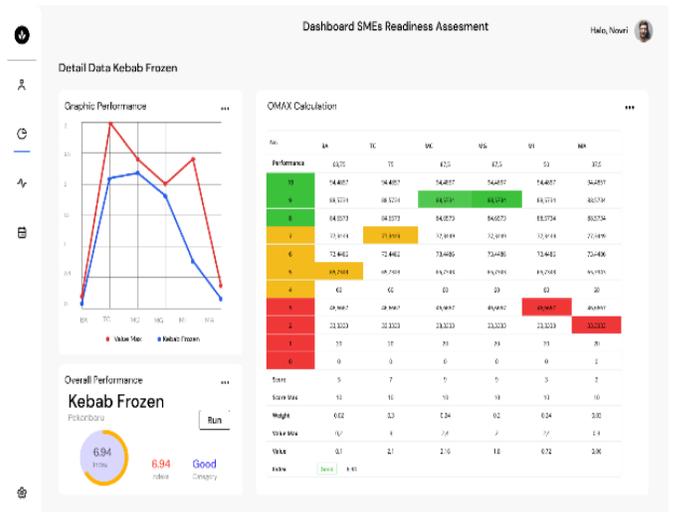

Fig. 6. SMEs OMAX Calculation for Case Study: Kebab Frozen.

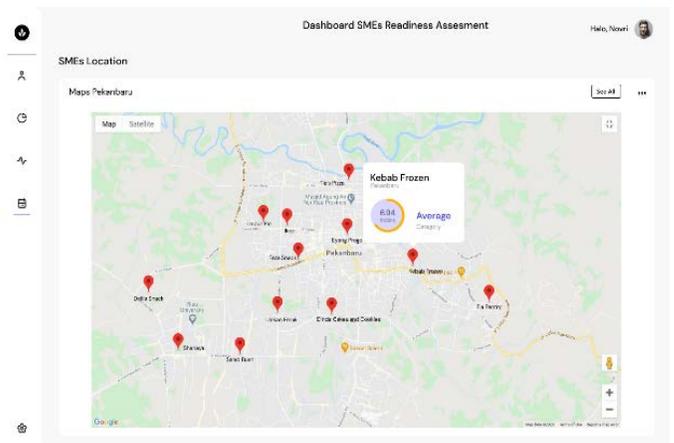

Fig. 7. SMEs Mapping Performance at Riau Province.

Furthermore, A Blackbox software evaluation was successfully conducted, and 128 functions were correctly completed to test the reliability and functionality of the dashboard, including the three parts of the AHP-questionnaires, the three aspects of Assessment-questionnaires, and the three of the SME General Analysis Task, one of SMEs surveying

and mapping functions, and 118 tasks of SMEs analysis. In addition, a UAT survey is carried out by a five Likert Scale questionnaire. In terms of user adoption of applications and functions, user-friendly applications, system interfaces, and utilization, 22 stakeholders and 118 SME participants were required to participate.

The survey showed that 85% of the respondents had no issues with the dashboard, and the application was designed to be user-friendly. The interface provided was very attractive, and 88% of respondents reported that the dashboard was constructive and will provide better clarity and understanding when reviewing formatted content, graphs, and tables. Concerning the dashboard utility, 90% of respondents have suggested that this application boost SMEs' efficiency for digital businesses' success. Furthermore, the dashboard examines SMEs' potential growth in Riau Province by defining policies, strategies, and supporting measures to improve digital business achievement.

## V. DISCUSSION

In this study, F-AHP weighting has been successfully identifying the outstanding factors in assessing the digital readiness of SMEs. F-AHP in DSS approach cascades the assessment of multi-criteria decision making in digital readiness constructs into detailed sub-indicators weighting and model development. For instance, this model provides transaction (TC) as the index of the top-weighted value down warding into sub-criteria TC-Education and TC-Financial Resource as the main criteria that would directly influence the general performance index of SMEs. In a nutshell, SMEs must take a comprehensive approach to the weighted priority of criteria and sub-criteria to enhance a sophisticated digital readiness index achievement. This assessment advises stakeholders to enforce these systems to support digitally-driven transaction settings by ultimately achieving the highest criteria and sub-criteria, such as TC-Financial Resources, Education, Culture, and TC-Technical Infrastructure. Furthermore, the issuance of regulations, policies, and understood the transaction-driven procedure, security, quality, and protections develop into the government's consideration and accountability of customers and SMEs practitioners. In addition, the adoption of technologies requires that entrepreneurs and innovative SMEs transaction flow encourage the forecasting of the future of networking, collaboration partnerships, shared services, expansion programs approaching digitalization, as well as funding requests from others both internally and externally, thus allowing digital commerce to thrive [12]. Besides, the digital transaction's success requires the involvement of leaders and empowerment by external stakeholders and employees in promoting the environment and technology in business production, management, marketing, technical infrastructure, skills, and resources [6]. The above initiative is considered growing into the greatest danger in SMEs' digitalization. Moeuf et al. (2018) substantiated that those managers and external experts play a unique role in the success and failure of a digitalized SME project [24].

Meanwhile, beholding on the OMAX calculation analysis index whereby 42.37% of SMEs in "Average" and 36.44% in "Bad" status indicates that SMEs in the Province of Riau need

to make a great deal of digital sustainability commitment. Herein, the OMAX scoring and leveling index has been flourishingly accurate in mapping the SME's performance and achievement. The integration of F-AHP and OMAX equip a deep and cascading performance analysis by considering the customized perceptions of stakeholders [35]. The Riau province condition reflects the generalization of SMEs' performance on Sumatra Island due to the possible growth of SMEs on this island. Furthermore, its geographical position is adjacent to the entrance and business transactions with several Southeast Asian countries such as Malaysia, Singapore, and Thailand, providing a considerable bonus opportunity in this area for accelerating the digital businesses, finance and investors, partnerships, and networking.

Corresponding to the dashboard system development and interface are interactively designed to provide decision-makers with a helpful overview and easy to interpret using gauges, graphs, traffic light strategies, and map analysis. According to Nadj et al. (2020), the dashboard's reciprocal analytical features strengthen the DSS operational process [36]. Herein, the model-driven DSS component has been software implemented in a hybrid analysis stage using F-AHP and OMAX approaches, and the integration of these in decision-making allows for better and optimized benefit analysis. Furthermore, OMAX and fuzzy blending bring new and meaningful success measurement values [11]. Meanwhile, data management alongside organizational knowledge is processed in the knowledge repository according to the SME's digital preparation model's parameters and sub-parameters. Hence, the knowledge recommendation analysis furnishes a new and innovative problem-solving way to aid SMEs in increasing and conducting the curative actions towards their successful preparedness for the sustainability of the digital business era.

## VI. CONCLUSION

The era of the new-normal has accelerated the implementation of digitization around the world. To sustain the nation's economy, Indonesia has made various breakthroughs to achieve digital success in all facets of life, especially for the SMEs industry, which plays an essential role in its economy. Despite SMEs having the slightest effect from the Covid-19 spread, they still need to adopt various solutions and digital acceleration to survive. The high risk of digital transformation and adoption leads the stakeholders to take action as well as digital preparation evaluation by considering the views perceived of both supply chain activities and technology. This study has successfully developed a DSS dashboard that measured SMEs' readiness towards digital business from 6 main variables and 24 sub-variables sets as criteria of SMEs' e-readiness model. The model-driven DSS application has effectively analyzed the requirements and employs the F-AHP to generate priority weight, and the views of stakeholders from government, academicians, investors, marketplaces, banking, and SME participants are considered weighted judgment in the dashboard calculation.

Furthermore, the OMAX analysis has empirically mapped 118 SMEs in Riau province with a levelling index and root cause analysis. The study reveals that SMEs' overall performance in Riau is measured by an average index,

requiring more government and stakeholders' attention for corrective actions. It shows that the overall achievements of SMEs in Riau are below the average index, which requires further consideration by the governments and stakeholders' corrective action. In terms of accessibility and utility, this dashboard application was tested and confirmed to advise decision-makers in addressing the current issues based on their review findings and the feedback presented.

#### ACKNOWLEDGMENT

This study received a grant from Universitas Islam Negeri Sultan Syarif Kasim Riau, Indonesia, through the DIPA funding number. 1171 / R / 2019. The authors are grateful to the support parties in this study, including the Ministry of Cooperatives and Small and Medium Enterprises, the Ministry of Communication and Information Technology, management of market places, Telecommunication Company at Pekanbaru and Central Jakarta, Department of Communication, Informatics, and Statistics of Riau Province, Integrated Business Services Center of Riau Province, Central Banks, Faculty of Science and Technology, Faculty of Economics and Social Sciences of Sultan Syarif Kasim Riau Islamic University, and several SMEs in Riau Province.

# A Novel IoT Architecture for Seamless IoT Integration into University Systems

Wafa Altwoyan, Ibrahim S. Alsukayti

Department of Computer Science, College of Computer, Qassim University  
Buraydah, Saudi Arabia

**Abstract**—IoT architectures play critical roles in guiding IoT system construction and enhancing IoT integration. However, there is still no standardized IoT architecture that meets the varying requirements of different IoT deployments. Although this has been a focus within the research community, no specific attention has been paid to optimizing an IoT architecture toward seamless IoT integration in educational environments. Moreover, different advanced system aspects have not been considered for designing an optimized IoT architecture. These include the need for complete security and privacy support, a highly responsive system, dynamic interactivity, and wide-range IoT connectivity. Such considerations are important considering the complexity and multidimensionality of integrating IoT in educational environments. In this paper, we introduced a novel IoT architecture with the main objective of facilitating the effective integration of IoT into university systems. It also aims at optimizing the IoT-integrated system with advanced aspects to enhance system security, responsiveness, and IoT connectivity. The proposed architecture provides a modular and scalable design of six architectural layers in addition to a vertical layer that provides security support across the architecture. Only the most relevant and critical layers are added to the architecture to maintain a practical trade-off between effective modularity and less complexity. Compared with other IoT architectures, the proposed one ensures high reliability, data management, full security support, responsiveness, and wide coverage while maintaining acceptable complexity.

**Keywords**—Internet of things; architecture; smart campus; education

## I. INTRODUCTION

Advancements in Information and Communication Technology (ICT) have recently enabled the effective transformation of conventional educational systems to a more efficient and sustainable level. The high dependency on technology and digital services allows substantial investment of recent technologies in enhancing traditional educational methods. The ICT revolution leads traditional learning to be moved to new paradigms such as e-learning and distance learning. This creates opportunities for further improvements regarding the educational activities and processes. Such technological advancements in the education domain can be even more optimized with the best leverage of recent technologies. One of these is the Internet of Things (IoT) technology which is projected to change several facets of the educational environment [1].

IoT provides a technological revolution that enables effective interaction between people, processes, data, and

things. It facilitates the effective provisioning of smart services in different domains including healthcare [2], industry [3], and agriculture [4]. In addition, learning is one of the most perceptible human actions affected by IoT, turning the educational process into a revolutionary system in the near future. IoT enables educational environments to be significantly extended by combining physical and digital objects. IoT finds its way into education to provide advanced support in enhancing many aspects. These include streamlining educational processes, making the most use of data, and improving sustainability. IoT can serve as a catalyst for improving the current knowledge-transfer model to be more interactive and collaborative. The teaching-learning process would be actively engaging with the efficient use of IoT in education systems [5].

However, integrating IoT in educational environments is still a challenging process. Careful consideration of the complexity and multidimensionality of such environments is important before going any further through this process. At the fundamental level, architectural planning is the key to optimizing IoT integration in educational environments. The importance of developing IoT architecture lies in its critical role in guiding system construction and facilitating IoT integration. Such a challenging IoT integration can be fundamentally simplified by developing an efficient IoT architecture. Despite the wide adoption of IoT technology in different domains, there is still no standardized IoT architecture that meets the varying requirements of different IoT deployments [6]. Several design approaches have been introduced for the development of an effective IoT architecture. They vary in granularity and the number of architectural layers in addition to considering different system aspects.

However, fundamentally addressing the efficiency and complexity of integrating IoT into the specific environments of educational institutions has not been considered yet. The focus has been only on addressing the main IoT system aspects, particularly data collection, transmission, processing, and application. No particular attention has been devoted to the specific characteristics of educational environments when integrated with IoT. These include the need for complete security and privacy support, highly responsive system, dynamic interactivity, and wide-range IoT-specific connectivity. Still there is a compelling need for effective design of an IoT architecture to facilitate IoT integration and accelerate IoT adoption in these dynamic environments. This paper aims at addressing such a need by establishing an IoT

architecture while taking into account advanced technological considerations. These include edge computing, IoT accessibility, cloud computing, and full security integration.

The following section, Section II, of this paper presents the related work. In Section III, an overview of the integration of IoT in education environments is provided. Section IV introduces the proposed IoT architecture. Then, a simple use case demonstrating the implementation of the proposed architecture is presented in Section V. A broad discussion is then provided in Section VI. Section VII concludes this research paper and presents the plan for future work.

## II. RELATED WORK

There has been a lack of consensus concerning IoT architectural design. Several IoT architectures have been proposed in the literature with different characteristics and properties. A well-known architecture that serves as a reference IoT architectural model is the three-layer architecture [7-9]. It provides a basic architectural design of the IoT functionality with three logical layers, namely the perception, network, and processing layers. A further improvement was made to this basic design to include the application layer at the top level [10-11]. This enables managing IoT services and applications in a more effective way for the end-users.

With the rapid development of IoT, such basic architectures become insufficient to realize the full functionality of IoT systems in an effective manner. They would not be able to efficiently fulfill the different requirements of emerging IoT applications. They can only be feasible at the initial stage of IoT system development. Therefore, other architectures were proposed with additional layers. One is the five-layers architecture which was introduced in [9] to not only realize the structure of IoT from a technical point of view but also a business and operational perspective. It incorporates a business layer at the top of the architecture to effectively enable the management of IoT applications based on certain business models and strategies. The other one is the six-layer architecture proposed in [12]. It includes additional layers between the perception and network layers for IoT data monitoring, preparation, storage, and security.

In addition, there have been different proposals focusing on the establishment of specific IoT architectures considering certain common aspects. These include SDN-based implementation [13] security-specific design [14], QoS provisioning [15], and service-oriented perspective [16]. Others focused on certain IoT communication technology such as the architectures proposed in [17] for provisioning 5G-enabled IoT systems. Customized architectures considering specific IoT applications have also been proposed in the literature. These include smart agriculture control [18], tourism management [19], smart metering [20], e-health [21], building automation [22], and water resource management [23]. However, no particular attention has been yet paid to addressing the effective development of an optimized IoT architecture for educational environments.

It can also be seen that these design approaches provide no adequate support for different important aspects. These include the need for security across the different levels of the IoT

systems. It is insufficient to address security at a specific layer of the architecture. Security support is critical at the different levels of data acquisition, access, communication, processing, and management. Another important consideration is the incorporation of advanced technologies that would make the deployed IoT system more sustainable. One of these technologies is edge computing which allows the system to be more responsive with very low latency. This is important considering that educational environments are more dynamic and interactive. Another dimension in this context is the need for an effective way to incorporate IoT-based connectivity into these environments. Remote educational areas can be provided with IoT-customized networking support to implement the different IoT applications and services. Therefore, IoT-based network access control is a critical consideration for the effective design of the IoT architecture.

## III. IOT INTEGRATION IN UNIVERSITY SYSTEMS

For understanding the challenges of integrating IoT into educational environments, we focus in this research work on the specific and demanding case of a university system. It is critical to look into such a complex process at the fundamental level and begin with investigating IoT integration at the infrastructural scale. This would be the initial stage toward the full realization of IoT-based university educational systems. This section presents and discusses the impact of introducing IoT into conventional university systems.

Fig. 1 shows an overview of a typical global university system that incorporates a complex setup of different networking segments, topological entities, interconnections, and computing resources. It has a core infrastructure that interconnects multiple LANs using wired and wireless connectivity. It also has a separate setup for supporting VPN communication with the core system. Internet access is also maintained using a private ISP link. The system also includes a data center having a farm of IT servers for managing different services. These include private servers for web, database, mail, file, and proxy management. Moreover, a set of network entities is used to interconnect the different parts of the system. Different types of switches and routers are deployed in a hierarchical structure. These are core and distributed switches in addition to Internet and local routers implemented at the different levels of the system.

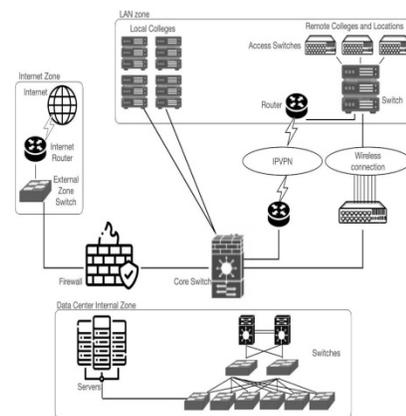

Fig. 1. A Schematic Overview of a Typical Conventional University System.

When the system is integrated with IoT, several IoT-enabling entities need to be introduced to the system. These entities are required to implement the new IoT-related functionalities of the integrated system. For example, IoT sensors and objects are required for enabling IoT data collection and acquisition. Another important functionality is connectivity management and network access control of the IoT devices. This requires special multi-function devices such as IoT gateways with multiple networking capabilities. Furthermore, IoT data in IoT-integrated systems is huge in volume and diversity thus high storage capacities and powerful processing capabilities are highly required. Expanding the current data center with additional IoT servers becomes mandatory. Otherwise, the system needs to be expanded with advanced intelligent computing technologies for effective data management.

It is clear that addressing seamless IoT integration in such systems incurs different challenges. These include the management of heterogeneous IoT devices deployed over vast and maybe remote areas. There is also a need for robust IoT access control considering a variety of IoT communication technologies of distinct properties. Moreover, IoT data management is critical at the different levels of the system. A considerable challenge in this context is addressing big data processing and analytics with a scalable, cost-effective, and flexible solution. Approaching such a challenge using advanced technologies such as cloud computing is the key to efficient and robust IoT data computation and management. Complementing this with the initial processing of the IoT data at the access level would improve resource utilization and performance. However, a trade-off should be maintained between this strategy and the limited capabilities of typical IoT devices at this level of the system. On top of all that, security support is another critical challenging aspect that needs to be fully addressed. Basic security support is insufficient as IoT data need to be secured throughout the different levels of the IoT-integrated system.

#### IV. PROPOSED IOT ARCHITECTURE

The current IoT architectures provide no support for critical advanced aspects as explained in Section II. The importance of these aspects can be seen when considering the complexity and dynamics of the education environments as discussed in the previous section. Taking into account these considerations, a novel IoT architecture is proposed in this section. The following subsections introduce the proposed architecture, present its main components, and discuss potential smart applications.

##### A. Architecture

The proposed IoT architecture is designed as a multi-layer architecture with the main objective of facilitating the seamless integration of IoT into educational environments. It also aims at optimizing the integrated IoT system with advanced aspects such as complete security support, responsive edge processing, and customized IoT connectivity. The proposed architecture provides a modular, scalable, and simple design that can effectively meet the high volume of IoT data and application demands in the targeted environments.

The proposed IoT architecture consists of six hierarchical layers and one vertical layer. A bidirectional connection flow is established between adjacent hierarchical layers. These are the IoT-object, access, edge-computing, infrastructure, cloud, and application layers that will be discussed in the following subsection. The focus here is on bridging the gap between IoT and legacy systems in educational environments. It encompasses most of the functionality that is implemented in the legacy systems into the infrastructure layer whereas the other layers facilitate the integration of the distinctive IoT functionalities. The architecture also has a vertical layer for providing complete security support across the different hierarchical layers of the architecture. This layer has a horizontal connection to each other layer to allow securing the system in a comprehensive manner. Fig. 2 shows an architectural representation of the proposed IoT architecture.

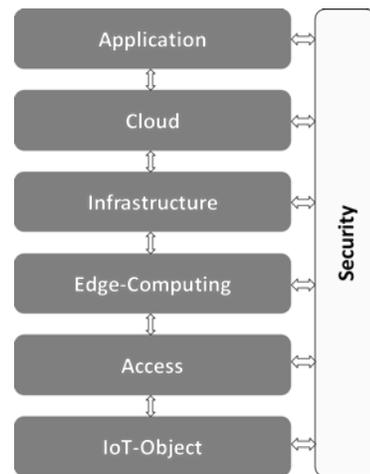

Fig. 2. Architectural Representation of the Proposed IoT Architecture.

The number of layers is selected to ensure effective granularity, modularity, and scalability. That is, each separate and distinctive functionality of the integrated system is embedded in a different layer. This would make IoT integration more simplified and standardized while considering all the essential components of the system. In addition, only the most relevant and critical layers are added to the architecture to maintain a practical trade-off between effective modularity and less complexity. The following part of this subsection describes and discusses each layer of the proposed IoT architecture.

1) *IoT-object layer*: The bottom layer of the architecture is a physical layer that incorporates all the different IoT objects. These include IoT sensors and actuators in addition to IoT-enabled physical objects. This layer manages IoT data collection and acquisition in addition to controlling requests destined for IoT devices. Furthermore, different aspects including deployment strategy, devices heterogeneity, resource management, and device identification are considered at this level.

2) *Access layer*: Management of the connectivity of IoT devices with the system is addressed in the access layer. This functionality can be realized using different IoT-based wireless communication technologies. These would include Bluetooth Low Energy (BLE), NB-IoT, 6LowPAN, ZigBee,

LoRaWAN, and Sigfox technologies in addition to WiFi and cellular connectivity. This layer controls network access of the IoT devices through different entities such as gateways, aggregators, and access points. It ensures that IoT data collected at the bottom layer is received and delivered to the upper layers for further handling and processing.

3) *Edge-computing layer*: Data transmitted from local IoT subnets through the access layer all the way to further layers can be pre-processed meanwhile. This would enable acting on IoT data at early stages in almost a decentralized manner. Such functionality is realized using the edge-computing layer by initially processing data at different edge nodes such as gateways and local servers. IoT data can be filtered, aggregated, deformed, compressed, and validated for optimized data provisioning and management. Early mining and analysis of the IoT data can also be performed at this layer.

4) *Infrastructure layer*: The core computing and communication of the system is handled at the infrastructure layer. It is the heart of the proposed architecture interconnecting the different parts of the system. The design of this layer enables encompassing and abstracting the core functionality of the university legacy system. This is a key design aspect for facilitating effective integration of the different IoT functionalities into the system.

5) *Cloud layer*: Data management and analysis are realized in this layer with full reliance on cloud technology. IoT data storage and processing are offloaded from the computing infrastructure to the cloud system. The main functionality performed at this layer is effectively managing storage capacities and processing capabilities for IoT data. This requires proper access control to cloud servers and resources. Another consideration in this layer is enabling intelligent IoT data analytics to provide added-value IoT services.

6) *Application layer*: the application layer defines many application-related aspects such as how to utilize the processed data, manage user access to the system, and request IoT services from the underlying layer. Processed IoT data is used at the application layer to produce application-specific services. These can be implemented for different IoT educational applications such as the smart classroom and smart library applications. It is the top layer of the proposed architecture facilitating direct interaction with IoT application users. Therefore, it is responsible for controlling user access to IoT applications and enhancing user experience.

7) *Security layer*: Security management is realized by a vertical layer that is logically interfaced with each level of the architecture. The design of this layer allows incorporating the different security mechanisms into the hierarchy of IoT-integrated systems. These mechanisms include data encryption, user authentication, access authorization, threats isolation, attack detection, and trust control.

## B. Main Components

To realize the proposed architecture, a set of new IoT elements need to be effectively incorporated into the integrated IoT system. This is presented in Fig. 3 which demonstrates how the legacy university system shown in Fig. 2 can be integrated with IoT. The incorporation of these elements is important to efficiently build up the backbone of the IoT-enhanced university system. Every new element is added to support the functionality of a specific layer. The main elements are presented and discussed in this subsection as follows.

1) *IoT devices*: IoT objects are physical entities embedded with sensors, firmware, processing units, and electronics to enable sensing, sending, and receiving data. IoT devices constitute the main source of data in IoT systems. The most common IoT devices are sensors, actuators, microcontrollers, smart wearables, and wireless cameras. These can be easily provisioned by the proposed architecture at a different scale. The management of these devices is realized at the IoT-object layer to facilitate software/firmware updates, device capability provisioning, and remote diagnostics.

2) *IoT connectivity*: IoT connectivity can be realized using a number of different IoT-oriented connectivity options with distinctive features. They vary in coverage range and power consumption while sharing some properties such as low data transmission rate. These can be classified into short and long-range communication protocols. For example, ZigBee and Bluetooth have short communication ranges whereas LoRaWAN and NB-IoT provide support for long-range communications. The proposed architecture is flexible enough to incorporate different communication protocols and support any potential connectivity requirements. It also supports different communication models such as the point-to-point and point-to-multipoint models. This would enable machine-to-machine communications which allow devices to establish connections among themselves without human intervention.

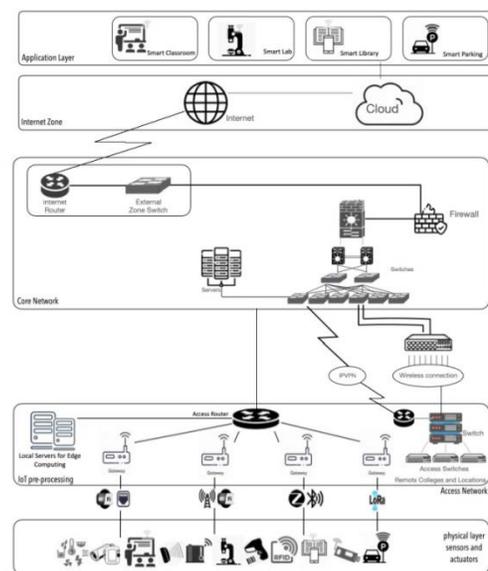

Fig. 3. A Schematic Overview of an IoT-Integrated University System.

3) *IoT gateway*: Gateways in IoT systems are essential devices to perform different functions. These include IoT data forwarding, protocol conversion, IoT node management, and security support. Gateways are typically deployed at the edge of the IoT network interconnecting IoT nodes to the infrastructure. The network stack of most of the typical IoT devices has no support for IP-based Internet connectivity which can be provided using a gateway. Gateways also provide an additional abstraction to address the heterogeneity and interoperability of IoT devices. In addition, new generation IoT gateways can also provide local caching and pre-processing of IoT data. In the proposed architecture, gateways are essential elements that operate at the access layer to provide all the aforementioned functions. Computing resources of the gateway devices can also be utilized for edge processing at the edge-computing layer of the architecture.

4) *IoT edge servers*: Edge computing can be realized in IoT systems by deploying edge servers in close proximity to the IoT end nodes. These servers then provide the required computing and storage resources to pre-process IoT data before being transmitted to the cloud. This would help in improving system reliability and availability. Edge servers operate at the edge-computing layer of the proposed architecture with the ability to support a distributed computing model. That is, edge servers deployed across the system can collaborate to provide real-time IoT data pre-processing in a scalable and distributed manner. This is important to improve system responsiveness as the speed and the volume of IoT data is increasing. However, edge servers are usually of limited computing and storage capabilities, unlike the largescale and powerful cloud servers. Therefore, it is critical to have a data management and processing framework to offload computation-intensive data processing to cloud servers.

5) *IoT cloud*: Cloud computing provides computing resources such as processors, storage, software, and networks as a service. It enables cost-effective data management, on-demand self-service, powerful data computing, and scalability. The proposed architecture enables the development of a cloud-based IoT system to enhance system flexibility and reliability. Relying on the cloud would make IoT integration easier and more effective. It enables unlimited, cost-effective, and on-demand data storage management without any infrastructure limitations and network restrictions. Given that IoT data is typically large and unpredictable, offloading IoT data processing and analytics to the cloud is a feasible strategy to alleviate considerable burdens on the infrastructure.

6) *IoT data*: IoT data is collected and acquired in different forms and from different IoT objects. These can be status, actionable, location, and automation data in structured and unstructured formats. IoT data is characterized by having a high volume, large-scale streaming, diversity, high dimension, time and space coloration, and high-noise environments. In the proposed architecture, IoT data is handled throughout the different levels of the system. It is collected at the IoT-object

layer and then get forwarded at the access layer to the core infrastructure of the system. During that, the data is pre-processed for initial filtration, aggregation, deformation, compression, and validation. Full management and processing of the IoT data are performed at the cloud layer which produces processed application-specific data. Mechanisms and algorithms for data format converting, machine learning, data mining, and reasoning can be performed on IoT data. The basic support that needs to be provisioned for IoT data is storage capacity and processing capabilities.

7) *IoT services and interfaces*: Once having the IoT-integrated system is established, different IoT services can be provided considering different applications. These services can be developed for different smart activities such as environment monitoring, surveillance, control and automation, face recognition, and productivity support. In addition, IoT users are provided with the required services and interfaces to interact effectively with the system in the context of different IoT applications. All these functionalities are managed at the application layer of the proposed architecture.

### *C. Potential Smart Applications in Educational Environments*

The proposed IoT architecture enables meeting the requirements of different potential smart applications in educational environments. These can include the smart classroom, smart lab, smart library, and smart parking applications. This would facilitate the development of an effective IoT ecosystem that can enhance the teaching-learning process, enrich the educational experience, and improve administrative activities to further limits. This subsection discusses the aforementioned smart applications which can be easily and effectively deployed using the proposed architecture.

All these smart applications require extending the current infrastructure of the university system with additional IoT entities. The proposed architecture supports the effective management of all these entities at the different layers of the architecture. In the smart classroom and lab setups, entities such as environmental and activity sensors, control actuators, and IoT-enabled objects are incorporated. The smart library application would mainly rely on RFIDs technology to tag and manage library resources. For the smart parking application, Infrared and Ultrasonic sensors are used to monitor parking lots. Smart cameras can also be deployed in these applications for smart recognition and AI-based services. For all the different applications, IoT device management is realized at the IoT-object layer.

These IoT devices are mostly main-powered, particularly in the cases of indoor smart applications. Therefore, the connectivity of such devices can be simply maintained using Ethernet and WiFi connections. This would ensure a high data rate and more reliable connections without adhering much to any IoT-oriented concerns regarding energy efficiency. It also makes network access control easier as no additional gateways are required. The proposed architecture also enables implementing IoT devices with other indoor connectivity options such as ZigBee and 6LowPAN if needed. These would be implemented in remote areas where poor or no WiFi coverage exists. In this case, appropriate gateways need to be

installed for interconnectivity management with the IP infrastructure. In the case of outdoor smart parking, it is challenging to have accessible Ethernet and WiFi connectivity. Therefore, long-range wireless communication protocols such as LoRaWAN and NB-IoT would be of significant use in these cases. The deployment of a smart parking setup using these protocols requires the provisioning of smart gateways that provides IP interconnectivity. The proposed architecture supports interoperability among all these different communication standards at the access layer.

Massive IoT data streams would be continuously generated in such interactive and dynamic applications. For large-scale deployments in educational environments, the demanding applications of smart classroom and lab would incur a high volume of IoT data. Accordingly, it can highly benefit from edge processing to provide real-time services. Multiple local edge servers can be installed at local LANs to pre-process IoT data streams. Distributed edge processing can also be realized by managing the operations of the widely deployed edge servers using a virtual controller. Such functionality can be practically implemented at the edge-computing layer of the proposed architecture. In the case of the smart parking application, LoRaWAN gateways enabled with the edge computing capability are a feasible solution. It would provide sufficient IoT data handling given the average flow of data in such a predictive application. It is important to note that the proposed architecture supports having both local edge servers and edge-enabled gateways to improve edge computing in the system.

For all the different applications, integrating the IoT ecosystem requires no considerable modifications and updates to the core infrastructure of the legacy university system. The smart classroom application, for example, may only require additional wireless access points to be installed and connected to a local LAN network. Even in the smart parking situation, any installed gateway is interfaced with the core infrastructure through a LAN access router and managed at the access layer of the architecture. In all the different cases, the core infrastructure would only experience an increase in the data rate and may require provisioning more bandwidth for QoS assurance. It though needs no further resource provisioning for data processing and management as the cloud layer is responsible for such functionality.

### V. USE CASE

The example presented in Fig. 4 shows an overview of the architectural structure and implementation components of a smart parking application in an educational environment. It demonstrates how the core computing infrastructure is seamlessly integrated with the IoT resources and functionality. The proposed architecture enables a seamless deployment strategy. It starts by connecting the core domain to the access and edge computing domains on one side while being interfaced with the cloud domain on the other side.

Only gateways with average computing resources are installed for each parking block to manage network access of smart parking sensors. LoRaWAN is the feasible connectivity option in this case considering that no easy access to local LANs would be available in outdoor areas. LoRaWAN-

enabled sensors and gateways are deployed as needed to have full coverage. On the other hand, smart gateways can be used to provide sufficient resources for pre-processing IoT data traffic streams. That is, streamed data in this case is typically received at average volume from the smart parking sensors. Only very basic sensor data indicating basic information such as the occupancy state of a parking lot is streamed in a textual format. Data can be filtered and aggregated while being timestamped at the edge-computing layer before being forwarded further to the cloud. However, car plate recognition can also be implemented to receive images from smart cameras at the entrance of a parking zone. For such a demanding AI-based service, intensive processing is performed at the cloud servers. At the top layer, smart parking services are provided using interactive user interfaces which are connected to back-end cloud servers.

Cross-layer implementation of full security support is achieved using different security mechanisms. These include but are not limited to authentication, authorization, encryption, and trust management. However, the system is scalable enough to implement additional security solutions at the different levels of the architecture. It is evident that the proposed architecture succeeds in guiding system construction and enhancing the adoption of the smart parking application. Seamless and flexible integration of the introduced IoT resources and functionality was achieved effectively in a plug-and-play fashion.

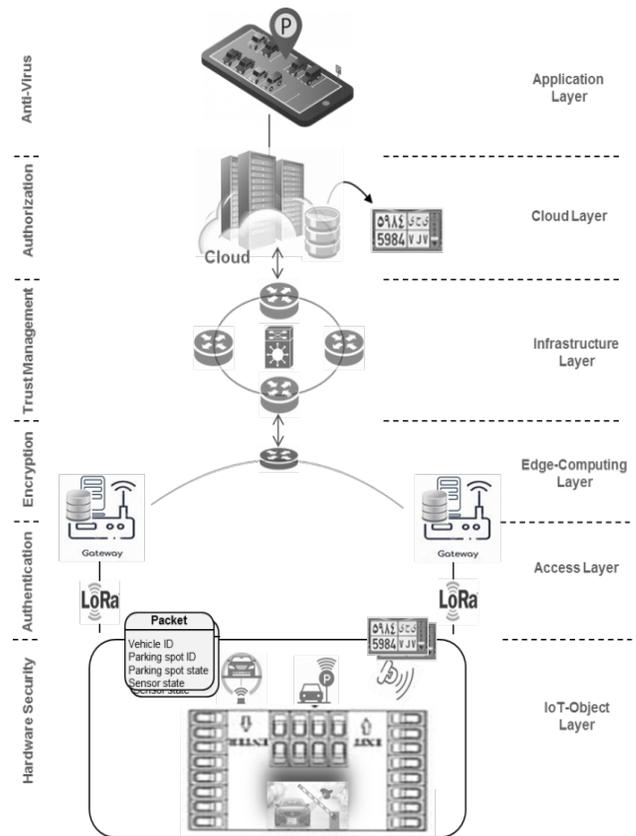

Fig. 4. Overview of a Simple use Case of a Typical Smart Parking Deployment.

## VI. DISCUSSION

It can be seen that one of the distinctive properties of the proposed architecture is the split of the networking functionality into two different layers: the access and infrastructure layers. Given the key role of networking support in any IoT-based system, this strategy is important to simplify the integration of IoT communications into the core networking infrastructure of conventional systems. IoT comes with different network access models that are managed at a separate level of the system. Isolating access control would enable effective connectivity among IoT devices and seamless transmission of IoT data over to the core network system.

In addition, the proposed architecture realizes the importance of edge computing for optimizing the responsiveness of the IoT-based system. By placing data pre-processing closer to the physical layer, it ensures that unacceptable latency is considerably alleviated irrespective of the expected high volume and dynamics of IoT data. Having IoT data handled closer to IoT end devices in the system would also improve data management and quality. Real-time processing becomes easy to implement for providing a variety of time-sensitive IoT services. Moreover, such a strategy helps in realizing more advanced support regarding different networking aspects such as user mobility and context-aware smart services.

Another important feature of the proposed architecture is encapsulating most of the functionality of the conventional systems into the infrastructure layer. This also includes all the networking entities and computing resources that constitute the core of these systems. Such a design approach would abstract the core functionality of the existing systems from the IoT integration process and avoid getting into the system complexity. This would be further enhanced with the reliance on cloud computing to realize effective IoT data management and processing. Accordingly, the proposed architecture emphasizes the importance of incorporating the cloud layer to achieve better reliability and less complexity. Furthermore, having a security layer that is interconnected to the whole system ensures the ability to provide complete security support. This design principle of the proposed architecture enables providing the different security services required at each layer.

Table I provides a comparison of the proposed IoT architecture against a set of different architectures. The inherent properties of the proposed architecture can meet different requirements that are critical to university systems. Compared with the other architectures, it provides a salable and modular design that allows elastic expansion of resources and entities to meet different IoT application requirements. It can also grow hierarchically into a different model incorporating other technologies. For example, the architecture can be adapted to accommodate the Blockchain technology in an additional sub-layer or instead of the cloud layer to realize a more decentralized data storage and processing. Encapsulating and abstracting the core computing and communication of the IoT-transformed system into the infrastructure layer makes the architecture more flexible for adaptation.

TABLE I. IOT ARCHITECTURES COMPARISON

Architecture	Scalability	Data Management	Security Support	Responsiveness	Wide IoT Coverage	Complexity
[7]	L	L	L	L	L	L
[9]	L	M	L	L	L	L
[10]	M	M	L	L	L	M
[12]	M	M	M	L	L	M
The Proposed Architecture	H	H	H	H	H	M

Compared with other basic architectures, the complexity of the proposed architecture is maintained at an acceptable level given the provisioned set of functionalities. Every layer of the architecture provides essential support to facilitate IoT integration and enhance the IoT system. Having a vertical layer for full security provision would add to its complexity but at the benefit of providing significant support of security at each level of the architecture.

## VII. CONCLUSION

Seamless integration of IoT in legacy university systems is still a considerable challenge. The proposed architecture in this paper efficiently addresses such a challenge to facilitate IoT integration and accelerate IoT adoption. It comes with a modular and scalable design allowing the effective abstraction of the legacy infrastructure of the university system. It is based on a seven-layer model that incorporates advanced technological considerations including combined edge-cloud computing in addition to effective IoT accessibility. In addition, the architecture is optimized toward complete security support using a vertical layer covering the whole system. It also provides responsive edge processing to support real-time communication with low system latency. The architecture also supports customized IoT connectivity and simplifies the deployment of heterogeneous IoT communication technologies. In comparison with other IoT architectures, the proposed one ensures high reliability, data management, security support, responsiveness, and wide coverage while maintaining acceptable complexity. The focus of the future work will be on studying how the proposed architecture can be extended to other specific IoT use cases. Another aspect that will be investigated is incorporating other technological advances such as Blockchain technology.

# Software Defined Network based Load Balancing for Network Performance Evaluation

Omran M. A. Alssaheli, Z. Zainal Abidin, N. A. Zakaria, Z. Abal Abas

Fakulti Teknologi Maklumat dan Komunikasi, Universiti Teknikal Malaysia Melaka, 76100, Melaka, Malaysia

**Abstract**—Load balancing distributes incoming network traffic across multiple controllers that improve the availability of the internet for users. The load balancing is responsible to maintain the internet availability to users in 24 hours by 7 days a week. However, the internet become unavailable since the load balancer is inflexibility, costly, and non-programmable for settings adjustment especially in managing the network traffic congestion. An increasing user using mobile devices and cloud facilities, the current load balancer has limitations and demands for the deployment of a Software-Defined Network (SDN). SDN decouples network control, applications, network services, and forwarding roles; hence makes the network more flexible, affordable, and programmable. Furthermore, it has been found that SDN load balancing performs intelligent action, efficient and maintains better QoS (Quality of Service) performance. This study proposes the application of SDN-based Load Balancing since it provides pre-defined servers in the server-farm that receive the arrived Internet Protocol (IP) data packet from various clients in the same number of loads and process orders for each server. Experiments have been conducted using Mininet™ and based on several scenarios (Scenario A, Scenario B, and Scenario C) of network topologies. Parameters used to evaluate the load balancing in SDN are throughput, delay, and jitter. Findings indicated that scenario A gives a high throughput, scenario B and C produce a low jitter values and scenario C produces the lowest delay. The impact of SDN brings a multi-path adaptive direction in finding the best route for a better network performance.

**Keywords**—Load balancing; software-defined network (SDN); SDN load balancing; network performance; Mininet

## I. INTRODUCTION

The network started in the late 1990s with electronic messaging (e-mail), followed by file transfer protocol (FTP) and more network services are used such as access multimedia files (audio or video) or content distribution in TCP/IP architecture [1]. An increasing usage of video streaming of the network user has shown in recent trends. There will be 5.3 billion total users by 2023 [2]. Moreover, the enormous growth of users is due to the use of applications in cloud services, such as Internet of Things (IoT) and Data Science. These applications and network services demand a huge volume of IP traffic transmissions in a high-speed data communication infrastructure.

In the legacy network, load balancing segregates inbound network packets that coming into the network and outbound the packets across the network through multiple controllers. In a simple definition, load balancing is to ensure availability of network services and applications to users for every 24 hours

in 7 days. As an analogy, load balancing performed as a traffic policemen standing in the middle of junctions and giving directions for vehicles to take turns to maneuver to avoid traffic jams or accidents.

Moreover, load balancing is responsible to balance an enormous volume of IP traffic across two or more Wide Area Network (WAN) that links without using complex routing protocols such as Border Group Protocol (BGP). The application of the balancing service produces an equilibrium network session over multiple connections in order to spread out the amount of bandwidth used by each Local Area Network (LAN) users, for example, browsing websites and accessing email.

Video streaming and gigantic data transmission from various users to another, demand another mechanism to be integrated with the load balancing in solving problems of delay, packet loss and high bandwidth utilization. Therefore, the objective of this study is to analyze the new mechanism in the load balancing and evaluate the network performance (jitter, delay and throughput) based on scenarios (A, B and C).

The following Section II describes the literature review of load balancing. Section III explains on materials and method used to perform the experiment environment of SDN using scenarios to represent the network topology. Section IV explains about results and findings of the study. Section V is the discussion that presents the challenges of doing the research. Section VI summaries the SDN load balancing and network performance evaluation based on scenarios.

## II. LITERATURE REVIEW

LAN and WAN needs an implementation of a load balancing mechanism to competently distribute arriving packet traffic over a collection of server farm. The importance of the load balancing located at servers and routing clients requires a maximum speed, and capacity utilization across servers in order to guarantees that no server is strained that reduce the efficiency [3] of network performance.

Therefore, load balancing manages the increasing number of IP traffic in the internet for a better network performance. In WAN environment, when one of servers is failed, the load balancing device reroutes traffic [4] to available server in the farm. As the additional server is included to the farm, the load balancing instantly sends requisition to the server group for acknowledgment and provides the alternative route for the traffic packet to travel.

Nevertheless, a major issue in the load balancing is the difficulty in managing large network using only a single server [5]. A single server in the topology design produces a bottleneck [6] condition as soon as all data packets queuing at the interface in the same time to get to the destination.

In fact, the load balancing is made of hardware-based-networks controller and requires system maintenance in managing huge IP traffic. On one hand, the manufacturer has hard coded the programmable controls that is easier to install and settings at the load balancer device. On the other hand, the load balancer performs a complicated route [7]–[9], difficult maintenance process, and is time-consuming.

Another issue related to the load balancing is the existing TCP/IP construction framework was not planned to fulfil the need of the large scale of video content distribution [10] and a high number of Internet users. To change the TCP/IP architecture involve enormous amount of expenditure. For a quick solution, a cost-effective approach to overcome the problem of TCP/IP stack is implemented using the software-defined networking (SDN) [5] since it creates another visualization layer for content processing and content distribution.

Load balancing networks are non-programmable [11] since the network administrator unable to perform new settings and the configuration is set by default that is session based load balancing. Fig. 1 shows the load balancing that uses the hardware-based-controller at the control plane for each data plane.

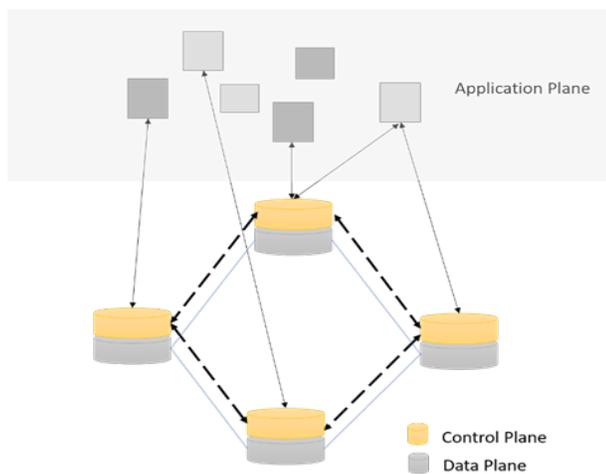

Fig. 1. Load Balancing in Network Architecture.

The configuration and setup are fixed and programmed according to functionalities and services to be provided. The control plane is situated at the data plane that increases the cost of implementation and installation of the networking infrastructure. The load balancing uses several techniques such as round robin, the least connection approach and software-defined networking load balancing.

The round robin approach is capable to forward total traffic packet by responding to DNS requests with a list of IP addresses from the nodes through poor connections and low bandwidth links. Round robin algorithm uses heterogeneous

servers [12] with different link of quality, measure the load condition, and variation of security restrictions based on several scenarios of network environment. For example, a set of identical servers is allocated to provide the same services such as centralized management and control; scalable, reliable and monitoring performance. Although each server has its own IP address, it is set up to utilize the same domain name. The DNS server keeps track of all IP addresses linked with Internet domain names. When a request for an Internet domain name and its related IP address is received, the entire addresses are delivered and return in a rotating order. This architecture considers only the distribution of the incoming traffic without considering the server's side [13]. Nonetheless, round robin algorithm predicts that every server has the same capability and resource specifications such as CPU and RAM, to handle equivalent loads.

The least connection approach brings the recent server load into account. The invitation is sent to the server that has served with the lowest number of connections. Each server is assigned to a unique number. If the number of alive connections on two servers is the same, the higher weighted server gets a new request. Every server in a pool is assigned an agent, which announced to the load balancer on its latest load. This real-time data is used to determine the server that should be used to best handle requests [14], which avoid overloading a server through numbers of server connections. However, in measuring the present acquaintances, the server capacity cannot be examined.

A SDN load balancing approach produces an efficient and has a higher speed [15] of network performance. SDN load balancing occupies an important position to solve over-load traffic problem in the network. In fact, the SDN itself is an evolving field in the networking systems and is highly in demand [2]. Google, Facebook, Yahoo, and Microsoft are adopting SDN through open standards development. A SDN produces a flexible, scalable, cost-effective and adaptive features that is ideal for high-bandwidth and complex application in the content distribution. The incorporation of a few low-level features of the network application instead of hardware implementation helps the network administrators to be more effective in managing multiple servers and complex networks.

In addition, SDN allows data to be obtained based on content rather than relying on the hostname and IP address of the device. This is because video or multimedia content is allocated in the cloud platform provider and less concern on the host identification or IP address of the cloud server location. With the combination element from SDN helps load balancing to be able to access data at anywhere and anytime.

SDN is deployed in various networks [16] such as organization and campus networks, data centers and Internet Exchange Points. Moreover, SDN architecture integrates the network control and forwarding function that allow a dynamic and programmable configuration in a cloud-based network monitoring for the new generation of network management. To improve the network performance, SDN offers a simulation platform for a better performance compared to the legacy network management.

The SDN load balancing is more lightweight [17] in terms of CPU utilization and time intervals. SDN load balancing provides features of stability, reliability and scalability [18] during data transmitting and receiving from one server to another. The advantage of SDN load balancing reduces the congestion but increase the speed in data transmission.

In SDN, load balancing performs as an “aware-routing” protocol, which is an essential element that aids availability and scalability, resulting in the shortest possible application response time. Millions of individuals are linked to the internet, resulting in increased web traffic, network congestion, and packet losses, thus, the use of load balancing strategies improves network efficiency. Moreover, the SDN load balancing brings benefits in terms of:

**A. Enhance end-to-end Network Quality-of-service (QoS)**

SDN load balancing enhances the overall networking system's efficiency and QoS [19],[20]. In terms of latency, reaction time, and network performance, QoS provides a better user experience.

**B. Optimize Resource Utilization**

Resource usage is critical, and it must be optimized for maximum efficiency. Bandwidth, processor, connection, and memory utilization [21] are all network resources that must be exploited.

**C. Decrease Transmission Latency**

The term "transmission latency" [22] states time taken for a switch to send information. Latency is affected by numerous aspects of switch performance, including congestion and data packet size. The switch load state is represented by congestion in the link, and SDN accumulates the data packets transferred within a transmission rate and session. Latency is a network performance characteristic that must be less than 100ms in order to maintain a good data delivery.

**D. Minimize Response Time**

Response time means time intermission of a server demands and transmit information are achieved [23]. Thus, the load balancing algorithm uses a distributed SDN network to minimize the response time.

**E. Avoiding Bottlenecks**

Network congestion creates bottleneck at the load balancer [24]. To avoid bottleneck, the SDN load balancing is configured to avoid the switch or controller to get overloaded. Configuration options that are optimized reduce resource use while increasing efficiency, scalability, and response time. The network performance is more effective, there is failover prevention and reduce bottlenecks.

**F. Maximize the throughput**

The SDN load balancing maximize throughput [25] during data transmission. A high throughput is vital for a good network performance since how much data could be delivered within a conversation, which traffic packets are distributed evenly to many nodes and in various types of platforms. The size of traffic packets is delivered in the same kilobytes over a period of time and from one node to another.

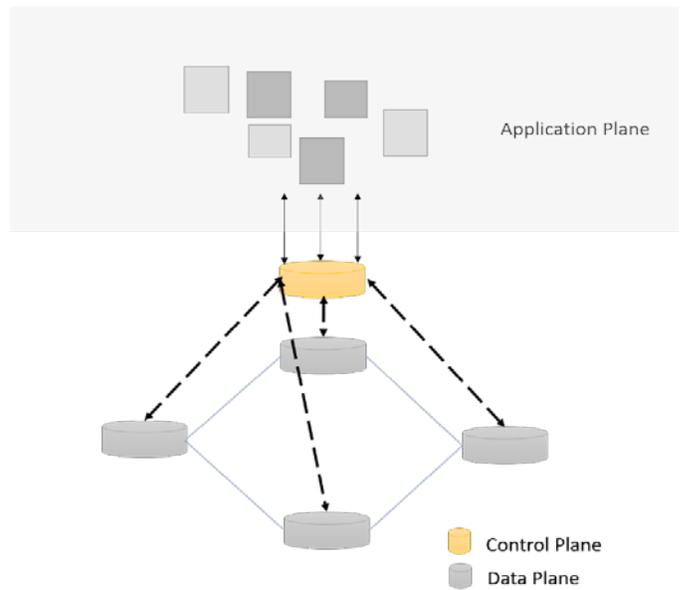

Fig. 2. SDN Load Balancing in Network Architecture.

Fig. 2 illustrates the SDN load balancing in the network architecture. The use of controller has been minimized and cost of installation is reduced. The data plane and the control plane are separated at a different location and space. The purpose is to allow users who use a huge multimedia data to access information from various locations regardless the operating system platform and the network architecture in a small expenditure.

The performance of SDN load balancing is based on parameters, which are throughput, delay and jitter.

Throughput provides information on the successful data packet travelling from one start point to the end point in a provided period. Packet arrival at the destination node in a fast speed is the key indicator for the best service performance in a network. Using throughput, the problem of packet loss is investigated to find the root cause of the problem. Load balancing maximizes throughput by decreasing response time intervals and decreasing data traffic jams.

Based on Equation 1, Mathematical calculation for the throughput can be calculated:

$$\text{Throughput, } \tilde{y}(N) = c \left( 1 - \frac{1}{1 + \frac{1+\beta}{1-\beta} N} \right) \quad (1)$$

Delay is the time taken for a message or data packets to travel from the source of destination, arrive at the destination node and get back to the source of destination. This is called as the round-trip time (RTT) of the network. Based on Equation 2, Delay is calculated:

$$\Pr(E = x) \begin{cases} \sum_{i=0}^{\infty} f_i(a), \sum_{i=0}^{\infty} f_i(b), & x = 0 \\ \sum_{i=0}^{\infty} f_i(a), f_{2x+i}(b) + \sum_{i=0}^{\infty} f_i(b), f_{2x+i}(a), & x > 0. \end{cases} \quad (2)$$

Jitter is defined as a variation in the delay of data packets flowing through the network from one node to another node. The jitter situation occurred when data packets do not reach

the destination node in the same arrangement as they were sent. The inconsistency of delay values during data transmission determines the quality of network services provided to Internet users. An outcome of the jitter is a higher a jitter value, a higher change of the delay and packet loss happened in the network. Based on Equation 3. Jitter is calculated:

$$\text{Jitter, } \sigma_c = \lim_{n \rightarrow \infty} \sqrt{\frac{1}{N} \sum_{n=1}^N (\Delta T_m)^2} \quad (3)$$

Thus, in this paper, the implementation of SDN load balancing with multiple servers is proposed for load balancing since it helps to prevent the bottleneck problem and reduces the data packet congestion in the network.

### III. MATERIALS AND METHOD

The method of network configuration in this study is implemented according to simulation-based-experiments using Mininet software [26] in a simple LAN [27] environment. Multiple servers are configured since a single server creates congestion in the network.

The performance measurement and monitoring response are analyzed through different scenarios of load balancing using network controller software tool. There are 3 scenarios implemented, which are scenario A, scenario B, and scenario C. Every scenario consists of SDN Controller, switches, and numbers of clients' connection, which is important for the evaluation. The servers act as a server pool connected to the SDN switch controller and as a data packet reaches at the SDN switch controller, the next selected server appears in the list of all servers on the network system. As a result, every server in the database handles orders with the same number of loads.

#### A. Scenario A

In this scenario, the topology is based on a simple design, which consists of four clients and two servers. The controller was created using an OpenFlow controller. Fig. 3 illustrates the topology consists of a switch controller, two servers and four hosts.

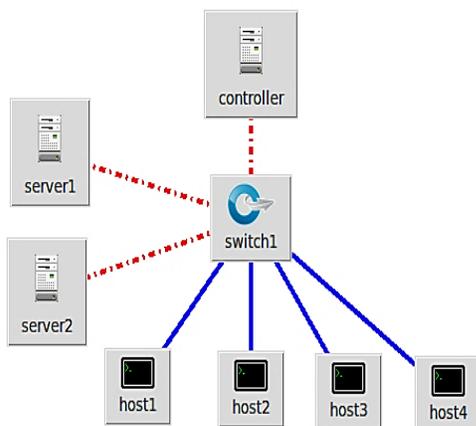

Fig. 3. Topology of Scenario A.

The load is utilizing all of the CPU assets on both web servers. Assume the load on those servers gets to be overwhelming and the Internet location execution diminishes drastically, fair basically includes a third server to the cluster giving extra assets. The arrange activity would at that point be disseminated over three servers as restricted to two.

#### B. Scenario B

The second scenario consists of four clients, and there are four server pools connected to the switch controller, which is the OpenFlow controller. Each host is located at a dedicated server, which helps to increase the outputs performance. The network performance is measured and monitored based on the delay, throughput and jitter values. Expected outcome of this experiment is to produce a lower delay, better throughput and lower jitter. Fig. 4 illustrates the scenario B experiment setup.

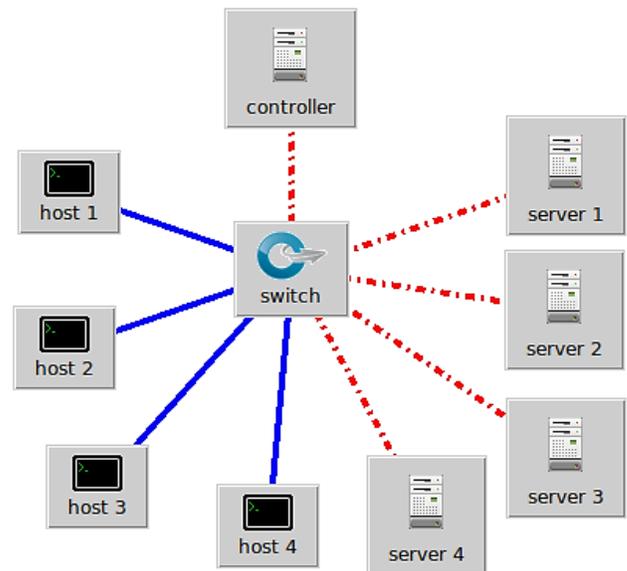

Fig. 4. Topology of Scenario B.

#### C. Scenario C

The third topology is scenario C consists of one switch controller connected to the four server pools, which support eight clients. The design is similar to the previous two topologies, but there is an additional number of clients. The load balancers lag in these design topologies where the response time and latency increase the load balancers. The SDN controller and the servers remain the same as in Scenario B, and the number of hosts is doubled into 8 hosts. Fig. 5 illustrates Network C.

For all scenarios, the OpenFlow controller is configured using the IP address of 10.0.1.1 and connected to the switch through servers with IP addresses of 10.0.0.1 and 10.0.0.2. The port number of 6633 is used for listening the network packet. The data is captured and tabulated as shown in Table I, Table II and Table III at Section IV.

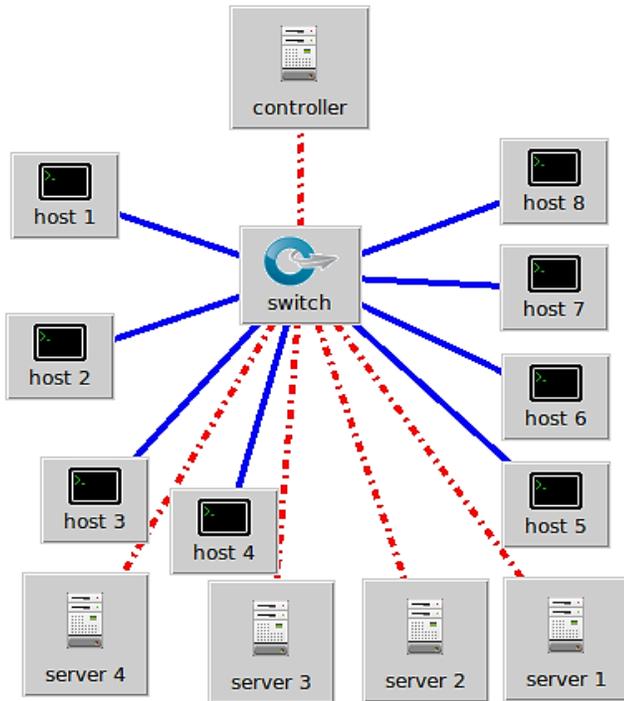

Fig. 5. Topology of Scenario C.

#### IV. RESULTS AND FINDINGS

The network performance is analyzed according to metrics, namely throughput, delay and jitter for every scenario. Comparison is done using simulation and outcomes are evaluated in scenarios based on the number of clients and servers. The result shows that the SDN load balancing is measured in traffic packet of Transmission Control Protocol (TCP) and User Datagram Protocol (UDP) traffic.

##### A. Throughput

SDN load balancing used a pox controller load balancing connected to number of hosts. Table I illustrates the result of throughput based on scenarios obtained from the experiment conducted.

TABLE I. THROUGHPUT FOR EVERY SECOND

Number of Request	Scenario		
	A	B	C
10	41,826	2016	1253
20	16,349	1324	4302
30	17,578	2255	5649
40	33,072	1901	4339
50	52,576	2235	6355
60	55,906	4857	4544
70	72,538	3991	4348
80	66,886	4768	5580
90	69,595	2990	6082
100	76,580	3839	5591

Based on the number of traffic packet requested and transmitted by the server, Scenario A shows larger amount of throughput as the number of traffic request increased. Meanwhile, the Scenario B and Scenario C illustrates an almost same range of values of throughput. Fig. 6 illustrates the throughput values in a form of graph for Scenario A, Scenario B and Scenario C for a better visualization and comparison.

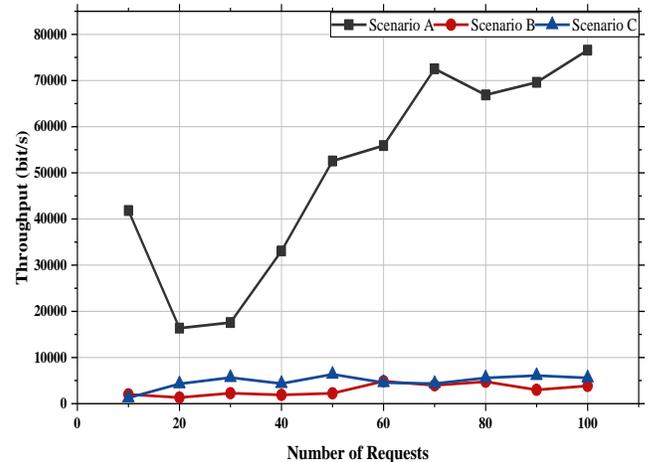

Fig. 6. Throughput Performance based on Scenarios.

Scenario A has given the highest throughput among other scenarios. Even though Scenario A only has two servers but with the SDN based switch controller helps the data transmission to be in effectively and efficiently delivered. Scenario B and Scenario C demonstrate a low throughput value. This is because data packets lost during transmission will cause poor or slow network performance, while poor performance indicates problems such as packet loss. Using performance to measure network speed is beneficial for troubleshooting because it can root out the exact cause of network slowdowns and alert administrators to packet loss-related issues.

##### B. Delay

The purpose of the SDN load balancing method is to reduce network lag and improve link load balancing by optimizing route calculation and multipath scheduling. Table II provides the delay values for Scenario A, Scenario B, and Scenario C.

Based on Table II, Scenario B indicates a highest delay even though a dedicated server has been provided for each node. Another finding shows that Scenario C shows a higher delay than Scenario A but changed after the number of requests increased at value of 20. After a peak at number of requests of 30, Scenario A keeps showing a constant delay. Fig. 7 presents the delay in a form of representative graph.

Based on results from Table II, Scenario C shows a continuous delay in time taken to transmit the packet. Scenario B shows imbalance condition of delay as the network is monitored to be slow in performance even though a dedicated server is provided to each node, which the concept of single server is not applicable using SDN controller. As a result,

Scenario C performs a slow in speed of data transmission in the network performance, Scenario B consists of the highest delay due to type of data packets travels depending on the application that the user used. Scenario A shows unstable condition at the beginning but then the delay is increasing as the number of packets are requested by clients.

TABLE II. DELAY FOR EVERY SECOND

Number of Request	Scenario		
	A	B	C
10	10,160	21,383	31,273
20	12,738	57,435	18,223
30	71,322	51,088	20,816
40	49,251	83,701	35,595
50	41,975	88,362	30,841
60	44,300	47,294	52,105
70	41,278	69,933	58,059
80	51,581	69,052	57,458
90	56,749	125,331	58,777
100	60,214	104,335	72,069

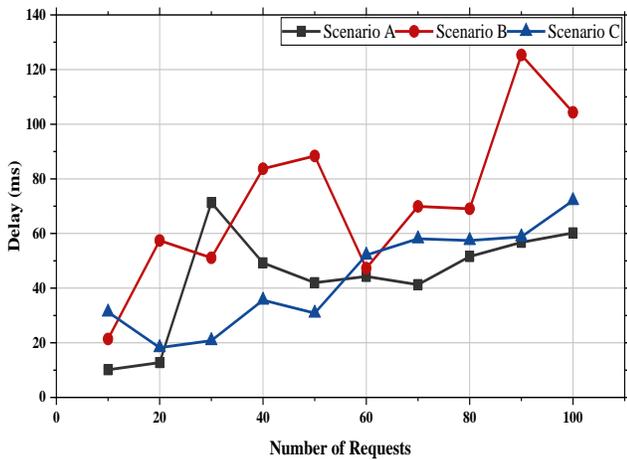

Fig. 7. Delay Performance based on Scenarios.

C. Jitter

Using SDN load balancing, jitter is measured to find the variation of delay in arriving packets to destinations. The variation of jitter represents the pattern or behavior when there is a route changed or congestion.

Table III shows the value of jitter obtained from the Scenario A, Scenario B and Scenario C. Based on the jitter values, Scenario B and Scenario C produce almost the same pattern of jitter since both scenarios using four servers with different number of clients. Finding shows that the jitter produces the similar variation of delay of the server that is designed with or without a dedicated server to a particular client.

Fig. 8 shows Scenario A has given an inconsistency condition compared to Scenario B and Scenario C. Scenario A demonstrates that the topology A built a large data packet queue that causes a huge delay and bursts of jitter. Finding found that Scenario A has a higher jitter than Scenario B and Scenario C because it processes the packet request more to transmit to the destination. Thus, it disrupts in the idle condition of transmitting data packets. The jitter is represented in a variance in time delay in milliseconds for data packets over a network.

Scenario B and Scenario C gives a reliable and scalable network performance. The jitter condition is noticeable as the graph pattern shows an almost constant variation form. For example, a user using Cisco WebEx or Microsoft Teams for online meeting has been several times disconnected. Not only that, user cannot hear the voice of another user or the voice quality has been distorted. Therefore, the longer the data packet arrives, the greater the negative impact of jitter on video and audio quality.

TABLE III. JITTER FOR EVERY SECOND

Number of Request	Scenario		
	A	B	C
10	1.127	0.998	1.000
20	2.237	0.986	1.006
30	0.001	1.008	1.008
40	0.007	1.013	1.002
50	5.481	1.001	1.016
60	6.852	1.021	1.001
70	0.032	1.004	1.034
80	4.440	1.019	1.009
90	2.307	1.011	1.017
100	1.006	1.007	1.029

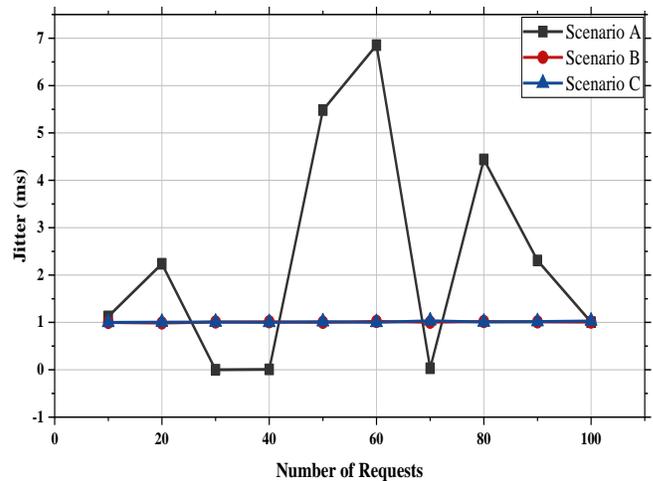

Fig. 8. Jitter Performance based on Scenarios.

## V. DISCUSSION

The outcome of this study showed that the application of SDN controller in load balancing brings a better scheduling mechanism, regardless of the number of clients requesting the packet to reach the destination. In addition, the number of servers deployed does not directly affect the overall network performance, especially in the case of network congestion and delays. Metrics are used to measure the SDN controller based load balancing in the network are throughput, delay and jitter.

According to the findings of this study, a SDN load balancer requires evidence regarding on the network's throughput. A start node delivers traffic to an end node to measure traffic on the path, and each packet is time-stamped. The packets are routed across the network's switches without bias decision, and the receiver determines the entire end-to-end delay of a packet based on the time-stamp provided. Similarly, to path measurement, each SDN switch stamps each packet with a time-stamp, which the receiver uses to calculate the transmission delay for each link in the path.

Another significant finding is that the excessive delay is caused by the SDN switch's relatively poor CPU throughput. A delay of 30 milliseconds or more, on the other hand, produce network distortion. The jitter must be less than 30 milliseconds for the video transmission to perform properly. Higher receiving jitter slows the network performance; produce a packet loss and audio quality concerns. The SDN controller behaves as expected, for instance, the response time tends to reduce as we add additional servers. When we compare a server farm with two servers to one with three servers, the response time is cut in half, but the result remains nearly constant as the number of servers increases.

## VI. CONCLUSION

Load balancing is crucial for ensuring the availability of network to users. Nonetheless, a high demand of Internet services from users creates an adoption of load balancing. The state-of-the-art indicates that SDN load balancing is highly recommended due to features such as lightweight, stability, reliability and scalability. SDN load balancing increases user interaction by enabling the administrator to monitor the condition of the servers, check the status of the balancer through log files, and set to disable mode for the balancing features at the specific faulty servers.

The SDN controller has been analyzed in the load balancing method for network performance evaluation, which is based on three simulated scenarios. Scenarios A, B, and C each used a number of servers and multiple clients connected to the servers to produce a different outcome, which is based on the delay, jitter and throughput. The network administrator is able to modify the SDN controller settings in a less expensive and more user-friendly way for a better network performance.

Further investigation on algorithms based on the field of artificial intelligence are needed to reduce the complexity of implementing SDN load balancing in enabling autonomous scheduling and intelligent routing functions.

# An Efficient Productive Feature Selection and Document Clustering (PFS-DocC) Model for Document Clustering

## Document Clustering using PFS-DocC Model

Perumal Pitchandi

Department of Computer Science and Engineering  
Sri Ramakrishna Engineering College, Coimbatore, India

**Abstract**—In mining, document clustering pretends to diminish the document size by constructing the clustering model which is extremely essential in various web-based applications. Over the past few decades, various mining approaches are analysed and evaluated to enhance the process of document clustering to attain better results; however, in most cases, the documents are messed up and degrade the performance by reducing the level of accuracy. The data instances need to be organized and a productive summary have to be generated for all clusters. The summary or the description of the document should demonstrate the information to the users' devoid of any further analysis and helps in easier scanning of associated clusters. It is performed by identifying the relevant and most influencing features to generate the cluster. This work provides a novel approach known as Productive Feature Selection and Document Clustering (PFS-DocC) model. Initially, the productive features are selected from the input dataset DUC2004 which is a benchmark dataset. Next, the document clustering model is attempted for single and multiple clusters where the generated output has to be more extractive, generic, and clustering model. This model provides more appropriate and suitable summaries which is well-suited for web-based applications. The experimentation is carried out in online available benchmark dataset and the evaluation shows that the proposed PFS-DocC model gives superior outcomes with higher ROUGE score.

### I. INTRODUCTION

With the vast expansion towards the web and Internet applications along with the growth of mobile phones leads to the growth of enormous textual information [1]. This drastic explosion of data generation not only produces mess over document clustering and summarization. This complexity is not only encountered by the humans' but also by the machines which lag in processing the massive data generated from various sources like (applications, technologies, and organizations) [2]. The evaluations towards the huge amount of data are generally non-structural and quite a challenging task. The drastic eruption of documents over the web necessitates the path for document clustering and summarization process [3]. It attempts to give a shorter version of documents by maintaining the necessary information. The extensive insight of data makes the

researchers to take appropriate decision by document clustering [4]. Thus, document clustering turns to be an essential approach in the growing world.

The document clustering or summarization helps in attaining a wider insight towards the data and offer decision making process [5]. For example, various social media applications like Facebook, Twitter and so on are used for personal causes for political and marketing purposes [6]. Recently, most of the political campaigns are made over these social media sources all over the world to reach the supporters in various regions. Therefore, the process of extracting the textual data is essential for successful political and marketing strategies [7]. Various real-time applications of document clustering are not constraint with these political and marketing strategies. For example, it is also employed for compressing the content for searching the outcomes over search engines along with the keyword for direct subscription towards the application [8]. Moreover, a proficient document clustering process over social media resources can preserve the user's trust relies on navigation among various contents [9].

The document summarization process includes huge challenge and the preliminary attempt is performed in 1950's when it uses features like phrase and word frequency to extracting essential sentences [10]. It is also considered as a huge demand in the field of research owing to its applicability. The finest way of summarization has to preserve the preliminary factors while assisting the users to have better insight towards the enormous volume of data in a faster manner [11]. The preliminary idea behind document clustering is to gather the more essential information in a clustered or with a compressed manner for certain tasks/users [12]. The clustering is also depicted as the gathering of data instances or the shortest document version which is gathered from the machine to attain most essential information is specific manner without human interventions. Moreover, the foremost definition is provided by [13], as 'text is gathered from one or more documents that provides essential information based on the source content and provides the shorter version of it'. Based on this definition, there are three different factors that have to be concentrated: 1) clustering can be done with one or more documents; 2) clustering should preserve the essential parts of original content and 3) clustering have to gather the

original source content without any reduction or alteration with original content [14].

There is various classification of document clustering process. Moreover, the process of document summarization is partitioned as: abstractive or extractive manner. The former model is to understand the textual content of the document profoundly and expresses the text in shorter manner. Subsequently, the target is to extract the document content to choose the most essential information [14]. It is extremely harder for the machine to generate the clustering of multiple documents which is smoother and understandable by the humans. In common practise, extractive approaches are generally used. From the various categories of document clustering process, recently, learning approaches are used for various documents clustering process [15]. The extractive process can be either supervised or unsupervised. In the former model, the problem is based on binary classification where the classes are defined with the summary; similarly, in the latter model, the ultimate target is to attain representative sentences. This research proposes a novel Productive Feature Selection and Document Clustering (PFS-DocC) model which is beneficial to handle the supervised and unsupervised challenges in an interpretable way. The anticipated model possesses the following characteristics:

1) Here, the challenges identified in clustering are considered as a single-objective problem. The clustering process attempts to identify the underlying data structure and provides the information for further classification purpose. Therefore, it enhances the performance of clustering algorithm.

2) The features are extracted with dynamical process via selective manner for all clusters. The clustering process should include the weight of the document by label discrimination to cluster the document.

3) The sentences are chosen in a way that it produces the clustering process in a non-redundant and coherent manner. The complex documents are placed at the top while remaining sentences are selected to gather the essential information with the redundancies.

The proposed Productive Feature Selection and Document Clustering (PFS-DocC) model obviates the requirement of feature engineering in a document clustering. Even though, the most crucial phase over learning process in feature selection and extraction, various work concentrates in sentence clustering process. In recent time, various attempts to make to predict the optimal feature set for clustering process. This process considers the feature relevance as binary issues, that is, whether the features are attained from feature patterns. The overview of the Productive Feature Selection and Document Clustering (PFS-DocC) model is shown in Section 3. The samples of the document are chosen based on the feature vectors. The final outcomes need to similar group of samples with the features of similar group. The weighted features show similar features with clustering. In document clustering process, these clusters specify whether the document is efficient. The preliminary contributions of this clustering process are given below:

1) This work introduces the theoretical model based on productive manner. Here, a novel concept is the process of document clustering. This model facilitates the process of clustering the documents which helps in choosing the document. More specifically, the process of designing the clustering model is to measure the document sentences by labelling '0' and '1', respectively.

2) The proposed Productive Feature Selection and Document Clustering (PFS-DocC) model have the ability to measure the significance of the features by class discrimination which is clustered with various dataset over the reported dataset.

3) Here, evaluation is done with online available dataset to compute the clustering process in an efficient manner. It validates that the clustering process is less redundant and possess more information in a competitive manner.

4) Also, based on the comparison with prevailing approaches, Productive Feature Selection and Document Clustering (PFS-DocC) model gives added advantages which are less interpretable. It clearly states that the process tracks the cluster of document which is essential to explain the decision performed by the end-users.

## II. RELATED WORK

Document clustering is considered as an unsupervised approach for semantic clustering with the similar documents. The embedded documents are determined as a vector space and predict the neighbours over the space along with the clustering model based on word extraction which is extensively utilized. There are various investigations that enhance the performance with cluster initialization and automatic parameterization. Moreover, these approaches consider that all the provided documents are autonomous and do not determine the relationship strength among them. The document clustering model helps to get rid of various limitations that determine the relationship along with the document significance which is extensively investigated.

Network-based document clustering [16] is determined based on the interconnection among the documents and carry out document clustering based on network characteristics. It is depicted as the graphs that comprises of vertices related to the edges. Based on this analysis, generally it is considered as the vertices pair related with the edges to project semantic relationships. Then the assumption is based on the link strength and authority over the provided documents measured and the documents are clustered based on provided parameters [17]. This document clustering model performs hyper-linked web document classification based on academic papers and society, and citations. These approaches are utilized to demonstrate the semantic relevance among the news [18]. Therefore, it employs various kinds of meta-data and applied to various document ranges. This model is utilized to link a document that relies on content. It inter-connects various shared words with preliminary text documents. Therefore, documents are clustered relies on dependent association among the prevailing network; even in case of meta-data with absolute completeness.

The process is formally defined to carry out network-based document clustering. Kusner et al., [19] depicts network based document clustering formally with probabilistic generative model and utilized to cluster the documents. Therefore, the modelling of probabilistic generative model is anticipated and not applicable for multi-label clustering where the document is provided for multiple clusters. Moreover, the model is not suitable for various domains which encounter highly complex documents like certain documents and mobile applications which are allocated to multiple clusters [20]. Based on various analyses, network based document clustering offers multi-labelling process. Here, neighbourhood graph-based weighted matrix is used to evaluate the relationship strength among the documents with clustering process, concept factorization, and matrix factorization [21].

Moreover, diverse ranking models like search rank over search engines, paper classification and hubness value process which are utilized to compute the link strengths and document significance between the documents [22]. Hubness values are extensively utilized for evaluating the document significance. For instance, HITS and PageRank approaches are used for analysing the flow of web pages to search the documents and allocate higher value authorization to possess enormous number of inter-links [23]. Thus, these approaches are adopted over various documents and assigns higher authority values with huge amount of inter-links. Moreover, these approaches are considered to be the favourable older documents and assigns low authority values for all the newer documents. Thus, meaning-based search engine is adopted to handle these issues and projects the meaning-based information with document significance and un-important factors [24]. Thus, it enhances the processing speed.

Thus, search engine based significant ranking documents are based on semantic relevance and concentrates on internal meaning information [25]. The limitations over these methods are extremely prone for abusing which specifies internal inclusion of essential irrelevant words in context to actual documents. Based on various approaches, the proposed model makes use of document significance with indices that are autonomous independently with the document content like number of downloads over the mobile apps [26]. The given model preliminarily reduces the abuse by handling these issues over the network-based document significance examination.

The embedding documents are considered as the conversion of documents which includes word set with latent vectors [27]. It is utilized to evaluate the distance among the provided documents and consequently clusters the similar documents during document clustering model [28]. This model is extensively utilized for embedding document techniques which is composed of inverse document frequency and term frequency, topic modelling approaches termed as Latent Dirichlet allocation [29]. Various investigators consider document clustering by adopting topic modelling document embedding with k-means algorithm. The functionality of topic modelling is enhanced using the measure of documents

with network modelling. This enhanced model uses document clustering.

Additionally, various researches are underway with word/document embedment with neural network approaches. The representative NN model is composed of word2vec which identifies the similar words form the input words. Similarly, Doc2vec predicts the word that offers the input document. In recent times, Doc2Vec, LDA, and TF-IDF are adopted to include the documentation [29]. The performance of document-clustering process is improved with the adoption of semi-supervised approaches that include the construction of initial-clusters which relies on words and enhances the similarity among the documents over the provided clusters via learning process. Word2Vec-based documents are used to predict, classify, and visualize social network neighbourhood [30]. Subsequently, embedding algorithm is alike of word2vec with certain exception and identifies the neighbourhood indeed of context words. In this research, a novel Productive Feature Selection and Document Clustering (PFS-DocC) model is proposed to reflect the document significance based on feature selection and document clustering. This model provides better performance based on consistent document information, document meta-data, and information clustered with input document. It is explained in the section given below.

### III. METHODOLOGY

This research model includes three different processes: pre-processing, feature selection, and summarization. The evaluation is done with MATLAB environment using DUC 2004 dataset. The comparison is done with various metrics like accuracy, precision, F1-score, recall, ROUGE 1 and ROUGE 2 score. Also, the evaluation is done with DUC 2003 and DUC 2004 benchmark dataset. An extensive analysis is done with a proposed Productive Feature Selection and Document Clustering (PFS-DocC) model. Fig. 1 depicts the block diagram of proposed PFS-DocC model.

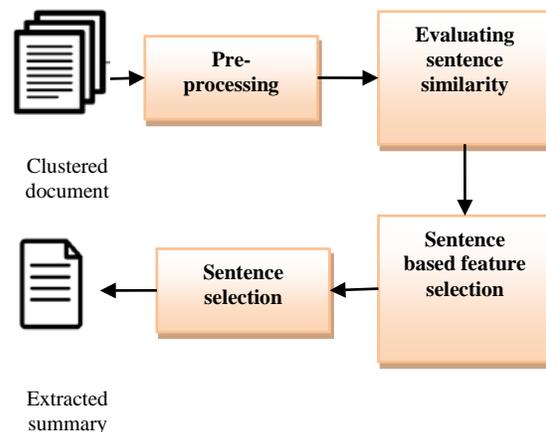

Fig. 1. Block Diagram of Productive Feature Selection and Document Clustering (PFS-DocC) Model.

### A. Dataset

The DUC 2004 uses paper documents, newswire from TDT and TREC collections. The data is used for training, summarization exploration from the produced by machine translation. The task involves summarization by question and represents various tasks. The official ROUGE measures of DUC 2004 were 1-gram, 2-gram, 3-gram, and 4-gram and longest sub-string scores. The manual summarization is used for running ROUGE was provided to available participants. Thus, the truncated summaries longer than the targeted length before evaluation and generates summaries lesser than target length. The maximal target length was depicted based on bytes (punctuation, whitespace, and alphanumeric) included. The maximal target length for short summaries was 75 bytes. The shorter summaries are 665 bytes.

### B. Pre-processing

The data (document) pre-processing is composed of linguistics, tokenization which provides a mathematical mode. It transforms the document content into sequence of terms which avoids punctuation and carries out removal of stop word ('a', 'an', 'in', 'etc.') are removed. There are enormous numbers of stop words.

### C. Productive Clustering

The target of adopting productive clustering is used as a process of information retrieval. The user needs to scan the provided descriptors for relevancy measure and demonstrate that the clusters are relevant by manual processing of various document instances. The iterative process uses multiple stages of productive clustering to assist user for predicting the appropriate documents. The initial clustering is provided with description or clusters to the users who selects clusters of own interest. The text instances over the chosen clusters are merged and clustered. This process is continued with appropriate set of documents. The automatic description of quality is crucial for facilitating users to predict which clusters the relevant text.

The productive clustering is performed by initially clustering and predicts the set of features related with cluster. It facilitates appropriate clustering algorithm (see Algorithm 2) to be adopted. The chosen features provide best information to the users based on the users' content (cluster). The preliminary process is to demonstrate the clusters with likely words over the cluster. But, the features are not optimal for establishing discrimination among various clusters. The scoring criterion includes information gain (mutual information).

### D. Feature Selection

For the provided clusters, the prediction of instances from the input clusters handle the conventional classification problem and selection of appropriate feature subset is more essential. The selection of smaller subset with maximal feature prediction is a complex task. In smaller feature subset, step-wise similarity measure is carried out to enhance the classification performance. The model should fit with the features which cannot scale the features that are encountered with the textual data. The proposed model should trace number amount of features. The feature selection process has

to ensure the process by positive correlation with target class, that is, feature occurrence rate of provided class which is higher than average rate.

---

#### Algorithm 1: Evaluating sentence score for similarity measure

---

**Input:** Array of sentences

**Output:** Similarity scores

1. Average weighted matrix  $[n][n]$ ;
  2. Scores  $[n]$ ;
  3. for  $i \rightarrow 1$  to  $n$  do;
  4. for  $j \rightarrow 1$  to  $n$  do;
  5. predict = identity - similarity ( $s[i], s[j]$ );
  6. Average similarity matrix  $[i][j]$  = average value (id);
  7. end
  8. end
  9. score = id (average similarity matrix);
  10. return scores;
- 

The productive clustering model is composed of two preliminary tasks: identifying the original occurrence of features based on cluster allocation and identifying the instances of certain cluster with smaller feature dimensionality set that functions as the cluster descriptions. This task offers an objective to automatically choose from clustering with various numbers of clusters. The cluster is related with various feature distributions with lesser frequency instances over the clusters. When the instances are allocated with similar cluster have same feature distribution where the cluster allocation is productive of feature occurrence. The successive task is the prediction of clustering membership with dependency over the selected clusters. The total information attained by clustering increases with clusters; however the complexity of finding the cluster membership increases with the fine-grained clusters. Also, the added numbers of clusters are more inherent and provide better trade-off among the number of features and prediction performance. The traceability process needs to be performed with number of available clusters and features for multi-document clustering process. The feature selection model is evaluated and chosen for candidate set.

In cluster creation process, the set of probable clusters are generated that varies from the total number of clusters which arises from various clustering process or various data specification. For all clusters, the model is trained to find the feature occurrence from allocated clusters. The association among the clusters are more productive. The feature subsets are chosen based on the selection mechanism. Specifically, feature subsets are predicted with positive constraints by changing regularization process. Every stage is allocated with standard modelling like clustering and model selection.

The productive framework is provided by allocating clusters that gives flat clustering. The clustering process is effectually executed with sparse data when the similarity among the data is utilized and changes the number of clusters to generate set of clustering process  $\phi = \{\phi_1, \dots, \phi_K\}$ . Here, various clustering process are chosen from the feature vectors that are attained from cluster assignments. The probability of the feature set occurrence is provided with cluster assignment  $\mathbf{y} = [\mathbf{y}^{(1)}, \dots, \mathbf{y}^{(C)}]$  which is expressed as in Eq. (1):

$$\text{prob}(X = 1|y) = \frac{1}{1+e^{(-X_0)}} \quad (1)$$

The above equation is expressed with binary features where  $X_0$  is bias compactness with coefficient of parameter vector  $u' = [x_0, x]$  and constant features are added with cluster allocation. The cluster is a supervised learning problem which includes both feature selection and training process. The cluster  $c \in \{1, \dots, C\}$  with feature subset prediction is expressed as in Eq. (2):

$$\arg \min E[\text{Loss}(x^{(c)}, \hat{y}^{(c)}) + \alpha \Omega(w^{(c)})] \quad (2)$$

Here,  $w^{(c)}$  is weighted co-efficient for providing the feature ranking with original cluster vectors. The feature constraints are related with the clusters positively. The feature subset reduces the computational cost of the provided model. For the provided cluster, the probability instances are allocated with the cluster as conditional random variables. It is expressed as in Eq. (3):

$$\text{prob}(Y = 1|x) = f_{w'}(x) \quad (3)$$

It is provided as the bias compactness with the integration of co-efficient and constant which is included at the feature vectors. The minimization problem with appropriate solution is expressed as in Eq. (4):

$$\arg \min_{w'} -\ln L(w') + \frac{\tau}{2} \|w\|_2^2 \quad (4)$$

Generally, the features are related with various non-zero coefficients. The equivalent constraints provide solution when the coefficients are zero. It is shown in Eq. (5):

$$\arg \min_{w'} -\ln L(w') + \gamma \|w\|' \quad (5)$$

Here,  $\gamma$  influences the number of features with non-zero co-efficient where the larger value of  $\gamma$  which yields better solution with non-zero co-efficient. These non-zero co-efficient are provided with chosen features. The suitable feature subsets are determined by sweeping the  $\gamma$  values. The feature subset and the weighted co-efficient are used to choose appropriate feature subset. Consider a feature subset  $S_1, \dots, S_j$  for certain cluster and optimal feature subset is chosen with Eq. (6):

$$\hat{j} = \arg \min -\ln L(w_j) + |S_j| \ln \sqrt{n} \quad (6)$$

Here,  $S_j$  is set of features that do not include feature subset. The coefficients are generated from the provided subset. The bias value sometimes influences the chosen subsets. The numbers of interpretable features are stable over the sample size variations. In practical condition, the feature subsets are restricted based on the size. The user needs to deal with enormous features to demonstrate the clustering process. Sometimes, the limit may reduce the productive performance; also it reduces the computational complexity with number of feature subsets during evaluation process. The analysis is done with publicly available dataset. The anticipated model is based on set of predictive features. The numbers of features are restricted with positive correlation among the clusters and classes. The positive constraints are provided based on classification performance.

For the computation of cluster predictions, here f1-score is used for individual clusters or classes where the summarization is resulted with the average of computed F1-score. The data instances are allocated with multiple clusters and not allocated with various available clusters. The instance possesses equivalent weight among distributed among the assigned values. The un-allocated instances are determined based on the valid group of added clusters. The mutual information is extracted from the discrete variables partitioning. The computation is done with automatic selection of total clusters whether the numbers of clusters correlate the maximal information content. The major drawback associated with existing approaches is the evaluation of multi-modal distributions of all features with higher computational complexity  $O(N^2)$ . The redundancy elimination is done with candidate features by setting the divergence among the multi-modal distributions. The scalability is done with the features of higher score over the targeted clusters.

This work concentrates in computing the appropriate selection of number of clusters with the Productive Feature Selection and Document Clustering (PFS-DocC) model. This model enhances and maximizes the information attained by the clustering algorithm. The experimentation is done to compute the information among the original clusters and the chosen clusters are varied based on proportional cluster number. The productive document clustering facilitates both the number of features and clusters which is utilized to determine the cluster. The user needs to select appropriate range data clusters with computational feasibility. The user needs to enhance the range of more optimal clustering process. The anticipated model is utilized to any data with weighted features. The productive  $r$  with productive features and cluster assignment is prediction with feature subset. The outcomes are attained based on the every cluster with minimal amount of feature subset which is essential to identify the instances that belongs to certain clusters. The productive clustering model is used to predict the cluster membership of given document. The relevance of the proposed PFS-DocC model is efficient to give higher amount of information with reduced data redundancy. The section below discusses the numerical outcomes attained with the analysis of proposed PFS-DocC model.

IV. NUMERICAL RESULTS AND DISCUSSION

The performance of the proposed Productive Feature Selection and Document Clustering (PFS-DocC) model based on clustering, information extraction, and non-redundancy and overall processing is evaluated. Some metrics like accuracy (%), recall (%), F1-score (%), and precision (%) are measured. For this evaluation, online available DUC 2004 dataset is a generic model for document clustering. It includes 50 clusters of new documents. These clusters include the summaries of various human references which are considered by the researchers for extracting the outcomes. It is essential to set the length of document clusters. The clusters over DUC 2004 organize 665 bytes where the pre-processing step is extremely needed for accuracy evaluation. Here, some essential pre-processing steps are performed with text documents. Generally, the documents are processed to predict the document source information from textual components. The initial process needs to eliminate the information tags such as <TEXT>, <DOC>, and so on for processing the documents.

The experimentation performance is measured with evaluation toolkit known as ROUGE which is a recall based evaluation metrics. It computes the efficiency of document clustering for evaluating the summaries generated by the humans. The ROUGE score evaluates the number of successive terms. After the completion of pre-processing steps, the similarity measures among the sentences are evaluated using the proposed Productive Feature Selection and Document Clustering (PFS-DocC) model. The probability occurrences of the words from the input clusters are used to identify the productive words. The clusters are summarized with the clusters over the dataset. The outcome of the discriminant analysis is measured with metrics like True Negative (TN), True Positive (TP), False Positive (FP), and False Negative (FN) are known as correct predictions with negative samples, correct prediction with positive instances, incorrect prediction with positive samples, and incorrect predictions with negative instances, respectively. It is expressed as in Eq. (7) - Eq. (10):

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{7}$$

$$F1 - score = 2 * \frac{Precision*Recall}{(Precision+recall)} \tag{8}$$

$$Recall = \frac{TP}{TP+FP} \tag{9}$$

$$Precision = \frac{TP}{TP+FP} \tag{10}$$

The simulation is carried out in MATLAB environment. Here, six different methods along with the Productive Feature Selection and Document Clustering (PFS-DocC) model are compared. The six methods are FLSA (ProbIDF), FLSA (Normal), FLSA (IDF), FLSA (Entropy), LDA, and LSA respectively. Similarly, metrics like Accuracy (%), F1-score (%), Recall (%), and precision (%) is evaluated. The accuracy of proposed Productive Feature Selection and Document Clustering (PFS-DocC) model is 98.9% which is 1.9%, 7.9%, 3.9%, 1.9%, and 38.9% higher than the prevailing methods. The F1-score of PFS-DocC is 99% which is 29.7%, 27.6%, 1.3%, 3.5%, 7.8%, and 1.3%, respectively. The recall of PFS-

DocC is 99% which is 27%, 26%, 4%, 6%, 10%, and 4% higher than the other models. Similarly, precision of PFS-DocC is 99% which is 33%, 30%, 4%, 6%, 10%, and 4% higher than other models. All these process includes 50 topics. It is shown in Table I. Fig. 2 depicts the performance metrics evaluation. Fig. 3 depicts the F1-score computation.

TABLE I. COMPARISON OF PERFORMANCE METRICS

Methods	Accuracy (%)	F1-score (%)	Recall (%)	Precision (%)	Topics
FLSA (ProbIDF)	97	69.3	72	66	50
FLSA (Normal)	91	71.4	73	69	50
FLSA (IDF)	95	97.7	95	95	50
FLSA (Entropy)	97	95.5	93	93	50
LDA	60	91.2	89	89	50
LSA	57	97.7	95	95	50
PFS-DocC	98.9	99	99	99	50

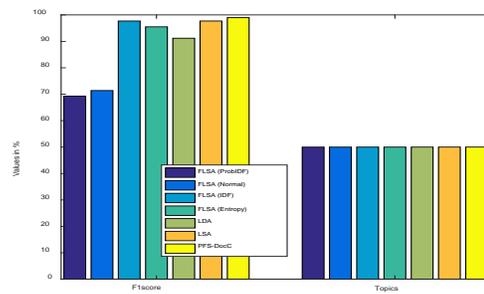

Fig. 2. Performance Metrics Evaluation.

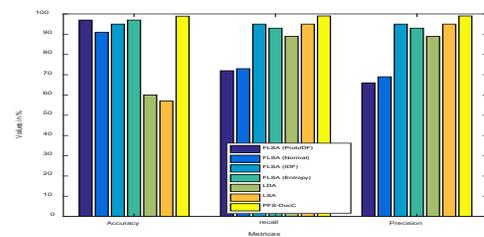

Fig. 3. F1-Score Computation for 50 Topics.

Table II depicts comparison of ROUGE 1 score and ROUGE 2 score with the evaluation toolkit. The comparison is done for ExDoS, Banditsum, HSSAS, summaRunner, NN-SE, LEAD-3, and PFS-DocC respectively. Rouge 1 score is 45 which is 3%, 4%, 3%, 6%, 10%, and 6% higher than other models. Rouge 2 score of PFS-DocC is 2%, 1.9%, 3%, 4%, 7%, and 4.7%, respectively. Finally, Rouge L score of PFS-DocC is 39 which are 4%, 7%, 4%, 2%, 1.5%, and 1% higher than other models (see Fig. 4). Table III shows the amount of information extracted, non-redundant, overall percentage achieved. PFS-DocC based information extraction is 30%; however for other approaches it is 27%, 23.5%, 20.5%,

17.6%, 13.5%, and 13% respectively (see Fig. 5). The avoidance of non-redundant data from PFS-DocC is 25% where the other data is 22.5%, 22.6%, 16.5%, 19.5%, 21%, and 23% respectively (see Fig. 6). The overall performance of PFS-DocC w.r.t information extraction and non-redundancy avoidance is 27%; whereas for other models it is 25%, 18.5%, 21.6%, 16.8%, 20.8%, and 22%, respectively.

TABLE II. ROUGE SCORE EVALUATION

Methods	Rouge 1 score	Rouge 2 score	Rouge L score
ExDoS	42	18.5	35
Banditsum	41	18.6	32
HSSAS	42	17.5	35
SummaRunner	39	16.5	37
NN-SE	35	13.5	37.5
LEAD-3	39	15.8	38
PFS-DocC	45	20.5	39

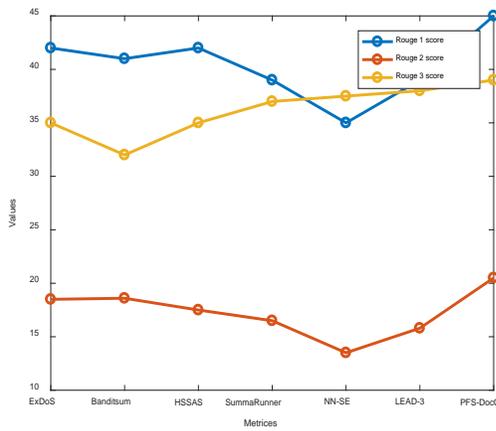

Fig. 4. ROUGE Score Computation.

TABLE III. INFORMATION EXTRACTION AND NON-REDUNDANCY PERCENTAGE

Methods	Information extraction	Non-redundancy	overall
ExDoS	27%	22.5%	25%
Banditsum	23.5%	22.6%	18.5%
HSSAS	20.5%	16.5%	21.6%
SummaRunner	17.6%	19.5%	16.8%
NN-SE	13.5%	21%	20.8%
LEAD-3	13%	23%	22%
PFS-DocC	30%	25%	27%

Table IV depicts the comparison of PFS-DocC without feature extraction is done with benchmark datasets, like DUC2002-ROUGE 1, DUC2002-ROUGE 2, Main-ROUGE 1, Main-ROUGE 2, DUC2004-ROUGE1, and DUC2004-ROUGE 2. The values of PFS-DocC (without feature extraction) are 53, 26.7, 42.5, 19, 55, and 57 respectively. Similarly, the values of PFS-DocC are 46, 22.5, 39.7, 15, 50, and 53 respectively (see Fig. 7 and Fig. 8).

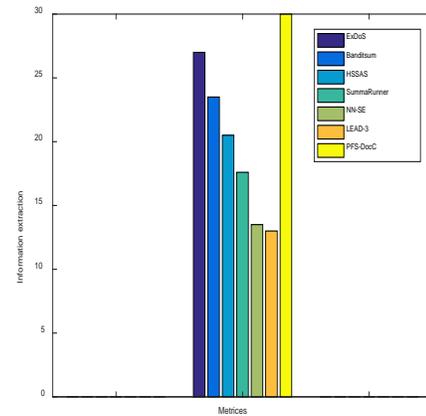

Fig. 5. Information Extraction.

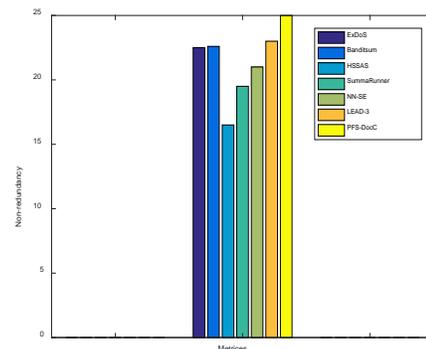

Fig. 6. Non-Redundant Data Extraction.

TABLE IV. PFS-DOCC COMPARISON (WITH / WITHOUT FEATURE SELECTION)

Methods	DUC2002-ROUGE E 1	DUC2002-ROUGE E 2	Main-ROUGE E1	Main-ROUGE E2	DUC2004-ROUGE E 1	DUC2004-ROUGE E 2
PFS-DocC	53	26.7	42.5	19	55	57
PFS-DocC + feature extraction	46	22.5	39.7	15	50	53

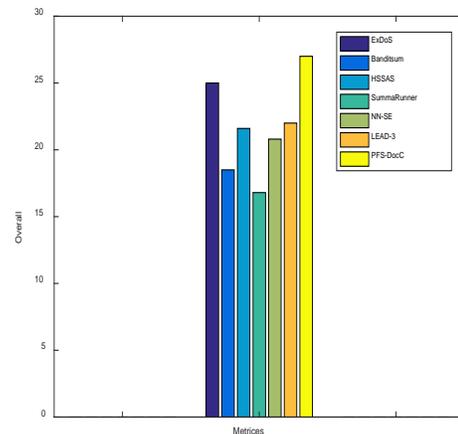

Fig. 7. Overall Performance Measure of PFS-DocC.

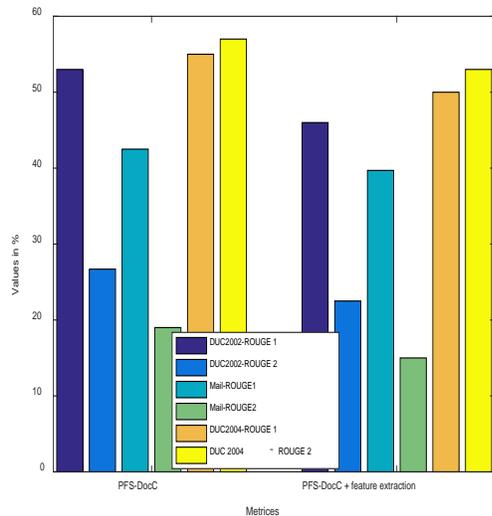

Fig. 8. PFS-DocC Performance (with / without Feature Extraction).

The similarity score is examined based on the sentence that is extracted from the central score. Initially, the document clusters are converted to connected sentence using various similarity scores. Based on the experimentation, the proposed PFS-DocC model enhances the summarization process attained from document clustering. After the extraction process, the sentences are provided with high score and include the summary length. It is essential to improve the extracted sentences which do not possess any redundant information. Therefore, to diminish the redundancy over any sentences with the similarity measure of extracted summary the proposed PFS-DocC is used.

## V. CONCLUSION

This research concentrates on proposing a novel Productive Feature Selection and Document Clustering (PFS-DocC) model with three essential steps that includes background knowledge, pre-processing, feature selection, and summarization (clustered document). It is to enhance the performance of the proposed PFS-DocC model. Here, DUC 2004 online available dataset is used for evaluation. The input from the dataset is given for pre-processing and further process is carried out. The similarity and the correlation among the clustered document are examined and summarized to extract the essential features for provided document. Therefore, the proposed PFS-DocC model enhances the performance of the clustering algorithm. The simulation is done with MATLAB environment.

The performance of the PFS\_DocC model is evaluated with the adoption of DUC 2004 benchmark dataset. The performance is measured using the ROUGE score toolkit. Various metrics like accuracy, F1-score, recall, and precision are measured for PFS-DocC model with 98.5% accuracy and 99% F1-score, recall, and precision. The outcome of the proposed PFS-DocC model is higher when compared to other approaches like FLSA (ProbIDF), Prob (Normal), FLSA (IDF), FLSA (Entropy), LDA, and LSA respectively. Similarly, the comparison is done with two benchmark dataset

known as DUC 2003 and DUC 2004 for evaluating the performance of PFS + DocC with and without feature selection process. Also, the information extracted and the non-redundant data evaluation is also done for the PFS + DocC model. The performance show better trade-off in contrast to prevailing approaches. However, there is a constraint, as the proposed PFS + DocC model does not provided for classification. It will be concentrated in future along with the optimization process.

## ACKNOWLEDGMENT

I thank the Management, Principal and Head of the department to support and provide the resources to carry out this research work.

**Abstract**—This paper proposes an approach that leverages real-time Image Classification to improve elevator safety. Elevators are a necessity for most multi story buildings. As a result, they play a crucial role in the lives of millions of people around the world. Despite this, there has been limited advancement in the technology used for elevator door operators. In the current system, elevators use multiple infrared transmitter/receiver pair of sensors to detect obstructions between the doors. This does not effectively detect smaller objects such as pets, small children, pet leashes etc. between the elevator doors which has led to thousands of tragic fatalities. This paper proposes an approach to tackle this challenge by leveraging Binary Image Classification to determine whether there is an obstruction between the elevator doors. This study includes the construction of a novel dataset of over 10,000 images and a comprehensive evaluation and comparison of several Machine Learning models for the proposed system. The results have produced novel findings that can be used to significantly improve safety and reliability of elevator door operators by preventing tragic fatalities every year.

**Keywords**—Binary image classification; machine learning; deep learning; elevator safety

## I. INTRODUCTION

In today's world, there are millions of multi-story buildings across the globe. Not only do elevators improve the convenience of vertical transportation, but they also play a vital role in providing accessibility for people with disabilities. It is clear that elevators have become a necessity in our daily life. It is estimated that the door operator works approximately 1.75 million times in 10 years [1].

In the early 2000s elevators were fitted with a retractable door edge such that if the elevator door came in contact with a person or obstruction while closing, the doors would stop closing. Modern elevator door operators use non-contact detection device which includes a photoelectric detection device, ultrasound monitoring device, red light curtain detector, electro-magnetic induction detector, and other inputs to detect obstructions between the doors [2]. However, many cases have shown that such technology has limitations when detecting small obstructions such as leashes, pets or children [3]. Because of this inefficiency, there are thousands of fatalities every year. Despite the widespread use of this elevator technology and the serious consequences of its inefficiencies, there has been limited research on the technology used for elevator door controllers. Although there has been growing

interest in developing Smart Buildings and Smart Cities, elevator door control remains an underexplored research area. There is a large scope to use modern techniques from computer vision and artificial intelligence to improve the existing elevator door control technology in a cost-effective manner. Widespread implementation of such improved systems has the potential to save lives and prevent injuries. This paper seeks to tackle the aforementioned challenge of improving the reliability and efficiency of elevator door operators.

Machine learning and image classification techniques – to the best of our knowledge – have not yet been used to address the challenge of improving the safety and reliability of elevator door operators.

The contribution of this paper is to:

- Propose a system that leverages machine learning and image classification techniques to overcome the shortcomings of existing elevator door control operators.
- Construct a novel dataset of over 10,000 images which serve as input to the proposed system. The images are captured by simulating the 8 positions along the top and sides of the elevator car door. Brightness augmentation is performed to improve the robustness of the system in different daylight conditions.
- Evaluate and compare the speed and efficacy of several machine learning models, namely Linear SVC, k-NN, Decision Tree, Random Forest, and CNN.
- Identify the most suitable classifiers for the proposed system based on the results of this study.
- Assess the feasibility of the proposed system based on the results of this study.

This paper proposes an approach to address the problem of elevator door operator obstruction detection to improve safety of the passengers entering and exiting the elevator in real-time.

The following section describes related research works followed by a description of the materials and methods. This includes details regarding the dataset construction, proposed system, models considered and evaluation metrics. Then the results of the study are presented. This is followed by the conclusion and future scope of the paper.

## II. RELATED WORK

In “Discussion on Improving Safety in Elevator Management”, [4] Feng ShuanChang et al. discuss the need to improve elevator technology given its direct relation to people’s lives. The authors also elaborate on the complexity of the elevator user unit and the lack of ownership for elevator maintenance among stakeholders which often leads to neglect of elevator safety.

Magota et al. [5] improve the opening-and-closing speed control of the elevator doors using ILQ design method with frequency shaping. The authors focused on developing a smoother and quicker elevator door control system rather than addressing the challenge of efficient obstruction detection.

Zeng et al. [6] propose the use of the atmega32 control chip and ov7620 image acquisition chip to tackle this challenge. The authors adopt an image processing-based approach by implementing Semi-Neighborhood Averaging Algorithm and Background Difference Method on the image pixels to identify the moving obstruction.

Various systems have been proposed in existing literature to predict the failure of elevators based on knowledge graphs [7] and neural networks [8]. Yanbin Guo et al. [9] propose a system to monitor the elevator for the most common faults based on multi-sensor fusion. This system includes a web client to view the live reports of the system and a camera to monitor the passengers inside the elevator car.

Amruthnath and Gupta [10] research the use of unsupervised machine learning algorithms, such as hierarchical clustering, k-means and fuzzy c-means, for predictive maintenance of elevators.

In “Machine Learning Modelling for Failure Detection of Elevator Doors by Three-Dimensional Video Monitoring” [11] Chih-Yu Hsu et al. propose a method for detection of elevator failure by using three-dimensional video monitoring. This method involves extracting the signal from the dynamic distances between elevator doors and modelling by trapezoidal curves. The failure detection is done by identifying these dynamical signal curves of the elevator doors using trained classifiers.

Wan et al. [12] study the use of least square support vector machine for diagnosing elevator various malfunctions using vibration signals from the elevator functions. The authors optimize the parameters of LS-SVM using K-fold cross validation.

Mishra and Huhtala [13] propose an algorithm to extract highly information features from the elevator data which is used to improve fault detection. This algorithm uses profile extraction and deep autoencoder feature extraction on the dataset.

The use of big data for fault warning of the elevator system has also been explored [14] [15]. Ming Zihan et al. [16] propose an alternate method for monitoring the elevator system by leveraging IoT.

Olalere and Dewa [17] employ a remote condition monitoring (RCM) approach for proactive maintenance of elevators. This approach uses vibration and machine-room temperature data acquired through IoT devices. Systems to protect passengers from the accidental movement of the elevator car have also been proposed in previous research [18] [19].

With the prevalence of big data, data mining technology and artificial intelligence have shown great promise in detecting the failure and evaluating the risk of elevators [20]. Wang et al. [21] study the use of Hadoop to design the data mining and analysis platform. The authors also use Hadoop to improve and parallelize the K-means and Apriori algorithms to mine the massive amounts of data from the elevator monitoring database.

A majority of existing research investigates the use of modern technology to improve maintenance of the elevator by remotely monitoring the overall elevator system for signs of faulty behavior or damage. However, related works do not address the shortcomings of existing elevator technology in effectively detecting obstructions between the doors.

In this paper, we tackle the aforementioned shortcomings by proposing a novel approach that leverages binary image classification to efficiently detect obstructions between the elevator doors. An image dataset of over 10,000 images was constructed to simulate the working of the proposed system. Several image classifiers were built, evaluated and compared on both the augmented and original image datasets.

## III. MATERIALS AND METHODS

### A. Dataset

The dataset was collected by simulating the 8 camera positions, as shown in Fig. 1, using a functional elevator in a multi-story building. This consisted of two cameras positioned at the top view of the elevator and 3 cameras at equidistant positions along each elevator car door. Each camera recorded videos of the various obstructions passing through the elevator car doors. Every fifth frame was extracted from the videos to compile the image dataset. The code to perform this frame extraction is displayed in Fig. 2. Each image was manually labelled as either ‘Obstruction’ or ‘No Obstruction’.

Brightness augmentation was performed on the images to simulate various lighting conditions. Thereby, improving the robustness of the obstruction detection at different hours during the day. Each image was augmented using 12 different brightness factors ranging from 0.5 to 1.6 as shown in Fig. 3. The code used to perform augmentation is displayed in Fig. 4. Grayscale augmentation was also explored however it had minimal effect on the performance of the binary image classification models. The images were divided into two datasets, namely side view images and top view images. A sample of the side view and top view images are shown in Fig. 5 and 6 respectively. The images captured have a size of 1,280 x 720 pixels as well as a horizontal and vertical resolution of 96 dpi. Each dataset is fairly balanced, as shown in Table I. The total size of both datasets together is 10,836 images.

### B. Proposed System

The elevator car carries riders between the floors of a multi-story building by moving up and down in the elevator shaft. Most elevators are automatic and do not have any personnel present to operate the elevator. Elevators have two doors, one fixed to the frame, mounted on the wall and one attached to the elevator car. When the elevator reaches the destination floor and parks, both of these doors open synchronously.

Fig. 5. Sample Side View Image.

Fig. 6. Sample Top View Image.

TABLE I. IMAGE DISTRIBUTION IN THE DATASET

View	Label	Number of Images
Side View	No Obstruction	4,128
Side View	Obstruction	3,204
Top View	No Obstruction	1,848
Top View	Obstruction	1,656

The proposed obstruction detection system will use 8 digital cameras as input devices. This includes three cameras mounted along each side of the elevator car door and two cameras mounted at the top of the elevator frame. Using multiple cameras located at various positions provides different views/perspectives of the obstruction passing through the elevator doors. This improves the effectiveness of the proposed system for detecting small or narrow objects which is a significant advantage over existing elevator door control technologies.

These cameras will capture images periodically every few milliseconds. These images are processed by the hardware and software system mounted in the elevator cars. Each image is passed to a pre-trained image classifier. The pre-trained model will perform binary image classification to determine whether there is an obstruction between the elevator doors. The proposed system will have two separate models for top view classification and side view classification respectively. By leveraging binary image classification using machine learning and deep learning, the proposed system will be able to detect obstructions with high accuracies in real-time.

If an obstruction is detected, then the signaling mechanism is triggered and a signal will be sent to the door controller to stop and reverse. Each camera has an LED light fastened next to it. If an obstruction is detected one of the images captured, the light next to the corresponding camera will turn on to notify the passengers about where the obstruction is detected. This also helps simplify the maintenance of the proposed system. If there is no obstruction detected, then the closing process will continue. The system continues to monitor for any obstructions until the gap between the elevator doors is too small to capture a digital picture. The methodology of the proposed system is illustrated in Fig. 7.

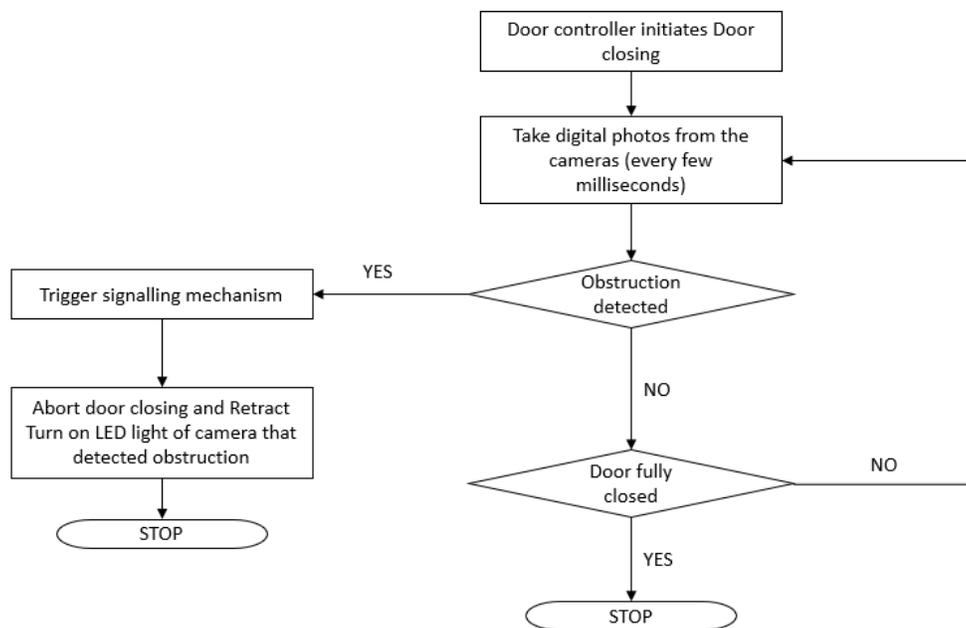

Fig. 7. Methodology of Proposed Elevator Obstruction Detection System.

### C. Models

Several machine learning and deep learning models were built and evaluated to determine the most suitable model for the proposed system. These classifiers were chosen based on their ease of use, solid performance, and popularity in related works which leverage binary image classification for real-world applications.

1) *Linear SVC*: Linear Support Vector Classifier (SVC) is a supervised machine learning algorithm. It can be used for both regression and classification challenges. In this paper, Linear SVC is used for image classification. The data points are plotted in the n-dimensional space and the algorithm identifies the best fit hyperplane which divides the data into categories.

2) *k-NN*: The k-Nearest Neighbours (k-NN) classifier has proven to be an effective classification model on numerous occasions. This model uses the labelled training data to predict the output. The predicted value is determined as the majority in the 'k' nearest neighbours. For the k-NN classifiers in this paper, k=3.

3) *Decision Tree*: Decision Tree (DT) is an algorithm which has a flowchart-like tree structure. The leaves of the tree represent the target or outcome variables. In this case, the leaves can take the value 'Obstruction' or 'No Obstruction'. The decision tree classifiers implemented in this paper have a depth of 3.

4) *Random forest*: Random forest is a combination of multiple tree classifiers where each tree is based on independently sampled random vector values. Since it consists of multiple trees, it is called a forest. While this algorithm requires more computational power and time than decision trees, it helps improve the accuracy and reduce overfitting.

5) *CNN*: Convolutional neural network (CNN) is a type of deep learning algorithm which establishes learnable biases and weights to various aspects in an input image in order to differentiate one from another. The CNNs implemented in this paper have the classic architecture as a Sequential model with Convolution layers, Pooling layers and ReLU layers.

### D. Evaluation

The speed and correctness of the predictions made by the classifier are crucial to determine which models would be suitable for the proposed system. The computation time of each model for test data prediction was calculated in seconds. Various metrics, namely accuracy, precision, recall and F1 score, were used to evaluate and compare the performance of the models.

In this paper, the binary classification task is defined such that each image is classified as either 'No obstruction' or 'Obstruction'. The True Positive (TP) attribute of the confusion matrix is defined as the number of images which contain an obstruction and were classified as 'Obstruction' by the model. Similarly True Negative (TN) is the number of images which contain no obstructions and were classified as 'No obstruction',

False Positive (FP) is the number of images which contain no obstructions but were incorrectly classified as 'Obstruction and False Negative (FN) is the number of images which contain obstructions but were incorrectly classified as 'No obstruction'

These confusion matrix metrics were used to calculate accuracy, precision, recall and F1 score. Accuracy is the number of correctly classified images over the total number of images. Accuracy is calculated using all four of the aforementioned components of a confusion matrix (1).

$$\text{Accuracy} = \frac{TN+TP}{TN+FP+TP+FN} \quad (1)$$

Precision is the ratio of true positives to all positives. It gives greater importance to false positives. A precision value closer to 1 indicates that the model is performing well. Precision is calculated using the True Positive and False Positive attributes. (2).

$$\text{Precision} = \frac{TP}{TP+FP} \quad (2)$$

Recall is a very important evaluation metric for the proposed system because it assigns more weightage to false negatives. A false negative in the proposed system means that the obstruction is present but it is not detected by the model. As a result, the doors will close normally and the person may be injured. Thus, it is crucial to minimize the number of false negatives. Recall is calculated using the True Positive and False Negative attributes. (3).

$$\text{Recall} = \frac{TP}{TP+FN} \quad (3)$$

F1 score is defined as the weighted average of precision and recall (4). If the F1 score is closer to 1, it indicates that the classifier has performed well.

$$\text{F1 score} = 2 * \frac{\text{Precision} * \text{Recall}}{\text{Precision} + \text{Recall}} \quad (4)$$

The models were built and evaluated separately for top view image classification and side view image classification.

## IV. RESULT AND DISCUSSION

The models and algorithms elaborated in the previous section were implemented and compared. Table II provides a detailed summary of the performances of each model for top view image classification. It can be seen that the k-NN model performed the best out of all the classifiers with an F1 score of 0.994 and accuracy of 99.8%. This was followed closely by the CNN model which had an accuracy of 98.9%. Among the models implemented on the original image dataset, both the Linear SVC and Random Forest models performed remarkably well with the same accuracy of 98.6%. All of models performed well with respect to the considered evaluation metrics.

Table III provides a detailed summary of the performances of each model for side view image classification. It can be seen that the k-NN and CNN models performed the best with accuracies of 99.8% and 99.3% respectively. Among the models implemented on the original dataset, k-NN performed the best with an accuracy of 95.4%.

TABLE II. MODEL EVALUATION AND COMPARISON FOR TOP VIEW CLASSIFICATION

Model Name	Dataset	Accuracy	Precision	Recall	F1 Score
Linear SVC	Top View images (Original)	0.986	0.99	0.98	0.99
k-NN	Top View images (Original)	0.973	0.98	0.97	0.97
Decision Tree	Top View images (Original)	0.945	0.94	0.94	0.94
Random Forest	Top View images (Original)	0.986	0.99	0.98	0.99
Linear SVC	Top View images (Augmented)	0.967	0.97	0.96	0.97
k-NN	Top View images (Augmented)	0.998	1.00	0.99	0.994
Decision Tree	Top View images (Augmented)	0.957	0.96	0.96	0.96
Random Forest	Top View images (Augmented)	0.977	0.98	0.98	0.98
Model Name	Dataset	Accuracy			
CNN	Top View images (Augmented)	0.98.9			

TABLE III. MODEL EVALUATION AND COMPARISON FOR SIDE VIEW CLASSIFICATION

Model Name	Dataset	Accuracy	Precision	Recall	F1 Score
Linear SVC	Side View images (Original)	0.93	0.94	0.92	0.93
k-NN	Side View images (Original)	0.954	0.96	0.95	0.95
Decision Tree	Side View images (Original)	0.797	0.84	0.78	0.78
Random Forest	Side View images (Original)	0.856	0.90	0.84	0.85
Linear SVC	Side View images (Augmented)	0.967	0.97	0.96	0.97
k-NN	Side View images (Augmented)	0.998	1.00	0.997	0.998
Decision Tree	Side View images (Augmented)	0.859	0.88	0.85	0.85
Random Forest	Side View images (Augmented)	0.889	0.91	0.88	0.88
Model Name	Dataset	Accuracy			
CNN	Side View images (Augmented)	0.993			

The speed of each classifier was evaluated and compared in seconds as shown in Fig. 8 to 11. The speed is the computation time for classifying the test data. This is an important metric for the proposed system since the classifier must be able to identify whether or not an obstruction is present in the captured image in real-time. The computation times of the models were measured for top view classification and side view classification separately. Top view classification refers to classifying the images captured by the two cameras positioned at the top of the elevator. Side view classification refers to classifying the images captured by the 6 cameras positioned along the sides of the elevator car door. The speed of each model was also measured separately for the original dataset and augmented dataset. It can be seen that the Decision Tree model consistently performed with the lowest computation time followed by the Random Forest model. However, there is a trade-off between speed and correctness of predictions as the Decision Tree classifier had the poorest accuracy among the models considered.

In this study, a novel system design which leverages state-of-the-art machine learning techniques to detect obstructions between elevator car doors is proposed. Furthermore, an end-to-end analysis of its feasibility is presented which includes construction of a dataset of over 10,000 images, implementation of several modern binary image classifiers, and

a thorough evaluation of model performances. This work advances the literature on improving elevator safety. The proposed system is designed to address the shortcomings of current elevator technology [2] by facilitating more effective detection of small and narrow obstructions through real-time image input. The use of machine learning techniques for elevator door control is – to the best of our knowledge – new. In contrast, a majority of existing works on improving elevator safety focus on detecting [9] [13] [14] [15] [20] and predicting [7] [8] elevator failure. Certain studies [6] focus on detecting only moving obstructions between elevator car doors whereas, the proposed system facilitates the detection of both moving and stationary obstructions.

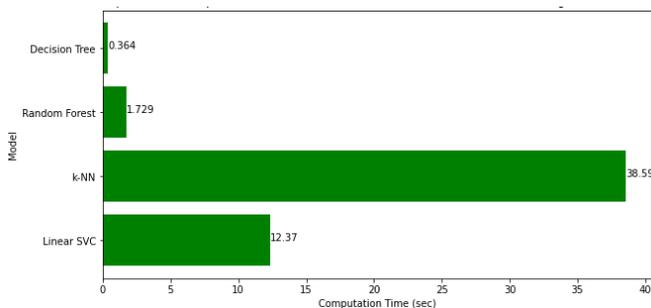

Fig. 11. Comparison of Computation Times for Side View Classification of Test Data (Augmented Dataset).

## V. CONCLUSION AND FUTURE WORK

Despite the widespread interest in the development of Smart Cities and Smart Buildings, very little advancement has been made in the technology used for elevator door operators. This paper proposes a novel elevator obstruction detection system that leverages modern technology such as binary image classification models, to improve the safety of elevators by effectively detecting smaller or narrower obstructions. This paper presents findings based on the evaluation and comparison of different binary image classification techniques for the purpose of obstruction detection. The considered models include Linear SVC, k-NN, Decision Tree, Random Forest, and CNN. A dataset was created through simulation of the proposed system using a functional elevator in a multi-story building. Brightness augmentation was used to improve the robustness of the models in different lighting conditions. The results of this paper show that it is feasible to develop the necessary models to perform image classification for the proposed system with high accuracies in real-time. All of the

models performed well with respect to the considered evaluation metrics. The k-NN and CNN models had the highest accuracies for both datasets. However, the k-NN model had one of the highest computation times, indicating that the CNN model may be more suitable for the proposed system. While the Decision Tree model had the lowest computation time, this model also resulted in the lowest accuracy when compared with the performances of the other classifiers considered.

The work presented in this study can be extended to include the storage of the images captured to further improve the performance of the model. The use of different machine learning and image processing algorithms can be explored. Additional data can be collected to increase the size and improve the quality of the dataset.

Improving the safety and reliability of elevators presents itself as an underexplored research area with the potential to have a positive impact on millions of lives around the world. With the continuous advancement in the field of machine learning, computer vision and artificial intelligence, the scope of this paper is vast. The results of this paper can be used to improve the safety of elevators by leveraging the efficacy and immense capabilities of modern technology.

## ACKNOWLEDGMENT

The authors would like to thank the institution Vellore Institute of Technology, Chennai for its constant support and for providing a conducive learning environment.

**Abstract**—The study's purpose is to create an LMS model that is adapted to the characteristics of university students to enhance the learning experience by utilizing various multidimensional learning resources in Cyber Pedagogy. This research and development study used the Analyze, Design, Develop, Implement, and Evaluate (ADDIE) instructional design framework as well as the Waterfall system development model to develop learning materials and infrastructure. The study involves 50 students from the Bali Institute of Technology and Business, as well as five lecturers and six judges at the expert test stage, namely learning media experts, learning design experts, and teaching experts, who were chosen through purposive sampling. The SMILE Model (Simple, Multidimensional, and Interactive Learning Ecosystem) is designed to meet the learning needs and expectations of today's largest market share of higher education, the millennial generation. The SMILE Model was developed successfully with ongoing assistance from researchers' students, particularly in the E-Tourism course. The implementation is accomplished through the combination of university E-Learning and the use of Microsoft Teams as a virtual learning platform alternative. During the COVID-19 pandemic, this was considered the new face-to-face norm.

**Keywords**—ADDIE; cyber pedagogy; e-learning; higher education; learning management system

## I. INTRODUCTION

The purpose of this research is to develop a web-based Learning Management System (LMS) model which is termed "SMILE" (Simple, Multidimensional, and Interactive Learning Ecosystem). SMILE can be accessed by utilizing a variety of browsers on mobile devices and desktop computers. SMILE is expected to help students understand learning in a more entertaining way, as well as provide a different approach to millennial generation learning activities to improve their performance.

The SMILE consolidates constructivism learning theory as well as cyber pedagogy. The principles of constructivism theory that underlie the SMILE model include how students construct their own knowledge, with the readiness of knowledge gained through real-world experiences, collaborative activities, reflection, and interpretation, with activities that allow students to have different understandings of knowledge and perspectives in interpreting it. Despite the fact that the SMILE model incorporates Cyber Pedagogy principles, each student has completed independence in

accessing multiple learning resources from any location, at any time, and in a variety of ways. Learning occurs in a multi-directional, egalitarian, inclusive, and non-bureaucratic manner, with interaction and feedback made available only when requested, both formally and informally, and students have complete control over the learning and teaching processes [1]. There are three actors (users) of the SMILE application who have varying levels of access, namely administrators, lecturers, and students. They will get a username and password to access the SMILE application and its features online.

Pyöriä, Ojala, Saari, & Järvinen discovered that the Millennial Generation, which is the current market share of higher education, may not be as homogeneous in fundamental learning strategies and attitudes as is frequently proposed; regardless of their general character traits in learning, there is no evidence that these traits affect their fundamental learning process. Many curricular strategies have been implemented to address alleged changes in the learning styles of Millennial students. Nothing has clearly demonstrated superior results in academic achievement or skill development for graduates, and there are concerns about Millennial student engagement in the learning process [2]. Furthermore, Conklin's research emphasizes the importance of student experience by establishing classrooms that encourage millennial learner autonomy and teachers who value their students' perspectives and experiences [3]. Problem-Based Learning (PBL), Student-Centered Learning (SCL), and Classroom as Organizations (CAO) all require learners to recognize and respect the ideas, thoughts, feelings, and relationships of other learners during the learning process by participating in learning experiences that other learners have made available to them [3]. Self-evaluation of their ideas may be considered. Learning experiences that are not conducive can undermine our efforts to stimulate students.

## II. LITERATURE REVIEW

### A. Cyber Pedagogy

"Cyber pedagogy" refers to the science or art of teaching in an online environment. Cyber Pedagogy focuses on motivations and teaching methods that are appropriate for the technology being used, rather than those that are best suited to the traditional face-to-face classroom context [1]. The Principles of Cyber Pedagogy include the following:

\*Corresponding Author.

- Each participant has access to an extensive set of resources that promote learning as an individual in a 24-hour environment.
- Procedures toward the source of learning are common, with many of them taking place solely, and in different ways.
- Internet resources are available dynamically and are constantly updated.
- The learning process is naturally spontaneous, contextual, and critical.
- Learning can come in different forms in an inclusive, equitable, and bureaucracy-free environment.
- Feedback and interaction are done formally and informally only when requested.
- Formal evaluations can be obtained at any time and in a number of ways.
- Participants in the learning process have complete control over the teaching and learning processes.

Indrajit also stated that universities should implement student-centered learning, where knowledge transfer is focused on students as part of Cyber Pedagogy and students have complete control over the learning process. In order for it to work, students must construct and reconstruct knowledge. When learning is integrated into an activity, it is most effective, and student experience produces outcomes that significantly improve learning. Student mentors direct, guide, and monitor students as they use all available Internet learning resources to ensure proper and optimal use [1].

#### B. Learning Management System in Higher Education

Each university's learning management system (LMS) is tailored to its specific needs. LMS development has made use of free (open source) production sites like Moodle, Sakai, and others, as well as systems developed by institutions themselves according to their own concepts. To name a few, below are some examples [4].

- Andrew Ng and Daphne Koller, both computer science professors at Stanford, founded Coursera, an online learning platform, in 2012. Coursera offers Massive Open Online Courses (MOOC), specialization programs, and degree programs in a variety of subjects in collaboration with universities and other organizations [5].
- edX, founded by Harvard University and MIT, is also one of the leading providers of open online courses (MOOCs). Similar to Coursera, edX is a global online course provider focused on students in higher education from a variety of disciplines. edX also offers a number of free courses [6].
- The Directorate General of Learning and Student Affairs of the Indonesian Ministry of Research, Technology, and Higher Education manages the Indonesian Online Learning System, known as SPADA Indonesia, which aims to promote equitable access to quality learning in higher education [7]. SPADA Indonesia enables students from one university to

take specific quality courses from other universities, and their learning outcomes are recognized equally by the college where they are enrolled [7]. Furthermore, Arifin contended that SPADA Indonesia was formed to address some of higher education's challenges, such as the limited capacity of higher education institutions, the low affordability of universities due to uneven distribution, and the fact that many universities still lack adequate and high-quality educational resources.

- The SEAMOLEC Open Learning Center is presented by the Southeast Asian Ministers of Education Organization's (SEAMEO) education research and development center. SEAMOLEC focuses on open and distance education, training, and the exchange of knowledge and resources within and beyond Southeast Asia. The mission of SEAMOLEC is to establish itself as a center of expertise of open and distance education, as well as to assist SEAMEO member countries in identifying educational problems and solutions in human resource development through open and distance education systems [8].

The Learning Management System (LMS) developed is termed SMILE (Simple, Multi-dimensional, and Interactive Learning Ecosystem). It is a Web-based application that can be accessed on mobile devices and computers using various browsers. SMILE is expected to help students understand learning in a more fun way and provide a different environment and approach to maximize student potential.

### III. RESEARCH METHODS

This study utilized the ADDIE instructional design framework, which covers Analysis, Design, Development, Implementation, and Evaluation [9], and the Waterfall system development model to develop learning materials and infrastructure that support students' learning. The Waterfall model, such as the ADDIE model, uses a structured framework for design that relies on completing each stage before going on to the next one. Requirement Analysis, System Design, Implementation, Testing, Deployment, and Maintenance are all part of the process [10]. By combining the two models, the designer's instructional team can perform more simple steps by formulating a cohesive model.

### IV. RESULT AND DISCUSSION

#### A. ADDIE Design Development

1) *ADDIE Model*: According to Eller, the ADDIE Model has a lengthy history dating back to the establishment of teaching system designs and has been continuously improved by a number of scholars and instructional designers. Although structural design and software design are two separate areas, they contain many similarities and intersect in ways that instructional designers, subject matter experts, and educators who utilize the final version might benefit from [9]. Fig. 1 illustrates the ADDIE Model of SMILE.

The Waterfall Method is used in the development of SMILE LMS, so as to organize and integrate all aspects of learning materials and activities. From there, it can be seen that the Waterfall Model intersects with the ADDIE Model. The Waterfall steps are indicated in Fig. 2.

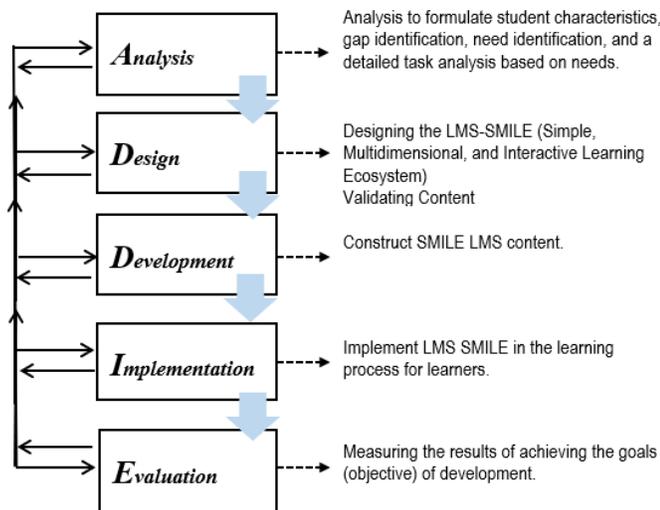

Fig. 1. ADDIE Model of SMILE.

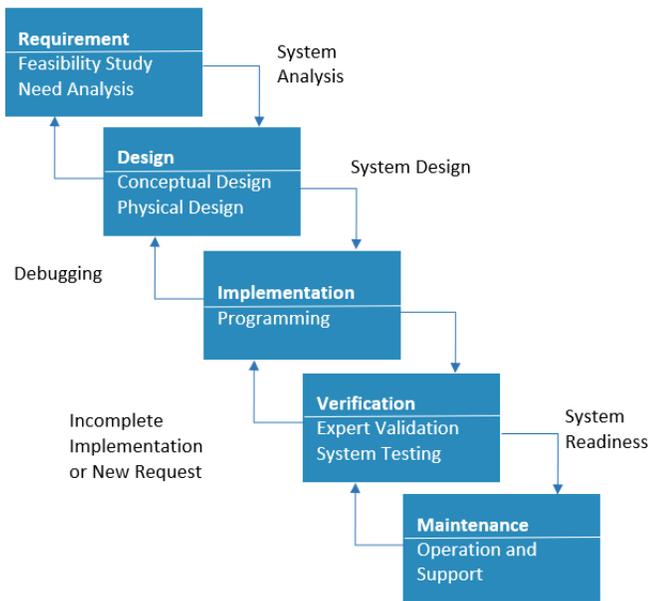

Fig. 2. Waterfall Model.

## 2) The waterfall model

a) *Requirements:* The needs analysis was included in the first stage of the waterfall model, and it involves both practical and non-functional requirements for the development of the SMILE LMS.

b) *Design:* The second stage is the design stage, in which the previous stage's system specification was explored and the system design was indeed prepared. In system design, Flow Diagrams, conceptual databases, and Entity Relationship Diagrams (ERD) are used to help with the overall system architecture concept. Fig. 3 describes an overview of the SMILE Design.

c) *Implementation:* Programming or coding is performed during the system's implementation stage, which is the design's interpretation into a computer-readable language. In addition, the generated program items will be subjected to verification.

d) *Testing:* At this stage, the system testing method of choice is Black Box Testing. It is a test method that involves observing the output results of data or conditions entered into the system without seeing how the data management process works. It is performed from the perspective of the user, enabling the identification of existing problems that can be resolved later.

e) *Deployment:* The SMILE is deployed into a live environment to be tested before being made available to users during this phase. This phase also includes user training programs to help users know how the system works.

f) *Maintenance:* This step involves providing support and maintenance for the SMILE to ensure that it runs smoothly. The main goal of this stage is to fix any errors, defects, or bugs that users encounter while using the Smile. Maintenance tasks include all processes needed to manage system continuity, enhancement, and improvement.

## B. The SMILE Model

The LMS design framework is generally based on the ADDIE learning design model and the Waterfall system development model, which are used as guidance in designing learning materials and infrastructure that support student learning processes. The waterfall model is a method used in software development. The stages begin with analysis, which then proceeds to the stages of design, coding, testing, and support [11]. It can be seen that the waterfall model intersects with the ADDIE model. The ERD of SMILE is shown in Fig. 4, while the conceptual database SMILE is shown in Fig. 5.

Fig. 6 to 11 depict a few of the SMILE user interfaces, including the Login page, User Profile page, Admin's dashboard, Student's Detail page, Lesson Plan page, and the Syllabus page.

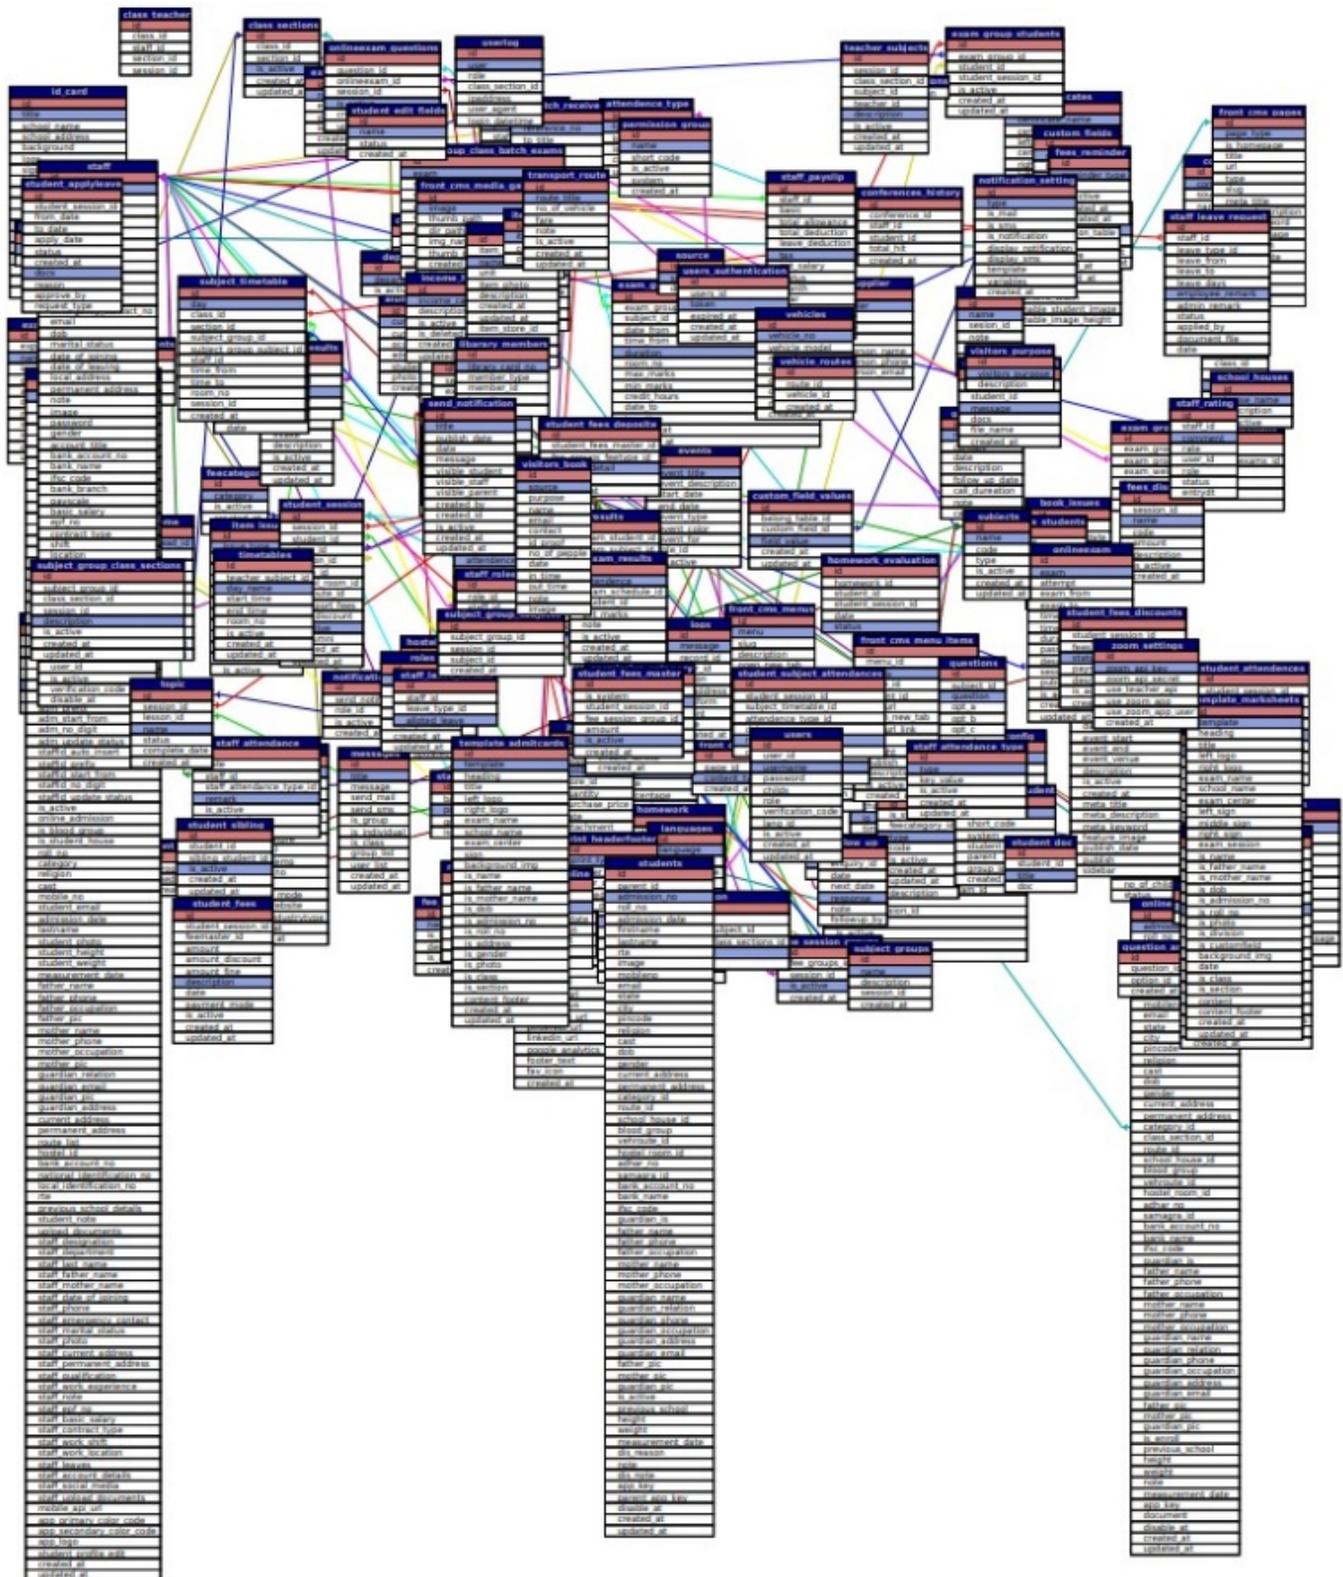

Fig. 5. SMILE Conceptual Database.

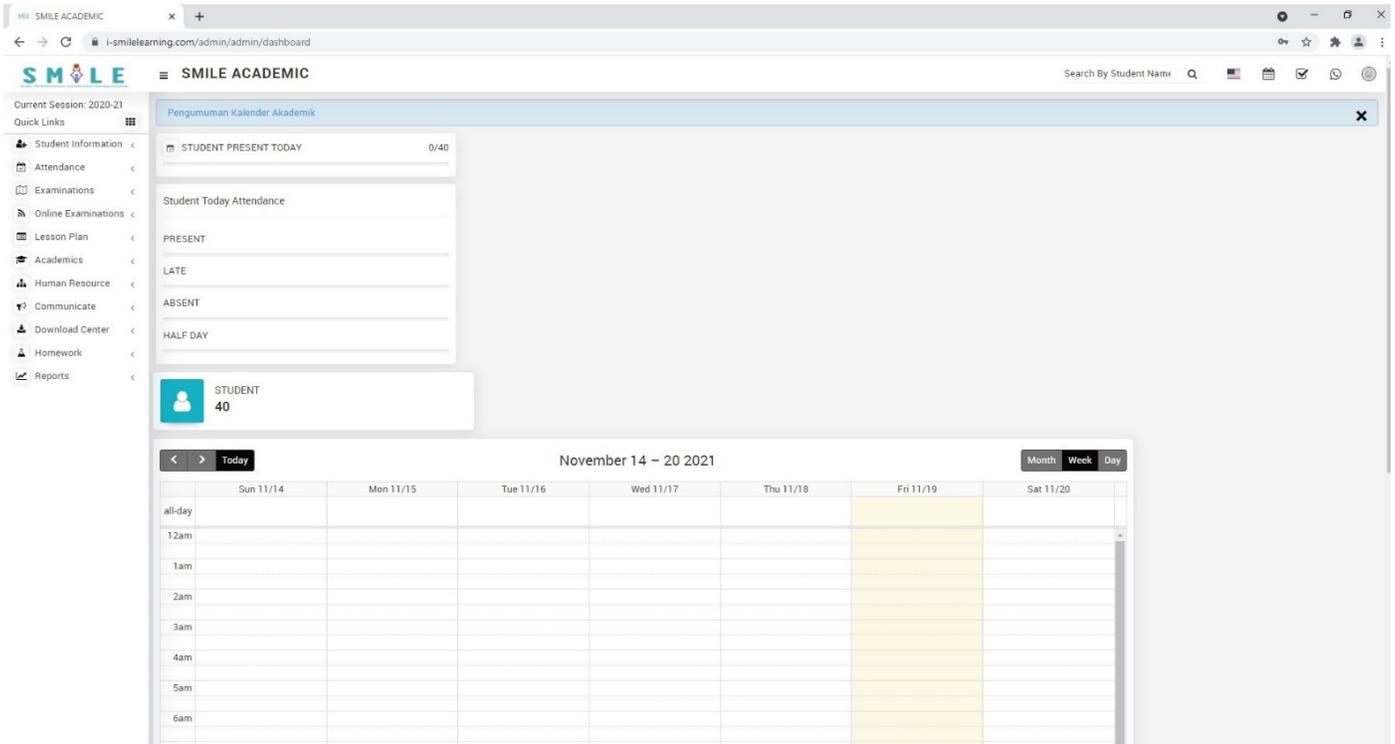

Fig. 8. Admin Dashboard Page for SMILE.

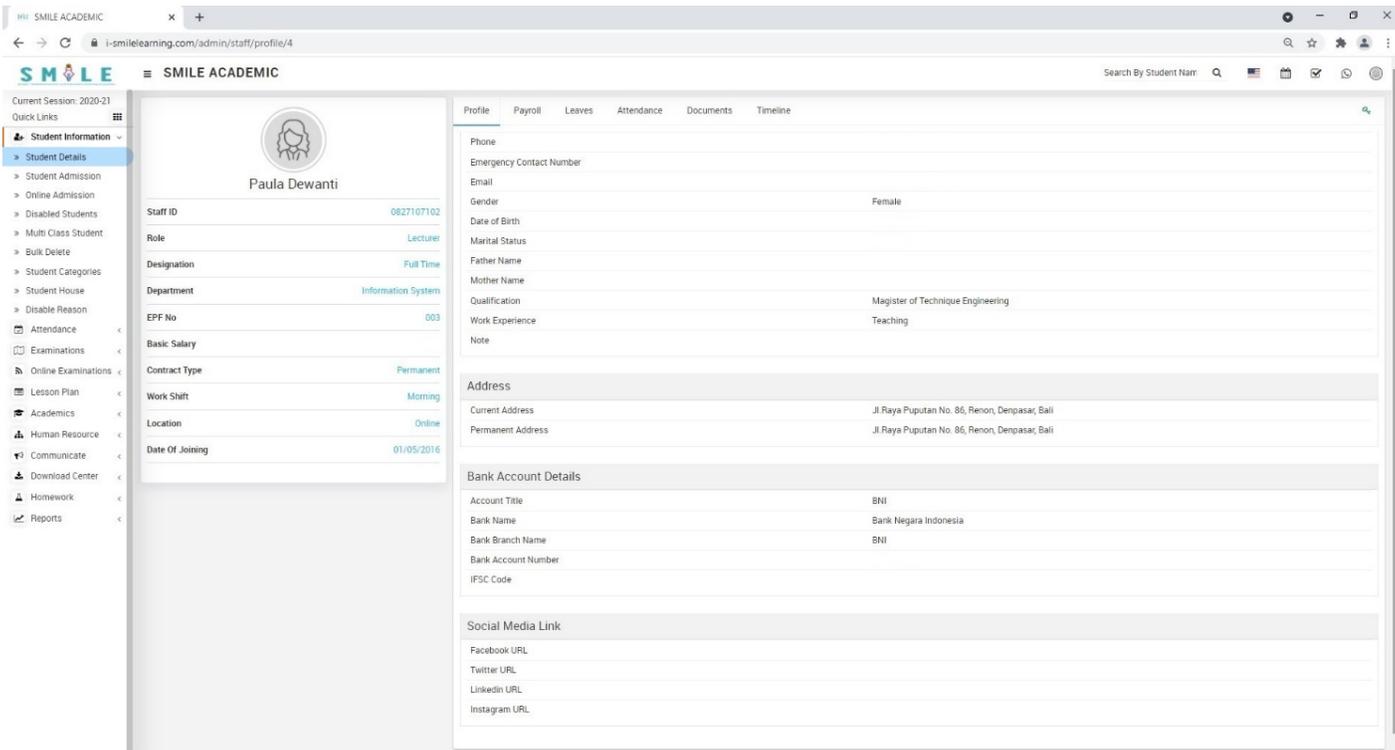

Fig. 9. Student Details Page for SMILE.

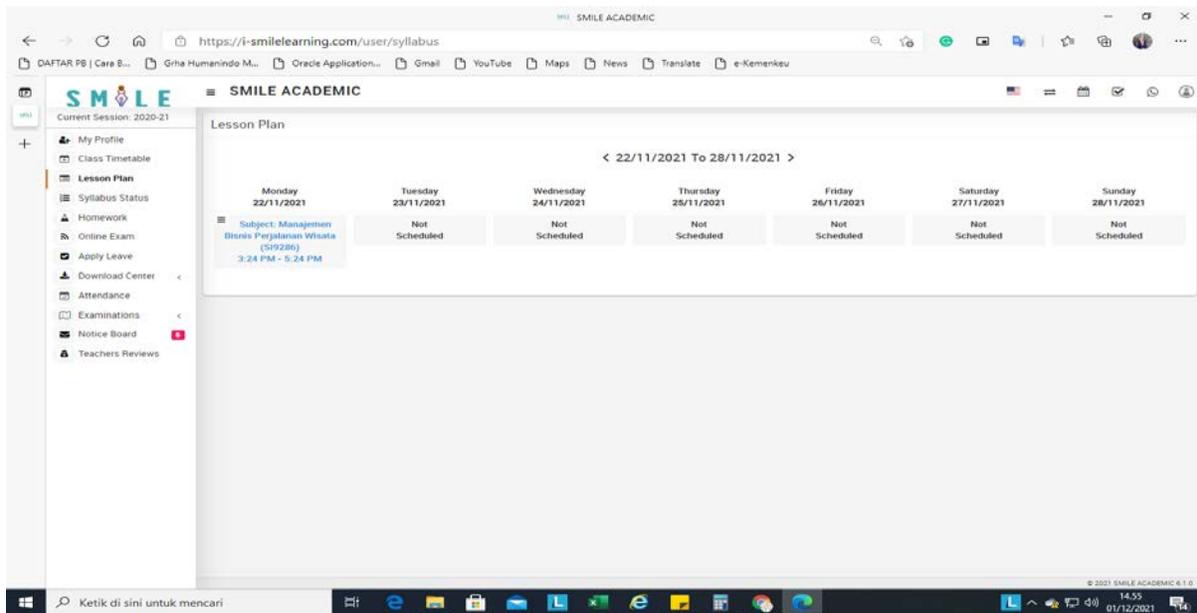

Fig. 10. Lesson Plan Page.

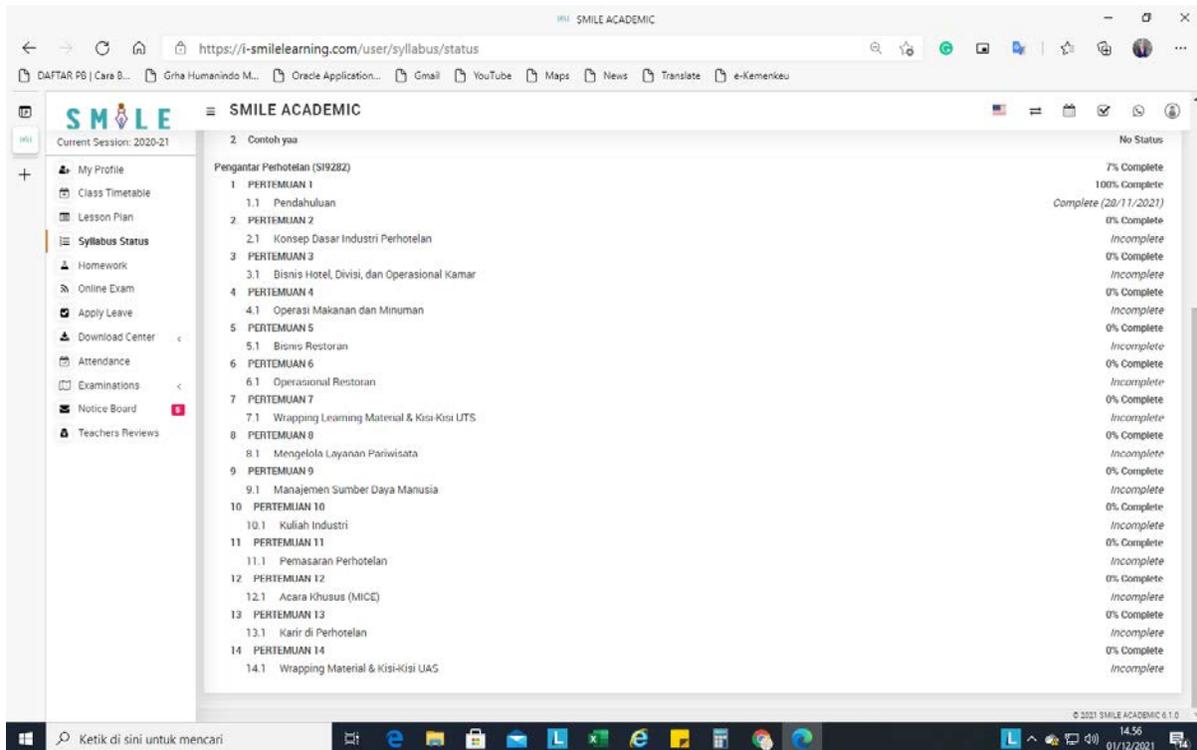

Fig. 11. Syllabus Page.

### C. Experimental Findings

Three material experts and three media experts used an evaluation sheet to assess the content and media validity of SMILE, which was then tested using Gregory's cross tabulation. The evaluation results show that the SMILE Learning Management System meets the requirements for validity. The system's usability was evaluated using questionnaires distributed to students and teachers, as well as observation sheets. The results of the usability tests show that

the developed SMILE Learning Management System meets the expectations of both students and teachers.

1) *Expert findings:* Tables I and II list the instruments and indicators that were measured.

The following steps were taken to obtain the validity data from the assessment by material experts and media experts [13].

TABLE I. LEARNING OBJECT REVIEW INSTRUMENT V. 1.4 [12]

No.	Rated Aspects
1	Content of Quality It is necessary to have veracity, accuracy, a well-balanced presentation of ideas, and an adequate level of detail.
2	Aligning Learning Objectives Learning objectives, activities, assessments, and student characteristics should all be interconnected.
3	Adaptation and Feedback Variability learner input or learner modeling motivates adaptive content or feedback.
4	Motivation Abilities to inspire and evoke interest or curiosity.
5	Design of Presentation Creating visual and auditory information to aid in learning and mental processing.
6	Usability of Interaction The user interface's predictability, ease of navigation, and the quality of the UI that supports features.
7	Accessibility Provide learners' support.
8	Reusability The ability to link various courses or learning contexts without modifying them.
9	Comply with Standards In accordance with international standards and requirements.

TABLE II. CYBER PEDAGOGY INDICATORS [1]

No.	Variable	Indicators
1	Mobility	The process method for learning resources is ubiquitous and can be from anywhere, anytime, and in various ways.
2	Location Awareness	The technology component is capable of providing information about the physical location of the device to other users or applications.
3	Interoperability	Users have the ability to exchange and use information. Learning takes place in a multi-way, egalitarian, inclusive, and non-bureaucratic way. Applications can interact with other applications through a mutually agreed protocol over various communication lines.
4	Seamlessness	Every student can access various learning resources freely and independently 24/7. Internet resources are dynamic, and are updated collectively every second.
5	Situation Awareness	The process of learning is intuitive, contextual, and critical in nature. a) Emotional self-awareness. b) Assertiveness. c) Self-esteem. d) Independence. e) Self-actualization.
6	Social Awareness	a) Effective communication. b) Effective learning.
7	Adaptability	Interaction and feedback can take place when and where it is desired—formally or informally. Evaluation of the learning procedure can be

No.	Variable	Indicators
		performed as many times as necessary.
8	Pervasiveness	Learners have full control over the learning and learning process.

a) To convert qualitative data to quantitative data, apply the Gregory content validity provisions as shown in Table III.

TABLE III. CROSS TABULATION OF THREE RATERS

Rate r I	Irrelevant				Relevant			
	Irrelevant		Relevant		Irrelevant		Relevant	
Rate r II	Irrelevant	Relevant	Irrelevant	Relevant	Irrelevant	Relevant	Irrelevant	Relevant
Rate r III	A	B	C	D	E	F	G	H

<sup>a</sup>. Notes of the Three Raters' Cross Tabulation

- A = The three raters disagree.
- B = Rater I disagree, Rater II disagree, Rater II agree.
- C = Rater I disagree, Rater II agree, Rater III disagree.
- D = Rater I disagree, Rater II agree, Rater III agree.
- E = Rater I agree, Rater II disagree, Rater III disagree.
- F = Rater I agree, Rater II disagree, Rater III agree.
- G = Rater I agree, Rater II disagree, Rater III agree.
- H = The Three Raters are Agree

b) The Gregory Formula is then used to calculate the score to generate the content validity.

$$V_i = \frac{H}{(A+B+C+D+E+F+G+H)} \quad (1)$$

where,

$V_i$  = Content Validity

c) Convert the average score to a qualitative value using the assessment factors listed in Table IV below.

TABLE IV. GUILFORD'S TABLE OF RELIABILITY COEFFICIENTS

Score Range	Classification
$\bar{X} > 0,80$	Very High
$0,60 < \bar{X} \leq 0,80$	High
$0,40 < \bar{X} \leq 0,60$	Moderate
$0,20 < \bar{X} \leq 0,40$	Low
$\bar{X} \leq 0,20$	Very Low

The SMILE LMS instrument has a coefficient of content validity of 1, which is classified as very high based on the conversion of the Guilford table.

2) User Usability Analysis: The Usability Testing method is applied using Nielsen's approach, which is classified into five instruments: learnability, memorability, efficiency, errors, and satisfaction. Using the 5-point Lickert Scale, from strongly disagreeing (1) to strongly agreeing (5). Tabel V shows the result from the lecturer's perspective.

TABLE V. USABILITY ANALYSIS

No.	Assessment Aspects	Likert Scale				
		1	2	3	4	5

A. Learnability						
A1	Learning Management System SMILE can be studied easily.				33.3	66.7
A2	I am pleased with the ease and speed with which information is accepted in detail, as well as with the SMILE Learning Management System in particular.				50.0	50.0
A3	I can easily comprehend the content and information presented in the SMILE Learning Management System.			16.7	33.3	50.0
A4	I can easily understand and comprehend plots from the SMILE Learning Management System's navigation.				50.0	50.0
A5	I was able to learn how to use the SMILE Learning Management System without any written instructions or a manual book.				50.0	50.0
B. Memorability						
B1	I have no trouble recalling how to use the SMILE Learning Management System.				50.0	50.0
B2	I can easily find and remember navigation directions and features on the SMILE Learning Management System.			16.65	16.7	66.65
B3	I find the SMILE Learning Management System easy to use.					100
C. Efficiency						
C1	I can easily access the menu on the SMILE Learning Management System.				50.0	50.0
C2	I can easily obtain the available information on the SMILE Learning Management System.				66.7	33.3
C3	I can quickly find the information I need by starting my search in the SMILE Learning Management System.				66.7	33.3
D. Errors						
D1	I haven't found an error when using the SMILE Learning Management System.			16.65	66.7	16.65
D2	I did not encounter any menu errors or mismatched functions while using the SMILE Learning Management System.				16.7	83.3
D3	In the SMILE Learning Management System, I can quickly locate the features and menus I'm looking for.			16.7	50.0	33.3
E. Satisfaction						
E1	I am pleased with the SMILE Learning Management System's overall interface design.				50.0	50.0
E2	I feel comfortable using the SMILE Learning Management System.				33.3	66.7
E3	The color mix and layout of the				66.7	33.3

	content on the SMILE Learning Management System are convenient to see.					
E4	When I saw the display on the system's dashboard, the SMILE Learning Management System exceeded my expectations.			16.7	33.3	50.0
E5	I found other supporting equipment such as file sharing, communication features such as chat and e-mail, as well as feature support.				50.0	50.0

The same approach was also used against the student's perspective. In the learnability aspect, 50.0% strongly agreed that the Learning Management System SMILE can be easily studied (A1), while the remaining 50% agreed. For (A2), 37.5% stated they strongly agreed, while 62.5% agreed. It follows with (A3) at 50.0% stated strongly agreed and 50.0% agreed. The (A4) got 37.5% strongly agreed, 50.0% agreed, while 12.5% tended to agree. I was able to learn how to use the SMILE Learning Management System without any written instructions or a manual book (A5); 37.5% of the students said they strongly agreed, while 62.5% said they agreed.

From the memorability aspect (B1), I have no trouble recalling how to use the SMILE Learning Management System. It is equally 50.0% between "strongly agreed" and "agreed". The results obtained from the student's perspective are in order: (B2) 37.5% strongly agreed, 50.0% agreed, and 12.5% tend to agree; and (B3) I find the SMILE Learning Management System easy to use; all the students stated that they strongly agreed.

The assessment continued with efficiency aspects; (C1) I can easily access the menu on the SMILE Learning Management System. It was strongly agreed upon by 50.0%, agreed upon by 37.5%, and tended to agree upon by 12.5%. I can easily obtain the available information on the SMILE Learning Management System; 37.5% strongly agreed, 50.0% agreed, with 12.5% inclined to agree. (C3) I can quickly find the information I need by starting my search in the SMILE Learning Management System; 37.5% strongly agreed, 50.0% agreed, and 12.5% tended to agree.

In terms of the errors' aspects, the result shows that 25.0% strongly agreed, 62.5% agreed, and 12.5% tend to agree on (D1). I haven't found an error when using the SMILE Learning Management System. It is followed by (D2). I did not encounter any menu errors or mismatched functions while using the SMILE Learning Management System; 37.5% strongly agreed, 50.0% agreed, and 12.5% tended to agree. On (D3), In the SMILE Learning Management System, I can quickly locate the features and menus I'm looking for, it stated that 37.5% strongly agreed, 50.0% agreed, and 12.5% tend to agree.

The assessment concludes with a satisfaction aspect, generating the following result: (E1). I am pleased with the SMILE Learning Management System's overall interface design. 25% of them strongly agreed, 62.5% agreed, and 12.5% agreed. (E2). I feel comfortable using the SMILE Learning Management System. 37.5% stated they strongly agreed and 62.5% agreed. (E3). The color scheme and layout of the content on the SMILE Learning Management System

are easy to understand. 37.5% strongly agreed, 50.0% agreed, and 12.5% agreed with some reservations. (E4). When I saw the display on the system's dashboard, the SMILE Learning Management System exceeded my expectations; 25.0% stated strongly agreed and 75.0% agreed. (E5). I discovered additional assistive equipment such as file sharing, communication features such as chat and e-mail, and feature support received 50.0% strongly agreed, 37.5% agreed, and 12.5 percent tend to agree responses.

#### D. Relevant Work

The developed Learning Management System (LMS) is identified as SMILE, which stands for Simple, Multi-dimensional, and Interactive Learning Ecosystem. It is designed to assist students in understanding learning in a relatively simple, insightful, and unique way in order to maximize their potential and competencies. It is accessible via mobile devices, personal computers (PCs), and various browsers [4].

McGreal's research outlines the organizational context that motivates the use of Open Educational Resources (OER) in teaching and learning, including policies, practices, development processes, and resources [14].

Meanwhile, Wang, Woo, Quek, Yang, & Liu explored the use of Facebook Groups in LMS development based on the availability of prospective pedagogical, interpersonal, and technical capabilities that enable the exchange of ideas, resources, announcements, and online discussions. Directly uploading files in various formats presents challenges, but this discussion lacks meaningful structure. Students can communicate and interact with one another with ease. Despite this, there is a failure to provide a safe social environment due to a lack of privacy [15].

Shin and Kang used a mobile application-based LMS to conduct research on student acceptance and its impact on learning objectives. Students at online universities, according to their findings, are open to the use of mobile technology as a new learning tool. Acceptance has a direct or indirect impact on student achievement. These findings help to improve our understanding of the use of mobile learning systems in higher education and provide useful guidelines for the development and implementation of mobile application-based learning management systems [16].

Mtebe claims that the use of LMS in universities in Sub-Saharan Africa is expanding, and the majority of the universities' limited resources are being used to develop LMS. Mtebe conducted a review of the literature on LMS use in Sub-Saharan Africa, as well as proposed strategies to assist institutions in using LMS more effectively while saving money [17].

The ideal didactic curriculum, according to Toohey, Wray, Wiechmann, Lin, and Boysen-Osborn, should include a mix of asynchronous and synchronous learning. A Learning Management System (LMS) such as Schoology, Canvas, or Blackboard can manage a Learning Resource Center (LRC) program, which provides students with video menus, interactive education modules, articles, quizzes, didactic recordings, and other assignments. Implementing an LMS in a

residency program can range from free (Schoology) to a per-student fee that may be covered by the university [18].

#### V. CONCLUSION AND FUTURE WORK

In this study, we look at how to design, validate, and determine the efficacy of a learning management system that relies on cyber pedagogy and national educational standards in the higher education e-learning ecosystem. The SMILE Learning Management System model was developed by integrating various learning resources based on the characteristics of the current generation of learners.

Usability testing was used to evaluate the efficacy of the SMILE prototype. The results are consistent with the observed initial objective of delivering a productive learning process in simple, interesting, and interactive ways through the use of various multi-dimensional educational resources inside the corridor of Cyber Pedagogy and National Education Standards.

This research can be enhanced in a number of different ways. This type of prototype can be developed in other universities with features tailored to the needs of each campus, including lecture content that is wide and varied, as well as the use of learning media that is simple to understand and tailored to the needs of students, to support an effective and efficient learning process.

#### ACKNOWLEDGMENT

The researcher would like to express gratitude to all of the students and professors who participated in the study. This research is based on the first author's dissertation, which has been submitted since 2021 at Ganesha University of Education. The researcher sincerely thanks the supervisor, who is listed as a co-author, for their expertise.

# Location-based Mobile Application for Blood Donor Search

Orlando Iparraiguire-Villanueva<sup>1</sup> , Fernando Sierra-Liñan<sup>2</sup> , Michael Cabanillas-Carbonell<sup>3</sup> 

Facultad de Ingeniería y Arquitectura, Universidad Autónoma del Perú, Lima, Perú<sup>1</sup>

Facultad de Ingeniería, Universidad Privada del Norte, Lima, Perú<sup>2</sup>

Vicerrectorado de Investigación, Universidad Norbert Wiener, Lima, Perú<sup>3</sup>

**Abstract**—Technological advances and the massive use of mobile devices have led to the exponential evolution of mobile applications in the health sector. Blood donation centers frequently suffer blood shortages due to lack of donations, which is why blood donation requests are frequently seen on social networks for blood donors in urgent need of a transfusion of a specific blood group. Mobile applications for blood donation are crucial in the health sector, since it allows donors and blood donation centers to communicate immediately to coordinate with each other, minimizing the time to perform the donation process. The present work was to develop a location-based mobile application for the search of blood donors, with the objective of increasing the number of donors, having a greater population reach, and reducing the time to search for blood donors. The results obtained show a significant increase of 39.58% in the number of donors, a reduction of 53.2% in the search time, and a greater population reach.

**Keywords**—Blood banks; location; mobile applications; donor; applicant; blood bank; mobile apps

## I. INTRODUCTION

Donating blood is helping to save the lives of those who need a transfusion in a selfless and supportive way. Worldwide, 118.5 million blood donations are collected, 40% of which are in high-income countries [30]. In Peru, approximately 270 thousand units of blood are needed per year to guarantee the normal supply of this resource in the blood donation centers of the Ministry of Health. In donation campaigns, thousands of units of blood are collected from donors, although much more are needed to meet the demand of applicants [1] [2]. Deterrents and motivations for voluntary blood donation may differ by age and ethnicity [3]. Blood donation centers often suffer from shortages, so it is the applicants who look for their blood donor, often without success, therefore, strategies for effective donor recruitment and retention are required. Blood donation centers still use traditional methods for donor recruitment, such as blood donation campaigns, word of mouth, social networks, etc., although they are still valuable, but they are becoming less and less effective [4]. In addition, the Ministry of Health's blood donation centers work in isolation, without integration with other health institutions, which affects the quality of service. In this context, information technologies and smartphones have become an ally for blood donation [5][29].

The present research proposes the development of a location-based mobile application for blood donor search

(DONAPE), for which the mobile application provides a direct location-based channel between blood seekers and blood donation centers. Achieving to increase the number of donors, improve the place of origin (geographical location) of donors and improve the search time.

The article is organized as follows. Section 2 describes the main related studies that have been conducted in the field of location-based blood donation and mobile technology. Section 3 presents the location-based mobile application development methodology and research method. Section 4 develops the case study. Section 5 describes and analyzes the results. Section 6 presents a brief discussion. Finally, Section 7 presents the conclusions.

## II. REVIEW OF THE LITERATURE

Currently, in order to guarantee the required supply of blood units, it is necessary to focus efforts on donor recruitment and retention. Therefore, it is important to know the characteristics of donors, their motives and deterrents to voluntary donation. In this context, technological progress has played a very important role in blood donation; technology has made it possible to streamline and automate processes. In this sense, a set of works related to the search for blood donors has been reviewed.

In [6] developed a mobile application for Android, which offers a simple and fast approach to searching for blood, where they can easily find donor and recipient data through their cell phones. While researchers at [7][8] developed cloud-based web applications to administer and manage the health system's blood units. These applications allow blood units to be allocated according to the severity of the case, availability of types and quantities. Along the same lines, the research work [9] proposed a method for allocating blood units, using a mobile application, which utilized a real-time hybrid algorithm to develop the blood unit allocation operation. In [10][11] [12][13] web and mobile applications were developed to manage blood donation, allowing to register, schedule, receive notifications and access information, synchronizing blood donation centers with emergency centers, to verify the availability of blood needed and to send a request to the nearest blood donation center.

Web applications for blood donation have also been developed using new technologies such as blockchain and learning algorithms. In [14][15] web applications were developed using blockchain technology, applying machine

learning algorithms to develop and evaluate models for classifying blood donors as returnees and non-returnees. In [16] [17] [18] proposed web-based applications to manage blood donation campaigns, with the aim of collecting and organizing data. The researchers at [19][20] developed web applications to monitor and investigate the risks involved with donors before and after the donation process.

Although previous studies considered many aspects of the blood donation process, each of them exclusively addressed issues related to web or mobile applications as managers for blood donation, forgetting the importance of managing the location of the donor and applicant. The main reason for this research is that through the mobile application we can manage the location of both the donor and the applicant to make and improve the blood donation service.

### III. METHODOLOGY

For the present work we chose to use the agile Scrum method to develop the project prototype. Scrum is an adaptive, iterative, fast, flexible and efficient framework. Scrum ensures transparency in communication and creates an environment of collective responsibility and continuous progress [21]. This method has 5 phases: initiation, planning and estimation, implementation, review and retrospective and launch, for the development of this project we will work with four processes, which are described below.

#### A. Sprint Planning

In this process, meetings are held to define the user stories, estimate the tasks and create the sprint backlog, and a time-box of eight hours is assigned during a month-long sprint [22]. In this process the Scrum team decides to complete the selected items in the prioritized product backlog to meet the sprint goal.

#### B. Sprint Development Work

In this process, the Sprint Backlog is implemented, no changes are made that affect the objective of the sprint, quality objectives are ensured, the scope is renegotiated with the product owner and the development team as it is developed. [23]. In this process it is possible to preview the inspection and the adaptation of the progress towards the goal according to the schedule of activities.

#### C. Sprint Review

The sprint review is conducted to demonstrate and validate the sprint, the Scrum Team presents the deliverables of the current sprint to the Product Owner. The Product Owner reviews the product increment against the agreed acceptance criteria and accepts or rejects the completed user stories [23].

#### D. Sprint Retrospective

In this process, a 4-hour meeting is held in a one-month sprint, and is developed as part of the sprint retrospective process. During this meeting, the Scrum team meets to review and reflect on the previous sprint in relation to the processes that were followed, the tools used, the collaboration and communication mechanisms, as well as other aspects of interest to the project [24].

A strength of Scrum lies in the use of cross-functional, organized and empowered teams that divide their work into short, concentrated work cycles called sprints.

The main characteristics of mobile applications are high performance and availability, which is why the client layer is developed offline, as shown in the architecture in Fig. 1.

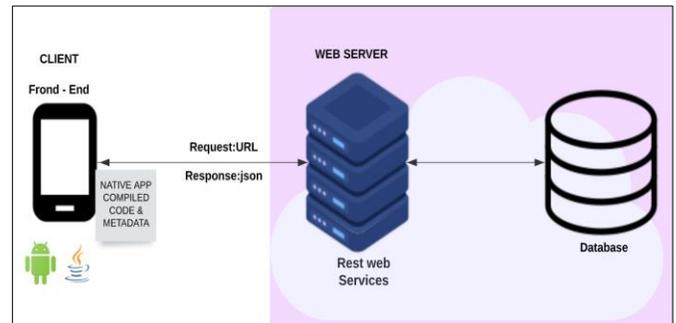

Fig. 1. Mobile Application Architecture.

### IV. CASE STUDY

This section details the development procedure of the mobile application prototype, following the life cycle methodology mentioned above. Likewise, Table I describes the tools to be used in the development of the case.

TABLE I. TOOLS FOR PROTOTYPE DEVELOPMENT

Software	Description
Android Studio	Development environment for the Android platform
Firebase	NoSql database
GitHub	Repository for version control
Figma	UI and UX design application
Play store	Online store service to distribute the mobile application.
Jira	Online software to manage project tasks.

The Scrum cycle starts with a stakeholder meeting, then the product owner develops the prioritized product backlog. Each sprint starts with a planning meeting where the prioritization of the stories is considered, and generally lasts from one to six weeks. Then, the sprint planning and time estimation for each of the user stories to be implemented is done.

#### A. Planification Del Sprint

In this section the analysis and identification of the requirements for the elaboration of the User Epics is performed, together with the descriptions of the functionalities that the mobile application will have, which are elaborated between the product owner and the Scrum team, and that can be improved during the project life cycle. This is an agile way to manage requirements without elaborating large amounts of documentation [25]. Table II describes the user epics that will be implemented for the development of the case study.

TABLE II. USER EPICS

#	Description
ADS-1	Manage the authentication module: The mobile application should have a login interface with security token for user registration and authentication
ADS-2	Manage the notification module: The mobile application must have the option of notifications to indicate to the user of requests.
ADS-3	Manage Google maps module: The mobile application must incorporate Google maps technology for real-time search of donors or applicants based on location.
ADS-4	Manage the health center location module: The mobile application, through geolocation, should locate the closest health centers for the blood donation process.
ADS-5	Manage the reporting module: The mobile application must show the available or connected donors, as well as the list of applicants..

Time estimation: In this phase the Scrum team decides to complete the prioritized product backlog, assigning the duration, priority and complexity for each of the user stories. There are many tools to estimate user stories, for this case Planning Poker is used to estimate and indicate the complexity whose value only makes sense to the development team [26]. The project estimate resulted in nine weeks, as shown in Table III.

TABLE III. PRODUCT BACKLOG

Description	Duration Weeks	Story point estimate	Priority	Epic
<i>Sprint 1: User authentication module</i>	<b>2 weeks</b>	<b>40</b>		
Implement the login interface		16	highest	ADS-1
Implement the interface for the registration of new users (donors and applicants).		14	highest	ADS-1
Implement the interface for password recovery		10	highest	ADS-1
<i>Sprint 2: notification module</i>	<b>2 weeks</b>	<b>35</b>		
Implement the notifications component in the startup interface		18	high	ADS-2
Implementing the tray where notification messages are received		17	high	ADS-2
<i>Sprint 3: geolocation module</i>	<b>3 weeks</b>	<b>40</b>		
Implement the google maps service in the application.		14	highest	ADS-3
Implement the real-time search option with the google maps service.		16	highest	ADS-3
Implement the search for the nearest health centers using geolocation.		10	highest	ADS-4
<i>Sprint 4: reporting module</i>	<b>2 weeks</b>	<b>33</b>		
Implement reports of available donors and applicants by geographic location.		17	medium	ADS-5
Implementing donor and applicant reports that have been attended to		16	medium	ADS-5

Project scope: understood as the sum of all product requirements and all work necessary to develop the final product/service [24]. The functionalities originate from the set of requirements established and analyzed together with the product owner. Therefore, in order to know the fulfillment of the project scope, the degree of progress of each of the user stories of the product backlog is verified, in order to know if the implementation is being carried out as planned.

Fig. 2 shows the hours that the team takes to develop the user story points, in order to verify in greater detail the degree of progress in the sprint estimates.

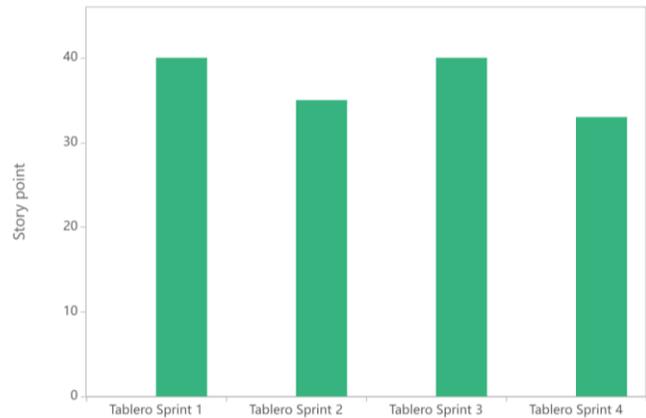

Fig. 2. Estimation of each Sprint.

### B. Sprint Development

In this process, the following sprints are developed:

1) *Sprint 1 (user authentication)*: In this Sprint the interface for the login Fig. 3, interface for the registration of new users (donor or applicant) and password recovery is developed. The user must have the access credentials to log in, otherwise, he/she will have to register his/her data as requested in the form. If the user forgets his/her password, the recovery process is performed.

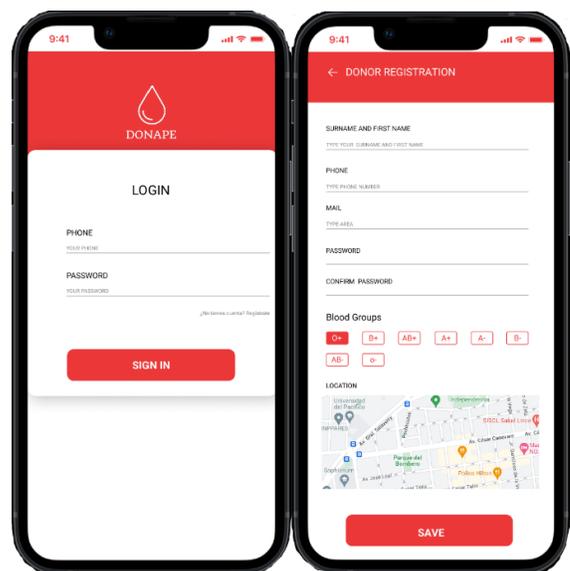

Fig. 3. Donor Login and Registration.

2) *Sprint 2 (notification module)*: In this second Sprint, the interface for the notifications module was implemented. As shown in Fig. 4, this component has two sections: 1 for the inbox, and another one located in the upper right part of the startup interface.

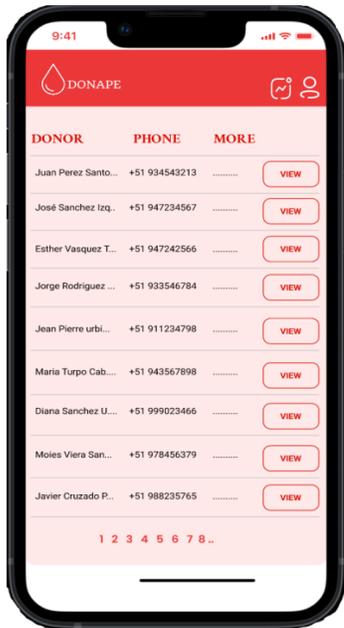

Fig. 4. Notifications and Tray.

3) *Sprint 3 (geolocation module)*: In this sprint, the Google maps service is incorporated into the prototype, in order to search for donors and locate donation centers, as shown in Fig. 5. In the first interface of Fig. 5, the applicant searches for blood donors. In principle, the algorithm performs the search based on the location of the applicant, prioritizing the proximity of the donor. Once the donor has been located, the applicant searches for the health center that has a blood bank, using the second interface in Fig. 5.

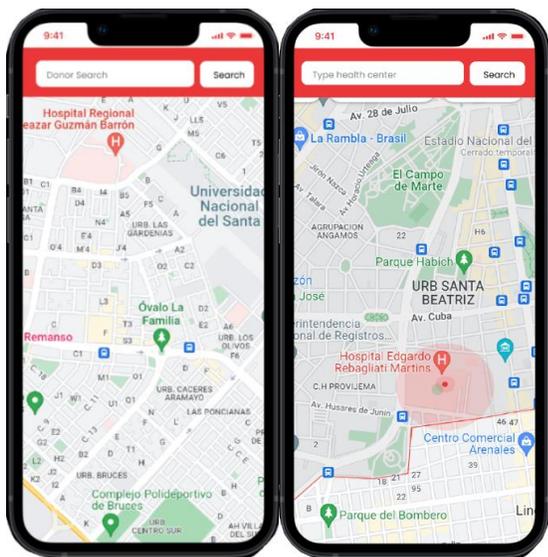

Fig. 5. Search for Donors (a) and Blood Donation Centers (b).

In the interfaces of Fig. 5(a), the first interface is where the applicant searches, chooses the donor and can contact immediately. (b) The second interface is used to search for the blood donation center closest to the interested parties, in order to carry out the blood transfusion process. The donor will be able to cancel the request through the application, in case they do not reach a mutual agreement.

4) *Sprint 4 (reporting module)*: In this sprint the donor reports are developed, where the names, city of origin, cell phone number, date of last donation and blood type can be displayed, as shown in Fig. 6.

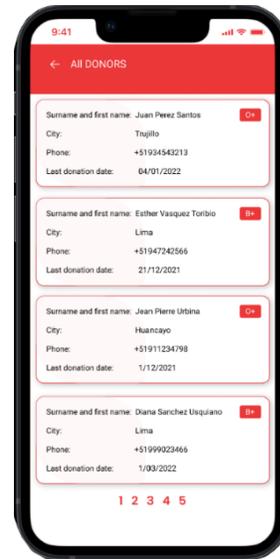

Fig. 6. Donor Report.

### C. Sprint Review

After the development of each Sprint, we proceed with the review, for this Scrum Team members and Stakeholders participate in the review of the sprint to accept the deliverables, the review time is two to three hours. At this stage the Scrum Team demonstrates the achievements of the sprint, specifying each of the new features. This provides an opportunity for the product owner to inspect in detail what has been completed so far and determine if changes should be applied to the sprint.

### D. Sprint Retrospective

The retrospective is the last step in a sprint. All Scrum team members attend this meeting, which is organized by the Scrum mater, this meeting together with the product owner, discusses important elements for future actions. This retrospective meeting covers both what went wrong and what went right. It also evaluates the process followed in the development of the sprints, tools, among other elements. It is also a space for new ideas or methods in order to continue improving the process and promoting good practices.

To demonstrate the results of the implementation of the mobile application, it was tested for 20 days. The design used was pre-experimental, with a pre-test and a post-test, since the online method was used (1). Table IV shows the elements of the design.

TABLE IV. DESCRIPTION OF PRE-EXPERIMENTAL ELEMENTS

Elements (1)	Description
Ge	Experimental group: the study is carried out in the Dlima laboratory for 20 days.
O <sub>1</sub>	It is the measurement before implementing the mobile application. Pre-test data measurement: experimental group.
X	Mobile application = object to be tested
O <sub>2</sub>	Measurement of post-test data: experimental group.

G<sub>e</sub>, O<sub>1</sub>, X O<sub>2</sub>

### V. RESULTS

This section describes the results related to the development of the research within the case study. In Peru there is no culture of voluntary blood donation, the need is permanent and the numbers required to cover the demand are high [1].

TABLE V. RESULTS OBTAINED IN THE PRE-TEST AND POST TEST

#D ia	KPI-1		KPI-2		KPI-3 (Horas)	
	P re	Po st	Pre	Post	P re	Po st
1	0	3	----	Piura – Olivos- Surco	8	4
2	0	2	----	Lince – Cercado	8	4
3	2	4	Lince - Surco	Trujillo – 2 Cuzco- SJL	6	3
4	1	2	Breña	Olivos – Huacho	8	4
5	1	2	Lince	Arequipa – Breña	8	4
6	2	2	Olivos -SJL	Breña – Tarapoto	4	4

18	2	3	Surco - olivos	Trujillo-Comas - SJL	4	3
19	1	3	Lince	Breña – Olivos – Cuzco	8	2
20	2	3	SJL - Comas	Trujillo – Piura - Breña	4	2

For the case study, we worked with the Dlima laboratory, a blood bank that offers a modern and highly reliable blood transfusion system. Since the beginning of the COVID-19 state of emergency, blood donations have dropped by more

than 70% due to fear of infection [27]. Since then, the laboratory implemented a set of strategies to search for donors and maintain the blood bank reserves and promote the culture of voluntary donation even in the context of a pandemic. One of the strategies was the proposal to develop a location-based mobile application to search for blood donors, with the following indicators: increase the number of donors (KPI-1), place of origin (geographical location) of the donors (KPI-2) and improve the search time (KPI-3). It is known that screening tests for hepatitis B and C, HIV, HTLV I and II, Chagas disease and syphilis are performed prior to blood transfusion. In our environment there are still prejudices regarding blood donation, therefore, the laboratory implemented a reward program that consists of performing a blood test known as "complete blood count" for any altruistic donor who decides to use the mobile application to donate blood. The data collection (Table V) for the pre-test measurement used a record type card and for the post-test the automated record of the mobile application.

Table VI shows the average results for each KPI; these results were derived from Table V. It should be noted that the districts of Lince, Breña, Cercado, Surco, Comas, Olivos and JSL belong to the city of Lima.

Fig. 7 shows that the average of KPI-1 has improved in the number of donors, in KPI-3 the average indicates that the time to search for donors has been reduced, in the same line, it is observed that in KPI-2 after the implementation of the mobile application, access to other regions of the country has been achieved.

To measure the indicators in Table VI, we used the scales of time in hours, quantity and distance.

TABLE VI. RESEARCH INDICATORS

Indicator		Pre-Test	Post Test
KPI-1	Number of donors	1.65	2.85
KPI-2	Donor origin	Lima	Lima + Provincia
KPI-3	Donor search time	5.45	2.9

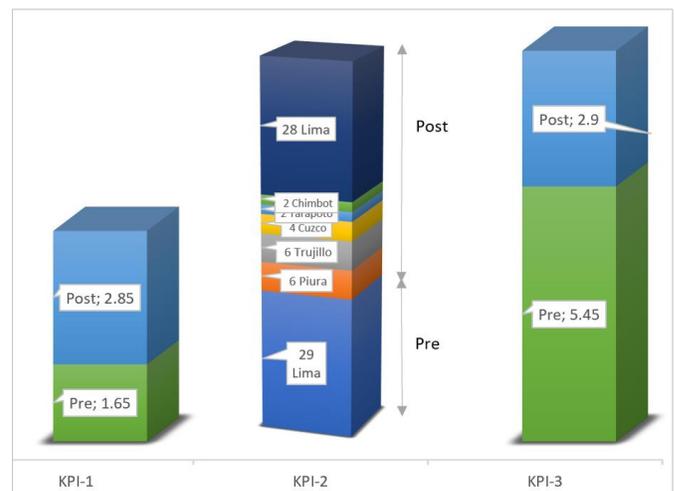

Fig. 7. Pre and Post Comparison of KPIs.

A. Results of the First Indicator (KPI-1)

Fig. 8 shows the normality test for KPI-1, where a standard deviation of 1.04 is observed with respect to the mean of 2.85 donors per day. Along the same lines, the data obtained show that the p-value is less than 0.05, which confirms that the information analyzed has a non-normal behavior.

Regarding the nonparametric Wilcoxon test (Table VII). It has an asymptotic significance level of 0.001, which is less than 0.05, which is the limit value for the acceptance of the hypothesis, therefore, it is stated that the implementation of the mobile application has a positive impact on attracting a greater number of blood donors.

	PRE-TEST KPI-1 POST TEST KPI-1
Z	-3.359 <sup>b</sup>
Sig. Asintótica(bilateral)	.001
Wilcoxon signed-rank test	
Based on positive ranges	

B. Results of the Second Indicator (KPI-2)

Fig. 9 shows the results of the second indicator, which evaluates the donors' place of origin. In the pretest, the origin of the donors belonged only to the city of Lima, including the districts (Lince, Surco, Breña, Los Olivos, SJL, Cercado and Comas), where a total of 29 blood donors were obtained. In the post test, with the use of the mobile application, a greater reach was achieved, obtaining blood donors from different cities in the country, such as: Piura, Trujillo, Cuzco, Tarapoto, Chimbote, among other districts of the city of Lima, totaling 48 blood donors. Therefore, we can affirm that after the implementation of the project, we have a positive impact on the population and a greater reach.

C. Results of the Third Indicator (KPI-3)

Fig. 10 shows the normality test for KPI-3, where a standard deviation of 0.9119 is observed with respect to the mean of 2.9 hours required to obtain a donor. In the same line, the data obtained show that the p-value is less than 0.05, which confirms that the information analyzed has a non-normal behavior.

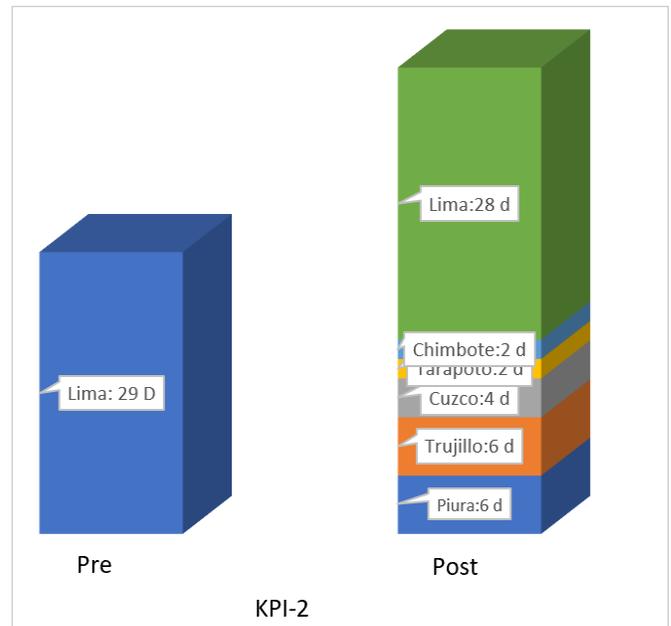

Fig. 9. KPI-2 Measurement Results.

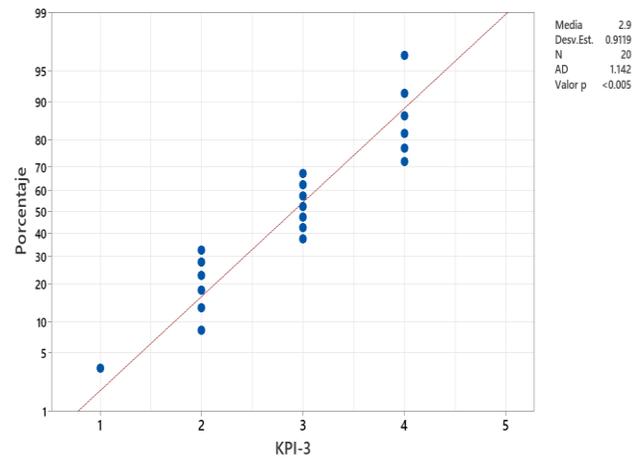

Fig. 10. KPI-3 Normality Test.

Regarding the nonparametric Wilcoxon test (Table VIII). It has an asymptotic significance level of 0.000, which is less than 0.05, which is the threshold value for the acceptance of the hypothesis, therefore, it is stated that the implementation of the mobile application has a positive impact with respect to measuring the time to recruit blood donors.

## VI. DISCUSSION

About the case study: the mobile application was made with Android Studio, Firebase, among other tools such as Jira, which was used to manage user stories, allowing a controlled monitoring by both the team and the product owner. A set of works related to blood donation has been reviewed, where technology is used as an ally for this purpose. Works such as: [16][17] developed mobile applications for blood donation integrating cloud services with the purpose of promoting and facilitating blood donation. In the meantime [12][13] In their projects, they focused on the development of mobile applications to manage notifications, access donor information and synchronize with the blood banks, all of which have undoubtedly contributed to the development of this work.

About the methodology: Scrum is an agile methodology for software development, in this group there is a set of methodologies based on agility. However, the main reason why Scrum was chosen for the development of the mobile application is the short iterations known as sprints that allow early deliveries of two to four weeks and in turn a quick feedback from users and stakeholders [28]. Among other advantages and benefits of the Scrum methodology we can highlight: it helps to manage and minimize project risks, it improves the relationship between cost and benefit, it allows the development of team skills, and it works mostly with small teams.

With respect to the limitations that were found in the research work and that could have affected the results, in principle there was no list of blood donation centers authorized by the ministry, and to a lesser extent the time it took for the play store to review the mobile application.

## VII. CONCLUSION

In this research article, a location-based mobile application was developed to search for blood donors, using the Scrum methodology, Google maps service to locate the donor and blood donation centers in real time.

After the implementation of the project, there was a significant increase in the number of blood donors by 39.58%, as well as a reduction of 53.2% in the time required to search for blood donors. The results show that donors from different cities in the interior of the country such as Piura, Trujillo, Chimbote, Cuzco and Tarapoto, representing 39.58%, however, it is important to note that the city of Lima continues to concentrate the largest number of blood donors, equivalent to 60.42% according to the case study.

The scientific contribution of this article is fundamental for the development of future work related to blood donation campaigns. With the data collected through the mobile application, it is possible to perform analytical processing, develop strategies with reward incentives to motivate blood donation, and add new functionalities so that doctors and patients can communicate.

Finally, it was demonstrated that the solution developed, manages to increase the number of blood donors, reduce the time to get donors, has greater population reach and in turn

has access to the information provided by the donor, and with this to perform actions in favor of those concerned.

**Abstract**—Cultivation of crops and their parallel production yields hugely depend upon the fertility composition of the soil in which the crops are being cultivated. The prime fertility factors which contribute towards the health of the soil are the available soil nutrients. Varying climatic conditions and improper cultivation patterns have resulted in unpredictable growth and yield of the groundnut crops, one of the major cause for the fluctuation seen in groundnut pod growth patterns and production, is the differing soil nutrient compositions of the land which is under cultivation. The unnecessary usage of excessive artificial fertilizers to boost the soil strength, without properly diagnosing the exact nutritional need of the soil required for the conducive growth of the crop has led to the imbalanced distribution of the soil's major macro-nutrients constituents such as (Phosphorous (P), Potassium (K) and Nitrogen (N)). In this research article, we have made a detailed investigation for nutrient prediction mechanism of the soil nutrient datasets taken under investigation of a specific geographic location from one of the major groundnut cultivating districts (Villupuram) in the state of Tamil Nadu and have proposed a Soil nutrients prediction scheme and optimal fertilizer recommendation model for sustainable cultivation of groundnut crop using Enhanced-1DCNN DLM. This Investigation model utilizes the natural compact robust features of 1DCNN in classifying the major macro nutrients(N,P,K)on the basis of low, Medium and high values. Based on the generated heatmap results the correlation between certain macronutrients and their corresponding micronutrient presence is classified. This proposed model has been compared for its performance and error measures with existing SVM, Naïve Bayes and ANN models and has proved to be outperforming all the compared baseline models by preserving the original data distribution with an overall accuracy of 99.78%.

**Keywords**—Soil nutrients; Enhc-ID-CNN DLM; nutrient classification; fertilizer recommendation

## I. INTRODUCTION

Farming activities across the globe, has started taking a different dimension in its approach serving to the changing socio-economical needs. The impact of technology has already started to make inroads in the agriculture sector, several nations have sensed it and are slowly in the process of

adapting precision based agricultural activities. India being one of the world's largest agriculture-based country, the scope and possibility of adapting precision-based agriculture has slowly gained importance. Groundnut is one of the most predominant oil seed, which has been cultivated in our country. This nutritious nut has been cultivated across the year In India, in three seasons, namely, the monsoon or rainy season which is called as Kharif, the winter season which is called as Rabi and the Summer. In India, one of the most important groundnut-growing states is Tamil Nadu, where groundnut is grown in five seasons: Adipattam (June-July), Karthikaipattam (October-November), Margazhipattam (December-January), Masipattam (February-March), and Chithiraipattam (March-April) (April-May). The kharif season accounts for nearly 80% of the country's total groundnut production [25][26][27][28]. As of 2018-19, the area under groundnut cultivation in Tamil Nadu was around 3.38 lakh hectares. For the best results, groundnut cultivation requires sandy loam or clay loam soil with good drainage. The soil should be deep, the pH should be around 5.5 to 7, and the fertility index should be high. The heavy soil was found to be unsuitable for cultivation due to harvesting difficulties. Because these crops are salt-sensitive, the soil should not be salty. Groundnut crop soil should not contain any rocks or clay, as this will reduce the crop's yield during harvest. For healthy germination and growth, the temperature in the cultivation area should be around 27-30 degrees Celsius. The ideal annual rainfall for crops is between 450 and 1250 millimeters. Groundnut farming is not suitable for high altitudes, cold, and frosty climates. The cultivation of groundnuts benefits from a consistent warm climate. The cultivation and production of the groundnut have been affected by many factors, one of the important issues which leads the cultivation land to be less fertile is by the usage of excessive number of artificial fertilizers on to the soil, without properly predicting the exact soil nutrient deficiency, such cultivation patterns make the soil infertile over a period of time, by thus there is gradual decline seen in the production rates of the groundnuts. Growth of the groundnut crops and higher groundnut pod formations hugely depend upon the underlying soil nutrient composition on which the crop has

been cultivated. There are many macro and micro nutrients which contributes towards the productive health of the crops. The major set of macro nutrients which include (Nitrogen, Phosphorous and Potassium) NPK, defines a important role in defining the productive nutrient composition of farm in which the groundnut is being cultivated. In addition to this basic macro nutrients, calcium, Sulphur and few other micro nutrients such as iron, zinc and manganese also contributes towards production of healthy groundnut pods, which rises the overall production yield of the groundnut crop [28][29][30]. Impact of artificial intelligence by the means of Machine learning and deep learning models have started creating a unique dimension in addressing complex problems through various quantifiable solutions across diversifying domains. In this research article, we have proposed a deep learning model (Enhanced 1DCNN DLM), for predicting the various soil nutrients constituents required for the sustainable cultivation of the groundnut crop. Mathematical models developed to predict soil nutrients composition must, in general measure possible physical quantities of the environment and provides formulas to describe the actual relationships between these soil-related parameters. Because of advances in computer modelling, empirical modelling methods have emerged as a dominant development model capable of extracting contextual physical quantities related to soil nutrient composition [19][20][31][34]. This empirical model is frequently used to choose a good model, correct physical quantities using the chosen model, and validate it to see how accurate it is at predicting soil fertility. These models must take into account relevant data, such as predefined input parameters and required output parameters. The input parameters, in particular, are chosen empirically with the goal of maintaining a minimum degree of correlation between them. To build predictive models, the majority of the major soil nutrient prediction schemes that have contributed to the literature have primarily used neural networks, linear regression, machine learning, and empirical formulas [2][3][5][10][18]. Soil nutrient prediction models based on deep learning have been found to be more robust and reliable in terms of prediction accuracy at this time. There are considerable amount of research directions defined through various data mining and machine learning methodologies, towards soil nutrient based crop prediction, soil fertility prediction and for soil fertilizer recommendation [24][23][22]. Crop based Soil nutrient prediction schemes towards identifying the exact nutrient composition of the land selected for agriculture and precise fertilizer recommendations based on the prediction made seems to be a novel approach for implementation, and through deep learning model the prediction the performance metrics will be more and error measures will be comparatively less when compared with existing machine learning models [6][7][11][12].

## II. RELATED WORK

Soil states a pivotal role towards determining yield of the crops, in recent years there where many data mining and machine learning-based investigations made on the basis of the soil nutrients availability and its proposed fertilizer recommendation schemes. These variety of machine learning based schemes have opened up a wide scope towards reaching

a more optimal soil nutrient prediction scheme more specific to particular crop cultivation patterns. Various base articles, pertaining to our research problem have been reviewed comprehensively in this context [13][14][15][16][17].

For classifications, Nikam et al.[1] defined a model involving J48/C4.5, knn, ID3, Artificial Neural Network, Support Vector Machine, and Naive Bayes. These classification methods are divided into three groups: statistical, machine learning, and neural networks. [1].

Three algorithms were used by J Gholap et al.[2] to define their work. J48(C4.5) and Jrip algorithms were used with 1988 soil instances in the J48: It is a very simple classifier that generates a decision tree with a 91.90 percent accuracy. The author also suggested that a future goal would be to develop a recommendation system that would suggest appropriate fertilizer based on the soil test sample and cropping pattern.

Dr. K. Arunesh et al. [9] investigated and experimented in 203 soil instances with 6 soil attributes from Virudhunagar District, Tamilnadu, India, and found that the Nave Bayes machine learning classification algorithm outperforms J48, random tree, JRip, and OneR,

Ramesh et al. [21] proposed a system that uses Naive Bayes, Bayes Net, Naive Bayes Updatable, J48, and Random Forest as classification algorithms. They used a dataset which comprised 1500 instances of Soil samples obtained from Department of Agricultural. In the classification of soil nutrients, J48 calculated 92.3 percent accuracy, while the Nave Bayes algorithm calculated 100 percent accuracy.

Using two algorithms, Nave Bayes and J48, Chiranjeevi M N et al. [5] proposed a system for analysing soil condition and nutrients which includes Potassium, pH, Nitrogen, EC, Phosphorus, OC, Sulphur, Iron, Zinc, Magnesium, Boron, and Copper at Belagavi Department of Agriculture in Belagavi. The Naive Bayes algorithm produced a better result than the J48 algorithm, correctly classifying the determined number of instances of the soil sample.

Naive Bayes Classifier had been applied to Tirupati, Andhra Pradesh soil, according to Bhargavi et al [8]. The soil data instances were all classified into different sand categories, such as loamy sand, clay, loam, sand, sandy loam, sandy clay loam, and clay loam.

Puno, J. C., et al. [18] proposed and developed a fully functional system using IP (IP enhancement, IP segmentation, and feature extraction) in MATLAB software. All 7 nutrient attributes are classified as L, M, H, S, D (Low, Medium, High, Sufficient, Deficient) values.

After experimenting with model 1 and model 2 for soil moisture estimation, Ahmad, S et al. [4] proposed a model based on five-year data with only one attribute for classification considered, namely VIC moisture. The author concluded that SVM model outperforms ANN and MLR models.

Juhi Reshma S R et al. [23] used Neural Networks to propose a recommendation system for predicting the number of fertilisers needed for a specific banana crop, as well as regression methods for upcoming plantations. Nitrogen (N),

phosphorus (p), and potassium (k) are the three most important soil nutrients for crop growth. By default, soil contains a specific amount of NPK, which varies by location. Each crop has its own set of requirements. A model is constructed in this paper to recommend the number of fertilisers required for the banana crop.

#### A. Extracts Inferred from the Literature

The limitations of the available soil nutrient prediction models considered towards the literature study across the recent years is drafted below.

1) Most of the available soil nutrient predicts models have been approached by data mining and machine learning algorithms, which devised the approach towards nutrient prediction, but there exist limitations in terms of learning accuracy.

2) Mostly the available machine learning schemes have not defined well defined a sustained prediction accuracy to fit the need, opening a wide scope for improvement.

3) Though there is a considerable amount of research contributions done towards predicting the soil nutrients and fertilizer recommendation, there is only a limited class of investigation done for crop specific soil nutrient prediction and fertilizer recommendation.

4) The comparison of error measures and performance metrics reached by the available ML defined soil nutrient prediction schemes extend a clear scope for improvement if learning can be further be deeply enhanced.

5) On the basis of the above drafted limitations, it has been proposed to propose an Enhanced -1D Convolutional Neural Network based Deep Learning Model (Enhanced-1DCNN DLM) to facilitate accurate estimation of soil nutrient prediction and fertilizer recommendation for the sustainable cultivation of groundnut crops.

#### B. Proposed Work and its Scope of Contributions

The major aids of the proposed Enhanced-1DCNN based Deep Learning Model is listed as follows:

1) The proposed model works towards the soil nutrients composition prediction and its necessary fertilizer recommendations, which aids towards the better cultivation of groundnut crops in the specific geographical location present in the Villupuram district(Tamilnadu).

2) The proposed scheme has within the substantial qualities of 1DCNN to achieve consistent and automatic extraction features which contributes towards the optimal prediction of soil nutrient composition.

3) This proposed enhanced 1DCNN model tries to address the limits which prevail in the available methods used for the process of prediction in terms of performance towards prediction, multifeatured processing capability, generalization, and prediction.

4) The proposed enhanced 1DCNN introduced layer level inner optimization and fine tuning towards the attainment of accurate soil nutrient(N,P,K) prediction.

5) Experiments of the proposed Enhanced-1DCNN DLM based soil nutrient prediction and fertilizer recommendation scheme is performed on the basis of metrics pertaining to increase in the rate of performance metrics as well as decrease in the error metrics by thus evaluating the advantages it poses in par with the baseline schemes used for the purpose of investigation.

6) The statistical and stability analysis was performed over the proposed model, which confirmed the stability of the utilized deep learning model for nutrient prediction and its respective fertilizer recommendation.

The other sections of this article are organized as drafted below. In the second section A comprehensive review was made on the available data mining and ML modelled soil-nutrient prediction schemes which have aided to the study of literature over the recent few years. The third section describes an inclusive view over the proposed Enhanced -1D CNN-scheme which predicts the soil nutrient composition of the soil dataset and recommends the suitable fertilizer adapting the layer-based feature optimization approach with appropriate validations. In the fourth section the proposed model's investigational results and its corresponding discussion pertaining towards predicting soil nutrient composition based on its metrics of performance and error measures in comparison with the baseline models has been discussed.

### III. EXPERIMENT METHODOLOGY

The proposed Enhanced-one dimensional CNN based DLM for predicting the soil nutrient composition serves towards achieving sustainable groundnut cultivation through optimal prediction of soil nutrient composition and recommendation of required fertilizer need of the crop under cultivation based on the (N, P, K) input given. This Enhanced-1DCNN DLM adopted the significant parameters of various macro and micro nutrients along with soil pH in the course of predicting optimal soil nutrient composition as depicted in Fig. 1. Most commonly CNN based deep learning models are used to analyse the images, Deep two Dimensional Convolution neural networks, which might have several hidden layers and heaps of parameters, can learn objects of complex dimensions and patterns on Being trained on a large visual dataset with labelled values. This unique ability, when properly trained, defines to be the prime tool for several applications involving Two Dimensional signals such as imageries and frames of videos. However, this might not be a feasible choice in many applications involving one Dimensional signals, particularly if the training data is infrequent or confined towards any particular application. To gap this problem, 1D CNNs are proposed and it has quickly achieved the desired optimal performance levels in a variety of applications. Another striking benefit of 1D CNNs is that its configuration is simple and compact, which only perform 1D convolutions, which drives the route towards the usage of on demand cost feasible implementation of the hardware. Considering the impact of 1D CNNs in analysing temporal data, we have chosen to perform the process of soil nutrient prediction based on the optimized 1D CNN, which performs flattened layer level enhancement of conventional 2D CNNs.

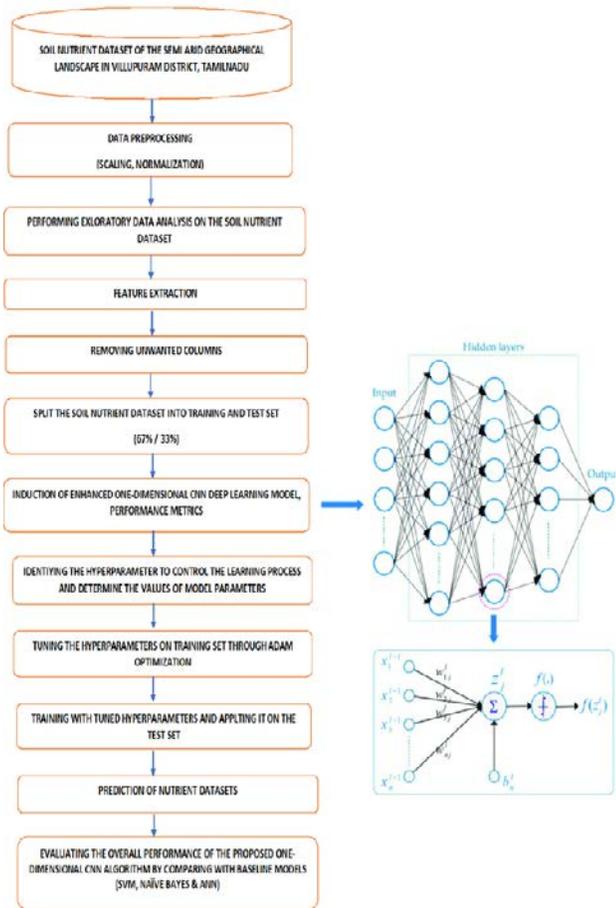

Fig. 1. Overall Process-flow Diagram for the Proposed Soil Nutrients Prediction Scheme using Enhanced 1D-CNN DLM.

### A. Objective and Methodology

The cultivation of groundnut crop has been largely impacted by the improper or lack of proper assessment techniques used to exactly find the nutrient composition of the land under cultivation and needed percentage of correct fertilizers to be used based on the prediction scheme of the nutrients. The growth and the production yield of groundnut crops is largely impacted by the nutritious content of the soil, there are various set of macro and micro nutrients which contribute towards the proper growth of the groundnut crop starting from the sowing of seeds till towards the groundnut pods become mature enough to get harvested. The major set of nutrients present in the soil which contributes towards the crops growth are “Nitrogen[N], phosphorous[P] and Potassium [K]”, apart from other micro nutrient such as “Calcium (Ca), Sulphur[S], Zinc[Zn], Iron[Fe], Manganese [Mn] and Boron[B]”, soil parameters such as “pH, Soil electrical conductivity (EC), and Organic carbon (OC)” are also responsible in fixing out the overall fertility index of the soil. In this article we have chosen a semi-arid geographical landscape which is the most conducive soil pattern for the cultivation of groundnut and performed the model evaluation based on the nutrient datasets obtained from one such. The above given Table I, defines the parameters involved in the evaluation of the proposed Enhanced -1D CNN DLM.

TABLE I. PARAMETERS INVOLVED IN THE EVALUATION OF PROPOSED ENHC-1D CNN DLM

Geographical location of the dataset	Gingee (Taluk), Villupuram (District.), Tamilnadu (State), India
Latitude	12.2529° N
Longitude	79.4160° E
Source of Dataset	<a href="https://soilhealth.dac.gov.in/NewHomePage/NutriReport">https://soilhealth.dac.gov.in/NewHomePage/NutriReport</a>
Macro Nutrients	“Nitrogen[N], Phosphorous[P] and Potassium [K]”
other Nutrients	“Calcium (Ca), Sulphur[S], Zinc [Zn], Iron [Fe], Manganese [Mn] and Boron[B]”
Soil core parameters	“pH, Soil electrical conductivity (EC), and Organic carbon (OC)”
Nutrient classification classes on the datasets	Low, Medium & High

Excessive usage of artificial fertilizers, pollution variants and changing weather conditions make a huge impact by downgrading the quality of the soil under cultivation, and hence Prediction of the soil nutrient composition stays to be a vital factor towards framing up a well-defined precision farming prototype to uphold the soil fertility index and the crop production yield.

In this research work, a proposed 1D-CNN based Deep learning model has been chosen to train the nutrient datasets conducive for the sustainable cultivation of groundnut crop. This proposed 1D CNN deep learning model serves to the need of bridging the gap between the exact soil nutrient prediction for the cultivation of groundnut crop and its production rates through the improved optimal soil fertilizer recommendation schemes.

The one-dimensional CNN model can aggregate local features and lessen the data dimensions through convolutional learning and pooling operations. As a result, by repeatedly using convolution operations and pooling operations, a deep convolutional neural network can extract high-level features while significantly reducing the dimension of the output. In this article, raw nutrient dataset is used directly as the input to deep neural networks, as a result, the timing of the deep convolutional neural network output's high-level features is not disrupted.

### B. Evaluation of the Proposed Model with Enhanced One-Dimensional CNN

A 1D CNN is a special case of a conventional neural network. Unlike traditional neural networks, in which the hidden layer is fully connected, a 1D CNN employs a unique network structure that alternates between the convolution and the pooling layers.

As shown in the above Fig. 2, the proposed 1D CNN has an input layer, three layers of convolutional ( $C_1, C_2, C_3$ ), fully connected two layers ( $F1, F2$ ) & an output layer. This 1D CNN stays to be an alternate enhanced version of 2D CNN.

These enhancements have proven to be more effective in certain applications which deal with 1D temporal data.

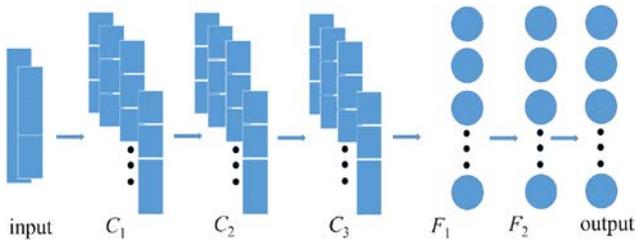

Fig. 2. Single CNN (1DS) Architecture.

Comparing with the 2D CNN, this 1DCNN are chosen to be more advantageous stating for the following reasons.

- The forward and the back propagation in one dimensional CNN require a simple array operation rather than a matrix operation.
- Due to its shallow Architecture, it involves in complex learning capability of 1D temporal data comparing with 2D CNN which has a deeper architecture, 1D-CNN are much convenient to train and use.
- The Complexity of involving more advanced hardware setup which includes the involvement of GPUs and cloud infrastructure in 2D-CNN is hugely reduced with respect to 1D-CNN where, general CPU implementation with a relatively fast processing speed makes 1D-CNN more opt for the usage.
- Compact 1DCNN have proven to be efficient in terms of performance pertaining to concise datasets.

As shown in the above Fig. 2, the 1D CNN Architecture consists of two distinct type of layers they are the “CNN-layers” in one Dimensional convolutions and pooling, and Fully-connected layers. The arrangement of a 1D-CNN is designed by the following hyper-parameters:

- The total levels of hidden CNN and fully connected layers (in our proposed Enhanced 1D-CNN model as shown in the above Fig. 2, there are 3 CNN layers and 2 fully connected layers).
- Defining the size for Filters in each CNN layer.
- Subsampling feature in each CNN layer.
- The choice of pooling and activation functions.

The input layer in 1D-CNN stays to be an inert layer which accepts the raw 1D temporal data as that of the conventional 2D-CNN. The output layer is a fully connected layer consisting of equal number of neurons as that of the number of classes. Fig. 3 depicts three consecutive CNN layers of 1D-CNN. As shown in the figure, 1D filter kernel has a size of 3 and a subsampling feature of 2. Here, the  $k$ th neuron in the CNN hidden layer  $l$  first performs a series of convolutions, the sum of which passes through the activation function  $f$  by a subsampling operation. In fact, this is the main difference between 1DCNN and 2DCNN, where the 1D array replaces the 2D matrix in both the kernel map and the feature map. Processing further, the raw 1D datasets are processed by the CNN layers and it starts learning to extract the features potential for the purpose of classification to be performed by

the Fully connected layers, as a result the process of feature extraction and classification are coupled together as a single process that which can be optimized so as to maximize the performance of the classification. This process of 1D CNN proves to be a major advantage as it results in the involvement of low computational complexity, since the only major operational cost is with the sequence of one dimensional convolutional which performs simply the linear weighted summing of two 1D arrays, which can be operated effectively during the forward and Back-Propagation operations in parallel.

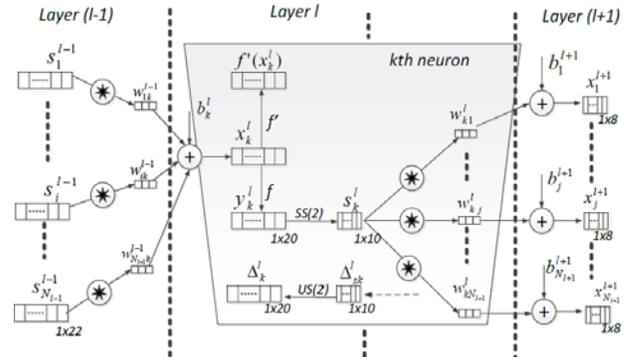

Fig. 3. Three Consecutive Hidden CNN Layers of a 1D CNN [33].

The procedure [33] of 1D Forward propagation (1D-FP) in each CNN-layer is shown in the equation (1) and the process of Back propagation is summed up as shown in the equation (2), is defined as follows:

$$x_k^l = b_k^l + \sum_{i=1}^{N_{l-1}} \text{conv1D}(w_{ik}^{l-1}, s_i^{l-1}) \quad (1)$$

After the computation of weight and bias, they can be utilized to update the biases and weights with the learning factor,  $\epsilon$  as,

$$w_{ik}^{l-1}(t+1) = w_{ik}^{l-1}(t) - \epsilon \frac{\delta E}{\delta w_{ik}^{l-1}}$$

and

$$b_k^l(t+1) = b_k^l(t) - \epsilon \frac{\delta E}{\delta b_k^l} \quad (2)$$

The process of forward and back-propagation in hidden 1D CNN layers is depicted below in the Fig. 4.

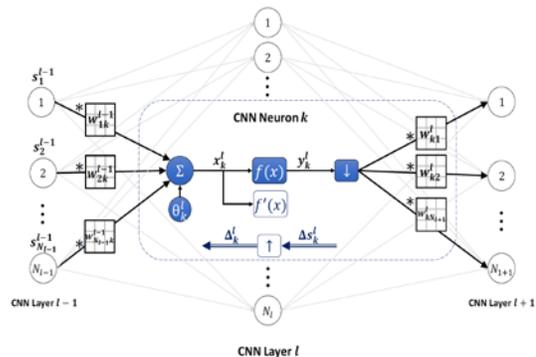

Fig. 4. CNN (Forward and Back-propagation in Hidden Layers).[33].

The process flow of the Back Propagation for the one-Dimensional temporal datasets in the training set can be stated as follows:

- 1) To initialize the weights and biases of the CNN.
- 2) For each Back Propagation iteration DO.
- 3) For each Nutrient Composition Value (Low, Medium, High) in the dataset, DO:
  - 4) FP: Forward propagation from the starting input level layer through the output layer to find the outputs of each neuron.
  - 5) BP: By Computing the delta error at the output level layer and to back-propagate it to first hidden layer to compute the delta errors,
  - 6) PP: To Post-process by computing the weight and bias sensitivities.
  - 7) Update: Updating the weights and biases by the (accretion of) sensitivities scaled up with the learning factor.

#### IV. EXPERIMENTAL RESULTS AND DISCUSSION

The evaluation of the proposed model using Enhanced 1D-CNN scheme and the benchmarked SVM, Naïve bayes and ANN schemes have been conducted based on the nutrient datasets of the Villupuram district obtained for a particular geographical region of Gingee. The dataset used for the current investigation is available online and it pertains to the years starting from 2016 to 2020. "Precision, recall score, F1-Measure, and Accuracy", as well as the error measures "RMSE, MAD, MAE, and R<sup>2</sup>" is calculated, and a comparison to the baseline models is derived through graphical comparisons for the proposed Enhanced ID-CNN. The datasets are mounted on Google Drive, and the model is evaluated on the Google Colab platform.

The training process of the proposed Enhanced ID-CNN structure is attained on the basis of Villupuram district nutrient dataset which are obtained from the online GIS servers, which are referred to the India soil Health System (soilhealth.dac.gov.in) maintained by the Indian Council of Agricultural Research. This web portal plays a prime role for providing soil related parameters across all the states in the country district wise. The soil nutrient constituents taken for the training purpose is obtained from the Tamilnadu state wise data of Villupuram district which spans over four years from (2016-2020). Data pre-processing is carried out before introducing into the model. The dataset is then partitioned based on the ratio of 67:33 for Training and Testing, respectively. Then the pre-processed data is inducted with the model evaluation of Enhanced 1D-CNN, during the process the model is evaluated for its performance measure and error metrics. The process of identifying the hyperparameters to control the learning process and to determine the values of model parameters is done by tuning the hyperparameters on the test set.

The proposed Enhanced 1D-CNN Deep learning model for predicting Soil nutrient composition for the sustainable

cultivation of the groundnut crop is a nascent Deep learning approach of this kind, hence for the purpose of evaluating the performance of the proposed Enhanced 1D-CNN model and its optimality consideration based on overall performance metrics and error measures it has been compared with standard and effective machine learning classifiers such as SVM, Naïve Bayes and ANN models and proved to be outperforming based on the evaluation results. The recommendation module evaluates the process of taking the given range of (N, P & K) values and generates the optimal fertilizers to be used for the sustainable cultivation of the groundnut crop. Since the general soil composition of the Villupuram district soil is Nitrogen Low by nature, the low predictions of Nitrogen below the minimum 17% of the basal need will have a nitrogen-based fertilizer recommendation for the sustainable cultivation of the groundnut crop, with respect to Phosphorous (P) based fertilizer recommendation, the higher percentage of phosphorous deposition found in Villupuram district soils along with the amount of needed phosphorous per hectare of groundnut cultivation demands a minimum of 35% of phosphorous requirement, which normally get satisfied due to its natural existence in the soil and hence rarely needs phosphorous based fertilizer recommendations. The requirement of Phosphorous is very much essential during the basal and flowering stages of the groundnut crops. The most important nutrient with respect to groundnut cultivation is the presence of Potassium(K), which is the most desirable nutrient required for the sustainable groundnut cultivation, starting from its early stage of growth till to its maturity, because it is responsible for making the crop disease resistive, regulates the water conditions within the plant cell, aids the crop in formation of proteins and chlorophyll and even often counterattacks the negative impacts of excess nitrogen supplements, supplied through fertilizers. To a minimum the percentage of Potassium will be nearly 55% in the total nutrient requirement for the sustainable cultivation of the groundnut crop, since the deposition of Potassium in the district of Villupuram seems to be in the Medium scale of level, fertilizers pertaining to Potassium are normally recommended when the predicted or the given values of Potassium is below the minimum scale required. The below Fig. 5, depicts the evaluation of the fertilizer recommendation module based on the given value of prediction.

Fig. 5. Fertilizer Recommendation Screen Shot.

A. Consideration of Performance Measures

- Accuracy: Adaptation of 1D-CNN has shown significant performance improvement in terms of the overall evaluation accuracy of the model in terms of classification. Comparative depiction of the accuracy of the proposed model is shown in Fig. 6.

$$ACCURACY = \frac{TP+TN}{TP+TN+FP+FN} \quad (3)$$

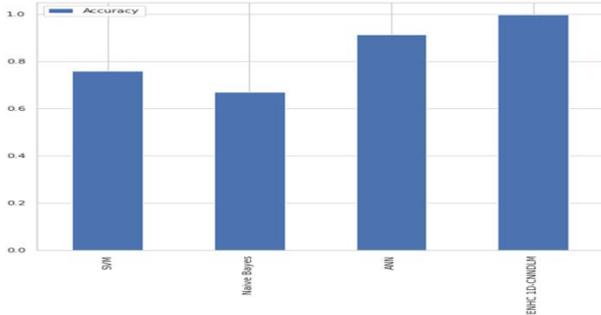

Fig. 6. Comparison of the Overall Prediction Accuracy of the Proposed Enhanced 1D-CNN.

- Precision: The overall Precision of the proposed Enhanced 1D-CNN described below is the ratio between the number of correctly identified positive predictions and the total number of positive predictions (True positive + False positive). Comparative depiction of the precision of the proposed model is shown in Fig. 7.

$$PRECISION = \frac{TP}{TP+FP} \quad (4)$$

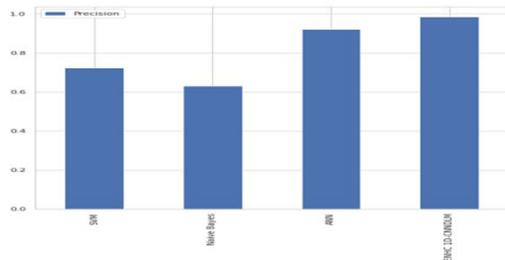

Fig. 7. Comparison of Precision Value for the Proposed Enhanced 1D-CNN.

Recall: As shown in Fig. 8, the recall value for the proposed Enhanced 1D-CNN is defined as the ratio of actually predicted true positive values to the overall sum of true predicted positive and false negative values.

$$RECALL = \frac{TP}{TP+FN} \quad (5)$$

F1-Measure: The harmonic mean of precision and recall is the F1 measure for the proposed Enhanced 1D-CNN, and its performance against the baseline model is depicted in Fig. 9 below.

$$F1 = 2 * \frac{PRECISION * RECALL}{PRECISION + RECALL} \quad (6)$$

e. Loss: This proposed Enhanced 1D-CNN Deep learning Model outputs a very minimal loss value by thus producing a more improved accuracy rate, The below Fig. 10 depicts it.

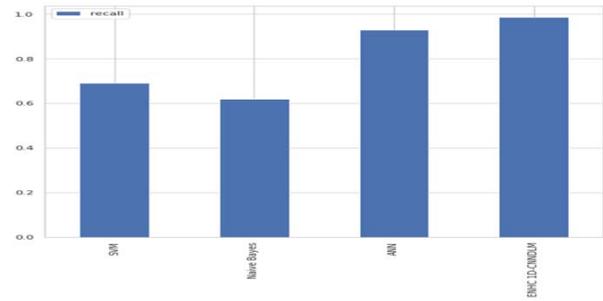

Fig. 8. Comparison over the Recall Score of the Proposed Enhanced 1D-CNN with Baseline Models.

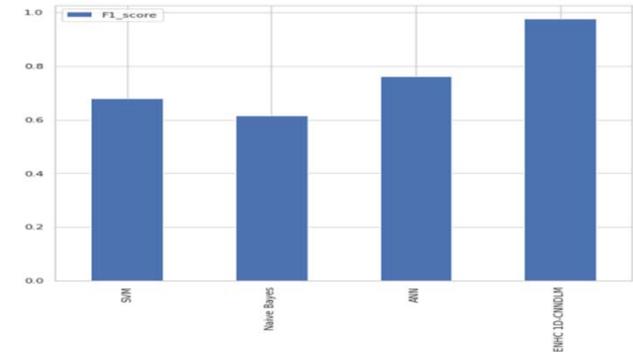

Fig. 9. Comparison over the F1-Measure of the Proposed Enhanced 1D-CNN with Baseline Models.

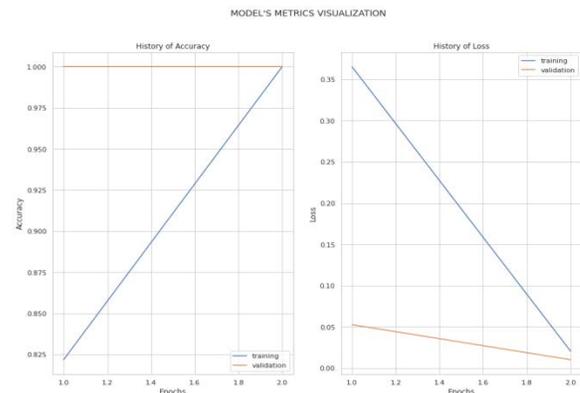

Fig. 10. Derived Accuracy and Loss of the Proposed Enhanced 1D-CNN.

The overall performance metrics of the proposed Enhanced 1D-CNN is depicted in Table II and its corresponding graphical representation is shown in the below Fig. 11.

TABLE II. PERFORMANCE METRICS OF THE PROPOSED ENHANCED 1D-CNN WITH THE BASELINE MODELS

	SVM	NB	ANN	ENHC ID-CNN/DLM
LOSS	0.23450	0.33670	0.9890	<b>0.02347</b>
ACCURACY	0.75894	0.66894	0.9124	<b>0.99789</b>
PRECISION	0.72345	0.62971	0.9197	<b>0.98524</b>
RECALL	0.69080	0.61987	0.9298	<b>0.98741</b>
F1_SCORE	0.67890	0.61620	0.7620	<b>0.97745</b>

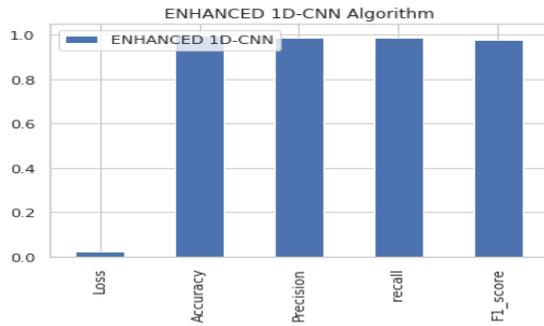

Fig. 11. Overall Performance Metrics of the Proposed Enhanced 1D-CNN.

Comparison of the Proposed Enhanced 1D-CNN with Baseline Models based on Performance measures, the below Fig. 12 depicts the optimality of the proposed model over other compared models.

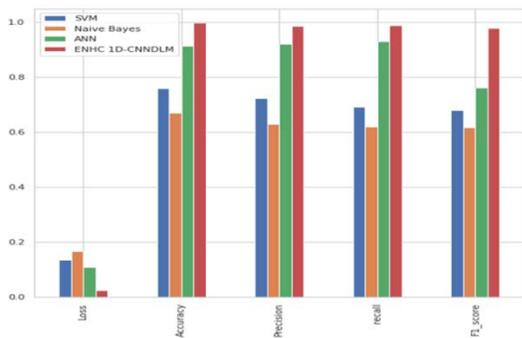

Fig. 12. Comparison of the Proposed Enhanced 1D-CNN with Baseline Models based on Performance Metrics.

### B. Consideration of Error Metrics

The square root of the difference between the predicted values of the used model and the actual values associated with the study variable (soil nutrient) determined over the total number of observations is known as the Root of the Mean of the Squared Errors (RMSE) [32].

$$RMSE = \sqrt{\frac{ACT_{Val} - PR_{Val}}{Obs_{No}}} \quad (7)$$

MAE: The difference between the predicted values of the used model and the actual values associated with the study variable (soil nutrient) determined over the total number of observations is depicted by the mean of absolute values [32].

$$MAE = \frac{ACT_{Val} - PR_{Val}}{Obs_{No}} \quad (8)$$

Where,  $ACT_{Val}$  and  $PR_{Val}$  represents the actual and predicted values and  $Obs_{No}$  is the number of observations.

MAD: The average distance between each data point and the mean is the mean absolute deviation of a dataset. It gives us an idea of how variable a dataset is. [32].

$$MAD = \frac{\sum \text{Absolute values of deviation from central measures}}{\text{Total no. of Observations}} \quad (9)$$

The shown Table III depicts the calculated error metrics in par with all the baseline models with the Enhanced 1D-CNN and the corresponding graphical representation as shown in

Fig. 13 shows the performance of the Enhanced 1D-CNN with a minimal loss in the process of prediction and hence optimality in terms of achieving low error metrics. The calculated Coefficient of Determination ( $R^2$ ) Value of the proposed Enhanced 1D-CNN scheme stands ahead in terms of evaluation with all the baseline models, and thus denotes how well the coefficient fits with the values in the training dataset.

TABLE III. COMPARISON OF THE ERROR METRICS COEFFICIENT OF DETERMINATION OF THE PROPOSED ENHANCED 1D-CNN WITH THE BASELINE MODELS

	SVM	NAÏVE BAYES	ANN	1D-CNN DLM
<b>RMSE</b>	0.8092	0.8872	0.7950	<b>0.4839</b>
<b>MAE</b>	0.6549	0.7872	0.6321	<b>0.2342</b>
<b>MAD</b>	0.3238	0.6871	0.2871	<b>0.2270</b>
<b>R<sup>2</sup></b>	0.6123	0.5321	0.9312	<b>0.9872</b>

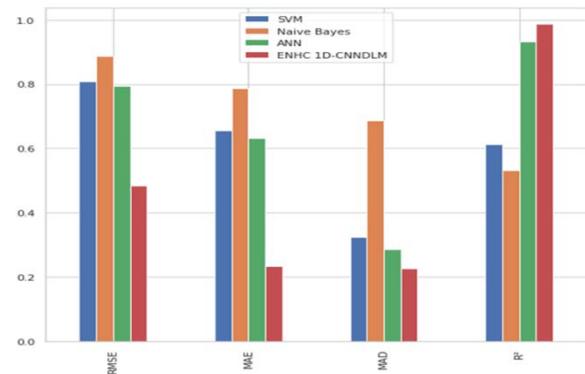

Fig. 13. Error Metrics and Coefficient of Determination ( $R^2$ ) Comparison of the Proposed Enhanced 1D-CNN with Baseline Models.

The proposed Enhanced 1D-CNN schemes' prediction efficiency is tested using the Villupuram district soil nutrient dataset by deriving the confusion matrix (see Table IV (A, B, C)). The computed confusion matrix for the proposed model, has shown evident prediction results by producing most optimal prediction accuracy rates for predicting the major macro nutrients of the soil Nitrogen (N), Phosphorous (P) and Potassium (K), based on the classification sets Low, Medium and High. This classification labels are defined on the basis of the nutrient dataset values, which represents the exact soil nutrient composition of these nutrients in the district of Villupuram.

The proposed Enhanced 1D-CNN model and the compared benchmarked schemes go through a three-step experimental process. Initially, the proposed Enhanced 1D-CNN model along with its benchmarked comparative models are compared for the performance measures such as (Accuracy, Precision, Recall, and F1-score) as well as error measures (RMSE, MAE, MAD, MAE). The model is also evaluated for its coefficient of determination value ( $R^2$ ) pertaining to the Villupuram district soil nutrient dataset. Figure 11 shows the performance of the proposed Enhanced 1D-CNN scheme and the benchmarked SVM, Nave Bayes, and ANN models in terms of mean accuracy and precision. The proposed Enhanced 1D-CNN deep learning architecture ensured maximum overall accuracy and precision, as the speed with which it deduced

robustness features that could potentially influence the prediction of soil Nutrient Composition was way ahead when compared with other learning models. As a result, the proposed Enhanced 1D-CNN scheme has the potential to improve accuracy by 23.89 per cent, 32.89 per cent, and 8.54 per cent over the baseline models SVM, Nave Bayes, and ANN, respectively.

TABLE IV. DERIVATION OF CONFUSION MATRIX DEPICTING THE PREDICTING EFFICIENCY OF (N, P, K) VALUES BY THE PROPOSED ENHANCED 1D-CNN, (A) CONFUSION MATRIX FOR PHOSPHOROUS CLASSIFICATION, (B) CONFUSION MATRIX FOR NITROGEN CLASSIFICATION, (C) CONFUSION MATRIX FOR POTASSIUM CLASSIFICATION

(A)

		PREDICTED PHOSPOROUS (P) COMPOSITION			
		LOW	MEDIUM	HIGH	Σ(LMH)
ACTUAL PHOSPOROUS (P)	LOW	378	1	0	379
	MEDIUM	0	592	2	594
	HIGH	7	0	580	587
	Σ(LMH)	385	593	582	1560

(B)

		PREDICTED NITROGEN (N) COMPOSITION			
		LOW	MEDIUM	HIGH	Σ(LMH)
ACTUAL NITROGEN (N) COMPOSITION	LOW	1260	1	0	1261
	MEDIUM	0	260	1	261
	HIGH	7	0	31	38
	Σ(LMH)	1267	261	32	1560

(C)

		PREDICTED POTASSIUM (K) COMPOSITION			
		LOW	MEDIUM	HIGH	Σ(LMH)
ACTUAL POTASSIUM (K) COMPOSITION	LOW	624	1	0	625
	MEDIUM	0	770	2	772
	HIGH	7	0	156	163
	Σ(LMH)	631	771	158	1560

Fig. 14. Heat Map Depicting the Correlations of the Soil Dataset.

The correlation between the variables is shown in Fig. 14 using a heat map. Correlation matrix that shows the relationship between two parameters in a dataset. The heat map is used in exploratory data analysis to check for correlations between the data. The heat map is used to visualize the parameter correlation matrices as well as to determine which parameters influence the output variable. The level of correlation between the various macro and micro nutrients, as well as pH, Electrical Conductivity (EC), and organic carbon (OC), has been absorbed in the heat map shown above. There is a strong correlation between the macro nutrient (Nitrogen) and the micro nutrient (Calcium), which is essential for the growth of groundnut crops during the time of pod formation, as shown in Fig. 14, but there are also instances of weak correlation. The value of heat map ranges from +1 to -1 where, Positive values indicate positive correlation, while negative values indicate negative correlation. A stronger linear association exists between data points that are closer together, whereas a weaker linear association exists between values that are closer to zero.

### V. CONCLUSION

The prime reason for the loss of soil quality is due to the improper soil and crop management strategies deployed in the process of farming. Excessive usage of chemical fertilizers without the exact knowledge of required nutrients for the cultivation of crops has led to the gradual decline in the soil quality which has contributed towards the gradual decline in the production yield of the crops. Groundnut Crops being the most predominant oilseed crop cultivated in the state of Tamil Nadu, its cultivation has seen too such impacts due to the excessive fertilizer usage and improper cultivation patterns without understanding the actual nutrient of the soil, one of the major causes for the fluctuation seen in groundnut pod growth patterns and production, is the differing soil nutrient compositions of the land which is under cultivation. In this research article we proposed a novel deep learning based approach adapting Enhanced 1D-CNN scheme, towards predicting the soil nutrient composition for the chosen soil nutrient dataset pertaining to the geographical landscape of Villupuram district in the state of Tamil Nadu. The experimental results carried out has clearly shown the effectiveness of the proposed Enhanced 1D-CNN DLM, in terms of the overall performance measures (Accuracy, Precision, Recall, F1 Score, Recall and a very minimal Loss value), the optimality of the proposed model has been compared for its effectiveness with baseline models such as (SVM, Naïve Bayes and ANN) and proven to be outperforming all the baseline models in terms of increased performance measures resulting in the overall prediction accuracy of 99.78% and very minimal error measures. The fertilizer recommendation based on the predicted nutrient composition of the soil makes this proposed model more productive in terms of addressing the objective of this research work. This proposed scheme for the sustainable cultivation of groundnut crop may be considered as a reference scheme for crop specific precision farming moving further.

# Performance Evaluation of Different Supervised Machine Learning Algorithms in Predicting Linear Accelerator Multileaf Collimator Positioning's Accuracy Problem

Hamed S. El-Ghety<sup>1</sup>, Ismail Emam<sup>2</sup>, AbdelMagid M. Ali<sup>3</sup>

Electrical Engineering Department, Faculty of Engineering, Aswan University, Aswan, Egypt<sup>1,3</sup>  
Oncology department, Faculty of Medicine, Ain Shams University, Cairo, Egypt<sup>2</sup>

**Abstract**—Radiation Oncology is one of the businesses that employs Machine Learning to automate quality assurance tests so that errors and defects can be reduced, avoided, or eliminated as much as possible during tumor therapy using a Linear Accelerator with MultiLeaf Collimator (Linac MLC). The majority of Machine Learning applications have used supervised learning algorithms rather than unsupervised learning algorithms. However, in most cases, there is a clear bias in deciding which supervised machine learning algorithm to use. And prediction findings may be less accurate as a result of this bias. As a result, in this study, an evidence is presented for a novel application of Logistic Regression technique to predict Linac MLC positioning accuracy, which achieved 98.68 percent prediction accuracy with robust and consistent performance across several sets of Linac data. this evidence was obtained by comparing the performance of various supervised machine learning algorithms (i.e. Logistic Regression, Decision Tree, Support Vector Machine, Random Forest, Naive Bayes, and K-Nearest Neighbor) in the prediction of Linac MLC's positioning accuracy problem using leaves' positioning displacement datasets with labelled results as training and test datasets. For each method, two parameters were used to evaluate performance: prediction accuracy and the receiver operating characteristics curve. Based on that evaluation, the right selection sequence was proposed for supervised Machine Learning algorithms in order to achieve near-optimal prediction performance for Linac MLC's leaf positioning accuracy problem. As a result, the selection bias, as well as the negative side effects (i.e. ineffective preventive maintenance plan for Linac MLC to avoid and solve causes of inaccurate leaf displacement such as motor fatigue and stuck problems) could have occurred were successfully avoided.

**Keywords**—Linear accelerators; logistic regression; performance evaluation; prediction methods; supervised learning

## I. INTRODUCTION

Machine learning applications have been utilized in different industries including Radiation Oncology [6]. In Radiation Therapy, some researches summarize potential various clinical applications such as head, neck, lung, and prostate cancer as well as radiation toxicity [1][2][3]. Other researches state that differences between planned and actual displacements of multi-leaf collimators (MLCs) are source of errors in dose distributions during radiotherapy [4]. However, Radiation Therapy is still considered niche area with big crude

data that needs extensive use of machine learning applications. And since the precision medicine in radiation oncology, radiation toxicity and complication factors are inevitable conditions for oncology patients after radiotherapy [1][4][5] and since most of time the use of popular supervised learning algorithms (e.g. Support Vector Machine and Decision Tree ) are supported by previous prediction accuracies in other industries regardless of differences in nature of the data itself which is considered a selection bias that may produce less accurate prediction results. So this paper focuses on performance evaluation of different popular supervised learning algorithms in the prediction of leaf displacement accuracy problem utilizing Linear Accelerator with Multi-Leaf Collimator (Linac MLC) by comparing two Criteria factors: the prediction accuracy of the algorithm and the corresponding receiver operating characteristics curve.

This work will help researchers tackling similar Linac MLC prediction problems with the same nature of displacement data to use logistic regression technique confidently to get near-optimal prediction. At the same time, this work will guide researchers in other business areas as well to follow the same evaluation process practice that is undertaken in this paper, prior to using a typical supervised learning algorithm with a typical data of certain nature, by this way, they can properly select the most suitable supervised learning algorithms that gives near-optimal prediction.

As follows, this paper will have seven remaining sections: Methods for supervised learning; Using supervised learning in Linac MLC; Methodology; Implementation; Results and discussion; Conclusion; Acknowledgment; References.

## II. METHODS FOR SUPERVISED LEARNING

This section gives a brief background on different supervised machine learning algorithms.

### A. Decision Tree (DT)

In machine learning, DT is one of the most useful and reliable classifiers. The decision tree has a hierarchical design that employs the divide-and-conquer strategy [7]. As a result, it can be used for classification. And reduced to a series of simple if-then statements [14].

### B. Support Vector Machine (SVM)

SVM is a supervised learning algorithm. SVM is used for classification in many applications. Using the margin concept, the Linear Support Vector Classifier determines an optimal separating hyper-plane. This represents the distance between the hyper-plane and the nearest points to it on either side, and can be maximized for better generalization [8].

### C. Random Forest (RF)

RF classifier is composed of several DTs, like how many trees build up a forest. Deep Decision trees frequently overfit the training data, which means that any minor change in the given data will produce a large variance in classification results. In other words, nature of training data makes them more likely to give wrong predictions with the test dataset. Random forest's decision trees needs to be trained using different portions of training dataset [9]. To classify a new sample, the sample's input vector must be passed down through the forest with each DT. Following that, each DT considers a different section of the input vector to determine the classification conclusion. The forest then decides whether to use the classification with the most 'votes' (for discrete classification outcomes, such as the MLC case study used in this research) or the average of all trees in the forest (for numeric classification outcome). Because the RF algorithm considers the results of multiple DTs, it can reduce the variance caused by considering only one DT for the same dataset [9].

### D. Logistic Regression (LR)

LR is a normal type of regression where two state variables can be modelled easily. Thus, it helps to determine the likelihood that a new sample is associated with a typical class. And if it's used to classify binary samples, an input sample with a probability value greater than 0.50 is classified as 'class A'; otherwise, it is classified as 'class B' [10].

### E. Naïve Bayes (NB)

The NB classifier is a categorization strategy that computes the likelihood of an event based on prior knowledge of the event's conditions. Despite the fact that features in a class may be interdependent, so it considers that an item in that class is not directly associated to any other items [11].

### F. K-Nearest Neighbor (KNN)

KNN classifier involves using a database to classify unknown cases. The observations are displayed in a three-dimensional space, with the number of qualities or features that each observation possesses indicated. Based on its similarity to other data points in the model, a new point is classified using some similarity measures [15]. KNN determines the new point's class by selecting the K closest points to the new example and voting for the most frequent class among them to be the new point's class, and so on, where K is the number of neighbors [8]. Fig. 1 illustrates the KNN method with  $k=1$ .

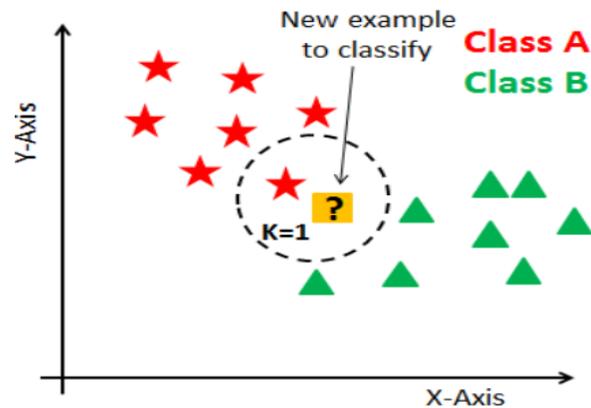

Fig. 1. Illustration of K-Nearest Neighbor Method with  $k=1$ .

## III. USING SUPERVISED LEARNING IN LINAC MLC

Because Modern radiotherapy procedures necessitate the use of high-precision beam shaping devices due to the reliance on administered dosage modulation. Random errors should be eliminated by paying close attention to the accuracy and performance of the MLC. Systematic errors must be identified and reduced [4][5].

Using Supervised Learning Algorithms to predict the problem of leaf displacement accuracy in a multi-leaf Collimator mounted in a Linear Accelerator Head will result in accurate positioning based on the shape of the tumor being treated while protecting other nearby body organs, thereby contributing to accurate radiation dose delivery to oncology Patients. Fig. 2 shows a photo of a Multileaf Collimator [12].

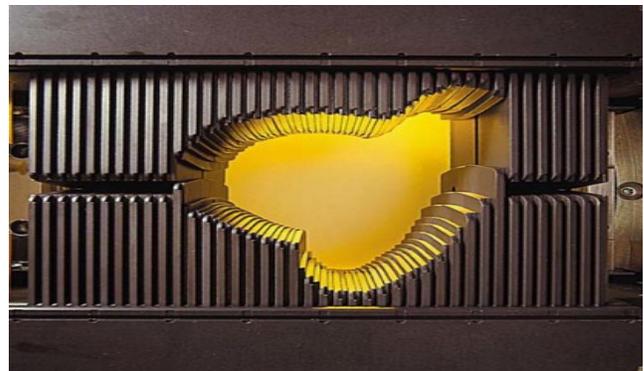

Fig. 2. Photo of Multi-leaf Collimator MLCi2 While A-Bank Leaves (Upper Leaves) and B-Bank Leaves (Lower Leaves) are positioned to take the Precise Shape of the Tumor so that the Treatment Beam can get through that Shape only [12].

## IV. METHODOLOGY

As shown in Fig. 3, the application-related Data (i.e. Linac MLC's Leaves' displacement Dataset) will be used for Training while developing the Learning model provided by the supervised Machine Learning algorithm, as well as for testing to evaluate the developed learning model. As a result, we could finally compute accuracy, draw the receiver operating characteristic curve (ROC), and evaluate the various algorithms.

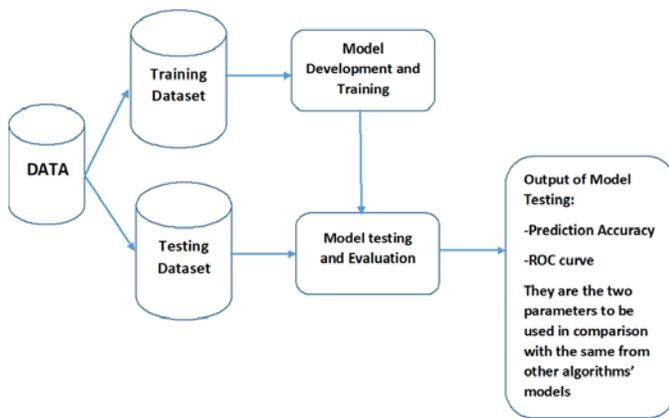

Fig. 3. Steps followed to Assess the Performance of SVM, Decision Tree, RF, Logistic Regression, NB and KNN Algorithms.

### A. Confusion Matrix

The confusion matrix shown in Table I is often used to describe the performance of a classification model (or “classifier”) on a set of test data for which the true values are known [8].

TABLE I. CONFUSION MATRIX FOR TWO CLASSES

	PREDICTED CLASS	
	POSITIVE	NEGATIVE
ACTUAL CLASS	TRUE POSITIVE (tp)	FALSE NEGATIVE (fn)
	FALSE POSITIVE (fp)	TRUE NEGATIVE (tn)

The above confusion matrix taught us that there are two possible predicted classes: "True" and "False" [8]. In this paper, for example, we predict the absence of a leaf positioning accuracy problem for a typical leaf out of 40 pair leaves in Linac MLC, as a result, we can extract and define the following terms:

**True positives (tp):** These are cases where the prediction was correct and the leaves did not have positioning accuracy problem.

**True negatives (tn):** These are cases where the prediction was correct and the leaves have positioning accuracy problem.

**False positives (fp):** These are cases where the prediction was incorrect and the leaves actually did not have positioning accuracy problem.

**False negatives (fn)** are cases where the prediction was incorrect and the leaves actually have positioning accuracy problem. Table I can be used to extract the following rules [3]:

$$\text{Accuracy} = (tn + tp)/(tn + fn + fp + tp) \quad (1)$$

$$\text{Error} = (fn + fp)/(tn + fn + fp + tp) \quad (2)$$

$$\text{Sensitivity} = \text{recall} = tp/(tp + fn) \quad (3)$$

$$\text{Specificity} = tn/(fp + tn) \quad (4)$$

### B. Receiver Operating Characteristics (ROC)

The receiver operating characteristics (ROC) curve and confusion matrix are frequently used to evaluate the diagnostic ability of supervised machine learning algorithms [7]. The Y axis of receiver operating characteristic curves has the tp rate and the X axis has the fp rate. That is, the "ideal" point is at the top left corner of the plot, where fp rate is zero and tp rate is one. However, this isn't very realistic, but it does imply that a larger area under curve (auc) is usually preferable. Fig. 4 depicts an example of evaluation for various ROC curves. Whereas the blue curve has the lowest auc, indicating poor prediction performance, the red curve has the highest auc, indicating excellent prediction performance [13].

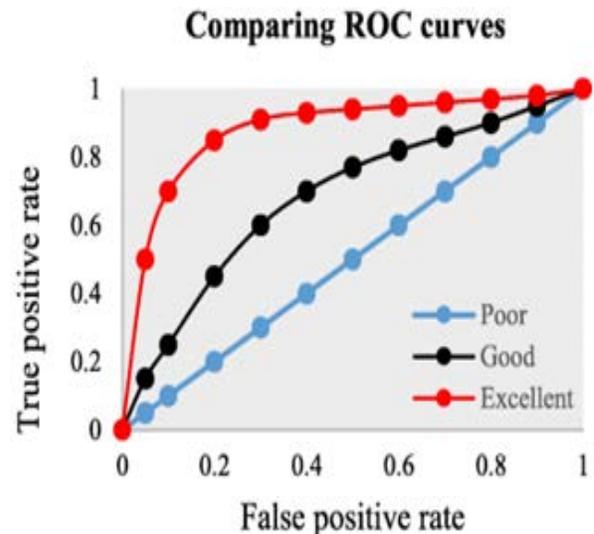

Fig. 4. Illustrates Example Evaluation for different ROC Curves; where Blue Curve is Poor because Area under Curve is the Lowest and Red Curve is Excellent because Area under Curve is Highest.

### C. Data Collection and Processing

Good test and training Dataset was collected over a working year (252 days) for an MLCi2 Multi-leaf Collimator (MLC) mounted in an Elekta Synergy Linear Accelerator. The MLC has 40 leaf-pairs Linac (80-leaves). The 40 leaf-pairs are numbered into two banks “A&B” as: (A1, A2,.....,A40 and B1,.....,B40). The tolerance of the leaf positioning accuracy is 2 mm, while the action level is 3 mm. Table II shows a sample of collected data with labeled input features and its associated labeled result (i.e. answer to question is there isn't positioning accuracy problem?).

As shown in Fig. 5, 70% of MLC leaves displacement dataset was used for training the supervised machine learning models (e.g. x\_train represents training features and y\_train is the labelled result of training dataset) whereas 30% of the dataset was used to test and evaluate the trained models (e.g. x\_test represents test features and y\_test is the labelled result of test dataset).

Data is then processed using Python 3.8 using PyCharm IDE. Python package (i.e. Scikit-learn 0.23.2) was used to implement DT, SVM, RF, LR, NB and KNN Classifiers.

TABLE II. SAMPLE CASES FOR DISPLACEMENT DATA CASES FOR 80 LEAVES MULTI-LEAF COLLIMATOR (TRUE:T /FALSE:F)

LINEAR ACCELERATOR MULTI-LEAF COLLIMATOR MLC LEAVES' DISPLACEMENT (A1,A2,...A40,B1,B2,...B40)										NO POSITIONING ACCURACY PROBLEM?	
A1	A2	A3	A4	A5	...	B37	B38	B39	B40	TRUE T/FALSE F	
0.24	0.99	0.42	0.38	1.17	...	0.24	1.28	0.62	1.04	A BANK LEAVES	B BANK LEAVES
0.38	1.1	0.46	0.34	0.94	...	0.55	0.36	1.1	0.61	T	T
0.42	0.84	0.84	0.92	0.24	...	1.09	0.96	0.75	0.77	A	B
0.55	0.74	0.38	1.15	0.95	...	0.75	0.59	0.46	1.06	T	T

										F	F

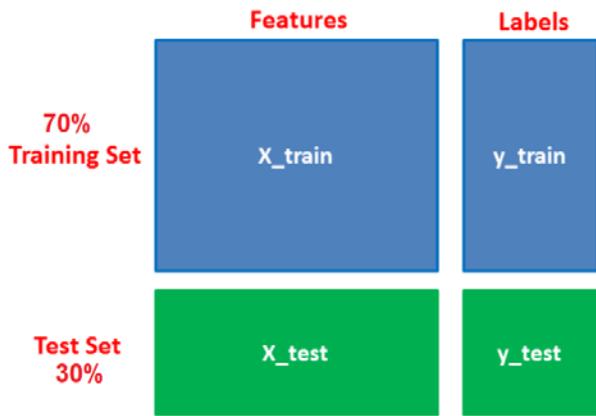

Fig. 5. Illustration of how Linear Accelerator Multileaf Collimator MLC Leaves' Displacement Dataset is Prepared for use by Machine Learning Algorithms.

## V. IMPLEMENTATION

### A. Prediction for MLC's Positioning Accuracy

Table III shows Measured Accuracy achieved by different Classifiers (i.e. DT, SVM, RF, LR, NB and KNN classifiers) in prediction of 40-pairs MLC's positioning accuracy problem.

TABLE III. EVALUATION OF SUPERVISED MACHINE LEARNING ALGORITHMS IN PREDICTION OF LINEAR ACCELERATOR MULTI-LEAF COLLIMATOR POSITIONING ACCURACY PROBLEM

		A-Bank Leaves	B-Bank Leaves
Decision Tree	Accuracy	94.74 %	93.42 %
Support Vector Machine	Accuracy	99.98%	97.37 %
Random Forest	Accuracy	97.36 %	98.68 %
Logistic Regression	Accuracy	98.68 %	98.68 %
Naïve Bayes	Accuracy	97.37 %	94.74 %
K-Nearest Neighbor	Accuracy	96.05 %	98.68 %

It shows that DT, SVM, RF, LR, NB and KNN classifiers were able to predict leaf positioning accuracy problem for Linac MLC successfully with average accuracy of 94.08%, 98.68%, 98.02%, 98.68%, 96.05%, and 97.37%, respectively. While Fig. 6 shows different ROC curves, one per each classifiers based on their prediction performance, so that we can compare between algorithms based on steepness of the curve and area under curve (auc). Where it's clear that red curve representing logistic regression algorithm has the highest ROC area under curve of 0.992, while green curve representing Decision Tree classifier has the lowest ROC area under curve.

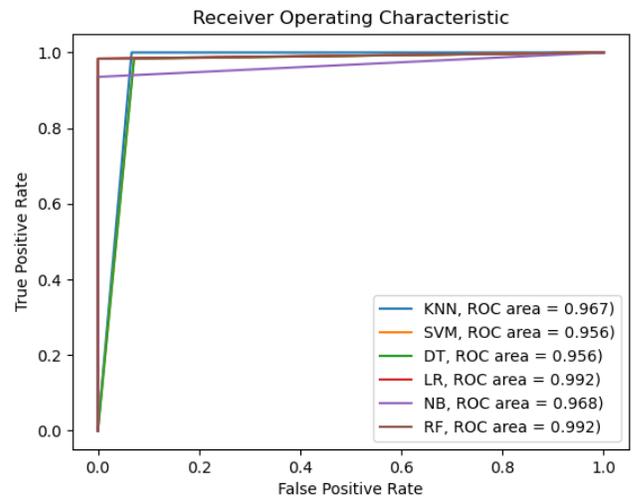

Fig. 6. Receiver Operating Characteristic Curve for Prediction of Linear Accelerator Multi-leaf Collimator's Positioning Accuracy per each Algorithm.

## VI. RESULT AND DISCUSSION

DT, SVM, RF, LR, NB and K-Nearest Neighbor classifiers were able to predict leaf positioning accuracy problem for Linac MLC successfully with average accuracy of 94.08%, 98.68%, 98.02%, 98.68%, 96.05%, and 97.37%, respectively.

Although DT has reasonable average accuracy of 94.08% but it's the lowest one amongst other algorithms. And the ROC curve for DT performance has the lowest steepness and

ROC area under curve as well. So it's not recommended to select DT as first choice to use on such MLC's leaves' displacement dataset nature. On the other side, SVM performed well with average accuracy of 98.68% but it showed lower steepness in ROC Curve and area under curve.

Other classifiers RF, LR, NB and KNN showed better area under curve, and their average prediction accuracies were RF with 98.02%, LR with 98.68%, NB with 96.02% and finally KNN with 97.37%.

However, it's important to note that, Logistic Regression Classifier has the highest ROC area under curve of 0.992 and it showed exceptional performance by having the same classification prediction accuracy of 98.68% over two different datasets of same structure and nature but different values (i.e. MLC's A Bank Leaves' displacements and MLC's B Bank Leaves' displacement) which indicates more performance stability than other classifiers even SVM itself. In this paper, bias of algorithm selection have been successfully avoided and the recommended selection should consider the relevancy order based on classifiers evaluation as shown in Table IV, in context of application area related to MLC's Leaves' displacement Data. And accordingly we do recommend using LR as first choice because it has highest average prediction accuracy and the most stable performance across different MLC's datasets of the same nature.

TABLE IV. PROPOSED SELECTION ORDER FOR CLASSIFIERS TO USE IN PREDICTION OF MLC POSITIONING ACCURACY PROBLEM

Classifiers	Average Accuracy	Selection Order
Logistic Regression	98.68%	1
Support Vector Machine	98.68%	2
Random Forest	98.02%	3
K-Nearest Neighbor	97.37%	4
Naïve Bayes	96.05 %	5
Decision Tree	94.08%	6

On the other hand and according to application area perspective, the high accuracy of the prediction for MLC's Leaves' positioning problem would enable the physicist in oncology center to design customized service/preventive maintenance plans for each individual Linac MLC treatment machine particularly. And that could help to avoid MLC movement failure during radiation therapy sessions.

## VII. CONCLUSION

This work is undertaken to avoid lower performance in prediction process of Linac MLC's positioning accuracy problem. In this paper, performance of DT, SVM, RF, LR, NB and KNN Classifiers is examined by measuring their prediction accuracies utilizing the same two sets of training and testing data for Linac MLC's leaves' positioning displacement data as well as receiver operating characteristic curves for the predicted outcomes per each algorithm. Findings in this study show that Logistic regression Classifier

has exceptional performance by producing the same classification prediction accuracy of 98.68% over two different datasets of same structure and nature but different values (i.e. MLC's A Bank Leaves' displacements and MLC's B Bank Leaves' displacement) which indicates more performance stability than other classifiers even SVM itself. The findings show that values and structure of data affect the prediction accuracy of supervised learning algorithm applications across different industries and not necessarily the same performance. In order to increase the prediction accuracy in the same time, further research work is needed on more training and test datasets over longer periods (e.g. five years), and a multi-institutional study (e.g. different healthcare providers which uses the same model of Linac MLC).

## ACKNOWLEDGMENT

The authors would like to thank the reviewers and editors for their constructive comments.

# Collaborative Course Assignment Problem to Minimize Unserved Classes and Optimize Education Quality

Purba Daru Kusuma, Ratna Astuti Nugrahaeni  
Computer Engineering, Telkom University  
Bandung, Indonesia

**Abstract**—This work proposes a collaborative course assignment model among universities. It is different from existing studies in educational assignment problems or course timetabling, where the scope is only within the institution or department. In this work, the system consists of several universities. A collaborative approach is conducted so that lecturers exchange is possible and conducted automatically. Each university shares its courses and lecturers. The optimization is conducted to minimize the unserved classes and improve education quality. The cloud-theory based simulated annealing is deployed to optimize the assignment. This model is then benchmarked with two non-collaborative models. The first model's objective is to minimize the unserved classes only. The second model's objectives are to minimize the unserved classes and improve education quality. The simulation result shows that the proposed assignment model is better in minimizing the unserved classes and improving education quality. The proposed model reduces 89 to 92 percent of the unserved classes ratio compared with the non-collaborative model.

## I. INTRODUCTION

Course assignment problem is a well-known study in operations research or optimization, especially in education. This popularity comes from the fact that course assignment is an important subject in educational operation. Moreover, circumstances in the educational operation are complex and diverse. First, the regulations in education among regionals or countries are different [1]. Furthermore, some institutions, especially universities, may have specific policies, needs, and objectives [1]. Although there is a generic form of course assignment model, many studies in this subject have specific circumstances that are transformed into objectives and constraints. The objectives include balancing workload [2], minimizing classes without lecturers [3], improving education quality [4], and so on.

Ironically, the scope of most existing studies in education timetabling and assignment problems is still within the university [5] or department [6]. On the other hand, lecturers are limited resources, like the timeslot and room. It means that these offered classes may not be conducted because no lecturers can handle these classes. The other condition is that these classes are still conducted, but the education quality may

be dropped because less competent lecturers serve these classes.

On the other hand, the online class is common today. Due to the COVID-19 pandemic, schools, especially universities, are forced to swift from face-to-face to online interaction [7]. Although the online mechanism still has several weaknesses, such as the degradation of the learning outcomes and lack of interaction [7], the online class has several advantages. The location boundaries are not considered anymore if students and lecturers have reliable internet access [8], especially in rural or remote areas [9]. Moreover, physical rooms are not needed too.

This online class creates opportunities for inter-universities collaboration. Lecturer exchange becomes possible and easy. Some lecturers may teach courses that other universities offer. Through this collaboration, a university can offer courses to its students, although it does not have competent lecturers. A university also can open more classes even though its own lecturers are limited. On the other hand, a university also can provide its lecturers to handle courses or classes beyond their formal homebase. Moreover, assigning a course to a more competent lecturer can improve the education quality. Unfortunately, most studies in education timetabling or assignments were conducted based on physical classroom scenarios. These existing assignment models cannot be implemented directly to tackle this collaborative and online circumstance. Studies in operations research in the education area that promote collaboration and online learning are challenging and potential.

Based on this circumstance, this work proposes a collaborative course assignment model. In this work, the system consists of several universities. Each university shares its several classes and lecturers that can be assigned collaboratively. Each class has a specific course and timeslot. On the other hand, each lecturer can provide several courses and specific timeslots. The objective is to minimize the unserved classes and maximize the education quality.

This assignment model is then optimized by cloud-theory based simulated annealing (CSA). This algorithm is an improved version of simulated annealing. Rather than its original version, CSA is a population-based metaheuristic algorithm where every individual acts independently [10]. In the end, the best individual is chosen as the final solution.

This algorithm is chosen based on several reasons. First, the metaheuristic algorithm is popular in optimizing many operations research studies, especially assignment problems. This popularity comes from its approximate approach so that excessive computation can be avoided, although it may promise near-optimal or acceptable solutions [11]. Second, simulated annealing is a simple algorithm that can easily be implemented, improved, or modified to solve many optimization problems. Third, as a population-based algorithm, CSA is proven better than its original form in providing better solutions [10].

The contributions of this work are as follows:

1) This work proposes a course assignment model conducted collaboratively. The system consists of several universities rather than a single university or department, as it is common in most studies in education assignment or timetabling problems.

2) The proposed model is developed for online classes so that physical rooms are not needed. It is also different from most studies in education assignments or timetabling problems where their circumstance is the physical classroom.

This work is the continuation of our previous works in operations research in the education area. Both previous studies were conducted for joint course programs. The first study focused on the course timetabling [12], while the second focused on the faculty assignment [13]. The difference between this current work and the previous works is that the university's interest is considered in this work. In these previous studies, the existence of the universities as entities that provide lecturers and classes is not considered.

The remainder of this paper is organized as follows. The shortcoming studies in education assignment problems and course timetabling are explored in the second section. The proposed model that consists of both conceptual model, mathematical model, and the algorithm is explained in the third section. The simulation scenario and result are described in the fourth section. The more profound analysis conducted on the simulation result and findings are discussed in the fifth section. Finally, the conclusion and future research potentials are summarized in the sixth section.

## II. RELATED WORK

In general, the assignment problem can be defined as allocating or assigning a certain number of objects to a certain number of other objects in the most optimal way [14]. The assignment problem consists of two components. The first component is the assignment [14], and the second component is the objective function [14]. An assignment is a combinatorial structure that consists of the link between a set of objects and another set of objects. The relationship between these sets of objects can be one-to-one, one-to-many, or many-to-many. On the other hand, the objective is the purpose of the assignment. The objective represents a valid measurement to evaluate the assignment's performance. Based on this concept, assignment problem becomes a part of operations research, and it is widely used in many areas, such as transportation [15], manufacturing [16], logistics [17], and so on.

In the education area, there are two well-known assignment problems. The first is the course timetabling problem [1]. The second is the faculty assignment problem [1]. In the course timetabling problem, a course will be allocated to certain timeslots and rooms. In the faculty assignment problem, the focus is plotting lecturers to the courses in the system. Both problems are at the operational level [1].

To date, there are huge numbers of studies conducting the assignment problem in the education area. This circumstance shows that operation research studies in education are still interesting. Besides, assignment problem in education is widely studied since there are various circumstances in the education institutions. This variety comes from several aspects, such as regulation, institutional objective, and local challenge [2]. Moreover, these studies are usually proposed based on certain specific objectives.

Many studies in the education assignment problem used metaheuristic algorithms as the optimization method. The use of metaheuristic algorithms comes from several reasons. First, the metaheuristic algorithm is a proven method used in many optimization studies. Second, this algorithm is proven to achieve a near-optimal solution with reasonable computation resources [11]. Third, the metaheuristic algorithm is a popular algorithm that has been studied extensively until now. To date, there are hundreds of metaheuristic algorithms that have been developed. Several well-known algorithms are also used in many education assignment problems, such as genetic algorithm [18], simulated annealing [19], tabu search [20], variable neighborhood search [6], genetic programming [21], and so on. Several shortcoming studies in the education assignment problems are summarized in Table I. In the last row, the positioning of this work is stated.

TABLE I. SHORTCOMING STUDIES IN EDUCATION ASSIGNMENT PROBLEM

Table I shows that all shortcoming operation research studies in education still adopt a conventional approach. The scope of these studies is within a university or department. Several studies conducted certain classes, which is relatively small. Moreover, all these studies used physical rooms in the system.

This circumstance makes the existing assignment models cannot be implemented directly in the future education environment. The online collaborative system faces many different circumstances than the face-to-face noncollaborative system. In the future, online learning will become more popular. Moreover, the emergence of online learning makes collaboration among universities more possible. Based on this problem, proposing an assignment model that eliminates the physical boundaries and promotes a collaborative approach as in this work becomes very important and interesting.

The future online learning also promises more efficient teaching system. The university can provide more classes without creating more physical rooms or building so that it can save more capital expenditure for the development and operational expenditure related to the new buildings or rooms, such as electricity, water, cleaning service, furniture, maintenance, and so on. This cost reduction in the end can reduce the educational cost so that the institution will be more competitive. This cost reduction can also be used to tackle the cost increase in other posts, such as employee salary, internet, and so on so that the increase in the tuition fee can be avoided. The online learning also improves the teacher's movement time. In the face-to-face learning, the teacher must move from the current room to other room or from the current building to other building to teach other classes. Moreover, when the university has several separated locations, this movement wastes more time.

### III. PROPOSED MODEL

This collaborative course assignment model consists of several entities: university, lecturer, and class. In the system, there are several universities. Each university has several lecturers and classes that will be shared in the system. It means a university still has a portion of its classes and lecturers that are not included in the system. These classes and lecturers will be managed exclusively by its homebase. Every lecturer can teach several courses, but their competence may be various among the courses. For example, a lecturer can teach database, algorithm, and object-oriented programming courses. His competence in teaching database is average but prominent in teaching algorithm and object-oriented programming. All lecturers have their available timeslots. A class is dedicated to a specific course and timeslot. In this model, students are already assigned to this class. Students are also abstracted and are assumed to take only one class per student. Fig. 1 illustrates the conceptual system. The blue dashed rectangles represent the universities, the blue circles represent the lecturers, and the yellow circles represent the classes.

The relationship between university, class, lecturer, course, and timeslot is as follows. The relationship between university and class is one-to-many. The relationship between university and lecturer is one-to-many. The relationship between lecturer and course is many-to-many. The relationship between lecturer

and timeslot is many-to-many. The relationship between class and lecturer is one-to-many. The relation between classes, courses, and lecturers are shown in Fig. 2. In Fig. 2, red circles represent the lecturers, blue circles represent the courses, and green circles represent the classes.

This proposed model has several hard constraints that cannot be violated [1]. These hard constraints are as follows.

- The number of universities, lecturers, and classes is predetermined [13].
- A lecturer cannot teach courses beyond his competency [13].
- A lecturer cannot teach multiple classes with the same timeslot [12].
- A lecturer cannot teach beyond his possible timeslots [12].
- Timeslot for every class is predetermined [13].
- A class cannot be conducted beyond the provided timeslots [12].
- A class cannot be taught by multiple lecturers [13].

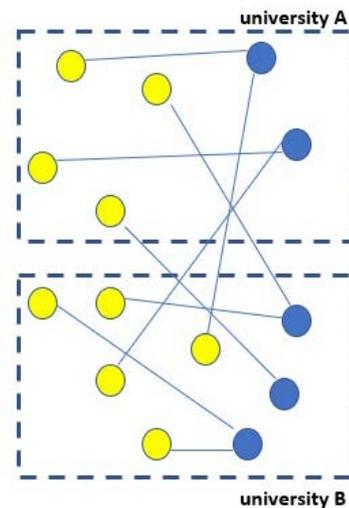

Fig. 1. Conceptual System.

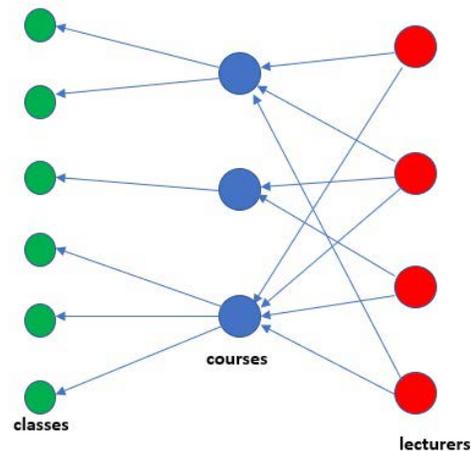

Fig. 2. Relation between Lecturers, Courses and Classes.

This proposed model has two objectives. The first objective is to minimize unserved classes. It becomes the primary objective. The second objective is to maximize the education quality, meaning that classes will be taught by the most competent lecturer wherever possible. The internal lecturer is prioritized to accommodate the university's interest.

There are two types of assignments. The first assignment is the intra-university assignment. The second assignment is the inter-university assignment. In the intra-university assignment, a class will be allocated to the possible internal lecturer exclusively. In the inter-university assignment, a class will be allocated to any possible lecturer without considering the lecturer's homebase. The collaboration is conducted in the inter-university assignment.

This process is then optimized by using cloud-theory based simulated annealing. As a metaheuristic algorithm, it consists of two phases. The first phase is initialization. The second phase is iteration. Both intra-university assignments and inter-university assignments are conducted in the initialization. In the intra-university assignment, several courses may remain unallocated to a lecturer or unserved due to the mismatch problem. These unserved classes will be assigned in the inter-university assignment. Meanwhile, the iteration phase consists of only the inter-university assignment. As in all simulated annealing algorithms, the iteration consists of external and internal loops. In the external loop, iteration runs from the initial high temperature to the end low temperature with a certain decrease rate [10]. In the internal loop, iteration runs from the first iteration to the maximum iteration [10].

Neighborhood search is conducted to improve the solution. The solution candidate is generated near the current solution. If this candidate is better than the current solution, then this candidate replaces the current solution immediately. Otherwise, this candidate may replace the current solution with a certain probabilistic calculation to avoid local optimal trap.

The mathematical model is then developed based on this conceptual model. Several annotations used in this mathematical model are as follows. Meanwhile, the process in the proposed model is shown in Algorithm 1.

<i>u</i>	university
<i>l</i>	lecturer

```

---

The explanation of Algorithm 1 is as follows. The algorithm's output is to find the best individual or solution that consists of the best assignment in meeting the primary and secondary objectives. The initialization consists of intra-university assignments and inter-university assignments that are conducted serially. The outer loop is the loop that runs from the initial high temperature to the end low temperature. The temperature decreases gradually based on the temperature decrease rate. Then, the inner loop consists of iteration from the first iteration to the maximum iteration. In the iteration process, a neighborhood search based on the inter-university assignment is conducted. This neighborhood search is conducted to produce a candidate. Then this candidate is evaluated by two fitness functions that represent the objectives. The first function is minimization, while the second function is maximization. The candidate will replace the current solution immediately only if its performance is better than the current solution in both fitness functions. If the first candidate's first fitness is worse than the current solution, it is rejected immediately. Suppose the candidate is better than the current solution only in the first fitness function. In that case, it may replace the current solution based on a probabilistic calculation

where the fitness gap and the current temperature are considered. After all iterations end, the best solution is selected based on the primary objective.

As it is mentioned previously, the proposed assignment model has two objectives. The first objective is minimizing the unserved classes. The second objective is maximizing the education quality. The first objective is the primary objective, while the second objective is the secondary objective. These objectives are formalized by using (1) to (6).

$$o_1 = \min(f_1(a)) \quad (1)$$

$$f_1(a) = \frac{n(S_u)}{n(S)} \quad (2)$$

$$S_u = \{s \in S | st(s) = 0\} \quad (3)$$

$$o_2 = \max(f_2(a)) \quad (4)$$

$$f_2(a) = \frac{\sum_{n(S_s)p(l,c)}{n(S_s)}, s \in S(l) \quad (5)$$

$$S_s = \{s \in S | st(s) = 1\} \quad (6)$$

The explanation of (1) to (6) is as follows. Equation (1) states that the first objective is to find a solution with minimum unserved classes. Equation (2) states that the first fitness function is obtained by dividing the number of unserved classes by the total number of classes. Equation (3) states that the unserved classes are classes that do not have lecturers. Equation (4) states that the second objective maximizes education quality. Equation (5) states that the education quality is obtained by dividing the summation of lecturers' competence related to the course and class with the number of served classes, and the class is taught by the lecturer. Equation (6) states that the served classes are classes that have lecturers.

The initialization process begins with the intra-university assignment process. Its mechanism is allocating every course to be taught by internal lecturers. This mechanism is conducted by collecting all internal lecturers who are available and competent to teach the selected course. Available means that the lecturer still has an available timeslot that is the same as the class timeslot. Competent means that the course taught in the class is on the lecturer's competence list. This mechanism is formalized by using (7) to (10).

$$st_i(s, l) = \begin{cases} 1, & u(s) = u(l) \\ 0, & \text{else} \end{cases} \quad (7)$$

$$st_a(s, l) = \begin{cases} 1, & t(s) \in T(l) \wedge st(t(l)) = 0 \\ 0, & \text{else} \end{cases} \quad (8)$$

$$st_c(s, l) = \begin{cases} 1, & c(s) \in C(l) \\ 0, & \text{else} \end{cases} \quad (9)$$

$$L_a(s) = \{l | st_i(s, l) = 1 \wedge st_a(s, l) = 1 \wedge st_c(s, l) = 1\} \quad (10)$$

$$l_{se}(s) = U(L_a(s)) \quad (11)$$

$$st(t(l)) = \begin{cases} 1, & \exists s, t(s) = t(l) \wedge l(s) = l \\ 0, & \text{else} \end{cases} \quad (12)$$

The explanation of (7) to (12) is as follows. Equation (7) states the internal status is 1 only if the class and lecturer are in the same university. Equation (8) states that the availability

status is 1 only if the class timeslot is within the lecturer's timeslot and the related lecturer's related timeslot is still available (open). Equation (9) states that the competence status is 1 only if the course in the class is within the lecturer's course list. Equation (10) indicates the set of available lecturers for the class. A lecturer is available if it meets all three statuses. Equation (11) states that the lecturer is selected randomly within the set of available lecturers. Finally, the timeslot status of the lecturer is set 1 if there exists a class in which the timeslot is the same as the lecturer's timeslot, and it is taught by the lecturer as indicated in (12).

The second step is the inter-university assignment process. This step is conducted only for classes that have not been assigned yet after the first step ends. In this step, the university status is not considered anymore. It means that a class can be taught by any available lecturer in the system. This process is formalized by using (13).

$$L_a(s) = \{l | st_a(s, l) = 1 \wedge st_c(s, l) = 1\} \quad (13)$$

Equation (13) shows that only two parameters determine the availability of a lecturer. The first parameter is the availability status, which is determined by using (8). The second parameter is the competence status determined by using (9). Finally, the lecturer is selected by using (12), where the set of available lecturers is determined by using (12).

There are several notes due to the initialization phase. First, this phase does not guarantee that there are no unserved classes. Second, the education quality determined by using (5) has not been optimized.

These notes become the reason to conduct the optimization process through iteration by using cloud-theory-based simulated annealing. In this algorithm, neighborhood search is conducted to improve the current solution. This search follows the inter-university assignment. This search is conducted by selecting several classes randomly. If there exists classes within these selected classes assigned to certain lecturers, then the lecturer-class link will be reset. Finally, the inter-university assignment is conducted for all unserved classes.

#### IV. SIMULATION AND RESULT

The proposed model is then implemented into a simulation to evaluate its performance. In this simulation, a certain number of universities are created. Then, a certain number of lecturers and classes attached to the universities are also created. Every class is conducted for a specific course within a specific timeslot. After these three entities are created, then the simulation runs to allocate these classes to a certain lecturer. The classes' course, lecturers' timeslot, lecturers' course, classes' university, and lecturers' university are generated randomly and follow a uniform distribution.

In this simulation, there are adjusted parameters and observed parameters. The observed parameters are the unserved classes ratio and the education quality ratio. The unserved classes ratio is a ratio between the number of unserved classes and the total classes. The education quality ratio is the average lecturer's competence score among the served classes. Meanwhile, the default value of the adjusted parameters is shown in Table II.

TABLE II. PARAMETERS' DEFAULT VALUE

Parameter	Default Value
$n(u)$	5
$n(C)$	20
$n(C(l))$	4
$n(S)$	200
$n(L)$	$n(S) / 2$
$n(T)$	15
$n(T(l))$	7

There are three simulations. The first simulation is conducted to observe the relation between the number of classes and the observed parameters. The second simulation is conducted to observe the relation between the number of lecturer's timeslot and the observed parameters. The third simulation is conducted to observe the relation between the number of courses conducted by a lecturer and the observed parameters.

The reason of choosing these parameters is as follows. The number of classes, lecturer's timeslot, and lecturer courses are resources that are easily to improve. In the online education environment, university can add more classes without creating new rooms or building which are necessary in the face-to-face teaching environment. The number of lecturer's timeslot is also easy to manage. Even though the total timeslot in a week is fixed, the number of lecturer's timeslot can be improved in several ways if it does not surpass the total timeslot. First, timeslots for the collaborative teaching can be increasing by reducing timeslots assigned for the non-collaborative teaching. Second, several lecturer's non-teaching activities can be shifted outside the teaching timeslots window. The number of lecturers courses is also can be improved easily if the teacher has enough preparation for the new course assignment, especially the courses that are near the current assignment. For example, lecturer that teaches algorithm course can also be assigned to teach other programming related courses, such as object-oriented programming. On the other hand, lecturer that teaches artificial intelligence can also be assigned to teach machine learning and deep learning courses.

This proposed model is benchmarked with two non-collaborative assignment models, in which both models are concerned with minimizing the unserved classes. There is a difference between the first model and the second one. The first model's objective is only to minimize the unserved classes. The second model is not only concerned with minimizing the unserved classes but also with maximizing the education quality. The first model is adopted based on the model proposed by Arratia-Martinez et al [3].

Meanwhile, the second model is adopted based on a model proposed by Wicaksono and Wisesa [28], where education quality is prioritized. But the second model is improvised so that the unserved classes are considered too. Moreover, the circumstance is also modified to be comparable to the proposed model. In this simulation, both models use cloud-theory-based simulated annealing too. They are fairly compared because the purpose of this simulation is not to compare the metaheuristic

algorithms but to compare the collaborative approach with non-collaborative ones.

The first simulation is conducted to observe the relation between the number of classes and the observed parameters. The number of classes ranges from 150 to 250 with 20 step size. Other adjusted parameters are set to default. The result is shown in Fig. 3.

Fig. 3a shows that in general, the increase of the number of classes makes the decrease of the unserved classes ratio. It occurs in both non-collaborative models. On the other hand, the proposed model produces a zero unserved classes ratio due to this scenario. It occurs when the number of classes ranges from 150 to 250 units. It means that the proposed model outperforms both non-collaborative models in this simulation. Comparing both non-collaborative models, the first model is better than the second one in creating a lower unserved class ratio.

Fig. 3b shows that the number of classes does not affect the education quality ratio. The education quality ratio tends to be stagnant in all number of classes. This circumstance occurs in all models. Comparing among models, all models are competitive. Meanwhile, the second non-collaborative model is the best one with a very narrow gap. The performance of the proposed model and the first non-collaborative model is almost equal.

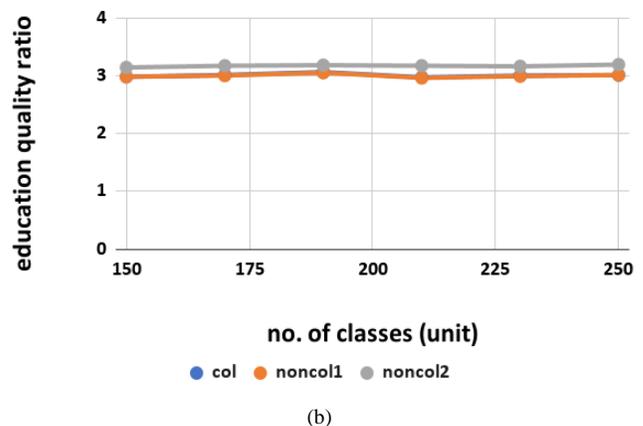

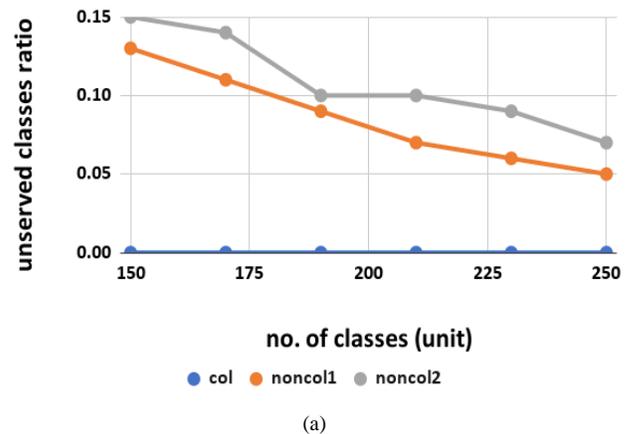

Fig. 3. Relation between the Number of Classes and Observed Parameters: (a) Unserved Classes Ratio, (b) Education Quality Ratio.

The second simulation is conducted to observe the relation between the number of lecturer's timeslots and the observed parameters. The number of lecturer's timeslots ranges from 4 to 8 with 2 step size. Other adjusted parameters are set to default. The result is shown in Fig. 4.

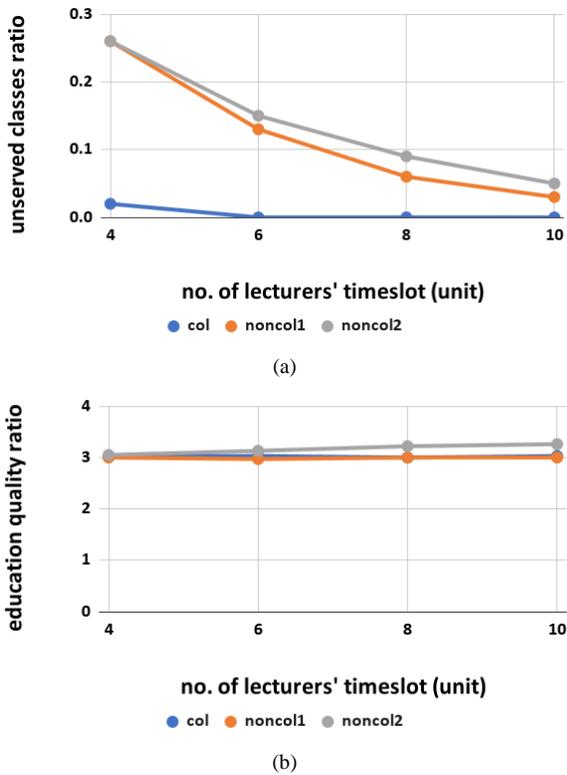

Fig. 4. Relation between the Number of Lecturers' Timeslot and Observed Parameters: (a) Unserved Classes Ratio, (b) Education Quality Ratio.

Fig. 4a shows that the increase of the number of lecturers' timeslot has made the unserved classes ratio decrease. It occurs in all models. Comparing among models, the proposed model performs as the best model. In the beginning, the unserved classes ratio is already very low. Then, the proposed model produces a zero unserved classes ratio when the number of lecturers' timeslot is higher than or equal to 6 timeslots. Meanwhile, the unserved classes ratio decreases significantly due to the decrease in the number of lecturers' timeslot but never reaches zero unserved classes ratio. In the beginning, the unserved classes ratio of the proposed model is only 8 percent of the non-collaborative models. It can be said that the proposed collaborative model reduces the unserved classes ratio by 92 percent relative to the non-collaborative models. The first non-collaborative model is better than the second non-collaborative model. The gap between these two non-collaborative models becomes wider due to the increase in the number of lecturers' timeslot.

Fig. 4b shows that the increase of the lecturers' timeslot creates different responses depending on the model. The education quality ratio tends to be stagnant for the proposed model and the first non-collaborative model. Meanwhile, the education quality ratio tends to increase less significantly due to the increase of the number of lecturers' timeslot for the

second non-collaborative model. The performance is almost equal between the models, but the second non-collaborative model has little advantage.

The third simulation is conducted to observe the relation between the number of lecturer's courses and the observed parameters. The result is shown in Fig. 5. The number of lecturer's courses ranges from 2 to 6 with 2 step size. Other adjusted parameters are set to default.

Fig. 5a shows that the number of lecturers' courses is inversely proportional to the unserved classes ratio. It occurs in all models. Comparing among models, the proposed model performs as the best model. In the beginning, the proposed model creates a very low unserved classes ratio. Then, the proposed model creates a zero unserved classes ratio when the number of lecturers' courses is higher than or equal to 4. Meanwhile, the first non-collaborative model performs better than the second non-collaborative model. In the beginning, the unserved classes ratio of the proposed model was only 11 percent of the non-collaborative model. It means that the proposed model reduces the unserved classes ratio of the non-collaborative model to 89 percent.

Fig. 5b shows that the increase in the number of lecturers' courses does not significantly affect the education quality ratio. The education quality ratio tends to be stagnant for the proposed model and the first non-collaborative model. Meanwhile, the education quality ratio increases less significantly for the second non-collaborative model.

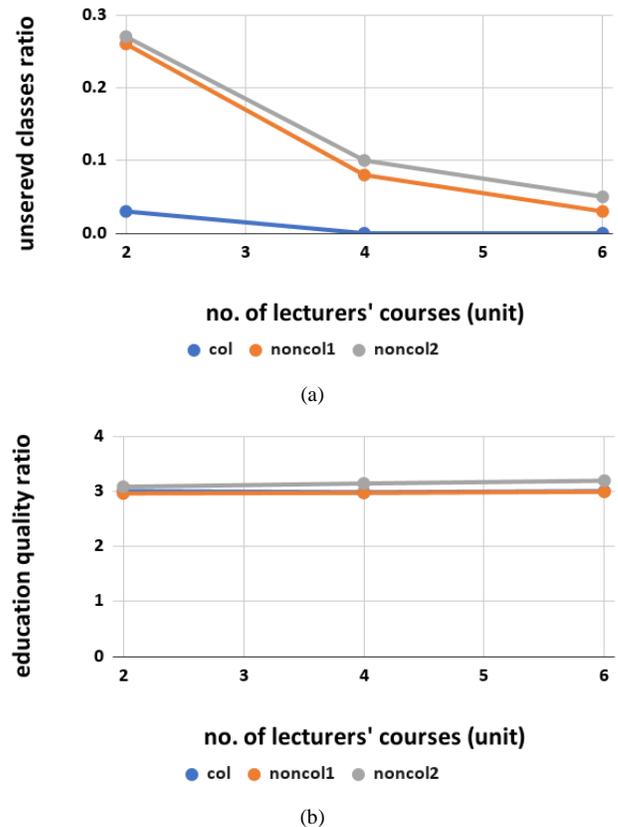

Fig. 5. Relation between the Number of Lecturers' Courses and Observed Parameters: (a) Unserved Classes Ratio, (b) Education Quality Ratio.

## V. DISCUSSION

There are several findings due to the simulation result. The proposed collaborative model is better in minimizing the unserved classes. This proposed model becomes the best model compared with both two non-collaborative models. The proposed collaborative model is competitive enough in maximizing the education quality. Meanwhile, the education quality among models tends to be equal.

All three adjusted parameters are inversely proportional to the unserved classes. The reason is as follows. The higher number of classes with the same number of courses makes the matching process easier. It is because in this simulation, the number of lecturers is proportional to the number of classes. The increase of the lecturers' timeslot also minimizes the unserved classes. It is because the lecturers' availability increases too due to the class predetermined timeslot. The increase of the lecturers' courses also minimizes the unserved classes. But the number of lecturers' timeslot is more significant than the number of lecturers' courses.

The simulation result shows that all three adjusted parameters do not significantly affect education quality. The reason is that education quality is put as the secondary objective during the optimization process. The new solution can replace the existing solution only if its unserved classes ratio is lower. It means that the unserved classes ratio is more prioritized than education quality. It is different from the model that adopts other multi-objective methods, such as non-dominated sorting, as it is used in the non-dominated sorting genetic algorithm (NSGA II) [29] or weighted sum method [30]. In these two methods, all criteria are treated equally. The NSGA II promises pareto optimal [29]. In NSGA II, a solution is better than another if it meets two rules. The first rule is that this solution is better or equal to its opponent in all parameters [29]. The second rule is that this solution is better than its opponent, at least in a parameter [29]. Meanwhile, the weighted sum method is simpler. It is conducted by aggregating all weighted parameters [30]. The weight represents the priority.

Finally, the result shows that the collaborative model tends to be better than the existing non-collaborative models as it becomes the main reason for this work. The collaborative model is proven to improve the quality of service in the context of reducing the unserved classes. The unserved class has become the classic issue in many operations research studies in the education area. In general, despite the chosen optimization method, reducing unserved classes is conducted by increasing the resources (rooms, lecturers, timeslots, and so on). This work shows that the unserved classes can be minimized without increasing resources through collaboration. This collaboration allows idle resources to be transferred to the more needed demand. But this collaboration occurs due to the existence of online learning so that the class can be conducted without physical appearance. This result also strengthens the statement that collaboration or resource sharing can give comparative advantage [31], for example, in improving the utility rate of resources and efficiency [32].

This theoretical result can be used as basis for the practical use in the online collaborative education system. Every

institution (university) can focus on the three aspects (number of classes, number of lecturer's timeslot, and number of lecturer's courses) to reduce the unserved classes. University can shift more classes provided in its own institution to be conducted in the collaborative system. It means that the opportunity of these classes will be conducted by lecturers from outside of the institution will be higher. Reciprocally, the institution can push more lecturers to join the collaborative system of more timeslots to be allocated in the collaborative system. Finally, every institution should encourage its lecturers to conduct more courses. In the current non collaborative system, a lecturer is difficult to teach other courses because these courses have been assigned to the colleagues. On the other side, in the collaborative system, the opportunity to teach beyond the lecturer's traditional courses is wider. This circumstance gives benefit for both parties. The institution will benefit by the reduction of the unserved classes. The lecturers will benefit by improving their skill, competence, and experience.

## VI. CONCLUSION

This work has demonstrated that the proposed collaborative model has met the objective of minimizing the unserved classes and maximizing the education quality. The simulation result shows that the proposed collaborative model outperforms both non-collaborative models in minimizing the unserved classes significantly. The proposed model reduces 89 to 92 percent of the unserved classes ratio compared with the non-collaborative models. On the other hand, the proposed collaborative model performs equally with the non-collaborative models to maximize education quality. The reason is that in this work, the unserved classes are more prioritized than the education quality, so minimizing the unserved classes becomes the primary objective while maximizing the education quality becomes the secondary objective.

This work has several limitations so that it can become the baseline for future improvements. This work has not discussed the financial aspect due to the collaborative approach. In general, any proposed approach should give financial incentives. Without financial incentives, universities will hesitate to adopt any collaborative approaches. Based on it, it is potential and important to propose a financial model that follows the collaborative assignment model. This financial incentive can be obtained through the efficiency of reducing the unserved classes without additional resources, i.e., lecturers or rooms. It means that this saving can be distributed to the existing lecturers and institutions. Second, this financial incentive should be transferred from the institution who owns the class to the institution whose lecturer conducts this class. This financial model should give win-win solution for both institutions.

**Abstract**—The Gujarati language is primarily spoken by Gujarati people living in the state of Gujarat, India. It is the medium of communication in the state of Gujarat. In the Gujarati language, ‘rudhiprayog’ i.e. idiom is a very much popular form of expression. It represents the real flavour of the Gujarati language. The idiom is a group of words saying one thing literally but means something else when we explored it in context. Like Gujarati verbs, idioms can be written in many forms. Due to different morphological forms of the same Gujarati idiom, Gujarati idiom identification is a challenging task for any machine translation system (MTS). Accordingly many forms also make idiom translation more complicated. In the current paper, Gujarati idioms in their different inflected forms are collected, analyzed and classified based on ending words. After classifying idioms, their base or root forms are identified. Base idiom form and their possible idioms forms are morphologically analyzed and rules are generated based on the relationship between base form and possible inflected forms of idioms. These rules are used to generate possible idiom forms from the base idiom form. Gujarati idiom in any valid inflected form can be dynamically detected from the Gujarati input text using the proposed novel morphological analysis based approach. The results are encouraging enough to implement the proposed model of rules for natural language processing tasks as well as a machine translation system for Gujarati language idioms.

**Keywords**—Gujarati; idiom; machine translation system (MTS); morphological analysis; natural language processing (NLP); rudhiprayog

## I. INTRODUCTION

Gujarati is the official language of Gujarat state of India and also recognized by the constitution of India. Gujarati is the Indo-Aryan branch of the Indo-European language family. It is spoken by more than 46 million people. Most of the people speaking Gujarati live in the Gujarat state. Also Gujarati communities spread in the UK, USA and all around the world. Gujarati language is used in newspapers, magazines, television, education, business, communication and in all type of media. Gujarati is written using the Devnagari script. In Gujarati language, two numbers singular and plural are used. Three genders masculine, feminine and neuters are used. Three cases nominative, oblique and locative are used. A Gujarati verb corresponds with a person, number and gender. These all are marked by suffixes attached to the verb root. These make Gujarati inflection fairly complex [1][2][3].

## A. Gujarati Idioms

Gujarati idioms are used in many forms for day-to-day communication in Gujarati language. Idioms are used by Gujarati people for expressing feelings and thoughts. Machine translation of Gujarati idioms is important for the communication with the other non-Gujarati people. Idiom is the phrase whose collective meaning is not the same as literal meaning of its individual words. Gujarati idioms like any other language idioms cannot be translated literally.

## B. Gujarati Idioms with Static Forms

Static idioms are the idioms where its different inflected forms are not possible. Static idioms can have only single form in Gujarati language. For example, અક્કલનો ઓથમીર ‘akkalano othamira’ (i.e. stupid) is the idiom in which other inflected form of idiom does not make any sense. Another Gujarati idiom example is એદીનો અખાડો ‘edino akhado’ (i.e. very lazy) where other inflected and valid idiom forms are not possible.

## C. Gujarati Idioms with Inflected Forms

Inflected idioms are the idioms where its different morphological forms are possible. Inflected idioms can be used by its different forms in the sentence. Inflected idioms are generally ended with Gujarati inflected verb form. Inflection can be applied on the last word of idiom that is usually base verb form. For example, ફાચર માર ‘phacara mara’ (i.e. to disrupt) is the base form of idiom. Its various inflected forms like ફાચર મારવી ‘phacara maravi’, ફાચર મારી ‘phacara mari’, ફાચર મારીને ‘phacara marine’, ફાચર મારવામાં ‘phacara maravamam’ are possible in the Gujarati sentence. Inflection is applied on the last word of base form i.e. on word માર here. Another example, ખટકો રાખ ‘khatako rakha’ (i.e. keep in mind) is the base form and its possible forms used in the sentences are ખટકો રાખ ‘khatako rakha’, ખટકો રાખવા ‘khatako rakhava’, ખટકો રાખવામાં ‘khatako rakhavama’, ખટકો રાખવો ‘khatako rakhavo’, ખટકો રાખી ‘khatako rakhi’, ખટકો રાખીને ‘khatako rakhine’, ખટકો રાખેલા ‘khatako rakhela’, ખટકો રાખેલો ‘khatako rakhelo’, ખટકો રાખો ‘khatako rakho’, ખટકો રાખ્યો ‘khatako rakhyo’; Inflected forms are applied on the last word રાખ ‘rakha’ here.

\*Corresponding Author.

#### D. Stemming of Idioms

Stemming is the important process in natural language processing. The purpose of stemming is to standardize words to their common base form. Stemming removes the affixes of the word to get the root word or base word or stem word [4][5][6]. For example, ફાચર મારવી 'phacara maravi', ફાચર મારી 'phacara mari', ફાચર મારીને 'phacara marine' are various inflected idiom forms used in the sentences; stem/base form of these idioms form is ફાચર માર 'phacara mara' (i.e. to disrupt). Another example, બચકો રાખ 'khatako rakha' (i.e. keep in mind) is the stem/base form of various inflected idiom forms like બચકો રાખવા 'khatako rakhava', બચકો રાખવામા 'khatako rakhavama', બચકો રાખવી 'khatako rakhavi', બચકો રાખી 'khatako rakhi', બચકો રાખીને 'khatako rakhine' etc. So ફાચર માર 'phacara mara' (i.e. to disrupt) and બચકો રાખ 'khatako rakha' (i.e. keep in mind) are the stem form of idioms. This stem/base form is stored once in the idiom database to recognize the idioms from the input text. Using this stem form, other inflected idioms forms can be generated.

The rest of the paper is organized as follows: Section II represents the literature review related to Gujarati idioms translation and its identification from the Gujarati text; Section III covers the methodology including idioms data collection and the steps of proposed model; Results and analysis are discussed in Section IV; finally conclusion, limitations and future work are discussed in Section V.

## II. RELATED LITERATURE REVIEW

Various machine translation system projects have been carried out, especially for the English idiomatic text. Few projects have been taken out for non-English languages containing idioms.

Microsoft Translator and Google Translate are machine translation systems support Gujarati language translation also. Microsoft Translator [7][8] and Google Translate [9][10] use Microsoft cognitive services and Google Neural machine translation system respectively. Both machine translation systems are very much accepted but failed in the correct translation of Gujarati idiomatic text.

Authors [11] employed a GIdTra for translating only Gujarati bigram idioms into English language. They used dictionary based approach for identifying Gujarati idioms from the input text. They focused bigram idioms to test their approach. Other forms of bigram idiom cannot be identified.

Modh and Saini [12] discussed various machine translation approaches for the Gujarati language. The researchers have implemented a context-based Machine Translation System (MTS) for translating Gujarati bigram and trigram idioms into the English language [13].

Researchers [14] experimented n-gram model and used IndoWordNet for getting synonyms of surrounding words of particular idiom. They also exercised various context windows sizes in the case of ambiguity in finding meaning. They also worked on diacritics and suffix based rules [15].

Muzny and Zettlemoyer [16] applied a supervised approach for the automatic identification of English idioms from the corpus of Wiktionary multi-word definitions. They claimed 65% precision level of accuracy.

Verma and Vuppuluri [17] experimented with the combination of dictionary knowledge and web knowledge for English idiom identification. Authors claimed their approach as language as well as domain-independent. They also accepted about non-availability of the meanings of idiom phrases.

Hubers et al. [18] studied on whether the age and emigration length affects the knowledge of idiomatic expressions in the Dutch language or not. They concluded that emigration length negatively affects emigrant idiom knowledge.

Kessler and Friedrich [19] experimented on 9-to-10-year old children whether children can predict idiom-final words. The authors concluded that children rapidly activate multi-word units for idioms and decompose them only after a short delay.

Bakir and Umbu [20] studied American Pie movie script and analyzed the typology of idiomatic expression and contextual meanings of English idioms. Ramadhan et al. [21] prepared a report on the adoption of English movies in learning English idioms for English undergraduate students.

Based on this literature review and study, researchers dealing with idioms face problems in accurate understanding, identification and translation of idioms. Very less work is done especially for the analysis and translation of Gujarati idioms. No researchers have tried to recognize Gujarati idioms from the Gujarati inputted text. No researchers have analyzed various idiom forms of Gujarati language.

The paper focuses on the study of Gujarati idioms and its various forms used in the sentences. The scope of this paper is to generate rules from the analysis of Gujarati idioms collection with their possible forms and implementing these rules in the algorithm for finding all types of Gujarati idioms within inputted Gujarati text. This implementation helps in the simplification and translation of Gujarati idioms to any language in the world.

## III. METHODOLOGY

Different Gujarati idioms are collected and categorized on the basis of static idioms and inflected idioms. Inflected idioms are again sub-categorized on the basis of different ending words. On the basis of analysis of collected Gujarati idioms, rules and base forms of idioms are generated. All base forms of idioms are stored in the idiom database. Finally, the idiom database and these rules are used in the dynamic generation of different forms of the same Gujarati idiom. This dynamic idiom generation helps in identifying all Gujarati idioms from the inputted text.

### A. Data Collection

Overall 3410 distinct Gujarati idioms are collected from different Gujarati language sources [22][23]. From these idioms, 6047 valid different Gujarati idiom forms are

collected. For example, ખટકો રાખવો 'khatako rakhavo' idiom is collected; its distinct and base form is ખટકો રાખ 'khatako rakha' (i.e. keep in mind). From the base form, many inflection forms are possible by adding suffixes and diacritics but valid inflected forms used in Gujarati language are ખટકો રાખવો 'khatako rakhava', ખટકો રાખવો 'khatako rakhavo', ખટકો રાખી 'khatako rakhi', ખટકો રાખીને 'khatako rakhine', ખટકો રાખેલો 'khatako rakhelo', ખટકો રાખો 'khatako rakho', ખટકો રાખ્યો 'khatako rakhyo' etc. These inflected idioms are analyzed with their different possible forms for the derivation and finalization of the stemming rules for idioms. Base forms of all idioms are stored in the idiom database for further processing.

**B. Idiom Classification**

By analyzing the idioms collection, it is found that the idioms can be classified by three ways: (1) n-gram wise where n=1 to 9 (2) m-meaning wise idioms where m=1 to 7 (3) Static idioms and inflected idioms. In this paper, third classification is focused to generate the idiom identification rules. Static idioms are the idioms where only single idiom form is possible and therefore stemming is not appropriate. Inflected idioms are the idioms where various idiom forms from the base form can be generated. In the current paper, inflected

idioms are analyzed. Various idioms with its inflected forms are analyzed to derive stem or base word form of particular idiom.

Table I shows the two types of idioms and its count. Static Gujarati idioms count is 215 and inflected Gujarati idioms count is 5832. Static idioms are the idioms where only single form of idiom is possible so stemming is not meaningful whereas inflected idioms are the idioms where stemming can be applied to derive base form or stem word. Inflected Gujarati idioms are usually ended with verb forms. This base verb form can generate other inflected verb forms of idioms by adding suffixes. For example, ફાચર મારવી 'phacara maravi', ફાચર મારી 'phacara mari', ફાચર મારીને 'phacara marine' are the inflected idioms; it is ended with the different verb forms of માર 'mara'; so base form of these idioms is ફાચર માર 'phacara mara'.

Inflected idioms can further be classified on the base of end words. Inflected idioms can be of four categories on the base of end character(s) or word. (1) Idioms end with વું 'vum' (2) Idioms end with વા 'va' or વામ 'vam' (3) Idioms end with વી 'vi' (4) Idioms end with વો 'vo'. Table II shows these four categories of idioms and their counts.

TABLE I. TYPES OF GUJARATI IDIOMS WITH REFERENCE TO STEMMING

Sr. No.	Types of Idioms	Count	Remarks
1	Static idioms	215	Not possible to derive stem/base word. Only single form of idiom is possible. No similar structure in idioms. Example એદીનો અખાડો 'edino akhado' i.e. very lazy, બારમો ચંદ્રમા 'baramo candrama' i.e. animosity, આડી વાટની ધૂળ 'adi vatani dhula' i.e. fruitless work, ઓઢવા આસ ને પાથરવા ધરતી 'odhava abha ne patharava dharati' i.e. very miserable situation, ગાંઠનું ગોપીચંદન 'ganthanum gopicandana' i.e. at own cost
2	Inflected idioms	5832	Stem word or base form can be derived. Other idiom forms can be generated from the base form. Idiom is usually ending with the base verb form. Example ફાચર મારવી 'phacara maravi' → ફાચર માર 'phacara mara' ખટકો રાખવો 'khatako rakhavo' → ખટકો રાખ 'khatako rakha' Here ફાચર માર phacara mara' is the base form of idiom ફાચર મારવી 'phacara maravi' and માર 'mara' is verb form.
	Total	6047	

TABLE II. INFLECTED IDIOMS WHERE STEMMING CAN BE APPLIED

Sr. No.	Inflected Idioms end with the word	Count	Example
1	વું 'vum'	2534	ગોથું ખાવું 'gothum khavum' i.e. make a mistake
2	વા OR વામ 'va' 'vam'	741	આકાડા વાવવા 'akada vavava' i.e. planting the roots of animosity ઝાવવાં નાખવાં 'jhavam nakhavam' i.e. to boggle
3	વી 'vi'	1370	અંખ ઠરવી 'ankha tharavi' i.e. to be satisfied
4	વો 'vo'	1187	ખોળો ખાલી હોવો 'kholo khali hovo' i.e. to be childless
	Total	5832	

Category 1 Idioms end with word વું : All idioms end with word વું are studied and can be further classified as shown in Table III; Idioms end with word એવું are 18, idioms end with word કવું are 68, idioms end with word કાવું are 2, idioms end with word ખવું are 133, idioms end with word ખાવું are 36, idioms end with word ગવું are 52 and so on. Corresponding base form of these idioms are derived as એવ, મૂક, સુક, રાખ, ખાવ, લાગ and so on. Table III shows a snapshot of partial data for the sub-categories of idioms end with word વું.

TABLE III. SNAPSHOT OF PARTIAL DATA OF IDIOMS END WITH THE WORD વું 'VUM'

Sr No.	Idioms end with the word	Count	Base or stem word derivation
1	એવું 'evum'	18	એવું 'evum' → એવ 'eva'
2	કવું 'kavum'	68	મૂકવું 'mukavum' → મૂક 'muka'
3	કાવું 'kaavum'	2	સુકાવું 'sukavum' → સુક 'suka'
4	ખવું 'khavum'	133	રાખવું 'rakhavum' → રાખ 'rakha'
5	ખાવું 'khaavum'	36	ખાવું 'khavum' → ખાવ 'khava'
6	ગવું 'gavum'	52	લાગવું 'lagavum' → લાગ 'laga'
7	ચવું 'chavum'	10	રચવું 'racavum' → રચ 'raca'
8	ચાવું 'chaavum'	1	ગૂંચાવું 'guncavum' → ગૂંચ 'gunca'
9	છવું 'chhavum'	6	પૂછવું 'puchavum' → પૂછ 'pucha'
10	જવું 'javum'	289	આંજવું 'anjavum' → આંજવ 'anjava'

Category 2 Idioms end with word વા or વાં: All idioms end with word વા or વાં are studied and can be further classified as shown in Table IV; Idioms end with word ઝવા are 1, idioms end with word ટવા are 6, idioms end with word ટવાં are 2, idioms end with word ઠવા are 4 and so on. Corresponding base form of these idioms are derived as સૂઝ, પલટ, વાટવા, ઊઠ and so on. Table IV shows a snapshot of partial data for the sub-categories of idioms end with word વા or વાં.

TABLE IV. SNAPSHOT OF PARTIAL DATA OF IDIOMS END WITH THE WORD વા 'VA' OR વાં 'VAM'

Sr No.	Idioms end with the word	Count	Base or stem word derivation
1	ઝવા 'jhava'	1	સૂઝવા 'sujhava' → સૂઝ 'sujha'
2	ટવા 'tava'	6	પલટવા 'palatava' → પલટ 'palata'
3	ટવાં 'tavam'	2	વાટવાં 'vatavam' → વાટવા 'vatava'
4	ઠવા 'thava'	4	ઊઠવા 'uthava' → ઊઠ 'utha'
5	ઠવાં 'thavam'	4	ઊઠવાં 'uthavam' → ઊઠ 'utha'
6	ડવા 'dava'	57	ઊડવા 'udava' → ઊડ 'uda'
7	ડવાં 'davam'	32	પડવાં 'padavam' → પડ 'pada'
8	ઢવા 'dhava'	12	કાઢવા 'kadhava' → કાઢ 'kadha'
9	ણવા 'nava'	11	ગણવા 'ganava' → ગણ 'gana'
10	થવા 'thavam'	16	થવા 'thava' → થવ 'thav'

Category 3 Idioms end with word વી: All idioms end with word વી are studied and can be further classified as shown in Table V; Idioms end with word તવી are 3, idioms end with word થવી are 33, idioms end with word દવી are 5, idioms end with word દેવી are 21, idioms end with word ધવી are 27 and so on. Corresponding base form of these idioms are derived as જીત, થવ, ખોદ, દેવ, બાંધ and so on. Table V shows a snapshot of partial data for the sub-categories of idioms end with word વી.

TABLE V. SNAPSHOT OF PARTIAL DATA OF IDIOMS END WITH THE WORD વી 'VI'

Sr No.	Idioms end with the word	Count	Base or stem word derivation
1	તવી 'tavi'	3	જીતવી 'jitavi' → જીત 'jita'
2	થવી 'thavi'	33	થવી 'thavi' → થવ 'thava'
3	દવી 'davi'	5	ખોદવી 'khodavi' → ખોદ 'khod'
4	દેવી 'devi'	21	દેવી 'devi' → દેવ 'deva'
5	ધવી 'dhavi'	27	બાંધવી 'bandhavi' → બાંધ 'bandha'
6	પવી 'pavi'	32	ચાંપવી 'campavi' → ચાંપ 'campa'
7	બવી 'bavi'	4	દાબવી 'dabavi' → દાબ 'daba'
8	મવી 'mavi'	12	રમવી 'ramavi' → રમ 'rama'
9	રવી 'ravi'	269	મારવી 'maravi' → માર 'mara'
10	લવી 'lavi'	58	ખોલવી 'kolavi' → ખોલ 'khola'

Category 4 Idioms end with word વો: All idioms end with word વો are studied and can be further classified as shown in Table VI; Idioms end with word ડવો are 138, idioms end with word પવો are 51, idioms end with word મવો are 19, idioms end with word રવો are 183, idioms end with word લવો are 31 and so on. Corresponding base form of these idioms are derived as પાડ, કાપ, જામ, ભર, ખેલ and so on. Table VI shows a snapshot of partial data for the sub-categories of idioms end with word વો.

TABLE VI. SNAPSHOT OF PARTIAL DATA OF IDIOMS END WITH THE WORD વો 'VO'

Sr No.	Idioms end with the word	Count	Base or stem word derivation
1	ડવો 'davo'	138	પાડવો 'padavo' → પાડ 'pada'
2	પવો 'pavo'	51	કાપવો 'kapavo' → કાપ 'kapa'
3	મવો 'mavo'	19	જામવો 'jamavo' → જામ 'jama'
4	રવો 'ravo'	183	ભરવો 'bharavo' → ભર 'bhara'
5	લવો 'lavo'	31	ખેલવો 'kheavo' → ખેલ 'khela'
6	લેવો 'levo'	27	લેવો 'levo' → લેવ 'leva'
7	વવો 'vavo'	139	આવવો 'avavo' → આવ 'ava'
8	સવો 'savo'	11	ખસવો 'khasavo' → ખસ 'khasa'
9	હોવો 'hovo'	39	હોવો 'hovo' → હોવ 'hova'
10	ળવો 'lavo'	53	ઢોળવો 'dholavo' → ઢોળ 'dhola'

C. Rules Derivation [for Dynamic Inflected Idioms Generation from the base form]

By studying and analyzing all four categories of inflected idioms specified in Table III to Table VI, base forms of all idioms are collected. Further, by detailed morphological analysis and using reverse rules generation process, rules are defined to generate various idiom forms from the given base form of particular idiom as shown in Table VII.

Table VII shows the collection of rules for generating dynamic inflected idiom forms from the idiom base form by adding diacritics as well as different suffix characters. For example: ખટકો રાખ 'khatako rakha' is the base idiom form as per Rule 1. As per rule 2, second inflected form ખટકો રાખવા 'khatako rakhava' can be generated by adding suffix 'વ' and diacritics 'ો' to base idiom ખટકો રાખ 'khatako rakha'. As per rule 3, third inflected form ખટકો રાખવાં 'khatako rakhavam' can be generated by adding suffix 'વ' and two diacritics 'ો', 'ં' to base idiom ખટકો રાખ 'khatako rakha'. similar way using remaining rules overall 43 different inflected idioms forms can be generated. All other inflected idioms forms can be generated by adding different character વ 'va' ય 'ya' ન 'na' લ 'la' ઈ 'i' as well as by adding different diacritics as shown in Table VII.

TABLE VII. RULES TO GENERATE POSSIBLE FORMS OF IDIOMS FROM THE BASE IDIOM

Rule No.	Rules Definition	Base form	Inflected idiom forms
1	Base idiom	ખટકો રાખ	ખટકો રાખ
2	Base idiom+'વ'+'ો'	ખટકો રાખ	ખટકો રાખવા
3	Base idiom+'વ'+'ો'+ં'	ખટકો રાખ	ખટકો રાખવાં
4	Base idiom+'વ'+'ો'+મ'+ં'	ખટકો રાખ	ખટકો રાખવામા
5	Base idiom+'વ'+'ો'+મ'+ં'+ં'	ખટકો રાખ	ખટકો રાખવામાં
6	Base idiom+'વ'+'ી'	ખટકો રાખ	ખટકો રાખવી
7	Base idiom+'વ'+'ુ'	ખટકો રાખ	ખટકો રાખવુ
8	Base idiom+'વ'+'ુ'+ં'	ખટકો રાખ	ખટકો રાખવું
9	Base idiom+'વ'+'ો'	ખટકો રાખ	ખટકો રાખવો
10	Base idiom+'ો'	ખટકો રાખ	ખટકો રાખા
11	Base idiom+'ો'+ં'	ખટકો રાખ	ખટકો રાખાં
12	Base idiom+'ો'+ય'+ુ'+ં'	ખટકો રાખ	ખટકો રાખાયું
13	Base idiom+'ો'+વ'	ખટકો રાખ	ખટકો રાખાવ
14	Base idiom+'ો'+વ'+ં'	ખટકો રાખ	ખટકો રાખાવા
15	Base idiom+'ો'+વ'+ં'+ં'	ખટકો રાખ	ખટકો રાખાવાં
16	Base idiom+'ો'+વ'+'ી'	ખટકો રાખ	ખટકો રાખાવી
17	Base idiom+'ો'+વ'+'ુ'+ં'	ખટકો રાખ	ખટકો રાખાવું
18	Base idiom+'ો'+વ'+'ો'	ખટકો રાખ	ખટકો રાખાવો
19	Base idiom+'ી'	ખટકો રાખ	ખટકો રાખી
20	Base idiom+'ી'+ન'+ે'	ખટકો રાખ	ખટકો રાખીને
21	Base idiom+'ુ'	ખટકો રાખ	ખટકો રાખુ
22	Base idiom+'ુ'+ં'	ખટકો રાખ	ખટકો રાખું

23	Base idiom+'ે'	ખટકો રાખ	ખટકો રાખે
24	Base idiom+'ે'+વ'+ં'	ખટકો રાખ	ખટકો રાખેલા
25	Base idiom+'ે'+વ'+'ો'	ખટકો રાખ	ખટકો રાખેલો
26	Base idiom+'ે'+વ'+ં'+ં'	ખટકો રાખ	ખટકો રાખેલાં
27	Base idiom+'ે'+વ'+'ી'	ખટકો રાખ	ખટકો રાખેલી
28	Base idiom+'ે'+વ'+'ુ'	ખટકો રાખ	ખટકો રાખેલુ
29	Base idiom+'ે'+વ'+'ુ'+ં'	ખટકો રાખ	ખટકો રાખેલું
30	Base idiom+'ે'+વ'+'ો'	ખટકો રાખ	ખટકો રાખેલો
31	Base idiom+'ો'	ખટકો રાખ	ખટકો રાખો
32	Base idiom+'ો'+ઈ'	ખટકો રાખ	ખટકો રાખોઈ
33	Base idiom+'ો'+વ'+ં'	ખટકો રાખ	ખટકો રાખોવા
34	Base idiom+'ો'+વ'+ં'+ં'	ખટકો રાખ	ખટકો રાખોવાં
35	Base idiom+'ો'+વ'+'ી'	ખટકો રાખ	ખટકો રાખોવી
36	Base idiom+'ો'+વ'+'ુ'	ખટકો રાખ	ખટકો રાખોવુ
37	Base idiom+'ો'+વ'+'ુ'+ં'	ખટકો રાખ	ખટકો રાખોવું
38	Base idiom+'ો'+વ'+'ો'+ં'	ખટકો રાખ	ખટકો રાખોવો
39	Base idiom+'ુ'+ય'+ં'	ખટકો રાખ	ખટકો રાખ્યા
40	Base idiom+'ુ'+ય'+ં'+ં'	ખટકો રાખ	ખટકો રાખ્યાં
41	Base idiom+'ુ'+ય'+'ુ'	ખટકો રાખ	ખટકો રાખ્યુ
42	Base idiom+'ુ'+ય'+'ુ'+ં'	ખટકો રાખ	ખટકો રાખ્યું
43	Base idiom+'ુ'+ય'+'ો'	ખટકો રાખ	ખટકો રાખ્યો

Rules definitions specified in Table VII are applied on the base idiom form to generate all possible idiom forms dynamically. These rules help in searching any inflected idiom form available in the input text.

D. Idiom Database Creation

Database of idioms is mainly required to store the distinct base form of idiom and its simplified Gujarati meaning. Idiom database is created with idiom column and other related columns like Gujarati meaning, English meaning etc. Static idioms are having single form so they are stored in idiom column as it is. For inflected idioms, their base form is stored once in the idiom column. Gujarati meaning column stores the meaning of particular Gujarati idiom in simple Gujarati words.

E. Proposed Model

Fig. 1 shows the algorithm steps for the proposed model.

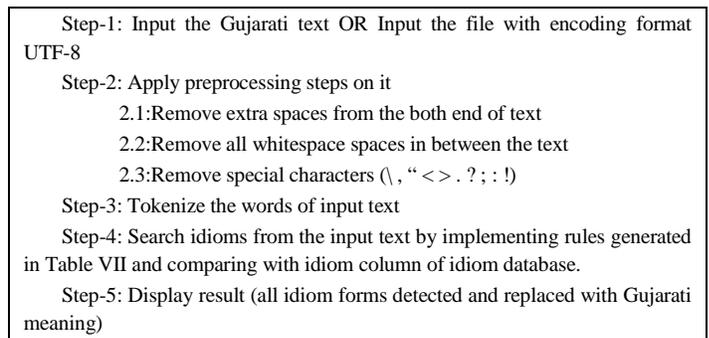

Fig. 1. Algorithm for the Proposed Model.

Input is the Gujarati idiomatic text that may contain any number of Gujarati idioms. Output will be the Gujarati text without any idiom. In the output text, all idioms will be replaced with the value of Gujarati meaning column. Other Gujarati text will remain as it is. Output is nothing but Gujarati text without any idioms. For example,

INPUT TEXT= કોઈ પણ કામમાં ફાયર મારવી એ તેનો સ્વભાવ છે. 'ko'i pana kamamam phacara maravi e teno svabhava che'.

FINAL OUTPUT= કોઈ પણ કામમાં વચમાં અડચણ નાખવી એ તેનો સ્વભાવ છે. 'ko'i pana kamamam vacamam adacana nakhavi e teno svabhava che'.

#### IV. RESULT AND ANALYSIS

Overall 7400 different idiom forms were entered as input text. Input text may contain one or more idiom phrases. Output results were obtained. The correctness of output results was verified by the two linguists with Gujarati mother tongue and doctorate degree in Gujarati language. The proposed model was able to detect all inflected idiom forms present within Gujarati text successfully. The input text is nothing but the Gujarati idiomatic text using any inflected idiom form and the output shows the replacement of Gujarati idiom with simple Gujarati meaning of the particular idiom. For example;

Example 1:

INPUT TEXT= ખટકો રાખવા ખટકો રાખી  
'khatako rakhava khatako rakhi'

FINAL OUTPUT= કોઈ વાત બરાબર ધ્યાનમાં રાખવી કોઈ વાત બરાબર ધ્યાનમાં રાખવી.

'ko'i vata barabara dhyanamam rakhavi ko'i vata barabara dhyanamam rakhavi'.

Example 2:

INPUT TEXT= વિદ્યાર્થીઓએ અભ્યાસ માટે ખટકો રાખવો જરૂરી બને છે. 'vidyarthi'o'e abhyasa mate khatako rakhavo jaruri bane che'.

FINAL OUTPUT= વિદ્યાર્થીઓએ અભ્યાસ માટે કોઈ વાત બરાબર ધ્યાનમાં રાખવી જરૂરી બને છે. 'vidyarthi'o'e abhyasa mate ko'i vata barabara dhyanamam rakhavi jaruri bane che'.

For understanding, ખટકો રાખ 'khatako rakha' (i.e. keep in mind) is the base form of idiom. Its many inflection forms are possible by adding suffix વ ય ન લ ઈ and/or by adding different diacritics. But only valid different forms are given for testing like ખટકો રાખવા, ખટકો રાખવામાં, ખટકો રાખવો, ખટકો રાખી, ખટકો રાખીને, ખટકો રાખે, ખટકો રાખેલા, ખટકો રાખેલો, ખટકો રાખો, ખટકો રાખ્યો, ખટકો રાખ્યા, ખટકો રાખ્યો; Proposed algorithm detects all the inflected forms of base form idiom ખટકો રાખ and so algorithm displays the output as Gujarati meaning of idiom as કોઈ વાત બરાબર ધ્યાનમાં રાખવી. Other Gujarati text will remain as it is in the output. Table VIII displays Output text for the given Input text. Output text is the

same Gujarati meaning for any inflected idiom form of the same base idiom.

TABLE VIII. DIFFERENT INFLECTED FORMS OF IDIOM AS INPUT AND CORRESPONDING OUTPUT

Sr No.	Input text	Output text (Gujarati meaning)
1	ખટકો રાખ 'khatako rakha'	કોઈ વાત બરાબર ધ્યાનમાં રાખવી 'ko'i vata barabara dhyanamam rakhavi'
2	ખટકો રાખવા 'khatako rakhava'	
3	ખટકો રાખવામાં 'khatako rakhavama'	
4	ખટકો રાખવો 'khatako rakhavo'	
5	ખટકો રાખી 'khatako rakhi'	
6	ખટકો રાખીને 'khatako rakhine'	
7	ખટકો રાખે 'khatako rakhe'	
8	ખટકો રાખેલા 'khatako rakhela'	
9	ખટકો રાખેલો 'khatako rakhelo'	
10	ખટકો રાખો 'khatako rakho'	
11	ખટકો રાખ્યા 'khatako rakhya'	
12	ખટકો રાખ્યો 'khatako rakhyo'	
13	ફાયર માર 'phacara mara'	વચમાં અડચણ નાખવી 'vacamam adacana nakhavi'
14	ફાયર મારવી 'phacara maravi'	
15	ફાયર મારી 'phacara mari'	
16	ફાયર મારીને 'phacara marine'	
17	ફાયર મારવામાં 'phacara maravamam'	
18	ભાંગરો વાટ 'bhangaro vata'	છૂપી વાત ખુલ્લી કરવી 'chhupi vata khulli karavi'
19	ભાંગરો વાટી 'bhangaro vati'	
20	ભાંગરો વાટવો 'bhangaro vatavo'	
21	ભાંગરો વાટ્યો 'bhangaro vatyo'	
22	ભાંગરો વાટીને 'bhangaro vatine'	

Features of proposed algorithm are as follows:

1) Applied algorithm is domain independent. Proposed implementation detects all Gujarati inflected idioms used anywhere in the input text and replaces all Gujarati idioms with simple Gujarati meaning.

2) Proposed model stores base form of inflected idiom in the database as single record. For example base form ભાંગરો વાટ 'bhangaro vata' (i.e. disclose a secret) is stored in the idiom database once, but it is used to generate all possible forms of the same idiom like ભાંગરો વાટી 'bhangaro vati', ભાંગરો વાટવો 'bhangaro vatavo', ભાંગરો વાટ્યો 'bhangaro vatyo', ભાંગરો વાટીને 'bhangaro vatine' etc.

3) Dictionary based approach is applied for searching static idioms from the input text because static idioms are having the single possible idiom form. No rules are applicable on static idioms as they are found in irregular forms like અક્કલની ખાણ 'akkalani khana' i.e. very intelligent person, આંખનો પાટો 'ankhano pato' i.e. disgusting, કાચું સોનું 'kacum sonum' i.e. very fertile land, ખાસડાને તોલે 'khasadane tole' i.e.

inferior, બારે દહાડા ને બારીસે ઘડી 'bare dahada ne batrise ghadī' i.e. persistent, માથે રાત જેવું ધાબું 'mathe rata jevum dhabum' i.e. utter darkness, વરઘોડાની વાડી 'varaghodani vadi' i.e. transient, વાડ તેવો વેલો 'vada tevo velo' i.e. people follows king etc.

4) Inflected idioms are generally ended with the words વું 'vum', વા 'va', વાં 'vam', વી 'vi', વો 'vo'. These idioms are collected and analyzed in Table III to Table VI. Considering limited number of idioms, base idiom forms of these idioms are collected manually. Using reverse process, algorithm is developed to generate all idioms forms from the base form. Only base forms of idioms are stored once in the idiom database.

5) Proposed algorithm generates all possible forms of idioms by applying all Table VII rules to base idiom form for detection of any idiom in the input text. So it sometimes rectifies minor spelling mistakes in the Gujarati idiom form automatically. For example, ભાંગારો વાટય 'bhangaro vatya' and ભાંગારો વાટવ 'bhangaro vatava' both are erroneous spelling forms of base idiom ભાંગારો વાટ 'bhangaro vata' i.e. disclose a secret; but the proposed algorithm considers and corrects both as ભાંગારો વાટ 'bhangaro vata' i.e. disclose a secret.

6) The proposed model is the first approach in Gujarati language that able to find out any valid and possible forms of Gujarati idioms present in the Gujarati text and provides Gujarati simplification of the particular idiom.

#### V. CONCLUSION, LIMITATIONS AND FUTURE WORK

The proposed rule-based model was successfully implemented and it successfully detected all the static and inflected Gujarati idiom forms from the Gujarati text. The proposed algorithm successfully detected all the idioms by implementing a dictionary-based approach as well as dynamic idiom form generation rule-based approach. The proposed algorithm generates all possible idiom forms dynamically to determine whether any inflected form of a particular base form idiom is present in the input text or not.

The proposed system can detect any form of the idiom from the Gujarati text but the thing is that the particular idiom base form must be present in the idiom database. The proposed system could not identify idiom that is not available in the idiom database. Future work is to collect all Gujarati idioms from possible sources to rectify this shortcoming. Also algorithm applies all the generated rules to all base form of idioms for generating possible idiom forms.

Based on the results obtained, it is advocated that the proposed system is worth implementation in the real world for machine translation of the Gujarati language. All pioneering machine translation systems for the Gujarati language including Google Translate and Microsoft Translator face the problem of idiom translation. The proposed system successfully identifies the Gujarati idioms available in the input text. The idiom identification method of the proposed model makes it easy for any machine translation system to deal with the Gujarati idiom. Additionally proposed system simplifies the idiom in terms of providing Gujarati meaning of that idiom. We believe that the output provided by the

proposed system is the text without any Gujarati idiom will be further useful for the translation of Gujarati idiomatic text to any other language in the world.

# Towards Employee Perceived Satisfaction in using Citrix Workspace Technology

Bandar Ali Al Fehaidi, Muhammad Asif Khan

Department of Information Systems, Taibah University, Madina al Munawwara, Saudi Arabia

**Abstract**—In view of increasing use of technologies and their impacts in businesses, companies are now using technology to accelerate business processes. However, some companies are still failing to achieve the desired promising results by using technology. Technology in any company succeeds only when the people working in the company accept the technology wholeheartedly and show diligence in learning and using it. In this research we have evaluated the perceptions about a technology called Citrix Workspace in a Saudi company to see whether workers are satisfied with this technology and how they find its usefulness at work. A theoretical framework Technology Acceptance Model (TAM) has been used in this research to study different variables. The data collected by employees within the organization has been analyzed in order to determine level of satisfaction with the technology and to know factors that keep the workers away from remote use of the technology. These results also help managers decide how Citrix Workspace technology or other such technologies can be used in remote sites of the company.

**Keywords**—Citrix workspace; employee satisfaction; secure remote access; mobile worker; TAM

## I. INTRODUCTION

These days working remotely has become an accepted practice in business organizations due to its ease, effectiveness and emerging technologies. Therefore, remote working and its applications need to be deeply understood from employees' perspectives. A Saudi company has been using Citrix Workspace platform to enable its employees to work anywhere and anytime. Citrix Workspace offers users a secure, single sign-on (SSO) channel to access all of the applications and content of an organisation's network so that it can be run across various appliances including laptops, smartphones and tablets, thereby enabling employees to work anywhere. It brings all employees applications, desktops and files into one place anywhere, anytime. Employees have access to everything they need in one location. This includes access to applications, desktop and their files with full desktop experience. Applications in Citrix Workspace can be collated in customized categories which make quick access to required application. Citrix Workspace integrates applications whether they are running in clouds or they are hosted on-premises. In order to use Citrix Workspace, employees use two factors authentication to access more than one-hundred applications and information systems to do their jobs anywhere. A reliable communication to the information systems, appliances and content workers has been founded to increase worker output and improve business performance. Technology has changed the way we interconnect with the world around us. It has

modified the way of learning, shopping, socializing and working. In today's workforce, technology has changed the way companies interact with their employees and make online business interactions [1-2]. In recent Corona-19 pandemic situation organizations allowed employees for remote working using various applications. The management of the Saudi company decided to allow employees of the company to work remotely using Citrix Workspace platform following the regular office hours. A part of the vision of the Saudi company in information technology and digital transformation is to deliver best practice, transparent and secure information technology and communication services to customer. Because Citrix Workspace is a new remote work system, the matter of estimating employees' satisfaction and performance with and perceptions of Citrix Workspace has received little attention. This motivated us to assess the level of satisfaction and performance of the employees using Citrix Workspace as a remote platform. This research will attempt to fill this gap by addressing variables that influence employees' satisfaction and performance with and perceptions of Citrix Workspace. Researchers have been evaluating performance of different technologies to determine effectiveness [3] that also motivated us to conduct this study.

Since the Citrix Workspace has been introduced recently, a little investigation has been conducted to determine the employees' satisfaction and performance in terms of ease of use and effectiveness. In order to conduct our research following research question has been devised to which answer will be sought:

“What are perceptions of employees' satisfaction and performance about Citrix Workspace?”

In order to answer the question, Technology Acceptance Model (TAM) is the best model to measure employees' acceptance and satisfaction with Citrix Workspace in the Saudi company. The model is one of the most predominate and common models of research. It concludes that perceived usefulness and perceived ease of use are central to determining an individual's attitude to using the technology and, thus, eventually relating to actual use. Researchers and companies have consequently been attempting to realise variables that positively impact an individual's acceptance of information technology, thereby finally supporting its use. In the information technology field, TAM is one of the better-known models for clarifying why people use technology.

TAM is a model used in information to assess individual's attitude in adoption of technology in working environment. It concludes the perceived usefulness and perceived ease of use

are central to this assessment. Researchers and companies have consequently been attempting to realize variables that positively impact an individual's acceptance of information technology, thereby finally supporting its use:

Based on the TAM, the following hypotheses have been developed:

H1: Perceived ease of use has a significant positive influence on perceived usefulness.

H2: Perceived ease of use has a significant positive influence on actual usage.

H3: Actual usage has a significant positive influence on user satisfaction.

H4: User satisfaction has a significant positive influence on performance.

This study aims to determine employees' satisfaction and performance with using Citrix Workspace and to address any factors that may lead to dissatisfaction.

## II. LITERATURE REVIEW

Remote working and work from home policies were promoted during 1970s in response to the hike in oil prices, but recent Covid-19 pandemic has given executives a serious thought to shift major section of workforce remotely [4]. Although Covid-19 has forced people to work remotely, but the success of this practice shows many will continue to work remotely on permanent basis and number of remote workers will rise in future. Organisations must take great care when approaching, designing, implementing, and fine-tuning their remote work solutions. The current context of the remote work revolution not only transforms any company into a possible case study but also provides an opportunity to investigate remote work trends at a worldwide level. This could possibly give all of the necessary evidence to justify adjusting remote work initiatives to different nations with different backgrounds [5]. This provides the basis for choosing the Saudi company as a case study to explore new remote work initiatives by assessing employees' satisfaction and performance of using Citrix Workspace as a remote work solution.

With regards to remote work solutions, for so many years organisations have relied on virtual private networks (VPNs) to allow remote workers access to their networks. However, when actions to contain the coronavirus led many businesses to shift from traditional office workspace to remote working, many more employees became remote workers. When this occurred, VPN technology proved insufficient to cope with the increasing need for a larger number of employees to work remotely. Consequently, Some IT departments shifted from VPN solutions to Citrix Workspace using on-premises servers without sacrificing security. With Citrix Workspace, system administrators are able to tailor and distribute any number of workspaces effectively and easily, each with its required applications, appliances, data, and networking services to be aligned with an organisation's needs for different uses [6]. Citrix system is widely used as a mean for remote working which has strong position in the market of remote applications and desktop virtualization [7]. Therefore, user satisfaction and

performance with Citrix Workspace need to be measured in the current study. In a study [8] it is reported that employees' productivity increased by 13% due to work at home and fewer breaks taken and better performance per minute. Furthermore, remote workers also reported extraordinarily high work satisfaction and their job exhaustion rate was approximately 50% decreased. Nevertheless, the study did not mention either technology used or relationship between technology and employees' satisfaction and performance which is core focus in the current study. In a separate study it is reported that in addition to saving money on traditional office workspace, employee satisfaction rankings were approximately 90 percent due to working remotely [9]. In another study it is reported that flexible work schedule has a positive impact on the life satisfaction of employees [10]. There is a positive relationship between flexible work schedules and worker satisfaction. A research study has addressed the impact of psychological happiness on employee satisfaction which can be linked to increased productivity resulting from flexible work schedules [11]. The research conducted by [10-11] has analysed the impact of flexible work schedules on worker satisfaction without determining which remote work solution was used as a variable which could affect employees' satisfaction.

### A. Perceptions of Ease of Use

There is a considerable body of empirical research indicating that perceptions of ease of use significantly influence the information system context [12]. Perceptions of ease of use refer to the extent to which an individual anticipates being able to utilise a system with relatively little effort or struggle [13]. It is widely suggested in the empirical literature relating to IS that the greater is a system's ease of use, the greater will be the perceptions of how useful that system is [14]. Several studies in the empirical literature have established a positive relationship between perceptions of ease of use and perceptions of how useful a system is [15].

### B. Perceived Usefulness

It is defined as "the degree to which a person believes that using a particular system would enhance his or her job performance" [13]. It is the perception of technology users which they build based on the results of their experience. In view of perceived usefulness, frequency of actual use of technology is suggested and its positive effect on individual's performance studied [16].

### C. User Satisfaction

When considering the context of information systems, it is necessary to establish whether use of the system results in the satisfaction of users [17]. In the current study, the satisfaction of users is gauged in terms of the extent to which users of the Citrix Workspace are satisfied with their decision to use the technology and whether it lived up to their expectations.

### D. Performance Impact

There are many reports in the empirical literature that higher levels of user satisfaction are associated with superior performance impact [16, 18-19]. Each of these investigations add to the existing body of knowledge and help to better understand the nature of the relationship between actual use and how individuals perform in the context of organizations.

Staff performance is influenced by the quality of the system and user satisfaction. If workers are satisfied with a computer system, it will add value and contribute to their performance and productivity [20]. The study also stated the impact of technology attributes on user satisfaction. The relationship between user satisfaction, performance and Citrix Workspace will be further investigated in the proposed research, as mentioned in hypothesis.

### III. METHOD AND DATA PREPARATION

The study was devised as a quantitative correlational research design to examine the relationship between employee satisfaction and performance using Citrix Workspace to work remotely within the Saudi company. A quantitative method was deemed most suitable in this research because quantitative researchers concentrate on exploring measurable phenomena using statistical techniques [21]. Correlational designs are suitable when the objective of the study is to examine the relationship between variables of interest. The TAM is used to measure the employees' satisfaction and performance when using Citrix Workspace. An online survey questionnaire was designed using Google Forms to collect data from the respondents and that data is analyzed to draw out results and findings. Questionnaire is a best tool to determine user intention, expectation and perception [22-23].

Based on the four hypotheses stated above, relationships between five variables will be examined. These variables are perceptions of ease of use, perceptions of usefulness, actual use, the satisfaction of users, and performance.

#### A. Survey Instrument and Data Collection

The main instrument to conduct the study is an online self-administered questionnaire which was developed for this study. The population of the study is users of Citrix Workspace from all departments of the Saudi company. The purpose of the survey instrument was to determine employees' level of satisfaction in using Citrix Workspace technology remotely. The questionnaire was distributed among all work areas of the Saudi company (Central, Western, Eastern and Southern region) and 191 responses were received. 5 of the responses were rejected because the respondents did not use Citrix Workspace at all. Consequently, the sample of the research was 186 responses.

The questionnaire consisted of two main sections with 39 items/statements. It included various types of questions such as the following: (1) rating scale questions utilizing a Likert-type 5-point scale (i.e. 1 = strongly disagree, 2 = disagree, 3 = neutral, 4 = agree, and 5 = strongly agree); (2) multiple choice single answer questions; and (3) an open question. The questionnaire was devised using Google Forms in the English and Arabic languages, as the workers mainly are native Arabic speakers. Google Forms is a website allowing users to create and disseminate surveys for business or individual purposes such as this research. Google Forms allows the survey creator to use a ready-made survey or create a customized one. The data results of surveys are collected and exported to Microsoft Excel so that they are ready to be used on SPSS software.

Participation in the research study was non-compulsory and participants were informed of the volitional nature and

confidentiality measures at the beginning of the survey. Moreover, the data were collected anonymously in the survey and we analysed and interpreted it during the research period, before being deleted at the end of the research.

### IV. RESULT AND DISCUSSION

In this study descriptive analytical method has been used to describe characteristics of the study respondents and their opinions around the components of the study. The hypotheses have been tested by means of Pearson correlation to explain the relationship between research variables at a significant level of 0.05. The internal consistency and reliability of the questionnaire were tested using SPSS version 23. After verifying the validity and reliability of the questionnaire test, a link of online questionnaire was distributed to the study population. Total of (191) questionnaires were retrieved, 5 participants were excluded from the study sample because they did not use Citrix workspace at all and the final study sample was 186.

Validity and reliability of the research questionnaire is an essential in the data collection phase, where these two essentialities ensure the procedure of getting precise and consistent data and results. Validity demonstrates whether the instrument or test measures what it is assumed to measure. It also refers to the ability of a study to measure what was set out to be measured or the validity of the resulting data. The measurement that needs to be valid is taken using instruments. In the case of the current study, the instrument was taken from empirical literatures and then modified according to the stated research objectives.

Before dissemination of the final version of the questionnaire for the research, a pilot test was conducted using an online questionnaire on Google Forms. The pilot test was conducted via Google Forms by asking experts users of Citrix Workspace in the Saudi company to complete the questionnaire using a link that directed them to Google Forms to complete the survey. For the purpose of the pilot test, 15 surveys were completed. During the pilot test, the participants were given an optional comment area on each question to provide feedback regarding the clarity of the question or any spelling or linguistic errors. Therefore, any modifications required to the expression of the questions could be made prior to the data collection process for the current research.

In order to evaluate reliability of the survey instrument, Cronbach's alpha test of reliability and internal consistency was done on all questionnaire variables and items. Cronbach's alpha test of reliability and internal consistency was done on the four scales. The alpha values were explained through the guidance determined by George and Mallery (2016), in which  $\alpha > .9$  Excellent,  $\alpha > .8$  Good,  $\alpha > .7$  Acceptable,  $\alpha > .6$  Questionable,  $\alpha > .5$  Poor, and  $\alpha < .5$  Unacceptable. So, for reliability, this research investigated Cronbach's alpha coefficients to gauge the reliability of each of the five variables in the questionnaire. Those variables are ease of use, usefulness, actual usage, user satisfaction, and performance. We calculated the internal consistency of the questionnaire by calculating Pearson correlations between items-items in each variable. Pearson correlation coefficients measure the strength and direction of a linear relationship between two variables. Table I

shows the Pearson correlation coefficients between items of each variable "ease of use, usefulness, user satisfaction, and performance impact" and the total score of the field. The Pearson correlation coefficients were ranged from 0.344 to 0.772 for Ease of use variable, from 0.872 to 0.907 for Usefulness variable, from 0.747 to 0.934 for User satisfaction variable, and from 0.780 to 0.867 for Performance impact variable, indicating that all the correlation coefficients shown are significant at ( $\alpha \leq 0.01$ ), thus the fields are considered valid of what is being measured. The correlation is significant at 0.01 level.

In order to measure the stability of questionnaire, Alpha Cronbach method and split-half coefficients were used. The split-half reliability method requires dividing up the variables' items into two parts and calculating correlations between the first half and the second half of each variable's items using Spearman's correlation test. It is clear from the results shown in Table II that the value of the Alpha Cronbach coefficient is high for each field, ranging from (0.739 to 0.960) which is greater than the recommended level of 0.7. As well as

Spearman's correlation coefficient which it was ranging (0.740 to 0.948), indicating very strong reliability of these items where their correlations were statistically significant at 0.01.

A total of 186 participants completed the questionnaires. Out of them, 172 (92.5%) were males and 14 (7.5%) were females. Most of the participants were from western region (49.5%). The age groups of the participants were as follows: 20 to 29 years (12.4%), 30 to 39 years (42.5%), 40 to 49 years (38.1%) and 50 years or above (7%). Most of them married and bachelor degree holders (67.7%). A large number of participants belonged to distribution and customer services (43.5%) followed by IT and digital transformation (25.8%). Table III depicts the statistical analysis of the variables under study that include mean, standard deviation and weighted percentage for the variables.

Participants' responses toward the items for Perceived ease of use variable, Perceived usefulness variable, User satisfaction variable and Performance impact variable have been represented graphically in Fig. 1, Fig. 2, Fig. 3 and Fig. 4a and 4b, respectively.

TABLE I. PEARSON CORRELATION COEFFICIENTS BETWEEN ITEM AND VARIABLE

Ease of use		Usefulness		Use satisfaction		Performance impact	
Item	Correlation	Item	Correlation	Item	Correlation	Item	Correlation
1	0.772	1	0.879	1	0.747	1	0.803
2	0.344	2	0.900	2	0.82	2	0.867
3	0.782	3	0.905	3	0.934	3	0.780
4	0.709	4	0.892	4	0.880	4	0.838
5	0.757	5	0.907			5	0.806
6	0.761	6	0.872			6	0.86
						7	0.832
						8	0.815
						9	0.860
						10	0.858

TABLE II. ALPHA'S CRONBACH AND SPLIT-HALF COEFFICIENTS

Variable	Cronbach's Alpha	Split-half reliability coefficients		
		Correlation coefficient	Length corrections	
			Spearman coefficient	Guttman coefficient
Perceived ease of use	0.739	0.587	0.740	0.733
Perceived usefulness	0.947	0.851	0.920	0.919
User satisfaction	0.863	.0761	0.864	0.834
Performance impact	0.960	0.901	0.948	0.947

TABLE III. STATISTICAL ANALYSIS OF THE VARIABLES

Variable	Item	Responses					Mean	SD	%
		Strongly agree	Agree	Neutral	Disagree	Strongly disagree			
Perceived ease of use	1	87	84	11	3	1	4.36	0.72	87.2

**B. Test of Hypotheses**

We postulated four hypotheses for our study in the beginning of this research. Now following are the tests for each of the hypothesis.

H1: Perceived ease of use has a significant positive influence on perceived usefulness.

This study found that there was statistically significant and strong positive relationship between perceived ease of use and perceived usefulness which is compatible with results of the study [24].

The Pearson correlation coefficient between perceived ease of use and perceived usefulness was a strong positive correlation, the value of the correlation coefficient was 0.669.

The correlation was statistically significant at the level of significance ( $\alpha \leq 0.01$ ).

H2: The Pearson's correlation between Perceived ease of use and actual usage.

The study revealed statistically significant positive relationship between perceived ease of use and actual usage at a statistical significance level. This is in common with other studies which found a significant relationship between ease of use and actual usage [25,26].

The Pearson correlation coefficient between perceived ease of use and actual usage was a weak positive correlation, the value of the correlation coefficient was 0.264. The correlation was statistically significant at the level of significance ( $\alpha \leq 0.01$ ).

H3: Actual usage has a significant positive influence on User satisfaction.

This states that actual usage has a significant positive influence on user satisfaction which is consistent with the findings of previous studies [27-28]; another statistically significant relationship was found between actual usage and user satisfaction.

The Pearson correlation coefficient between actual usage and user satisfaction was a moderate positive correlation, the value of the correlation coefficient was 0.394. The correlation was statistically significant at the level of significance ( $\alpha \leq 0.01$ ).

H4: User satisfaction has a significant positive influence on Performance.

Higher satisfaction implies higher performance as the same finding was found in parallel studies indicate that the higher the user satisfaction, the higher performance impact [27, 29].

The Pearson correlation coefficient between user satisfaction and performance was a very strong positive correlation, the value of the correlation coefficient was 0.838. The correlation was statistically significant at the level of significance ( $\alpha \leq 0.01$ ).

## V. CONCLUSION AND FUTURE WORK

This study has helped to understand if a relationship existed between an employee's satisfaction and performance with using Citrix Workspace to work remotely. The remote work has become more important with advent of Covid19 and employees have been given access of using technologies remotely [30].

The results revealed that there is a high level of satisfaction among respondents regarding the decision to use the Citrix Workspace. The main motive for most of the participants to use Citrix Workplace was their ability to work remotely. There is statistically significant positive relationship between perceived ease of use and perceived usefulness. Also this study revealed statistically significant positive relationship between perceived ease of use and actual usage. Another statistically significant relationship was found between actual usage and user satisfaction the relation was found to be positive. This

study also revealed statistically significant relationship between user satisfaction and positive performance impact.

For future research, findings of this study may lead to similar studies being conducted to measure users' satisfactions and performance with other remote work platforms in other Saudi organisations. Furthermore, they can be used as a road map to apply TAM to conduct investigations and research to assess employees' satisfaction and performance with using other information systems in Saudi Arabia and other places.

**Abstract**—In the age of the industrial revolution, industry and machinery are elements of the utmost importance to the development of human civilization. As industries are dependent on their machines, regular maintenance of these machines is required. However, if the machine is too big for humans to look after, we need a system that will observe these giants. This paper proposes a convolutional neural network-based system that detects faults in industrial machines by diagnosing motor sounds using accelerometers sensors. The sensors collect data from the machines and augment the data into 261756 samples to train (70%) and test (30%) the models for better accuracy. The sensor data are sent to the server through the wireless sensor network and decomposed using discrete wavelet transformation (DWT). This big data is processed to detect faults. The study shows that custom CNN architectures surpass the performance of the transfer learning-based MobileNetV2 fault diagnosis model. The system could successfully detect faults with up to 99.64% accuracy and 99.83% precision with the MobileNetV2 pre-trained on the ImageNet Dataset. However, the Convolutional 1D and 2D architectures perform excellently with 100% accuracy and 100 % precision.

## I. INTRODUCTION

Industries are getting smarter day by day. Early identification of fault inside industry machinery plays a significant role in this modern era. To increase the productivity of production systems, precise production techniques are vital. Extensive research has been done to detect early faults and classify those machines and defects. Monitoring the faulty machines and taking remedial action makes for a safe environment and reduced failures [1]. Researchers have suggested different classifiers for the early diagnosis and detection of faults. Over time, machines have become complex, and for complex machines, data-driven methods have shown efficiency, whereas non-parametric methods are applied for extracting related information from the data [2, 3]. Machine learning algorithms such as SVM have significant difficulty in selecting features for identifying defects, particularly in induction motors as seen in [4]. Deep learning addresses the problem of feature selection by extracting features directly from raw data. Deep learning models are not precise enough when the amount of data is not sufficient. Generalization is

also a significant drawback for deep learning algorithms. Accuracy is dependent on the proper distribution of data. Later, Transfer learning methods start getting famous in the Fault Detection and Diagnosis (FDD) field to prevent industry anomalies [5, 6]. Transfer learning methods learn from a place that is enriched in data, and later these models are applied in a place where the amount of data is an issue. This research has used Convolution 1D, Convolution 2D, and MobileNetV2 architecture to detect faulty machinery.

A sufficient amount of research has been done to find better classifiers for detecting faults in industrial machinery. An Artificial Intelligence-based fault detection system has been proposed by Lei et al. For learning features from raw signals, they present a sparse filtering and neural network [7]. Boukra et al. proposed a hybrid method based on feature reduction uses two parameters. Their proposed method is not manipulated by load conditions [8]. Machine learning algorithms are used for identifying faults in the motor drive where supervised learning plays a significant role [9]. Although supervised learning downs efficiency with unwanted data. Feature extraction from raw signals plays a significant role in detecting induction motors' faults. Wavelet analysis, time-domain analysis, frequency domain analysis, time scale frequency analysis, and time scale frequency analysis all aid in the extraction of characteristics [10-12]. The features extracted here affect accuracy in classification and proper fault recognition. Deep learning reduces this problem. Deep learning algorithms show a significant result in detecting faults for bearings and gearboxes [13]. Deep CNN shows remarkable accuracy in fault diagnosis from raw vibrating signals in the anti-noise domain [14]. Deep learning models are not efficient enough when the amount of training data is not sufficient. Transfer learning models show better accuracy when the amount of data is less. Adversarial transfer learning algorithms can identify erroneous signals by first converting them to RGB pictures and then training the model on those images [15]. Transfer learning-based autoencoders are proposed by Wan et al. [16]. High fault classification results have been shown by VGG 19 in detecting faults in induction motors [17].

In the study, the authors worked with the Dataset obtained from Case Western Reserve University to detect the fault of bearings of the machinery based on a wireless IoT framework. The Dataset was further divided into sub-classes and

environments. After label encoding and splitting to training and test set, the processed data were classified using CNN algorithms. The classification methods of MobileNetV2, Convolution 1D, and Convolution 2D are used. The performance of the algorithms is then measured to determine the best method to detect faults in machines in industries.

## II. LITERATURE REVIEW

The diagnosis of bearing faults is a hot topic in mechanical condition monitoring. The key phases in bearing defect diagnostics are feature extraction and pattern classification from monitoring data. The bearings will create extra vibrations when a specific bearing element fails. The fault characteristic frequency is a connection between the frequency of the extra vibration and the bearing speed. We can locate the failing bearing by analyzing the original vibration signal's frequency components [18].

Feature extraction techniques used in classical signal processing for bearing defect diagnostics using vibration signals include the Hilbert– Huang transform (HHT), the wavelet transform, empirical mode decomposition, and approaches. HHT was used by V.K. Rai et al. [19] to extract frequency domain features from bearing fault data to identify bearing fault categories. Xinsheng Lou et al. [20] used wavelet transform and neuro-fuzzy classification to develop a novel ball bearing problem diagnostic system. The wavelet transform was employed to retrieve the accelerometer signal's feature vectors. Once the adaptive neural-fuzzy inference system had been trained to categorize the feature vectors, it was used to classify data. The suggested approach worked effectively even with a variable load.

SVMs were effectively used in the area of fault diagnostics by P. Konar et al. [21]. The feature vectors were extracted using a continuous wavelet transform (CWT), and the monitoring data for the three-phase induction motor was classified using a support vector machine (SVM). In order to recognize the early problem of the bearing, Zhuanzhe Zhao et al. [22] presented an intelligent fault detection approach based on a backpropagation (BP) neural network. It was suggested that the intrinsic mode functions (IMFs) be first acquired using a wavelet packet decomposition approach, and then the EMD method was utilized to get them. A BP neural network with three layers was built to recognize the monitoring signal fault pattern.

Using naive Bayes classifier and Bayes net classifier carried out fault diagnostics [23]. Before using the suggested technique, the vibration signals are wavelet-analyzed to extract the discrete wavelet features, then utilized as input into the Bayes net for classification.

An EMD method was utilized by Lei et al. [23], and a kurtosis-based method was offered to identify the sensitive characteristics for defect diagnostics based on bearing vibration signals. When dealing with nonlinear, non-stationary, and composite signals, Lin et al. [24] employed an enhanced EMD

approach to extract features. The acoustic emission data from bearing tests were pre-processed using He et al.'s short-time Fourier transform (STFT) approach [25]. Feature selection techniques were commonly used to choose the most representative features from the collected data, including linear discriminant analysis (LDA) and principal component analysis (PCA). A diagnostic defect technique based on decision trees and PCA was reported by Sun et al. [26]. After feature extraction, PCA is used to minimize the number of features.

S. G. et al. [27] developed a continuous wavelet transform and CNN approach to accurately, robustly, and generally diagnose rotating machines faults. This study by S. S. et al. [28] demonstrated that deep convolutional neural networks (DCNNs) could learn from various sensor outputs to identify induction motor faults with consistency and accuracy. By including freshly produced extra features for self-update to incorporate new aberrant samples and fault classes, W. Y. et al. [29] used a wide convolutional neural network to increase diagnostic performance and incremental learning capabilities.

This research proposed a solution based on a wireless Internet of Things architecture for detecting machinery bearing faults using data from Case Western Reserve University. The Dataset was augmented in 261756 samples and further divided into sub-classes and environments. In order to classify the processed data, CNN methods were used after label encoding and partitioning it into training (70%) and test sets (30%). MobilNetV2, Convolution 1D, and Convolution 2D classification algorithms are used. For industrial machine fault detection, compare several algorithms' results side by side to see which one performs better.

## III. PROPOSED METHODOLOGY

Fig. 1 depicts a ZigBee-based wireless sensor network (WSN) concept for the proposed fault diagnostic technique. The WSN was created to gather accelerometer sensor data from a variety of industrial bearings. The TMS320F28335 digital signal microcontroller is utilized as a microcontroller unit (MCU) in the WSN model, collecting data from accelerometers and transmitting it through an XBee (Pro Series 3) radio transmitter. In addition, the XBee module is used to configure a coordinator gateway that receives signals from sensor nodes and sends them to the diagnostic server, which hosts the suggested fault diagnosis model. The ZigBee network protocols are used to create a mesh network of XBee devices. Besides, fault diagnosis methods comprise the following steps: a) data collection through accelerometer sensors, b) apply DWT to decomposed signals, c) preprocess data steps including creating a set of classes, set reshaping, and label encoding, d) splitting the dataset into 30% for testing and 70% for training, e) then classify data for fault detection and evaluate the performance.

To identify defects, the suggested approach used convolutional neural network algorithms. The proposed method's process is shown in Fig. 1.

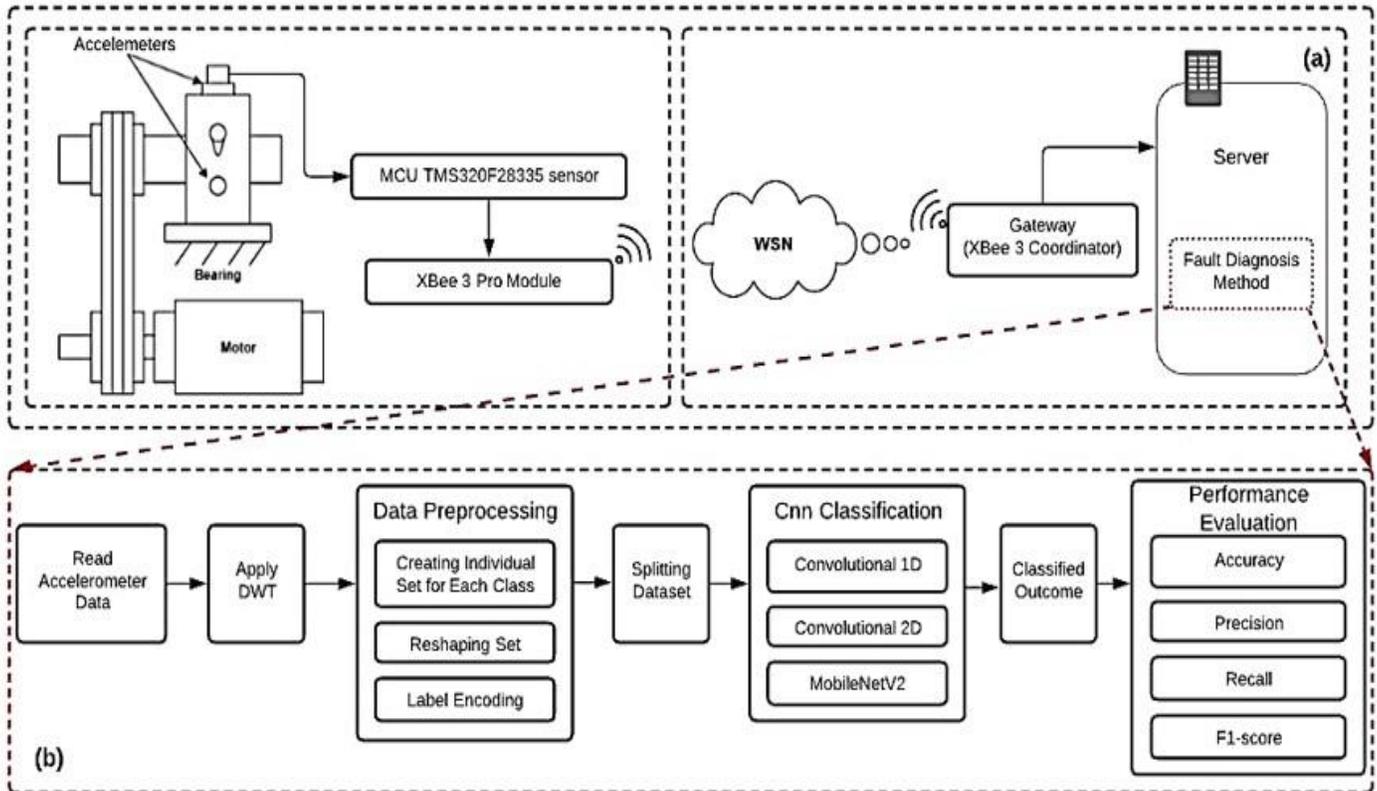

Fig. 1. Wireless Sensor Network ZigBee based and (b) Proposed Fault Diagnosis Approach.

#### A. Data Collection and Pre-Processing

In this study, the Case Western Reserve University dataset [30] is used as a standard guide to assessing the efficiency of the fault detection algorithm. The CWRU data center examined a 2 hp Reliance electric induction motor for regular bearings, single-point drive end (DE), and fan end (FE) faults under diverse settings. Accelerometers with magnetic bases connected to the housing were used to gather vibration data. At both the driving and fan ends of the motor casing, accelerometers were installed at midnight. An accelerometer was also connected to the motor that supported the base plate in specific tests. A 16-channel DAT recorder was used to capture vibration data, then analyzed in a MATLAB environment. MATLAB (\*.mat) format is used for all data files. For drive and bearing problems, digital data was captured at 12000 samples per second and data was gathered at 48000 samples per second, the final dataset volume was around 261756 samples [31]. Data on speed and horsepower was collected using a torque transducer/encoder and manually recorded.

The dataset included three working environments with the following conditions:

- 1) Data collection at 12000 samples per second.
- 2) Motor load range 0~2.
- 3) Fault diameter 0.007 inches.

So, from the big data warehouse of the CWRU data center, we gathered a dataset of 16 signals, of which four were normal baseline. The rest had four inner race faults, ball and outer race

faults each. These 16 significant signals were individually sliced into 5949 samples so we can later reshape them as needed for feeding into the neural networks. Hence, the total length of the Dataset is 23796 samples and augmented the final Dataset into 261756 samples. The dataset is homogeneous and balanced. A simulator of data collection from bearing based on Accelerometer's sensors is shown in Fig. 2.

The faults were artificially introduced on the SKF Drive End bearing (6205-2RS JEM) using Electro-Discharge Machining. For environments 1, 2, and 3, the collected data provide a varied motor speed of 1797, 1772, and 1750, respectively. Fig. 3 shows the histogram of all elements in the data collection used in the analysis.

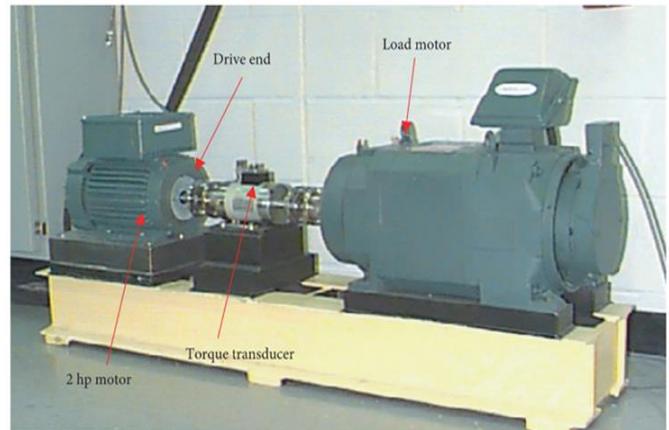

Fig. 2. Accelerometers Sensors placed on bearing Simulator of CWRU.

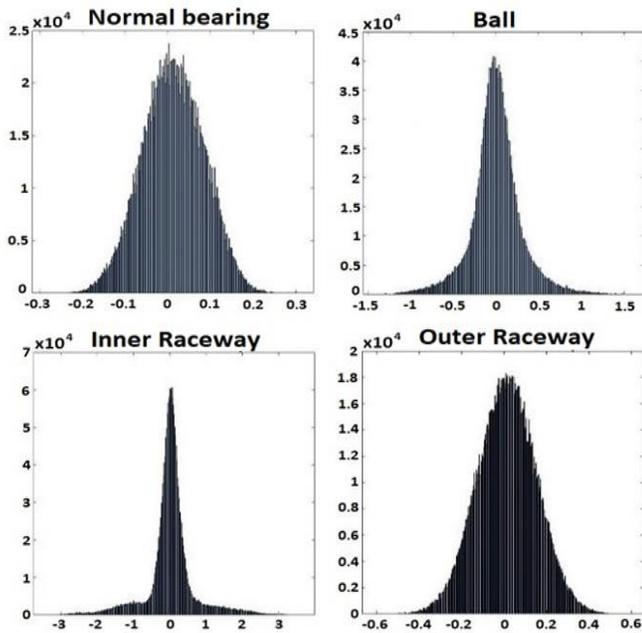

Fig. 3. Histogram for all Elements in Dataset.

We started by loading all of the signal data and creating three sets of data. Label Binarizer was used to label the products and reshaped all three datasets. This work used a random seed value of 0.2 and utilized 30% of our data for testing and 70% of our data for training.

For training our model with Convolution 1D, Convolution 2D, and MobileNetV2 used Tensorflow and Keras library because of its convenient coding environment and ability to train a state-of-art algorithm for signal processing and computer vision.

**B. Convolution 1D and Convolution 2D**

The 2D in Conv2D refers to the fact that each channel in the input and filter is two-dimensional, while the 1D in Conv1D refers to the fact that each channel in the input and filter is one-dimensional. Normalizing the data in our Convolution 1D and Convolution 2D models initially set up the first hidden layer with 100 nodes and implemented the RELU activation feature. MaxPooling1D was used with a pool size of 2 to minimize the dimension feature. The second and third convolution layers have 32 and 10 nodes, respectively. The signals were translated into NumPy arrays to speed up the computation. For backpropagation, the learning rate was set at 0.001 and used Categorical Cross-Entropy and the Adam optimizer equation to calculate the loss function. The categorical Cross-Entropy loss function is used for the multiclass classification of the dataset. After applying all of the optimizers (Adam, Nadam, Adagrad, RMSProp, Adadelta, SGD, Adamax), Adam optimizer is chosen for the highest accuracy on the dataset. Since the batch size for instruction is 32, and the decay is set to 0.1. Tables I and II depict the convolution 2D and convolution 1D models, respectively.

**C. MobileNetV2**

MobileNetV2 is a CNN architecture that tends to be efficient on mobile devices. MobileNetV2 has 32 filters on its

initial fully convolution layer. There exist 19 residual bottleneck layers. It is utilized for image classification, object detection, quantization, and so on [32].

Two types of blocks are introduced in MobileNetV2.

- 1) Residual block of stride 1.
- 2) Block for downsizing with 2 strides.

Both the blocks are made up of three layers, as illustrated in Fig. 4. With 1x1 convolution, the ReLU6 activation mechanism is used in the first layer. On the second sheet, a depth-wise is added, and the third layer is also a 1x1 convolution, save for some non-linearity. The activation mechanism of ReLU is often included in the third layer [33]. MobileNetV2 performs well when the mathematical operations and the number of parameters are kept low. The MobileNetV2 architecture is about 35% faster than the previous version, MobileNetV1.

TABLE I. PROPOSED CONVOLUTION 2D MODEL

<sup>a</sup>. The shape and parameters are determined by the layers of the Convolutional 1D model. Numerous layers have been introduced.

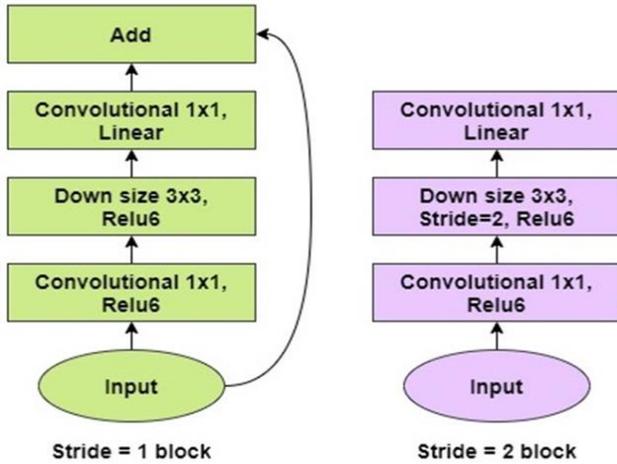

Fig. 4. MobileNetV2 Architecture.

The base layer of the MobileNetV2 platform has been frozen and replaced with the proposed trainable layer. The Relu activation feature is extended to 512 nodes in the proposed layer. In the output sheet, there are 4 nodes and a SoftMax activation mechanism for classifying faults. The loss function is determined using categorical cross-entropy, and the learning factor is set to 0.001.

#### D. Performance Measures

Precision, recall, f1-score, and accuracy evaluate the models' performance after completing the training and testing phase. Precision is the closeness of the measurements to each other, while accuracy is the proximity of the measurements to a particular value. The equations used to calculate the measures are stated in Eq. (1) and Eq. (2). The ability of a model to identify all of the data points of relevance in a dataset is referred to as recall. F1-score measures the rate of recognizing real threats and not being distracted by false alarms. The measures of Eq. (3) and Eq. (4).

$$Precision = \frac{TP}{TP+FP} \quad (1)$$

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \quad (2)$$

$$Recall = \frac{TP}{TP+FN} \quad (3)$$

$$F1 - Score = 2 * \frac{Recall*Precision}{Recall+Precision} \quad (4)$$

In the Equations, TP represents true positive, TN represents true negative, and FP and FN represent false positive and false negative.

#### IV. RESULT ANALYSIS AND DISCUSSION

The proposed methods can successfully identify faulty machinery with high accuracy [34]. After processing collected data samples, all three elements (inner raceway, outer raceway, and ball) considered in our Dataset were found to have 0.011 inches fault depth.

#### A. MobilenetV2 Result Analysis

Table III shows that the best training accuracy was at epoch number 17, where the accuracy was 99.86 percent, and the best validation accuracy was 99.64 percent. The model has a 99.83 percent precision.

Fig. 5 depicts the precision of training and testing for each epoch and the data loss graph for MobileNetV2 in the training and test sets. The graph shows that with increasing epochs, detection accuracy increases, and data loss gradually decreases for both training and test sets.

The classification report for each class (normal, ball, inner and outer raceway) of the test dataset is shown in Fig. 6. The model shows high performance for all the classes individually.

From the test data, the heat map is shown below in Fig. 7. The MobileNetV2 predicted 19229 properly in a normal class, where 222 samples are not correctly predicted. In the case of the class ball, 20572 samples are correctly predicted, where 425 data are not correctly predicted. Similarly, in the case of inner class and outer class, 18571 and 17604 samples are correctly predicted, where 749 and 1155 samples are improperly classified.

TABLE III. DATA LOSS AND ACCURACY OBTAINED FROM MOBILENETV2

Epoch	Training Set		Testing Set

10	0.77	99.97	0.19	100.0

<sup>a</sup>Data sample of the Convolution 1D's 10 epochs.

The data loss and accuracy graph are shown in Fig. 8. For the ten epochs, accuracy increases and data loss decreases from training data and test data.

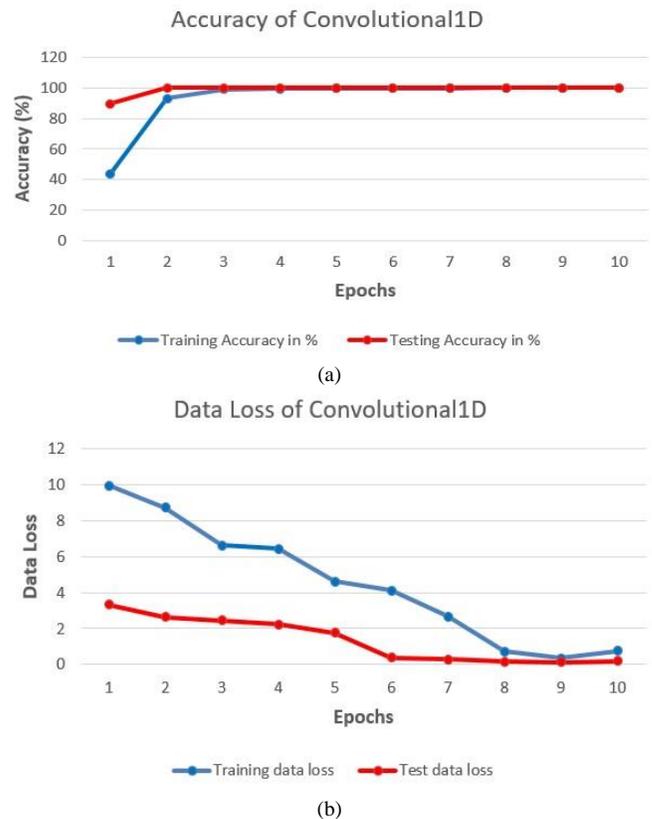

Fig. 8. (a) Data Accuracy, (b) Data Loss Graph, of Convolution 1D.

The scores of precision, recall, accuracy, and f1- score are shown in Fig. 9. The model provides perfect scores for each of the performance tests for all the data classes.

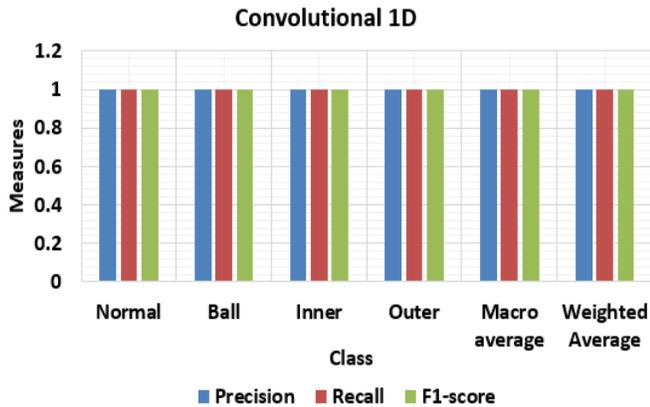

Fig. 9. Classification Report of Convolution 1D.

In Fig. 10, the heat map demonstrates the predicted and non-predicted test data. The Convolution 1D accurately predicted 19451 samples in a normal class; however it incorrectly predicted 0 samples. A total of 20997 samples are accurately predicted when it comes to the class ball, whereas no samples are incorrectly predicted. Additionally, 19320 and 18759 samples from the inner and outer classes are accurately predicted, but no samples are incorrectly classified.

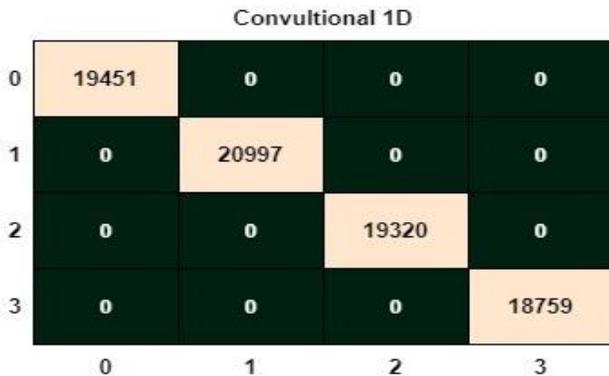

Fig. 10. Heat Map for Convolution 1D.

### C. Convolution 2D Result Analysis

In Table V, the result of Convolution 2D is stated. Both the training and validation sets have an accuracy of 100%. The model shows high accuracy on each epoch. Additionally, the data loss for the test set is much lower.

The data accuracy and loss graph are seen in Fig. 11. It is seen that the data loss for the training set gradually decreases with the increased number of epochs. The accuracy rate stays consistently high for the test set, and the data loss stays consistently low on each epoch.

The classification report in Fig. 12 illustrates that the Conventional 2D model shows a perfect performance score throughout all the classes of the test Dataset, the same as the Conventional 1D model.

TABLE V. THE DATA LOSS AND ACCURACY OBTAINED FROM CONVOLUTION 2D

Epochs	Training data loss	Training Accuracy in %	Test data loss	Testing Accuracy in %
1	12.04	84.95	0.07	99.98
2	10.67	99.78	0.06	99.95
3	8.35	99.84	0.03	99.94
4	7.55	99.92	0.03	100.0
5	6.21	99.97	0.02	99.93
6	3.00	99.99	0.03	99.98
7	1.96	99.89	0.03	100.0
8	0.97	99.97	0.02	100.0
9	0.033	100.0	0.02	99.94
10	0.031	99.99	0.02	100.0

<sup>b</sup>Data sample of the Convolution 1D 's 20 epochs.

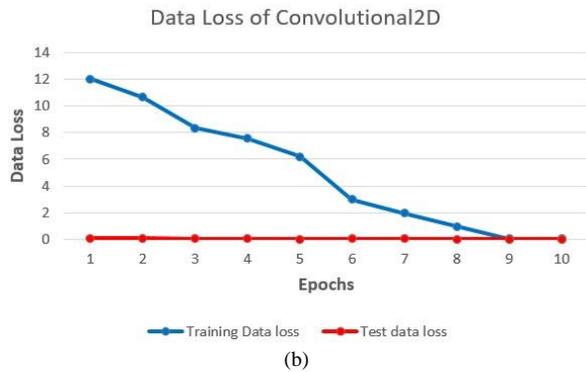

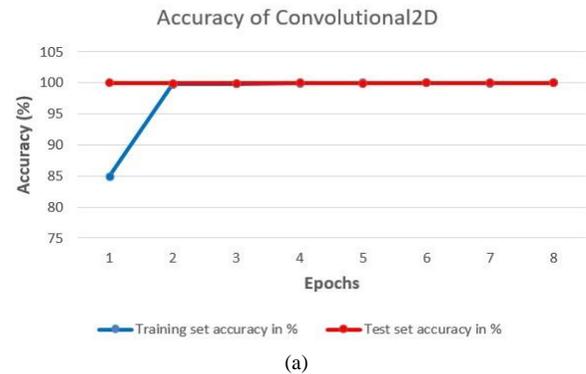

Fig. 11. (a) Data Accuracy, (b) Data Loss Graph using Convolution 2D.

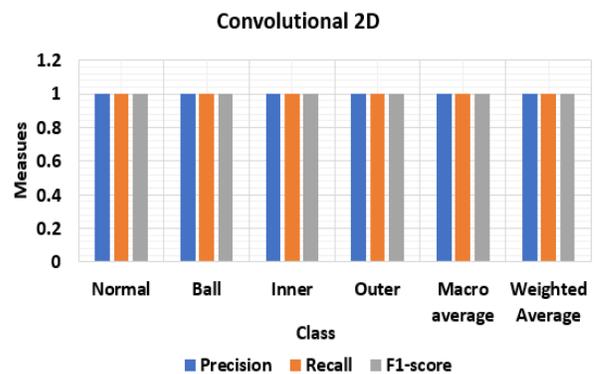

Fig. 12. Classification Report of Convolution2D.

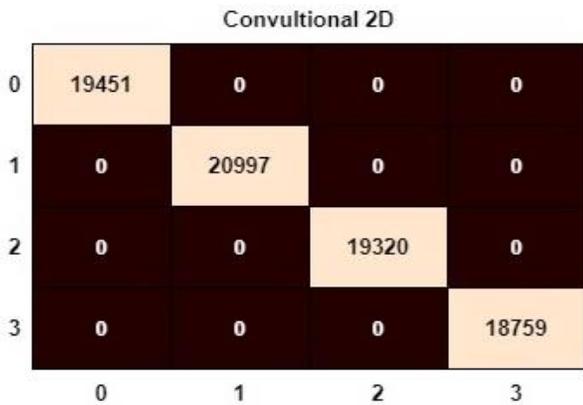

Fig. 13. Heat map for Convolution 2D.

In Fig. 13, the heat map is illustrated the predicted and non-predicted test data. The Convolution 2D successfully predicted 19451 samples in a normal class, yet it wrongly predicted Nil samples. When it comes to the class ball, a total of 20997 samples are properly predicted, while nil samples are wrongly predicted. Furthermore, 19320 and 18759 samples from the inner and outer classes are properly predicted, so the predicted rate is 100%.

D. Result Discussion and Comparison

The CNN algorithms used in the study all show promising results. MobileNetV2 shows the accuracy of 99.64% and lowest data loss of 0.01, whereas both the Convolutional 1D and 2D show a perfect accuracy score of 100% at the 10th epoch with CPU time of 82.5secs/epoch and 93secs/epoch, respectively. The comparison among the performance of the algorithms' prediction is illustrated in Table VI.

TABLE VI. COMPARISON OF THE ALGORITHMS

CNN Models	Ep	Tr_loss	Tr_Acc in %	T_loss	T_Acc %	CPU_T secs/Ep
M_NetV2	20	0.006	99.86%	0.01	99.64%	108.65
Cn_1D	10	0.77	99.97%	0.19	100.0%	82.5
Cn_2D	10	0.03	99.99%	0.02	100.0%	93.0

<sup>a</sup>Convolution 1D and Convolution 2D Perform better with highest accuracy and low CPU time than MobileNetV2. Here, Epochs is abbreviated 'Ep', Training loss is abbreviated 'Tr\_loss', Training accuracy is abbreviated 'Tr\_Acc', Test loss is abbreviated 'T\_loss', Training Accuracy is abbreviated 'T\_Acc'. CPU Time is abbreviated 'CPU\_T'.

All three algorithms of the proposed system achieve very high performance in detecting faults in machinery. However, fault detection has been done in the past using other machine learning algorithms [35-37]. A comparison of the performance of such algorithms with the proposed system is made in Table VII. From the comparison, it is observed that even though CNN and GAN algorithms achieve an accuracy of over 97%, it is much lower than the accuracy achieved by the algorithms proposed in the study.

The proposed system successfully detects a fault in industrial machinery up to 100%. Compared to the existing techniques, the performance is much higher. It is essential to detect faults with the highest accuracy in industrial machinery, as even a minor increase in fault detection accuracy might prevent a tragic accident. Since the machines used in industrial work generally contain a lot of small or big parts, at the same

time, machines themselves can be huge, maintaining it can be difficult for humans. The proposed fault detection system can be used to make the process automatic and efficient. Using the system, the sound vibration from the machinery can be processed by MobileNetV2, Convolution 1D, and Convolution 2D to detect faults in the machines to avoid future hassles.

TABLE VII. COMPARISON OF THE PROPOSED SYSTEM WITH EXISTING SYSTEMS

Models	Proposed System	Existing System 1 [38]	Existing System 2 [39]	Existing System 3 [40]	Existing System 4 [27]
MobileNetV2	99.64%	-	-	-	-
Convolutional 1D	100%	-	-	-	-
Convolutional 2D	100%	-	-	-	-
SVM	-	97.3%	-	-	-
CNN	-	98.1%	-	-	-
SVM + PCA	-	74.4%	-	-	-
Stack Denoising Auto Encoder	-	-	91.67%	-	-
GAN	-	-	97.96%	-	-
DNN	-	-	94.4%	-	-
ANN	-	-	-	95%	-
ANN + 10-fold Cross Validation	-	-	-	93.54%	-
CNN	-	-	-	-	71.67% 86.67% 98.33%

<sup>a</sup>A comparison between the proposed study and existing related work. Proposed study offers better findings than existing related studies.

V. CONCLUSION

As scientific and technical knowledge increases, mechanical equipment becomes more sophisticated and automated. Mechanical equipment relies significantly on spinning mechanical components like bearings and lead screws to work properly. Damaged or failed bearing components will cause equipment failure and fatalities. As a result, monitoring the bearing components' performance is essential. This article presented a viable method for bearing defect detection based on accelerometer sensors and the wavelet transformation (DWT) signal processing methodology, with a ZigBee-based wireless sensor network architecture for effectively sending data to a diagnostic server. MobileNetV2 architecture pre-trained model compares the model with two custom CNN models: 1D and 2D deep CNN architectures. A bearing dataset collected by accelerometers sensors is used to validate the models that consist of 4 types of fault signals. Upon the four classes, we have achieved a satisfactory result. With MobileNetV2, the system was able to identify problems with 99.64% accuracy and 99.83% precision. It achieves up to 100% accuracy and precision when utilizing the Convolutional 1D and 2D architectures. In the future, the proposed architecture may be tested with more parameters besides

implementing hybrid transfer learning models and the most reliable IoT framework.

**Abstract**—Digital medical image has a potential to be manipulated by unauthorized persons due to advanced communication technology. Verifying integrity and authenticity have become important issues on the medical image. This paper proposed a self-embedding watermark using a spiral block mapping for tamper detection and restoration. The block-based coding with the size of 3×3 was applied to perform self-embedding watermark with two authentication bits and seven recovery bits. The authentication bits are obtained from a set of condition between sub-block and block image, and the parity bits of each sub-block. The authentication bits and the recovery bits are embedded in the least significant bits using the proposed spiral block mapping. The recovery bits are embedded into different sub-blocks based on a spiral block mapping. The watermarked images were tested under various tampered images such as blurred image, unsharp-masking, copy-move, mosaic, noise, removal, and sharpening. The experimental results show that the scheme achieved a PSNR value of about 51.29 dB and a SSIM value of about 0.994 on the watermarked image. The scheme showed tamper localization with accuracy of 93.8%. In addition, the proposed scheme does not require external information to perform recovery bits. The proposed scheme was able to recover the tampered image with a PSNR value of 40.45 dB and a SSIM value of 0.994.

**Keywords**—Fragile watermarking; self-embedding; image authentication; self-recovery; medical image; spiral block mapping

## I. INTRODUCTION

The development of internet technology has grown exponentially in the last decade. Internet technology made digital multimedia data easy to be distributed to the world. With the rapid development of information technology, multimedia data was produced and sent seamlessly without boundaries and limitations. The digital image can be produced by various electronic devices such as digital cameras and X-ray machines for medical images [1], [2]. In addition, there are many available images editing software to modify these digital images, such as Photoshop, Lightroom, and GIMP. However, the advancement of this software also enables unauthorized modification to a digital image that makes it hard to identify the authenticity and integrity of the images. The medical images require the images to be authentic to prevent false decisions under some circumstances. Thus, any alteration or slight modifications cannot be accepted. Digital images could be modified by unauthorized persons for illegal use. The modification can be invisible or visible to the human eye. Furthermore, the illegal modification may lead to illegal action against the law. Image watermarking techniques can be

an alternative solution to authenticate digital image content [3].

Digital image watermarking is the process of embedding a watermark into digital images [4]. The watermark itself can contain a logo, serial number, or a security key. The watermark is then embedded into the cover image to be visible or imperceptible. An example of a visible watermark is a transparent logo as seen embedded in the corner of an image to prevent copyright violation. However, this type of watermark was prone to watermark removal by simply cropping or overlaying the new watermark over the original watermark. Hence, the researcher primarily focused on the imperceptible watermark with a security feature to not be easily removed by any attack. Digital watermarking techniques can be used to protect copyright and authenticate digital image content. There are three types of image watermarking: robust, semi-fragile, and fragile watermarking. Robust image watermarking is mainly used for copyright protection so that any modification on the image content, the embedded watermark should be resistant against several attacks. In contrast, semi-fragile and fragile watermarking are primarily utilized for image authentication. Fragile image watermarking is not resistant to any modifications on the watermarked image. Fragile watermarking has been widely used to detect tamper localization and authenticate the image content. Fragile watermarking does not allow modification to the image content, while semi-fragile image watermarking will tolerate minor changes to the image, such as image compression [5], [6].

A fragile image watermarking for authentication provides four important aspects which are watermark generation, insertion technique, tamper localization, and tamper recovery. The watermark generation presented a way to generate a watermark image to be embedded into the cover image. The existing schemes use the part of the cover image as the watermark image, which is called self-embedding fragile image watermarking [7], [8]. The watermark generation also can be obtained from a set of embedding bits that contains the authentication bit and recovery bits [9], [10]. The embedding watermark in fragile watermarking can be performed by modifying the bits of the host image. The embedding of watermark bits into the first Least Significant Bit (LSB) made it invisible to the human eye [11]. The embedding of the watermark into the second LSB significantly contributes to the reconstruction error. Lastly, the tamper recovery algorithm plays a key role in recovering the tampered area of the image.

The recovered image quality depends on the size of the tampered area.

Image authentication techniques can be used for verifying or authenticating the integrity of digital media content. Image authentication can be classified into passive and active authentication. Active authentication requires preliminary data from the original image. This data could be stored on a secured database so that the authentication can be done by comparing the data from the database and the extracted data from the receiving ends [12]. Another scheme directly embedded the data into the cover images, so it does not need any intermediate database to store the authentication data, while it slightly reduces the quality of the image [13], [14]. In addition, some active authentication schemes also support tamper recovery along with authentication and tamper detection [15], [16]. In contrast, passive authentication was performed without requiring any preliminary image information for authentication. Passive authentication was categorized as forgery dependent and independent. On one hand, forgery dependent will only detect some types of forgery, such as copy-move and splicing forgery. This type of forgery may not leave any visual trace, but the inconsistencies of the underlying statistics can detect it. On the other hand, forgery independent will detect the tampered image based on the visible artifacts left during the resampling process and lighting inconsistencies [17]. Thus, passive authentication has limited tamper detection capability depending on its forgery types and the visual artifacts left behind. Furthermore, passive authentication did not support tamper recovery compared to active authentication [18], [19].

The existing authentication schemes still do not achieve high accuracy in tamper detection. The high accuracy of tamper detection is significantly important for achieving the high quality of the self-recovered image. Therefore, this study presents three-layer authentications with a spiral block mapping that can support tamper recovery. The parity bit of each block is extracted to obtain the authentication bit for the first level. If the bit value is the same, then the second authentication bit will be computed and compared with the average pixel of its block image. If the average pixel of the sub-block is greater than the average pixel of its block, then the third authentication is performed to check the output of the second layer authentication in three RGB channels. The proposed scheme embeds the image content itself into the host image based on a spiral block mapping. The embedding process will be performed for each block of  $3 \times 3$  pixels, the nine least significant bit is modified for authentication and recovery. The proposed embedding scheme utilized a set of conditions bits. The recovery bits are embedded into the different locations of sub-block images. The proposed spiral block mapping can detect any tamper occurred on the watermarked image. The proposed scheme will produce a higher accuracy of the tamper detection and higher quality of the recovered image than other existing schemes after tampering the image.

## II. RELATED WORK

Belferdi et al. [15] presented a self-embedding fragile watermarking scheme for color image tamper detection and

recovery. The scheme implemented the Bayer pattern to reduce the size of embedding watermarks into the original image. The watermark was generated from the original image by decomposing the image into red, green, and blue channels. The scheme converted the color watermark into a grayscale image by using the Bayer filter to reduce the watermark size. This filter selects one color sample from each color channel. This grayscale watermark was decomposed into four sub-blocks to improve security and enhance robustness. Each sub-image was then permuted three times based on automorphic permutation using three keys to ensure maximum security. Finally, each permuted sub-images is converted into a binary sequence and embedded three times into the least significant bits (LSB) of the three RGB components of the host images. The scheme can improve detection accuracy if one channel was destroyed.

Gul and Ozturk [20] showed a fragile image of watermarking and tamper-detection based on the SHA-256 hash function. The scheme divided the cover image into non-overlapping blocks with the size of  $32 \times 32$  pixels. Each block was then sub-divided into four sub-blocks of  $16 \times 16$  pixels. The watermark was generated using the entire SHA-256 hash value of the first three sub-blocks. The resulting 256-bit binary watermark was embedded into the least significant bit (LSB) of the fourth sub-block. The tamper detection works by comparing the hash value of the first three blocks to the extracted watermark obtained from the fourth block.

Hisham et al [2] presented a watermarking scheme for tamper detection and self-recovery. The scheme presented a spiral pattern during embedding the watermark image. While the pattern of embedding a watermark in the LSB does not give effect to the quality of the watermarked image and security. The spiral pattern did not work for the non-square image; some parts of the image can't be embedded using a spiral pattern. The embedding watermark using a spiral pattern doesn't give any contributions to the watermarked image especially for modifying LSB. The embedding scheme was performed on each block of  $8 \times 8$  pixels. Each block was divided into sub-block with the size of  $4 \times 4$  pixels. Each sub-block with the size of  $4 \times 4$  was embedded by nine bits, including two ( $v$  and  $p$ ) authentication bits and seven recovery bits. The scheme considers only 9 bits over 16 bits of LSB on each sub-block. The scheme did not fully utilize the rest of the seven bits for embedding watermark images. The scheme has the potential to consume a large computational time and it did not optimize the embedding space of the host image. The recovery bits in the scheme are generated from the average pixel value on its image sub-block. The scheme is designed to recover the tampered area by using an average value of its sub-block image with the size of  $4 \times 4$  pixels. If any small tamper occurred in the sub-block of  $4 \times 4$  pixels, the average pixel value will replace it. The scheme has the potential to produce less quality of the recovery bits due to average pixels, even if the tamper that occurred was a small area.

## III. PROPOSED SCHEME

### A. Proposed self-embedding Watermark

The experiments utilize seven medical images with different sizes namely "Abdomen", "Brain", "Breast",

“Chest”, “Eye”, “Teeth”, and “Womb” images. The block diagram of the proposed scheme is depicted in Fig. 1.

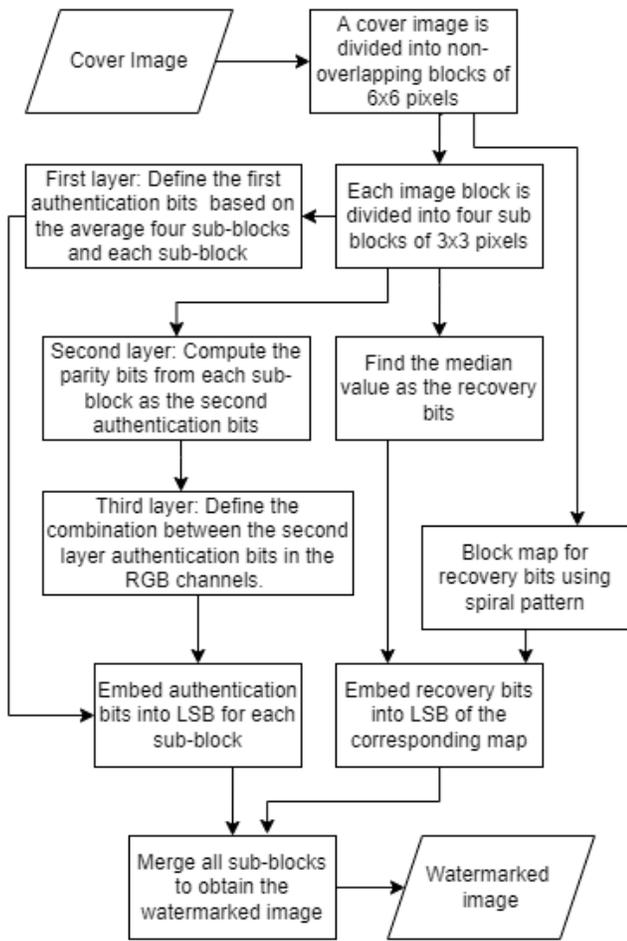

Fig. 1. Block Diagram of the Proposed Embedding Scheme.

A watermark image is obtained from the two bits,  $v$  and  $p$  for authentication and seven bits of the sub-block recovery. Each pixel of the cover image was embedded with watermark bits on the LSB of the cover image. The selected sub-block of  $3 \times 3$  pixels in the embedding watermark is to achieve an optimal embedding of two authentication bits and seven recovery bits into the LSB of the cover image. The modifying LSB of the cover image does not give a significant effect on the quality of the medical image. The following steps discuss the proposed self-embedding watermark:

1) A cover image is divided into non-overlapping blocks of  $6 \times 6$  pixels. Then, each block is divided into four sub-blocks with the size of  $3 \times 3$  pixels. The visualization of the block and four sub-block images is shown in Fig. 2.

2) The average pixel value of image block  $AvgB$  is calculated, and each of its sub-block  $AvgSB$ .

3) The first authentication bits were computed by comparing the average image block of  $6 \times 6$  pixels  $AvgB$  and each of its sub-block with the size of  $3 \times 3$  pixels  $AvgSB$ . If the average  $AvgB$  is larger than  $AvgSB$ , the authentication bit denoted as  $v$  is 1, and vice-versa.

4) The second authentication bits were generated from the parity bits of each sub-block. The authentication bit denoted as  $p$  is 1 if the parity number is equal to an odd number, and 0 if the parity bit is an even number.

5) The first and second authentication bits are embedded in each LSB of each sub-block. The illustration of each embedding authentication bits,  $v$  and  $p$  into the sub-block is shown in Fig. 3.

According to Fig. 3, the white region represents the original bit of pixels on each sub-block,  $P$  represents the pixel value,  $v$  is the first layer authentication bit and  $p$  is the second layer authentication bit.

6) The recovery bits of each sub-block are generated by finding the median value of its sub-block. The seven most significant bits of median pixel value are used as recovery bits. The recovery bits are embedded based on a spiral pattern as visualized in Fig. 4. In the proposed scheme, the authentication bits and recovery bits are embedded in different locations. The recovery bits on the first block are embedded into the nineteenth block and so on. The recovery bits for each block are embedded based on the spiral block mapping as shown in Fig. 4. The proposed spiral block mapping can avoid tampered coincidence.

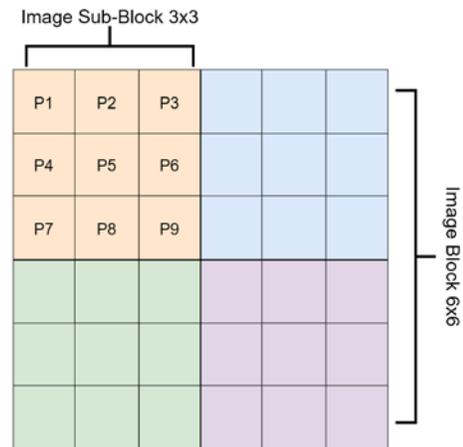

Fig. 2. Illustration of Image Block and each of its Sub-block.

MSB Bit								LSB	Authentication bits

7) The self-embedding watermark is repeated for all sub-blocks to obtain the watermarked image.

#### B. Proposed Tamper Detection and Recovery Scheme

The watermarked images are tested under several attacks such as blur, unsharp, cloning, mosaic, noise, removal, and sharpen images. The proposed scheme provides two-level authentications. The procedures of tamper detection are defined by:

1) *First-level authentication:* A tampered image is divided into non-overlapping blocks with the size of  $6 \times 6$  pixels. Then, each block is divided into four sub-blocks with the size of  $3 \times 3$  pixels. The extract bit  $v$  from LSB on the first pixel of its sub-block in the watermarked image. The parity bit of each block is computed, if the parity number is an odd number, the parity bit  $v'$  is set to 1, otherwise, set it to 0. The parity bit  $v'$  is compared with the extracted  $v$  from each LSB of its sub-block. If the bit value of  $v'$  and  $v$  are not equal, then mark it as a tampered image, otherwise, no tamper is detected. In addition, if the bit value between  $v'$  and  $v$  is the same, then the second authentication bit  $p$  will be checked in the second level authentication.

2) *Second-level authentication:* In the second authentication bit, the extracted bit  $p$  from LSB on the second pixel is compared with the  $p'$  represents algebraic relation between sub-block with the size of  $3 \times 3$  pixels and block image with the size of  $6 \times 6$  pixels. The average pixel of each sub-block is computed and compared with the average pixel of its block image. if the average pixel of the sub-block is greater than the average pixel of its block, the  $p'$  is 1, otherwise, the  $p'$  is 0. If the bit value of  $p'$  and  $p$  are not equal, then mark it as a

tampered image, otherwise, no tamper is detected. The proposed authentication is defined in Algorithm 1 as follows:

#### Algorithm 1. The proposed multilayer authentication levels

---

```

Input:  $v, v', p, p'$ 
1   $\alpha = 0;$ 
2  for  $i=1$  to 4
3  if ( $v \sim v'$ )
4  # mark as tampered sub-block
5   $\alpha = 1;$ 
6  else
7  if ( $p \sim p'$ )
8  # mark as tampered sub-block
9   $\alpha = 1;$ 
10 elseif ( $\alpha == 1$ )
11 # mark as tampered sub-block
12  $\alpha = 0;$ 
13 else
14 # mark as untampered sub-block
15  $\alpha = 0;$ 
16 end
17 end

```

---

Output: tampered, untampered sub-block

---

where  $v$  denotes the extracted bit from LSB on the first pixel of its sub-block in the watermarked image,  $v'$  represents the parity bit of each sub-block,  $p$  is the extracted bit from LSB on the second pixel of its sub-block, and  $p'$  represents algebraic relation between sub-block and block image. The  $\alpha$  value is 1 if the sub-block is marked as a tampered sub-block. The  $\alpha$  value is used as a reference of its block that has tamper detection. If the previous sub-block has tampered with the attack, the next sub-block has a possibility of tampered image.

3) *Third-level authentication:* The third layer authentication checks the result obtained from the second layer authentication in three RGB channels. If an image block of the RGB channel is detected as a tamper, then set all blocks of RGB channels on its block locations to be tampered. This third layer authentication further reduces the false-negative detection. The diagram of the proposed tamper detection and the recovery bits is shown in Fig. 5.

#### C. Evaluation of the Proposed Scheme

The proposed tamper detection algorithm is evaluated by using a confusion matrix such as True Positive Rate (TPR), False Negative Rate (FNR), and False Positive Rate (FPR). TPR represents the ratio between the detected area against the real tampered. The highest TPR means that the tamper detections are correctly detected in the tampered regions. In contrast, FNR means the ratio between the undetected area compared to the real tampered area. The high FNR means inaccurate tamper detection in the tampered area of the images. Next, the FPR represents the ratio between the false detected area against the untampered area. The range of FPR values is between 0 to 1, the higher FPR value represents the higher detection of the untampered area as tampered area or false detection. The proposed scheme is also measured in terms of precision and accuracy for evaluating tamper detection. The TPR and FNR are defined by [11]:

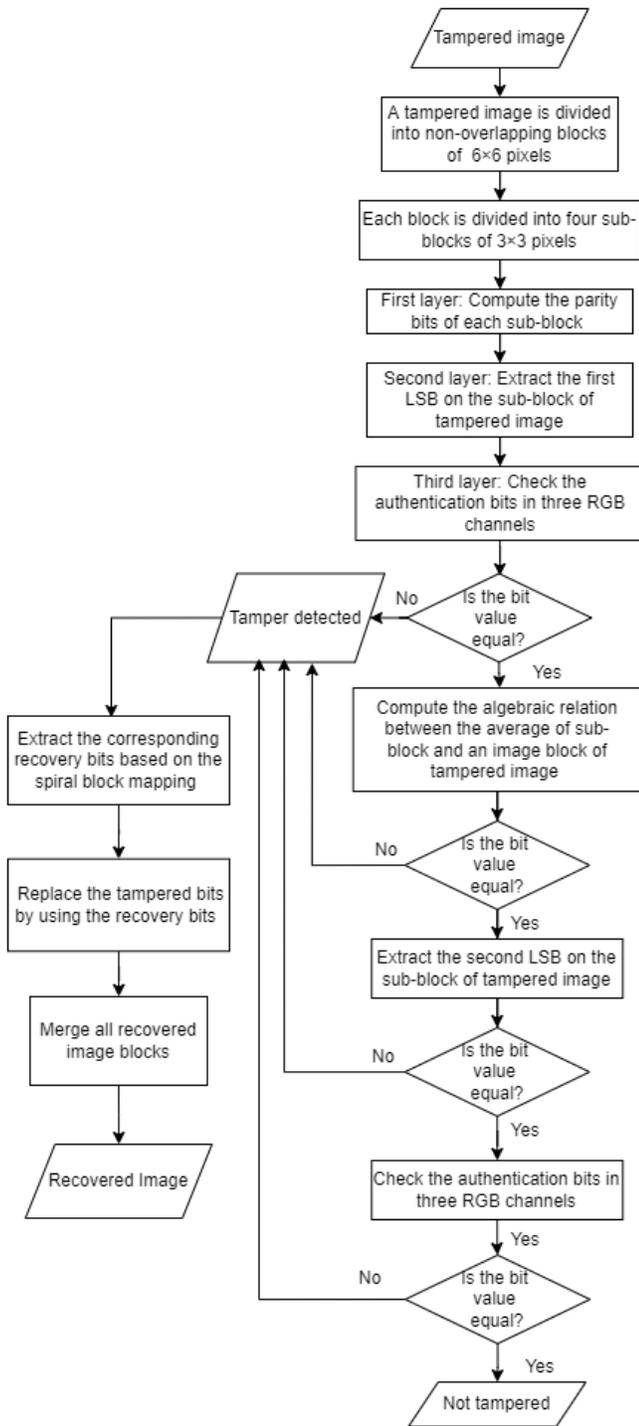

Fig. 5. Block Diagram of the Tamper Detection and Recovery Schemes.

$$TPR = \frac{TP}{TP + FN} = \frac{TP}{P} = 1 - FNR \quad (1)$$

$$FNR = \frac{FN}{TP + FN} = \frac{FN}{P} = 1 - TPR \quad (2)$$

where  $TP$  represents the number of true-positive tampered pixels,  $FN$  denotes the number of false-negative tampered pixels,  $P$  represents the number of real tampered pixels. The  $FPR$  is defined by:

$$FPR = \frac{FP}{FP + TN} = \frac{FP}{N} \quad (3)$$

where  $FP$  represents the number of false-positive tampered pixels,  $TN$  denotes the number of true-negative tampered pixels,  $N$  represents the number of untampered pixels. The precision and accuracy of the tampered detection are defined by [11]:

$$Precision = \frac{TP}{TP + FP} = \frac{TPR}{TPR + FPR} \quad (4)$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} = \frac{TP + TN}{P + N} \quad (5)$$

The precision represents the precise tamper detection on the image. The higher precision value means that the proposed scheme was able to produce high true positive values and low false-positive values. The accuracy of tampering detection is evaluated in order to measure the effectiveness of the proposed scheme. High accuracy on tamper detection can improve the recovery bits of the tampered image.

The quality of the watermarked image and recovered image is evaluated in terms of the imperceptibility by using PSNR, MSE and SSIM. The PSNR is defined as follows [21]-[24]:

$$PSNR = 10 \log \frac{(S)^2}{MSE} \quad (6)$$

$$MSE = \frac{1}{MN} \sum_{i=0}^{M-1} \sum_{j=0}^{N-1} (f(i, j) - g(i, j))^2 \quad (7)$$

where  $f(i, j)$  is the original medical image,  $g(i, j)$  is the watermarked image,  $M, N$  denotes as the row and column sizes of the medical image. MSE represents the difference value between original and watermarked image,  $S$  denotes a maximum pixel value of the medical image. The SSIM is defined as follows [25]-[32]:

$$SSIM(x, y) = [l(x, y)]^f \cdot [c(x, y)]^g \cdot [s(x, y)]^h \quad (8)$$

where  $\alpha > 0, \beta > 0, \gamma > 0$ , are parameters to define the relative importance of the three components  $l, c$  and  $s$ . The SSIM index is defined as three similarity terms of luminance, contrast, and structural between two local windows. The SSIM considers image degradation as the perceived change in structural information, separating the measure of similarity into luminance, contrast, and structure [33]. The range SSIM value in between 0 to 1, the higher SSIM value indicated that the watermarked image is structurally similar to the original cover image.

#### IV. EXPERIMENTAL RESULTS

The proposed scheme embeds self-image content as a piece of watermark information on the least significant bit (LSB) of the cover image. Each pixel of the cover image has 8-bits of information which corresponds to the range of pixel values 0 to 255. Embedding watermark information into LSB has some advantages include less distortion on the watermarked image and fast embedding watermark image. Thus the embedding LSB algorithm can preserve the quality of the cover image. The embedding watermark by using LSB can provide high sensitivity against an altered image. A small

altered image into the pixel value can be identified. Therefore, the LSB method has been widely used on fragile watermarking for image authentication. This study proposed a self-embedding scheme for tamper detection and restoration in the medical image by using multilayer authentications. The visual original covers a medical image, a watermark image obtained from its image content and the watermarked image is shown in Fig. 6.

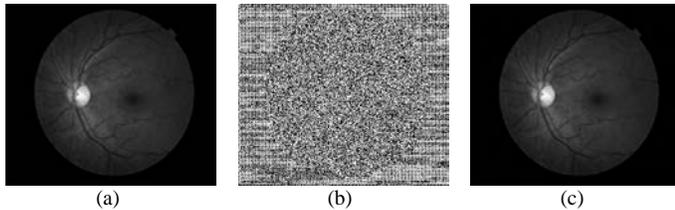

Fig. 6. (a) Original Eye Image, (b) Watermark Image, (c) Watermarked Image.

According to Fig. 6, the experimental results showed that the proposed scheme achieves high quality of the watermarked image with the PSNR value of 51 dB. The experimental results of the proposed scheme have been compared with the scheme by Hisham et al. [2]. The imperceptibility of the watermarked image in terms of MSE, PSNR, and SSIM is shown in Table I. Referring to Table I, it can be noticed that a scheme by Hisham et al. [2] achieved a lower MSE value compared with the proposed method. In addition, the scheme also produced higher PSNR and SSIM values than the proposed scheme.

A scheme by Hisham et al. [2] embedded nine bits out of sixteen bits as watermark information on each sub-block of 4x4 pixels. A scheme by Hisham et al. [2] used a sub-block size of 4x4 pixels which contains 16 pixels on each sub-block. All pixels are not embedded by the watermark bits, only nine bits 56.25% of pixels are modified on the LSB of the sub-block pixels. The remaining seven bits 43.75% are maintained as original bits or unmodified. The proposed scheme embedded the watermark bits on the sub-block of 3x3 pixels which contains 9 pixels. All the pixels are modified with watermark bits on the LSB of each sub-block. The proposed scheme embeds two bits as authentication bits and seven bits as recovery blocks as the watermark bits. Modifying all pixel values of the sub-block image can contribute to the reconstruction error. Therefore, the scheme by Hisham et al. [2] produced higher PSNR and SSIM values than the proposed scheme. The comparison of the existing methods using the block-based scheme for image authentication is shown in Table II.

Referring to Table II, it can be noticed that modifying 1 LSB of the cover image produced a higher quality of the watermarked image with a PSNR value of 50 dB above. Schemes by Huang et al. [7], Sing et al. [10], and Tohidi et al. [19] did not inform the detection accuracy. In addition, the existing watermarking schemes based on block coding required an original cover image or external information in

order to recover the image. The schemes by Belferdi et al. [15] and Tohidi et al. [19] embedded watermark information into the first and second LSB of the cover image. The schemes produce PSNR values of about 44 dB. At the same time, the schemes produced high distortion on the recovery image. The schemes by Belferdi et al. [15] and Tohidi et al. [19] produced the quality of the recovered image with PSNR values of 40dB and 32 dB respectively. The schemes by Huang et al. [7] and Sing et al. [10] embedded watermark data into the first, second, and third LSB of the image. The scheme produced a PSNR value of about 39 dB due to modifying 3 LSB on the cover image. The recovered image still produced a PSNR value of 41 dB and 39 dB, respectively. Even though the scheme presented a self-embedding watermark, it still required reference bits for authentication. A scheme by Hisham et al. [2] was able to produce high imperceptibility of the watermarked image with a PSNR value of 53 dB. The scheme embedded nine bits out of sixteen bits for authentication and recovery bits. The remaining seven bits are maintained as the original bits. Therefore, the scheme can achieve a high PSNR value of the watermarked image. While the scheme produced low accuracy on the tamper detection due to limited embedding watermark for each sub-block. A scheme by Hisham et al. [2] also required reference bits for recovering the medical images. The scheme produced a quality of the recovered image with a PSNR value of 40 dB. The proposed scheme achieved a slightly low quality of the watermarked image compared with a scheme by Hisham et al. [2] with a PSNR value of 51 dB. In addition, the proposed scheme provides higher accuracy of tamper detection than a scheme by Hisham et al. [2]. The proposed scheme produced a superior quality of the recovered image than the existing benchmark of the watermarking schemes. The proposed scheme is tested under various tampering rates, and then the results are evaluated by using True Positive Rate (TPR), False Negative Rate (FNR), and False Positive Rate (FPR). The comparison of the TPR, FNR and FPR under various tampering conditions is listed in Table III.

TABLE I. THE COMPARISON OF THE IMPERCEPTIBILITY PERFORMANCE BETWEEN THE PROPOSED SCHEME AND A SCHEME BY HISHAM ET AL. [2]

Medical Image	PSNR (dB)		SSIM	
	Hisham et al. [2]	Proposed scheme	Hisham et al. [2]	Proposed scheme
Abdomen	53.6267	51.1424	0.9995	0.9992

Teeth	53.6523	51.1339	0.9978	0.9961
Womb	54.1882	51.6033	0.9970	0.9910
Average	53.7508	51.2981	0.9974	0.9942

TABLE II. COMPARISON OF THE QUALITY, TAMPER LOCALIZATION, RECOVERY OF THE EXISTING WATERMARKING SCHEME

Method	PSNR Embedding	Embedding Location	Detection	PSNR Recovery	Recovery	Authentication type
Hisham et al. [2]	53.7508 dB	1 LSB	0.7668	40.7861 dB	Require original cover image	Active
Belferdi et al. [15]	44.2495 dB	2 LSB	1.0000	40.7300 dB	Using Bayer Pattern	Active
Huang et al. [7]	39.0900 dB	3 LSB	-	41.3200 dB	Using ROI & RONI	Active
Sing et al. [10]	39.8600 dB	3 LSB	-	39.1400 dB	Using Block Truncation Coding	Active
Tohidi et al. [19]	44.0000 dB	2 LSB	-	32.0000 dB	Using Compression Strategy	Active
Proposed scheme	51.2981 dB	1 LSB	0.8774	44.7922 dB	Not require the original cover image	Active

The watermarked medical images obtained from the scheme by Hisham et al. [2] and the proposed scheme are tested under various attacks and each tamper attack was subjected to the same size of the attack. According to Table III, the seven medical images have been tested under various tampering rates. The experimental results show that the proposed scheme achieves a higher average TPR than a scheme by Hisham et al. [2]. The scheme by Hisham et al. [2] presented multilayer authentication based on a set of conditions on the average value of sub-block and parity bits of sub-block with the size of 4x4 pixels. The scheme has the potential for detecting 75% certainty of the tampered sub-block. First, the parity bit on each sub-block was compared with the first extracted bit of its sub-block. The first layer authentication has a probability of being 50% undetected. The second layer authentication performed a comparison of the average sub-block and block image. This stage also provided a 50% probability of the previous undetected tampered area. The proposed scheme presented multilayer authentication bits by considering the previous tampered block. The first layer authentication compared the average value of the sub-block with the size of 3x3 pixels and block with the size of 6x6 pixels. If the bits are not equal, the sub-block was marked as tampered sub-block and the  $\alpha$  was set to 1. Otherwise, the bits are the same, then the second layer authentication is computed to check the authenticity of bits. The second layer of authentication compared the parity of bits on each sub-block with the extracted bits obtained from LSB on its sub-block. If the bit values are not the same, then the sub-block was assigned as a tampered sub-block. In addition, if the  $\alpha$  value is

1, the sub-block image was marked as a tampered block. If the previous sub-block has a tampered with, its block image has a high probability tamper. The proposed tamper detection algorithm successfully increased the detection rate compared with the scheme by Hisham et al. [2]. A scheme by Hisham et al. [2] produced an average TPR rate of 76.68%. The proposed scheme successfully detects the tampered image with a high TPR rate of 87.74%. The accuracy of the tamper detection scheme under various tamper attacks is shown in Fig. 7.

According to Fig. 7, the proposed scheme also provided a slightly higher FPR rate than the scheme by Hisham et al. [2], it does not significantly affect the reliability of the proposed scheme. It has been proven by achieving a higher accuracy rate compared to the scheme by Hisham et al. [2] as shown in Table III. According to Table III, our scheme produced slightly lower precision than the scheme by Hisham et al. [2]. The proposed scheme achieved higher accuracy than other schemes with an average accuracy of about 0.997. Both schemes provide multilayer authentication for detecting tamper images. Our scheme proposed tamper localization by using multilayer authentication with considering the previous sub-block  $\alpha$ . Referring to Fig. 7, it has been proven that the proposed authentication algorithm can improve the accuracy of tamper detection. The proposed authentication algorithm can detect higher accuracy of the tamper localization compared with the scheme by Hisham et al. [2]. The proposed scheme is also able to recover bits against various tampered attacks. The experimental results of the recovered image are listed in Table IV.

TABLE III. COMPARISON OF THE TPR, FNR AND FPR UNDER VARIOUS TAMPERING RATES

Average	40.7861	<b>44.7922</b>	0.9930	<b>0.9948</b>

The watermarked images obtained from the proposed scheme were tested under various tamper attacks. Each watermarked image was tampered with using the common attack in the medical images such as blurring, unsharp masking, copy-move, mosaic, noise, removal, and sharpening. Each attack is carried out in a round shape with a diameter of 60 pixels to simulate a real-world attack. The visualization of the comparison between the proposed scheme and other existing schemes for the recovered image is depicted in Fig. 8.

The scheme by Hisham et al. [2] used the spiral block mapping for embedding watermark and retrieved the recovery embedded bits from another block by using pseudorandom equations. The secret key used the total number of blocks in the image. This block mapping introduced a tamper coincidence problem during the recovery process. The recovery bits may be altered due to randomized blocks. Therefore, the scheme was not able to retrieve the embedded recovery bits. In addition, the scheme only can be performed with the square image size. The block numbering starts from the center of the image and spirals outward to the edge of the image. If the image input is not a rectangle, then the block mapping algorithm will not be able to handle outside the

square area in the center of the image and the outside area will be unprotected. This study proposed a spiral inward block mapping started from the top-left of the image and ended in the center of the image. To solve this tamper coincidence problem, the proposed method maps the first half of spiral inward mapping to the second half of the spiral block mapping. This technique greatly decreases the tamper coincidence problem during the recovery bits. This approach also can overcome the square-image problem presented by Hisham et al. [2]. The proposed method successfully protects all the image pixels as well as the rectangle images. The proposed method successfully recovers the image from the tampered image. The proposed scheme achieved higher quality recovered images than the scheme by Hisham et al. [2] with an average PSNR value of 44.7922 dB and an average SSIM value of 0.9948. The proposed scheme presented a smaller sub-block code with the size of 3x3 pixels for embedding watermark. Our scheme proposed a spiral block map to prevent the tamper coincidence problem. The proposed scheme is also tested under different tampering rates. The quality of the recovered images is shown in Fig. 9.

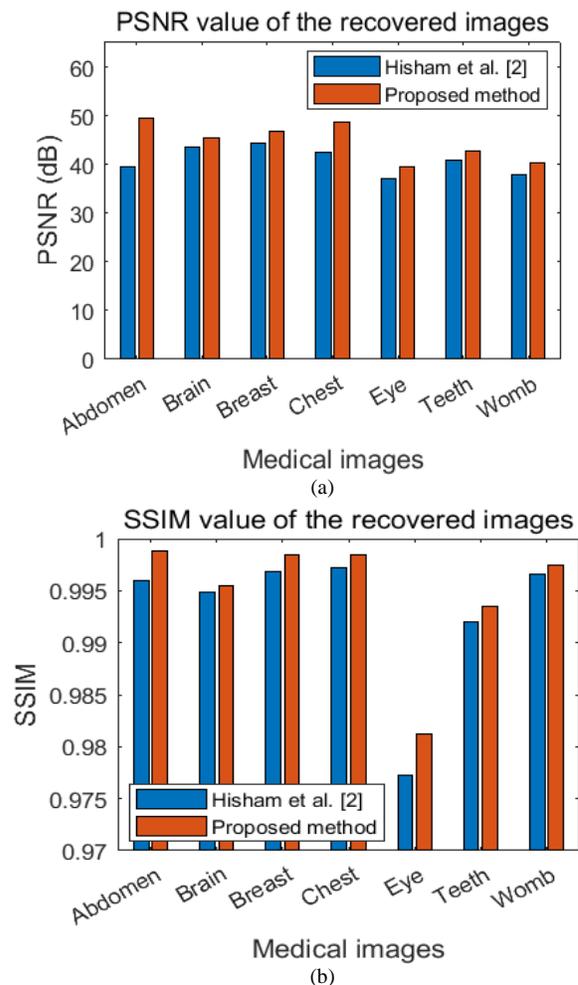

Fig. 8. The Quality of the Recovered Image from the Proposed Scheme and a Scheme by Hisham et al. [2] (a) PSNR (b) SSIM.

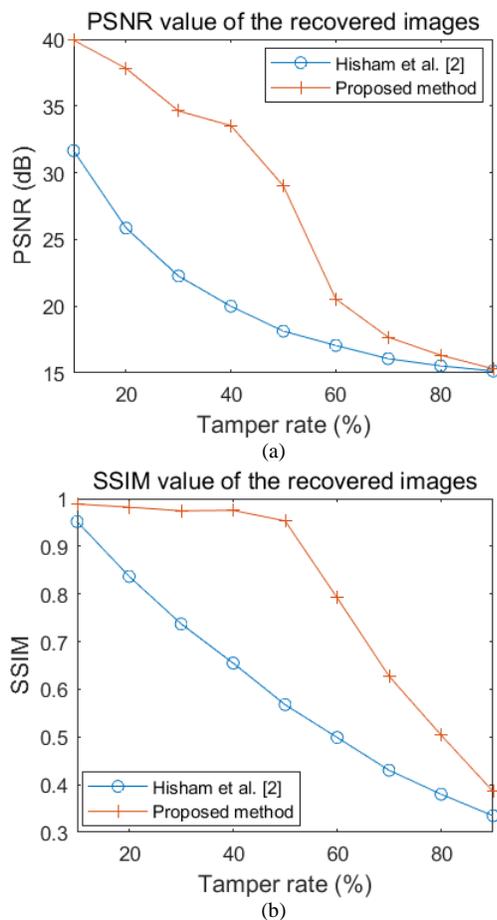

Fig. 9. The Quality of the Recovered Image: (a) PSNR Value, (b) SSIM Value under different Types of Tampering Rate.

In order to evaluate the effectiveness of the proposed scheme, the different amounts of tampering rates are applied to the watermarked image. The experimental results have shown that the proposed scheme achieved superior quality of the recovered image under different tampering conditions. According to Fig. 9, it can be seen that the proposed scheme can achieve high image quality of the recovered image under tampering rates of 10%, 20%, 30%, 40%, and 50%. The quality of the recovered image decreased when the watermarked image tampered with the tampering rates of 60%, 70%, 80%, and 90%. The proposed scheme can achieve PSNR values of 40db under 10% tampering rate, 35dB under 30% tampering rate, and significantly decrease to 20dB under 60% tampering rate. The proposed scheme produced a high-quality image in terms of SSIM value of 0.99 under tampering rates of 10%, 20%, 30%, 40%, and 50%, while it suddenly decreased when the watermarked image was tampered with at a 60% tampering rate. The visual tamper detection and recovered image from the tamper attack are shown in Fig. 10.

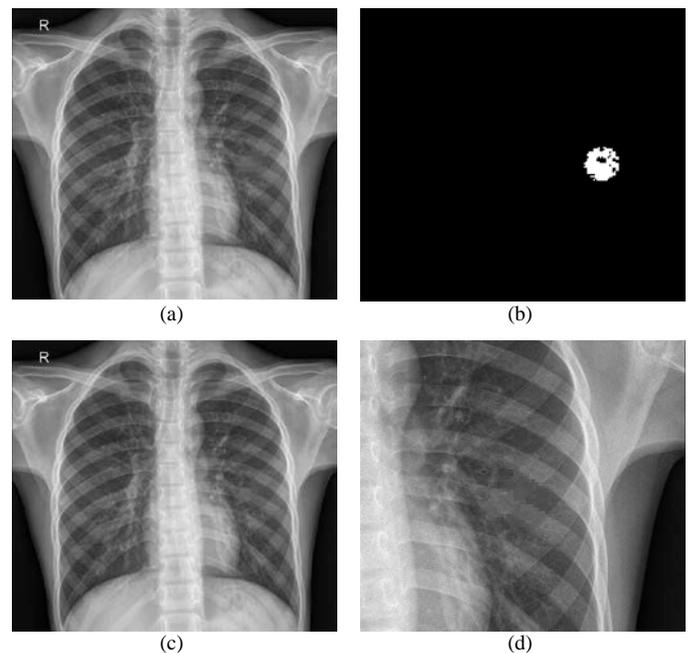

Fig. 10. (a) Tampered Image, (b) Tamper Detection, (c) Image Recovery, (d) Image Recovery with Zoom in 200%.

According to Fig. 10, the proposed scheme was able to recover the tampered image using the mosaic attacks. Fig. 10(a) shows the tampered “Chest” image by a mosaic attack where the tampered area is shown on the right side. Fig. 10(b) presented that the proposed scheme can show the tamper localization as shown in the white color. The proposed scheme can achieve a detection rate value of 85.23% for the tampered “Chest” image. Next, Fig. 10(c) shows the recovered “Chest” image, and the recovered image with zoom in 200% is shown in Fig 10(d). According to Fig. 10(d), our scheme can achieve high quality of the recovered image, it is closer to the original medical image. In addition, the proposed scheme can achieve high accuracy of tamper detection. The visual comparison of the recovered image between Hisham et al. [2] and the proposed scheme is shown in Table V. The detail visual tamper detection and recovered image under various attacks is shown in Tables VI and VII.

## V. CONCLUSION

This research has presented self-embedding a watermark for medical image authentication and recovery. The watermark bits have been generated from its image content; it consists of two authentication bits and seven recovery bits. The first authentication bit is obtained from the comparison between an average pixel of sub-block and block image. The second authentication bit has been generated from the parity bits of each sub-block. The recovery bits are determined by finding the median value of each sub-block. The recovery bits are embedded in the different locations based on spiral block mapping. The proposed scheme maps the first half of spiral inward mapping to the second half of the spiral block mapping.

TABLE V. VISUAL COMPARISON OF THE QUALITY OF THE RECOVERED BITS UNDER VARIOUS TAMPERING RATES

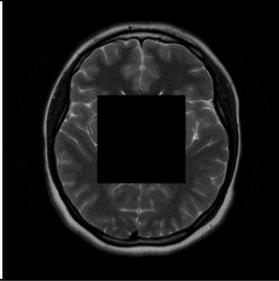

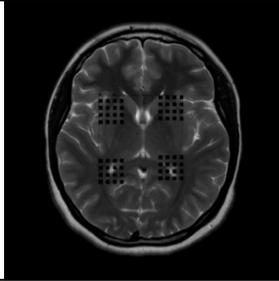

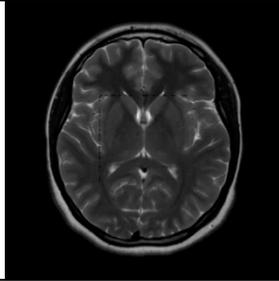

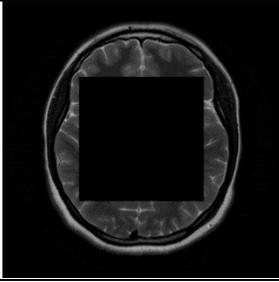

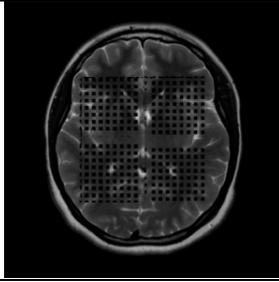

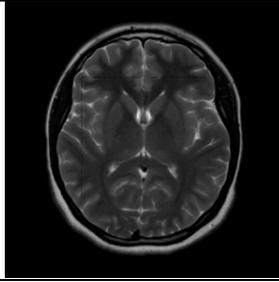

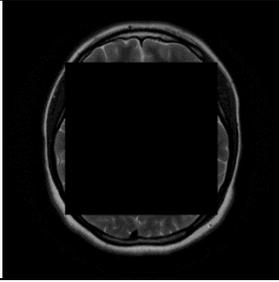

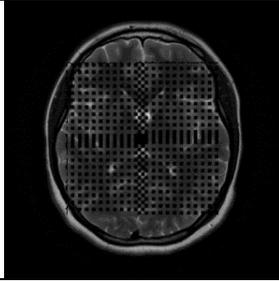

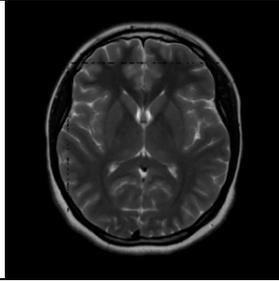

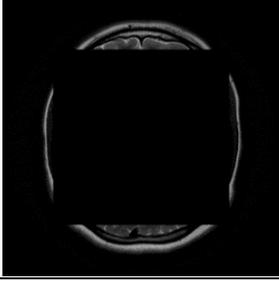

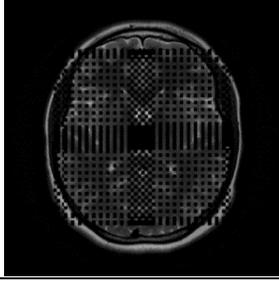

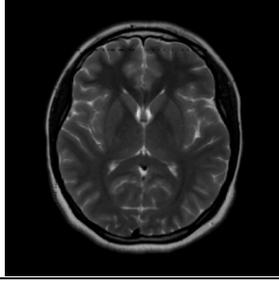

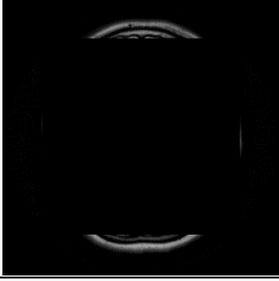

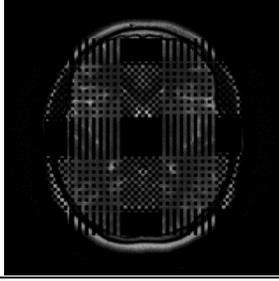

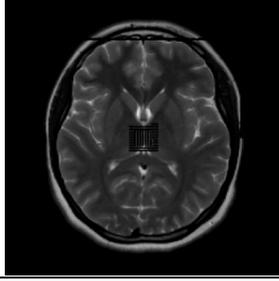

Tampered Image (Tampering rate)	Recovered Image	
	Hisham et al. [2] (PSNR / SSIM)	Proposed Method (PSNR / SSIM)
		
Tamper rate: 10 %	31.6484 dB / 0.9516	39.9283 dB / 0.9885
		
Tamper rate: 20%	25.8563 dB / 0.8368	37.8172 dB / 0.9822
		
Tamper rate: 30%	22.2600 dB / 0.7372	34.6273 dB / 0.9744
		
Tamper rate: 40%	19.9915 dB / 0.6550	33.5292 dB / 0.9754
		
Tamper rate: 50%	18.1313 dB / 0.5677	29.0157 dB / 0.9533

TABLE VI. VISUAL TAMPER DETECTION AND RECOVERED IMAGE FROM THE PROPOSED SCHEME UNDER VARIOUS TAMPER ATTACKS

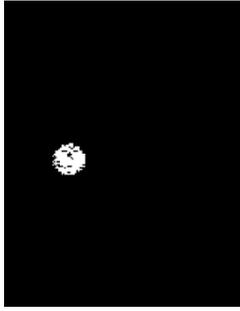

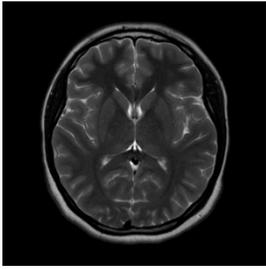

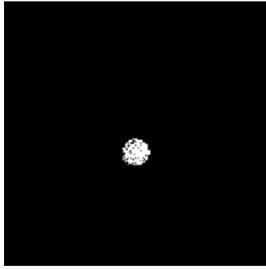

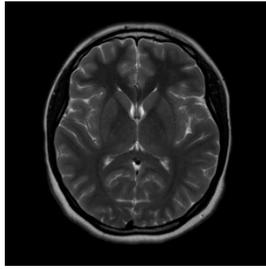

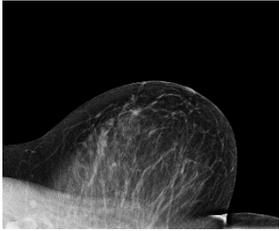

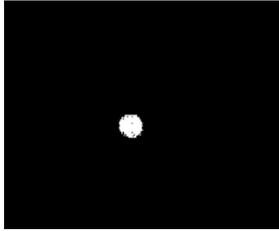

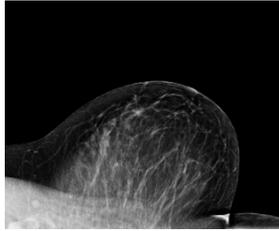

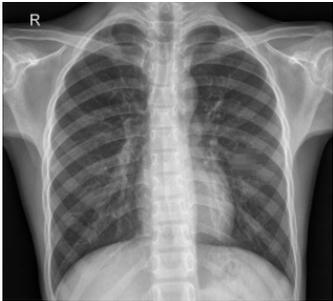

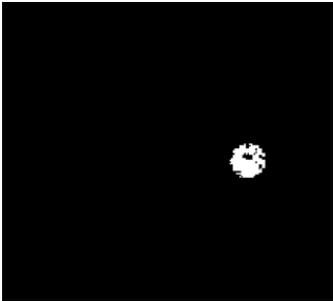

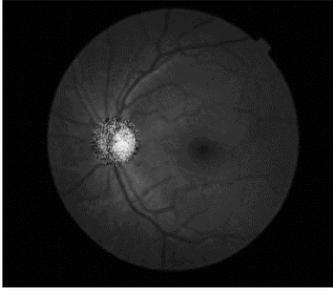

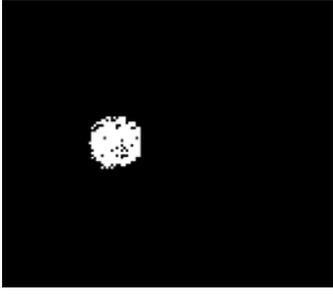

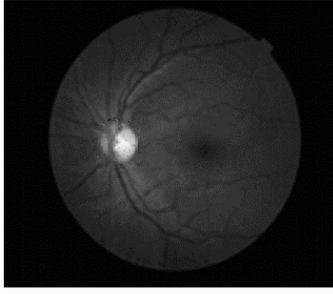

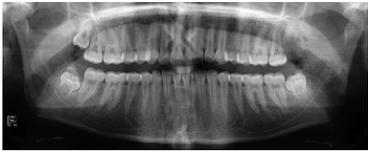

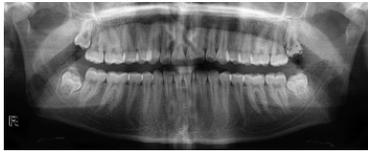

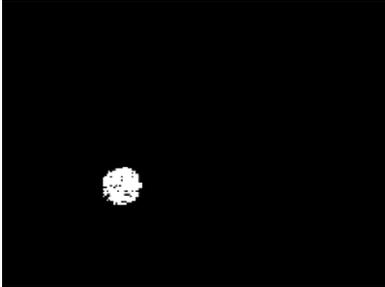

Tampered Image (Tampering rate)	Tamper Detection (TPR / FNR / FPR)	Recovered Image (PSNR / SSIM)
		
Blurring 0.94 %	0.8566 / 0.1434 / 0.0012	49.4710 dB / 0.9988
		
Unsharp masking 0.70 %	0.8642 / 0.1358 / 0.0010	45.4482 dB / 0.9955
		
Cloning 0.64 %	0.9523 / 0.0477 / 0.0006	46.8068 / 0.9985

TABLE VII. VISUAL TAMPER DETECTION AND RECOVERED IMAGE FROM THE PROPOSED SCHEME UNDER VARIOUS TAMPER ATTACKS

Tampered Image (Tampering rate)	Tamper Detection (TPR / FNR / FPR)	Recovered Image (PSNR / SSIM)
		
Mosaic 0.8 %	0.8523 / 0.1477 / 0.0014	48.8064 dB / 0.9984

		
Noise 2.01 %	0.8790 / 0.1210 / 0.0023	39.6542 dB / 0.9812
		
Removal 1.35 %	0.8409 / 0.1591 / 0.0013	42.9007 dB / 0.9935
		
Sharpening 0.91 %	0.8962 / 0.1038 / 0.0011	40.4584 / 0.9975

The watermarked images have been tampered with using different types of attacks. The proposed scheme was also evaluated by using tampering ratios of 10%, 20%, 30%, 40%, and 50% tampering rates. The experimental results show that it can improve the accuracy of tamper detection. The scheme achieved an average TPR value of 0.87 and an accuracy of 93%. In addition, the proposed scheme performed superior quality of the recovered image than the existing benchmark. The proposed scheme achieved high accuracy of the recovered image under various tamper attacks with a PSNR value of 44.79 dB and an SSIM value of 0.994.

**Abstract**—In the field of communication, Mobile Ad-hoc networks (MANET) have become popular and widely used. However, there are many security challenges in communication through these networks due to the presence of malicious nodes. The aim of this article is to present a novel adaptive threshold trust based approach for isolating malicious nodes to establish secure routing between source and destination. Many existing cryptography methods are complex and do not properly address the elimination of malicious nodes. Several trust-dependent mechanisms have been proposed that supplement old traditional cryptography- related security schemes. But it is observed that most of these trust based approaches are using direct trust and comparing with static trust threshold. This article proposes a novel method, secured trust with adaptive threshold (STAT) that uses the Adaptive threshold technique (APTT) combined along with secure trust based approach (STBA) to evaluate the node trustworthiness for efficient routing. Secure trust for a node is calculated based upon three tier observations that includes direct, neighbor, self-historical to enrich the trust factor and adaptive trust threshold is determined based upon network parameters dynamically. Node's secure trust is compared with adaptive trust threshold computed to isolate the malicious nodes from routing. The proposed method is compared with two cases where routing is performed without any trust calculation and routing with trust calculation and compared with static trust threshold approach. Results show significant performance of the proposed work in terms of metrics like packet delivery ratio, delay, throughput, false positive detection ratio and packet drop ratio. The proposed method STAT effectively isolates the malicious nodes and establishes secure routing.

**Keywords**—Node trustworthiness; misbehaving nodes; secure trust; static threshold; adaptive threshold; secure routing

## I. INTRODUCTION

MANET's are considered to be connected on an infrastructure that provides better linkage between the nodes and its environment [1]. These networks are considered as a part of many applications today [2]. However, though its wide application in many fields, MANET's are vulnerable to many attacks and especially due to its dynamic network topology. These attacks can be overcome using many schemes which are

related to the identifying the malicious nodes. These schemes work on the principle that the trust values of the nodes are to be calculated. Later these trust value calculations are compared to the static threshold values known as trust threshold in order to make appropriate routing decision by isolating the malicious nodes. This threshold defines the tolerability of a node in a network [3]. The security challenges of MANET's are identified in the case of their scalability, resource utilization, dynamic topology, and even power consumption and usage. Other challenges are related to the secure environments of the networks [4].

Many trust based schemes proposed have actually made use of static thresholds to identify trust of the node [5]. This type of methods are prone to drawbacks like high error rates. These error rates will influence the timeframe of dropping malicious nodes from routing. Nodes due to environment glitches may drop the packets in some cases. They may also be categorized as malicious nodes due to static threshold strategy which is taken without any consideration of network behavior. Network behavior plays important role in MANET's due to its infrastructure less hierarchy. Existing trust based mechanisms are based upon the two tier observations either direct or combination of direct and indirect trust computations. All these trust based approaches are comparing the evolved trust with static threshold for identifying malicious nodes. As MANET's are dynamic in nature, there is always a need to compute adaptive trust threshold based on network parameters that change dynamically time to time for every node. Every node should have its trust threshold factor computed dynamically. Node's trust value should be compared with adaptive trust threshold to decide its trustworthiness. It is observed from the limitations of the existing methods, there is need of computing node's trust factor with more sophisticated approach and calculation of node's trust threshold using network parameters in adaptive mode.

The proposed work deals with the isolation of malicious nodes. Secure trust computation scheme is used to compute nodes trust value and it is combined with adaptive trust threshold technique (STAT). The work emphasis on adaptive

trust threshold technique (APTT) instead of using static trust threshold, where first one is employed here along with sound research on the background on MANET and its challenges in the real-time applications. The study is proposed with a model which aims to design the threshold (adaptive in nature) of each and every node in the network to match the topology of the network. The research is also furnished with enough and appropriate mathematical model and formulas to introduce the Adaptive trust and proposed scheme. Satisfactory results are obtained such that it can be tested by implementing any routing protocol of choice.

Towards the end, the goal of this work is to address the challenge of adaptive trust threshold computation and combining it with three tier observations for generating secure trust in order to establish secure routing.

This article is organized with Introduction to the security challenges in MANET's in Section I. Background research on MANETs and related work is presented in Section II, after that the proposed model is implemented in Section III along with simulation results in Section IV. The conclusions and future directions are given in Section V.

## II. RELATED WORK

It is found from many researches usually in their proposed trust schemes fixing a threshold value which ranges between 1 and 0 to decide the fact that the node must be given access to process towards the routing phase or not [6].

Authors in [7] proposed trust computation based on user and self evidences. They evaluated the trust between the range 1 and 0. In [8], direct observations based on probability assignment between two nodes are proposed which also uses the scale of 0 and 1 for trust evaluation. Probability centric model is used for the evaluation of trust in [9] that considers the trust within the values 0-1 and uses static trust threshold concept. A scheme is presented to append the nodes trust values of nodes, according to their behaviors in [10]. A method based on reputation using the concept of polling is proposed in [11]. A local voting trust establishment strategy based on discrete scale for mobile adhoc networks is proposed in [12]. All these approaches are considering the static trust threshold commonly for all the nodes to isolate malicious nodes from routing.

This work finds its grounds on the fact that MANET's are known for their Dynamic Topology where a fixed calculation and pre-defined trust value doesn't make sense [13]. Mobility is also dependent on the behavior of the network. The evaluation of the mobility is seen in many researches which show that it can be considered as a part of the proposed model [14]. Node failures associated with the link also imposes as a threat in real-time scenarios [15]. Hence, all the time considering the static trust seems ignoring the problems that arise due to MANET behavior. This forces that an adaptive nature is to be employed.

Nodes in MANET's will move randomly time to time that leads to the raise of Node degree, a network factor. Every node in the network is linked to the fact that it is going to change for every second that can be interpreted as Rate of Link change. Average trustworthiness of the nodes in 1-hop

distance is considered to compute the Adaptive threshold [16]. These are the metrics usually considered for the Topology. Hence, they do play an important role in defining the network topology as well as in secure transmission.

In the case of static methods, the threshold was based on the link as it changes in a linear fashion [17]. But in this case, every node is having its own environment which will obviously affect the link change. It is also stated by the researchers that each node might individually experience the change which is to be evaluated. These can be determined using metrics like node mobility and other parameters.

Hence, the proposed method for adaptive trust threshold computation aims towards estimating the link change at every node, node degree and average nodes trustworthiness which helps for better performance in the real-time scenarios.

## III. PROPOSED METHODOLOGY

The proposed work computes the nodes trust based on three tier observations which are quantified into a single value to represent the secure trust factor of the node under consideration in first stage (STBA). In second phase, adaptive trust threshold is evaluated based on the network factors (APTT). In third phase, the evaluated secure trust factor is compared with adaptive trust threshold to classify the nodes category (STAT). It isolates the malicious nodes and performs secure routing only with those nodes evolved as trustworthy. The proposed approach suits to the real time environment which represents the minimum gathering in any real time scenario like a small conference. Work flow is shown the Fig. 1.

### A. Secure Trust based Approach (STBA)

Secure Trust based approach evaluates nodes resultant secure trust value as a combination of direct, neighbor observations and nodes self-appraisal/historical trust as given in equation 1.

$$\text{Resultant Secure Trust} = \text{Direct Trust} + \text{Neighbour Trust} + \text{Historical Trust/Self-appraisal of Node} \quad (1)$$

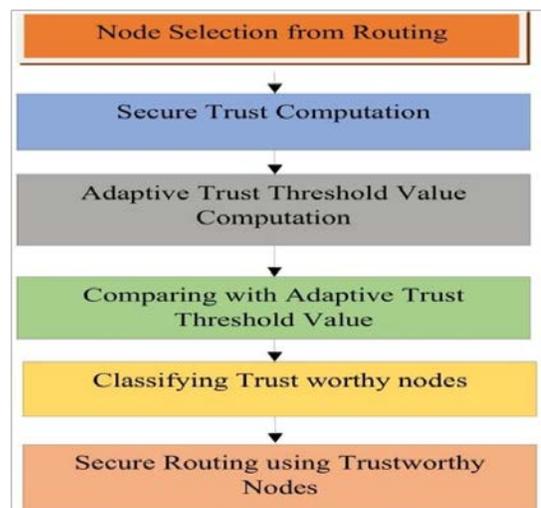

Fig. 1. Work Flow of the Objectives.

Direct Trust (D) : Data Packet Ratio(DF) and Control Packet Ratio(CF) is generated based on the data packets and control packets forwarding nature of the node. Direct Trust is calculated using equation 2.

$$\text{Direct Trust, } D = t_1 * DF + t_2 * CF \quad (2)$$

Where  $t_1 + t_2 = 1$ ,  $t_1, t_2$  are corresponding weight given to Data Packet Ratio and Control Packet Ratio.

Neighbour Trust (N): All the neighbouring nodes in 1 hop distance will quantify their trust observations on the node specified for which trust is calculated using the equation 3.

Neighbour Trust,

$$N = (k_1 * T_1 + k_2 * T_2 + k_3 * T_3 + k_4 * T_4 \dots + k_n * T_n) / (\text{Total No of Nodes within 1 Hop distance}) \quad (3)$$

Where  $T_1, T_2, T_3, T_4 \dots T_n$  are trust observations by the neighbour nodes. And  $k_1, k_2, k_3, k_4 \dots$  are corresponding weights given to the neighbour nodes based on their distance in the network.

Nodes Self-Appraisal (H): Nodes can rate themselves with a trust value based upon their performance in terms of packet forwarding. Self-Appraisal is quantified based on equation 4.

$$\text{Self-Appraisal, } H = \text{No of Packets forwarded properly} / \text{Total no of packets received} \quad (4)$$

Then,

Secure Trust is evaluated based on equation 5.

$$\text{Secure Trust (STBA), } T = m_1 D + m_2 N + m_3 H \quad (5)$$

Where  $m_1, m_2, m_3$  are corresponding weights assigned to the trust observations.

### B. Adaptive Trust Threshold (APTT)

Adaptive trust threshold computation has to represent many different network factors. Each node in the network may encounter various conditions such as node degree variations, rate of link changes and average neighborhood.

Network Parameters to be considered are:

#### 1) Node Degree - $\sigma$

It is defined as No of nodes in 1 hop neighbourhood. The statics are presented as follows.

Node n at time t,  $n(t) = 0$ , i.e.

Min Node Degree = 0, then it is considered as no neighbours for that node.

Max Node Degree = all are directly connected to Node  $\mu$ . Node Degree has a direct impact on Trust Threshold; the higher number of nodes in its 1-hop neighbourhood. The higher is the threshold value and vice-versa. Optimal Threshold Value for the Node Degree is calculated based on the equation 6.

Optimal Threshold value

$$\Sigma \sigma = \sigma n / |T| \quad (6)$$

Where, T = total number of nodes

$\sigma n$  = Node Degree of node 'n'

and 2 Hop connectivity may be considered.

#### 2) Rate of Link Changes - $\eta$

Neighborhood changes occur in MANETs frequently due to Network Mobility. A Node can determine its Neighbor Mobility by computing the Neighborhoods rate of link changes. Higher Mobility leads to higher rate of link changes in Nodes Neighborhood.

Rate of Link changes at Node  $\mu$  is given by equation 7.

$$\eta \mu = \lambda \mu + \mu \mu \quad (7)$$

Where,

$\lambda \mu$  = Number of new nodes coming in, means Neighbours of Node

$\mu$  = Total Link arrival rate at Node  $\mu$

$\mu \mu$  = Total number of nodes moving out of Node's  $\mu$  transmission range for time interval.

Minimum Link Rate changes,  $\eta \mu_{\min} = 0$  = No new nodes arrival, No Link Breakages, implies Temporary Static then considered as no mobility.

Maximum Link Rate changes,  $\eta \mu_{\max}$  = When all the direct neighbors are out of the transmission zone, considered as High mobility.

If the rate of change in Neighborhood is high, set Low Threshold (to avoid false positives).

If the rate of change in Neighborhood is low, set High Threshold (Network is static).

Optimal Threshold value for the Rate of link change factor is given by equation 8.

Optimal Threshold

$$\Sigma \eta = 1 - \eta \mu / 2 \sigma \mu \quad [22] \quad (8)$$

Where  $\eta \mu$  = Rate of Link Changes of node ' $\mu$ '

$\sigma \mu$  = Node Degree of node ' $\mu$ '

#### 3) Average Neighborhood Trustworthiness - $\tau_{avg}$

The formula for  $\tau_{avg}$  is given by equation 9.

$$\tau_{\mu \text{ avg}} = 1/n \sum_{j=1}^n T_j \quad (9)$$

Where,  $T_j$  = Trust of all the neighbour nodes of Node  $\mu$  on it, where Self-appraisal/Historical Trust of nodes is taken into consideration.

$\tau_{\mu \text{ avg}} = 1$ : Good Nodes are available, High Trust Worthy, set High Threshold.

$\tau_{\mu \text{ avg}} = 0$ : More Misbehaving Nodes are available, Low Trust Worthiness, set Low Threshold value.

Optimal Threshold value at node  $\mu$  for malicious node isolation given by equation 10.

$$\xi_T = \tau_{\mu \text{ avg}} \quad (10)$$

Combining all the network parameters for estimating the proposed adaptive trust threshold using equation 11.

Final adaptive trust threshold,  $\xi_\mu$  is

$$\xi_\mu = (a \xi_\sigma + b \xi_\eta + c \xi_T) / (a+b+c) \quad (11)$$

Where  $\xi_\sigma$  = Optimal threshold value of Node Degree of the Node

$\xi_\eta$  = Optimal threshold value of Rate of Link.

Changes of the Node.

$\xi_T$  = Optimal threshold value of Average.

Neighbourhood Trustworthiness of the Node.

And a,b,c are constants and a+b+c is considered for higher throughput, and the Node Degree and 2 Hop connectivity are given importance. So subsequently  $\alpha$  should have more weight.

Then Decision of isolating a node depends upon.

T, Trust Evaluated of the node  $\geq$  Adaptive Trust Threshold -  $\xi_\mu$ , Node is decided as Trusted Node.

T, Trust Evaluated  $<$  Adaptive Trust Threshold -  $\xi_\mu$ , Node is decided as Un Trusted Node, then, isolate the node from routing.

### C. Proposed Algorithm for Adaptive Trust Threshold

Considering the 2-hop connectivity an algorithm is proposed for the adaptive trust threshold as follows:

**Algorithm** Optimal adaptive trust threshold computation

**procedure Secure Trust(T, D, N, H)**

```

{
// T = Secure trust of the Node
// D= Direct Trust of the Node
// N=Neighbor Trust of the Node
// H=Historical Trust/Self Appraisal of the Node
Step:1 Node trustworthiness is initiated, for each and every node
Step:2 Data Packet Forward ratio is
DF = w1 * (Dforw / Dtd) + w2 * (Ddrop / Dtd) + w3 * (Dmr / Dtd) + w4 * (Dfi / Dtd)
Step:3 Control Packet Forward Ratio is
CF = w1 * (Rreq / Rreq) + w2 * (Rrep / Rrep) + w3 * (Rerr / Rerr) + w4 * (Rtack / Rtack)
Step:4 Direct Trust, D = t1 * DF + t2 * CF
Step:5 Neighbour Trust, N = (k1*T1 + k2*T2 + k3*T3 + k4*T4... +knTN) / (Total No of Nodes within 1 Hop distance)
Step:6 Self-Appraisal, H = No of Packets forwarded properly/Total no of packets received

```

```

Step:7 Secure Trust(STBA), T = m1D + m2N + m3H
}
end procedure

```

**procedure Network Parameters (T<sub>avg</sub>,  $\xi_\sigma$ ,  $\xi_\eta$ )**

```

{
//Tavg = Average Neighborhood Trustworthiness
//  $\xi_\sigma$  = Optimal Threshold value of Node Degree
// $\xi_\eta$  = Optimal Threshold value of Rate of Change in Linkage
Step:1 if new node appears then  $\tau_{avg} = \tau_{avg} +$  Threshold of new node.
Step:2 Calculating the optimal threshold through node degree using  $\xi_\sigma = \sigma n / |T|$ 
Step:3 Based on the mobility of the network calculate the total Change of rate of linkage using  $\xi_\eta = 1 - \eta \mu / 2 \sigma \mu$ 
Step:4 if  $\tau_{avg} = 0$  then consider it as Malicious node.
Step:5 The threshold for malicious node is calculated
 $\xi_T = \tau_{avg}$ .
}
end procedure

```

**procedure Adaptive Threshold ( $\xi_\mu$ ,  $\xi_\sigma$ ,  $\xi_\eta$ ,  $\xi_T$ )**

```

{
//  $\xi_\mu$  = Adaptive Trust Threshold
// $\xi_\sigma$  = Optimal Trust Threshold of Node Degree
//  $\xi_\eta$  = Optimal Trust Threshold of Rate of Link Changes
// $\xi_T$  = Optimal Trust Threshold of Average Node Trustworthiness
Step:1 Overall Adaptive Trust Threshold is calculated using
 $\xi_\mu = (a \xi_\sigma + b \xi_\eta + c \xi_T) / (a+b+c)$ 
}
end procedure

```

**procedure Routing Decision (T <sub>$\mu$</sub> ,  $\xi_\mu$ )**

```

{
// T $\mu$  = Secure trust of the Node  $\mu$ 
//  $\xi_\mu$  = Adaptive Trust Threshold of the Node  $\mu$ 
if (T $\mu$  <  $\xi_\mu$ ) then malicious node, isolate the node
else
Trustworthy node, Involve in routing process
end if
}
end procedure

```

## IV. EXPERIMENT AND RESULT ANALYSIS

Network Simulator 2 (NS2) is used for simulation of desired network. The network traffic is maintained with a size of 512Bytes with a packet rate of 200 and 100 packets per second. The malicious Nodes are defined in the physical layers. Hence, considering the parameters for configuration, the trust and other metrics are calculated. To analyze the results, the network configuration parameters and simulation parameters are given in Table I.

TABLE I. SIMULATION PARAMETERS

Simulation tool	NS2
Number of Nodes	100
Malicious Nodes	18
Propagation Model	Two ray ground
Malicious Nodes Declaration	0t
Topography	700*500(M)
Simulation Time	500s
Mobility(r)	5m/s

The simulations are carried out for three design goals in which the last scenario is the proposed method where calculations are obtained from the Adaptive trust threshold.

The parameters used to evaluate the results are Packet Delivery Ratio (PDR): It is defined to be the ratio denoting the number of packets received at the destination and the number of packets sent from the source [18].

Packet Drop Rate (PPR): It is defined as a ratio of the number of lost packets to the total number of sent packets [19].

False Positive Detection (FPR): It denotes the ratio the count of good nodes wrongly identified as malicious to the total available count of nodes. It is also used to calculate the FPR (False positive rate) [20, 21].

Malicious Node Detection Ratio (MDR): it gives the ratio of malicious/misbehaving nodes from the total nodes from the network [20, 21].

Throughput (T): It usually defines the amount of data transferability of a network through a period of time [20,21].

Delay (D): This shows the time frame from delivering the packets through source and destination. [22].

These parameters are considered to evaluate the performance of three occurrences, where the first occurrence routing without any prior trust calculation.

The second occurrence considers the routing with nodes trust computation using the methodology Secure trust based approach (STBA) but compared with static trust threshold factor for node isolation.

Third occurrence is the proposed work, routing with Secure trust combined with Adaptive Trust threshold (STAT) which is the combination of Computation of Secure trust (STBA) and Computation of Adaptive trust threshold (APTT). More emphasis is on computation and comparison of Adaptive trust threshold. Results proved the proposed scheme with adaptive trust threshold comparison performs well over other two occurrences mentioned.

#### A. Result and Analysis

1) *Secure Trust Based Approach Computation (STBA):* Secure Trust is computed based upon the three tier observations using the above mentioned equations. Results obtained for secure trust are tabulated in Table II.

2) *Adaptive Trust Threshold Computation (APTT):* Adaptive Trust Threshold is computed based upon network parameters Node Degree  $\sigma$ , Rate of Link changes  $\eta$ , Average Node Behavior  $\tau_{avg}$  using above mentioned equations. Results generated are tabulated in Table III. Identification of malicious nodes and their isolation using proposed STAT method with Node's Secure Trust computation and comparison with Adaptive Trust Threshold is shown in Table IV.

Node	Node Secure Trust	Adaptive trust Threshold - $\xi_{\mu}$	Decision
0	0.75451	0.665777	Trustworthy
1	0.63364	0.594324	Trustworthy
2	0.11376	0.667425	Malicious
3	0.15714	0.61242	Malicious
4	0.17976	0.695953	Malicious
5	0.08865	0.594764	Trustworthy
6	0.009225	0.669176	Malicious
7	0.2052	0.754351	Malicious
8	0.55416	0.549934	Trustworthy
9	0.612425	0.589824	Trustworthy
10	0.6562	0.590844	Trustworthy
11	0.81688	0.756381	Trustworthy
12	0.82108	0.763691	Trustworthy
13	0.88885	0.725761	Trustworthy
14	0.4397	0.387154	Trustworthy

**B. Performance Metrics**

1) *Packet delivery ratio*: It was observed that for 100pkts/s, out of 50000 packets sent, 47550 packets received, Packet Delivery Ratio is 95.1% for the proposed method, 91.1 % for the second case where trust is compared with static trust threshold, 53.2 % in case of third design goal where routing involved without trust calculation and for 200pkts/s, out of 100000 packets sent, 79235 packets received, Packet Delivery Ratio is 79.2%. In case of proposed method, 75.3%, 30.1%. In case of second and third case, respectively whereas in Fig. 2, shows the Packet Delivery ratio of all the three design goals.

**C. Packet Drop Ratio**

From the simulation, it was observed that for 100pkts/s, out of 50000 packets sent, 2451 packets lost, Packet Drop Ratio is 4.9% for the proposed method, 5.8 % for the second case where trust is compared with static trust threshold, 43.3 % in case of third design goal where routing involved without trust calculation and for 200pkts/s, out of 100000 packets sent, 20785 packets lost, Packet Drop Ratio is 20.765%. In case of proposed method, whereas it is 23.4%, 69.2% for second and third design goal. Fig. 3 shows the Packet drop ratio for the three cases compared.

**D. Throughput**

From the simulation, it was observed that for 100pkts/s, Throughput is 380.4kbps for the proposed method, 358.2kbps for the second case where trust is compared with static trust threshold, 211.6kbps in case of third design goal where routing involved without trust calculation and for 200pkts/s, Throughput is 633.4kbps in case of proposed method, whereas it is 603.5kbps, 229.2kbps for second and third design goal. In Fig. 4, throughput efficiency of the proposed method STAT is shown.

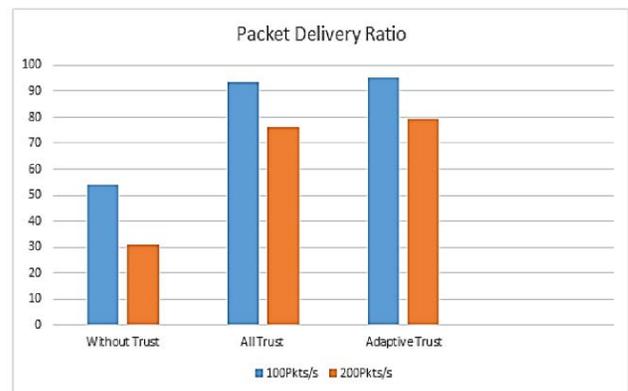

Fig. 2. Packet Delivery Ratio Analysis.

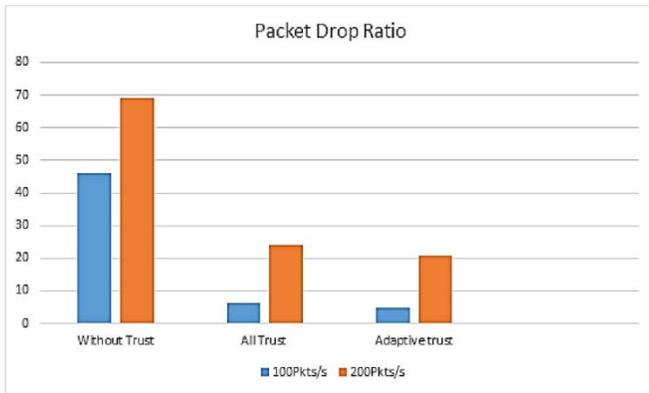

Fig. 3. Packet Drop Ratio Analysis.

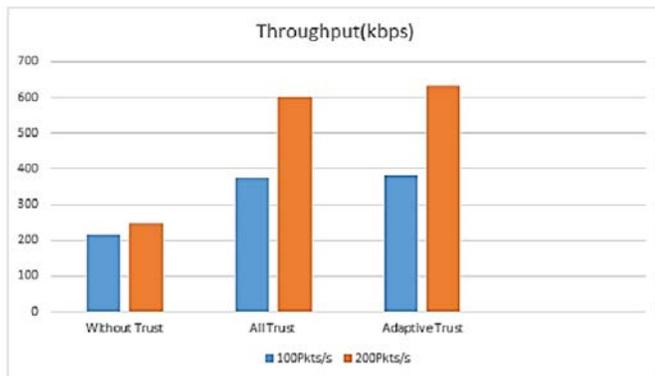

Fig. 4. Analysis of Throughput.

E. Delay

Delay is observed as 187ms for 100pkts/s in case of proposed method, 198ms for the second case where trust is compared with static trust threshold, 232ms in case of third design goal where routing involved without trust calculation and for 200pkts/s, Delay is 270ms in case of proposed method, whereas it is 287ms, 302ms for second and third design goal. Fig. 5 depicts the delay parameter in case of three scenarios mentioned and proves the efficacy of the proposed method. Delay in the network in case of packet delivery is illustrated as follows.

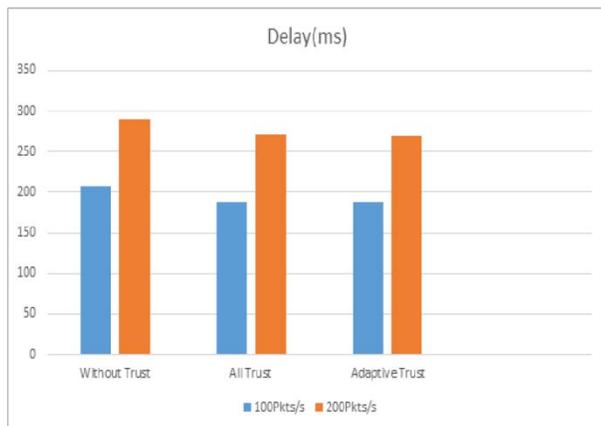

Fig. 5. Delay in the Network.

F. False Positive Detection Rate

False Positive Detection Rate is found as 52% in case of proposed method, 44% for the second case where trust is compared with static trust threshold. In Fig. 6, False Positive Detection Rate is shown for the proposed method.

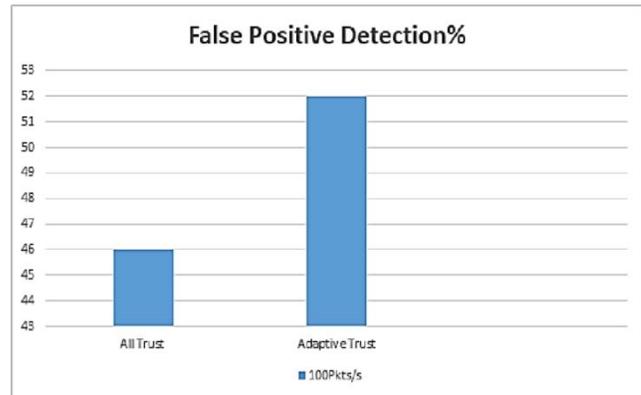

Fig. 6. False Positive Detection Ratio Analysis.

G. Malicious node Detection Rate

Malicious node Detection Rate is found as 23% in case of proposed method, 21% for the second case where trust is compared with static trust threshold. In Fig. 7, proposed method is performing better compared with the secure trust (static threshold) in terms of malicious node detection rate.

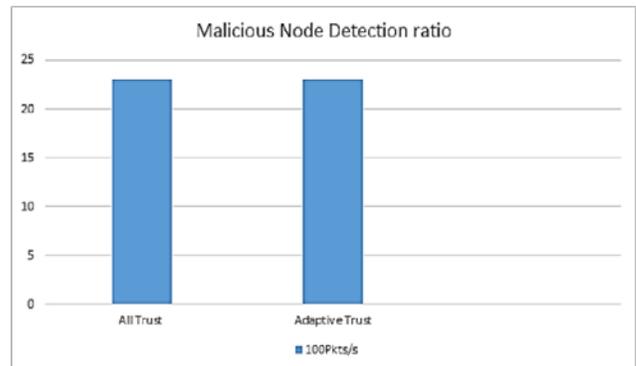

Fig. 7. Detection of Malicious Nodes.

From results, it is interpreted that computation of adaptive trust threshold based on the network parameters when combined with secure trust mechanism, efficiently identifies the malicious nodes which are dropping packets and good natured nodes which are delivering packets and can be used for mobilization.

V. CONCLUSION

The work presented here shows a strategy which can be used to detect the nodes which are misbehaving in a network by considering the network parameters which plays an important role in network. The results evaluated and shown in Fig. 2 to 7 prove the efficacy of the proposed work STAT. The Packet delivery ratio for the method proposed (Adaptive trust Threshold) shows significant growth along with less packet

loss ratio as well which makes it easy to consider the technique proposed in the real-time traffic networks. The proposed method is evaluated and seemed better performing than other methods in particular with methods that uses static trust threshold. Results proves the efficiency of the proposed method when compared with other approaches like routing without trust calculation and routing with trust computation and static threshold approaches. The further scope of the work will be extended by considering the Power consumption scenarios in the networks in case of trustworthy nodes.

**Abstract**—This study developed an application ontology related to the medical tourism supply chain domain (MTSC). The motivation for developing an ontology is that current MTSC studies use a descriptive approach to provide knowledge, which is difficult to comprehend and apply. The formalization of MTSC knowledge can provide medical tourism stakeholders with a shared understanding of the medical tourism business. As a result, the MTSC domain requires efficient semantic knowledge representation. Ontology is a popular approach for integrating knowledge and comprehension because it presents schema and knowledge base in an accurate and relevant feature. This paper employed the ontology engineering methodology, which included specification, conceptualization, and implementation steps. The conceptual model and facets of the MTSC are proposed. The MTSC objective and scope are tested with semantic competency questions against SPARQL Query formulations. The ontology metrics evaluation was used to verify the ontology quality including the external validation done by the domain experts. The results showed that the MTSC ontology has an appropriate schema design, terminologies, and query results.

**Keywords**—Medical tourism; application ontology; supply chain; ontology development; knowledge representation

## I. INTRODUCTION

The medical tourism (MT) industry is considered a high-value business that can generate a high income for the service providing country [1]. MT is a part of health tourism that focuses on medical intervention to improve or restore an individual's health [2]. MT is a specialized service and differs from general tourism in that medical tourists often have a significant problem and need of medical service, along with the desire to travel as well [3]. The medical tourism supply chain (MTSC) is distinct from both the general and health tourism supply chains. MTSC emphasizes medical and travel intervention, as well as relationships with connected parties who assist the major service providers in both the medical and tourism sectors.

At present, the MT business knowledge tends to relate to the key player side [4]. MT business activities are fragmented between stakeholders [5, 6]. Activities are short-lived interactions between a medical tourist and the providers. As a result, some MT actors are deficient in knowledge of the supply chain (SC). Since the MT business is being challenged by many factors such as the global situation, consumer demand, and business competition [7, 8], a new paradigm for enabling MT success is to integrate intra- and inter-

organizational processes [9]. Understanding the MTSC is therefore important.

One method for developing concrete knowledge is to use ontology [10, 11]. Ontology supports aligning the understanding of knowledge by presenting it in an explicit specification and in a meaningful manner [11]. Ontology links the information relationships to a semantic structure. For over a decade now, organizations have used ontologies to build mutual comprehension in the SC [12, 13]. The ontology ideas emphasize making the practitioners understand business logistics, roles, and activities in the SC. We can see studies where ontologies are used for describing SC models, such as [14, 15, 16]. However, an ontology for encouraging MT practitioners to understand the MT business has not been reported. Previous MT studies have emphasized descriptive explanations [4, 6, 17, 18, 19]. At the same time, there is no mention of MT in the SC ontology. Numerous studies have avoided establishing semantic knowledge as a support to MTSC model. Practitioners in MT still lack explicit knowledge that would help them better understand the industry.

Current studies lack a shared understanding of MTSC model between practitioners. Therefore, strengthening business comprehension is of great importance to the business participation and the SC management. This study contributes to the visual linkage of MTSC model.

The paper's key contribution is the MTSC ontology, which was built for the MT domain and enhanced by domain experts. This study developed semantic knowledge utilized in the MT context, to represent MTSC knowledge by using ontology-based tools. The MTSC conceptual model and facets are proposed based on literature extraction and domain expert knowledge. The ontology engineering methodology is presented, adopting ontology engineering methodology of [10, 20]. The instances used for implementation are from Thailand. The evaluation of ontology is performed using the semantic competency questions and the well-known metric-based ontology quality analysis [21, 22]. Domain specialists in the MT industry assisted in the enumeration of terminology and the validation of ontology quality during the development of the ontology.

## II. LITERATURE REVIEW

The paper includes MTSC and ontology engineering methodology terms. The literature review discusses the MTSC characteristics and processes followed by a discussion of

\*Corresponding Author.

ontology engineering methodology and ontology evaluation. Then the previous ontology works are examined for MTSC ontology development.

#### A. Medical Tourism Supply Chain

SC is a term used for over a decade. The SC was originally associated with the manufacturing industry, from raw material procurement to manufacture, delivery, and distribution to clients or customers [23]. The system is interconnected and requires performance management [24]. The expected outcome of SC management is improved quality of operations and products that promote profits for the organization [25]. The actors involved in the SC cycle are grouped to suppliers, producers, transporters, distributors, and customers [14]. At each stage of the SC system, products are produced and transmitted depending on business objectives.

Subsequently, the SC system was introduced in the service business. MT industry has been examined using this concept [26]. MTSC is a network of individuals and organizations who handle information, product or service, and financial flows [27]. The objective of MTSC is to manage the healthcare and tourism processes for improving product and service value for all actors and for creating profits to the organization [26]. The two primary industries that MT is associated with are health and tourism [28]. The MTSC involves a process flow from beginning to end that encompasses the transfer of products or services from providers to customers (internal and external) [6, 19].

The MTSC processes commence with the marketing process to attract medical tourists followed by medical tourists' decision-making regarding service, then making the necessary travel arrangements, followed by diagnostic activity and travel to the destination for medical treatment [6]. The subsequent recovery care is the main activity, involving the rechecking of the treatment result and assessing health risks. During the process of medical services in the destination country, medical tourists can participate in tourism activities [6, 18]. At the end of the process, the relevant activities are tourist departure, tracking potential symptoms, and follow-up activities at the country of origin [27, 29]. The actors in MT business are those who participate in the MTSC processes [4, 18]. Actors come from diverse industries and have various business objectives and roles including activities to be carried out inside and outside the organization [12, 15, 28]. The goods or services are produced by actors and delivered to others.

#### B. Ontology Engineering Methodology

Ontology engineering methodology is a method for aligning understanding of knowledge by presenting it in an explicit specification and in a meaningful manner [11]. Ontology links the information relationships to a semantic structure. Organizations use ontology to build mutual comprehension in the general business and in context-specific domains.

The goal of ontology development is to express knowledge in such a way that both people and computers can comprehend it [22]. Developing an ontology usually begins with recognizing the need for a certain purpose [20]. Then an ontology is created. Many methodologies can be used to

develop an ontology. For example, the method of [22] designing and evaluating an ontology combined six steps: scenario motivation, informal competency questions, first-order logic: terminology, formal competency questions, first-order logic: axioms, and completeness theorems; methodology of [20] relating to the knowledge process consisted of five steps: feasibility study, ontology kickoff, refinement, evaluation, and maintenance; the method of [10] consists of seven steps: determining the ontology domain and scope, considering and reusing existing ontologies, enumerating ontology terms, defining the classes and hierarchy, defining class properties, defining the facets, and creating instances; the method of [30] combines development and support processes that can run in parallel with all of the development phases.

We can see that [22] focused on ontology development, whereas [20] detailed all steps in the process of maintaining. Identically [30] enumerated the entire process, but the steps were complex. On the other hand, [10] proposed the clear steps of ontology creation than other studies considered although they did not have much detail relating to the ontology testing process.

Taking into account the ontology development and quality testing objectives, this study employs a hybrid waterfall methodology by combining waterfall methodologies from [10, 20]. The creation of an ontology involves three major steps.

1) *Specification* The purpose is to gather informal knowledge about the domain. The specification step develops the conceptual taxonomy of MTSC ontology.

2) *Conceptualization* The purpose is to organize and structure the information into semantic framework. The conceptualization step defines the classes, objects and instances of ontology.

3) *Implementation* The purpose is to implement, verify and validate the ontology. The implementation step creates a concrete ontology with an ontology implementation tool and validates the ontology quality.

#### C. Ontology Evaluation

The ontology evaluation indicates the quality of the ontology. This study defines the quality as ontology should be validated by robust approaches in technical aspects and domain experts' involvement. The methodology used in this paper adheres to the semantic competency questions method of [22] and the ontology metrics proposed by [21].

The semantic competency questions technique [22] generates answers to competency questions. The ontology concept is tested against SPARQL Query formulations. Domain experts will involve in the evaluation process by verifying competency questions and answers.

The ontology metrics [21] combine three evaluation aspects.

1) Ontology schema metrics assess ontology design and its capabilities for representing rich knowledge. The proposed metrics are as following:

Relationship richness (RR) relates to an ontology having many interrelated relationships. RR is a percentage representing the number of connections between classes with multiple relationships. If the percentage closes to one, it demonstrates ontology has various connections other than class-subclass. On the other hand, if RR value closes to zero then ontology does not have many relationships.

Attribute richness (AR) relates to an ontology having a sufficient amount of knowledge. AR is a number representing the amount of knowledge that ontology conveyed. The high AR means ontology has a high average attribute or knowledge per class. On the other hand, the lower AR means ontology has less knowledge.

Inheritance richness of schema (IRs) relates to an ontology having a wide knowledge distribution. IRs is a number representing the ontology's ability to arrange knowledge into multiple categories and subcategories. The low IRs means ontology is a very detailed knowledge, while the high IRs reflects a broad spectrum of generic knowledge.

2) Knowledgebase metrics assess the amount of knowledge representation and the design efficacy of the ontology. The proposed metrics include:

Class richness (CR) relates to an ontology having a class with knowledge. CR is a percentage representing the use of class with instances. The high CR indicates ontology has rich knowledge in class. By contrast the low CR reflects low knowledge.

Average population (P) relates to an ontology having described the schema's whole knowledge adequately. P is a number representing the average knowledge per class. The high P shows sufficient knowledge of schema, while the low P means insufficient knowledge representation.

Cohesion (Coh) relates to an ontology having relationships among nodes and edges. Coh is a number representing the isolated components. A high Coh indicates that the ontology knowledgebase has lost its connection. If the Coh value is small, it means that knowledge is connected.

3) Class metrics investigate the knowledge distribution of all ontology classes. The proposed metrics include:

Importance (Imp) concerns the instance distribution in each class. Imp value shows which classes have enough instances and which classes have fewer instances.

Connectivity (Cn) concerns the relationship of the instance in one class over another class. Cn number refers to how well instances are linked together.

Readability (Rd) concerns whether the ontology contains human-readable descriptions. Rd is calculated from comments, labels, or captions of ontology.

#### D. Medical Tourism Supply Chain Ontologies

MTSC ontology is categorized as application ontology because the terminology depends on both specific tasks that are MT processes and the domain that encompasses health and tourism [31]. Ontology has been proven to help practitioners clarify SC models including fragmented processes [32].

However, during this research, no ontology for building MTSC comprehension was discovered. Therefore, the common SC ontologies based on SC definition given by [23] and ontologies related to health tourism domain were reviewed.

Üreten and Döler [14] present SCM ontology derived from the common concept of SC. There are four main classes: Agent, Product, Operations, and Flow. The Agent subclasses include supplier, producer, transporter, distributor, and customer. Agent has data properties that are production activity type, utility created, size, geographic location, service content, and make-buy decisions. The Product is identified to two subclasses: Goods, Services. Goods have data properties: process type, weight, size, resistance, durability, characteristics, and product type; while Service has service content, property, location, and degree of customer contact. The Operation subclasses are Plan, Source, Make, Deliver, and Return. There are sub-activities in a given operation. The Flow has three subclasses: Material, Money, and Information, with flow direction and flow between properties. There are relationships between the common classes. SCM ontology shows that Agent and Product have a link with produces object property. Also, Agent links with Operation by operation performed property and by contrast Operation has an inverse property performed by to Agent.

Ye, Yang, Jiang, & Tong [15] introduce Onto-SCM ontology for sharing the SCM conceptualization. The idea of Onto-SCM is evolved from general SCM. The ontology combines five main classes: SC\_Management, SC\_Structure, SC\_Activity, SC\_Resource, and SC\_Item. The SC\_management implies the management of SC operation in which activities and the important elements are linked from the remaining four main classes. SC\_Structure classifies agent classes into five subclasses: Dyadic\_Structure, Serial\_Structure, Divergent\_Structure, Convergent\_Structure, and Network\_Structure. The SC\_Structure has Strategy that is derived from Goal class and has SC\_Process that implies the implementation of SC to achieve the goal. SC\_Activity has Activity class. Activity has sub-activity property that is connected under the interval time. SC\_Resource presents resources used in SCM. There are four resource classes: Production\_Resource, Storage\_Resource, Transportation\_Resource, and Human\_Resource. Each resource has a role. SC\_Item refers to products produced from SC. There are three item classes: Offer, Business\_Order, and Plan. Offer has meant the products that are separated to Product or Service. Business\_Order means the flow of object that transfers from one activity to other. Onto-SCM can explain the relationship between the activity and goal, the agent who performs activity, and the resource used in SCM at a given activity.

Soares, Azevedo, and Sousa [16] propose an ontology to support the process flow management of semiconductor manufacturing. The ontology helps agents to communicate regarding the requirement of the business's particular planning and control system. There are three semantic processes: Organizations, Plans Management, and Orders Management. Organizations have VE Unit class that represents the agents involved in the SC process. Plan management has three main classes: Plan presents the semantics of activities; Planning presents the semantics of action to implement Plan; Resource

presents the necessary entity that serves a given activity. Resource class has a capacity as a data property, which means the allocation of resources used in each activity. Order management includes the classes of Order and Product. Order has been described by Order Item and its data properties such as quantity, due date, delivery date. Product is produced by supplier that is included in VE Unit.

Vegetti et al. [33] propose ontology for the SC domain. The goals are to demonstrate the SC structure, process, resource, and application evaluation. The structure identifies SC infrastructure, including roles, and combines the following classes: Supply Chain, Organizational Unit, Organizational Unit Role, and Functional Area. The process dimension defines SC's processes and subprocesses, including the execution of a process within a specific timeframe. Process, Process Occurrence, Temporal Relationship, and Utilization are the classes that make up the process. The resource dimension depicts resource utilization and its role in the SC process. The resource combines the classes Resource and Resource Role. Each class has data properties as well as relationships to other classes.

Spoladore et al. [34] propose health tourism ontology. The goal is to connect natural resources with visitor demands. There are six main classes: Destination, Descriptor, Variable, KPI\_Families, Optima, and Target\_Groups. The Destination explains the tourism inflows, whereas Descriptor focuses on regional services and characteristics. The Variable, KPI\_Families, and Optima depict the value that health tourists will receive. Target\_Groups has six subclasses that explain different types of health tourists. Chantrapornchai and Choksuchat [35] provide an ontology that collects information on health tourism. Many classes make up the ontology, including Product, Package, Facility, Service, Treatment, and so on. Almost every class has subclasses; for example, the Service class has two subclasses: BeautyService and Massage. Ontology has re-used classes and inferred concepts.

Previous studies [14,15,16,33] created ontologies using the core SC concept. This study may benefit from some structure design. However, there is a difference between the SC and MTSC concepts. For example MTSC agents are grouped based on service provided to medical tourists such as medical providers, medical tourists, tourism providers whereas SC agents are derived from general industry such as suppliers, customers, transporters. The MTSC involves the process of utilizing medical tourists' services until the follow-up process, while SC includes the process of producing items until selling products to customers. The flow of data, money, and product differs between MTSC and general SC. Medical tourists' service requests and consumption of services are the objects exchanged between or within the activity flows of MTSC. On the other hand, SC's flows are concerned with raw materials, physical goods trading, and purchase orders.

Taking into account the health tourism ontologies [34, 35], the earlier designs focused on gathering and formalizing information for tourist decision-making. The MTSC domain cannot be represented by previous ontology structures. Some health tourism terms, on the other hand, can be reused. The considerations for the reuse of ontologies are discussed in the

following section. Table I compares previous studies that were unable to provide semantic knowledge about MTSC.

TABLE I. COMPARISON OF PREVIOUS ONTOLOGIES WITH THE PRESENT WORK

Aspects	Domain	Target user	Source of knowledge	MTSC related
[14]	General industry	Practitioners	International standard	No
[15]	General industry	Practitioners	Previous work, case study	No
[16]	Semiconductor industry	Practitioners	Previous work, case study	No
[33]	Food industry	Practitioners	Previous work, case study	No
[34]	Health tourism	Tourists, government	Case study	No
[35]	Health tourism	Tourists	Case study	No
This Work	Medical Tourism	Practitioners	Previous work, case study	Yes

### III. BUILDING A MEDICAL TOURISM SUPPLY CHAIN ONTOLOGY

The goal of ontology development is to express knowledge in such a way that both people and computers can comprehend it [22]. Developing an ontology usually begins with recognizing the need for a certain purpose [20]. This study used a hybrid waterfall methodology with three key steps in the formation of the MTSC ontology adapted from [10, 20].

#### A. Specification

1) *Determination of ontology domain and scope:* The MTSC ontology focuses on the MT domain. This ontology represents the domain knowledge model that captures information of the MT attributes based on MTSC concept. The competency questions were created and measured the degree to which the ontology nailed its purpose and scope [22]. As a basis, the ontology should answer general questions, for example:

- How many actors are featured in the MTSC?
- What is the actor's primary role in the MTSC?
- What is the main process chain of MTSC?
- What are the activities in a given MTSC process?
- What is the core product produced in MTSC and by whom?
- How many flows do appear in the MTSC?

For complex knowledge representation, the ontology should answer further questions, for example:

- Which actors are involved in a given MTSC process?
- What is the actor's role when involving a given MTSC activity?

- What are the flows that are activated in a given MTSC activity?
- What are the inputs and outputs that relate to a given MTSC activity?
- What is the direction of the MTSC flow in each activity and between whom?

2) *Consideration of the existing ontology:* The literature demonstrates the use of ontology to explain the SC semantically. Although the existing ontologies did not pertain to the MTSC domain, there is some idea that can be reused. Previous ontology for sharing SC information at the top-level [14] has been considered as a starting point for the MTSC ontology model and the idea of the class (actor, action, product, and flow) is re-used. Some terminology from [35] is taken into account in the MTSC ontology. However, there is no ontology in the MTSC domain that represents enough terminologies. As a result, the next step involves the enumeration of terminology.

3) *Enumeration of important terms in the ontology:* Because terms constitute the foundation of an ontology, it's critical to be precise and unambiguous about the main terms and their associated attributes. The motivation of the ontology representation is derived from [14]. Fig. 1 shows an ontology model. The model is composed of seven main concepts: MT actors, MT processes, MT activities, MT roles, MT products, MT flows, and MT flow between.

MT actors represent the semantic knowledge of who is involved in the MTSC. MT actors can be organization units, companies who participate in MTSC system, or even individuals. MT actors have a role in MTSC. The MT actor and MT role conceptual model are derived from the stakeholder investigations [36, 4, 37, 18].

MT processes and MT activities represent the semantic knowledge of operations performed in the MTSC. The process description visualizes the logistics and flow of information and includes many activities. MT processes have been activated by MT actors. The actions of MT actors cause the forwarding of MT products and MT flows. The MT process and MT activity conceptual model is suggested by [6, 29, 27, 18].

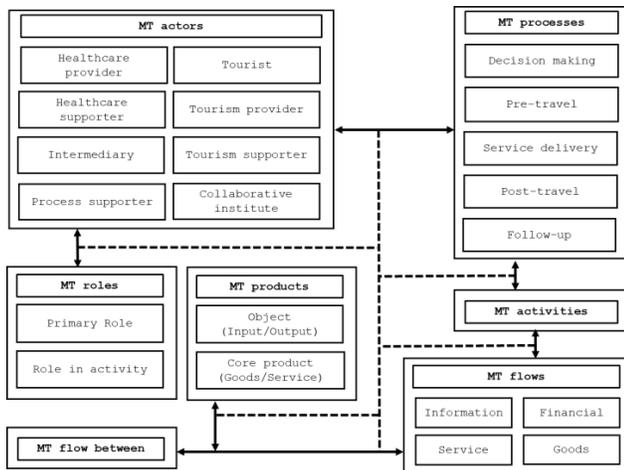

Fig. 1. MTSC Ontology Representation Adopted from [14].

MT products represent the semantic knowledge of objects produced from MT actors including objects required to perform activity. MT product conceptual model is captured from [14, 18, 35].

MT flows represent the semantic knowledge of object movement from a process starting point to the end of MTSC system. Flow is a thing with distinct and independent existence and involves the transfer of an object between respective activities and actors. The MT flow and MT flow between conceptual model is extracted from [14, 6, 29, 18].

This study focuses on the trustworthiness and practical benefits of ontology. Interviews with MT experts were used to build and verify the ontology structure and terminologies. Sixteen domain experts who have experience in MT business from Thailand, took part in the face-to-face interviews. The interviewing techniques begin by presenting the ontology design and components. Second, interviewers were requested to corroborate the ontology conceptualization and share MT knowledge. The final stage is to summarize the understanding and double-check the accuracy of the interview results with the interviewers right away. Table II lists the brief profiles of the MT experts who assisted with the interview parts.

TABLE II. NUMBER OF MT EXPERTS IN THE INTERVIEW SECTIONS

MT Domain Group	Number of MT experts	Approximate experience in MT
Health provider (Hospital, Dental clinic)	4	10-20 years
Tourism provider (Hotel, Tour operator)	3	15-20 years
Collaborative institute (University)	2	12-25 years
Health and tourism supporter (Interpreter, Insurance, Shop, Restaurant)	7	5-21 years

As a result of sharing knowledge with domain experts, terms such as important MT actor terms, process and activity names, and linkages among terms were discussed according to actual usage. The initiated terms can be used to advance the construction of ontologies. The obvious benefit of bringing in a diverse group of experts is that they can share their knowledge and illustrate relationship design approaches.

**B. Conceptualization**

1) *Definition of the classes and the class hierarchy:* The class hierarchy is designed using the top-down approach [10]. Classes and subclasses are categorized based on MTSC ontology model designed with the terms mentioned earlier. The ontology classes are as follows:

MT\_Actor: refers to the stakeholders involved in the business and has eight subclasses.

MT\_Product: refers to the objects produced by actors including input/output used in activities and has two subclasses.

MT\_Process: refers to the processes in MTSC.

MT\_Activity: refers to the activities that are part of the process.

MT\_Flow: refers to an entity that transfers objects within an activity or from one activity to another activity and has four subclasses.

MT\_FlowBetween: refers to the interaction of the actors in any flow.

MT\_Role: refers to the responsibility/task of actors in MTSC and has two subclasses.

2) *Definition of classes-slot properties:* The data properties were defined as the qualification for each particular class. Table III identifies data property, representation, and domain usage of ontology creation in this study.

TABLE III. DATA PROPERTIES OF MTSC ONTOLOGY CLASSES

Data property(Domain usage)	Representation
hasActorName(MT_Actor)	Name of actor
hasActorDesc(MT_Actor)	Description of actor
hasPrimaryRoleDesc(PrimaryRole)	Description of primary role
hasRoleInActivityDesc(RoleInActivity)	Description of role in activity
hasProductDesc(MT_Product)	Description of product
hasProductType(MT_Product)	Type of product: goods, services, input, output
hasProcessDesc(MT_Process)	Description of process
hasActivityDesc(MT_Activity)	Description of activity
hasFlowDesc(MT_Flow)	Description of flow
hasFlowDirection(MT_Flow)	Direction of flow: one-way, two-way

Object properties are defined to link the relationship between two instances. Table IV shows the object properties with the boundaries of their inferences between domains and ranges.

3) *Creation of instances:* This step provides values to the defined classes and properties. For the instances of MTSC ontology, they are derived mainly from academic literature and a case study for credibility and practicality. The case study is from the document of experienced private hospital agency in Thailand that provides medical tourism services to foreign patients. The knowledge obtained from the experiences correlates with academic education. The knowledge agents presented in MTSC are reliable and can be used to explain MTSC.

For example, Hospital/Clinic is an instance of the MT\_Actor class and the HealthProvider subclass. Its data property is hasActorName and the attributions of the property are "Hospital, Clinic, Health Institution, Health Center, Medical Center". This implies that the hospital/clinic has multiple names used in the MT business. We present an excerpt of the instances of the MTSC ontology in the implementation section.

TABLE IV. OBJECT PROPERTIES OF ONTOLOGY CLASSES FOR ROLE-BASED RECOMMENDATION

Object property(Domain > Range)	Inference	Cardinality
hasPrimaryRole(MT_Actor > PrimaryRole)	An actor has primary role	1,1
hasRoleInActivity(MT_Actor > RoleInActivity)	An actor has role in activity	1,N
makeProduct(MT_Actor > MT_CoreProduct)	An actor makes core product	1,1
performActivity(MT_Actor > MT_Activity)	An actor performs activity	1,N
consistOfActivity(MT_Process > MT_Activity)	A process consists of activity	1,N
activateFlow(MT_Activity > MT_Flow)	An activity activates flow	1,N
isPerformedBy(MT_Activity > MT_Actor)	An activity is performed by actor	1,N
relateToProcess(MT_Activity > MT_Process)	An activity relates to process	1,1
getInput(MT_Flow > MT_Object)	A flow gets input to perform activity	1,N
returnOutput(MT_Flow > MT_Object)	A flow returns output after performing activity	1,N
isFlowBetween(MT_Flow > MT_FlowBetween)	A flow is action between actors	1,N

C. Implementation

1) *MTSC ontology with protégé 5.0:* This study implemented an ontology by using Protégé 5.0 software with OWL language. The tool can present knowledge and collaborate with other tools and is available as software implementation [38]. The OWL is a markup language focusing on semantic web representation and mostly manipulates XML language expressions. The MTSC ontology taxonomy is presented using OntoGraf (Protégé-OWL plugin). Fig. 2 shows the MTSC hierarchy and relationships in the top-level design.

Fig. 3 and 4 present an excerpt of the instances of the MTSC ontology.

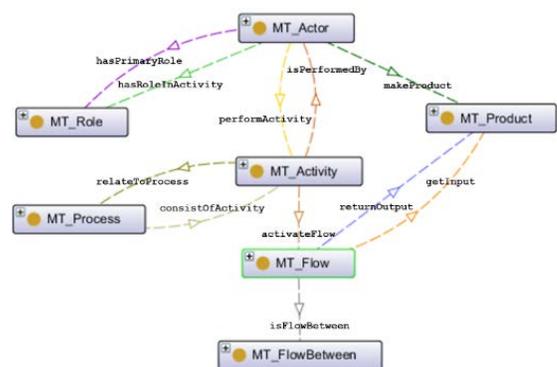

Fig. 2. A Top-level Hierarchy of MTSC Ontology.

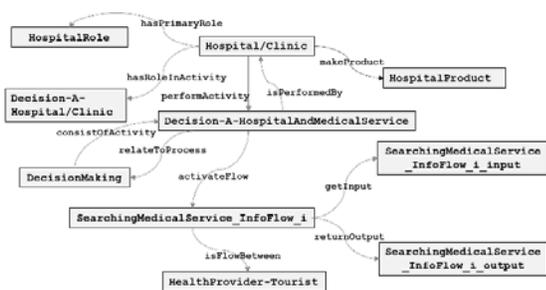

Fig. 3. An Excerpt of Health Provider Instance of MTSC Ontology.

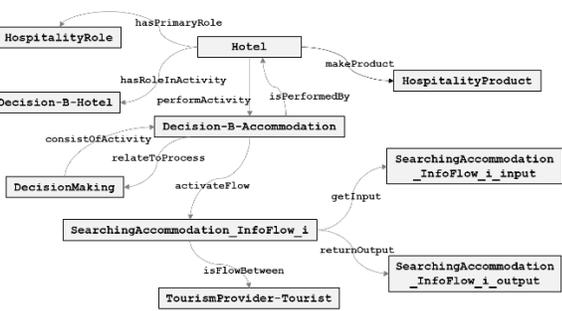

Fig. 4. An Excerpt of Tourism Provider Instance of MTSC Ontology.

2) *Ontology evaluation*: The MTSC ontology is assessed by competency questions and ontology metrics. The MTSC objective and scope are tested against SPARQL Query formulations. The query results were supposed to address competency questions. Some sample questions as SPARQL queries are as follows:

CQ: How many actors are featured in the MTSC?

SELECT ?Actor ?ActorName ?ActorDesc

WHERE { ?Actor p:hasActorName ?ActorName.

?Actor p:hasActorDesc ?ActorDesc. }

The sample answer:

Actor	ActorName	ActorDesc
Bank/ForeignExchangeProvider	Bank, Financial compa	"A financial institution that is legally responsible for deposits and withdrawals, currency exchange, and other financial tra
FoodSupplier	"Food supplier, Food m	"A producer who produces food products and distributes them to individuals or organizations that have purchased the p-
GovernmentAgency	"Accreditation body, Ed	"A government agency that has established and controlled policies, functions, and measures for stakeholders managem
HealthCareMarketer	"Healthcare marketer,	"A marketing public relation operator who promotes medical services to be known"
Hospital/Clinic	"Hospital, Clinic, Health	"A health care provider who offers medical services to medical tourists"
Hotel	"Hotel, Accommodation	"A hospitality provider who offers accommodation and facilitation for tourists based on their intended purpose"
InsuranceCompany	"Insurance company, In	"An insurance company that is legally licensed to operate the insurance business, has a duty to pay compensation to the
InternationalTransport	"Airplane, Bus, Boat"	"An international transporter who offers international travel in various forms such as planes, boats, cars, trains."
Interpreter/Provider	"Interpreter, Translator"	"A communication mediator who helps bridge understanding between the speaker and the audience"
LocalTransporter	"Local transporter, Bus,	"A local transport provider who services at destination country such as train, subway, taxi, minibus, domestic airplane."
MedicalSupplier	"Medical supplier, Medi"	"A medical device manufacturer, modern medicine provider, including traditional medicine provider who produces and
MedicalTourist	"Medical Tourist, Tours"	"A foreign tourist who intends to use medical tourism services"

CQ: What is the actor's primary role in the MTSC?

SELECT ?Actor ?PrimaryRole ?PrimaryRoleDesc

WHERE { ?Actor p:hasPrimaryRole ?PrimaryRole.

?PrimaryRole p:hasPrimaryRoleDesc ?PrimaryRoleDesc. }

The sample answer:

Actor	PrimaryRole	PrimaryRoleDesc
Bank/ForeignExchangeProvider	FinancialRole	"Provides deposit and withdrawal services including currency exchange and other financial transactions"
FoodSupplier	FoodSupplierRole	"Produces food products and sells them to individuals or organizations that have purchased the products"
GovernmentAgency	GovernmentAgencyRole	"Issues policy, functions, and measures for industry direction and coordination between stakeholders"
HealthCareMarketer	HealthCareMarketerRole	"Promotes medical services and medical tourism industry to be known"
Hospital/Clinic	HospitalRole	"Offers and serves medical services to medical tourist"
Hotel	HospitalityRole	"Offers and serves accommodation and facilitation for tourists"
InsuranceCompany	InsuranceRole	"Operates the insurance business and has a duty to pay compensation to the insured from the events that occur ur
InternationalTransporter	IntertransporterRole	"Provides international travel in various forms such as planes, boats, cars, trains to medical tourists"
Interpreter/Provider	InterpreterRole	"Communicates between the doctor and the patient using the patient's preferred language"
LocalTransporter	LocalTransporterRole	"Services local travel such as trains, subways, taxis, minibuses, domestic airplanes"
MedicalSupplier	MedicalSupplierRole	"Manufactures medical devices, modern medicines, traditional medicine, and medical-related goods that used m-
MedicalTourist	MedicalTouristRole	"Obtains medical tourism services"

CQ: Which actors are involved in a given process of MTSC?

SELECT ?Actor ?Process ?Activity

WHERE { ?Actor p:performActivity ?Activity.

?Process p:consistOfActivity ?Activity. }

The sample answer:

Actor	Process	
HealthCareMarketer	DecisionMaking	Decision-A-HospitalAndMedicalService
HealthCareMarketer	DecisionMaking	Decision-D-Intermediary
Hospital/Clinic	DecisionMaking	Decision-A-HospitalAndMedicalService
Hospital/Clinic	FollowUp	Follow-A-TrackSymptom
Hospital/Clinic	PostTravel	Post-B-ShareExperience
Hospital/Clinic	PreTravel	PreTravel-A-ReserveHospitalAndService
Hospital/Clinic	ServiceDelivery	Service-C-ReceiveMedicalService
Hospital/Clinic	ServiceDelivery	Service-D-DischargePayment
Hospital/Clinic	ServiceDelivery	Service-F-PostOperativeCare
Hotel	DecisionMaking	Decision-B-Accommodation
Hotel	PostTravel	Post-B-ShareExperience
Hotel	PreTravel	PreTravel-B-BookAccommodation

Table V summarizes the result of ontology metrics.

TABLE V. THE ONTOLOGY SCHEMA AND KNOWLEDGEBASE METRICS ASSESSMENT RESULT

Metrics	Ontology schema metrics			Knowledgebase metrics		
	RR	AR	IRs	CR	P	Coh
MTSC ontology	50%	4.70	0.70	100%	15.78	0

The ontology schema metrics reflect the quality of ontology structure for representing knowledge. The RR result (50%) indicates that MTSC ontology has many connections other than class-subclass, such as object property relationships. The AR result (4.70) indicates that the ontology has a good average of attributes per class. There are many types of knowledge presented. The IRs result (0.7) indicates that the ontology has a general distribution of subclasses and is not considered detailed knowledge. Overall, the MTSC schema metrics indicate good quality of structure design.

The results of knowledgebase metrics show that all ontology classes are implemented to deliver knowledge by the CR result of 100%. The P result (15.78) indicates that this ontology has a not too small knowledge in schema. The Coh result (0) indicates that all components in the ontology are used to describe MTSC. Overall, the knowledgebase metrics have appropriate values. The MTSC ontology has enough knowledge representation.

Fig. 5 presents the class metric results. The class metrics results indicate that the most important classes are MT\_Product, MT\_Role, and MT\_Flow. The Imp result makes logical because these three classes store detailed knowledge. The central connectivity is MT\_Actor followed by MT\_Activity and MT\_Flow. The Cn result reflects that the MTSC can explain knowledge using actors and activities as the center linked with other knowledge classes. Rd reflects that almost all of the classes provide descriptions for the users to understand. Overall, the class metrics have appropriate values.

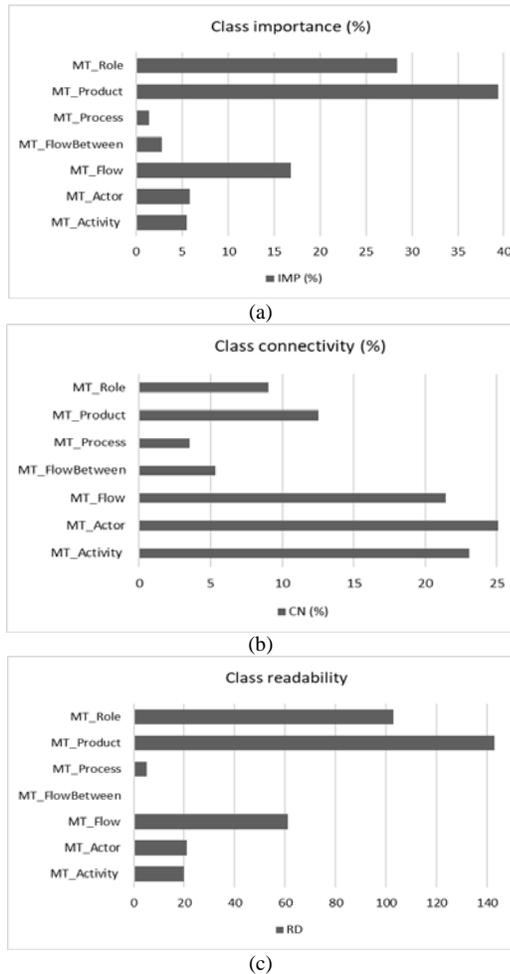

Fig. 5. Class Metric Results in Values of (a) Imp, (b) Cn, and (c) Rd.

The MTSC ontology has a good knowledge distribution. This study was carried out with the collaboration of domain experts. The answers to SPARQL Queries and the ontology metrics values were verified by experts. The findings are adequate to clarify the study's goal and scope. The same group of 16 experts approved the MTSC ontology. Ontology structure and terminologies have quality.

#### IV. DISCUSSION

This study presented the development of an application ontology for representing MTSC knowledge. The ontology engineering methodology consisted of specification, conceptualization, and implementation steps. The steps are

enriched with knowledge engineering techniques and present a practical conceptual design. The key views of MT were verified. The MTSC ontology combines seven main classes namely 'MT\_Actor', 'MT\_Role', 'MT\_Process', 'MT\_Activity', 'MT\_Flow', 'MT\_FlowBetween', and 'MT\_Product'; and has sixteen subclasses. The class conceptualizations can describe MTSC structurally. The concepts are in line with general SC presented by [14].

This MTSC ontology provides instances of 21 actors, 21 primary roles, 5 processes, 20 activities, 21 core products, 122 objects, 82 roles in activity, and 61 flows. The MTSC logistics has two main routes: medical services or tourism services. The MTSC process is divided into five stages. The actor involved in all processes is a medical tourist. The players on the service side who are involved in all processes of the medical side and tourism side are the health provider and tourism provider, respectively, including many supporters. MTSC ontology offers four types of knowledge flows as in [14]. Flow provides insights into how activities contribute to the flow and who is involved in that activity and flow in MT context. MTSC logistics are different from general SC logistics [23]. The MTSC activities are different from general SC which involves stakeholders. The short flows do not pass data to the next step like a production line, such as flow of providing an interpreter during treatment, or flow of selling souvenirs. However, the knowledge flow representation is consistent with MTSC process of [6] and [18]. Core products in MTSC ontology are mostly classified as services that are different from general SC where the products are usually tangible [16].

The ontology evaluation employed competency questions and ontology metrics. Domain experts had verified the quality of structure, design, and usefulness. According to SPARQL Query results, the MTSC ontology can answer semantic questions given in the Specification section. It denotes that the ontology is trustworthy in terms of objective and scope. The ontology metric results reflect the suitability of ontology structure and design. The body of knowledge generated is sufficient to describe the MTSC. Knowledge is distributed in an acceptable manner.

#### V. CONCLUSION

MTSC ontology generates a clear business understanding for stakeholders in the MT domain. The ontology construction demonstrated a high-quality development approach that can be replicated. The ontology development incorporated academic material and case studies into the acquisition process. The collaboration of domain experts in many activities makes ontology more dependable and efficient. The proposed ontology comprises concepts relevant to the MT domain. The ontology can describe the supply chain of the medical tourism domain: it can tell who is involved in which processes, what roles they play, and what flows are taking place. Based on the evaluation results, the ontology design and knowledge representation are of a quality.

We plan to apply the ontology in our next work a role-based recommendation system. Stakeholders can use the system to learn about MTSC and the ontological relationship that exists in the MT domain. The expertise used in this paper, however, came from a case study. The limitation of this study

is that some aspects of the overall challenges may have been overlooked as a result of the different perspectives. Those who will use this work context must examine how well it fits within the framework of the business area.

# Stochastic Marine Predator Algorithm with Multiple Candidates

Purba Daru Kusuma, Ratna Astuti Nugrahaeni  
Computer Engineering, Telkom University, Bandung, Indonesia

**Abstract**—This work proposes a metaheuristic algorithm that modifies the marine predator algorithm (MPA), namely, the stochastic marine predator algorithm with multiple candidates (SMPA-MC). The modification is conducted in several aspects. The proposed algorithm replaces the three fixed equal size iteration phases with linear probability. Unlike the original MPA, in this proposed algorithm, the selection between exploration and exploitation is conducted stochastically during iteration. In the beginning, the exploration-dominant strategy is implemented to increase the exploration probability. Then, during the iteration, the exploration probability decreases linearly. Meanwhile, the exploitation probability increases linearly. The second modification is in the prey's guided movement. Different from the basic MPA, where the prey moves toward the elite with small step size, several candidates are generated with equal inter-candidate distance in this work. Then, the best candidate is chosen to replace the prey's current location. The proposed algorithm is then implemented to solve theoretical mathematic functions and a real-world optimization problem in production planning. The simulation result shows that in the average fitness score parameter, the proposed algorithm is better than MPA, especially in solving multimodal functions. The simulation result also shows that the proposed algorithm creates 9%, 19%, and 30% better total gross profit than particle swarm optimization, marine predator algorithm, and Komodo mlipir algorithm, respectively.

**Keywords**—Metaheuristic; marine predator algorithm; stochastic system; production planning

## I. INTRODUCTION

Optimization is a subject that is widely used and studied. Optimization is implemented in many areas, especially in operations research, such as manufacturing [1], logistics [2], transportation [3], education [4], finance [5], and so on. Optimization becomes more important because of its objective nature to maximize productivity or output or minimize resources within certain constraints and limitations. This circumstance often occurs in real-world problems, from the simple one like managing the school bus route to the complex one, such as handling the production process in manufacturing that builds products with many components, such as cars, airplanes, ships, and so on.

In general, optimization methods can be divided into two groups: exact and approximate. The exact methods have an advantage that true or global optimal is guaranteed to find. The problem is that the exact method needs excessive computation resources in solving complex and large dimension problems. On the other hand, approximate methods do not guarantee that global optimal can be found. The objective of approximate

methods is to find near-optimal or acceptable optimal while avoiding local optimal [6], especially in multimodal problems. Fortunately, the approximate approach is popular because of its adaptability to computational resource constraints. The metaheuristic algorithm is a well-known and widely used method that uses an approximate approach. In metaheuristic, optimization is achieved during iteration.

Many studies have proposed new metaheuristic algorithms in this last decade. Many algorithms were inspired by nature, especially animals. These algorithms were developed based on animal behavior during foraging, such as grey wolf optimizer (GWO) [7], dragonfly algorithm (DA) [8], whale optimization algorithm (WOA) [9], and so on. Besides foraging, several algorithms were developed by mimicking animal behavior during reproduction, such as Komodo mlipir algorithm (KMA) [10], red deer algorithm (RDA) [11], Cuckoo search algorithm (CSA) [12], butterfly optimization algorithm (BOA) [13], and so on.

Besides proposing a new algorithm, many studies in metaheuristic algorithms were conducted to modify the existing algorithm. These modifications were conducted to improve the algorithm's performance or to make the algorithm more suitable to solve specific problems. Several well-known algorithms that have been widely modified or combined are genetic algorithm (GA), particle swarm optimization (PSO), simulated annealing (SA), tabu search (TS), and so on. Farag et al. [14] improved the binary-real coded genetic algorithm with k-means clustering to solve the unit commitment problem. Deb et al. [15] developed a non-dominated sorting genetic algorithm (NSGA II) derivative of a genetic algorithm to find pareto optimal in solving the multi-objective optimization problem. Sylie et al. [16] hybridized the PSO with proportional fair scheduling (PFS) to solve resource allocation in the orthogonal frequency division multiplexing (OFDM) transmission for future long-term evolution (LTE) and 5G networks.

One shortcoming metaheuristic algorithm is the marine predator algorithm (MPA). This algorithm is a metaphor-inspired algorithm that mimics the behavior of sea predators, such as shark, marlin, and swordfish, during hunting prey [17]. This algorithm is one of the rare metaheuristic algorithms that uses iteration to control the exploration and exploitation. The iteration is divided into three phases. The first phase conducts exploration [17]. The second phase conducts both exploration and exploitation [17]. The third phase conducts exploitation [17]. Exploration is mostly conducted by implementing the Brownian motion, while exploitation is conducted by implementing the Levy movement.

Even though this algorithm is new, it has been used in many optimization studies, such as in task scheduling [18], power system [19], hydrothermal scheduling [20], and so on. Moreover, studies conducted on MPA modification have been found but are still limited. Based on this circumstance, this MPA is still potential to modify. Several studies in metaheuristic, such as KMA [10], also used MPA as a performance comparison.

Based on this opportunity, this work proposes modifying and improving the basic MPA. As metaheuristic algorithm, the proposed model consists of conceptual model, algorithm in pseudocode, and the mathematical model. In this work, the proposed model is evaluated by implementing this proposed model into the simulation to solve the theoretical mathematical optimization problem and a real-world optimization problem. In this simulation, the convergence and sensitivity of the algorithm are also evaluated.

The contributions of this work are as follows.

- 1) The proposed algorithm replaces the static division of the iteration with the stochastic approach where the opportunity to conduct exploration or exploitation changes during the iteration.
- 2) This work proposes the existence of several candidates during the Brownian motion or Levy movement, where their fitness score is considered to become the prey's next move.
- 3) This work implements the modified version of MPA to optimize real-world production planning problem.

The remainder of this paper is organized as follows. The mechanism of the basic MPA is discussed in the second section. The model of the proposed algorithm that consists of a conceptual, algorithm, and mathematical model is explained in the third section. The fourth section explains the simulation to evaluate the proposed algorithm's performance. In this work, there are five simulations. The first to fourth simulations are conducted to evaluate the proposed algorithm's performance in solving 23 well-known optimization functions. The fifth simulation is conducted to evaluate the proposed algorithm's performance in solving a real-world production optimization problem. The more profound analysis related to the simulation result and findings is discussed in the fifth section. Finally, the conclusion and the future research potential related to this work are summarized in the sixth section.

## II. RELATED WORK

The marine predator algorithm is a metaheuristic algorithm that adopts sea predator behavior or movement during foraging or hunting prey [17]. This algorithm combines Brownian motion and Levy movement. Levy movement is a derivative of random walk movement whose characteristics are closely related to sea predators, such as shark, swordfish, or marline, during searching for prey [21]. In this algorithm, the Levy movement is combined with the Brownian motion to conduct exploration and exploitation. MPA consists of two sets of agents: predators and prey. The adoption of the Levy movement is like the Cuckoo search algorithm (CSA). CSA is developed based on the parasitism behavior of cuckoo birds

during finding a nest for their eggs [12]. In CSA, the cuckoo implements the Levy movement only [12].

This algorithm divides exploration and exploitation depending on the iteration. It is very different from many common metaheuristic algorithms, such as particle swarm optimization, genetic algorithm, harmony search (HS), and so on, where the decision of running the exploration or exploitation does not depend on the iteration. MPA focuses on avoiding local optimal in the early phase and improving the solution in the later phase.

Although rare, one example of an algorithm where the exploitation-exploration decision depends on the iteration is simulated annealing (SA). In general, SA focuses on exploitation by conducting neighborhood search in every iteration [22]. Exploration is conducted by accepting a new worse solution based on some probabilistic calculation to avoid local optimal [22]. In SA, the outer loop iterates from the initial high temperature to the final low temperature. When the temperature is high, the new worse solution is easily accepted. During the decrease in temperature, accepting the worse solution becomes more difficult [22]. In the end, a new worse solution is hard to accept. This exploration-to-exploitation approach is like MPA but with different mechanism.

In MPA, the iteration is divided into three phases with the same duration. In the first phase, the process focuses on exploration by implementing the Brownian movement for all prey. The objective is that local optimal should be avoided in the early phase. In the second phase, the population is divided into two equal-size groups. The first group consists of preys that conduct exploration by implementing the Brownian movement. The second group consists of preys that conduct exploitation by implementing the Levy movement. The objective is that the algorithm focuses on improving searching quality. In the third phase, all populations focus on exploitation by adopting the Levy movement. This division is illustrated in Fig. 1.

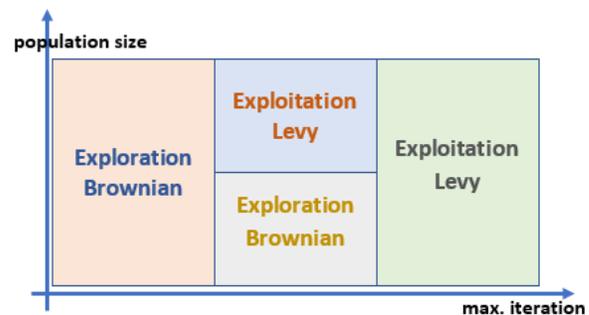

Fig. 1. Static Division in Marine Predator Algorithm.

There are several sequential processes in every iteration. The first process is the prey's movement which is explained earlier. The second process is updating the predators. The prey replaces its related predator only if its fitness is better than its related predator. The third process is the eddy formation. This eddy formation is another method used in MPA to avoid local optimal. This process is conducted stochastically based on the fish aggregating device affects that range from 0 to 1. There are two possible actions related to this process based on

probabilistic calculations. If a certain generated random number is below the fish aggregating devices, the prey randomly conducts a long jump within its local problem space that narrows as iteration goes. Otherwise, this prey will move toward two randomly selected prey at a certain speed.

In the prey's guided movement, whether Brownian movement or Levy flight, only one location is considered, as shown in Fig. 2. This location may be within the path between the prey and the elite or the extended distance from the elite. The determination of this new location depends on the step size, which is determined stochastically depending on the selected movement and the gap between the predator and the prey. The fitness value is not considered.

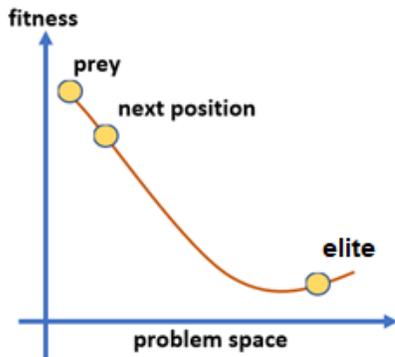

Fig. 2. Guided Movement in Marine Predator Algorithm.

Moving toward the best solution is common in many metaheuristic algorithms. In particle swarm optimization (PSO), each agent moves toward local best and global best with a certain proportion [23]. In Komodo mlpir algorithm (KMA), female mates with the highest quality big male to produce two offspring [10]. The first offspring is close to the female, and the second one is close to the highest quality big male. Then, offspring whose fitness is better becomes the replacement. Meanwhile, the small male moves toward the big male. In the red deer algorithm, this idea is implemented during the fighting between the male commander and stag and the mating of the commander and harem [11].

Even though the MPA is proven as a competitive algorithm, there are several questions or review due to this algorithm. First, is there any possible method to conduct exploration-to-exploitation approach despite this fixed division during the iteration? Second, is there any method to improve the movement of the prey rather than the small step size?

There are several possible modifications due to this basic MPA mechanism. The first is eliminating the fixed size division of the iteration while the concept of exploration dominant in the early iteration and the exploitation dominant in the later iteration is still adopted. The second is to create several new location candidates for prey during the guided movement. Their fitness score is considered so that the prey moves to a more promising location.

### III. PROPOSED MODEL

In this section, the proposed model will be discussed in detail. The model consists of a conceptual and mathematical

model. The conceptual model explains the concept and the difference between the proposed algorithm and the original MPA, especially in the exploration and exploitation division and the improvement of the guided movement. The mathematical model consists of the main algorithm of SMPA-MC and the mathematical formulae following the algorithm.

Like MPA, this proposed algorithm consists of two sets of agents: preys and predators. Both preys and predators have equal population sizes. The relation between prey and predator is one-to-one. After the prey moves, then their fitness score is evaluated. If the prey's fitness score is better than the predator's fitness score, then the predator moves to the prey's location.

As a metaheuristic algorithm, SMPA-MC consists of two parts: initialization and iteration. In the initialization, the initial prey and predators' location is generated randomly within the problem space using a uniform distribution.

As a derivative version of MPA, the iteration affects the exploration and exploitation division in this proposed algorithm. Unlike MPA, where this division is divided into fixed three phases, this division is conducted based on a stochastic approach in this proposed algorithm. In the beginning, the probability of exploration is high. Contrary, the probability of exploitation is low. During the iteration, the probability of exploration declines linearly while the probability of exploitation climbs up linearly. At the end of the iteration, the probability of exploitation is high, while the probability of exploration is low. This mechanism is illustrated in Fig. 3.

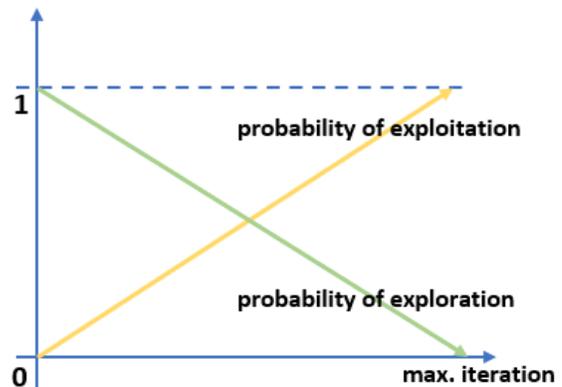

Fig. 3. Stochastic-based Exploitation and Exploration.

The guided movement of the proposed algorithm is also different from the MPA. This proposed algorithm generates multiple candidates between the prey and the elite. The inter-candidate distance is equal. One candidate whose fitness is the best among these candidates is then chosen as the best candidate. This mechanism is adopted from KMA, especially in the mating process between the highest quality male and the female [10]. The difference is that in KMA, sexual reproduction only produces two offspring. In this proposed algorithm, the guided movement generates multiple candidates. The best new generation or candidate becomes the replacement. Then, this best candidate location becomes the prey's next location. This concept is illustrated in Fig. 4.

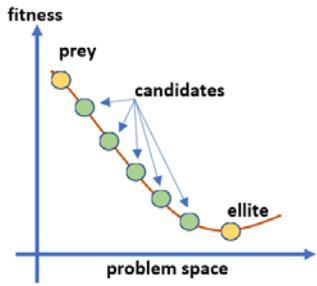

Fig. 4. Guided Movement with Multiple Candidates / Alternatives.

Different mechanism also occurs during the eddy formation. During this process, there are two possible actions. The first is that the prey moves randomly within its local problem space. In the beginning, the local problem space is wide. During the iteration, this local problem space decreases linearly too. It also reflects the transition from exploration to exploitation during the iteration. The second action is that the prey moves to a location in the middle of the prey's current location, and the other prey's location is selected randomly. Although the mechanism during eddy formation is different, the motivation is the same.

This conceptual model is then interpreted into sequential steps. These sequential steps are as follows.

- Step 1: generate initial preys and predators.
- Step 2: set initial iteration.
- Step 3: generate several candidates based on the movement that is chosen stochastically.
- Step 4: select the best candidate to replace the current prey.
- Step 5: update the related predator.
- Step 6: implement eddy formation.
- Step 7: if the maximum iteration has not been reached, go to step 3. Otherwise, iteration stops.
- Step 8: select the best predator to become the final solution.

This conceptual model is then transformed into a mathematical model. The mathematical model consists of two parts: main algorithm and formulae. The main algorithm is shown in algorithm 1. Meanwhile, several annotations used in the mathematical model are as follows.

$b_l$	lower bound
$b_u$	upper bound
$c$	candidate
$c_{best}$	best candidate
$C$	set of candidates
$f$	fitness
$fad$	fish aggregating devices
$P$	population
$r$	predator
$R$	set of predators
$t$	time / iteration
$t_h$	time threshold
$t_{max}$	maximum iteration
$y$	prey
$Y$	set of preys

**algorithm 1: SMPA-MC main algorithm**

```

1 //initialization
2 for i = 1 to n(P)
3   generate (yi)
4   generate (ri)
5 end
6 //iteration
7 for t = 1 to tmax
8   generate (th)
9   for i = 1 to n(P)
10    if U(0, 1) < th then
11      for j = 1 to n(C)
12        generate-guided-exploitation (cj, yi, ri)
13      end
14      cbest = select best candidate (C)
15    else
16      for j = 1 to n(C)
17        generate-guided-exploration (cj, yi, ri)
18      end
19      cbest = select best candidate (C)
20    end if
21    yi = cbest
22    ri = update (yi, ri)
23    if U(0,1) < fad then
24      yi = limited random move (yi, th, li)
25    else
26      ysel = U(Y)
27      yi = half move (yi, ysel)
28    end if
29  end
30 end
31 sfinal = find best (R)

```

All predators' and preys' initial location is generated in the initialization process. This initial location is generated randomly within the problem space. This process is formalized by using (1) and (2). Equation (1) generates the prey's initial location, while (2) is used to generate the predator's initial location. All predators and prey are distributed randomly within the problem space.

$$y = U(b_l, b_u) \tag{1}$$

$$r = U(b_l, b_u) \tag{2}$$

The iteration process runs after the initialization process ends. At the beginning of every iteration, a time threshold is calculated. This threshold determines whether this iteration is conducted for guided exploitation or guided exploration. The time threshold is calculated by using (3).

$$t_h = \frac{t}{t_{max}} \tag{3}$$

A random number is then generated, and it follows uniform distribution as shown in algorithm 1. If this random number is less than the time threshold, guided exploitation is conducted. Otherwise, guided exploration is conducted. In both guided exploration and exploitation, several candidates are generated. Then, the best candidate is selected among these candidates. After the best candidate is selected, this candidate replaces the related prey. This process is formalized by using (4) to (6). Equation (4) is used for the guided exploitation. Equation (5) is used for the guided exploration. Equation (6) formalizes the best candidate selection.

$$c_j = r + \frac{j}{n(C)}(r - y) \tag{4}$$

$$c_j = y + \frac{j}{n(C)}(r - y) \tag{5}$$

$$c_{best} = c \in C \wedge \min(f(c)) \quad (6)$$

The predator location is then evaluated after a prey moves to its new location. If this prey's fitness score is better than the predator's fitness score, then this prey becomes the new predator. This process is formalized by using (7).

$$r' = \begin{cases} y, & f(y) < f(r) \\ r, & \text{else} \end{cases} \quad (7)$$

The last process in every iteration is applying the eddy formation. There are two possible actions in this process. The selection determined stochastically end depends on the fish aggregating devices value. This process can be limited to random movement or half movement. A prey will move randomly within its local problem space in the limited random movement. On the other hand, in the half movement, a prey will move to the middle between its current location and other prey selected randomly. The limited random movement is formalized using (8), while the half movement is formalized using (9).

$$y' = y + (2U(0,1) - 1)(1 - t_h)(b_u - b_l) \quad (8)$$

$$y' = y + \frac{y_{set} - y}{2} \quad (9)$$

The complexity of this algorithm, as it is presented in big O notation, is  $O(t_{max}.n(P).n(C))$ . This presentation means that the complexity is the multiplication between the maximum iteration, population size, and the number of candidates.

#### IV. SIMULATION AND RESULT

The proposed algorithm is then implemented into a simulation to observe its performance. There are five simulations conducted in this work. The first simulation is conducted to evaluate its performance in solving mathematical problems. The second simulation is conducted to evaluate its performance in achieving the convergence condition. The third simulation is conducted to evaluate the proposed algorithm's performance related to the fishing aggregate devices. The fourth simulation is conducted to evaluate the performance related to the number of candidates. The fifth simulation is conducted to evaluate its performance in solving a real-world problem.

In this simulation, the proposed SMPA-MC algorithm is compared with several algorithms: PSO, HS, hide object game optimizer (HOGO), KMA, and MPA. The reason for choosing these algorithms as a comparison is that these algorithms use distinct exploration-exploitation mechanisms. PSO and HS represent the well-known old-fashioned algorithm. HOGO and KMA represent the shortcoming algorithms that hybridize many common methods. MPA is chosen to observe the performance improvement due to modifying its basic form.

PSO is a well-known algorithm that is developed based on swarm intelligence. In PSO, each agent moves to a new location depending on the weighted cumulative method among its current location, its local best, and the global best [23]. The global best represents the collective intelligence shared among agents, and it is updated every time a new local best is found [23].

HS represents the non-population-based metaheuristic algorithm. Moreover, this algorithm is the simplest one among other algorithms. The exploration-exploitation decision is conducted based on the stochastic approach [24]. A new solution can be generated from the harmony memory (exploitation) or anywhere else within the problem space (exploration) based on the harmony memory considering rate (HMCR) [24].

HOGO represents a game-based algorithm. It mimics the behavior of the old hide-object game. This algorithm is also a population-based algorithm that consists of a set of agents. The agent's movement depends on the global best, the global worst, and the randomly selected agent through a weighted cumulative method [25]. An agent tends to move toward the global best and avoid the global worst [25].

KMA represents a hybrid metaheuristic algorithm. It combines swarm intelligence and an evolution system. The males conduct the PSO-like movement by moving toward the better big males [10]. On the other hand, the evolution system is conducted by the female by mating with the highest quality big male to generate better offspring [10]. Meanwhile, exploration is conducted by parthenogenesis or asexual reproduction [10].

MPA represents an algorithm where the current iteration affects the decision to conduct exploration or exploitation. In KMA, HOGO, HS, and PSO, the iteration does not affect the decision. It also represents a population-based algorithm where an agent consists of two engaged agents: prey and predator.

There are several common parameters used in the simulation. These parameters are shown in Table I. The value of population size and maximum iteration represents the moderate computation process. The weights in PSO represent the balance movement.

TABLE I. PARAMETERS DEFAULT VALUE

Parameters	Default Value
population size	20
maximum iteration (except HS)	200
maximum iteration (HS)	4000
fishing aggregate devices (MPA and SMPA-MC)	0.2
current speed weight (PSO)	0.5
social weight	0.5
cognitive weight	0.5
number of candidates (SMPA-MC)	10

In the first simulation, the proposed algorithm is implemented to solve or find the global optimal of the given functions. There are 23 functions to be solved. Seven functions are unimodal functions. Six functions are multimodal functions. Ten functions are fixed dimension multimodal functions. The seven unimodal functions include Sphere, Schwefel 2.22, Schwefel 1.2, Schwefel 2.21, Rosenbrock, Step, and Quartic. The multimodal functions include Schwefel, Rastrigin, Ackley, Griewank, Penalized, and Penalized-2. The fixed dimension multimodal functions include Foxholes, Kowalik, Six Hump Camel, Branin, Goldstein-Price, Hartman 3, Hartman 6, Shekel

5, Shekel 7, and Shekel 10. The detail of the functions, which consists of formulae, dimension, problem space, and global optimal, is shown in Table II. Meanwhile, the result is shown in Table III.

Table III shows that in general, the proposed algorithm performs well and meets the metaheuristic criteria in finding the near-optimal solution and avoiding the local optimal trap. Moreover, the proposed algorithm can find the true optimal solution in solving five multimodal functions: Shekel Foxholes, Kowalik, Six Hump Camel, Branin, and Goldstein-Price. Unfortunately, its performance is not so good in solving Hartman 3 function.

Compared to other algorithms, the proposed model is competitive enough. Its performance is superior in solving 10

functions. Meanwhile, HOGO has become the most challenging algorithm due to its outstanding performance in solving 9 functions. Compared with MPA, the proposed SMPA-MC is better at solving 13 functions. Most of these are multimodal functions, especially the fixed dimension multimodal functions with narrow problem space. The proposed algorithm also outperforms at least three algorithms in solving 22 functions.

The second simulation is conducted to evaluate the performance of the proposed algorithm in achieving the convergence situation. This simulation is conducted by solving the 23 benchmark functions. There are three maximum iterations in this simulation: 50, 100, and 150. The result is shown in Table IV.

TABLE II. BENCHMARK FUNCTIONS

No	Function	Model	Dimension	Problem Space	Global Opt.
1	Sphere	$\sum_{i=1}^d x_i^2$	10	[-100, 100]	0
2	Schwefel 2.22	$\sum_{i=1}^d  x_i  + \prod_{i=1}^d  x_i $	10	[-100, 100]	0

Table IV shows that in general, the convergence performance of the proposed algorithm is good. It achieves convergence in the early iteration while solving all fixed dimension multimodal functions. Besides, it also achieves convergence in the early iteration in solving the Schwefel 2.22 and Shekel Foxholes functions. Otherwise, it needs a higher maximum iteration to achieve convergence.

The third simulation is conducted to observe the sensitivity of the fishing aggregate devices related to the proposed algorithm's performance. The fishing aggregate devices are chosen due to its role in determining the exploration mechanism. In this simulation, there are three values of the fishing aggregate devices: 0.25, 0.5, and 0.75. These values represent the low, moderate, and high fishing aggregate devices. The result is shown in Table V.

Table V shows that the sensitivity of the fishing aggregate devices is various depend on the problem to solve. The increase of the fishing aggregate devices worsens the proposed algorithm's performance in solving the most of unimodal functions, except Schwefel 2.22. On the other hand, the fishing aggregate devices do not affect the proposed algorithm's performance in solving most of the multimodal functions.

The fourth simulation is conducted to evaluate the sensitivity of the number of candidates related to the proposed algorithm's performance. In this simulation, there are three values of the number of candidates: 5, 10, and 15. These values represent the low, moderate, and high number of candidates. The result is shown in Table VI.

Table VI shows that in general, the number of candidates has positive relation the proposed algorithm's performance. The increase of the number of candidates tends to improve the performance. This circumstance occurs in all functions: unimodal functions and multimodal functions. In the beginning, the improvement is significant. But, after the algorithm reaches its peak performance, the improvement is less significant. In some functions, such as Schwefel 2.22 and Goldstein-Price, the peak performance is achieved in the small number of candidates.

The fifth simulation is conducted to evaluate the performance of the proposed algorithm in solving the real-world optimization problem. An algorithm test using a real-world optimization problem is needed to prove that the algorithm is good theoretically and practically. In this simulation, the proposed algorithm is implemented to optimize the production planning process in a manufacturing company.

The simulation scenario is Muslim socks manufacturer in Bandung, Indonesia. This company produces 40 product items. Half of them are long socks, while half others are short socks. Six items are fast-moving products while the others are moderate ones. The most fast-moving products are the light brown socks, both short and long. The other fast-moving products are white socks and black socks. Each item should be produced within the minimum and maximum production ranges. On the other hand, there is a limitation in the storage and financial capacity so that all produced socks cannot surpass the total production quantity. The maximum total capacity is only 5,250 dozen. The characteristics of every item are shown in Table VII. The production quantity is presented in dozen while the price is presented in rupiah. The objective is to maximize total gross profit.

TABLE VII. PRODUCT DESCRIPTION

Product ID	Min. Production (dozen)	Max. Production (dozen)	Gross Profit (rupiah/dozen)
1	500	1000	24,000
2, 3	200	400	24,000
4-20	50	100	24,000
21	500	1000	30,000
22, 23	200	400	30,000
24-40	50	100	30,000

This optimization problem can be seen as a Knapsack optimization problem. The concept of the Knapsack problem is that there is a space with a limited capacity [26]. On the other hand, there are several products to pick up. The objective is to determine the items, and the quantity picked to minimize or maximize the objective parameters.

The proposed algorithm is compared with PSO, HS, KMA, and MPA in this simulation. Due to its characteristic as a multi-dimension problem with a large search space, the maximum iteration for PSO, KMA, MPA, and SMPA-MC is set at 300. Meanwhile, the maximum iteration for HS is set at 12.000. The result is shown in Table VIII.

TABLE VIII. REAL-WORLD PRODUCTION PLANNING SIMULATION RESULT

Algorithm	Total Gross Profit (rupiah)
proposed (SMPA-MC)	186,589,200
PSO	171,114,000
HS	188,959,800
MPA	157,104,600
KMA	143,143,100

Table VIII shows that the proposed SMPA-MC outperforms three algorithms in creating better total gross profit. Its total gross profit is 9% higher than PSO, 19% higher than MPA, and 30% higher than KMA. On the other hand, its performance is only 1% lower than HS. This result shows that although HS is inferior in solving a theoretical mathematic problem, its performance is superior in solving real-world high dimension problems.

## V. DISCUSSION

In general, Table III shows that the proposed SMPA-MC algorithm is better than the original MPA in solving multimodal functions. Its superiority especially occurs in solving multimodal functions with low dimension and narrow problem space, as indicated by the last ten functions. On the other hand, MPA is better at solving unimodal functions. The proposed algorithm is better at avoiding local optimal trap (exploration), while the MPA is better at finding the near-optimal solution or more precise solution. In the context of the method used in these algorithms, it is shown that the Levy movement creates more precise solutions than a uniform random or simple random walk.

There are several notes due to the competitiveness of the proposed algorithm. All metaheuristic algorithms use iteration to improve their current solution [6]. The result in Table IV

shows this circumstance. Some functions can be solved faster, while others need more iteration, such as high dimension functions or functions with large problem space. Besides, an algorithm may be better in the early iteration, which means they are better in finding the convergence. On the other hand, some algorithms may be worse in the early iteration but better in the long run.

Metaheuristic is also identic with adjusted parameters. These parameters are provided to tune the algorithm's performance in the adaptation of many optimization problems. The inferior performance of PSO, HS, and KMA in Table III may come from the adjustment. By implementing different adjustments, an algorithm may perform better or worse depending on the problem it faces. It means that competing with one algorithm with the others is not the only tool to judge the algorithm's performance.

The adjustment also affects to the performance as it is shown in Table V and Table VI. Although exploration is important to avoid the local optimal trap, targeted exploration is proven more effective rather than the fully randomized exploration, especially in the later iteration. Higher fishing aggregate devices makes the probability of the fully randomized exploration higher. It means, the searching process will restart at location somewhere in the problem space and it is not productive in the later iteration. In some circumstance, the number of candidates gives positive results. But, after the algorithm reaches its peak performance, the increase of the number of candidates does not improve the algorithm's performance significantly.

Table III also strengthens the no-free-lunch theory [27]. Although, in general, PSO and HS are inferior compared to HOGO, MPA, and the proposed SMPA-MC, they are still superior in solving several functions. PSO is superior in solving four functions, while HS is superior and can find the true optimal solution in solving three functions.

As shown in Table VIII, the real-world simulation result demonstrates that superiority in solving a high-precision mathematical problem may not work in solving real-world problems. In theoretical mathematic problems, the parameters are usually represented in floating-point numbers. Very little difference between two floating-point numbers may give a significant gap in the result. An algorithm can achieve better performance by generating a more precise floating-point number. This process can usually be conducted by making small and high-precision step sizes during the guided movement. Small step size is usually achieved by generating a more precise random number, for example by using Levy movement or normal distribution. On the other hand, uniform random is usually less precise.

On the other hand, many real-world problems do not need very precise floating-point numbers. Many of them usually use integer numbers, especially in operations research. Many studies in operations research use integer numbers, for example, to find the number of products that should be produced or ordered. It is impossible to produce goods, for example, shoes, cars, and so on, in a fractional quantity. This circumstance makes the high precision optimization algorithm, such as KMA, MPA, or HOGO, lose their advantage.

REFERENCES

Moreover, the objective function in real-world problems is simpler than the theoretical mathematic problems. In real-world problems, especially in operations research problems, most of their objectives can be presented in multi-variate linear functions, such as minimizing total tardiness [28], production cost [29], travel distance [30], and so on. This objective can be achieved by accumulating these parameters in all dimensions, for example by accumulating all due date penalties of all executed orders or accumulating the total quantity of all unexecuted orders due to limited production or storage capacity. This objective is even simpler than Sphere and Schwefel 2.22 functions, which are the simplest among 23 benchmark functions. But in real-world problems, some optimization problems use a multi-objective model.

This circumstance is also related to the popularity of the algorithm. Many studies in optimization, especially operations research, still use old-fashioned algorithms, such as genetic algorithm, tabu search, simulated annealing, or variable neighborhood search. This phenomenon indicates that these algorithms are still well-proven and competitive enough to solve real-world problems. However, they are often beaten by the shortcoming algorithms in solving mathematical functions. Besides, the mechanism of these old-fashioned algorithms is simple so that they are easy to modify or hybridize.

VI. CONCLUSION

This work has demonstrated that the proposed algorithm, the stochastic marine predator algorithm with multiple candidates, has proven as a good metaheuristic algorithm. It has achieved two main objectives of metaheuristic algorithm: finding a near-optimal solution and tackling the local optimal. The simulation result shows that its performance is competitive in solving optimization problems theoretically and practically. Among 23 benchmark functions, it achieves true optimal solution in solving 5 functions. Compared with other algorithms, its performance is also superior in solving 10 functions. This algorithm also outperforms the original form of the marine predator algorithm in solving 13 functions, which means 57 percent of total functions. Practically, it is also competitive in solving real-world problems. It outperforms particle swarm optimization, marine predator algorithm, and Komodo mlipir algorithm in optimizing production planning problems. Its performance is 9%, 19%, and 30% better than these three algorithms consecutively.

This work has shown that improving the existing algorithm is also important compared to proposing a new algorithm. This improvement can be conducted by modifying the current form of the algorithm or hybridizing this algorithm with another algorithm to combine the advantage of every algorithm. In the future, modifying the marine predator algorithm is still possible and challenging. Besides, implementing this proposed algorithm to solve more real-world optimization problems is still potential, especially in solving combinatorial problems, such as scheduling, timetabling, etc.

**Abstract**—To prevent fraud in e-shopping, the High-Speed Key Transmission Technique (HSKT) is primarily focused on safe and effectual transactions of payments and product content. The privacy of users, traders, trader information, product content, and the payment procedure are all protected by this framework. High speed key transmission is also committed to providing an effective, sensible approach to privacy in order to minimize the complexity of applications and the load on consumers. This paper proposes a new key transmission technique that allows users to conduct multi-banking account transactions from a single location. The proposed system is devoted to preventing unwanted people from gaining access. The secret key is used to represent access mechanisms, allowing authorized users to verify the transaction if and only if its characteristics meet secret key access requirements. Finally, the proposed high-speed key transmission technique (HSKT) improves the chances of success and throughput by reducing the time it takes to decrypt and encrypt, the amount of energy it uses, and the average delay.

**Keywords**—Secret key; encryption; decryption; transaction; HSKT

## I. INTRODUCTION

Payment issues plague e-commerce applications including electronic transactions using Visa otherwise debit cards, net banking, PayPal, or other tokens take more inconsistency issues since it is more vulnerable to being targeted. To prevent fraud in E- shopping, the high-speed key transmission method (HSKT) is primarily focused on safe and efficient payment processes and product content [1-5]. The privacy of users, traders, trader information, product content, and the payment procedure are all protected by this framework. HSKT is also committed to providing an effective, sensible approach to privacy in order to minimize the complexity of applications and the load on consumers. This method allows users to conduct multi-banking account transactions from a single location. This system is devoted to preventing unwanted people from gaining access [6-10].

The secret key used to represent access mechanisms, allowing authorized users to verify the transaction characteristics meet secret key access requirements. Finally, HSKT reduces decryption and encryption time, energy consumption, average delay, and increases achievement rate and throughput compared to other sites, which incur greater consequences if information is lost or modified. Although, the

Indian government took positive steps encouraging rapid expansion of E-commerce enacting cyber-laws, by lowering framework taxes. People are hesitant to make online purchases due to concerns about security and installation methods [11]. Additionally, there are fraudulent debit cards and credit cards that happens to anybody when shopping online.

E-commerce applications suffer from payment problems; for instance, automated transactions using Debit cards or Visa, PayPal or Net banking, or methods by the way of other tokens partake added consistency issues and are more likely to be targeted than other sites because they suffer more consequences if information is lost or modified. Although, the Indian government has made significant steps to promote the rapid growth of E-commerce by enacting cyber legislation, lowering framework taxes, and so on. People are hesitant to make online purchases due to concerns about security and installation methods.

## A. Objectives

The resulting ones are the main objectives of this work:

- To create a High-Speed Key Transmission (HSKT) technique that will allow for safe and quick financial transactions while preventing fraudulent behavior.
- To use a privacy method to keep track of traders and consumer content profiles.
- To provide an E-Commerce information retrieval system that is both effective and secure for both merchants and consumers.

To enhance the suggested method's success rate by reducing encryption and decryption time, average delay, and energy usage when compared to current methods.

## II. LITERATURE REVIEW

The term "cryptography" comes from the Greek and means "the process of making data unintelligible." This prevents an unauthorized user from getting their hands on sensitive information. To put it another way, it's a method for concealing data in transit [12]. As soon as the transmitter uses cryptographic methods and a particular key to turn the data into cypher text, it is sent to the recipient. Encryption is the name given to this technique. To decrypt a message, the receiver uses a known key to decipher the ciphertext. Decryption is the term for this step.

There are two types of cyphers known as symmetric (or secret) and asymmetric (or public). In order to accomplish security, each of them makes use of a discrete and distinct set of techniques. Symmetric key cryptography focuses on the structure of simple repeated cryptographic processes, while asymmetric cryptography relies on the complexity of a mathematical problem [13].

To save energy, network designers should employ symmetric key cyphers to encrypt data sent by sensor nodes. Due to resource limits, standard cryptographic techniques cannot be used on sensor nodes. For these networks, a key management method provides the best security. Before exchanging information, nodes must safely exchange keys. The key management is a multi-operational approach where the initial key is produced, then disseminated and traded across the nodes, then utilized by the sender and recipient, and finally abandoned and renewed. Thus, key management system essential processes are: creation, distribution, exchange, usage, abolish, and refresh. WSNs are managed in several ways [14].

Conventional public-key cryptosystems have a major drawback in that in order to provide the high degree of security required, the key size must be suitably big [15]. In the third place, we have hybrid key cryptography, which brings together symmetric and public key elements. It combines the best features of the two approaches. Public-key cryptography (PKC) has been demonstrated to be a viable method of encrypting data [16]. PKC is gaining traction in WSNs because it is capable of solving two basic and challenging challenges, namely authentication and symmetric key distribution, using DSA and Diffie-Hellman key exchange [17][18]. For sensor nodes with limited resources, ECC is an excellent choice since it has less overhead than RSA, but ECC operations are still hefty [19]. ECC is superior to RSA in terms of security [20].

### III. PROPOSED METHODOLOGY

It concentrated on the cryptography algorithms. The reader can get a clear comparison of the key length and the analytical view of the cryptography methods to be utilized in the real-time applications utilizes the model. Where, AES, DES and Blowfish algorithm are discussed details with their key generation, key comparisons, encryption and decryption process. All conventional method is evaluated on regular postponement, energy intakes, throughput, encryption and decryption time. Blowfish algorithm is more secure for increasing the key size. It compared to other symmetric key algorithms and offered less processing time and rounds [21-25].

The secure and efficient payment transaction (SEPT) approach aims to prevent hackers from tracing one's online transaction. Initially, entering account numbers are very simple. Hence, the system gathers account numbers with allotted password details. Next, due to a multi encryption method, consumer will receive interim password for activating the account. Finally, Aadhar number should be entered to validate the consumer profile verifications and activate the account for further transactions [26-30].

#### A. Implementation Preprocessing Steps for SEPT

Implementation preprocessing steps are as follows Authentication process, Purchase Request, Authorization Demand, Authorization Response, Cardholder Authentication Demand, Cardholder Authentication Response and Ending Payment and Secure and Efficient Payment Transaction (SEPT) Approach.

The system has highly concentrated on the secure and efficient payment transactions to avoid fraudulent action. The study's primary goal is to provide an effective smart method to protect privacy while avoiding the complexity of apps and consumer burden. The study explains about HSKT algorithm with their system workflow, implemented modules, the implementation details, mathematical proof, operational details, and dataflow diagram. It explains the implementation, logical, analytical, and view of HSKT.

The HSKT method is used to get a clear concept of the logical and the analytical view of the proposed HSKT method for implementing in the real-time e-commerce applications. The proposed methodology ensures secrecy and efficiency in payment transactions of product content to avoid fraudulent activity in e-commerce.

#### B. Implementation Pre-Processing Steps for EHSKT

Implementation preprocessing steps are as follows Admin, Product Upload Module, Product Update and Product History, User Authentication, Product Search, View Shopped Products, Order Process and Payment Process. For safe and quick financial transactions, as well as to prevent fraudulent behavior, a High-Speed Key Transmission (HSKT) Technique is suggested. The suggested method generates a unique id for financial transactions using a UUID (Universally Unique Identifier). To prevent fraud, the proposed system produces a Unique ID (Identifier) that consists of a mix of numbers, alphabets, and special characters. This method allows users to conduct multi-banking account transactions from a single location. The suggested system is devoted to preventing fraud and unauthorized users.

The approach enhances the RSA methodology by using a 4096-bit key length, which makes it more successful for creating and distributing secret keys in hazardous settings. The secret key of authorized user is used to represent access mechanisms in this case, allowing transaction to be verified if and only if transaction features satisfy secret key access criteria. Vertical or horizontal partitioning of data is often anticipated. In case of horizontally partitioned data, several places collect the same set of information about distinct entities. The proposed system created security based on data attributes. The suggested method reduces the time required for encryption, decryption, and key complexity. The suggested design approach is as follows: Setup:

The method accepts a collection of numbers, alphabets, and a special character  $k$  as an input parameter and reverses public key PK and user secret key, USK. For the creation of unique transaction IDs, PK is used.

1) *Secret key generation*: Generating two large random prime numbers  $h$  and  $k$  and it has approximately equivalent size to item  $N = hk$  necessitated 4096 bits length. Computing  $N = \text{secret key exponent } SE, 1 < SE < \phi$  becomes  $SE = 1 \pmod{\phi}$ . The private key is  $(SE, h, k)$  and public key is  $(N, i)$ . Maintain all the values of  $SE, h, k$  and  $\phi$  secretly. When using  $SE$ , the private key is sometimes expressed as you need as the value of  $N$ . We could write the key pair as  $((N, I SE)$  at other instances.

Modulus is a term that refers to the number  $N$ . The exponent is also known as the public exponent, encryption exponent, or simply exponent. The secret key exponent ( $SE$ ) is also known as the decryption exponent.

This method will utilize the access tree structure  $h$  and  $k$  as well as the user secret key  $USK$  as inputs. This method uses a secret key or signature  $S$  that allows the user to verify transactions for specific users. Only an authorized user may generate using  $USK$ . Transactions Validations:

The user has the ability to make modifications, such as generating a message digest of the material to be shared. Exponent  $DE$  between 1 and  $N-1$  is used to represent this message or content digest. Calculates the signature  $S = DESE \pmod{N}$  using the private key  $(N, SE)$  and sends it to the recipient. On the receiver's side, calculate integer  $x = S_i \pmod{N}$  using the sender's public key exponent  $(N, I$  Calculates the message or content digest of the data that has been signed independently. It calculates the expected representative integer  $x'$  by encoding the expected message digest if  $x = x'$ , the signature is correct.

It takes user input together with their signature  $S$  in order to initiate the key access structure's payment validation process. The suggested method validates payment transactions if and only if the set of payment characteristics matches the user signature in the access tree.

2) *Encryption*: The user may get the receiver's public key and represent the plaintext content as a positive integer  $PI$  with  $1 < PI < N$ , compute the ciphertext  $CT = PI \pmod{N}$ , and send the ciphertext to the receiver in the following methods.

3) *Decryption*: Based on the size of  $SE$  and  $N$ , the receiver uses his/her private key  $(N, SE)$  to compute  $PI = CTSE \pmod{N}$  using his/her private key  $(N, SE)$ . It retrieves plain text from a message or a  $PI$  that represents content.

### C. Working with EHSKT Technique System Constraints

$H$  and  $K$  are two important prime numbers with bit widths of 4096 that are kept hidden. The size difference between the two sizes must be large enough in the security scenario.

$N = H * K, \phi = (H - 1) (K - 1)$ , and  $\phi$  is kept secret. Our software utilizes a 4096 bit modulus EHSKT implementation.  $PI$  can use only positive integer, but then great general separation with respect to  $N$  and  $\phi$  should be  $1. SE * i \equiv 1 \pmod{\phi}$  where  $i$  is an integer.

$PK (PI, N)$  referred as public key  $PK$ , whereas  $SK (SE, N)$  is the private key. Considering  $PT$  equals plaintext,  $(PTPI) SE \equiv PT \pmod{N} \equiv PT \pmod{H}, PT \pmod{K}$ .

Process

Encryption:  $CT = \text{Enc}(PI, PT) = PTPI \pmod{N}$ .

Decryption:  $PT = \text{Dec}(SE, CT) = CTSE \pmod{N} = CTSE \pmod{H}, CTSE \pmod{K}$ .

Operations

Choose two big prime numbers and calculate  $N$  and  $\phi$ . To speed up encryption select  $PI = 3$ . Depended on  $PI$  and  $N$  then  $SE$  can be estimated. "Calculate  $PTkey \pmod{H}, PTkey \pmod{K}$ , where the key can be  $PI$  as well as  $SE$ .

For  $\phi = (H-1)(K-1)$  is even,  $PI$  may be tried from 3. As a result,  $PI$  can be raised by 2 once.

The following is an example of a  $PI$  computation algorithm:

```
BigIntegerComputePI(BigInteger phi)
{
    BigInteger PI=3; BigInteger division=0;
    While (GCD(phi,PI)!=1) // Here Greatest Common Divisor is the
    function to calculate the greatest common division of two integers,
    and it can be executed with EuclidAlgorithm.
    { PI=i+2;
    }
    Return i;
}
GeneratePublicKey(BigInteger PI)
{
    BigInteger one = BigInteger.ONE; BigInteger two =
    one.add(one); BigInteger key = one.add(two);
    while(PI.GCD(key).compareTo(one) != 0)
    {
        key = key.add(two);
    }
    Return key;
}
GeneratePrivateKey(BigInteger N, BigInteger DE)
{
    return DESE mod N; // SE is secret key exponent
}
public BigInteger Encryption(BigInteger PI)
{
    powerModule(PI)
    Encryption CT= PTPI mod N
}
public boolean Decryption(BigInteger CT, BigInteger SK)
{
    BigInteger VS = powerModule(SK); if(VS.compareTo(SK) == 0)
    return true; Decryption PT=CTSE mod N;
    return false;
}
public boolean VerifySignature(BigInteger CT, BigInteger SK)
{
    BigInteger VS = powerModule(SK); if(VS.compareTo(SK) == 0)
    return true; return false;
}
}
```

## IV. RESULT AND DISCUSSION

### A. Comparative Analysis of Closest Conventional Approaches

For safe payment in financial transactional processes, DES, AES, and BLOWFISH are used. As shown in Table I, it also

supports the suggested technique for reducing delay, encrypting time, energy usage, decryption time, and increasing throughput, and it was discovered that blowfish has the best score for each given constraint for the corresponding parameter.

The suggested method is evaluated based on average delay, throughput, encryption time, energy consumption, and decryption time, as shown in Fig. 1. Based on average delay, throughput, encryption time, energy consumption, and decryption time, Blow Fish (BF) is calculated using Data Encryption Standard (DES) and Advanced Encryption Standard (AES) methods. The nearest competitor is AES. The data confidentiality and integrity were supplied by AES. AES fails to reduce key complexity, and it readily compromises key privacy. Blow Fish (BF) has enhanced security for safe and fast financial transactions while also preventing fraud. Blow Fish (BF) improves 7.02 percent by 0.40 AD (Average Delay), 2.45 EC (Energy Consumption), 0.52 ET (Encryption Time), and 0.68 DT (Decryption Time) (Throughput). Finally, the article argues that the Blow Fish (BF) algorithm is the best.

**B. Comparative Analysis of Closest Conventional Approaches using RSA**

The RSA (1024) and RSA (2048) key length is used for secure and efficient payment transaction process. It also supports proposed methodology for minimizing the average delay, encryption time, decryption time as shown in Table II seen that RSA (2048) shows best score on every specified constraint for the respective parameter.

TABLE I. ENCRYPTION TIME, DECRYPTION TIME FOR E-COMMERCE AVERAGE DELAY, THROUGHPUT, ENERGY CONSUMPTION

Algorithm	Encrypti on Time (s)	Decrypti on Time (s)	Average Delay (s)	Throu ghput (Kbps)	Energy Consumpti on (Joules)
AES	0.314	0.321	49.1367	5.27	72.087
DES	0.434	0.451	48.7766	28.13	83.087
BF	0.262	0.253	48.7349	35.2	85.544

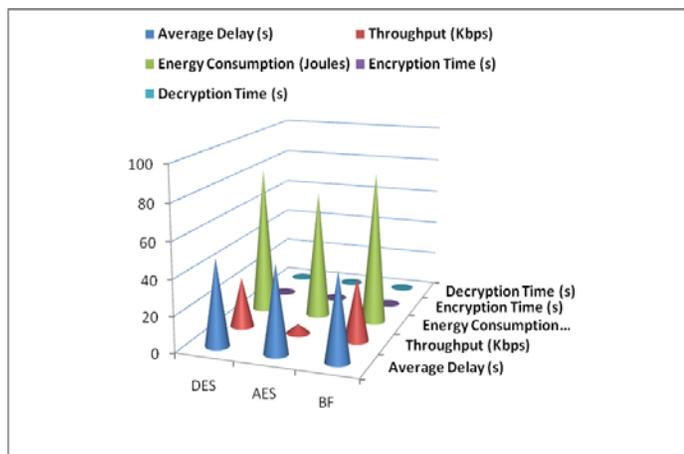

Fig. 1. Encryption Time, Decryption Time for e-Commerce Average Delay, Throughput, EnergyConsumption.

Based on the observation of Fig. 2 is estimated RSA algorithm utilizing key length of 1024 and 2048 bits. The RSA algorithm set the public exponent keys 1 to 3. Since, it offers better performance in key validations. The public exponent is generally utilized in constrained surroundings anywhere various validations have to occur. The results utilizing other exponents, key generations are more proficient, and validations are efficient. Finally, the performance of the RSA algorithm is good for security.

The cryptography method is used for the protection of information. These methods are utilized for decryption and encryption process over information. The Secure and Efficient Transaction System through RSA algorithm set the public exponent keys and it offers better performance in key validations. The public exponent is generally utilized in constrained surroundings, anywhere various validations have to incur security.

It concentrates on the secure and efficient payment transaction system and subsequently formulates new criterion functions for secure payment framework. It also prohibits hackers from tracing one's online transaction. The proposed system works based on Aadhar for secure payment transaction systems. Here, Aadhar act as a unique identification number (UID). The design narrated above in this chapter, is utilized to get a clear idea of the logical and analytical view of the proposed Encryption and Decryption process of Secure and Efficient Transaction System through Aadhar approach for real-time applications. The study explains the secure payment system through Aadhar ID for internet or web-based business using secure and efficient payment transaction with RSA algorithm process flow, mathematical steps. The system workflow diagrams and security of payment system details are displayed. It explains the implementation, logical, analytical, and mathematical view of secure and efficient payment transaction algorithm. Here RSA algorithm uses 2048 key size. It enhances protection for secure payment process.

TABLE II. DECRYPTION TIME, AVERAGE DELAY AND ENCRYPTION TIME

Algorithm	AverageDelay (s)	EncryptionTime (s)	Decryption Time (s)
RSA(1024)	2.5	4.52	3.12
RSA(2048)	2.9	5.13	4.13

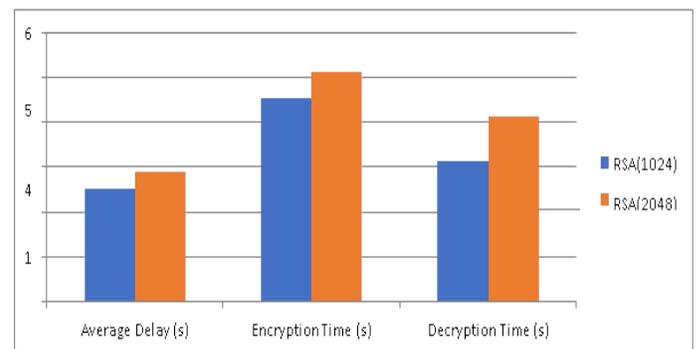

Fig. 2. Decryption Time, Average Delay and Encryption Time.

C. Simulation Result

The proposed technology represents a mathematical model to estimate the performance of Customer Success Rate, Mean of Transaction Time (MTT), and Reliability (R) to find the effectiveness of Secure and Efficient Payment Transaction with Aadhaar technology. The proposed technology expresses the payment process in secure and efficient way in e-commerce applications.

1) *Customer success rate (CSR)*: The customer success rate refers to the person's discernment that utilizing a specific framework to deal with. It considered one of the most influential features behalf of new technology adoption like as the customer success rate. It has an effect on the attitude, self-visibility, and instrumentality with utility. The impact of the perceived customer success rate has been exhibited in various database forums with various setting. The customer success rate is depending upon the attitude and aim whose details are explained in equation (1).

$$CSR = \frac{T_{FR} + T_{Ju}}{T_F + T_{I_1} + FT_F + FT_{I_1}} \quad (1)$$

Where, TF Transaction Fail, TT is Transaction True, FTF is False Transaction fail and FTT is False Transaction True. This derivation notifies that CSR mostly based on some features condition.

2) *Mean of transaction time (MTT)*: The mean of transaction time is estimated by separating the total value of all exchanges by the number of exchanges or sales. This can be estimated on a day-day, month to month or yearly premise. The mean of transaction time is exhibited in equation (2).

$$MTT = \frac{\text{Total Transaction Value}}{\text{Number of Salee.}} \quad (2)$$

3) *Reliability (R)*: A client's total number of partnerships with an organization and its products. Client experience management is a fundamental component of client relationship management. The client's overall impression of the organization and contributions is reflected in the overall experience. In equation, the suggested approach provides a mathematical model for Reliability (R) (3).

$$\text{Reliability} = \frac{\text{Performances of Process} - \text{Exceptionation of Products}}{\text{Total}} \quad (3)$$

Table III represents the Customer Success Rate, Mean of Transaction Time (MTT) and Reliability (R) with payment data for secure and efficient payment transactions. The proposed technology displays their average values for respective parameters with the respective data. The SEPT with Aadhaar technology is evaluated with the existing technology; namely, POS (Point of Sale), Mobile-based technology, Micro-ATM, Kiosk. According to Table III, it noticed that SEPT approach is best method compare than other existing method that have the best result on every specific aspect for the respective parameter.

Based on Table III, the proposed technique SEPT with Aadhaar ID computes Customer Success Rate, Mean of

Transaction Time and Reliability for identifying the effectiveness of the technology. Fig. 3 shows the payment processing of CSR,R and MTT values. The proposed method is evaluated with POS payment technology, Mobile payment technology, Micro-ATM payment technology and Kiosk payment technology existing method on behalf of Customer Success Rate, Mean of Transaction Time, and Reliability. The POS technology depended on resolutions with or without Smart Card for payment process. A customer to offer their payment data in the transaction for a product or service utilizes it. However, there are many forms of POS frameworks utilized in numerous company types and it have privacy problems. The proposed method is providing efficient schemes for secure payment transaction process. Micro ATMs permit clients to perform fundamental economic exchanges utilizing only their unique number and fingerprint as unique evidence (according to a Bank Identification Number for inter-bank exchanges). However, it has manual access to all submitted document works. Kiosk payment technology is banking resolutions utilizing little bandwidth Internet for connectivity. However, it fails to maintain customer success rate and transaction time of payment process. The mobile payment technology is the nearest competitor on overall parameters. Mobile-based technology for transaction achievement will be able to meet their requirements and expectation much better than other delivery resolutions or platforms. However, it fails to maintain security and transaction time for all most cases. Proposed technique reduces 0.6 MTT (Mean of Transaction Time) and improves 0.9% (Reliability) and 0.9% of CSR (Customer Success Rate). Finally, the study concluded that the suggested SEPT technique outperforms all other evaluation matrices and input characteristics. As a result, the SEPT is the best technique in terms of overall characteristics.

TABLE III. AVERAGE CUSTOMER SUCCESS RATE (CSR), RELIABILITY (R) AND MEAN OF TRANSACTION TIME (MTT) FOR 50 USER PAYMENT PROCESSING WITH VARIOUS SIZE OF TRANSACTION RECORD SIZE

Technology	CSR	MTT	Reliability
POS	4.05	2.6	3.6
Mobile	1.8	1.5	2.24
Micro-ATM	3.4	2.4	3.2
Kiosk	2.9	2.1	2.51
SEPT	4.95	0.9	4.5

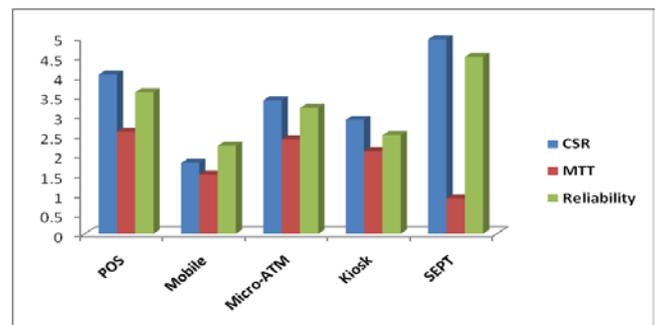

Fig. 3. Customer Success Rate (CSR), Reliability (R) and Mean of Transaction Time (MTT) for Payment Processing.

#### D. HSKT Technique

To prevent fraud, the HSKT investigates performance indicators to enhance security for safe and fast financial transaction processes in e-commerce applications. It provides evaluation metrics such as average delay, throughput, energy usage, encryption time, and decryption time.

1) *Average delay*: The timing difference between current data packets received as well as preceding data packets transmitted is evaluated using the HSKT method in the stages. In equation, the suggested approach is defined as a mathematical model for the average delay in equation (4). The average delay (AD) is calculated as follows:

$$\text{Average Delay} = \frac{\text{Pkt Received Time} - \text{Pkt Sent Time}}{\text{time}} \quad (4)$$

Where Pkt is Packet and Received time is received time.

2) *Throughput*: The throughput is an average of successful finance transactions and client record maintenances. The proposed method is described as a mathematical model for throughput in equation (5). Throughput is evaluated as:

$$\text{Throughput} = \frac{\sum_0^n \text{Packets Received} (n) * \text{Packet Size}}{1000} \quad (5)$$

Where n is number of packets.

3) *Energy consumption*: Over the simulation period, the energy usage is really the difference between the new and residual energy. The energy consumption graph depicts the total amount of energy used in the Tx and Rx modes throughout the whole operation. Tx mode is used when one process transmits data to another process. Tx Energy of a process state is the amount of energy needed to transmit a data packet. Tx energy is calculated depending on the size of the data packet (in bits). When a process state receives the packet from some other process state, it is in Rx mode. RX energy is the amount of energy required to receive a data packet. In equation (6), the suggested approach is defined as a mathematical model (7). The following is an estimate of the Energy Consumption (EC):

$$\text{Energy Tx} = (330 * \text{data Size}) / 2 * 106 \quad (6)$$

$$\text{Energy Rx} = (230 * \text{data Size}) / 2 * 106 \quad (7)$$

Where Tx is initial energy and Rx is residual energy.

4) *Encryption time (ET)*: The encryption time finds to changes over the plaintext into the ciphertext. The encryption time depended on the message chunk size and the key size and illustrated in milliseconds. It has direct impact on the execution of the HSKT technique. The HSKT technique has the less encryption time, to create the encryption technique responsive and quick. The proposed methodology is defined as a mathematical model in equation (8). The Encryption Time (ET) is estimated as:

$$EP = (I, CT\{EP_i\} \in I) \quad (8)$$

Where EP is an encoding process, and I is an attribute set. CT is ciphertext.

5) *Decryption time (DT)*: The decryption time is a total time required to recuperate the plaintext from the ciphertext. For this purpose of HSKT technique is quick and responsive, it is attractive that the time taking for decoding is similar to the encryption time, and it is measured in milliseconds. A mathematical model in equations is used to describe the suggested approach (9). The following is an estimate of the Decryption Time (DT):

$$EP(EP_i, ski) = EP(g, g)^{pi(0)s} \quad (9)$$

EP is an encoding process, and sk is a secret key.

With traditional methods, Table IV shows the Average Delay, Throughput, Energy Consumption, Encryption Time, and Decryption Time for various input restrictions. The suggested technique compared current methods to different types of algorithms such as DES, AES, and BF. On the basis of Table IV, it can be concluded that the suggested approach outperforms current methods. The method calculates Average Delay, Throughput, Energy Consumption, Encryption Time, and Decryption Time, as well as displaying average values for each parameter with specific data.

As shown in Fig. 4, the HSKT is computed using the average delay, throughput, encryption time, energy consumption, and decryption time. The suggested HSKT is computed using Data Encryption Standard (DES), Advanced Encryption Standard (AES), and Blow Fish (BF) techniques based on average delay, throughput, encryption time, energy consumption, and decryption time. The method that comes closest is BF. AES ensured the secrecy and integrity of the data. AES, on the other hand, fails to decrease key complexity and often compromises the secrecy of critical keys. The framework provides details about the programming environment, execution steps for the experimental process, tabular result, and comparative analysis of the proposed HSKT technique. It discovers the complete overview of how the proposed systems works, what is the necessary software required to implement this methodology. How these approaches are best when compared to other methods. The average delay, throughput, encryption time, energy consumption, and decryption time of the HSKT method are all assessed. The findings of the HSKT approach are compared to the nearest traditional methods in tabular and graphical form. HSKT enhances privacy for safe and fast financial transactions while also preventing E-commerce fraud. The HSKT improves by 59.8% and lowers 4.73 AD (Average Delay), 23.91 EC (Energy Consumption), 0.95 ET (Encryption Time), and 0.85 DT (Decryption Time) (Throughput). Finally, the study argues that the suggested HSKT technique outperforms all other evaluation matrices and input parameters.

TABLE IV. AVERAGE DELAY, THROUGHPUT, ENERGY CONSUMPTION, ENCRYPTION TIME AND DECRYPTION TIME FOR 50 USERS WITH VARIOUS DATA SIZES

Algorithm	Average Delay (s)	Throughput (Kbps)	Energy Consumption (Joules)	Encryption Time (s)	Decryption Time (s)
DES	48.7766	28.13	83.087	0.434	0.451
AES	49.1367	5.27	72.087	0.214	0.221
BF	48.7349	35.2	85.544	0.262	0.253
EHSKT	13.334	95.16	48.168	0.119	0.136

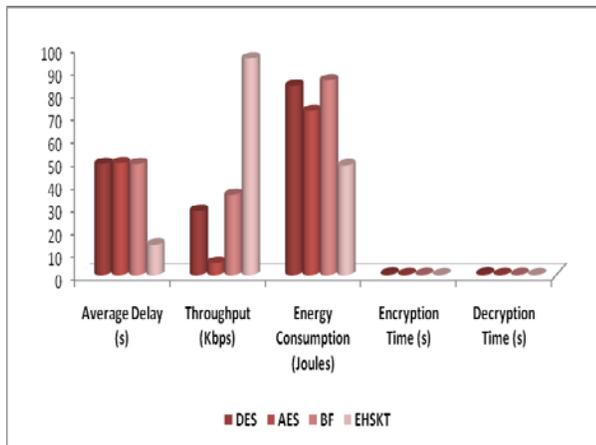

Fig. 4. Average e-Commerce Delay, Throughput, Energy Consumption, Encryption Time and Decryption Time.

### V. CONCLUSION

The World Wide Web is the most important resource in contemporary business, since it opens up new business possibilities. E-commerce refers to an online store where goods is sold or purchased electronically. The High-Speed Key Transmission (HSKT) Technique was created to provide secure financial transactions, protect product content privacy, and prevent fraud. The privacy system keeps track of and controls the content profiles of merchants and clients. To prevent fraudulent behavior, the proposed approach increases throughput of safe besides effectual payment transactions, as well as the privacy of product content. The proposed method shows better results in performance parameters. In future, the method needs to focus more on transmission delay.

**Abstract**—Automated document classification is the machine learning fundamental that refers to assigning automatic categories among scanned images of the documents. It reached the state-of-art stage but it needs to verify the performance and efficiency of the algorithm by comparing. The objective was to get the most efficient classification algorithms according to the usage of the fundamentals of science. Experimental methods were used by collecting data from a sum of 1080 students and researchers from Ethiopian universities and a meta-data set of Banknotes, Crowdsourced Mapping, and VxHeaven provided by UC Irvine. 25% of the respondents felt that KNN is better than the other models. The overall analysis of performance accuracies through various parameters namely accuracy percentage of 99.85%, the precision performance of 0.996, recall ratio of 100%, F-Score 0.997, classification time, and running time of KNN, SVM, Perceptron and Gaussian NB was observed. KNN performed better than the other classification algorithms with a fewer error rate of 0.0002 including the efficiency of the least classification time and running time with ~413 and 3.6978 microseconds consecutively. It is concluded by looking at all the parameters that KNN classifiers have been recognized as the best algorithm.

**Keywords**—Document classification; machine learning algorithms; text classification; analysis

## I. INTRODUCTION

Document classification is a vital research area or topic since the establishment of digital documents used widely [1]. This is one of the major parts of the manual effort. More tech companies outsource the job and business processes people have to sort the documents of the packages manually. There is the availability of the hundreds of documents types. Nowadays, text classification is an important task because of the very large amount of text documents required to deal with day-to-day activities. In general, document classification can be classified as topic-based document classification and document genre-based classification. Topic-based document categorization can be classified documents according to their topics [2]. Also, texts can be written in many different genres, for example, academic papers, advertisement updates, political news, and movie reviews. Genre referred to the way a text is

made, the way it was modified, the identification of language used, and the type of listeners to whom it is addressed. Existing studies on genre classification found that task differs from the categorization of topic-based [3]. Commonly, most data based on genre classification were collected from the newspaper, web, noticeboards, and live broadcasts.

The classification is an information retrieval from the metadata, manually classified, or via an automatic classifier retrieving information from the content. As manually classifying documents can be a time-consuming and inconsistent task. It is usually not beneficial on a larger scale. Instead, automatic Document Classification is suggested to solve the categorization of retrieved information, because of the automatic process for larger systems [4].

Although some degree of automation is achieved that helps to search through keywords and expressions the accuracy and efficiency of such solutions are questionable and not satisfactory. An approval of efficiency matters to show the user's satisfaction that needs assessing and analyzing machine learning algorithms. It increases the satisfaction of automated document classification. The document classification contains many concepts as Fig. 1 shows.

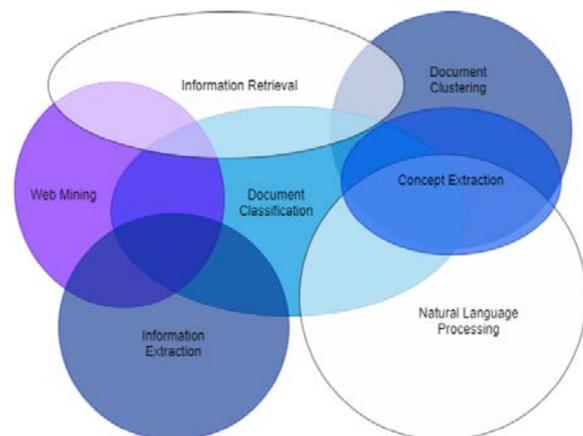

Fig. 1. By [5] Venn Diagram of the Text Mining Area.

This study is organized as follows, In Section 1, Introduction is presented. Section 2 presents different types of Classification Algorithms. Section 3 describes the related works. Section 4 introduces the Methodology. Section 5 shows the Results and Discussions of the study. Conclusions and recommendations are discussed in Section 6 and Reference is cited in Section 7.

## II. CLASSIFICATION OF ALGORITHM

### A. Logistic Regression

According to [6], the binary outcomes either something happens or nothing happens, yes or no, pass or fail, living or dead are calculated using logistic regression. In addition, two factors were described: independent and dependent variables, which were examined to determine the binary outcome based on whether the outcomes were numeric or categorical. The independent variables might be categorical or numeric, but the dependent variable was categorical all the time and stated in equation (1):

$$P(A=1|B) \text{ or } P(A=0|B) \quad (1)$$

Whereas, A and B calculate the probability of the dependent variable and independent variable consequently.

Positive or negative connotation {0, 1} word or tree, grass and flower which was common object contained in a photo calculated by probability of each object between 0 and 1 R. Wolf, 2021.

### B. K-Nearest Neighbor (KNN)

The objects in KNN were categorized as [7], defined, and filled by selecting numerous labeled training examples with the shortest distance from each other. The k-nearest neighbor classification method stood out with its simplicity and commonly used techniques for text categorization, Even if classifying items took longer when a large number of training samples were provided. Even with multi-categorized documents, this strategy works well for regulating categorization jobs. KNN should be chosen manually, and some of them can be determined by calculating the distance between each test object and all of the training samples.

### C. Decision Trees

A decision tree is a tree in which internal nodes are labeled with terms, according to [8]. The branch was labeled by numerical data, while the leaf was labeled by categories. The "divide and conquer" method was employed in decision tree concepts. [8], further stated that each node in a tree corresponded to a collection of cases. Terms should check whether these were under the same label or not, according to this entire training example. Then, if not the same label, select partitioning terms from the pooled classes of documents with similar values for the term and place each of them in a distinct subtree.

### D. Random Forest

The random forest algorithm was the enlargement of the decision tree, as mentioned in [6]; constructing the actual world an axis of decision tree from training data in the real world. It essentially normalizes data so that it bonds to a

nearby tree on the data scale. Random forest prototypes are important because they solve the decision tree's problem of unnecessarily "pushing" data points into a category.

### E. Naive Bayes Algorithm

A Naive Bayes classifier [9] is a "simple probabilistic classifier based on Bayes' Theorem and strong independence assumptions." It calculates the document's subsequent probability of being assigned to multiple classes and assigns the document to the class with the highest subsequent probability, employing the autonomous feature as the probability model. As a result, the existence of one feature in a classification task has no bearing on the existence of other features.

### F. Perceptron

A threshold function serves as an activation function in a perceptron, which is an artificial neuron. Assume an artificial neuron with input signals  $x_1, x_2, \dots, x_n$  and associated weights  $w_1, w_2, \dots, w_n$  with  $w_0$  for constant, [10]. If the output of a neuron is assumed to be a perceptron, the equation is as follows in (2).

$$O(x_1, x_2, \dots, x_n) = \begin{cases} 1, & \text{if } W_0 + W_1x_1 + \dots + W_nx_n > 0 \\ -1, & \text{if } W_0 + W_1x_1 + \dots + W_nx_n \leq 0 \end{cases} \quad (2)$$

### G. Support Vector Machines

Support Vector Machines (SVM) are utilized for text classification which is a supervised classification algorithm. Text classifiers must cope with a large number of features [11] with high-dimensional input space. It is also capable of handling vast feature spaces and employed in place of adequate protection that is not based on the number of features. Furthermore, the majority of text categorization issues are linearly separable. Therefore, SVMs were developed to locate and search for linear separators.

### H. Gaussian Naive Bayes

Gaussian Naive Bayes is also known as Gaussian NB which is based on the Gaussian Normal Distribution and supports continuous data, as specified by [12]. It's a Naive Bayes variation to compute continuous data, continuous values were often associated with each class and distributed according to the normal distribution.

## III. RELATED RESEARCH

Automated document classification is the machine learning fundamental that refers to assigning automatic categories among scanned images of the documents. KNN is the most researched topic by most researchers, with the most important aspect being to perform a detailed study over survey applications that were performed by implementing introductory data mining books and survey reports that were documented by [13], which proposed many improvements of KNN algorithms for implementing data classification. Another noteworthy study by [14] was on the weighted KNN classification method based on various symbolic characteristics, in which the distance was measured and calculated before being depicted in the form of tables to produce real-valued distances from symbolic domains that

also represent features. The authors claim that the suggested method outperforms existing algorithms such as KNN because it was tested on three different application areas, with the key advantage being training speed and ease of implementation.

[15], an optimization function based on the "leave-out-out cross-validation" technique and "greedy hill-climbing technique" and introduced three major "decision tree algorithms" was published that focused on an adjustment of weight while implementing KNN for identifying optimum weighted vector by using an optimization function that was based on the "leave-out-out cross-validation" technique and "greedy hill-climbing technique" and introduced three major "decision tree Many other studies conducted extensive surveys of applications based on various decision tree algorithms in the fields of machine learning and data mining technologies [16].

SVMs are a type of classification algorithm that works by examining a feature space and attempting to build a hyperplane to divide data points belonging to distinct classes [16][17]. It worked by employing a kernel function to translate data onto a higher-dimensional space and defining the hyperplane. Although SVMs are binary classifiers by nature, they can be adjusted for multiclass issues by employing pairwise classification, which treats a problem as a series of binary problems. The illustration in support vector machines is comprised of self-learning kernels, where the survey was demonstrated in SVMs and their mathematical foundation. Major parts of SVMs were applied to the implementation of text categorization in other works [18].

Many scholars used Decision Trees to solve the challenge of automatic affect identification. This was a simple classifier that used data observations and map observations to make class ownership decisions [16] [17]. It works by repeatedly querying a test instance for more information about the classes to which it may belong using a set of if-then rules.

#### IV. METHODOLOGY

##### A. Data Collection

The interviews were taken as a data collection tool from nine first-generation Ethiopian universities either face-to-face or via the medium of wire. We focused to question from research students, senior teachers, and individual researchers.

Our objective was to get the most efficient classification algorithms according to usage and level of understanding of the fundamentals of science. 720 research students, 225 teachers, and 135 individuals of computing domain as the sum of 1080 were questioned using the Question: "which algorithm is better for document classification, in terms of simplicity and accuracy?" We gave them eight different classification algorithms including; KNN, SVM, Naive Bayes, Gaussian, Perceptron, Random Forest, Logistic Regression, and Decision Tree.

Gaussian NB, Perceptron, Random Forest, Logistic Regression, and Decision Tree.

All of the interviewees did not answer the question, which makes a response rate of 92% (appx). 25% of the respondents felt that KNN is the most used algorithm and 20% of the respondents said that SVM is better in their experience. 15% agreed that Perceptron is the most popular and used, another

15% suggested that Gaussian NB is easy for them and the rest have recommended as described in Fig. 2.

Therefore, the study was compared with four different classification algorithms that the respondents felt were the most used classifiers with a response rate of 15% or above are, KNN, SVM, Perceptron, and Gaussian NB which were included in the analysis.

##### B. Experiments

This study was used on a whole meta-data set called Banknotes, Crowdsourced Mapping, and VxHeaven provided by UC Irvine [19] holds information about the different categories of data. We used the Irvine dataset to get the exact performance of every algorithm. Overall, functions and commands were used in the platform of Python 3.7.

The detail of the data is mentioned in Table I which is employed to perform the k-Fold cross-validation technique for training and testing the datasets were used. Here, the value is assumed as k=10 which shows the unbiased result of the datasets. KFold() Scikit-learn class used with an argument of the number of splits whether to shuffle the sample. We created an instance that splits a dataset into k folds split returned each group of train and test sets after calling the split() function. Index of a way returned into the original data samples of observation to use for train and test sets on each repetition.

Fig. 3 illustrates the first 10 rows in the banknotes dataset that were used to train and test the algorithm. Similarly, all the datasets were trained and tested.

1) *Datasets*: All the files are images in which banknotes are pictures of various banknotes and measuring different properties of currency and in particular, they categorized each of these banknotes as either counterfeit banknotes or not counterfeit (authentic).

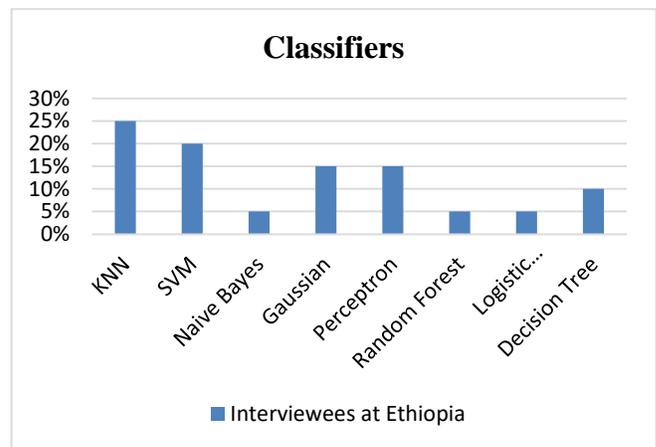

Fig. 2. Classifiers for Interviewees in Ethiopia.

TABLE I. DATASETS AND DATA SIZE

Datasets	Data Size	Text Size
Banknotes	1372	10-fold Cross-Validation
Crowdsourced Mapping	10546	10-fold Cross-Validation
VxHeaven	2598	10-fold Cross-Validation

Crowdsourced Mapping Images were taken through satellites of different land cover classes of the farm, forest, orchard, and water being categorized. VxHeaven is the detection of malware observed through various features of the text in the Operating System.

2) Machine learning algorithms were evaluated using a resampling procedure called k-Fold cross-validation. A dataset is split into o number of groups known as k-Fold. The score with high variance may change the idea based on data to fit the algorithm or overestimate the skill of the algorithm due to biased data if the value of k is selected poorly. Here, k=10, which is less biased of the algorithm than another method to split the train or test result.

Each row of the dataset represents the banknote and has four different input values. These inputs have an output value of 0 or 1. 0 means a genuine (authentic) bill and 1 means a counterfeit bill.

So, this study used supervised learning to begin to predict some sort of function that can take four values as input and predict the output would be the algorithm was built using Python language, Jupyter Notebook as a compiler, and libraries including, Pandas, Scikit-Learn, and Matplotlib.

### V. RESULT AND DISCUSSION

In evaluations, data were divided into two different sets, training and testing datasets using the k-Fold model. Training data sets were used to build the algorithm (classifier) and then tested the classifier for the prediction of the goal.

#### A. Confusion Matrix

A confusion Matrix is also known as an Error Matrix that is used to define the analyses of classification algorithms on a set of test data for which the true values are well known. It is a table that has two dimensions; actual value and predicted value as Table II illustrates.

TABLE II. TRUTH TABLE OF CONFUSION-MATRIX

Actual	Predicted		
		No	Yes
	No	TN	FP
	Yes	FN	TP

TN: True-Negative, TP: True-Positive, FN: False-Negative, FP: False-Positive.

```
df = pd.read_csv("banknotes.csv")
print(df.head(10))
```

	variance	skewness	curtosis	entropy	class
0	-0.89569	3.00250	-3.606700	-3.44570	1
1	3.47690	-0.15314	2.530000	2.44950	0
2	3.91020	6.06500	-2.453400	-0.68234	0
3	0.60731	3.95440	-4.772000	-4.48530	1
4	2.37180	7.49080	0.015989	-1.74140	0
5	-2.21530	11.96250	0.078538	-7.78530	0
6	3.94330	2.50170	1.521500	0.90300	0
7	3.93100	1.85410	-0.023425	1.23140	0
8	3.97190	1.03670	0.759730	1.00130	0
9	0.55298	-3.46190	1.704800	1.10080	1

Fig. 3. Sample of First 10 Rows of Banknotes.

So, the confusion matrixes of mentioned classification algorithms are illustrated in the below matrixes.

Confusion Matrix 1.1 KNN	363	1
	0	322
Confusion Matrix 1.2 SVM	389	7
	0	290
Confusion Matrix 1.3 Perceptron	382	1
	9	294
Confusion Matrix 1.4 Gaussian NB	348	39
	60	239

The evaluation metrics are classified in Accuracy, Precision, Recall, Error Rate, and F-Score which are described in paragraphs (1), (2), (3), (4), and (5) consecutively below that what variable function for their parameters calculated. The summary of all the evaluations of the analyzed algorithm is shown in Table III.

1) *Accuracy*: It is close to the measured value to the actual (true) value.

$$Accuracy = \left( \frac{TP+TN}{\text{Total Tuples in Test Dataset}} \right) \quad (3)$$

The accuracy of these four algorithms; KNN, SVM, Perceptron, and Gaussian NB were scored 99.85%, 98.98%, 98.54%, and 85.57% respectively.

2) *Precision*: It is an evaluation analysis technique that finds the closeness of the measured values to each other.

$$Precision = \left( \frac{TP}{\text{Predicted Yes}} \right) \quad (4)$$

Performance of precisions of algorithms KNN, SVM, Perceptron, and Gaussian NB were 0.996, 0.976, 0.996, and 0.856 respectively.

3) *Recall*: The ratio of all correctly predicted positive predictions was measured using Recall.

$$Recall = \left( \frac{TP}{\text{Actual Yes}} \right) \quad (5)$$

The algorithms, KNN, SVM, Perceptron, and Gaussian NB reached 100%, 100%, 97%, and 79% respectively.

4) *Error rate*: It is an evaluation analysis technique that calculates the number of all incorrect predictions divided by the total number of the datasets. The worst error rate is 1.0 and the best error rate is 0.0.

$$Error Rate = 1 - Accuracy \quad (6)$$

KNN, SVM, Perceptron, and Gaussian NB algorithm errored 0.002, 0.011, 0.015, and 0.145 respectively of error rate declares.

5) *F-Score*: It is an evaluation analysis technique that calculates the harmonic mean of precision and recall.

$$F\text{-Score} = \left( \frac{2(P*R)}{P+R} \right) \quad (7)$$

Where *P* is Precision and *R* is Recall.

TABLE III. EVALUATED TECHNIQUES WITH PARAMETERS FOR THE ALGORITHM

Evaluation Technique	Analyzed Algorithm			
	KNN	SVM	Perceptron	Gaussian NB
Accuracy	99.85%	98.98%	98.54%	85.57%
Precision	0.996	0.976	0.996	0.856
Recall	100%	100%	97%	79.90%
Error Rate	0.002	0.011	0.015	0.145
F-Score	0.997	0.987	0.982	0.826

All algorithms: KNN, SVM, Perceptron, and Gaussian NB were marked 0.997, 0.987, 0.982, and 0.826 respectively in the F-Score evaluation shows.

### B. Evaluation Time

Time is one of the important parameters to check the efficiency of any algorithm. It helps to test a comparative algorithm. Timing of classification of document and execution were tested and analyzed using datasets as shown in Table IV and Table V. Performance of execution was measured in python using the timeit() function. Although python is slower than C++ libraries.

The optimization Table IV shows the least classification time and running time of KNN is ~413 and 3.6978 consecutively which is the lowest of another algorithm.

TABLE IV. EXECUTION TIME OF CLASSIFICATION TIME OF THE ALGORITHM

File Size (MB) (Datasets)	Classification Time			
	KNN	SVM	Perceptron	Gaussian-NB
0.22	~400	~409	~413	~411
0.4	~422	~428	~437	~438
0.32	~417	~419	~433	~434
Average	~413	~418.67	~427.6667	~427.6667

TABLE V. EXECUTION TIME OF RUNNING TIME OF THE ALGORITHM

File Size (MB) (Datasets)	Running Time			
	KNN	SVM	Perceptron	Gaussian-NB
0.22	3.6827	3.6828	3.7055	3.7076
0.4	3.7155	3.716	3.7188	3.7189
0.32	3.6952	3.6954	3.6967	3.6966
Average	3.6978	3.69807	3.707	3.7077

## VI. CONCLUSION

In this comparative study, we compared the performance and efficiency of various machine learning classification algorithms. KNN, SVM, Perceptron, and Gaussian NB using a meta-data set created by UC Irvine as an experiment. Authors estimate that the used data set is the meta-size of the data whose training and testing procedure was taken using k-Fold methods and experiments. K-Fold cross-validation technique

for training and testing of the datasets was used where the value of k=10 was assumed. In addition, the study focused on identifying a better algorithm for document classification that executed well on different meta-data sets. However, it was assessed that the accuracies of the tools depend on the data set used. Also, noted that the classifiers of a special group did not perform with equal accuracies in terms of the overall performance accuracies algorithm. KNN performed better than the other classification algorithms with a fewer error rate of 0.0002 the efficiency of the least classification time and running time with ~413 and 3.6978 microseconds consecutively. It is concluded that KNN classifiers have been recognized as the best algorithm for document classification with a percentage accuracy of 99.85%, recall value of 100%, and f-Score of 0.997. There would be platform variations of the algorithm that might be the case of study in the future.

### ACKNOWLEDGMENT

This paper is written by us using meta-data. We thank each other for the collaboration, collection, and execution of data that we passed. Authors are working in the area of Artificial Intelligence and substitute areas like machine learning, and deep learning including data sciences. These sciences are heavily dependent on the tools and algorithms used and tested in the data of different fields. Authors considered carrying out more into the domain. This work is not supported by any funder or our affiliated organization.

**Abstract**—The state-of-the-art misinformation detection techniques mainly focus on static datasets. However, a massive amount of information is generated online and the websites are flooded with this legitimate information and misinformation. It is difficult to keep track of this changing information and provide up-to-date accurate status of webpages giving either legitimate information or misinformation. Therefore, to keep the features up-to-date, authors have proposed evolving sentimental Bag-of-Words approach. This involves, updating sentimental features every time the new or changed web contents are read. This process accumulates the sentimental features at different time intervals that can be utilized to detect misinformation in URLs and upgrade the status of the webpage with timely information. Apart from sentimental features, other state-of-the-art features viz. syntactical, Part-Of-Speech Tagging (POST), and Term-Frequency (TF) are updated in a timely manner and utilized to detect misinformation. The model performed well with the support vector machine showing an accuracy of 80% while the decision tree classifier showed less accuracy of 56.66%.

**Keywords**—Misinformation detection; healthcare; incremental learning; sentiment analysis; bag-of-words

## I. INTRODUCTION

In an era of the information explosion, the volume of information available on the web has increased rapidly. Social media and the web as a whole have become an important source of information for people due to its easy access, low cost, availability, and popularity [1], [2]. At every moment millions of people access the internet to share information and interact over social media. This information has many hidden patterns inside. In one of the surveys in 2012 from the USA, it was found that 49% of people have connected to social media and the web to disseminate information, while in 2016 over 62% have accessed social media regularly to browse news articles [3], [4]. Therefore, the data disseminated on the web and social media have become the topic of interest for many researchers.

This large volume of proliferated data can cause the spread of misinformation. The misinformation or false information is inaccurate or incorrect information that is confirmed with existing evidence [4]. The false information may appear in the form of fake news, rumor, satire news, hoaxes, misinformation, disinformation, and opinion spam [3]. Thus, a massive amount of false information has been observed to spread in an uncontrolled fashion over the web.

The misinformation propagated via the web gets spread quickly, resulting in a widespread impact on people, business, healthcare, politics, and all other aspects. For example, in the 2016, USA presidential elections, the spread of misinformation resulted in public shootings. Also, rumors about the outbreak of the Zika virus were portrayed as a bioweapon and that the Zika vaccine is developed to depopulate the earth had been the considerable activity on Twitter and Facebook [5]. Hence, the persistent effects of misinformation are harmful and can contribute to violent conflicts which may lead to the death of people, especially in the healthcare domain. A substantial quantity of fictitious and fabricated information passes through the web creating an untrustworthy feeling among the public. Thus to raise the reliability of the web and social networks and reduce the detrimental effects of misinformation, detecting and combating false information has become the need of time and is highly recommended [6], [7].

Detecting misinformation is a challenging task due to three key reasons. First, to verify information with factual data; the second is the unavailability of structured data in a specific domain; third, adapting to the changing web data [4], [8]. The researchers have been keen on finding the answers to these challenges and detecting misinformation from raw text data. The detailed process of detecting misinformation is explained in the related work section of the paper.

The sentimental features are exclusively used in the literature to detect misinformation, fake news, rumors, etc.

\*Corresponding Author

The studies have observed that the sentiment polarity features in misinformation and true information are totally different. For misinformation, there are more negative words that may be due to guilt or tension while writing wrong information leading to very strong negative sentiment [9]. In a study of identifying prominent features to detect rumor propagation authors found that rumors are dominated by sentiments like anxiety, and uncertainty [10]. In [11], authors considered sentiment analysis as one of the important factors to assess information credibility.

Although there is a sufficient machine learning-based model in the literature to detect misinformation using sentiment features, the authors did not find any work dealing with newly emerging data in the healthcare domain. As the data change gradually during the period of time the sentimental words may also alter i.e. increase or decrease and it may affect the percentage of misinformation. As information in the real world is time-critical and newly emerging data needs to be adapted accordingly by the model, the efforts are required to furnish the newly arriving data, thus making it a challenging task [4], [12]. Hence, a technique like incremental learning is most suitable to handle this new chunk of data arriving at different time intervals due to its less memory requirement and short training time [13].

Therefore, in this research authors have used incremental learning to record the sentimental changes occurring in the data by generating sentimental “Bag-of-Words” in the healthcare domain and thus detect the change in percentage of misinformation at different time intervals. The aim is to find the URLs showing legitimate content initially and which later spread misinformation at different time intervals and vice versa and detect a change in the percentage of misinformation.

Hence, the objectives of this study are as follows: 1) Generate a sentimental “Bag-of-Words” for healthcare domain, 2) Incrementally evolve the sentimental “Bag-of-Words” using sentiment relevance score function, 3) Generate fact-check dataset of 100 URLs related to the healthcare domain, 4) Extract features to detect misinformation 5) Use state-of-the-art machine learning classifiers to classify the URLs as legitimate or non-legitimate, 6) Identify and study the change in URLs at Time T1 and T2 in terms of misinformation and sentiments.

The remaining sections of the paper are structured as follows: Section 2 defines the literature survey in the field of misinformation detection using sentiment analysis and incremental learning in the healthcare domain, Section 3 explains the methodology, Section 4 discourses the results and discussion and Section 5 describes the conclusion and Section 6 elaborates on limitations and future enhancements.

## II. LITERATURE SURVEY

This section discusses the outline of related work, which are focused on: (i) misinformation detection techniques, (ii) Incremental Learning and sentiment analysis approaches and their applications, (iii) application of incremental learning in the healthcare domain (iv) application of sentiment analysis in the healthcare domain. Although tasks (ii), (iii), and (iv) are effectively examined independently, there is a shortage of

research that would merge them and come up with a sentiment analysis-based approach for detecting misinformation, which would be capable of controlling changes in newly arriving data. In other words, there is no implementation of a model which would detect misinformation in the healthcare domain with incremental learning and sentiment analysis on a real-world dataset. Similar efforts by [14], incorporate behavioral features with linguistic features to detect misinformation. However, the proposed research categorically focuses on using incremental learning to accommodate newly arriving information into the model along with the sentiment and linguistic features so that the real-time changes are incorporated in the model.

### A. Misinformation Detection Techniques

The researchers are keenly driving in with a lot of efforts to detect misinformation. Several supervised, unsupervised and semi-supervised machine learning and deep learning-based algorithms exist which can detect misinformation. Machine learning is the component of Artificial Intelligence that can acquire knowledge and progress with past experiences [3], [4].

The basic process of detecting misinformation using machine learning techniques contains the following steps: data collection, data pre-processing, manual classification in case of the gold standard dataset using expert knowledge, feature extraction, and classification. The latest machine learning models from the literature have used features like content/syntactical features, user-specific features, sentiment features, grammatical features, linguistic features, image-specific features. Upon identifying and extracting the required feature set, the significant machine learning classifiers are used to perform the classification viz. Support Vector Machine, Naïve Bayes, Random Forest, Decision Tree, Logistic Regression, k-Nearest Neighbors [3]. Feature Extraction is a significant aspect of misinformation detection as the effectiveness of machine learning algorithms is mainly dependent on feature extraction. According to [11] sentimental features are considered to be crucial in detecting the credibility of contents. Hence, authors have considered sentimental features as central features in this study.

### B. Incremental Learning and Sentiment Analysis

Sentiment analysis is the process of detecting sentiment polarity in terms of positive and negative words in a text. However, the user perception of data in terms of sentiment polarity may change as time passes. The static models designed require updates to adapt to the changes. The incremental learning affords to adapt to these changed instances of data with the efficient cost of computations. Hence, incremental learning and sentiment analysis together can tackle the problem of sentiment shifts and new word generations [15], [16]. In the literature, researchers have used sentiment analysis to detect commuter emotions using incremental learning by computing emotion density at different time intervals [17]. Sentiment analysis with incremental learning benefits to make a more granular analysis of the user’s opinion. In another research, lexicons are built dynamically and evolved incrementally for Arabic text. Thus,

incremental learning helps to build and expand the lexicons dynamically [18].

### C. Incremental Learning in Healthcare

Incremental learning in healthcare was used in literature to enhance the predictive accuracy and decrease the computation time of classification many disease diagnosis systems have used incremental learning techniques, incremental SVM, and incremental PCA. Incremental learning was applied to the numeric datasets to classify diabetes disease using a combination of support vector machine, Expectation-Maximization, and Principal Component Analysis [19]. An incremental knowledge-based health management information system is designed to fetch and process the electronic medical records and expert guidance to accommodate the knowledge system [20]. In another approach, for newly arriving chunks of data, the network was trained using incremental learning by remembering the earlier patterns of data. This approach helped the researchers to discover heart rate changeability patterns in mobile healthcare services [21]. Hence, the newly arriving chunk of data of electronic medical records is captured using incremental learning techniques.

### D. Sentiment Analysis in Healthcare Domain

The sentiment analysis determines the dominant sensitive views from the text to know about the author's approach towards sentiments as either positive, negative, or neutral. In the state-of-the-art techniques, [22] the researchers collected medical terms from the Unified Medical Language System (ULMS) and clustered similar documents with medical terms using Latent Dirichlet Allocation (LDA) to form condition topics. The sentiment analysis helped the user to identify the feelings of other users with similar conditions. The researchers have been using sentiment analysis to discover the tendency of sentiments about vaccination like measles vaccine, and HPV vaccine through social media platforms. Sentiment libraries like VADER, Google Cloud Sentiments are used for analysis. Machine learning techniques such as TF-IDF, K-means clustering, and topic modeling using Latent Dirichlet Allocation (LDA) are applied for sentiment classification [23]–[25]. These investigations help the health experts or researchers to identify the various reasons for vaccine scares or hesitancy and take corrective actions to improve vaccine uptake. Sentiment analysis is proved as efficient and consistent while dealing with huge amounts of data [11]. However, the existing sentiment polarity libraries are restricted to general-purpose sentiments and not towards domain-based sentiments. To acquire improved accuracy of sentiment analysis, domain-based sentimental libraries are essential. However, due to the scarcity of such domain-based sentiment libraries in the healthcare domain, it is essential to generate sentimental Bag-of-Words in the healthcare domain [18].

### E. Research Contributions

With the proposed system platform following are the research contributions.

- 1) Generation of sentimental Bag-of-Words (BoW) using incremental learning.
- 2) A novel sentiment-based incremental machine learning model to detect misinformation from web URLs.
- 3) Analyzing the performance of the proposed model.

## III. METHODOLOGY

Fig. 1 shows the diagrammatic representation of the proposed model. The detailed techniques are discussed in the following section.

### A. Data Collection and Pre-Processing

This section explains the methodology used to collect the dataset for misinformation detection. To fetch the web URLs, a Google search engine is used. Google is extensively used for collecting information online. According to the statistics, 60% of desktop users and 90% of mobile or tablet users use Google while searching [11]. Initially, the authors identified and shortlisted 25 keywords related to the healthcare domain by identifying the most frequently occurring words in the healthcare domain. Table I displays the 25 keywords used for data collection. The various combinations of these keywords are used in the query for the Google search engine and the top 100 URLs are fetched every time, resulting in a group of 500 URLs. These 500 URLs were a mixture of healthcare URLs, non-healthcare URLs, and duplicate URLs. Thus, the authors manually segregated the URLs into two categories healthcare and non-healthcare, and also removed duplicate URLs and the final set of 100 URLs was used for analysis. Further, authors along with domain experts performed fact-checking of URLs and manually categorized 100 URLs into legitimate and non-legitimate based on contents, contact information available on the website. Also, the authors have considered URLs from the CoAID [26] dataset after verifying them with domain experts. The authors observed that maximum legitimate URLs are from .gov, and .edu domains while non-legitimate URLs are from other domains. Further, URLs are pre-processed to get cleaned data. The process begins with the grouping of data from web URLs and generated words. Regular expressions are used to remove punctuations, and numbers from the data. The pre-processing technique sanitization was used to transform the words into lower case, followed by the stop-word removal technique which is applied to reduce the corpus size by removing unnecessary words not providing any useful information. Also, all the single characters and duplicate data are removed to further minimize the corpus size and build quality information. In addition, 2 wordlists are developed manually containing Bag-of-Words (BoW) with sentiment polarity of 452 positive words, and 341 negative words by using healthcare URLs after carefully understanding the meaning of each word, especially the core medical terms by referring to MeSH (Medical Subject Headings) dictionary which explains the biomedical terminologies [27] and taking expert opinion about the usage of those words. Table II displays the sample words list of manually labeled sentiments of words.

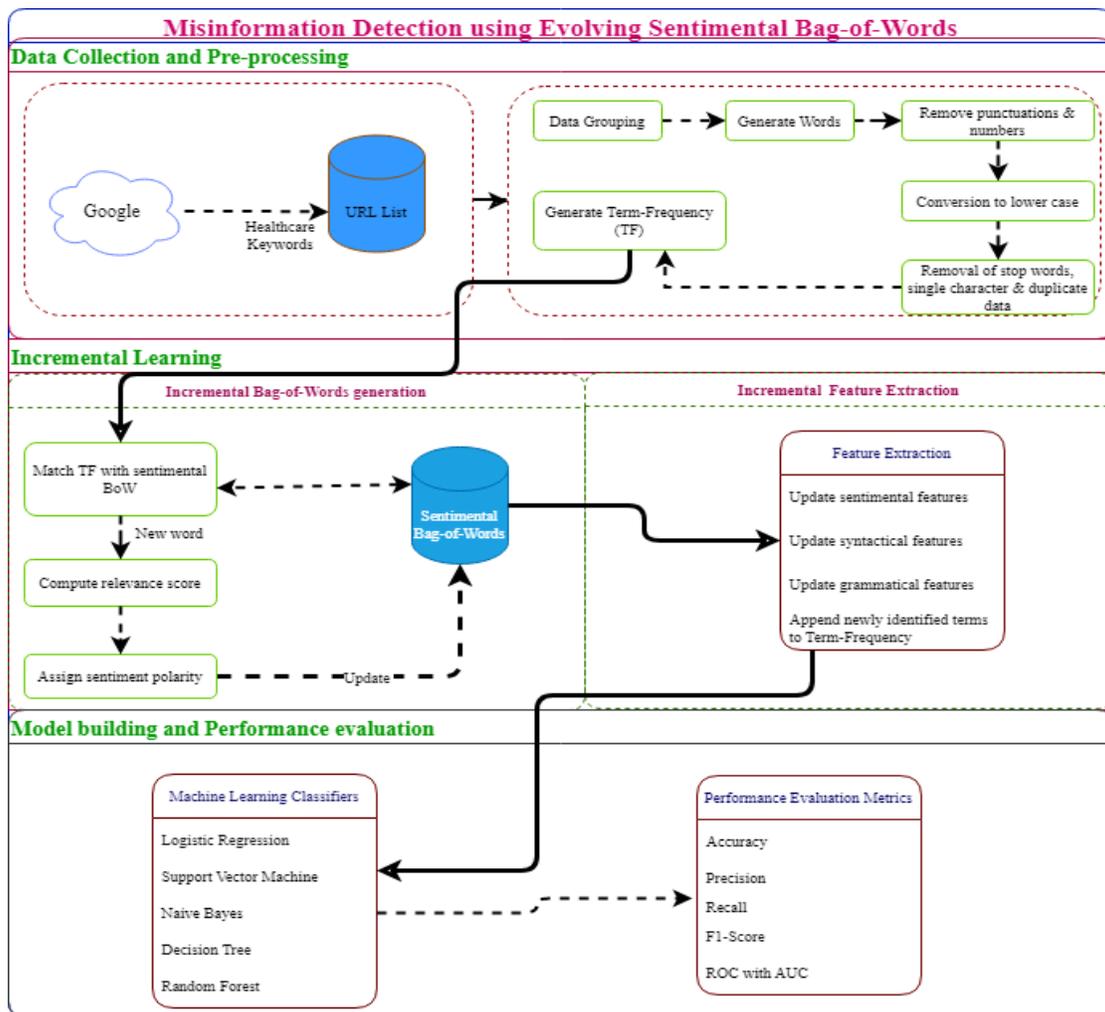

Fig. 1. Process of Healthcare Related Misinformation Detection Model.

TABLE I. LIST OF KEYWORDS FOR GOOGLE SEARCH

Sr. No.	Keyword Name	Sr. No.	Keyword Name
1	Doctor	14	Consultation
2	Medical	15	Ambulance
3	Pharmacy	16	Medicare
4	Healthcare	17	Medi-claim
5	Chronic	18	Surgery
6	Disease	19	Damage
7	Treatment	20	Specialist
8	Prevention	21	Kill
9	Therapy	22	Chemical
10	Medication	23	Organ
11	Illness	24	Infection
12	Clinic	25	Vaccine
13	Cancer		

TABLE II. SAMPLE OF MANUALLY DEVELOPED WORD LIST

Sr. No.	Positive Words	Negative Words
1	Survivors	Abnormal
2	Lifesaving	Scary
3	Protect	Depression
4	Painless	High-risk
5	Specialists	Illegal
6	Safeguard	Fatigue
7	Relieving	Crime
8	Efficacy	Die
9	Support	Funeral
10	Raised	Ruth
11	Inspiring	Fear
12	Careful	Threatening
13	Cure	Damaged
14	Ability	Abolished
15	Better	Harm

**B. Incremental Learning**

Upon getting cleaned data, the term-frequency is generated and matched every term with the sentimental “Bag-of-Words”. Here, each term is referred to as a word. These newly arriving words are assigned sentiment polarity using the sentiment relevance score function; thus, updating the sentimental bag-of-words incrementally. This function generates synonyms and antonyms of the newly arriving word using the WordNet library of the NLTK tool. To find the closeness between newly arriving words and their synonyms and antonyms authors have used Jaccard similarity co-efficient. The Jaccard similarity coefficient of sets A and B is given by  $|A \cap B| / |A \cup B|$ . It is the fraction of the intersection of the number of elements of A and B to the number of elements of their union. It is used in various applications like mail filtering [28] to find the co-occurrence of values of all pairs of words in an email. Further, the threshold value was chosen after carefully analyzing the synonyms and antonyms generated. For example, for the word “good” the relevant words above 0.5 were honourable=0.9, beneficial=1.0, effective=1.0, etc. while below 0.5 were like satisfactory=0.4, fair=0.33, etc. Hence, the threshold of 0.5 was decided manually to assign sentiment polarity to a new word. However, for the first batch of 10 URLs, it was observed that Bag-of-Words was upgraded with the most relevant words, but during the second batch of 10 URLs, there was an addition of a few irrelevant words. Hence, authors again sensibly tried identifying the best applicable threshold value which could fetch only relevant synonyms or antonyms of the word. This was possible with a change in the threshold of 0.95 instead of 0.5. After using a new threshold value of 0.95, for the next batches of URLs, it showed a good collection of relevant words. Therefore, choosing the right threshold value can improve the collection of the most relevant sentimental “Bag-of-Words” in the healthcare domain. This process continues in an incremental fashion. The relevance score function is defined as shown in Fig. 2. Next, incremental learning is adopted to update features. This is achieved by fetching the URLs at time T2. Thus, URL TF has

computed again at time T2 and these terms are matched with bag-of-words to get the final list of terms. These newly arriving terms are appended to TF. Also, based on changed bag-of-words the sentimental, syntactical, and grammatical features are extracted and updated. The syntactical features consist of word count and sentence count. Grammatical features contain a number of verbs, nouns, adverbs, adjectives, and pro-noun. While sentiment-based features include a number of positive, negative words, the percentage of positive and negative words. The final set of 11 features is as listed in Table III.

**C. Model Building and Performance Evaluation**

To build the model, five different state-of-the-art supervised classification algorithms Logistic Regression (LR), Support Vector Machine (SVM), Naïve Bayes (NB), Decision Trees (DT), and Random Forest (RF) are used. Further, the performance of the model is evaluated based on confusion matrix, accuracy, precision, recall, f1-score, ROC, and AUC.

```

Input: word
Output: sentiment score for the word
Algorithmic Steps:
1. Procedure relevance_score (word)
2. Generate synonyms and antonyms for a given word
3. For every synonym 'w'
4.   jd = Jaccard Similarity Coefficients (word, w)
5.   if jd <= 0.95, append w with "word" sentiment
6.   else if jd > 0.95, append w with "word" antonym
7. For every antonym w
8.   id = Jaccard Similarity Coefficients (word, w)
9.   if id <= 0.95, append w with "word" antonym
10.  elseif id > 0.95, append w with "word"
    sentiment
11. End Procedure
    
```

Fig. 2. Function to Compute a Relevance Score.

TABLE III. DESCRIPTION OF EXTRACTED FEATURES

Feature Type	Feature	Description
Syntactical Features	w_count	Total number of words
	s_count	Count the number of sentences in the document
Sentiment Features	pw_count	Positive Words Count
	nw_count	Negative Words Count
	perc_pos	Percentage of Positive Words
	perc_neg	Percentage of Negative Words
	sen_net_score	Sentence Net Score
Grammatical Features (POST)	verb_count	Count of verbs in the document
	nouns_count	Count of nouns in the document
	adverbs_count	Count of adverbs in the document
	adj_count	Count of adjectives in the document
	pronoun_count	Count of Pronouns in the document

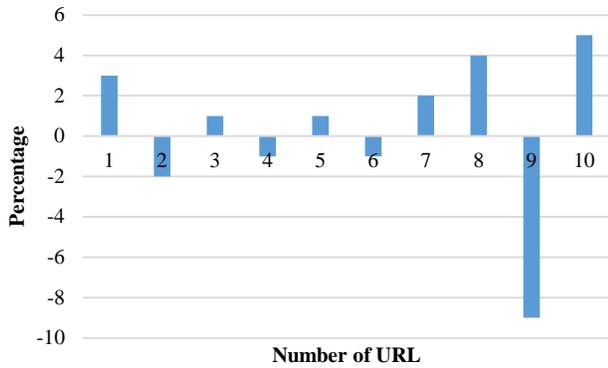

Fig. 8. Fluctuation in the Percentage of Misinformation in Updated URLs.

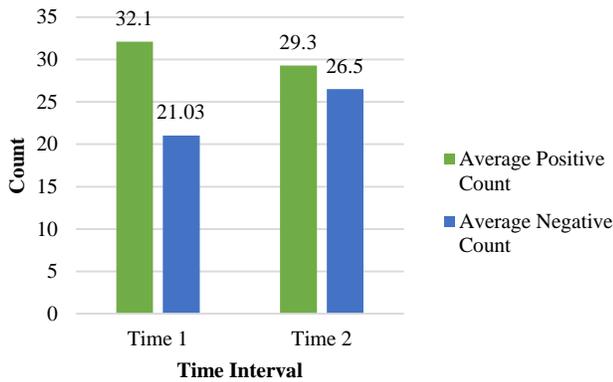

Fig. 9. An Example Legitimate URL showing Average Positive and Negative Word Count after First (TIME 1) and Second (TIME 2) Iteration.

Fig. 9 depicts the updated positive and negative word count in the URL. The experimental results show that the URL has more positive words and fewer negative words in the first iteration whereas showed an increase in the number of negative words in the second iteration and a decrease in the number of positive words. The experimental results among updated URLs i.e. URLs with changes in textual contents in the second iteration show 61% of average positive count and 39% of the average negative count. It is observed that 39% of negative changed URLs showed a change in misinformation. Fig. 8 shows this fluctuated change in misinformation. Fig. 10 and Fig. 11 display the sentiment median values and standard deviation of sentiment values for legitimate and non-legitimate URLs respectively. It is observed that in legitimate URLs the positive sentiment values are more compared to negative sentiment values. In non-legitimate URLs, the negative sentiment values count is superior to positive values. Fig. 12 depicts the increase in Bag-of-Words for the first batch of 10 URLs. Fig. 13 shows the increase in Bag-of-Words after 10 batches of 10 URLs each. Also, the same URLs were scraped again on 3rd April 2021 to observe the increase or decrease of words in sentimental “Bag-of-Words”. Thus, it can be seen from Fig. 14 that the Bag-of-Words evolved over time reaching up to 1069 words at T1 and 1663 words at T2. Fig. 15 shows the total number of positive and negative words generated at time T1 and dT2, respectively.

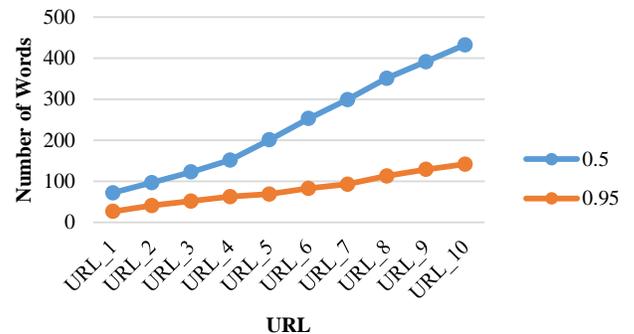

Fig. 12. Increase in Bag-of-Words based on Threshold Value.

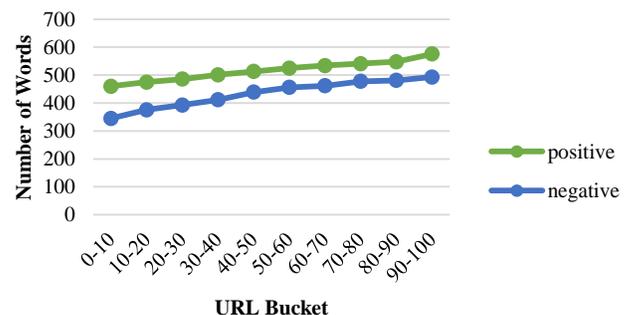

Fig. 13. Increase in Sentiment Words per 10 URLs.

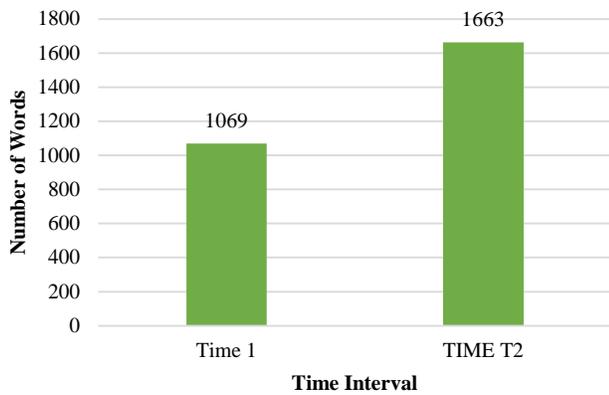

Fig. 14. Total Number of Words Generated at Time T1 and T2.

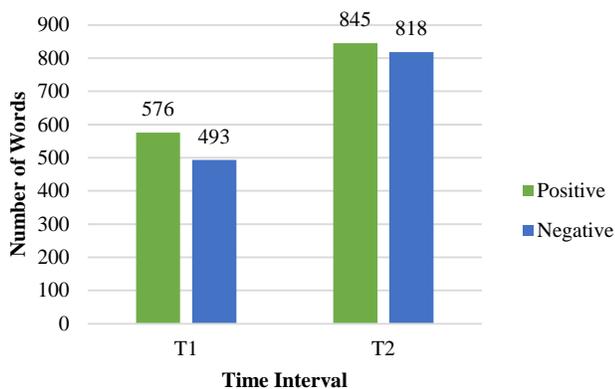

Fig. 15. Total Number of Positive and Negative Words at Time T1 and T2.

### A. Theoretical Implications

While there is a reasonable volume of earlier research to detect misinformation on the web in the healthcare domain, these methods do not adapt to the recurrently changing data and are thus unable to encounter the sentimental changes occurring in the data. Theoretical Implications of the study are as follows. First, the study describes a facet of incremental learning and sentiment analysis to generate evolving sentimental “Bag-of-Words” in the healthcare domain. This

theoretically generated knowledge can be suitably implemented in the other domains like politics and business which are more susceptible to misinformation generation. Hence, this is an important theoretical contribution. Secondly, the study defines a new aspect by developing sentiment analysis and incremental learning models for false information detection. The study presents a collaborative process of incremental learning and sentiment analysis to classify healthcare-related web URLs as legitimate or non-legitimate. The authors have experimentally verified and confirmed the importance of sentimental features and incremental learning in false information detection. These results have exposed new factors of false information change and its detection, proposing an incremental learning and sentiment features-based model. These observations have certainly augmented the knowledge base of misinformation detection in the healthcare domain.

### B. Practical Implications

Practically, results indicate that this evolving Bag-of-Words can be used to find the sentiment intensity of the articles in the healthcare domain. The sentiment shifts of the patients can be studied using “Bag-of-Words” in the healthcare domain. Thus, these outcomes could help Researchers, Scientists, Doctors, Patients, and Organizations to employ them to detect false misinformation and mitigate it.

### C. Comparison with Existing Research with SVM Model

Table IV shows the comparison of studies in healthcare domain. It can be seen that proposed model have outperformed the existing techniques.

TABLE IV. COMPARISON OF PROPOSED MODEL WITH EXISTING STUDIES

Ref. No.	Domain	F1-score
[29]	Healthcare	0.75
[30]	Healthcare	0.64
<b>Proposed Model</b>	<b>Healthcare</b>	<b>0.84</b>

TABLE V. CLASSIFICATION RESULTS OF MODELS BASED ON ACCURACY (IN %)

Features Combination	Logistic Regression	SVM	Naïve Bayes	Decision Tree	Random Forest
Syntactical Features	37.10%	37.10%	40.10%	51.61%	56.00%
Syntactical Features + Sentiment Features	73.33%	76.66%	73.33%	53.33%	63.33%
Syntactical Features +Sentiment Features+ Grammatical Features	76.6%	80%	73.33%	56.66%	66.66%

## V. CONCLUSION AND FUTURE ENHANCEMENTS

In this research, we have proposed a method to detect healthcare-related misinformation using sentiment-based incremental learning approaches. This framework can help to analyze and identify misinformation using central features such as sentiments and other features consisting of syntactic and grammatical features. A relevance score function assigns the sentiment to the newly arriving words using the Jaccard distance measure. The model was built with five machine learning classifiers viz. LR, SVM, NB, DT, and RF. The results show that SVM has outperformed other classifiers with an accuracy of 80%. The decision tree classifier showed the lowest accuracy of 56.66%. Thus, it was observed that incremental learning plays a crucial role in determining the consistency of correct information by detecting changes in the percentage of misinformation at different time intervals.

## VI. LIMITATIONS AND FUTURE ENHANCEMENTS

The research has several benefits in terms of finding misinformation in the healthcare domain, but it does have certain limitations too. Firstly, though authors have used the BoW approach, the n-gram approach can be used to correctly predict the sequence of occurrence of words. The second limitation is the dataset size. It is a need to increase the dataset to thousands to verify the change in accuracy.

In the future, the authors are willing to dynamically assign threshold to the sentiment relevance score which may lead to more accurate Bag-of-Words, and later build the model using incremental clustering techniques to handle the real-time data.

**Abstract**—The Covid-19 pandemic has intensified the online learning activities, which have becoming the most crucial platforms for learning sessions. With these online learning activities, a major concern arises particularly on the security of educators and students' data. Every element in an online learning system can be a potential target of hacking or attack. Therefore, this paper examines students' awareness of data security in online learning. Google forms have been used to gather the students' feedback. Forty-two (42) students, involving the secondary school, pre-university and university students, responded to the survey questions. The results show that most of the respondents are well aware of how to keep their data safe in online learning. It is discovered that the level of awareness about data security in online learning amongst the students is commendable. The findings of this study indicate there are various ways to secure students' data especially during online learning.

**Keywords**—Covid-19; IR4.0; education 4.0; online learning; data security

## I. INTRODUCTION

The massive spread of Covid-19 virus has disrupted many human activities all around the globe. One common daily activity, which has been significantly affected by Covid-19, is education. The Covid-19 pandemic has caused UNICEF, WHO, and IFRC to appeal when the virus situation spreads rapidly, schools must be closed in the 'Prevention and Control of Covid-19' spreading in schools [1]. On 8th April 2020, it was reported that 220 million post-secondary students across 175 countries [2] had experienced severe disruptions to their education given that their colleges and universities were forced to shut down in order to stop the spread of the virus [3]. This represents 13 percent of the total number of students affected globally [4]. Hence, most educational institutions have opted for online learning platforms to ensure that learning sessions continue to operate within the pandemic [5, 6].

Online learning is "a type of delivery method used in distance education that allows synchronous and asynchronous exchanges of resource over a communication network" [7] by using various devices with internet access such as mobile phone, laptops, and computer [8, 9]. Online learning is seen as

a tangible form of technological development that is not restricted to the current 4.0 Industrial Revolution (4IR) only [10]. Haseeb (2018) denotes that online learning is one of the important aspects for future education or Education 4.0 to produce highly creative graduates [11]. The Education 4.0 is a global framework introduced by the World Economic Forum (2020) to ensure a high-quality education within the context of the 4IR and the future of the new global economy and society [12]. For example, the 4IR has observed that learners play a critical part in their learning activities, as well as a flexibility in the method and ambience of learning provided to them in many online classes given by higher learning institutions [13].

It is apparent that the current and future of education relies greatly on the use of advanced technology and automation whereby online learning plays a central role [14]. Fig. 1 illustrates the major trends of Education 4.0.

In fact, the Covid-19 pandemic has brought about tremendous challenges on students having to go through online learning sessions [15]. According to Chung et al. [16], the pandemic's quick shifts have had a significant impact on students and lecturers at higher education institutions critically. Many lecturers and students in schools all around the world have expressed their frustrations with adopting online learning platforms for teaching and learning. The ramifications of this epidemic are unexpected, according to Shahzad et al. [17], and it has transformed the education system into a new teaching and learning paradigm.

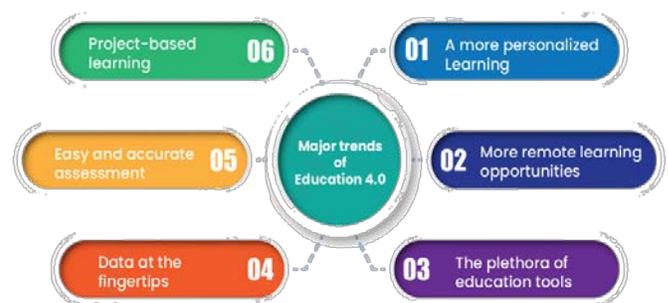

Fig. 1. Major Trends of Education 4.0.

Indeed, various aspects of the new education system such as the curriculum, the role of educators, student positions as well as assessments have been modified to cope with current trends [18, 19]. For instance, educators need to fill in students' data and update them constantly. Students, on the other hand, need to access their online learning platform persistently to obtain information and instructions related to their assignments and exercises. When everything is done online, the data security of educators and students has becoming a crucial concern. This is especially true when the users commit malicious acts and access the data illegally. These malicious acts include instilling viruses and malicious code such as worms and Trojan horses into the device with the intent to steal users' information. Every component of an online learning system is vulnerable to hackers or attacks.

Data security is to protect valuable and sensitive personal data such as email and bank information. Valuable data comprise of educational information that collected, stored and managed by universities as well as confidential information such as financial data, phone numbers, and sensitive personal information about students' personal life and family data are the goldmine for hackers. In data security, the processes and technologies should be used to safeguard the data is a crucial element in protecting personal data at best. The created, collected, stored, and exchanged data is a valuable asset. Safeguarding data from corruption and unauthorized access by internal or external hackers protects individual's data from being stolen and used without his or her consent and knowledge.

Researchers have devised a number of remedies and methods to increase security in online learning in response to rising dangers, particularly during current epidemic. This paper reports on a study that investigated students' understanding on data security as they are taking online learning during the Covid-19 pandemic. The reminder of this paper is organized as follows; Section II presents related works on online learning and data security, Section III describes methodology, Section IV depicts results and discussion, and Section V concludes the paper.

## II. RELATED WORK

### A. Online Learning

Online learning refers to the teaching and learning method carried out in a web-based environment [20]. With access to the internet, the learning process can be conducted anywhere and anytime with the use of gadgets or online platforms which are accessible by any users. There are various teaching and learning applications available on the internet such as Google Classroom, Google Meet, Microsoft Teams, Skype, WhatsApp, and Zoom. Most educators and students depending on their own teaching and learning needs utilize these applications.

The occurrence of the Covid-19 pandemic has instigated the implementation of online learning on a vast scale worldwide. Interactions between educators and their students have now changed from a face-to-face to screen mode. This unexpected transition has led to many challenges encountered by both the educators and students. Some students are facing internet connectivity problems and lack of digital devices for

their virtual learning [21]. Likewise, most lecturers are experiencing various challenges including financial, physical, and mental issues [22]. Most of them are grappling with the demands of online learning lessons and the advanced technologies in their attempt to ensure that learning takes place without disruption [20].

### B. Security in Online Learning

Security in online learning relates to the safeguarding of resources against deliberate or unintentional usage [23]. According to previous research, there are three main needs for security: confidentiality, integrity, and availability [24], as shown in Fig. 2.

Confidentiality refers to the protection of sensitive information against unauthorized access as well as the absence of illegal dissemination [25]. Many online learning environments have a huge number of users (among them students, visitors, instructors, tutors, and administrators). To protect access to the proper user, both a login mechanism and a robust delimitation designating registered users and user groups are necessary [24]. Security precautions such as authentication and encryption are widely used to secure personal information.

Integrity, a critical element of security, refers to "the protection of data from intentional or accidental unauthorized changes" [24]. It also denotes "the absence of improper system alterations" [25]. It assures that "information and data have not been accidentally or maliciously modified or destroyed, and are in accurate, correct, and complete original form" [26]. Access control is the key to maintaining integrity in the online learning environment [24].

Availability means the readiness for correct service [24]. It connotes that any authorized users whenever needed can access an online learning system [24]. Additionally, it assures that "information and communication resources are readily accessible and reliable in a timely manner by authorized persons" [26]. Availability can be destroyed mainly by denial of service and/or loss of data processing capabilities [24].

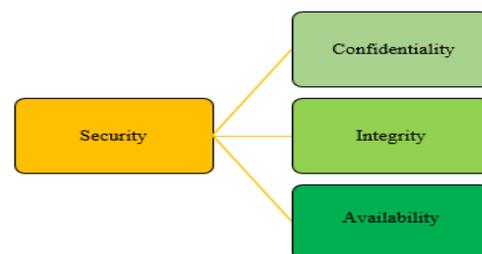

Fig. 2. Basic Requirements of Security.

## III. METHODOLOGY

Google forms questionnaire was used to acquire feedback from students in this study. The questions were designed to measure the level of awareness among students on their understanding regarding data security in online learning. A total of 42 students responded the survey. The respondents include secondary school students, pre-university students, and university students. The methodology for conducting this research is shown in Fig. 3.

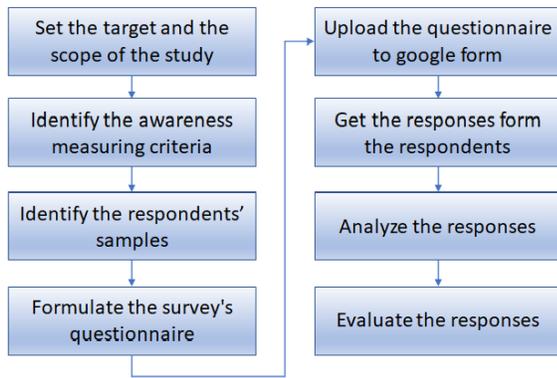

Fig. 3. Methodology.

This paper targets to measure the students' awareness level and practice of data security while they use online learning. The students' awareness level has been measured based on the following indicators:

- General awareness about online security.
- Using anti-virus on the device that they use for online learning.
- Using two factor authentications when logging in to the online learning application.
- Practicing logging out of online learning applications after using them.
- Using their own personal device individually or sharing the device with other students.
- Awareness about the confidentiality of the data that the student share in online learning.
- Using common information such as birthday, identity card (IC) number, matric number as the passwords for their online learning software.
- Using online learning platform on public computers or Wi-Fi such as in the library.
- Sharing the information in trusted website only.

#### IV. RESULT AND DISCUSSION

Forms Questionnaire. Fig. 4 shows the gender of the respondents. As the figure depicts, 71.4% of the respondents are male while the remaining 28.6% are female.

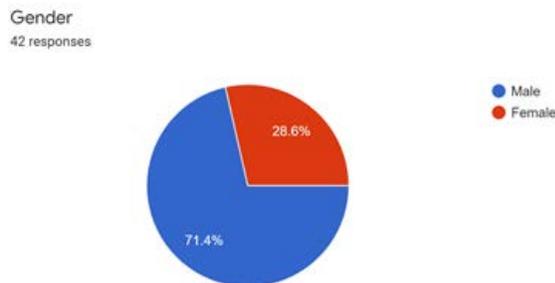

Fig. 4. Gender of the Respondents.

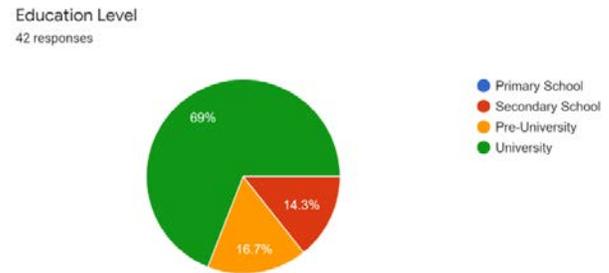

Fig. 5. Educational Level of the Respondents.

Fig. 5 exhibits the education level of the respondents whereby 69% of the respondents are university students, 16.7% are pre-university students, and 14.3% are secondary school students.

Fig. 6 displays the respondents' awareness about online security. The highest percentage of students, 50% of them, is well aware about online security. On the other hand, the lowest percentage, 2.4% of them, represented respondents who are unaware about online security. Meanwhile, the chart shows that almost 4.8% of the respondents have little awareness, 16.7% have awareness, and 26.2% have excellent awareness about online security.

As can be depicted from the figure, the majority of respondents are aware about online security, which indicates a positive result. However, it will be a lot better if all the respondents are very well aware about online security since this will prevent them from any malicious actions such as data theft.

Fig. 7 shows whether or not the respondents have practiced online security in online learning. The highest percentage of the respondents, almost 42.9% of them, has practiced online security well. On the other hand, the lowest percentage of them, almost 2.4%, are unaware about practicing online security. Meanwhile, the chart shows that also 4.8% have practiced a little, 19% have practiced, and 31% have very well practiced the online security. An overall result indicates that most of the respondents have at least used an anti-virus in their electronic devices in order to protect their devices from virus such as Trojan [27]. However, it is speculated that half of the respondent have never practiced online security. For example, they do not used two factor authentications to secure third party platforms.

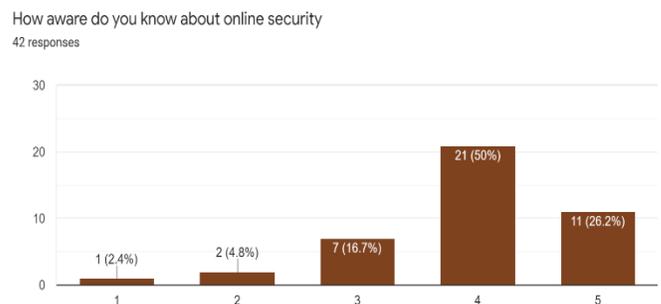

Fig. 6. Awareness about Online Security.

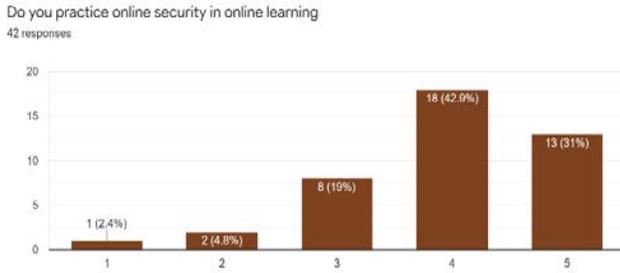

Fig. 7. Respondents Practice Online Security in Online Learning.

Fig. 8 shows that 83.3% of the respondents have used antivirus software during online learning. On the other hand, 16.6% respondents have not used any anti-virus software and that they are aware of the importance of it particularly in online learning. The pie chart clearly depicts that majority of the respondents have used anti-virus. This is due to the fact that anti-virus is a common software that can be easily installed in most devices.

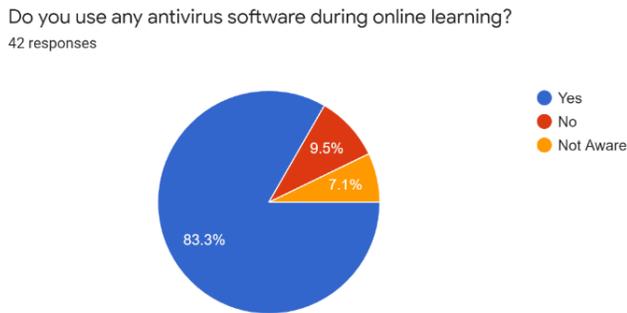

Fig. 8. Use Antivirus Software during Online Learning.

Fig. 9 shows whether the respondents log out of the online learning applications software after using them. It is obvious that half of the respondents log out of the applications software after using them while 40.5% of them do not. 9.5% of the respondents are not sure whether they log out after using the applications software or not.

It is important to note that 50% of the respondents, who log out from the applications software after using them, are those who are very much aware of online security and thus, logging out after using the applications has become a common practice to them. These respondents understand the risks of not logging out of the applications software. For example, they are aware of the risks when someone else uses their devices and gets an access to their personal information like e-mails. It can be concluded that another 50% of the respondents, who do not log out of the applications software, are less mindful and unconcerned of the effects of their actions.

Fig. 10 illustrates the respondents' answers on whether or not they have used two factor authentications during their online learning. The results depict that 52.4% of the respondents have used two factor authentications for their online learning platform. On the other hand, 35.7% of them have not used two factor authentications for online platform while the remaining 11.9% are not aware about using two factor authentications for online learning platform.

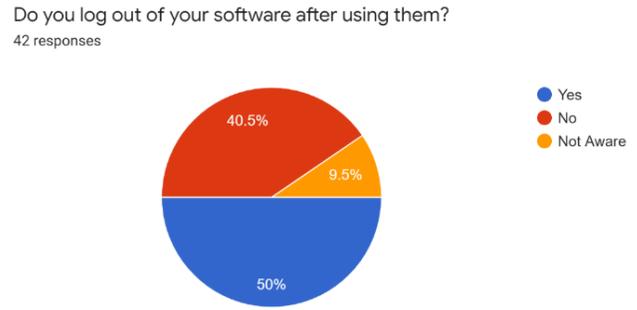

Fig. 9. Log out of Software after using them.

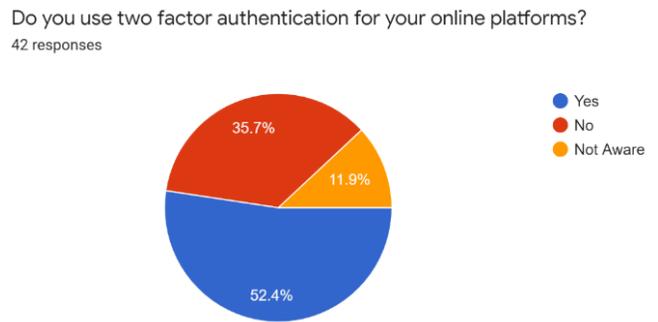

Fig. 10. Use Two Factor Authentications for Online Platforms.

This indicates that some respondents are totally not aware of the function of two factor authentications. This is rather dangerous as other users using their e-mail's accounts or passwords can easily access their accounts.

The respondents were asked whether they have individually used their own devices or they have shared their own devices with others during online learning. Fig. 11 presents the results in which approximately 69% of the respondents used their own personal devices, whilst, 23.8% indicated that they shared their devices with others during online learning. The remaining 7.1% of the respondents are not sure whether they have used their own device or they have shared devices with others during online learning.

The results indicate that it is better for the respondents to use their own personal devices instead of sharing the devices with others as this can avoid from sharing their data with others. By having their own devices, the respondents can also manage their files more strategically and efficiently. If the respondents share their devices with others, there is a possibility that they may unintentionally expose their confidential information.

Fig. 12 shows whether the respondents are aware about the data that they share in online learning including the privacy of the data like personal information, pictures and location. Majority of the respondents, 66.7%, are aware about the data their share in online learning. Conversely, 33.3% of the respondents are not aware about the of the privacy data they share in online learning.

Do you use your own device or do you share your device with others during online learning?  
42 responses

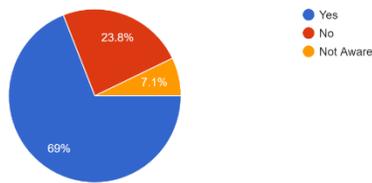

Fig. 11. Use Own Device or Share Device with others during Online Learning.

Do you use common information such as birthdays, ic number, matric number as passwords for your online learning software's password?  
42 responses

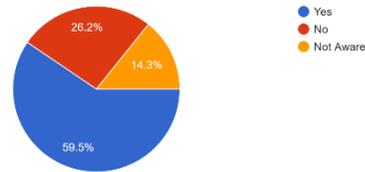

Fig. 13. Use Common Information as Passwords for Online Learning Software Password.

Are you aware of the data you share in online learning regarding the privacy of the data? (example-personal information, pictures, location etc.)  
42 responses

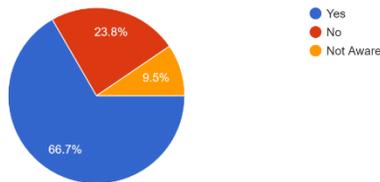

Fig. 12. Aware of the Data you Share in Online Learning.

The respondents should be aware of the data that they share in online learning especially when it involves confidentiality of the data. This is because hacker could either use the respondents' information to blackmail them or sell their data to other parties. It is recommended that 33.3% of the respondents to take classes about data security or use self-reading to gain more information about the importance of protecting data especially during this pandemic.

Fig. 13 shows whether the respondents use common information such as birthday, identity card (IC) number, matric number as the passwords for their online learning software. 59.5% of the respondents have been using common information for their online learning software's password. This is probably because it is easier for the respondents to remember their password whenever they want to log in into their accounts. 26.2% of the respondents have not used common information for their online learning software's password.

This indicates that the respondents are alert that most hackers these days can easily guess users' password particularly their personal data such as birthdate or real name as their passwords. Next, 14.3% of the respondents are not aware or unsure if they use common information for their online learning software's password.

Fig. 14 shows whether the respondents have ever used online learning platform on public computers or Wi-Fi such as in the library. The figure shows that 54.8% of the respondents have not used online learning platform on public computers or Wi-Fi such as in the library. This is generally because of the pandemic that forces the students to do their online learning at home [28]. 38.1% of the respondents have used online learning platform on public computers or Wi-Fi such as in the library or even McDonald's.

Have you ever use online learning platform on public computers or Wifi such as in the library?  
42 responses

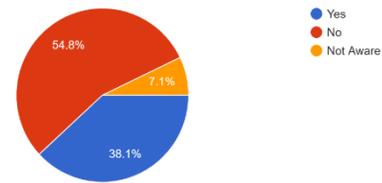

Fig. 14. Use Online Learning Platform on Public Computer or Wi-Fi.

This indicates that some of the respondents have been using the university Wi-Fi or even library during this pandemic. The remaining 7.1% of the respondents are not aware whether they have ever used online learning platform on public computers or Wi-Fi in public places such as in the library.

Fig. 15 presents the respondents' answers on whether or not the website in which they share their information is trusted and legitimate. The respondents' awareness helps to avoid sharing important information with irresponsible people.

The results show that 66.7% of the respondents are aware that the websites which they share information is secure and legit, while 33.3% of the respondents are not aware about it. This result is disturbing given that generally 1 out of 3 respondents is not aware about the danger of the websites that can be potentially a scam to steal important information, money, and private information.

Are you aware if the websites that you share your information is legit?  
42 responses

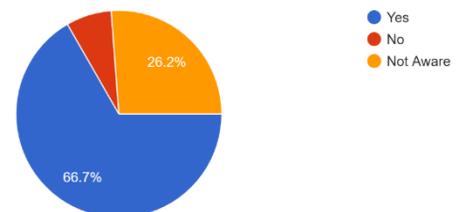

Fig. 15. Awareness if the Websites that you Share your Information is Legit.

## V. CONCLUSION

The demands of the use of technology, especially during the Covid-19 pandemic, have led to the growth of end user devices and the widespread of online learning around the globe. Indeed, these massive applications of online learning bring along with them various security risks to many users. Nevertheless, it is safe to say that online learning is still at its premature and impulsive phase because most educators and students alike are still struggling in getting themselves familiar with its applications and operations. Concurrently, its providers are still taking the security risks of online learning lightly although it has become the most vital means of learning in the world today. It is important to note that most providers had to opt for an impulsive execution of the information and communication technology without taking into consideration relevant security concerns such as two-factor authentications. This was deliberately done to ensure that learning continues regardless the challenges experienced by students and educators during the pandemic. Given this scenario, it is discovered that most of them are not concerned about the importance of online security. This is evidenced in the study in which students at various levels of education were found to be insensitive towards the crucial needs to protect data security when conducting online learning. It is recommended that the stakeholders, such as the Ministry of Higher Education and the university, to enforce on data security in online learning. Online talks and forums on the most effective ways of online learning security should be conducted for educators and students to enhance their awareness. Therefore, data security awareness among students is essential.

## ACKNOWLEDGMENT

We would like to acknowledge the Network and Communication Technology Research Group for the assistance and support they have provided. This survey has been conducted by UKM Students from TK2133-Data Communication and Telecommunication class.

**Abstract**—Automatic key-phrase extraction (AKE) is one of the most popular research topics in the field of natural language processing (NLP). Several techniques were used to extract the key-phrases: statistical, graph-based, classification algorithms, deep learning, and embedding techniques. AKE approaches that use embedding techniques are based on calculating the semantic similarity between a vector representing the document and the vectors representing the candidate phrases. However, most of these methods only give acceptable results in short texts such as abstracts paper, but on the other hand, their performance remains weak in long documents because it is represented by a single vector. Generally, the key phrases of a document are often expressed in certain parts of the document as, the title, the summary, and to a lesser extent in the introduction and the conclusion, and not of the entire document. For this reason, we propose in this paper KP-USE. A method extracts key-phrases from long documents based on the semantic similarity of candidate phrases to parts of the document containing key-phrases. KP-USE makes use of the Universal Sentence Encoder (USE) as an embedding method for text representation. We evaluated the performance of the proposed method on three datasets containing long papers, namely, NUS, Krapivin2009, and SemEval2010, where the results showed its performance outperforms recent AKE methods which are based on embedding techniques.

**Keywords**—Key-phrase extraction; natural language processing; semantic similarity; embedding technique; universal sentence encoder

## I. INTRODUCTION

The explosive growth in the number of digital documents has prompted researchers to find effective ways to analyze and summarize all these documents [1]. AKE is one of the best document content analysis solutions. Researchers have used several techniques to improve the performance of key-phrase extraction [2]. Sentence embedding [3] is a recent technique that has been used to select key-phrases using a similarity measure [4]. Most of these methods perform less well, especially in long documents, because the document contains a large amount of information, which negatively affects its representation by a single vector. In general, most documents contain the title, abstract, introduction, and conclusion. These are the parts likely to contain key-phrases. The calculation of the similarity between the candidate phrases and the document must therefore take this factor into account.

The objective of this article is to propose KP-USE, a new, unsupervised method for key-phrases extraction from documents. KP-USE divides the document into five main parts:

title, abstract, introduction, body, and conclusion. It represents each part by a USE technique [5] as a sentence embedding technique, in which the semantic similarity between candidate key-phrases and document is based on the phrases proximity to these parts, giving preference to parts that often contain key-phrases.

The rest of the article is organized as follows. In Section 2, we discuss related works. The USE sentence embedding technique is presented in Section 3, and then we present the proposed method for key-phrase extraction in Section 4. We empirically evaluate KP-USE in Section 5. Finally, we conclude the article in Section 6.

## II. RELATED WORK

In this section, we will talk about the most important related work to automatic key-phrases extraction, and in addition, we will introduce sentence embedding techniques.

### A. Key-phrases Extraction Approaches

Over the past twenty years, many automatic methods of key-phrase extraction have been proposed. Siddiqi et al. in [6] classify these approaches into three sets, supervised, Semi-Supervised and unsupervised methods. Generally, the extraction by supervised approaches can be considered as a binary classification problem, where the candidate phrases are classified either as a key-phrase or a non-key phrase. While unsupervised methods rely on ordering candidate phrases based on calculating the score from one or more weights.

While Papagiannopoulou et al. in [2] suggested classifying these methods according to the approved techniques, methods based on statistics such as [7], [8], [9]. Graph-based methods such as [10], [11], [12]. Methods that use binary classification such as [13], [14]. Methods based on deep learning as [15],[16], [17] and methods based on embedding techniques such as [18], [19], [20].

### B. Sentence Embedding Technics

Sentence embedding is an efficient way to convert textual data into fixed-length multidimensional vectors. Sentence embedding methods can be classified into two categories: (i) non-parameterized methods such as SIF [21], uSIF [22], and GEM [23] which rely on a simple technique, by encoding the words that make up the sentence and averaging the resulting vectors as a vector representing the sentence. However, this technique neglects information about word order and sentence semantics. (ii) parameterized more complex methods and generally perform better than unparameterized models [24].

The popularity of encoders has led to a great evolution of these methods. Conneau et al. propose in [25] InferSent is a technique based on a supervised RNN model predicting the semantic relations between pairs of sentences. Universal Sentence Encoder [5] is a trained and optimized technique for short sentences and paragraphs, it is based on two encoder models, Transformer and Deep Average Network (DAN). Subramanian et al. propose in [26] a more complex model for learning sentence embeddings in a multitasking configuration. Reimers and Gurevych propose in [27] Sentence-BERT, which also uses a Siamese network to create BERT-based sentence embeds [28]. Generally, Parameterized methods outperform non-parameterized ones on many tasks, but they are computationally expensive and require more training time.

### III. UNIVERSAL SENTENCE ENCODER

Universal Sentence Encoder (USE) is a sentence embedding model that encodes a sentence or paragraph into a 512-dimensional vector. This vector encodes the meaning of the sentence and can therefore be used as input for NLP tasks such as document classification, key-phrase extraction, and textual similarity analysis.

#### A. USE Process

The idea of USE is to encode sentences into 512-dimensional vectors, via an encoder. These vectors are used in many NLP tasks. Depending on the errors made in these tasks, USE again reproduces vectors for these sentences. Fig. 1 shows the USE process.

The USE process begins with a tokenization operation, where sentences are converted to lowercase and tokenized into tokens. In the second step, USE encodes the sentence.

#### B. Encoder

USE offers two architectures for encoding the sentence. The first is based on a transformer consisting of six layers. Each layer has a feedback network preceded by a self-attention module that takes into account word order and context when generating each word representation. Fig. 2 shows USE architecture with transformer encoder.

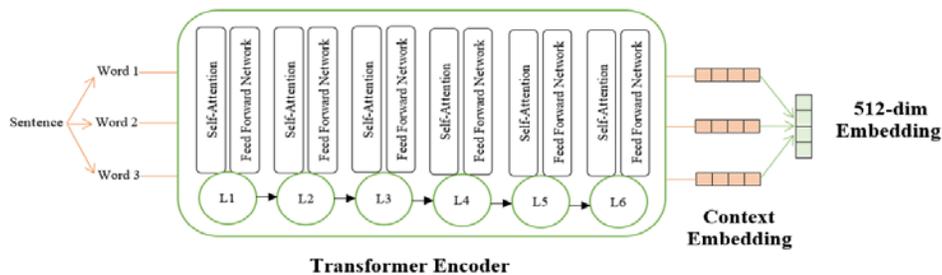

Fig. 2. USE Architecture with Transformer Encoder.

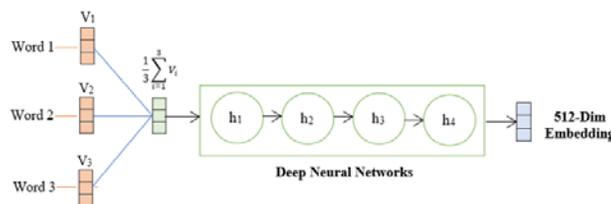

Fig. 3. USE Architecture with Deep Average Network.

The second is based on Deep Average Network (DAN) proposed by Iyyer et al in [29], where the vectors of the words in the sentence are averaged. The resulting vector is then passed through a 4-layer deep neural network (DNN) to obtain a vector of 512 dimensions. Fig. 3 shows USE architecture with DAN.

Generally, the result obtained through the transformer is very precise but requires more calculation time. It is therefore difficult to use for long texts, whereas DAN generates text encoding in less time but with less accuracy than a transformer.

#### C. Multi-task Learning

After the encoding of the sentences, either by transformers or by DAN. USE relies on multi-task learning (MTL) [30] to exploit commonalities and differences across tasks. This improves its learning efficiency and the accuracy of its predictions in the vector representation of sentences. Also, the authors of USE exploited a set of sources as training data. In addition to Stanford Natural Language Inference (SNLI) corpus [31], some web resources such as Wikipedia, web news, question and answer web pages, and discussion forums were also used.

Once USE has been trained, it can be used to represent any text, whether it is a phrase, a sentence, or a paragraph, with a 512-dimensional vector.

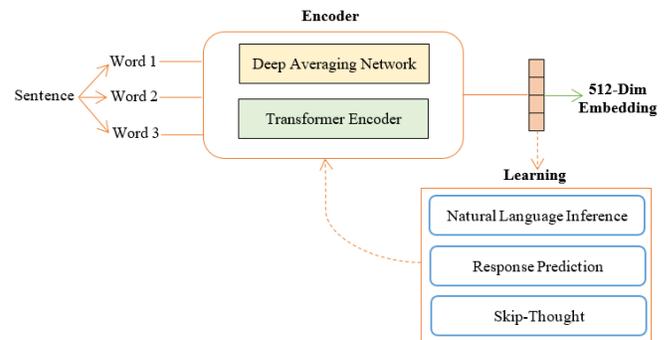

Fig. 1. Universal Sentence Encoder Process.

D. Evaluation of USE

To show that embedding USE provides a better text representation. The authors used semantic similarity in the different tasks of SentEval [32]. They also preferred using angular distance (Formula 2) as a measure of similarity rather than cosine (Formula 1) because, in their opinion, it gave better results.

$$sim(p, q) = \frac{\sum p_i q_i}{\sqrt{\sum p_i^2} \sqrt{\sum q_i^2}} \tag{1}$$

$$ang\_sim(p, q) = 1 - \frac{1}{\pi} arccos(sim(p, q)) \tag{2}$$

- **DataSet:** Binary classification and sentence similarity tasks in SentEval are used to evaluate the quality of sentence representations. Table I shows the datasets

TABLE I. DATASETS USED TO EVALUATE THE PERFORMANCE OF USE

Dataset	Number of samples	Task
Text REtrieval Conference (TREC) [33]	6 000	Question and answering
Customer Reviews (CR) [34]	4 000	Product reviews
Subjectivity Summarization (SUBJ) [35]	10 000	Subjectivity/Objectivity
Multi-Perspective Question and Answering (MPQA) [36]	11 000	Opinion polarity
Movie Reviews (MR) [37]	11 000	Sentiment
Stanford Sentiment Analysis (SST) [38]	67 300	Sentiment

TABLE II. USE PERFORMANCE ACCORDING TO EACH ENCODING MODEL

Dataset	USE DAN	USE Transformer
TREC	91.19	92.51
CR	80.97	87.43
SUBJ	92.65	93.87
MPQA	85.38	86.98
MR	74.45	81.44
SST	77.62	85.38

IV. KP-USE APPROACH

In this section, we propose KP-USE, which is a new method for key-phrases extraction from documents.

A. KP-USE Process

The KP-USE process presented in Fig. 4 shows that our method consists of five main steps:

used to evaluate the performance of USE. These datasets are used by USE authors to evaluate the two USE models, Transformer and DAN.

- **Results:** The experimental results showed the performance of USE in many tasks, whether in the transformer model or the DAN model. In Table II, we show the results of the two models for different datasets.

We also observe that encoding by transformer generally works better than encoding by DAN. On the other hand, the USE authors point out that the complexity of the transformer-based model is  $O(n^2)$ , while the DAN model is  $O(n)$ . Therefore, the transformer model is slower than the DAN model; especially with increasing sentence length.

Step 1: Extraction of candidate key-phrases;

Step 2: Split the document into five main sections;

Step 3: Vector representation of main sections and candidate key-phrases by USE;

Step 4: Calculate the score of each candidate key-phrase;

Step 5: Sorting the candidate key-phrases according to their score and extracting the phrases with the best score as key-phrases.

B. Candidate Key-phrases

The process of candidate key-phrases extraction (Fig. 5) begins with removing non-text data from the document, as well as converting all text to lowercase, and translating foreign words from the text into the language being studied. Then, the tokenization technique is used to convert the cleaned text into an array of tokens, to determine the grammatical category of each word using the Part-Of-Speech Tagging (POST) technique.

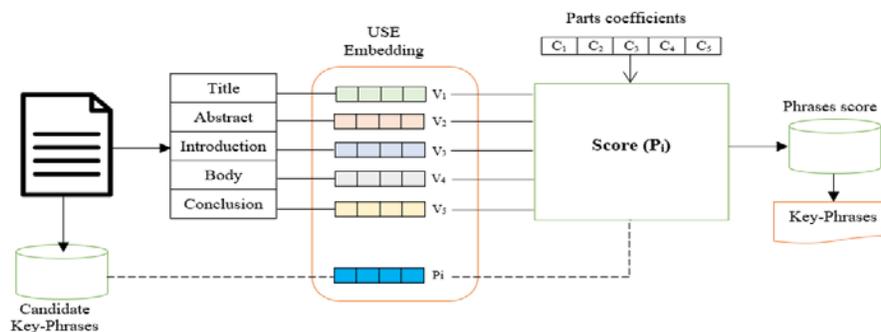

Fig. 4. The KP-USE Process.

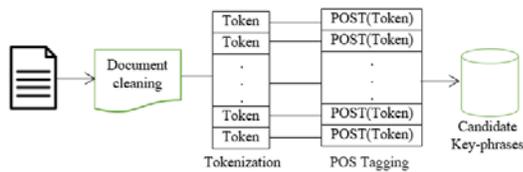

Fig. 5. Candidate Key-phrases Process.

Several AKE approaches have noted that key-phrases are noun phrases composed of one or more words such as [1], [39], and [40]. According to [19], the gerund form of a verb (VBG) can be used as a noun and the past participle form of a verb (VBN) can be considered as an adjective in the composition of key sentences. Therefore, (NN.\*|JJ.\*|VBN|VBG)\*(NN.\*|VBG) is the proposed pattern for candidate key-phrases extraction.

### C. Document Fraction

Through our analysis of more than 50 scientific papers, we noticed that most of the key-phrases are semantically similar to the title of the article and are often mentioned in the abstract and to a lesser extent in the introduction and the conclusion. Based on this result (Table III), we propose to split the document into five parts, namely title, abstract, introduction, and conclusion, while the fifth part comprises the rest of the document. To favor the parts similar to the key phrases. In Table III, we propose for each part a proximity coefficient which will be used when calculating the similarity between the candidate phrases and the document.

TABLE III. THE PROXIMITY COEFFICIENTS FOR EACH PART

Section	Average Similarity	Coefficient
Title	0.61	3
Abstract	0.68	3
Introduction	0.42	2
Body	0.14	1
Conclusion	0.35	2

Some documents may not have one of the five parts. In this case, KP-USE considers the proximity coefficient of the non-existent part to be zero. Therefore, there will be no effect on the calculation of the similarity between the candidate phrases and the document. Thus, we will be able to apply KP-USE to any document.

### D. Sentence Embedding

Our method proposes to extract key-phrases from the document based on the calculation of semantic similarity between the candidate key-phrases and the five parts of the document that have been identified in Table III. Before calculating the similarity, we must first represent the phrases candidate and the five parts by vectors. For this, we exploit USE as an embedding technique to obtain vectors of 512 dimensions. We test USE for encoding models, Transformer and DAN, to see which works best.

### E. Candidate Key-phrase Score

The score of any candidate key-phrase is expressed by its semantic similarity with the document. This score is calculated based on the similarity of the candidate phrase to each of the

five parts of the document, which is calculated by Formula 1. To exploit the proximity coefficient of each part of the candidate phrase, KP-USE uses Formula 3 to calculate the score for each candidate key-phrase.

$$Score(P_i) = \frac{1}{\sum_{j=1}^5 C_j} \sum_{k=1}^5 sim(V_k, U_i) \times C_k \quad (3)$$

$P_i$ : The candidate key-phrase  $i$ .

$U_i$ : the vector that represents phrase  $i$ .

$V_k$ : The vector that represents part  $k$ .

$C_k$ : Coefficient of part  $k$ .

$C_j$ : Coefficient of part  $j$ .

### F. Key-phrases Extraction

After calculating the score for each candidate key-phrase, KP-USE ranks these statements in descending order based on the score. KP-USE allows the user to choose the number of key-phrases to extract. The highest-rated phrases as key-phrases in the document.

## V. EXPERIMENTAL EVALUATION

In this section, we will present the datasets that were used to evaluate KP-USE. Additionally, we will verify which of the two models exploited in USE performs better in AKE by evaluating their performance using the precision, recall, and F1-score metrics. Then, we compare the performance of our method with other AKE methods based on embedding techniques.

### A. Datasets

To evaluate the performance of our method, we used three datasets that are considered the most widely used in evaluating key-phrase extraction approaches, which are.

- NUS [41], is a set of scientific data, consisting of 211 conference papers where each paper contains between 4 and 12 pages. Keywords were identified by the volunteer students where each student was asked to read three articles and extract the keywords.
- Krapivin2009 [42]: It is considered one of the largest datasets in terms of number documents, containing 2,304 research articles in the field of computer science. The keywords of the articles were identified by the authors and checked by the reviewers.
- Semeval-2010 [43]: This is one of the most widely used data sets for evaluating keyword extraction approaches. It consists of 244 scientific articles belonging to the field of computer science, where the number of article pages varies from 6 to 8 pages. The keywords for each article are defined by the authors and professional editors. Table IV shows the statistics for the three datasets.

The most important feature of the datasets used is that they contain scientific papers consisting of 4 and 15 pages, i.e. each paper contains the five parts we have discussed in Table III will confirm the credibility of the results we will obtain.

TABLE IV. DATASETS USED TO EVALUATE KP-USE

Dataset	Type of doc	Docs	Language	Tokens per Doc	KP per Doc	Annotation
NUS	Full paper	211	EN	8398.30	11.00	Reader
Krapivin2009	Full paper	2304	EN	8040.74	6.34	Author
SemEval2010	Full paper	244	EN	7961.20	14.70	Author/Reader

### B. Evaluation Metrics

Several evaluation metrics are used in key-phrase extraction [44]. Researchers generally prefer three metrics, namely precision, recall, and F1 score because of their validity and ease of use. These are the same metrics we will use to evaluate KP-USE.

- Precision: To evaluate the precision of the approach, we use this metric. Its value is expressed as the proportion of correctly extracted key-phrases compared to the total number of extracted key-phrases. To calculate the precision, we use formula 4.

$$Precision = \frac{Correct\ KeyPhrases}{Extracted\ KeyPhrases} \quad (4)$$

- Recall: To evaluate the completeness of key-phrase extraction, we use the recall metric, which expresses the proportion of correctly extracted key-phrases among the author's or reader's selected key-phrases. To calculate the yield, we use formula 5.

$$Recall = \frac{Correctly\ Keyphrases}{Assigned\ Keyphrases} \quad (5)$$

- F1 Score: There is often an inverse interaction between precision and recall. When precision is high, recall is low. For this, the F1 score is used, to combine precision and recall. To calculate F1 score, we use formula 6.

$$F1\ Score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (6)$$

### C. Comparison of USE Models

To choose the appropriate encoding model for KP-USE, we experimented with extracting key phrases using both encoding models, Transformer and DAN. Table V shows the performance of KP-USE according to each model according to the F1-Score metric on the three datasets NUS, Krapivin, and Semeval2010 for top 5 (F1@5), top 10 (F1@10), and top 15 (F1@15).

From the results obtained, we find that KP-USE based on the Transformer model performs better than KP-USE based on the DAN model in all the datasets used. Although the complexity of the Transform model is higher than that of the DAN model, we prefer to use the Transformer-based model because it achieves promising results.

### D. Performance Comparison

We compare KP-USE with three methods which are also based on embedding techniques namely EmbedRank [45] is an unsupervised method that uses the Sent2vec [46] embedding technique for the representation of phrases and documents. SIFRank [18] is an unsupervised key-phrase extraction method based on the SIF [21] and ELMo [47] embedding model. The third approach is MDERank [20], this is an unsupported approach. It implicitly embeds position and frequency offset information by encoding the document using BERT embedding technique [48].

In general, the results obtained by KP-USE remain acceptable compared to the performance of the other methods at the level of long documents. Table 6 present these results.

TABLE V. KP-USE PERFORMANCE ACCORDING TO TRANSFORMER AND DAN MODEL

Model	NUS			Krapivin			Semeval		
	F1@5	F1@10	F1@15	F1@5	F1@10	F1@15	F1@5	F1@10	F1@15
KP-USE Transformer	0.07	0.08	0.10	0.10	0.14	0.14	0.15	0.20	0.19
KP-USE DAN	0.03	0.06	0.10	0.08	0.11	0.11	0.12	0.16	0.17

TABLE VI. KP-USE PERFORMANCE COMPARED TO EMBEDRANK, SIFRANK, AND MDERANK

Approach	NUS			Krapivin			Semeval		
	F1@5	F1@10	F1@15	F1@5	F1@10	F1@15	F1@5	F1@10	F1@15

KP-USE	0.07	0.08	0.10	0.10	<b>0.14</b>	<b>0.14</b>	<b>0.15</b>	<b>0.20</b>	0.19

## E. Discussion

KP-USE is an unsupervised AKE method that takes advantage of the USE embedding technique to represent text vectorially. KP-USE relied on splitting the text to focus the search for key-phrases in the parts that might contain them, and this split also helps to improve the embedding of the document because instead of just being represented by a single vector, each part is represented by a vector. What also characterizes KP-USE is that the similarity calculation takes into account the parts of the document which often contain key-phrases, unlike other methods which consider all parts of the document to be of the same degree of importance, which makes KP-USE more efficient than these methods, especially in long documents. KP-USE can also be applied to short documents, where the importance coefficient for any part that does not exist in the document is zero, so the similarity calculation between candidate phrases and the document is not affected. KP-USE performance could be improved even more if we could develop it to be able to predict key-phrases that are not mentioned in the document.

## VI. CONCLUSION

In this paper, we proposed KP-USE, an unsupervised method of extracting key-phrases from the document based on the USE embedding technique which uses the Transformer network model. Our method splits the document into five parts, namely title, abstract, introduction, body, and conclusion, to favor the parts likely to contain key-phrases while calculating the semantic similarity between the candidate key-phrases and the document. KP-USE was evaluated on three datasets continent of long documents, namely NUS, Krapivin, and Semeval 2010. F1-Score results showed that the performance of KP-USE was superior to the performance of unsupervised methods based on embedding techniques and on the calculation of semantic similarity to extract key-phrases. In the future, we will develop KP-USE to predict key-phrases not mentioned in the document.

**Abstract**—Among the category of nonlinear processes, the Continuous Stirred Tank Reactor (CSTR) is one popular unit that finds application in various verticals of chemical process industries. The process variables within the CSTR are highly interactive; hence developing control strategies become a laborious task as it can be viewed as a Multi Input Multi Output (MIMO) system. Often the CSTR is assumed as a Single Input Single Output (SISO) system and during the development of control strategies or algorithm, the main objective is on maintaining only a single process variable closer to its set point, even though many measured variables form part of it. On the contrary, when compared to a SISO system, the MIMO control includes sustaining different controlled variables at their appropriate set points concurrently; thereby achieving an improved efficiency. The components' concentration and the temperature inside the CSTR are highly interactive in nature and exhibit reasonably high non-linear steady state behaviour. Both the interaction and non-linear behaviours pose challenges to the overall system stability. A stabilizing Proportional + Integral (PI) controller employing Stability Boundary Locus (SBL) concept is designed for a CSTR which eventually encapsulates both the stability and closed loop performance in its design procedure and analysed through simulation in MATLAB with the results presented.

**Keywords**—Nonlinear process; interaction; multi input multi output control; closed loop performance; stability

## I. INTRODUCTION

A process industry consists of various process units coupled together to perform a process operation and hence they are typically Multi Input and Multi Output (MIMO) systems. However, to implement process control strategies, process units are treated as Single Input Single Output (SISO) systems [1,2]. The most important notion is in maintaining a particular process variable closer to the set point, although quite a few measured variables are part of it [3]. Generally, the interactions amongst those variables are not considered in the control system design. This results in the augmented use of energy and therefore upsurges the plant's operational costs. In contrast to SISO, the MIMO control objective performs to maintain quite a lot of controlled variables at their desired set points at the same time. For the control of MIMO systems, design technique

of single loop tuned controller can't be implemented directly due to the heavy interaction between the loops that inflict intricacies in the control system design. For a MIMO system two kinds of control system design exists. The first type is the multivariable control method, where a solitary control algorithm oversees the control of all interacting loops within the process therefore the fail-safe design becomes more complicated [4]. The second type is the Multiloop control, a kind of multiloop control of individual loop that demonstrates a natural immunity to the loop failure thereby resulting in an easy and potent fail-safe design. The interaction within the CSTR is phenomenal with the Biggest Log modulus Tuning (BLT) [5,6] been implemented earlier [7] and in this present work, the performance of the same CSTR system is analyzed by employing Stability Boundary Locus (SBL) concept through simulation in MATLAB. The SBL concept graphically defines a boundary in the parametric design plane of the controller, to separate the stable and unstable regions of a feedback control system. The value addition of this paper lies in implementing the proposed stabilizing PI controller employing the Stability Boundary Locus (SBL) concept to specify the choice of controller parameters that results in the stable operation of the chosen highly non-linear CSTR process.

The paper is structured as below. In the subsequent sections, related work and then the equations related to the CSTR model and parameters are provided, followed by the multiloop control scheme. The next section details the design steps involved in the MIMO systems to plot the stability boundary loci to calculate stabilizing PI controllers for all the varied operating points of the CSTR. Simulation results to validate the control performance of the proposed method followed by discussion and conclusion are provided afterwards.

## II. RELATED WORK

Nusret Tan et al. (2006) have proposed a method to compute all the parameters of a PI controller which stabilize a control system [8]. Hanwate and Hote (2014) have designed a PID controller for cart inverted pendulum system based on the concept of stability boundary locus [9]. A mathematical model of the DC motor control system has been derived by Praboo

and Bhaba (2014) based on the model fractional order PI{\lambda} controller using the stability boundary locus method to satisfy the required gain margin (GM) and phase margin (PM) of the system [10]. The work by Deniz et al. (2016) has introduced an integer order approximation method for the numerical implementation of fractional order derivative/integrator operators in control system based on fitting the stability boundary locus (SBL) of fractional order derivative/integrator operators and SBL of integer order transfer functions [11]. A generalized approach to identify all stabilizing PI controllers for processes with time delay that depends on modeling higher order plant transfer functions by a first order plus dead time model has been proposed by Kaya and Atiç (2016) from which the normalized form of the obtained model and controller transfer functions were used for plotting the stability boundary locus plane [12]. The computation of all stabilizing PI controllers for third order systems obtained using the Boundary locus and Kronecker summation method to guarantee the stability of a feedback system was proposed by Amarendra Reddy et al. (2017) [13]. The paper by Atic and Kaya. (2018) has proposed a method by which all PID controller tuning parameters, satisfying stability of any unstable time delay processes, can be calculated by forming the stability boundary loci [14]. A method based on stability region locus and the Mikhailov criterion for stability test has been proposed to determine the parameters of PI controllers to control a TITO (two-input two-output) NCS (networked control systems) with intrinsic and network induced time delays has been proposed by Mohamed-Vall (2021) [15].

### III. CSTR MODEL AND PARAMETERS

An irreversible first order exothermic reaction (A→B) occurring in a CSTR as presented in Fig. 1 is considered. A cooling jacket that surrounds the reactor get rid of the heat produced during the reaction. It is assumed that perfect mixing occurs within the CSTR and also any changes in the volume owing to the reaction are considered negligible. As per the above assumptions, jacket water tends to be perfectly mixed with a continual water hold up happening within the jacket and the weight of the CSTR metal walls also being regarded negligible [16]. The fundamental model along with the resultant operating points of the CSTR is provided in Table I [17, 18] and the same has been taken up for the simulation studies.

The dynamics of process variables in the CSTR is given by;

$$\frac{dC_A}{dt} = \frac{F}{V} C_{A0} - \frac{F}{V} C_A - C_A K_0 e^{(-E/RT)} \quad (1)$$

$$\frac{dT}{dt} = \frac{F}{V} T_{in} - \frac{F}{V} T - \frac{H_r C_A K_0 e^{(-\frac{E}{RT})}}{\rho C_p} - \frac{UA}{\rho C_p V} (T - T_c) \quad (2)$$

$$\frac{dT_c}{dt} = \frac{F_c}{V_c} (T_{cin} - T_c) + \frac{UA}{\rho_c V_c C_{pc}} (T - T_c) \quad (3)$$

From the modelling equations of CSTR, it is evident that the process variables  $C_A$ ,  $T$  and  $T_c$  remain to be a nonlinear function. Also due to their interactive nature, they cannot be determined independently. The Table I exhibit the CSTR's steady state operational considerations taken up herein.

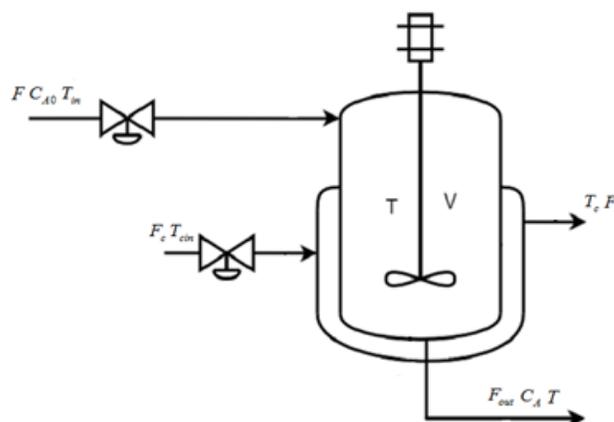

Fig. 1. Continuous Stirred Tank Reactor.

TABLE I. NOMINAL CSTR PARAMETERS AND VARIABLES

Variable	Description	Nominal Operating Values
V	Reactor volume (l)	50
$F_{in}$	Reactor's inlet volumetric flow rate (l/min)	50
$F_{out}$	Reactor's outlet volumetric flow rate (l/min)	50
$C_A$	Component A concentration in the outlet stream (mole/l)	-
$C_{A0}$	Feed concentration of component A (mole/l)	1
$K_0$	Pre-exponential factor (l/min)	$7.8 * 10^{10}$
E	Activation energy in the Arrhenius equation (Cal/mole)	E/R=8567
R	Universal gas constant (Cal/mole. K)	
$\rho$	Density of inlet and outlet stream (g/l)	900
$C_p$	Inlet and Outlet streams - Heat capacity (Cal/g.K)	0.329
T	Reactants temperature in the reactor (K)	-
$T_{in}$	Temperature of the Inlet stream (K)	350
$H_r$	Reaction's Heat (Cal/mole)	$-5*10^4$
UA	Heat transfer term (Cal/min. K)	$5*10^4$
$T_c$	Jacket's coolant water Temperature (K)	-
$\rho_c$	Jacket's coolant water density (g/l)	1000

### IV. MULTILoop CONTROL OF CSTR

A CSTR is a specialized MIMO system that contains two controlled variables (CV), reactor concentration and temperature. These controlled variables have to be maintained at their nominal operating values. Relative Gain Array (RGA) analysis is carried out on the considered CSTR model to recommend the best pairing [19].

Based on the loop pairing, it is proposed that, to attain the best closed loop performance, the flowrate of the inlet coolant water  $F_c$  ought to be paired with the concentration of Component A in the outlet stream  $C_A$  and the inlet flowrate  $F$

need to be paired with the reactor temperature T. The multiloop control structure engaged in this effort is given in Fig. 2.

The RGA analysis is carried out for the proposed CSTR model and is calculated as given in (4).

$$\lambda = \frac{F_c}{F} \begin{bmatrix} 3.9880 & -2.9880 \\ -2.9880 & 3.9880 \end{bmatrix} \quad (4)$$

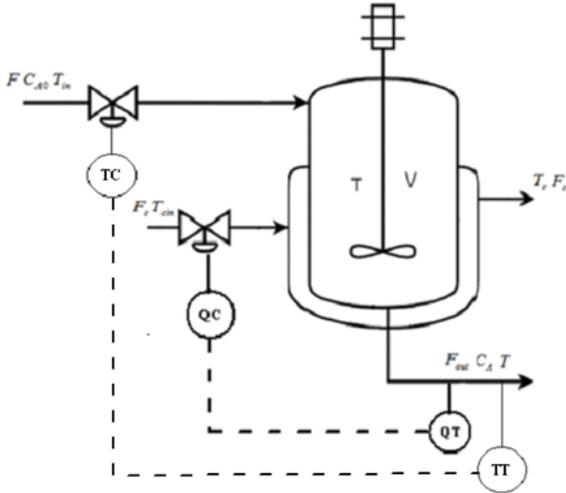

Fig. 2. Multiloop Control Scheme for CSTR.

The RGA analysis specifies that  $F_c$  needs to be paired with  $C_A$ , and  $F$  paired along with  $T$  to offer superior control. As  $\lambda_{ij}$  is seen as a small positive value, the gain in closed-loop is considerably greater than in open-loop. This phenomenon may be a source for decline in performance or instability when the loop is closed. This accentuates that, an input in open-loop that possess small influence on a specific output will hold a noteworthy effect in closed-loop owing to feedback as well as coupling.

#### V. DESIGN OF MULTILoop STABILIZING PI CONTROLLER FOR CSTR

The robust performance and simplicity of the stabilizing PI (Proportional + Integral), PID (Proportional + Integral + Derivative) and lag/lead design find themselves being extensively used in the process industries. The Stability Boundary Locus (SBL) method performs the computation of the PI controller parameters which stabilizes the control system proposed by [20,21]. A stability boundary locus in the  $(K_c, K_i)$  plane is plotted and the stabilizing values of P+I controller parameters are evaluated. This method does not necessitate sweeping over the parameters and also does not require linear programming to solve a set of inequalities. The stabilizing PI controller evolved from the stability boundary locus not only guarantees the stability but also the desired closed-loop transients are obtained [8]. The following sections explain briefly the design steps involved in the MIMO systems.

##### A. Stabilizing PI Controller for First Order Plus Dead Time (FOPDT) Process

For a SISO system with,

$$G_p(s) = G(s)e^{-\theta s} = \frac{N(s)}{D(s)}e^{-\theta s} \quad (5)$$

and a P+I controller of the form

$$G_c(s) = K_c + \frac{K_i}{s} \quad (6)$$

where the problem is to compute the PI controller parameters that stabilizes the specified system [22,23]. The system's closed loop characteristic polynomial  $P(s)$  [24] is;

$$P(s) = sD(s) + (K_c s + K_i)N(s)e^{-\theta s} \\ = a_n s^n + a_{n-1} s^{n-1} + \dots + a_1 s + a_0 \quad (7)$$

It is to be noted that all coefficients or some of the coefficients  $a_i$ ,  $i = 0, 1, 2, \dots, n$  are the function of  $K_c$ ,  $K_i$  and  $e^{-\theta s}$  depends on the order of polynomials  $N(s)$  and  $D(s)$ . There exist 3 eventualities for a stable polynomial's root to cross over the imaginary axes, (i.e., the polynomial turns out to be unstable) in the parameter space approach. (i) Real Root Boundary: At  $s = 0$ , a real root crosses over the imaginary axis. As a result, the real root boundary can be attained from  $P(s)$  in (7) by substituting  $s = 0$  which provides  $a_0 = 0$ . (ii) Infinite Root Boundary: At  $s = \infty$ , a real root crosses over the imaginary axis. Therefore, the infinite root boundary can be denoted by considering  $a_n = 0$  from (7) (iii) Complex Root Boundary: The polynomial typified by (7) becomes unstable at  $s = j\omega$  while the roots cross the imaginary axis that signifies the real and the imaginary parts of (7) all becoming zero at the same time. Hence the complex root boundary can be attained as given below. The numerator and denominator polynomials of  $G_p(s)$  can be decomposed into their equivalent odd and even parts by replacing  $s$  with  $j\omega$  which yields.

$$G(j\omega) = \frac{N_e(-\omega^2) + j\omega N_o(-\omega^2)}{D_e(-\omega^2) + j\omega D_o(-\omega^2)} \quad (8)$$

For the sake of simplicity  $(-\omega^2)$  will not be part of the ensuing equations. The closed loop characteristic polynomial of (7) can be written as;

$$\Delta(j\omega) = [(K_i N_e - K_c \omega^2 N_o) \cos(\omega\theta) + \omega(K_i N_o + K_c N_e) \sin(\omega\theta) - \omega^2 D_o] \\ + j[\omega(K_i N_o + K_c N_e) \cos(\omega\theta) - (K_i N_e - K_c \omega^2 N_o) \sin(\omega\theta) + \omega D_e] \\ = R_\Delta + jI_\Delta = 0 \quad (9)$$

Upon equating the real and imaginary parts of  $\Delta(j\omega)$  to zero;

$$K_c[-\omega^2 N_o \cos(\omega\theta) + \omega N_e \sin(\omega\theta)] + \\ K_i[N_e \cos(\omega\theta) + \omega N_o \sin(\omega\theta)] = \omega^2 D_o \quad (10)$$

$$K_c[\omega N_e \cos(\omega\theta) + \omega^2 N_o \sin(\omega\theta)] + \\ K_i[\omega N_o \cos(\omega\theta) - N_e \sin(\omega\theta)] = -\omega D_e \quad (11)$$

Splitting into

$$Q(\omega) = \omega N_e \sin(\omega\theta) - \omega^2 N_o \cos(\omega\theta) \\ R(\omega) = \sin N_e \cos(\omega\theta) + \omega N_o \sin(\omega\theta) \\ X(\omega) = \omega^2 D_o \quad (12)$$

$$S(\omega) = \omega N_e \cos(\omega\theta) + \omega^2 N_o \sin(\omega\theta)$$

$$U(\omega) = \omega N_o \cos(\omega\theta) - N_e \sin(\omega\theta)$$

$$Y(\omega) = -\omega D_e \quad (13)$$

Then (10) and (11) can be denoted as

$$K_c Q(\omega) + K_i R(\omega) = X(\omega) \quad (14)$$

$$K_c S(\omega) + K_i U(\omega) = Y(\omega) \quad (15)$$

Solving (14) and (15)

$$K_c = \frac{X(\omega)U(\omega)-Y(\omega)R(\omega)}{Q(\omega)U(\omega)-R(\omega)S(\omega)} \quad (16)$$

and

$$K_i = \frac{Y(\omega)Q(\omega)-X(\omega)S(\omega)}{Q(\omega)U(\omega)-R(\omega)S(\omega)} \quad (17)$$

Upon substituting (12) and (13) into (16) and (17), it is found that,

$$K_c = \frac{(\omega^2 N_0 D_0 + N_e D_e) \cos(\omega\Theta) + \omega(N_0 D_e - N_e D_0) \sin(\omega\Theta)}{-(N_e^2 + \omega^2 N_0^2)} \quad (18)$$

$$K_i = \frac{\omega^2(N_0 D_e - N_e D_0) \cos(\omega\Theta) - \omega(N_e D_e + \omega^2 N_0 D_0) \sin(\omega\Theta)}{-(N_e^2 + \omega^2 N_0^2)} \quad (19)$$

It can be perceived that if the denominator of (18) and (19)  $N_e(-\omega^2) + \omega^2 N_0(-\omega^2) \neq 0$ , then the stability boundary locus,  $l(K_c, K_i, \omega)$  can be constructed in the  $(K_c, K_i)$ -plane. Whereas if at any specific value of frequency, the denominator of equations (18) and (19)  $N_e(-\omega^2) + \omega^2 N_0(-\omega^2) = 0$ , then it implies that the frequency value should not be used. Here a discontinuous stability boundary locus will be attained which won't be problematic as far as the stabilizing controller's computation is concerned. When the stability boundary locus is attained, it becomes essential to assess if the stabilizing controllers are existent or not. This is because the stability boundary locus, the real root and infinite root boundary lines may perhaps split the parameter plane into stable and unstable regions. It can be seen that the line  $K_i = 0$  can split the parameter plane  $(K_c, K_i)$  into two regions viz. stable and unstable. In this case the line  $K_i = 0$  is the real root boundary line attained by substituting  $\omega = 0$  in (7) and then equating it to zero as a real root of  $\Delta(s)$  of (7) may cross over the imaginary axis at  $s = 0$ .

Generally, for a transfer function, the order of  $D(s)$  is greater than the order of  $N(s)$  which guarantees no infinite root boundary line. The stability boundary locus is seen to be reliant on the frequency  $\omega$  that varies from 0 to  $\infty$  which signifies the importance of frequency gridding. The lessening of the range of frequencies that desires to be gridded can be effectively achieved by employing the Nyquist plot based method as provided in [25]. Here we need to find only the real values of  $\omega$  that satisfy  $\text{Im}[G(s)] = 0$  where  $s = j\omega$ . As the controller operates in this frequency range, it indicates that the frequency below the critical frequency  $\omega_c$  or the ultimate frequency can be considered. For that reason, in order to get the stability boundary locus over a likely smaller range of frequency such as  $\omega \in [0, \omega_c]$ , the critical frequency can be employed. As the phase of  $G_p(s)$  at  $s = j\omega_c$  is equal to  $-180^\circ$ , it can be written as;

$$\tan^{-1}\left(\frac{\omega N_0}{N_e}\right) - \tan^{-1}\left(\frac{\omega D_0}{D_e}\right) - \omega\theta = -\pi \quad (20)$$

$$\text{or } \tan(\omega\theta) = \frac{\omega(N_0 D_e - N_e D_0)}{N_e D_e + \omega^2 N_0 D_0} = f(\omega) \quad (21)$$

### B. Implementation of SBL Algorithm for CSTR Control

From the models obtained in the resultant three operating regions of the CSTR, the stability boundary loci for the loops are obtained using (16) and (17). The boundary loci are depicted in Fig. 3. The  $(K_c, K_i)$  points are obtained by varying  $\omega$  from 0 to  $\omega_c$  in steps of 0.001 accordingly. The Multiloop controller parameters are obtained from stability boundary locus [26] using weighted geometrical centre with the aid of (22) and (23).

$$K_c = \frac{1}{n} \sum_{j=1}^n K_{cj} \quad (22)$$

$$K_i = \frac{1}{2n} \sum_{j=1}^n K_{ij} \quad (23)$$

The steady-state profile has yielded the notion of operating the CSTR at three diverse operating regions. In order to investigate the multiloop control of the CSTR, the operating points are prudently selected as per the steady-state input-output response as low ( $F = 70$  l/min,  $F_C = 60$  l/min), middle ( $F = 31$  l/min,  $F_C = 99$  l/min) and high ( $F = 25$  l/min,  $F_C = 115$  l/min).

The steady-state value of the three chosen operating regions is presented in Table II.

TABLE II. OPERATING POINTS OF CSTR-MIMO PROCESS

Operating Region	$C_A$ (mole/l)	T (K)	$T_C$ (K)
Low	0.05725	390.4	341.1
Middle	0.7963	318.3	306.1
High	0.8178	314.1	304.3

The MIMO model for the chosen three operating regions (low, middle and high) obtained using the process reaction curve (PRC) method are specified from (24) to (26) respectively.

$$G(s) = \begin{bmatrix} \frac{0.84e^{-0.1s}}{0.3s+1} & \frac{-0.46e^{-0.15s}}{0.75s+1} \\ \frac{-0.0017e^{-0.15s}}{0.45s+1} & \frac{0.0015e^{-0.25s}}{0.75s+1} \end{bmatrix} \quad (24)$$

$$G(s) = \begin{bmatrix} \frac{0.5e^{-0.1s}}{1.2s+1} & \frac{-0.2e^{-0.05s}}{1.35s+1} \\ \frac{-0.0025e^{-2.05s}}{1.35s+1} & \frac{0.0039e^{-1.35s}}{1.65s+1} \end{bmatrix} \quad (25)$$

$$G(s) = \begin{bmatrix} \frac{0.48e^{-0.1s}}{0.9s+1} & \frac{-0.04e^{-0.4s}}{0.6s+1} \\ \frac{-0.00068e^{-3.3s}}{1.2s+1} & \frac{0.00056e^{-0.9s}}{1.8s+1} \end{bmatrix} \quad (26)$$

For the locally linearized models, the Multiloop controllers are designed at the chosen three operating points by employing the SBL technique. For the control scheme, the feed flow rate ( $F$ ) and coolant flow rate ( $F_C$ ) remain the manipulated variables (MV) whereas the concentration of component A ( $C_A$ ) and reactor temperature ( $T$ ) are the controlled variables. The design stage involves finding the PI controller parameters initially by means of the Ziegler Nichols method [27] for individual loop, with the multiloop controller parameters

adjusted thereupon by making use of the detuning factor  $f$ . For this CSTR process, the detuning factor 'f' for the chosen three operating regions is estimated to be 1.195, 1.275 and 1.26 correspondingly.

### C. Control Performance of Multiloop Stability Boundary Locus (SBL) method – Reactor Concentration Control

To investigate the closed loop system behaviour with the controller so designed, the concentration setpoints are changed over all the three operating regions. The Feed concentration  $C_{A0}$ , the temperature of the Inlet stream  $T_{in}$  and the inlet coolant water temperature in the jacket  $T_{cin}$  act as the disturbances for this system, which are intentionally changed from the nominal values at various sampling instants. All the figures in this and subsequent sections consist of two halves. The top half shows the trends of the process variables (PV) for the changes in the setpoints and disturbances. The bottom half

displays the corresponding changes in the manipulated variable which drives the PV to the setpoints. Fig. 4, 6 and 8 show the servo and regulatory responses for the operated low, middle and high regions.

It is found that the reactor concentration tracks the setpoint changes without any offset and at the same time the disturbance rejection is also phenomenal. The three different disturbances in the CSTR mentioned earlier are introduced intentionally at the sampling instances of 40, 80 and 190 respectively. The rejection trend shows how effectively the disturbances are removed. Fig. 5, 7 and 9 show the interaction effect of concentration on the reactor temperature. In all the above-mentioned figures it is found that the process being MIMO in nature, remains susceptible to the interaction effect. However, the degree of interaction is very much reduced due to the effective SBL design methodology.

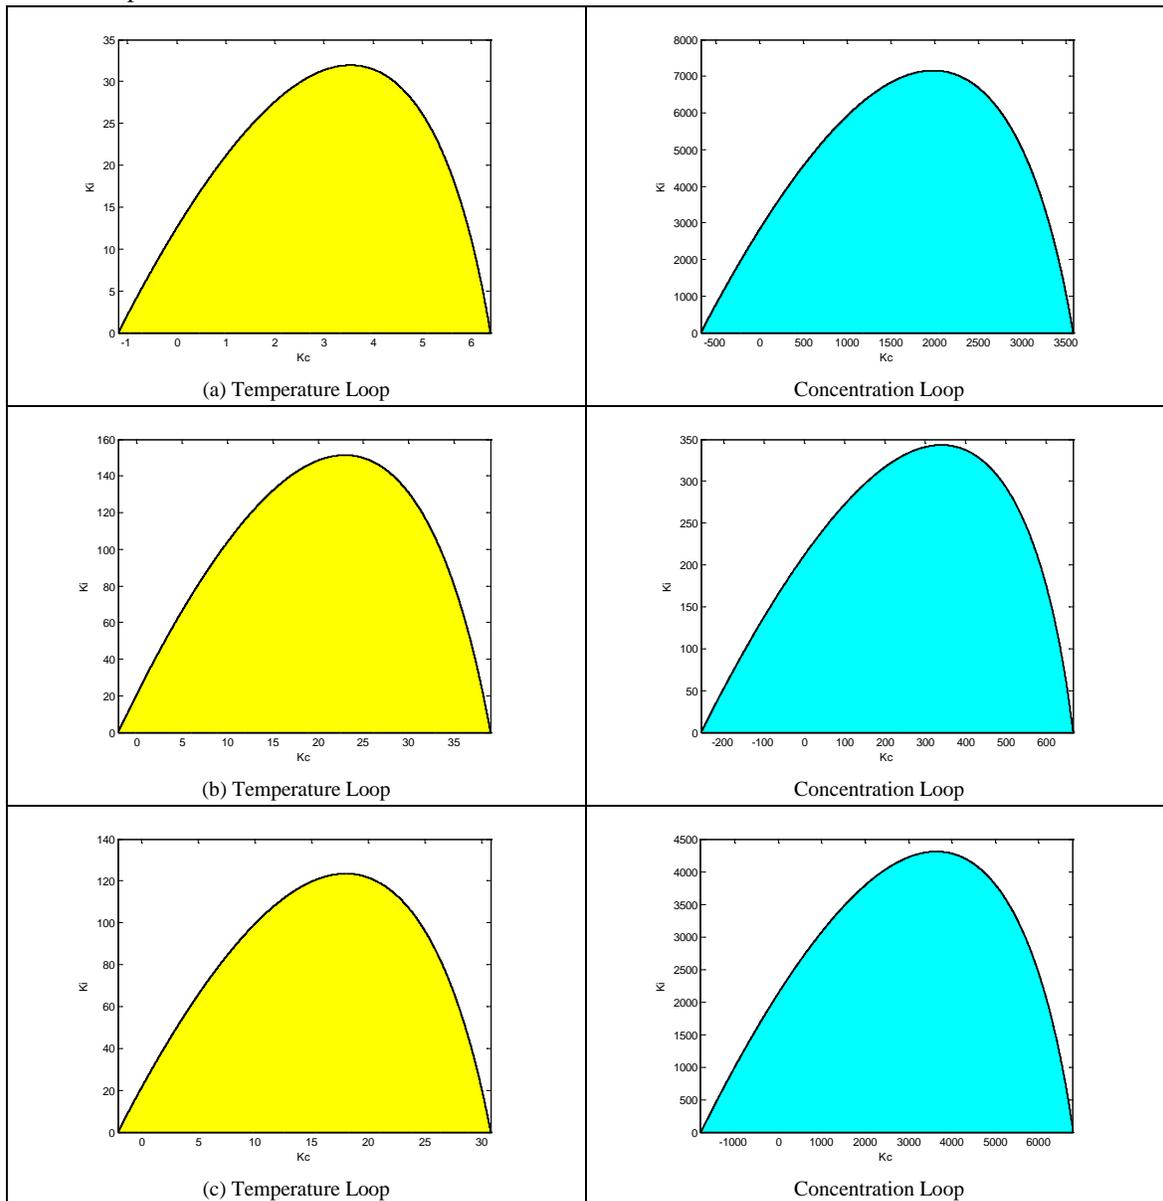

Fig. 3. Stability Regions of the CSTR Process (a) Low (b) Middle (c) High.

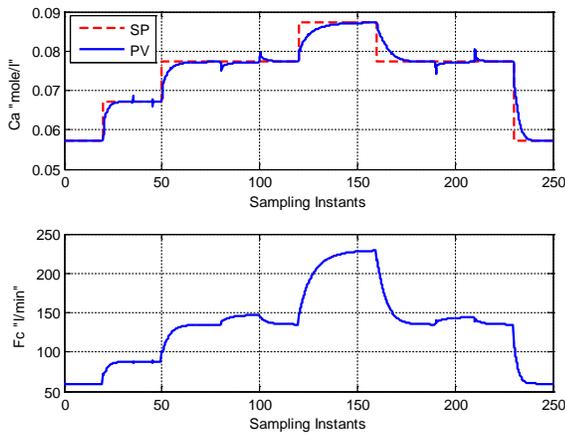

Fig. 4. Servo and Regulatory Responses of Multiloop SBL Design for Concentration Control at Low Region.

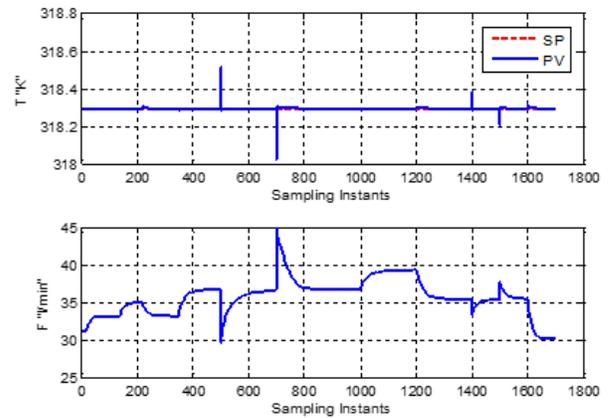

Fig. 7. Interaction Behaviour of Temperature with SBL Design for Concentration Control at Middle Region.

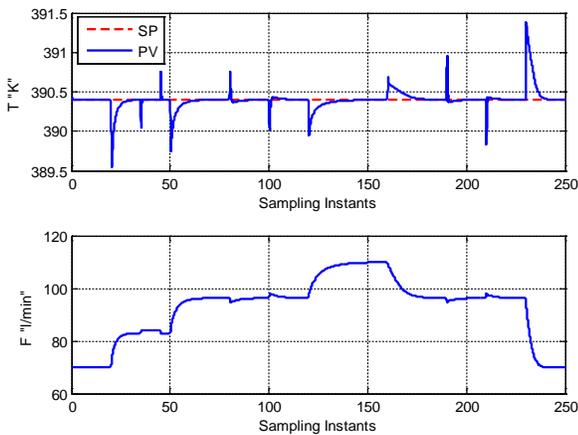

Fig. 5. Interaction Behaviour of Temperature with SBL Design for Concentration Control at Low Region.

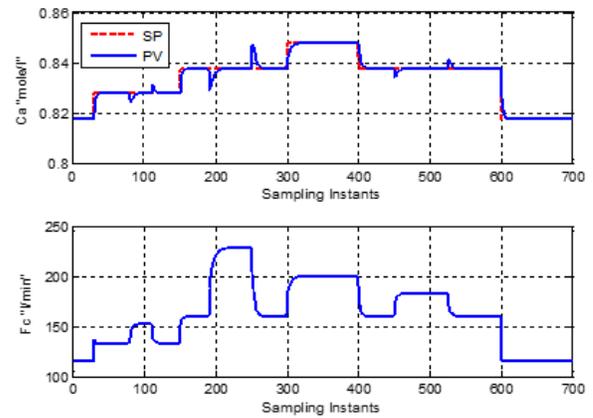

Fig. 8. Servo and Regulatory Responses of Multiloop SBL Design for Concentration Control at High Region.

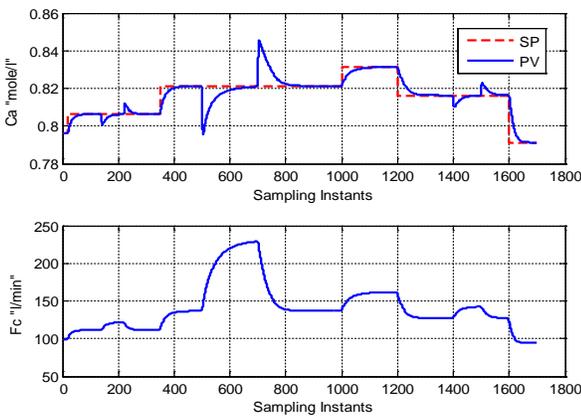

Fig. 6. Servo and Regulatory Responses of Multiloop SBL Design for Concentration Control at Middle Region.

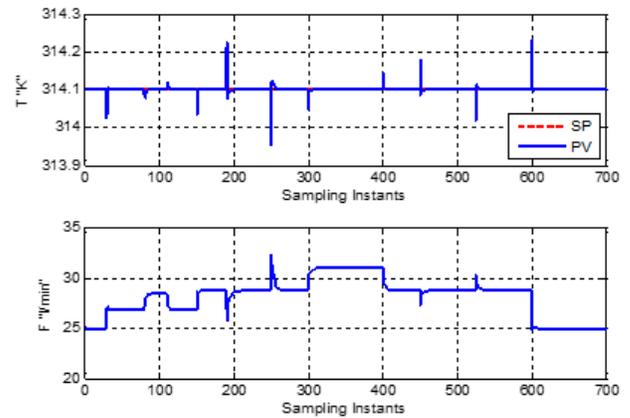

Fig. 9. Interaction Behaviour of Temperature with SBL Design for Concentration Control at High Region.

**D. Control Performance of Multiloop Stability Boundary Locus (SBL) Method - Reactor Temperature Control**

The closed-loop performances of the designed controller are studied in all three chosen operating regions of the CSTR. The servo and regulatory responses are obtained for the analogous setpoint and disturbance patterns employed already for concentration control. Fig. 10, 12 and 14 show the servo and regulatory responses. The step change in the setpoints is made at various sampling instances in both directions to check the setpoint tracking feature of the designed controller. It is found that the designed controller behaves well.

The bottom halves of the figure show the trend of manipulated variable (the feed flow rate). It is also observed that the SBL method smoothly rejects the interaction effect on concentration due to changes in temperature setpoints and disturbances which are recorded in Fig. 11, 13 and 15.

The spikes in the trends on the top halves of the figures show the deviation of concentration from its constant nominal values at various sampling instances. The servo and regulatory responses are obtained for both the concentration and temperature control as per the controller tuning constants obtained using multiloop controllers based on the Stability Boundary Locus method and the same is provided in Table III.

The servo and regulatory performances of the designed controller are analyzed by computing the ISE (Integral square error) and IAE (Integral Absolute Error) [28] at various operating points within the three operating regions of the CSTR. The performance indices are computed during concentration and temperature control and tabulated. Table IV and Table VII display the performance measures calculated for each setpoint change during concentration and temperature control respectively. The performance measures computed during disturbance changes are given in Table V and Table VI for concentration and temperature control, respectively.

## VI. DISCUSSION

One of the important traits of a Multiloop controller is the smooth removal of interaction among the loops thereby providing the operator with the freedom to operate near the limits. The SISO control design conveniently ignores the interaction effect and thereby made the design easy at the cost of performance degradation. As the CSTR is operated as a MIMO system, the interaction of change in the temperature on the concentration and vice versa are dominant. The performance of the designed Multiloop PI controller using the SBL design method is analysed by intentionally perturbing the CSTR with setpoint and disturbances at three different operating conditions. The performance is quantified for the control of both the concentration and temperature with ISE and IAE. The effect of interaction is captured and presented alongside the servo and regulatory response plots at various operating conditions. They show that interaction plays a meagre role under SBL control and hence only a slight deviation from the nominal values are recorded. By a scrutiny of the response plots along with the performance metrics it is found that the suggested Multiloop control based on SBL design method performed indubitably well under various test conditions as presented in the paper.

## VII. CONCLUSION AND FUTURE WORK

A Multiloop control philosophy is tried on the CSTR utilizing a powerful SBL design technique. One interesting feature of the SBL method lies in its simple design procedure, which involves considering only the diagonal elements, hence the interaction dynamics are discarded during its design phase. As an extension of this work, Multivariable control strategies can be implemented to analyze the interaction effects.

**Abstract**—Automatic License Plate Recognition (ALPR) has been an important research topic for many years in the intelligent transportation system and image recognition fields. License Plate (LP) detection and recognition has always been a challenging issue due to several factors, including different weather and lighting, unavoidable data acquisition noise, and requirement for real-time performance in state-of-the-art Intelligent Transportation Systems (ITS) applications. Different techniques have been proposed based on machine learning, deep learning, and image processing for the detection and recognition of LPs. This paper proposes a method that performs vehicle LP detection and character recognition with high accuracy by using artificially generated multi-exposure images of the LP. First, one under-exposed and three over-exposed images are generated from a reference image taken from the camera. Then, LP detection and character recognition algorithms are applied on these five images – one real image and four synthesized images. At each character location in LP, the character detected with the highest confidence level among these images is selected as the final predicted character. The system is fully automated, and no pre-processing, calibration, or configuration procedures are needed. Experimental results show that the proposed method achieves high accuracy and works robustly even in challenging conditions. The proposed method can be used in any existing ALPR system and the results on three recent ALPR techniques show that the accuracies are further improved when they are combined with the proposed method.

**Keywords**—License plate detection; character recognition; multi-exposure images; convolutional neural networks

## I. INTRODUCTION

Automatic License Plate Recognition (ALPR) has become a popular topic of study and development in recent years. In modern urban societies, there is a constant demand for powerful intelligent systems for transport security and monitoring, as well as to assist in automating toll collection [1], traffic law enforcement [2], border control [3], private space access control [4], and road traffic monitoring [5]. Intelligent Transportation Systems (ITS) became a necessity in the quest to turn cities into smart cities. ALPR is an important part of ITS because it includes complex computer vision operations of object segmentation, and recognition [6, 7, 8]. As a result, there is a need to make the license plate (LP) recognition systems robust in a wide variety of backdrops and other environmental elements such as illumination, camera angle, and noise and

distortion level in images, which make ALPR a challenging task. To recognize car licenses plates in restricted backdrops, a variety of advanced computer vision technologies and artificial intelligence algorithms have been developed [5, 7, 9], which may not work very well in dynamic conditions. In addition, it is impossible to cover entire range of roads, highways, or motorways with stationary/fixd ALPR cameras on ground, bridges, and utility poles [10]. Therefore, it is important to solve the relevant technical issues and develop ALPR systems for dynamic backgrounds, which can be mounted on mobile platform to patrol the area.

The main contribution of this paper is to increase the accuracy of detection and recognition of licenses plates with the help of multiple images taken at different exposure times. However, to avoid the use of complex hardware, and to keep the technique compatible with the existing ALPR systems, we capture only one image at a fixed exposure setting and synthesise others variants using a camera model. This model, for each image captured by a mobile camera, generates four additional images for different exposure times 0.5, 1.5, 2, and 2.5. Thus, we have five images of a scene at different levels of brightness. Our hypothesis is that in dark and very bright conditions when the original image is under/over exposed, some of the synthesised images should show the LP and its characters better than the original image captured by the camera. ALPR can be done on each of the five images and results can be combined to detect and recognize LP at high accuracy.

To validate the performance of the proposed technique, we develop a deep learning based baseline ALPR system, and observe the improvement in its accuracy as result of applying the proposed method. Our ALPR system uses You Only Looks Once (YOLO) algorithm [11] to detect licenses plates. After the detection process, the images are fed into a Convolutional Neural Network (CNN) model for the recognition of characters and digits on the plate. We train both modules using a custom dataset of LPs extracted from real traffic videos captured in Saudi Arabia. Using multiple exposures as suggested above, the accuracy of the plate detection reaches 100%. The recognition phase is more challenging, as we have included some very challenging LP images, having faded digits, rusted plates, and varying size and lighting. However, we see a very significant improvement in recognition too, when images at

multiple exposures are used. Our CNN model returns the confidence level with which a character is recognized. We pick the individual characters predicted with the highest confidence level, if there are mismatches found in the results obtained from multiple plates.

As we capture only one real image of the vehicle at a fixed exposure setting, and generate the rest artificially, the proposed technique works with existing ALPR systems without requiring any changes in their capturing modules. It can be used as an add-on to their existing software. We experiment with several existing ALPR systems and observe significant increase in their accuracy, especially in the challenging scenarios.

The rest of work is organized as follows. In Section II, existing works related to each ALPR stage are discussed. This is followed by presenting the fundamental idea of the proposed ALPR method in Section III. Experiment results are presented in Section IV. Concluding remarks and ideas for future work are given in Section V.

## II. RELATED WORK

For LP detection, segmentation, and identification, several ALPR systems have been suggested. Various object detection approaches have been used by researchers to handle the LP detection step. Chen et al. [12] have reduced the YOLO model layers from 27 to 13, consisting of 7 CNN layers and 6 fully connected layers. They call this a tiny model which is used to detect only one single class. A total of 36 classes are used in which 10 classes are used for numeric data, 25 for alphabets, and 1 for plate recognition. A Taiwan License plates dataset was used and results were reported with 98.22% detection accuracy and 78% recognition accuracy.

Tourani et al. [13] divide LPR into two parts: plate detection and character recognition. A YOLOv3 model is used to detect the LP which is cropped from the image and resized to 224 x 224 pixels. Both color and grayscale images are used and the last layer of the first YOLO model is modified. For character recognition, a second YOLOv3 model is used. The method got 97.77% accuracy in detection and 95.05% in character recognition on Iranian license plates dataset.

Laroca et al. [1] used two CNN arranged in a cascaded manner to detect car frontal or back-views and LPs, having the lowest false positive rate. Rashtehroudi et al. [14] have combined the Optical Character Recognition (OCR) and segmentation method which is used for digit recognition with the help of the YOLO algorithm. Using some preprocessing steps in the first stage of the technique, they remove camera angle issues by applying a Hough Line transform and rotational filters based method on the license plate. In the second stage, they apply the Bradley method to minimize the effect of light angle on the image. After this, the noise level is reduced, and a YOLO model is trained with 1000 images. Ozbay et al. [2] used a smearing method which is a morphological process on preprocessed images. Gou et al. [15] used top-hat transformation, vertical edge detection, and morphological procedures to detect the license plate.

Yonetsu et al. [16] used two-stage YOLOv2 for precise license plate detection to decrease false detection, and thus

boost the detection rate. Jain et al. [17] used edge information and geometric characteristics to extract license plate candidates, which are then fed to a CNN classifier for license plate detection. Liu et al. [18] used a YOLOv3 detector. In their method, the picture is divided into  $T \times T$  (where  $T$  is a natural integer) rectangles, and bounding boxes and class probability are predicted in each rectangle. The rectangle with the highest confidence level is detected in the proposed technique. Wang et al. [19] utilize a vertical projection approach in which they scan license frames from left to right until a projection region with a width bigger than a preset threshold is discovered. Izidio et al. [20] created a CNN model based on synthetic imagery. Khan et al. [21] purposed a framework for LP recognition addressing the issues of low image resolution, light conditions, blurriness effect due to motion of vehicle, height, and noise. Zhang et al. [22] created three networks in their proposed method. The first network is a CNN cascade model for fast and accurate plate detection. The second network is Recurrent Neural Network (RNN) for a segmented free recognition. The third network is Generative Adversarial Networks (GAN) to enhance ALPR accuracy.

## III. PROPOSED METHOD

In this section, we explain the method to synthesise images at multiple exposure from a given image captured at a fixed exposure. Then we explain several steps in designing an ALPR system that leverages the information contained in multiple images to achieve high detection and recognition rates.

### A. Synthesising Multiple Exposures

The quality of images taken by a camera is affected by ambient light, and in very dark or bright images, it becomes difficult to discern the characters. Therefore, it is necessary to adjust the exposure time of the camera according to surrounding lighting conditions. However, it is not always possible to find a suitable setting automatically, and therefore an easier way could be to acquire multiple images at different exposure times and read the LP from the best image to increase the recognition accuracy. Capturing multiple images of a scene at different exposure settings requires more sophisticated hardware to achieve higher frame rate, especially when the vehicle and the camera are moving. In this article, we use a camera model to artificially create various images corresponding to different camera exposure times (multi-exposure images) from a single image. The proposed technique does not require changes in the existing hardware used for LP recognition and is a post-processing module that can be added to the existing systems for enhanced accuracy.

The accumulated light at a sensor location  $p$  for  $\Delta t$  units of time defines a sensor exposure  $E(p) \cdot \Delta t$ , where  $E(p)$  is sensor irradiation at  $p$ . Then, the pixel intensity value  $L(p)$  at sensor location  $p$  is defined as a function of sensor exposure as.

$$L(p) = f(E(p) \cdot \Delta t) \quad (1)$$

where,  $f$  is called the camera response function. Among various models to estimate the camera response function [23, 24], many camera manufacturers adopt a gamma curve to design the response function [25, 26]. In general, a camera response function is assumed to be a gamma curve, in which case the intensity value at pixel location  $p$  is represented as.

$$L(p) = f(E(p) \cdot \Delta t) \approx (E(p) \cdot \Delta t)^\gamma \quad (2)$$

If multiple images  $L_1, L_2, \dots, L_n$  are acquired at different camera exposure times  $\Delta t_1, \Delta t_2, \dots, \Delta t_n$ , we can obtain a gamma corrected exposure time ratio  $\alpha_i^j(p)$  [26] between  $L_i(p)$  and  $L_j(p)$  as

$$\alpha_i^j(p) = \frac{L_j(p)}{L_i(p)} \approx \left( \frac{E(p) \cdot \Delta t_j}{E(p) \cdot \Delta t_i} \right)^\gamma = \left( \frac{\Delta t_j}{\Delta t_i} \right)^\gamma \quad (3)$$

Since  $\Delta t_i, \Delta t_j, \gamma$  are known constants and the value  $\alpha_i^j(p)$  is the same for all the pixels in an image, the image  $L_k$  corresponding to camera exposure time  $\Delta t_k$  can be artificially generated from the reference image  $L_r$  by multiplying  $\alpha_r^k$  at each pixel in  $L_r$ . In this article, four images are generated: one under-exposed image ( $\alpha = 0.5$ ) and three over-exposed images ( $\alpha = 1.5, 2, 2.5$ ) with respect to the reference image  $L_r$  with the expectation that one of these five images (including the reference image) will provide better quality for discerning LP numbers under given ambient lighting conditions.

We apply our LP detection and recognition algorithm proposed next in this section to each of these five images. The algorithm returns a value of confidence level for each detected alphanumeric. Among the characters detected multiple times in these five images, we take the one detected with the highest confidence level.

### B. Data Collection

To improve the detection model's accuracy, an adequate amount of labeled data is required. In this part, we explain the data collection procedure to train and test the LP detection and recognition networks. First, the videos of vehicles were recorded using a camera positioned on a moving car. The data is collected from the real traffic in Saudi Arabia and includes different LPs of different color and size according to vehicle type and size. In our study, we only consider cars' LPs which are 32cm by 16cm in size. We created a framing algorithm that extracts frames from the recorded videos. A total of 950 frames containing cars were extracted and stored in the Portable Network Graphics (PNG) format at 1920x1080 resolution. The dataset comprises frames containing LPs with easily readable

text, as well as several challenging LPs in which text is faded, covered with mud, or distorted in several other ways. Some samples are shown in Fig. 1.

After extracting these frames, we applied different exposures ( $\alpha = 0.5, 1.5, 2, 2.5$ ) to them using the method described above and thus a total of 3800 frames were obtained. A typical set of five frames is shown in Fig. 2, where the frame marked as 1x is captured by the camera while the rest are generated using our model stated above. To produce more realistic scenarios, we applied augmentation techniques such as gray scaling, brightness variation, rotation of LPs, and flipping and rotation of digits and characters. This way, in total, we got 5000 unique images of LPs in our dataset.

Each frame in the dataset is labeled using LabelImg tool [27]. The software gives XML files that contain coordinates of bounding boxes.

### C. Detection and Recognition

We train YOLOv5 network [28] for detection of LPs, on a computer equipped with Rx 570 GPU. YOLOv5 is considered a better model for object detection compared to its competitors YOLO [18], YOLOv3 [20], and Faster-RCNN [29] in terms of storage, processing speed, and auto anchoring. The training images are fed into the object detection model YOLOv5, along with the XML files extracted in the previous step mentioned above. Using transfer learning, we extract the weights of YOLOv5. As shown in Table I, we split the dataset: 70% data for training the model, 10% for the validation process, and 20% for testing. At convergence, we got 98% accuracy in LP detection on the testing dataset. After detecting LP, we move to the next step which is the segmentation of the dataset and distributing the LP characters among 27 classes of digits and alphabets. LPs in Saudi Arabia use only 17 characters and 10 digits, as shown in Fig. 3, and there are three letters and four digits in an LP. For the recognition process, a convolutional neural network with convolution layers at the beginning and fully linked layers at the end is used, as shown in Fig. 4, where the layers are labeled as follows:

Conv<number of filters><size of filters>

Fig. 1. Some Samples of License Plates in our Dataset.

Fig. 2. Five Images of the Same Scene at different Camera Exposures. The Second Image from Left is Captured with Camera while the Rest are Synthesis using a Camera Model.

TABLE I. DATA SPLIT RATIO OF TRAINING DATASET FOR LP DETECTION

Dataset	Split Percentages	Number of Frames
Training	70%	3500
Testing	20%	1000
Validation	10%	500

Fig. 3. LP Dataset.

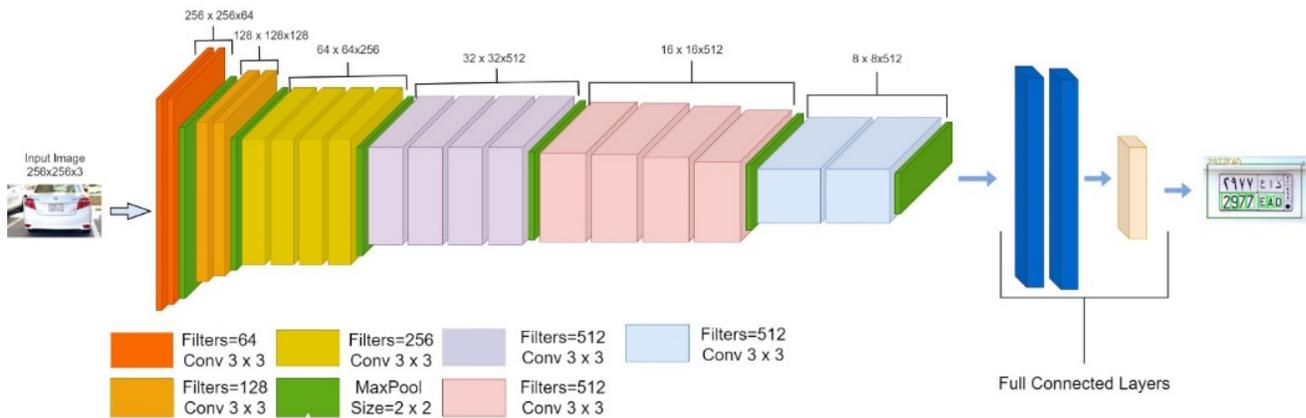

Fig. 4. Proposed CNN Architecture.

The size of the kernel is 3 x 3 and input image size is 416 x 416 x 3. To extract rich information from a given image, we used several alternating structures of multiple convolutional layers and nonlinear activation layers. We used activation function ReLU with stride size 1 and Maxpool layer with size 2x2. The output is passed to another completely linked layer with 4096 neurons and then to another fully connected layer with 1000 neurons. At the end of the network, SoftMax is used to make the final decision. At the input stage, the ReLU [30] function is applied while the Sigmoid [31] function is used at the output stage. For optimization, we employ the Adam optimizer with an initial learning rate of  $\alpha_0 = 1E - 4$  and we use categorical cross-entropy as the loss function which is commonly used in multi-class classification problems. This function deals with problems in which the output of the model belongs to a specific class. To protect our model from overfitting, we drop some values of our neurons and use early stopping which saves us from the long execution time taken by the model for training. For the training of this model, we split the dataset into training, validation, and testing sets with the same ratio as shown above in Table I.

Several methods have been proposed for the detection and recognition of LP. In the proposed method, we extract a frame

from a video containing vehicle LP and apply the proposed multi-exposure method to that frame. YOLOv5 is used to detect the LP from frames. Once the LP is detected, we crop the LP part from the images and apply a sliding window approach [32] with our custom CNN model on that cropped image to detect and recognize LP digits. The output of the CNN contains 27 confidence levels, one for each class. After going through the whole frames, we get coordinate of each character with its class label and confidence level. Then, at each character coordinate in LP, the confidence levels of class labels derived from images with different exposure times are compared. Finally, the class label with the highest confidence level is determined as the final predicted character.

In the proposed technique, only the LPs with Intersection over Union (IoU) values greater than 0.69 are detected, and the character class label is selected based on the highest confidence level obtained from the CNN model. IoU is a measure of the overlapping of the annotated and the predicted bounding boxes. We come up with that number after conducting a series of experiments on different LPs. A number of experiments are conducted on the dataset for the optimum value of IoU. If we chose a value less than 0.69, then it detects some objects containing features like LPs.

#### IV. RESULT AND DISCUSSION

In this section, we conducted experiments to verify the effectiveness of our proposed methodology. The PyTorch framework was used for all the experiments. To calculate the accuracy of detection and recognition we use the following equations:

$$\text{Detection accuracy} = \frac{\text{total number correct detections}}{\text{total number of images}} \quad (4)$$

$$\text{Recognition accuracy} = \frac{\text{total number of correct recognitions of alphanumeric characters}}{\text{total number of alphanumeric characters}} \quad (5)$$

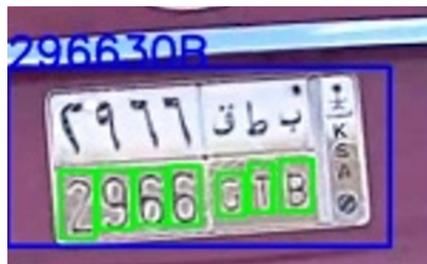

We test the trained modules of detection and recognition of LP using our testing dataset. Results are shown in Table II. A 95.34% detection accuracy is achieved on 1x exposure time images and 95.75% on multi-exposure images. For recognition of each digit and alphabet, augmentation and multi-language

repudiate techniques [33] proved helpful. We get the overall recognition accuracy of 68.2% for 1x exposure time images and 75.965% recognition accuracy for different exposure time images. One example demonstrating the effectiveness of using multi-exposure images is shown in Fig. 5. The alphabet G and T are not recognised in the single exposure time image whereas they are recognized by the proposed technique of using multi-exposure images.

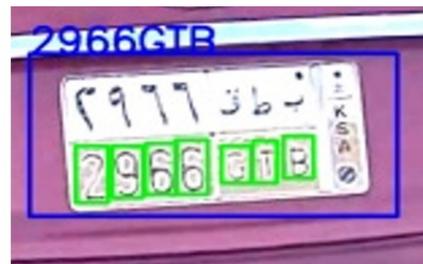

The proposed multi-exposure techniques can work with other existing techniques and improve their accuracy. We demonstrate this using three recent techniques [11, 33, 34]. In [11], the authors used YOLOv5 for the detection of LPs and digits, and proposed a custom CNN architecture for characters recognition. The authors of [33] used YOLOv5 with 19 CNN layers for detection of each class on Saudi Arabia LPs. In [34], thresholding and OCR techniques were used to recognize the digits. We applied the proposed multi-thresholding technique to all these three methods [11, 33, 34] and observed significant improvement in their accuracy, as shown in Table II.

TABLE II. COMPARISON OF DETECTION AND RECOGNITION ACCURACY WITH SINGLE AND MULTI-EXPOSURE IMAGES

Methods	Detection Single Exposure	Detection Proposed multi-exposures	Recognition Single Exposure	Recognition Proposed multi-exposures
[11]	94.39%	95.15%	66.58%	73.45%
[33]	95.34%	95.75%	66.34%	74.585%
[34]	83.3%	83.49%	69.975%	71.8%
Proposed Method	95.34%	95.75%	68.2%	75.965%

#### V. CONCLUSION

In this paper, we proposed a method utilizing multi-exposure images to improve both detection and recognition accuracies in ALPR. The proposed approach aims to present an efficient system for automatically detecting and recognizing license plates (LP) in unconstrained real-time settings with the help of different exposure time images. The proposed ALPR system is trained and evaluated on a custom dataset containing 5000 images. Experimental results show that the accuracies of the existing ALPR methods can be improved by using multi-exposure images. In this work, the multi-exposure images are generated artificially. Therefore, for the pixels having very dark or bright shades, the synthesised values may not be very accurate, however, still a significant improvement in accuracy of recognition is observed. In future work, we plan to further improve the accuracy of ALPR by using real images captured at multiple exposure times.

#### ACKNOWLEDGMENT

The authors extend their appreciation to the Deputyship for Research & Innovation, Ministry of Education in Saudi Arabia for funding this research work through the project number MoE-IF-G-20-12.

# An Urban Water Infrastructure Management System Design with Storm Water Intervention for Smart Cities

Edward B. Panganiban<sup>1</sup>, Rafael J. Padre<sup>2</sup>, Melanie A. Baguio<sup>3</sup>, Oliver B. Francisco<sup>4</sup>, Orlando F. Balderama<sup>5</sup>  
Isabela State University, Echague, Isabela, Philippines<sup>1, 2, 3, 5</sup>  
Cauayan City Local Government, Cauayan City, Isabela, Philippines<sup>4</sup>

**Abstract**—Cauayan City is one of the hubs of economic development and activities in the northern part of the Philippines. Since this is an urban area, there is a tendency for people and businesses to converge, which results in higher water demand. At present, the combined distribution efficiency of its water infrastructures under the management and supervision of the Cauayan City Water District (CCWD) is only 87% or with a combined distribution loss of 10%, which is 1282.50m<sup>3</sup> losses per day. This study suggests the necessity to introduce new and innovative water management technologies and systems adapted to climate change to address the city's needs. Problems that need to be addressed include a low-efficiency performance of the existing water infrastructure systems, lack of management tools for more efficient delivery of water services, limited service coverage of the water district due to limited water resources, and depletion and contamination of aquifers and other water sources since shallow aquifer is mainly utilized. Hence, a decision-support application based on geographic information systems (GIS) for managing urban water infrastructure with Storm Water intervention is a designed solution to address the needs of the city. The combination of decision support systems (DSS) and geographic information systems (GIS) was presented in this paper to maximize and properly utilize water infrastructure. One of the tools used as DSS is MIKE Operation. This is a complete GIS-integrated modeling tool that enables users to make sound decisions and create future concepts for urban storm water systems - cost-effective and resilient to change. A conceptual framework and relevant methodologies were presented as a guide for the success of the designed new technology.

**Keywords**—Water infrastructure; geographic information systems; storm water; decision support systems; water management

## I. INTRODUCTION

Cauayan City in Isabela is one of the country's first smart cities and one of the Philippines' premier agro-industrial hubs [1]. This advancement in science and technology is being acknowledged by the Department of Science and Technology (DOST). Since urban areas, such as Cauayan City, are the hub of economic development and activity, there is a tendency for people and businesses to converge, which results in higher water demand.

At present, Cauayan has a total of fifteen (15) water pumping stations and eight (8) elevated water tanks serving only 12,067 households (29%) out of 30,207 households (71%). The combined distribution efficiency of these water infrastructures under the management and supervision of the

Cauayan City Water District (CCWD) is only 87% which is accounted for the 9,229.63 cubic meters of metered water out of the distributed water of 10,518.13 cubic meters daily or with a combined distribution loss of 10% which is 1282.50 cubic meter losses per day [2]. This study suggests the necessity to introduce new and innovative water management technologies and systems adapted to climate change to address the need of the city like improving the performance of the existing water infrastructure systems, lack of management tools for more efficient delivery of water services, limited service coverage of the water district due to limited water resource and depletion and contamination of aquifers and other water sources since shallow aquifer is mainly utilized. Hence, a GIS-based decision support tool in managing urban water infrastructure with the Storm water intervention is a designed solution to address the need of the city.

To maximize and properly utilize water infrastructure, the merging of decision support systems (DSS) and geographic information systems (GIS) is required to provide a visualization tool and the necessary spatial database for turning a basic geographical query into a sophisticated spatially and analytical distributed modeling tool [3], [4]. Reitsma [5] defines a DSS for water resource applications as computer-based systems which integrate state information, dynamic or process information, and plan evaluation tools into a single software implementation. One of the tools used as DSS is called MIKE Operation. It is a complete GIS-integrated modeling tool that enables users to make sound decisions and create future concepts for urban storm water systems - cost-effective and resilient to change [6], [7].

The general goal of this paper is to establish a management tool for urban water infrastructure to help decision-makers, policymakers, and managers in Cauayan City, Isabela. Its specific goals are to assess and analyze the risk of urban water infrastructure systems in Cauayan City, establish a decision support system for optimal water infrastructure management, and design, build and test an urban Storm water storage system integrated with monitoring sensors.

## II. LITERATURE REVIEW

### A. Rain/Storm Water Harvesting

In the municipality of Erisos, on the island of Kefalonia in northern Greece, rainwater is collected in twenty-three ferroconcrete rainwater storage tanks. This was developed in

the 1970s and positioned at the bottom of cement-paved hill slopes acting as catchment areas ranging from 600 cubic meters to 3,000 cubic meters [8].

This Storm water harvesting infrastructure system was constructed at Brimbank Park, Melbourne, Australia, to irrigate 1.47 hectares of park public open space, utilizing a 1.7 hectares carpark as the principal storm water catchment. The system design featured a 2,000 cubic meter storm water storage tank, a 450 mm storm water collecting pipe, a 600 m<sup>2</sup> bioretention/filtration system, a 150 mm pressure main with a 35 kW pump, and a sprinkler system with a 125 mm manifold and 50 mm laterals [9].

Rainwater harvesting [10] supplies water for drinking, sanitation, and increasing the productivity of agro-ecosystems in Kenya's semi-arid savannah towns of Kaijado and Lare. Roof water harvesting for residential reasons (drinking and sanitation), runoff collecting in ponds for small gardens, trenches for groundwater recharge, and afforestation were among the technologies implemented [11].

The rainwater harvesting system built at Sapilang, Bacnotan, La Union, which consists of roofs, gutters, downspouts, a filter, and a storage tank, can collect rainfall to feed and maintain the drinking water requirements of 8-12 family members [12].

### B. Storm Water Infrastructure

To augment the existing water supply, G.C. Dandy et al. (2019) emphasized the significance of having alternate water sources in many cities, such as storm water collection and processed wastewater. Harvesting schemes for Storm water that complement current water systems, according to them, are complicated because they are made up of integrated components set that execute the duties of collecting, storing, treating, distributing, and discharging. Furthermore, while selecting and evaluating Storm water harvesting solutions, factors must be considered. These are environmental, economic, environmental, technical viability, and social variables [13].

According to the International Water Association, IWA (2019), population increase and urbanization are adding strain on urban water supplies. According to UN predictions, by 2025, fifty percent of the world's demographic would be residing in water-stressed regions. Furthermore, the current worldwide health catastrophe caused by COVID-19 emphasizes the availability of clean water to ensure a healthy population [14].

K.A. Feehan et al. Rainwater collecting has been performed for generations and was formerly the principal technique of acquiring water for home usage, according to (2012). Increasing water needs, water consumption limitations, new storm water management rules, and the expansion of low-impact development (LID) and "green construction" methods have rekindled interest in rainwater collection [15].

### C. SWH Management

Stormwater harvesting (SWH) is one alternative water resource that might replace typical urban water supply while

also providing a variety of social and environmental advantages. This addresses water scarcity by increasing resilience to the effects of climate change [16].

Urban planning for Water Sensitive Urban Design (WSUD) has been inconsistent, lacking direction and yielding sub-optimal results. Green storm water management infrastructure is being used more widely throughout the world to mitigate the negative effects of climate change and urbanization while also delivering several ecosystem services. WSUD is also used in Australia, Low Impact Development (LID) in the United States, Sponge City systems in China, and Nature-Based Solutions (NBS) in Europe [17].

### D. GIS-Based Decision Support Tool for SWH

In the research of Shao, H. et al. (2017) said that an open-source geographic information system (GIS) based decision support system (DSS) for constructing modeling economic costs, water quality/quantity advantages, and BMP scenarios at the farm field, watershed scales and subbasin can be established. This DSS included a Soil and Water Assessment Tool (SWAT), a farm economic model, and an optimization model in an open-source GIS program called Whitebox Geospatial Analysis Tools, The DSS was applied to 14.3 square kilometers of Gully Creek watershed in southern Ontario, Canada, a coastal watershed that flows directly into Lake Huron [18].

Rainwater harvesting systems (RWHSs) have been recognized as a simple and effective technique to alleviating the deterioration of urban water stress. A recent study addressed the temporal-spatial complex of rainfall and proposed a GIS-simulation-based decision support system (DSS). Sensitivity study confirmed that, as compared to the previous generalized technique, this DSS increased the information value. As a result, the DSS, which provides more holistic and complete support, has been highlighted as a valuable instrument for mitigating the problem of urban water stress. This is a comprehensive method for promoting domestic RWHSs in a large-scale water-saving scheme that incorporates water consumption reducing equipment (WCRE) and gray water reuse (GWR) [19].

B. Mbilinyi and colleagues introduced a decision support system (DSS) based on a geographic information system (GIS) that employs remote sensing (RS) and a short field survey to identify possible areas for RWH technologies. The DSS receives soil texture, maps of rainfall, soil depth, slope, drainage, and land use as inputs. This produces maps of suitable locations for bench terraces, water storage systems, borders, and stone terraces as outputs. The findings of their study, which included testing and validation of the generated DSS, suggested that the tool may be used to anticipate probable locations for RWH technologies in semi-arid environments with high accuracy. The majority of anticipated RWH innovations were identified through testing in extremely high and highly appropriate places (41.4 percent and 40 percent, respectively). During the assessment, 36.9 percent of RWH techniques were located in moderately appropriate sites, with 23.6 percent discovered in very highly suitable and extremely suitable places [20].

MIKE OPERATION consists of MIKE 11 and MIKE Basin modeling tool, which has GIS features, and an easy-to-use online modeling framework for water prediction and operational control. It is intended for model-based forecasting services as well as online operational management of river systems, water collecting systems, and water transportation systems. This is also a simple real-time system for real-time modeling, optimizes water distribution collection systems, and controls the groundwater (CTNN Report, 2017) [21].

The MIKE 11 program was used to assess the water resources in the catchment of the Strymonas River. It also simulated unstable water movement in surface water bodies and catchment runoff [22].

MIKE basin software is used in the Pinho river's hydrographic basin. This is helped by a geographic information system to represent the basin both spatially and temporally. Thus, allowing for easier visualization and interpretation of findings. According to the acquired data, it was confirmed that the hydrographical basin now satisfies the considered water demands. The DSS has proven to be a valuable instrument in assisting decision-making in the examined river basin [23].

### III. MATERIALS AND METHODS

#### A. Conceptual Framework

Fig. 1 shows the conceptual framework of this paper. For the inventory of existing water infrastructure, the list of existing water infrastructure will be obtained from the City Planning and Development Council (CPDC) and from the Cauayan City Water District (CCWD). These infrastructures will be validated using a handheld Geographic Positioning System (GPS) and will be assessed. In Data Processing, Design, Construction, and Evaluation of the Storm water

Storage System and Water Distribution Control System, all the data collected will be processed using MIKE Operations with GIS software.

Risk analysis of urban water infrastructure systems in Cauayan City will be done using Fuzzy Fault Tree Analysis (FFTA). Data about natural hazards, human-made hazards, and operational hazards will be obtained from internet-based information and survey form. At the same time, the development of urban digital model/system for water infrastructure involves the development of an urban digital model/system for water infrastructure will be implemented based on two steps (Fig. 2), such as the establishment of the urban digital model and utilizing a sensing layer for data collection. The Geographic Information System will play a role in these steps.

#### B. Construction of the Urban Digital Model

The first stage is to create an urban digital model that emphasizes the contents of the urban constructed and natural surroundings. The digital model gives geolocation and characteristics for each urban component (attributes). GIS will be used to produce a digital model of urban 'horizontal components' including the natural environment, urban networks, and transit facilities while establishing information modeling will be used to represent vertical components like structures. The combination of BIM and GIS results in a powerful tool for constructing an urban digital model utilizing georeferenced data and presenting this data in an intuitive manner. The combination of which will be integrated with MIKE Operations to come up with real-time simulation-based optimization. MIKE Operations will be used to optimize water distribution and collection systems. It will also be used to establish real-time data management and forecasting and monitor leaking water in the distribution system, minimizing the losses within the water infrastructure.

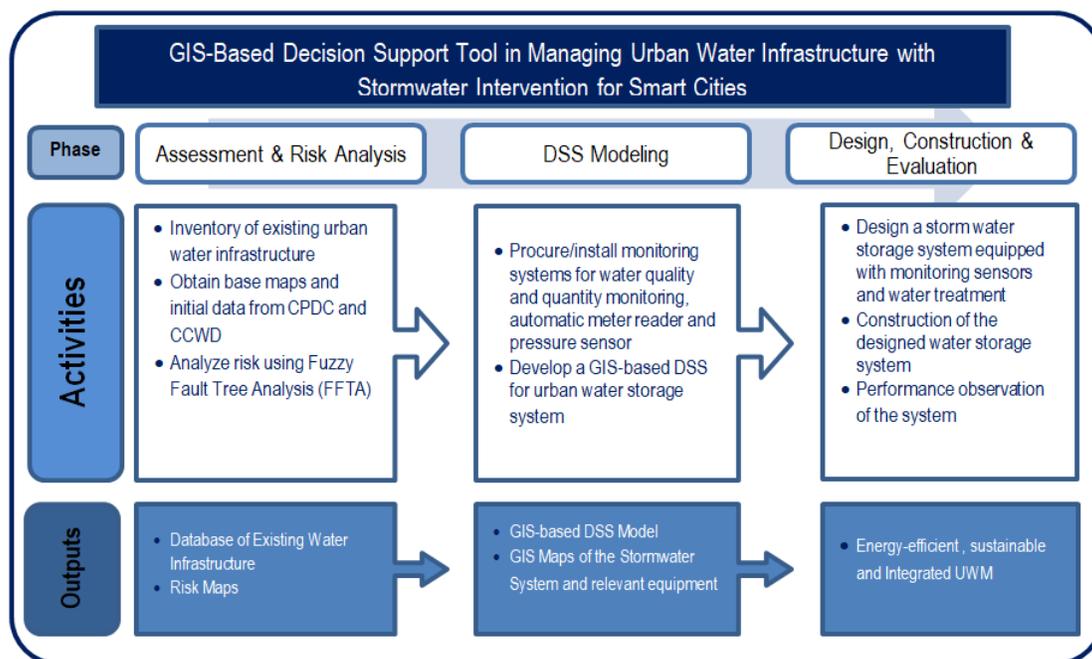

Fig. 1. Conceptual Framework.

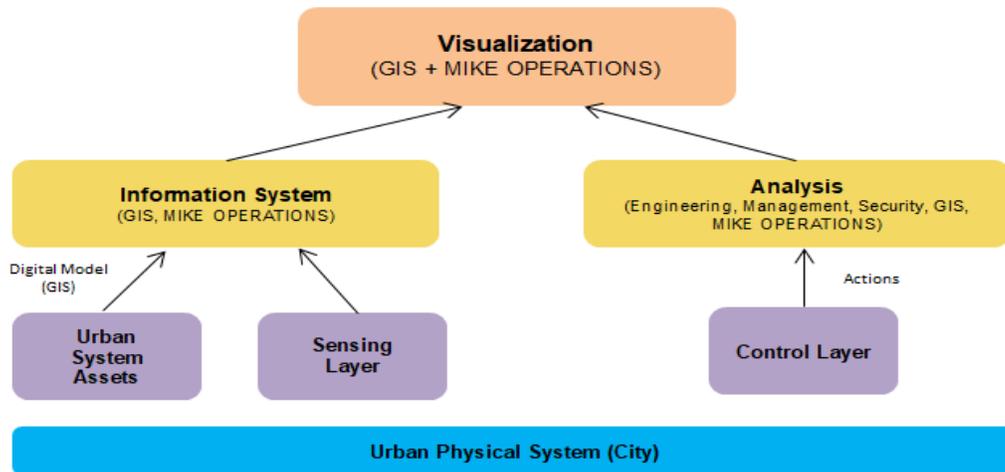

Fig. 2. Steps for the Implementation of Smart City Programs.

### C. Sensing Layer

The second phase is to build the sensing layer, which will convey urban operational data to the smart city information system. This layer's sensors will be employed to monitor urban networks and infrastructure. Data can also be complemented with audio recordings, videos, and images, resulting in urban big data. Some of the sensors that will be utilized to monitor energy and water utilities are seen in Fig. 3. Water usage will be tracked using automatic meter readers (AMRs), water pressure will be tracked using pressure sensors, and water quality will be tracked using water quality devices (conductivity, turbidity, chlorine, pH). In the drainage system, sensors will be employed to monitor water level, flow, and quality (pH, temperature, turbidity, etc.). It enables the early identification of floods. Sensors will be installed in the district heating system to record fluid temperature, pressure, flow, and the status of the valve. It enables early defect identification and system performance enhancement. GIS + Mike Operations allows you to view the monitoring system and the characteristics and state of the sensors. It also allows you to see real-time and historical data on GIS maps.

1) *Input Data:* Since the rainfall and design method are site-specific, the rainfall data should be gathered for the design site. The capacity of nearby sewer systems should be analyzed.

2) *Design Data:* The tank will be designed according to the choice of controllable measures. The pumping rate and operation rules will be specified. The infiltration capacity will be determined based on site conditions and soil characteristics.

### D. Design and Construction of Intervention Storm Water Infrastructure Systems

The storm water intervention facility has a total catchment area of three hectares with a storage capacity of 1750 cubic meters. Fig. 4 depicts a schematic diagram of the planned storm water infrastructure system, including the various components (examples include a storage tank, a flushing treatment device, groundwater recharge tank, UV treatment, elevated tank, suction pumps, valves, piping, and a water

quality monitoring system). The recommendation to consider runoff water from the surface/roads aside from rainwater and Storm water falling from the roof is not feasible because the design storage capacity of the storm water is limited only to one (1) hour rainfall duration, which is enough to fill the storage tank. On the other hand, elevating the water storage tank in the new design and system is much appreciated. However, the said recommendation is not feasible considering that the building structures in the proposed site were not uniform regarding the number of the storey (i.e., BJMP and PNP buildings are four storey buildings while others are two-storey and one-storey buildings). Elevating the storage tank with this physical condition still requires motor pumps and heavy foundation structures. In addition, the space of the proposed site had limited space. Hence, when covered, the space occupied by the proposed subsurface storage tank will be useful for other purposes. Nevertheless, the recommendations will still be considered a possible option when scaled up to other areas.

### E. Water Distribution Control System

The water distribution control system illustrates in Fig. 5. The monitoring and control system will measure values for pipe steel analysis through online and offline systems. The pipe steel analysis can distribute pressure control to the appropriate distribution amount and set values for the monitoring and control system. The demand assignment, parameter setting, and database update are also under pipe steel analysis.

### F. Statistical Data Analysis

The statistical analysis to be employed is the following Rainfall Frequency Analysis for rainfall data analysis, Regression analysis for the performance of the storm water infrastructure. Secondary statistical data on the projection of population, water demand, and a groundwater abstraction rate from 2020 to 2050 was obtained from the study of Alvarez et al. (2020) on Benchmarking of the water supply and wastewater management system of a Smart City: the case of Cauayan City.

IV. RESULT AND DISCUSSION

A. Differentiation (GIS-Based Decision support Tool in Managing Water Infrastructure)

The authors compared the designed methods versus the existing practices locally and abroad regarding the various GIS-based decision support tools in Managing water Infrastructure. This is presented and summarized in Table I.

B. Differentiation (Storm Water Harvesting Infrastructure)

In terms of comparison between the designed methods over existing Storm water Harvesting Infrastructure, Table II presents the difference in various parameters indicated.

C. Risk Management Plan

Table III and Table IV show the risk management solution or a proposed contingency plan in case there will be challenges that will happen during the duration of the designed method.

TABLE I. DIFFERENTIATION (GIS BASED DECISION SUPPORT TOOL IN MANAGING WATER INFRASTRUCTURE)

Parameters	Designed Method	Existing Practices (Local)	Abroad
Management Practices	GIS-based decision support tool in managing urban water infrastructure with storm water intervention.	Conventional - Non ICT tool management without water intervention (CCWD) as a practice	GIS-Based Management Tool
Performance Distribution Efficiency	Low distribution losses ( 2%)	Distribution Losses is 13 %	Distribution Losses 3-4%
Equipment tools	<ul style="list-style-type: none"> <li>- Instruments with digital output (meters and sensors), such as water quality monitoring, flow meters, rain gauges, and other environmental parameters.</li> <li>- Real-time acoustic leak detecting devices</li> <li>- video camera-based asset management</li> <li>- Smart water measuring devices to monitor its use</li> <li>- Pressure monitoring to identify leaks and optimize pumps, UV treatment</li> <li>- GIS software</li> </ul>	Manual monitoring pressures, flow meters, and leakages	<ul style="list-style-type: none"> <li>- Flowmeters, rain gauges, monitoring of water quality as well as other environmental parameters.</li> <li>- Acoustic leak detecting devices in real-time</li> <li>- Asset management using video devices</li> <li>- Smart water systems to monitor their use</li> <li>- Pressure monitoring to detect leaks and optimize pumps</li> <li>- GIS/SCADA software</li> </ul>

TABLE II. DIFFERENTIATION (STORM WATER HARVESTING INFRASTRUCTURE)

Parameters	Designed Method	Existing Practices (ISWM-Cebu)	Abroad
Design function of storm water infrastructure	Storm water collection and groundwater recharge facility equipped with water monitoring (quality) and treatment system. For flooding control, groundwater recharge and water supply for government offices will be implemented.	Rain and storm water collection with wastewater treatment  Water supply for cleaning and gardening	SWH was designed to harvest rainwater with an infiltration facility and redirect rainwater to sewer systems. Other designs were used for irrigation and toilet flushing.
Design Capacity	-1750 cubic meter + groundwater reservoir	- 60 cubic meter	4 -40 cubic meter
Efficiency	90%	75%	30% to 90%
Cost of Investment	Php 3Million Or Php 1714.30/ cubic meter	Php 2Million Or 33,330.33 per cubic meter	Php 30,000,00/cubic meter
Water Dependence	-Reduced water dependence to 90%	-Reduced water dependence to 75% during month	
Component	-Primary storm water treatment facility (Green filter) - Storage Tank - pipe and fittings *Groundwater recharged Tank *Elevated water Tank *UV treatment *Water quality assessment facility	-Primary storm water treatment facility (Green filter) - Filtration system based on the micro membrane (MF System) - Rainwater Remote Administration System Integrated - Rainwater Drainage in Case of Emergencies - Water Treatment System for Reuse	-System of its collection -An inlet filter -Diverter for the first flush -Tank for storing items -Overflow -Treatment methods -Pump -Flow metering -An indicator of water level

TABLE III. RISK MANAGEMENT

Cause of delay	Solution
The foreseen major risk of the paper may be caused by a change of Leadership in the LGU and the procurement of needed materials.	There must be a signed Memorandum of Agreement (MOA); involve the university finance department during the inception activity, and perform intensive monitoring during the procurement process.

TABLE IV. OTHER POSSIBLE RISKS

Item	Risk	Designed Contingency Plans
Conduct Training and meetings	Restriction in the conduct of trainings and meetings	Activities will be undertaken using a combination of a face-to-face meeting in small groups and video conference with those affected by travel restrictions. A fully-equipped virtual conference venue will be set up at ISU.
Acquisition of software/ and equipment	Difficulty in the purchase and delivery of equipment due to travel restrictions	Sets of software will be acquired online; All equipment for purchase is locally available; hence delivery mode would be made by couriers or using ISU official vehicles under special permits
Data gathering	Restriction to travel due to community quarantine protocols	Since travels are in the provincial/ regional jurisdictions, special permits will be secured, and gathering in the field will be made using local assets.
Coordination with stakeholders	Travel difficulty for a face-to-face coordination meeting	Coordination will be made by online calls and videoconferencing.
Reports presentation and submission to PCIEERD	Travel restrictions to Manila for meetings and submission with the presentation of reports	It will be done by video conferencing and online mode.

## V. CONCLUSION AND RECOMMENDATIONS

The authors determined the potential outcomes, socio-economic impact, and environmental impact through various analyses of the designed methods and materials identified. It improved the efficiency and quality of urban water services of Cauayan City and developed an integrated, energy-efficient, and sustainable urban storm water management. The potential socio-economic impacts of this paper are; at least 90% of distribution losses will be reduced (from 13% to 2% distribution losses), at least 10% of the energy used from water supplies of government offices situated in the area will be reduced, reduces the cost to build storm drain Infrastructure and at least 10% increase of income by laundry businesses. In terms of environmental impact, the construction of the GIS-based decision support tool in managing urban water infrastructure includes reduced standing water and localized flooding, reduced storm water runoff into the combined sewer system, promote infiltration and groundwater recharge, removal or reduction of contamination of hazardous elements to the surface water or groundwater resources, protection or rehabilitation of natural and artificial waterways and conserved water by increasing distribution efficiency.

For its sustainability plan and scaling-up, pilot intervention and its feasibility and acceptability are demonstrated in this pilot scale, the steps that will be undertaken for scaling-up are a policy recommendation for adoption. This is through city legislation and a roll-out of technology in clustered urban watersheds will be conducted. The technology set-up will also be incorporated in the designed Cauayan City Drainage Master Plan study in 2022 since LGU-Cauayan City and Cauayan City Water District (CCWD) are committed to accept and adopt the paper and they are willing to scale up to other areas within the city.

Finally, in terms of the coverage of the paper, the urban water infrastructure with the storm water infrastructure will be piloted at Cauayan City, Isabela. The storm water infrastructure has a catchment area of 3 hectares only. The

design specification of the said storm water infrastructure was based on hydrologic data obtained from the site (i.e., from a roof to a storm water harvester).

#### ACKNOWLEDGMENT

We want to extend our sincerest gratitude to the Department of Science and Technology – Philippine Council for Industry, Energy, and Emerging Technology Research and Development (DOST-PCIEERD) for funding this paper. Likewise to the Local Government Unit of Cauayan City and Cauayan City Water District for being the cooperating agencies of this paper. Finally, Isabela State University as the implementing agency.

# Sentiment Analysis on Amazon Product Reviews using the Recurrent Neural Network (RNN)

Roobaea Alroobaea

Department of Computer Science

College of Computers and Information Technology

Taif University, P. O. Box 11099, Taif 21944, Saudi Arabia

**Abstract**—In this paper, the problem of sentiment analysis on Amazon products is tackled. In fact, sentiment analysis systems are applied in all business and social fields. This is because the opinions are at the center of all human activities, and they are key influencers of our behaviors. In this study, the recurrent neural network (RNN) model is used to classify the reviews. Three Amazon review datasets were applied to predict the sentiments of the authors. In conclusion, our results are comparable to the best state of the art models with an accuracy of 85%, 70% and 70% for three datasets.

**Keywords**—Sentiment analysis; natural language processing; deep learning; RNN

## I. INTRODUCTION

Sentiment analysis is the area of study that investigates people's opinions and feelings, attitudes, and emotions. It is one of the most active research fields in natural language processing. It is widely studied in data mining field. Therefore, this research has been extended outside science to cover management and social sciences. The increasing importance of the sentiment analysis overlaps with the evolution of social media, such as chat rooms, blogs, micro-blogs, Twitter [1]. For the first time in human history, there are huge amount of opinions in a digital form for analysis. The sentiment analysis systems are applied in all the business and social fields because of that the opinions are at the center of all human activities. Thus, they are significant influencers of our behaviors. Our beliefs and perceptions of reality as well as the selections we do are conditioned by how others see and value the world? For this reason, when a decision should be made, the opinions of others are often sought. This is true not only for individuals, but also for organizations. On Amazon, Internet users give their opinions on products. However, these reviews vary from a product to another and are used to improve and alert companies that have negative reviews of their products [1]. The aim of this paper is to use the recurrent neural network (RNN) model to classify the reviews of three Amazon review datasets<sup>1</sup> to predict the sentiments of the authors. The rest of the paper is organized as follows. Section two presents a definition of the sentiment analysis. Section three deals with the state-of-the-art. Section four introduces the methodology. Section five gives the results and experiments performed on the Amazon datasets. Finally, the last section concludes the paper.

## II. CONTRIBUTIONS

The contributions in this study can be summarized as; 1) Arabic data set are used in this research because few research have been done in this area [12]. 2) We present a method using RNN to predict sentiment of authors. 3) We compare our proposed model to Long short-term memory (LSTM), Gated Recurrent Unit (GRU), and Convolutional Neural Network (CNN).

## III. LITERATURE REVIEW

### A. Sentiment Analysis

Sentiment analysis, also called the opinion mining, is a sub-field of computer science besides. It is considered as a part of an automatic natural language processing and aims to classify feelings expressed in texts. There are other related names slightly referring to different tasks, such as opinion mining, sentiment mining, subjectivity analysis, effect analysis, and emotion analysis [2].

Furthermore, sentiment analysis is made using one of two fundamental methods, which are rule-based classifiers and machine learning classifiers. The former are rules derived from the linguistic study of a language that are utilized to sentiment analysis. The latter is statistical machine learning algorithms that are used to automatically learn sentiment signals [1][2]. Therefore, there are two terms that should be defined which are sentiment and opinion. In the literature review, there is confusion between these two words. In the Oxford Dictionary, feeling is defined as a point of view or opinion that is held or expressed as an emotion. For the word opinion, it is a belief, or a judgment formed about something, which is not necessarily based on facts or knowledge but on the beliefs or opinions of a group or of the majority of people. Consequently, it can be said that the term of feeling is a person's emotion about something, while the term of opinion represents or shows a person's point of view. According to [3], sentiment analysis, also well-known as opinion mining, is the field of study that analyzes people's opinions, feelings, evaluations, attitudes, and emotions. There are two methods that are used to automatically learn sentiment signals which are supervised and unsupervised learning methods. The former involves the presence of two sets of data which are a training set and a test set. The method is called supervised since the system is trained on a training sub-set, which contains models that have already been processed. The latter (unsupervised), which recommends only one data set, requires the system to autonomously restructure the

<sup>1</sup> <https://data.world/datafiniti/consumer-reviews-of-amazon-products>

information so that the most similar data will be placed in the same group [4].

Furthermore, there are three analytical approaches which are lexicon-based approach, corpus-based approach, and a Hybrid approach (mixed approach) [4]. Regarding the Lexicon-based approach, it identifies the polarity of a text using two sets of words, the first expresses a positive feeling and the second expresses a negative feeling. Then, the model counts in the text the number of positive words and that of negative words while the sum gives an overall evaluation of the text feeling. Therefore, if the number of positive words outweighs that of the negative ones, the text is considered positive, conversely, the text is considered negative or neutral if the numbers are equal [4].

In terms of Corpus-based approach, the automatic sentiment analysis based on corpora requires the creation of two manually annotated corpora. The first is the learning corpus, which is used to train an automatic system. It includes notes added by human annotators. Thus, a system can perform an analysis on its own while the second uses the test corpus, which is trained to verify the performance of the automatic system. In an ideal scenario, the results of the analysis performed by the automatic system should fully correspond to those of the learning corpus. Therefore, in order to maximize the automatic system's performance, it is important that the learning corpus is representative for the test corpus. [4] gives an example of algorithm like neural network.

In addition, Hybrid approach takes advantage of the previous two methods there are three ways to do it. The first is to use linguistic tools to develop the corpus and then classify the texts using a supervised learning tool. The second way is to use machine learning to build the body of opinion needed for the lexicon-based approach. The third way is the combination of the two previous approaches and the collection of their results [5]. Furthermore, the next section will show the related works on the sentiment analysis.

#### B. Related Work on Sentiment Analysis

Although the field of sentiment analysis is an emerging field in the natural language processing community, the work done for the Arabic language is still extremely limited [6]. Indeed, most of the research studies have focused on the polarity classification of documents to avoid the excessive cost of sentence annotation. Also, to adopt the machine learning-based approach to escape the excessive cost of creating the lexicon of opinion with good coverage [7]. Thus, the obstacle that slows the advancement of the field of the sentiment analysis for Arabic is the unavailability of resources in terms of annotated corpora and lexicons of opinion.

In this context, [6] are among the first researchers who were interested in constructing an opinion lexicon for the Arabic language. In fact, their work was part of the development of a tool that enables to classify the stakeholders' opinions in the business field. Therefore, the starting number of words to be set were more than 600 positive words, 900 negative words and 100 neutral words. The evaluation tests performed showed good accuracy but a low recall. In addition, [7] proposed the combination approach based on three steps for

the classification of Arabic documents according to their polarities. They used an opinion lexicon constructed from the English Lexicon SentiStrength after having done the translation and consulted online dictionaries to enrich the lexicon with the synonyms of the already existing words. However, the size of the lexicon was not mentioned and the accuracy of the classification tool for the lexicon-based step is 48.7%. Also, [8] presented the lexicon "Sifaat", a manually constructed lexicon containing 3325 adjectives categorized in three classes: positive, negative, and neutral. The results of the assessment showed an improvement of 6% in the classification of subjectivity and 40% in the classification of polarity. The authors also proposed to extend the lexicon by translating three English opinion lexicons, namely the SentiWordNet, the Youtube lexicon and the General Inquirer. However, this method focused only on adjectives that have not been evaluated. Furthermore, [9] proposed to create a lexicon by translating 300 words of SentiStrength. Then, enriching it with synonyms and emoticons. The last version of the lexicon included 3479 entries 1262 of which are positive and 2217 are negative. The results of the experiment on the collected corpus reached 59.6% in terms of accuracy. As for [10], they proposed to build an Arabic version of SentiWordNet, which is an opinion lexicon derived from the WordNet database, by going through two stages: updating the base of the WordNet Arabic 2.0 by mapping the WordNet 3.0 for English, and also the base obtained from the SentiWordNet 3.0 for English. In fact, the lexicon coverage assessment reports that 5% of the words in the annotated corpus are not in the lexicon.

In this study the Arabic data set and RNN model will be used to predict sentiments of authors. Next sections will explain the methods uses and demonstrate that our results surpass those obtained by the best deep learning models like LSTM, CNN and GRU.

## IV. METHODOLOGY

In 2005, things started to change. In fact, the outlook on the field of artificial intelligence has dramatically changed with the machine learning while the emergence of deep learning, which accounts for the bulk of research conducted by specialists, especially as it intervenes in many areas, such as natural language processing. Deep learning (DL) is a branch of machine learning, where the latter is a branch of artificial intelligence, in which machines can learn by knowledge and gain skills without the human contribution. Therefore, based on artificial neural networks, the algorithms encouraged by the human brain, learn from large amounts of data. Consequently, DL enables models composed of multiple processing layers to understand descriptions of data with multiple levels of abstraction. [11].

### A. Deep Learning vs. Machine Learning

Machine learning (ML) is a sub-field of artificial intelligence (AI), which focuses on designing systems that learn or improve performance based on the data. These systems are intended to train a safe set of algorithms for larger amounts of data that can help classify future data. ML is divided into Supervised Machine Learning and Unsupervised Machine Learning. The former is the most generic form of machine learning. It aims to make the algorithm "learn" by comparing

its actual output to the "taught" outputs in order to check for errors and modify the model accordingly. The latter is also known as learning from observations. The learning algorithm in this method finds common points on its own among its input data. On the other hand, in a machine learning process, the algorithm must be instructed on how to make an accurate prediction using more information (for example, by manually performing an extraction of the relevant features) [7]. In fact, Deep Learning (DL) algorithms can learn to make an accurate prediction through their own data processing, thanks to the structure of the artificial neural network. For example, they ignore manual steps and feature extraction, but the modeling process is automatically performed. Another major difference is the fact that deep learning algorithms evolve with the data. Therefore, to succeed in the deep learning application, a large volume of data and large dimension are needed to train the model by adding one or more GPUs (graphics processor) to quickly process the data. This implies that, if these elements are not needed, it is better to use machine learning rather than deep learning.

Indeed, feature extraction is one of the greatest challenges of traditional machine learning models, which has been automated by deep learning models to enable them to achieve a particularly high accuracy rate for computer vision tasks. Therefore, the ability to manage a large number of features makes deep learning powerful when it comes to unstructured data [13]. Nevertheless, DL algorithms can be overkilled for less complex problems because they need access to a large amount of data to be effective. On the other hand, the deep learning algorithms success depends on the availability of more training data. In fact, Google, Facebook, and Amazon have already started using it to analyze their massive amounts of data. In practice, all deep learning algorithms are neural networks, also called ANN. ANNs are information processing models that simulate the functioning of a biological nervous system. They are similar to the way the brain manipulates information at the functional level. Actually, all the neural networks are made up of interconnected neurons that are organized in layers. Then, the details of the neuron and the description of its functioning will be explained in the next part. In fact, what forms the neural networks are the artificial neurons inspired by the real neuron that exists in our brain [13].

On the other hand, the activation function is an essential component of the neural network. This function consists in checking whether the neuron is activated or not by calculating the weighted sum of the inputs and adding the bias. This is a nonlinear transformation of the input value. Moreover, the nonlinearity is particularly important in neural networks however, without the activation function, a neural network simply becomes a linear model [14]. Actually, there are many types of these functions, such as sigmoid function, ReLu function, and Softmax function. The distinct types of neural networks available for use, such as Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN) [15] [16].

### B. Steps of our Approach

Deep Learning has been proven to be effective in many complex problems using artificial neural networks to learn and extract patterns and information significant from the data [15].

Therefore, we find many contributions that attempt to adapt this approach as a solution to the problem of sentiment analysis. In this research, the proposed model (RNN) will be used. Also, other types of neural networks will be applied as comparison experiments to the proposed model. Now we are going to present the tasks necessary to conduct this work as showed in Fig. 1.

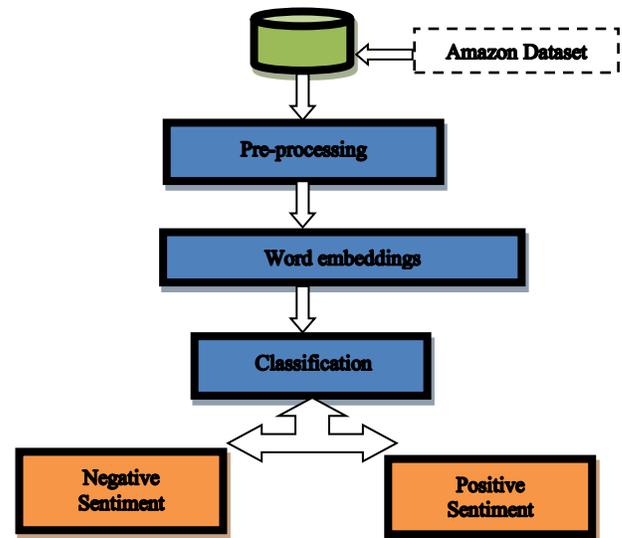

Fig. 1. Architecture of our Method.

- Pre-processing is preparing the dataset to have an excellent quality. This is important tasks that must take place before using a dataset for model training. In order for the models to be professionally trained and to provide the expected results, the data used must be representative, clean, precise, complete, and well labeled. For example, for the prediction the feelings of comments from social networks, the corpus must contain the same type of documents. The preparation of these data is therefore a crucial step [4].
- Word embeddings are the mapping of words to number vectors real in a reduced dimensional space. Word embedding vectors represent words and their contexts; thus, the words with similar meanings (synonyms) or with close semantic relations will have more similar embeddings. In addition, word embeddings should reflect how the words are related to each other. For example, the inscriptions for "man" should be "King" like "woman" is "queen". Since learning word embeddings takes time and the power of calculation, the method started with pre-trained incorporations.
- In the classification step, we apply the RNN model in order to predict the sentiment of the author. We have two output classes: positive sentiment (Happy, in love, smile, etc.) and negative (afraid, not happy, angry).

### V. RESULT AND DISCUSSION ON AMAZON DATASETS

For this system to function, the method has to go through the following experiments. The proposed method is validated in two steps, in the first amazon dataset, the corpus is divided into 4,149 test comments, which (which represents 20% of the

dataset) to assess this model and have its precision, and 16,593 training comments, and obtain as precision 75% for the training and 70% for the test. Fig. 2 shows the results.

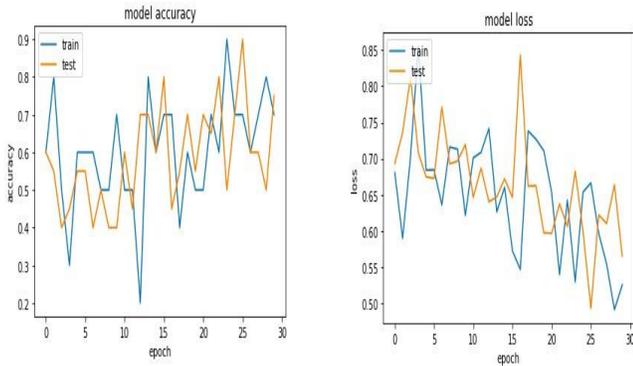

Fig. 2. Precision and Error of this Model for the First Test.

In the second experiment, the data is trained using binary sentiment classification model on a dataset 2 of 66666 items, 33333 positives and 33333 negatives, as shown in the Fig. 4. The best accuracy is obtained with 25 epochs for training and also for test. For the loss, the minimum value is also obtained with 25 epochs for test and 27 for training. Additionally, the corpus is divided into 6667 test comments (which represent 20% of the dataset) to test the model and have its accuracy, and 59999 training comments. Then, we obtained 90% as precision for training and 85% for the test. Fig. 3 shows the results plotted in graphs. For the loss, the best value is obtained with 27 epochs.

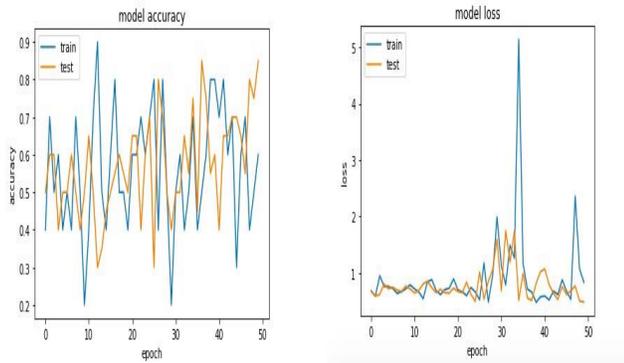

Fig. 3. Precision and Error of the Model for the Second Test.

In the third experiment, we trained our binary sentiment classification model on a dataset 3 of 49,870 items, more than 24,900 positives and 24,900 negatives. Moreover, the corpus is divided into 9973 test comments (which represent 20% of the dataset) to evaluate our model and have its accuracy, then 39897 training comments, where results are 90% for training and 70% for accuracy. For the loss, the best results are obtained with 17 epochs for training and 30 epochs for test. Fig. 4 shows the results plotted in the graphs.

In the first validation, the model was applied to the three data sets mentioned above and the evaluation was made in terms of the accuracy and recall metrics, as summarized in the Table I. Accuracy is the number of relevant documents found compared to the total number of documents proposed for a

given query. The recall is defined by the number of relevant documents found with regard to the number of relevant documents that the database has [17].

Our decision to choose different datasets based on their size was to see how a DL model works in two situations where we have a large and small amount of data. For the final tests on the datasets, we trained the 30-epoch model. From what we have as results, the effectiveness of the proposed model and the possibility of its use in this area. For second validation, three models were applied on the same data sets as shown in Table II. Our results obtained using RNN are compared with three most known deep learning Models. In fact, our results surpass those obtained by CNN. For LSTM and GRU we did not obtain encouraging result.

In the third validation, as shown in Table III, we compared our results on the dataset amazon reviews2 with Palash experiments. It can be noted that Palash participated on the kaggle3 competition on Amazons' reviews datasets. Palash presents a method using bidirectional LSTM, for the document representation he based on n-grams (a chunk from 2 to 6 grams) to classify sentiments (positive, negative). The best result for his experimentation is obtained using 5-grams. In Comparison with the last study, we obtained the best result for the accuracy with 96%, but we did not surpass those of Palash for the recall.

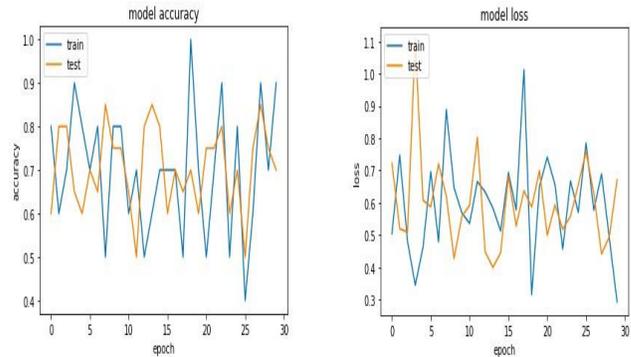

Fig. 4. Accuracy and Loss of our Model for the Third Test.

TABLE I. RESULT ON THREE AMAZON DATASETS

Amazon data	Training	Test	Accuracy
20742	16593	4149	70%
66666	59999	6667	85%
49870	39897	9973	70%

TABLE II. COMPARISON BETWEEN 4 DEEP LEARNING MODELS IN TERMS OF ACCURACY

Deep Learning Model	LSTM	GRU	RNN	CNN
DATA1	76	80	85%	83
DATA2	68	65	70%	70
DATA3	68	64	70%	68

TABLE III. COMPARISON RESULTS WITH PALASH4 STUDY USING  
BIDIRECTIONAL LSTM AMAZON REVIEWS DATASET CONTAINING 400000  
REVIEWS

	Bidirectional LSTM (Palash)	Our Model
Accuracy	94%	96%
Recall	90%	85%

## VI. DISCUSSION

Experiments have shown that our system is efficient compared to other models (GRU, LSTM, etc.). Indeed, for the three datasets our system has obtained the best precision. Nevertheless, for recall we found a worse result than LSTM. Indeed, Lstm used by Spalash gave 90% against our model 85% for the Amazons corpora, our results were less good for data-one and three because the size is minimal, while the results for corpus two were encouraging since we had 66,000 documents.

## VII. CONCLUSION

In this paper, we aimed to contribute to the sentiment analysis field by presenting the tools and Arabic datasets, as well as the steps we have followed to obtain the appropriate results for our model. In fact, our sentiment classification model helped us to correctly categorize more than 85% of all the 7480 test items, which means that our system has correctly categorized more than 5984 items. Moreover, the experiments proved that as the size of the training data increases, the accuracy rate increases, which implies that the percentage of the test dataset is as important as it was in the first experiments. Therefore, our model performs well if we use it for the sentiment analysis problem, where the amount of learning data plays a significant role. The proposed system succeeded in obtaining an accuracy of 85%. As Future work, we will depend on multilingual corpora to predict sentiments. Also, we will use reviews about Covid-19 in KSA twitter to predict emotions of people in period of virus vaccination.

# Arabic Sign Language Recognition using Lightweight CNN-based Architecture

Batool Yahya AlKhuraym, Mohamed Maher Ben Ismail, Ouiem Bchir  
College of Computer and Information Sciences  
King Saud University, Riyadh, KSA

**Abstract**—Communication is a critical skill for humans. People who have been deprived from communicating through words like the rest of humans, usually use sign language. For sign language, the main signs features are the handshape, the location, the movement, the orientation and the non-manual component. The vast spread of mobile phones presents an opportunity for hearing-disabled people to engage more into their communities. Designing and implementing a novel Arabic Sign Language (ArSL) recognition system would significantly affect their quality of life. Deep learning models are usually heavy for mobile phones. The more layers a neural network has, the heavier it is. However, typical deep neural network necessitates a large number of layers to attain adequate classification performance. This project aims at addressing the Arabic Sign Language recognition problem and ensuring a trade-off between optimizing the classification performance and scaling down the architecture of the deep network to reduce the computational cost. Specifically, we adapted Efficient Network (EfficientNet) models and generated lightweight deep learning models to classify Arabic Sign Language gestures. Furthermore, a real dataset collected by many different signers to perform hand gestures for thirty different Arabic alphabets. Then, an appropriate performance metrics used in order to assess the classification outcomes obtained by the proposed lightweight models. Besides, preprocessing and data augmentation techniques were investigated to enhance the models generalization. The best results were obtained using the EfficientNet-Lite 0 architecture and the Label smooth as loss function. Our model achieved 94% and proved to be effective against background variations.

**Keywords**—Arabic sign language recognition; supervised learning; deep learning; efficient lightweight network based convolutional neural network

## I. INTRODUCTION

Communicating with others is an important skill for humans to interact with their environment community. In its absence, exchanging experience and expressing its opinion and feelings become a very challenging task. In fact, communication allows the discussion of different types of issues that concern humans in order to address them and come up with appropriate solutions to facilitate their daily life. Besides, communication is a censorious factor for individual's mental health [1]. Actually, communication types can be categorized into four groups: (i) verbal, (ii) non-verbal, (iii) visual and (iv) written communication.

Hearing Impaired (HI) persons are actually affected by their disability, and cannot ensure regular communication with others. They typically use non-verbal gestures as a visual

communication type that relies on hand movements and facial expressions [2]. On the other hand, deaf people use sign language as their primary communication technique, where sign language is based on visual-motion codes. This codified system is defined using standard positions and hand movements supported by facial expressions [3]. Typically, hearing impaired people use hand gestures, called signs, to interact with others. Commonly, for existing sign languages, the main signs features are the handshape, the location, the movement, the orientation and the non-manual component. Thus, sign language recognition system assists people with hearing disabilities to communicate with healthy persons. Particularly, such recognition systems are meant to deliver the semantic corresponding to hand gestures of sign language to the interlocutor.

Sign language is considered as a descriptive language which it composed of hand gestures and facial expression. Arabic Sign Language (ArSL) used in approximately 22 Arab countries with different gestures. The discrepancy noted for some word gestures can be attributed to the cultural diversity between these countries. Despite this lack of uniformity of ArSL, all of the 22 countries use the same gestures for the Arabic letters and numbers [4]. Fig. 1 shows the standard Arabic sign language that expresses the Arabic alphabets.

Next sections are mention and discover the main types of ArSLs recognition systems, first, image-based ArSL recognition, can be categorized into three main groups: (i) continuous, (ii) isolated word, and (iii) alphabet recognition systems. Typically, those systems contain five major stages, where each single stage is meant to achieve a particular task. Namely, those five stages are: acquisition of images, preprocessing the images, then extraction the features from that images, after that the images segmentation, and lastly classification process.

Second, alphabet recognition, signers usually perform letters signs independently in the context of alphabet recognition scenario. To represent letters, static poses are used, and the size of vocabulary is minimal. Although the Arabic alphabet includes 28 letters, ArSL considers 39 signs [5]. Actually, the 11 added signs reflect simple signs that combine two letters. Third, word sign recognition, its techniques are relying on further analysis of the images. These techniques are more practical than alphabet recognition, but the alphabet recognition is less complex than word recognition. The major purpose of using word sign recognition is process various images in a sequence.

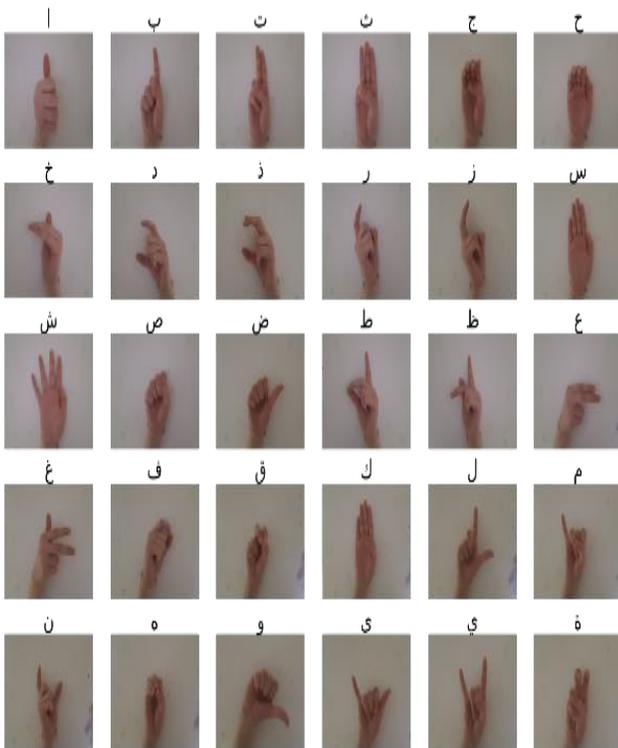

Fig. 1. Unified Alphabets for Arabic Sign Language.

Deep learning is introduced in Artificial Intelligence (AI) as a sub-group of machine learning [6]. For image recognition issues, deep learning algorithms have provided efficient solutions. In deep learning, Convolutional neural network (CNN) is considered as a class of deep neural networks commonly exploited in computer vision. The optimization of CNN networks can be introduced as a set of algorithms or methods used to alter the neural network attributes like weights, learning rate for reducing the loss costs, and provide an accurate result. In particular, Adam optimizer is an optimization algorithm for stochastic gradient descent used to train the models of deep learning [7]. In 2019, Google introduced new family of CNNs named EfficientNet [8]. EfficientNet proved to have lower number of parameters and Floating-Point Operations Per Second (FLOPS) and yield competitive accuracy [8].

In this project, we propose an image-based ArSL recognition system that relies on lightweight Efficient Network (EfficientNet) [8] to enhance the overall ArSL recognition performance and reduce the number of parameters and hence the time complexity. Standard performance measures and real datasets will be considered to evaluate the performance of the proposed system.

## II. RELATED WORK

ArSL recognition is even more challenging than ASL due to the considerable similarity between some of its letters signs. Recently, several approaches have emerged to address issues relevant to ArSL recognition. Particularly, researchers have investigated glove-based and glove-free approaches for ArSL classification. Both approaches rely on machine learning techniques but to different extent. In this situation, some

models employ deep learning techniques, while others deploy shallow classification models. This literature surveys aims at giving an overview on state-of-the-art deep-learning and shallow-model based ArSL recognition approaches.

### A. Shallow Model based Approaches

An ArSL recognition system was proposed in [9]. Specifically, a framework based Scale-Invariant Features Transform (SIFT) features was designed to extract the visual properties of ArSL gestures. In fact, SIFT extraction algorithm encloses five main steps. First, it requires rolling together with the Gaussian filter of different widths with the image. It is essential as it can help demonstrate the Gaussian function pyramid's difference. The extrema of the Gaussian pyramids are identified by comparing each point to its neighbors. The removal of main points at the extremes that are thought to be susceptible to noise are situated on edge. The next important thing is to determine the orientation. Next, in order to achieve that, it creates a histogram. It can be created from the sample points' gradient orientations. Finally, for the purpose of a local image region, a descriptor is produced. Afterward, a Linear Discriminant Analysis (LDA) was conducted to achieve dimensionality reduction. The researchers fed the resulting feature to classifiers: K-Nearest Neighbor (KNN) and Support Vector Machine (SVM). The test results revealed that SVM outperformed KNN with a 98.9% accuracy. In [10], the authors introduced a similar approach to the one outlined in [9]. Although, their approach used LDA alongside Gaussian Mixture Model to fit the dataset. The experiments relied on a dataset collected using two dual Leap Motion Controllers (LMC). Two native signers were involved in the collection of 100 Arabic signs. The proposed framework achieved an accuracy of 92%, which is relatively higher than for similar sensor-based techniques.

In [11], a system for automated ArSL recognition using visual descriptors was introduced. The system was designed to generate a large number of visual descriptors in order to provide an effective ArSL alphabet recognizer. In particular, a one-versus-All SVM was used to classify the generated visual descriptors. According to their findings, the Histograms of the Oriented Gradients (HOG) descriptor significantly outperform the other descriptors. In addition to this, as far as the ArSL recognition is concerned, the method that was brought forward attained 90.55% of recognition accuracy.

Other researches were conducted to develop ArSL recognition schemes based on the nearest neighbour classification. Specially, in [12], a lexicon of 80 words was considered and a sensor-based dataset was collected. This dataset was then used to assess the performance of the glove-based ArSL recognition system. Following the data labeling stage, a low-complexity preprocessing and feature extraction techniques were deployed in order to capture the data temporal dependency. Additionally, a Modified K-Nearest Neighbor (MKNN) was utilized to classify the outputs. The system achieved a sentence recognition rate of approximately 98.9%. The approach was considered superior to vision-based approaches pertinent to classification rates. Similarly, in [13], a KNN algorithm was also used in the design of an ArSL algorithm. With regards to the classification rates, it was witnessed that the method outperforms the methods that were

vision-based. In an ArSL algorithm design, the use of the KNN algorithm was done additionally. There were various things that were included in the system. These things included histograms and their comparisons and generation, image masking, narrowing and clipping of images, and recording and questioning of images. A test for the glove recognition and hits was done. The test was done on the established algorithm, and ultimately, around 90% of the hit rate was attained by most of the characters. As the algorithm did not possess an engine, which is a self-learning one, it was regarded as imperfect and faulty. The researchers in [14] suggested a method for detecting hands and faces based on skin profiles using input images translated to YCbCr color space. As image transformation, morphological dilation operation was also used. The Prewitt operator was used to detect hand form edges, and the Principal Component Analysis (PCA) was applied to achieve dimensionality reduction and obtain the final feature. The experiment showed a 97% accuracy on KNN based on 150 signs and gestures.

A Gray Level Co-occurrence Matrix (GLCM) feature was used to implement an ArSL transformation system suggested in [15]. Despite the fact that the system was not deep learning-based, it had four phases: processing, feature extraction, matching technique, and display translation. A mixture of 15 GLCM and histogram features is used to remove features. The system correctly recognized nineteen Arabic alphabets with a 73% accuracy rate, according to the test results. Existing systems used Hidden Markov Models (HMMs) to identify the ArSL in various ways and techniques. HMMs help developers create signer-independent systems that do not need gloves or attached sensors. The authors in [16] described an HMM-based automated ArSL recognition system. The main three steps of keeping the tabs on and detecting the hand involved tracking the fingerprints, detecting the edge, and identifying the skin. In order to reduce error rate and improve the detection of edge significantly, a certain type of algorithm was utilized. That algorithm is referred to as a Canny algorithm [17] where this algorithm acts like an optimal edge detector. For all of the frames, it was scrutinized that whether the outline of the image was rounded or not. Along with that, for the purpose of assessing observed regions of skin, an integrated component analysis was also deployed. Although the experiment yielded 82.22% detection rate, the device only used eight features per frame. As a result, the system's ease of use relies heavily on fewer features. In [18], several spatiotemporal feature extraction techniques that could be used to recognize isolated ArSL both offline and online were introduced. The researchers used forward, backward, and bi-directional projections to extract video-based movements. Now, to make certain that in order to delineate the video series, little amount of coefficients was used, and to terminate the terrestrial reliance, all of the errors were gathered and assembled into one particular image. The model that was proposed encompassed filtering such as a low pass filtering, Radon transformation, and Zonal coding. Along with these, it also includes a 2-D transformation. The experimental findings showed that in the identification of ArSL, output accuracy ranged from 97% to 100%. Different techniques involved various pattern recognitions and feature extraction techniques such as PCA, Local Binary Patterns (LBP), and the HMM were used in [19]. Hands and heads were

detected, attached components were labelled, and features were extracted accordingly. The experiments were based on 23 isolated Arabic words performed by three different signers. If we talk about the experiment done initially, the rate of the system recognition was computed in the absence of skin segmentation. Moreover, the rate of recognition with the features such as PCA-only, accompanied by the 30 eigenvectors, reached approximately 99.8%. The combination of LBP and PCA features with HMM led to the achievement of 99.9% recognition rate with 20 eigenvectors. LBP was applied in the description of the shape and texture of images, while PCA was used in the reduction of dimensionality. In [20], the researchers presented a method for creating a smart glove that can recognize ArSL. They did not report the accuracy of the simulation device, even though it was found to be cost-effective. In [21], the implementation of a mobile-based system was outlined. Since it contains several levels, the system tends to be compatible with a self-supervising system for deep learning. The results include details about the system's compatibility but no indication of its accuracy. The method described in [22] can also be thought of as a non-deep learning approach. Because the data was not reliable, the system relied on blob tracking using Euclidean distance. According to the report, the system had a 97% recognition rate based on a dataset of 30 different words.

#### B. Deep Learning based Approaches

In [23], a vision-based system for recognition for the Arabic sign language was proposed. It relies on CNN architecture to translate gesture images into Arabic speech in a supervised manner. This system detects hand sign alphabet and speaks out the corresponding Arabic letter using deep learning model. The feature extraction, considered as the first essential component of the system was followed by the classification component. During the feature extraction phase, the system transfers the input images into a three-dimensional (3D) matrix for depth, width and height specification. Then, the pooling layer reduces the size by decreasing the parameters number. After that, the classification is achieved through the fully connected layer. The reported performance attained 90% for the accuracy. Another Arabic sign language recognition system based on fine-tuning deep CNN was proposed in [24]. The system was evaluated using a set of 32 hand gestures categories. The system adapted Residual Network (ResNet-152) [25] and Visual Geometry Group (VGG-16) [26] as typical deep learning architectures, but with soft-max layer classification after the fully connected layer to improve the prediction performance. The input images fed into the resulting networks are two-dimensional (2D) images unlike in [23]. The reported accuracy was nearly to 99%, which considered as a very high accuracy. In [27], the researchers proposed an ArSL recognition system based on LeCun Network (LeNet-5) [28]. The considered network is composed of seven layers. The first four layers are responsible for the feature extraction process from the image. The last three layers are responsible for the classification task to categorize the input images into their corresponding meaning. The dataset used in that work contains 7869 Arabic sign language letters and numbers. The testing phase of the system has been done using 80% of dataset as a training set. An accuracy of 90.0% was achieved by their model. In [29], a different ArSL recognition system based on

deep CNN was depicted. The system aims at reducing the number of parameters in order to extract and detect the hand gestures. A collection of 50000 images including signs performed by a population of signers from various age groups. The system achieved an accuracy of 97% as best performance reported in their experiments. In [30], the authors investigated different transformation techniques for features extraction. The extracted features were then conveyed to the classification model for the prediction the Arabic sign. This study has compared three different classification methods. Namely, they used SVM, KNN and Multilayer Perceptron (MLP) for classification. The association of MLP with Hartley [30] transformation technique achieved nearly to 99% accuracy as recognition rate. Different approaches, such as image-based and sensor-based, were introduced in [31]. The proposed system for Arabic sign language recognition deepened on using a very common technique called Leap Motion Controller (LMC) [32], used as a backbone for this system. The LMC device aimed to detect the hand in order to provide the hand location and motion to facilitate the feature extraction process to classify the Arabic letters correctly. The system achieved a higher performance rate compared to Naive Bayes classifier with 98%, and 99% compared to the MLP neural networks. These results were obtained using 2800 images of Arabic sign language letters. Coupled with the findings in [30], the results show that MLP can be used successfully with LMC in the development of ArSL systems. Likewise, the researchers in [33] proposed an ArSL recognition system based on MLP neural networks for digital-sensor. The system achieved approximately 88% accuracy rate by recognizing 50 different dynamic markers represented by two signers. In [34], the authors developed an Arabic Sign Language Alphabet Translator (ArSLAT) system. Their system includes five stages: pre-processing, frame determination, category, features extraction, and finally the classification stage; for features extraction using translation scale and rotation invariant to achieve the flexibility of system; applied comparison between accuracy of system by using MLP and Minimum Distance Classifier (MDC) [35]. In addition, the result illustrated that system with MDC has an accuracy with 91%, while the MLP with system has 83%. In [36], a model was proposed to recognize the hand gestures of ArSL letters using supervised learning techniques and natural user interface libraries with the LMC skeleton [37] and Kinect [38]. In order to predict the hand captured from an input images that fed to the system in 3D manner as the system introduced in [30]. The results showed that their system can recognize 22 out of the 28 alphabets with 100% accuracy.

In [39], the researchers developed an ArSL recognition system based on Recurrent Neural Networks (RNN). This system relies on four different phases: acquisition, processing, feature extraction, and recognition of image. The processing of the image requires a colour system called Hue, Saturation, and Intensity (HSI) to extract the features associating with colour layers. As result, this system accomplished 95% accuracy in the recognition of 28 ArSL letters. In [40], an Adaptive Neuro-Fuzzy Inference System (ANFIS) [41] was used for ArSL recognition. The system is based on gestures that represent the

Arabic alphabets. Designing the system of many ANFIS networks in order to training on one gesture per network. Pre-processing the hand gesture to extract the features for classification process. The result of this system attained 93.55% accuracy in detecting 30 Arabic letters. On the other hand, a deep learning framework for isolated Arabic Sign Language gestures recognition was proposed in [42]. The purpose of that framework is to encounter three different challenges faced by different ArSL recognition systems. The challenges are: hand segmentation, extract features, and recognition of gesture sequence. To handle these challenges, the authors proposed three different networks. Namely, they used DeepLabv3+ for segmentation process, Convolutional self-organizing map for features extraction process, and lastly the Bi-directional long short-term memory for classification process. Finally, for testing, they used 3450 images that expressed 23 isolated words from three signers and accomplished approximately 89.5% accuracy.

In conclusion of this section, one can notice that existing related works can be categorized into two main different groups: (i) Approaches for ArSL recognition systems based on shallow machine learning models, (ii) deep learning based approaches. Both categories include different classification techniques and methods to recognize alphabet, numbers, words and sentences of Arabic Sign Language. In this project, we achieved our aim by proposing a lightweight based CNN-architecture to enhance the computational and classification efficiency of the ArSL recognition system.

### III. PROPOSED METHOD

We proposed an Arabic sign language (ArSL) recognition system based on lightweight EfficientNet CNN [43]. The proposed system is intended to translate automatically hand gesture images into the corresponding Arabic sign language letter. ArSL recognition problem is tackled as a supervised deep learning using a lightweight EfficientNet network. This choice of deep architecture aims at achieving a good trade-off between the ArSL recognition rate and the model complexity. In other words, the proposed research seeks a lightweight deep learning model to ensure high ArSL recognition accuracy. In particular, we adapted two EfficientNet models learned from the baseline model, EfficientNet-B0 [44]. Specifically, we scaled it down in terms of number of channels, depth and resolution. In other words, the CNN-based EfficientNet is the backbone structure of our proposed architecture.

The classification task is performed using fully connected (FC) layers where an FC layer hosts neurons which manage comprehensive connections. These connections determine a previous layer's activation. Also, when specific input and output are present, their representational mapping is aided by the FC layer. This layer borrows the regular neural network principles to execute its assigned functionalities. However, this FC layer works with one-dimensional data. The three-dimensional to one-dimensional data transformation would require the use of a flatten function for the proposed system to be implemented successfully. Subsequently the output will be the Arabic letter that associated with the input image of Arabic sign language.

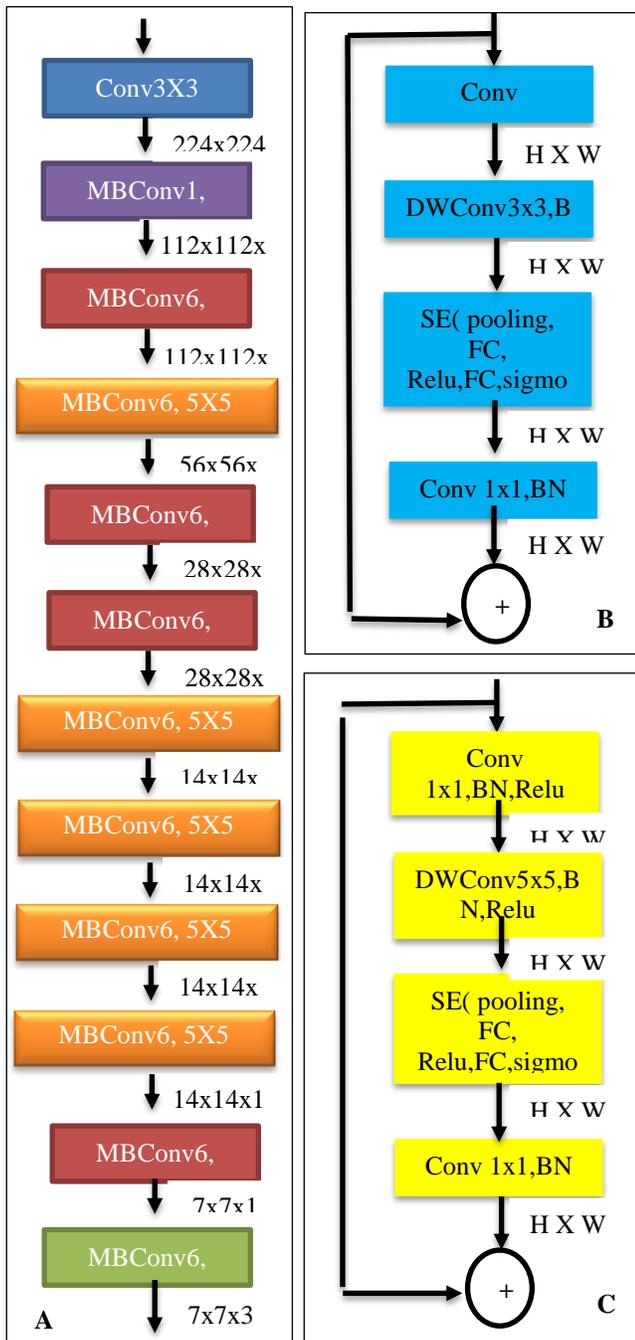

Fig. 2. Model Architecture (A) A Lightweight EfficientNet, (B) MBConv6 (k 3x3) and (C) MBConv6 (k 5x5).

One should note that since the input size tends to be bigger than the feature map size, the implementation of padding becomes the ideal solution to overrule the feature map shrinkage. It helps match the input with stride and kernel size. The resulting system state would yield an improved performance. On the other hand, the natural position of the pooling layer is between convolution layers. It serves the objective of reducing dimensionality and lessening the computations involved. The successful implementation of the pooling layer is due to the fewer number of parameters in play.

The proposed pooling is max pooling. It scans all windows and takes the highest value resulting in a reduced feature map size.

The proposed model uses inverted residual block called (MBConv) as the main building block of the architecture. In fact, MBConv is a mobile inverted bottleneck. It encloses a squeeze-and-excitation optimization [45] element. This mobile inverted bottleneck can be perceived as an inverted residual block that includes a  $1 \times 1$  convolution layer with batch norm and Rectified Linear Unit (Relu). It is also followed by a  $3 \times 3$  or  $5 \times 5$  depth-wise convolution with batch norm and Relu. Besides, a pooling-based Squeeze-and-Excitation (SE) optimization block is added. Next, FC layer and a Relu followed by FC layer and a sigmoid are stacked. It is worth noting that the scaling (i.e., Multiplication Operator (MUL)) aims at multiplying each channel by the input feature to obtain the final output of the SE Block. Finally, a  $1 \times 1$  convolution layer with batch norm is inserted. Note that the inverted residual block exhibit skips connection between the layers. Fig. 2 details the proposed network architecture. Besides, the loss function is the one that used to compute the difference between the logit of the real class and the logit of the output class. Since our task is a multi-class problem, multi-class cross entropy is generally used in such problem. However, a “label smoothing” technique was introduced for robust modeling [46], and it has been used in various state-of-the-art-models ranging from image classification to language translation and speech recognition in an attempt to improve accuracy by using a weighted mixture of targets from the dataset with uniform distribution instead of the hard targets to compute cross entropy.

#### A. Dataset

We collected real ArSL images to be used in the planned experiments. The collection images were captured using diverse smartphones. More than twenty volunteers participated in the collection of this dataset. Each volunteer performed thirty gestures corresponding to ArSL alphabet. Each character from this alphabet is represented using ten instances. This yields a total of 5400 images. Fig. 3 shows sample of our dataset for the Arabic letter “Baa”. As one can see, those images exhibit different visual properties of their background. This choice is meant to make the ArSL recognition task even more challenging. In other words, this would prove the ability of the proposed model to capture the most relevant visual features in order to discriminate better between the different ArSL alphabet classes.

#### B. Training Framework

The network will be trained like any usual CNN, by feeding the training input and output are fed to the model. Then, the model will keep iterating the training process through forward propagation and backpropagation. However, using EfficientNet has some requirements to use the pre-trained layers’ weights and continue the training process on the added layers. Where the size of RGB-images of sign gestures will be reduced to  $224 \times 224$  to enter the network in training phase. Then, the CNN-based feature extraction processes the captured imaged for feature maps detection. After that, these maps enter the Lightweight EfficientNet to produce potential hand gestures of the input. Finally, the scaled feature maps are

conveyed to FC layer classifier to generate the ArSL alphabet prediction. Then the model, using the output, will backpropagate and adjust the weights.

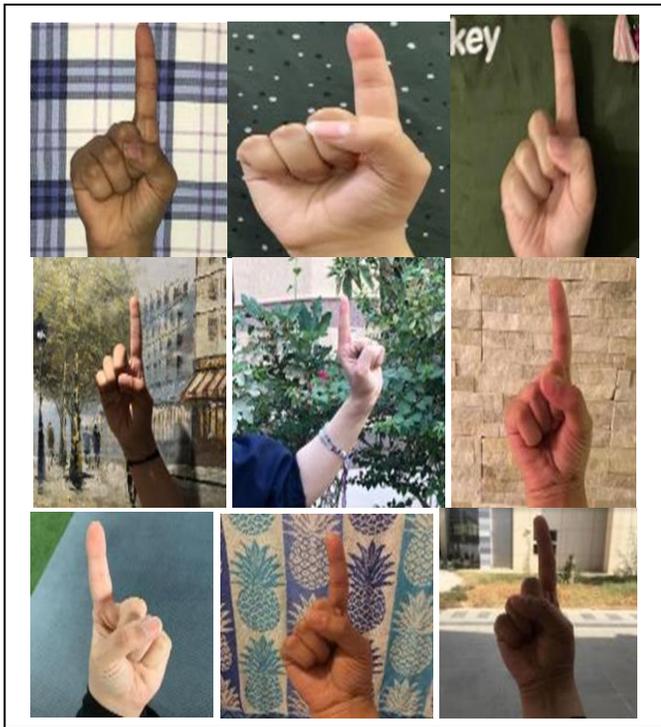

Fig. 3. Sample Images of “Baa” Letter from our Collected ArSL Data.

#### IV. RESULT

In order to evaluate the proposed models, we conducted four experimental scenarios. In the first one, we investigated the effect of segmentation on the system performance. Specifically, we fed the designed model with original and segmented (just the rectangle of hand was used as input) images. In this scenario Adam algorithm [7] was used to optimize the loss function. In the second scenario, we analyzed the system behavior when a Cross Entropy function is used as loss function in addition to Cross Entropy Label Smoothing. Same as in the first scenario, Adam optimizer was used here too. The third scenario was dedicated to the application of different versions of EfficientNet Lite model to see which model yields the best performance. As previous, Adam optimizer was used. The fourth scenario was designed to analyze the system behavior when four optimizers were applied in addition to Adam. In this scenario, to speed up the experiences, the lightest model (EfficientNet Lite 0) was the base model and all images were segmented.

One should note that the dataset described in Section III. proposed method is split into three subsets: (i) A training set including 4320 (80%) of images, (ii) A test set that includes 540 (10%) of the total number of images, and (iii) A validation set that represents 540 (10%) of the total number of images. For deep learning, the best practice is to use train/test/validation split rather than cross validation. All experiments were conducted using Nvidia K-80 GPUs associated with 16 GBs of RAM. The EfficientNet Lite network as well as the training, validation and the test

procedures were implemented using Pytorch library [47]. Moreover, five pre-trained models published in [48] were exploited in our experiments.

Table I summarizes the three first scenarios settings. Actually, there are 9 EfficientNet Lite versions; however, the pre-trained weights are available only for the first five models from Lite 0 to 4. We decided that reporting the results of the lighter and heavier model could be concise and more informative. Where Table II reports the performance measures obtained using these models and the test data outlined earlier, *Model 4* (the lightest version with segmented data and label smooth loss function) outperformed the other models, and achieved an accuracy of 94.30%.

##### A. Impact of Segmentation

The lightest models, Model 2 and Model 4, attained an accuracy of 94.30% and 84.54%, respectively. This shows the impact of segmentation of the model performance. This considerable difference in performance is expected. In fact, the segmentation eliminates the undesirable image parts and artifacts and allows the models focus and learn from the relevant content and discard the irrelevant regions. On the other hand, Fig. 4 shows the evolution of the accuracy during the training and validation phase. As one can see, the gap between the training and the validation curves is larger in the case of unsegmented data.

TABLE I. MODEL SETTINGS.

Model name	w / Segm	w/o Segm	CrossEntropy	CrossEntropyLabel Smooth
EfficientNet_Lite 0 <b>Model 1</b>		✓	✓	
EfficientNet_Lite 0 <b>Model 2</b>		✓		✓
EfficientNet_Lite 0 <b>Model 3</b>	✓		✓	
EfficientNet_Lite 0 <b>Model 4</b>	✓			✓
EfficientNet_Lite 4 <b>Model 5</b>		✓	✓	
EfficientNet_Lite 4 <b>Model 6</b>		✓		✓
EfficientNet_Lite 4 <b>Model 7</b>	✓		✓	
EfficientNet_Lite 4 <b>Model 8</b>	✓			✓

TABLE II. SUMMARY OF RESULTS OBTAINED BY MODEL EVALUATION ON TESTING DATA

Model name	Accuracy (%)	F-measure (%)	GFlops	# params
EfficientNet_Lite 0 M1	79.73	80.21	0.4	3.41M
EfficientNet_Lite 0 M2	84.54	84.80	0.4	3.41M
EfficientNet_Lite 0 M3	87.83	87.53	0.4	3.41M
EfficientNet_Lite 0 M4	<b>94.30</b>	<b>94.24</b>	0.4	3.41M
EfficientNet_Lite 4 M5	88.60	88.83	2.64	11.76 M
EfficientNet_Lite 4 M6	87.26	87.36	2.64	11.76 M
EfficientNet_Lite 4 M7	91.95	91.96	2.64	11.76 M
EfficientNet_Lite 4 M8	91.28	91.18	2.64	11.76 M

*params*: Number of model parameters, *GFlops*: Floating operation per seconds.

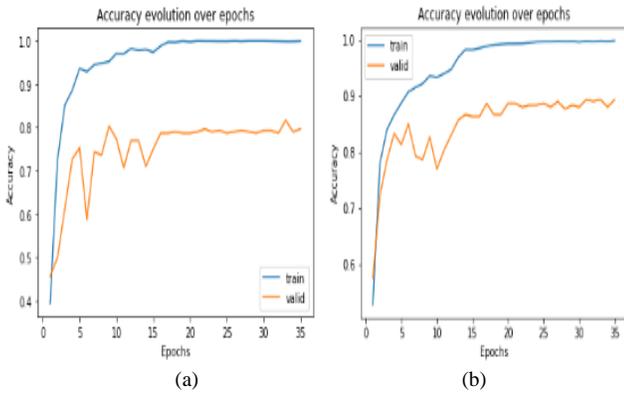

Fig. 4. Accuracy over Epochs, (a) Model 2: Unsegmented Images were used. (b) Model 4: Segmented Images were used.

### B. Impact of Label Smooth on Loss Function

The following results were obtained by evaluating the lightest pair of models, Model 3 and Model 4 in Table II. They illustrate the impact of the Label Smooth on the Cross Entropy loss function. An increase of 5% in accuracy can be noticed for the models using the Label Smooth. In fact, the Label smooth is typically used as a regularization technique that improves the model generalization. Particularly, Fig. 5 shows a larger gap between train and valid curves when no label smooth is used. This proves that the model over fits the training data before using this regularization technique.

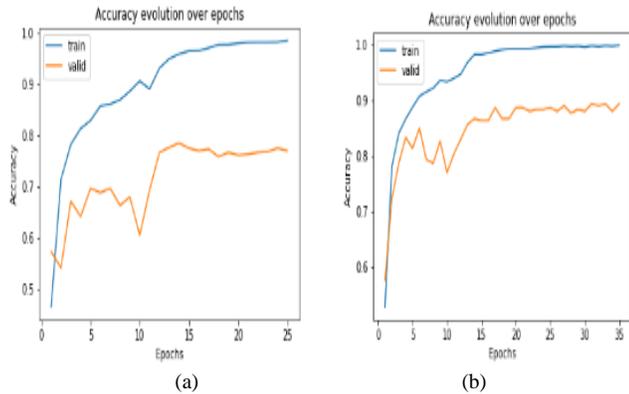

Fig. 5. Impact of Label Smooth Regularization: (a) Model M3: without Label Smooth. (b) Model M4: with Label Smooth.

### C. Impact of Optimizers

In these experiments, we tried to investigate five different optimizers known as Adam, RMSprop, AdamW, Adadelta and SGM optimizers. In order to figure out the best optimizer among them that had a good effect on the Model 4 to produce a good performance rate for recognition process of ArSL. Table III summarizes the results obtained from the fourth scenario when changing the optimizer in the training loop.

In fact, Model 4, the lightest version with optimal settings, is used for evaluation in this experiment. Namely, the optimizers used are Adam [7], RMSprop, AdamW, Adadelta and SGD algorithms. In RMSprop, stochastic gradient is applied with mini-batch and adaptive learning rates. Instead of accumulating prior gradient values, Adadelta adapts the learning rate using a moving window of gradient updates.

Adam combines the good proprieties of RMSpro and Adadelta. It uses Momentum and adaptive learning rate, in other words, the learning rate is gradually adjusted over time. It remains the most prevalent optimizer used in deep learning. Similarly, AdamW optimizer is a variation of Adam optimizer in which the optimization is performed for the weight decay and learning rate separately. Under particular circumstances, it is assumed to have a faster convergence rate than Adam. SGD is an optimizer that updates the weights for each training sample over a limited-size subset of data. As expected, Adam outperforms all others.

TABLE III. MODEL PERFORMANCE ON TESTING DATA USING DIFFERENT OPTIMIZERS

Model 4		
Optimizer	Accuracy	Loss
Adam	94.30%	0.054432
RMSprop	93.29%	0.055978
AdamW	92.62%	0.055098
Adadelta	89.94%	0.060984
SGD	86.93%	0.070220

### D. Impact of Data Augmentation

We noticed in the experiment scenarios, the training and validation images are augmented using random horizontal flip transformation. Table IV shows the performance achieved with and without data augmentation. As it can be seen, the flip transformation increases the Accuracy and F-measure by more than 3%.

TABLE IV. IMPACT OF DATA AUGMENTATION

Settings: Model 4		
	Accuracy	F-measure
With Horizontal Flip transformation	94.30%	94.24%
Without Horizontal Flip transformation	91.16%	90.98%

### E. Result of EfficientNet\_Lite 0 Model 4 on Arabic Sign Language

In the following, we report the performance measures recorded for letters obtained by Model 4. Specifically, accuracy, the precision, recall and F-1 measure in Table V. Most letters are recognized correctly despite the similarities in some gestures like (“shin: ش”, “sin: س”), (“dhad: ض”, “sad: ص”), (“thal: ذ”, “dal: د”), and (“ray: ر”, “zay: ز”) as depicted in Fig. 1 above. Further analysis showed that the 10 instances of each letter used in test are from the same signer. However, very few instances within one letter were not recognized. This is due to the intra-class variation or the inter-class similarities in gestures mentioned above. The least correctly classified letters are “Ra ر” (70%) and “Ain ع” (70%), where extra data could help to improve recognizing those two letters. On the other hand, there are 13 letters out of 30 with a 100% precision, where the rest of the alphabets did not have low precision except two letters with 70% as discussed before; applied different measures to assess Model 4 in order to provide an overview of its functionality and performance.

TABLE V. PERFORMANCE MEASURES OBTAINED USING MODEL 4

	Accuracy	Precision	Recall	F1
Model 4	94.30%	94.3%	94.46%	94.13%

V. CONCLUSION

Hearing-impaired people are suffering from the communication with others in an easy way since they have to learn the sign language, which considered as their formal language to interact with community. The overall performance of image-based solutions for this problem depends on the segmentation quality and the choice of the features that should encode the main visual properties of the sign language gesture. The existing solutions exhibit considerable rooms for improvement for the ArSL language recognition solutions which typically rely on heavyweight Convolutional Neural Network (CNN) models. The common hardware is insufficient for the existing models to deliver sufficient in real time in order to interpret the ArSL into Arabic spoken language. EfficientNet, introduced by Google, contains many CNNs layers that have high accuracy and also improve the efficiency of the models by reducing the number parameters and the computational cost. In this project, we proposed a system to recognize the Arabic sign language (ArSL) using a CNN based lightweight EfficientNet. Particularly, the proposed architecture contains two phases, feature extraction and classification in order to process the input image to produce the Arabic alphabet associated to that input. During this first phase of the project, we provided an overview on the background required for this research. Moreover, we conducted a literature review to survey existing relevant ArSL recognition system and approaches. We applied a real dataset to develop and deploy a system serving for the interpretation of letters of Arabic sign language. Then, standard performance measures adopted to assess the performance of the proposed system and compared its results with state-of-the-art approaches particularly VGG and ResNet.

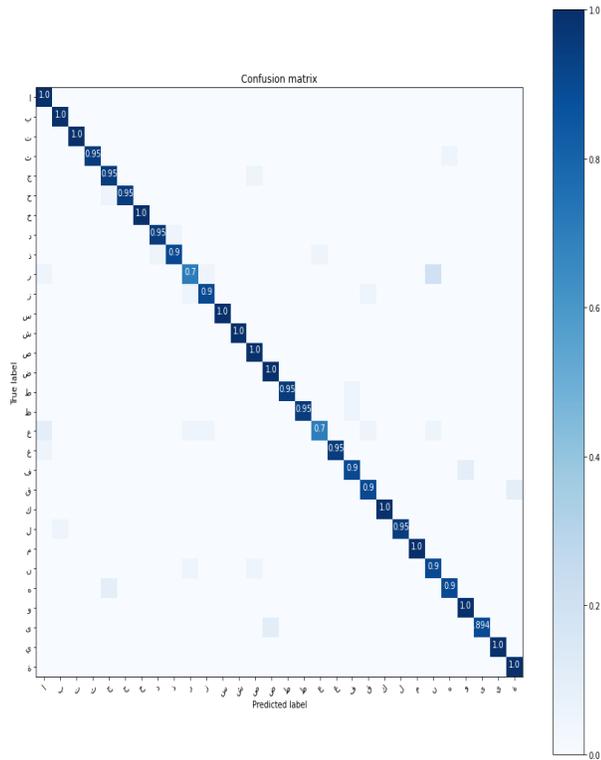

Fig. 6. Confusion Matrix obtained using Model 4.

Fig. 6 illustrates the confusion matrix obtained by the evaluation of the Model 4 by accuracy measure. Where it expresses a visual chart related to the predicted label of letters produced by Model 4 and the true label letters. As we can see here, two diagonal squares with a light color and an accuracy value of 0.7 corresponding to the letters (ra, 'ر') and (Ain 'ع'), respectively.

F. Comparison with other Existing Work

A comparison of the proposed recognition systems versus some of the most relevant work that cultivated the highest accuracy for ArSL recognition was conducted. We compared the results obtained by our best model, Model 4 (lightest version) to the work proposed in [48]. This existing work is a two Faster R-CNN technique based on VGG-16 and ResNET-18. As can be seen in Table VI, our model outperforms the existing works in term of accuracy by 1%. Furthermore, the size of our model is very small compared to the size of compared models.

TABLE VI. GLOBAL COMPARISON TABLE BETWEEN EXISTING WORK IN [48] AND THE PROPOSED METHOD

Model	Accuracy	# of parameters
Faster R-CNN(VGG-16)	93.2%	138M
Faster R-CNN(ResNET18)	93.4%	11M
EfficientNet_Lite 0 Model 4	94.30%	3.41M

As a future work, we propose to investigate Transformer for vision computer, a convolutional neural network (CNN) free deep learning architecture [49] based on self-attention mechanism. Where vision Transformer attains excellent results compared to state-of-the-art convolutional networks while requiring substantially fewer computational resources to train. Furthermore, we recommend extending this work to recognize the Arabic sign language words or common expressions.

ACKNOWLEDGMENT

This work was supported by the Research Center of the college of Computer and information Sciences at King Saud University, Riyadh, KSA. The authors are grateful for this support.

# Review of Industry Workpiece Classification and Defect Detection using Deep Learning

Changxing Chen, Azween Abdullah, S.H. Kok, D.T.K. Tien

School of Computer Science and Engineering, Taylor's University, Subang Jaya, Malaysia

**Abstract**—Object detection and classification denotes one of the most extensively-utilized machine vision applications given the high requirements put forward for object classification and defect detection with the rise of object recognition scenes. Notwithstanding, conventional image recognition processing technology encounters specific drawbacks. Its benefits and limitations were duly compared upon selecting several typical conventional image recognition techniques. Resultantly, such recognition approaches required multiple manual participation elements and extensive manpower with restricted object identification. As a branch of machine learning, deep learning has attained more optimal results in the image recognition discipline. In the classification and defect detection of industrial workpieces, over 70 literature reviews of deep learning algorithms across multiple application scenarios for classical algorithm model and network structure assessment based on the deep learning theory. Relevant network model performance was compared and analyzed based on network intricacies parallel to natural image classification. Six research gaps were found based on the reviewed algorithm pros and cons. The corresponding six research proposal in workpiece image classification was highlighted with prospects on the workpiece image classification and defect detection direction development. It provides an empirical solution for the selection of workpiece classification and defect detection deep learning model in the future.

**Keywords**—Convolutional neural network; image processing; image recognition; defect detection; deep learning

## I. INTRODUCTION

In line with the proposal of artificial intelligence [1], optimal computational intelligence performance in mathematical theory and computing power enriches the artificial intelligence theoretical framework and catalyzes artificial intelligence development. Perceivably, artificial intelligence constitutes a part of computer science following the emergence of industry 4.0. Artificial intelligence could enhance the level of organizational astuteness with substantial implications across multiple sectors. Deep learning and artificial intelligence machine learning depict a broad range of application disciplines, such as image recognition, network security, speech recognition, and natural language processing with significant breakthroughs. Various artificial intelligence recognition systems have been consistently developed with distinct functions and forms for economic and social advantages [2]. The fundamentals of artificial intelligence imply machine learning with algorithms. Multiple image recognition techniques require flexible adoption based on distinct application prerequisites to fulfill various image recognition task requirements in the practical application process. Under the computer vision category, image

recognition, which simulates human vision using computers or image-based instruments, facilitates computers to comprehend the recognized entities with algorithms to substitute human eye functions. Conventional image recognition method development proved relatively slow pre-artificial intelligence development. Such recognition techniques were previously based on the object feature descriptor for image recognition and matching with limited discussions on conventional image recognition approaches [3]. The deep learning theory was derived from the conventional neural network under the deep neural network. This theory has eventually become the mainstream of image recognition methods with a distinct object recognition concept simultaneously, it is widely used in pattern recognition [4, 5], image recognition has made breakthroughs upon introducing deep learning into the image processing field while resolving multiple problems that could not be managed by conventional approaches.

Workpiece surface defect is one of the most important factors affecting the product quality of mechanical workpiece. The traditional manual visual inspection method is easy to be affected by manual experience and subjective factors, which lead to inaccurate test results and cannot meet the current inspection requirements and the on-line production requirements of automatic production line. Machine vision inspection has the advantages of high automation, high recognition rate and non-contact measurement. It has gradually become the mainstream method and development trend of surface defect detection. According to the current inspection and classification requirements of workpiece manufacturers, combined with the actual situation of the industrial site, starting from solving the actual impact, workpiece classification and defect recognition are carried out through machine vision. Machine vision classification and detection algorithm can solve the problems of many types and large quantities of workpieces.

A substantial number of factory workpieces (common components in industrial manufacturing) are extensively employed in industrial production. The prerequisites for workpiece recognition speed and accuracy continue rising as opposed to manual workpiece classification strategies with low efficiency and accuracy. In this vein, classification detection denotes high subjectivity. The recent emergence of artificial intelligence technology and computer vision and its application has been extensively employed in industrial sites to catalyze industrial parts classification development. This study summarized the common conventional image recognition approaches, presented specific common image recognition techniques under deep learning, and compared the method performance and effects on other applications.

## II. IMPORTANCE OF INDUSTRY WORKPIECE CLASSIFICATION

Workpiece denotes a product manufacturing process component where the machining object in machining or generation (a single part or combination of specific ones) is assembled. The advent of artificial intelligence includes novel application prerequisites for the factory flow production mode given the perpetual improvement of labor cost on the industrial site and highly stringent product quality requirements. Automatic workpiece assembly is highly significant post-artificial intelligence development as the conventional artificial assembly line production mode failed to complement advanced industrial production. As such, industrial automation must be established to optimize manufacturing industry competitiveness. Accelerated automation transformation and the optimization of conventional sectors remain as one of the fundamental points to catalyze industrial development. The artificial intelligence-industrial site integration is inextricably linked for high productivity, novel changes, and industrial development possibilities. Industrial assembly is highly essential in the entire production process as each industrial site requires distinct parts. On another note, a sophisticated industrial production line encompasses workpiece classification and detection. Notably, the robot arm completes the assembly, sorting, and other relevant tasks involving various industrial parts post-classification and detection. Some industrial part sorting proves unsuitable for workers to sort and detect due to industrial site risks when the application scenarios are sufficiently enriched as follows: the monitoring state in the parts-sorting process, sorting process control, and workpiece classification emergency treatment in the industrial site. High requirements are reflected for industrial part detection accuracy and equipment process control stability.

The conventional manual workpiece sorting approach depends on manual operation for parts classification realization. This technique requires high worker's proficiency with substantial product quality implications. Specifically, the equipment of refined workpieces hampers production sorting. As product sorting and detection period in the entire production cycle proves time-consuming, production optimization depends on whether the automatic product line sorting process could be actualized. The means of scientifically controlling the industrial site workpiece classification denotes a complexity that must be regarded and resolved by relevant personnel in encouraging continuous industrial development through automation and intelligence. Machine vision systems, with image processing as one of the pertinent technologies, are increasingly implemented to resolve classification issues. It is deemed necessary to recognize workpieces for target workpiece classification realization. Image recognition is a processing application technology in deep learning and a fundamental task in computer vision. The diversified industrial parts demand substantially challenges the manufacturer's production and classification level given the adverse environment and intricate background within the industrial field. It is considered challenging to recognize the image and resolve the problem with conventional image feature selection based on interference factors: light and workpiece placement background. The industrial workpiece images to be classified

are typically complex and ambiguous in practical production and application, thus rendering it intricate to structure an appropriate workpiece image classification approach. Observably, image classification denotes one of the difficult problems to be resolved in image classification and detection tasks.

## III. GENERAL OPEN SOURCE WORKPIECE DEFECT DATASETS

Image datasets to highlight workpiece defects and classification remain lacking to date given the novelty of image defect detection studies. Current online public datasets generally constitute daily necessities, faces, and animals. Most recognition-oriented publications are performed on conventional image classification datasets [6]. Conventional image processing algorithms are typically incorporated into traditional surface defects and classification techniques. Artificial design features and classifiers are commonly implemented compared to the clear classification in computer vision. Specific datasets were adopted to complement the deep learning neural network training. The image formats typically encompass JPG and BMP and JPEG and RGB. Specific datasets in industrial disciplines, such as polished workpieces and customized CNC lathe workpieces do not possess public datasets. The lack of corresponding image training sets would inevitably restrict the promotion of deep learning applications in workpiece recognition. Data incongruence and dataset annotation need to be resolved despite the presence of constructed workpiece dataset pictures.

Current industrial dataset usage could accelerate the deep learning algorithm model development while public, reliable, and open-source industrial datasets could compare distinct deep learning detection algorithms. This section briefly elaborates extensively-utilized industrial datasets following the industrial workpiece classification strategy and the broad industrial dataset application for defect detection as shown in Table I.

TABLE I. GENERAL OPEN SOURCE WORKPIECE DEFECT DATASET

Dataset	Literature	Type Quantity	Image Size	Number of Images
NEU surface defect database	[7]	6	200*200	1800
Severstal steel defect dataset	[8]	4	1600*256	12568
DAGM 2007 dataset	[9]	10	Grayscale 8-bit PNG format	11500
Kolektor surface defect dataset	[10]	50	width: 500 px height: from 1240 to 1270 px	399
Rail surface defect dataset	[11]	2	variable size	195

The dataset derived from the NEU surface defect database was gathered and generated by several Northeastern University teachers. Six surface defect types were demonstrated with each type entailing 300 picture samples with a total of 1800 grayscale pictures provided through the bounding box. The picture size was 200\*200 pixels. The datasets implied rolling scale

(RS), cracking (CR), pitting surface (PS), plaque (PA), inclusion (in), and scratch (SC). As shown in Fig. 1. Multiple defect types inevitably appeared on the metal workpiece surface during the production process [12]. The dataset was employed to train and classify the surface defect deep learning algorithm [13]. Notably, the artificial feature extraction approach could be integrated with the deep learning algorithm for optimal workpiece classification accuracy amidst insufficient samples.

The Severstal steel defect dataset provided by Severstal steel entails four strip steel surface defect types to locate and classify surface defects on steel plates. A total of 12568 training and 5506 test sets were identified with an image size of 1600\*256 [14]. This dataset was analyzed with a per-pixel basis evaluation [15] with the potential as a high-quality defect detection baseline. As such, the deep learning model demonstrated better generalization and higher prediction accuracy in forecasting steel plate surface defects with the Severstal dataset [16]. The deep learning algorithm trained the data and optimized the defect detection learning model for gap identification compared to the other algorithms. In this vein, the deep learning algorithm model was structured while enhancing detection accuracy.

The DAGM 2007 dataset encompasses 10 defect image types with each containing 575 training images and 575 test images: training and test sub-datasets with the same size and a distinct number of label images, as shown in Fig. 2. Every picture encompassed the images saved in grayscale 8-bit PNG format for weak supervised industrial optical detection learning and training. The variance between dataset images proved to be minimal. The recognition algorithm model requirements are considerably high in accurately classifying the defects despite the presence of label files [9]. The accuracy and speed assessment of the fabric defect detection model algorithm using the dataset [17] catalyzed the elevation from the low-resolution feature map to the high-resolution fusion feature counterpart with iterations for optimal prediction outcomes.

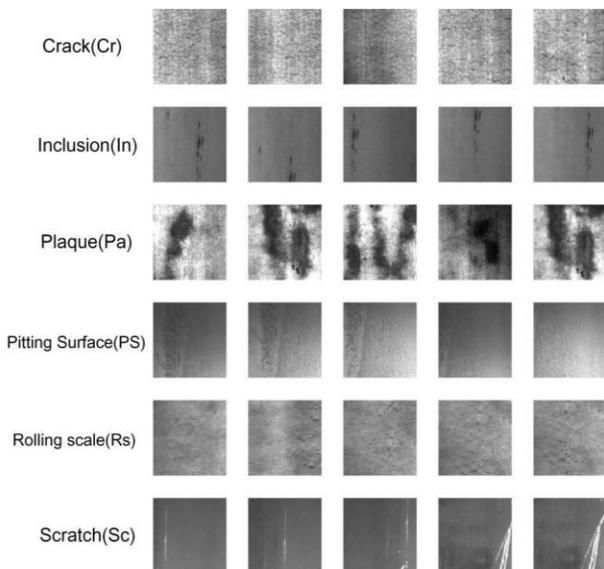

Fig. 1. The Six NEU Types of Surface Defect Images.

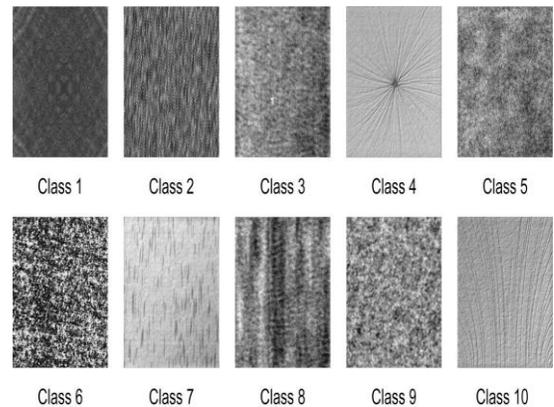

Fig. 2. DAGM Dataset:10 Types of Surface Defect Images.

The Kolektor surface defect dataset primarily gathered defect electronic commutator images, which were subsequently collected under uniform illumination. Labeled pictures were also provided, as shown in Fig. 3. The variance between the pictures proved to be minimal with only one defect picture in every defect type, such as a workpiece with small damages or cracks that are challenging to identify with human eyes. Only 52 defect images were visible in the entire dataset [10], thus significantly facilitating workpiece defect detection tasks.

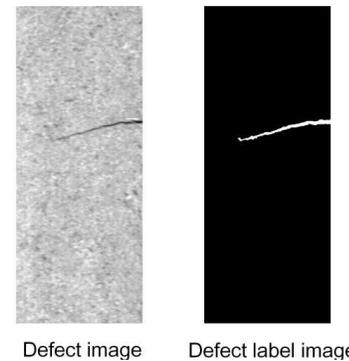

Fig. 3. Kolektor Defect Picture and Labeled Defect Picture.

The rail surface defect dataset implies the train track defects (train track surface crack image) marked by track surface inspection experts. The dataset encompassed 195 challenging images with every image entailing at least one defect and complex and noisy background [18]. Test and prediction datasets could be offered for the deep learning algorithm model to completely detect complex background information defects.

The detection and classification performance of the deep learning algorithm model correlates to image quality, which would then impact performance indicators involving model classification accuracy. Sample incongruence would also influence the classification outcomes with a substantial variance between training and test image quality [12]. Perceivably, the model prediction impact was associated with the model itself and the dataset [13]. More high-quality image data samples could facilitate optimal deep learning model algorithm development for high classification and detection performance.

#### IV. TRADITIONAL APPLICATION METHODS OF IMAGE RECOGNITION

Image recognition denotes computerized image processing, analysis, and understanding to determine multiple target and object types. This approach implies a practical deep learning algorithm application [19], such as online workpiece recognition for grinding burn and wheel wear following a self-clustering neural network [20]. Feature matching was primarily utilized for workpiece object recognition in the preliminary stage. Computer key visual features [21] were employed for high detection rates. Meanwhile, Salve et al. recommended a means of shape measurement for object recognition [22]. Dalal et al. utilized the histogram of gradient (HOG) descriptor to compute each stage impact on its performance [23]. Effective gray and rotation invariant texture classification techniques were also incorporated in the early stage under the local binary mode [24]. Tuzel et al.'s research integrated region descriptors with target detection and texture classification [25]. As an astute classification system under machine vision, it essentially classifies the peeled open heart fruit core and shell [26].

K. Xia et al. structured a workpiece sorting system in line with a machine vision industrial robot to complete the sorting operation and fulfill subsequent requirements using image edge detection [27]. Some of the applications depicted in bottleneck identification, which varied from current intuitive approaches, structured a bottleneck identification model following the shortest completion delay time for the overflow load computation of every machine to fulfill each workpiece delivery and optimally determine bottlenecks [28]. Y. Guan et al. employed the affine scale invariant feature transformation (a-sift) technique to identify the rough matching feature points between the assessed and planned workpiece towards workpiece identification by making the identified affine change [29]. Hu's invariant moment was implemented to complement the extracted contour with the target counterpart within the template image for target workpiece identification [30].

Regarding workpiece detection and recognition, conventional approaches typically require manual feature selection and extraction to outline the features as vectors and utilize the similarity measurement function to match the (i) workpiece feature vectors to be identified and (ii) template workpiece [31]. The advent of image recognition remains stunted given its inapplicability in big-scale industries following the low efficiency of conventional sliding window approaches and feature robustness. Table II compares six typical methods and their subsequent categories.

Although conventional image recognition techniques primarily outline objects with artificially-designed features, it is deemed impossible to manually extract rich image feature information from objects with intricate feature designs, thus challenging the recognition problem. As such, a data-driven approach (convolutional neural learning network) proves necessary for image feature data comprehension and processing. The image classification approach with a convolutional neural network could derive the target feature value from the (i) image that is challenging in manual feature extraction or the (ii) image dataset encompassing significant noises compared to the traditional image recognition

counterpart. For example, the workpiece dataset in the industrial field demonstrated good robustness to the training and recognition image upon deriving this eigenvalue with the convolution neural learning network. The extracted feature sequence was simultaneously conveyed to the deep neural learning network, which could further elicit the fuzzy features in the image convolution features and forecast the labeled workpiece image. Workpiece image recognition under the convolutional neural network could integrate the two-step workpiece detection and recognition into one, efficiently determine the novel workpiece information encompassed in the image, and save model space and computation with vital and practical significance for project implementation. Convolutional neural network, a deep neural network with a convolution structure, has recently been incorporated into multiple image recognition scenarios. This network inputs the original image into the network. Every network node conveys the image data post-data pre-processing and outputs the probability distribution on the category label with layer-by-layer weight iterative update and computation.

TABLE II. TRADITIONAL METHODS OF TYPICAL IMAGE RECOGNITION

Methods	Reference	Recognition Object	Advantages	Disadvantages
SVM classifier	[32]	tomato	Detect with the least number of features	Extensive color analysis was required
Moment invariant method for edge detection	[33]	workpiece	Able to measure the roughness of a rotating workpiece	Specific measurement environments were required
Template matching method	[34]	workpiece	Simple, practical, and fast recognition speed	The recognition effect was deemed poor for the workpiece with ambiguous feature points
Feature extraction classification	[35]	workpiece	Effectively resolve the problems of unclear features and inaccurate recognition in a complex environment	The recognition robustness was deemed poor without fulfilling the universality of recognition
ROI extraction method	[36]	Air-bearing workpiece	A block matrix was developed using reference pixels and tolerances	Reference pixels were required
Method based on Zernike Moments	[37]	Complex workpiece	Insightful to detect ignored loading attachments and inaccurate assembly positions	The identified object needed to be located

## V. IMAGE RECOGNITION METHOD BASED ON DEEP LEARNING

Deep learning constitutes a subclass of machine learning in traditional techniques. Object image feature extraction heavily relies on the manually-designed feature extractor, which requires expert designer knowledge to conduct intricate parameter adjustment process experiments in the model. Notably, the developed model could only determine objects in a particular environment with low generalization and robustness. The number of image feature parameters permitted in the feature extractor design is restricted following the developers' manual adjustment of model parameters. As a branch of artificial intelligence, deep learning neural network reflected higher adaptability with the advent of artificial intelligence as opposed to conventional machine vision techniques. This network is deemed more extensive in the universality of article recognition given that the deep learning algorithm primarily entails data-driven image feature extraction for a deeper, more efficient, and accurate representation of the image dataset using the image learning of big samples compared to the conventional method. A series of image recognition techniques under deep learning could attain highly precise and optimal recognition to resolve multiple intricate image recognition scenarios. This section emphasizes four classical segmentation approaches based on deep learning: AlexNet [38-40], Yolo [41-43], VGG net [44-46], and ResNet [47-49].

### A. AlexNet

Hinton's and Alex Krizhevsky's revolutionary AlexNet neural network (AlexNet) algorithm [38-40] championed the 2012 Imagenet competition. Specifically, Imagenet entails a large image recognition database encompassing marked pictures. AlexNet focuses on the full connection layer function with a total of eight layers: five convolutions and three full-connection. In a three-channel color map with 227 pixels in length and width ( $227 \times 227 \times 3$ ), the image is incorporated into the first layer to be convoluted into  $11 \times 11 \times 3$ . Every convolution kernel generates a novel pixel while all the convolution kernels subsequently slide through the  $227 \times 227 \times 3$  pixel picture with a stripe of four. Following the convolution output layer resolution computation, the convolution pixel layer data is duly computed with a convolution output of  $55 \times 55 \times 96$  in the first layer. The total convolution parameters of the first layer imply 35K as only the convolution kernel in the convolution layer entails neural network parameters post-calculation. Meanwhile, the second-layer characteristic map is transmitted to the third counterpart until the seventh-layer output data is fully connected with 1000 neurons from the eighth counterpart. The outcome was generated through softmax, which was utilized as a 1000 input image category for the classification score with the following attributes: (1) AlexNet algorithm converted the traditional neuron activation function  $f(x) = (1 + e^{-x})$  to  $f(x) = \max(0, x)$  with a rectified linear unit (relu) as an activation function that was extensively utilized in artificial neural network. The typical four-layer network with relus and tanh as an activation function attains the faster convergence speed effect involving relu in the CIFAR-10s experiment dataset compared to the conventional tanh activation function; (2) AlexNet utilized two techniques to

resolve over-fitting issues: data enhancement and dropout. The original picture was cropped to be employed as network input in data enhancement while dropout was utilized to deter over-fitting and promote effective fusing. Regardless, the network model computing cost is exorbitant despite the feasible computation following the use of a graphics processor (GPU) in the training process.

### B. YOLO

The You Only Look Once (Yolo) revolutionary neural network algorithm [41-43] resolves object detection (a regression problem) to avoid several reiterated prediction works and complete the input from the original image to the output of the image category following a separate end-to-end network. Yolo entails specific prerequisites to incorporate the image input size into the network, scale the image size to the specified size, classify the picture into  $S \times S$  grid, and make predictions in every small grid. Based on Fig. 4, the category probability forecasted by each grid and the confidence predicted by each box were multiplied until the score correlated to every box and category. The non-maximum suppression approach was then utilized to derive the classification outcomes. Essentially, Yolo is deemed beneficial as it disregards the extraction process of region proposal and rapidly identifies objects with minimal background error detection rates and inaccurate background knowledge. This algorithm implies high generalization, which is unlikely to crash when incorporated into fields or unforeseen inputs. Notwithstanding, the error-prone  $S \times S$  grid at the frame regression stage leads to inaccurate object positioning. A large missed detection rate is identified in the presence of multiple small targets in a network. The subsequent Yolo version continues to rectify such complexities. Specifically, Yolo V3 elevates detection performance, particularly in the multi-scale fusion approach, to resolve low detection performance post-defect optimization. On another note, a cross-layer connection is presented to optimize small target detection performance.

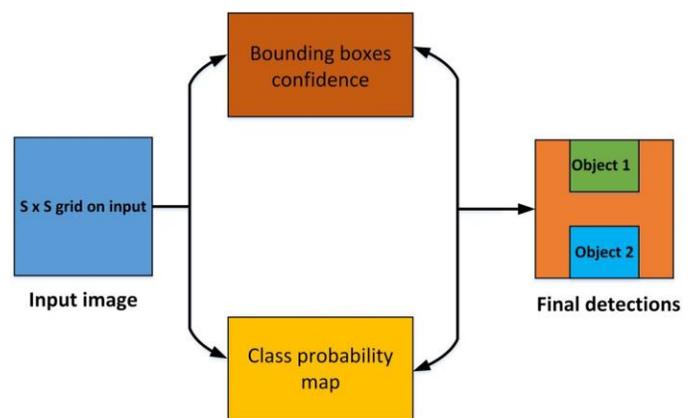

Fig. 4. Yolo Diagram Algorithm Process.

### C. VGG Net

The VGG net [44-46] model is characterized by a substantial number of layers, including multiple network layers ranging in depth between 11 and 19. The deep learning-model performance correlation is examined to enhance the overall recognition performance by improving the network layer

depth. This model aims to transform the convolution of the larger core layer into multiple smaller-layered convolution cores. Vggnet-16 and Vggnet-19 are extensively employed to render the entire network to be highly effective. The VGG also denotes a five-layer convolution and two full-connection layers for image feature extraction and one full connection layer for feature classification akin to the AlexNet framework. Fig. 5 illustrates the Vggnet-16 network structure diagram. The convolution layer kernel in the Vgg net structure is 3\*3. Three groups of 3 \*3 convolution layers connected with a 1\*7\*7 kernel were employed with the same effect. In terms of model benefits, the number of parameters is duly reduced. The original parameter (C\*7\*7) was transformed into 3\*C\*3\*3 for a convolution layer with C kernels. Despite the presence of more parameters and deeper levels, VGG requires lesser iterations to initiate convergence given the depth and small filter size function as the post rule while the pre-initialization operation is performed on some layers. Such advantages could increase the non-linear correction layer, mitigate gradient disappearance and over-fitting issues, and optimize the model training speed. The network structure attributes simultaneously facilitated it to regulate the number of parameters while eliciting more image features to prevent over-computation and structure intricacy.

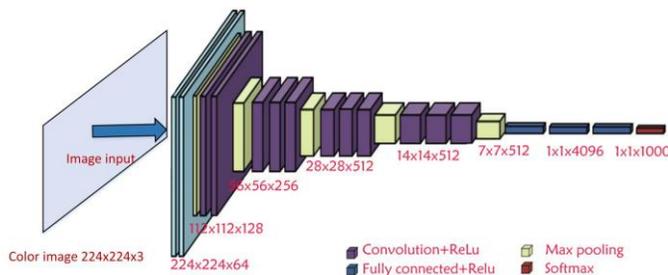

Fig. 5. Network Structure of VGG16 Adapted from [45].

#### D. ResNet

The proposed ResNet [47-49] algorithm model resolves the deepening of network layers despite the initially-enhanced accuracy. This precision would worsen if the number of network layers continues to increase. In other words, the network model could alleviate the degradation problem in network training. Regarding the conventional deep learning algorithm, the layers to which the gradient could not be conveyed are not trained when the number of network layer increases. Thus, the effect is not as robust as the shallow network with adequate layers as the error rate would rise with the increase in layers. The ResNet algorithm model puts forth the residual module in resolving the degradation problem. Based on the notion underpinning this method, the network at layer N is derived from the network at layer N-1 with conversion. It is connected to the upper-layer network for

gradient propagation, which subsequently resolves the gradient disappearance caused by the neural network passing through depth. Thus, the residual structure is presented. Following Fig. 6, the output layer  $H(x) = F(x)$  is changed to  $H(x) = F(x) + x$  where the network loss function  $f(x, w)$  is extended to the multi-layer neural network using the back propagation gradient value formula. The front-layer network gradient becomes smaller with the increased number of layers 'n' in the neural network and the return of errors. Thus, the gradient would not disappear even with multiple network layers. On another note, ResNet could develop the residual module in the form of a small kernel with the other layers utilizing full convolution excluding the full connection layer for classification, which could substantially optimize the calculation speed. This residual block structure method is employed for reference as ResNet entails multiple algorithm types with a network depth of 50, 101, and 152. The ResNet model performance significantly varies with distinct sizes. Overall, this model needs to be structured based on the actual application context.

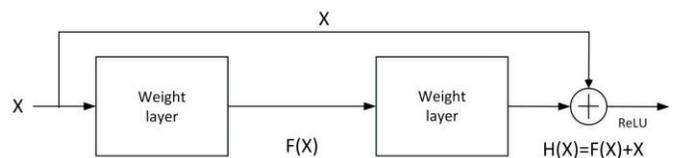

Fig. 6. Residual Block Structure.

#### VI. PERFORMANCE COMPARISON

Based on recent research, image recognition technology could flexibly select multiple algorithms for recognition based on various application scenarios in actual recognition tasks regarding deep learning. Some might even need to integrate different recognition methods in obtaining the most optimal recognition accuracy. It is deemed pivotal to develop a set of robust and stable recognition algorithms with high market value and application possibilities following the intricate recognition environment, which is subject to more illumination or other interference. Fundamentally, relevant literature adopts four parameters to compute the following metrics (accuracy, precision, recall, and F1-score) as the evaluation indices of algorithm advantages and disadvantages. As the primary problem to be solved, accuracy could further optimize the empirical depth in the image recognition field with a highly positive effect on the efficient incorporation of multiple technologies and the development of relevant disciplines. This study primarily summarized the deep learning technology application to image recognition. Table III presents (i) the recent comparison of model precision and loss of value in deep learning algorithms, (ii) evaluations on the technological complexities encountered in the workpiece image classification application, and (iii) specific study gaps.

TABLE III. DEEP LEARNING ALGORITHM COMPARISONS

Literature	Model	Object	Accuracy	Loss rate
[50]	LeNet-5	Oil–water two-phase flow	88%	High (loss rate)
	VGG-16	Oil–water two-phase flow	98.3%	Median (loss rate)
	AlexNet	Oil–water two-phase flow	99.3%	Low (loss rate)
[41]	YOLO	Insulator	90%	3.8% (class fault)
	Fast R-CNN	Insulator	84%	4.1% (class fault)
[48]	ResNet-18	Apple leaf	99%	8.9%
	ResNet-34		97%	1.23%
	VGG		89%	2.43%
[51]	VGG-16	Chest X-ray images	97%	NA
	ResNet		86.7%	
	ResNet-50		98%	
	AlexNet		96.5%	
	ResNet-50+SVM		95.38%

[65]	Meta-learning	Classical image	92.48%	NA

Notes: NA - Not Available

The accuracy rate in Table III denotes the percentage of the number of correctly predicted samples in the total number of samples or the proportion of precisely-predicted outcomes in the total number of samples. The formula of accuracy is shown in (1), essentially, TP implies a positive prediction with an actual prediction that is true. The TN denotes a negative and true forecast. The FP demonstrates a positive forecast with an actual prediction that is false. The FN denotes the forecast to be negative with an actual prediction that is false. The FP and FN reflect prediction error values, which means that the pre-determined target is not discovered. Several relevant detection indicators (accuracy) imply the proportion of accurate forecasting outcomes in all positive predictions. Recall rate denotes the proportion of accurately-predicted findings in all positive occurrences. In deep learning classification and detection tasks, the precision of appropriate techniques is typically assessed based on statistical findings. High TP and TN reflect high precision and optimal detection impacts of the deep learning model.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

Based on Table III, the deep learning algorithm model accuracy is fundamentally between 80% and 99%. The designed model evaluation accuracy is significantly enhanced compared to conventional techniques, thus implying the application effect of the deep learning model to be more ideal. Despite the diversification of model evaluation methods in theoretical and practical research, such studies remain considerably scattered given the primary utilization of the accuracy evaluation index for model assessment. Accuracy implies the accurately-forecasted image proportion in objective evaluation and classification. Although the high precision value in outcome detection or classification assumably reflects a high recall value, this evaluation index might prove contradictory in some cases. For example, an accurately-forecasted outcome in prediction would demonstrate a 100% precision value albeit with a significantly low recall value. Meanwhile, all the outcomes returned with a recall of 100% would denote substantially low precision. Hence, most studies do not employ such evaluation predictors for model assessment.

Despite there being no unified recognition technique for small target workpiece identification in workpiece recognition, relevant researchers have recommended multiple detection methods under deep learning to resolve the problems associated with small target detection. Notwithstanding, different study objects could ascertain whether precision or recall is high based on the required judgment following relevant research.

Detection approaches have undergone continuous optimization to manage multiple classification and detection problems involving deep learning image datasets and fulfill the application requirements in actual scenarios. The high-dimensional semantic features of image data could be elicited by convolution and non-linear layers, which is much better than traditional detection performance approaches. Image is more vulnerable to noise, thus significantly increasing workpiece classification and interpretation complexities in the industrial field. It is deemed pivotal to determine how to fully

utilize the evaluation index information of in-depth learning in serving the workpiece identification and classification application requirements and alleviate data processing intricacies for optimal workpiece classification, detection, and interpretation within the industrial field.

## VII. RESEARCH GAP

The research gaps are summarized in Table III.

1) The recognition algorithm still requires a specific optimization level, specifically through image feature extraction, to further enhance the image recognition rate following experimental data, computing equipment, and research time issues. Such image features could be conveniently extracted by the convolution filter following [50]. Empirically, the accuracy of the three aforementioned deep learning network algorithms proves relatively high. Simultaneously, a small number of target image misrecognition would not impact the traffic pattern recognition outcomes. Literature [61] could substantially optimize the recognition and classification rate with the image feature extraction approach.

2) The number of deep learning network parameters consumes much time, power, and hardware resources in the actual training process, which complicates the neural network application. The benefits of speed and accuracy in algorithm recognition are highlighted in [41]. Recognition accuracy could be further optimized given the increased number of trained images despite its time consumption and high cost.

3) In terms of computing power limitation, a higher image resolution could enhance the number of extracted image features through the algorithm given the low image resolution in the training dataset. Following [47], an optimized classical depth learning algorithm model could significantly enhance low image resolution performance. Test time augmentation (TTA) was adopted to improve the image while the derived image prediction accuracy data proved better than other depth learning algorithm models.

4) Concerning workpiece classification and recognition algorithms, the newly-proposed algorithm performance could be assessed and examined to accelerate the iterative update speed of the theoretical algorithm. The number and type of database samples failed to fulfill the prerequisites and match the workpiece defects generated by practical applications following the inadequate public datasets of some types based on the current workpiece defect database. Most of the algorithms could not be fairly compared given the absence of an agreed database standard [66]. Despite the presence of extensively utilized workpiece defect datasets, such as NEU [7], UCI [67], and Rail surface [68], the odious industrial setting poses substantial complexities to the workpiece defect image dataset of the actual industrial production line.

5) Deep learning training requires sufficient training datasets in the workpiece image dataset production. It is deemed necessary to ascertain the means of training a model that could precisely detect images through a restricted number of sample datasets. Data optimization served to enhance

segmentation accuracy. The deep learning benefits minutely differed across multiple evaluation indicators with high precision. Fundamentally, the evaluation indices were not extremely low.

6) Several deep learning algorithm models might not apply to specific application scenarios given the emergence of more relevant counterparts. It is deemed feasible to develop a novel deep learning algorithm to enhance the impact of workpiece classification and recognition. For example, [69] integrated the computational advantages of a 2D FCN network and the ability to resolve 3D spatial consistency without influencing segmentation accuracy. Given the palpable limitations, the resolution of recognized pictures and speed calculation require improvement as network calculation precision serves to increase with the number of computations. This accuracy could be improved [40] through integrations with other methods albeit with low precision in some image recognition scenarios. Despite the improved effects, some room for improvement is still available. Regarding parameter optimization, [65] proposed that tests could be performed on non-trained tasks. Meanwhile, classification could be realized even with minimal training: a direction worthy of the effort.

### VIII. RESEARCH PROPOSAL

1) Workpiece image classification algorithms could strive to fuse image feature extraction into one step and enhance recognition accuracy. Regarding the recognition target limitation, the extracted image required a strong expression while the recognition and classification rate proved relatively low. This situation adversely influenced the recognition of intricate or unclear images given its complexity in feature image extraction. The algorithm model could be learned in depth from the noise dataset with the possible identification of low feature target images in line with [62], thus broadening the deep learning application range. Specifically, [63] employed the edge feature extraction approach to determine the internal and external features of the recognition target image contour. The image features were distinguished post-feature point extraction. The deep learning algorithm model was subsequently presented for feature training towards high recognition accuracy. Meanwhile, [56, 57] utilized the deep learning method to fuse image features and resolve the target image feature ambiguity or relatively indistinguishable recognition rates.

2) Given the presence of issues involving extensive training and prediction periods, future workpiece image classification algorithm studies could consider how to mitigate network model redundancy, optimize the number of network layers, and shorten the computation time while simultaneously ensuring recognition accuracy to some extent. Based on [48], shallow networks could also reflect optimal recognition accuracy and low error rates with even better recognition impacts than deep networks. Palpable target detection errors or reiterated identification in employing the same algorithm for target detection and limited training time resembles the

drawbacks highlighted in conventional neural networks following [52, 53].

3) Deep learning algorithm could further enhance recognition accuracy with optimal hardware and image acquisition. AS affirmed by [59], low resolution and multiple datasets could be utilized for the deep learning algorithm to realize classification. The usage of more epochs improved training accuracy while surface accuracy could be optimized by the number of iterations. Regarding the disadvantage, the loss value would be too high in the iterative process. The same deep learning method demonstrated minimal variance in recognition accuracy under multiple levels, specifically in small target images, with improved computer algorithms [54].

4) Further enhance network generalization (particularly in restricted datasets), optimize small dataset detection, and integrate the conventional recognition. The means of developing an algorithm with strong applicability require further examination for thousands of object types. Regarding limited sample collection, a more widely-disseminated collection database was established in the public counterpart following [51] and a dataset in line with their actual application scene by gathering six chest X-ray image databases. The gathered database should be relevant to the research. Detection algorithm with convolution neural network to improve microfeature extraction and segmentation capacity and model accuracy in the follow-up. As deep learning technology was employed for dataset pre-processing albeit with relatively ideal experimental effects.

5) It is also rendered possible to optimize moving image recognition, develop a recognition model towards dataset expansion, and enhance the recognition model adaptability to the actual industrial setting in the process of moving image recognition. For example [55] could further determine the range of textures and features, such as color while [58] employed the deep transfer learning technique to assess tongue images and resolve the complexities in gathering adequate marker image samples. The recommended approach implied better classification accuracy. Essentially, [70] outlined the mapping relationship between image classification input feature vector and image category and structured a moving image recognition model.

6) The incorporation of deep learning algorithm benefits into specific fields or different but relevant disciplines or problems has garnered more attention towards completing or improving the learning effect of target fields or tasks. Ensemble learning is a promising and experimentally-proven technology. Based on [60], deep learning approaches significantly influence intricate tasks, such as image feature extraction, segmentation, and semantic classification. Meanwhile, [64] mitigated the network complexity by pruning the redundant depth algorithm model parameters to derive a small and efficient classification model, enhance the runtime reasoning speed of neural network, and elicit the favored classification effect with minimal calculation and

computational workload in the future. The incorporation of meta-learning into deep learning denotes a viable method.

## IX. CONCLUSION

This study reviewed the recent development of deep learning in image recognition, emphasized specific deep learning image method types, summarized and compared similar algorithm performance, examined the advantages and disadvantages of every deep learning algorithm based on different application scenarios, and flexibly selected deep learning classification methods to effectively improve the recognition effect. highlighting six research proposals for workpiece image recognition and defect detection. Empirical solutions are provided for the selection of future deep learning models for artifact classification and defect detection.

Many actual influencing factors and complex situations are present in workpiece recognition. In other words, it is challenging to apply the model derived by conventional methods to the actual circumstance. Research on the deep convolution neural network given its prevalence in computer vision tasks has made a significant breakthrough, thus proving the potential of deep learning in image classification. There are also limitations in the research of workpiece recognition, in terms of theoretical experiments on images, there is no research on image acquisition and recognition of workpieces in practical application scenarios, and it is necessary to build recognition systems to carry out research on practical workpiece recognition applications based on multiple factors such as light, angle and placement position.

In the future work, more methods will be reviewed to enhance the generalization ability of the model and improve the practical application ability of the model in the industrial field, which is also the improvement direction proposed by the future in-depth learning research work. At the same time, it can effectively and reducing the dataset is also one of the priorities of the future work.

**Abstract**—The chili agrosystem faces many challenges, and the enterprise architecture (EA) artifacts as the building block of a chili enterprise system (ES) are not exist. This research is a qualitative systematic literature review as part of developing intelligent ES to examine chili's production, consumption, and price. The first step toward ES development is recognizing worthy chili EA and EA frameworks that characterize existing chili market conditions. The study aims to answer three research questions (RQ) and uses a state-of-the-art approach, employing predetermined keywords, to six research databases and data gathered from the corresponding institutional agencies. The findings on RQ1 revealed eight dynamics chili main supply chain patterns and data segregation among institutional agencies. The RQ2 disclosed numerous studies on EA; however, none offered for the chili agrosystem. In addition, the RQ3 results are multiple and expose different EAF characteristics. Again, no study considers its applicability to the chili agrosystem. To conclude, the strength of enterprise architecture for the chili enterprise system is the resulting deliverables that fall into three categories. These are factors of the chili agrosystem, enterprise, and architecture factors. Of many available frameworks, the Zachman framework - The Ontology gives more offerings.

**Keywords**—Chili agrosystem; enterprise architecture; intelligent enterprise; supply chain; Zachman framework

### I. INTRODUCTION

Chili is an essential complementary ingredient for most Indonesian daily cuisines. Most chili farmers will plant chili when prices are high, resulting in an ample supply of chili and causing prices to fall. On the other hand, chili farmers do not grow chili when prices are low, resulting in a scarcity of chili, and eventually, prices will rise. Chili pests and diseases can also influence the supply of chili. Reference [1] analyzes the socio-economic and agro-ecological aspects of chili production. The results show that harvest losses due to pests and diseases are high. Also, the chili agribusiness risks for chili farmers are production, price, economic, and institutional risks [2]. These risks are interrelated. These risks that bring negative impacts are production risks due to plant diseases, markets due to price volatility, and monetary risks faced by chili farmers.

The chili supply chain has not been implemented efficiently and effectively in its management [3]. Most distribution chain actors face several barriers, such as losses, decreased products, and inefficiencies in the delivery period. The study of [4] stated that the chili supply chain is lengthy and unoptimized, including not entrusting the Village Owned Enterprises (called Bumdes) and the Indonesian Farmers Shop (called TTI).

Reference [5] had identified 23 profiles of agro-industrial enterprises. The classification characteristics used are the location in the food chain and industry (field of activity), organizational forms and company law, company size, trade turnover, volume level, and technical and technological innovation base of the company (facilities and production technology used). Other characteristics are features of the company's structure (complexity, the presence of vertical and horizontal integration), the level and possible likelihood of production diversification, the company's price segment, the degree of product differentiation, the width and geography of market presence, the nature of influence in the market (the company's position in the market).

The importance of this research is longing for reconciling chili price volatilities due to supply and demand discrepancy. Here, establishing an intelligent enterprise system for chili agrosystem is an intended way of managing its supply to align with the market demand. Chili farmers and chili trade operators often faced obstacles in the distance, the high logistical costs to distribute seeds, fertilizer, pest medicines, and chili production from production centers to all areas in Indonesia. It creates a complex distribution of chili from producers to end consumers. Moreover, the condition of infrastructure is inadequate, especially in remote areas, and lack of technology to extend the shelf life of chilies to prevent them from rotting before reaching end consumers throughout Indonesia. The red chili supply chain requires a model compatible with various supply chain patterns occurring in Indonesia.

This study is part of the research on establishing intelligent enterprise systems to examine the production and consumption of chili. The first step towards its development is to recognize suitable chili enterprise architecture (EA) that characterizes existing conditions. The purpose of our study is incredibly inquisitive in:

- identifying the current problems in the existing chili agrosystem,
- investigating EA and its EA framework (EAF) suitable for the chili agrosystem, and
- determining open challenges and areas for enhancement.

The study's direct audience for this paper is threefold. Firstly, we target researchers interested in a state-of-the-art overview of the area of the chili agrosystem. Secondly, we aim at researchers in the quest for the most helpful chili enterprise

\*Corresponding Author.

architecture. Thirdly, we target chilies' farmers and or groups of farmers and its supply chain actors and stakeholders that would like to find out suitable enterprise architecture framework to improve the value of farmer exchange rates.

## II. PROPOSED METHOD

This study used a state-of-the-art approach using previous latest ideas and methods from 2015-to 2020. To do this, we conducted a systematic literature review to lead our choice in determining the chili agrosystem enterprise architecture of available evidence and topic, including identifying shortcomings, inclinations, and voids in knowledge and indicating the direction it is beneficial to prompt further research. This section illustrates the foundation of this state-of-the-art by defining the state-of-the-art research questions and search keywords. We use a systematic literature review to answer the following state-of-the-art (STA) research questions.

### A. State-of-the-Art Research Questions

EA and EAF are not new problems, and various methodologies, methods, and approaches offer to describe EA and EAF practices, including its implementation case studies. Our research aimed to ascertain the current issue of chili agrosystem and the quest for EA and EAF application for chili agrosystem, in particular, to answer the following research questions:

- RQ1 What is the Indonesia chili agrosystem outlook?
- RQ2 What is the state-of-art of EA?
- RQ3 What is the state-of-the-art of EAF applicable for the chili agrosystem?

In this study, the word ‘agrosystem outlook’ represents a series of activities and processes to characterize, develop, and maintain the delivery of fresh produce from farmers or grouped farmers to end consumers from the agri-business perspective. The words state-of-the-art of EA and EAF follow the description in Miriam Webster Dictionary. State-of-the-art determines the level of development (such as devices, procedures, processes, techniques, or science) that is achieved at a given time and can be used due to modern methods. Our study determines the state-of-the-art mostly in its implementation success factors.

### B. Search Process

The search process is carried out by searching relevant articles using the list of keywords depicted in Fig. 1. The search applied to six research databases: IEEE Xplore, ACM Digital Library, Science Direct-Elsevier, Taylor and Francis, Springer Link, and Google Scholar, published between 2015 and 2020.

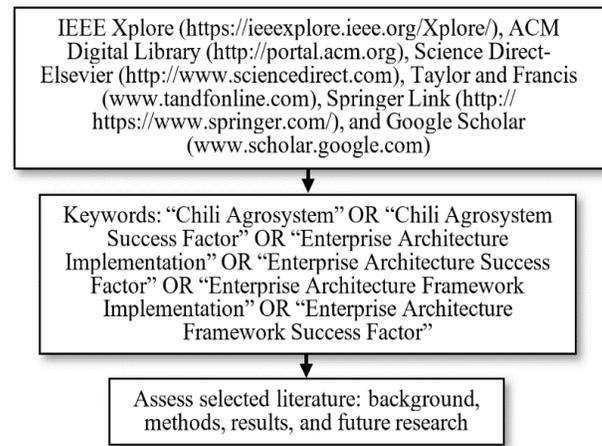

Fig. 1. Keywords Search flow Applied on Various Research Databases.

### C. Scope of the State-of-the-Art Conduction

Our study defines the construct and guidelines for managing the STA as follow:

- Inclusion criteria: English peer-reviewed journal papers and conferences proceeding.
- Exclusion criteria: Book, Book Chapter, Indonesian peer-reviewed studies, government publication, studies irrelevant to the research questions, duplicate studies (by content and title), and short paper (e.g., poster).

Concerning the exclusion criteria, prospect papers that are not a specific approach for chili and practice are not within the scope of this research. This study intends to focus on practices and critical success factors of chili agrosystem and implementation of EA and EAF. Table I present the application of the query based on the keywords: “chili agrosystem,” “chili agrosystem success factor,” “enterprise architecture implementation,” “enterprise architecture success factor,” “enterprise architecture framework implementation,” or “enterprise architecture framework success factor.” Table II depicted the citations of the selected 32 papers obtained using Google Scholar.

III. RESULT AND DISCUSSION

A. RQ1 – Chili Agrosystem Outlook

The need for chili (red chili and cayenne pepper) for Indonesia's large cities with one million or more is around 800,000 tons/year or 66,000 tons/month. During the festive season or religious holiday, the need for chili usually increases by about 10-20% of regular requirements [6]. An enormous chili consumption per month indicates the need for national chili production and consumption system integrated with planting time management. The Ministry of Agriculture collects data and information on the production and area of chili commodity land, the Central Statistics Agency (BPS) handles export and import data, and the Ministry of Trade bears chili prices on the domestic and international markets.

Red chili land area from 2014-to 2018 experienced a decrease of -3.99%. On the contrary, the chili harvested area experienced an increase in growth of 22.50% (Fig. 2). Production of red chili and cayenne peppers grew by 0.04% for red chilies and 14.75% for cayenne peppers. The productivity of cayenne pepper experienced positive growth of 13.07%, while the productivity of red chili experienced a negative growth, which decreased by 0.13%. However, the productivity of red chili is better when compared to the productivity of cayenne pepper.

The consumption of red chili commodities is relatively high, especially in periods that coincide with religious holidays. According to [7] data, the highest red chili consumption per capita per month occurred in the province of West Sumatra (0.59 kg/month), followed by Bengkulu (0.44 kg/month) and Banten province (0.42 kg/month) (Fig. 3.a). Whereas the highest level of consumption of red chili per ton per year in 2017 occurred in Banten province (93,234 tons/year), followed by West Java province (61,657 tons/year) and North Sumatra province (55,194 tons/year). Regardless of its consumption, in general, the national supply and demand projection showed a surplus (Fig. 3.b). Nevertheless, price fluctuation occurs every year.

Chili plantations spread in almost all provinces in Indonesia. According to [8], the three largest large chili production centers in 2018 are West Java (274,037 tons),

Central Java (171,796 tons), and North Sumatra (155,835 tons) (Fig. 4). The three largest cayenne pepper production centers in 2018 are Banten (453,338 tons), West Kalimantan (20,530 tons), and DI Yogyakarta (141,771 tons).

Fig. 4 indicates that the province determines the priority of the type of chilies to be planted. For example, West Java chili production in 2017 was 134,910 tons, but in 2018 there was no data available for the production of cayenne pepper; on the contrary, in the year 2018, West Java's red chili production was the highest in Indonesia, which was 274,037 tons. In 2018 the production of red chili in Banten province was only 6,712 tons, but in the same year, Banten produced the highest production' of cayenne in Indonesia, which was 453,338 tons.

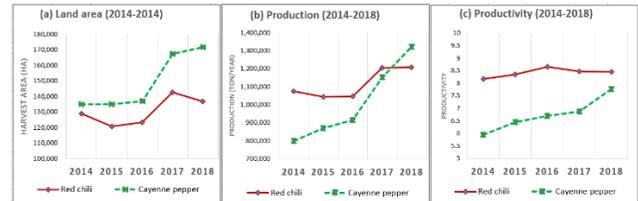

Fig. 2. (a) Land Area, (b) Production and (c) Productivity of Chili and Cayenne Pepper Year 2014-2018.

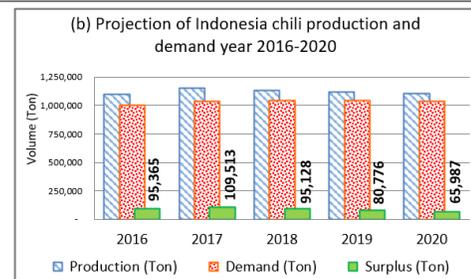

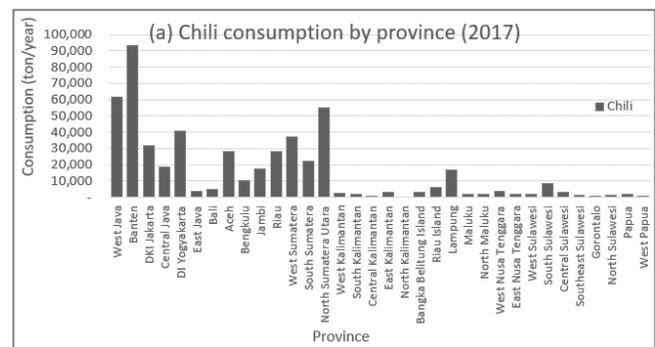

Fig. 3. (a) Year 2017 Consumption of Red Chili (Adapted from Agriculture Ministry, 2019) and (b) Year 2016-2020 Chili Projection of Supply and Demand (Adopted from [9]).

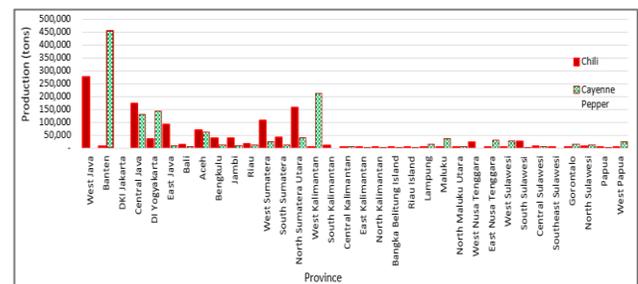

Fig. 4. Red Chili and Cayenne Pepper Production by Province Year 2018.

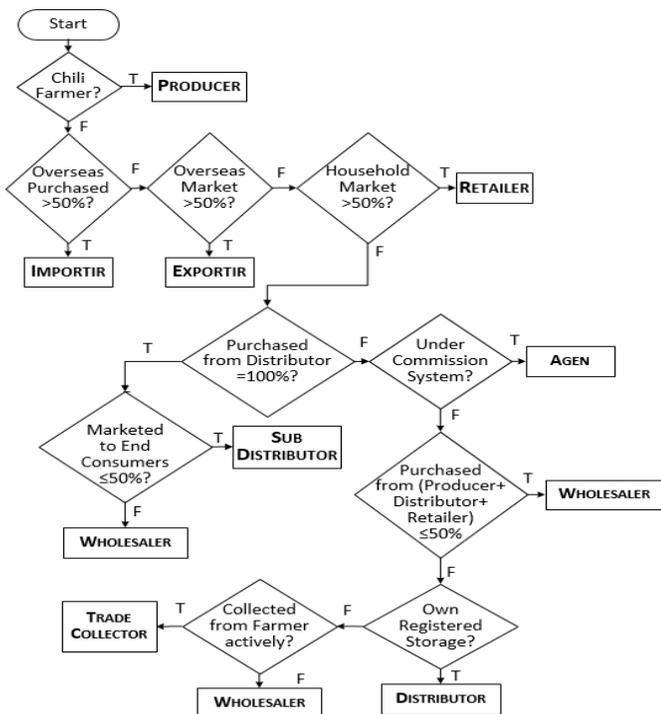

Fig. 5. Flowchart Determination of Chili Supply Chain Actors (T-True, F-False) (Adopted from [9]).

In 2018, the Indonesia Central Bureau of Statistics, known as Badan Pusat Statistik (BPS), surveyed the pattern of red chili distribution implemented by agrosystem red chili actors in 2009, 2015, 2017, and 2018 [9]. The actors of the red chili agrosystem consist of two groups, namely businesses and non-trade businesses. Trade businesses comprise medium, large and small companies that act as distributors, sub-distributors, agents, wholesalers, merchants, exporters, importers, or retailers (Fig. 5). Also, non-trading businesses/companies are red chili farmers as producers.

The BPS 2018 survey observed eight patterns of Indonesia's red chili trade system upstream to downstream. The most common red chili trade system pattern in 17 provinces in Indonesia is Pattern No. 1, which involves four actors in the red chili trade system (Table III). The most minor chili trade system operators are Pattern No. 6 and Pattern No. 8, which involve three red chili trade system actors. Almost all trading patterns involve retailers to end consumers. Meanwhile, DKI Jakarta has the most different supply chain patterns of the red chili trade system: red chili from outside the province rather than from farmers (producers) directly. DKI Jakarta obtains red chili from West Java, Central Java, and East Java provinces. In this survey, the definition of end customers is households, other business activities (restaurants, restaurants, catering businesses, hospitals, and hotels), processing industries, and government and non-profit institutions.

The BPS 2018 survey also analyzed the margins of trade and freight (MTF) merchant compensation as a supplier of goods. The MTF value is the difference between sales with the purchase value or the price difference from producers to final

consumers. The MTF calculation considers the main trade patterns (see Table III). Nationally, the MTF of red chili is 47.10% [9]. Regarding prices reaching the final consumer, the province with the lowest MTF is Riau Island province, with a total MTF of 15.25%, while the highest MPP occurs in South Kalimantan province, with a total MTF of 130.76% (Fig. 6). The MTF values greater than 100% also occur in Bengkulu and Maluku provinces. The high MTF value is mainly affected by transportation costs.

Data and information on the production and land area of strategic food commodities are managed separately by the Ministry of Agriculture, export and import data by the Ministry of Trade (Ministry of Trade), and the strategic food commodity price data by the Central Statistics Agency (known as BPS). The Ministry of Agriculture, BPS, and the Ministry of Trade has a separate work unit called the Data Center and Information System (Pusdatin). The Pusdatin manages the database of strategic food commodities following the domain of its authority. Also, to monitor price movements, in the year 2017, Bank Indonesia launched the National Strategic Food Price Information Center (PIHPS) on the [hargapangan.id](http://hargapangan.id) (Fig. 7). The PIHPS provides information on strategic food commodity prices daily; the enumeration is from Monday to Friday at 09:00-11:00 AM, reported to Bank Indonesia at 10:00-12:00 AM, and published at 01:00 PM West Indonesia Time. The number of samples is two retailers per traditional and modern market (primary market) per commodity in 82 districts/cities locations.

TABLE III. MAIN RED CHILI DISTRIBUTION PATTERN IN INDONESIA YEAR 2018 (ADOPTED FROM [9])

Pattern No.	Supply Chain Pattern	No. of Provinces
1.	Farmer → Trade Collector → Retailer → End Consumer	17
2.	Farmer → Trade Collector → Wholesaler → Retailer → End Consumer	4
3.	Farmer → Wholesaler → Retailer → End Consumer	5
4.	Farmer → Agent → Wholesaler → Retailer → End Consumer	2
5.	Other Provinces → Wholesaler → Retailer → End Consumer	1
6.	Farmer → Retailer → End Consumer	3
7.	Farmer → Distributor → Retailer → End Consumer	1
8.	Farmer → Trade Collector → End Consumer	1

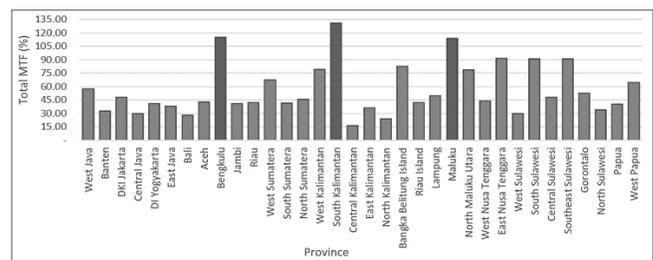

Fig. 6. Margin of Trade and Transportation Costs by Province (Adopted from [9]).

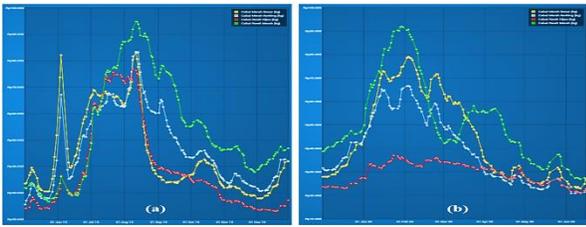

Fig. 7. The Menu Prices of Producers on Chili Commodities in West Java in the Graphic Report Format showed Fluctuating Prices: (a) Period May 2, 2019 until December 30, 2019 and (b) Period December 2, 2019, up to June 16, 2020.

### B. RQ2 – State-of-the-Art of Enterprise Architecture

An enterprise architecture (EA) is a series of structured models that represent the building blocks of an enterprise system. The architecture framework simplifies processes and guides architects in all areas of architectural development, providing a set of conventions, principles, and practices. Reference [10] successfully identified 15 EA artifacts used by the 14 EA stakeholders interviewed. The artifacts are used to align with the goals and objectives of EA utilization in every part of the EA process and potential users that will use the produced artifacts. Further, [11] conducted an empirical analysis of 27 organizations and succeeded in identifying 24 EA artifacts that benefit organizations, explaining their practical use, and analyzing the empirical validity of the most popular EA conceptualization. Additionally, [12] reveal the post-implementation review apply to artifacts practices aiming to evaluate: the initiation of the implemented artifacts, the management and conducting EA artifact development, and the control of future change to the developed artifacts. The practices in the first category are business strategy, risk management, planning, and architectural method. The practices in the second category are governance, continuity, and stakeholder satisfaction. Lastly, the practices in the third category are alignment, architecture technique, management, and integration.

Reference [13] conducted a Monkey platform survey of 747 respondents (311 responded, 133 completed) and identified four success factors for EA management (EAM). These are the quality of EAM products, quality of EAM infrastructure, quality of EAM service and delivery, and EAM organization anchoring. Also, [13] suggested further research related to applying four EAM principles, which are determining EAM infrastructure, creating stakeholder awareness, providing high-quality EA products and services, and ensuring stakeholder commitment. Prior to that, [10] study review on over 100 special publications identifies six critical success factors (CSFs). Of the six CSFs, three CSFs successfully support the EA program implementation process. These are monitoring and compliance, commitment to using architecture, and consultation and communication.

The complexity of EA implementation and its bureaucratic business functions and complex IT structures become challenging problems for organizations. Reference [14] uses axiomatic design as a systematic approach for EA to analyze current enterprise capability and map the requirement of business, data, application, and technology layer of EA as the design domain aligned with the organization's strategic goals.

Meanwhile, [15] measured implementation factors from the points of view of the experts and practitioners. The measurement comprises 27 factors that construct the 6-factor of internal process, 6-factor of learning and growth, 6-factor of authority support, 3-factor of cost, 3-factor of technology, and 3-factor of talent management. Analysis results have shown that there is no significant agreement between the experts and the practitioners except for rules and process of internal process category, the political influence of authority support category, and financial resources of cost category factors.

Further, [16] affirmed that EA program success derives primarily from how architecture is practiced rather than what is practiced. Meanwhile, [17] develop the CSF model of team capability, communication, top management commitment, technology and infrastructure, and governance. Reference [17] model indicated that governance gives the highest factor in successful EA implementation.

The study of [18] obtained 13 critical success factors (CSF) enterprise architecture implementation for the public sector (Fig. 8). In general, CSF that influences the successful implementation of EA in the public sector is technical development (68% articles) and frameworks and methodologies (50% articles). It is unavoidable that the people factor influences successful EA implementation. A study of [19] identified seven types of people factors. Five people factors have proven to have an association with successful EA implementation. These are skilled EA talent, centralized enterprise architect team, talent management plan, talent retention program, and EA learning culture. Surprisingly, the remaining two factors with a minor association with EA implementation are trained EA talent and certified EA talent.

To obtain benefits from EA, the findings of [20] highlight the importance of EA service capability and dynamic capability in creating benefits from EA. Reference [20] gives three recommendations. Firstly, how dynamic capabilities are activated through EA service capability and how projects and organizations benefit. Secondly, longitudinal studies are needed to fully understand how and why EA service capability develops over time, that is, reflecting the maturity of EA. Lastly, longitudinal studies will lead to a better understanding of the process to achieve organizational benefits. Also, [21] suggests three future works to carry out. Firstly, group the current EAIM problem into three main categories: modeling, development, and maintenance. Secondly, the identification of factors is evaluated from surveys of different EA project stakeholder groups (Fig. 9). Lastly, to carry out the effectiveness of EA implementation using factors and practices that affects the EA implementation.

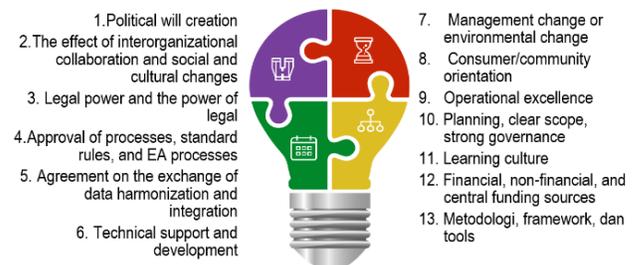

Fig. 8. CSF Implementation of EA in Public Sector (Adopted from [18]).

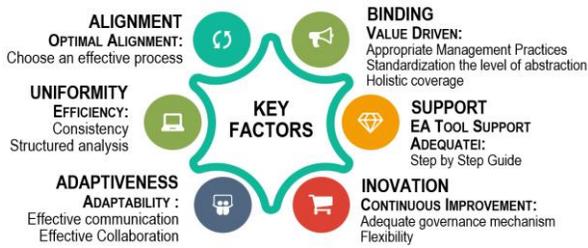

Fig. 9. Key Factors that Influence the Effectiveness of EAIM (Adopted from [21]).

The increasing flow of information and system integration in organizations and along the trade chain is one of the main challenges organizations need to address. Reference [22] proposed EA 4.0, which is an extended EA for the context of Industry 4.0. The EA 4.0 component consists of the EA model, data from enterprise information systems and IoT devices, and advanced analytics. His study reflects the Model4Insight platform that is still under development. For the record, EA 4.0 requires an EA model at a more detailed level, requires new skills, and works together with experts or data scientists.

Meanwhile, [23] uses a hybrid evaluation method for enterprise architecture that considers the organizational culture aspect encompassing the management sustainability variable consisting of governance, continuity, integration, and maintenance. Further, [24] uses EA to improve investment quality in information technology (IT). According to [25], top-quartile organizations use more EA artifacts to prepare IT investment decisions, specifically heat maps, policies, roadmaps, business capability models, and landscape diagrams.

One framework and approach that fits all does not apply in the case of EA because the different fields in which EA operates have unique/different field-specific requirements and specifications [25]. They suggest further research: (i) SOA requires further research on developing methods and models, and tools that directly measure service response time at higher accuracy; (ii) Issues and challenges to EA design; (iii) EA for healthcare needs to address aspects of organizational culture and professional culture; and (iv) Technology and methodology issues to guide the development of EA. Also, communication along the wide-distributed geography gives other challenges that might create a knowledge gap.

In [26] successfully identified current issues on cloud terminology, complexity theory, agile or adaptation, big data, things, entrepreneurship, intelligence, and sustainability. Based on their systematic literature review results, [26] recommended the need for further research on issues related to whether there was a mismatch between EA's academic efforts and EA in practice. Besides, trend analysis shows the number of publications in specific industries, such as health, manufacturing, and government issues. To fully understand the differences and similarities across the industry, further research has to be more detailed. Nevertheless, [27] developed Agile enterprise architecture (AEA) for geographically distributed Agile development (GDAD) environment. The study creates measurement model evaluation and 26 measures comprise of AEA (7-item), communication efficiency (5-item), communication effectiveness (4-item), on-time completion (2-

item), on-budget completion (2-item), software functionality (3-item), and software quality (3-items).

### C. RQ3 – State-of-the-Art of EA Framework

The architecture framework has several benefits [28]. The benefits are supporting stakeholders' decision-making about enterprise design and operations, improving users' trust that using reference architecture will be successfully applied to projects, and facilitating enterprise design communication. The architecture framework may be applied to various systems and enterprise scenarios. Another benefit of the architecture framework is building a general way to organize, interpret, and analyze architectural descriptions and identify architecture problems, generic stakeholders, viewpoints, and levels of abstraction. Besides, the architecture framework implements reuse and provide unified and unambiguous terminology definitions.

EA frameworks are differentiated according to their field of application [28]. Some EA frameworks frequently used are the Zachman Framework, the Open Group Architecture Enterprise (TOGAF) Architecture Development Method (ADM), Federal Enterprise Architecture Framework (FEAF), Department of Defense Architecture Framework (DoDAF), Ministry of Defense Architecture Framework (MODAF), Adaptive Enterprise Architecture Framework, and EA3 Cube Framework. In essence, the development of many EA Frameworks uses the Zachman Framework as its foundation (see Fig. 10 for EA framework evolution). Reference [29] mentioned that the existing EAF is too overwhelming for small-medium enterprises (SMEs). Hence, [29] developed a CHOOSE metamodel, an acronym for “maintain Control, employing a Holistic Overview, that is based on Objectives and kept Simple, of your Enterprise.” Following evaluation and validation through five SMEs, CHOOSE metamodel includes only four essential concepts (goal, actor, operation, object), each applying to four primary EA focus (what, why, who, how). That supports [26] study that most EAF focus on EA implementation and EA artifacts development lacks implementation evaluation methods.

Reference [30] chose the Zachman framework in developing a system-of-system (SoS) architecture. DoDAF and MODAF are not suitable for SoS, while the TOGAF, FEAF, and Zachman frameworks are suitable. Based on the Zachman framework guidelines, the development of architectural SOS is best to use agent-based simulation integrated with SysML and UML. Meanwhile, [31] conducted an Agile modeling language study and provided a diagrammatic integration of machine-readable from several aspects of the Zachman framework. In [31] study, the 'What' aspect of dealing with the concept of Linked Enterprise Data environments, such as graph servers, graph databases, and RESTful HTTP requests with PHP-based programming languages with SPARQL queries for client requests. Agile modeling method engineering (AMME) creates and develops Agile modeling tools related to semantics, syntax, and functionality, namely environments such as ADOxx commonly used in prototyping. The primary key lies in the AMME, which provides tools to make prototyping in agile modeling [31] quickly.

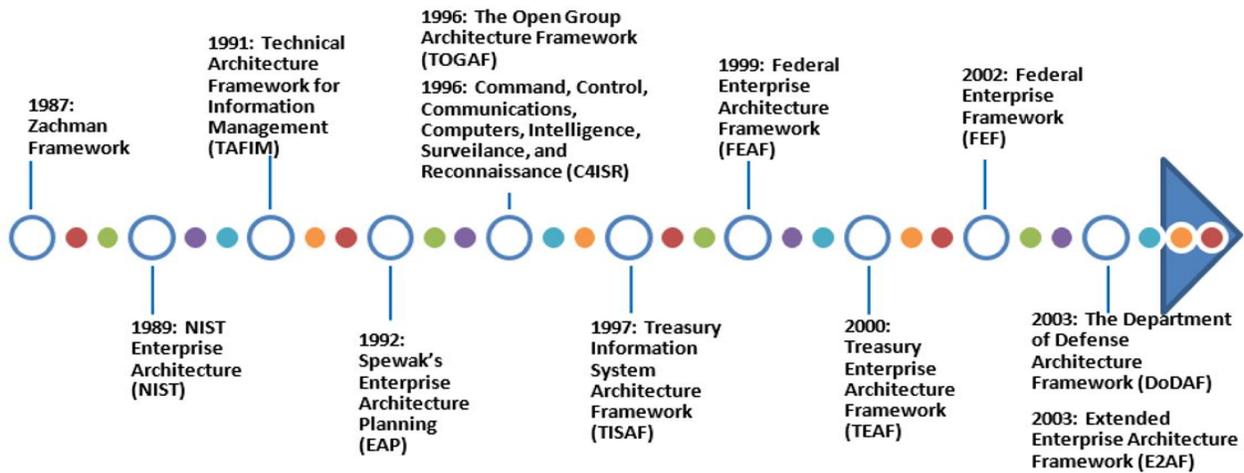

Fig. 10. The Evolution of EA Framework (Adopted from [28]).

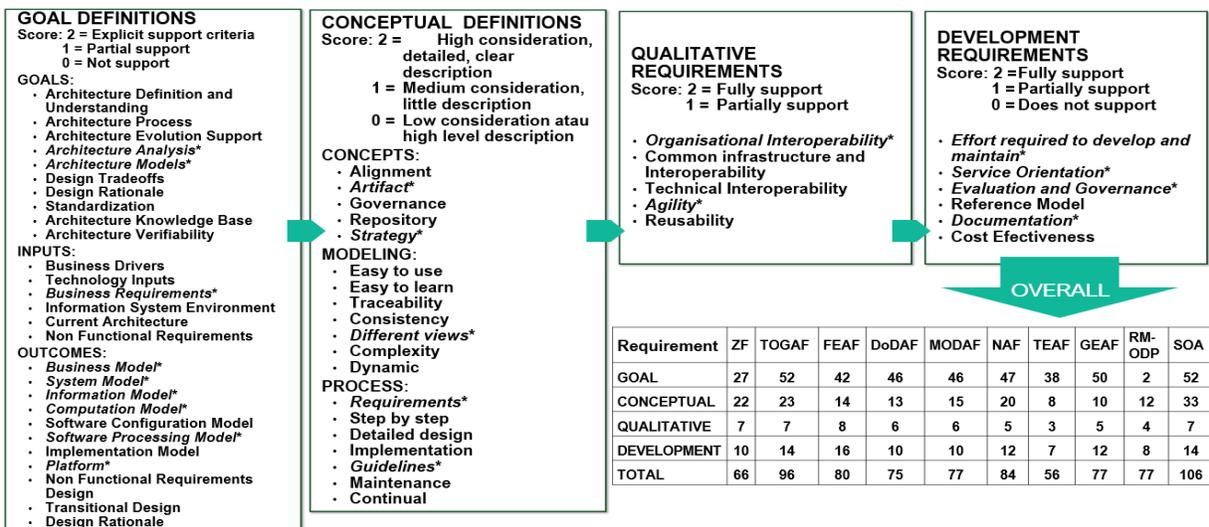

Fig. 11. Stages of Comparative Analysis on ten EAFs and their Final Results (Adopted from [9]).

At present, there are more than 100 EAF available and used by four user groups: industry, government, open-source, and proprietary defense [32]. On critical IT infrastructure (CITI) design, [32] selected the EAF producing the ten most popular EAFs, resulting from usage percentage of the Zachman framework (25%), SOA (15%), TOGAF (11%), DoDAF (11%), FEAF (9%), British Ministry of Defense Architecture Framework (British MODAF) (2%), NATO Architecture Framework (NAF) (1%), TEAF (1%), Gartner EAF (GEAF) (3%), and ISO Open Distributed Processing-Reference Model (RM-ODP). Further, [32] scored each criterion on goals definitions, conceptual definitions, qualitative requirements, and development requirements (Fig. 11). Comparative analysis of [32] shows that the highest total overall score for CITI design is SOA and TOGAF. Almost all EAFs surveyed ignored or had less description of the rationale architecture design, even though needed in CITI design. Some EAFs include documentation of system boundaries and assumptions. Therefore [32] stated that the foundation of architecture must include criteria, benefits, and risks.

To propose an effective EA implementation methodology (EAIM) using the list of products in each EAIM phase (Fig. 12), [33] firstly identified EAIM criteria and compared its uses on four EAF (Table IV). Considering the complexities of EA implementation, [33] exploration found that no effective methodology existed. Nevertheless, the proposed EAIM aligns business and IT, integrates application and infrastructure, defines appropriate objectives and vision, governance plan, and step-by-step guidelines.

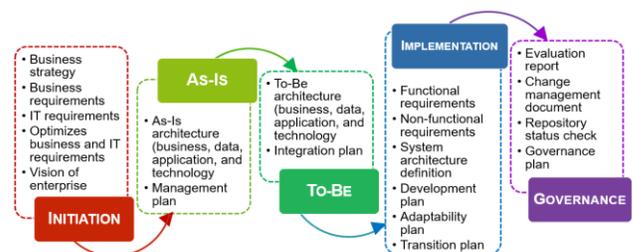

Fig. 12. List of Products by EAIM Phase to Measure Effective EAIM (Adopted from [33]).

TABLE IV. COMPARATION OF EAIM CRITERIA AMONG EAF

Identified EAIM Criteria	EAP	TOGAF	FEAF	DoDAF
Iterative	-	++	-	-

<sup>a</sup>. Note: ++ Fully consider/support/exist/all/easy;

<sup>b</sup>. + Partly consider/partly support/partial/somewhat/easy;

<sup>c</sup>. - Not consider/not support/not exist/particular/difficult

In [34] selected the EAF for e-Government by applying the Multiple Criteria Decision Making (MCDM) method with the Analytical Hierarchy Process (AHP) tool to select four EAFs, namely the Zachman framework, FEAF, TOGAF, and TEAF. The AHP results showed the highest ranking of EAF are Zachman framework (30.76%), FEAF (25.23%), TOGAF (24.13%), and TEAF (19.13%). The results of the matrix combination show the preference attributes for the Zachman Framework, which are the preferred framework attributes, knowledge base, and architecture evolution support.

In [35] explored EA in the future using the Zachman framework version 3.0 - The Enterprise Ontology perspective. The world's challenges are even more significant with a global market that affects social transformation and government instability. The results of the exploration of [35] are fourfold. First, various non-technical domains must contribute to the progress of EA. Secondly, insight into systems thinking and complexity science. Thirdly, there is no significant progress on EA related to new enterprise realities (e.g., virtual, boundaryless, heterogeneous culture, and retention knowledge). Lastly, many advances have been discussed but are still very early. Reference [36] identified 14 criteria to evaluate EAF artifacts. These criteria are applied for the Zachman Framework, TOGAF, FAF, EAP, The Enterprise Architecture, and DoDAF by three designated experts with overall perceived results 90.87% usable, 97.62% relevant, and 90.48% correct.

As the implications, further study using manageable chili enterprise systems requires bringing farmers closer to end consumers that enhance farmers' welfare [37]. Farmers might utilize a predictive analytics model to plan optimal chili production schedules and plan logistics and distribution chains to several regions to reduce the production cost and increase profit for the farmer [38] [39]. Chili agrosystems may be considered family companies and small-medium enterprises with a multidimensional concept with several variables, including actors, attributes (motivation and activities), and consequences or outcomes [40]. The smart enterprise system has to build knowledge foundations, bearing in mind the technology-assisted organization, leadership, and management models [41]. Therefore, enterprise architecture implementation and critical success factors and artifacts may address using various methods (Fig. 13).

Fig. 13. Horizontal Dendrogram of State-of-the-Art Results.

#### IV. CONCLUSION

This study's main findings are that using an enterprise architecture framework might provide better solutions to guide the supply chain management in governing the price volatility of the chili agrosystem. Even though the proposed methods do not represent the entire publication, they suffice the goals. Chili agrosystem implicates multiple mechanisms, such as the array of heterogeneous production centers and productivity, dynamic and variably supply chain patterns, unappealing trade and freight margin, and segregated chili datasets among associated institutions.

There are diverse open challenges and areas for further studies. Conforming to the results, we contribute three lines of work, particularly if we consider that some problems are to be solved. Firstly, enterprise architecture is unique depending on the nature of the enterprise: government institutions, non-governmental agencies, e-commerce, virtual organization, or any organizations. Hereupon, resolving the current problem can probably be separated into three primary classes containing modeling, development, and maintenance. Next, each enterprise architecture framework has its well-defined characteristics.

Consequently, enterprise architecture choices are not general but depend on the nature of the enterprise. Last, the chili agrosystem outlook demands the availability of an integrated creation of a chili dataset for chili farmers or groups to access. The existence of the chili dataset can better enhance the economic, social, institutional, and environmental appearances of the chili agrosystem.

In conclusion, the strength of enterprise architecture relies upon three factors of the resulting deliverables. These are enterprise, influencing, and architecture factors. Nevertheless, of many available frameworks, the Zachman framework gives more offerings for developing an intelligent enterprise system of fresh chili. We suggest a thorough study investigating these factors to achieve a suitable framework for the chili agrosystem. Further study is also required on various supply chain patterns using a Zachman enterprise architecture framework to improve the efficacy of the chili agrosystem.

#### ACKNOWLEDGMENT

This work was supported by the Computer Science Department, Faculty of Mathematics and Natural Science, IPB University.

# Virtual Reality Application for Pain Management: User Requirements

Ioan Alexandru Bratosin<sup>1</sup>, Ionel Bujorel Pavaloiu<sup>2</sup>, Nicolae Goga<sup>3</sup>, Andreea Iuliana Luca<sup>4</sup>

Department of Engineering in Foreign Languages, University Politehnica of Bucharest, Bucharest, Romania<sup>1, 2, 3</sup>

Faculty of Psychology and Education Science, University of Bucharest, Bucharest, Romania<sup>4</sup>

**Abstract**—The usage of fully immersive Virtual Reality applications for pain relief is still in an exploratory stage. In consequence there is a need to understand the user perspective and wishes regarding this kind of product. To address this issue, this paper presents quantitative research in order to establish the functional and non-functional requirements of our application. Voluntary response sampling was used for the research (N = 55). The inquiry form contained questions regarding serious game content, eagerness for testing, performance, resource consumption optimization, portability, data security, accessibility. The questionnaire was shared via Google Forms. The answers were collected and interpreted. The study revealed that a significant part of the participants was willing to test the application and that they would use an immersive Virtual Reality application during a normal treatment session if the opportunity is available. As functional requirements, the following were considered important: the presence of animals in game, a bright environment and nature-based background sounds. The following non-functional requirements were considered important: game optimization, portability, data security, accessibility, graphics quality and a short learning curve.

**Keywords**—Virtual Reality; user requirements; serious games; therapy

## I. INTRODUCTION

A subject of major significance for researchers is the usage of software application like serious games in fields like psychology [1,2], economics [3], medicine [4,5], automotive industry [6], etc. One of the ideas for serious games is to examine research hypotheses [7] in a safe and controlled environment. Another purpose is to facilitate the instruction of personnel with the objective of significantly decreasing the material and human resource costs [7].

In order to provide the best user experience during different test phases of the application or during personnel training, there is a prerequisite to ensure that the functional and non-functional requirements are properly defined for the type of application being developed. A user questionnaire can be used to examine the suitability of the requirements [8, 9], depending on the type of target population, while the method of sampling can range from convenience or voluntary sampling to random simple, stratified, or clustered sampling [10].

Virtual reality (VR) pain therapy is a new domain [11], where the applications developed are not created based on a predefined template or established requirements. The applications used in VR therapy (VRT) for pain relief range from non-interactive VR applications [12], interactive VR

application not meant for pain relief [13] to custom made applications [11]. All of them had one factor in common, they provided a certain efficiency in pain relief and all users would recommend the therapy. Another thing to notice is the variety in the applications used, they do not have a standard and they are not based on predefined requirements for virtual reality therapy [12, 13].

The main benefit of this research and the approach presented is the definition of a functional and non-functional requirement template on which VR software applications for pain relief therapy can be developed. This would ease the creation of VR applications meant for pain relief as well as improving the effects of VR on pain treatment as the applications created would be developed around the user's needs.

This paper is divided in two main sections after presenting Section I, Introduction. The second section presents a literature review containing the state of the art in the use of user questionnaires for obtaining relevant data. This section is divided in 2 sub-sections. The first sub-section deepens the subject towards a more specific topic; functional and non-functional requirements (FRs and NFRs) for software application and the second sub-section that describes the use of serious games, VR applications in medicine and the need for establishing a suitable protocol for defining the FRs and NFRs. The third section contains the evaluations done on the user questionnaire in order to verify its validity and relevance towards the presented research subject. The section starts with a description of the user's opinion on multiple functional and non-functional requirements and continues with an evaluation of their relevance by taking into consideration statistical parameters of the responses.

## II. LITERATURE REVIEW

Assessing the usability of an application is a very important part in the development process [14] and it can be assessed through various methods, such as quantitative measures. Although questionnaires are among the best-known measures of user experience (UX), due to the high heterogeneity of the instruments [15], choosing the best tool to assess UX became a difficult task. Each of these formats has advantages and disadvantages which will be discussed further. In this regard, an extensive analysis has been made [15], indicating that the majority of usability questionnaires contain short items measured on a Likert scale. The System Usability Scale (SUS) is a short – 10 items – questionnaire that can be used to assess the general impact of an application. This questionnaire is

highly employed due to the short completion time and flexible structure and it can be used in many practical settings, such as medical field [16], including the adaptation on applications for pain [17].

The System Usability Scale was created to assess the usability of a product or service and has been widely used in numerous areas such as VR rehabilitation and health services [18], VR learning [19] and VR training, and also for VR locomotion techniques [20] and it is one of the most widely used standardized questionnaires for the assessment of perceived usability [21]. A plethora of studies proved the reliability of SUS scale [22]. The SUS has many advantages, one of the most important being its flexibility [23] that allows it to assess a wide range of technologies.

Usability tests are conducted with either samples of participants who meet specific health criteria [18] or the general population [23], and most of the time is based on convenience sampling [24] a type of non-probability sampling used in research [25]. Apart from the sampling method, another issue to be taken into consideration is the sample size, which can be determined through statistical techniques by estimating the variance of the dependent measure(s) – for task-level measurements – or through more complex formulas and techniques in the case of problem-discovery usability measurement [26].

Overall, the heterogeneous state of art for UX questionnaires raises several issues to be taken into consideration when analysing perceived usability. However, as discussed above, questionnaires are one of the most widely used tools in assessing UX due to their efficiency and practicality. In addition to those, in the paper [27] is indicated that the usability research may benefit from VR technology for user research and human-product interaction.

#### A. Functional and Non-functional Requirements for Medical Applications

The process of developing software applications needs to fulfil several requirements, which are usually divided into functional requirements (FRs) and non-functional requirements (NFRs). FRs correspond to the capabilities of the system, whereas NFRs (e.g., being user-friendly, capability, performance, stability etc.) describe the overall proprieties that a system [28] must have and they may not be directly related to specific system components [29]. Due to their nature, NFRs – also called “system features” [30] - are more abstract requirements, therefore more difficult to define and quantify.

A recent analysis of requirements, made by Stamm et al. [31] for a VR intervention on a group of geriatric patients with chronic back pain in order to determine their importance, analysed the requirements for the overall system - software, hardware and gamification or game integration. Among the most important requirements, the participants listed: an individual briefing for the system, presenting instructions in a detailed manner and that the length of the exercise to be a maximum of 30 minutes (i.e., in accordance with the safe and healthy warning of the oculus advising 10-15 minutes break every 30 minutes). Also, the “user-friendly handling of the system” was important to ensure a safety regulation. Another

important factor, highlighted by the authors, is the age of the participants, as elder participants have special requirements [32] and would need additional training in using the equipment.

#### B. Virtual Reality in Medicine

Virtual Reality is a domain that is continuously expanding its utility in the medical domain [33] due to its capabilities of simulating environments that closely resemble reality. The rendering of almost photorealistic scenes and the use of controllers with haptic feedback allows virtual reality surgical simulators to increase the skills of surgeons without endangering the patient. Medical applications can range from dentistry [34], intravenous-insertion, chest-tube insertion, central venous placement catheter simulators to therapeutic treatment of physical affection [35] or mental health disorders [36] like phobias.

VR and augmented reality (AR) are studied for their capabilities of increasing surgical accuracy, decreasing the overall length of surgery and improving surgery techniques [37] where the author shows the use of the enhanced view provided through the digital generated images. One of the research reviews was focused on pedicle screw placement where it was found that AR increased both accuracy and efficiency with thoracic pedicle screws. It was used as well in training up to 51 residents in this type of surgery and it was demonstrated that they had benefited from the AR technology. A clinical trial that used 20 patients for spinal fixations displayed a high level of 94.1% accuracy for the thoracic pedicle screw operation with the help of AR [38]. For the training mechanism in VR for spine surgery, in paper [39] it is revealed that the group which used the “ImmersiveTouch” VR simulator had better performance levels in all statistics like trajectory, depth of screw error and breach, compared with the control group that used the usual training methods. The success was determined by the 3D anatomical precision and representation of the model. The overall use of VR technology was reviewed [34], regarding the simulation of different medical procedures (i.e., laparoscopic [40] with LapSim, Lap Mentor, orthopaedics with TraumaVision, Proedicus KSA VR or other surgeries with Visible Ear Simulator). The HipNav VR simulator was developed for orthopaedics, and it contains a kinematic model of the hip joint and tools for specific procedures [41]. The main use of surgical simulators is to provide advanced training, automatic scoring and analysis of the intervention with objective metrics, so the VR surgical simulators improve overall performance and lead to less injury to patients during the real operation [42].

Another application of VR technology is for pain management, due to the lack of negative effects after the treatment unlike opioids. To validate the effects of VR on acute or chronic pain, a significant number of randomized trials are required. A randomized trial was performed on 120 subjects, half VR, the other control to test the efficacy of VR [43]. The patients were hospitalized with an average pain score greater than 3 on a scale from 1 to 10. They have used an Oculus Gear set with a set library of VR application. The outcome was patient-reported pain using a numeric scale and then compared pre and post intervention and after 48 and 72 hours. The result obtained was a positive one, as there was an observed

difference in favour of VR. The result was more noticeable on patient with pain score greater than 7. The major areas where VR interventions are used include burn and wound care, intravenous insertions, dental procedures and surgery, where the first target is anxiety reduction [43]. Most of the results support the use of Virtual Reality for pain management in paediatric populations. But as the study points out, there is a need for the standardization in this domain to facilitate the creation, and research of VR software and hardware for pain management purposes. The paper [44] shows a review of multiple studies that have conducted clinical studies to verify the efficiency of VR with encouraging results. It proposes as well the combination of VR with Music Treatments (MT) to further reduce pain through mechanism that implicates distractions, mood regulation, and engagement. Further research is required to explore the combination of the two treatment types and assess their effectiveness.

A major issue with the previously described applications in the review studies [11] and [33] is the definition of their requirements. The main component that is stressed and showed importance in reducing pain in VR therapy is the immersive quality of the application, ease of use and environment. These qualities can be vastly improved by applying a combination of standardized and customized user forms to obtain the expectations of the users before the actual implementation of the application. This would lead to an improved design method for VR software application as well as the improvement of the effect of VR on pain therapy.

The main objective of the current research is to establish a template on which the initial stage of development for VRT applications can be eased and improved. This would lead to an improvement in the quality of VRT software and to its effects on therapy.

In conclusion, Virtual Reality is a new technology that requires continuous research through randomized clinical trials, creation of viable functional and non-functional requirements and a robust and standardized framework to analyse its effects.

### III. GAME4PAIN REQUIREMENTS

Following the previous discussion, in this paper the focus is on establishing the proper functional and non-functional requirements for the current VR application that is being research and developed by us. The end purpose of this application is to be applied as a pain relief alternative or as a secondary option to opioids in order to decrease the consumption of pain ameliorating drugs.

The study used a sample population of 55, from which 32.7% (18) male and 67.3% (37) female. The majority were in the age group of 18-24 years old - 83.6% (46), with a few in the age group of 25-34 - 12.7% (12), while the 35-44 and 45-60 groups of ages contained each 1.8%, one person.

The questionnaire provided to the volunteers included a set of 3 questions regarding their experience with VR applications, if any and their willingness to test a VR application for pain relief if they had the occasion (Table I). The first question asked was if the participants have received any VR treatment before.

The following answers were recorded: 36 of them did not receive any, 5 received full immersive VR, 6 Mobile VR, 7 persons Games and only one person TV based treatment.

The majority of participants expressed their enthusiasm to try the VR application for pain relief if they had the occasion, 34 people gave a positive answer, 18 were undecided and only 3 persons would not like to try.

The second part of the questionnaire in Table II consisted in establishing the functional and non-functional requirements, for this part there were 13 questions with answers on a scale from 1 to 5. In this part of the form, the questions were about the importance of various elements in the game e.g., background music, sunlight level, complexity level, the importance of wildlife and NFRs e.g., data security, accessibility, graphics quality, learning curve.

#### A. Functional and Non-functional Inquiry Form Analysis

From the analysis of the form questions mean and standard deviation results from Table II, the results show that the majority of the respondents are enthusiastic regarding the test of a fully immersive VR application given the mean score of 4.27 out of 5 with a relatively low standard deviation of 0.95. For the next item there is a similar high interest in having animals in the game with a mean score of 4.25. Regarding the fishing system the average is almost in the middle with 3.33 but as the standard deviation reach 1.44 it signifies that the opinions are likely opposed. A majority would like to have a fishing system implemented as a functional requirement while others are not interested.

Another interesting finding is that the subjects would prefer a luminous setting that simulates sunlight as it seen in question 5 and 6 where they affirm that the presence of sunlight affects their mood in a positive way.

TABLE I. USER ATTITUDE TOWARDS VR FOR PAIN RELIEF THERAPY

Question	Answer variant	Percentage of N=55
Have you ever received a Virtual Reality treatment? If so, what type?	None	65.5%
	Full Immersive VR (e.g. Oculus Headset VR)	9.1%
	Mobile VR	10.9%
	Games	12.7%
	TV	1.8%
Would you prefer a full immersive VR experience over a normal TV/Game intervention during treatment?	Yes	61.8%
	No	5.5%
	Maybe	32.7%
Would you like to try a Virtual Reality game for the amelioration of pain, alongside usual treatment?	Yes	69.1%
	No	9.1%
	Maybe	21.8%

TABLE II. FR AND NFR FORM RESPONSE ANALYSIS

Question	Mean/ Standard deviation
1.How Interested would you be in testing a fully immersive VR application during treatment? (1 = Not at all, 5 = Very much)	4.27/0.95
2.Are you interested in having animals in the game? (1 = Not at all, 5 = Very much)	4.25/1.004
3.Are you interested in having the option to fish in the game? (1 = Not at all, 5 = Very much)	3.33/1.44
4.Would you prefer music or nature sounds to run in the background? (1 = Music; 5 = Nature)	3.65/1.40
5.Do you think that the level of sunlight in a game affects your mood in a positive way? (1 = Not at all, 5 = Very much)	3.96/1.05
6.Do you think that the level of sunlight in real life affects your mood in a positive way? (1 = Not at all, 5 = Very much)	4.22/1.08
7.How important you consider optimizing resource consumption. (How well the game runs on your device). (1 = Not important at all, 5 = Very important)	4.38/0.87
8.How important you consider the game having a short learning curve. (to be easy to learn) (1 = Easy, 5 = Hard)	3.33/1.14
9.How Important is Portability (ability to run on different operation system devices) (1 = Not important at all, 5 = Very important)	3.89/0.99
10.How Important is Data Security. (1 = Not important at all, 5 = Very important)	4.67/0.58
11.How Important is Accessibility (1 = Not important at all, 5 = Very important)	4.60/0.60
12.How Important is the Graphics quality (1 = Not important at all, 5 = Very important)	4.40/0.87
13.How would you consider the application having an in-depth Game Mechanics (the number of actions you can do in a game and the complexity) (1 = Simple Game, 5 = Complex Game)	3.98/0.83

As non-functional requirements regarding the application difficulty in question 8, the opinions are pointing towards an average learning curve, but with a high game complexity in question 13. There is a need to take in consideration the age of the group as its mostly young adults, and they would lean towards a challenging game, but due to the nature of the application as it is meant to be enjoyable to the target audience of persons that suffer from acute or chronic pain, therefore a slightly simpler application with a short learning curve would be more appropriate. In regard to NFRs for accessibility, graphics quality, data security, portability and resource consumption, all the results with high means of 4.40 and deviations under 1 indicate that they are essential in developing the application.

### B. Scale Assessment

To validate the measurements from (Table III) a Principal Component Analysis (PCA) with varimax rotation was used [45]. By Kaiser’s criterion, 5 principal components were extracted with Eigen values over the cutoff of 1. The final components chosen based on having at least three variables with a minimal loading of 0.3 [46] where Component 1 (I1, I5, I6, I7) and Component 2 (I9, I10, I11, I12), resulting in a total variance of 37.84%.

TABLE III. FR AND NFR FORM QUESTIONNAIRE

Item Number	Question
I1	How Interested would you be in testing a fully immersive VR application during treatment?
I2	Are you interested in having animals in the game?
I3	Are you interested in having the option to fish in the game ?
I4	Would you prefer music or nature sounds to run in the background?
I5	Do you think that the level of sunlight in a game affects your mood in a positive way?
I6	Do you think that the level of sunlight in real life affects your mood in a positive way?
I7	How important you consider optimizing resource consumption.(How well the game runs on your device).
I8	How important you consider the game having a short learning curve.(to be easy to learn)
I9	How Important is Portability(ability to run on different operation system devices)
I10	How Important is Data Security.
I11	How Important is Accessibility
I12	How Important is the Graphics quality
I13	How would you consider the application having an in depth Game Mechanics(the game and the complexity)

Next, to identify the latent factors measured, an exploratory factor analysis (EFA) was applied by using IBM SPSS v.25 software [47], with a principal axis factor extraction method and varimax rotation. The Kaiser-Meyer-Olkin Measure of Sampling Adequacy had an acceptable value of (KMO = 0.57) using the minimum acceptable value of 0.50 [48], and Bartlett’s Test of Sphericity was significant ( $p < .001$ ).

By Kaiser’s criterion [48], there were 5 factors with Eigen values above the cutoff of 1; however the procedure could not be completed due to a Haywood case [49]. As advised in IBM SPSS statistics a downside for this criterion may be the overestimation of the number of factors to retain. Most of the present communalities are lower than 0.70, therefore, Kaiser’s rule might be inappropriate for this type of data. By Cattell’s criterion [50], the scree plot and the previous principal component analysis suggest 2 extraction factors. Therefore, the analysis was executed with 2 fixed extraction factors. According to [51], only the items with a interpreted factor loading with an absolute value more than 0.3 were taken in consideration. Based on this cutoff, three items were not included in the analysis due to having too much uniqueness (I2, I3, I8), and the final structure included Factor 1 (I1, I4, I5, I6, I7) and Factor 2 (I9, I10, I11, I12, I13). The EFA resulted in a 10-item scale, explaining 34.53% of the total variance (Table IV).

Furthermore, the reliability analysis indicated an acceptable internal consistency for Factor 1 ( $\alpha = 0.78$ ) and a modest one for Factor 2 ( $\alpha = 0.65$ ). Although, a sample size of at least 50 is adequate for behavioral sciences, the internal consistency coefficient proved to be sensitive to both sample size and number of items, especially if the Eigen value for the first factor is lower than 6 [51]. Moreover, [52] showed that for

sample sizes of 50, the loadings should be around 0.80 for a stable structure. In this case, a higher sample size may be advisable in the future.

TABLE IV. ITEM ANALYSIS AND FACTOR LOADINGS

Rotated Factor Matrix	Factor	
	1	2
I5	0.90	-
I6	0.78	-
I7	0.70	-
I1	0.56	0.34
I4	0.40	-
I11	-	0.78
I12	-	0.57
I9	-	0.55
I10	-	0.51
I13	-	0.31
Variance registered after rotation in %	34.53%	

Overall, the findings indicate that an adequate VRT application is required to have a simplified user interface to allow a fast comprehension of the system by the user with a robust framework that provides data security, accessibility and portability. A second important criterion is to have a simple objective, well described with simple game mechanics to avoid confusion. A third trait is immersion characterized by a high graphic quality, as immersion is the main goal of any VRT application. The analysis in this paper provides insight for how future work in this domain should be approached as well as what criteria VRT applications should follow.

#### IV. CONCLUSION

This article explored the establishment of functional and non-functional requirements for a Virtual Reality application that can be used for pain relief treatments based on the answers obtained from the user questionnaire using voluntary random sampling. The following high priority FRs and NFRs have been observed: immersive environment, presence of an illumination system that simulates daytime lighting, natural background sounds, interactive animal type objects, engaging mechanics, resource optimization, secure data storage, accessibility and improved graphics quality.

For future work, the goal is to implement the learned findings and requirements in a VR application meant for pain therapy. This application will be tested in a real environment where its effects can be observed. The experiment will be followed by a second questionnaire for user experience using the voluntary random sampling method, in order to verify the initial findings concerning the FRs and NFRs as well as its effect on pain relief.

# Integration of Convolutional Neural Networks and Recurrent Neural Networks for Foliar Disease Classification in Apple Trees

Disha Garg, Mansaf Alam  
Computer Science Department  
Jamia Millia Islamia  
New Delhi, India

**Abstract**—Automated methods intended for image classification have become increasingly popular in recent years, with applications in the agriculture field including weed identification, fruit classification, and disease detection in plants and trees. In image classification, convolutional neural networks (CNN) have already shown exceptional results but the problem with these models is that these models cannot extract some relevant image features of the input image. On the other hand, the recurrent neural network (RNN) can fully exploit the relationship among image features. In this paper, the performance of combined CNN and RNN models is evaluated by extracting relevant image features on images of diseased apple leaves. This article suggested a combination of pre-trained CNN network and LSTM, a particular type of RNN. With the use of transfer learning, the deep features were extracted from several fully connected layers of pre-trained deep models i.e. Xception, VGG16, and InceptionV3. The extracted deep features from the CNN layer and RNN layer were concatenated and fed into the fully connected layer to allow the proposed model to be more focused on finding relevant information in the input data. Finally, the class labels of apple foliar disease images are determined by the integrated model for apple foliar disease classification, experimental findings demonstrate that the proposed approach outperforms individual pre-trained models.

**Keywords**—Artificial intelligence; deep learning; transfer learning; convolutional neural network; recurrent neural network; LSTM

## I. INTRODUCTION

Agriculture began in neolithic era and has continued to this day. However, the situation of agriculture is deteriorating day by day as a result of harsh variations in climatic conditions and human malpractice. Diseases in trees, animals, and grains are dangerous and can kill agriculture if not detected early. Various plant diseases can spoil the surrounded plants and trees. But due to a lack of knowledge and expertise, it is not possible to diagnose such diseases. As a result, experts are doing everything possible to assist farmers in overcoming these diseases.

Apple (*Maluspumila*) is commercially the most important fruit and is fourth among the most widely produced fruits in the world [1]. The growth of apple trees is affected by the assault of numerous foliar diseases such as scab, black rot, and rust [2]. Because of resemblance in appearance in the early

stages of tree growth, correctly classifying and identifying all forms of foliar diseases in apple trees is a difficult challenge for farmers. Early disease identification is important for effective and timely disease control. Incorrect and/or delayed diagnosis may result in disease transmission because small insects can damage the whole tree and rapidly it can become a larger and more costly issue.

The manual classification of these diseases can be unnecessarily cumbersome, time-consuming, and costly. Speeding up this method has many advantages, including lower costs, reduced effort. Various plant disease classification systems are designed to support non-expert and non-botanist users in automatically distinguishing plant diseases. Because of this, cost and time can be reduced with accurate identification. Machine learning (ML) [3][4] and deep learning (DL) [5-11] have received a lot of interest in recent years for automatic disease and pest detection in trees and plants. Usama Mokhtar et al. [3] implemented SVM-based disease detection of tomato leaves. They used the dataset of 800 healthy and unhealthy leaves for disease classification. Authors performed feature extraction using Grey-Level Co-occurrence matrix (GLCM) and achieved a classification accuracy of 99.83%. Shima Ramesh et al. [4] implemented plant disease detection, and they achieved the highest classification accuracy (70.14%) using the random forest technique among the various machine learning algorithms. These machine learning techniques use manual feature extraction, but deep learning algorithms solve this problem effectively.

For automatically detecting crop diseases, convolutional neural networks (CNNs) have become common. Moreover, numerous studies on the identification of apple diseases also have been published in the literature using pre-trained CNN models since 2017. Table I summarizes the contents of these articles.

The problem with these models is that these models cannot extract some relevant image features of the input image. In this paper, the performance of combined CNN and RNN models is evaluated by extracting relevant image features. For this, transfer learning was used in which the pre-trained weight parameters on the ImageNet dataset are transferred to CNN and combined with the extracted features of RNN in the model.

TABLE I. STUDIES TO CLASSIFY APPLE LEAVE DISEASE USING PRE-TRAINED CNN MODEL

Reference	Task	Dataset	Method	Accuracy	Pros and Cons
(Peng Jiang et al. 2019) [1]	Real time apple leaf diseases classification	26,377 images of apples diseased leaves	VGG-INCEP	97.14 %	Detects disease spots of various sizes on the same leaf
(Yong Zhong, Ming Zhao 2020) [12]	Identify apple leaf diseases	2462 images of 6 apple leaf diseases	DenseNet-121	93.71 %	Cannot overcome the impact of data imbalance
(Xiaofei Chao et al. 2020) [13]	Early diagnosis and accurate identification of apple tree leaf diseases	2970 images of diseased and healthy leaves	Xception and DenseNet (XDNet)	98.82 %	The diversity of dataset is not enough
(GuanWan g et al. 2017) [15]	Image-Based Plant Disease Severity Estimation	50,000 images of healthy and diseased crops-38 class labels	VGG16 trained with transfer learning	90.4%	Lacking number of parameters to compare the results
(Bin Liu et al. 2017) [16]	Identify apple leaf diseases	13,689 images of diseased apple leaves	AlexNet, image generation technique	97.62 %	Image generation technique can enhance robustness of CNN model

Contributions of the CNN-RNN combined network are as follows:

- To classify leaf diseases, Pretrained CNN models and RNN were used.
- The performance of combined network was evaluated.
- The suggested integrated model performs better than pre-trained networks, according to the findings of the experiments.

The remaining part of the article is laid out as follows: Section 2 presents a review of current scholarly publications relevant to this article. Section 3 contains the methodology, dataset collection and description, data preprocessing, an integrated network, and its layers. In Section 4, the training and fine-tuning of an integrated model is described. Section 5 contains the experimental setup as well as the model classification findings. In Section 6, the proposed model is compared with existing techniques. Section 7 concludes the paper.

#### A. Motivation

When the current work is examined on image classification, it was observed that researchers have paid a lot of attention to combining multiple models. Deep models with

multi-modality perform better in terms of classification accuracy, precision, recall, and f1 scores. JananiVenugopalan et al. used a combination of models to diagnose Alzheimer's disease at an early stage[17].Md. Zabirul Islam et al. [18] used X-ray images to combine CNN and LSTM for the identification of a novel coronavirus (COVID-19).Aydin Kaya et al. [19] used the combination of RNN and CNN models for plant classification. It is also found that deep feature concatenation is extremely efficient. This sparked the interest in combining RNN and CNN, as well as the notion of concatenating features from pre-trained CNN and RNN models.

## II. RELATED WORK

Many pieces of research on the identification of plant diseases have been carried out so far. Genetic algorithms [20] [21], artificial neural networks [22], Bayes classifiers [23], and fuzzy logic [24] have been used in previous studies to identify and classify plant leaf diseases having a higher level of accuracy.

DL has been extensively researched in recent years for disease and pest identification in plants [9] [10] [25] [26]. Previous research has also shown that CNN is ideally suited for high-accuracy detection and diagnosis of plant diseases automatically. Some of these studies used CNN-based models that had been pre-trained, while others created their models based on CNN or pre-trained models.

Alvaro Fuentes et al. (2017) [5] proposed a faster region-based CNN for tomato diseases and pests recognition in real-time. Authors utilized a huge data-set for testing and training, comprising of 5000 images to develop these systems. These systems are capable of detecting nine distinct diseases and pests. The authors used a faster RCNN, but this model has a poor identification rate and a lot of pattern variability in certain disease groups.

Belal A. M. Ashqar and Samy S. Abu Naser (2018) [6] used deep learning approach to develop tomato leaves disease detection system. They used 9000 images of diseased and healthy tomato leaves for training of deep CNN to classify 5 diseases. They achieved 99.84 % accuracy. To perform detection and diagnosis of diseases in plants, Konstantinos P. Ferentinos (2018) [7] developed a convolutional neural network model using diseased and healthy 87,848 images of plant leaves. They trained various models. Among all CNN models, VGG achieved an accuracy of 99.53% with the best performance. The authors used the VGG model on diseased images and had a decent success rate, but this model is far from being a generic method.

Aravind Krishnaswamy Rangarajan et al. (2018) [8] have performed the classification of disease in tomatos by using pre-trained DL and its algorithm. Authors have used AlexNet and VGG16 pre-trained architectures on PlantVillage consisting of 13262 images and achieved 97.29% classification accuracy for VGG16 net and 97.49% for Alex-Net. However, other transfer learning models need to be evaluated for this dataset.

Additionally, Geetha ramani G. and Arun Pandian J (2019) [9] proposed a model to identify diseases in plants using Deep

CNN. For training, they used a dataset that included 39 different plant leaf classes as well as background images. Authors used the following 6 types of data augmentation methods: principal component analysis (PCA), gamma correction, flipping, noise injection, color augmentation, scaling, and rotation. They achieved a classification accuracy of 96.46% for this proposed model. Despite their high success rate, authors were unable to completely exploit important image features using deep CNN.

Moreover, Edna Chebet Too et al. (2018) [10] performed the comparison of InceptionV4, VGG16, ResNet with 101, 152, 50 layers, and Dense-Nets with layer number as 121. Among all structural designs, Dense-Nets achieved the testing accuracy of 99.75 percentages. With an increasing number of epochs, DenseNets has the potential to increase accuracy without overfitting. However, computational time can be improved.

TABLE II. PREVIOUS STUDIES BASED ON DEEP LEARNING FOR THE OTHER PLANT SPECIES

Author	Plant species	Model used	Best Results	No. of images
Mehmet MetinOzguven, Kemal Adem [27]	Sugar beet	Faster R-CNN	92.89%	155
Aravind-Krishna swamy Rangarajan, Raja Purushothaman, Aniiirudh Ramesh [8]	Tomato	AlexNet VGG16 net	97.49% 97.29%	13,262
Geetharamani G., ArunPandian J [9]	Different plant disease	Deep CNN	96.46%	61,486
Karthik R et. al. [28]	Tomato	Attention embedded residual CNN	98%	95999
Sladojevic et al. [20]	Plant leaves	CNN based model	96.3%	2 589
Honghua Jiang et.al [29]	weed and crop recognition	GCN-ResNet-101	97.8%	6000
Gensheng et al. [26]	tea leaf	VGG16	90%	4 980
Ashqar et al. [6]	Tomato	Deep CNN	99.84%	9000
Jihen Amara et al. [11]	Banana	LeNet	98.61%	3700
Srdjan Sladojevic et al. [30]	Different plant disease	deep CNN	96.3%	30880
Sharada P. Mohanty et al. [31]	Different crops	GoogLeNet	99.35%	54306

One of the most significant gaps of the current studies in the field of plant disease detection is a significant decrease in classification performance [12, 15, 26] of the models on real images collected in fields compared to images taken in a controlled environment so there should be availability of large public datasets [14] [27]. Table II summarizes the findings of related investigations.

### III. METHODOLOGY

The overall method for detecting foliar diseases in an apple tree dataset is represented in Fig. 1 in several phases. The apple foliar disease dataset was utilized as the training data for the CNN-RNN network. The training accuracy, validation accuracy, training loss, and validation loss were calculated at each epoch. Confusion matrix, accuracy, precision, recall, and f1-score were used to evaluate the performance of the proposed system. It is also observed the minimum training and minimum validation loss and corresponding accuracies.

#### A. Dataset

High-resolution and real-life symptom images of different apple foliar diseases have been manually captured with angles, illumination, noise, and surfaces. This dataset for the Plant-Pathology Challenge is made available and open to the group through "https". It's an integral component of FGVC (Fine-grained visual categorization) which is a workshop at CVPR(Computer -Vision and Pattern- Recognition) 2020. This dataset has four types of classes (a) Apple scab, (b) Black rot (c) Cedar apple rust (d) healthy. Sample images of each class are given in Fig. 2. Proposed model, however, is not limited to this dataset and can be used on a variety of plant disease datasets. Table III shows the count of total images in the dataset, which has previously been separated into the train set and test set.

#### B. Preprocessing

Dataset is enhanced to increase the model accuracy and reduce over-fitting. Apple foliar disease dataset contains RGB images of arbitrary sizes. All of the images were scaled to a resolution of 299 by 299 pixels and to be compatible with the initial values of the network, all pixel values were divided by 255. After that, sample-by-sample normalization was carried out. The efficiency of end-to-end training can be greatly improved by normalization. Finally, the training images are subjected to a variety of random augmentations, such as random rotation, shearing, zooming, and flipping.

#### C. Development of the Integrated Model

A proposed integrated CNN-RNN model is based on pre-trained CNN. The models mainly contain different layers of pre-trained CNN models, one RNN layer/LSTM layer and one softmax layer. The images are re-sized to fit the input layers of the pre-trained models such as Xception, VGG16, and InceptionV3. After this, deep features were extracted from these pre-trained models and then different shape of the output is found for different pre-trained models. For inceptionv3 the output shape is found as (None, 8, 8, 2048). For VGG16, the output shape is received as (None, 9, 9, 512) and for the Xception model (None, 10, 10, 2048) is received as an output shape. The input is provided to the LSTM layer using the reshape technique. After analyzing the time characteristics, a softmax layer/fully connected layer predicted class labels of the input images that were categorized into four categories: scab, black rot, cedar apple rust, healthy.

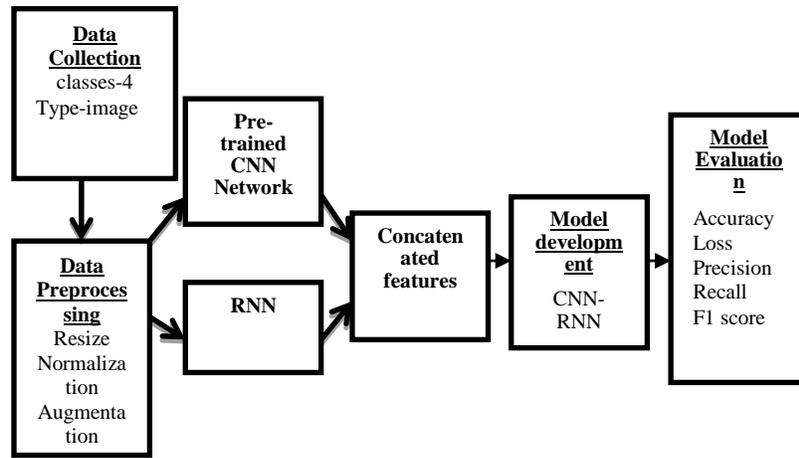

Fig. 1. Proposed System.

Fig. 2. The Apple Foliar Dataset Sample for Four Classes.

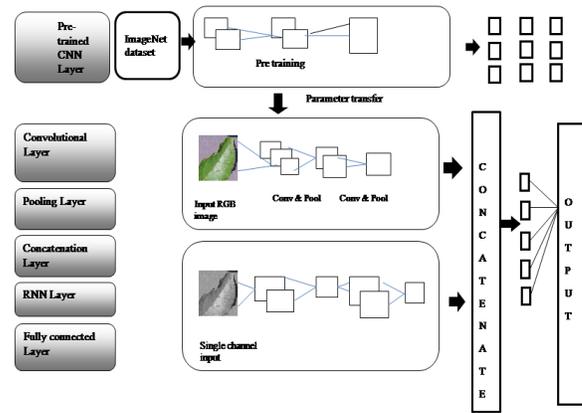

Fig. 3. Integrated Model.

TABLE III. IMAGE COUNT IN THE DATASET

Dataset	Apple scab	Black rot	Cedar apple rust	Healthy	Total
Training	4032	3974	3520	4016	15542
Testing	1008	994	880	1004	3886
Total	5040	4968	4400	5020	19428

RNNs can handle non-sequential data as well as sequential data, according to several pieces of research [32]. Improved RNN models, such as LSTMs allow for long sequence training, conquering issues such as vanishing gradients. Vanishing gradients is a problem where a deep neural network is not able to transmit valuable gradient information from the output to the input end of the model. RNN methods for sequentially processing the data of variable-length and fixed sizes have been presented in a few recent papers [33]. LSTM may be used to collect the images having discriminating regions for fine-grained classification [34]. LSTM (Long Short-Term Memory networks) has a "processor" that determines whether or not the information is useful. The Integrated model is illustrated in Fig. 3 with four layers: Pre-trained CNN layer, RNN layer, concatenation layer, softmax, or fully connected layer.

All layers of an integrated model are briefly described as follows:

1) *Pre-trained CNN layer*: For initializing weights of CNN model, pre-trained weight parameters are used. ImageNet is used for pre-training and it is a common dataset to develop different architectures. It is broad enough (1.2 million images) to construct a generic model. Transfer learning indicates that these pre-trained networks can generalize to images that are not part of the ImageNet dataset. By fine-tuning the model, changes can be made to it that was not previously possible.

2) *Convolution layer*: Convolution operations with feature maps are performed with this layer using convolution windows of various sizes. The effect of applying a convolution over an image is a feature map. The row index and column index of resulted matrix is denoted by  $u$  and  $v$  respectively. The number of weight parameters varies as the window size changes. Convolution and pooling are two types of computations that can be done in the early layers of CNN. The convolution layer has the following operation as in (1):

$$S(u, v) = (M * F)(u, v) = \sum \sum M(u+m, v+n) F(m, n) \quad (1)$$

In (1), M indicate the input matrix. F represents the  $m \times n$  size 2D filter of and S denotes the 2D feature map output.  $M * F$  denotes the convolutional layer operation. Rectified linear unit (ReLU) is the activation function which is used after the convolution operation to improve nonlinearity in feature maps. ReLU calculates activation by keeping the threshold at zero. It may be mathematically represented as in (2):

$$f(y) = \max(0, y) \quad (2)$$

3) *Pooling layer*: To minimize the number of parameters, this layer down samples a given input representation. By using max-pooling which is the most frequent approach, the size of resulted image can be reduced by retaining image information. As a convolution layer, the pooling layer also uses filters of different sizes.

4) *RNN/LSTM Layer*: An input layer, a hidden layer, and an output layer are present in RNN and CNN. The most significant aspect of RNN is the interaction of these hidden layers. The input and hidden layer nodes are linked. Output layer takes the outcome of the hidden layer. Hidden layer receives information from the output layer node. There exist various adjacent hidden layer nodes.

In this article, LSTM is used which is a form of RNN. LSTM is made up of memory blocks and these blocks are recurrently connected blocks. Each has 3 multiplicative gates (input, output, forget gate) and one or two memory cells that are recurrently connected. The input gate monitors how much data it should read, forget gate monitor whether it should forget the value of the current cell, and the output gate monitor whether it should output the new cell value.

5) *Concatenation layer*: The concatenation layer concatenates features derived from the CNN and RNN. Feature concatenation is a powerful technique for combining many features to improve classification accuracy.

6) *Softmax layer or fully connected layer*: The features of RNN and CNN are concatenated and forwarded to the softmax layer, which generates the input image class labels.

#### D. Long Short-term Memory (LSTM)

A cell with three gates (input, output, and forget) makes up an LSTM unit. LSTM can choose which information is lost and which is remembered. An LSTM layer is made up of memory blocks, which are recurrently connected blocks. It can be assumed that these blocks are a differentiable variant of a computer's memory chips. Every block has one or more than one recurrently linked memory cells, as well as 3 multiplicative units. These units continuously provide analogs of reading, Reset and Write operations for the cells. The following are the gate equations:

$$i_t = \sigma(W_i[h_{t-1}, x_t] + b_i) \quad (3)$$

$$f_t = \sigma(W_f[h_{t-1}, x_t] + b_f) \quad (4)$$

$$O_t = \sigma(W_o[h_{t-1}, x_t] + b_o) \quad (5)$$

$$gt = \tanh(W_i[h_{t-1}, x_t] + b_i) \quad (6)$$

$i_t, f_t$  and  $o_t$  represent input gate, forget gate, and output gate respectively.  $\sigma$  denotes the sigmoid function. The weight for the respective gate(x) neurons is represented by  $W_x$ . The output of the previous LSTM block (at timestamp t-1) is  $h_{t-1}$ .  $x_t$  is the input at the current timestamp.  $b_x$  is the bias for the corresponding gate(x). In (3),  $h_{t-1}$  and  $x_t$  are passed through the sigmoid layer and used to decide that which part of the information is needs to be added. (6) Obtains new information when  $h_{t-1}$  and  $x_t$  are passed through the tanh layer in (8):

$$c_t = i_t g_t + f_t c_{t-1} \quad (7)$$

$$h_t = o_t \tanh(c_t) \quad (8)$$

The new and previous cell states are denoted by  $c_t$  and  $c_{t-1}$ , respectively.  $g_t$  is the current information.  $g_t$  and  $C_{t-1}$  are combined in (7). The final output  $O_t$  is calculated in (5) and it gets multiplied with  $c_t$  which transfers new information through the tanh layer.

#### IV. CNN-RNN NETWORK TRAINING AND FINE-TUNING

To classify apple foliar diseases, the combination of CNN models and RNN was used. There were a training phase and a testing phase in the proposed method illustrated. In the training process, firstly on the ImageNet dataset, CNN model was pre-trained and the parameters of this pre-trained network were used for initializing the new CNN model, this is called fine-tuning. When the entire layers of CNN have been frozen, the RNN model was trained. After the completion of training, layers of the CNN model were unfrozen and the whole CNN-RNN model was trained.

Test images that were pre-processed were fed into the CNN-RNN model. By using the softmax layer, the classification results were obtained. In this experiment, the proposed model is built on two layers: Conv and pool. These are the first few layers of pre-trained models, already trained on ImageNet dataset. In this proposed model, the above two layers were moved to the same place to allow the transmission of features. The CNN transfer learning model uses RGB input, whereas RNN uses a single-channel input. The aforementioned layers were trained on jointly on the apple foliar disease dataset. The training process was terminated after predetermined epochs.

#### V. EXPERIMENTAL RESULTS

The proposed work is implemented in two parts:

Part 1: Implementing transfer learning using CNN

Part 2: Implementing RNN

RNN uses randomly initialized parameters while CNN uses pre-trained weight parameters. During the training phase, the gradient of the cross-entropy loss function is used to iteratively update these weights. Firstly, all layers of CNN were frozen then RNN and the last classification layer of CNN were trained. Then training samples are calculated with the help of an RMSProp optimizer. Then we defrosted all layers of CNN and the whole CNN-RNN model was trained then Adam optimizer was used to calculate the samples of training. For the whole network, 0.0001 was used as a learning rate.

Since the problem is multi-class, the categorical cross-entropy/softmax loss function is used. Keras and TensorFlow2.5.0 with python 3 were used on an Intel(R) Core(TM) i5-2.9 GHz CPU for implementing models. Furthermore, we were carried out the experiments on an NVIDIA Tesla T4 GPU with 2.32 GB of RAM.

A. Evaluation Indices

The following indices were used to compare the performance of the individual and integrated systems: True Positive (TP): The class of interest was correctly categorized. True Negative (TN): Classified correctly as not the class of interest. False Positive (FP): The class of interest was incorrectly categorized. False Negative (FN): Not the class of interest was incorrectly categorized. Accuracy is represented in (9), Precision is represented in (10), Recall is represented in (11) and F1 score is represented in (12). Mathematical expression of all these metrics is represented below:

$$\text{Accuracy} = \frac{(TP+TN)}{(TN+FP+TP+FN)} \tag{9}$$

$$\text{Precision} = \frac{(TP)}{(TP+FP)} \tag{10}$$

$$\text{Recall} = \frac{TP}{(TP+FN)} \tag{11}$$

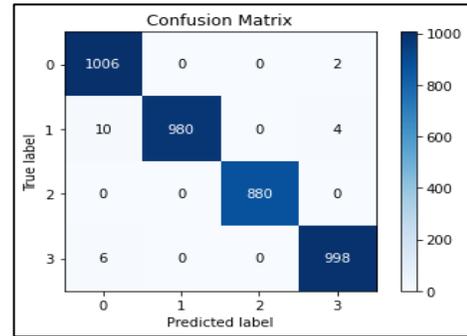

$$\text{F1 score} = \frac{2*TP}{(2*TP+FP+FN)} \tag{12}$$

B. Result Analysis and Discussion

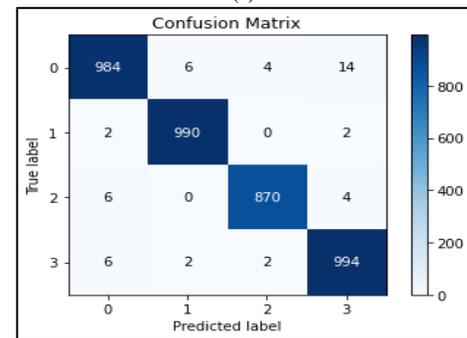

Fig. 4 illustrates the confusion matrix of the pre-trained CNN model and the proposed CNN-RNN models for apple foliar disease classification. Fig. 4(a) represents Xception-LSTM, Fig. 4(b) represents Xception, Fig. 4(c) represents VGG16-LSTM, Fig. 4(d) represents VGG16, Fig. 4(e) represents InceptionV3-LSTM and Fig. 4(f) represents Inception V3. In the confusion matrix, apple\_scab is represented as class 0, black\_rot is represented as class 1, cedar\_apple\_rust is represented as class 2, and healthy leaves are represented as class 3. The Xception model misclassified 44 of 3886 test images, whereas the proposed Xception-LSTM model misclassified 22 of them. Among the 3886 test images, 266 were misclassified by the VGG16 model, whereas the proposed VGG16-LSTM model misclassified 45 of them. Similarly, 60 were misclassified by the InceptionV3 model, whereas the proposed InceptionV3-LSTM model misclassified a total of 14 images. The proposed integrated CNN-RNN networks outperformed the individual pre-trained CNN networks in terms of TP and TN values, as well as reduced FN and FP values. Table IV shows the observed results of pre-trained CNN models and CNN-RNN models in terms of minimum training loss with corresponding training accuracy, and minimum validation loss with corresponding validation accuracy and Xception-LSTM accuracy and loss are depicted in Fig. 5(a) and 5(b).

Fig. 6(a) and 6(b) depict accuracy and Xception loss, respectively. VGG16-LSTM accuracy and loss are depicted in Fig. 7(a) and 7(b). VGG16 accuracy and loss are depicted

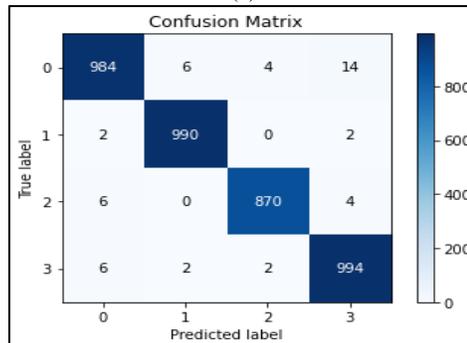

in Fig. 8(a) and 8(b). InceptionV3-LSTM accuracy and loss are depicted in Fig. 9(a) and 9(b). InceptionV3 accuracy and loss are depicted in Fig. 10(a) and 10(b). Performance evaluation for pre-trained CNN models and CNN-RNN models may be seen in the loss and accuracy figures.

TABLE IV. COMPARISON OF INTEGRATED MODELS AND INDIVIDUAL MODELS IN TERMS OF MINIMUM LOSS AND CORRESPONDING TRAINING AND VALIDATION ACCURACY

Model	Training		Validation	
	Loss	Accuracy	Loss	Accuracy
<b>Xception</b>	0.0144	99.87	0.1408	98.86
<b>Xception-LSTM</b>	0.001	99.94	0.0111	99.69
<b>VGG16</b>	0.0345	98.87	0.206	93.08
<b>VGG16-LSTM</b>	0.0028	99.94	0.0468	99.07
<b>InceptionV3</b>	0.0464	99.59	0.3042	98.24
<b>InceptionV3-LSTM</b>	0.0011	99.94	0.0027	99.9

Among the total number of 30 epochs, Minimum training loss and corresponding training accuracy of the Xception were found at .0144 and 99.87% respectively at epoch 20 whereas .0010 and 99.94 for Xception-LSTM model at epoch 10. The minimum validation loss and corresponding validation accuracy of Xception model were found .01408 and 98.86% respectively at epoch 30 whereas .0111 and 99.69 for the Xception-LSTM model at epoch 13. Similarly, the minimum training loss and corresponding training accuracy of the VGG16 model were found at .0345 and 99.87% respectively at epoch 27 whereas .0028 and 99.94 for the VGG16-LSTM model at epoch 22. The minimum validation loss and corresponding validation accuracy of the VGG16 model were found at .206 and 93.08% respectively at epoch 25 whereas .0468 and 99.07 for the VGG16-LSTM model at epoch 29. Minimum training loss and corresponding training accuracy of the InceptionV3 model were found .0464 and 99.59% respectively at epoch 19 whereas .0011 and 99.94 for

InceptionV3-LSTM model at epoch 12. The minimum validation loss and corresponding validation accuracy of the InceptionV3 were found .3402 and 98.24% respectively at epoch 10 whereas .0027 and 99.9 for InceptionV3-LSTM model at epoch 10.

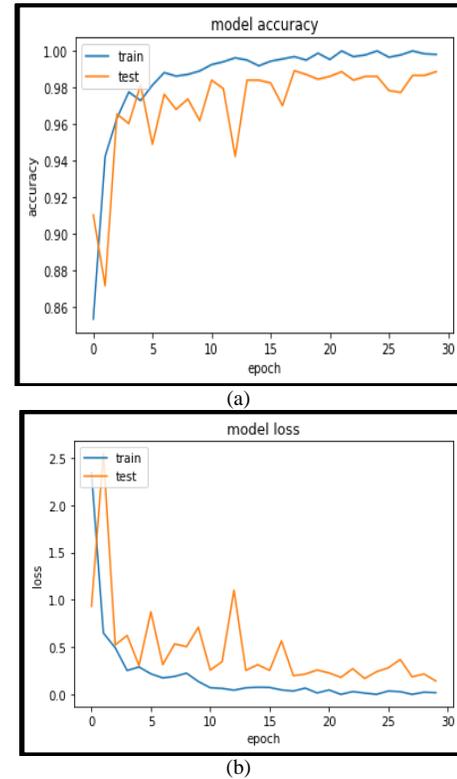

Fig. 5. (a) Accuracy (Xception-LSTM) (b) Loss (Xception-LSTM).

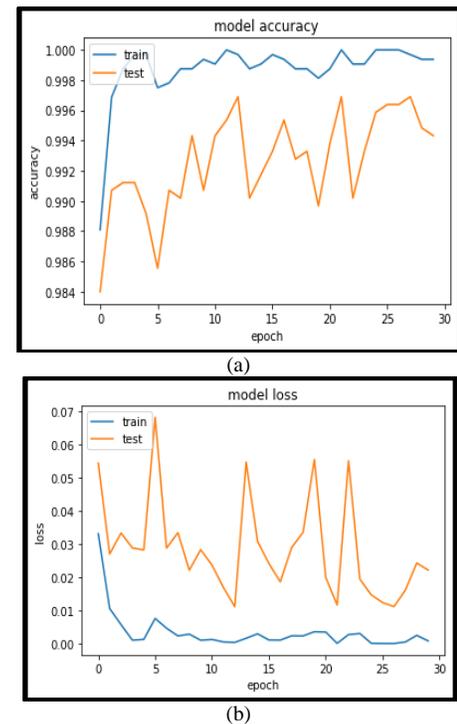

Fig. 6. (a) Accuracy (Xception) (b) Loss (Xception).

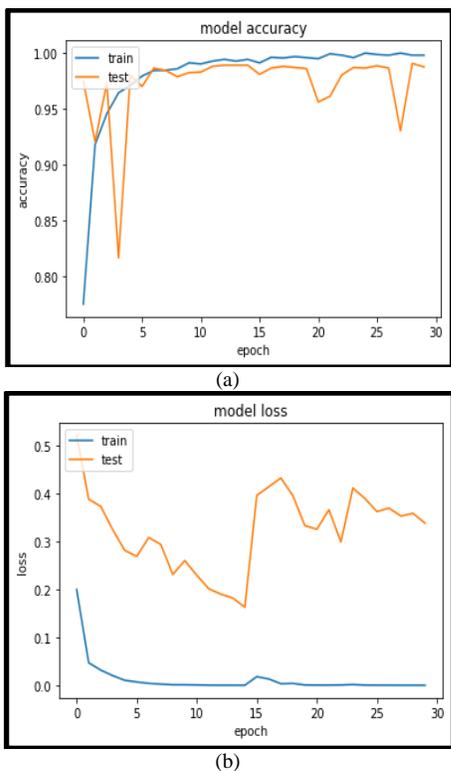

Fig. 7. (a) Accuracy (VGG16-LSTM), (b) Loss (VGG16-LSTM).

Results presented in Table IV shows that combined models have given the highest accuracy when the loss was minimum as compared to individual model. It can be seen in both the cases, training results as well as validation results.

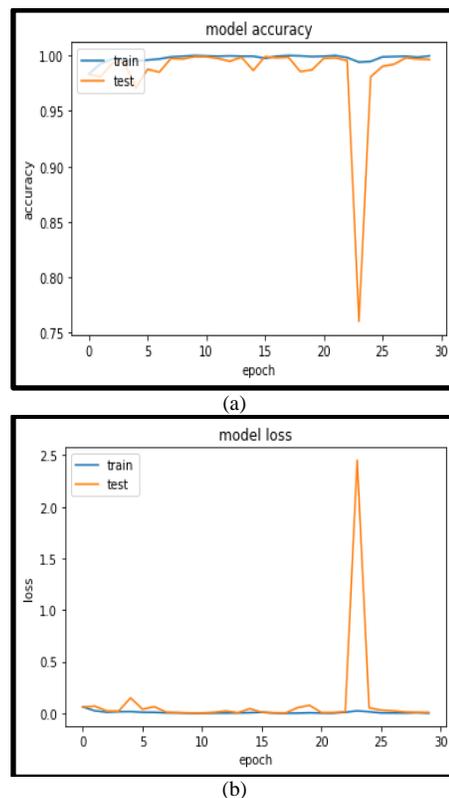

Fig. 9. (a) Accuracy (InceptionV3-LSTM) (b) Loss (InceptionV3-LSTM).

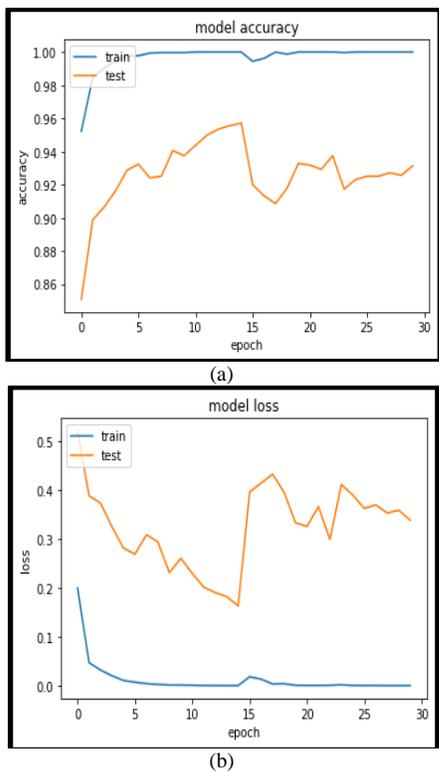

Fig. 8. (a) Accuracy (VGG16) (b) Loss (VGG).

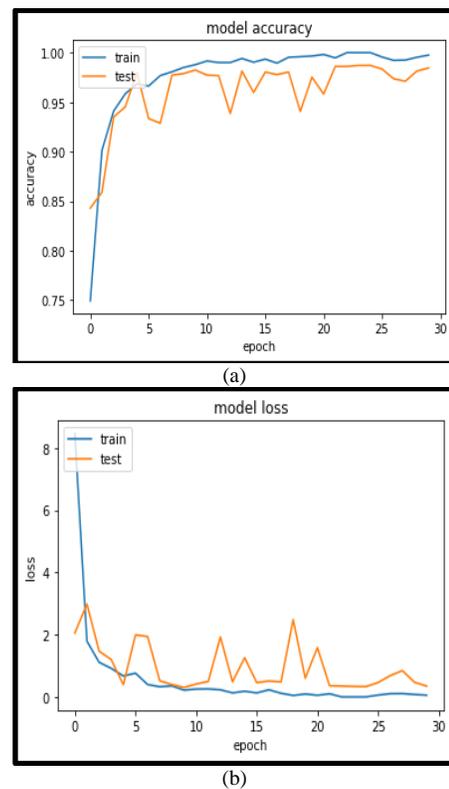

Fig. 10. (a) Accuracy (InceptionV3) (b) Loss (InceptionV3).

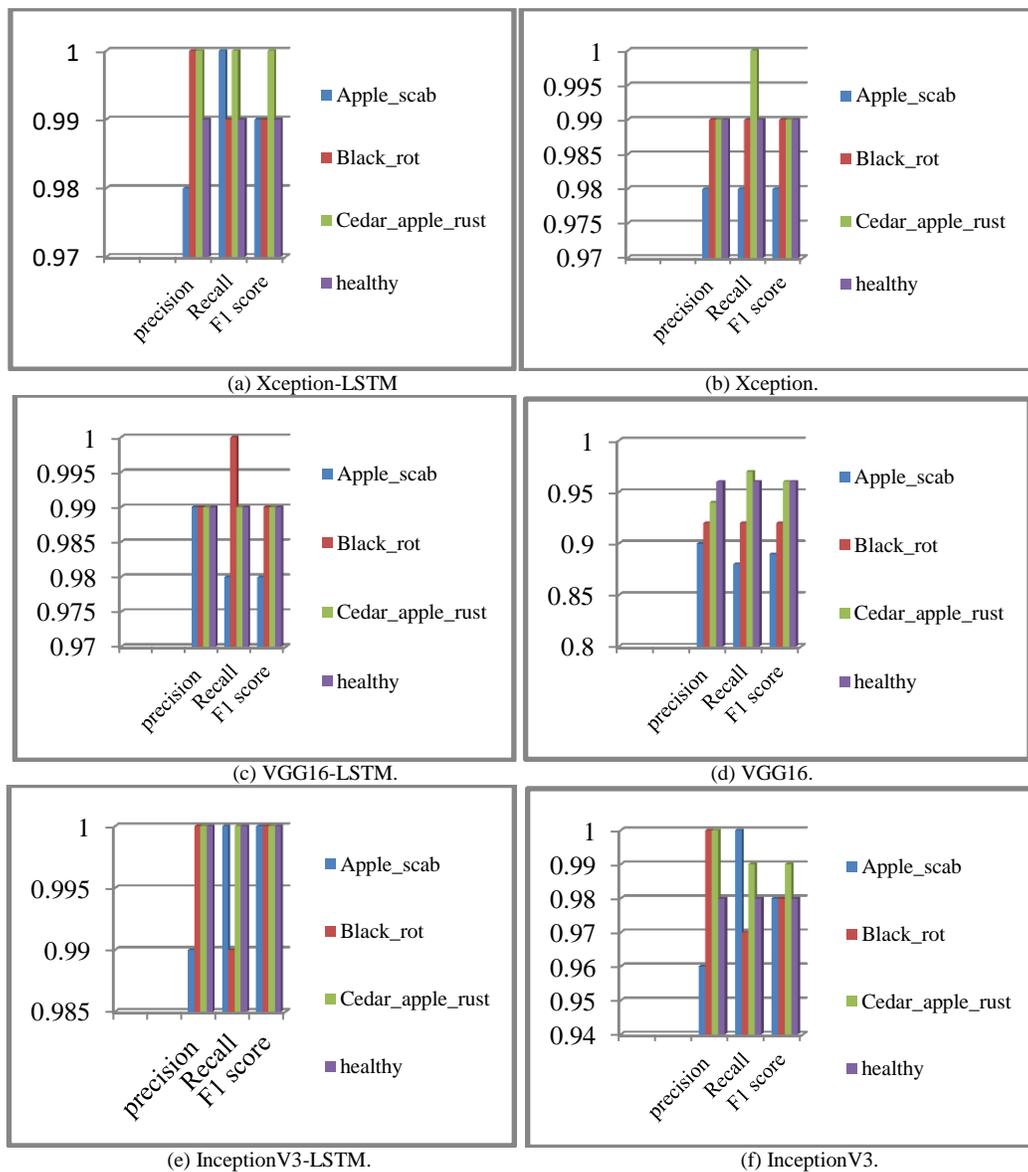

Fig. 11. Precision, Recall, and f1 Score of CNN-LSTM Models and pre-trained CNN Model.

Fig. 11 depicts precision, recall, and f1 score findings. As per the results, integrated models achieved good score in terms of precision, recall, and F1 score as compared to individual Pretrained CNN models. Xception scored 98.75% precision, 99 % recall, and 98.75% f1 score for all four classes, whereas Xception-LSTM achieved 99.25 % precision, 99.5 % recall, and 99.25% f1 score for all four classes. Similarly, VGG16 model achieved 93% precision, 93.25% recall and 93.25% recall and VGG16-LSTM model achieved 98.75% precision, 99% recall and 98.76% f1 score. InceptionV3 achieved 98.5% precision, 98.5% recall, 98.25% f1 score and InceptionV3-LSTM achieved 99.75% precision, 99.75% recall, 99.9% f1 score for all the classes.

## VI. COMPARISON WITH EXISTING METHODS

Many deep CNN architectures have recently been suggested for the classification of apple diseases. Earlier, Densenet-121, XNet (Xception and DenseNet), VGG-

INCEP, VGG16 model, AlexNet were used. For comparisons, pre-trained models were randomly selected such as Xception, VGG16, and Inceptionv3 for apple diseases detection. As seen in Table V, the suggested approach outperformed all other pre-trained models. Among three experiments, InceptionV3-LSTM produces the highest accuracy score as 99.8%. The benefits of the suggested integrated model are as follows:

- Pre-trained CNN models were used for reducing training complexity that saved time to train a model.
- The deep features in images can be extracted and classified automatically using proposed system.
- Based on the apple foliar disease dataset, proposed approach performed the best in comparison to current approaches in terms of classification.

TABLE V. A COMPARISON OF THE PROPOSED SYSTEM TO EXISTING METHODS FOR CLASSIFYING APPLE LEAF DISEASES

Author	Deep Learning model	Overall Accuracy
(Yong Zhong, Ming Zhao 2020) [12]	Densenet-121	93.71%
(Xiaofei Chao et al. 2020) [13]	XDNet (Xception and DenseNet)	98.82%
(Peng Jiang et al. 2019) [1]	VGG-INCEP	97.14%
(Marko Arsenovic et al. 2019) [14]	Pretrained CNN models	93.67%
(Saraansh Baranwal et al. 2019) [2]	GoogLeNet	98.42%
(GuanWang et al. 2017) [15]	VGG16model	90.4%
(Bin Liu et al. 2017) [16]	Deep CNN based on AlexNet	97.62%
<b>Proposed work</b>	<b>Xception-LSTM</b>	<b>99.5%</b>
	<b>VGG16-LSTM</b>	<b>99%</b>
	<b>InceptionV3-LSTM</b>	<b>99.8%</b>

The main purpose of this research is to achieve good results in detecting foliar diseases in apple trees. The experimental results revealed that the proposed CNN-RNN network outperforms the individual CNN models.

### VII. CONCLUSION

To create combined neural network architecture for apple foliar disease image classification, the features of CNN and RNN models are merged in this work. When comparing separate models to the integrated models, the assessment findings reveal that the integrated models generated better outcomes. InceptionV3-LSTM received the maximum accuracy score of 99.8%. Second highest accuracy score of 99.5% was found for Xception-LSTM and the lowest accuracy score was found for VGG16-LSTM as 99%. Despite this performance, these integrated models may have some improvement also. Training on 30 epochs was performed. We can increase the number of epochs in the future. Another improvement can be investigating the success of these models for other agricultural applications, such as weed identification and plant classification, other plant disease detection. Other deep neural network models will be utilised in future studies to detect apple leaf illnesses in real time, such as Faster RCNN (Regions with Convolutional Neural Network), YOLO (You Only Look Once), and SSD (Single Shot MultiBox Detector). Furthermore, more forms of apple leaf illnesses and thousands of high-quality natural images of apple leaf diseases must be collected in order to identify more diseases in a timely and efficient manner.

**Abstract**—Cities are currently dealing with major difficulties that no longer allow slight adjustments to the way cities operate. Instead, local officials must devise creative, transformative solutions. Fortunately, novel approaches to municipal administration and technological advancements are providing city officials with new and beneficial tools. As a result of these improvements, citizens, businesses, and other groups in the city will be able to actively participate in implementing the reforms. In a nutshell, technology can assist cities in becoming smarter. This paper highlighted the implications of the management challenges of cities, the types of cities, and the issues that cities face during epidemics. A coordinated approach that reacts to both COVID-19 and climate change is required to avoid negative outcomes from both. To figure out how Malaysian city administration works and how important information and communication technology is in Malaysian smart cities, it is important to look into technology and data opportunities.

**Keywords**—Cities; modern city; smart city; COVID-19; information communication technology (ICT); challenges; data; geographic information system (GIS)

## I. INTRODUCTION

Cities today are facing enormous challenges. A small sample of cities from throughout the world deserves special attention [1]. By 2025, 600 cities will account for over 60% of global growth [2]. Currently, the city houses half of the world's population. The globe is seeing tremendous urbanization [3],[4]. The high urban population growth trajectory is not just an intriguing reality; it also causes a demanding urgency for sustainable development and improved livability. The growth of cities is fraught with difficulties. Although cities account for less than 2% of the world's territory, they use almost three-quarters of the world's natural resources and are the primary source of greenhouse gas emissions [5]. Rapid urbanisation has resulted in a loss of essential capabilities that make a place habitable, such as waste management challenges, resource shortages, air quality, human health problems, traffic congestion, and insufficient, degrading, and ageing infrastructure [6].

Social and organisational issues, rather than technical, physical, or material issues, are another group of issues. Multiple different participants, high levels of interconnection, opposing ideals, and political and social complexity are all linked to concerns. Problems get vicious and convoluted in this way [7]. While behind Singapore, Japan, and South Korea, and Taiwan, China, Malaysia is the fifth most urbanised economy

in East Asia. Malaysia's three major cities, together with Georgetown City and Johor Bahru, account for over 60% of the country's urban population. For financial services, Kuala Lumpur's economic growth rate per worker is just around 0.46 of Hong Kong's. The cost of living in Kuala Lumpur is 83% more than in New York City [8]. In 2017, over 75% of Malaysia's population lived in cities and metropolitan regions. As a result, Malaysia is one of the most urbanised countries in Southeast Asia. Malaysia's urban population was 77.2% in 2020. Malaysia's urban population expanded from 34.3% in 1971 to 77.2% in 2020, expanding at a 1.67% yearly pace [9].

Malaysia created (Malaysia Urban Information Network [MURNInet]) in 2002 [10]. The plan was renamed MURNInet 2.0 by the (Federal Department of Town and Country Planning Peninsular Malaysia) in 2017 to reflect current urban developments [11]. The (National Urbanization Policy [NUP]) was designed in 2006 by the Federal Department of Town and Country Planning as part of a comprehensive and integrated framework to supply excellent urban services that would assure the establishment of safer, systematic, contemporary, and interesting cities (Federal Department of Town and Country Planning, 2006) [12]. However, because of the many properties of urban planning, many strategies have lived side by side with NUP over time [13]. The smart city goal is not just for medium and large cities; it is equally vital for smaller towns and cities. This research sought to answer the following question: What are the modern city's challenges? What are the challenges confronting Malaysia's urban community? Whether technology and data opportunities have aided in the resolution of these issues is unclear?

The remainder of the paper is summarised as follows: The 2<sup>nd</sup> section is about the challenges of modern cities; the 3<sup>rd</sup> section, the challenge of city management, outlines the opportunities associated with technology and data in Section 4, while Section 5, talks about cities' types; the following section, about the benefits of integration; and Section 7, presents the conclusion and goal of the research.

## II. MODERN CITIES' CHALLENGES

And according to the United Nations, urban regions are home to 55% of the world's population [14]. By 2050, the percentage is predicted to climb to 68%. With few exceptions, metropolitan areas are expected to grow and diversify. The issues cities confront today include the following as

\*Corresponding Author.

urbanisation grows Table I, particularly in Asian and African countries [15]. The city's challenges are illustrated in "Fig. 1".

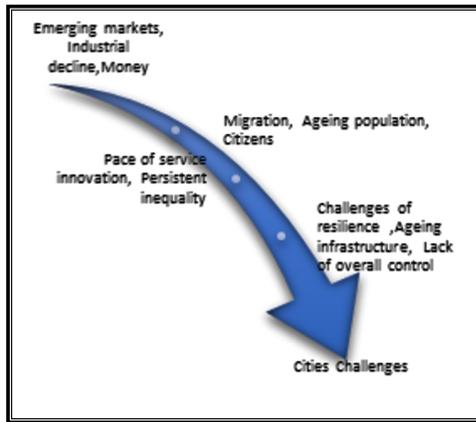

Fig. 1. Cities' Challenges.

TABLE I. CHALLENGES TYPE AND DETAILS

Type of Challenges	Challenges details
Resilience challenges	Challenges of Resilience Extreme weather[16], food shortages[1], and energy shortages have a significant impact on cities all around the world[17] [18], [19].
Emerging markets	In addition to rising market development, the increasing middle class is predicted to grow from three to six million people by 2050[15]. This will exacerbate economic resource competitiveness. The global race for talent and capital is on[20]. Malaysian cities, such as Kuala Lumpur, must now compete not only with other Malaysian cities but also with global cities[21].
Migration	Many cities are seeing continued inward migration, which is producing traffic jams, pollution, and a rise in service expectations[22]. Even though modern cosmopolitan cities offer a more diverse cultural environment, disparities in social standards might harm social cohesiveness across many populations[23].
Deflation of the industrial sector	In contrast, the population of certain cities is declining while industry is falling [24],[25]
Ageing population	The ageing population is facing an increasingly negative influence on both overall income and government service expenses[26].
Citizens.	As digital technology becomes increasingly widespread in all parts of life [22], citizens demand governmental services and become clients [27].
The pace of service innovation	Because of the quick rate of growth in people's daily lives, long-term planning is becoming increasingly challenging[28].
Ageing infrastructure	Most of the infrastructure in Kuala Lumpur cities [29]will need to be updated or renovated in the next few years to make it suitable[30].
Lack of overall control	Specific organisations decide many critical choices affecting urban life with a limited[31], segmented emphasis, instead of considering the town's overall influence[19]. Many areas of urban life are also influenced by regional or national government or agency actions[1].
Money	It's difficult to get the long-term investment finance required to address municipal problems[32], particularly when business models, innovation strategies[33], or modern tech are involved, and especially when budgets are tight[34].
Ageing infrastructure	Over the next several years, a considerable proportion of the infrastructure in global cities will need to be replaced or retrofitted to try and be fit for its purpose [1], [35]

### III. CITY MANAGEMENT CHALLENGES

Cities may be thought of as complicated creatures with a plethora of organizations and infrastructures providing the services required for them all to function correctly Fig. 2. Because the municipal government directly manages only a few important municipal services [36], it should carry out its long-term strategic management role in collaboration with other city stakeholders [37].

The huge number of independent stakeholders who contribute directly or indirectly to the city's overall functioning impeded the city's capacity to function as a cohesive entity [37]. To complicate things worse, independent city systems are becoming more complicated while also becoming more interdependent in ways that are frequently poorly understood [20]. For example, both the electrical and information technology systems are critical components of every other municipal system, and any failure in one of them is likely to have a cascading impact on the others. Smart City Framework Standard [PAS181] examines a city's traditional operating paradigm and identifies the issues that result from a lack of coordination and integration across city systems [38], [30]. This operational model is depicted in Fig. 3.

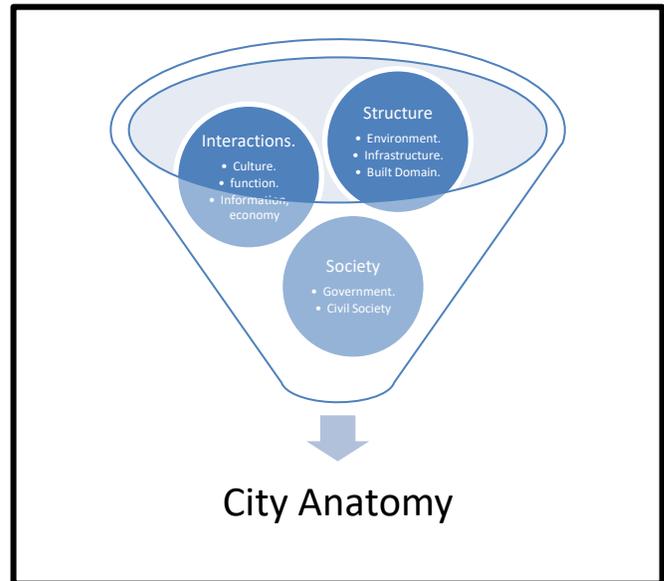

Fig. 2. City Anatomy.

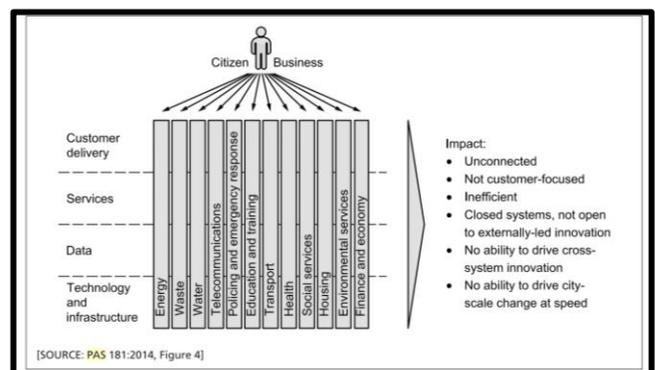

Fig. 3. Citizen Business[39].

Equally difficult is the fact that each city has its own history, set of traits, and geographic location, all of which present distinct difficulties and possibilities for municipal officials to consider. A city must also be run in a way that takes into account its wider social context and the unique opportunities and problems it faces.

#### IV. TECHNOLOGY AND DATA OPPORTUNITIES

Following technological advancements in data utilization Fig. 4 municipal leaders now have new tools and chances for successful transformation that may help them solve these issues.

1) The ability to connect, the digital connection, is rapidly expanding, no longer confined to using computers to access the virtual world; can now use cell phones, tablets, and monitors to access the information, offer feedback, and communicate with one another, anywhere at any time [40].

2) Sensors are a type of device that detects changes in the environment. Sensors, and also smartphones and other digital technology [41], are increasingly being integrated into the built environment, with a rising percentage of people carrying them. This can provide local authorities with a more complete, real-time picture of what's going on in their community [42].

Three more factors are linked to these changes:

- Information. Every two years, the volume of digital data virtually doubles. With the growing usage of (GIS) Geographical Information Systems, data from multiple sources may be connected based on location, providing a much fuller picture of what's going on in the city's many neighbourhoods and districts. It backed this up with open standards from the (Open Geospatial Consortium [OGC]) and the (World Organization for Standardization's Technical Working Group 211 [ISO/TC211]) [43]. The capacity to specify a geographic reference, and support access to link data the strong argument for sharing it among departments, agencies, industry, and research organisations [44].
- Trend analysis. The capacity to interpret and deduce meaning from this data is likewise quickly improving [45]. While smartphone applications and devices may already deliver contextualised information to users on a face-to-face basis as they go about their daily lives, quantum computers can scan large amounts of raw data and provide answers to more challenging problems [46].
- Working together. The growing usage of the internet is facilitating a more collaborative connection between customer and provider, resulting in patients, for example, having a more active part in controlling and measuring their health issues [47].

These developments are allowing for the development of tools that will allow people, businesses, and local authorities to respond to issues faster and with more evidence. These are the tools:

- In order to make better decisions for city administration and long-term planning, make data more accessible and affordable, as well as give people the ability to see and analyse it, so that they can do so.
- Encourage collaboration between government entities, citizens, residents, and government agencies.
- Establish innovative techniques for connecting city systems to enable a more holistic approach to city issues and possibilities, assist in city administration and also to enable integration at a much more detailed level, reducing the risk of a major collapse.

Those instances are relevant to current technical developments. They'll be followed by a steady flow of additional technological advancements, such as the utilisation of new materials, robots, new building methods, as well as domestic industry (e.g. 3D printing). The goal for cities is to foster a continual innovation culture, using innovative technology to serve citizens and improve the city's quality of life.

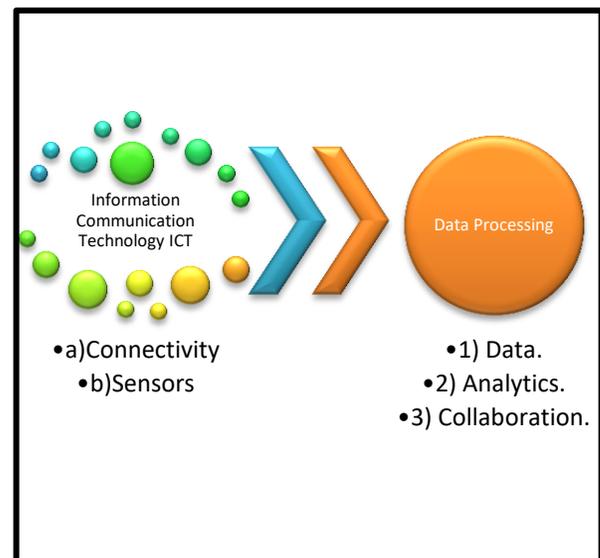

Fig. 4. Technology and Data Processing.

#### V. TYPE OF CITIES

##### A. Healthy Cities

Healthy cities, smart cities, and sustainable cities have all emerged as major themes in the modern evolution of cities. The epidemic has shown that having healthy cities as a development criterion is equally critical. Preventing future infections and disease outbreaks would require improving urban medical infrastructure to accommodate the influx of patients with new illnesses and interruptions in medical care, especially public health programmes like vaccination [48]. The present urban primary health care infrastructure must be physically and financially enhanced, as well as monitored, surveillance, and accountability systems that are effective and sophisticated. There must also be minimal friction, and all levels of healthcare must collaborate using a pandemic-related operating procedure that is unique and standard [16].

Digital tools can improve healthcare delivery and strengthen health infrastructure. The COVID-19 situation has increased the usage of telehealth services, which residents had been hesitant to use [49]. The rapid surge in the usage of digital health peripherals will provide the necessary proving ground for the evolution of health-tech that complements rather than replaces traditional types of health care [48]. With innovation education and power levelling programmes being implemented in medical, nursing, and paramedical curricula, this transformation in healthcare delivery will also push digitally aware health personnel [50].

### B. Green Cities

The absence of open spaces, inefficient resource administration for the afflicted people and interruptions in power consumption are only a few of the fissures caused during the COVID-19 crisis. These are issues that have their foundation in the absence of resilient and sustainable urban development. To avoid detrimental consequences from both COVID-19 and the climate problem during pandemics, a coordinated approach that reacts to both must be developed. Prioritize circular economic structures, sustainable urban transportation, and increased green building and renewable power investment [51].

To make cities robust and sustainable in the face of future pandemics, the transportation industry will need to integrate with the green agenda [55]. Adjustments in transportation preference and user behaviour because of congestion phobia must be balanced against institutional decisions on how to ease bottlenecks. Creating well-ventilated public transportation, enforcing congestion limitations and pricing, and supporting non-motorized transportation are some of the approaches to accomplishing this balance [56].

### C. Inclusive Cities

Much before the epidemic, there were discussions about the necessity for cities to consider the needs of their vulnerable populations. This crisis has given the pain of the vulnerable a new depth, and it has sparked a discussion about what might be done to prevent similar pain in the future.

An urban-planning framework that incorporates sex-disaggregated data collection on the number of people, number of homes, pockets and regions of susceptibility, as well as sanitation and hygiene services readily available services, is needed to support pandemic responses [52]. There can be no preparedness or response plans until the percentage of people who live in susceptible locations is known, as well as information on the municipal facilities accessible to them. A concerted effort to collect up-to-date data on formal and informal settlements, as well as labourers in cities, is required to accurately estimate the funds needed to ensure appropriate access to housing, food, sanitation, and services in the financial sector [53].

A gendered study of the pandemic's influence on job losses and employment patterns is also required for post-pandemic rehabilitation efforts. To prevent the harshest effects of future pandemics, improved data management must be included in urban design. This data, together with the efficient coordination

that municipal systems can offer, will be critical in the delivery of critical services to the most vulnerable..

### D. Rising Cities

In the post-pandemic future, cities' sociological, physical, and economic infrastructure will shift dramatically. Building architecture and workplace layouts will alter as a result of health restrictions put in place during an emergency, with safety being the priority.

At the same time, cities will continue to build skyscrapers and slums, as long as their urbanisation goals are met. However, the most effective urban growth strategy will be one that integrates formal employment generation with the construction of viable housing plans [52].

It may reinvent cities as solitary centres of trade, business, and knowledge as the post-pandemic globe shrinks and the rapid pace of globalisation slows. Commodity and labour movement will be restricted within clearly defined governing zones, and cities may emerge as self-sufficient entities [54].

The COVID-19 problem will force significant changes in how to design, govern and live in cities. The perception of cities as dense hives of continual social contact may need to be rethought, must accept this and guarantee that systems, whether in transportation, housing, work, or financial investments, endure the adjustments that come with it. While it may appear unachievable shortly, parties must work together to implement measures that will help avert future crises and lessen the pandemonium's negative short-term implications [52].

## VI. BENEFITS OF INTEGRATION

The streetlamps in Malaysia are turning white. The cause is more complex than you may believe. In Malaysia, seventy-five per cent of street lamps are beyond the age of twenty-five [55]. LEDs are being used to replace incandescent bulbs, which might cut your energy bill in half and save you money on maintenance, with a (return on investment [ROI]) of years [54]. If they were changed, they might also be used as key resources for a Wi-Fi communication network, a hub for a parking system as well as other sensors, a position for air pollution monitoring, and a CCTV stand [56].

Development is one of Kuala Lumpur's major urban redevelopment projects, and it will eventually provide housing, employment, and educational opportunities for 8,419,566 people [57]. The integrated planning and management of water, power, gas, heat, and data services under the control of a single asset owner is a crucial aspect. This integration will allow for significant cost savings and implementation of innovative technology solutions in energy supply, renewable energy, and other areas, all of which will contribute to increased levels of sustainable development and an aimed decrease in CO2 emissions of over 50% compared to 2005 levels [58].

## VII. CONCLUSION

The goal of this research was to assess the obstacles that Malaysia's urban community faces, as well as whether government policies have been effective in resolving these

issues. Rising crime rates, a lack of economic prospects, air pollution, and traffic congestion are concerns from the viewpoint of urban residents. The survey found that the government's policies were in line with the public's concerns. However, it would be ideal if the urban population were given the chance to take part in the development of policies on urban livability and contribute comments. The third principle of the City Competitiveness Master Plans (CCMP) framework could not be examined since the data used in this study was obtained from the public domain. As a result, future studies will create particular survey questions that can capture the finer aspects of urban living issues.

The most important message is that cities' prospects would be significantly improved if they could effectively seize opportunities and handle the issues they confront. Below are a few key themes for forthcoming comments on important research and policy activities. When cities are well-managed, they can take advantage of strong tools like innovation and technology, public participation, effective governance, and the ability of communities to bounce back.

**Abstract**—Sanskrit falls under the Indo-European language family category. Gujarati, which has descended from the Sanskrit language, is a widely spoken language particularly in the Indian state of Gujarat. The proposed and realized Machine Translation framework uses a grammatical transfer approach to translate the written Sanskrit language to Gujarati. Because both languages are morphologically rich, studying the morphology of each item is difficult but necessary to incorporate into implementation. To improve the implementation accuracy and translation clarity, an in-depth research of the creation of Nouns, Verbs, Pronouns, and Indeclinables, as well as their mappings, has been carried out. Tokenization, lemmatization, morphological analysis, Sanskrit-Gujarati bilingual synonym-based dictionary, language synthesis, and transliteration are the proposed framework's primary components. The implementation outcome was tested on 1,000 phrases, using the automated Bilingual Evaluation Understudy (BLEU) scale which yielded a value of 58.04. It was also tested on the ALPAC scale, yielding the Intelligibility score of 69.16 and the Fidelity score of 68.11. The results are encouraging and prove that the proposed system is promising and robust for the implementation in the real world applications.

**Keywords**—Bilingual synonym dictionary; Gujarati; lemmatization; machine translation system (MTS); morphological analyzer; Sanskrit; synthesizer; transliteration

## I. INTRODUCTION

Aside from computers' incredible processing capacity, researchers have traditionally found it difficult to create and execute Machine Translation Systems (MTS) with great precision. The complexity of natural languages is due to lexical, semantic and contextual aspects, sophisticated morphological nature, and most importantly the pragmatics and discourse, which refers to the speaker's intent. The designing and the implementation of a Machine Translation (MT) system can be done in a variety of ways.

In this paper, a technique for constructing a symbolic MT implementation from Sanskrit to Gujarati is offered due to rare availability of bilingual parallel corpora which form the basis for machine learning techniques. A pure dictionary-based translation system uses no intermediate

representation to convert from source to target language.

The Machine Translation (MT) approaches could be classified broadly into four categories, as is depicted diagrammatically in Fig. 1. Notably, two of these four broad categories can be further divided into two sub-categories for each broad category. Historically speaking, the correlation of the categorization of the machine translation approaches existing in the pertinent scientific literature could also be done for the rationalistic, empirical and the hybrid approaches.

For the present research work, a dictionary has been used to accomplish the task, as it will offer a word to word transformation through sub-tasks like morphological analysis supplemented with lemmatizer, grammatical transfer, synthesis. It will later rearrange the words in the sentences of the target language. The method is simple to use, but it is not versatile enough to be applied several other pairs.

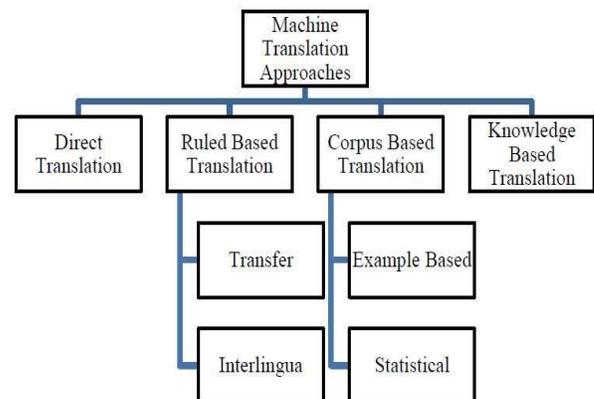

Fig. 1. MT Approaches [2].

The transfer approach is more complicated than the preceding one since it examines properties as lexical, syntactic & semantics and morphological aspects of language. Because it is built to accommodate various languages, the Interlingua approach is still more versatile than transfer. Interlingua is used to construct an intermediate representation of natural language also known

\*Corresponding Author

as pivot language which is then transformed to target [1]. The relativeness of Direct, transfer, and interlingua methods are strategically connected, as shown in Fig. 1. If a significant number of labelled, aligned, or parallel corpora are available, the corpus-based technique tends to be accurate enough. Because the grammatical mechanics of a language have no effect on corpus-based models, a single corpus-based MT model can be used to train a model in any language.

## II. LITERATURE REVIEW

The amount of study and money invested on the MT system after World War-II is notable. However, after the Automated Language Processing Committee (ALPAC) issued a report in 1966 CE, the funding for the MT system was substantially decreased. After the 1990s, a ray of optimism emerged, thanks to lower computer hardware costs and increased memory and calculation capacity, which led to new techniques. MT-related work used to be limited to languages such as English, Russian, French, and Spanish, but in today's world, MT systems are being developed for a wide range of languages, including Sanskrit.

As shown in Fig. 2, Cancedda et al. [3] presented a diagrammatic representation of the various methods used for machine translation. Many MT systems use Sanskrit and Gujarati in some form or another. Rathod and Sondur presented English-Sanskrit Translator and Synthesizer (ETSTS) which is a combination of rules and example-based MT implementation which transforms sentences to speech [5]. E-Trans is an English to Sanskrit MT tool based on Synchronous CFG proposed by Bahadur et al. The language representation part is implemented through SCFG [6]. Subramaniam [7] built Sanskrit to English rule-based translator. Sandhi Splitter, Translation Generator with Morphological parser are the two important components of the implementation. English to Sanskrit Example-Based MT system is developed by Mishra and Mishra [8] [9]. The main components of the system are Part-of-Speech (POS) tagger, Gender-Number-Person (GNP) detection, as well as Noun, Root Verb, and Adverb detection. A nice piece of work which translates Sanskrit to Hindi has been developed at Jawaharlal Nehru University (JNU). Word sense disambiguation, anaphora resolution, prose order generation, and other modules were studied by the researchers while it was claimed that Yoga and Ayurveda will be added to the system's capabilities [10]. AnglaBharti MT system translates English to Sanskrit. It is based on Paninian Grammar rules also known as PLIL code [11]. Raulji and Saini [4] presented a comparison of the various machine translation systems involving Sanskrit and Gujarati as the language pair.

Sreedeepta and Idicula [12] developed Sanskrit-English MT implementation based on Interlingua. In analysis of language, LFG is used which helps in finding semantic relation between words in a sentence. The semantic analysis was done through Karaka analyzer through Paninian grammar framework. Using interlingua approach, Sanskrit to English MT is developed by Sreedeepta and Idicula [12].

It used Lexical Function Grammar (LFG) build using Paninian Karaka Analysis. The karaka analysis is used to analyse syntactico- semantic relations between words in a sentence. Gupta et al. developed Sanskrit to English MT system. The system is based on grammatical aspect of the language pair [13]. Singh et al. [24] deployed the hybrid usage of Neuro Machine Translation (NMT) and Rule Based Machine Translation (RBMT) to design the MTS for the Sanskrit-Hindi language pair. Akhand et al. [25] while reviewing the MT systems for the Bangla language, found that no MTS exists that involves Bangla-Sanskrit language pair. In addition to the above mentioned MT systems, the researchers have also attempted to evaluate the accuracy of MTS. For instance, Sabtan [26] used the data of social media itself as a language for translation. Ehab et al. [27] investigated the MT using the example based approach for the language pair comprising of Arabic and English languages. Pudaruth et al. [28], similarly, discussed the Rule Based Machine Translation (RBMT) system for the language pair comprising of English and Creole.

Given the richness of the Sanskrit language, there have been several attempts by the researchers involving the analysis of the language. Derivative nouns [29], word segmentation and morphological parsing [30], noun declension and verb conjugation [31], dependency parsing [32], lemmatization [33], and constituency mapper [34] are a few such instances. Similarly, for the Gujarati language, the researchers have explored chunking [35], stemming [36], inflections [37], lexicon-based analysis [38], speech recognition [39], character recognition [40], and spell checking [41]. Based on the detailed literature review till date, we have observed that there is a definite dearth of research on MTS for the Sanskrit-Gujarati language pair. It has also been observed that no formal research works are dedicated to the morphological analysis, comparison and linking of both languages together. The present research work bridges all these gaps and presents not just the theoretical framework but also the working model of the MTS involving these two Indian languages. The results have been found to be encouraging and motivating. Rest of the paper is organized as follows: Section III presents the characteristics of Sanskrit and Gujarati languages while Section IV presents a detailed discussion on the research methodology. This is followed by a section each on results, and conclusions and future work.

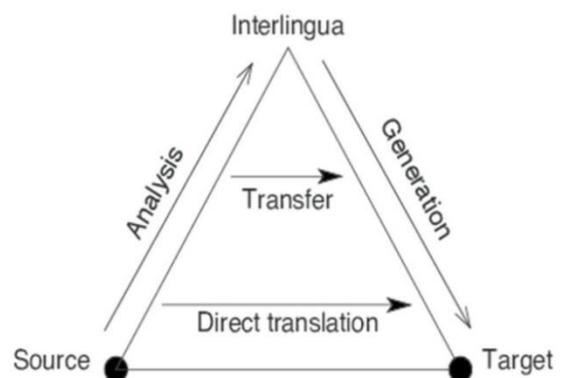

Fig. 2. The Translation Methods [3].

### III. CHARACTERISTICS OF SANSKRIT AND GUJARATI LANGUAGES

Sanskrit and Gujarati are included in the Indian Constitution as scheduled languages historically belong to Indo-Aryan family of languages. Gujarati is less ordered and regular than Sanskrit. Sanskrit is rich and morphologically structured hence tends to be focused internationally for research in computational linguistics domain. Gujarati is official language of state of Gujarat. Apart from state of Gujarat, it is also spoken in adjoining parts of Rajasthan, Madhya-Pradesh and Maharashtra states of India.

Many Gujarati community are also found in countries viz. UK, USA, Canada, Australia, New Zealand, and few African continent’s countries. Sanskrit is an ancient spoken language with tradition dating back to the Vedic period since 2000 BCE. Gujarati is a contemporary language compared to Sanskrit, with a spoken heritage dating back to roughly 1100 CE. [14] [15] [16]. Sanskrit is written in a variety of scripts, the most common of which being Devanagari [17], whereas Gujarati is written in Abugida script, which is a variant of Devanagari. Table I lists a few characteristics of these language pairs [18].

TABLE I. CHARACTERISTICS OF SANSKRIT AND GUJARATI LANGUAGES

LanguageElements	Sanskrit	Gujarati
Consonants	33	33
Vowels	12	12
Gender (3 genders ineach)	Masculine	Masculine
	Feminine	Feminine
	Neuter	Neuter
Number (3 numbers in Sanskrit and 2 in Gujarati)	Singular	Singular
	Dual	Plural
	Plural	Plural
Case Markers (8 Cases in each)	Nominative	Nominative
	Accusative	Accusative
	Instrumental	Instrumental
	Dative	Dative
	Ablative	Ablative
	Genitive	Genitive
	Locative	Locative
	Vocative	Vocative
Persons (3 persons ineach)	First	First
	Second	Second
	Third	Third
Tense (6 tenses in Sanskrit and 5 inGujarati)	Present	Present
	Aorist	Past (Simple)
	Past (Imperfect)	Past (Imperfect)
	Past (Perfect)	Past (Perfect)
	Future (First)	Future
	Future (Second)	Future
Moods (4 in Sanskrit and 3 in Gujarati)	Imperative	Imperative
	Potential	Potential
	Conditional	Conditional
	Benedictive	No equivalent

### IV. METHODOLOGY

The strength of the language analysis performed on the source and target languages determines the success of a rule-based system. Better findings come from a thorough examination of source and target language divergence and similarity mappings. The rule-based paradigm is given here, with an emphasis on grammatical similarities and divergence between Sanskrit and Gujarati, as well as extensive dictionary support. Due of its complexity, the main MT work entails a large number of subs and ancillary tasks. The following sub- sections present the various Natural Language Processing (NLLP) and Computational Linguistic (CL) tasks to finally yield complete MTS. The diagrammatic flow of the working of the proposed system is depicted in Fig. 3. The input text provided in Sanskrit language gets translated to the Gujarati language after passing through stages like tokenization, morphological analysis, lemmatization, translation, synthesis and transliteration.

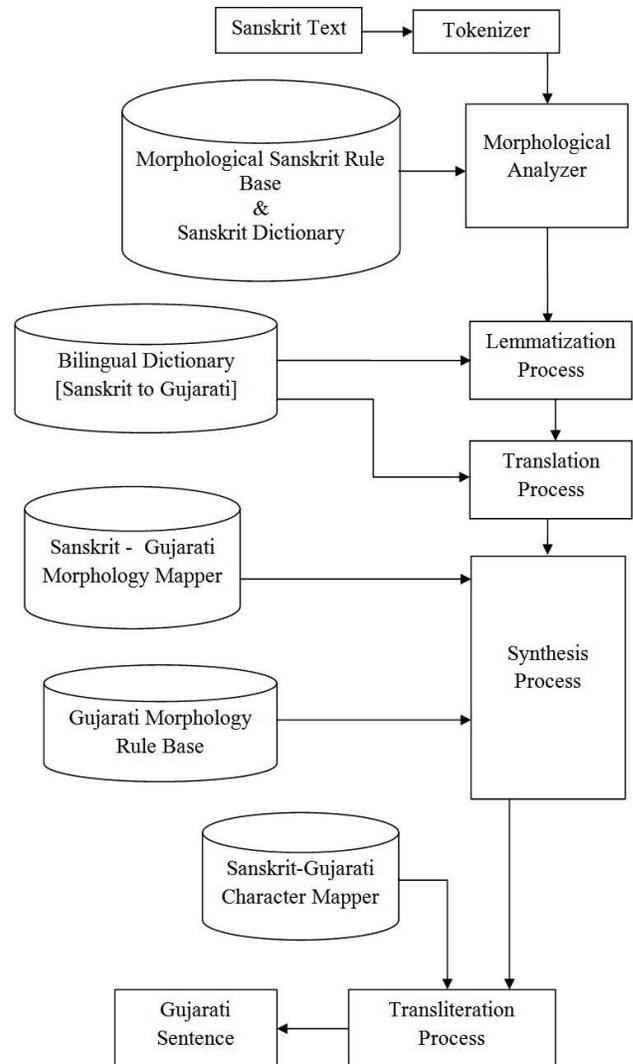

Fig. 3. Framework of Sanskrit-Gujarati MT Implementation.

1) *Tokenization phase*: Tokenization is the process of breaking down paragraphs into sentences, with each sentence serving as a token. If the sentence is broken down into multiple words, each word serves as a token. Because Sanskrit has a lot of word morphology, the text has to be tokenized into words before it can be properly analyzed. In the language, space separates each word. Fig. 4 depicts the procedure. The single vertical line depicts end of sentence ('|') with 2404 as its Unicode and double vertical lines ("||") depicts end of poetic stanza with 2405 as its Unicode. These two symbols are used to Sanskrit sentence tokenizers. Although the use of '.' (full stop) in modern Sanskrit literature is incorrect, it is nonetheless included in the method for Sentence Boundary Detection (SBD). The space delimiter is used to tokenize Sanskrit words.

2) *Morphological-analysis phase*: Except for indeclinables, every Sanskrit word can reflect its unique grammatical qualities by adding inflection to the root word. Indeclinables are words that do not possess any kind of inflectional variants and hence added to dictionary/wordnet. Sanskrit pronouns also have irregular declension patterns; hence they were entered straight into the datastore. The inflectional affixes of the remaining nouns are examined using a grammar rule base and dictionary. The surface grammatical information for the word is provided by the Sanskrit dictionary, such as pronoun, noun, verb, and so on. The G (Gender)-N (Number)-C (Case) labels for nounconstituent and adjective constituents are used to tag a word using deep structure research employing Sanskrit grammatical rules [19]. For verbs, there are Tense-Aspect-Modality (TAM), Person, Number, 'Parasmaipada', and 'Aatmanepada' labeling modes [19]. Finally, morphological analyzer produces words that have been tagged with grammatical information. To quickly develop the prototype, high-frequency words from corpora of about 75000 words were used to find 75 stop-words, which were then put to the dictionary. This reduces translation time-complexity [20]. The author in [42] presents Sanskrit stop-word analysis while comparison of such analyzers is presented in [43]. The algorithm is shown in Fig. 5 as a logic flow diagram.

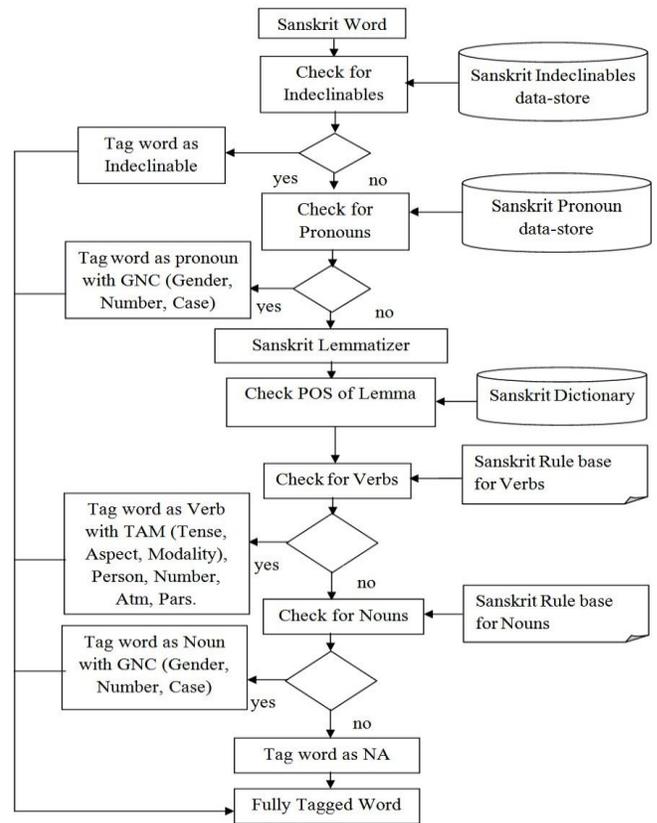

Fig. 5. Morphological Analyzer.

3) *Lemmatization phase*: A lemma (root word or dictionary form) is derived from an inflected word using this method. Nominal and verbal inflections abound in Sanskrit. If Aatmanepada and Parasmaipada are included, a single Sanskrit noun has 24 variants and 18 verb variants in its inflected forms. As a result, storing all Sanskrit words with such inflection forms necessitates a large number of dictionary entries, and computational retrieval becomes time-consuming. As a result, the dictionary will only contain Sanskrit terms in their basic form. After applying suffix stripping rules, the lemmatizer examines the token and searches the dictionary for the word. Fig. 6 depicts the process diagram.

4) *Translation phase*: For the translation procedure, the lemma obtained from the Lemmatizer phase is used as the input. The obtained lemma is compared with a bilingual Sanskrit- Gujarati dictionary. It is notable that the output of the lemmatization phase is the root form of the word. It is also noteworthy that we have directly implemented the lemmatizer instead of a stemmer which does not necessarily give the root form. The Sanskrit root word is matched within a bilingual Sanskrit-Gujarati dictionary to get the Gujarati equivalent as mentioned in Fig. 7. To get the Gujarati equivalent, the Sanskrit root word (Sanskrit lemma) is matched in order. The order of matching is as follows: Indeclinables, Pronouns, Verbs, and the remaining Nominals.

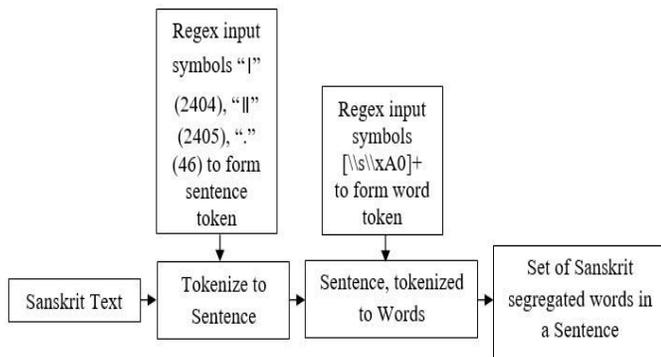

Fig. 4. Tokenizing Sanskrit Text.

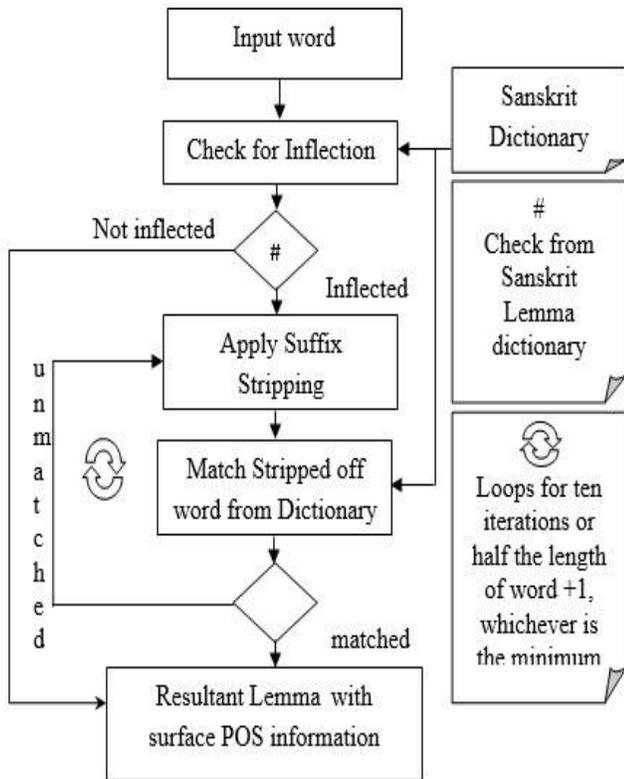

Fig. 6. Sanskrit Lemmatizer.

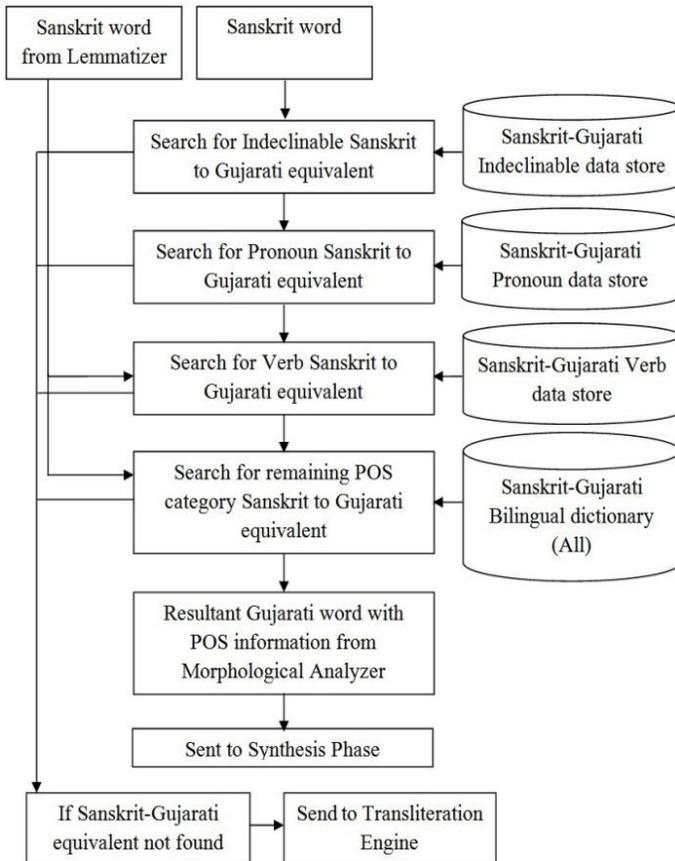

Fig. 7. Translation Phase.

5) *Synthesis phase*: This phase has mapping repository of morphology of Sanskrit to Gujarati for various Parts of Speech (POS) including nouns, adjectives and verb constituents. Based on the morphological rules derived from the grammar of the source language, it maps to rules of target language and is finally applied on Gujarati lemma to form a meaningful word. Fig. 8 depicts this process diagrammatically.

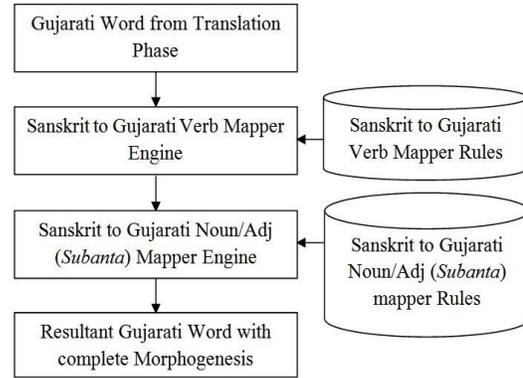

Fig. 8. Synthesis Phase.

6) *Transliteration phase*: The process of converting language script X to language script Y without harming pronunciation is called as Transliteration. Here the unmatched words from the translation phase are supplied to the transliteration phase, which finally changes Sanskrit (Devanagari) script into Gujarati (Gujarati-Devanagari) equivalents script letters while maintaining their pronunciation. Unmatched terms are mostly seen in the Named Entity class. A Unicode UTF-8 Devanagari scripted font is used to identify the single characters of a Sanskrit word. To generate UTF-8 Gujarati script characters, add 384 to the word, as illustrated in Fig. 9. Because Sanskrit and Gujarati are both free-word order languages, rearranging words in a phrase has little impact on the meaning of the sentence.

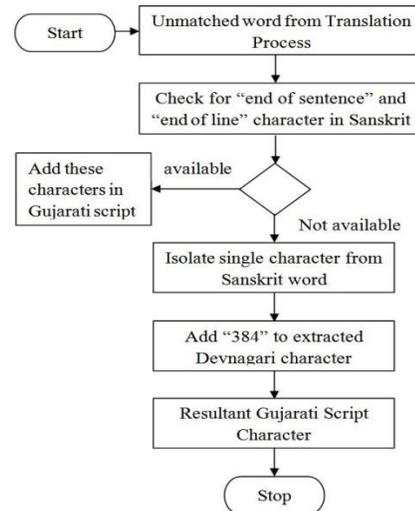

Fig. 9. Transliteration Phase.

## V. RESULTS AND FINDINGS

Automatic evaluations are significantly more objective because they cover a limited element of the attributes to be examined, whereas human evaluations are too subjective. As a result, it's impossible to compare machine and human results. For morphologically complex language pairs, evaluation by human is considered appropriate, albeit arduous, resource-intensive, and time-intensive task. Despite the fact that BLEU is inappropriate for language with rich morphological characteristics and does not even handle word synonym factor and inflections. The suggested implementational framework is evaluated using the Bi-Lingual Evaluation Understudy (BLEU). However, the general acceptance of BLEU in the MT community is the rationale for its use in evaluation. BLEU was curated and designed by Papinene et al. at IBM [22]. Pn is a modified n-gram precision used by BLEU. Because the BLEU approach is based solely on Precision, it does not use Recall. However, it compensates for recollection by including a Brevity- Penalty feature for short sentences that are translated. The formula can be found below.

$$BLEU = BP * \exp\left[\sum_{n=1}^N \left\{ \left(\frac{1}{n}\right) * \log(Pn) \right\}\right]$$

Here,

N = Maximum n-gram (n=1 to N) BP = Brevity Penalty

Here 1000 sentences from varied grammatical categories were chosen to test the system [21], the implemented algorithm received a BLEU score of 58.04. The ALPAC scale was used to assess the same set of sentences manually. The Automated Language Processing Committee's (ALPAC) Fidelity and Intelligibility measure is a two-scale metric [23]. The identical set of sentences used in BLEU were manually assessed using ALPAC's Intelligibility and Fidelity scale by ten language specialists. The Intelligibility score was 69.16, while the Fidelity score was 68.11.

## VI. CONCLUSION AND FUTURE WORK

To implement a rule-based system is always a challenge due to complexity of rules as well as the number of rules. This is particularly true for morphologically rich languages like Gujarati and Sanskrit. The challenge is to cover each and every grammatical element. Through the proposed implementation, the robust results are obtained due to inclusion of each grammatical feature in details. The unique MT framework on Sanskrit to Gujarati received satisfactory results utilizing the ALPAC's manual scale on intelligibility and fidelity parameter. It also received good results on the BLEU scale. As the architectural implementation may improve the results by covering a larger range of dictionary words and accounting for any grammatical language exceptions, in future we will consider these additional elements as well. Also on availability of huge bilingual corpus in future, machine and deep learning frameworks can be implemented to make the system more accurate and generic.

# Detection and Analysis of Oil Spill using Image Processing

Myssar Jabbar Hammood AL-BATTBOOTTI, Nicolae GOGA, Iuliana MARIN

Faculty of Engineering in Foreign Languages  
University POLITEHNICA of Bucharest  
UPB, Bucharest  
Romania

**Abstract**—Thousands of oil spills occur every year on offshore oil production platforms. Moreover, ships that cross rivers to reach the harbor cause spills each year. The current study focuses on IRAQI marine and rivers, especially Al-Bakr, Khor al-Amaya, ABOT oil terminal and SHAT AL-Arab river inside Al Başrah oil terminal. In order to mitigate and manage oil spill impacts, an unmanned aerial vehicle has proven to be a valuable tool in mitigating and managing incidents. To achieve high accuracy, the objective of the current research is to analyze captured images for rivers, identify oil pollution and determine its location. The images were taken from the Iraqi Regional Organization for the Protection, General Company for Ports of Iraq, Iraqi Ministry of Environment and online websites. In the current paper is presented a software framework for detecting oil spills, pollution in rivers and other kinds of garbage. The framework based on artificial intelligence is divided into two parts: a training model and an operational model. In the training model part, a machine learning model is applied, which is one of the fastest and most accurate methods, integrated inside PipelineMLML. Thus, the object detection technique used can identify one or more categories of objects in a picture or video. Furthermore, the locations of objects can be identified with the help of neural networks. In the operational mode, models can identify oil spills in images.

**Keywords**—*PipelineMLML; oil spill; artificial intelligence; machine learning*

## I. INTRODUCTION

Oil spills damage the environment, destroy natural resources, and harm public health. The environment is often exposed to huge pollution following oil spill incidents. As proof of the significant pollution risk associated with offshore oil and shipping crude oil products through these waters, one only needs to consider the British Petroleum Deepwater Horizon incident in 2010 and the huge marine disaster. The information technology era has always been important for different industries, therefore, software systems based on machine learning models have been developed to perform object detection in the past years. The accuracy and efficiency of object detection improved dramatically with the advent of machine learning and deep learning. As a result, these technologies were pivotal for the advancement of computers. The common programming library, PipelineMLML, is designed to enhance the accuracy and reliability of an object detection system.

Deep neural networks (DNN), convolutional neural networks (CNN) have gained fame for their ability to process visual data. Recently, sensor image-based Artificial intelligence has become a key component in a wide range of software applications because of its capability to solve several problems [7]. It can, for example, identify objects and recognize them as one of these issues. A set of applications that use these features are autonomous driving, video surveillance, and healthcare [8, 9, 10].

The current research combines these advances in artificial intelligence, especially in the detection and recognition of objects in the oil and gas industry in order to avoid unwanted incidents based on video monitoring and machine learning. Drones are used to capture photographs or video of the observed regions which oil spills can occur. The triggered files are uploaded on the system's framework to be further analyzed and visualized from a ground station by an oil and gas expert. Machine learning models have been created for two cases, when an oil spill happens in the environment, as well as when it is not present. The models are used to be consumed and to predict the occurrence of oil spill disasters. The overall solution is appropriate spill management and continuous surveillance, speeding up the decision making process. Drones can quickly collect critical data. A big challenge, like reflectance can be solve by adding to the drone's camera a polarizing filter. The problem of oil dissolution is tackled by our solution, as it analyzed four factors, namely a normal spill, areas of water color retreat, leaks in surrounding soil based on their color and crude oil spills.

The limitations of the proposed solution are given by battery life and weather conditions, like extreme wind. Gasoline engines for drones can be an alternative, but they will be noisy and emit exhaust.

Due to there being no effective method of automatic detection for oil pipelines, it forces oil companies to dedicate a lot of human resources to patrol them manually [1]. As a result, operating costs of enterprises are high, while the used detection methods cannot stop oil pollution. This is because manual checks or different technologies that exist are not able to detect oil spills on time.

In the current study the design and development of an intelligent and automated method for detecting oil spills using image merge with deep convolutional neural networks (DCNNs) and a cluster of algorithms. By using these

technologies, one of the most effective solutions for identifying and recognizing spills can be created. In summary, this study contributes to: 1. provide a method to ensure a smooth and uninterrupted flow of river environments monitoring; 2. provide full vision and awareness of oil pollution and different garbage.

The paper is organized according to the following structure: Section 2 describes related work regarding object detectors based on ML.NET, Artificial intelligence detection. Section 3 specifies the materials and methods included in the current paper, concerning drone data. The processing model method is outlined in Section 4. Section 5 mentions usage of the detection method and discusses the results obtained based on experimental analysis. Finally, Section 6 summarizes the main conclusions drawn from the current study, while Section 7 details the ideas for future development of the applied detection, recognition, and tracking algorithms.

## II. LITERATURE REVIEW

Geographic information systems, spatial statistical methods and computational modeling are used to assess the impacts of oil spills [11, 12, 13, 14, 15]. Special attention must be provided in order to monitor and predict the appearance, existence of oil spills that endanger the marine environment, having a crucial impact over time.

Several closely related works have been analyzed in the context of oil spills in the surrounding environment. Existent state-of-the-art models for oil spill risk assessment include multiple factors and focus on uncertainty. A research regarding the Baltic Sea spills from ship wrecks included into its state-of-the-art model a probabilistic calculation of the sum of factors (construction work, corrosion, diving, earth quakes, military activity, ship traffic, extreme weather and trawling) that can lead to dangerous consequences [21]. The gap which exists in this model, but is considered by our proposed system is that real-time events happen in a short amount of time and drones ease decision making. Other oil spill models [22] do not consider oil dissolution [23, 24]. The paper's model analysis this factor, along with watercolor retreat areas and leaks in surrounding soil.

A solution used in Brazil involved the usage of radars in order to determine marine oil rig spills as well as it can determine features and feed based on a logistic regression classifier method [2]. The methods included convolutional neural networks and logistic regression classifiers. The best results were obtained for vertical direction of electromagnetic waves, namely polarized ones. In the case of polarized images, more target information is obtained by the object as the light gets reflected [20]. Polarization ensured accuracy of the acquired image information.

Another research done by Germans and Mongolians focused on oil spill detection in the Caspian Sea, also based on radar images, the water surface images which presented dark slicks on a bright background were analyzed using the EnviView and NEST programs [3]. The outcomes were obtained after doing the comparison between their

contamination and navigation maps. The training part of the machine learning algorithm consists in automatically image annotations and matching them with infrared images to generate a dataset, but the training stopped when the neural network has failures when it cannot improve during five consecutive epochs. 7 CNN segmentation architectures and 8 feature extractors are used during the analysis.

A researcher from Belgium [4] studied the Antwerp port environment using drones with thermal infrared cameras. As in paper [2], the used method involved convolutional neural networks. The accuracy reached 89% when involving infrared cameras for oil spill detection in water. A group of researchers from Algeria and France experienced a hybrid swarm UAV monitoring, The UAV swarm plan the trajectory and gather nautical data based on a modified Boustrophedon algorithm, along with an unsupervised natural image classification.

Crude oil spillage is another factor which was analyzed in the current paper. Cases were reported in Southern Iraq, at Rumaila, Basra [18]. Based on the extracted soil samples, it was found that the international standard limits of heavy metals content were exceeded. The contaminated soil can affect the neighboring regions. Our research does not imply physical samples of soil. Real-time image processing coming from drones is sufficient to determine the risk of an oil spill.

A group of researchers studied the impact of crude oil spill using the multispectral satellite Landsat 8 OLI imagery [19]. The analysis was done using machine learning models. 1205 polluted vegetation and wetland hectares were studied during 2015-2018. In the following two years, based on the normalized difference vegetation index and chlorophyll index vegetation, it was found that the region started to recover according to remediation initiatives. The downside of the multispectral Landsat 8-OLI remote sensing imagery is that its' measurements are influenced by irradiance variation, sensor calibration and drift, atmospheric attenuation and radiance path. The drone of our solution can scan the observer region from distance, as well as closely. Moreover, the drone will be trained to navigate in regions with reflectance of the surrounding terrain.

The researcher did not study the influence of unmanned aerial vehicle (UAV) speed variations which have an effect upon the consumed energy [5], reaching a lower level of energy consumption. Another group of researchers from Latvia [6] also included a group strategy, as for paper [5], based on multi remote piloted aircrafts, such that oil spills are analyzed.

The previous mentioned papers are analyzed in Table 1 from the point of view of strengths and weaknesses. Our contribution is also specified as a comparison to the analyzed closely related work (selection made; similar conclusions can be drawn for other reported research as well).

The result of the conducted analysis shows that the purpose of the current paper is clearly defined. Three core areas are combined to provide a solution to mitigate oil spills, sense danger at distance, determine geographic information and perform computational modeling.

Drone monitoring can be done even during cloudy weather based on a cost-effective solution, compared to multispectral satellites.</p> <p>2. No sun angle atmospheric correction is needed.</p>

### III. FRAMEWORK OVERVIEW

#### A. Materials and Work Component

This research focus to determine oil spills relies upon images. At present, deep learning can be used to analyze images so that UAVs in the future work, are able to detect oil spills automatically and accurately.

The current paper describes a framework for object detection and recognition based on drones equipped with a high-resolution camera and gimbal path controller. The used computer for the simulation of the proposed framework was a Macbook Pro laptop with an i9 processor, 2.30 GHz, and 16 GB RAM. The framework uses computer neural networks to locate and recognize objects in images or videos in real-time. Object detection and recognition can be performed in many programming languages. In this paper, the algorithm is built using ML.NET, an open-source, cross-platform, and machine learning framework designed by Microsoft and publicly released in 2018 to offer the power of machine learning (ML)

to .NET applications to cover various scenarios, like sentiment analysis, oil price prediction, recommendations, and classification of images.

The system identifies the class of objects (oil pollution and illegal bilge water dumping), and their precise location. Classification can predict objects in an image. Object recognition and detection modules were designed for use with oil and gas pipelines. The solution can also be adapted to different environments by adjusting these frameworks according to the same structure.

### B. Study Area

As part of Phase 2, part of the images with which the model is trained are taken from the deep sea south of Iraq (for a more detailed description of all areas from where images are taken for training see next section) the main oil harbor at Al Başrah [16], known as ABOT, the marine loading terminal for oil being located at almost 50 kilometers south-east the Al-Faw Peninsula, in the Persian Gulf. Together with its other terminal, the Khawr al 'Amīyah Oil Terminal, KAAOT, both terminals offer the main export source for more than 80% of Iraq's gross domestic product. The SHAT AL-Arab river is used to reach the Al Başrah oil terminal and its fauna and flora are put in danger in case of a disaster, like an oil spill.

The exported crude oil which is produced in the southern Iraqi oil fields, is carried via three 1.2 m diameter pipelines to the southern part of the Al-Faw peninsula, as well as undersea to the ABOT platform [16]. One 1.2 m and two 0.81 m pipelines supply the KAAOT platform.

The facilities of ABOT are able to transfer daily up to 3 million barrels (Mbbbl) of oil when all four supertanker berths operate at maximum capacity and have a maximum draft of 21 m [17]. Three single-point mooring systems (SPM) were included in the year 2012, each having a design rating of 800 thousand barrels of oil daily, and two additional SPMs to increase the total loading capacity to 6.4–6.6 Mbbbl of oil per day [17]. The KAAOT facility possesses a shallower depth and its two berths can be used for Suezmax oil tankers with capacities up to 1 Mbbbl and has a transfer capacity of about 240 kbbbl of oil daily [17].

### C. Oil Spill Dataset

In this research to identify oil spills, the dataset gathered with help of: 1) <http://ropme.org> (Regional Organization for the Protection - ROPME) was initially established in 1979, was convened in Kuwait, 1978. The Conference adopted in 1978 included the Action Plan for the Protection and Development of the Marine Environment and the Coastal Areas of Bahrain, Iran, Iraq, Kuwait, Oman, Qatar, Saudi Arabia and the United Arab Emirates the Kuwait Regional Convention for Co-operation on the Protection of the Marine Environment from Pollution. ROPME Information regards the geographic coordinates and timestamps of the pollution provided by the General Company for Ports of Iraq through the pollution department. 2) General Company for Ports of Iraq / pollution department; 3) Ministry of environment / Southern office; 4) online websites.

## IV. PROCESSING MODEL METHOD

The current processing model used images taken from the Iraqi Regional Organization for the Protection, General Company for Ports of Iraq, Iraqi Ministry of Environment and online websites.

The future research will focus on how the raw dataset will be gathered from several aerial images. The trained model which was used in the current paper will analyze and identify an oil spill based on the main algorithm framework explained in the present article. The analysis process will be in real-time or after transferring data to the ground station. Moreover, the operator will make sure to double-check the spill detection alert.

Every image will be resized and segmented on board. When oil is detected, the system will gather all related information. The information will regard two major factors. The first factor, onboard cameras, will capture raw aerial images that provide information about spill size and locations. The second factor, UAV hardware will provide altitude, flight speed, flight path and GPS coordinates to help identify both the UAV and spill locations during data collection. Moreover, the triggered data will be sent to the ground station, where actions can be taken.

The current paper application developed with ML.NET contains several steps (Fig. 1):

- Load data – Raw data is loaded into memory.
- Create a pipeline – The pipeline contains the steps that transform data or train a machine learning algorithm. ML.NET offers different transformational steps, like one-hot encoding and several machine learning algorithms.
- Train a machine learning model – When the pipeline is created, training can begin. This is done based on the Fit() method.
- Evaluate – The evaluation of the model can be done at any point and supplementary decisions can be taken according to evaluations.
- Save – When the model is trained, it is saved into a file. The resulting application is created based on one microservice which trains and evaluates the machine learning model, and the other microservice uses it.
- Load – The created machine learning model can be loaded and applied for further predictions.

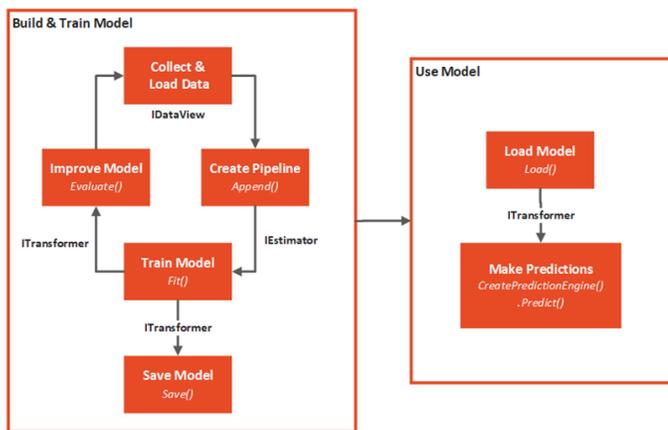

Fig. 1. Machine Learning Part Building Model Steps.

V. DETECTION METHOD AND RESULTS

The system is designed to capture pictures and video along pipelines that extend in or out of fields and through the trained model, the algorithm begins to analyze collected data either in real-time or after transmission to the ground station where it starts to analyze data.

The following factors are taken into consideration to detect possible leaks:

- A normal spill occurred.
- Areas of water color retreat were identified.
- Leaks in surrounding soil were detected by observing their color.
- A crude oil spill occurred.

UAVs also have the capability to detect anomalies along with pipeline networks normal category spills, such as construction or roadwork that might compromise pipeline integrity. If any unusual situations occur, namely leaks, explosions, attacks, or any other unusual events, they provide real-time video and alert notifications. In order to assist the teams to value different situations and provide clear information to emergency crews, the detection framework is depicted in Fig. 2.

Fig. 3. ML.NET Machine Learning Model.

The training model of the proposed framework included a ML.NET machine learning model, as illustrated in Fig. 3. The operational model was implemented using ML.NET.

127 different scenarios were tested, namely, 1) normal spill for 40 images, 2) watercolor retreat areas for 50 images, 3) larks in surrounding soil for 20 images, 4) crude oil spill for 23 images. The previous mentioned factors were included in the study, as illustrated in Fig. 4.

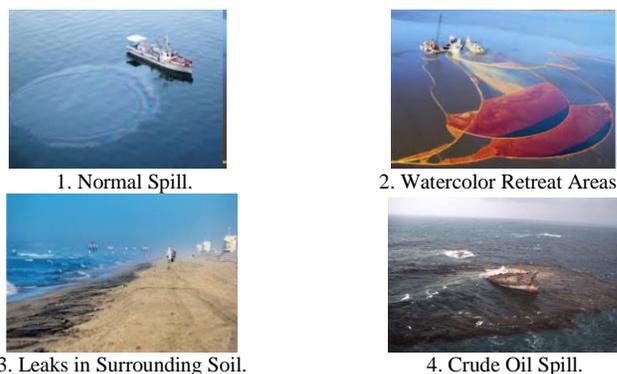

Fig. 4. Leak Factors.

The probabilities of the studied leak factors based on 127 different images are displayed in Fig. 5. On the X axis are placed the studied situations, namely normal spill, watercolor retreat areas, leaks in surrounding soil and crude oil spill. On the Y axis are the true and false probabilities for every studied case, the values varying between 0 and 1. The rectangles represent the most frequent range of points belonging to every category. All the dots are probability values.

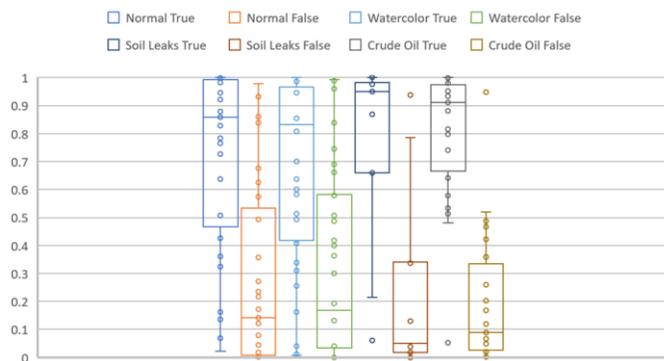

Fig. 5. Probability Variations based on Studied Leak Factors.

TABLE II. CLASSIFICATION TABLE BASED ON THE FOUR STUDIED SITUATIONS

Situation	Probability values			
	True Positive	False Positive	False Negative	True Negative
Normal spill	0.8777745	0.122255	0.233689	0.766311
Watercolor retreat areas	0.858818	0.121182	0.265185	0.734815
Leaks in surrounding soil	0.900071	0.099929	0.112232	0.887758
Crude oil spill	0.847981	0.152019	0.266434	0.733566

The true positive, false positive, false negative and true negative values for all the analyzed cases are displayed in Table 2. The determined accuracies were 71.67% for normal spills, 70.88% for watercolor, 73.13% for soil leaks and 79.74% for crude oil spills.

According to the overall results, it was clear that in 99% of the cases, the triggered situation was a broken ship / pipe, while for 28 cases, the situation was good. The following table shows the probabilities for the four analyzed situations.

The highest certainty value was obtained for leaks in surrounding soil, namely 90%, followed by normal spills, with a probability of 87.77%. Close by were the water retreat areas with 85.88% and crude oil spill with 84.79%. The overall true positive rate in case of an oil spill was 87.11%, with a false positive value equal to 12.38%. The false negative value was determined to be 21.93% and true negative of 78.06%.

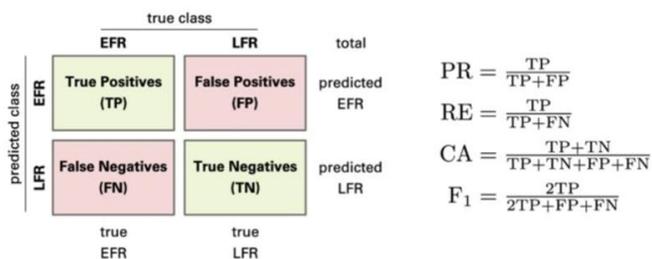

Fig. 6. Confusion Matrix.

Precision, recall, accuracy and F1-measure formulas as illustrated in Fig. 6. Precision (PR) indicates how accurate the proposed oil detection model is and it is equal to 87.55%. Recall (RE) computes how many actual positives are captured in the model and the value for it is equal to 79.88%. Accuracy (CA) is influenced by true negative values and it is equal to 82.80%. A better measure is represented by F1-measure which is a means to determine a balance between precision and recall. The value for it is equal to 83.54%.

### VI. CONCLUSION

Oil pollution prevention and response in marine accidents consists of a series of steps and procedures. In this study, it was demonstrated how deep learning and artificial intelligence can be used to accomplish this goal.

The framework proposes a clearly useful method despite its condition being dependent on hypothetical parameters of any

given event (normal spill, watercolor retreat areas, leaks in surrounding soil, crude oil spills). 127 cases were analyzed and the results provide good outcomes. Dangerous situations have been correctly determined based on the precision, recall, accuracy and F1-measure values which have been computed, proving that the solution can be further used in real-case scenarios. The system proved that it filled the gap of oil dissolution detection.

### VII. FUTURE WORK

The proposed system will be useful especially in waterways near populated areas. The reason is caused by the fact that densely populated settlements have narrow passageways, canals and straits, leading to extensive oil transportation. Accurate decisions and speed are imperative in such sensitive areas. For the responsible coastal authority, accident response management is crucial and the costs for cleaning oil spills need to be decreased.

Future work will include an oil spill system modeling which will help to integrate breakthroughs. The demand for oil will not decrease soon and the production of spill accidents will also endure. Models will be created to understand the emergence of oil spills, spatiotemporal dynamics and to enhance the response to mitigate such situations. Moreover, different datasets will be tested to prove the scalability of the currently proposed work.

# Smart Information Retrieval using Query Transformation based on Ontology and Semantic-Association

Ram Kumar\*, S. C. Sharma  
Indian Institute of Technology Roorkee, India

**Abstract**—A notable problem with current information retrieval systems is that the input queries cannot express user information needs properly. This imprecise representation of the query hampers the effectiveness of the retrieval system. One method to solve this problem is to transform the original query into a more meaningful form. This paper proposes an ontology-based retrieval system that transforms initial user queries using domain ontologies and applies semantic association during the indexing process. The proposed system performs a semantic matching between an ontologically enhanced query and index to capture query-related terms. To show the performance of the proposed system, it is evaluated using standard parameters like precision, recall, and NDCG. In addition, the authors presented a comparison between the proposed and existing retrieval systems on three test datasets. Experimental results on these datasets indicate that the use of ontology and semantics has significantly increased the retrieval efficiency obtained by baseline. This work highlights the importance of ontology and semantics in information retrieval.

**Keywords**—Ontology; semantics; information retrieval; query transformation; indexing

## I. INTRODUCTION

In this digital age, the fast rate of data generation created a massive collection of data. It becomes a challenging task for computer users to extract relevant information from this large data collection. World Wide Web [1] is one such collection with billions of such web pages. Information Retrieval System (IRS) enables web users to find the desired information from such extensive resources. Search engines are commercially available IRS, which play a vital role in finding information online. Nowadays, the search engine has become the primary means to find websites. The simple Web search engine retrieves information from Web pages using keyword matching between queries and documents. The Web is rapidly growing, and different users seek focused information; now, it has become a must for search engines to utilize semantic techniques to satisfy users' information needs [2]. Using Semantic search, the machine can also understand the user's interest and the context in which the search is issued; this will help in providing the most relevant information to the user's search need. Traditional search engines need to adopt new changes to find exact information from the Web.

Ontology-based information retrieval is a small step in this direction. This can meet those challenges that were not met by traditional retrieval systems. The authors propose an ontology-

based retrieval system for finding the most relevant search results.

The Internet is a collection of interlinked documents (billions in numbers) distributed over the most extensive network. In the last two decades, the web has grown exponentially. The large scale of the Web made it almost impossible to retrieve desired information without any tool. That's why internet user searches the web for the topic of their interest using a search engine. A search engine [3] is a software program or tool to find information from many web pages distributed over the internet. A search engine searches the document for entered set of keywords and returns a list of results in links to relevant resources. These links are Uniform Resource Locators (URLs) of those documents where any or all of the searched keywords can be found. A search engine provides results quickly using high-speed systems working globally known as index servers. The searched URLs are accessed using a program called a web browser.

Sir Tim Berners-Lee defines the Semantic Web [4] as an extension of the current web in which information is given well-defined meaning, better enabling computers and people to work in cooperation. Semantic search is a search where humans and machines try to find concepts behind terms used by different users. The Semantic Web supports more efficient discovery, automation, integration, and data reuse. Semantic Web languages have been developed to describe knowledge using a new W3C standard. These are RDF(S) (Resource Description Framework/Schema), OWL (Web Ontology Languages), and OIL, DAML+OIL. Most of these standards relied on Ontology for releasing the dream of the semantic web. Gruber [5] defines ontology as a specification of a shared conceptualization.

Ontology always includes a vocabulary of representational concept labels to describe a shared domain. These concept labels are usually called terms (lexical references) associated with entities. Ontology is one of the essential concepts used in the semantic web infrastructure. These days, researchers use the Semantic Web and Ontology to manage data in information retrieval systems. The Semantic Web simplifies and improves knowledge-intensive applications through ontology by addressing weaknesses in information retrieval, matching data, and data integration on the current Web. The semantic web aims to provide an extra machine-understandable layer, simplifying programming and maintenance efforts for knowledge-based web services.

\*Corresponding Author.

This paper proposes an ontology-based retrieval system that transforms initial user queries using domain ontologies and applies semantic association during the indexing process. The main contributions of this paper are:

- Firstly, this paper proposes an ontology-based information retrieval system.
- Secondly, this paper implements the semantic approach in the indexing of documents.
- And finally, it also demonstrates how ontology-based search systems outperform the baseline.

The rest of the paper is organized as, in Section II, the authors present related work, Section III shows the proposed methodology, architecture, and algorithm. The experimental setup is given in Section IV. Section V presents the results and its discussion; we conclude in Section VI.

## II. RELATED WORK

By establishing successful approaches to overcome the difficulties in providing a more specific description of a user's information need, Ontology and Semantics took a giant step forward. Furthermore, it has also outperformed traditional IRS in terms of retrieval results. Researchers have adopted various techniques to transform query terms for performing retrieval. Some of them are given below.

Maxat Kulmanov et al. [6] employed fuzzy ontology in this study to aid with query transformation for an IRS. This procedure generates a dictionary of concepts from a given domain and an exterior ontology and then assigns fuzzy memberships via ConceptNet. They have used ConceptNet Global Ontology to determine fuzzy membership. By adding semantic weights to every one of the Concept-Net Ontology's semantic relations, the researchers created fuzzy membership for all these relations.

The researcher of this study [7] provides an overview of the methods for computing similarity using ontologies and incorporating them into machine learning techniques; they discuss how ontology embeddings and semantic similarity measures can leverage the background knowledge contained in ontologies, as well as how ontologies could provide restrictions that enhance machine learning methods.

The reference [8] established a mechanism for semantic query expansion based on domain ontologies. It expanded on synonyms, hypernyms, and similar words. Adding a similarity function to a system improved the quality of the formed query and the search engine results. Using a programming language domain enabled the system to be evaluated manually by impartial and experienced personnel.

Prilipsky et al. [9] proposed a hybrid Personal Knowledge Management (PKM) system to extract and store helpful information. The software-assisted PKM is the most effective one. Many software tools are used to retrieve concept mapping, tagging, flashcards, and hyperlinking. These tools are added to the traditional PKM to make it flexible and extendable. The advantage of the state-of-art work is a single solution using PKM instead of integrating all the functionalities from different tools.

Kim et al. [10] proposed an i-Dataquest prototype for a graph-based information retrieval system. I-Dataquest prototype contains three steps, data pre-processing, query pre-processing, relevance evaluation, and feedback. The graph data integrates the query with all syntactic and semantic extensions to retrieve the required answer. The PAINT'R dataset is selected, which is the same as the data of the manufacturing company.

Esposito et al. [11] proposed a hybrid query transformation approach. This approach is used in Information retrieval-based QA systems. It is based on lexical resources and word embeddings. In the query expansion for the question-answer system, the answer for the user-defined question is retrieved from an already formulated database having a particular required domain. This method modifies the natural language questions to enhance proper semantics to get the required sentences. The author used WordNet to produce appropriate nouns and verbs for the user questions. Then as per the sense of the question, the answer is retrieved using the Word2Vec model, which is created using a semantic similarity metric. The main drawback is that this approach uses only nouns and verbs for evaluating the query; it does not consider other syntactic categories, such as adjectives and adverbs.

## III. METHODOLOGY

The problem with current IR systems is that the input queries are generally too short and too ambiguous to express the user's information needs. Such imprecise representation of users' information needs directly affects retrieval performance. In other words, it can be said that a simple query can't satisfy users' information needs.

### A. Problem Formulation

Vocabulary mismatch between the query and documents. Let's consider a document collection with  $D$  relevant documents for a user query  $Q$  to understand this problem. For representing a single concept,  $Q$  and  $D$  may use different vocabulary. A traditional retrieval system performs only keyword matching between query and document. It does not detect similarity between  $Q$  and  $D$ . The authors address this problem using semantic and ontologies, which provide shared meaning for two different terms.

### B. Proposed Information Retrieval System

To solve the above-stated IR problem, the researchers propose a novel ontology-based retrieving system as shown in Fig. 1. The steps of the proposed system are as follows:

- 1) The user's information need is specified by a user query (typically made of keywords) entered via the user interface.
- 2) The initial query is processed using domain ontology and query processing operations. Same operations are applied to document collection by semantically association module for Indexing purposes.
- 3) Index building from the document source is an offline process performed by the indexing module.
- 4) The transformed query is a semantic representation of user information needs.

5) This query is executed by searching using a semantics module to retrieve a set of relevant documents. Fast matching between query keywords and documents terms is done by the index structure.

6) The set of retrieved documents is then ranked according to the estimated relevance with respect to the term matching score.

7) The user then examines the set of ranked documents; he might point to a subset of the documents as useful and thus provide feedback to the system.

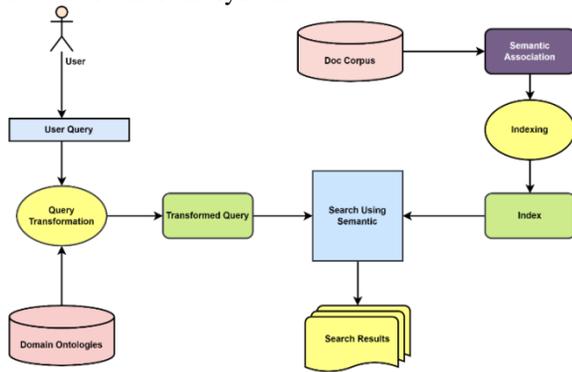

Fig. 1. An Ontology-based Semantic Information Retrieval System.

1) *Query processing*: To discover the documents that meet the user's information requirements, the query must first pass through a pre-processing module, which converts it into a more precise or machine-readable format. The matching module receives this type of question, known as a processed query. A typical search engine query consists of several terms. A list of terms with weights can also represent such a query. A standard information retrieval system will provide a high percentage of pages relevant to the user's query after matching. If the sender of the inquiry finds a page relevant to the topic for which the query was submitted, it is considered relevant.

2) *Indexing*: The IRS indexes millions of web pages containing a comparable number of distinct terms. Indexing can be defined as a process that collects, parse and store data to facilitate fast and accurate information retrieval. During indexing, a search engine records the words and phrases from downloaded pages; then, it prepares an index based on this data. It stores terms in an inverted file structure known as an inverted index. An inverted index stores the positions of text for each occurrence of a term. Another reason for indexing web pages by search engines is that it carried out processing like lexical analysis similar to the query processing phase, which improves the performance of search engines. In full-text indexing, virtually every word in the document is employed as an index term.

Indexing is an integral part of every search engine because it optimizes the query performance by improving the response times considerably. Along with Indexing, search engines also perform ranking, which is an attempt to see how good an approximation to "importance" can be obtained from just the link structure of the web. The index is built from text

documents by the indexing module. Preparing an index is an offline process that parses text documents into tokens. Various text operations are performed on these tokens, transforming them into indexing terms.

3) *Search using semantics*: In this module, query keywords are matched with index terms. It retrieves those documents from the index that contain given query terms. It is typically a standard search for processed query terms in an index of documents. The degree of matching between a page and a query, called the similarity, can be measured by the number of terms they share. A similarity score between query and index terms is calculated to rank returned documents. A simple approach is to match query keywords with index terms and return the URLs of those documents that contain matching terms. This keyword or syntax matching between query and document can be improved with semantic matching.

The computational processing required for an NLP-based query having a probabilistic weighted model is more than an unweighted, Boolean matching model. Ranking scores all retrieved documents according to a relevance metric. One of the fundamental difficulties in information retrieval, the scientific/engineering subject that underpins search engines, is ranking query results. The task is to rank or sort the documents in D according to some criterion such that the "best" results appear first in the result list displayed to the user, given a query q and a collection D containing documents that fit the query. Traditionally, ranking criteria have been described in documents relevance to a query's expressed information demand. These graded documents are returned to the user using a user interface.

**Algorithm 1: Pseudo Code for The Proposed OBS-IRS**

Input	:	User Information need
Output	:	Retrieved relevant documents
		<i>start</i>
Step 1	:	Formulates the initial query $q$ and submits it via the user's interface
Step 2	:	Query transformation module process $q$ using domain ontology
Step 3	:	$q$ is transformed to a more machine-readable form $q'$
Step 4	:	QT utilizes domain knowledge from ontology dataset
Step 5	:	Build Index $I$ ;
Step 6	:	Process documents from Doc Corpus using semantic association
Step 7	:	Apply Index preparing method Inverted Index on fetched pages
Step 8	:	for terms extracted from doc with semantic data
Step 9	:	Semantic Search
Step 10	:	Match $q'$ with index terms
Step 11	:	Start for
Step 12	:	each term in $q'$
Step 13	:	if ( $q'$ term and index term have the same meaning)
Step 14	:	Retrieve document according to the matching function
Step 15	:	End for
Step 16	:	Apply Ranking on documents
Step 17	:	Return search results
		<i>end</i>

### C. Query Transformation

The initial user query is not able to represent his information need properly. Our system uses three main query transformation techniques.

1) *Query expansion*: The IR use of Query Expansion (QE) has been the subject of research [12]. As seen in manual search, it can be seen that the user reformulates their search query. They do it because they didn't get the exact result of their original query. In the QE, the IRS improves the user's query by automatically expanding it. This can be done in several manners, like providing suggestions by guessing the user's intention according to the user's past behaviour.

This technique adds additional terms to the user's initial query based on local and global information resources analysis. This analysis focuses on finding semantically related terms to the original query. These target resources can be the whole document collection, the initially retrieved documents set, or documents from the computer. Expansion of queries [13] with matching terms improves performance in terms of recall. However, any method must find similar terms carefully during this process because it may lose gain in terms of precision.

2) *Query refinement*: Researcher use this refinement technique to improve the matching between queries and documents. The process of reflecting user needs with high accuracy is called query refinement [14]. In this process, the feedback by the user plays an important role. It generates a new query after applying the refinement process. Research on query refinement is not as dominant as query expansion.

3) *Query suggestion*: Query suggestion is also a part of the query transformation module. The most common form is spell checking during query processing by any search engine. The user is offered replacements to the initial query. These alternatives are more specific to the user's information need. Query suggestions provide more detailed descriptions of the search concept. This technique uses the extensive query history collected by web applications [15]. To implement query suggestion, the retrieval system generates a new query. It is different from the QE because it does not always add new terms to the initial query. Table I shows the query transformation approaches concerning their behavior on user feedback.

TABLE I. SUMMARY OF QUERY TRANSFORMATION METHODS

	Query expansion	Query refinement	Query suggestion
Generate new query		Yes	Yes
Expand original query	Yes		
User feedback before modification	Yes	Yes	
User feedback for final modification			Yes

### IV. EXPERIMENTAL SETUP

For the experiment, the authors used Terrier [16] retrieval system. It is an open-source tool for IR experiments developed by Glasgow University, UK. Three standard datasets are also used for comparing the results of both approaches.

#### A. Datasets

The first dataset, ANTIQUE [17], is a non-factoid community question answering dataset. It is a collection of 2,626 open-domain non-factoid questions from a diverse set of categories. The Cranfield [18] is a small curated dataset extensively used in information retrieval experiments. There are 226 queries (search terms), 1400 documents, and 1837 (evaluations) in the dataset. The TREC MRT dataset [19] helps fill evaluation gap issues in IR. Due to the sensitive nature of medical records, data constraints are the overarching factor for Medical Records.

#### B. Evaluation Metrics

The authors used three standard evaluation parameters to evaluate our results. The detailed information about these measures is given below.

1) *Precision (P)*: It is the fraction of retrieved documents that are relevant. It measures the quality of the results [20]. It is also known as positive predictive value. It can be calculated at different values, denoted as Precision at k (shortened as P@k). It can be calculated using Eq (1).

$$\text{Precision} = \frac{\#(\text{relevant items retrieved})}{\#(\text{retrieved items})} \quad (1)$$

2) *Recall (R)*: It is the ratio of relevant documents that are retrieved. It can be seen as a measure of the quantity of documents corresponding to an information need [21]. It is also known as sensitivity. Being ratio, it has a value between 0 and 1. It can be calculated using both equations given below as Eq. (2).

$$\text{Recall} = \frac{\#(\text{relevant items retrieved})}{\#(\text{relevant items})} \quad (2)$$

3) *Normalized Discounted Cumulative Gain (NDCG)*: To represent non-binary relevance, the use of cumulative gain or specifically normalized discounted cumulative has been increasing. It is a widely accepted evaluation parameter in the IR community [22]. It can also be calculated at a given rank cutoff (e.g. ndcg\_cut\_10). It can be calculated for k, top search results. For query, j form a set of queries Q, consider R(j,d) as relevance score is given to document d, it is mathematically calculated by Eq. (3).

$$\text{NDCG}(Q, k) = \frac{1}{|Q|} \sum_{j=1}^{|Q|} Z_{kj} \sum_{m=1}^k \frac{2^{R(j,m)} - 1}{\log_2(1+m)} \quad (3)$$

### V. RESULT AND DISCUSSION

To show the performance of the proposed and baseline system, the authors evaluated both on three datasets. The parameter used to judge the performance are precision, recall, and NDCG. The results were taken at different levels such as 10, 20, 50, and 100 top documents. The detailed discussion for each parameter is given in the following subsection.

### A. Precision Analysis

Fig. 2 shows results for the precision on the ANTIQUE dataset. Here you can see that the proposed combination of semantics and ontology outperformed the baseline results. For p@10, the value for the ANTIQUE dataset was 0.2356 in the baseline model, whereas it was 0.2452 for the proposed system. For P@20, values of baseline and proposed were 0.2322 and 0.2396. The value of @50 was 0.2145 and 0.2292. At the 100 documents, the precision values of baseline and proposed were 0.2012 and 0.2086. This shows that the proposed approach performed better for all values of precision. Fig. 3 shows results for precision on the Cranfield dataset. For this dataset also, the proposed retrieval outperformed baseline retrieval. Similarly, in Fig. 4, you can see the precision results for the TREC MRT dataset; our system was also better in terms of P@10, P@20, P@30, and P@100 results.

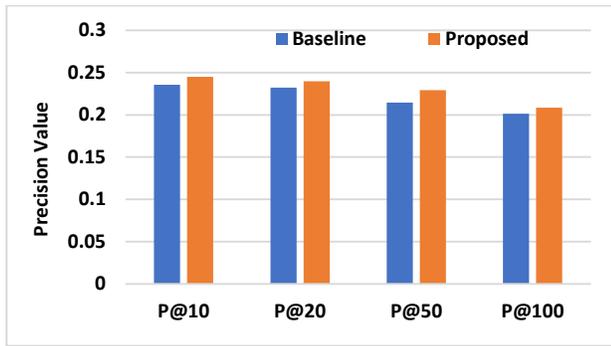

Fig. 2. Precision Comparison between Baseline and Proposed on ANTIQUE.

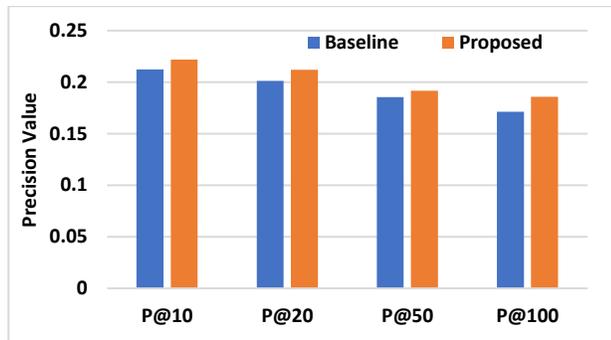

Fig. 3. Precision Comparison for Baseline and Proposed System on Cranfield.

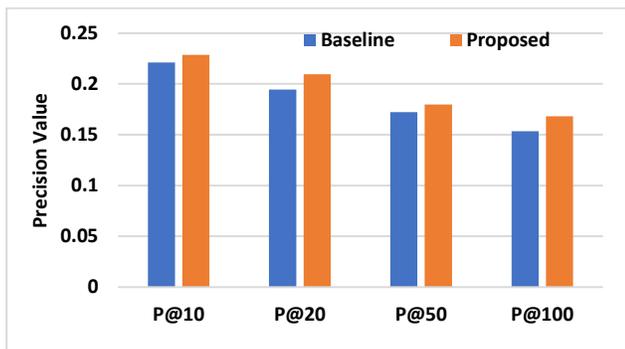

Fig. 4. Precision Comparison for Baseline and Proposed System on TREC MRT.

### B. Recall Analysis

The results for recall measures on the ANTIQUE dataset are shown in Fig. 5. Here you can see that the proposed system outperformed the baseline. For R@10, the baseline achieved a value of 0.3234, and the proposed system achieved 0.4321. The values for baseline and proposed at R@20 were 0.3745 and 0.4023. The best value of R@50 is 0.4421 given by the proposed approach. For R@100, baseline achieved 0.5122, but our semantics method gave 0.5622. In Fig. 6 comparison between baseline and proposed on Cranfield is presented. The graphical representation in Fig. 7 shows that the proposed methods have beaten the baseline for TREC MRT results.

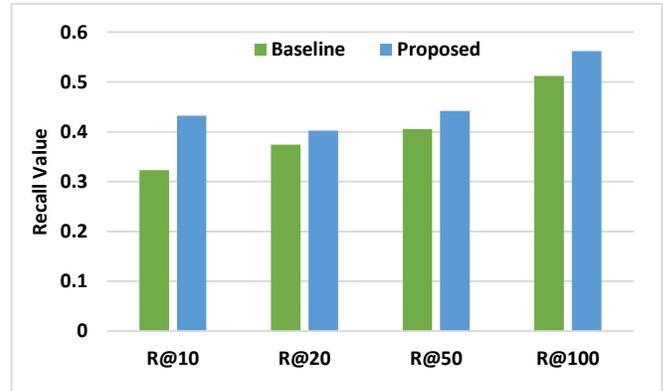

Fig. 5. Recall Comparison between Baseline and Proposed on ANTIQUE.

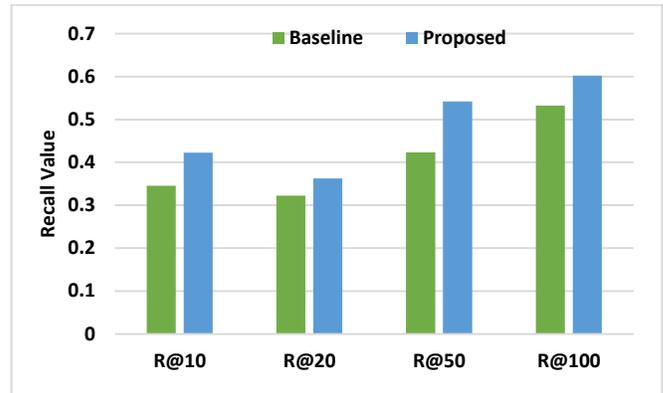

Fig. 6. Recall Comparison between Baseline and Proposed on Cranfield.

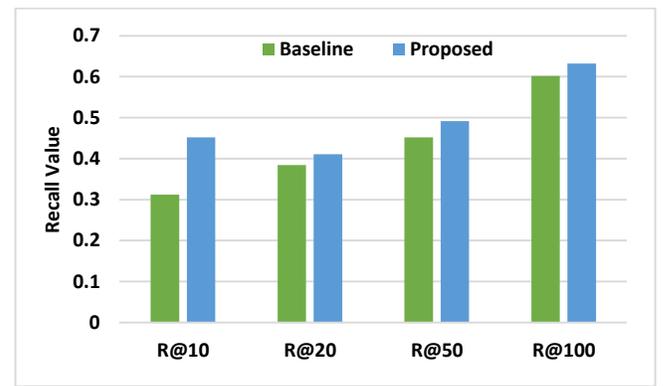

Fig. 7. Recall Comparison between Baseline and Proposed on TREC MRT.

### C. NDCG Analysis

From Fig. 8, you can see NDCG results for the ANTIQUE dataset, for cut10 proposed approach gave 0.2168, whereas for baseline value was 0.2101. In comparing cut20 results, the authors found that the difference between baseline and proposed is less than 0.0028. For cut50, the value for the ANTIQUE dataset was 0.2045 in the baseline model, whereas in the proposed system corresponding value was 0.2128. For cut100 value for the proposed was 0.2162 higher than the baseline. Fig. 9 and Fig. 10 show NDCG results for the Cranfield and TREC MRT dataset, respectively; from these comparisons, the authors found that the ontology method outperformed the baseline.

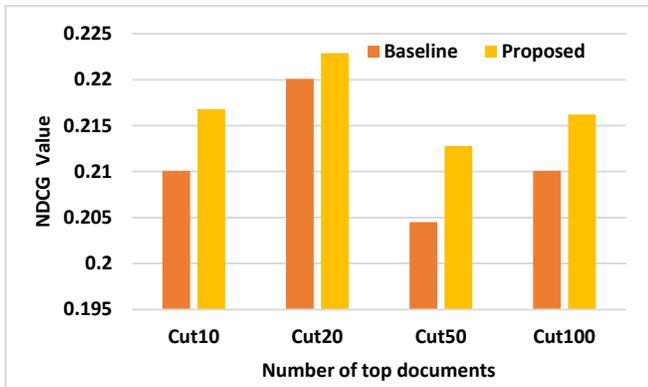

Fig. 8. NDCG Comparison between Baseline and Proposed on ANTIQUE.

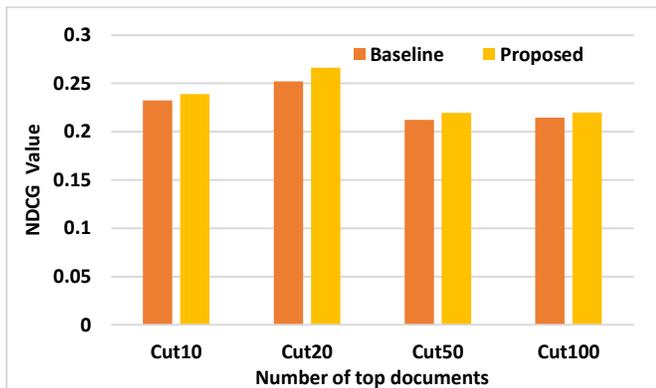

Fig. 9. NDCG Comparison between Baseline and Proposed on Cranfield.

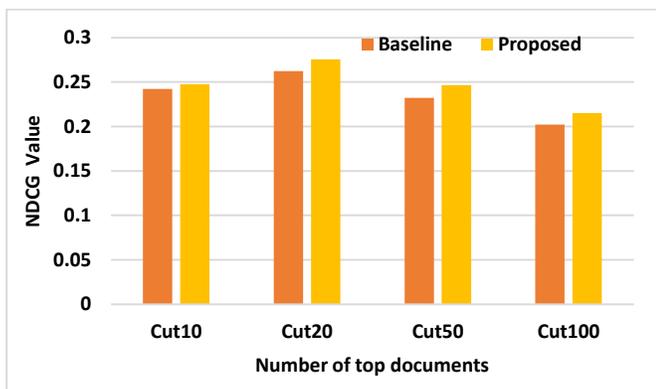

Fig. 10. NDCG Comparison between Baseline and Proposed on TREC MRT.

### VI. CONCLUSION

The results of ontology-based query transformation have shown that if any IRS uses domain ontologies for query processing, its retrieval performance improves. Similarly, semantic association in the indexing process helped to capture the related terms from documents. Hence both modules of the proposed system abetted to retrieve relevant documents as per the user's information need. The different comparisons between the proposed and the baseline results proved that the author's hypothesis is correct. The use of ontology and semantics techniques delivered better results on all three datasets. The proposed system achieved 4% high precision at 100 top documents for ANTIQUE dataset. The recall values on Cranfield dataset at top documents increases by 13%. The NDCG parameters values at top 100 retrieved documents is 6% higher than baseline results. So, it is undeniably an efficient system for retrieving relevant documents from the extensive collection of unstructured data.

The authors conclude that query transformation using ontology has a high impact on retrieval performance. Use of semantic matching and domain-specific knowledge helped IR users to find documents that satisfy their information need. The authors hope that commercial search engines will utilize the full benefit of domain ontology and semantics in near future.

**Abstract**—Character segmentation in Unconstrained Arabic handwriting is a complex and challenging task due to the overlapping and touching of words or letters. Such issues have not been widely investigated in the literature. Addressing these issues in the segmentation stage reduces errors in the segmentation process, which plays a significant role in enhancing the accuracy of the Arabic optical character recognition. Therefore, this paper proposes a hybrid approach to improve the accuracy for interconnection, overlapping or touching character segmentation. The proposed method includes several stages: removing extra shapes such as signatures from the document. Using morphological operations, connected components and bounding box detection, detect and extract individual words directly from the document. Finally, the touching characters segmentation is achieved based on background thinning and computational analysis of the word's region. The proposed method has been tested on KHATT, IFN/ENIT database and our own collected dataset. The experimental results showed that the proposed method obtained high performance and improved the accuracy compared to other methods.

**Keywords**—Arabic handwritten character recognition; connected components; word segmentation; character segmentation; morphological operators; overlapping and touching characters

## I. INTRODUCTION

Recently, electronic devices and modern technology have become an important and essential in human daily life. A lot of efforts and time were spent to protect and maintain valuable historical documents, letters, and books into digital images for scientific, service, and future uses. Optical recognition systems appeared as significant tools to avoid the loss of such valuable documents which convert text images into editable digital texts. There are various uses of machine learning techniques in Optical Character Recognition (OCR) systems; the gap is still largely due to unlimited obstacles in Arabic handwriting. Comparing OCR to Latin and other languages with the recognition of Arabic, the Arabic recognition system is still incomplete and unsatisfactory. In today's world, interested parties in the field of documenting are required to save digital images possible to modify, i.e., repairing deterioration in historical books, correcting errors, using a text part of it in other applications.

Converting text images into editable digital forms is called Optical Character Segmentation (OCR) [1]. The text images

are either printed or handwritten. The deficiencies of Arabic handwriting OCR systems are more complex than printed and incomplete. Because handwriting does not abide by the font's criteria, specific size, different font and size style writing for a word repeated several times in the same document itself, other problems of interconnection, overlapping and touching, and difference gaps among word/sub-words increase the complexity of Arabic handwriting. There are common factors that make Arabic handwritten as well as printed text complex such as Arabic nature cursive, writing from right to left, connecting the letters, and so on.

Arabic handwritten character recognition has the same situation as other languages. In some cases, it seems to be more complex depending on the language, the challenges it faces, and difficulties for line, words [2]-[4] and the challenges in character segmentation of the input document images. These challenges, such as interconnection letters word, cursive overlapping, touching existence of ligatures, diacritical marks and the position and number of dots above or under some letters. These challenges may lead to misclassification and unsatisfactory results. However, some of these challenges were recognized by many researchers in the OCR field using machine learning techniques [2].

The deficiencies are based on the failure of the Arabic character segmentation stage. Cursive, overlapping, and unrestricted writing challenges are the most long-term barriers to correct segmentation. A study [1] presented a projection profile technique for Arabic characters segmentation; which was tested and evaluated successfully in Arabic database with various sizes, styles, and font types. But it is limited to the Arabic printed document. The proposed system fails to deal with handwriting documents.

Another study [4] presented a solution for overlapping and touching Arabic characters segmentation by overlapping set theory and contour tracing. It is low accurate when segmenting the multiple touching letters. While [6] suggested a hybrid method focusing on the middle point of the word area. This study was focused on handwriting documents in the Hindi language. This method succeeded in fragmenting the multi-touching letters, and to apply it to the Arabic language; it needs to be developed because the Arabic calligraphy starts from right to left.

The segmentation solutions for single/ multiple touching, overlapping challenges, and interconnected characters problems still need to be expanded to include more Arabic handwritten documents. Achieving progress in respect to Arabic text recognition is hindered by such obstacles and challenges. Moreover, the complexity of finding a solution to the segmentation of overlapping and touching Arabic handwritten words or characters made few researchers interested in addressing these two problems and developing techniques to address these complex problems. These two challenges created gaps in attempts to process them, i.e., there is a gap of at least two years between every two research works (Ouwayed et al., 2009, Belaïd & Ouwayed, 2011, Aouadi, N. et al., 2013, Aouadi & Kacem, 2017, Ullah et al., 2019, AbdAllah, N., & Viriri, S. 2021, Ahmed et al., 2022 as a review survey). These are some of the motivations that encouraged us to propose a hybrid approach to reduce these complexities and improve segmentation techniques.

This article proposed hybrid approach to segment the Arabic handwritten document into direct words with an objective to enhance and increase the accuracy ratio of Arabic handwritten character segmentation while dealing with overlapping, interconnected, and touching Arabic handwritten documents. The work was divided into eliminating non-textual appendages in documents, segmentation, and extracting words from the image using connected components and thinning techniques. A hybrid method is used with computation analysis of the word's region to segment a word into characters. The middle point is detected to extract the structure features for dealing with the input, which contains the touching overlapping character and distinguishes from isolated character based on calculating the vacant space index value. The hybrid method has been proven to be a flexible and efficient method to deal with various renewed database. The contributions of this study are listed below:

- 1) Proposing a hybrid approach for character segmentation in Arabic handwriting that addresses the challenges of segmentation of touching characters eliminates the signatures from input document images and segments words directly from the input images, including wavy lines.
- 2) Creating a new database for Arabic handwriting to evaluate the proposed hybrid approach.

This article is organized as follows: Section 2 reviews the existing studies related to Arabic characters, Section 3 describes the methodology for character segmentation, Section 4 discusses the experimental results, and Section 5 concludes the study.

## II. RELATED WORK

The challenges of touching and overlapping lead the researchers to focus and work on line/ word/ character segmentation. The OCR systems depend on hybrid techniques, which are considered better than other systems in accuracy, speed, and flexibility in dealing with renewable databases. It is appropriate for dealing with handwritten documents as indicated in [7]. The researchers suggested a method in which they used a technique based on connected components. Then, it selects the estimating and the alignment transformation of

these connected components, stored in segmented models by templates for two most similar Connected Components (CCs) of the touching words. Finally, it separated the CCs into two regions using the Centre Points of these regions.

The authors [4] introduced a solution for touching Arabic characters by using a hybrid approach for character segmentation. The proposed method to split through letters is by selecting the touching point by overlap set of theory and endpoints of Arabic word and then tracing the boundaries of the touching letters to segment them individually. The segmentation is good, just dealing with single touching characters. Due to the differences in positions of words in different documents, the hybrid methods need to be improved and developed to give better results in the future. The authors [8] suggested a method for touching Arabic characters segmentation based on template segmentation. This method creates a dictionary file. This file contains a template for each touchpoint with its necessary details. Then it is compared with the input images to identify a sample from the dictionary file. As mentioned earlier, the template method is difficult to apply in handwritten character segmentation. It saps computer hardware to save each touchpoint in a template for detecting similar touching points. The runtime is very long and tedious. Fatal flaws in the handwritten character segmentation.

In the study [9], the authors used a segmentation method that extracts topographic features. These features identify potential segmentation points of the characters block connected. The segment of the possible points is based on the average width of the character. The study achieved approximately 70% of character segmentation. Moreover, many errors in segmenting, handwritten Arabic characters, mainly the letters which connect from two sides. While in [10] suggested a method to segment touching handwritten Arabic characters. It first detects the intersection points and the beginning ligature's pixel near the upper line from the baseline. The process starts from this point (ligature's pixel) to pursue the descending character to the intersection point and respect a different angular corresponding to the descending character curvature. The proposed method was tested on 100 Arabic document images containing 256 touching lines. However, the success ratio reached 94% of the segmentation. But it is inappropriate for the segmentation of multiple touching components. Three methods from the literature were compiled and already developed. So, it is a mixture method. The hybrid method is suggested by [11] to segment the touched printed and handwritten Latin characters (obviously, the success of segmentation for handwritten characters. will be the highest efficiency and accuracy in printed characters). The disadvantage of this method is that it was tested on a few images of documents. Therefore, the success rate is insufficient and unsatisfactory.

The problems of overlapping, interconnection, and touching in handwritten Arabic characters make the segmentation process complicated task. From the aforesaid literature review, it was noted that these issues had been extremely slightly discussed in previous studies. In addition, period intervals between those studies were absolutely longer. However, there are shortcomings in solving these problems, which involves limitation in the studies related to Arabic

databases and lack in performance of segmentation of the multiple-touching Arabic characters. The proposed methods are suitable for the segmentation process but are inflexible in dealing with morphological differences. Therefore, this study aims at developing a hybrid method to address the above-mentioned problems.

### III. PROPOSED METHOD

This section describes the methodology of the proposed work as shown in Fig. 1. Initially, the pre-processing is performed for the input image to improve low quality and prepare for the next stage. Then, it segments the whole document into individual words, especially if the input image contains wavy lines. If the input image includes shapes or signatures, the approximate polygon methods remove these shapes. In contrast, the signatures are extracted and removed from the document based on the connected component analysis. Finally, divide the words into isolated letters.

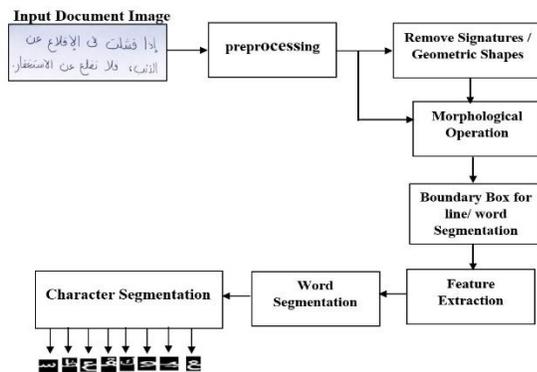

Fig. 1. Block Diagram of the Proposed Method.

#### A. Pre-processing

In this work, a new database is created which contains old and modern handwritten documents. The quality of the collected images is good, medium, and many of them lack lighting. The problem of poor and unstable lighting in the whole document is big obstacle to make the pre-processing stage complicated as shown in Fig. 2, where the different spots of lighting in same (one) document, which lead to a lack in performing the segmentation process. Using some filters such as Gaussian Filter, Median Filter, Low pass Filter, Custom Filter, etc. which give enhancement in these images, but the results are poor because the most challenge was the unstable lighting in the image documents in which one image has different contrast lighting. The results, on the other hand, were good when the input images with stable lighting were applied which is similar to applying IFN/ENIT or KHTT database, because these databases have Binarization images.

One of the challenges faced when collecting the images, some of the images have poor quality and resolution as shown in Fig. 2. The image (a) is darker than others. Its histogram (b) placed at 0 - 200 to represent (the) pixel value in x-axis

takes the image (a) pixel value and the value placed at 0 to 200 that indicated the values grouped at black values, this represents the image (a) consisting of more black pixels compared to other gray level value. The image (c) is a low contrast image, its histogram (d) is placed at almost the center towards white. The image (e) is a bright image where its histogram (f) values are placed at 170 towards white 255, which indicated the image (e) has more white pixels. Although the preprocessing approaches were applied to these images the results were not good.

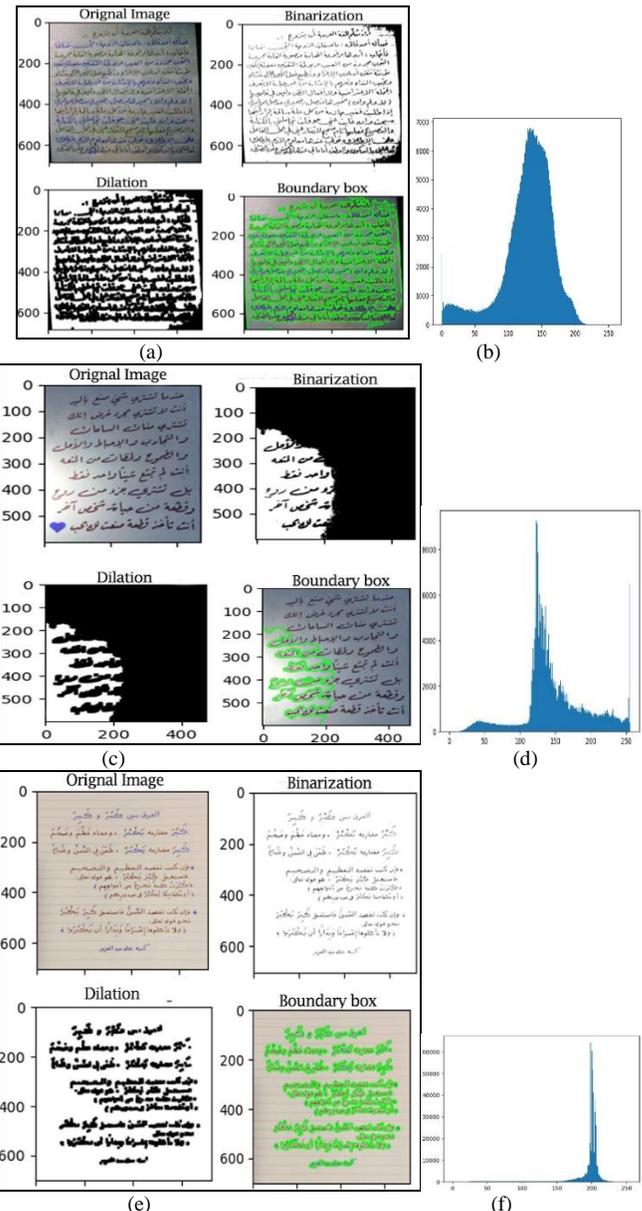

Fig. 2. Different Lighting and Histogram of Intensity Distribution. (a), (c) and (e) are the Input Document Images, While (b), (d) and (f) are the Original Images' Intensity Distribution Histogram for showing the Intuition about the Contrast Brightness Intensity Distribution.

### B. Removing the Signatures

Many images of documents contain signatures, so before shifting to the next stages of Arabic OCR stages, it should eliminate these signatures to help to word and character segmentation. The method is used to remove these signatures depending on Connected Components and find out the thresholding average as shown in Fig. 2. By using image processing, the regions of connected pixels were recognized by this algorithm. It commonly gives the same result. In other words, the given input image is scanned by these connected components along with this attached signature. The next step is gathering the pixels into new components connectivity i.e. the elements of the image connected to the same intensity values of each pixel and showing the link with other values. Therefore, the components will be recognized, and every pixel will be highlighted with a specific colour (color labelling). Each pixel may highlight with a grayscale according to the located component.

Fig. 3. Block Diagram for removing the Signatures.

Now-a-days, classification of each connected component along with the assorted dissociates are essential to many analysis applications of image's machine-driven. In this process, the whole image, from left to right and top to bottom, is scanned to recognize the region of each pixel which is connected to the image's component. In other words, it can be said the adjacent pixels of each component share constant value  $V$ . it can be applied to binary or grayscale images, and it measures connectivity differently. Before applying the mask technique move over, the input image should be a binary, 8-connectivity where a mask created and each pixel and its surroundings is are checked using this 8-connectivity. The operator moves over the image to scan rows individually until it arrives at 'p' point, It examines the remaining eight neighbours of the labelled pixel (at any stage, 'p' is the labelled pixel) for which  $V = [1]$ . Then it examines the four neighbored labelled pixels from right to left and from the upper diagonal direction, which were already encountered in the scan. According to previous details of the scan, the term 'p' is classified when the process finds an adjacent value equal to '1'. Then the label is assigned to 'p'. At the same time, if other neighbours have the same value, all of the labels will be assigned. The equivalencies will be noted; if all pixels are 0, a new label will be given to 'p'. This process is followed by the initial scan of the label pair area units and sorted into equivalent categories (classes and distinct labels). The next step is the second scan of the image in which every label is replaced by the equivalent category, even though the labels may not be identical.

A Scikit image library provides an exciting feature to identify and label the connected components. This library is used to check the scanned input image documents and find these connected components with their labels in addition to grey and color labels. It turns out that the largest connected component is the signature compared with word components. Therefore, if it is possible to extract the largest component of the whole document, the signature can be recognized.

However, using large connected components can extract unwanted words, lines, or other shapes. Therefore, a threshold value is used to solve this problem, it is used to detect outliers, i.e., any lines, structures, and texts that do not belong to signatures are calculated after a series of experiments which have been performed. In terms of a mathematical formula (1), which is obtained based on experimental results. It gives quite effective recognition of signature's regions in dealing with most A4 size scanned documents. Table I shows the obtained values representing the signature region's characteristics. The place of the signature is determined based on the biggest of the connected component's value and then compared with the average of this region to extract the signature to delete. Fig. 4 shows the identification of the signature's region from a sample set of images.

$$\text{const\_A4} = [100 + (250 * (\text{average}/84))] \quad (1)$$

TABLE I. FEATURES OF SIGNATURE' REGIONS

Sample Images	Biggest Components	Average	Small Components	Big Components
A	924	162.508772	583.657059	10505.82707

Fig. 4. Extraction of Signatures from Sample of Images.

### C. Line Segmentation

Separating the input images into isolated lines is successful with high accuracy in documents which may contain printed, historical or handwritten texts, these documents' lines have gaps between them that are orderly spaced [12], and the handwriting is on lined sheets. These gaps are ordered and

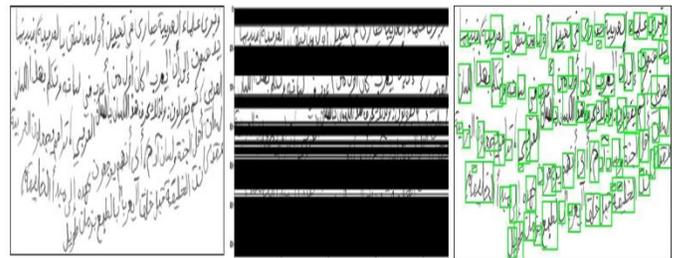

these gaps may be almost empty of noises or unimportant objects. Because the feature of the gaps between the lines is the most important for the success of lines segmentation and extraction individually for using another application, in skew correction with multiple slanting or copy particular lines to other programs. Many handwritten documents lack clear orderly gaps between the lines, which are close, touching, and sometimes wavy. These gaps may be spaced at one side and touching or overlapped at the other. These challenges make the line segmentation process difficult and complex. Many studies have proposed techniques to solve these challenges and achieve satisfying success despite the convergence, contact and overlap between the lines. A study [13] proposed an A\* path planning algorithm to line segmentation directly. The localization of each line is detected by two steps: Binarization method and projection profile analysis. The author's experiments tested handwritten historical documents from the MONK and the Saint Gall dataset. The study [14] presented a method of line segmentation based oriented anisotropic Gaussian Kernel, in which the authors divided the input text image into connected components achieved by Boundary Boxes. The method was tested on a sample of English Handwritten documents. In [15], the authors used midpoint detection technique for every two lines or words. The technique was tested on Gurmukhi printed and handwritten (Handwritten scripts are orderly distances among the lines) scripts (Punjabi). Their results achieved 95% of success. Study [5] also used a technique and a database containing English historical documents. The line regions were detected using rough detection throughout black/white transition map which is used to extract the lines through corresponding lines axes and skeletonization. PROHIST database was used in this study and achieved 82.18% of accuracy.

After it converted the input image into binarization in preprocessing phase, the input image locates the text (object) areas of the white background where the text is black. The process Uses Dilation operations to make the pixels' value of each line. This pixels' value has a single value so the line is considered one-component [16]. The starting and ending four points of each component determine the bounding box location among these points around the line component [17]. This boarded rectangle is segmented for each line, returned the segmented line to its original size using the erosion operation and the thinning method to give a better distance between words in preparation for their segmentation. Then the matrix of the rectangle border is saved into an image.

The overlapping and touching challenges between lines, make the dilation operation more extended, two or more lines are considered one component [18]. These challenges are solved by tracing the contour points of the touching area horizontally and overlapping vertically, using the method (direction contour tracing) in [18]. It traces the overlap path with calculation operations. This method is not good in separating lines in Arabic Handwritten documents because of the stretching of strokes and some letters are written vertically and extendly, such as these letters 'أ', 'ك', 'ظ', 'ط', 'م'. Also, most line segmentation techniques fail to segment wavy lines.

#### D. Word Segmentation

As it was mentioned earlier, many of the input images contain lines skewness, touching, overlapping, wavy and more closely spaced lines, where the line extraction fails, so the lines are separated into two or more lines as shown in Fig. 4. In the study [13], Hidden Markov models were used for word segmentation from the entire document directly. Current study, the words or sub-words are segmented by applying the Connected Components method for overcoming and solving many challenges such as the distance between words is less than that between sub-words and overlapping in one word. The Boundary Box function is used to extract them. These two methods achieved a higher success rate and are better than dividing the lines before the words, as shown in Table III.

(a) Original Image. (b) Bad line segmentation. (c) Words segmentation.

Fig. 5. Segment the Document Image into Words.

Fig. 5(a) shows a sample of a document image which contains wavy and touching lines. Many methods were applied to segment the lines in such image. The line segmentation methods such as projection profile method, a method based on tracing, another method based on contours, third method based on baseline, forth method based on morphological operation or other methods. These methods did not succeed in extracting the lines as shown in Fig. 4(b), where the first line only was successfully extracted. The rest of the lines were considered one component, or extracted a part of a particular line with previous or next line in the same process. Fig. 4(c) shows the words were extracted directly from the document with better accuracy and success.

#### E. Character Segmentation

This step is crucial to the segmentation stage. After overcoming the previously mentioned, challenges as much as possible, such as different light spots in the input image and existing shapes or signatures. After the success of words/sub-words segmentation, the character segmentation follows.

First, detecting the touching of characters: The Connected Components method is used to solve the overlapping problem between characters. It is also used to measure the weight of the character. A threshold value has been fixed to evaluate the weight. If the obtained value is less than the threshold, it can be considered a single character and split automatically. If the value is greater, it can be regarded as a touching character using the variable:

Tc (2) is the aspect ratio of the touching character is greater than the character is automatically split. In order to determine the touching characters using the variable (Tc), this aspect needs to be improved due to the similarity between interconnected and touching of Arabic characters. The touching characters are defined by.

$$T_c = \frac{e^g}{1 + e^g} \quad (2)$$

Where  $g = \frac{w}{h}$ , w is width of the character, and h is height. After identifying the touching character, it is classified as either horizontal, vertical or multiple touching.

By comparing the two values of height and width, the type of touching is determined by  $g = h1 > w1$  the touching is vertical.  $g = w1 > h1$  the touching is horizontal. While the multiple touching is defined as  $g = w2h2 > w1h1$ .

Second, using hybrid approach by following these steps:

1) Find the area of a word/ sub-word throughout detect the start point and endpoint of this area, allocate the area on width (w) and height (h). (w, h = contour area(word)).

2) Using thinning, closing and opening operation

3) Using midpoint steps to separate word/ sub-word isolated.

- The vacant space index value is calculated on the word/ sub-word's constrained such as width and height.
- Check the previous pixel and the next one (i+1, i+2, i-1, i-2) to save the column values and check if broken character appears.

4) Saved the vacant space between the characters in array\_index.

- Detect the centre value of every vacant space between the characters until the end of the word.

$$M\_point = (start\ index + last\ index)/2.$$

- This mid-point as a centre value is considered as the detection points to split the isolated character.

5) To determine the existence of joining (touching) characters, the total number of characters in a word is calculated.

6) Total value of characters is detected by the ratio of width and height.

$$Total = \frac{width}{height}$$

7) Total value of characters is compared with the segmentation point.

$$Value\ of\ M\_point = total + 1.$$

8) If joining character is exist then number of segmentation points does not exceed the total no of characters in a single word. Otherwise go to f.

9) f- Calculate the distance sequentially between the middle values, if the distance above 110% of height, there must

be a joining character present, which could be single or multiple joining characters.

10) Using clustering method to find the cluster in identified area of importance of the character in the middle part.

11) Discover the region of importance cluster between M\_point1 + 10-(M\_point2 +10) to obtain the heap of pixel.

- Scan every column to determine the cluster, if pixel calculate is found to be 10 then it is considered as joining point of the character.
- By leaving three columns in a row, you can segment the joining character.
- The new segmentation points should be extracted.
- Split the word from all the segmentation points.
- Show the results as in Fig. 6.

Fig. 6. Sample Images Show the Character Segmentation Isolated, Touching and Joined Characters.

#### IV. EVALUATION METRICS

Evaluate the performance of the proposed hybrid approach for character segmentation. The performance evaluation metrics used by [19] are followed; the same evaluation strategy was also applied in this work, which uses five factors for evaluation: successful segmentation rate (SR), precision (P), recall (Re), correct segmentation rate (CS), and F-measure (Fm). The authors are illustrated in Equations 3-7. These factors are figured out by counting the number of matches between the resultant segmented words and then characters by the algorithm and ground truth characters in text word segments.

$$SR = \frac{NCC}{NCR} * 100 \quad (3)$$

$$P = \frac{(NCc+NCo)}{NCr} \quad (4)$$

$$Re = \frac{(NCc+NCo)}{NCg} \quad (5)$$

$$CS = \frac{NCr-(NCi+NCo)}{NCg} \quad (6)$$

$$F_m = \frac{(Re*P)}{(Re+P)} * 2 \quad (7)$$

Where **NCg**: Number of ground truth words, characters respectively.

**NCc**: Number of segment correct words, character isolated.

**NCr**: Number of segmentation results (words, characters).

**NCi**: Number of incorrect segmentations for words, characters.

**NCo**: Number of over segmentation of touching in words, characters.

## V. EXPERIMENTAL RESULT AND DISCUSSION

This section describes the implementation and evaluation of the proposed method. The proposed method was implemented using Python 3.8.8, Open CV environment (Spyder4[MSC V.1916 64 bits]), Win 11 pro 64\_bit OS, with Intel(R) Core (TM) i5-9300HF CPU 2.40 GHz, RAM 8 GB.

The proposed method is tested on three Arabic databases. The images of the first database that have been collected were 2,300 handwritten text images, 20156 lines, 302,348 words; the ground-truth value of lines and words were calculated manually and estimated. The collected images are obtained from a scanner and also through social media. These images contain shapes, graphics and signatures. Some of these images are poor in quality and lighting. In such cases, the pre-processing methods such as filters, binarization morphological operation, normalization, skew correction were applied for image purification. The shapes were removed based on the size of the shape region while the signatures were removed from the document images. 140 images contain signatures as shown

in Fig. 3. Removing the signatures process was successful in 122 images, the process failed in 7 images, over-segmentation of signatures was noticed in 11 images. However, features of any word's region are similar to features of signature's region results in being removed as shown in earlier Fig. 3.

The proposed method failed in 170 images with a failure rate of 7% due to the poor quality of the images sent through social media. 15,721 lines were segmented correctly. Table IV shows the results of line, word, sub-words or characters segmentation. Because lines are touched, closed, wavy, or slant, the words, and sub-words were directly extracted from the input image. Arabic word's letters may be interconnected overlapped, so the segmentation process of a word depends on the gaps between every two words or sub-word. Table II and Fig. 6 show the experiment results.

KHATT database contains 1000 images of Arabic handwritten forms written by 1000 writers from different countries, 9327 lines, 165890 words [20]. And IFN/ENIT database involves 26459 words which are names of Tunisian cities [21]. Testing the proposed model on three databases was in stages: First, constant documents were segmented into lines, while inconstant documents contain overlap, wavy, or touching problems which are mostly segmented into direct words. The hybrid approach achieved high success rates, as shown in Table II which figures out the distribution of success rates over the three databases. The proposed method achieved a lower accuracy rate in our database for the following reasons:

- 1) Poor lighting and quality problems.
- 2) Degradations in the document images.
- 3) Colored images, while the images in the other two databases are binary.
- 4) Our database involves more documents than the other two databases.

Table II and Fig. 7 show the words and character segmentation for three databases. In addition, 1450 Arabic handwritten document images were taken from the three mentioned databases. This study focused on images containing overlap and touch problems of words or characters and wavy lines. Table III illustrates the results of the proposed method.

TABLE II. SEGMENTATION ACCURACY OF WORDS AND CHARACTERS

Databases	Number of:		Correct Segmentation		Incorrect Segmentation		Accuracy Rate	
	Words	Characters	Words	Characters	Words	Characters	Words	Characters
KHATT	165890	589924	161411	548629	4479	41294	97.3%	93%
IFN/ENIT	26459	212211	24342	188867	2910	12732	92%	89%
Our DB	302348	1257191	275136	1111356	27211	150863	91%	88%

TABLE III. SEGMENTATION ACCURACY OF TOUCHING WORDS AND CHARACTERS

Inputs	NCg	NCr	NCo	NCi	NCc	SR	P	Re	Fm	CR
words	26468	25409	985	833	25357	99	1.00	0.99	1	89.130
characters	79404	74639	2896	2328	74071	99.23	1.00	0.96	0.99	87.4

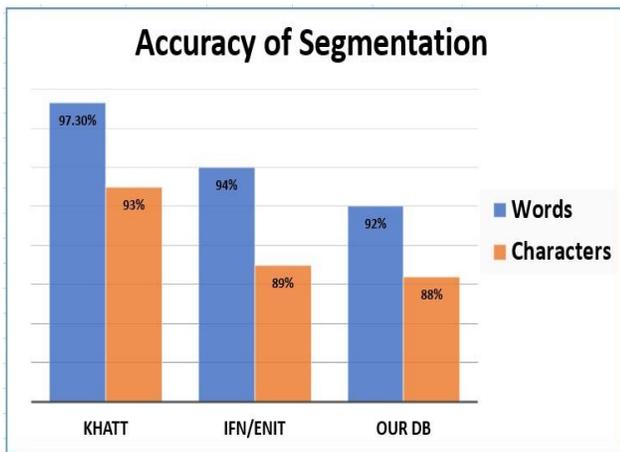

Fig. 7. Segmentation Accuracy of Words and Characters for each Database.

Second: 26468 Arabic handwritten words were taken from the three databases, which contain complex touching and overlapping problems. The ground-truth value of lines and words was calculated manually in our database. The statistics of the performance measure for words, as shown in Table III, indicate that the segmentation rate was 99% successful (SR); this segmentation rate is divided into over-segmentation, correct and incorrect segmentation. The accurate segmentation rate (CR) for words is 89%; Recall (Re), precision (P) and F-measure (Fm) obtained approximately 1.00, respectively. The performance measure indicates that the incorrect segmentation rate is approximately 11%; it means that the number of over-segmentations is 985 words (NCo), and 833 words are missed or incorrect segmentation (NCi). As for segmentation, the number of touching Arabic letters is 79404. These letters are either isolated from the word's origin or have single or multiple touching. Table III also indicates that 99% of the total segmented Arabic letters, 87% of the correct segmentation (CSR), and 13% of them was wrong segmentation. 79404 of touching characters were segmented. (P) was 0.96. (Fm) and (Re) were 1.00. Table IV shows the types of challenges in Arabic handwriting obtained from Table III.

Table V shows the comparison results between the outputs of this work with previous works that discussed such problems. On the other hand, the comparison results are difficult because of the different documents collected by researchers from various Arabic handwritten sources that involve these relevant challenges. The primary purpose is to reach satisfactory and accurate solutions even though the collected documents differ, but the essence of the problem is common. It should be noted that the comparison results are based on the findings of the researchers' works.

TABLE IV. SHOWS THE ACCURACY OF THE HYBRID METHOD IN EACH TYPE OF INPUTS

Type of Characters	No of characters	Correct Segmentation	Accuracy
Isolated	28401	26696	94%
Single Touching	32573	28012	86%
Multiple Touching	18430	15186	82%
Total	79404	69452	87.4%

TABLE V. COMPARISON ANALYSIS

Reference	Technique	No. of images	Types of Input	Segmentation ratio
(Aouadi & Kacem, 2017) [22]	Nearest model selection and detect the model's parts centres	820	Segment touching lines and words.	94%
(Ullah et al., 2019) [4]	Overlapping Set Theory and Contour Tracing	220	Segment a single touching character	97.2 %
Proposed method	Hybrid approach	huge	Segment a overlapping and single/multiple touching characters	90%

## VI. CONCLUSION

Characters segmentation in Arabic handwritten is a complex task. However, to improve the efficiency of the recognition system, it is desirable to enhance the character segmentation process in Arabic handwritten. To this extent, this article proposed a hybrid approach for Arabic handwritten character segmentation considering the overlapping or multiple touching issues. The proposed approach aims at improving the efficiency of the segmentation stage. The evaluation is conducted over Arabic handwritten databases which contain more complex challenges than the previously existing ones. The results showed that the proposed approach was highly efficient in word segmentation. And it is an effective, feasible and flexible approach in the segmentation of interconnected, overlapping or multi-touching Arabic characters. But errors or over-segmentation may occur in multi-touched characters. Therefore, in future work, the problem of over-segmentation of multi-touch characters will be considered. Pre-processing operations have also to be improved in formatting very poor documents.

**Abstract**—The museum visit is having a crisis during the COVID-19 pandemic. SMBII Museum in Palembang has a remarkable decrease of visitors up to 90%. A strategy is needed to increase museum visits and enable educational and tourism roles in a pandemic situation. This paper evaluates the machine learning model for exhibition recommendations given to visitors through virtual tour applications. Exploring unfamiliar museum exhibitions to visitors through virtual museum applications will be tedious. If virtual collections are ancient and do not display any interest, they will quickly lead to boredom and reluctance to explore virtual museums. For this reason, an effective method is needed to provide suggestions or recommendations that meet the interests of visitors based on the profiles of museum visitors, making it easier for visitors to find exciting exhibition rooms for learning and tourism. Machine learning has proven its effectiveness for predictions and recommendations. This study evaluates several machine learning classifiers for exhibition recommendations and development of virtual tour applications that applied machine learning classifiers with the best performance based on the model evaluation. The experimental results show that the KNN model performs best for exhibition recommendations with cross-validation accuracy = 89.09% and F-Measure = 90.91%. The SUS usability evaluation on the exhibition recommender feature in the virtual tour application of SMBII museum shows average score of 85.83. The machine learning-based recommender feature usability is acceptable, making it easy and attractive for visitors to find an exhibition that might match their interests.

**Keywords**—Machine learning; recommender system; museum exhibition; virtual tour; pandemic

## I. INTRODUCTION

As institutions with educational and tourism purposes, museums must maintain their existence during the pandemic that impacts museum visits. The museum must transform into a modern museum based on digital technology to maintain its roles in pandemic situations. Utilizing the internet of things technology will benefit museums. Visitors can interact with museum collections without having physical contact with the collections, including through applications based on Augmented or virtual reality, robotics, and games [1]. Visitors can explore the museum through a virtual museum application [2]. With this application, visitors can explore every corner of the museum and the collections displayed as if they were exploring the real physical museum [3].

The problem arises when exploring the museum through a virtual tour without a guide. Visitors will be confused and need

extra time to explore each exhibition room with many collections. As a result, it can lead to boredom due to the lack of clarity in the exhibition that attracts visitors and spends more time visiting [4]. Visitors will immediately leave the boring virtual space to look for other exciting spaces for educational and tourism purposes [5], especially during the pandemic where physical activity is limited. It needs a method that intelligently understands visitors' interest in the museum's exhibition and presents exciting and interactive information that satisfies visitors to explore the virtual museum.

Machine learning has been proven its effectiveness in understanding user profile and providing recommendations [6]. Based on the user profile, this algorithm learns the information extracted from past data to provide prediction of tourist destinations [7] and recommendations [8] or museum experience improvement [9]. Machine learning does not require formulating a mathematical model to predict or provide recommendations to users. The model is built based on the collected data for training the model [10]. Good training data will produce good recommendations as expected.

This study evaluates several machine learning classifier models to provide exhibition recommendations that match the user profile of a virtual museum. The boredom because of too long browsing the virtual museum displaying collections that do not match the user's interests will make the user exit the virtual tour application. Machine learning is expected to predict and recommend exciting exhibitions and match user requirements or profiles, reducing browsing time or finding interesting collections for virtual museum visitors [11]. Visitors can quickly enjoy exciting presentations and interact virtually with the collection through a virtual tour application based on machine learning recommendations, reducing boredom due to monotonous information presentations [12]. Visitors' interest will be indicated in the performance of the museum's educational and tourism roles. Visitors' knowledge about museums is expected to increase, and visitors' interest in museums through the information presented virtually [13]. The visitor will visit the physical museum when possible during a pandemic after being interested in virtual exploration and might have an economic impact on physical museums to improve the museum visit.

## II. LITERATURE REVIEW

Traditional museums have been transformed into modern museums based on digital technology and have begun to

\*Corresponding Author.

develop based on artificial intelligence and Internet of Things technology. During the pandemic, digital museums enabled museums to play their role in tourism and education by conducting virtual museum exhibitions. Like a tour guide, the exhibition recommender feature in the virtual tour application makes more accessible exploration when visitors are unfamiliar with the museum.

#### A. Use of Museum's Exhibition Virtual Tour Application

The museum's exhibition display museum's collections that attract visitors. The visitors' experience and satisfaction depend highly on the exhibition environment [14]. Visitors can visit for a long in the museum space or even experience boredom and immediately leave negative sentiments. It impacts return visits to the museum or will affect the interest of new visitors to visit the museum.

Modern museums are transformed based on digital technology to survive in the digital era and meet the millennial's needs for speed of access to information based on internet technology with an exciting and interactive presentation [15]. The museum, identical to ancient and boring collections, presents a monotonous exhibition system, so it needs a touch of digital technology for educational and tourism purposes. The current pandemic hinders visits to physical museums and geographical constraints, such as in Indonesia, where museums with historical and cultural collections are spread across the archipelago, became barriers for visitors. Internet-based technology enables to remove the barriers. Computer technology that can present museum collections and exhibits and allow visitors to explore the museum as if they were in the real environment of a physical museum is a 360-degree virtual tour application. This technology allows visitors to interact with the museum, that presents an image of the real museum environment and interacts with 360-degree views [16]. Visitors can explore independently without the limitations of distance, space and time like a physical museum.

Some museums have integrated virtual tour applications into their virtual museums. However, it will not be easy to explore each static museum exhibition without a guide who plays a vital tourism role [17]. Suppose in a physical museum there is a guide who can suggest and direct visitors to collections or exhibitions that might interest visitors. In that case, a virtual museum should also be equipped with a virtual guide feature to reduce boredom while exploring the museum through a virtual tour application. Some museums in Indonesia [18] have integrated the virtual tour 360-degree feature in their virtual museums (Table I). However, none integrates a feature as a recommender that gives suggestions like a tour guide. The virtual museum was designed as an information system without interactive features for visitors' experience enhancement and engagement. The virtual tour feature adds value to attract physical museums because visitors will still come to physical museums to interact and experience the real museum environment, which is not obtained through virtual museums [19]. Virtual tours will engage visitors to the physical museum for tourism or educational purposes. More features need to be developed and integrated into the virtual museum for the museum's role optimization.

#### B. Machine Learning for Recommender System

Machine learning methods have been applied to various fields such as education, economics, tourism, and cultural heritage. Machine learning models that have proven their effectiveness in the cultural field, especially museums, include K-Nearest Neighbor (KNN), Decision Tree, Random Forest, Neural Network, and Support Vector Machine [11]. Machine learning analyzes user profiles for various application purposes to improve performance, including education [20], economics and industry [21], and socio-culture [11]. An application of machine learning for museums is a recommender system. It is software providing suggestions related to decision making [22]. A recommender system is built to attract tourist visits for the tourism sector. It enables visitors to find what they need in a large museum [23]. Machine learning is applied by analyzing tourist profiles to find destinations that match the profile based on historical data. This method is effective for tourists to find travel destinations easier, especially for unfamiliar tourists with the destinations, products, or tourism services provided. ML classifier used for filtering and recommending a cultural item to explore, such as museums [23], was implemented in a mobile app but did not discuss the ML classifier selection phase. ML was also proven to give suggestions for museum curators regarding the preventive actions to be taken for historical buildings conservation [24]. However, it has no deep discussion on data processing and ML performance analysis. The app has not been built yet for user feedback evaluation, especially for the pandemic situation when users have limited access to the physical, cultural heritage such as the museum, and the climate changes during the pandemic might affect the building.

The museum is one of the exciting spaces for tourism and learning. The museum collections can be thousands, such as in the Sultan Mahmud Badaruddin II (SMBII) Palembang museum, making it is not easy for visitors to find collections

that interest them. Monotonous exhibition rooms, ancient and many collections can make visitors feel bored and not excited exploring the museum virtually by just staring at the screen. The role of the tour guide is needed to provide suggestions for visits to the exhibition rooms that meet the interests of visitors so they continue to explore the museum. They are expected to provide positive sentiment for repeat visits or influence other people to visit the museum. A recommender system can act as a tour guide in the virtual museum. It gives guidance to collections or exhibitions that might interest visitors. The recommender system has been proven effective in improving students' learning achievement [25], [26]. Moreover, the recommender system is expected to enhance visitors' experience in culture education and tourism at the museum.

### III. RESEARCH METHODOLOGY

This research methodology is divided into two stages. The first is evaluating the machine learning model performance, consisting of data preparation, data processing, and performance analysis. The second stage is developing a virtual tour application implementing a machine learning model based on the performance analysis results in the first stage of this research. Fig. 1 illustrates the research methodology.

#### A. Data Preparation

The dataset was developed based on measurement of the research variables related to visitor's profile. Research variables consist of independent variables and a dependent variable. The museum exhibitions interest dependent variable was influenced by 6 (six) independent variables: age, gender, origin, education, occupation, and motivation [27]. This study uses data of visitors' visits to the SMBII museum in Palembang, South Sumatra, during the COVID-19 pandemic. SMBII museum visitors remarkable decrease up to 90% during the pandemic and impact on collected data. This study assumes that museum visitors are only Indonesian citizens. Several methods are used for data preparation. Data collection was conducted using a questionnaire at the SMBII museum.

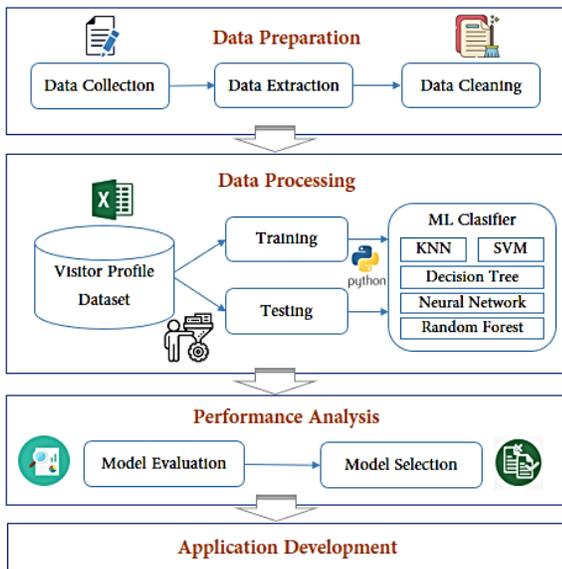

Fig. 1. Research Methodology.

1) *Instrument*: Data were collected utilizing a questionnaire containing several questions related to the visitor's profile. The questionnaire was divided into two parts. The first part contains questions related to the identity of the respondent and the second part relates to the respondent's interest in visiting the SMBII museum. After exploring the physical museum, respondents were asked to choose their favourite or most interesting exhibition room in the SMBII museum. Table II describes exhibition rooms at the SMBII museum.

TABLE II. EXHIBITION ROOMS IN SMBII MUSEUM

Exhibition	Room View
<p><i>Srivijaya Kingdom:</i></p> <p>Display artefacts from the Srivijaya Kingdom, the largest kingdom in Asia</p>	
<p><i>Pre-Palembang Sultanate:</i></p> <p>Display collection on Pre-Palembang Sultanate, a transition era after the Srivijaya Kingdom</p>	
<p><i>Palembang Sultanate:</i></p> <p>Display artefacts collection related to Palembang Sultanate, such as SMBII painting and suit</p>	
<p><i>Colonial:</i></p> <p>Display artefacts related to colonial era such as weapon</p>	
<p><i>Life Cycle:</i></p> <p>Display collection of life equipment used by Palembang society in the past</p>	
<p><i>Art:</i></p> <p>Display collection related to arts and cultures that exist since the Srivijaya Kingdom</p>	
<p><i>Craft:</i></p> <p>Display artefacts of traditional craft such as Songket and the tool to produce it</p>	

2) *Respondent*: Respondents are visitors who visited the SMBII museum during the COVID-19 pandemic. This study uses n = 550 samples with various respondents' profile to build the dataset of museum visitors during the COVID-19 pandemic. Table III describes the demographics of the

respondents to develop this research dataset. After the data collection, the next step is data extraction by performing the tabulation and coding process of the data to be processed quantitatively with the machine learning (ML) model that will be tested in this study. To optimize the results of the ML classification, then the data cleaning was conducted. The possibility of incomplete data, duplication and various noises interfering with the classification process is carried out on the extracted data. The clean data is saved in .csv format with the Excel tool and ready for data processing.

TABLE III. RESPONDENT'S DEMOGRAPHY

Factor	Criteria	Frequency	Percentage
Gender	Male	200	36%
	Female	350	64%
Age	<22	330	60%
	22-30	151	27%
	>30	69	13%

	Undergraduate	254	46%
	Post Graduate	20	4%
Origin	Palembang	414	75%
	South Sumatra	46	9%
	Sumatra	34	6%
	Others	56	10%
Occupation	Student	415	76%
	Teacher/ Lecturer	83	15%
	Employee	41	7%
	Others	11	2%

**B. Data Processing**

The dataset will be processed using some machine learning classifier models to analyze the profile of SMBII museum visitors who visit the museum in the COVID-19 pandemic situation and provide recommendations for exhibitions room that might match the visitor's interests. The dataset is divided into 80% training and 20% testing dataset. The process began with training machine learning classifier models using the training dataset. The classifier is used to classify the visitor's exhibition interest. The classifiers are Decision Tree, SVM, NN, Random forest, and KNN. The testing dataset tests the ML classifier in classifying visitor profiles and predicting interest in visiting museum exhibitions. Furthermore, the performance of the machine learning classifier model is analyzed and evaluated based on indicators of classification effectiveness accuracy, including cross-validation (CV) accuracy and F-Measure [20], [26]. A confusion matrix is also used to visualize the classification performance of ML classifier. Fig. 2 presents the confusion matrix used for the SMBII exhibition rooms interests classification, where P, Q, R, S, T, U, V represent the exhibition rooms in SMBII museum. The machine learning classifier performance indicators for exhibition classification are formulated based on the confusion matrix. Accuracy and the F-Measure formula are shown in equations (1) and (2). Based on the evaluation results of the

classification effectiveness indicators obtained, selecting the best machine learning model is carried out. The selection result will be implemented for exhibition recommendation in the SMBII museum's virtual tour application. The recommendation feature is integrated into the virtual tour application and acts as a tour guide to the user who visits the virtual museum. The effective recommendation will shorten the user's time exploring museum exhibitions minimize the boredom of staring at the screen browsing for collections in museum's exhibitions.

$$Accuracy = \frac{(AA+BB+CC+DD+EE+FF+GG)}{\text{Number of Samples}} \tag{1}$$

$$F - Measure = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{2}$$

where Precision and Recall are measured by using formula (3) and (4),

$$Precision = \frac{1}{7} \left( \frac{AA}{AA+BA+CA+DA+EA+FA+GA} + \frac{BB}{AB+BB+CB+DB+EB+FB+GB} + \frac{CC}{AC+BC+CC+DC+EC+FC+GC} + \frac{DD}{AD+BD+CD+DD+ED+FD+GD} + \frac{EE}{AE+BE+CE+DE+EE+FE+GE} + \frac{FF}{AF+BF+CF+DF+EF+FF+GF} + \frac{GG}{AG+BG+CG+DG+EG+FG+GG} \right) \tag{3}$$

$$Recall = \frac{1}{7} \left( \frac{AA}{AA+AB+AC+AD+AE+AF+AG} + \frac{BB}{BA+BB+BC+BD+BE+BF+BG} + \frac{CC}{CA+CB+CC+CD+CE+CF+CG} + \frac{DD}{DA+DB+DC+DD+DE+DF+DG} + \frac{EE}{EA+EB+EC+ED+EE+EF+EG} + \frac{FF}{FA+FB+FC+FD+FE+FF+FG} + \frac{GG}{GA+GB+GC+GD+GE+GF+GG} \right) \tag{4}$$

**C. Museum's Virtual Tour Application Development**

The SMBII museum virtual tour application was developed in this study. The application development applied the Multimedia Development Life Cycle (MDLC) methodology, which consists of 6 stages (Fig. 3) [28],

Fig. 3. MDLC Methodology.

1) *Concept*: The SMBII museum’s virtual tour application concept is formulated at this stage by concerning the implementation of a machine learning model selected based on machine learning model performance analysis results of visitor profiles for museum exhibition recommendations.

2) *Design*: The design is conducted in line with the formulated concept of the SMBII museum virtual tour application. The design of the interface specifications and the functionality of the application using UML modelling is carried out at this stage. Fig. 4 shows the design of the virtual tour application’s use case model diagram. The design is also carried out on the virtual tour asset content in videos, images, text, audio that will be part of the use case: Gallery, Museum History, and Virtual Tour.

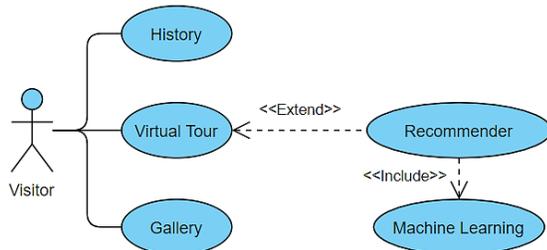

Fig. 4. Use Case Diagram of SMBII Museum’s Virtual Tour App.

The Gallery use case will display information on SMBII museum collections and events. The History use case delivers the historical background of the SMBII museum as a cultural heritage protected by the Indonesian government, and the Virtual Tour use case allows users to explore the museum virtually from 360-degrees views. The Recommender use case is extended in the virtual tour use case. This use case includes machine learning to classify the exhibition room that interests visitors as a basis for recommendations given to visitors to quickly find the exhibition room that might match their interests to explore.

3) *Material collecting*: Multimedia has been designed and constructed utilizing various appropriate tools then collected for integration in the SMBII museum’s virtual tour application environment. Table IV describes specific tools that must be prepared for data acquisition of asset content of the virtual tour app.

4) *Assembly*: The assembly is carried out on each virtual tour’s asset in various file formats collected in the previous stage into a virtual tour application that users can run and access. The virtual tour app in this study is designed to be web-based, which makes users can use a browser to run a virtual tour of the SMBII museum without doing the application installation process.

5) *Testing*: Testing is carried out on the SMBII museum’s virtual tour application to ensure each feature successfully carried out its functions as expected, including the machine learning-based exhibition recommender feature. The System Usability Scale (SUS) test was carried out to measure the level of usability of the recommender feature applied to the SMBII museum’s virtual tour application by taking  $n = 15$

respondents. The samples  $n$  were proven effective in generalizing the test results. The samples  $n$  were proven effective in generalizing the test results [29]. Fig. 5 presents the rating of usability based on the SUS score.

6) *Distribution*: After passing the testing stage, the application is uploaded to the server so that the public can widely use it via the internet to explore Palembang’s cultural heritage virtually through the SMBII museum’s virtual tour application, which provides machine learning-based exhibition recommendations. This recommender feature provides an alternative tour guide for visitors to explore the exhibition room that matches the interest of the SMBII museum’s visitors.

Not Acceptable	Acceptable	Excellent

Fig. 5. Rating of SUS Score.

#### IV. RESULT AND DISCUSSION

The final output of this research methodology is the SMBII museum’s virtual tour application that effectively applies a machine learning model for museum exhibition recommendations. The selection of the ML model was based on the evaluation results of several ML classifier models’ performance that were tested using the SMBII museum’s visitor profile dataset built in this study.

##### A. Dataset

The dataset contains 550 SMBII museum visitor’s records consisting of data fields: age, gender, origin, education, occupation, motivation, and exhibition, representing research variables. Each variable can be related that affects the other. This study designed the exhibition variable as the dependent variable and the other six variables as independent variables. A heatmap diagram in Fig. 6 illustrates the correlation value between variables in the data set. The correlation score ( $r$ ) is in the range of  $-1 < r < 1$ , which indicates the strength of the relation between the two variables. The closer the  $r$  score is to 1, the stronger the relationship with a positive or negative impact [10].

In this study, the positive and negative signs are ignored for the numbers from the data do not indicate the numeric level but rather the label of the data coding results in the data extraction process for a quantitative approach to data processing. From the illustration in Fig. 6, it is known that the variables that have a high impact on visitors’ interest in the exhibition space are gender, origin, and occupation variables, with the strongest correlation being the education variable where  $r = 0.16$ . The

educational background of visitors gives the most substantial impact in determining the interest in the exhibition room, which is also influenced by the motivation variable where  $r = 0.14$ . The visitor's education is high school and undergraduate in average came to visit a museum with the motivation of educational purposes for study or doing assignments, which is 74% (Fig. 7) with interest in the Srivijaya Kingdom exhibition room as much as 24% and the Palembang Sultanate exhibition room 34% of visits (Fig. 8). The two exhibition rooms present a collection of culture and history regarding the city of Palembang as the oldest city in Indonesia.

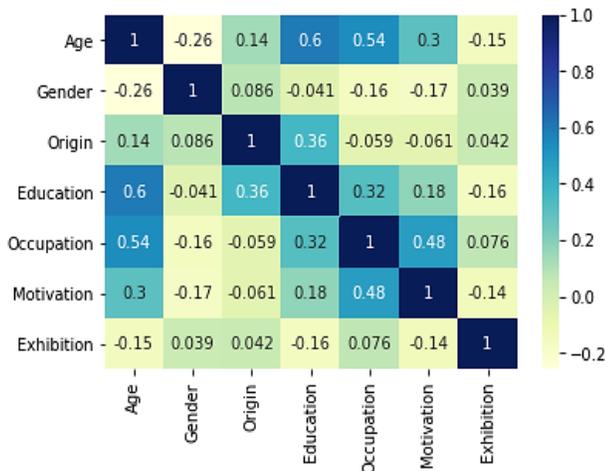

Fig. 6. Data Correlation Heatmap.

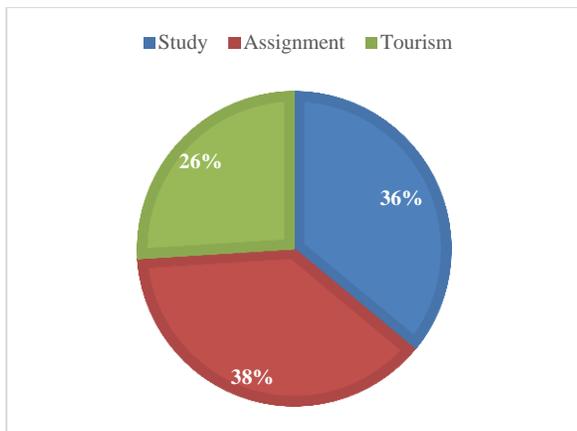

Fig. 7. SMBII Museum Visitors' Motivations.

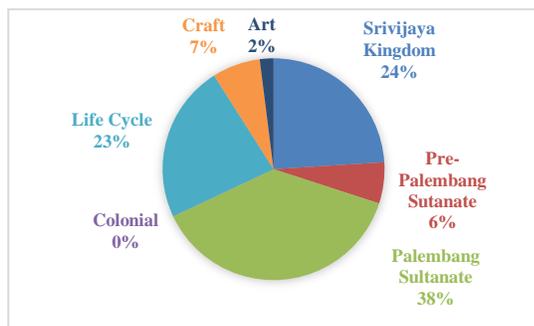

Fig. 8. Visitors' Exhibition Rooms Interests in SMBII Museum.

### B. Machine Learning Evaluation for Exhibition Recommendation

Evaluation of the machine learning model for the classification of visitors' interest exploring exhibition rooms in the SMBII museum is used to select the best model applied to the exhibition recommender feature for museum visitors through the virtual tour application developed in this study. Evaluation is carried out on the value of cross-validation accuracy and F-Measure of each machine learning model as an indicator of model performance using a dataset divided into training and testing data. Table V presents the evaluation results based on the cross-validation accuracy and F-measure indicators. Fig. 9 illustrates a graphical comparison of the performance levels of the ML classifier model evaluated in this study. Based on these results, it is known that the best model for classifying exhibition room interest in the SMBII museum based on visitor profiles is KNN with CV accuracy = 89.09% and F-Measure = 90.91%. The RF method also has high accuracy with a difference of 0.18% but a lower F-measure of 0.91%. F-measure scores were obtained based on precision and recall values using different testing data.

Cross-validation accuracy uses data that allows the same training at testing. Therefore, F-measure can show the level of accuracy when the model is used to predict or provide exhibition recommendations that match the interests of visitors to the SMBII museum. The confusion matrix shows the prediction accuracy by calculating the results of true and false predictions. It is illustrated in Fig. 10. It shows a hundred samples of testing data were true predictions. Ten samples were false predictions where the labeled-3 is the most correctly predicted, namely the Palembang Sultanate exhibition room, the favorite exhibition for visits in SMBII museum. The final selection stage determines the KNN model with the best performance for the exhibition recommender feature included in the SMBII museum's virtual tour application.

TABLE V. MACHINE LEARNING MODELS PERFORMANCE FOR CLASSIFICATION OF VISITORS' EXHIBITION ROOM INTERESTS

Classifier	Accuracy	F-Measure
KNN	89,09%	90,91%
DT	86.55%	90,00%
NN	77.64%	73.64%
SVM	53.09%	53.64%
RF	89.27%	90.00%

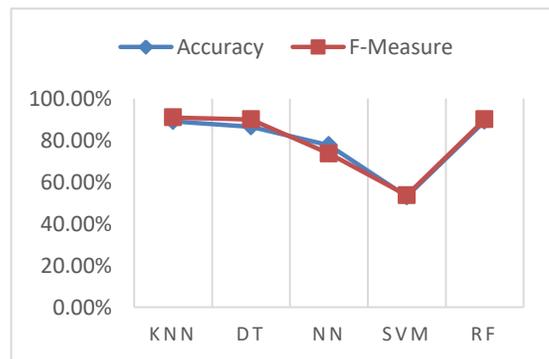

Fig. 9. Machine Learning Models Performance Comparison Visualization.

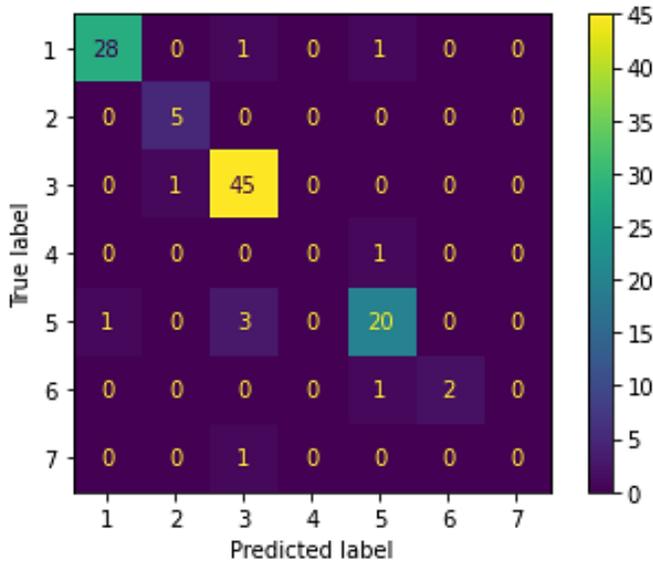

Fig. 10. Confusion Matrix of Data Testing Results.

### C. Exhibition Recommendation in Virtual Tour Application

The SMBII museum's virtual tour application was constructed utilizing 3D Vista software. The app enables users to explore the virtual museum like the physical museum with 360-degree views. Fig. 11 is the home page design of the SMBII museum's virtual tour app, which is run on a browser,

There is a tour recommender feature for visitors unfamiliar with the SMBII museum exhibition rooms on the home page. It is Pemandu Pintar (or Smart Guide) feature menu. This feature aims to help visitors find exhibition rooms and collections that are expected to match the interests of users as museum visitors who come with various demographic and motivational backgrounds, including studying, doing assignments, or tourism. Fig. 12 illustrates the interface design of an exhibition recommender feature that applies machine learning to suggest an exhibition room that might match user profiles. The user can input their profile, and then the app processes it by performing the KNN classifier. The machine learning result is presented to the user as a recommendation for starting exhibition room touring from the most interest for visitors predicted by machine learning model (Fig. 12). Users may decide to follow the given exhibition recommendation or explore the museum from the virtual museum entrance. By following the exhibition recommendation given by the machine learning classifier, users will be directed to the recommended exhibition room and then independently explore each corner of the room in 360-degrees views (Fig. 13).

An evaluation was conducted on the usability of the machine learning-based SMBII museum exhibition recommender feature in a virtual tour application. The respondents for SUS testing in this study consider variables with a strong correlation score,  $r > 0.1$ , on exhibition where there are independent variables: age, education, and motivation. Therefore, some samples are taken in portions based on the variable's value with the highest  $r$  score, namely the education variable, while the other variables are taken randomly. The number of samples  $n = 15$ , the minimum size of

samples is obtained for SUS testing and contains all education variable values. Table VI represents the SUS scoring results. Based on these results, it is known that the average SUS score for the exhibition recommender feature is 85.83, which can be categorized as excellent acceptable [30]. This score shows that the exhibition recommender feature implementing the best machine learning model for museum visitor profile analysis, KNN, has a good usability value to meet user needs for exhibition recommendation through SMBII museum's virtual museum application.

TABLE VI. SUS SCORING RESULTS

Respondent ID	Education	Age (years)	Motivation	SUS Score
1	High School	13	Assignment	95
2	High School	13	Assignment	95
3	High School	14	Assignment	67.5
4	High School	14	Assignment	67.5
5	High School	14	Assignment	95
6	High School	19	Study	95
7	High School	19	Study	100
8	High School	20	Study	87.5
9	Under Grad	25	Study	72.5
10	Under Grad	27	Tourism	67.5
11	Under Grad	28	Tourism	80
12	Under Grad	33	Tourism	70
13	Under Grad	37	Tourism	100
14	Post Grad	39	Study	95
15	Post Grad	41	Tourism	90

#### D. Limitations and Contributions

The developed SMBII museum virtual tour is assumed to be only intended for visitors to Indonesian citizens, so the dataset used has limitations, namely on regional origin and occupation factors. The profiles of the respondents of the developed dataset are dominated by museum visitors from Palembang city who were students. The situation of the COVID-19 pandemic is a reason for the small number of visits to the SMBII museum, so not much data has been collected for variations of visitor profiles. The dataset will affect ML's ability to predict visitor interest in the museum exhibition room. The more varied the data used for training, the better ML's ability in testing, especially for SMBII museum exhibition recommendation. It is necessary to add a variety of datasets to improve ML performance for predictions and recommendations of museum exhibition in the SMBII virtual museum tour application. In addition, it needs to test the ML classifier model for different datasets. The SMBII Museum is a cultural heritage that stores various collections of cultural objects. It is necessary to test whether the KNN method is still the best to recommend a visit to an exhibition if the museum presents collections other than cultural objects, such as history, art, and others.

Hopefully, a recommendation that matches visitors' interests in the museum's exhibition can provide convenience in exploring and enjoying the presentation of the museum's collections for learning and tourism purposes while reducing boredom in exploring the monotonous virtual exhibition room and making it less attractive to visitors. Visitors can quickly find the exhibition offerings that match their interests. The findings of this study can be a baseline for determining an effective ML method to be applied in an intelligent virtual tour application of a museum as a strategy to increase museum visits and enable educational and tourism roles in the COVID-19 pandemic. The recommendation feature that implements ML has proven effective in making it easier for visitors and is expected to reduce boredom in exploring the virtual museum.

#### V. CONCLUSION

This study evaluates the machine learning model for exhibition recommendations given to visitors through virtual tour applications based on user or visitor profiles. The machine learning-based recommender feature in the virtual tour application will act as a tour guide that gives suggestions to the exhibition room, which might interest the museum's visitors. The best machine learning model was selected based on its performance assessed based on the cross-validation accuracy and F-measure scores. The dataset of visitor profiles consists of the exhibition variable as the dependent variable, and the independent variables are age, gender, origin, education, occupation, and motivation. The results of the correlation analysis show that the motivational variable has the strongest correlation to exhibition interest with a score of  $r = 0.16$ . The dataset is then processed using the machine learning model to classify the exhibition room interest based on the profile of visitors to the SMBII museum, namely the KNN, DT, NN, SVM, and RF models. Based on testing results, it is known that the best machine learning model for classifying interest in visiting the SMBII museum's exhibition room is the KNN model with cross-validation accuracy = 89.09% and F-Measure = 90.91%. These results indicate that the machine learning model effectively predicts the interest in the SMBII museum's exhibitions room and can be applied to provide recommendations for virtual museum visitors.

The SMBII museum's virtual tour application applied the KNN method for the recommender feature of the museum's exhibition was developed using MDLC methodology. For usability evaluation, SUS testing was conducted to evaluate the usefulness of the exhibition recommendation features in the application. The testing results obtained the average SUS score = 85.83, which indicates that the recommender feature in the virtual tour application is acceptable for the user. This feature makes users easily find exhibition rooms that match their interests and explore interactive museum spaces, reducing boredom in exploring museum exhibitions with lots of rooms and thousands of historical and ancient collections, especially for millennial students. Based on the SUS scores can also be concluded that the machine learning based exhibition recommendation is easy to be used and is expected to attract public interest in visiting museums that increase museum visits for educational or tourism purposes, especially during the COVID-19 pandemic.

**Abstract**—One of the most common bone diseases in humans is osteoporosis, which is a major concern for the public health. Osteoporosis can be prevented if it is detected at an early stage. The research agenda consists of two phases: pre-processing of X-ray images of the spine and analysis of texture features from trabecular bone lumbar vertebrae L1-L4 for detecting osteoporosis. The preprocessing involves image enhancement of texture features and co-register the images in order to segment the L1-L4 regions in the lumbar spine. Range filtering and Pyramid Histogram of Orientation Gradient (PHOG) are used to analyze texture features. Input images are filtered with a range filter to adjust the local sub range intensities in a specified window to detect edges. Then a PHOG algorithm is designed to determine both the local shape of an image texture and its spatial layout. Based on texture features of lumbar vertebrae L1-L4, classify them as normal or osteoporotic using neural network (NN) models with L2 regularization. In an experiment, X-ray images and dual-energy X-ray absorptiometry (DXA) reports of individual patients are used to verify the system. DXA reports describe a statistical analysis of normal and osteoporotic results. However, the proposed work is categorized according to the texture features as normal or osteoporotic. 99.34% classification accuracy is achieved; cross-validation of these classified results is done with the DXA reports. Diagnostic accuracy of the proposed method is higher than that of the existing DXA with X-ray. Further, the area under the Receiver Operating Characteristic (ROC) curve for L1-L4 had a significantly higher sensitivity for osteoporosis.

**Keywords**—Cross validation; image enhancement; lumbar spine; lumbar vertebrae; neural network; osteoporosis; PHOG; regularization; trabecular bone; texture features; x-ray images

## I. INTRODUCTION

Osteoporosis is a disease which affects the density and strength of bones. A bone's density is the amount of bones (bone mineral density-(BMD)), while its strength (quality) is the fibers in the bones. Osteoporosis leads to weaker, more porous and more brittle bones, as well as a greater risk of fractures [1]. This paper proposed an efficient model for

assessing osteoporosis in the lumbar vertebrae L1-L4 using L2 regularized neural network. The model consists of two parts, first part of the system is a pre-processing of an X-ray spine image in order to visualize the fine textures of the trabecular micro architecture of L1 - L4 vertebrae using the following steps: initially, the X-ray image needs to be enhanced by improving the visual quality, and then, the input images need to be aligned into the same plane by using co-registration, and finally, segment the image. As part of the segmentation process, the primary objective is to determine the region of interest (ROI) in the image, namely between the L1 and L4 vertebrae, in order to improve the actual segmentation. As illustrated in Fig. 1, the second part of the system uses PHOG texture features to detect osteoporosis in the L1-L4 lumbar vertebrae using NN with L2 regularization in order to classify normal and abnormal images.

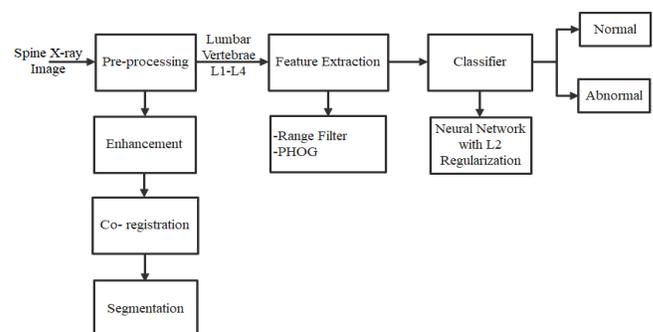

Fig. 1. An Overview of the System Model.

This paper makes the following contributions: The proposed technique for the detection of osteoporosis in the lumbar spine (L1-L4) is described in Section I. Section II outlines the related work of other methods that have been developed so far. The Section III Database detail description is used to test the system. A preprocessing stage was described in Section IV to improve image quality. An in-depth discussion of image texture feature extraction was presented in

Section V. NN networks are regularized by L2 in Section VI, used as a classifier. The Section VII presents a detailed simulation study and discussion. The final Sections VIII and IX of the report summarize the proposed system and the future work required to improve its performance, respectively.

## II. RELATED WORK

Osteoporosis is a disorder in which there is a loss of bone mass and abnormally degenerated bone architecture, especially, hips, spine, and wrist, known as osteoporosis [2]. Among osteoporotic fractures, spine fractures are the most common and are a major health concern among the elderly. Consequently, osteoporotic fractures require early diagnosis of patients at high risk. Typically bone density scans are used to detect osteoporosis, among which the dual energy X-ray absorptiometry (DXA) is considered as a common technique to measure bone size and bone mineral density (BMD). Various studies that deal with BMD measurements have been conceded by analyzing image texture features using an X-ray's. An easy and inexpensive method for diagnosing osteoporosis has been proposed based on analysis of image texture features using X-rays. In conjunction with a machine-learning algorithm, a fractal model was utilized to develop the software, using pixel variations for grey levels[3] . An osteoporosis patient's bone structure value (BSV) is estimated from BMD using spine radiograph images. It is necessary to conduct further studies to determine BSV's potential to be a reliable assessment of treatment effects and future fracture risk in individuals with osteoporosis and those without it. The first group had 83 patients treated for osteoporosis alone, while the second group had 76 patients treated for both osteoporosis and lumbar spinal stenosis (LSS) [4]. The T-scores over the first year as well as after a year, two years, and three years were confirmed. Two groups were compared on mean BMD and changes in BMD over three years. In addition, three-year BMD improvements were evaluated along with their relationship to initial BMD change and related factors. Study participants were given ibandronate dose for newly diagnosed osteoporosis, so LSS was examined for its effect on BMD. The study was focused only on whether LSS could improve bone mineral density in the treatment of osteoporosis, clinical outcomes related to osteoporosis treatment, such as osteoporotic fractures, were not assessed in the follow up. An alternative approach to determining the extent of bone loss caused by osteoporosis is fractal analysis when studying spinal CT (computed tomography) images [5]. Based on the results of the study and the K-NN (K-Nearest Neighbor) classifier, a computerized system based on CT images could assist physicians in making initial diagnoses in difficult cases. Overall the system provides 81% classification accuracy; an alternative method is required to improve the system performance. By using the Picture Archiving and Communication System (PACS), the lumbar vertebra was measured in QCT (Quantitative computed tomography) and the HU (Hounsfield unit) of its vertebral body in conventional CT [6,7]. The correlation between the T-score of conventional CT and the T-score of QCT was estimated using a multiple regression algorithm. Further, a logistic regression algorithm was applied to predict osteoporotic and non-osteoporotic vertebrae. With QCT data, the predictor modeling algorithm

estimated similar T-scores. In HU, similar results are observed as with QCT, with the exception of one osteoporotic vertebra that did not demonstrate discordance with an accuracy rate of 92.5% was recorded. The predictive accuracy will improve with more collected data. The purpose of study is to find out whether recurrent neural networks are capable of predicting osteoporotic fractures by analyzing spine images [8]. It explores the best design directions for such prediction models by experimenting with various network architectures. Transfer learning gives the advertised benefits, such as faster training speeds and greater suitability for larger datasets. By segmenting and finding vertebral edges, can diagnose the compression and locate the anomaly using Morphometric features and measurements using CT images [9,10]with 88.3% accuracy. There are challenges involved in finding the midpoint in the vertebral body and passing it to the next closest midpoint on the vertebral body boundary to analyse 3D textures, extracted the gray-level co-occurrence matrix Haralick, Wavelets (WL), local binary patterns (LBP), histogram of gradients (HoG), and harmonic alternator patterns (HAR) [11]. The texture-features and vBMD data extraction, fractured vertebrae were excluded. An assessment of prevalence of osteoporosis fourfold cross-validation was conducted to evaluate vertebral fractures. There is a correlation between vertebral level parameters and classification results. Mark-Segmentation-Network and Bone-Conditions-Classification-Network are used to analyze diagnostic CT images to automatically detect bone conditions [12]. The system achieves receiver operating characteristic curve area of 0.9167 and accuracy of 76.62%. Feature extraction from lumbar vertebra CT images as well as other clinical characteristics might be relevant to the diagnosis of the bone condition to improve the system performance. As compared with the traditional Osteoporosis Self-Assessment Tool for Asians (OSTA) model, the ANN, SVM, RF, and LoR models performed significantly better in both men and women [13].

## III. DATABASE DETAILS

According to Table I, 80 numbers of samples are used in the process of developing the proposed system. Initially Digital X-ray images of the lumbar spine (lateral view) are taken for processing. Dr. A Ramalingaiah, Orthopedic, provided the images from Abhilasha orthopedic hospital in Banashankari at No.271,3rd Stage, 5th Block, 100ft Road, Bangalore; the lumbar spine of 80 subjects in 2D, JPEG format. An experiment has been conducted to test the system by collecting 20 control subjects (normal) as well as 60 pathological (osteoporotic or abnormal) X-ray images, as well as DXA reports on the same people. In the DXA report, the L1-L4 lumbar spine statistical analysis status details are provided for each person.

TABLE I. RAW DATA BASE

Lumbar spine X-ray image	No. of Subjects (80)	DXA reports (80)
Controlled Subjects (Normal)	20	20
Osteoporotic Patients	60	60

Among 80 subjects, the segmentation algorithm correctly considers 18 (normal) out of 20 and 58 out of 60 (abnormal), which means  $18+58=76$ . A total of 304 ROI images of lumbar spine images (L1-L4) are extracted from each subject, and  $18 \times 4 = 72$  and  $58 \times 4 = 232$  results in 304 ROI images.

#### IV. PREPROCESSING STAGE

In the preprocessing stage, an adaptive histogram equalization (AHE) and a co-registration are used to obtain L1-L4 region of interested sub images with enhancement.

##### A. AHE
