An image enhancement technique is adapted in this proposed work to provide a more interpretable image, for better quality input to the next phases of the work. A contrast-limited (CL) AHE process is used to enhance the contrast of grey scale image. Rather than processing the entire image, CLAHE focuses on small regions ( $8 \times 8$ ) of it, called tiles. Divides an image into a number of rectangular contextual regions. It calculates for each region independently by AHE. By enhancing the contrast of each region, the output histogram approximates by the distribution of its parameters. The Rayleigh distribution is used to create a contrast transform function, which depends on the input image type. Using this distribution, imagery appears more natural. Bilinear interpolation [14] is then used to combine the neighbouring blocks, eliminating artificial boundaries. Contrast can be reduced in homogeneous areas to prevent noise from being amplified. With clip-limit (0.01), further prevent the oversaturation of homogeneous areas of an image. In such areas, the histogram of an image is dominated by a high peak because many pixels are within the same gray scale range. The spine lateral view enhanced image (b) and the input image (a) as shown in Fig. 2.

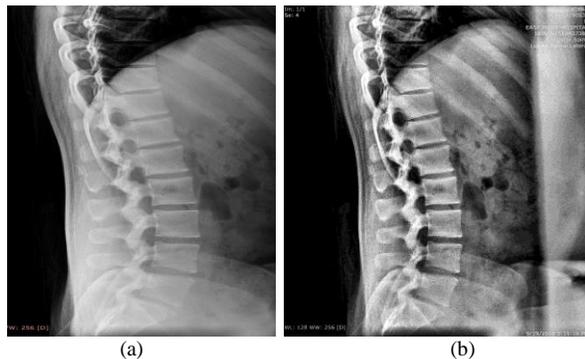

Fig. 2. (a) Input Image (b) Enhanced Image.

The algorithm-1 comprises into three major components in CLAHE: tile generation, histogram equalization, and bilinear interpolation.

---

##### Algorithm 1

Input:  $M \times N$  image, output: Enhanced image

1. Sections (sub image) are divided in the input image. These sections are referred to as tiles of  $N \times N$ .
  2. Obtain the histogram distribution for each tile.
  3. Minimum and maximum values are found through binary search based clipping [15] in the distribution and clipped portions are redistributed.
  4. In the next phase, bi-linear interpolation is carried out to combine the neighbouring blocks. The resultant one is an
- 

enhanced image with greater contrast.

5. The entropy [16]  $H$  is calculated using (1)

$$H = -\sum (h_c \times \log(h_c)) \quad (1)$$

In this case,  $h_c$  is the histogram counts.

6. Ensure  $N \leftarrow N + 2$ .

7. In order to measure the entropy  $H_{i+1}$  of the contrast-enhanced image, Where  $i = 1, \dots, N$  repeat steps 2 through 5 with a new window size.

8. If  $H_{i+1} < H_i$  stop, otherwise repeat  $N < 8$ .

9. It is certain that the enhanced image with the largest  $H$  value will also have better quality, and enhanced image is obtained at the output.

10. According to the experimental results, binary search has been shown to be an effective algorithm in terms of clipping and redistributing the pixels.
- 

##### B. Co-registration

Several biomedical imaging applications require the co-registration of images. The images may be obtained from the same sensor or from different sensors, and the spatial resolution might be the same or different. During co-registration, all images in the series are aligned spatially so that any feature in one image overlaps as well as its footprint in every other image [17,18]. An image is typically selected as the reference to which all other images are aligned during co-registration. The best reference image can be selected from the database, which contains all the features of lumbar spine lateral view. The co-registration process involves identifying common features in the reference and warping the other images that is the ones to be co-registered [19]. In the process, tie points are used to determine the locations of common features. The warped image is aligned to the reference using a polynomial function after enough tie points have been generated.

In Fig. 3, an example of the output of a co-registration process as illustrated. In part (a), the reference image is the normal image that all the target images are aligned to the same feature plane; the target image (b) does not resemble the reference image, as it represents osteoporosis; c) is overlaid image of R and co-registered, the co-registered image is completely aligned with the reference image using Geoscience extended flow optical lucas- kanade iterative (Gefolki) is a co-registration software [20,21]; overlays R and C in different colour bands to form a composite RGB image. A grey region indicates the same intensity of the two images in the composite image. Magenta and green colour regions indicate differences in intensities. (d) An image co-registered with the R image that shows the exact alignment of the T features.

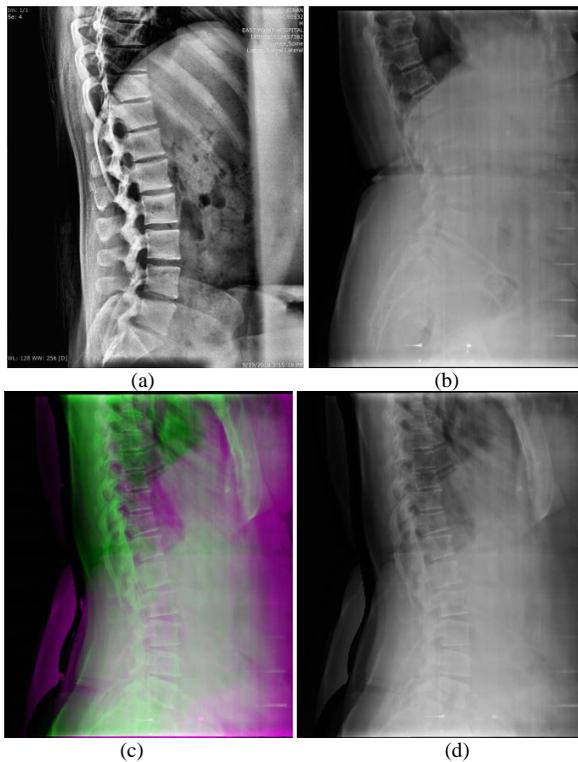

Fig. 3. (a) Reference (R) Image (b) Target (T) Image (c) Overlaid R and Co-Registered (C) Image (d) Co-registered Image.

#### Algorithm 2

A pixel alignment of two images can be divided into three steps: initialization of input image R and T of the same size, calculation of GeFolki flow, and resampling.

1. Homothety, rotation and scaling is used to make size of T to size R, denoted as T'.
2. GeFolki flow, the transfer from coordinates of T' to R by a matrix W.
  - W is composed of the y-displacement component (column) and the x-displacement component (row) for applying on the T' image.
  - In the software, GeFolki function takes as arguments T', R, and parameters, with order as radius = 64; -8:16, level = 4, iteration = 5, contrast\_adapt=false, and rank=4 as parameters.
  - A variety of radius sizes can be tested iteratively; it is a decreasing vector starts from biggest (64) radius to the smallest (16) one in steps of 8. The algorithm is more robust when the radius is large. Radii must be selected as small as possible when the flow on the image changes rapidly.
  - For the purpose of finding large displacements, create a pyramidal structure of the down sampled images in different levels. In a pyramid, the number of levels affects the size of the movements.
  - The total number of iterations required to run the gradient method for the minimum search.
  - Set contrast\_adapt is false for homogeneous images to look contrast inversion.
  - Changing the intensity value of T' with lower rank of pixel in the neighborhood within the specified window size (9×9).
3. Finally, transform the T' image to superimpose it with the R image. By resampling the image on a new coordinate grid, this operation creates the flow matrix W. Resampling is done using bilinear interpolation.

#### C. Region L1-L4 Sub Image Selection

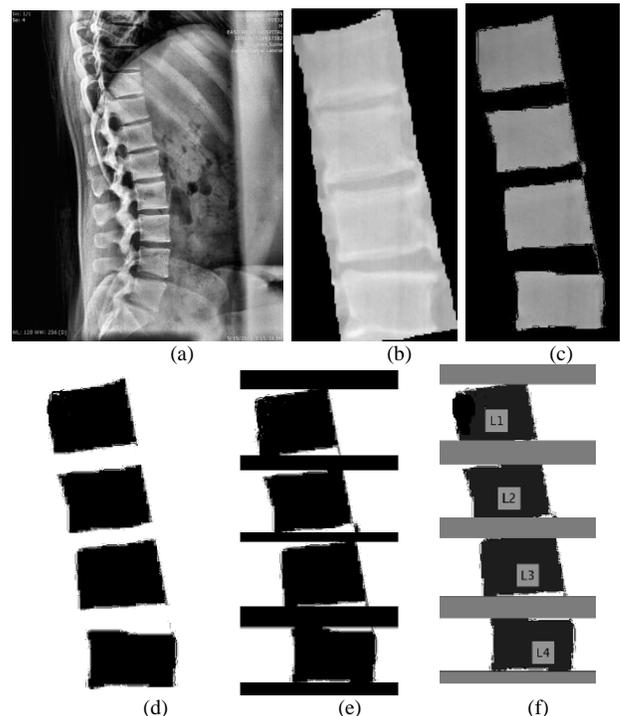

L1-L5 are the five vertebrae that make up the Lumbar Spine. As the largest vertebrae in the body [22][23], the lumbar spine bears the most weight. In contrast to the thoracic spine, Lumbar spines region have more range of motion.

There is limited rotational movement in the facet joints of the lower back. In this work L1-L4 is the region of interested subimage. An illustration of the interested region selection process is presented in Fig. 4 of (a)–(g) and explained in Algorithm 3.

#### Algorithm 3

1. The lateral spine view X-ray images are read from the input.
2. Obtain the border coordinates of the freehand drawn region from L1-L4, and divide the result by an array of 2-dimensional matrices that is subimage
3. Using the subimage object, produce a binary image mask.
  - It returns a mask that is associated with the subimage object B over the target image.
  - The target image must be contained within the same axes as the subimage.
  - Mask is a logical image the same size as the target image.
  - Mask is false outside the region of interest and true inside.
  - Multiplied mask with the input image to produce segmented L1-L4 region.
4. Create the inverted binary image from segmented image  
 segmented image pixels >255;  
 Seg\_inv=0;
 

```
else
Seg_inv= segmented image;
make it into a proper binary image for foreground
Inv_binary_im = Seg_inv < max (Seg_inv (:))/2;
```
5. Create the isolated L1-L4 image with equal distance and equal image size
  - find the bar rows  
 bar\_rows = sum (Inv\_binary\_im, 2) > 0.9 \* size (Inv\_binary\_im, 2);
  - make a bar image  
 im\_bars = false(size(Inv\_binary\_im));  
 im\_bars (bar\_rows, :) = true;
  - remove the bars from the image  
 im\_nobars = Inv\_binary\_im & ~im\_bars;
6. Label each lumbar vertebrae by finding its centroid.
7. Select only the connecting pixels on the ROI images for L1, L2, L3, L4.

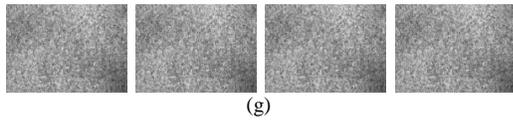

Fig. 4. Interested Region Selection Process (a) Original LS view Image (b) Cropped Image (c) Segmented Image (d) Inverted Binary Image (e) Isolated L1-L4 Image (f) Labelled Image (g) ROI Image of L1, L2, L3, L4.

## V. FEATURE EXTRACTION

The feature extraction process involves two stages; Range filter and PHOG. The range filter is used to adjust the local sub range intensities within the specified window size of  $3 \times 3$  neighborhood pixels in the input image. In a local sub-range the pixels are analyzed according to their statistical range to detect edges.

The PHOG objective is to determine the local shape of an image texture and its spatial layout. By considering the orientations of edge distribution within the sub-image as well as the spatial arrangement, the image is tiled into regions at multiple resolutions to obtain texture features.

### A. Range Filter

It operates on morphological utilities such as dilation and erosion of the image to regulate the maximum and minimum pixel values in the specified window [24]. Subsequently, it utilizes the padding operation on these morphological utilities. In Fig. 5, (a) the input and its corresponding histogram are clearly visible, showing the right-hand side of the histogram occupied by the input image and (b) the filter output and its histogram shows that the pixel ranges are narrowing by connecting local neighbors as edges, which reveals more defined texture in the image. In Fig. 6(a) and (b), the range filter response is shown for an abnormal image. A normal and abnormal image can't be distinguished by looking at them. Range filtering connects local neighbors as edges to narrow the histogram of the input.

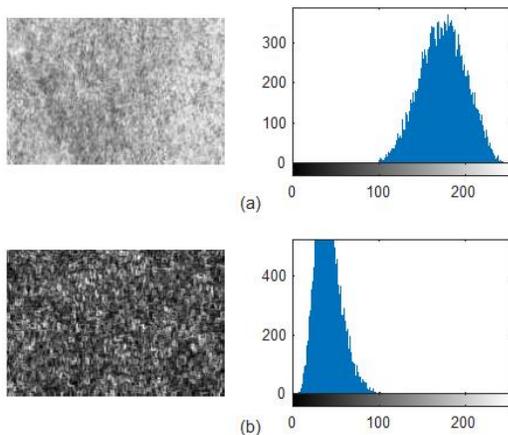

Fig. 5. Range Filter response for Normal Image (a) Input and Histogram (b) Output and Histogram.

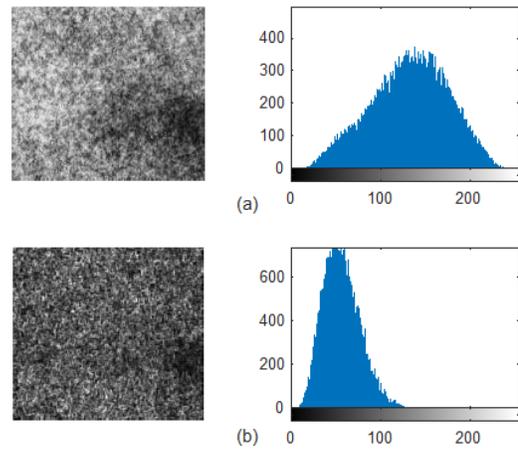

Fig. 6. Range Filter response for Abnormal Image (a) Input and Histogram (b) Output and Histogram.

### B. PHOG

By extracting pyramid histograms of oriented gradients (PHOG) from the image are useful to discriminate between normal and abnormal texture features. It was first presented in [25]. Using HOG, a range filter response image can be divided into small cells, HOGs for each cell are computed, normalized with block patterns, and each cell is given as a descriptor [26]. HOG features describe the outline and local structure appearance in the image by describing their distribution of intensity gradients. Using this method, intensity invariance is maintained by counting the appearance of gradient orientations. A descriptor is generated in four main steps:

- Computation of gradients and orientation.
- Bin Orientation.
- Block descriptors.
- Normalization of blocks.

1) *Computation of gradients and orientation*: In the first step, when an image sample is provided,  $f(i, j)$ , then the magnitude of the gradient,  $M(i, j)$ , and angle,  $\theta(i, j)$ , can be obtained using (2) and (3) by considering the pixel difference.

$$M(i, j) = \sqrt{(f(i+1, j) - f(i-1, j))^2 + (f(i, j+1) - f(i, j-1))^2} \quad (2)$$

$$\theta(i, j) = \tan^{-1} \left( \frac{f(i, j+1) - f(i, j-1)}{f(i+1, j) - f(i-1, j)} \right) \quad (3)$$

Histograms of orientations generated by gradients of samples within a region around the centered point are called orientation histograms. Histograms of orientations are divided into eight bins, each covering 360 degrees. In the histogram, samples are weighted according to their gradient magnitude.

2) *Bin orientation*: In the second step of the calculation, the cell histogram is created. The algorithm assigns a weighted vote to each pixel within each cell depending on the values found in the gradient calculation and its orientation. Depending on whether the magnitude gradient and its orientations from 0° to 360°, the histogram evenly distributed over 0° to 180° or 0° to 360°. The optimum number of bins in the histogram are considered as 8 bins as mentioned in [27]. Various bin number will be tested in this paper experimentally.

3) *Block descriptors*: For gradient strength to be normalized locally under different illumination conditions, cells must be organized into larger with the spatially connected blocks. HOG descriptors are then constructed as concatenated vectors of corresponding normalized cell histogram components compiled from all block regions. Each cell contributes to the final descriptor more than once if these blocks overlap. Block geometries consist of two main types: the rectangular R-HOG block and the circular C-HOG block. There are three parameters that characterize R-HOG blocks: the number of cells per block, the number of pixels per cell, and channel per cell histogram. Each R-HOG block is computed at one scale, but with an orientation not aligned. As well as encoding spatial form of information, R-HOG blocks are used. There are two types of circular HOG blocks (C-HOG): those with a single central cell and those with angularly divided central cells. The C-HOG blocks can be defined by four other factors: center bin radius, the additional bins radius expansion factor, and the number of radial bins. Shape context descriptors are similar to C-HOG blocks in appearance, but they differ greatly because they contain multiple orientation, whereas single edge presence count are used to formulate the shape contexts.

4) *Normalization of blocks*: Gradient magnitude varies greatly over a wide range due to variations in pixel intensity on a local level [28]. Therefore, effective local contrast normalization is essential for good performance. They typically involve separately normalizing each block of cells after grouping them into blocks and normalizing of each block is obtained by using L1-norm and L2 -norm illustrated in (4) and (6). L1- norm is defined as the sum of the vector's absolute values and L2 -norm as a square root of the sum of all squared vector values. Consider a non-normalized vector  $v_b$  which contains all histograms in a given block,  $\|v_b\|_k$  be its k-norm of the vector for  $k=1$  (L1-norm) and  $k=2$  (L2-norm) and  $e$  be the normalization constants should be small to prevent division by zero.

$$v_{b_{L1}} = \frac{v_b}{\|v_b\|_1 + e} \quad (4)$$

Square root of  $v_{b_{L1}}$  is described in (5), by using the Bhattacharya distance between pixels, descriptor vectors can be represented as a probability distributions.

$$\text{Square root of } v_{b_{L1}} = \sqrt{\frac{v_b}{\|v_b\|_1 + e}} \quad (5)$$

$$v_{b_{L2}} = \frac{v_b}{\sqrt{\|v_b\|_2^2 + e^2}} \quad (6)$$

L2- hys: By attenuating the maximum pixel values of  $v_b = 0.2$ . Renormalizing, hysteresis thresholding can be achieved for L2 norms [29]. Renormalize the univariate feature vector so the values in each are no larger than 0.2. This will limit the effect of large gradient magnitudes. As a result, it is less important to match the magnitudes for large gradients, while the distribution of orientations is more important.

Determine the HOG for Level-0 that indicates for entire image as shown in Fig. 7(a). Throughout the entire HOG operation,  $N=8$  bins are fixed. Each bin in the histogram represents how many pixels fall within a certain range of angles. In the next step, divide the image into four blocks, and compute HOG for each block as shown in Fig. 7(b). Repeat the process recursively until the depth  $L=3$  as shown in Fig. 7(c) and (d). Several levels of pyramids are used to divide the input image, histogram composed of  $N$  bins, and Level-0 is characterized by a  $N$ - vector. An image with Level-1 is described as a  $4 \times N$ -vector. The PHOG descriptor represented using (7).

$$D_{PHOG} = N \sum_{l=0}^3 4^l \quad (7)$$

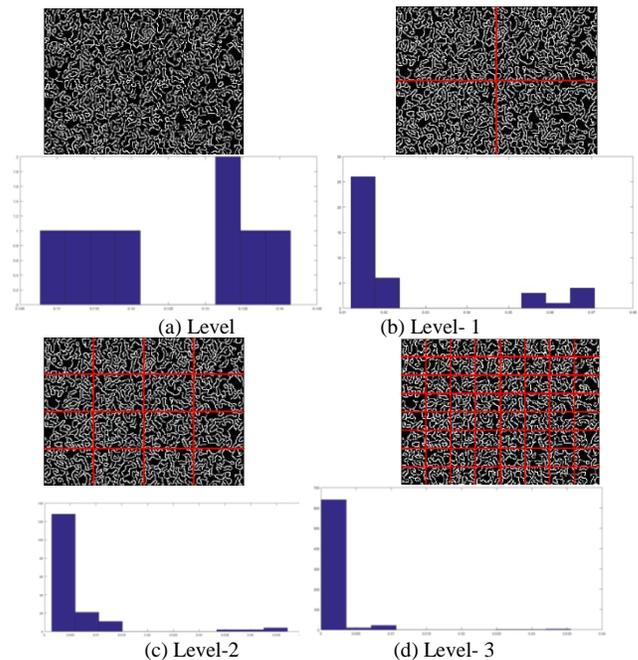

Fig. 7. PHOG Schematics at different Resolution Levels.

Create one vector by concatenating the histograms with the same level. The final PHOG descriptor of an image is obtained by concatenating all the vectors in each pyramid level that pertain to the spatial properties of an image. By setting  $N = 8$  and  $L = 3$ , the PHOG descriptor ( $D_{PHOG}$ ) has a length of  $8 * (1 + 4 + 16 + 64) = 680$ .

## VI. CLASSIFIER

Data can also be classified into identifiable groups or features using neural networks [30]. A neural network based classification becomes a very powerful prediction network. It achieves two goals: Lowering the prediction error by training and testing similar patterns of behavior; and minimizing the number of training samples within a training data set, resulting in more efficient training.

### A. Neural Networks with L2 Regularization

A technique known as L2 regularization of neural networks (NNs) reduces the likelihood of the model overfitting, thus improving its performance. NNs are mathematical functions used to train the network and make predictions. The training refers to finding values for weights and biases needed to define the NN. Excessive training of a neural network may lead to model overfitting. Thus, when a neural network model is trained to predict the values from used training data, it does so with little error and high accuracy, but when the model is applied to new, previously unknown data, it does not work well. Parameter optimization is used to determine weights and biases in a way that minimizes error between computed and true results.

1) *L2-Regularization*: During L2 regularization, a new regularization term was added to the loss function of the neural network [31]. As part of regularization, the proposed work utilizes Euclidean-Norm or L2-Norm for the weight matrices, which is the sum of all the squared weight values of any given matrix. By dividing the scalar regularization parameter  $\lambda$  by two, add the regularization term to the regular loss function. The following steps are used to implement the neural network with L2 regularization.

2) *Activation function*: The logistic regression [32] hypothesis is defined as in (8)

$$h_{\theta}(x) = g(z); z = \theta^T \times x \quad (8)$$

$\theta$  – weights and  $x$  -input

The sigmoid function  $g$  is defined as in (9).

$$g(z) = \frac{1}{1 + e^{-z}} \quad (9)$$

3) *Cost function*: Probabilities of an observation can be predicted with the cost for the observation, with a minimum amount of error. A given observation  $x$  has a cost (error) associated with it if the class label is  $z$  can be defined in (10).

$$Cost(h_{\theta}(x), z) = \begin{cases} -\log(h_{\theta}(x)) & ; \text{if } z = 1 \\ -\log(1 - h_{\theta}(x)) & ; \text{if } z = 0 \end{cases} \quad (10)$$

As a result, the total cost for all the  $m$  observations in a dataset is given in (11).

$$J(\theta) = \frac{1}{m} \sum_{i=1}^m Cost(h_{\theta}(x^{(i)}), z^{(i)}) \quad (11)$$

$(x^{(1)}, z^{(1)}), (x^{(2)}, z^{(2)}), \dots, (x^{(m)}, z^{(m)})$  are the  $m$  number of training datasets.

4) *Cost function and gradient*: The cost function in logistic regression is defined in (12).

$$J(\theta) = -\frac{1}{m} \left[ \sum_{i=1}^m z^{(i)} \log(h_{\theta}(x^{(i)})) + (1 - z^{(i)}) \log(1 - h_{\theta}(x^{(i)})) \right] \quad (12)$$

Regularization L2 helps to avoid over fitting in the model by adding a penalizing component for high weights. Equation (13) gives the regularized cost function for logistic regression.

$$J(\theta)_{new} = \frac{1}{m} \sum_{i=1}^m Cost(h_{\theta}(x^{(i)}), z^{(i)}) + \left( \sum_{j=1}^n \|\theta_j\|^2 \right) \frac{\lambda}{2m} \quad (13)$$

- $\left( \sum_{j=1}^n \|\theta_j\|^2 \right) \frac{\lambda}{2m}$  is the regularization term.

- $\lambda$  is the regularization factor.

- $\frac{1}{m} \sum_{i=1}^m Cost(h_{\theta}(x^{(i)}), z^{(i)})$  loss function.

The gradient of the cost function is a vector where the  $i^{\text{th}}$  element is defined as follows:

$$\frac{\partial J(\theta)}{\partial \theta_{(i)}} = \frac{1}{m} \left[ \sum_{j=1}^m (h_{\theta}(x^{(j)}) - z^{(j)}) x_i^{(j)} \right]; \text{ for } i = 0$$

$$\frac{\partial J(\theta)}{\partial \theta_{(i)}} = \frac{1}{m} \left[ \sum_{j=1}^m (h_{\theta}(x^{(j)}) - z^{(j)}) x_i^{(j)} + \lambda \theta_{(i)} \right]; \text{ for } i \geq 1$$

5) *Learning parameter optimization*: In order to efficiently train NN, gradient descent can be implemented to determine the optimal parameters for a regression model [33]. During training and testing, the accuracy of the algorithm was maximized, while the computation time was reduced through parametric  $\lambda$ ,  $\theta$  optimization and number of iterations. Calculate the optimal cost function  $J(\theta)$  according to parameters  $\theta$ . Determine the optimal parameters  $\theta$  for the logistic regression cost function based on a fixed dataset of  $x$  and  $z$  values. For a given dataset  $(x, z)$ , computes the logistic regression cost and gradient based on a training data and a specific value of  $\theta$ . Lastly, it gives the cost and  $\theta$  values. After the trained data is plotted, the decision boundary will be based on the final  $\theta$  value as shown in Fig. 8.

6) *Prediction:* A NN's hidden layers make it better suited for predictive analytics. Predictions are based on the output and input nodes of linear regression models. Consequently, they are cost-prohibitive because they require enormous computing power [34]. Furthermore, neural networks perform best when trained with extremely large data sets. By using supervised learning techniques such as data clustering, each neuron's weight can be determined. In the supervision training process, by feeding sample inputs and outputs to the algorithm, weights are derived until the inputs and outputs are closely matched, that is, weights are optimized. Using a sigmoid activation function on the output layer, it is easy to make predictions for the input test, so predicted label will be either 0 or 1.

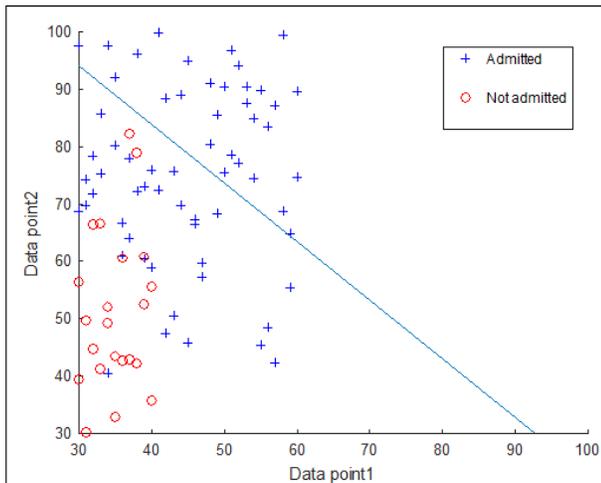

Fig. 8. Trained Data with Decision Boundary.

VII. RESULT AND DISCUSSION

An experimental result is carried out in three stages: A) preprocessing B) feature extraction C) classification.

A. Preprocessing Stage

There are 80 X-ray lumbar spine images collected; 80 x 4 =320, vertebrae of L1-L4 are the actual ROI images, but in reality only 76 ROI images have been correctly segmented (76 x 4 =304), where all four segmentations (L1-L4) are correct in 76 images. Table II shows the true and false segments of L1-L4. Out of 80 images, 77 reflect true segmentation of L1, while 3 reflect false segmentation. The results for L2 were 78 true and 2 false, L3 was 77 true and 3 false, and L4 was 76 true and 4 false.

As shown in Table III, the data base can be used to detect osteoporosis in the lumbar vertebrae L1 - L4. A total of 76 correctly segmented images are considered for the processing (76 x 4 = 304). For testing the system, a 2-fold cross validation is applied. This is accomplished by using 152 samples for supervised samples and 152 samples for testing.

B. Feature Extraction Stage

The texture features were extracted from 304(L1-L4) samples of ROI images using PHOG. For N=8 bins, Table IV shows the levels and the corresponding descriptors.

Concatenated level descriptors are used to classify samples based on their attributes.

C. Classification Stage

Table V shows the osteoporosis detection classification accuracy based on the concatenation of all the levels descriptor are 696 with parameter optimization lambda varying from 0 to 1. If lambda is greater than 1, the system takes more iteration and becomes more complicated. Consequently, it was determined that for classification accuracy, when lambda is higher, the likelihood of over fitting during training is reduced, and gives maximum accuracy. During training, the model was iterated 27 times, with  $\lambda = 0.9$ . In large-scale implementations, a small change in the parameter can produce more effects. By taking the 184 and 40 descriptor with parameter optimization lambda varying from 0 to 1, the classification accuracy is reduced by reducing the size of the descriptor. Fig. 9 displays the graphical presentation of the system's osteoporosis detection classification accuracy with lambda. In order to improve the accuracy, lambda plays a vital role in terms of number of iterations and computation time.

TABLE II. SEGMENTATION OF L1-L4

ROI Segmentation	L1	L2	L3	L4
True	77	78	77	76
False	3	2	3	4

0.1	25	96.89	99.01	19
0.3	25	97.45	99.05	21
0.6	26	98.56	99.12	22
0.7	27	100	99.34	25
0.9	27	100	99.34	25

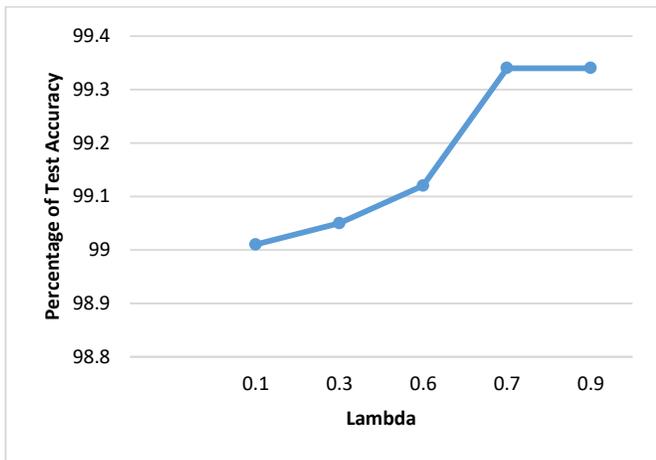

Fig. 9. Graphical Representation of Accuracy with Lambda.

A confusion matrix with multiple classifiers can be used to evaluate system performance as shown in Table VI. Testing the proposed system is based on a detailed analysis of the database, as shown in Table III. With L2 regularization, NN has fewer False Positives (FP) and False Negatives (FN), which leads to less overfitting and more accuracy, flexibility, and works well in classifying events. When compared with other classification techniques, the overall performance of the system leads to better True Positives (TP) and True Negatives (TN). Based on NN with L2 regularization, a 2-fold cross-validation gives good results for L1 through L4. Fig. 10 illustrates 2-fold cross validation using different classifiers for system assessment. Thus, NN with L2 Regularization can produce the smallest FP and FN, resulting in a more accurate system. Using 2-fold cross-validation for the lumbar spines L1-L4, Table VII describes the systems average performance using the various classification methods. The system is tested for 2-fold cross validation for descriptor 696 with lambda 0.9. Sensitivity (True positive Rate-TPR) is the percentage of actual positive results that were correctly predicted. The specificity indicates how many negatives were correctly predicted out of actual negatives. Probability of successful positive predictions is measured by precision [35,36]. The recall measures the proportion of true positives for which the prediction was correct. Precision and recall are expressed as the harmonic mean, this method accounts for both false positives as well as false negatives which is termed as F1-score [37]. NPV (Negative Predictive Value) is the probability that someone will not have the specific disease, even after testing negative for it. According to all the above mentioned measures the NN with L2 regularization techniques attain the best classifications and overall the system measures the trueness of the test samples accurately.

Fig. 11 shows how system performance can be represented from a graphical point of view using the Receiver Operating Characteristic (ROC) curve. The red line represents the area under (AU) ROC. Essentially all of the images of test samples are classified into abnormal and normal images based on the curves occupying 99 percent of the region. This diagonal line

shows an average AUROC value of 0.5 is found in ROC curves of random predictors. In order to determine if the model is useful, the random predictor is often used. ROC curves plotted in terms of sensitivity (TPR) versus 1-specificity (false positive rate). This model gives better classification against false positive and true positive rates since the AUC approaches 1, that is it is more accurate. Based on the comparison of different methods in Table VIII, the proposed approach is found to be better than those adopted by the other methods in terms of accuracy, sensitivity, specificity, and F1-score. Because, the overall design will enable more accurate classification methods of osteoporosis detection with the help of preprocessing and significant image texture feature extraction using PHOG.

### VIII.CONCLUSION

Millions of people worldwide suffer from osteoporosis, especially those who are aging. The purpose of this study is to reduce risks of bone fracture by exploiting the effectiveness of osteoporosis with the help of X-ray images. The aim of this study is to reduce the bone fracture risks by exploring the effectiveness of osteoporosis. In this research work, preprocessing step allows experimentally extracting the texture features of trabecular bone structure, allowing visualization of fine texture features of internal trabecular bone. An analysis of texture features is helpful for identifying the significant features that allow the images to be classified. By using these texture features, NN with L2 regularization achieves better system performance in regards to classifying the normal and osteoporotic L1-L4 images. The contribution of this paper is to understand the diagnose of osteoporosis in lumbar vertebrae L1-L4 of spine X-ray image more accurately so that risk factors can be avoided with less cost.

### IX. FUTURE WORK

To improve the diagnostic accuracy with the help of spine X-ray image of lumbar vertebrae, it is necessary to make a standard dataset that can be used universally by researchers so that one can set the standard analysis of trabecular bone micro architecture to reduce error classification. A reliable and cost-effective system is needed to overcome the drawbacks of DXA, such as lack of measurement of soft bone (trabecular) and set the standard benchmark to analyze BMD. For the bone density to be calculated, a machine learning algorithms should combine with larger number of clinical reports and X-ray imaging data in order to avoid bone risk factor.

### ACKNOWLEDGMENT

The authors would like to thank Dr. A Ramalingaiah M.S (ortho) Orthopedic Doctor, Bangalore. No.271 Abhilasha Orthopedic Hospital 5th Block 100ft Rd Banashankari 3rd stage Bangalore - 560085, India for providing X-ray image of spine (raw-data) and DXA report. We sincerely acknowledge and are grateful for their guidance and suggestions.

**Abstract**—Speech Recognition is an emerging field in the area of Natural Language Processing which provides ease for human machine interaction with speech. Speech recognition for digits is useful for numbers oriented communication such as mobile number, scores, account number, registration code, social security code etc. This research paper seeks to achieve recognition of ten Gujarati digits from zero to nine (૦ to ૯) by using a deep learning approach. Dataset is generated with total 8 native speakers 4 male 4 female with the age group of 20 to 40. The dataset includes 2400 labeled audio clips of both genders. To implement a deep learning approach, Convolutional Neural Network (CNN) with MFCC is used to analyze audio clips to generate spectrograms. For the proposed approach three different experiments were performed with different dataset sizes as 1200, 1800 and 2400. With this approach maximum 98.7% accuracy is achieved for spoken digits in Gujarati language with 98% Precision and 98% Recall. It is analyzed from various experiments that increase in dataset size improves the accuracy rate for spoken digit recognition. No of epochs in CNN also improves accuracy to some extent.

**Keywords**—CNN; Deep learning; digit; Gujarati; speech recognition

## I. INTRODUCTION

Speech is the most common medium used by humans for communication. Humans express their thoughts in the form of speech. Speech recognition is the emerging field in the area of Natural Language Processing [1]. Performance and Accuracy of Speech recognition process depends upon the speaker's mental state, emotions, accent, style and ease of speaking and environment. Human speech includes various parameters such as words, sentences, digits and fillers. Speaker feels more comfortable when he is communicating in his native language. In general, people have good command and control over their native language as they have learnt it from their childhood. Speech recognition with native language provides better performance and accuracy with the use of algorithms [2]. Generally the speech recognition process focuses upon identification of words and sentences. Very little work has been done by researchers regarding digits recognition in Gujarati language. Digits recognition with deep learning includes zero to nine numbers identification using optimized algorithms.

Gujarati is Indo-Aryan language and used as native language for people living in Gujarat state in India. It is spoken by 55.5 million people in India. Gujarati language includes 34 consonants, 12 vowels, 10 digits and 106 special symbols.

\*Corresponding Author.

Speech recognition related to the Gujarati language is a challenging task due to morphological structure, language barrier, dialects and limited resources [3]. This research paper mainly focuses upon digit recognition in Gujarati language using deep learning approach.

Deep learning is a subfield of machine learning that includes various methods and functions that imitates human behavior and knowledge. Deep learning algorithms apply a hierarchy of nonlinear transformation to the input values and generate statistical models as output that can predict results in future on their own. Deep learning approaches require large amounts of data for training and require more computation resources [4]. There are several forms of neural networks such as Recurrent Neural Network (RNN), Convolutional Neural Network (CNN), Artificial Neural Network (ANN) and Feedforward Neural Network (FNN). Most popular deep neural network is Convolutional Neural Network (CNN) to understand and analyze data in visual form.

In the proposed approach for digit recognition for Gujarati language CNN model was implemented. For the analysis process, dataset was prepared with 8 speakers with 2400 labeled audio clips. Different dataset sizes are used as input to CNN to analyze the impact on accuracy.

## II. LITERATURE REVIEW

Gunawan, A. (2010) [5] developed a digit recognition system from zero through nine using HMM and MATLAB for GUI. Spoken digits were in an isolated structure with 34 male and female speakers. They have created two different modules for isolated and continuous speech recognition. To check effect of variation of environment on accuracy they have selected noisy and clean environment. In a clean environment, in multi-speaker mode for isolated and continuous speech average accuracy found is 96%. For speaker independent mode, average accuracy is 78%. In noisy environments, in multi-speaker mode for isolated and continuous speech average accuracy found is 80%. For speaker independent mode average accuracy is 61.6%. They have concluded that recognition accuracy depends upon some factors such as noise rate and microphone quality.

Chapaneri and Jayaswal (2013) [6] have proposed a speaker-independent system for isolated digits using WMFCC. They have used SOLA based techniques and IFDTW to reduce time complexity for recognition. The overall accuracy of the proposed system for recognition 0 to 9 was 99.16%. They have

concluded that the system performs 22 times faster with higher accuracy and lower computational overhead achieved using WMFCC and FIFDTW.

Datta et al., (2021) [7] have done comparative analysis for methods to recognize zero to nine digits. For comparison they have analyzed cepstral and MFCC. They have concluded that the feature extraction method MFCC performed with better results compared to cepstral in command based systems.

Kurian, C., & Balakrishnan (2013) [8] have developed speaker-independent systems for connected digits for Malayalam language using Perceptual Linear Predictive (PLP) cepstral coefficient and Hidden Markov Model (HMM). For the training phase they have recorded 20 sets of continuous digits of 21 speakers from the age group of 20 to 40 years in an office environment. For the proposed system they have achieved 99.5% recognition accuracy by averaging word accuracy.

Sen O. et al. (2021) [9] created a convolutional neural network model to recognize Bangla spoken digits from 0 to 9. They have used Mel Frequency Cepstrum Coefficient (MFCC) for feature extraction and Convolutional Neural Network (CNN) for digit recognition. They have developed a proposed model using python,keras and tensorflow for 4000 spoken occurrences with parameters such as gender, accent and age. Measured accuracy with 10 fold cross validation was 96.7%.

Zerari N. et al. (2019) [10] proposed a framework for digit recognition using neural network. For feature extraction they have used Mel Frequency Cepstral Coefficient (MFCC) and Filter Banks (FB) coefficients. They have applied a proposed model on two different datasets one for spoken digits and another for spoken TV commands for different age groups for a total of 88 Arabic native speakers from which 44 were male and 44 were female. Total first digit database entries were 8800 tokens and the second TV command database includes 10000 instances. It is analyzed that the delta-delta feature used to characterize speech recognition signals gives better accuracy over 96% compared to MFCC and FB.

Dhanashri D. & Dhonde S. (2017) [11] have proposed isolated word speech recognition using HMM and DNN for acoustic modeling. Dataset for digit sequences samples were collected in a quiet environment at 20 kHz with 55 men and 57 women. System accuracy is measured for three different hidden layers such as 300,400 and 500 units. Accuracy achieved for 300 hidden layer units is 83.67%, for 400 its

85.44% and for 500 units its 86.06%. They have analyzed that proposed model accuracy can be improved by increasing the number of hidden layer units.

Wazir A. & Chuah J. (2019) [4] have proposed Arabic digits speech recognition model using Recurrent Neural Network (RNN). Feature extraction is done with MFCC and extracted features are fed into the Long Short Term Memory (LSTM) network. They have collected total 1040 data points from different countries and dialects. For the training phase 840 data points were used from 1040 data points and achieved 94% with minimum loss. In the testing phase total 200 data points were included and 65% accuracy was achieved. They have found that the most recognized digit is '0' with 80% accuracy and the worst recognized digit is '6' with 60% accuracy.

Hamidi M. et al. (2020)[12] have presented analysis of Amazigh digit recognition with IVR system for speaker-independent systems in noisy environments. They have used open source software Asterisk 1.6, Ekiga softphone and CMU Sphinx Tools. They have selected 22 Moroccan native speakers of both genders male and female. They have concluded that minor degradation in accuracy found for SNR as low 3 and 9 db. Major degradation was found with decoded speech signal and best recognition rate at 3 db.

Swedia E. et al. (2018) [13] have proposed a deep learning approach for Indonesian digit recognition using LSTM. For feature extraction they have used LPC and MFCC techniques and compared their performance. They have recorded total 7990 speech digits with 12 coefficients of MFCC and 12 for LPC. They have concluded that Indonesian speech recognition gives better performance using MFCC with 96.58% compared to LPC with 93.79%.

Swastika R. et al. (2017) [14] have performed comparative analysis for four deep learning architectures such as DBN-DNN, LSTM, TDNN and CNN. For feature extraction MFCC and LPC techniques are used. They have used TIDigits dataset which includes 226 speakers from which 111 men and 114 women each uttered 77 digit sequences. Kaldi speech recognition toolkit is used for training and decoding processes. They have concluded that CNN gives the best recognition performance in a noisy and reverberant environment compared to other three architectures. There are also research instances where the authors worked for printed Gujarati characters, for instance [15]. A comparative study of Literature review is presented in Table I.

TABLE I. COMPARATIVE STUDY OF LITERATURE REVIEW

Authors	Year	Spoken Language	Methods / Techniques	Category of Tokens	Accuracy
Gunawan [5]	2010	English	HMM	Digits	96%

### III. METHODOLOGY

The methodology to recognize digits in Gujarati language using CNN includes 6 major steps depicted in Fig. 1.

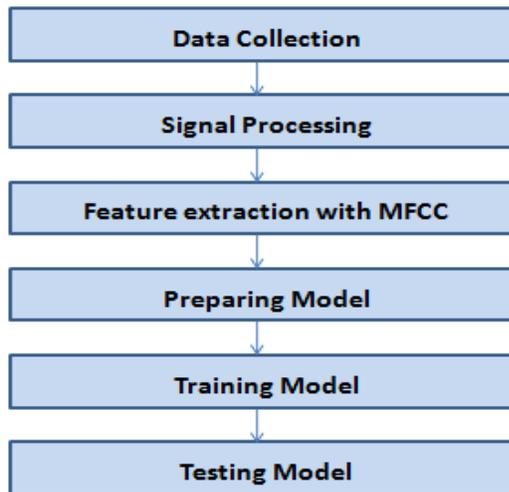

Fig. 1. Flowchart of Steps for Proposed Model.

#### A. Data Collection

For data collection, 8 native speakers, comprising 4 males and 4 females, of the Gujarati language were selected. All 8 speakers were between the age group of 20 to 40. For recording purposes Audacity software was used and recording

is performed in a lab environment. Total 30 occurrences of 0 to 9 digits were spoken by each speaker. Dataset consists of 0 to 9 digits in Gujarati with English language representation listed in Table II. Total 2400 occurrences (8 speakers \* 10 digits \* 30 occurrences) were used for the proposed speech recognition model. Collected data is split in two parts: Training and Testing. For data division 80:20 ratios are followed from total collected data. From 2400 total occurrences 1920 (80% of 2400) were used for training the model and 480 (20% of 2400) occurrences used for testing purposes. All the audio files are collected and stored in wav format.

TABLE II. DATASET OF DIGITS (0 TO 9) IN GUJARATI AND ENGLISH REPRESENTATION

Digit in Gujarati	Pronunciation in Gujarati	Digit word in English	Digit in English numeric
૦	૦- શૂન્ય	0	zero
૧	૧- એક	1	one
૨	૨- બે	2	two
૩	૩- ત્રણ	3	three
૪	૪- ચાર	4	four
૫	૫- પાંચ	5	five
૬	૬- છ	6	six
૭	૭- સત્ત	7	seven
૮	૮- આઠ	8	eight
૯	૯- નવ	9	nine

### B. Signal Processing

Speech signals are non-stationary signal combination of voiced and unvoiced signals. From actual speech signals, it is required to extract voiced segments without silence and noise. Data segments with silence are not useful for feature analysis. To remove noise from signals, audacity has a provision with noise reduction option through which we can control by specifying how much dB value we want to consider as noise from 0 to 24 (maximum) dB values.

For processing, first we have removed noise from recorded audio files. Through Audacity noise reduction parameters can be set with residue data that is removed. It provides ease to select a voice sample window which contains useful information about speech signals. The dataset containing a total of 2400 occurrences of the 10 digits, from 0 to 9, were recorded by the speakers in Gujarati. Noise parameters are set to preferences and selected tracks are stored with reduced noise.

### C. Feature Extraction with MFCC

Raw data is not used directly in the model training process because it contains noise and other unnecessary parameters that affect accuracy of the model. Feature extraction is an important step in the speech recognition process. Extracted features are used as input to the model to generate text sequences. In the model, extracted features as input, gives better performance compared to raw audio signals. To extract spectral frames from speech signals, we have used the MFCC technique which is a widely used technique for feature extraction. First audio signal is converted from analog to digital with a sampling frequency 16 kHz. To improve model performance, pre-emphasis increases the energy in higher frequency for better phone detection.

To differentiate phones from audio signals, segments are divided into window width 25ms. From each segment, we have extracted 39 features. Hamming window is used to divide signal into segments without noise in a high frequency region. By applying Discrete Fourier Transform (DFT) to convert the time domain of a signal into frequency domain for easy analysis.

By modeling human hearing property into a model at the feature extraction step can improve the performance of the model. For mapping actual frequency with human hearing frequency, mel scale parameter is used. At lower energy humans can easily identify increased levels compared to higher energy. To adapt the same human behavior in the system, log is applied to Mel-filter.

After DFT transformation, the time domain and frequency domain are inverted. The lowest frequency is the highest frequency in the time domain. So inverse transform IDFT (inverse Discrete Fourier Transform) of log of magnitude of signal is generated which is called a cepstrum. After applying IDFT, MFCC includes 12 coefficients to extract signal sample energy as features.

In the dynamic feature generation step, with 13 features, MFCC technique generates first order derivatives and second order derivatives for each feature so total 26 features generated. Derivatives are calculated with differences between

coefficients of audio signals to understand transition. Calculated 39 features generated by MFCC for each audio signal that was included as input to the speech recognition system.

### D. Deep Learning Approach

Deep learning includes various sub domains such as computer vision, digital signal processing, music classification and automatic speech recognition. With the popularity of virtual assistants like Alexa, Google Home and Siri, the field machine learning systems are promoted at a higher level for speech to text or action. All these systems work upon audio signal processing using deep learning concepts.

### E. CNN

Neural networks include a major part as Convolutional Neural Network. CNN is made up of neurons that have learnable weights and biases. It includes various application implementations such as image processing, object identification and classification. CNN can also be used for speech recognition as it can be applied on acoustic models and define convolution layers to each overlap acoustic frames. It extracts phones, pitch, frequency and gender features from acoustic frames according to weights of the network. Convolution Layer is the first layer of CNN that is the core building block and performs major computational tasks. It is a mathematical operation that merges two sets of information. CNN includes three main aspects: locality, weight sharing and pooling. Before start processing input data it is necessary to reduce non-white noise through locality. Weight sharing is used to improve robustness of model and overfitting and reduce weights. Pooling or subsampling process reduces the size. The input image is resized to optimal level to input into the convolutional layer. CNN Architecture is shown in Fig. 2.

In CNN, a filter or kernel is available that is placed in a sliding window over some of the pixels of the image depending upon kernel size to produce feature maps in different convolutional layers. In this step, through element wise multiplication each original pixel value of the image is multiplied with values in the filter. The sum of multiplication values is generated.

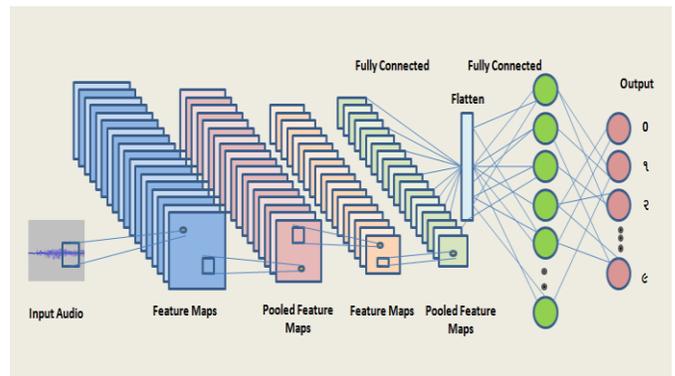

Fig. 2. Convolutional Neural Network.

If the value found is too low then there is nothing to compare in the activation map by curve detector filter. By adding more filters input data can be verified in depth of the activation map. The second layer called the Activation layer,

ReLU (Rectified Linear Unit) function is applied to increase non-linearity in the CNN as images consist of objects that are not linear. In the third pooling layer, that involves downsampling of features. Common pooling layer uses 2 X 2 max filters with stride of 2 that is non-overlapping filter. Max filter returns max value in the feature from selected region. Last layer is known as a fully connected layer that pooled a full feature map matrix into a single column that was used for processing in a neural network. All the features are combined in a network through fully connected layers.

#### F. Preparing Model

The dataset consists of a total 2400 occurrences both from male and female speakers. It consists of 10 spoken digits recording from 0 to 9. Recording of the dataset was performed using audacity software with 22050 Hz monophonic 16-bit audio files with .wav format. Google colab is used to implement and execute neural networks to get GPU and TPU as a runtime environment. It is free and easy to use. Librosa python library is used to extract spectrograms from audio files. Total dataset is splitted into training and testing data with 80:20 ratios. From a total 2400 audio files, 1920 files were used in the training session. The algorithm is written in python with TensorFlow library using Keras open source library as python interface. Each spectrogram file is stored with PNG format. Spectrogram images of different digits in Gujarati are depicted in Fig. 3. All spectrogram images belong to classes ranging from 0 to 9. Then data is split into training and testing sets. We have used sequential types to build a layer wise model in keras.

In the training phase, input images of the spectrogram are passed to a 2D convolutional layer (Conv2D) with filter size of 32. There are 2 layers as Conv2D layers. First layer consists of 64 nodes and the second layer consists of 32 nodes. With kernel size of 3, 3 X 3 filter matrix is used. For two layers activation function ReLu (Rectified Linear Activation) is used. A 'Flatten' layer is added between conv2D and dense layer to transform the resultant vector into 1 dimensional vector. Dense is the standard output layer used in neural networks. Mainly 10 different nodes were added in layers ranging from 0 to 9. Resultant vector is passed to a fully connected dense layer with a Softmax function that concludes the output in sum up to 1 to represent it in the form of probabilities. Based on the highest priority, prediction series can be generated. After setting all the parameters for the model, compilation is done with three parameters. Compiling process includes optimizer, loss and metrics. SGD (Stochastic Gradient Descent) optimizer is added from keras as it is an iterative method for optimizing objective function. The 'categorical\_crossentropy' is used for loss function which indicates the model performance. Third parameter Accuracy metric is used to show accuracy of model on validation data.

#### G. Training Model

To train a model, fit () function is used with training data and validation data as test data with number of epochs. Epochs specify the total number of model cycles for data. We can get better model performance by increasing the number of epochs up to some extent. For proposed model, 500 epochs were set to analyze neural network performance.

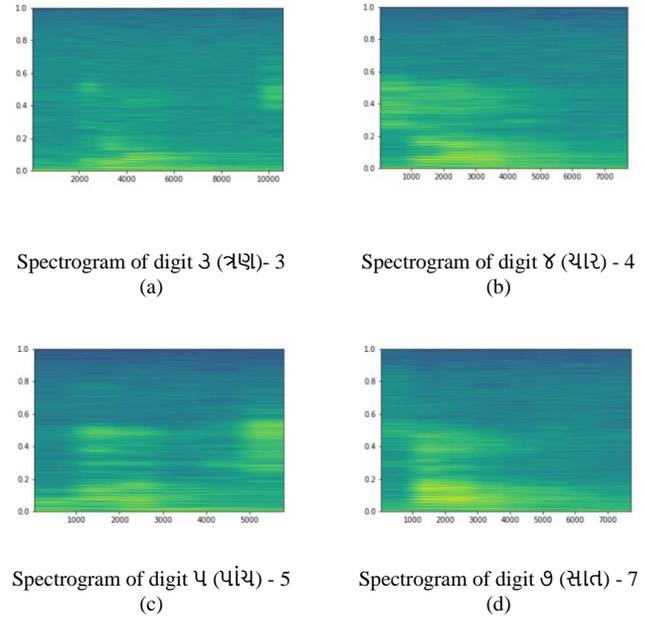

Fig. 3. Spectrogram of different Digits Spoken in Gujarati.

#### H. Testing Model

To predict the output based upon test data, predict\_generator function is used. It generates an array with 10 digit numbers. Each digit range represents the digit classification according to probability.

### IV. RESULT AND DISCUSSION

The experiment was executed with training and testing of data to create a neural network. The proposed approach includes a total 2400 occurrences of spoken digits 0 to 9 in Gujarati language. The model is developed with Python programming language with Keras and Tensorflow libraries. The model is executed three times with varied dataset sizes as 1200, 1800 and 2400 digits. The result analysis with various data sets is depicted in Table III. In the first iteration with 1200 dataset values, received accuracy was 58.6% with 58% precision and 58% recall. In the second iteration, accuracy achieved is 78% with 78% precision and 78% recall. In the third iteration with 2400 occurrences, 98.7% accuracy is achieved with 98% precision and 98% recalls.

It is analyzed that accuracy of recognition improves with dataset size. The result can be viewed in graphical form depicted in Fig. 4.

TABLE III. RESULT ANALYSIS WITH VARIOUS DATASET SIZES

Experiment No.	Data set size	Learning Rate	No. of Epochs	Batch size	Accuracy %	Precision %	Recall %
1	1200	0.01	500	32	58.6	58	58
2	1800	0.01	500	32	78	78	78
3	2400	0.01	500	32	98.7	98	98

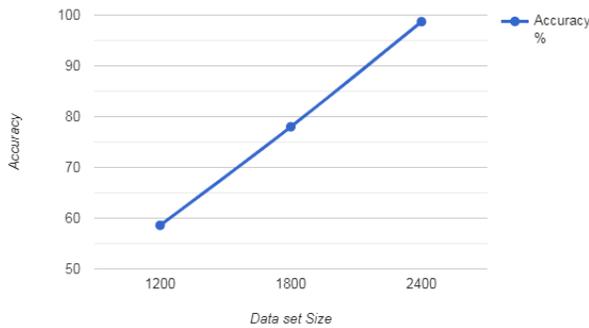

Fig. 4. Accuracy Measure for Various Dataset Sizes.

It is observed that CNN gives better performance with speech recognition compared to other related approaches described in literature review.

### V. CONCLUSION

Speech recognition is a very important and useful application to interact with machines using speech. This emerging field includes many challenges like dataset size, noisy environment, age, gender, dialect and mental state of the speaker and many more. Speech wav files for Gujarati digits are stored and features extracted with MFCC technique. In this research paper, digit recognition for Gujarati language is performed using CNN.

Speech is passed and processed as input into multiple convolutional layers. For model training Tensorflow and Keras are used with python. Maximum Accuracy rate of recognition out of three experiments with different datasets size for all digits 0 to 9 is found 98.7%. It is observed that accuracy for speech recognition models can be improved by increasing the size of the dataset. Deep learning approach implemented with CNN trained with a large dataset gives better performance. In the future the proposed model can be enhanced to observe results for major parameters such as age, gender and dialect of the speaker that affect the speech recognition result.

**Abstract**—The deadly COVID-19 pandemic is currently sweeping the globe, and millions of people have been exposed to false information about the disease, its remedies, prevention, and origins. During such perilous times, the propagation of fake news and misinformation can have serious implications, causing widespread panic and exacerbating the pandemic's threat. This increasing threat factor has given rise to considerable research challenges. This article is mainly concerned about fake news identification and experimentation is specifically performed considering COVID-19 fake news as a case study. Fake news is spread intentionally to mislead the people and therefore we need to identify user's involvement and it's correlation with additional features. The aim of this research is to develop a model that can predict the essence of a tweet given as an input with the help of multiple features. Our strategy is to make use of the tweet's text as well as the user's metadata and develops a model using natural processing technique and deep learning method. In this process, we have analyzed the behavior of the accounts, observed the impact of the various factors that can lead to fake news. The experimental analysis shows that hybrid model with text and content features have generated a benchmark result than the existing state of art techniques. We have obtained a best F1-score of 0.976 during the experimentation.

**Keywords**—Fake news; machine learning; natural language processing; deep learning

## I. INTRODUCTION

Fake news and its consequences have the ability to impact a wide range of institutions, from a citizen's lifestyle to a country's international relations. Widespread use of social media sites been generating and exchanging more content than ever before, some of which is deceptive and has little bearing on fact. So far several related works has been carried out for collecting and identifying fake news, however no commercially viable system exists yet. Fake news isn't a new phenomenon but it has new repercussions and effects. Fake news can lead to the collapse and failure of the world's largest economies by mass exploitation, and it can be one of the most devastating "internet wildfires." Aside from political ramifications, fake news can and has resulted in personal defamation, distorted perspectives, and mass incitement on a variety of topics. It is much easier for the sources to produce this news than it is for people to embrace and share it. Fake news is the biggest danger to our ostensibly functioning democracy; in addition to distorting and corrupting ideologies, it has also resulted in real effects such as cyber defamation, cyber stalking and other cyber-attacks.

Detecting and identifying fake news on a social media is a difficult challenge. The rapid dissemination of false news has an impact on millions of people and their actual surroundings. The propagation of fake news is not a new issue on the social media sites [1]. Several firms and well-known individuals utilize various social media networks to promote their products and build their reputation. All of these operations persuade numerous people to share and enjoy the news. As a result of this process, fake news spreads over the web. In terms of a certain issue, the content, style, and media platform of fake news change with time and fake news tries to falsify linguistic information. Fake news may contain genuine evidence within a fabricated framework to promote a false assertion [2]. The term fake news has coined in the 2016 US Election primarily, which encouraged academicians and researchers to do the research in this direction [3]. The researchers tried to gather the data from various resources and then checked the actual authenticity of the news being spread. Since then people have been utilizing a variety of manual techniques to do the fact-checking, such as using fact-checking websites. These websites are crucial in spotting false news on the internet. There are a number of fact-checking and fake news identification research projects, methods, and applications available, most of which look at the issue from a veracity classification standpoint. Misinformation, disinformation, hoax, and rumor are all terms used in similar literature to describe fake news. The term "misinformation" refers to the spread of incorrect information without consideration of the real intention. The goal of misinformation is to fool the intended recipient of the information. Rumours or hoaxes are purposely crafted to appear accurate. The fake information is for the gullible. The person may not realize the actual authenticity and believes in on what is being spread through social media especially the social sites eager to increase their viewership.

### A. Covid 19 – An Infodemic

Covid 19 Infodemic has become more like a disease which is spreading rapid faster in the society through the dissemination of false information. Verifying the veracity, authenticity, and accuracy of given information is extremely difficult, especially when it concerns a horrifying disease that poses a threat to humankind. [4] COVID19, a virus that first appeared in Wuhan, China, in December 2019, has spread to 213 nations, regions, or territories throughout the world, resulting in roughly 3,478,418 fatalities as of May 24, 2021.

This infodemic posed a serious problem for public health along with social media channels including as Facebook, Instagram, WhatsApp and Twitter have become key sources of information on the crisis. In the COVID19 battle, fighting the infodemic is a new front. People trust the information that appeals to their emotions and personal opinions than information that is considered factual or objective in the 'posttruth' era. The following figure shows the news trend encountered during the Covid time. Fig. 1(a) shows plot of 50 most commonly used words in real tweet, whereas Fig. 1(b) shows plot of 50 most commonly used words in fake tweet.

The epidemic and infodemic elements of a pandemic are the two sides of the coin in today's highly digitalized society. This infodemics are usually fuelled by a combination of human and non-human system (bots), all of whom are pursuing essentially unknown aims. In this perspective, we present a methodology to detect fake tweets using the COVID-19 epidemic as a case study by using ensemble learning models with machine learning and Deep Learning Techniques.

In this research work, we have studied the differences between fake and real tweet based on behavioral, content based and comment based features of the tweet. The methodology implemented tackles the problems of fake tweet with the help of natural language processing toolkit and performs tweet text analysis as well. Different from the existing work, we take into consideration not only text characteristics, however also used user account characteristics for better results.

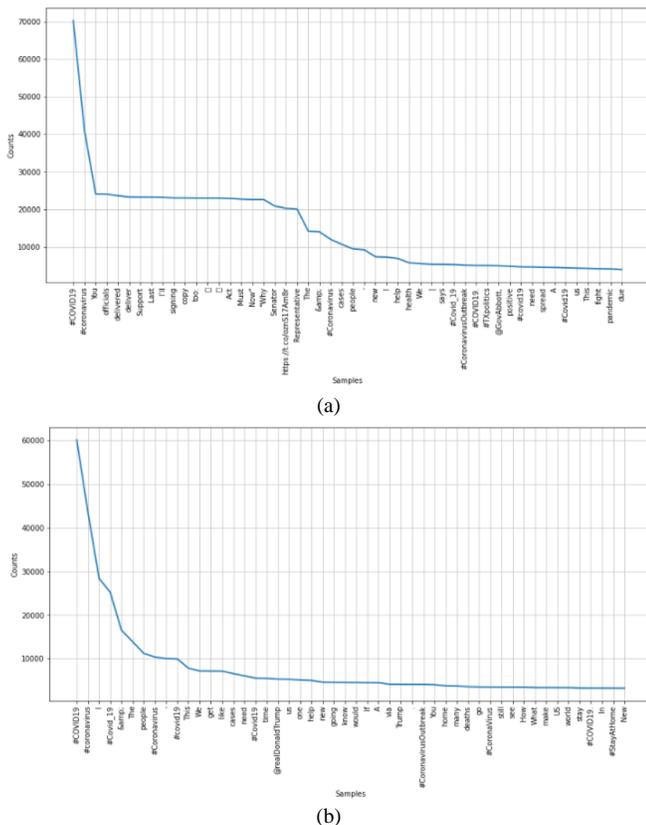

Fig. 1. (a) Shows Plot of 50 most commonly used Words in Real Tweet, (b) Shows Plot of 50 most commonly used Words in Fake Tweet.

The related work of fake news detection has been presented in Section II. Section III gives systematic overview of approaches used for Fake Tweet detection process. A Methodology along with model implementation has been discussed Section IV. The experimental setup and results are reviewed in Section V whereas Section VI makes the conclusion and recommendations for further research.

## II. RELATED WORK

Since all individuals communicate through a virtual world using social media, the methods of identifying fake information have been researched. Fake information spread by many social network users utilizing various platforms for financial or personal benefits. The evolution of social networking platforms encourages users to transmit and exchange information about their activities. However it has created a challenge for the researchers who want to secure user data from a variety of dangers. For researchers, detecting harmful information in the form of false news has become a significant challenge.

Looking back in time, misleading news isn't a new issue. Since a long time, there has been widespread anxiety about such news. The scientific community began to pay attention to the issue of fake information in the early 2000s, which expressed itself in the form of paid posters, review spam and rumor detections. The term "fake news," on the other hand, was popularized during the 2016 US Presidential Election [5] [6]. The impact of such news was unclear, although it spread some gossip, uncertainty, and deceit among users. Because of the growing media environment erroneous political information has also been circulating widely. The content of the news and the social circumstances are the most important factors in the fake news identification. News is classified into two categories: textual and visual, however emotions are also integral part of the news content. In addition, deep neural networks [7] [8] are used to frame latent textual representation.

Many of the researcher have also used different supervised and unsupervised, adversarial, user response methods. [9] Here author had created a false news detection algorithm utilizing machine learning approaches along with n-gram analysis. Here, author employed numerous characteristics collected using two distinct approaches and evaluated in six different machine learning settings. TF-IDF used as feature extraction method, and Support Vector Machine algorithm has been used in experimentation. In [10] researcher had developed a model to detect hoaxes or non-hoaxes distributed on social media platforms such as Facebook and created an automated fake news credibility inference algorithm to detect fake information. Here, [11] author had analyzed numerous variables such as user profile data and the relationship between users and the originator of the fake news. In [12] author, suggested a graph neural network-based technique and analyzed non-Euclidean data using a graph neural network. They often avoided certain written content by using unseen data for implementation. In addition, [13] author proposed model using twelve classifiers and evaluated on three datasets. The false prediction ratio of these ML classifiers is used to merge them. Based on their performance measures, Linear Support Vector Classifier, Logistic Regression and Passive Aggressive along with TF-IDF, CV, and HV feature extraction methods. In [14]

developed a volunteer-based crowd annotation tool by combining the perspectives of multiple stakeholders, the system were based on the Micro Mappers platform for English and Arabic tweets. To promote additional studies, [15] published consolidated content named CORD-19, which comprises 59,000 publications regarding COVID-19 and information associated with coronaviruses. The researchers have tried a variety of techniques to combat the COVID-19 Infodemic in recent months.

In [16] performed spatio-temporal analysis of the flow of information and the transmission of COVID-19. Author proposed a model [17] trained on several Indic Languages wherein fake news dataset tweets had performed better due to syntactic features. In Hindi, the model showed 79 percent and in Bengali 81 percent F-Score. [18] [19] conducted substantial research on the usage of machine learning strategies to resolve numerous COVID 19 difficulties. In [20] analyzed Facebook ads from 64 countries and discovered that about 5% of them included potential disinformation. However, none of these methods helped to address the disinformation issue by providing an explanation for the supplied fake assertion.

In [21] employed a natural language inference (NLI) model that was upgraded by adding internal semantic relatedness scores and ontological WordNet elements and performed claim verification on the FEVER Dataset. In [22] proposed a model developed using natural language processing methods and used different algorithms of machine learning, and deep learning that comprises of a categorization strategy that employs new twitter attributes. The approach is built in tandem with Apache Spark and achieved 79% accuracy using random forest algorithm. The author also noted that the emotion of tweets is essential in tweet categorization. In the process of detecting misleading information, [23] collected data from various fact-checking websites, performed filtering, preprocessing and feature selection operation on the text part of tweets and observed that Neural Network, Logistic Regression and Decision Tree classifiers has given the best performance from the different perspectives.

Here author used [24] two distinct methods to build a model that can implement constraint based task. To improve F1-score across several test sets by executing impact data purification with a high cleansing percentage (25%) and experimented a model with a 99 percent cleaning percentage and obtained the 54.33 percent F1 score and 61.10 percent accuracy. In this paper, author [25] had developed a BERT-based model with other important Twitter features. In addition, the method was extended to many Indian languages, and a mBERT-based model was used with Hindi and Bengali datasets and provided a methodology to solve the issue of data scarcity in low-resource languages. Using the annotated data, the model observed 81%, 79% percent F-Score in Bengali and Hindi Tweets, and 81 % F-score with zero shot model.

Although all of the aforementioned research indicated that studying and detecting fake news in the social media using various techniques is successful however several limitations were found. In some of the approaches various learning algorithm has been used to detect the fake news, which involves more processing time and brings limitation to the

various accuracy parameters due to size of the dataset. Most of the technique concentrates only the text pattern of news, however there could be few factors that could differentiate between fake and real content.

In summary, fake content detection on any social media is a challenging task. A deep analysis is needed to identify user's involvement through various features. An exploratory study is performed in this article to explore the link between the content-based, comment-based, sentiment-based, and behavior-based characteristics, as well as the interrelationship between them. Furthermore, a hybrid model is proposed based on the integration of the text and metadata and tested on various standard deep learning and machine learning algorithm.

### III. A SYSTEMATIC OVERVIEW OF APPROACH USED FOR FAKE TWEET DETECTION

The methodology implemented in this paper tackles the problems of fake tweet with the help of natural language processing toolkit and deep learning algorithms. Ultimate aim of the research is to classify each tweet into 2 distinct categories i.e. "real" or "fake". Experimentation has been carried out with the perspective wherein combination of user and content features will be used along with the tweet text. We have used multiple input models for the experimentation to handle continuous and numeric features efficiently.

#### A. Dataset used for the Experimentation

The dataset we selected contains the tweets of users from 29-03-2020 to 15-04-2020 using the following hashtags: #epitwitter, #coronavirusoutbreak, #covid19, #coronavirus, #ihavecorona, #corona, #coronavirusPandemic. From about 11 April 2020, the dataset also included the following additional hashtags: #StayHomeStaySafe, #TestTraceIsolate. The dataset contains variables as given: location, hashtag, title of the tweet, tweet text alongwith tweet account details. Dataset does not include retweets, although a count of retweets is provided as a variable. Alongwith the 'retweet\_count' some of the other features are also included in the dataset i.e. 'favourites\_count', 'followers\_count', 'friends\_count' which has been successfully used for improving the accuracy of the model. Around 303692 tweets have been used for the experimentation during the process, among which 156612 were fake tweets whereas 147080 were real tweets.

#### B. An Exploratory Analysis for Data Insight

An Exploratory Data Analysis has been performed for preliminary investigations on data in order to identify patterns, spot anomalies, testing hypotheses, and validating assumptions using summary statistics and graphical representations. The process of computationally identifying and classifying viewpoints in a text, with the goal of determining whether the writer has a +ve, -ve, or neutral attitude toward a certain topic, product, etc.

Fig. 2 shows Polarity and subjectivity score with sentiment and subjectivity flag wherein the subjectivity score range between [0.0, 1.0], polarity score shows in the range [-1.0, 1.0], wherein 1.0 being very subjective and 0.0 being highly objective.

	polarity	subjectivity	sentiment_flag	subjectivity_flag
0	0.000000	0.000000	neutral	objective
1	0.000000	0.000000	neutral	objective
2	0.541667	0.708333	positive	subjective
3	-0.100000	0.200000	neutral	objective
4	0.250000	0.333333	neutral	neutral

Fig. 2. Polarity and Subjectivity Score with Flag.

Subjective sentences generally refer to personal opinion, emotion or judgment whereas objective sentence refers to factual information. Subjectivity is a float value which lies in the range of [0,1]. Here the value 0.7 represents that subjectivity is more, which ultimately refers that mostly it is a public opinion and not a factual information. Polarity, also known as orientation is the emotion expressed in the sentence. It can be positive, neagtive or neutral. Polarity is float value which lies in the range of [-1,1], here 0.5 refer to positive sentence.

Next distribution of user and content variables and relationships between other variables has been studied using pair plots in which the favorites, re-tweet, followers and friends count considered as a parameters.

Fig. 3 shows that favorites count and friends count are positively correlated. It also appears that re- tweet count and followers count has partial effect on favorites count. However during the analysis, all the features have been tested individually as well as in the combination to determine their impact on the tweet credibility detection. Furthermore, efficacy is also been tested with tweet content and user features in the deep learning and machine learning environment.

### C. Approach used for Fake Tweet Detection

Extracting features from the content of the tweet is a reliable pattern recognition system and hence using natural language processing (NLP) is the most obvious solution to automatically identify fake news. To begin with this approach, data preprocessing has been carried out on tweet text part. Data preparation is a key stage in the modeling process, and the outcomes are dependent on how well the data has been preprocessed. In this approach, text normalization is performed which includes: converting numbers into words, converting letters, removing white spaces and punctuations, removing numbers and stop words. Pre-processed tweet text has been further given to the different vectorizer. For machine learning algorithms, TF-IDF is employed as it assigns a frequency score to words by emphasizing those that occur more often inside a document but not across documents. For deep learning algorithms, Glove has been used to obtain vector representations for words.

Tweet text feature is nothing but the pre-processed and normalized text through which the credibility of the content can be verified. Tweet text analysis done with NLP techniques has been able to evaluate the credibility of the tweet to some extent. However, text feature alone may not be enough to give better accuracy when it comes to detect the credibility. Features

that come along with the tweet can be called as metadata of the tweet for exa. quote, favorites, retweet, followers, friends can play major role in the process of evaluation of the tweet because here tweets becomes more than strings with certain metadata added to them. This metadata becomes the features as an additional input dimension for an algorithm. With this perspective, we have tried to assess the tweet credibility by checking media content, account information and text characteristics. So here we have used 4 user features i.e. 'favorites\_count', 'retweet\_count', 'followers\_count', 'friends\_count' along with processing of tweet text that can make significance difference to the prediction of the news. Here we have tried to evolve a methodology to rate the credibility of the tweet based on the correlation with the additional features. In this phase, a tweet and user content feature has been used to perform the classification of the tweet.

- Behavioral Feature - considers user characteristics and linked user account attributes.
- Content based features - considers content of the tweet.
- Comment based features – considers the characteristics of the tweet itself.

The aim of our approach is how well multi-features-based method will be able to differentiate between the fake and real tweet. In this regards, we have tested different baseline algorithms like Random forest, logistic regression, Decision Tree, Naïve Bayes, XGBoost , Convolutional Neural Network , Bidirectional LSTM, and hybrid algorithm like CNN-BiLSTM for the tweet classification using the text and metadata features of the tweet. The methodology and algorithm have been discussed extensively in the next section that ultimately shows the flow of the process. Following tables are used to show features used for studies. Table I shows Tweet content features and Table II shows User content features used during the studies.

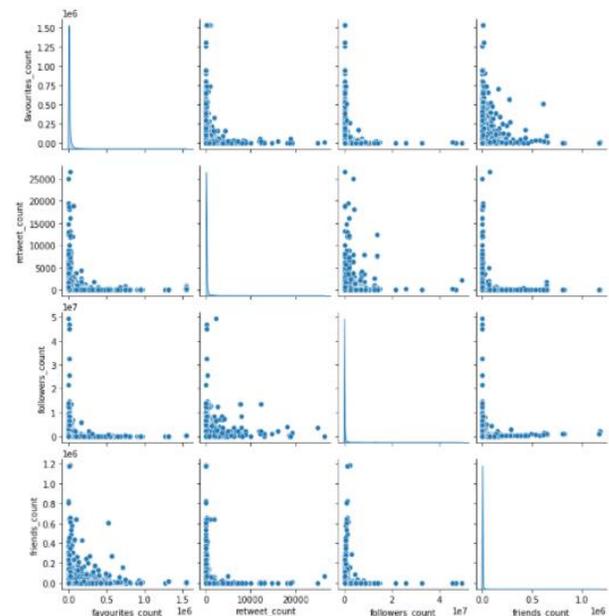

Fig. 3. Correlation between the Tweet Content Features.

TABLE I. TWEET CONTENT FEATURE USED FOR STUDY

Feature	Name	Type	Description
TC1	Title	Textual	Short text of the tweet, it is a summary of the topic's highlight
TC2	Text	Textual	Extended part of tweet that gives topic's details.
TC3	Source	Textual	Indicates source of the tweet.
TC4	is_quote	Boolean	A quote tweet is a re-tweet with some additional text attached. This parameter determines whether or not the selected tweet contains a quote.
TC5	is_retweet	Boolean	A retweet re-sends selected tweet. This field checks whether the selected tweet is a retweet.

TABLE II. USER CONTENT FEATURE USED FOR STUDY

Feature	Name	Type	Description
UC <sub>1</sub>	favourites_count	Numerical	It's the number of tweets that given user has marked as favourite or in the account's lifetime, the number of Tweets this user has liked.
UC <sub>2</sub>	Retweet_Count	Numerical	Retweet count always apply to the original tweet only, there is no counts for a "retweet" tweet, only the original, retweeted tweet. For example, if tweet B is a retweet of tweet A, and C is a retweet of B, in the end So in this example: B will have a count of 0, and so will C. A will have a retweet count of 2. As more individuals repost the tweet, this number may vary.
UC <sub>3</sub>	Followers_Count	Numerical	No. of followers of the twitter account.
UC <sub>4</sub>	Friends_Count	Numerical	It shows the number of friends of twitter account. However the ratio of followers to friends may well impart some useful information about the way in which the twitter account is being used.

#### IV. MODEL IMPLEMENTATION

##### A. Fake Tweet Detection with text and user Features using Statistical Approach

A statistical model is designed to derive the inference about the relationship between the variables and further used to predict the fake tweets. Based on the exploratory analysis, we have found the relationship between the user and content parameters, which are from different domain (i.e text and numeric). These features are combined further to build a model. In order to create a model that can handle continuous data and text data, following algorithm is used. Our dataset  $d$  has total of  $n$  data points:  $(d_1, y_1), (d_2, y_2), \dots, (d_n, y_n)$  respectively, where  $d_i$  is the  $i$ th tweet and  $y_i$  is its label. Each input sample,  $d_i$  comprises 2 input sub-sets here — tweet content feature ( $d_{TC}^i$ ) and user content feature ( $d_{UC}^i$ ).

Algorithm for Tweet and User features using Statistical Approach.

- Read tweet content feature ( $d_{TC}^i$ ).
- $nlp\_input(V_{TC}) \leftarrow$  Process the  $d_{TC}^i$  data using.
- Preprocessing.
- Read all user content feature ( $d_{UC1,UC2,UC3,UC4}^i$ ).
- $tw =$  Convert to a matrix of TF-IDF features ( $V_{TC}$ ).
- Concatenate the features ( $tw, UC_1, UC_2, UC_3, UC_4$ ).
- Splitting into Train and Test set.
- $Model \leftarrow$  classifier ( $\cdot$ ).
- $Model.fit$  (features\_train data).
- Prediction= $Model$  (features\_test data).

Experimental model 1 used Machine learning approach with combination of text and user feature which consists of Text Pre-processing, Tokenization, TF-IDF vectorizer for text part and then converted all the features generated from metadata and n-gram frequencies of the text into a matrix. Each row represents a tweet and each column the value of one of user features. Further we have used different classifier algorithms like Random Forest, Naïve Bayes, Logistic Regression, Naive Bayes, Decision Tree and XGBoost for the experimentation.

##### B. Fake Tweet Detection with text and user Features using CRED\_Tweet Model

In this approach, algorithm operates in two phases. In the first phase extraction,  $d_{TC}^i$  data i.e. text input is processed using regular expression with the help of nltk library to perform basic data cleaning operation and then pre-trained glove model is used to convert text into embedding. In the next phase, User features  $d_{UC}^i$  are then interpolated to higher dimensional dense feature vectors termed meta\_input  $d_{UC}^i$  through separate convolution kernel. In the proposed (CRED\_Tweet) model shown in Fig. 4, a combination of multiple inputs CNN-BiLSTM architecture is successfully used providing text and metadata information through different convolution layers.

Here, vocabulary size  $V$  is used to represent the tweet text of length  $N$ . The embedded input is passed through 3 different convolution layer Conv1D (128, 5, activation='relu') followed by max pooling layer. Here, in the convolution layer used 128 filters. The convoluted vectors is been given to Bidirectional LSTM layer with 128 internal unit with dropout=0.3 and kernel\_regularizer attributes and further to flatten. In the next phase, User features  $d_{UC}^i$  are then interpolated to higher dimensional dense feature vectors termed meta\_input  $d_{UC}^i$  through separate convolution, pooling and flatten layers and further concatenated both the dense tensors,  $Z_i^{(ht)} \oplus X_i'$ . The vector  $Z_i$  is then passed across a fully connected network, with the probability distribution across the two classes being regularized using a dropout layer.

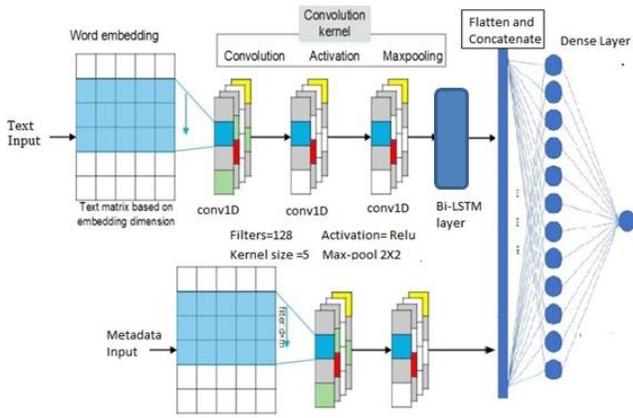

Fig. 4. Block Diagram of CRED\_Tweet Model using user and Content Features.

### Phase I: Extracting text features

In this model, tweet text features (TC) and User content feature (UC) are based on a variant of CNN and processed individually through two different CNN model as the nature of both the feature are different i.e. text and numerical respectively. Although CNNs are mostly employed in image classification [26] or object identification, they have also demonstrated noteworthy performance in several Natural Language Processing (NLP) applications including text classification [27] [28]. Using the convolutional approach, the neural network produce local features around each word of the neighbouring word in the first phase and later they are combined using a max operation. As a result, we use CNN to model textual characteristics for the identification of fake news. Fig. 4 shows the layered processing of the CRED\_Tweet model using user and content features.

Let  $Z$  be the text input, here maximum length of the tweet considered as  $n$  and padded with sequence length  $m$ .  $\in d^1_{TC}$ .

$$Z_i^{TC} = Z_{i,1} \oplus Z_{i,2} \oplus Z_{i,3} \oplus \dots \oplus Z_{i,n} \quad (1)$$

Here, each tweet is been re-presented as a matrix and then convolution filter are applied to derive new features. Here, we have used convolutional filters  $w \in R^{Hl \times Wl \times Dl \times N}$  to construct the new features. Equation (2) shows default convolution function. When the word matrix is been processed through a convolution layer, it can produce the feature  $Z_i$ .

$$Z = W^T \cdot X + b \quad (2)$$

$$Z_i = f(W^T \cdot Z_i^{TC} + b) \quad (3)$$

Here the  $b$  represents the bias, and  $\cdot$  is the convolutional operation. A layer or convolution kernel includes convolution layer, activation layer and pooling layer as shown in Fig. 4. The function  $f$  is the non-linear transformation and also includes ReLU activation layer here.

$$Z_i = \max\{0, Z_i\} \quad (4)$$

During the experimentation,  $Z_i$  has been passed through 3 different convolution layers of 128 neurons and having filter size = 5 and activation=relu. The filter generates a feature map by running over every potential window of words in the tweets.

A max-pooling layer [24] is utilized to get the maximum feature map. The maximum value is denoted as  $Z_i'$ .

$$Z_i' = \max\{Z_i\} \quad (5)$$

By saving the most significant convolutional findings for false news detection, the max-pooling layer can considerably increase the model's robustness. The CNN has the advantage over the LSTM as it decreases the number of dimensions in the input features that must be provided to a sentiment classifier or a natural inference prediction model after the feature extraction stage.

These token vectors ( $Z_i'$ ) are further encoded using a Bi-LSTM, using the forward and backward layers which processes the  $N$  vectors in opposite directions. a hidden state  $h_{ft}$  is emitted by the forward LSTM at each time-step, which is concatenated with the corresponding hidden state  $h_{bt}$  of the backward LSTM to produce a vector  $ht \in R^{Hl \times Wl \times Dl \times N}$ .

$$Z_i(ht) = Z_i(h_{ft} \oplus h_{bt}) \quad (6)$$

### Phase II: Extracting metadata features

Let  $X$  be the metadata numeric input  $\in d^1_{UC}$ .  $X_i^{UC}$  has been passed through 2 different convolution layers of 128 neurons and having filter size = 5 and activation=relu.

$$X_i^{UC} = X_{i,1} \oplus X_{i,2} \oplus X_{i,3} \oplus \dots \oplus X_{i,n} \quad (7)$$

$$X_i = f(W^T \cdot X_i^{UC} + b) \quad (8)$$

$$X_i = \max\{0, X_i\} \quad (9)$$

$$X_i' = \max\{X_i\} \quad (10)$$

At the end, concatenate both the features (text and metadata) feature.

$$Z_i' = Z_i(ht) \oplus X_i' \quad (11)$$

A convolutional network's fully connected layers are essentially a multilayer perceptron that used to map the  $m^{(l-1)}_1 \times m^{(l-1)}_2 \times m^{(l-1)}_3$  activation volume from the preceding various layers into a class probability distribution. As a result, the multilayer perceptron's output layer will contain  $m^{(l-1)}_1$  output neurons, where  $i$  specifies the number of layers in the multilayer perceptron.

$$y_i = f(Z_i') \quad (12)$$

Pred ( $y$  for given  $d_i$  TC,  $d_i$  UC ;  $\theta$ ) = activation function( $f$ ) on ( $Z_i'$ ).

Here,  $Z_i'$  signifies the changed vector after passing through the relevant feed forward sub-network and sigmoid activation function, while  $\theta$  denotes the model parameters employed throughout the experiment.

### Loss function and optimizer:

The aim of any optimization problem is to minimize the cost function, which means of measuring how accurate the data is. We utilized Binary cross entropy in this case, which compares each of the predicted probabilities to the actual class output, which can be 0 or 1. The score is then calculated, penalizing the probabilities depending on their deviation from the predicted value. This refers to how close or far the value is

to the real value. The negative average of the log of corrected projected probability is shown by Binary Cross.

$$\text{Entropy.Loss} = \text{abs}(y_{\text{pred}} - y_{\text{actual}}) \tag{13}$$

Total params: 72,578,510  
Trainable params: 72,578,510  
Non-trainable params: 0

Fig. 5. Fitting the Convolutional Neural Network with Bilstm Model.

Optimizers are techniques or strategies for changing the characteristics of a neural network, such as weights and learning rate, to minimize losses. To minimize losses, the optimizer determines how to alter the weights or learning rates of the neural network. Adam optimizer has proven benchmark outcomes above existing state-of-the-art algorithms by training the neural network in less time and more effectively. Fig. 5 shows fitting of the convolutional neural network with Bi-LSTM model. From the given figure, we can analyse how multiple inputs of different types are processed here through different layers. Continuous input i.e. text or content features of the tweets has been processed through convolutional layers and then passed through Bi-LSTM layer whereas metadata features i.e. user features has been processed through separate convolution layer, then concatenated output of both layer and provided further to fully connected layer for final predictions. In this process, total trainable parameters encountered are 72,578,510.

Precision: Conversely, precision score represents the ratio of true positives to all events predicted as true. In our case, precision shows the number of articles that are marked as true out of all the positively predicted (true) articles:

$$\text{Precision} = \text{TP} / (\text{TP} + \text{FP}) \tag{14}$$

Recall: Recall represents the total number of positive classifications out of true class. In our case, it represents the number of articles predicted as true out of the total number of true articles.

$$\text{Recall} = \text{TP} / (\text{TP} + \text{FN}) \tag{15}$$

F1-Score: F1-score represents the trade-off between precision and recall. It calculates the harmonic mean between each of the two. Thus, it takes both the false positive and the

false negative observations into account. F1-score can be calculated using the following formula:

$$\text{F1} = 2 \cdot (\text{Precision} \cdot \text{Recall}) / (\text{Precision} + \text{Recall}) \tag{16}$$

Accuracy: Accuracy is often the most used metric representing the percentage of correctly predicted observations, either true or false. To calculate the accuracy of a model performance, the following equation can be used:

$$\text{Accuracy} = \text{TP} + \text{TN} / (\text{TP} + \text{TN} + \text{FP} + \text{FN}) \tag{17}$$

The predicted results are evaluated with confusion matrix and other measures like True negative rate (Specificity), True positive rate (TPR), Precision, Recall (Sensitivity), F1-score, accuracy, PRC (Precision-Recall curve) and ROC (Receiver operating curve) etc. Tables III and IV shows the performance results of various parameters. Performance of several user profile categories, tweet content elements, and a combination of both has been examined. The best accuracy found is with decision tree 92.56 among all the ML algorithms along with 92.13 % precision and 92.54 % recall. However the further experimentation with deep learning approaches had shown a benchmark result over the existing state of art techniques.

Deep learning-based analysis has a higher accuracy and detection rate than machine learning. In the experiment 2, CNN with Bi-LSTM is used with the embedding layer and convolution layers with 128 tensors, 5 filters and with relu activation. Further Bi-LSTM is used with 128 neurons and 0.3 dropout and recurrent dropout, with regularizers.l2 (0.01). User features are also separately processed through different CNN layer with with 128 tensors, 5 filters and with relu activation. ‘Relu’ and ‘softmax’ activation function used in dense layer. Model is further compiled with ‘binary\_cross entropy’ loss and ‘adam’ optimizer and found best accuracy with 97.60 with text and metadata feature as shown in Table IV. Size of train set, test and validation set is as given here: 242953, 151846, 151846. The result shown in Table IV, deep learning scenarios, shows that combining certain features is based on user content and tweet content improves accuracy. Among all the algorithms, CRED\_Tweet Approach had achieved 98.44 % precision, 96.56 % recall and 97.60 % accuracy.

TABLE III. SHOWS ACCURACY PARAMETERS FOR DIFFERENT MACHINE LEARNING CLASSIFIERS WITH TEXT AND METADATA FEATURES

Measures in %	LR	NB	RF	DT	XG Boost
Precision	85.17	91.80	91.72	92.13	90.91
Recall	91.02	74.40	90.97	92.54	91.41
F1 score	87.98	84.15	91.64	92.55	91.41
Accuracy	87.98	84.39	91.65	92.56	91.42

TABLE IV. SHOWS ACCURACY PARAMETERS FOR DIFFERENT DEEP LEARNING CLASSIFIERS WITH TEXT AND METADATA FEATURES

Measures in %	Bi-LSTM	CNN	CRED_Tweet Approach
Precision	87.22	98.41	98.44
Recall	93.02	95.44	96.56
F1 score	90.01	97.04	97.60
Accuracy	90.01	97.05	97.60

### C. Analysis of the Result

The performance of the statistical ML models has been observed using ROC and precision-recall curve. ROC curves summaries the trade-off between the true positive rate and the false positive rate for a predictive model with varying probability thresholds whereas Precision-Recall curves illustrate the trade-off between a predictive model's actual positive rate and positive predictive value when different probability thresholds are used. The integral or an estimate of the area under the precision-recall curve is summarized as AUC (Area under curve). Fig. 6 illustrates ROC-AUCs and PRC-AUCs for the deployed models. Here, Random Forest and XG Boost Algorithm gives 0.97 %, Naïve Bayes gives 0.83 %, Logistic Regression and Decision Tree gives 0.93 % ROC-area under curve. The precision-recall curve is constructed by calculating and plotting the precision against the recall for different classifiers at a variety of thresholds. PRC identifies the Positive Predictive Value (precision) for each corresponding value on the sensitivity (recall) scale. Here, Random Forest and XG Boost Algorithm gives 0.97 %, Naïve Bayes gives 0.81 %, Logistic Regression and Decision Tree gives 0.94 % and 0.89 % respectively area under curve for PRC. In our experimentation, Decision Tree had the best precision and recall i.e. 92.13% and 92.54 % with the 92.56 % accuracy which is best among all the algorithms.

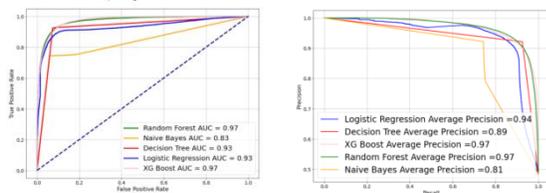

Fig. 6. Shows ROC and Precision-Recall Curve for LR,DT,RF,NB and XG Boost Classifier with Text and Metadata.

During the analysis, all the metadata features have been tested individually as well as in the combination to determine their impact on the tweet credibility detection. However, it has been observed that combination of both news content and user content features improves detection rate. The proposed hybrid model CRED\_Tweet trained in order to improve work in this domain. The model outperforms LSTM with similar weights and shorter training time in terms of test accuracy. As a result, quicker training with CNN is feasible, decreasing the training time required for big datasets. Fig. 7 shows the plots of the training and test accuracy and loss values of the model over the 05 epochs. Model loss figure shows good fit learning curve which shows that training and testing loss that decreases to a point of stability remains almost the same in all epochs.

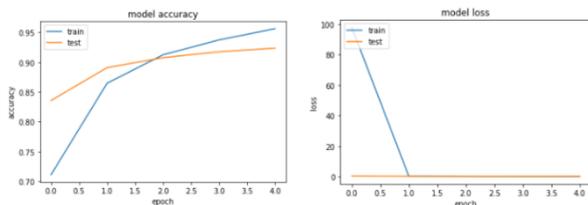

Fig. 7. Shows Accuracy and Loss of CRED\_Tweet Model.

### D. Comparative Analysis

We compare the CRED Tweet model to a few state-of-the-art approaches, which are listed below. TI-CNN technique used by author [29] with text and picture for fake news detection is by combining implicit and explicit characteristics. This technique has used 8,074 real news and 11,941 fake news which gave 92.2 % precision, 92.7 % Recall, 92.10 % F1-score and accuracy. In [30], author have used machine learning approaches with multiple features extracted from different sources, which used 2282 Buzz Feed news related to US election and found 85% AUC with Random Forest, 80 % with KNN and 86 % with XGB. [13] Here author have used Multilingual Approach for Fake Tweet Detection. For Indic i.e. Bengali and Hindi Languages & English give 92.75% Precision, 62.95% Recall, 75% F1-score and 81% accuracy. In [22] various machine learning algorithm has been experimented on Covid-19 epidemic fake news dataset which contains 5000 real tweets and 5000 fake tweets. The method gives 85 % precision, 82% F1-score and 79 % accuracy. Table V and Fig. 8 shows comparative evaluation with other approaches w.r.t precision, recall, F1-score and accuracy parameter.

TABLE V. SHOWS COMPARATIVE EVALUATION OF CRED TWEET WITH OTHER APPROACHES

Author	Methodology	Dataset	Results	Limitation
Yang et al. 2018 [29]	TI-CNN technique to evaluate picture and text for fake news analysis by combining explicit and latent characteristics..	20,015 news, i.e., 11,941 fake news and 8,074 real news	Precision-92.2 Recall-92.7 F1-score-92.10	The model trained only on CNN which may work better with picture but for text RNN model is needed.
Reis et al. 2019 [30]	Machine learning approaches are used with multiple features extracted from different sources	2282 Buzz Feed news related to US election	RF-85% KNN - 80% SVM - 79%	Accuracy for detecting fake account is very low due to small dataset.
D. Car et al. 2020 [25]	Multi-Indic-Lingual Approach used for COVID Fake-Tweet Detection	COVID-19 multilingual tweet dataset for Indic Languages (Hindi and Bengali) & English	Precision-92.75 Recall-62.95 F1-score-75.00	Accuracy for detecting fake account is very low due to small dataset.
Y. Madani et al. 2021 [22]	The various machine learning algorithm has been experimented on Covid-19 epidemic fake news dataset	FakeNewsNet dataset contains 10,000 fake and real tweets (5000 fake tweets and 5000 Real tweets).	RF-79%, DT-62%, LR-60%, SVM-72% NB -53%, MLP-48 %	Accuracy for detecting fake account is very low due to small dataset.

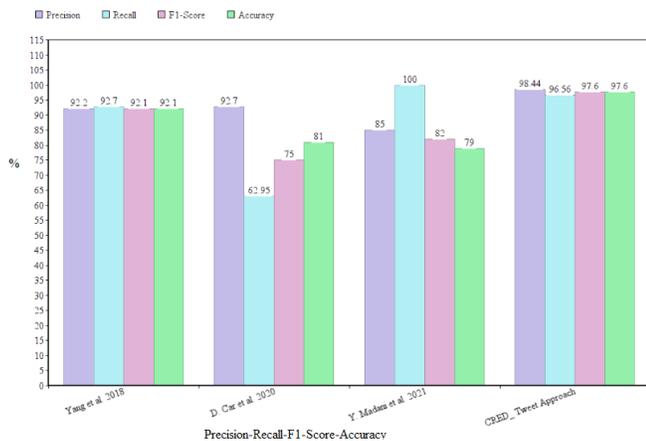

Fig. 8. Comparative Evaluation with other Approaches.

With respect to all the approaches specified above, CRED Tweet Approach uses CNN - Bi-LSTM for Tweet content feature and CNN model for user content features. In this approach 303692 tweets has been used for the experimentation during the process, among which 156612 were fake tweets whereas 147080 were real tweets. CRED\_Tweet Approach had achieved 98.44 % precision, 96.56 % recall and 97.60 % accuracy which is considerably better, also the size of the dataset used during the experimentation is quite large as compared to other state-of-the-art approaches.

The methodology implemented in this paper tackles the problems of fake tweet with the help of natural language processing toolkit and deep learning algorithms. Ultimate aim of the research is to classify each tweet into two distinct categories i.e. “real” or “fake”. Experimentation has been carried out with the perspective wherein combination of user and content features will be used along with the tweet text. We have used multiple input models for the experimentation to handle continuous and numeric features efficiently.

## V. CONCLUSION

In this research work, we have studied the differences between fake and real tweet based on behavioral, content based and comment based features of the tweet and further help to classify fake tweets in an extremely dedicated domain of COVID-19.

The methodology implemented tackles the problems of fake tweet with the help of natural language processing toolkit and performs tweet text analysis as well. Different from the existing work, we take into consideration not only text characteristics, however also used user account characteristics for better results and we have found that the efficacy of fake tweet detection is improved using tweet content features and user content features.

Our proposed model outperforms better than other baseline deep learning and machine learning approaches. Overall, the use of ANN in the identification of fake news appears to be promising. Aside from CNN and Bi-LSTM, we'll look at more complex neural network architectures in the future. When traditional models are combined with task-specific function engineering techniques, they can be extremely useful. In future,

we aimed at doing in-depth exploratory analysis on the tweet in order to find out the indirect features that can affect the credibility of the news. Despite the enormous amount of existing works on fake news identification and detection, there is still room for improvements, and new profound developments into the nature of fake news can lead to more effective and accurate models.

# Integration of Ensemble Variant CNN with Architecture Modified LSTM for Distracted Driver Detection

Zakaria Boucetta<sup>1</sup>, Abdelaziz El Fazziki<sup>2</sup>, Mohamed El Adnani<sup>3</sup>  
Computer Science Engineering Laboratory  
Faculty of Sciences, Cadi Ayyad University  
Marrakech, Morocco

**Abstract**—Driver decisions and behaviors are the major factors in on-road driving safety. Most significantly, traffic injuries and accidents are reduced using the accurate driver behavior monitoring system. However, the challenges occur in understanding human behaviors in the practical environment due to uncontrolled scenarios like cluttered and dynamic backgrounds, occlusion, and illumination variation. Recently, traffic accidents are mainly caused by distracted drivers, which has increased with the popularization of smartphones. Therefore, the distracted driver detection model is necessary to appropriately find the behavior of the distracted driver and give warnings to the driver to prevent accidents, which need to be concentrated as serious issues. The main intention of this paper is to design and implement a novel deep learning framework for driver distraction detection. First, the datasets for driver distraction detection are gathered from public sources. Furthermore, the Optimal Fusion-based Local Gradient Pattern (LGP) and Local Weber Pattern (LWP) perform the pattern extraction of the images. These patterns are inputted into the new deep learning framework with Ensemble Variant Convolutional Neural Network (EV-CNN) for feature learning. The EV-CNN includes three different models, like Resnet50, Inceptionv3, and Xception. The extracted features are subjected to the architecture-optimized Long Short-Term Memory (LSTM). The Hybrid Squirrel Whale Optimization Algorithm (HSWOA) performs both the pattern extraction and the LSTM optimization. The experimental results demonstrate the effective classification performance of the suggested model in terms of accuracy during the detection of distracted driving and are helpful in maintaining safe driving habits.

**Keywords**—Distracted driver detection; ensemble variant convolutional neural network; hybrid squirrel whale optimization algorithm; local gradient pattern; local weber pattern; optimal fusion-based pattern descriptors; long short term memory

## I. INTRODUCTION

The complicated traffic road systems have four different elements like environment, roads, cars, and people. If these four elements are not coordinated, then it leads to road accidents [1]. Recent research reveals that more number of accidents nearly 90% of accidents are caused due to driver error owing to their drunkenness, distraction, and fatigue. Mostly, car accidents highly occur because of the reason of driver distraction. Some of the actions of the drivers like eating or drinking, switching to a favorite radio station and using

mobile devices lead to accidents as they only need to focus on the driving towards road without any distraction [2] [3]. Distracted driving mainly causes the wrong lane changes those results in severe traffic accidents. National Highway Traffic Safety Administration (NHTSA) defines distracted driving as “any activity that diverts attention from driving, including talking or texting on the phone, eating and drinking, etc.”. The rapid development of onboard electronics like smartphones and navigation systems are designed as supplementary factors that influence the distraction of the driver [4]. Hence, it is essential for developing in-depth research on determining their occurrence mechanisms, distracted driver attitude, and developing their respective solutions. This can be done for enhancing driving safety and reducing the frequency of distracted driving behaviors [5] [6], [7].

Many research works have been made for identifying the behavior of distracted drivers at different levels. The Gaussian Mixture Model (GMM) model is developed by collecting the parameters of vehicle motion through in-car GPS for judging whether the distraction occurred or not in the driver [7]. The collected vehicle data in the running state is utilized in the existing model based on support vector machine technology and has differentiated them into three classes like high cognitive load distraction, low cognitive load distraction and no distraction [8]. The dynamic parameters regarding the brake baffle position and acceleration baffle position are gathered and involved five diverse machine learning approaches for distinguishing the visual distraction of the driver, lane lateral deviation and longitudinal/lateral acceleration, where the vehicle speed is used in the model. This model achieves an accurate identification of the distraction state of the driver. Recently, the detection approaches of distracted driving relies on the dynamic estimation of vehicle operating parameters like lane deviation, steering wheel angle, acceleration, and vehicle speed for determining the distraction [9] [10]. On the other hand, this methodology requires the installation of additional exclusive data acquisition tools in the vehicle [11]. Concerning the different kinds and specifications, the accuracy and completeness of data acquisition devices are varying which is not beneficial for the application in the practical driving environment.

Various vision and physiological sensors are vastly utilized in monitoring the driver's status. Physiological sensors are commonly limited to estimating particular driving behavior. In

order to evaluate the fatigue and somnolence of the driver, EEG and EOG [12] are mostly used in the existing model. However, these sensors are cost-ineffective and need certain prior information like gaze direction. Some approaches are developed for detecting distracted driver behaviors using vision, vehicle driving status, and physiological parameters. According to the development in computing hardware, neural networks, and camera technology, complete features are allowed to be obtained from complex images. Convolutional Neural Networks (CNNs) [13] are commonly used for certain complex tasks in image processing. Recently, different approaches have been developed in the deep learning concept for solving the problems related to image recognition and classification [14] [15] [16]. These approaches are used for extracting the features from the images and utilized for performing the classification. Yet, the distracted behavior is detected by involving a single pre-trained model, which leads to an overfitting problem that further results in detection failures in practical applications. Therefore, a new distracted driver detection model needs to develop using a deep learning approach.

The main contributions of the research work are described as follows:

- To design a new distracted driver detection model with the support of the suggested hybrid optimization algorithm using the developed ensemble learning for feature extraction through the improved deep learning model for distracted driver detection to reduce traffic accidents by warning the distracted drivers.
- To develop an optimal fusion-based pattern extraction approach by combining the extracted patterns of LGP and LWP for maximizing the entropy of the developed HSWOA-based pattern images.
- To integrate an ensemble variant-CNN for extracting more significant features from the ResNet50, Inceptionv3, and Xception networks for ensuring the highly essential features for the proposed model.
- To develop an improved deep learning model named O-LSTM for detecting distracted driver behavior with the help of suggested HSWOA by optimizing certain parameters in LSTM for enhancing the accuracy and precision of the detection in the proposed distracted driver detection model.
- To introduce the hybrid optimization algorithm named HSWOA for optimizing the fusion weights of the optimal fused patterns and for tuning the hidden neurons and number of epochs of the LSTM to achieve accurate detection performance and to improve the overall performance of the proposed model.
- To evaluate the efficiency of the proposed model by comparing it with diverse heuristic algorithms and also with the different classifiers under various quantitative measures.

The rest of the sections in the proposed model are stated as follows. The Section II discusses the exciting works and their challenges. The Section III explains the proposed distracted

driver detection model using deep learning approaches. The Section IV conveys the optimal fusion-based pattern extraction of the proposed model. The Section V narrates the ensemble variant-CNN-based feature extraction phase for the proposed model. The Section VI describes the detection phase and suggested HSWOA of the proposed model. The Section VII depicts the achieved results of the proposed distracted driver detection model. The Section VII concludes the developed distracted driver detection model.

## II. LITERATURE SURVEY

### A. Related Work

In 2020, Omerustaoglu et al. [17] have developed the distracted driver detection approach based on vision data for improving the generalization ability of the proposed model. The dataset was obtained as the sensor data and driver images that were acquired from the practical drives. The distraction of the driver was identified through the two-stage model with the help of deep learning approaches. This proposed model was validated and shown that proposed model was enhanced the overall performance of both the fused approaches based on the public dataset. In 2021, Huang et al. [18] have implemented a hybrid form of deep learning framework for finding the distracted behaviors of the drivers by processing the image features. The co-operative pre-trained model was developed for enhancing the accuracy while detecting the driving activity in the system with the help of combined deep learning architectures. The simulation analysis has shown that the proposed model has secured better classification accuracy in the detection of distracted driver behavior and also confirmed the potential capability of maintaining the safety driving without any accidents.

In 2021, Jegham et al. [19] have proposed a Kinect sensor for recognizing the safe driver with the multimodal signals from the sensors. Then, the attention-based network was developed for performing the cognitive process towards the deep network by concentrating on the motion and silhouette of the driver that was acquired from the correlated driver scenes. The analysis results have revealed that the proposed model was highly effective in terms of providing high classification accuracy when compared with the conventional methods. In 2020, Ou and Karray [20] have suggested a novel driver distraction detection model using an improved deep learning approach for determining distracted behavior in different driving conditions. Initially, the generative models were designed for generating the images related to diverse driving conditions and then, the discriminative models for classifying the generated images. The collected dataset was correlated with newly generated training samples, and then, the deep learning approach was trained for recognizing the distraction. The suggested framework has proved that the generative models have a high ability to produce driver images under diverse driving conditions.

In 2021, Pal et al. [21] have investigated a deep learning model for classifying and identifying the distracted behavior of drivers to alert them at the right time and also has ensured an effective solution for the problem. The integrated model has divided the driver activity into ten different categories that have also included with the safe driving class. When the

distracted driver was observed, the proposed model has detected the event and eliminated the accidents by alerting the drivers. In 2021, Rao et al. [22] have integrated a detection model for identifying the distraction behavior of the driver using the driving images that were captured using an in-vehicle camera. Here, the whitening of the image has occurred for minimizing the correlation and redundancy of the pixel matrix. The analysis results have shown that a higher accuracy was acquired through the proposed model in detecting the distraction behavior when compared with the existing machine learning models.

In 2021, Kumar et al. [23] have proposed a deep learning-based detection model for finding driver distraction behavior. This introduced model has provided superior performance based on the practical environmental inputs, which was determined by comparing it with the other state-of-the-methods. The suggested approaches have secured high scores in all the quantitative measures for classification. In 2021, Dunn et al. [24] have implemented the data from the two different driving studies by incorporating the automatic-equipped vehicles with the help of a driving automation system in order to analyze the driver behaviors. The analysis results have ensured with significant insights of the driving automation systems under diverse operational phases. Here, the overreliance and overtrust on the advanced technologies have reduced certain safety benefits of these proposed systems.

### B. Problem Statement

How to correctly identify whether the driver is in a distracted driving state and provide the necessary warnings for the driver to avoid potential safety risks has become one of the

most concerning issues. Many techniques have been developed earlier, and some of them are given pros and cons as mentioned in Table I. CNN and LSTM-RNN [17] reduce the overfitting problem and improve the overall accuracy rate. However, it shows the performance loss owing to the viewpoint of the car and camera are not the same as in the public datasets as their collection setup. HCF [18] achieves a good identification rate and also achieves better classification performance. Yet, when the number of training samples is increased, the performance rate can be affected. DSA [19] enhances the classification capability by choosing the highly essential regions from the images. However, it is slightly suffered from high illumination variation particularly focusing at the front view. CNN [20] efficiently reduces the computational time using the feature selection process. Still, it does not be applicable for real-time applications as it needs to be enhancing the effectiveness of the controller. CNN [21] efficiently detects the distracted regions. Yet, it is difficult to train the data and the computation of the network is slow. Deep CNN [22] attains a better accuracy rate at a faster speed. However, more memory is required to train the data. CapsNet [23] attains better accuracy, precision and recall values even with the utilization of less model parameters. On the other hand, it does not consider the detection of drowsiness, which is a significant non-visual feature. VCC NDS and DAF NDS [24] show effective performance on studying the Over-trust and overreliance on driving automation. But, it includes a very less number of samples for investigation. Hence, owing to the consideration of these existing challenges, it is well-determined to develop a new driver distraction model for avoiding traffic accidents caused by drivers.

TABLE I. FEATURES AND CHALLENGES OF EXISTING DISTRACTED DRIVER DETECTION MODELS

Author [citation]	Methodology	Features	Challenges
Omerustaoglu <i>et al.</i> [17]	CNN and LSTM-RNN	It reduces the overfitting problem and improves the overall accuracy rate.	It shows the performance loss owing to the viewpoint of the car and camera are not the same as in the public datasets as their collection setup.
Huang <i>et al.</i> [18]	HCF	It achieves a good identification rate. It achieves better classification performance.	When the number of training samples is increased, the performance rate can be affected.
Jegham <i>et al.</i> [19]	DSA	It enhances the classification capability by choosing the highly essential regions from the images.	It is slightly suffered from high illumination variation particularly focussing at the front view.
Ou and Karray [20]	CNN	It efficiently reduces the computational time using the feature selection process.	It does not be applicable for real-time applications as it needs to be enhancing the effectiveness of the controller.
Pal <i>et al.</i> [21]	CNN	It efficiently detects the distracted regions.	It is difficult to train the data. The computation of the network is slow.
Rao <i>et al.</i> [22]	Deep CNN	It attains a better accuracy rate at a faster speed.	More memory is required to train the data.
Kumar <i>et al.</i> [23]	CapsNet	It attains better accuracy, precision and recall values even with the utilization of less model parameters.	It does not consider the detection of drowsiness, which is a significant non-visual feature.

### III. ARCHITECTURAL VIEW OF DISTRACTED DRIVER DETECTION WITH DATA COLLECTION

#### A. Architectural Description

Before, the classification of a distracted driver is performed in two different ways. In the first way of method, wearable sensors are used for computing physiological and biomedical signals like heart rate, muscular and vascular activities and brain activity. However, the above-mentioned method has certain disadvantages like user involvement and hardware cost. In the second way of method, the cameras are used for classifying distracted drivers, where diverse vision-based approaches are involved for monitoring the distracted behaviors in practice such as fatigue-related features from the driver's face, body postures, gaze and head pose detection. Mostly, the vision-based techniques are incorporated as the two-step structure, where the significant features are obtained from the original data based on the hand-crafted techniques, and next, the classifiers are considered according to the hand-crafted features. If the two-step structure is used in the approach, then the approach was not able to acquire an optimal trade-off among the hand-crafted features and robustness of the trained classifier. The vision-based approaches are involved with the decision trees and Support Vector Machines (SVMs) for detecting distracted drivers, which seeks most of the research. CNNs are generally utilized for complex tasks related to image processing. Deep learning models have been developed rapidly into speech recognition, natural language processing, and computer vision and ensured promising outcomes for solving the distracted driver detection problem. Recently, various deep learning approaches like DenseNet, ResNet, Inception, VGGNet, and AlexNet have been developed for handling the problems related to image recognition and classification. These techniques are used for extracting the significant features from the images and are considered for image classification. But, the recognition of distracted driver behavior based on the single pre-trained model may lead to overfitting issues that further result in detection failure. Therefore, it is required to develop a new distracted driver detection model using ensemble learning approaches that are diagrammatically represented in Fig. 1.

A new distracted driver detection model is developed and processed under various steps for detecting distracted driver behaviors while driving to ensure safe driving and to avoid traffic accidents with the help of deep learning and a hybrid optimization algorithm. The input driver images with both safe driving and distracted behavior images are obtained from publicly available resources. The collected input images were considered for the optimal fusion-based pattern extraction phase. This phase concatenates the pattern extracted from two different pattern extraction approaches like LGP and LWP, where the optimized weights for respective patterns are incorporated for maximizing the entropy of the extracted patterns. The fusion weights are optimized with the help of a suggested hybrid algorithm named HSWOA, which is implemented by combining the features of SSA and WOA.

Then, the optimized patterns are given into the developed EV-CNN, in which the deep features are extracted from the pooling layers of the ensemble variants of CNN like ResNet 50, inceptionv3 and xception for obtaining the most accurate features of the proposed model to the detection phase. Further, the extracted features are subjected into the developed O-LSTM, where the suggested HSWOA is used for optimizing the number of hidden neurons and number of epochs of LSTM to improve the accuracy and precision of the proposed model. At last, the distracted driver behaviors are detected using the implemented O-LSTM.

#### B. Data Collection

The proposed distracted driver detection model collects the required images from the "https://www.kaggle.com/c/state-farm-distracted-driver-detection/data: access date: 2021-12-27". Here, the dataset consists of the driver images of doing some actions such as reaching behind, doing makeup, talking on the phone, eating and texting. The dataset is comprised of ten classes to predict the driver distraction behavior with both the test and train data. The input images of the proposed distracted driver detection model are represented as  $IM_p^{indriv}$ , where  $p = 1, 2, \dots, P$  and  $P$  show the total number of collected driver images from the dataset. The sample images for ten classes are listed in Fig. 2.

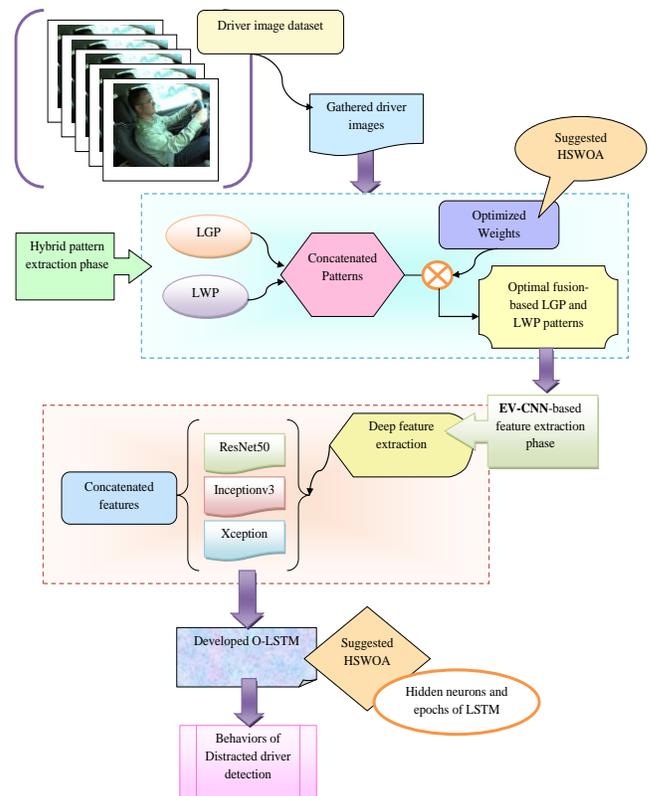

Fig. 1. The Proposed Architecture of a New Distracted Driver Detection Model.

Class description	Image 1	Image 2	Image 3
Class 1: Safe driving			
Class 2: Texting-right			
Class 3: Talking on the phone-right			
Class 4: Texting-left			
Class 5: Talking on the phone-left			
Class 6: Operating the radio

IV. PRIMARY STEPS OF DISTRACTED DRIVER DETECTION:  
OPTIMAL FUSION APPROACH

A. Optimal Fusion-based Pattern Extraction

The proposed distracted driver detection model utilizes the LGP and LWP for extracting the patterns from the input images  $IM_p^{indriv}$  to attain the accurate performance while detecting distracted drivers while driving. LGP [25] is used for providing the transformation of output image, which is independent of the global intensity variations. This approach is employed for ensuring the facial features but, it is highly sensitive to the local variations along with the edge components in the human face. Similarly, LWP [26] is utilized in the proposed model as it provides superior performance over other descriptors. However, this model considers only four pixels on both the vertical and horizontal directions that are insufficient to represent the local information. Therefore, the pattern extracted from the LGP and LWP is integrated with the optimized weights, respectively using the suggested HSWOA for enhancing the detection performance and to overcome the existing challenges. Here, the optimized fusion weights with the LGP-based pattern is denoted by  $\alpha$ , and the optimize weights with the LWP-based pattern is indicated by  $\beta$ . The optimal fusion-based patterns are obtained through in Eq. (1).

$$Pt_z^{of} = (Pt_x^{LGP} * \alpha) + (Pt_x^{lwd} * \beta) \quad (1)$$

The main objective  $FF_1$  of optimizing the weights of the extracted patterns is to maximize the entropy of the proposed model that is given in Eq. (2).

$$FF_1 = \arg \max_{\{\alpha, \beta\}} \left( \frac{1}{EN} \right) \quad (2)$$

Here, the term  $EN$  denotes the entropy, which is computed through the Eq. (13). Entropy  $EN$  gives “the amount of loss of data in a given input which provides the required information for feature extraction”. This is shown in the Eq. (3).

$$EN = \sum_{x=0}^{X-1} Pt_x \log Pt_x \quad (3)$$

The total number of patterns is expressed as  $X$ . The entropy needs to be maximized for acquiring the efficient optimized pattern for the distracted driver detection model. Finally, the Optimal fusion patterns are denoted by  $Pt_z^{of}$ . The optimal fusion-based pattern extraction with LGP and LWP is represented in Fig. 3.

B. LGP

The input images  $IM_p^{indriv}$  are subjected to the LGP technique for extracting the local gradient pattern in the neighboring by involving the intensity gradient profile of the neighborhood measure. Therefore, the LGP value of  $IM_p^{indriv}$  is computed for each pixel  $(a_d, b_d)$  using Eq. (4).

$$LGP(a_d, b_d) = \sum_{i=0}^l t(h_i - \bar{h}) 2^i, \quad (4)$$

$$t(a) = \begin{cases} 1, & a \geq 0 \\ 0, & \text{otherwise} \end{cases}$$

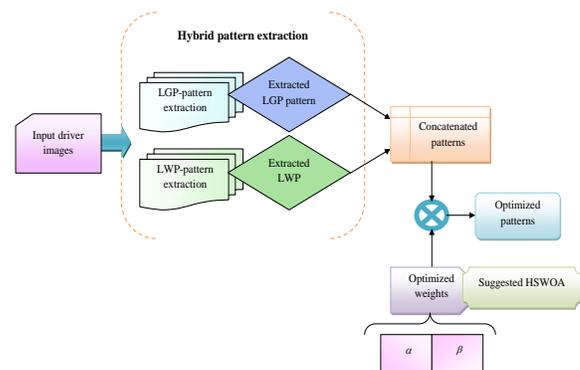

Fig. 3. Optimal Fusion-based Pattern Extraction for the Proposed Distracted Driver Detection Model.

Here, the term  $h_i$  represents the gradient of the neighboring pixel  $I$  and the average gradient of the neighboring pixels are denoted as  $\bar{h}$  that are calculated as given in Eq. (5) and Eq. (6).

$$h_i = |T_i - T_c| \quad (5)$$

$$\bar{h} = \left(\frac{1}{8}\right) \sum_{i=0}^7 h_i \quad (6)$$

The extracted patterns are obtained from the LGP technique that is expressed as  $Pt_x^{LGP}$ .

### C. LWP

The proposed distracted driver detection model employs the input images  $IM_p^{indriv}$  for extracting the patterns to determine the distracted driver. LWP is the pattern extraction technique by determining the ratio of variations present in the pixel intensity. This is said to be stimulus information under the visual perception. Differential excitation computes “the ratio of change in pixel intensity between center pixels against its neighbors”. It identifies the local salient visual patterns. The differential excitation is estimated at central pixel  $\varepsilon(y_s)$  using Eq. (7).

$$\varepsilon(y_s) = \arctan \left\{ \sum_{j=0}^{q-1} \left( \frac{y_j - y_s}{y_s} \right) \right\} \quad (7)$$

Here, the term  $q$  denotes the number of neighbors on a circle of radius  $B$  and  $y_s$  indicates the intensity value of the central pixel. If  $\varepsilon(y_s)$  is determined as positive, then it influences the surroundings pixel to be lighter than the present pixel. In contrast, if  $\varepsilon(y_s)$  is determined to be negative, it influences the surrounding pixels are darker than the present pixel. The orientation component of LWD is estimated through Eq. (8).

$$\theta(y_s) = \arctan \left\{ \frac{y_{\left(\frac{q}{2}-B\right)} - y_{(B)}}{y_{(q-B)} - y_{\left(\frac{q}{2}-B\right)}} \right\} \quad (8)$$

The extracted patterns using LWD are denoted as  $Pt_x^{lwd}$ .

## V. ENSEMBLE LEARNING-BASED FEATURE EXTRACTION FOR DISTRACTED DRIVER DETECTION

### A. Ensemble Learning Model

The proposed distracted driver detection model extracts diverse features from the optimized patterns  $Pt_z^{of}$  for performing efficient detection performance in the developed model using the suggested HSWOA. CNN-based techniques

[27] are selected in the proposed model as it provides better recognition features with the utilization of its more layers and it is independent of the human efforts when implementing its functionalities. Then, the extracted deep features from the pooling layer of the ensemble variant model, where the ResNet50 [28], inceptionv3 [29] and xception [29] approaches are used. ResNet50 in the proposed model contains huge number of layers, which can be trained without enhancing the training error percentage. Similarly, inceptionv3 in the proposed model gains high performance and effectively utilizes the computing resources with less computation load. Xception provides superior performance when utilizing in the larger image classification dataset and ensures higher computational efficiency. The significant features are obtained from the ensemble variant model from the extracted deep features for the distracted driver detection phase. Finally, the extracted features from the three approaches are concatenated and put forwarded to the O-LSTM-based detection. The developed EV-CNN-based feature extraction is depicted in Fig. 4.

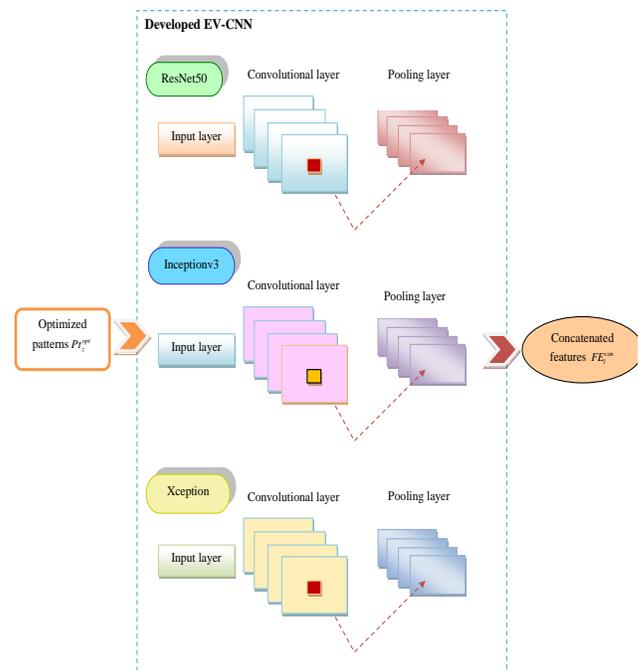

Fig. 4. Feature Extraction of Proposed Distracted Driver Detection Model using EV-CNN.

### B. ResNet Model

The proposed distracted driver detection model uses the ResNet50 technique for extracting the significant features from the optimal fusion-based pattern images. The ResNet [30] ensures improved performance even when more number of images is given into it. This model is developed using the skipping connections that is made on the two to three layers with ReLU and batch normalization. The residual learning is applicable to the multiple layers of architecture. The residual block of the ResNet is computed using the Eq. (9).

$$Ol = J(in, U + in) \quad (9)$$

Here, the term  $O_l$  denotes the output layer,  $in$  shows the input layer, and the residual map are represented by the function  $J$ . The residual block on the ResNet is processed when the dimensions of the input layer and output layer are the same. Additionally, each block of the ResNet contains two or three layers. The first two layers of the ResNet express the “GoogleNet by doing convolution  $7 \times 7$ ” and max-pooling at the size of  $3 \times 3$ . The extracted features from the pooling layer of ResNet50 are represented as  $FE_g^{RES}$  that is computed with the number of 400 features.

### C. Inception Model

The extracted deep features  $DF_f^{cmn}$  are used for obtaining the essential features from Inceptionv3 approach for the proposed distracted driver detection model. Inception model is used for clustering the sparse convolution kernel structure into the diverse dense sub-convolution kernel combinations. Convolutional filters with various sizes are employed for acquiring the diverse receptive fields. The training procedure of the inception is described initially with the input deep features into the three convolution layers of the inception model. Three convolution layers are performed with kernels of  $3 \times 3$  along with the one max pooling layer for extracting the low latitude features from the input deep features. Further, two convolution layers are used with the help of kernels of  $1 \times 1$  and  $3 \times 3$  and also with the one max pooling layer are utilized for extracting the features. Then, the three pooling layer is used for obtaining the high-dimensional features from the input deep features. The extracted features from the pooling layer of inception model are counted to be 400, which are indicated by  $FE_h^{ine}$ .

### D. Xception Model

The proposed distracted driver detection model uses the xception technique for extracting the significant features from the deep features  $DF_f^{cmn}$ . Xception model employs 36 convolutional layers for performing the feature extraction based on the CNN. These convolutional layers are sorted accordingly into the 14 modules, which are covered by the linear residual connections. The input deep features  $DF_f^{cmn}$  are considered to the Convolutional kernels for extracting the features. The output of the convolution layer is computed using Eq. (10).

$$B_p = f(CK_p * B_{p-1} + c_p) \quad (10)$$

Here, the term  $B_p$  denotes the output of  $P^{th}$  convolution layer; the activation function is indicated by  $f(\cdot)$ , the convolution kernel is represented by  $CK_p$ , convolution operation is denoted by “\*” and the offset parameter is shown by  $c_p$ . The feature maps are given into the separable convolution for feature extraction. Here, the separable convolution is utilized for minimizing the parameters count

and computation complexity in the model. The extracted features from the pooling layer of the Xception model are counted to be 400 that are denoted by  $FE_k^{xcep}$ .

Finally, the extracted features from ResNet50, Inceptionv3 and Xception are concatenated into a single set of features, which is expressed by  $FE_l^{con} = FE_g^{RES} + FE_h^{ine} + FE_k^{xcep}$ , where  $l = 1, 2, \dots, L$  and  $L$  denotes the total number of concatenated features for the proposed distracted driver detection model.

## VI. HYBRID META-HEURISTIC-BASED DISTRACTED DRIVER DETECTION

### A. LSTM-based Detection Model

The concatenated features  $FE_l^{con}$  are utilized in the O-LSTM [31] for classifying distracted driver behaviors to avoid traffic accidents. The classification phases are made stronger by the recurrent structures of the deep learning algorithm and so, the external memories are needless for storing the output. The recurrent structures of the LSTM classifiers provide less complexity in computation. The four components such as “cells, input gate, output gate and forget gate” are presented in the LSTM network. The cell carries the data and passed to the input and output gate. The forget gate is initially used for determining the information passed through the network that is shown in Eq. (11).

$$c_t = \sigma \left( B_c \cdot \left[ k_{t-1}, (FE_l^{con})_t \right] + w_c \right) \quad (11)$$

Here, the terms  $\sigma$  and  $k_t$  are correspondingly shown as sigmoid activation function and the output of the hidden state. The weight matrices are described as  $B_c, B_g, B_h, B_q$  and the input variable is given as  $FE_l^{con}$ . Then, the cell output, output gate and forget gate are represented as  $g_t, q_t$  and  $G_t$ , respectively. The biased values of these gates are portrayed as  $w_c, w_f, w_h, w_q$ . The input gate is formulated in Eq. (12).

$$g_t = \sigma \left( B_g \cdot \left[ k_{t-1}, (FE_l^{con})_t \right] + w_f \right) \quad (12)$$

Further, it updates a new cell states using sigmoid function that generates the new vector  $\hat{G}_t$  that is shown in Eq. (13).

$$\hat{G}_t = \tan k \left( B_h \cdot \left[ k_{t-1}, (FU_{g^*}^{opt})_t \right] + w_h \right) \quad (13)$$

For updating the old cell into new cell, the earlier state is integrated with forget gate and added more parameters that is given in Eq. (14).

$$G_t = g_t * G_{t-1} + c_t * \hat{G}_t \quad (14)$$

Finally, the output gate provides the cell state using the output of the sigmoid of output gates that are given in Eq. (15) and Eq. (16).

$$q_t = \sigma \left( B_q \cdot \left[ k_{t-1}, (FE_t^{con})_t \right] + w_q \right) \tag{15}$$

$$k_t = q_s * \tan k(d_t) \tag{16}$$

The sigmoid activation function of the LSTM classifier is represented as  $\sigma$  with hyperbolic tangent  $\tanh$ . The distracted driver behaviors are detected using the developed O-LSTM model that is depicted in Fig. 5.

**B. Objective Model**

The detected distracted behavior of the driver shows the accurate detection outcomes based on the developed O-LSTM with the suggested HSWOA. The detected results of the proposed distracted driver detection model are obtained as the various classes of safe driving and distracted driving behaviors. The objective function of the proposed distracted driver detection model is to maximize the detection accuracy and precision that is given in the Eq. (17).

$$Ofun_{(2)} = \arg \min_{\{HN_{lstm}^{hm}, Ep_{lstm}^{ep}\}} \left( \frac{1}{ay + pr} \right) \tag{17}$$

Here, the term  $HN_{lstm}^{hm}$  and  $Ep_{lstm}^{ep}$  are represented as hidden neurons and the number of epochs of the LSTM, respectively. The developed HSWOA optimizes the number of hidden neurons in the range of [5,255] and number of epochs in the interval of [5, 20]. Accuracy  $ay$  is measured as the “closeness of the measurements to a specific value” as given the Eq. (18).

$$accy = \frac{(t^p + t^n)}{(t^p + t^n + f^p + f^n)} \tag{18}$$

Here, the true positive and true negative values are shown as  $t^p$  and  $t^n$ , respectively and false positive and false negative values are given as  $f^p$  and  $f^n$ , respectively. Precision  $pr$  is explained as “the fraction of relevant instances among the retrieved instances” as given in Eq. (19).

$$pr = \frac{t^p}{t^p + f^p} \tag{19}$$

The solution encoding of the suggested HSWOA is shown in Fig. 6.

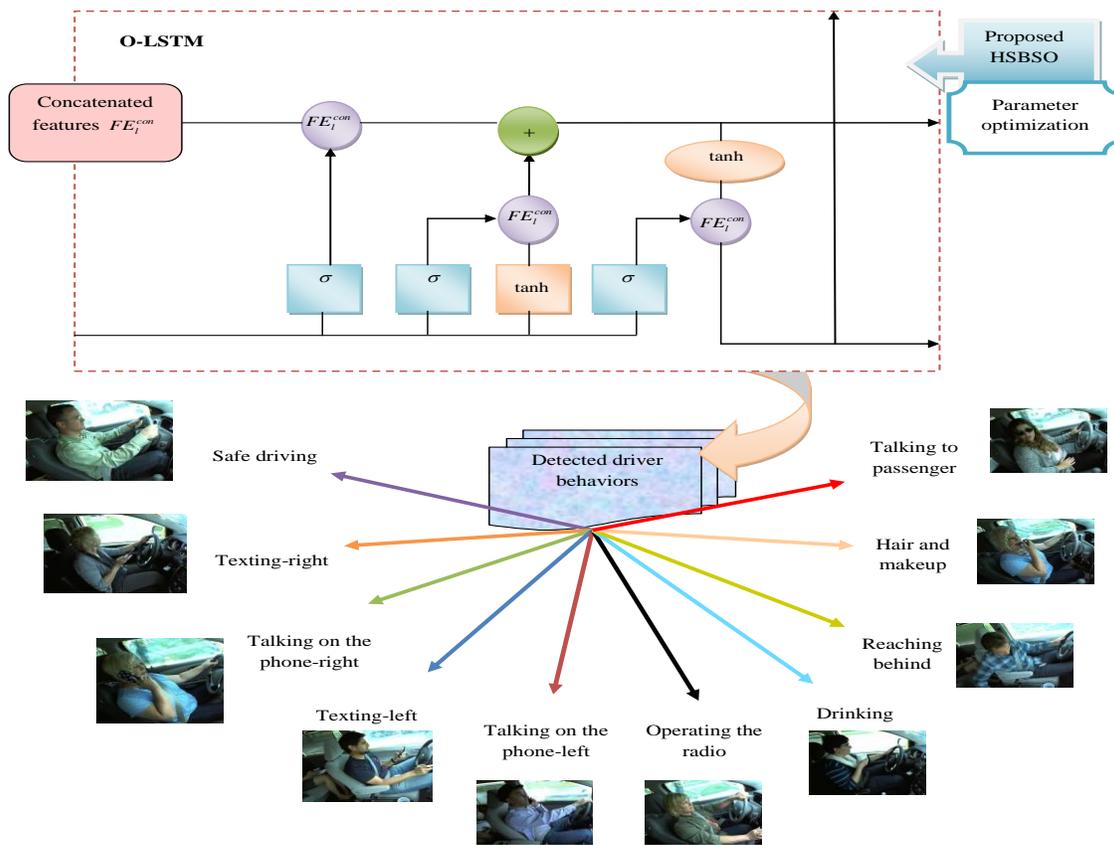

Fig. 5. Proposed O-LSTM-based Distracted Driver Detection Model

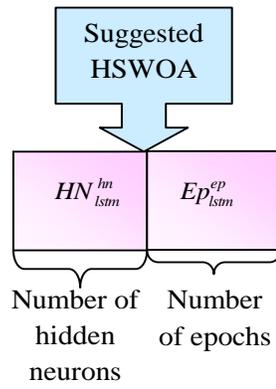

Fig. 6. Solution encoding of the Proposed Distracted Driver Detection Model using the Developed HSWOA.

### C. Proposed HSWOA

The proposed distracted driver detection model employs the suggested HSBSO for reducing the training complexity in LSTM by optimizing its hidden neurons and epochs and also tuning the weights of the extracted deep features from the developed EV-CNN. WOA [31] algorithm is chosen for the proposed model due to the ability to solve the real-time optimization problems, which is also simple and easy to implement. But, it does not contain the capability to balance the exploration and exploitation phase. Also, it is easily falls into the local optimum problem. To overcome these challenges of WOA, a meta-heuristic algorithm named SSA [32] is adopted into WOA. Thus, the HSBSO algorithm is developed by adopting the features of SSA into the WOA algorithm. The SSA algorithm is capable of generating the optimal solution for high-dimension optimization problems at the limited time period. In the proposed HSBSO, two random variables  $c$  and  $d$  are introduced, which are determined by the fitness-based computations that are shown in Eq. (20) and Eq. (21).

$$c = \text{abs}(f(j) - \text{bestfit}) \quad (20)$$

$$d = \text{abs}(\text{worstfit} - f(j)) \quad (21)$$

Here, the term  $f(j)$  denotes the fitness of the current solution and the best fitness value and worst fitness value are denoted by  $\text{bestfit}$  and  $\text{worstfit}$ , respectively. If the condition ( $c > d$ ) is satisfied, then the position update takes place using the SSA otherwise, the position update takes place according to the WOA algorithm.

SSA [26] is implemented based on the motivation of the jumping mechanism and gliding strategies of the flying squirrels. The entire optimization process was carried out in the summer and winter phase. Initially, considered the count of the population is  $PP$  and the upper bound and lower bound of the search space are regarded as  $z_U$  and  $z_L$ . Every individual in the population is generated according to Eq. (22).

$$z_a = z_L + \text{rnd}(1, dd) \times (z_U - z_L) \quad (22)$$

Here, the term  $\text{rnd}$  denotes the random number at the range of 0 to 1,  $z_a$  indicates the  $a^{\text{th}}$  individual and the dimension of the search space is expressed by  $dd$ . The SSA algorithm needs only one squirrel at the tree and so, equal number of trees and squirrels are present in the search space. Here, the squirrels are categorized based on the fitness of the population into three diverse varieties such as individuals located at hickory trees  $f_{hk}$  with the minimum fitness, individuals located at acorn trees  $f_{ac}$  with the ranking of second fitness and individuals located at normal trees  $f_{nt}$ . Then, the foraging behavior is designed mathematically as follows.

The position of the flying squirrels in the acorn nut trees  $f_{ac}$  that jumps to hickory nut tree. Here, the new position of the squirrels is computed in Eq. (23).

$$z_{ac}^{\text{new}} = \begin{cases} z_{ac}^{\text{old}} + rd_G GC(z_{hk}^{\text{old}} - z_{ac}^{\text{old}}) & \text{if } r_1 \geq PR_{pd} \\ \text{random position} & \text{others} \end{cases} \quad (23)$$

Here, the gliding constant is indicated by  $GC$  and the random function  $r_1$  is determined from the interval  $[0, 1]$ . The random gliding distance is shown by  $rd_G$  that is computed in Eq. (24).

$$rd_G = \frac{hh_G}{\tan(\phi) \times cv} \quad (24)$$

The terms  $cv$  and  $hh_G$  are considered as the constant values and the gliding angle  $\tan(\phi)$  is calculated in Eq. (25).

$$\tan(\phi) = \frac{F}{M} \quad (25)$$

The drag force is represented by  $F$  and the lift force is expressed by  $M$  and these two forces are computed as follows.

$$F = \frac{1}{2\rho v^2 s C_{dd}} \quad (26)$$

$$M = \frac{1}{2\rho v^2 s C_{ll}} \quad (27)$$

Here, the terms  $\rho$ ,  $v$ ,  $s$ ,  $C_{ll}$  and  $C_{dd}$  are indicated as the constants. Several numbers of squirrels are located on the normal trees that are migrated to the acorn nut trees for getting food resources, where the new position is decided by Eq. (28).

$$z_{nt}^{\text{new}} = \begin{cases} z_{nt}^{\text{old}} + rd_G GC(z_{ac}^{\text{old}} - z_{nt}^{\text{old}}) & \text{if } r_2 \geq PR_{pd} \\ \text{random position} & \text{others} \end{cases} \quad (28)$$

Here, the term  $r_2$  denotes the random function that is determined from the interval  $[0,1]$ . Similarly, some squirrels in the normal tree are changed its location to the hickory nut tree, in which the new position of the squirrel is formulated in Eq. (29).

$$z_{nt}^{new} = \begin{cases} z_{nt}^{old} + rd_G GC(z_{hk}^{old} - z_{nt}^{old}) & \text{if } r_3 \geq PR_{pd} \\ \text{random position} & \text{others} \end{cases} \quad (29)$$

Here, the term  $r_3$  indicates the random function that is determined from the interval  $[0,1]$ .

Estimate the seasonal monitoring condition: This step is to avoid the local minima problem. Here, the seasonal constant  $SE$  and the respective minimum values are correspondingly computed in Eq. (30) and Eq. (31).

$$SE_c^m = \sqrt{\sum_{t=1}^q (z_{ac,t}^m - z_{hk,t}^m)^2}, m = 1, 2, 3 \quad (30)$$

$$SE_{cMIN} = \frac{10E - 6}{\frac{j}{(j_{max})^{2.5}}} \quad (31)$$

Here, the number of iterations is indicated by  $j$  and maximum number of iterations is denoted by  $j_{max}$ . The season is determined through the condition  $SE_c^m < SE_{cMIN}$ . When  $SE_c^m < SE_{cMIN}$  is satisfied, the winter season is started or else the season will be unchanged. When the summer season arises, all individuals update their position to  $f_{hk}$  that is shown in Eq. (32).

$$z_{nt}^{new} = z_L + LEVY(nm) \times (z_U - z_L) \quad (32)$$

The levy distribution is known to be strong tool for enhancing the global exploration capability for most of the optimization algorithms that is given in Eq. (33).

$$LEVY(y) = 0.01 \times \frac{dr_p \times \sigma}{|dr_q|^{\frac{1}{\beta}}} \quad (33)$$

Here, the two different functions denoted by  $dr_p$  and  $dr_q$  that is in the range of  $[0,1]$  and the constant is indicated by  $\beta$  and also the term  $\sigma$  is computed through Eq. (34).

$$\sigma = \left( \frac{\Gamma(1 + \beta) \times \sin\left(\frac{\pi\beta}{2}\right)}{\Gamma\left(\frac{1 + \beta}{2}\right) \times \beta \times 2^{\frac{(\beta-1)}{2}}} \right) \quad (34)$$

Finally, the algorithm stops when the maximum count of iterations is fulfilled.

WOA [31] is encouraged by the hunting behavior of humpback whales. These whales usually catch the pack of small fishes in their close surfaces for their food sources. This foraging happens by generating various bubbles in the circular direction around their prey. This unique behavior is known to be “bubble-net feeding method of humpback whales”.

1) “Encircling prey”: Every whale is indicated as the search agent. The abilities of the humpback whales are intended to identify the prey location and encircle them. WOA is initiated the searching without knowing the position of the optimal solution in the search space and then, the target food source location is considered as the current optimal solution. If the best candidate is identified, then all other candidates will update their position based on the best solution. The encircling behavior of the whales is represented as given in the Eq. (35).

$$\vec{B} = \left| \vec{A} \cdot \vec{z}^*(j) - \vec{z}(j) \right| \quad (35)$$

$$\vec{z}(j+1) = \vec{z}^*(j) - \vec{C} \cdot \vec{B} \quad (36)$$

Here the current iteration among the search agent is given as  $j$ , the position of the current solution and the best solution are defined as  $z$  and  $z^*$ , respectively and the coefficient vectors are denoted as  $\vec{C}$  and  $\vec{A}$  that are formulated in the Eq. (37) and Eq. (38).

$$\vec{C} = 2 \cdot \vec{b} \cdot \vec{V} - \vec{b} \quad (37)$$

$$\vec{A} = 2 \cdot \vec{V} \quad (38)$$

Here, the random vector is given as  $V$  that lies in the interval of  $[0,1]$  and the convergence factor is shown as  $b$ , which simultaneously reduces from 2 to 0 with maximizing the number of iterations.

2) “Bubble net attacking method”: This hunting behavior of whales is classified into two phases namely “shrinking and encircling of the prey” and “spiral upward encirclement and suppression”. The shrinking and encircling method is attained by decreasing the value of  $V$ . If  $|C| \leq 1$  satisfied, then the new position is updated for the search agent using the Eq. (36). The spiral-based position updating takes place for reaching their food destination which is equated in Eq. (39).

$$\vec{z}(j+1) = \vec{B}' \cdot e^{sr} \cdot \cos(2 \cdot \pi \cdot r) + \vec{z}^*(j) \quad (39)$$

Here, the random number is denoted as  $r$  in the range of  $[-1,1]$  and the constant  $s$  is utilized for indicating the shape of logarithmic spiral. Term  $\vec{B}' = |z^* - z|$  shows the distance between the search agent and best solution. WOA selects the hunting mechanism among these two behaviors by assuming

the same probability for updating the positions of the search agents that is shown in the Eq. (40).

$$\vec{z}(j+1) = \begin{cases} \vec{z}^*(j) - \vec{C} \cdot \vec{B} & \text{if } P < 0.5 \\ \vec{B} \cdot e^{sr} \cdot \cos(2 \cdot \pi \cdot r) + \vec{z}^*(j) & \text{if } P \geq 0.5 \end{cases} \quad (40)$$

3) *Searching for prey*: WOA contains the ability to balance the “exploitation and exploration phase” due to the size of vector  $\vec{C}$ . If  $C \geq |1|$  satisfied, then the position of search agents is updated through the random vector for establishing the global optimal solution by reducing the local minima. This is depicted in the Eq. (41).

$$\vec{B} = \left| \vec{A} \cdot \vec{z}_{RN} - \vec{R} \right| \quad (41)$$

$$\vec{z}(j+1) = \vec{z}_{RN} - \vec{C} \cdot \vec{B} \quad (42)$$

Here, the random vector is indicated as  $z_{RN}$  and the best optimal solution that is position of prey is identified as  $z^*$ . The pseudo code of the proposed HSBSO is given in Algorithm 1.

**Algorithm 1:** Proposed HSBSO

```

Initialize the population along with its parameters
Evaluate the fitness of every individuals

Compute two variables  $c$  and  $d$  using Eq.(20) and Eq. (21), respectively
Determine the best and worst fitness values
While (until reaching the stopping criterion) do
    If ( $c > d$ )
        Solution updating based on SSA
    Else
        Solution updating based on WOA
End
End while
Obtain the best optimal solution
End
    
```

The hybrid optimization algorithm is used for enhancing the overall performance of the proposed model especially in the pattern extraction phase and detection phase, which reduces the overall burden of the proposed model. The flowchart of the proposed HSWOA is depicted in Fig. 7.

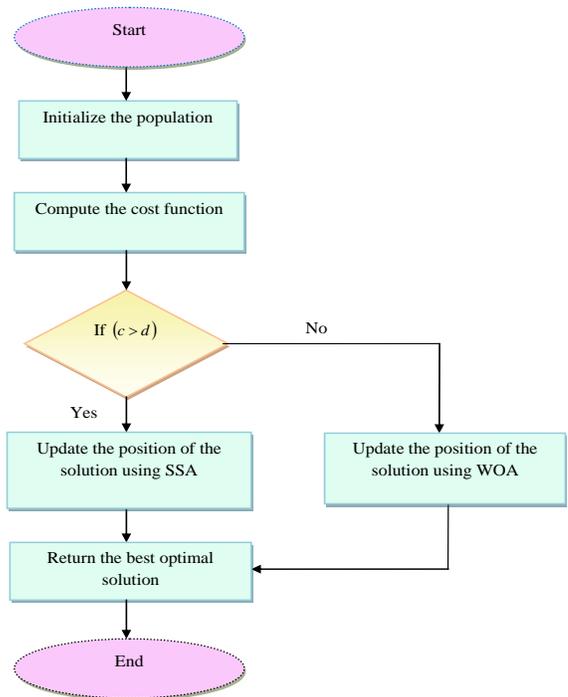

Fig. 7. Proposed HSWOA for Distracted Driver Detection Model.

VII. RESULT AND DISCUSSION

A. Experimental Setup

The platform used for implementing the proposed distracted driver detection model was Python and certain experimental analysis was performed for testing the suggested model using several quantitative measures. The experimental analysis was mainly focused on comparing the performance between the proposed model and conventional meta-heuristic algorithms and also with different classifiers. The involved quantitative measures were classified as positive or Type I measures and negative measures or Type II measures. This experimental analysis was undergone with a population count as 10 and maximum iterations count as 10 for the proposed distracted driver detection model. The proposed HSWOA was compared with other meta-heuristic algorithms like “Particle Swarm Optimization (PSO) [33], Grey Wolf Optimizer (GWO) [34], SSA [32] and WOA [31] and machine learning algorithms like Neural Network (NN) [30], Convolutional Neural Network (CNN) [27], Long Short Term Memory (LSTM) [35], and Ensemble Learning Model (ELM) [17]”.

B. Performance Metrics

The performance of proposed distracted driver detection model is evaluated using various quantitative measures that are given as follows.

1) MCC (mc) is “a measure of the quality of binary classifications of testing” as given in the Eq. (43)

$$mc = \frac{t^P \times t^N - f^P \times f^N}{\sqrt{(t^P + f^P)(t^P + f^N)(t^N + f^P)(t^N + f^N)}} \quad (43)$$

2) Specificity (spt) is “the proportion of negatives that are correctly identified” as represented in the Eq. (44):

$$spt = \frac{t^N}{t^N + f^P} \quad (44)$$

3) NPV (nv) is described as “the sum of all persons without disease in testing” as denoted in Eq. (45):

$$nv = \frac{t^N}{t^N + f^N} \quad (45)$$

4) F1-score (F1) is determined as “the measurement of the accuracy in the conducted test” as given in Eq. (46):

$$F1 = 2 \times \frac{2t^P}{2t^P + f^P + f^N} \quad (46)$$

5) FDR (fdr): is “a method of conceptualizing the rate of errors in testing when conducting multiple comparisons” as denoted in Eq. (47):

$$fdr = \frac{f^P}{f^P + t^P} \quad (47)$$

6) Sensitivity (sen): is “the proportion of positives that are correctly identified” as denoted in Eq. (48):

$$sen = \frac{t^P}{t^P + f^N} \quad (48)$$

7) FPR (frp): is defined as “the ratio between the numbers of negative events wrongly categorized as positive (false positives) and the total number of actual negative events” as given in Eq. (49):

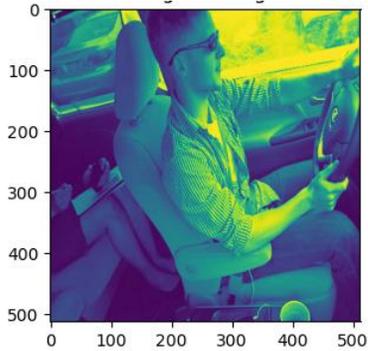

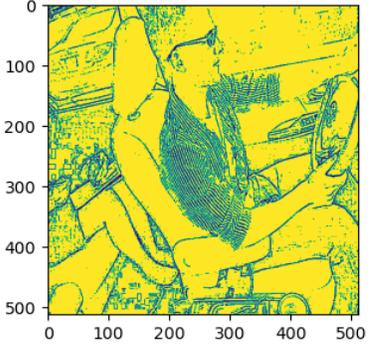

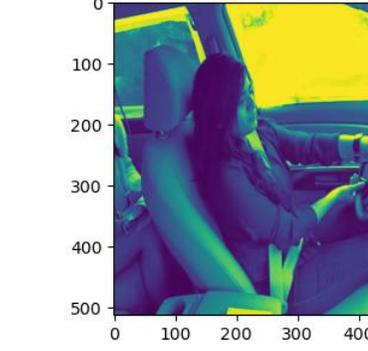

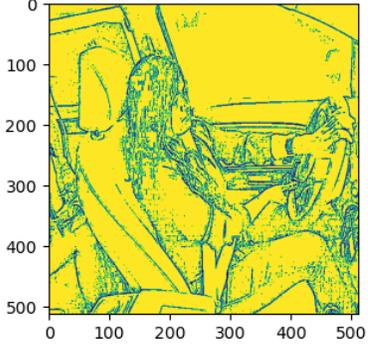

$$fpr = \frac{f^P}{f^P + t^N} \quad (49)$$

8) FNR (fnr): is “the proportion of positives which yield negative test outcomes with the test” as given in Eq. (50):

$$fnr = \frac{f^N}{f^N + t^P} \quad (50)$$

### C. Optimal Fusion-based Pattern Extracted in the Proposed Distracted Driver Detection Model

The resultant image of the optimized patterns from the LGP and LWP in the proposed model is given in Fig. 8.

Image description	Original images	Optimal fusion-based LGP and LWP images
Image 1		
Image 2		

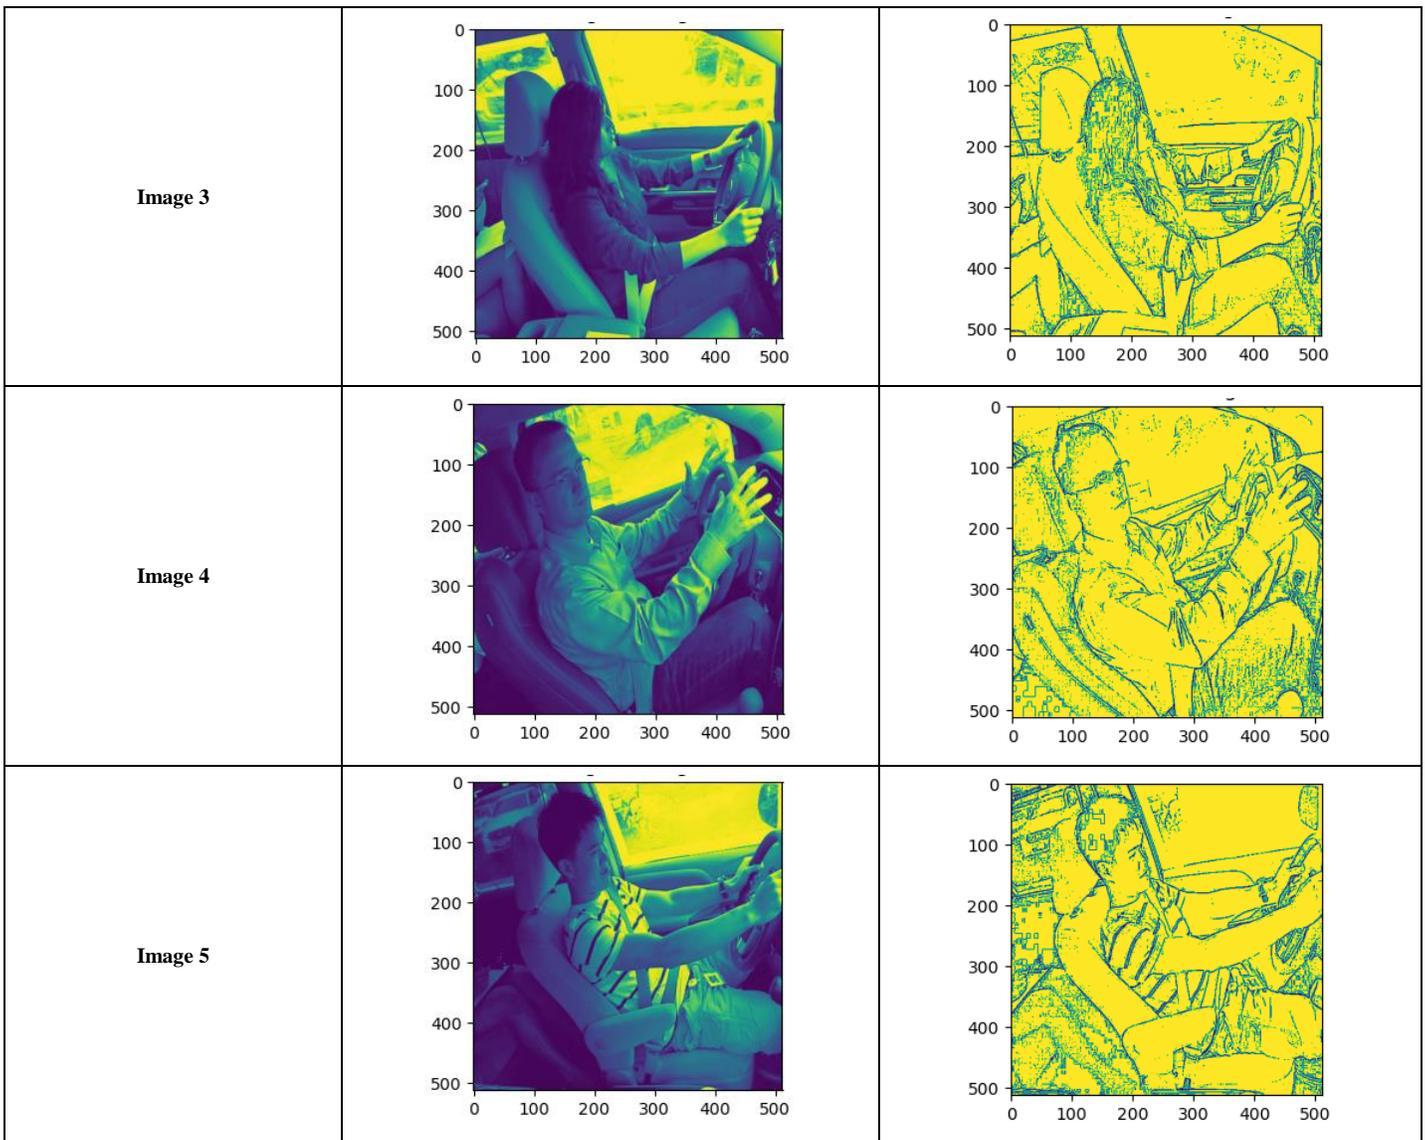

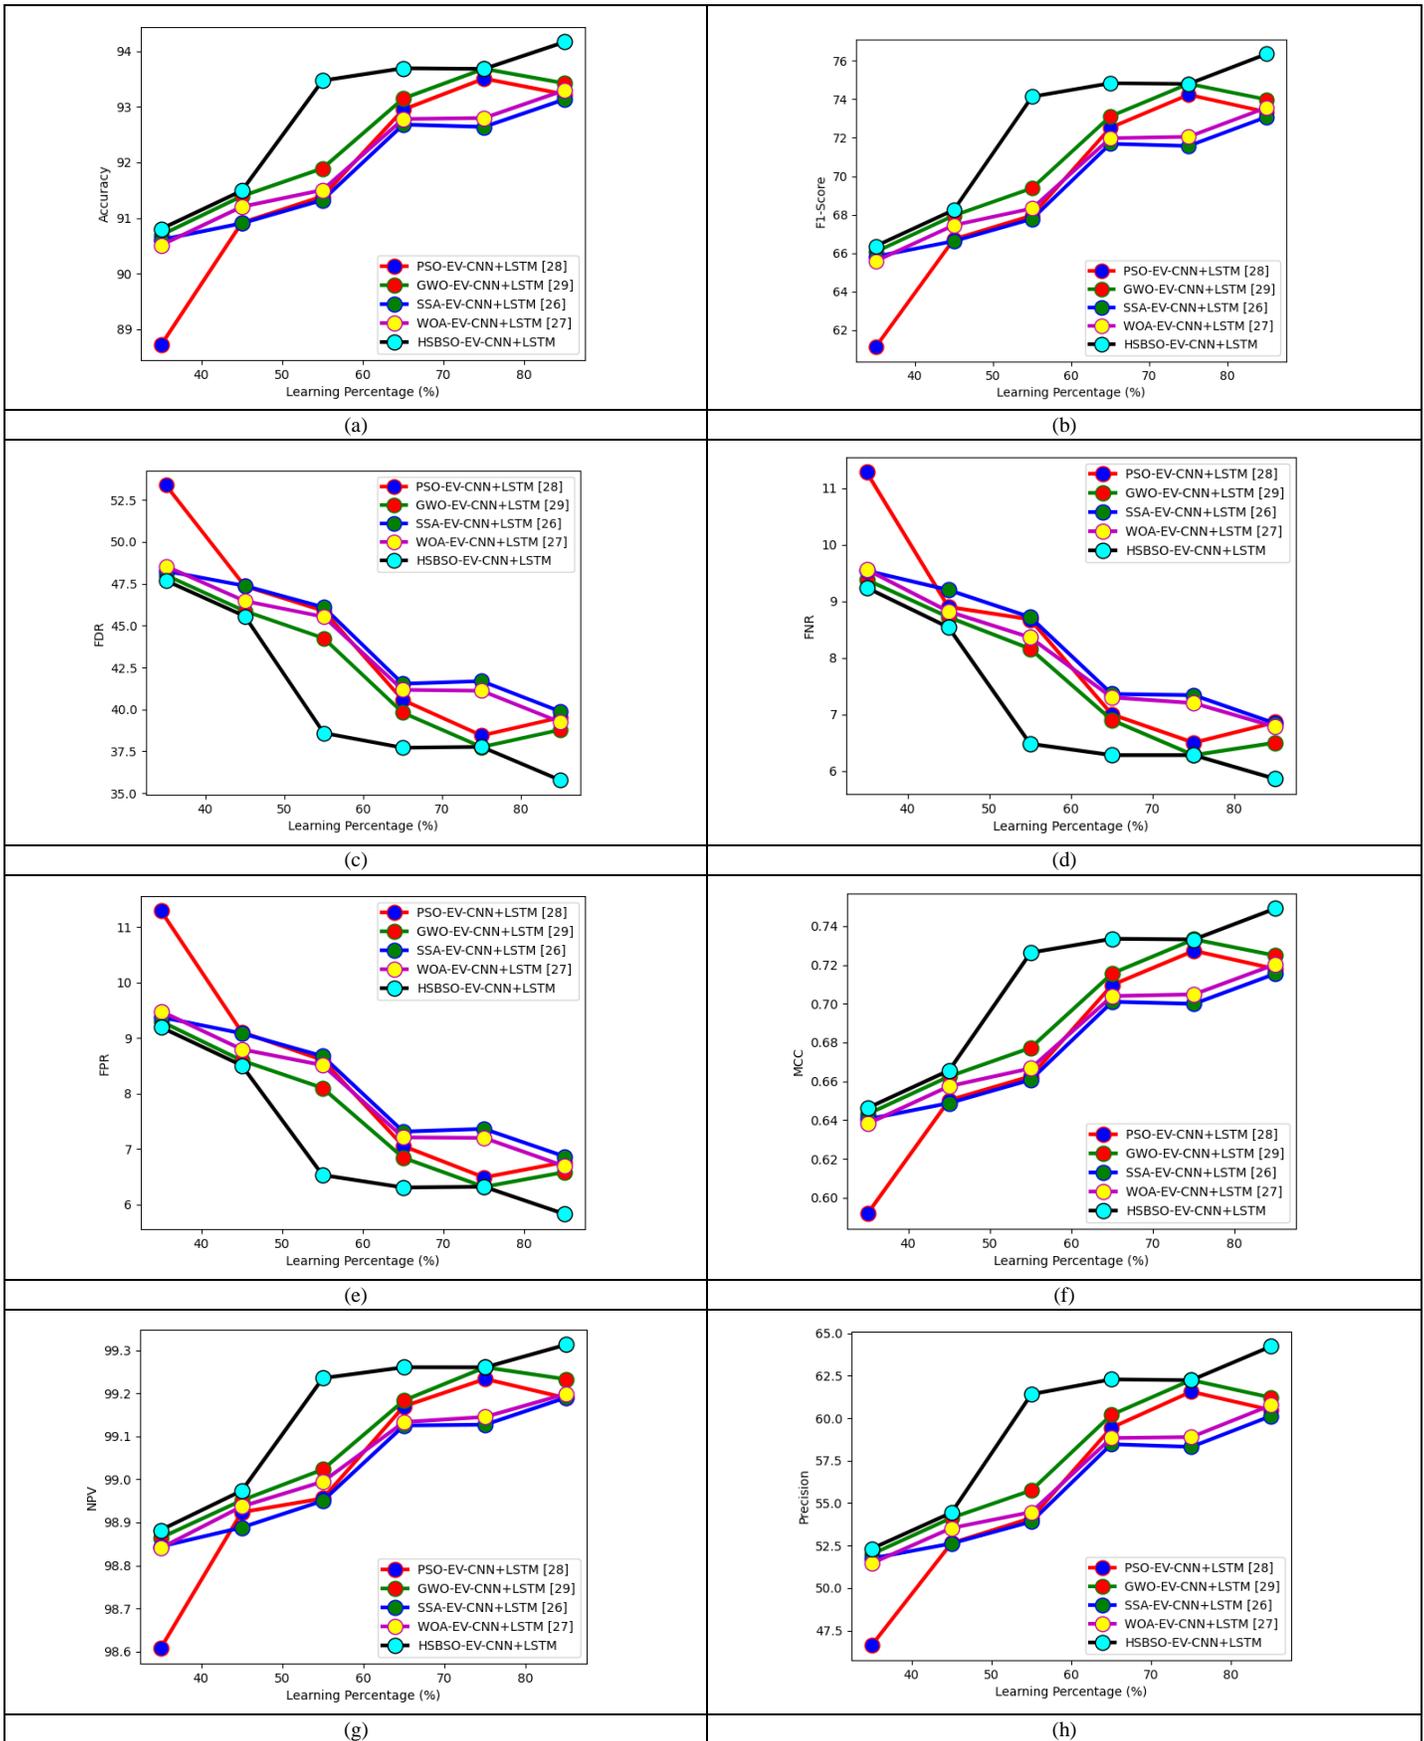

Fig. 8. Original and Optimal Fusion-based LGP and LWP Images of the Safe Drivers and Distracted Drivers.

#### D. Performance Analysis on Accuracy based on different Meta-heuristic Algorithms

The performance analysis on accuracy for the proposed distracted driver detection model is tested by comparing with the different meta-heuristic algorithms as shown in Fig. 9 at varying learning percentages. The performance of the proposed HSWOA-EV-CNN+LSTM shows 0.21%, 0.64%, 0.53%, and 0.21% improved accuracy than the PSO-EV-CNN+LSTM, GWO-EV-CNN+LSTM, SSA-EV-CNN+LSTM and WOA-EV-CNN+LSTM, respectively at the learning percentage as 70 on dataset 2. While observing the accuracy and F1-Score of the proposed model, it shows a slight low performance at the iteration of 40, which has been increased at the iterations of 50, 60 and 70 that performance is maintained with a slight increase in performance until the iteration of 80. Thus, the overall performance of the proposed algorithm for the developed distracted driver detection model secures enhanced performance than other existing methods.

#### E. Performance Analysis on Proposed Model with different Classifiers

The performance analysis for the proposed distracted driver detection model is evaluated by comparing with different classifiers is depicted in Fig. 10 at varying learning percentages. The performance of the proposed HSWOA-EV-CNN+LSTM contains 6.66%, 6.66%, 7.86% and 4.34% higher accuracy than the NN, CNN, LSTM and ELM, respectively at the learning percentage of 35 on dataset 3. When considering the FNR of the proposed model, it ensures an increased performance rate on increasing the number of iterations. In the MCC analysis on the proposed model, it secures 0.6 values at iteration 35 that is increased to 0.7 at the iteration of 55 and in the further two iterations of 65 and 75, the MCC value has been enhanced than in the prior iterations. Thus, the overall performance of the proposed HSWOA-EV-CNN+LSTM for the proposed distracted driver detection model shows higher performance than other conventional methods of distracted driver detection.

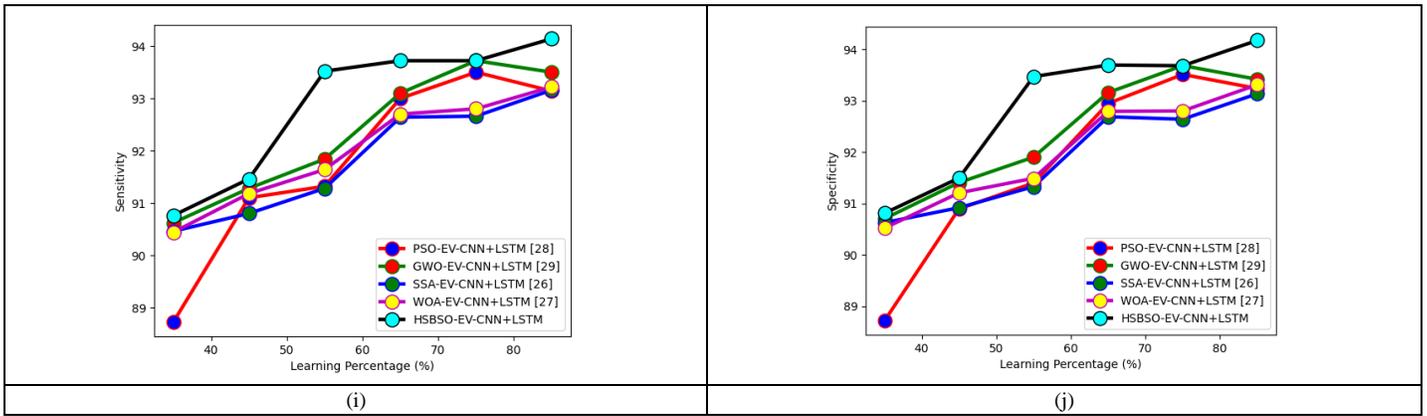

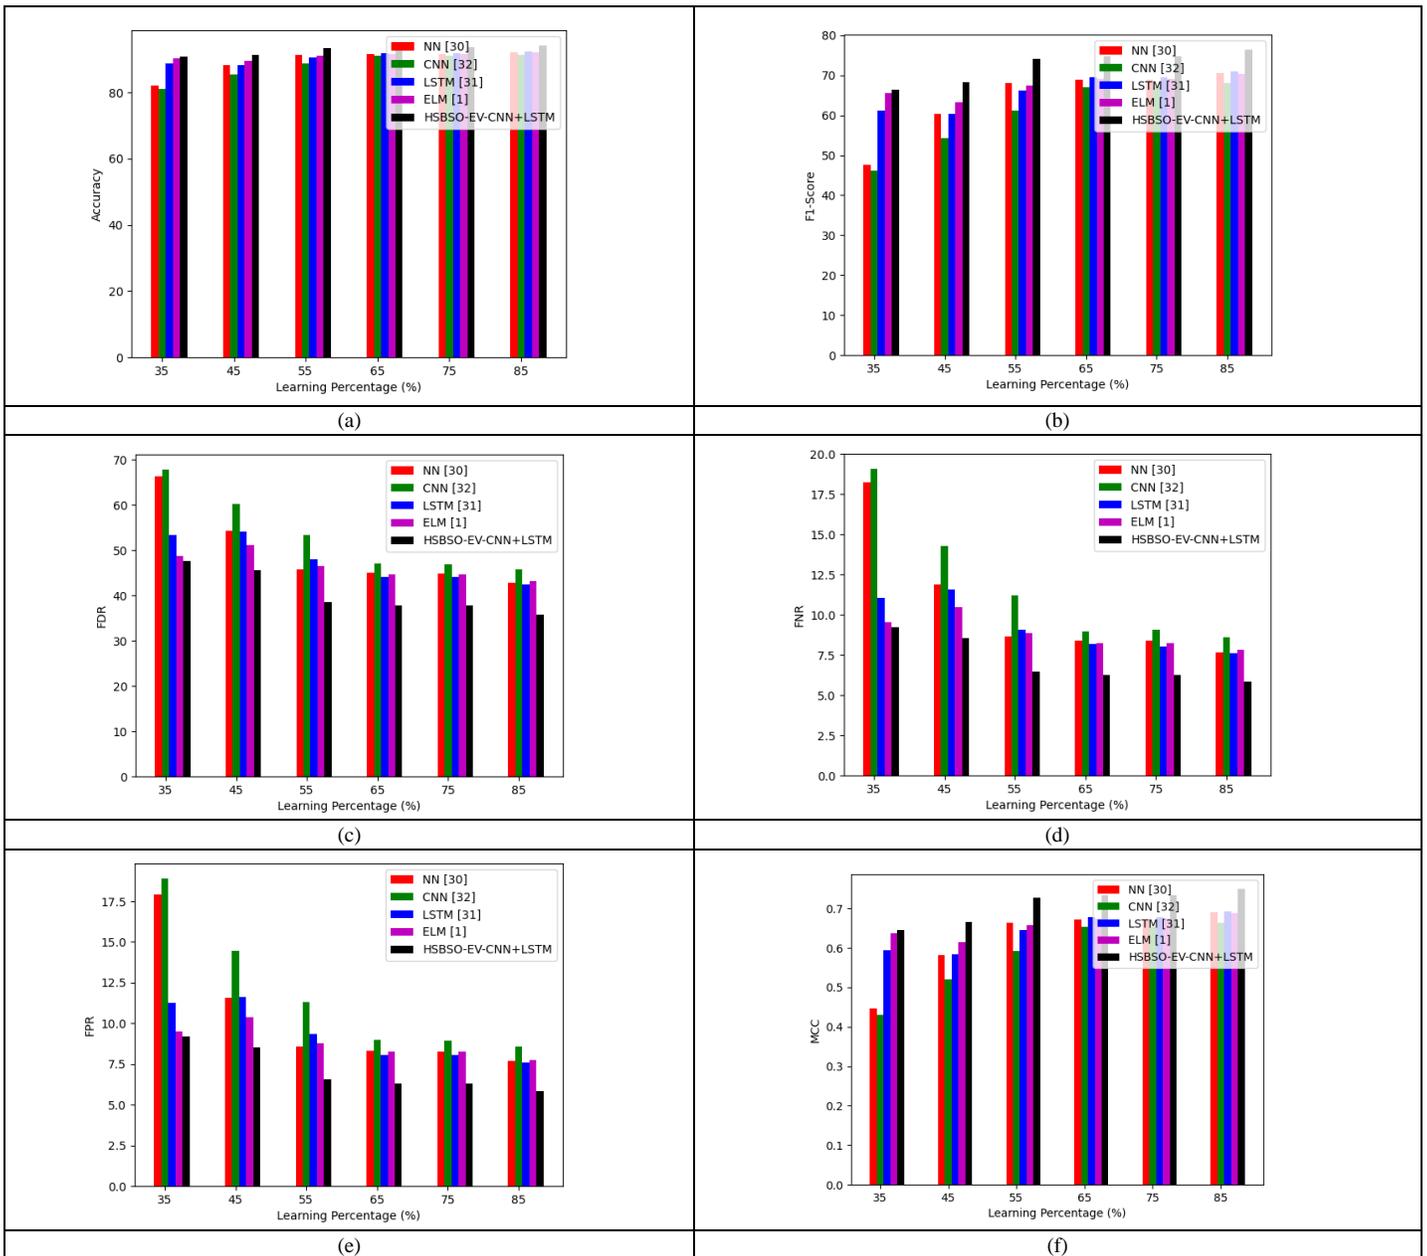

Fig. 9. Performance Analysis on Suggested Distracted Driver Detection Model with Conventional Meta-heuristic Algorithms in Terms of “(a) Accuracy, (b) F1-Score, (c) FDR, (d) FNR, (e) FPR, (f) MCC, (g) NPV, (h) Precision, (i) Sensitivity, (j) Specificity”.

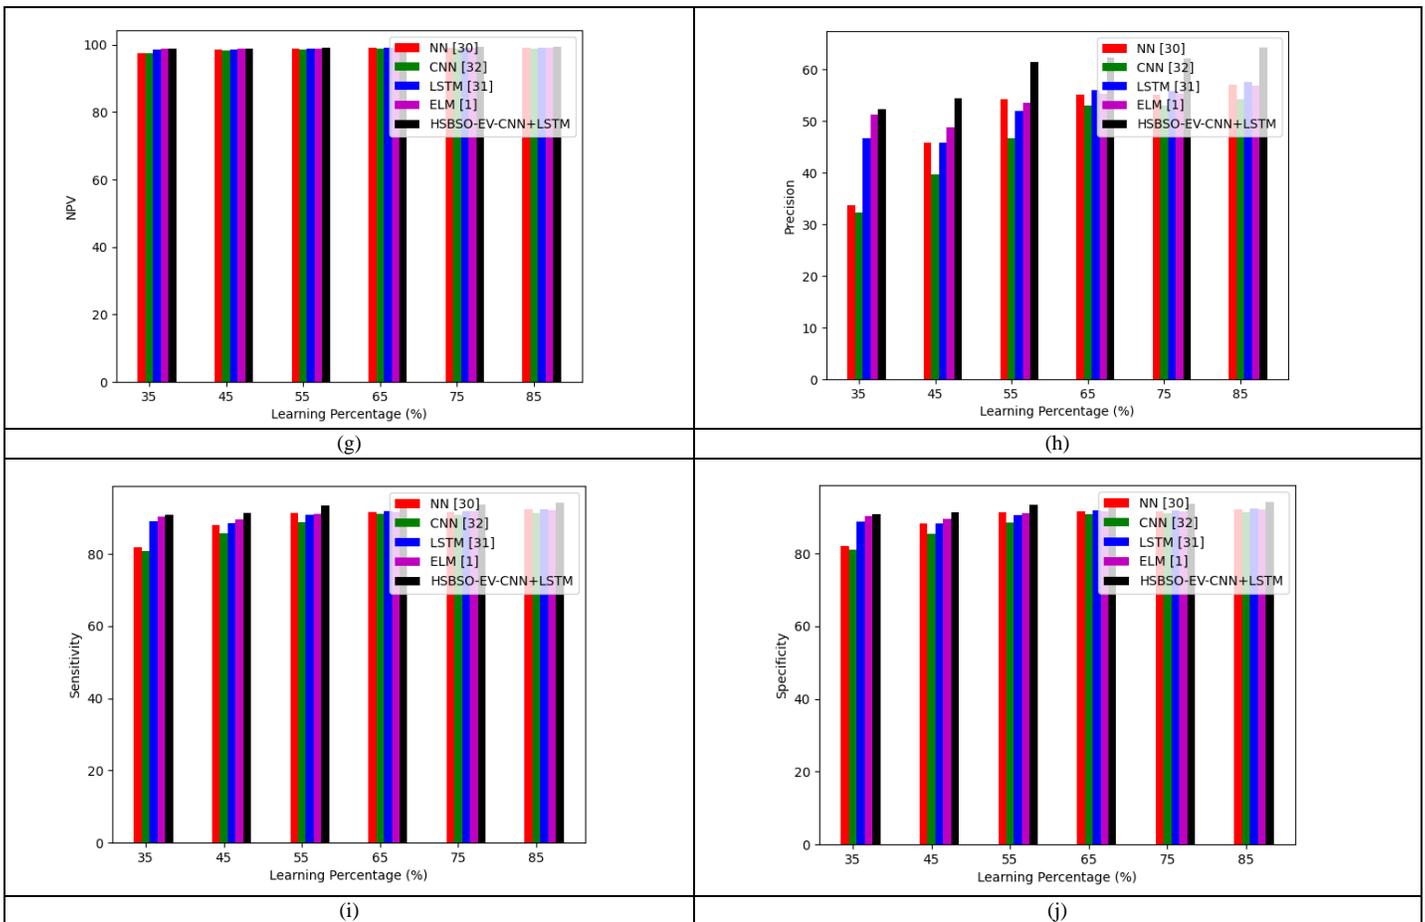

Fig. 10. Performance Analysis Accuracy of the Suggested Distracted Driver Detection Model with Existing Classifiers in Terms of “(a) Accuracy, (b) F1-Score, (c) FDR, (d) FNR, (e) FPR, (f) MCC, (g) NPV, (h) Precision, (i) Sensitivity, (j) Specificity”.

#### F. Overall Performance Analysis for the Proposed Model based on different Meta-heuristic Algorithms

The overall performance analysis for the proposed distracted driver detection model is estimated by comparing it with the different meta-heuristic algorithms as depicted in Table II. The performance of the proposed HSWOA-EV-CNN+LSTM is 0.36%, 0.59%, 0.62% and 0.38 superior to the PSO-EV-CNN+LSTM, GWO-EV-CNN+LSTM, SSA-EV-CNN+LSTM, and WOA-EV-CNN+LSTM, respectively when the observing the performance of precision. In all the performance measures, the proposed model shows enhanced performance in detecting distracted driver behaviors through the given images. Therefore, the proposed distracted driver detection model enhances its performance more than the existing methods.

#### G. Overall Performance Analysis for the Proposed Model based on different Classifiers

The overall performance analysis of the proposed distracted driver detection model is tested by comparing it with the different classifiers as expressed in Table III. The performance of the proposed HSWOA-EV-CNN+LSTM provides 1.88%, 3.55%, 4.4% and 1.06% enhanced MCC than the NN, CNN, LSTM and ELM, respectively. The proposed distracted driver detection model using the suggested HSBSO shows enhanced performance in all quantitative measures particularly provides higher values in the accuracy, precision, specificity and MCC than the conventional techniques. Therefore, the proposed distracted driver detection model provides improved performance than the existing methods.

### VIII. CONCLUSION

### REFERENCES

This paper has presented a new distracted driver detection model using suggested HSWOA along with the developed EV-CNN and improved LSTM approach. The gathered input images were initially given into the optimal fusion-based pattern extraction, where the two methods like LGP and LWP were used for generating the optimally fused patterns. These patterns were integrated with the optimized weights based on the proposed HSWOA. Then, the optimized patterns were acquired and considered for the developed EV-CNN approach for extracting the most significant features of the patterns. Further, the extracted features were subjected into the developed O-LSTM, which has been improved by optimizing certain parameters using the developed HSWOA. At last, the distracted driver behaviors were detected using the developed O-LSTM. Through the performance analysis, the proposed model using the developed HSWOA-EV-CNN+LSTM has secured 1.33% enhanced than NN, 1.83% improved than CNN, 2.2% better than LSTM and 0.84% elevated than ELM in terms of accuracy. Therefore, the proposed distracted driver detection model has ensured enhanced performance using developed O-LSTM along the suggested HSWOA than the existing methods for future work; we intend to increase the efficiency of the proposed solution by addressing additional driving style data along with road surface information, which will help improve the generalization of the distracted driver detection model.

**Abstract**—Cyber-physical system has a bigger impact on the present and future of the engineered systems. The integration of cyber-physical system with other technologies often poses challenges that are unique in the fields of design, implementation, and applications. This study explores the definitions of the integrated cyber-physical system from different perceptions, how cyber-physical systems evolved, emerging fields of research in cyber-physical systems. Efficiency, reliability, predictability, and security are some of the challenges that cyber-physical systems pose in the overall implementation. cyber-physical systems when integrated with the Internet of Things evolves into a hybrid technology that advances the technology aspects. The CPS-IoT models complement each other offering useful insights to deal with engineering systems and control modules.

**Keywords**—Cyber-physical system; internet of things; industrial internet (ii); industry 4.0

### I. INTRODUCTION AND MOTIVATION

Cyber-Physical Systems are modelled on the collaboration of 3C's - computation, communication and control that are discrete and logical (cyber entity) and the natural and artificial systems that are administered by the laws of physics (physical entity). Both the entities are linked through sensors and actuators. Sensors, computational and physical world are closely integrated in CPS. CPS includes both conventional embedded systems and control systems that are presumed to be remodelled by emerging methodologies and integration of the Internet of Things.

IoT is the base or enabling technology for cyber-physical systems. Cyber-physical systems can be contemplated as the advancement of IoT as complete conception and perception, and which possess a strong ability to control the physical world. Cyber-physical systems also include the traditional embedded and control systems, evolving them into innovative methodologies. IoT connects the information acquiring devices like sensors and RFID (Radio Frequency Identification) wireless sensor networks and cloud computing technology for reliable transmission and information processing. On the other hand, CPS is a control technology that is scalable and reliable and is the integration of computing, communication, and control of IoT. However, IoT concentrates on information transmission and processing, whereas CPS not only has the can sense but also possesses a strong ability to control. In CPS, cyber and physical elements are interlinked with one another, which are running on spatial

and temporal scales, which reveal numerous and definite behavioural process and collaborate with each in many forms that vary the context.

CPS is transdisciplinary which merges mechatronics, computation theory, Internet of things, wireless sensor networks, theory of cyber nets, design and process science. The process of control is related to embedded systems using feedback loops. CPS and the Internet of Things share the same architecture which makes them similar but a higher between physical and computational elements is defined in CPS. In contrast to traditional embedded systems, CPSs are specifically represented as a structure of interacting elements with physical input and output rather than standalone devices [1]. Applications of CPS include healthcare and industrial automation, control technology, distributed energy system, aircraft control and so on [2]-[4]. CPS will bring change to the existing physical systems in engineering and advances in economic welfare.

### II. CPS HISTORY AND DEFINITION

CPS refers to next generation engineered systems. The word cyber-physical system came around 2006 by Helen Gill at the National Science Foundation (NSF). Cyber-physical system is often confused with "cyber security" where there is no relation with the physical processes. CPS is the tight combination of computations, algorithms, and physical devices. The perception of the technologies is that it associates the real world with the information world. CPS connects by means of the popular technologies such as Internet of Things (IoT), Industry 4.0, the Industrial Internet (II), Machine-to-Machine (M2M), Industrial Internet of Things (IIoT).

#### A. Definition of CPS

This field of research overlaps with various fields of science and engineering, computer science and networking should come together in collaboration with multiple fields such as automation and control, civil engineering, mechanical engineering, etc. Therefore, CPS definition may vary from their viewpoint.

E.A.Lee describes CPS as "the integration of computations and physical processes. Embedded computers and network monitor and control the physical process, usually with feedback loops where physical processes affect computations and vice versa [5]."

\*Corresponding Author.

R. Baheti describes CPS as “the new generation of systems with integrated computational and physical capabilities that can interact with humans through many new modalities. The ability to interact with, and expand the capabilities of, the physical world through computation, communication, and control is a key enabler for future technology developments [6].”

Department of Science and Technology (DST) – Government of India launched a Interdisciplinary Cyber Physical System (ICPS) to promote research and development in this emerging field. The simple architecture of CPS is shown in Fig. 1. The collaboration of the physical and cyber world in CPS will assure real-time, reliable, trustworthiness of the systems. Physical systems collect the data from sensors in CPS systems dynamically guaranteeing the accuracy of the data collected. The data is sent to the cyber world for the processing of information based on the service needs mainly uncertainty management, statistical analysis, and feedback control. These systems are designed in such a way that they self-adapt. CPS is a 3C technology i.e., computation, communication, and control that takes wireless sensor network and Internet of Things.

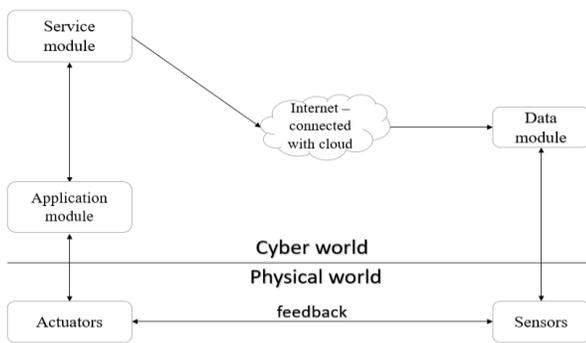

Fig. 1. Working idea of Cyber-Physical System

### B. Characteristics of CPS

CPS has both physical and cyber-world. In the physical-world, CPS interacts through sensors adapting embedded computing technology. The cyber-world of the CPS deals with computations and control. The CPS upholds the following characteristics [7]:

- **Cyber capability in every physical component:** The physical system design is as important as the logical design. It involves hardware design and size, management, connectivity establishment, system testing. Engineers have an understanding in their fields of systems, they acquire the technical characteristics of sensors, actuators and how they process the raw data to the next layer. The higher degree of automation and control in CPS demands the maximum network coverage.
- **Networked at multiple and extreme scales:** CPS entrust networks to sensors and actuators to collect data and process them. The infrastructure of networking has to be very large frequently. Networks should be able to perform on different domains such as personal

transportation systems, healthcare, remote interaction, industrial automation. These domains require a new communication notion that provides concrete and outline together with online adaption for productive use of bandwidth. This leads to scalable, open and adaptive communication [8]. CPS demands networking to be in large and multiple scales to meet the need without compromising the Quality of Service (QoS).

- **Multiple spatial-temporal constraints:** The CPSs are conceptualized to 3C technology i.e communication, computation and control with the physical world. These require the interaction between the components of CPS in time and space. Constraints such as event detection and action decision should be implemented accurately and appropriately to meet spatial and temporal correctness [9].
- **Unconventional computational and physical substrates:** The need for unconventional computation in CPSs is because of its dynamic reconfiguration and its communication with the physical world in real-time to adapt them to specific needs. Since the evolution in computation takes place, the physical substrate should comply with the computation as well.
- **High degree of automation, control loops closed at many scales:** The emerging amount of data on CPS, coupled with the need for systems to be robust and handle real-time environment which leads to self-learning. The automation is important for the system to go forward. The control object is the inbuilt operation of CPS. This object can reform itself and change the physical flow command. The control aspect of the CPS is the basis for dynamic systems and plays a crucial role in feed forwards control loops.
- **Dynamic recognizing termed as open system:** This characteristic of the CPS includes reorganizing and reconfiguring which can automatically adapt to the environment and develop rules based on the domain requirements and alters the external physical environment to meet the conditions according to present rules.

### III. RESEARCH DIRECTIONS OF CPS

CPS is the integration of the multidisciplinary heterogeneous systems and has decentralized models. These systems exhibit behaviours that are not predictable in advance, which makes the research possibilities expansive. The researchers recently concentrate on the architecture pattern, computational theory, and control of the feedback system. Other research fields such as system reliability, information processing, system design software, and CPS security system are focused on recently.

#### A. Architecture of CPS

Many architectures for CPS have been proposed so far, the 5 Component architecture has 5 levels: Connection level, Conversion level, Cyber level, Cognition level, Configuration level [10]. These levels emerge the process for such interdependent systems and overcome the limitations to meet

the demand of the target system. These levels process and monitor the information, and coordinate with the physical systems that relate to the cyber computational space. 8 Component architecture is an evolution of 5C architecture that includes three other components in addition to Connection level, Conversion level, Cyber level, Cognition level, Configuration level. The included components are Coalition, Customer, and Content [11].

ACPS architecture where not only the highest level of abstraction is provided but also integrates the physical, cyber, and human components [12]. Service-Oriented Architecture (SOA) supports this model to achieve the adaptive and dynamic vision. 3C architecture is the most commonly used architecture in all applications [13]. This architecture reinforces smart manufacturing in industries and supports the industrial revolution i.e., Industry 4.0. The three components in this architecture are the human component (HC), Physical component (PC), and Cyber component (CC). A smart factory framework is developed which considers the physical and cyber aspects of the system architecture to offer the solution and improve efficiency [14].

Though many Cyber-Physical Systems' architectures meet the expectations of the target system or applications, there is yet a need for further developments as most of these models are clearly defined for a certain set of applications. Researches on architecture are restricted to specific applications and their advancements, the development conditions due to which the interdependence of various demands are not studied. CPS architecture is the foundation of research and progress, so the proposed models must be integrated and improvised based on the present system structure and should accommodate the development of CPS. However, a unified architecture for CPS is required which calls for further research in the architecture.

#### B. Control of CPS

The foundations of control theory in Cyber-Physical Systems are yet to be established strongly. Converting the input actions into appropriate control actions, in a multimodal application that involves sensors and actuator parameters based on the user actions [15]. An independent way to control the cyber and physical resources, where a new control strategy is provided for data centers to attain stability for the CPS applications [16].

A robust control approach that is modular, promises the stability and performance of the target system automatically due to which the input-output analysis where a standard analytic method is used [17]. The role of control in the cyber-physical system must be addressed because of their impact on the future Internet of Things, wearable electronics, human interaction machines, and many other fields. The analysis of control theory in CPS helps in building the foundations of CPS stronger. A unified approach must be dealt with towards the control strategies that include temperature set-points, adjusting the pressure set-points, monitor air temperature, dimming or turning off the lights, etc. Predictability is one of the challenges to the control of CPS. To ensure predictability, aspects of the model should be accounted such as input and output behaviour, execution, and programming. Uncertainty affects the model or system's guaranteed behaviour [18].

The traditional control theory only meets the targets of CPS control based on the applications or present event models, but the theory should also manage the transmission and response of feedback control where further research prevails.

#### C. Data Sciences and Data Processing Technologies for CPS

The data is collected by the systems, must be transformed into knowledge to create value. The scope of future smart systems lies in the methodologies and techniques of Data Science. A vast amount of data is collected from the sensor networks and many solutions for data science problems have been discovered. CPS follows a data-driven approach to learn patterns and predict the models, also analyse their environment, and based on their observations. Data processing, in general, includes collection, preparation, input, processing, interpretation, feedback control, and the response from the physical environment after receiving the commands.

Reliability is an essential need for a cyber-physical system as it is applied for safety and critical systems. CPS is intended to process a huge volume of data and run continuously in real-time, where an Automatic Reliability Improvement System (ARIS) is proposed to improve the reliability. ARIS works as a data-centric runtime monitoring system, where anomalous data is indicated and a data quality analysis is performed using computational intelligence and self-tuning techniques for system reliability [19]. The existing Internet of Things is turned into a complex cyber-Physical Social System (CPSS) when people use their social networks and personal computational resources which leads to the generation of huge volume passive data to process. A data processing pattern that is based on stream processing technology, that uses a cluster of edge devices to distribute the workload is introduced. The feasibility of this approach is guaranteed through a demonstration of an intelligent surveillance system that is stationed on the edge device [20]. Present researchers on the methodologies and techniques of Data Science in CPS face challenges in processing and transmission technology of data, safety control, real-time capability, robustness, control and hybrid systems and reliability.

#### D. Security and Privacy of CPS

The security and privacy protection of the established internet security does not meet the requirements of physical system security in CPS which is randomly distributed sensors over the pervasive wireless network. Most of the present security policy uses a centralized network that trusts a third-party operation. The new security framework that considers the flexibility, privacy protection, transaction security, transparency, efficiency, trust mechanism, data integrity, resilience, the trustworthiness of data that combines with control and information.

Blockchain technology, which is a distributed register that is shared between peer networks is proposed as a unified three-level architecture to identify the possibilities and also adapt, develop and incorporate this with the manufacturing in industry 4.0. The data flow and the communication are incentivized in the structure of the existing cyber-physical system structure to assure safety and reliability [21]. Differential privacy techniques are considered efficient to

protect privacy in CPS which can be achieved through certain modifications in the architecture of CPS and can be implemented in cyber-physical systems applications [22].

However, there are some challenges in cyber-physical system from a research perspective. Robustness, safety, and security due to the environment and errors in the physical devices making it a critical challenge. Location, time, and tag-based data can be a threat to security. Merging the systems to create a hybrid system to create an efficient feedback control is required. The architecture of the CPS must be designed in a way that is very rational at every level and it should consider all the physical device information, protocols should be designed at a large-scale. Collecting the raw data at a vast amount from the sensor and mobile networks is one of the major challenges to focus on. Integration and modification should be done at every level of CPS design, communication and computation are to be predicted at all scales and model the time information.

#### IV. CYBER-PHYSICAL SYSTEM-INTERNET OF THINGS

The CPS can be considered as an evolution of IoT with more intelligence and interactive operations, adapting the architecture of IoT. CPS enriches the interaction between human-to-human, human-to-machine, machine-to-machine not only in the physical world but also in the virtual world, also includes conventional embedded and control systems that will not be altered by novel approaches. IoT and CPS when introduced in the industry, brings many benefits and extends the scope such as awareness, prediction, comparison, reconfiguration, maintenance. The evolution of IoT and the development of CPS is prominent in certain applications - Real-Time Physical Systems (RTPS), based on real-time parameters with a suitable feedback control policy based on dynamic adaptations [23]. A controller is designed for a nominal model that stabilizes the large-scale CPS [24]. The vulnerability of robotic surgery is reduced by designing a collaborative robotic cyber-physical system [25].

CPS is the integration of physical and cyber systems where embedded computing devices act as physical entities and communication, computation, and control are cyber entities, whereas IoT shows the interconnection of different end-devices that communicates with each other through the internet. Decentralized control among the interconnected end-devices is intended by IoT. Sensing, processing, storing, and networking are some of the common capabilities of both CPS and IoT.

When CPS was emerged and introduced alongside IoT some of the similar characteristics of CPS and IoT must be identified, familiarized, and contrasted to understand their respective roles in the system where they are used. New strategies for communication and control have been introduced making the system more safe, secure, and sustainable which are the fundamental attributes of the CPS.

The advanced communication technologies, alongside wireless communications, lead to the development and implementation of CPSs considered as the higher-level systems of IoT. These technologies include wearable devices, sensors in healthcare, intelligent systems where cloud

computing is applied. CPS in IoT deals with the interaction of the intelligent systems, applications that are user-friendly and interactive, optimization in the IoT-enabled CPS, and control of the distributed systems. The characteristic of the CPS must be enhanced due to the higher requirements and efficient performance. The performance of the CPS elevates the levels of IoT. In short, CPS is the next evolution of M2M systems where smart information processing and IoT are regarded as the future technicalities.

##### A. Internet of Things enabled Cyber-Physical System

CPS and IoT are intertwined for better and unified solutions, where the users, machines and the environment interact with each other. Defining the interface for the IoT technologies, control of the global system, integration of the IoT devices and physical environment, which is tied together with the communication infrastructure, along with control module are some of the challenges when IoT has enabled alongside CPS on a large scale. The performance of real-time analytics should be considered as another challenge as the large amount of data collected has to undergo a mining process for better results.

The development of the CPSs which adopt the IoT paradigms aids in several applications of the CPS. Design complexity, modeling the hybrid systems, smart control design, sensor reliability, specified IoT sensor and actuation design for CPSs, and security and privacy are some of the key challenges for IoT-enabled CPS.

The infrastructure and control of the large-scale system and the network monitoring are used for better communication and coordination among the modules. This may have a negative effect on the network structure and needs to be upgraded for efficiency and accuracy. Enhanced Expander Membership Protocol [26], having features such as addressing the real-time network issues, limiting the negative effects on the network structure, and recovering the global connectivity efficiently and is also fault-tolerant and scalable. These support the challenges addressed by the CPS network structure. A Fragmented-Iterated Bloom Filter [27] is introduced to manage the distributed network in the event-based cyber-physical system. This is efficient in memory management and computation.

Considering the functional and non-functional requirements during the implementation of the IoT-enabled CPS, the challenges such as scheduling mechanisms, vulnerability to security attacks, applications development, etc. An integrated development environment that is model-driven in cloud computing supports the application development, code generation, and compilation and simulations for the IoT-enabled CPS applications.

COMFIT [28] has two modules, the App Development Module and the App Management and Execution Module, providing an environment where every needed action is performed for the code to develop the app. The scheduling mechanism in the implementation of IoT-enabled CPS needs to be efficient and scalable. The Bayesian Network [29] is used for scheduling algorithms where stability and operational capability have high priority. The vulnerabilities to the

security attacks are tackled using game-theoretic principles, providing a scheduling mechanism that is effective based on the game.

### B. Integration of CPS and IoT

A Cyber-physical system, in general, is the collaboration of communication, computation, and control with the physical world on a large scale. They are considered as a form of wireless sensors and actuator networks. On the other hand, the interconnection of heterogeneous devices that communicate through the internet is called the Internet of Things. These heterogeneous devices can be referred to as smartphones, laptops, RFID, etc. are intelligent agents that share the information with the systems and people which makes them a part of CPS. Therefore, the integration of CPS-IoT is a solution to many technological challenges and is used in many application domains.

The integration of Environmental IoT with the cyber-physical clouds [30] results in a complex distributed system that supports the comprehension of interdependencies and management in the natural environment. A three-stage approach is deployed - The Abstraction representation, Network-centric representation, Node-centric representation. These technologies provide higher opportunities in the application domain by supplementing each other.

The integration of wireless devices, wearables that are fast and have a working real-time algorithm to cyber-physical systems allows in numerous aids to the medical applications. The author in [31] presents a system by integrating the complimenting technologies that provide comfort to the patients and the data collection from devices is efficient.

An adaptive interface approach [32] that supports both the development and the utilization of the CPS-IoT is proposed. An IoT toolkit with a multi-layer interface that allows users to improve the interaction with sensor and actuator networks is presented. The full potential of the IoT-CPS integration interface can be utilized, with the aid of the presented adaptive interface.

The integration of the CPS for real-time IoT operations [33], resulting in the effective control of actions based on the environmental objects. This helps in the real-time operations in the manufacturing units and Industry 4.0 applications. The integration of CPS with various technologies leads to emergent properties and unpredictable behaviors. The development of IoT and high-speed network leads to the possibilities of the physical world meeting the cyber world. The convergence of Body Area Sensor Networks (BASN) and CPS made the technologies reach their threshold point, making hand pattern recognition smart and safe [34].

### C. CPS-IoT Models

The integration of IoT and CPS evolved over time to complement each other and has some very useful applications and insights; however, IoT and CPS have distinct origins. CPS primarily deals with engineering the systems and the control stance, in contrast, the IoT deals with networks and the information technology that digitalizes the physical world, also having the sensing and actuating capabilities. The vision

of IoT is the effective interaction between digital and physical entities, enabling the information and communication technologies to their full potential [35]. Despite the distinct origins of CPS and IoT, their models overlap each other. The author in [36] present four overlap models: Partial overlap, Equivalence, CPS as a subset of IoT, IoT as a subset CPS.

IoT and CPS, despite having the same goals as reducing the communication gap between the cyber world and physical world; also has some evident differences [37] - IoT is an open network infrastructure that connects the objects in the physical world through the internet and the data is processed through information technologies. The CPS is all about the control of the physical world through feedback, implementing an Automatic Reliability Improvement System, forming operator-in-the-Loop.

CPS encompasses both open and closed-loop control systems, addressing the human-interaction and for the feedback implements the Human-in-the-Loop (HITL) control system [38], where IoT is all about open-loop systems. IoT and CPS overlap with each other in many aspects making the terms and definitions distinct. IoT usually senses the physical world, processes the data by monitoring these technologies. The IoT application is also used in the control module in the CPS through integrating certain edge devices [39].

Cyber-Physical Systems, link the physical world with that of the virtual world which is defined as the Internet of Things and its services making CPS a subset of IoT. The applications such as IoT-connected smart home systems, a tracking device based on the geolocation [40] are IoT specialized which excludes the CPS making the proof for the above statement. Cyber-physical systems feature collaboration and the coordination of 3C's, physical elements, and its integration with the cyber world of information processing. The greater focus is on the control for the CPS, leaving IoT a simple platform of CPS. IoT senses the physical world through sensors, the internet keeps them connected with each other, collects data, and processes them - CPS also does the same, additionally targets the control of the physical processes addressing the human-machine interaction through feedbacks, which IoT does not feature making IoT as a subset of CPS. The sensor or actuators' activity is collaborated to achieve a goal where CPS uses IoT systems as a platform [41].

The Industrial Revolution is also known as Industry 4.0 or Industrial Internet (II) is one of a kind and next-generation advancements in CPS, where everything is smart and connected in the real-time environment. The unique features of CPS, that IoT does not comply makes it distinct and also clarifies that IoT is not everything that CPS is [42]. Control, platform, internet, and human-machine interactions give the perspective for CPS-IoT overlap models. The definitions of CPS and IoT evolve based on hybrid systems. Physical and human components in the systems and their applications. The perspective of CPS/IoT models allows the idea for the innovation of new applications domains, making its use unified. The integration of CPS-IoT proposes a solution for many challenges making the approach towards a problem solver.

## V. APPLICATIONS OF CYBER-PHYSICAL SYSTEM

The use of CPS in various application domains is to make large-scale systems adaptable, efficient, functional, reliable, and autonomous. CPS has three major advantages - they ensure real-time data collection from the physical world, feedback to the cyber world to perform the control module, a computational process that makes the cyber world stable [43]. These advantages are contributing factors to use CPS in certain domain applications. There are some definite areas where CPS has made potential progress such as technological innovations, system architecture, production systems, design and model of a system, and real-world applications. The CPS can almost be applied to many disciplines and also have trans-disciplinary applications. Numerous categories such as agriculture, energy management, education, weather, and environmental monitoring, medical devices, process control, smart homes, industry 4.0/smart manufacturing, security, wearable devices, transportation system, and traffic prediction are the areas where CPS can be applied.

### A. Environmental Monitoring

Wireless sensor networks can be considered as a pillar for CPS. CPS analyzes the surrounding environment through sensor nodes that are deployed in diverse locations with human intervention. These sensor nodes detect both natural and man-made disasters, such as flooding, fire, release of toxic gases, abundant rainfall, etc. which in turn influences the balance of the environment. [44] investigates the impact of the abnormal environmental conditions and the failures caused to the system, which is dealt with by a framework that interacts between cyber-physical system and its environment. A Functional Failure Identification and Propagation (FFIP) framework detects the component failures by analyzing the environmental conditions or loss of the functionality in the system in the environmental surroundings.

The author in [45] uses technologies based on Wireless Sensor Networks (WSN), multi-agents, and cloud computing to monitor the real-time environment status. The CPS paradigm using the technologies operates in a volatile environment providing flexibility and scalability. The three-layer architecture of CPS, where WSN makes sure the data is acquired from physical nodes integrated with sensors and transferred to other layers to supervise the operations of CPS using the decision rules and data analysis.

### B. Transportation System

Smart transportation deals with real-time information analysis. Autonomous driving vehicles, Vehicular Cyber-Physical Systems (VCPS), and Intelligent transportation are major advancements of CPS in the transportation domain. Autonomous driving vehicles show almost no fatalities compared to human-driven vehicles ranging from cars to planes. Coordination is the key to smart transportation; it is achieved through the means of 3C's - communication, computation, and control.

Considering the traffic measurement, a privacy-preserving point-to-point function is considered where the number of traveling vehicles is measured based on geographical location by the intelligent cyber-physical road systems. Bit arrays are

used to collect data and maximum likelihood estimation (MLE) is used to obtain the measurement result [46]. The co-optimization and co-regulation schemes for both cyber and physical resources are considered by examining the sampling patterns in time-variations, scheduling of sensors, control mechanism, feedback scheduling, and motion planning and resources for Cyber-Physical Vehicle Systems (CPVSSs) [47].

The prediction of road traffic has been one of the most useful applications of CPS and is accurate. Here, an operator-in-the-loop is added to the framework so that based on the prediction, the traffic in the certain location can be prevented and a retrospective analysis can be done to prevent the road traffic.

## VI. CONCLUSION

The CPS has an impact on the socio-economic life of its users. This paper conducts a review on the definition of CPS and its history, different fields of research, the integration of IoT-CPS, and how they complement each other and its applications. The research areas of CPS and its advancements have been part of many emerging trends in the information technology fields such as IoT, cloud computing, big data, cloud computing, Industrial Internet, Industry 4.0.

**Abstract**—It is critical to select the model that best fits the situation while analyzing the data. Many scholars on classification and regression issues have offered ensemble techniques on tabular data, as well as other approaches to classification and regression problems (Like Boosting and Logistic Model tree ensembles). Furthermore, various deep learning algorithms have recently been implemented on tabular data, with the authors claiming that deep models outperform Boosting and Model tree approaches. On a range of datasets including historical geographical data, this study compares the new deep models (TabNet, NODE, and DNF-net) against the boosting model (XGBoost) to see if they should be regarded a preferred choice for tabular data. We look at how much tweaking and computation they require, as well as how well they perform based on the metrics evaluation and statistical significance test. According to our study, XGBoost outperforms these deep models across all datasets, including the datasets used in the journals that presented the deep models. We further show that, when compared to deep models, XGBoost requires considerably less tweaking. In addition, we can also confirm that a combination of deep models with XGBoost outperforms XGBoost alone on almost all datasets.

**Keywords**—Deep learning; XGBoost; NODE; TabNet; DNF-net; statistical significance test; tabular geographical data

## I. INTRODUCTION

Deep learning has gained popularity in a variety of fields in recent years, including medicine, engineering, and agriculture. The exponential growth of data is most likely to blame. Deep learning algorithms have shown to be effective in a variety of domains, including audio [1], images [2], and text data [3]. Many architectures exist in these domains that are capable of converting raw data into meaningful exemplifications. Because the most common type of data is in tabular format, which consists of rows and columns with a variety of parameters, These types of data are used in real-world applications in a variety of fields, including medicine, agriculture, academia, and geography. Traditional and ensemble machine learning approaches, such as Logistic model tree (LMT), Decision tree (DT), Random forest (RF), Gradient Boosted decision tree

(GBDT), and others, are used to process these tabular datasets, and these models still outperform deep learning on tabular data. When using a deep learning model on tabular data, there are a number of issues to consider, including missing data, data integrity i.e., mixed data (nominal, numerical, and categorical), data imbalance, data overfitting, and a lack of specific knowledge about the dataset's structure. When tabular data is taken into account, boosting machine-learning algorithms like XGBoost perform better, according to the “no free lunch” (NFL) theorem [4] [5]. Since then, the authors [6] [7] have implemented deep learning on the tabular dataset in their research, and it has been demonstrated that the deep learning model outperforms GBDT. However, because each study was conducted on different datasets, one of the major flaws in their approach is that there was no benchmark dataset [8] [9]. So, based on these papers alone, it's difficult to claim that deep learning always outperforms traditional and ensemble algorithms like GBDT when dealing with tabular data [10].

Since the number of research studies using deep learning on tabular data is growing, there is no standard benchmark model in deep learning from which we can conclude that deep learning always outperforms traditional machine learning on tabular data. As a result, the main goal of this paper is to see if any deep learning model is a good fit for these types of tabular dataset problems. Furthermore, in this paper, we attempt to evaluate the proposed deep learning models on tabular datasets, as well as implement XGBoost on various algorithms, with a focus on a historical geographical dataset from India's Kashmir province [11].

This paper is structured as: Section 2 provides a basic background of deep learning and ensemble models on the tabular data. Next, Section 3 presents the experimental setup where dataset descriptions are presented and furthermore this section defines the implementation details with optimization parameters and statistical significance test. Section 4 defines the experimental results and model evaluation. Section 5 defines the overall working of the paper. Finally, the conclusion and future strategies have been suggested in Section 6.

## II. REVIEW OF LITERATURE

In this section, we present studies that used deep learning approaches and ensemble approaches to predict rainfall using a tabular geographical dataset. This section is divided into two subsections: Section 1 contains several studies that use deep learning models on tabular datasets, and Section 2 contains some model ensemble approaches that use the same tabular geographical dataset and record individual performances.

### A. Deep Learning on Tabular Geographical Dataset

Salman et al. [12] (2015) use a variety of deep learning techniques, including recurrence neural networks (RNN), convolutional neural networks (CNN), and conditional restricted Boltzmann machines (CRBM), to look for hidden patterns in the dataset. These techniques were used in the Indonesian region, with data collected from the national weather service center for environmental forecasting (NOAA). This study used a dataset that spanned 35 years, from 1973 to 2009. Initially, RNN was applied to a dataset containing ESNO variables. RNN produces results with a higher level of accuracy, according to the findings.

Emiley et al [13] (2016) present a deep learning architecture-based accumulated daily rainfall prediction. This research employs auto encoders to reduce non-linear attribute relationships and a multi-layer perceptron (MLP) for prediction. This hybrid architecture was then compared to previously implemented techniques, and it was discovered that the model performs better for daily rainfall prediction when using root mean square error (RMSE) and mean squared error (MSE) statistical approaches. This research was carried out in the Colombian city of Manziles, where the data was grouped into a daily time series spanning the years 2002 to 2013.

Devi et al. [14] (2017) propose an artificial neural network (ANN) model for a reliable forecast mechanism. This method was used to analyze spatial and temporal data from the Nilgiris district in Tamil Nadu, India. Performance was measured using a variety of statistical parameters such as correlation coefficient, MSE, and so on. When compared to time delay neural network (NN) and other ANN models, the best model in this study is a wavelet Elman model. This research also develops a system for early landslide warnings based on the wavelet Elman model.

According to Geetha et al. [15] (2018), using deep learning techniques for meteorological purposes on a time series dataset will significantly improve accuracy precision. This research uses deep learning architectures such as LSTM and ConvNet to analyze time series data from 468 months in various locations. Later, it was discovered that increasing the number of hidden layers improves the model's performance for daily rainfall prediction when using RMSE and MAPE statistical approaches.

Yen et al. [16] (2019) proposed using Echo state network (ESN) and deep Echo state network (DeepESN) algorithms to apply deep learning models to rainfall prediction. This research uses hourly rainfall data from southern Taiwan from 2002 to 2014, spanning a period of 12 years. When the DeepESN algorithm's correlation coefficient was compared to ESN and commercial neuronal network algorithms like BPNN and SVR,

the study concluded that it is a reliable algorithm. It was suggested that DeepESN could be used globally on larger sets of data to predict rainfall based on the results obtained.

Manoj et al. [17] (2020) proposed a hybrid deep learning model (BLSTM-GRU), for the monthly prediction of rainfall. The experiment was conducted using data obtained from Bhutan's National Center of Hydrology and Meteorology Department (NCHM). To test the data's predictive capability, various NN algorithms such as LSTM, CNN, BLSTM, and GRU were used. LSTM outperforms the other techniques with a MSE score of 0.0128, but the hybrid model BLSTM-GRU outperforms LSTM by approximately 41% with a MSE score of 0.0075.

Zeelan et al. [18] (2020) claimed that deep learning models can learn from nonlinear data with less error. The Multi-layer perceptron (MLP) and Auto-encoder NN are used in this study to predict the rainfall. The accuracy parameters used in this study were RMSE and MSE, and these implemented models were later compared with other machine learning models on the same set of data, with the study concluding that MLP and Auto-encoder NN perform significantly and can be used as a solution to all available approaches.

Ari Yari et al. [19] (2021) present a rainfall prediction comparative analysis study. The authors use deep learning (DL) models and simple rainfall estimation approaches based on traditional machine learning algorithms. The study was conducted in five major cities across the United Kingdom (UK), with data collected spanning roughly 20 years (2000-2020). The bidirectional LSTM network and stacked LSTM with two hidden layers performed best after the proposed model was evaluated. One of the study's major flaws was the model's inability to generalize the data. That is, the model over-fits the training data in most cases, which makes it difficult to record accurate, predicts in the testing and validation sets.

Razeef et al. [20][21] (2020,2022) proposed a neural network approach to predict the rainfall on the time series data of UT of J&K, India. Rainfall was predicted using a Grey Wolf-based neural network model. The data in this study spans 30 years, from 1990 to 2020, and includes variables such as maximum temperature, humidity, minimum temperature, wind, vapor pressure, and others. When using RMSE, PRD values, and MSE statistical approaches, it was discovered that the model performs better for daily rainfall prediction. This model was later compared to non-linear autoregressive models with exogenous inputs (NARX), and the study concluded that when both models are used together, non-linear time series data would perform better.

According to the literature reviewed in this study, many deep learning models have been utilized for various time-series prediction applications, but they have yet to become a standard algorithm in the artificial intelligence arena. We must analyze the performance of these models using varied threshold datasets, and these techniques must be re-evaluated as a result.

### B. Model Ensembles on Tabular Geographical Dataset

Zaman et al. [22] (2019) use an ensemble distributed decision tree (DDT) approach to improve classification

accuracy on a historical geographical dataset. The experiment was conducted on a tabular dataset containing approximately 6000 records with five different parameters. When the DDT approach was used, there was no performance improvisation, according to this study.

Patil et al. [23] (2020) use machine learning algorithms to forecast rainfall based on a variety of variables such as temperature, humidity, wind speed, and rainfall. These algorithms include linear regression and NN, and the type of data fed to it, according to the study, determines the accuracy of the algorithm. That is, when the dataset of different structures is used, we may get different accuracies and require some modifications. Furthermore, the accuracy of DT's was found to be superior to other techniques used on the same type of data in this study.

Sheikh et al [24] (2021) proposed a stepwise machine learning approach on the discrete data collected from the Indian Meteorological Department (IMD), Pune India. The implemented model, known as LMT, employs logistic regression functions at the DT's leaf nodes. The logistic functions on the leaf nodes combine the final output of the constructed DT into linear models, which were examined and revealed a significant improvement in accuracy performance. The accuracy of the constructed DT on the same set of data is 66 percent, but when the logistic functions are applied to the leaf nodes, the accuracy jumps to 87 percent. The dataset used in this study was from J&K's Kashmir province, and it covered the years 2012 to 2017, with around 6000 data rows.

Since there are other ensemble [25-29] and deep learning approaches such as NODE, TabNet, DNF-Net, and Boosting (XGBoost, CatBoost, GBDT) [30-33]. These models perform better on larger datasets, and we use the entire training dataset to train the model.

### III. EXPERIMENTAL SETUP

#### A. Dataset Description

In this study, we employed a variety of tabular datasets from diverse fields which are used in various classification and regression problems. Some of these datasets have heterogeneous features, while others have just homogeneous

features. There are approximately seven tabular datasets that have already been used by various academics in their publications, and we have used one additional dataset that has yet to be used by any researcher. In the experimental operations, roughly 80000 samples were taken, and the datasets range from 7 to 1600 parameters. The seven datasets are obtained from TabNet, NODE, and DNF-Net studies, and each dataset has been well-trained and preprocessed in its respective paper. These datasets include Blastchar [34] (Source: Kaggle), Higgs Boson [35] (Source: Kaggle), Microsoft MSLR [36](Source: MSLR-WEB10K), Forest Cover Type [37] (Source: Kaggle), Epsilon [38] (Source: PASCAL Challenge 2008), YearPrediction [39] (Source: Million Song Dataset) and Gas concentrations (Source: OpenML) [40]. These datasets have also been adjusted and relative values were calculated, resulting in a standardized data with a zero mean value and unit variance. As a result, we won't go into detail about these datasets in this study; instead, we'll just establish the historical geographical dataset that we will be implementing latter. The historical geographical dataset has been collected from three different locations in Jammu and Kashmir's UT. These three locations are in the province of Kashmir, but they are quite far apart. The data spans five years, from 2012 to 2017. At these locations, the average annual rainfall is around 1700 mm. The data consists of 5491 records with a total of 9 explanatory characteristics, including minimum temperature (°C), maximum temperature (°C), station ID, season, year, humidity at various intervals, and the target parameter rainfall, which shows the quantum of rainfall measured in millimeters [41-43].

In Fig. 1, the reader can find a brief description of the data. It has gone through an ETL (Extract, Transform, and Load) process to achieve data integrity, normalization, and standardization.

To normalize the dataset's range of parameters, we use the function (1), as given below:

$$X = \frac{X - \mu}{\sigma} \tag{1}$$

The data was scaled using the R tool's built-in function 'Scale.' We also use relative values of each attribute to normalize the training data. The tabular (Table I) and graphical (Fig. 2) representation of the dataset is shown.

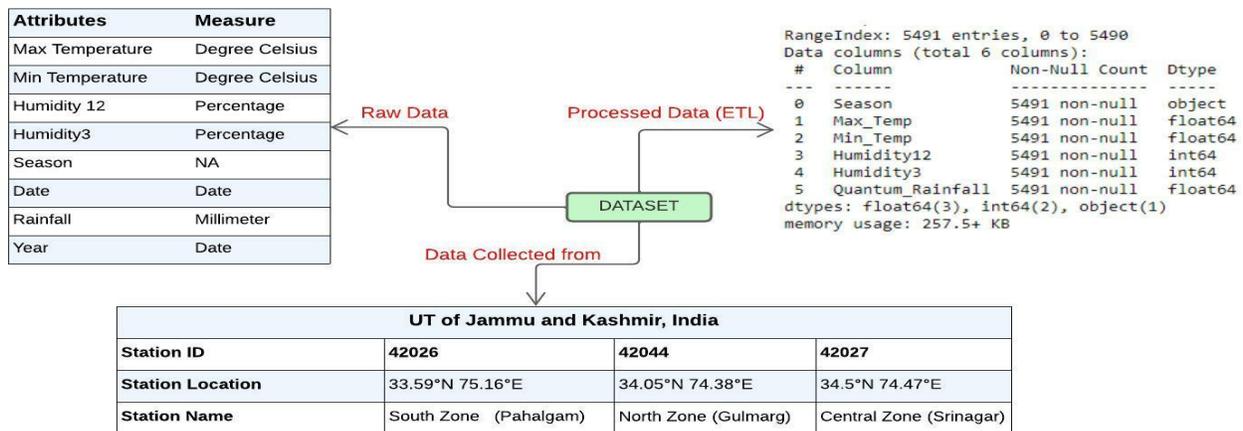

Fig. 1. Historical Geographical Dataset Description.

TABLE I. TABULAR REPRESENTATION OF GEOGRAPHICAL DATASET WITH RELATIVE VALUES

MA X	Relative Frequency (MAX)	MIN	Relative Frequency (MIN)	Hum 12	Relative Frequency (Hum12)	Hum 3	Relative Frequency (Hum3)	Rf	Relative Frequency (Rf)

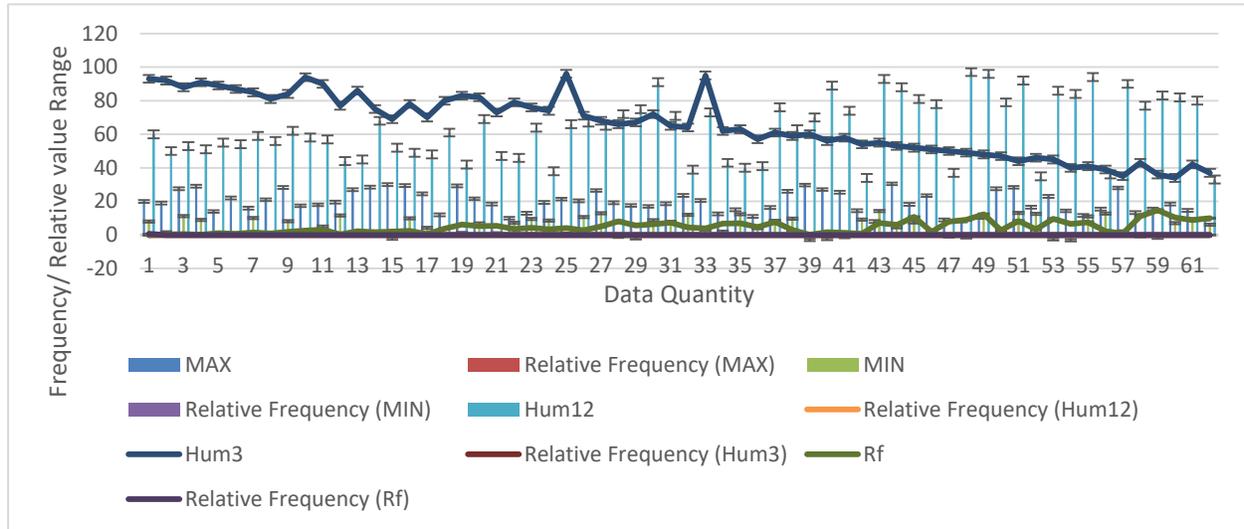

Fig. 2. Graphical Representation of Geographical Dataset with Relative Values.

A total of 70% of the data is used for training, while 15% is used for validation and testing, i.e. 3844 samples were randomly selected for training, 823 samples for validation, and the remaining 823 samples were selected for testing.

Thus, the overall description of the tabular datasets used in this paper is shown in Table II.

### B. Implementation Details

1) *Optimization process:* To pick the model hyperparameters during the optimization phase, we used the HyperOpt parameter-tuning package. To optimize the results on the validation set, this technique first uses Bayesian optimization, followed by hyperparameter search on each dataset utilized in this study. There were around 7-9 main hyperparameters, which in the case of a deep learning model include the number of nodes, layers, and, most importantly, the learning rate.

To optimize the hyperparameters all the datasets used in this study were initially divided into three individual splits, which include training split, testing split and validation split. In partitioning process, we use stratified random sampling partitioning to split the data. The below tabular representation (Table III) shows the individual splits of the datasets in order to optimize the model.

Around 1000 steps of search were performed on each set of data in order to maximize the validation set's findings, and only the set of hyperparameters with the smallest loss for the final configuration were chosen.

2) *Metrics evaluation and statistical significance test:* In the case of classification issues using discretized data, we simply utilize cross-entropy loss metrics to evaluate the datasets. It calculates the impurity at each stage of the data and the total entropy loss in the end. Furthermore, when the data is continuous in nature, such as in regression situations, statistical parameters such as RMSE, mean signed difference (MSD), and MAE are used. We reported the performance of each dataset on their respective test sets based on these metrics. We also have Friedman's testing for statistical significance in addition to these cross entropy and RMSE, MAE measurements. Friedman's testing has the advantage of assuming that data is not evenly distributed. Using Friedman's hypothesis, we compare all of the classifiers to the baseline classifier. The null hypothesis is rejected at a certain level of confidence (90 percent in this study) if the p-value for any model pair is less than 0.05; otherwise, the hypothesis is not rejected.

TABLE II. TABULAR DATASETS DESCRIPTION

#### IV. EXPERIMENTAL RESULTS

##### A. How Effectively can Deep Learning Models Generalize to other Datasets?

The performance of deep learning models on the aforementioned datasets is proposed in this study, and the individual outcomes are compared to the XGBoost technique. The performance of each algorithm on each dataset is

presented in the table below. The mean and standard error of each model's performance on the datasets are shown in the Table IV. The best performance of the dataset is presented for each model, and it was discovered that the model with the lowest value is considered to have the best performance. Friedman's testing was utilized to perform a statistical significance test between the models with a 90% confidence level.

TABLE IV. RESULTS AND PERFORMANCE OF EACH TABULAR DATASET BASED ON EACH MODEL USED IN THIS STUDY. FOR YEAR PREDICTION MSE IS USED AND CROSS ENTROPY IS USED FOR ALL OTHER DATASETS. THE VALUES WITH LOWER VALUE IS BETTER AND THESE VALUES ARE THE AVERAGES OF DIFFERENT TRAINING RUNS WITH STANDARD ERROR OF MEAN (SEM)

Model	Blastchar	Higgs Boson	Microsoft (MSLR)	Forest Cover Type	Epsilon	Year Prediction	Gas Concentration	Historical Geographical Dataset
NODE	21.36 ± 0.23	21.21 ± 0.67	54.62 ± 3e-2	4.25 ± 0.17	<b>10.26 ± 1e-2</b>	76.88 ± 0.16	2.25 ± 0.22	14.76 ± 0.12
DNF-Net	27.91 ± 0.18	23.71 ± 0.88	55.78 ± 3e-2	4.01 ± 0.09	12.42 ± 4e-2	82.06 ± 0.15	<b>1.45 ± 0.08</b>	15.36 ± 0.18
TabNet	23.66 ± 0.16	<b>21.15 ± 0.22</b>	55.09 ± 2e-2	<b>3.02 ± 0.15</b>	11.96 ± 3e-2	82.89 ± 0.11	1.86 ± 0.10	14.62 ± 0.16
XGBoost	20.41 ± 0.23	21.83 ± 0.34	54.39 ± 2e-2	3.21 ± 0.11	11.23 ± 2e-2	75.68 ± 0.08	2.06 ± 0.32	13.45 ± 0.19
Simple Ensemble	21.22 ± 0.15	22.49 ± 0.41	54.44 ± 3e-2	4.15 ± 0.16	11.38 ± 4e-2	78.65 ± 0.16	2.41 ± 0.18	13.67 ± 0.15
Deep Ensemble & XGBoost	<b>20.13 ± 0.16</b>	22.36 ± 0.51	<b>54.21 ± 1e-2</b>	2.86 ± 0.05	11.35 ± 1e-2	<b>75.01 ± 0.22</b>	1.66 ± 0.06	<b>12.13 ± 0.15</b>
Deep Ensemble w/o XGBoost	24.36 ± 0.31	22.45 ± 0.55	55.53 ± 3e-2	3.57 ± 0.11	10.88 ± 1e-2	79.01 ± 0.17	1.91 ± 0.17	14.15 ± 0.14

There are some observations based on the results, as given in the table. To begin with, the models almost outperform unknown datasets on original datasets. On each dataset, the XGBoost model nearly outperformed all deep learning models such as NODE, DNF-Net, and TabNet. As we can see, the XGBoost model outperforms deep learning models in 5 of the 8 datasets, and these datasets had significant p-values ( $< 0.05$ ), indicating that the results were significant. We can also see that the deep learning model has not consistently performed. The authors claimed in their study that deep learning models outperform other models, but this was only true for the datasets included in their study. As a result, when distinct datasets are involved, this conclusion is unjustifiable. We can also observe that the Deep ensemble and XGBoost model beats individual models in the majority of cases, i.e. it outperforms 5 individual models out of 8, and the p-value in these 5 cases was substantially less than 0.05, indicating that the null hypothesis is rejected.

Now, in order to evaluate these models and see which one is better for a given dataset, we compared the relative performance of each model (NODE [44], TabNet [45], DNF-Net [46][47], and so on) to the best model for that dataset. For example, assume we used the historical geographical dataset in table (Table IV) and compared the relative performance of the models to choose the model with the best performance (Deep Ensemble & XGBoost in this case). We discovered that Deep Ensemble & XGBoost had the best relative value gain of 2.46 percent, with XGBoost coming in second with 3.86 percent, TabNet with 8.67 percent, DNF-Net with 10.55 percent, and NODE with 13.23 percent. The tabular representation of average relative performance deterioration on unseen datasets is shown (Table V).

With these findings, we discovered that deep learning does not always outperform other methods. When compared to XGBoost, Deep Ensemble, and XGBoost, the deep learning model performs the worst when trained on datasets other than those used in the original studies. Only two choices exist for the lowest performance results. Either there is a selection bias

or there is a difference in hyperparameter optimization. Furthermore, the results in the original papers reflect the results that we have reported, excluding the possibility that implementation errors were the cause of our observation.

#### B. Model Evaluation: Is it required to apply both the XGBoost and Deep Models in Combination?

In this section, we will see which model performs better in all scenarios when compared to other models. We employed four types of models in table (Table V), including deep models (TabNet, DNF-Net, and NODE), XGBoost, Deep ensemble with XGBoost, and Deep ensemble without XGBoost. When comparing the performance of deep learning models to XGBoost and combined Deep ensemble & XGBoost Models on various data types, we discovered that deep learning models perform poorly in most circumstances. The question now is whether we require a combined XGBoost and Deep model. To answer this, we can see that in 6 of the 8 examples, the combined ensemble and XGBoost show significant results. Simple ensemble did not produce any improvised results, although competing with deep learning model results. Furthermore, when we look at the Deep ensemble models without XGBoost, we can observe that it did not do well in any situation when compared to any other model. As a result of this analysis, we can conclude that for tabular datasets, we require both deep ensemble and XGBoost in combination.

TABLE V. AVERAGE VALUES OF ALL THE MODELS IMPLEMENTED ON EACH DATASET WITH LOWER VALUE TREATED AS BEST

Model	Average Relative performance (%)
Deep Ensemble w/o XGBoost	7.10 %
XGBoost	3.86%
Deep Ensemble & XGBoost	2.46%
TabNet	8.67%
DNF-Net	10.55%
NODE	13.23%
Simple Ensemble	4.23%

REFERENCES

In real-world situations, time and resources are limited when it comes to training a model for a new dataset and optimizing its hyperparameters. As a result, it's fascinating to learn how difficult it is to do so for each model. Calculating the number of computations required by the model is one way to assess this. Floating point operations per second (FLOPS) is a common unit of measurement. However, because each parameter set has a different FLOPS number, comparing various models in this way when optimizing model parameters has become impossible [47].

V. DISCUSSION

This study was based on deep models that had already been deployed by several academics on a tabular dataset [12-14]. Deep models were applied to tabular datasets (Forest CoverType, Higgs, Gas Concentration, Epsilon [30], MSLR [31], Year Prediction [32], Blastchar [33], and so on) by the authors in their publications, and they argued that deep models exhibit some promising outcomes. However, their research was limited to a single dataset. We used one more tabular dataset (Geographical dataset) in this research and attempted to construct all of the deep learning and ensemble models. On all of the datasets utilized in this study, we also investigated various possible tradeoffs that are required in real-time applications, such as hyperparameter tuning, metrics evaluation, and Statistical Significance test. Our results reveal that the performance is similar to what the authors have shown in their respected publications, but when we tried to compare the performance of different datasets on the models used by the authors in their study, the deep learning results were not as good as the original datasets. We next looked at XGBoost and ensembles of deep models with XGBoost and without XGBoost, and discovered that the XGBoost model outperforms deep models. However, as seen in the table, the ensemble of XGBoost models with Deep models outperforms the XGBoost model alone. Furthermore, optimizing a new dataset using deep models is a difficult procedure, whereas optimizing a new dataset using ensemble models with XGBoost is quite simple [48].

VI. CONCLUSION AND FUTURE STRATEGIES

This research demonstrates that using various deep learning algorithms on tabular data does not improve performance. We also used XGBoost on these datasets, which produced some promising results when compared to deep models, and we used ensemble deep learning with and without XGBoost to see how it affected the performance of each dataset. On these tabular datasets, an ensemble of XGBoost models without deep learning never performed well, but when we looked at the overall performance using an ensemble of deep models with XGBoost, the results were astounding. This ensemble deep model with XGBoost beats all previous models, and our enhanced models pave the way for future study on tabular datasets in terms of comparing performance and assisting researchers in determining the best technique for optimizing hyperparameters. Our findings will also aid in the development of new models (such as CatBoost, where learning rates are uniformly distributed) that are simple to optimize and can compete with the performance of ensemble deep models such as XGBoost and many others.

**Abstract**—Internet of Things (IoTs) offer significant benefits to various applications, including homes automation (HA), environmental monitoring, healthcare, homeland security, agriculture, and many others. Consequently, the trend of IoTs is rapidly evolving in many new sectors leading to higher comfort, better quality of life, and conveniences that can offer optimum consumption of valuable resources for the users. This paper presents a low-cost and flexible HA system that uses different sensors and other resources to control commonly used home appliances and connected devices by establishing IP connectivity to access, manage, and monitor them remotely. To enable remote access, an android-based application was developed to monitor and control the home devices. Edge computing (EC) platform is used in the proposed system to enhance reliability and robustness when the computation offloading is required. The system operates automatically according to the environmental conditions in the home based on the home occupants' requirements. The outcomes of the proposed system reveal that it greatly supports the concept of smart HA and capable to significantly reduces the wastage of electricity via optimum utilization.

**Keywords**—Smart home; Internet of Things (IoTs); home automation; android application; raspberry pi; edge computing

## I. INTRODUCTION

Recent advancement in smart phones and inexpensive open-source hardware platforms has empowered the development of low-cost home automation (HA) systems using Internet of Things (IoTs). This decade has seen an enormous attention and interest in sensors and sensor networks. Billions of devices are connected to internet already and further increasing sharply with the passage of time. Considering the current progress and the importance of IoTs, 31 billion devices have been connected in 2020 and this figure can reach to 75 billion by 2025 [1-3] as detailed facts are represented in Fig. 1. The devices include smart appliances (lights, fans, refrigerators, air conditioners, ovens, washers etc.), security and safety systems (PIR motion detector sensors, monitoring cameras, smoke and fire detectors sensors etc.), and other smart home energy equipment, like smart lighting, thermostats, and actuators.

HA is a way of life by utilizing wireless sensors and other modern smart technologies that can make a home to accomplish different sets of operations or tasks automatically and remotely whenever they are required. Based on recent success of IoTs for HA system, it is becoming reality in

improving the quality of living by making it more comfortable due to many embedding intelligences into sensors and actuators and connecting them intelligently for smart homes. The IoT market has generated revenue around \$300 billion in 2020, and the value of Smart Home market worldwide has reached to \$43 Billion. This is nearly three times more than that in 2014 [4-6].

Homes and offices chores can be automated by using the internet to control and monitor the household devices by considering the environmental conditions and the human comfort. Many vendors have introduced and producing a range of HA devices to regulate and control the indoor ventilation or environment. For this a variety of wireless sensors and home controlling products including home energy monitor, smart plugs, smart temperature thermostats, outlets, sockets, and smart vents etc. are available. Remote controlling or monitoring is not only the facility of HA system but more importantly it helps to minimize operating costs and saves electricity or other resources. Moreover, it can be ideal for the aged and disabled people [7].

The edge computing (EC) platform has a lot of advantages and useful applications related to smart HA. Its prominent benefits are minimizing the latency issues, providing location awareness and mobility support, real time response, less cost for data processing in terms of less bandwidth consumption, home inside environment control without the home resident's intervention, timely weather predictions and many more. In IoTs, each equipment can consume a huge amount of energy if its communication is not optimized [8, 9]. Further, many applications are response sensitive so to satisfy time critical applications, EC can be greatly helpful. In addition, for the smart devices, local computation is cheaper in terms of energy consumption due to less physical distance for data communication because devices may generate data at every single moment and required processing on the collected data. During their data transmission, they required more energy if the transmission time is high, and they utilize more communication channels as well. For instance, when CCTV cameras' data is stored in the cloud, it means far away from the end devices that it requires more bandwidth and more time for data transmission comparatively to the EC. So, in the case of EC, due to less distance it takes less time and consumes less bandwidth for data transmission. In this example EC is therefore saving resources in terms of energy, time, and communication channel cost etc. [10].

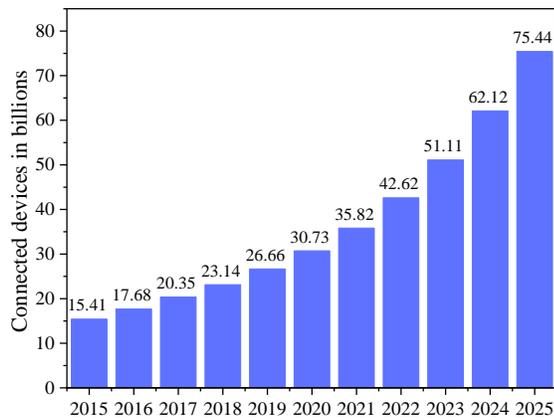

Fig. 1. The Current and Expected Number of Devices that will be connected to Internet on Yearly basis.

In this paper we present a HA system using IoTs, android application, that involving the EC platform. The significance of our designed system is that there is no need to change or replace the current household appliances, as it offers options to connect these devices through a control panel. The main component in the control panel is Raspberry pi which controls all the home appliances. Several sensors are connected/integrated to Raspberry pi for it to receive various measurements like temperature, humidity, light intensity etc., for which it can control the appliances in considering the resident requirements. The whole system consists of commonly used home appliances (lights, fans, switches, power plugs, air conditioners etc.) different sensors (light sensor, PIR sensor, temperature sensor etc.), Raspberry pi 4, power relays, and a touch screen panel as shown in Fig. 5. The effectiveness of the designed system (i.e., for integrated sensors with the home devices and switches), reveals that it greatly achieves the concept of smart HA.

#### A. Some Major Applications of HA

Some major applications are discussed here to support the concept of HA. With the help of IoTs, it can recognize or notice the resident's certain habits or activities e.g. exercising, showering, sleeping times, hence IoT can regulate the home interior environment accordingly [11] such as changing the temperature or environment of a house, by smartly controlling windows/door entry points. Doors can be operated automatically only when residents enter or leave the room. Same concept can be applied to the car garage. Windows shutters can be adjusted according to the outside temperature and light intensity, or closed fully in case of raining [12, 13].

Security or safety is always the prime concern of any house. It can be greatly improved by IoT concepts. For example, human presence or any moving object, particularly at the room entrances and the main gate, can be detected by using PIR motion detection sensor, hence enhancing the security. The safety of home residents can certainly be attained efficiently by installing some sensors for smoke or fire detection, sensing the odd materials in water, and storms prediction etc. An automated safety alarm can mitigate the loss or harm based on the received information. Security and safety systems can be beneficial to elderly and disabled people for

them to control or react appropriately to the home appliances/devices during critical conditions [14].

Home gardens, lawns, indoor plants can be made smarter by IoT. Sensor(s) can be fixed in root of plant or in the soil to identify the moisture level to trigger a motor pump to irrigate/water the plants [15]. Other than that home devices can be controlled according to an individual routines and behaviors. For example, music can be turned on/off or its volume can be tuned depending on the routines or schedules of the home residents. Likewise, it is possible to define morning or evening routines to adjust the bathroom water heater or windows shutters to operate in considering the weather conditions [16, 17]. The aforementioned and some other major examples of IoTs are illustrated in Fig. 2.

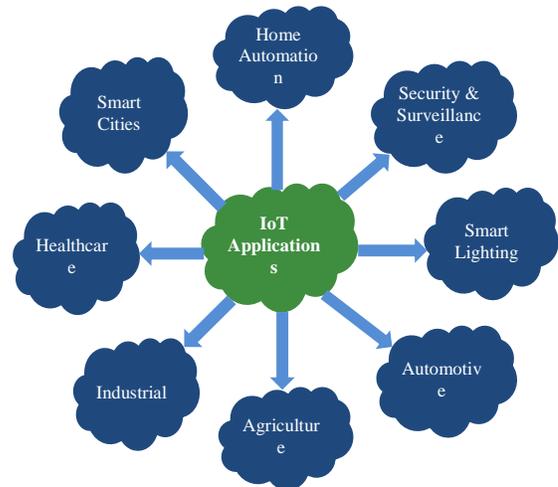

Fig. 2. Major IoT Application Domains.

## II. RELATED WORK

The use of IoTs to control the home appliances to achieve the concept of smart home keep attracting the researchers and engineers [18, 19]. Adding IoT based facilities to home environment can enhance the quality of life for home resident and proving blessing for the elderly and disabled people that depends on caregivers or institutional care [20]. There are various wireless technologies suitable for remote data transfer such as Wi-Fi, RFID, and cellular connectivity has been utilized to embed various levels of intelligence in the HA. Further, by introducing the IoTs, the research and implementation of HA are getting more and more attention from the research community.

An IoT based system was proposed in [21] to reduce the cost and power consumption by utilizing the solo computing platform. The system used Arduino and Android smart phones through virtual buttons and sliding switches, user could control and observe the home devices using text and voice commands. A similar work was presented in [12] to provide the facility for monitoring smart home and was especially useful for the disabled persons. The proposed system was customizable to allow changes be made according to the needs of future requirements.

In [22], the Bluetooth 4.0 protocol was used to provide the communication among the users and smart home devices.

Users could control the home devices with their mobile phones or tablets. The drawback of the system was the control was restricted to a short range due to Bluetooth technology. To conserve the home energy, the authors have designed a system by using different sensors like temperature sensors, motion detection sensors and luminance sensors to automate the home appliances like air conditioners, fans, lights, etc. and the proposed system can save electricity usage as well [23].

A reliable and low cost HA system using Arduino microcontroller and various other sensors was offered in [24] to access and control the home devices (fans, lights, TV, etc.) with the help of smart phone application or web-browser. Similarly, another HA system was presented in [25] which used a micro-web server at home side with the IP connectivity allowing user to interact home devices with the smart phone. Different sensors were used like current sensor and temperature sensor to automate the home appliances. Further, authors proposed [26] a system to control the home appliances for HA. In the proposed system four types of sensors were considered i.e., temperature sensor, PIR sensor, smoke and gas sensor, and ultrasonic sensor to automate the home environment and intrusion detection.

For the home security purposes, many systems have been proposed, few of them are discussed here. In [27], authors designed a system to improve the home security by utilizing the cameras to capture pictures to share the information on who entered the house or room. Another system was presented in [28], to enhance the home security by using some sensors, and the advantage of this system was cost effectiveness. Data could be transferred between the devices and controllers by using one or more communicating technologies like Wi-Fi, GSM, ZigBee or Ethernet. ZigBee and Bluetooth were used for data sending among the sensors and CPU. These data sharing technologies were used due to easy implementation and low power usage.

Involving the edge/fog computing in smart home system can be very effective and useful for computation offloading to minimize the latency and gives good real time response. So, researchers have integrated edge/fog computing in their smart HA systems. In [29], authors presented a framework for HA system by involving the fog computing to achieve the concept of energy optimization. With their proposed system, the network traffic and delays were minimized for smart homes. In addition, by involving the EC platform, a system for electrical demand prediction for the smart homes was presented in [30]. An intelligent edge node was used for their system that stored heterogeneous data, but the analysis and processing were done at the cloud node. The system can collect data by the IoT devices from the environment, and provide a better quality of service and greater scalability of computing resources through the EC.

Further in [31], the authors proposed an IoT based system by involving the EC for the smart buildings and homes. In the designed system, the facilities like temperature control, energy consumption monitoring, safety, comfort level were considered. The system addressed issues like scalability and interoperability. A brief comparison of characteristics of IoT, edge and cloud computing are presented in Table I.

TABLE I. CHARACTERISTICS OF IOT, EDGE AND CLOUD COMPUTING [32]

Characteristics	IoT	Edge	Cloud
Deployment	Distributed	Distributed	Centralized
Components	Physical devices	Edge nodes	Virtual resources
Computational	Limited	Limited	Unlimited
Storage	Small	Limited	Unlimited
Response time	NA	Fast	Slow
Big data	Source	Process	Process

Many literatures have made significant contributions to the design and development of HA systems. However, most of these efforts mainly focused on switching and controlling the home appliances rather than remotely monitoring the home environment. The system provided in this article carried a unique architecture for IoT based HA with the help of an android application which saves energy via optimum utilization and reduces the latency when the data is required for computation offloading, hence can be beneficial irrespective of regional or location dependencies.

### III. PROPOSED SYSTEM

Considering the factors and challenges discussed in literature review, we designed a low cost, flexible and standalone home monitoring and controlling system. The developed system contains different controllers, relay modules, Raspberry Pi with Wi-Fi support, and various sensors. The main equipment and devices used are: light sensor, air sensor, PIR (passive infrared sensor), smoke detecting sensor, hall effect sensor, Raspberry Pi, display panels (touch screen), and Android application.

To manage and control the home appliances or against the data measurements by various sensors, a smart interface is designed with the help of an Android-based application to enhance the system usability. The significant feature of the system is that it is customizable according to various requirements and scenarios with little configurations and minimum re-coding. The major advantage of our system is that there is no need for replacement of the current household appliances, the existing devices can be connected to a control panel forming part of the smart HA system.

In the designed system, we utilize the Hall Effect sensor and passive infrared (PIR) sensor to observe and monitor moving activities when these are required. The mentioned sensors are positioned or installed at the entry and exits points to and from the rooms and relevant home space. In addition, these activity monitoring sensors can be useful in dealing with suspicious or intrusion activities. To identify the light intensity, light sensor is utilized so that system can decide when the room or house lights will be turned on/off. Measuring the air temperature and its intensity helps to make auto switched on/off of air conditioners and fans or making decisions regarding air control in the smart home. For smoke detection, smoke detector sensor is installed to make timely alarm warnings to escape from fire disaster. Various other sensors can be equipped or considered according to the needs or requirements of the system or the home residents.

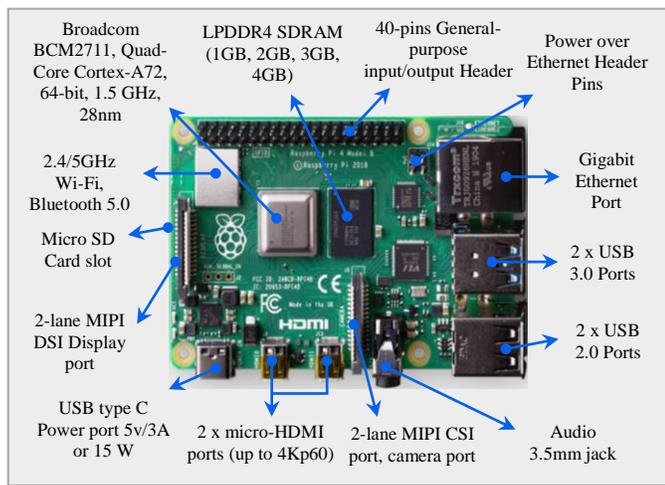

Fig. 3. Raspberry Pi 4 Model B Overview.

Raspberry pi plays the role of main controlling unit where all the sensors pass their measurements to it for taking further actions. Raspberry pi has many features like Wi-Fi connectivity, Bluetooth facility, and it can be connected to a display panel. In case of extra memory requirements, external memory storage can be used [33]. For utilizing the Wi-Fi or wired internet connection facility, it can be connected to the internet where we can easily control its operations through the android application. In the case of unavailability of internet, Raspberry pi can be connected via Bluetooth. To make it functional we have written a code for it, so that it could perform various tasks for our proposed system. Raspberry pi receives instructions as inputs from different sensors or from residents then it sends command(s) to home appliances via power relays. Various components and specifications of Raspberry Pi 4 model B are shown in Fig. 3.

Fig. 4 (block diagram) illustrates the basic components for the proposed system, where raspberry pi is connected to smart phone, to a display screen, and to an internet connection. It is coupled with different sensors and power relays and these

power relays perform the operations of switched on/off the home appliances according to the given instructions of Raspberry pi. In the diagram, it shows how the proposed HA system components interact with each other.

In the proposed system we have considered eight power relays, but these can be extended according to the needs or number of appliances. The power relays are used to switch on/off the appliances according to the instructions from Raspberry pi. As mentioned, the Raspberry pi is connected to the internet via wired or Wi-Fi connection, so Android-based smart phone or smartwatch can be used to control the operations of Raspberry pi. It can receive the instructions as an input from the smartphone or smartwatch or can send the notifications to them for the HA system. Further, a display panel is attached to Raspberry pi where user can see the operations accomplished or by touching the digital buttons on the screen to control the home appliances. Fig. 5 illustrates example of equipment and appliances that can be setup for the proposed HA system.

The designed system can automatically open or close the doors or garage when detecting the human presence. The Raspberry pi can also receive the current weather forecasts from internet then it can automatically open/close the windows or curtains, or on/off the required appliances and home temperature can be regulated accordingly.

If the number of cameras is higher and they record a huge volume of data, then the produced data can be stored in the EC where later on features extraction or processing tasks can be done at this platform (i.e., EC). So, for the computation offloading, EC is added which makes our proposed system more robust and more reliable especially when the task is time stringent or having more data size for computation.

If the resident doesn't have mobile phone and wants to control something at home, then it can regulate the home appliances by using touch screen which as displayed in Fig. 6. But this is not the main motive of our designed system, although we can say it is a facility whenever in the case of unavailability of mobile phone.

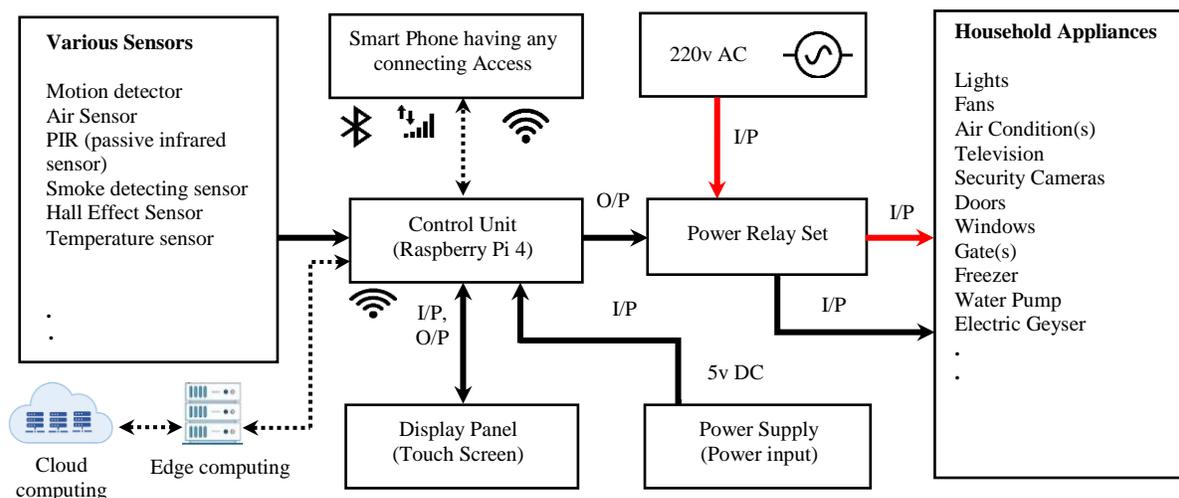

Fig. 4. Block Diagram for the Designed System.

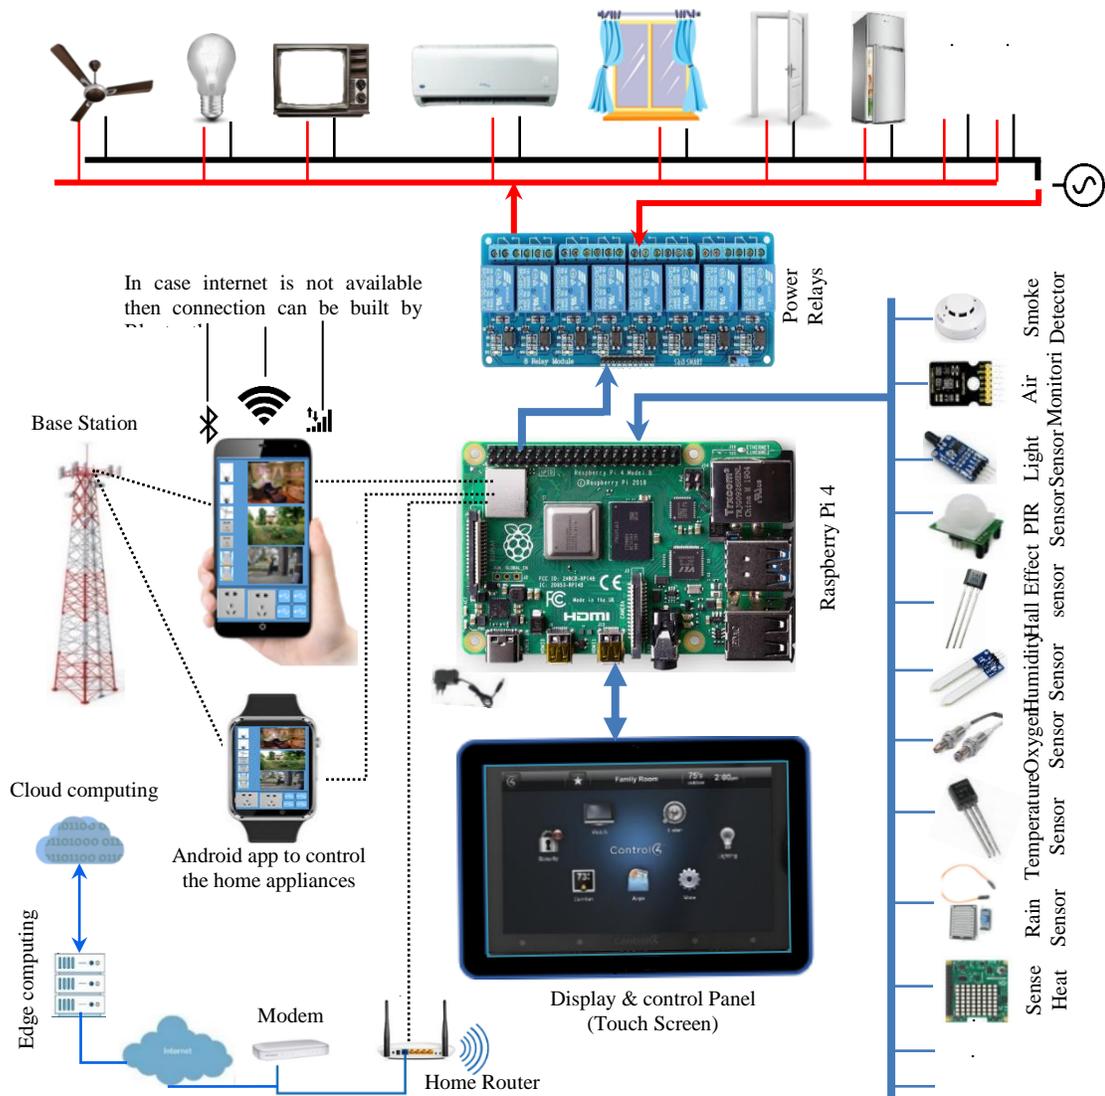

Fig. 5. Example of Equipment and Appliances Connected for the Proposed HA System.

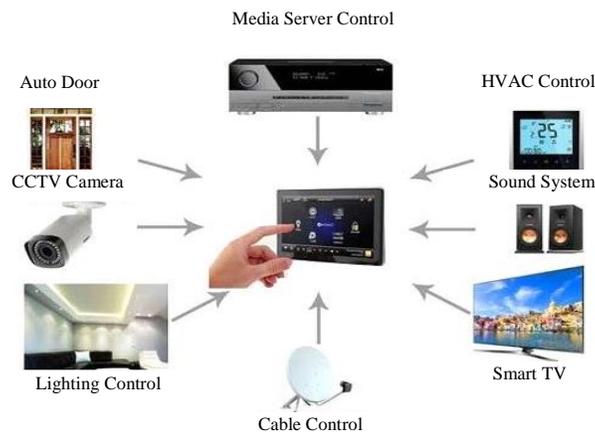

Fig. 6. Illustrates when the Mobile Phone is Unavailable, Touch Panel can be Utilized.

To use the designed system, the user needs to install the developed application. After checking the internet connectivity, user will use its user id and password for login to access the

home appliances. Afterward login access, the system shows the available rooms, where a specific room will be selected for switching on/off the device(s).

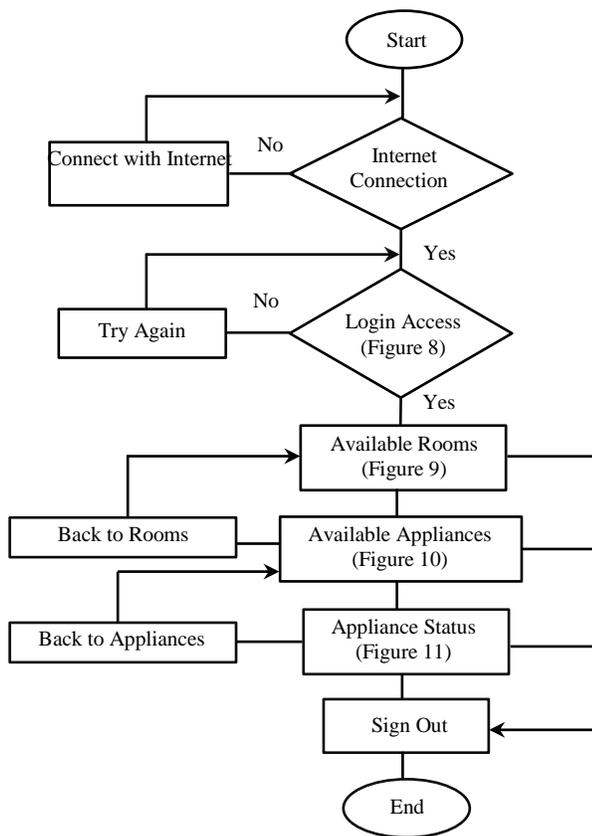

Fig. 7. Process Flow for the Developed System.

**Algorithm 1: Smart HA System**

```

1: Input: Instruction from Android App, 220-volt input to home
   appliances, inputs from different sensors to Raspberry Pi 4
2: if Internet connection available then
3:     if Login Access granted (Figure 8) then
4:         show Available Rooms (Figure 9) || Sign out
5:         if select Available Room (Figure 9), then
6:             show Available Appliances (Figure 10) || Sign out
7:             if select Available Appliances (Figure 10), then
8:                 show Appliance Status (Figure 11) || Back to
                   Room || Sign out
9:             if select Back to Rooms, then
10:                goto line number 4
11:            if select Appliance Status (Figure 11) then
12:                Modify the applicane status (i.e., ON/OFF
                   etc.) || Back to Appliances || Sign out
13:            if select Back to Appliances, then
14:                goto line number 6
15:            end if
16:        else Try Again
17:        end if
18:    else Connect with Internet
19:    end if
20: Output: Home appliances are operated automatically
           according to the residents' desires
    
```

Next, the screen will display the information of available appliances in that room. By clicking on the desired appliance user can see its status like either it is on or off. By choosing the options on the display, resident can on/off the household devices or manage the desired operation. Fig. 7 (flowchart) and the Algorithm 1 present the whole mechanism and working behavior of the proposed system.

*A. Android Application*

After installing the HA system application, the user can login by using the user ID and password or can create an account as shown in Fig. 8. After successful login, Fig. 9 shall appear as the main interface screen. The information about room environment and weather conditions like temperature will be available on this screen. Further this main screen has a list of all available rooms. User will select the desired room for controlling the appliances, for example if the user selects bedroom 2, then the next screen is opened as in Fig. 10 showing the list of all available appliances for the selected room. Here, the user can control or navigate the desired appliance for the selected room and also the user can see the current status of a particular appliance.

User can select any appliance from the list. For instance, if the desired appliance is air conditioner, then user can switch on/off this appliance like in Fig. 11 (screen), and can change its functions/intensity like temperature or fans speed, etc. An additional feature of this application is that user can set the timings for different appliances like when the lights to be turned on/off. The system is capable for reminding the owner by sending the notification(s) about the current weather and home environment conditions. It can send the alert(s) when motion sensors detect suspicious activities or when someone trying to access application as unauthorized user.

*B. Challenges during System Designing and Application Development*

Installation of different types of sensors in home appliances particularly when these are designed by different vendors, can be a major challenge in developing a HA system [34, 35]. Hence, there must be an appropriate mechanism for data controlling and processing capabilities to manage the entire system effectively. Although availability of reliable internet connectivity plays a key role in many cases, at certain locations they may not be feasible. Further, professionals are needed to develop the system by considering the various home situations and the dependability of sensors on the home devices. Another issue is that the confidential information of a person in house can be leaked during the data transmission, so proper data security mechanisms must be well defined for home data. To achieve the goal of "HA or connected home", several professions like electrician, builders, locksmith, gasman, etc., may be involved for their skills, expertise, and businesses according to market demands. Often the mentioned occupations may not have entire knowledge about the HA and there must be some predefined standards when they are installing the home devices especially when these devices are from different vendors.

Fig. 8. Sample Screenshot of the Developed Application for Login Access.

Fig. 9. Sample Screenshot of the Developed Application for Selecting the Desired Room.

It is usual that smart home automation systems come with regular upgrades or patches, so customized configurations or alterations must be supported in such system.

It is normal that appliances or devices are of different types and manufactured by multiple manufactures. So, there should be one application that can deal with all of them. As such, developing a generic application for HA system not only comes with a variety of technological problems but security is

also a major challenge that must be considered. Risk factors are often involved when sending or exchanging a home's confidential information on the internet. It is important to examine all the technicalities of home appliances or devices and security matters when sharing the private information like presence of location to someone whom are unauthorized. Our developed application effectively deals with the above-mentioned situations.

Fig. 10. Sample Screenshot of the Developed Application for Selecting the Desired Appliances.

Fig. 11. Sample Screenshot of the Developed Application for Adjusting the Functions of Desired Appliances.

#### IV. RESULT AND DISCUSSION

Our design has considered an average size of house consisting of two bedrooms, one guest room, one TV lounge, one dining hall, one kitchen, and one car garage. It has appliances including three air conditioners, 3 room heaters, one fridge, one water heater, seven fans, one microwave oven, one washing machine, and 12 lights. We assumed that it is in Multan city, Pakistan where the weather conditions are normally around 5°C to 20°C in winter and 30°C to 45°C during the summer. Electricity bills are higher in summer comparatively to the winter due to more air conditioners usage.

##### A. Electricity Consumption of Existing System against the Designed HA System

For electricity consumption analysis ‘current and voltage clock meter’ are utilized, to capture key energy consumption information. Data from these meters, allow us to calculate the electricity usage in the aspects of cooling, heating, and lighting of the house. Three methods were used to measure the electricity utilization i.e., day-wised, monthly, and annually. In the first case, power consumption is calculated for a single day by comparing the existing electricity system with the designed HA system and this is demonstrated in Fig. 12. By this method, owner(s) know the home power consumptions at different times of a day. So, with this data, resident(s) can plan at which time to save the electricity or the timings when the wastage of electricity can be best avoided.

The electricity consumption is measured in per Kilowatt hour (kWh). That is, one unit of electricity or kWh can be calculated as follows:

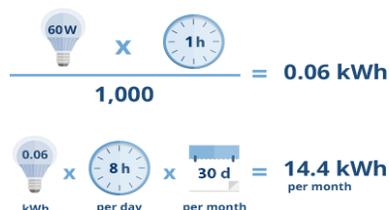

$$\text{Energy consumed} = \text{Power} \times \text{Time}$$

$$\text{Electricity unit (kWh)} = \frac{\text{Power (in watts)} \times \text{Time (hours)}}{1000}$$

A lightbulb of 60 watts used for 8 hours per day (240 hours per month) will consume electricity in one month as follows:

(watts/1000 = .06 kilowatts)

$$06 \text{ kW} * 8(\text{hours}) * 30(\text{days}) = 14.4 \text{ kWh}$$

In the second case, these calculations were performed on monthly-wise. The months in which more cooling are required are May to August and are considered as the peak of hot weather in Pakistan. To attain the comfort level of 20°C-27°C (68-80°F), a normal size home consumes average of 700 to 900 kWh per month of electricity in these months. Whereas to maintain the comfort level for the winter months which required more heating, i.e., December to February, it required normally 500 to 600 kWh. In considering the same house environment but with the involvement of the designed HA system, the power consumption was around 100 to 130 kWh per month lesser than the existing system. This comparison of

the electricity consumption shows that the proposed HA system significantly lowered the power consumption. The developed HA system, helps to save the electricity by 15%-20% per month. Fig. 13 presents the comparison, and clearly showing that the developed system consumed less electricity than the existing system.

To attain the comfort level of 20°C - 27°C (68-80°F), one house can consume around 7180 kWh per year when it is not using the designed HA system, but when it is integrated with the designed HA system then the consumption drops to around 6100 kWh annually. Comparison of these power consumptions annually are depicted in Fig. 14.

The proposed HA system saves on average of 1080 kWh of electricity per year for one house. It is beneficial to mentioned that this amount can be greater when considering to integrate this system in larger number of houses. Conservatively, for a housing society having 8000 houses, the saved electricity can be reaching to 8,640,000 kWh per year. This amount is saved within one year.

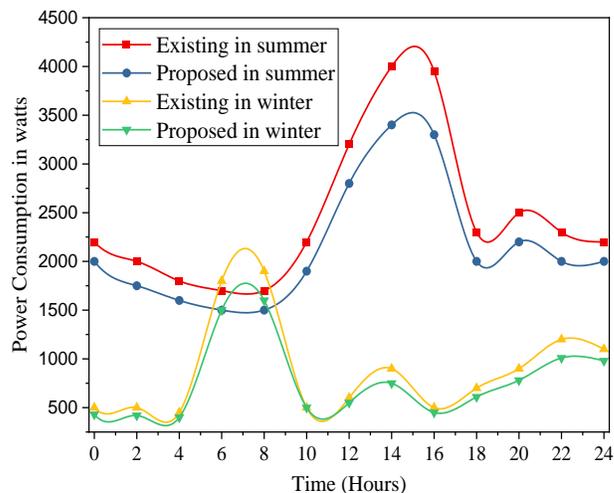

Fig. 12. Hourly Energy Consumption Graph for One Day, Comparing the Existing System to the Designed HA System.

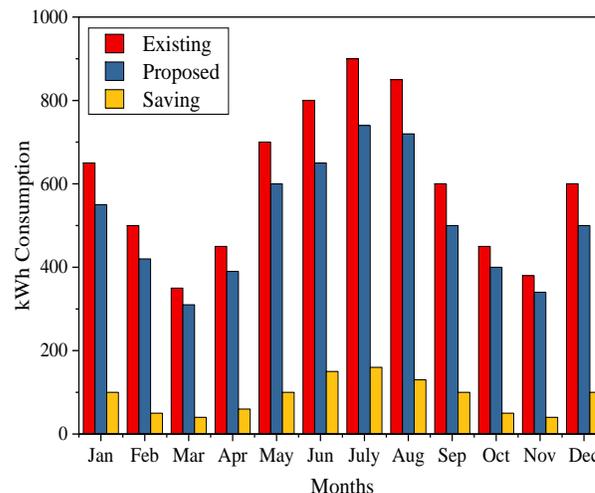

Fig. 13. Comparison of Monthly kWh Consumptions between Existing System and the Developed HA System.

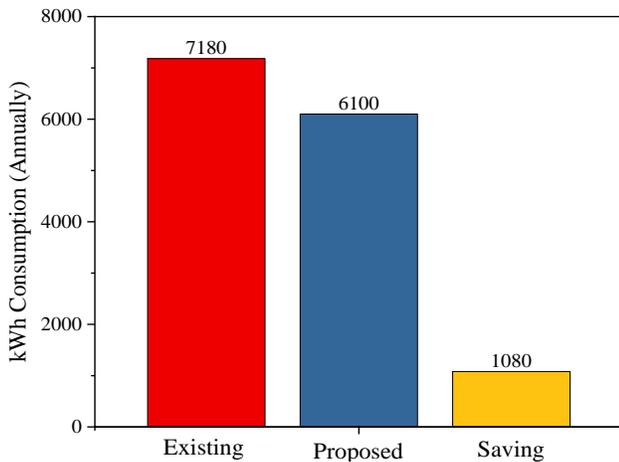

Fig. 14. Yearly Comparison of kWh Consumptions.

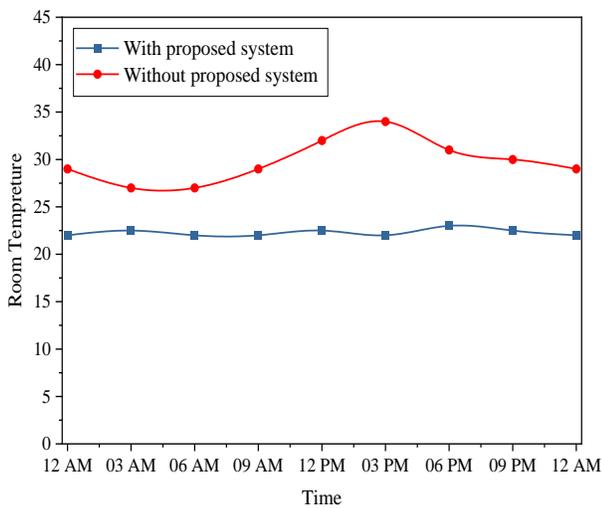

Fig. 15. Room Temperature in Summer Season with and without the Involvement of the Designed HA System.

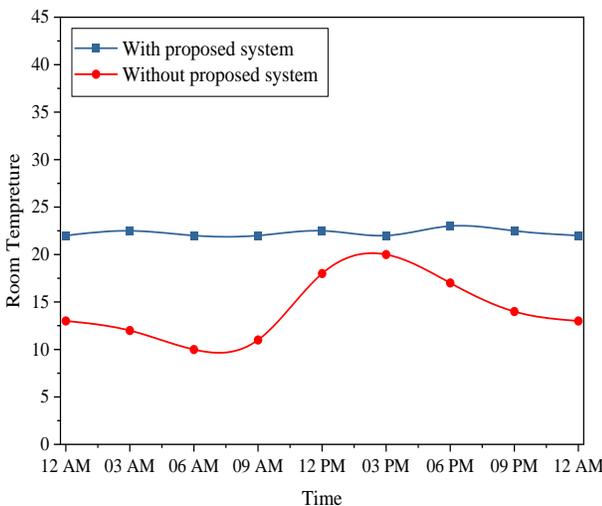

Fig. 16. Room Temperature in Winter Season with and without the Involvement of the Developed HA System.

The comparison of the room temperature in summer and winter seasons, with and without the involvement of the developed system is illustrated in Fig. 15 and Fig. 16, respectively. The temperature was measured with respect to hourly time for a single day. It can be seen that the designed HA system is able to maintain the desired room temperature without major fluctuations in both seasons (summer and winter). The temperature data was taken by using temperature sensor. With the available data, the residents of a home can analyze the home environment from anywhere and can take the necessary actions to save electricity. It is clear that without the involvement of the proposed system, there are large variations in room temperature. So, the concept of our smart HA is greatly beneficial to consumers.

#### B. What have been Achieved?

- Smart use and control of home devices or appliances by the proposed HA system.
- Designed HA system saves energy because appliances operate only when they are required, while automatically switched off when they are not needed, thus reduces the wastage of electricity (around 18%).
- No need to replace the current appliances because changes are made and required only for the control unit.
- Connectivity with internet makes HA system more robust and provide intelligent work flow according to the prediction on home appliances.
- HA system provides home alarms and warnings features to prevent any loss of home appliances/properties.
- Generate timely notification for voltage fluctuations that helps to save home appliances from potential faults or problems.
- The system is good enough and capable to control a large size of house with the variety of electronics and electrical devices easily.
- EC is integrated in the proposed system to improve its reliability and making it more robust for the computation offloading.
- The motion monitoring sensors can be greatly useful in sustaining the home security by sending timely alert to the resident or house owner.
- It is an Android app that can be easily installed and used by users with Android smart phone.

The developed HA system can control how and when a home device will respond and act to attain desired home environment. It offers a fully controlled and convenient environment and helps to reduce the energy expenditures. It can assist the users and residents to control any mishap and unpredicted incidents that may happen at home.

#### V. CONCLUSION

In this paper, an energy efficient and flexible HA system is presented for controlling and monitoring the home appliances using the smart phone-based Android application. Edge computing is used in the system to enhance reliability and

robustness in computation tasks offloading. The system uses IoT-based networking functions to remotely control and monitor the home appliances. The proposed application allows home user/resident to conveniently control the commonly used appliances in a home. The application and the overall hardware architecture for controlling are flexible for easy modification when new appliances or new features in application to be added or remove to support new home requirements. The system operates automatically according to the home environmental conditions set by the home occupants' requirements. The developed HA system enhances the automation, security, remotely controlled, user friendly, more home comfort by saving around 15% to 20 % electricity through the properly configured HA system.

In future work, we are planning to enhance the system's features and its coverage area, as well as adding more functions and options to extend its robustness. The enhanced system can cater for garden and lawn. Adding in extra intelligence to the future system to capture the behavior of the home residents, thus setting the home environment more naturally.

#### ACKNOWLEDGMENT

This research was conducted in Universiti Teknologi PETRONAS (UTP) under the YUTP grant scheme with the reference code of #RG2022-0754, the cost center of 015LC0-413, and the project title of "Edge Computing Oriented IoT Operation and IoT Resources Optimization".

Department of Computer Science and Engineering, Obafemi Awolowo University, Nigeria<sup>2,3,4</sup>

**Abstract**—Research papers and expertise recommendation systems have been operating independently of one another, resulting in avoidable search queries and unsatisfactory recommendations. This study developed an integrated recommendation system to harmonize research papers and expertise recommendations in the academic domain for enhanced research collaboration. It aims to address issues related to the isolated existence of these systems. A recommendation algorithm was developed to synergize the research paper and expertise recommendation models. The Cosine similarity function between user query and available research papers as well as experts, was combined with selected criteria to achieve recommendation. The synergized model was simulated and evaluated using Precision, Recall, F-measure and Root Mean Square Error as performance metrics. The findings showed that the harmonization of research paper and expertise recommendation approaches provides a holistic and enhanced approach towards research paper and expertise recommendation. Thus, academic researchers now have a reliable way to recommend experts and research papers, which will lead to more collaborative research activities.

**Keywords**—Research paper; expertise; recommendation systems; academic

## I. INTRODUCTION

The ever-increasing growth of data has resulted in the discovery of new research areas within the computer science field, among which is recommender systems. As the amount of available data grows, the problem of managing the information becomes more difficult, which culminates in information overload. The need to address the challenges associated with information overload led to research on information filtering. The Recommender system, as a subclass of the Information Filtering System, is a completely automated system that analyzes users' preferences and predicts users' behaviors. The research interest in recommender systems is still very high, perhaps due to the practical significance of recommendation tasks. Recommender systems collect various kinds of data to create their recommendations [1].

An Expertise Recommender (ER) system offers a means by which scarce resources, in the form of human experts, can be identified and accessed [2]. It is a system designed to facilitate identifying individuals who have the necessary expertise to solve a specific problem [3] [4]. In systems for recommendation of human expertise, the interest is "expert" instead of items [5] [6] like movies or books, as in the case of other recommender systems. Mobile agent technology is one of the approaches that have been implemented for expertise

recommendation [7] [8] [9]. Available literature has shown recommendation systems for human expertise to be a valuable instrument incredibly, crucial in scholarly research for managing knowledge.

Research Paper Recommender (RPR) systems have emerged to ease the problem of finding publications relating to researchers' areas of interest [10] and are designed to offer the right publication to the right researcher in the right way. Thus, some users may be interested in the works (research papers or publications) of the expert (researcher) rather than the expert. This is reflected in the search for a research paper (i.e., documented knowledge of the expert) without necessarily being interested in the researcher (expert).

These two aspects of recommender systems are utilized within the academic research domain. The research papers and expertise recommender systems have greatly contributed to improving research collaborations in academia by bridging the knowledge and physical distance among researchers. However, it is mostly the case that a researcher in a particular domain must have either directly or indirectly interacted with one or more researchers in the research domain or certainly perused many research publications in order to elicit knowledge about a particular research project. These publications might be from the researcher (s) that has been directly interacted with or from different researchers.

The success of the recommender system in academics as a tool for collaboration in research is evident in the literature. In recent years, a detached approach to the issues of a research paper and expertise recommendation has existed. However, the academic research concept requires that a researcher be exposed to both direct and indirect contributions of fellow researchers for acceptable research output. The existing expertise recommender systems have not considered using explanations for more details about the researchers' expertise, while the research paper counterpart considered concept similarity of articles without the methods, which resulted in a misleading and unsatisfactory recommendation. Furthermore, both systems experience sparse ratings and function independently, thus, providing partial information about the same academic domain, thereby causing avoidable search queries. There is a need for a holistic approach rather than the current separate approach to expertise and research paper recommendations in academics, and also a system that will harmonize the concept or method similarity of research papers and explanation-based expertise recommendations for an enhanced recommendation.

Thus, in this paper, an attempt is made to concurrently address expertise recommendation and research paper recommendation in a unified recommender system using an integrated recommendation concept. The remaining sections of the paper are organized as follows: Section II discusses the related works while the methodologies applied to achieve the desired results are presented in Section III. The results obtained as well as the interpretations are presented in Section IV. The conclusion of the study is contained in Section V and future work is presented in Section VI.

## II. RELATED WORK

There are numerous works in the areas of expertise and research paper recommendations. A survey of available literature on research expertise recommendations shows that academic research expertise systems are less common. However, the increase in available data on academics and their publications has sustained research in the area.

In several researches, a recommender system was developed based on expert and item category by extending recommendations beyond the frequency of rating from users [11] to using trust-aware social web service recommendations mechanisms [12], a triangulated approach [2], bi-directional feedback approach [13] [14], ontology based approach [15], social network-based approach [16], [17], [18], Clustering analysis approach, expertise modeling [19], Knowledge-based approach [20], graph-based approach [21] Citation network graph approach [22] [23] [24], random walk graph approach [25], Content Based Filtering and Collaborative Filtering concepts [26], and association rule approach [27] with the aim of improving the accuracy of the expert recommendation predictions. The factors of topic relevance, expert quality, and researcher connectivity are considered useful in recommending experts in the science-based research community. For example, researcher modeling approach was applied to recommend experts in scientific communities in [28], a co-author recommendation based on powerful and similar peers that suggests future co-authors for scientific article writing was also proposed in [29]. However, these approaches did not address rating sparsity and cold start problem efficiently.

On the other hand, research paper recommendations are another area that is well explored. Nowadays, much of the world's new knowledge is largely captured in digital form and archived within a digital library system. Also, a huge number of academic papers are constantly being published through several conferences and journals. These trends lead to information overload, where users find an overwhelming number of publications that match their search queries but are largely irrelevant to their latent information needs [30]. Thus, most researchers rely on key-based search or browsing through proceedings of top conferences and journals to find their articles of interest [31]. However, according to [10], the challenge is not just to provide researchers with very rich publications at any time, any place, and in any form, but to also offer the right publication to the right researcher in the right way. To achieve this crucial objective, several researchers have initiated some novel approaches depending on their perspectives. Some of the recommendation approaches in the literatures are set theory and graph theory concepts [32] [33]

[34], user's preferences, user's requirements and opinion mining approach [30], [35], [36], [37], content-based approach [38], [39], collaborative filtering approach [10] [31] [40], source-independent framework [41], tagging approach [42] and algorithms like an unsupervised algorithm called Paragraph Vector [43], shortest paths algorithm [44], that provide personalized research papers recommendations regardless of the research field and regardless of the user's expertise.

It was observed in all of these approaches that an atomistic approach was being used to address issues related to the research paper and expertise recommendation in the same academic domain, whereas the academic system requires a researcher to be exposed to both direct and indirect contributions of fellow researchers in order to produce acceptable research output. The need to alleviate the challenges of the current isolated approach to research paper and expertise recommendation necessitated this study.

## III. METHODOLOGY

In this study, the focus was to improve the existing expertise and research paper recommendation models and, as well, synergize them for better recommendations in academics. The details provided in the expertise recommendation part of the integrated system will assist expertise seekers by providing more details about the available experts to guide their choice among recommended experts. Also, in addition to the existing concept semantics-based research paper recommendation, the study will reduce the chances of recommending the wrong research paper to users by combining the concept semantics with the method semantics of research publications to build similarity between research papers for improved recommendation.

In this study, the following research questions were addressed:

- How could the expertise recommendation be enhanced by incorporating explanation to provide more details about the experts' knowledge?
- How could the research paper recommendation be enhanced by combining semantic relationships between concepts and methods used in a research paper?
- How could recommendations be enhanced by synergizing (i) and (ii) above, since both deal with recommendations for the same academic domain?

### A. Conceptual Model

The developed model was conceptualized on the basis of building a synergy between two independent but related recommender systems. The improvements are presented as follows.

1) *Proposed expertise recommendation model:* The existing ER with user classification [13] is being improved by incorporating explainable recommendations to provide further details about the depth of knowledge and research interests of the experts for more effective and persuasive recommendations. The conceptual view of the proposed

expertise recommendation approach, presented in Fig. 1, demonstrates the search query as the key input to the system. The search query gets processed through matching with the available experts in the database based on relevance. This is carried out in the "Query/Expertise Matching" section by searching through the database of experts. However, in the database of experts, the experts are classified according to their academic qualifications, which help to differentiate their level of knowledge. An explanation which contains a summary of available information about the knowledge depth and research interests of each expert is generated for each expert using the recommendation logic while the experts are clustered using the tag-based K-Means clustering algorithm. The "Recommendation" segment then presents a list of experts with explanations arising from the calculations in the "Recommendation Logic" segment through computation of the likeness cosine linking the user query with the available data in the target database.

2) *Proposed research paper recommendation model:* The existing concept-based research paper recommendation system [37] is also being improved by incorporating similarity between methods applied by researchers to solve problems as published in journals. This is because it considers that each published research article consists of two major parts – the concept and the method (s) employed to actualize the concept. Thus, the deficiency of the existing system is addressed by incorporating the similarity in the methods used to solve the problem identified in the research publications into the existing concept-based approach as shown in Fig. 2. The figure shows the search query section where the user inputs keywords relating to the desired research paper. The user's query is then processed by matching it with the available research papers in the database. The recommendation logic is then applied to generate a list of suitable research papers using the tag-based K-Means clustering algorithm. The user then views the recommendation list.

3) *The developed integrated recommendation framework:* It was observed that though the systems for research papers and expertise recommendation currently exist independently, the dataset utilized in either case is about the same domain, i.e., the academic domain. For instance, expertise recommender systems make use of datasets of published research papers to build the expertise domain of the experts by extracting relevant texts from the publications. Therefore, the two recommended systems are synergized as presented in Fig. 3, which shows that the dataset is pre-processed and loaded into the database. The user profile is created during the first access to the system. Subsequent access requires only the login information of the user, which is entered through "User Info". The "User Identifier" authenticates the user using available user profile information in the database. Once the user is authenticated, the user can then search for the desired information through the "User Query" section. The user query is then processed by applying the cosine similarity function to determine the available experts and research papers in the

desired area as specified in the user query. If the user query is available, then the "Recommendation Logic" segment is activated to perform tag-based K-Means clustering of experts and research papers, matrix factorization, and generation of details for the recommendation. The result of this segment is then pushed to the "Recommendation" segment where the list of recommended experts with details and the list of recommended research papers are displayed.

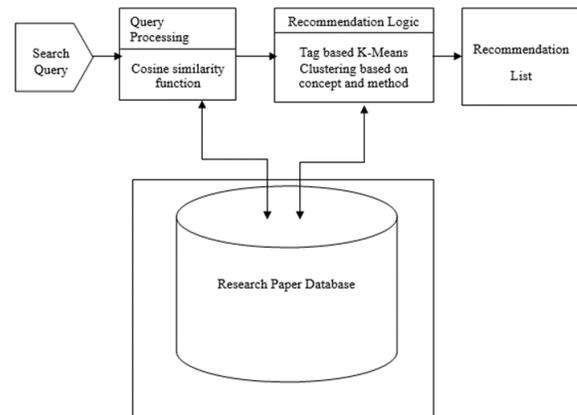

Fig. 2. Improved Research Paper Recommendation System.

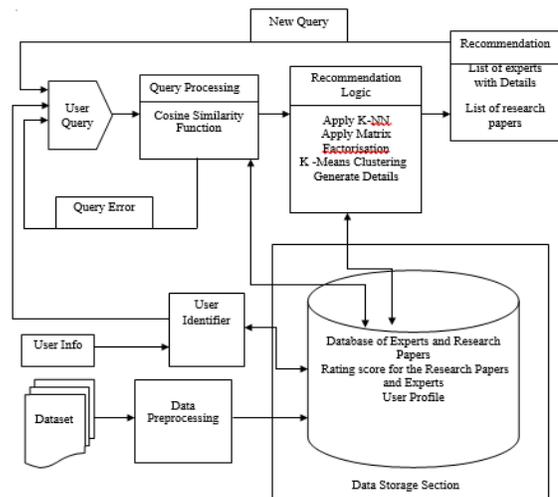

Fig. 3. Proposed Integrated Expert and Research Paper Recommender System.

### B. Mathematical Formulation of the Developed Model

The developed model was formulated on the basis of building a synergy between two related sets to achieve a common goal. The related sets considered in this study are a set of experts, i.e., researchers, and a set of research papers, as presented in Equation 1 and Equation 2, respectively. The reviewed literature shows that there are certain features and criteria for expertise and research paper recommendation. A few of the attributes include quantity of publications for target expert, number of citations for target research paper, and user rating, while the criteria for recommendation constitute a combination of selected features.

$$E = \{e_1, e_2, e_3, \dots, e_n\} \quad (1)$$

$$R = \{r_1, r_2, r_3, \dots, r_n\} \quad (2)$$

where

$E$  represents the set of experts and  $R$  represents the set of  $n$  distinct research papers  $r_1$  to  $r_n$  while  $e_1$  to  $e_n$  represent distinct experts.

Since the dataset of published articles is also utilized for research paper recommendation, in which case, keywords or key phrases from the publications are extracted for the purpose of recommendation, this study therefore considers the possibility of bridging the two independent but related recommendation systems and approaches in order to synergize both systems for enhanced recommendation. To achieve the synergy, the information theory of synergy and the set theory are applied. The set of experts and the set of research papers are then combined into a unified set as presented in Equation 3 and Equation 4, respectively.

$$D = E \otimes R \quad (3)$$

This implies that:

$$D = \{(x, y) \mid \text{for all } x \in E, y \in R\} \quad (4)$$

Therefore:

$$D = \{(e_1, r_1), (e_2, r_2), \dots, (e_n, r_n)\} \quad (5)$$

$E$ ,  $R$ ,  $e_1$  to  $e_n$  and  $r_1$  to  $r_n$ , retain their previous meanings while  $D$  represents the unified set.

Applying the information theory of synergy, the set of experts, “E”, can be viewed as variable  $X_1$  while the set of research papers “R” is variable  $X_2$ . These two related sets are then combined to form the unified set “D” of research papers and experts, which is represented by the third variable “Y”.

Furthermore, the recommendation for the experts is achieved by calculating the impact of the expert in the chosen research area using Equation 6 while incorporating the rating function presented in Equation 7. The impact of an academic researcher in a particular domain obtained through research publications could be helpful for profiling the research expertise or experience of tertiary institutions and other academic institutes, either for the purpose of appointment, collaboration or consultancy.

$$E_{\text{impact}} = \sum_{i=1}^n \frac{1}{i} \left( \frac{1}{T_p} (N_{(cp)}^i + N_{(jp)}^i + N_{c,i}) + (A_{re})^i \right) \quad (6)$$

such that;

$$(A_{re})^i = \frac{R_{e,i}}{N_{u,i}} \quad (7)$$

where;

In Equation 6, the number of years of experience through research publication is represented by “ $i$ ”, which ranges from 1 to  $n$ , where the value of “ $n$ ” is determined by the user.  $N_{cp}$  signifies the quantity of conference articles the expert has published, while  $N_{jp}$  signifies the quantity of journal articles the expert has published within the interval of years specified by the user.  $T_p$  is the total number of publications by the expert within the specified period, which is the addition of  $N_{cp}$  and  $N_{jp}$ .  $N_c$  represents the number of citations for the papers published by the expert, while  $T_c$  represents the total citations of all publications in the area of research publication.  $(A_{re})^i$  represents the average rating for each expert over a given year interval. Also, in Equation 7,  $A_{re}$  retains its meaning in Equation 6,  $R_e$  is the total rating for the experts and  $N_u$  is number of users that rated the expert.

1) *Matrix factorisation*: The research paper recommender system and the expertise recommender system are usually associated with rating sparsity, which was addressed using matrix factorisation. In the matrix factorization approach, every item denoted by  $i$  is linked with a vector  $x_i \in K^f$  and every user denoted by  $u$  is linked with a vector  $y_u \in K^f$ . The item  $i$  refers to expert or research paper while  $K^f$  represents the features. Given any item denoted by  $i$ , the components  $x_i$  determine the degree to which positive or negative factors are contained in the item. Given any user  $u$ , the elements of  $y_u$  determine the degree of the user’s interest in items with high matching positive factors or negative, as the case may be. The resultant dot product,  $x_i^T y_u$ , reflects the interface between the user denoted by  $u$  and the item denoted by  $i$ — the general interest of the user in the features of the item. This sums up the rating for the item denoted by  $i$  provided by the user denoted by  $u$ , which is presented as  $\hat{r}_{ui}$ , resulting in an approximation.

$$\hat{r}_{ui} \cong x_i \cdot y_u \quad (8)$$

2) *Model formulation algorithms*: Algorithm 1 shows the procedure for developing an integrated research paper and expert recommendation. The algorithm for predicting user ratings using matrix factorization is presented in Algorithm 2, while the algorithm for the K-Means Clustering Algorithm is presented in Algorithm 3.

## IV. RESULT AND DISCUSSION

The developed model was simulated and evaluated in Anaconda with Python version 3.7 environment. The Jupyter Notebook was deployed to provide the Graphical User Interface (GUI) for visualizing the data and the results of the simulation process, and Pandas for data manipulation and analysis. Furthermore, Surprise, which is a Python *scikit* for building and analyzing recommender systems that deal with explicit rating data, was also utilized to apply matrix

factorization and cosine similarity functions to the dataset. The detailed results are presented as follows.

### A. Analysis of the Dataset

The dataset, sourced from the Scopus database used in this study, contained two thousand (2000) documents while the papers with ratings of one (1) and above were one thousand, four hundred and fifty-one (1451) documents. The cross-validation method was used to validate the dataset using the train\_test\_split of the scikit-learn library. The data was analyzed and divided into two sets- Eighty percent (80%) training and Twenty percent (20%) testing. The number of records in the training dataset was one thousand, one hundred and sixty (1160) while the number of records in the test dataset was two hundred and ninety-one (291). The analysis of the actual dataset used in the study is presented in Fig. 4 and 5. Fig. 4 shows the distribution of ratings over the dataset, where the rating value of 4 (four) appeared most common among the rated publications, while many of the publications had a zero (0) rating. Fig. 5 shows the distribution of articles over the conference proceedings. It shows that articles are more than conference.

The articles are one thousand and two hundred (1,200) while the conference papers are Eight hundred (800).

### B. Simulation Results

In order to ascertain the effectiveness of the developed model using the dataset, the Matrix Factorization algorithm was first applied to address sparse ratings. Then the K-Means algorithm was applied to cluster the publications according to their domain of relevance using the ratings. The Cosine

similarity algorithm was further applied to generate similarities for the top one hundred (100) publications, considering each publication as a user case as shown in Fig. 6. The time taken to complete the computation of the similarities was 0:00:00.614037 seconds, which implies that the system is capable of delivering recommendations fast. The detailed results are as follows:

1) *Simulation results of the existing expertise and research paper recommender systems:* Tables I and II show the results of the selected existing models for expertise recommendation [13] and research paper recommendation [37] systems. The table shows the True Positive (TP), False Positive (FP), True Negative (TN) and False Negative (FN) values over ten (10) iterations, where;

- TP implies true positive and represents relevant experts and research papers recommended.
- FN implies false negative and represents irrelevant experts and research papers recommended.
- FP implies false positive and represents relevant experts and research papers not recommended; and
- TN implies false negative and represents irrelevant experts and research papers not recommended.

In Table I, the values for the TP, TN, and FN fluctuated whereas the values for the FP remained constant for all iterations, which suggest that all recommended items were relevant. In Table II, the values for the TP, TN, FP and FN fluctuated, which suggests that the precision is not maximum.

Algorithm 1 Research Paper and Expert Recommendation Pseudocode

---

Input:  $\vec{R}_u$ , User Query  
 $D$ , Dataset of Experts & Research papers  
Return:  $RL$ , list of recommended research papers & experts

1. Begin
2.  $RL \leftarrow \emptyset$ ;
3.  $\vec{R}_u \leftarrow \emptyset$ ;
4.  $\vec{R}_v \leftarrow D$ ;
5. Prompt  $\vec{R}_u$ ;
6. Compute  $Cos\_Sim(u, v) = \frac{\vec{R}_u \cdot \vec{R}_v}{|\vec{R}_u| \cdot |\vec{R}_v|}$ ;
7. IF  $\exists \vec{R}_u \notin D$ ;
8.  $RL \leftarrow$  Not available, enter new search;
9. IF  $\exists \vec{R}_u \in D$ ;
10. Search;
11. Run K-Means Algorithm;
12. Run Matrix Factorisation and K-NN;
13. For each expert in  $D$  identified in Line 9; do
14. Calculate  $E_{impact} = \sum_{i=1}^n \frac{1}{i} \left( \frac{1}{T_p} (N_{(cp)}^i + N_{(jp)}^i + N_c^i) + (A_{re})^i \right)$ ;
15. Generate details - "the expert is recommended because he has: "+ $N_{cp}+N_{jp}$  "conference & Journal publications cited " + $N_c$  "with average rating" + $A_{re}$  "over the past three years";
16. For each research paper in  $D$  identified in Line 9; do
17. Generate  $(A_{rr})_i = \frac{R_r \cdot i}{N_u \cdot i}$  and  $(N_c)_i$  ;  
Where  $A_{rr}$ , is the average rating for each research paper,  $R_r$  is the total rating for the research paper and  $N_u$  is number of users that rated the research paper and  $i$  represents interval in years in all cases.
18. Return  $RL$ ;
19. End

---

**Algorithm 2: Rating Prediction Using Matrix Factorization**

Input: training matrix  $Z$ , the number of features  $K$ , Regularization Parameter  $\lambda$ , Learning Rate  $\epsilon$   
Output: row related model matrix  $X$  and Column related Model Matrix  $Y$

1. Initialize  $X, Y$  to uniform real  $(0, \frac{1}{\sqrt{k}})$
2. Repeat
3. For random  $z_{ij} \in Z$  do
4. Error  $\leftarrow X_i * Y_j - V_{ij}$
5.  $X_i \leftarrow X_i - \epsilon(\text{Error} * Y_j^T + \lambda X_i)$
6.  $Y_j \leftarrow Y_j - \epsilon(\text{Error} * X_i^T + \lambda Y_j)$
7. End for
8. Until convergence

**Algorithm 3: Tag Based K-Means Clustering Algorithm**

Input: Target number of clusters  $K$ , Dataset of research papers  $D$ , Set of tags  $R_c$  and  $R_m$   
Output: An assignment of research paper to clusters using tags.

1. Start
2. Initialization: arbitrarily choose  $K$  midpoints of cluster  $C_1, C_2, C_3, \dots, C_k$
3. Calculate: estimate the space connecting every data position and group midpoints
4. Affection: allocate the data position to the group midpoint whose space from the group midpoint is least of all the group midpoints.
5. Bring up to date / calculate: Redo calculation of the latest cluster midpoint using  

$$V_i = \frac{1}{\alpha_i} \sum_{j=1}^{\alpha_i} X_j$$
 where, ' $\alpha_i$ ' signifies the amount of data positions in  $i^{\text{th}}$  group and  $\mathbb{N}$  is a set of natural numbers. Redo calculation of the space connecting every data position and latest obtained group midpoints.
6. Discontinue condition: do again the Affection steep pending when no data position was assigned again.
7. Stop

7	54	23	168	46
8	87	6	185	13
9	88	12	179	12
10	76	5	186	24

The values showed that the existing systems were able to recommend available experts and research papers from the database based on the dataset and the user’s query.

2) *Simulation results of the developed expertise and research paper recommender systems:* Tables III and IV show the results of the developed system for expertise recommendation over ten (10) iterations. The values for the TP and FN fluctuated, whereas the values for the FP and TN remained constant. The results show that the respective developed systems were able to recommend available experts and research papers from the database based on the dataset and the user’s query.

3) *Simulation results of the developed integrated system:* The results of the developed system for the integrated system of Expertise and Research paper recommendation over ten (10) iterations are presented in Table V. The values show the capability of the developed integrated research paper and expertise recommendation system to generate useful sets of research papers and experts according to the user’s query. This is in line with the set theory because a collection of expertise and research papers were defined as a set and when the recommendation is zero (0), it implies an empty set. The values are also in line with choice theory because each recommended set of expertise and research papers was based on an assumed user’s choice of query using the available keywords in the database.

C. Evaluation Results

The performances of the existing and developed expertise and research papers recommendation systems were evaluated using precision, recall, F-measure, accuracy, and Root Mean Square Error (RMSE) as follows: The detailed results are as follows:

- Precision shows the recommended system’s capacity for showing only relevant experts, while trying to minimize mixing them with irrelevant ones. This is calculated as follows:

$$\text{Precision (P)} = \frac{TP}{TP+FP} \tag{9}$$

- Recall represents the coverage of relevant experts and research papers that the recommender system can generate. In other words, it measures the capacity of the system to generate all the relevant experts and research papers present in the database. This is calculated as follows:

$$\text{Recall (R)} = \frac{TP}{TP+FN} \tag{10}$$

- The recommendation accuracy, which indicates the correctness of the recommendation, is calculated using Equation 11.

$$\text{Accuracy} = \frac{(TP+TN)}{(TP+TN+FP+FN)} \tag{11}$$

- The F-Measure, i.e., the harmonic mean, gives a combined output of both precision and recall for each system. This is calculated as follows:

$$F_1 = 2 \frac{X \cdot Y}{X + Y} \quad (12)$$

where X = Precision and Y = Recall.

- The Root Mean Square Error (RMSE) is used to measure the error in the predicted ratings of the recommender system. It is an error in predicting user ratings to address rating sparsity. This is calculated as follows:

$$RMSE = \sqrt{\frac{\sum_{n=1}^N (\hat{r}_n - r_n)^2}{N}} \quad (13)$$

Where:  $\hat{r}_n$  means the predicted rating while  $r_n$  means the true rating. N is the number of rating prediction pairs between the actual data and prediction result.

1) Evaluation of the existing and developed expertise recommendation system: Table VI and Fig. 7, Table VII and Fig. 8 show the evaluation results of the existing and the developed Expertise recommender systems respectively. Both systems gave a constant average precision value of 1.00, which implies that all the recommended experts were relevant. Also, the developed system gave an increase of 17% in average recall value, an increase of 7% in accuracy, an increase of 13% in F-measure, and a decrease of 0.35% in the root mean square error (RMSE) over the existing expertise recommender system. The decreased RMSE value of the developed system implies that there is a wide margin between the minimum and maximum values of the user ratings as contained in the dataset.

TABLE VI. EVALUATION RESULTS OF THE EXISTING EXPERTISE RECOMMENDATION SYSTEM

Iterations	Precision	Recall	Accuracy
1	1	0.86	0.95
2	1	0.35	0.76
3	1	0.64	0.87
4	1	0.63	0.82
5	1	0.55	0.85
6	1	0.46	0.81
7	1	0.72	0.91
8	1	0.79	0.94
9	1	0.54	0.84
10	1	0.58	0.89
<b>Average</b>	<b>1</b>	<b>0.61</b>	<b>0.86</b>
<b>F-measure</b>			<b>0.75</b>
<b>RMSE</b>			<b>2.06</b>

TABLE VII. EVALUATION RESULTS OF THE DEVELOPED EXPERTISE RECOMMENDATION SYSTEM

Iterations	Precision	Recall	Accuracy
1	1	0.93	0.98
2	1	0.63	0.87
3	1	0.67	0.89
4	1	0.45	0.81
5	1	0.86	0.95
6	1	0.77	0.92
7	1	0.92	0.97
8	1	0.91	0.97
9	1	0.95	0.98
10	1	0.73	0.91
<b>Average</b>	<b>1</b>	<b>0.78</b>	<b>0.93</b>
<b>F-measure</b>			<b>0.88</b>
<b>RMSE</b>			<b>1.71</b>

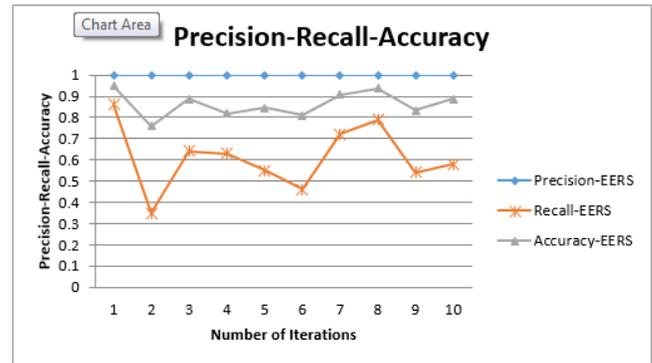

Fig. 7. Evaluation Graph for the Existing Expertise Recommendation System (EERS).

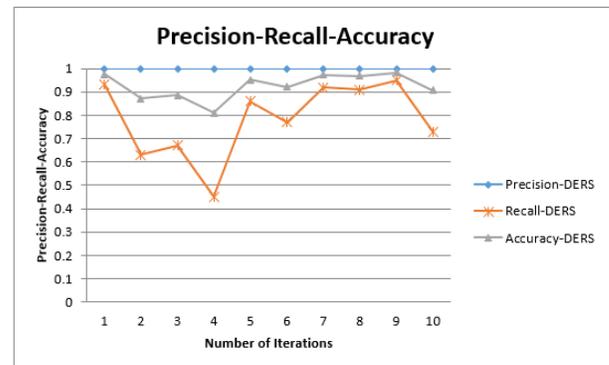

Fig. 8. Evaluation Graph for the Developed Expertise Recommendation System (DERS).

2) *Evaluation of the existing and developed research paper recommender systems:* Table VIII and Fig. 9, Table IX and Fig. 10, show the evaluation results of the existing and the developed paper recommender system, respectively. The result of the developed system gave an increase of 26% in precision value, an increase of 18% in average recall value, an increase of 12% in accuracy, an increase of 22% in F-measure, and a decrease of 0.47% in the root mean square error (RMSE) over the existing paper recommender system. The decreased RMSE value of the developed system implies that there is a wide margin between the minimum and maximum values of the user ratings as contained in the dataset.

3) *Evaluation results of the developed integrated system:* Table X and Fig. 11 show the evaluation results of the developed integrated system over ten (10) iterations. The resulted precision value implied that 90% of all the recommended research papers and experts were relevant, which is a very satisfactory performance. The resulted recall value implied that 73% of all relevant research papers and experts were recommended. The resulted accuracy value implied that the correctness of the recommendation was 86%. The resulted F-measure value implied that the combined effect of precision and recall is 81%, which shows that the capability of the developed research paper and expertise recommender system to recommend relevant research papers is very satisfactory. The lower value of 1.69 root mean square error is the effect of matrix factorisation to address rating sparsity.

The results showed that the proposed integrated system performed well based on Precision, Recall, and F-Score and RMSE values. The proposed expertise recommendation component was consistent with the existing system with an average precision value of 1.00, which is an implicit improvement with respect to the recommendation conditions. However, it performed better than the existing system in terms of recall, with average values of 0.61 and 0.76 for the existing and proposed systems respectively, implying a 15% improvement. Furthermore, the proposed research paper recommendation component outperformed the existing system based on precision values by 26% and recall values by 18%. Collectively, the integrated system proved to be reliable by recording appreciable average precision and recall values of ninety percent (90%) and seventy-three percent (73%), respectively, in addition to eighty-one percent (81%) harmonic mean.

## V. CONCLUSION

This study has introduced an invaluable means of ensuring reliable recommendation of expertise and research papers in academic research, which would translate into enhanced collaborative research activities among academics. The study concludes that incorporating the similarity of keywords of methods used in carrying out research as reflected in the published research paper to the similarity of keywords of the concept of the research greatly improved the recommendation of relevant research papers. Furthermore, evaluating the expertise of the researchers (experts) using the expert's impact criteria and proving more details about them, also enhanced the recommendation of the relevant experts to the expertise seeker. Finally, the synergized research paper and expertise recommendation system greatly facilitated the simultaneous finding of relevant research papers and experts using a single query, thereby reducing too many avoidable and unnecessary queries, and saving time. Thus, this combined approach to research papers and expertise recommendations is a positive dimension towards achieving great research experience and collaboration among researchers in an academic environment.

## VI. FUTURE WORK

The cold start problem continues to surface even as research for a better solution continues. Further studies would consider how to incorporate a reviewer's feedback as an implicit rating to alleviate this challenge in and enhance the results obtained from the matrix factorization method in the research paper recommendation component. The evaluation criteria for expertise will be expanded to make them more robust, while efforts will also be made to create a context-sensitive recommendation for the integration system.

## ACKNOWLEDGMENT

This Research was funded by the TETFund Research Fund" and Africa Centre of Excellence OAK-Park.

# Organizational Architecture and Service Delivery Re-Alignment based on ITIL and TOGAF: Case Study of the Provincial Development Bank

Asti Amalia Nur Fajrillah, Muharman Lubis, Irmayanti Syam  
Department of Information System, Telkom University  
Bandung, Indonesia

**Abstract**—The operations function area is the core function areas of the development bank to serve its customer related to the financial needs. Interestingly, the total scope of services provided in this case can be categorized as small or not optimal compared to the total population of its coverage area in the West Java and Banten. The lack of customer confidence in the services offered can be said as one of the reason cause by the unpreparedness of organization to adopt business agility and technological innovation as their alignment framework. Thus, as the beginning, IT planning in the function area can be utilized as the solution to be implemented to increase the service delivery performance through strengthening the organizational architecture. To support this, Enterprise Architecture (EA) should align business and IT with mapping ITIL best practice as a foundation and practical direction to bring the company operational services to have sustainability in growth, profit and satisfaction. This study delivers the roadmap design using the TOGAF framework to identify the current state of the company and the desired IT architecture with business strategies in the area of operations functions.

**Keywords**—Organization; service; innovation; alignment; ITIL; TOGAF; alignment

## I. INTRODUCTION

Information Technology (IT) is one of the functional aspects that is needed to support the operational performance of a company or organization to achieve the objective based on the designated of vision and mission. Indeed, IT can be a differentiating factor between companies especially to provide insight of innovation within organizational architecture and ensuring the service delivery of core competence to the market segment. Therefore, the IT application has become the main focus in helping companies achieve success and excellence amid increasingly fierce business competition, which in the further lead to the creation of competitive advantages that bring uniqueness of the company. The rapid progress of IT is expected to be able to facilitate every processes related to company information, from collecting, processing, to reporting information. Actually, many important issues for bank that should be considered due to the emergence of advanced technology that drag the business process to be shifted dramatically that influence on how to perceive towards the importance of architecture such as personalization security and policy, universality of interaction and communication, leveraging access with clear separation and easy integration, service component development as well as disruptive

innovation of financial technology [1, 2, 3, 4]. Thus, the key to successful execution related to the time when the deployment of IT can efficiently support the achievement of strategies, goals, and business needs. Thus, the alignment between IT strategy and business strategy can provide solutions to organizations that rigorously and frequently face pressure from competitor or even the supplier. The development of the role of IT and the increasing value of high investment have led to increasing demands for the added value that mostly the company go to IT to provide the answer.

Actually, organizational architecture composed of strategy, structure, systems, skills and culture that provide room for operation to satisfy the customers in delivering the product or service to certain extent that allow sustainability. In this era of transformation, many business processes are successful due to the utilization of the existing technology to create competitive advantage. However, achieving these benefits is not easy with numerous problems faced by the company that often occur as the business environment change both from within and outside the company. Often, it occurs continuously that force the companies to adapt to the new environment, which of course required a lot of resources if they do not want to fail. Other problems that arise turned out to be from internal namely declining employee performance, lack of controlling from the leadership in responding to dynamic market or even the lack of achievement in the company targets or incomplete task on schedule lead to huge impact to the growth, profit and of course customer satisfaction.

The complexity of the existing problems with the development of IT is directly proportional and has penetrated various industrial sectors. One of the clearest examples is the use of IT in the banking industry, wherein the utilization of IT related products can provide a variety of services to consumers with fewer workers. Therefore, the use can be called as not optimal due to several restrictions that bank cannot do by the regulation such as that the investment or the ownership to real sector. As with any business, banks need to be aware of wise spending due to limitation to convert its profit into real assets. In addition, the banking industry today also is facing a series of new situations that specifically support the need for efficiency with the changing customer preferences and expectations, new competition and new technologies influence the nature of banking services. By moving to a technology-based digital model while retaining an important aspect of traditional interpersonal business models are extremely difficult because

the regulation has set the categories of business that bank can do or cannot do. Of course, to stay competitive, banks need to invest in technology, marketing, automation, and self-service capabilities, as well as improve traditional investments in traditional branches and systems. All of these changes are occurring in an industrial environment that is witnessing narrowing margins, slowing deposit growth, and the potential situation for a recession with optimization of customer driven strategy. Thus, the basic premise of solution for this collection of problem by realignment of organizational architecture and service delivery through restructuring and withdrawing a low-margin business line to migrate with a business line that is essentially more cost-effective and makes the bank more profitable. By setting this direction as the priority, bank can take a strong approach to strategic planning, assessing the minimum commitment of resources needed to compete in a particular business area, and identifying opportunities to differentiate themselves from their competitors. In many cases, this means that traditional banks may choose to terminate the unconventional businesses such as professional financing and payment processing.

On the contrary, these strategic shifts may require banks to increase their investment and costs in the short term to improve profitability and efficiency in the long run. In this case, development bank in west java has compiled key performance indicators (KPI) to provide periodic evaluations for productivity and profitability, which engaged directly in financial services by applying IT governance. Based on the current strategic plan, there are several processes that have not met their targets, both in terms of business, data, applications, and technology. This study wants to explore the realignment process with formulating the roadmap by using the combination of TOGAF as EA framework for organizational architecture and ITIL as service delivery model. Implementation of information systems (IS) that are aligned with the organization requires the existence of a roadmap to define major goal in desired goal of company to establish business architecture, IS and technology that can align business strategies with IT. As provincial development bank in Indonesia, it has the objective to support the master plan and government policy through distributing credits as well have role for intermediacy and restructurization of business, especially in the era of pandemic. Thus, the risk should be identified and controlled concusively to maintain the profitability in the above average for return of equity and sharings.

## II. LITERATURE REVIEW

### A. Organizational Perspectives

To succeed in today's competitive business environment, companies need a clear business strategy that is supported by other organizational strategies. By defining coordination as a strategic consensus or organizational fit, it is suggested that the strategic priorities be adjusted at the operational level to support the business unit level [5], [6]. Organizational resilience is portrayed as an important ability of the organization to cope with unprecedented changes in the business environment, fierce market competition, etc., and prosperity to achieve global success. To deal well with volatile

external and internal changes, flexibility provides organizations a fast and easy way to improve business processes [5], [7]. Therefore, organizational resilience can be defined as a business need related to rapid response or the ability of an organization to detect unexpected changes in customer demand, competitors' strategy, business environment, etc. This means that agile organizations can respond quickly and efficiently to changes in the market. With regard to the relationship between strategic integrity of IT business and organizational agility, external factors such as environmental uncertainty are one of the issues that should be considered a mitigating role. When the external environment is uncertain, companies need to anticipate imminent changes and adapt their organizational strategies to environmental changes [8].

Process-level values are a major factor in enabling IT-based strategic design. This affects the performance of IT resources and creates unique resources that cannot be easily replicated as a job. They facilitate the functional activity of the agility or operational capabilities of an organization, they facilitate the transfer of dynamic capabilities from the diversity between companies, or the way in which their functional processes are carried out, which are complementary resources and capabilities [9]. Many factors are said to explain the conditions under which labor value is created, that is, organizational, industrial and macroeconomic factors, i.e. shortage of qualified personnel and training, can adversely affect the success implementation [10]. Information technology poses a difficult dilemma for current management, which proper investment can provide a competitive advantage over competitors while the IT budget allocation with the increased burden of measuring yield, the result is not good at best [11]. Through critical analysis of the relationship between the six aspects of the overall value of e-government, which are the improvement of management efficiency, open government (OG) function, and improvement of ethical and professional behavior have been closely linked to improve government management [12].

Other studies described cost, time, convenience, personalization, proper communication, ease of information retrieval, trust, adequate information, and participation in decision-making to explain most of the overall e-government perception [13], [14]. Organizations are implementing changes to adapt to rapid context within turbulent environments; these changes often affect business and IT. In most cases, changes affect organizational elements which do not clearly define adaptation and exclude elements that could lead to inconsistencies or misalignment [15], [16]. It is the responsibility and duty of officials or managers in the face of environmental uncertainty to understand important events and their changes to prepare the proper response towards how they affect the organization. Agility allows organizations to provide survival in such environments quickly, innovatively and creatively. It requires rapid changes in company structure and composition, which can be implemented in various strategic planning activities [17].

### B. Technological Innovations

Interestingly, there is a productivity paradox that investment in information technology does not ultimately affect productivity growth [18]. Despite apparent efforts by the

scientific community to articulate the vision of strategic alignment of IT and business, IT and business are inevitably very dynamic, so the application of the organization to the real world still suffers from a gap. Contributions on the topic have grown very rapidly, but the relationship between assumptions and conclusions is inconsistent and inconsistent. The main reason is that the proposed model is highly conceptual and detached from the actual reality of the organization [19], [20], which is related to distorted vision of myopia as another paradox in this area. Meanwhile, organizations also question the return on investment in formal security awareness strategies intertwined with training, campaigns, and reward systems [21]. This can improve ethical and unethical perceptions of IT in users, but these perceptions are often vague, making it difficult to monitor their effectiveness.

The use of technology must address the quality of information such as accuracy, completeness, timeliness and reliability related to the data subject that should be available to the public where innovation should be properly designed [22], [23]. However, keep in mind that innovation alone is not enough to sustain a work life without being integrated with corporate strategy, readiness, employee motivation, and business vision. Therefore, learning from the failures of today's enterprises that have lost control of the market can provide general insights into how innovation works [24]. Various infrastructure network organizations bring direct efficiency to data delivery and processing, enabling networks to be recognized as a data flow model with the technological elements underlying communication between computer systems [25]. To improve profits, growth, satisfaction, performance, business strategy from competition and supplier pressure, companies can take full advantage of information technology and take standard operating steps to maintain service. You need to help your organization achieve its goals [26], [27].

### C. Business Objectives

Complex business processes designed on the standards of each product and component can make process automation, customization, and customization difficult. Therefore, the realization of new projects is the creation of business case study documents that are responsible for identifying current customer requests and finding potential clients, maximizing business value and improving corporate governance structure and begins with a feasibility study [28]. It is necessary to build an information system that helps you create fast and efficient services within the business goals associated with your organization's vision and mission [29]. Competition between companies has become a major trend towards business service delivery where certain standard such as ITSM (Information Technology Service Management) has been utilized as a source of practical guidance for creating process improvements [30].

On the other hand, maintaining the integrity of business and information technology has four perspectives: strategy implementation, technology transformation, competitiveness, and service level. In supporting the business vision, one of the primary functions that greatly support the services a company provides is the logistics and maintenance functions. Second, to support your company's business operations, you need to use the right IT applications and devices to optimally manage your

family and provide your company requirements to serve your customers. Scalability is the most important feature of an IT architecture and has a major impact on all aspects of a project, so it is important to incorporate it into the enterprise architecture design [31]. Therefore, it is best to design a business evaluation before providing a business service. In this case, outcome questions can influence service design and provide information that can help you set realistic expectations. You may need to collect data before you can provide the service, but you can get a successful evaluation after providing the service. Some evaluation questions can be overcome with current employee data, accounting, or company performance such as costs of keeping turnover. Moreover, new data such as changes in skills, supervisors, and customer satisfaction are needed to compare performance over different time periods and interpret business service outcomes [32].

By emphasizing the level of business and IT integration that represents the administrative aspect of the organization and the value that IT contributes to, which represents the complexity aspect of the system in business. Assessing the degree and level of consistency can deliver specific detail on the state of business objective. These can reflect the coordination profile of the organization, which ultimately consists of an operational resource profile, a strategic resource, and a weapon profile [33]. Top management should provide a technical view to better clarify the logic and options associated with the IT strategy that support the chosen business strategy. Therefore, the role of the IT manager should be that of the technology engineer by efficiently and effectively designing and implementing the required IT infrastructure that is compatible with the external components of an IT strategy [34]. Every business unit has its own business requirements, and while IT departments need to make standards cost-effective, they need to be analyzed [35]. IT governance enables both business and IT personnel to fulfill their responsibilities to support business and IT integration and create commercial value from IT-supported business investments. Business strategy drives the design of information system infrastructure and organization through new technology capabilities [36], [37].

### III. METHODOLOGY

The TOGAF ADM framework and ITIL best practices have essentially the same cycle. For the difference, TOGAF focuses on developing business architecture and ITIL's scope of IT development is effective and efficient. TOGAF does not cover runtime development and maintenance, namely how services are produced to be delivered. To build an EA with the TOGAF approach in meeting market needs in a sustainable cycle, it is necessary to add additional phases to ITIL best practice, namely service operation, so as to improve operational services. The advantages possessed by ITIL are the general concept and a series of integrated best practices that can help companies meet market needs in a sustainable cycle. These best practices provide a competitive advantage through value creation and agile change. Companies that adopt ITIL can be optimized in service provision, because service levels have been agreed upon so that it is easy to provide consistent service. Apart from the advantages offered by ITIL, there are also disadvantages, namely the large cost because the concept

is comprehensive. ITIL is holistic, covering the entire IT governance framework. In addition, in its utilization, it requires special training by employees, so it can be said that ITIL is less flexible as can be seen in Fig. 1.

If the attention to alignment is greatly recognized, its implementation remains very limited. Therefore, this means that while the actors in the organization cannot distinguish between alignment and imbalances, the lack of a method for assessing alignment makes the task at the decision level very difficult [38]. Today, building a robust information system is not enough. To enable companies to perform, compete and evolve, business information systems and processes must be permanently coordinated and fully aligned with their strategies. In today's dynamic business environment, TOGAF can be effectively applied to any business enterprise due to its nature as open consortium framework. This is a series of operations aimed at developing software to meet customer requirements and obtaining solutions through cross-functional teams. Prior to ITIL and TOGAF combination, the mapping process to understand the overall knowledge, perspectives and characteristics of both methodologies and to coordinate strategies makes appropriate transition based on workflow, continuous learning and organizational culture. ITIL can interact with IT service providers and the business world to facilitate compliance with TOGAF principles regarding business requirements and ongoing business communications. From an ITIL perspective, this process provides a comprehensive understanding of the company's initial requirements. TOGAF will then help you prioritize your requirements as can be seen in Fig. 2. The concept of service level management complements the management of business relationships related to non-functional requirements.

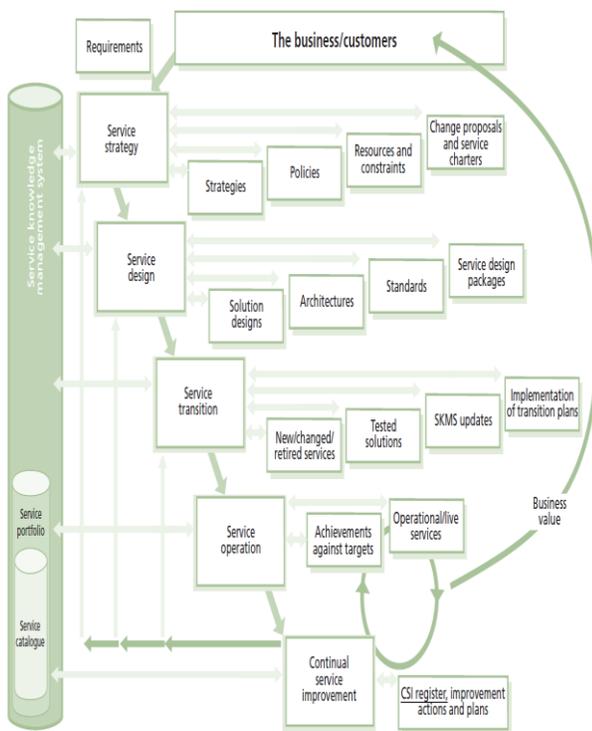

Fig. 1. Lifecycle of ITIL Integration.

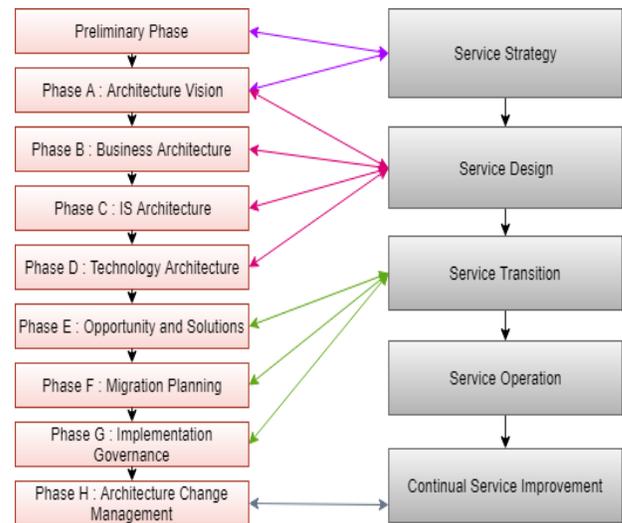

Fig. 2. TOGAF and ITIL Mapping.

#### IV. RESULT AND ANALYSIS

##### A. Mapping the Function and Structure

In carrying out their respective functions, it is necessary to map the organizational structure into a diagram. The organizational structure is a picture that describes the type of organization, the position of the organization's department, and the type of authority of the official, the field and work relations, the line of command and responsibility, the span of control and the organizational leadership system. The organizational structure of a company displays a hierarchy that contains the components that make up the company, which clearly describes the position, function, rights and obligations of each position within the scope of the company, as well as the work relationship between individuals. With the existence of an organizational structure, it can be seen the work relationship between units and roles within the company so that it is able to build good communication in running the company's business. Another goal is that each component in the company can function optimally and be able to move the wheels of the company efficiently and effectively as they should. In carrying out their respective functions, it is necessary to map the organizational structure into a diagram. The organizational structure is a picture that describes the type of organization, the position of the organization's department, and the type of authority of the official, the field and work relations, the line of command and responsibility, the span of control and the organizational leadership system.

Executives need to set the direction for IT initiatives. They need to establish policies regarding obtaining, using, and disposing of company information assets. Business priorities are set when the value is expected to be realized only by the business executives, as the sponsors or protagonists can drive the realization of value from IT related projects. Information technology itself cannot provide value. Therefore, business policies must be translated into IT organization priorities and projects. It is important to have this partnership to ensure that the right IT priorities are set. Means of the governance process for these include steering committees, IT business coordinators, resource and budget allocation processes, IT

organizations, and evaluation. However, IT executives must play their part in prioritizing workloads that are rated as the biggest hurdles by non-IT executives [39].

### B. Service Strategy

IT is an important facilitator for today's organizations to function properly by allowing IT companies to change the way they organize their business processes, communicate with their customers, and provide services. A consistent description of the different focus areas in EA can provide insights, enable communication between stakeholders and guide complex transformation processes. At the same time, the emergence of new products and services is often separated by many companies or enterprises' IT such as IT and IT products that support business and management components, or those embedded in products and industrial automation. It should be tightly integrated into what supports. One of the potential benefits of such an integration is the ease of accessing the data collected by a large number of instances of the product's IT during operation. Enterprise architecture is likely to be a vehicle to support both the ongoing coordination of business and information technology, product-specific IT integration and enterprise IT [40]. Service strategies provide a direction for organizations to define their business strategies and are effectively supported by IT strategies through several key activities such as market definition.

A sufficient set of EA focal areas allow you to design your organization in a "sufficiently appropriate" way to minimize resource use within EA modeling. In this case, it may be appropriate to reduce the number of typical focus areas. A possible way to do this is to integrate people and network focus areas into the organizational structure and integrate jobs and time into business processes. An enterprise architecture that supports and improves enterprise operations, aligns business with integrated enterprise information systems, responds to change, and helps organizations present their business strategies [41]. Additionally, the expert advisor can be used as a means to coordinate business and IT strategies, developing innovative ways to rethink the scope of business processes using management-related information and IT resources to drive effectiveness. [42]. However, the competitive advantage depends on customer satisfaction, process life cycle, resource management, task allocation and scheduling, estimated cost [43], and core competencies related to maintainability and sustainability.

As the environment changes and business needs change rapidly, executives need to be updated every time to manage their business more effectively. Companies need to make information available not only at the business unit level, but also at the organizational level. To improve information at the organizational level, you need to incorporate all the information held by your business unit. Computers are now the most important thing in data processing, as computer media is now used by almost everyone in all disciplines and it increases the power of computers in terms of physical form, equipment, software, and hardware. The increasing need for data and information in the business functions of higher education institutions is the driving force behind the use of information systems [43]. Today's IT development is growing rapidly and has a huge impact on the endless business competition between

companies with information technology plays an important role in business activities.

Simplification of the business processes can increase the productivity and profits. As a result, many companies want to use better technology as a basis for competing with their companies and other competitors. The better the technology you use, the more competitive your company will be and the greater your ability to achieve your goals. It can also improve the service with customer care, production and business innovation [44]. In the information system engineering stage, the data to be achieved and the applications to be built are combined to meet architectural principles and visions and enable business engineering visualization. Therefore, all companies that want to improve the effectiveness of their business operations and want to be superior to other companies in the commercial competition strive to implement information technology in their business [45], [46]. Unfortunately, the vast majority of organizations try to create synergies, but ultimately they are separated in a piecemeal fashion that makes it difficult to find and manage results. Creating synergies requires more than just concepts and strategies. An enterprise value proposition outlines a strategy for creating value through alignment, but does not explain how to achieve it. The alignment strategy should be complemented by the alignment process. The amendment process, as well as budget preparation, should be part of the annual governance cycle. When plans change at the company or business unit level, executives may need to readjust their organization in new directions.

### C. Service Design

Service design provides guidelines for developing services and service management processes. It covers design principles and methods for transforming strategic goals into a portfolio of services and service assets. To achieve a competitive advantage, technology development requires good planning. EA often links a company's technical systems to elements of strategic management. It is also a technical and management practice that aims to improve the performance and quality of a company by helping to design technical resources, business processes, and strategic directions to help the company achieve its goals. In addition, the corporate architecture also aims to create a suitable environment for the company so that it can properly implement the business operations according to the corporate strategy. EA frameworks typically consist of business engineering, information engineering, application systems engineering, and infrastructure technology engineering. This is an important way to the company's success and plays a major role in increasing its demands for speed, agility, efficiency and quality [47], [48]. Dynamic business requires more and more data flows to departments to support decision making, timely and efficient sourcing of spare parts, inventory management, accounting, human resources, and product distribution. It gets more complicated with functional units [48].

Consistency between business strategy and information technology is required by the fact that most organizations grow organically and that company design is primarily based on intuition rather than well-defined and executed principles. Actually, the solution can be offered is through business

process improvement or reengineering through analyzing existing processes develops the ability to increase the managerial decision-making, allowing organizations to better understand IT functions by linking business functions with existing IT resources, and is expected to be able to do so. The target business process should accommodate the simplification in the sense not only allowing the automation but also the flexibility and customization in the activity flow [49].

An overview of the fundamental vision of Architecture and Architecture is provided through areas that include business, data, applications, and technology for business applications, technology infrastructure and enterprises. Defining the architectural vision is an important step in an organization's value chain analysis [50]. These companies must make a high level of effort to extract value from their IT infrastructure, align them with strategic objectives, and gain their advantage over their competitors. Service migration improves functionality and improves new or modified services by identifying service requirements when designing services to be effective and fulfilled in the service process and controlling the risk of failure or outage by clarifying the guidelines for moving to operational.

All aspects of the company influence the effectiveness and efficiency of information systems or information technology applications in business processes [51]. EA can provide insights into the current use of IT in business operations. It can also provide insight into the future use of IT in business operations. Finally, the roadmap for the evolution of the IT overview from the current situation to the future, along with the temporary state between them, can support the company's direction in operations and delivery services [52]. Therefore, support activities can add value to the main products a company provides, such as a company's infrastructure, to support the system and support the daily core activities of the company.

Human resource management is related to employee management such as recruitment, training and compensation. It has to work for the identification purpose for the sake of improvement and maintaining the service as the customers' expectation. On the other hand, technology development relates to all techniques for converting inputs into outputs, which helps reduce the amount of time while running the main activity. As can be seen in Fig. 3, the monitoring and controlling architecture should allow the process alignment towards business initiative and plan especially related to validating report and risk management. In addition, financing consists of obtaining the inputs or resources for supplying raw materials and negotiating until the appropriate price is obtained [53].

**D. Service Transition**

Data Dissemination Diagram is a diagram that describes the relationship between application components, data entities, and business services. The purpose of this artifact is to show the relationship between business services and the applications and data used. This diagram also shows how logical data is physically represented in application components. Unlike the processes and technologies, organizations are made up of different characteristics of people, organizational structures, communication models, and cultures, business processes are

viable and available technologies are critical to the success of ITIL's implementation but the primary ingredient related to the competence and determination of the employee [54], [55]. The main issue with implementing ITIL is the fact that ITIL tells organizations "what they have to do" but "how they should do" is not clear [56], [57]. Today, there is no complete framework that can be used as a comprehensive framework for IT governance to ensure consistency between service management and organizational concepts and manufacturing. In fact, different frameworks are often used as complements, most often at the same time. In addition to the difficulties associated with managing both initiatives, parallel EA and ITIL projects involve overlapping investment and costs. In fact, using a shared infrastructure does not allow you to avoid repeating data, procedures, and personnel or to comply with different initiatives (ITIL and EA) [58].

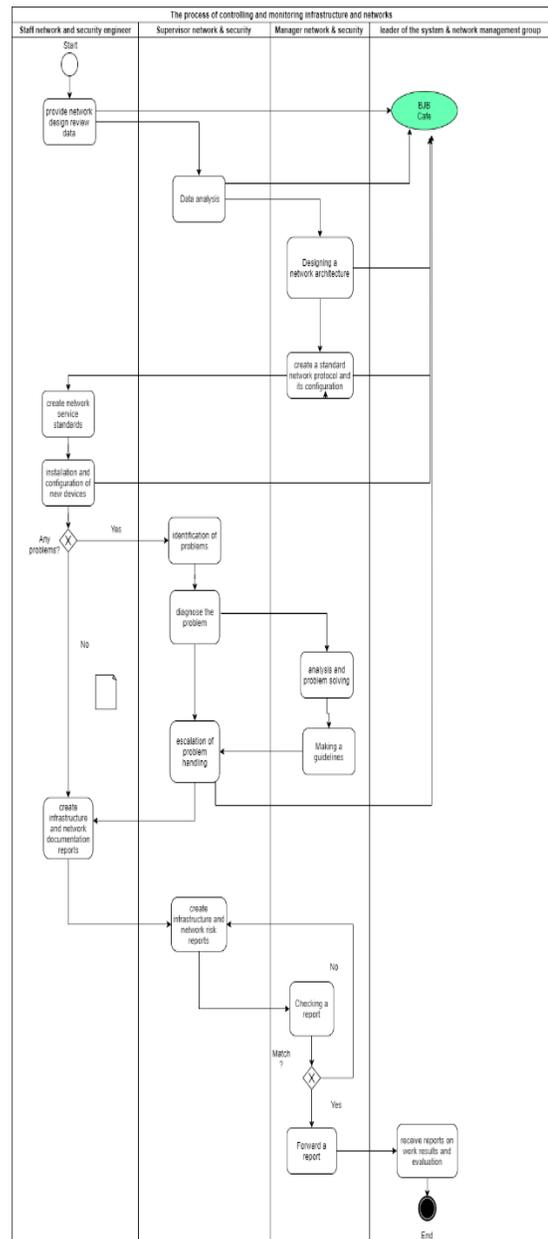

Fig. 3. Controlling and Monitoring Infrastructure.

Brown and Winter [59] proposed an EA extension to incorporate ITIL and SOA. In their proposal, EA is an important concept, but ITIL only considers IT operations. The EA provides an overview of the IT architecture, and ITIL is designated as an important part of the management process for providing services. Along with IT services, the concept of SOA is also integrated into the EA at the application architecture level. ITIL and SOA are integrated into the EA as a framework for providing IT services, and this integrated research focuses only on the IT services provided. On the other hand, Thorne is in close agreement with his previous research, working on the relationship between ITIL and TOGAF, but with a different focus, which mentioned that EA is a spiritually fundamental concept of organizational engineering, with a focus on EA development, and includes ITIL as a framework for the operational model of the IT services provided. In his research, he argued that both frameworks can be used together by mapping the two approaches. TOGAF covers EA development, participates in the conceptual life cycle of products, and ITIL guarantees the delivery and management of IT services to users and consumers [60].

As can be seen in Fig. 4, API or microservice become primary choice in order to allow hybrid infrastructure to be taken in the network management system that accommodate legacy system to be integrated with high end technology. Despite the perceived need for different teams and tools,

TOGAF requires an EA repository and ITIL requires a configuration management database (CMDB), so the two frameworks complement each other. It fits. A recent study [61] promoted by the Prophet of God provides a service-based framework for the EA to meet the ITSM requirements of ITIL V3 and extends the EA to include the service architecture layer of ITIL service design. This indicates that it is necessary. An IT service architecture model has been proposed and is the service layer of EA. However, it does not explain how to do this or the relationships between architectures. Therefore, to be able to implement an effective and efficient system requires planning, implementation, organization, and evaluation according to the needs and values of each organization [62]. Interestingly, previous studies have shown that ITIL adoption has increased, the number of operational benefits achieved has increased, and the level of maturity of business alignment with IT has increased [63]. To maintain results, IT service upgrades identify critical success factors (CSF) as benchmarks for improving IT service implementations. Or achievement, goal conditions need fairness process, recommendations to eliminate gaps that occur in each process. Establish IT service management policies and guidelines that consist of policy documents, standard operating procedures (SOPs), and other related document attachments from operational equivalence. The results of assessing the fairness of the process have led to the achievement of the goal, and there are some records to help the goal be achieved continuously [64].

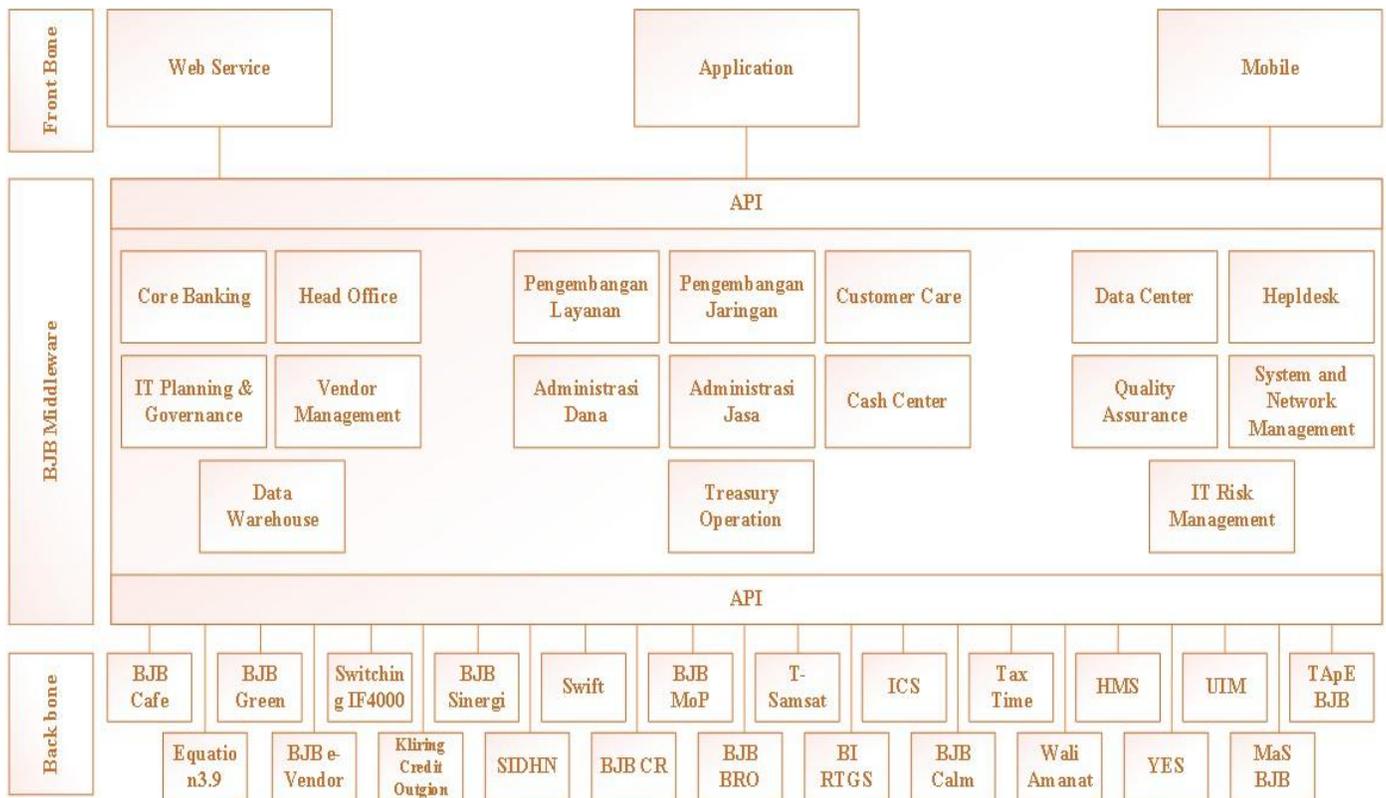

Fig. 4. Targeting Infrastructure Network Management.

Apply information technology in a timely and appropriate manner according to your current business strategy, objectives, and needs to align your business requirements with the relevant IT services. To the extent that IT applications, infrastructure, and organizations enable and support business strategies and operations, including processes, to achieve this by aligning information system (IS) capabilities with business goals [65]. However, many IT development teams do not pay attention to program management frameworks and standards, so planning, reporting and monitoring work results, especially if not all employees of the team have sufficient experience. It becomes difficult to control. It would be desirable for each Software Company and IT consultant to implement common frameworks and standardizations so that the software development process is more oriented and high quality services are produced to increase the business relation [66], [67].

E. Service Operation

As can be seen in Table I, the service operation manages the services the company is currently using, focuses on service management practices, and ensures that the service provider's service to its customers is effectively achieved. Degree 1 (Unstructured Data Exchange), is an unstructured data exchange. Degree 2 (Structured Data Exchange), is a structured data exchange and has certain method. Degree 3 (Seamless Sharing of Data), is an exchange of data using a system so that the data has been automated. Degree 4 (Seamless Sharing of Information), is a continuation of Degree 3 where information exchange occurs in real time. Code for data types includes A: Formal message exchange, B: Common data exchange, C: Complete data exchange and D: Real-Time data exchange.

TABLE I. IT OPERATION

		IT Operation			
		IT handling Problems	IT Asset Governance	System Testing	Secured Application and Users
IT Operation	IT handling Problems	4D	4D		4D
	IT Asset Governance	3C	4D		3C
	System Testing	2B		4D	3C
	Secured Application and Users	3C		2B	4D

Creating business value is generally discussed as an established, thoughtful, and anticipated process that revolves around the maturity of the process and the capabilities of the target organization [68]. Consistency with business needs, achievable level of service through negotiation, predictable and consistent operation, efficiency of service delivery, services and processes that can be measured and improved, IT services and potential current and future business needs. A common language that defines alignment, improved quality of IT services, and long-term costs for delivering short-term services, better communication between suppliers and customers, and terms [69]. Lack of project management contributes significantly to project failure without communication or

tracking of employee comments throughout the ITIL implementation process. Administrators sought to implement ITIL as part of their business rather than as a project, without considering a stable organizational culture.

According to end users, most employees weren't interested in implementing ITIL because top management didn't notify them of the need for ITIL, and most employees weren't willing to commit to the project. It should be noted that after management began asking about their lack of commitment to new processes, employees began to change their behavior towards ITIL certification in their relevant duties [70]. The research results shown that the most mentioned factors for implementing ITIL are training (21%), senior management commitment (18%), awareness (11%), and change management (9%). %, operational implementation and maintenance (7%) and project management (7%) [71]. Changes in organizational culture can be laborious and time consuming and can be difficult to achieve within the scope and time frame of a process project such as ITIL. Open and honest relationships with vendors are important and are usually discussed in the context of strategic and long-term outsourcing projects. Effective coordination between multiple vendors is critical to a successful implementation [72].

The facilitative condition is required in the implementation, which is defined as the degree to which an individual believes that there is an organizational and technical infrastructure to support the use of the system. If there is a top management commitment, this will provide the project with the resources and funding needed to train consultants, staff, and acquire the necessary skills [73]. Understanding the reasons behind the success or failure of an ITIL implementation requires an analysis of the types of problems by corporate actors regarding the relevance of the ITIL critical success factors implementation and their reflexive self-judgment. Employees make their own decisions and act in ways that enhance or weaken the rationalization of IT department resources [74]. Therefore, to support organizations in the IT sector and to make them more service-oriented, current best practices need to include a modern service-oriented perspective [75]. Competitiveness is the sum of all the factors that contribute to business continuity in a competitive environment, and understanding the importance of adopting good business practices by a company is a continuous activity that provides a competitive advantage that is useful for expansion.

This can be defined as gaining a position in a favorable, profitable and sustainable market, making it difficult to enter new competitors and efficiently searching for new markets. The data show that companies are more interested in results related to the operational part of information technology, and do not show focus, management, or oversight related to management's strategic vision. There may be other factors related to the corporate culture. It prioritizes operational activities due to the business impact on innovation. This includes different types of changes, depending on your organization's resources, capabilities, strategies, and requirements [76], [77]. It is imperative that each organization analyze the context listed for market demand, as there is room to implement innovation in the industry without investigating or analyzing its impact on competitiveness.

#### F. Continual Service Improvement

Continuous Service Improvement (CSI) has room for improvement at all stages of the service lifecycle by measuring and improving the efficiency, effectiveness, service levels, technologies, and processes used to manage the entire service, which in the end support on how to identify the area. The most important goal of an IT plan is always to align IT features and activities with business objectives and requirements, such as making decisions about the scope, size, and pace of IT projects. However, aligning IT with business goals requires a stable, reliable, and relatively homogeneous business foundation in the form of a widely accepted, committed transportation plan. Unfortunately, the availability and reliability of this business plan is arguably the best for most organizations. Even if available, the business plan often expires after the IT planner accepts the business plan. In many cases, the time lag between the business planning process and the IT planning process is too long to allow [78]. In conducting business operations, organizations face specific challenges, issues, and issues that arise from the expectations of their respective sectors and clients. In general, satisfaction comes from comparing emotions that resemble a passenger's image with real or physical situations. Dissatisfaction does occur when the actual situation does not meet the customer's terms and standards [79]. However, simplifying business processes by eliminating unnecessary areas and activities is the first step for an organization to better control and manage the flow of infrastructure development.

In fact, attention should be paid to the impact of organizational changes that are consistent with growing interest in strategies for creating an appropriate organizational culture with project managers and leadership action capabilities [80]. Unfortunately, many large companies are inefficient in implementing their needs applications due to the difficulty of implementation and the complexity of the implementation process [81]. When you start using the product, the executive can add value in the form of personalization or personalization to increase user participation, and when starting to use the required product, the social or environmental awareness of distribution by the general approach of representing the finished product through certain changes cause many problems. Knowing the right things about the company's business processes can create a specific model for more effective and efficient user engagement lead to continual improvement taking into account the many factors that a company can consider implementing software, which is expected to be possible in the long term execution [82]. By linking IT and business with ITIL, you can strengthen communication between IT and business, share knowledge, increase efficiency, and link activities within your organization [83]. With ITIL, you help deliver value by increasing effectiveness, competition and market space while increasing customer satisfaction. The resource department is responsible for protecting the confidentiality, availability and integrity of service assets by providing accurate configuration information and ensuring that only allowed components and allowed changes are used [84], [85].

The role of technology in banking has already been mentioned several times, but given its widespread impact at the enterprise level, the use of technology and automation is also worth paying attention to individually as part of an overall efficiency improvement effort with comprehensive goals are in three aspects. Firstly, providing an application that allows customers to execute transactions and obtain information on a self-service basis without the effort of employees. Secondly, using the technology to reduce the time employees spend searching for information. Lastly, using the automated business rules and decision making models to move work faster and more efficiently throughout your business. Improving vendor management does not just mean putting pressure on sellers to lower prices. Rather, it is a focused effort designed to maximize the value possible from the seller's relationship. Choosing a vendor that closely matches your bank's business goals is important. Maintaining strong vendor performance is supported by SLAs and vendor scorecards for monitoring performance issues such as system availability, response time, and direct costs. These tools help you get a more complete picture of your vendor relationships. Ultimately, improving the organizational success and profitability of a bank requires more than just efficiency. Successful banks must be able to provide value and service to their customers at competitive prices and still generate acceptable profits.

There is no one-size-fits-all approach. Some banks are actively promoting electronic account opening, remote capture of deposits via smart devices, and accounts designed to be virtually paperless. Other banks with large corporate customers often take a completely different approach, focusing on personalized services by relationship managers and support teams dedicated to each eligible account. The high-value businesses created by this approach can offset the additional costs. Other useful tools include visual metrics and performance charts, as well as "in-line" incentives such as rewards that are directly related to individual or group performance and practices, as well as organizational performance and resilience.

Many organizations have also succeeded in redefining work roles, using more flexible work arrangements, providing mobility for offsite work, and outsourcing more professional activities. Electronic documents can be step-by-step with minimal delay and virtually no additional cost. Most importantly, electronic imaging enables parallel processing of documents, allowing multiple steps in progress of a transaction to be completed at the same time. Of course, digital signatures, signature panels, and online processes can often take you one step further by eliminating paper altogether. Technology not only helps automate core processes, but also plays a clear role in efforts to improve banking channels. This affects not only how customers interact with banks, but also how banks communicate important information internally and manage sales and customer relationship activities. Other basic ways to reduce costs include integrating vendors and measuring costs for similar services on the market. Also, keep in mind that vendor relationships can affect a regulator's view of a company's risk profile as can be seen in table II that showed the roadmap for improment and maintaining the demand.

TABLE II. ROADMAP

No	Project	Estimation Duration (Month)	Period																			
			Year-1				Year-2				Year-3				Year-4				Year-5

The alignment will give better understanding of business management about the importance of information systems, while at the same time improving your understanding of business goals and objectives. Through technological innovation, information systems managers are also increasing the return on IS investment [86]. Indeed, the strategic integrity of business and information systems has been consistently reported as a major concern for business and IT managers in various industries. IT business integration gives organizations greater flexibility and increases the return on their IT investment. This will increase profitability and maintain competitive advantage. Therefore, failure to take advantage of information technology can have a significant negative impact on a company's performance and survival [87]. Business and Information Technology (IT) safety refers to the optimal synchronization of business objectives, dynamic processes and related technical services provided by information technology innovation. This has been taken into account by researchers, IT executives, and consultants since the early 1970s [88]. The stronger impact on financial performance was driven by operational adjustments that suggested that achieving the link between the organization and the IT infrastructure was of prime importance to the model organization. Indeed, it has been suggested that infrastructure and coordination of operations are more important than information technology and business strategy coordination [89].

V. CONCLUSION

The complexity of the existing problems with the development of Information Technology is directly proportional and has penetrated various industrial sectors. In the IT Operation function, namely: IT management and management that has not been good, limited automation, control of information security that is less effective, and

technological infrastructure that does not support business needs. Some of the problems mentioned certainly cause many parties to be disadvantaged, especially the company's business operations and allow for over and even low budget in the company. Another impact obtained is that it can pose a fatal risk in the development of IT that allows fraud to occur so that the Management Information System (MIS) becomes unreliable. It also causes delays when processing reports between units and from branch offices to the center. In its design, EA uses a framework that will provide a blueprint that is used systematically to identify the current state of the company and the desired IT architecture design. Besides, to achieve alignment between IT strategies and business strategies that support optimization of IT governance, a best practice is needed that is used as a foundation for company operational services. The integration between the framework and best practice is expected to complement each other and produce an EA design to support the achievement of the company's strategic goals. Development bank as government owned company engaged in banking that uses the key performance index as an indicator used to determine how far the strategy has been carried out by the company by the company's vision and mission. Therefore, it is expected for verification and validation model can be utilized to evaluate project that has been delivered in respected period as well to analyze the benefit delivered that align with IT business perspectives.

**Abstract**—This paper proposes a new approach to solve the problem of lack of information in rating data due to new users or new items, or there is too little rating data of the user for items of the collaborative filtering recommendation models (CFR models). In this approach, we consider the similarity between users or items based on the lasso regression to build the CFR models. In the commonly used CFR models, the recommendation results are built only based on the feedback matrix of users. The results of our model are predicted based on two similarity calculated values: (1) the similarity calculated value based on the rating matrix; (2) the similarity calculated value based on the prediction results of the Lasso regression. The experimental results of the proposed models on two popular datasets have been processed and integrated into the recommenderlab package showed that the suggested models have higher accuracy than the commonly used CFR models. This result confirms that Lasso regression helps to deal with the lack of information in the rating data problem of the CFR models.

**Keywords**—UBCF-LASSO; IBCF-LASSO; Lasso regression

## I. INTRODUCTION

The recommendation models [1][2][7] are widely used in the fields of commerce, education, and entertainment. It saves users time when searching for needed information easily and quickly based on transaction data or rating data of users in the past. For example, Facebook displays ads related to keywords that users search for; YouTube automatically jumps to clips like the clips the user just watched. The Amazon sales site has been very successful in using the recommendation model [8]. Products are rated by users on a scale of 1 to 5 when they shop online. Transactional information and customer evaluations for products are collected to assist in increasing the accuracy of the recommender model. Therefore, every time a customer visits the website, they are always suggested products that are predicted from previously collected data.

The above example shows that the recommender system plays a very important role in e-commerce [4] and many areas of daily life around us. Therefore, building a good recommendation system to find products according to user requirements is the desire of not only researchers but also an

important investment in the development strategy of each company.

Many collaborative filtering recommendation models have been successfully applied in the field of online e-commerce [4][7][10]. It is also considered as one of the effective solutions to solve the problem of information explosion for online systems with a rapidly increasing number of users. These recommender models recommend users what products they need to buy based on the results of their ratings on the products. To predict products according to user preferences based on a rating matrix, collaborative filtering recommendation models perform calculations based on the efficient exploitation of statistical methods and data mining techniques [13]. However, collaborative filtering recommendation models still face objective problems that need further research and improvement. It is a matter of lack of information in rating data of users due to new users or new items, or too little rating data of users for items.

In this study, we propose a new method to improve the accuracy of collaborative filtering recommendation models due to the lack of user rating information (new users, new items, and sparse data) by looking at the correlation relationship between users or products based on Lasso regression. In particular, the proposed models are built based on two similarity methods: the similarity method is built based on Lasso regression [15] and the similarity method is built based on rating data [13].

This study is structured into six sections. Section one includes an overview of the recommendation models and research questions. Section two briefly reviews the linear Lasso regression. Section three presents the steps to calculate the similarity based on the linear Lasso regression. Section four proposes the collaborative filtering recommendation models based on similarity Lasso regression. Section five shows the experimental results of the proposed models on two popular datasets (MovieLens and Jester5k) integrated into the recommenderlab package [13]. The concluding section presents a summary of the results achieved.

## II. COLLABORATIVE FILTERING

A recommendation system is based primarily on a set of users, a set of items, and a set of user ratings based on those data items; represented in a matrix (see Fig. 1).

Collaborative filtering [7][1][13] is the process of determining the missing values / ratings from a rating matrix. Let  $U = \{u_1, u_2, \dots, u_m\}$  be a set of  $m$  users and  $I = \{i_1, i_2, \dots, i_n\}$  be a set of  $n$  items obtained from a certain supermarket.

Ratings [13][7][1] are stored in a  $m \times n$  user-item rating matrix  $R = (r_{jk})$  where each row represents a user  $u_j$  with  $1 \leq j \leq m$  and columns represent items  $i_k$  with  $1 \leq k \leq n$ .  $r_{jk}$  represents the rating of user  $u_j$  for item  $i_k$ . The values of  $r_{jk}$  is rated from 1 to  $q$  (for example  $q = 5$ ) or missing. From this point of view recommender systems solve a regression problem to predict missing values [13] (see Fig. 1).

The first approach is to predict the rating value for a user – item pair. Suppose we have a dataset about the interest of  $m$  users (users) in  $n$  products (items), corresponding to an  $m \times n$  matrix, where the element in row  $i$ , column  $j$  represents the price value the rating of the  $i$ th user on the  $j$ th item. Our work is to fill the empty values in the matrix, in other words, we will predict the user's rating value on the items that the user has not rated.

In fact, we don't really need to predict all user ratings on items to make recommendations to users. Instead, we just need to suggest  $k$  most suitable products (items) to the user or determine  $k$  users that best match the item. To find the most suitable  $k$  items for the user, we need to calculate the "distance/similarity/compatibility" to find the  $k$  neighbors ( $k$  – neighborhood) that best match the user  $u_a$  (see Fig. 2).

Collaborative filtering algorithms are also divided into memory-based and model-based [18].

### A. User-based Collaborative Filtering

User-based recommendation uses the similarity of a group of users' purchasing or purchasing patterns to predict what items that user will buy or choose.

### B. Item-based Collaborative Filtering

Item-based recommendation will use similarity in the purchase relationship of items to predict which items the user will buy or choose.

	$i_1$	$i_2$	$i_3$	$i_4$	$i_5$	$i_6$	$i_7$	$i_8$
$u_1$	?	4.0	4.0	2.0	1.0	2.0	?	?
$u_2$	3.0	?	?	?	5.0	1.0	?	?
$u_3$	3.0	?	?	3.0	2.0	2.0	?	3.0
$u_4$	4.0	?	?	2.0	1.0	1.0	2.0	4.0

## III. LASSO REGRESSION

Lasso Regression (Least Absolute Shrinkage Selection Operation) [15] [19] was first proposed by Robert Tibshirani in 1996.

$$\hat{\beta}^{lasso} = \operatorname{argmin}_{\beta} \sum_{i=1}^n (y_i - \beta_0 - \sum_{j=1}^p x_{ij} \beta_j)^2 \quad (1)$$

$$\text{subject to } \sum_{j=1}^p |\beta_j| \leq t \quad (2)$$

In Lagrangian form [19]:

$$\hat{\beta}^{lasso} = \operatorname{argmin}_{\beta} \left\{ \frac{1}{2} \sum_{i=1}^n (y_i - \beta_0 - \sum_{j=1}^p x_{ij} \beta_j)^2 + \lambda \sum_{j=1}^p |\beta_j| \right\} \quad (3)$$

This is a good method to narrow predictors by removing unimportant attributes based on the absolute value of the weights of the regression model by the following formula:

$$\hat{\beta}(\lambda) = \sum_{i=1}^n (y_i - \beta_0 - \sum_{j=1}^p \beta_j x_{ij})^2 + \lambda \sum_{j=1}^p |\beta_j| \quad (4)$$

The purpose of the Lasso regression model is to minimize prediction errors [6][15]. In practice, the tuning parameter  $\lambda$  controls the strength of the penalty, when  $\lambda$  is large enough some of the coefficients  $\beta$  are exactly zero, in this way can reduce the dimensionality of the model. The larger the parameter  $\lambda$ , the more coefficients  $\beta$  shrink to zero.

There are many advantages to using Lasso regression, first, it can provide a good prediction accuracy because shrinking and removing the coefficient can reduce the variance without significantly increasing the standard deviation. This is especially useful when we have a small number of observations and many attributes.

In addition, Lasso regression helps to increase the interpretability of the model by removing variables that are not related to the explanatory variable, which also avoids the overfitting of the model. So, Lasso regression is a good choice to build a recommendation model that avoids underfit or overfit when we choose too few or too many variables in the model.

## IV. LASSO-BASED SIMILARITY

As described in the previous section, Lasso regression could build a good predictive model for large datasets by selecting important attributes and removing unimportant attributes in the dataset. This method can give good prediction

results on a sparse matrix, and it is suitable for overcoming the weakness of the lack of rating data of the collaborative filtering recommender model.

Therefore, the function to calculate the user similarity matrix based on Lasso regression is built as follows:

**LUS (rating matrix; newdata)**

**Input:** rating matrix, newdata  
**Output:** URM (user result matrix)

Begin

Step 1: Building Lasso regression based on rating matrix  
User\_Lasso = Lasso (rating matrix);  
Step 2: Using Lasso regression to build user similarity matrix  
For each row of the rating matrix

Begin

Value = predict (User\_Lasso, newdata)  
URM = cbind (URM, Value)

End

Step 3: return (URM)

End

Like building a user similarity matrix, the function to calculate the item similarity matrix based on Lasso regression is built as follows:

**LIS (rating matrix; newdata)**

**Input:** rating matrix, newdata  
**Output:** IRM (item result matrix)

Begin

Step 1: Building Lasso regression based on rating matrix  
Item\_Lasso = Lasso (rating matrix);  
Step 2: Using Lasso regression to build item similarity matrix  
For each column of the rating matrix

Begin

Value = predict (Item\_Lasso, newdata)  
IRM = cbind (IRM, Value)

End;

Step 3: return (IRM)

End;

**V. RECOMMENDATION FRAMEWORK**

This section presents the content of two proposed models based on Lasso regression: the UBCF-LASSO model and the IBCF-LASSO model. The UBCF-LASSO model is designed based on the user similarity matrix integrated between the Lasso-User-Similarity (LUS) matrix calculated by the linear regression Lasso and the user similarity matrix calculated from the rating data in the way of the traditional UBCF models [12][13]. Similar to the above approach, the IBCF-LASSO Model is designed based on the integrated item similarity matrix between the LIS matrix calculated by the linear regression Lasso and the item similarity matrix calculated from the rating data in the way of the traditional IBCF models [12][13].

**A. UBCF-LASSO**

The UBCF-LASSO model is designed with two input parameters: the user's rating matrix for the items:  $R_{U \times I} = [r_{i,j}]$  with  $U = \{u_1, u_2, \dots, u_n\}$  is  $n$  users;  $I = \{i_1, i_2, \dots, i_m\}$  is  $m$  items, and  $u_a$  is a user who needs recommendation.

The UBCF-LASSO model has an overall block diagram design structure as follows.

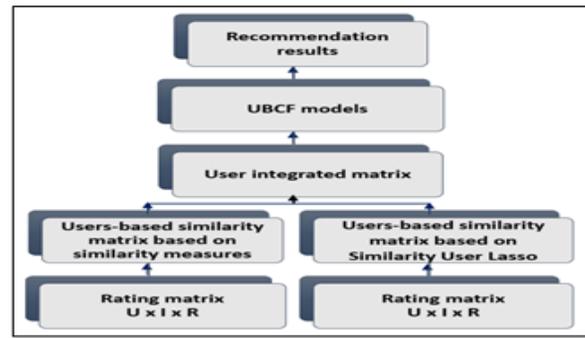

Fig. 3. UBCF-LASSO Model.

Fig. 3 shows the implementation steps of the UBCF-LASSO model. In the first step, the model builds a user similarity matrix from a rating matrix based on the similarity measures. In the second step, the model continues to build the user similarity matrix from the rating matrix based on the LUS. In the third step, the model builds the integration matrix by adding two user similarity matrices from the two steps above. In the last step, the model uses the integration matrix to predict the items to recommend to the user  $u_a$  (who needs recommendation).

**B. IBCF-LASSO**

The IBCF-LASSO model is designed similar to the UBCF-LASSO model with two input parameters: the user's rating matrix for the items:  $R_{U \times I} = [r_{i,j}]$  with  $U = \{u_1, u_2, \dots, u_n\}$  is  $n$  users;  $I = \{i_1, i_2, \dots, i_m\}$  is  $m$  items, and  $u_a$  is a user who needs recommendation. However, when building similarity matrices, the model calculates similarity values based on item similarity.

The IBCF-LASSO model has an overall block diagram design structure as follows.

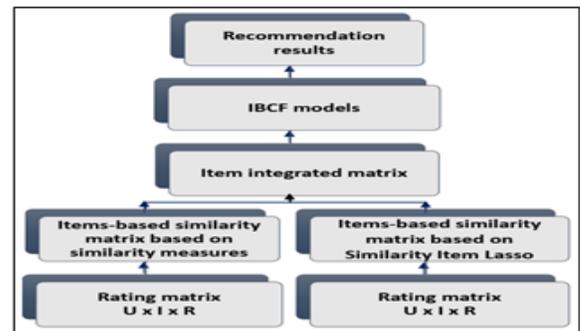

Fig. 4. IBCF-LASSO Model.

Fig. 4 shows the implementation steps of the IBCF-LASSO model. In the first step, the model builds an item similarity matrix from a rating matrix based on the similarity measures. In the second step, the model continues to build the item similarity matrix from the rating matrix based on the Lasso-Item-Similarity (LIS). In the third step, the model builds the integration matrix by adding two item similarity matrices from the two steps above. In the last step, the model uses the integration matrix to predict the items to recommend to the item  $i_a$  (item needs recommendation).

## VI. EXPERIMENT

### A. Datasets

The experimental part is deployed on two popular datasets for research on collaborative filtering models, which are the MovieLens dataset (100k) [3][13] and the Jester5K dataset (5k sample) [11][13]. These two datasets have been processed and integrated into the recommenderlab package [13].

The MovieLens dataset was collected through the MovieLens website during the seven-month period from September 19th, 1997 through April 22nd, 1998. The dataset contains about 100,000 ratings (1-5) from 943 users on 1664 movies. This dataset is stored in the sparse matrix format of the "realRatingMatrix" class. This matrix is similar in structure to the size of the dataset with rows equal to the number of users, columns equal to the number of movies, and nearly 7 percent of the cells of the matrix have rating values between 1 and 5 (the "null" value is "0").

The Jester5k is a dataset of the Jester Online Joke Recommendation System collected from April 1999 to May 2003. It contains a sample of 5,000 anonymous users who rated 100 jokes. This dataset is also stored in the sparse matrix format of the "realRatingMatrix" class. However, this dataset has two major differences from the MovieLens dataset. The first is that each user must have a rating for more than 30% of the total jokes. The second is that the rating value for jokes is a real number value between -10.00 and 10.00 (the "null" value is "99").

Both above datasets are randomly selected using the k-fold cross-validation technique (with k=5) [13][17]. This technique requires performing k times to evaluate the proposed models. In each evaluation, the models use one-fold as the testing set and the other k - 1 folds as the training set. This technique always makes sure that each tuple (row) has at least one occurrence in the testing set. The overall evaluation result of the proposed models is the average result of k times evaluations.

### B. Tools

The experiments in this study were performed on the ARQAT tool developed in the R language by our research group [14][16]. In this ARQAT tool, we integrate the recommenderlab [13][16] and the glmnet [6][16] packages. The recommenderlab is a framework for developing and testing recommendation algorithms while the glmnet fits generalized linear and similar models via penalized maximum likelihood. This ARQAT tool also includes functions for experimental deployment such as: preprocessing of experimental data, calculating similarity matrices, installing recommendation models and methods of evaluating recommendation models.

### C. MovieLens

1) *Accuracy based on model's predicted values:* The method of calculating model accuracy based on predicted values is a method of measuring the deviation between the predicted model's values and the user's actual rating values. In this study, we use three common measures: MSE (Mean Squared Error), RMSE (Root Mean Square Error), MAE

(Mean Absolute Error) [5][9][13] to compare the error value of the proposed models with the error value of traditional CFR models.

To ensure the accuracy of the results of comparing the models, we experiment on 4 models: UBCF-LASSO, IBCF-LASSO, UBCF [13], and IBCF [13] with the same training set and testing set.

The results of the comparison of error indexes (RMSE, MSE, MAE) of the four models are presented in TABLE I. This result shows that the model UBCF-LASSO (RMSE: 1.140918; MSE: 1.301695; MAE: 0.892930) has an error value lower than that of the UBCF model (RMSE: 1.146269; MSE: 1.313934; MAE: 0.902714) and the IBCF\_LASSO model (RMSE: 1.320553; MSE: 1.743861; MAE: 0.944156) with a lower error value than the IBCF model (RMSE: 1.388423; MSE: 1.927719; MAE: 1.050939) on the MovieLens dataset.

2) *Accuracy based on model's recommendation results:* The method of evaluating the accuracy of the model based on the recommendation results is a method of determining the accuracy of the model by comparing the model's prediction results with the user choices on the testing set. This method uses the confusion matrix to calculate the values of the indicators: Precision, Recall, and F-measure [5][9][13]. Precision and Recall are two commonly used metrics used to evaluate recommender models.

To get the comparison results for this evaluation method, we run all four models: UBCF-LASSO, IBCF-LASSO, UBCF, IBCF on the same training set and testing set.

The results of comparing 3 indexes (Precision, Recall, and F-measure) of the 4 models are detailed in Fig. 5. This result shows that the UBCF-LASSO model has a higher Precision index than the UBCF model (Precision: 0.6 vs. Precision: 0.5) and the IBCF-LASSO model has a higher Precision index than the IBCF model (Precision: 0.5 vs. Precision: 0.4).

3) *Comparing Prec/Rec ratio of models:* As mentioned in section 2 above, Precision and Recall are two commonly used metrics to evaluate recommender models. However, in some cases when Precision and Recall are inversely proportional to each other, we can use a harmonious combination of Precision and Recall evaluating the overall efficiency of the model. Specifically.

In this study, we build a comparison chart based on the Precision/Recall ratios [13] of four models to better see the performance of the proposed models compared to other published models.

TABLE I. MODEL'S ERROR INDICATORS ON MOVIELENS

CRF models	Error indicators		
	RMSE	MSE	MAE
UBCF	1.146269	1.313934	0.902714
UBCF-LASSO	1.140918	1.301695	0.892930
IBCF	1.388423	1.927719	1.050939
IBCF-LASSO	1.320553	1.743861	0.944156

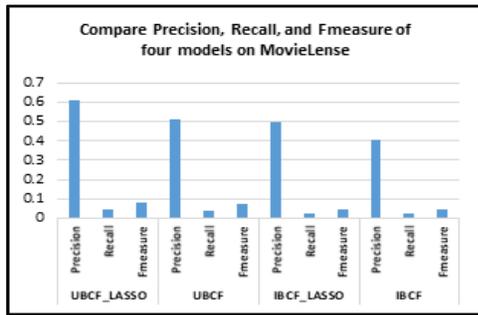

Fig. 5. Comparison Chart of Indicators: Precision, Recall, and F-measure of Four Models on MovieLense.

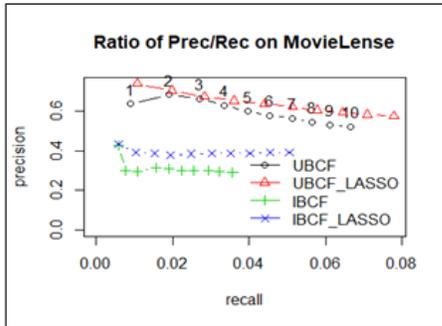

Fig. 6. Comparing the Prec / Rec Ratio of Four Models on MovieLense.

Fig. 6 shows that the UBCF-LASSO model has a better Precision/Recall ratio curve than the UBCF model and the IBCF-LASSO model also has a better Precision/Recall ratio curve than the IBCF model on the MovieLense. The result shows that Lasso regression has increased the accuracy of two models: UBCF-LASSO and IBCF-LASSO. This shows that Lasso regression is suitable to overcome the weakness of the lack of rating data of the CFR models.

#### D. Jester5K

1) *Accuracy based on model's predicted values:* In this section, the two proposed models continue to be evaluated for accuracy on the real number ranking dataset. The experimental content deployed on four models is like that deployed with the MovieLense dataset.

From the experimental results, we continue to calculate the error indexes (MSE, RMSE, MAE) of the two proposed models to compare with these indexes of the traditional CFR models.

The results of the comparison of error indexes of the four models are presented in TABLE II. This result shows that the model UBCF (RMSE: 5.380568; MSE: 28.950510; MAE: 4.243284) has an index of error that is higher than that of the UBCF-LASSO model (RMSE: 5.256894; MSE: 27.634931; MAE: 4.096698). Meanwhile, these indicators on both IBCF-LASSO and IBCF models are almost equal.

2) *Accuracy based on model's recommendation results:* In this evaluation, we continue to experimentally run four models on the Jester5K dataset and compare the accuracy indexes (Precision, Recall, and F-measure) of two proposed models with the accuracy indexes of two traditional CFR models.

The results of comparing the three above indicators of two proposed models and two traditional CFR models are presented in Fig. 7. This result shows that the accuracy indexes of the two proposed models are higher than those in the traditional CFR models. Especially, the precision value of the UBCF-LASSO model is higher than the precision value of the UBCF model (Precision: 0.898 vs. Precision: 0.698) and the precision value of the IBCF-LASSO model is higher than the precision value of the IBCF model (Precision: 0.647 vs. Precision: 0.447).

3) *Comparing Prec/Rec ratio of models:* Like the experimental part on the MovieLense dataset, we continue to build a comparison chart based on the Precision/Recall ratios [13] of four models to better see the performance of the proposed models compared to other published models. Fig. 8 shows that the two proposed models both have a higher Precision/Recall ratio curve than the two traditional CFR models. This result again shows that Lasso regression has increased the accuracy of the CFR models on the Jester5K dataset. This once again confirms that Lasso regression helps to deal with the lack of information in the rating data problem of the CFR models.

TABLE II. MODEL'S ERROR INDICATORS ON JESTER5K

CFR models	Error indicators		
	RMSE	MSE	MAE
UBCF	5.380568	28.950510	4.243284
UBCF-LASSO	5.256894	27.634931	4.096698
IBCF	5.844125	34.153799	4.410457
IBCF-LASSO	5.849720	34.219222	4.413152

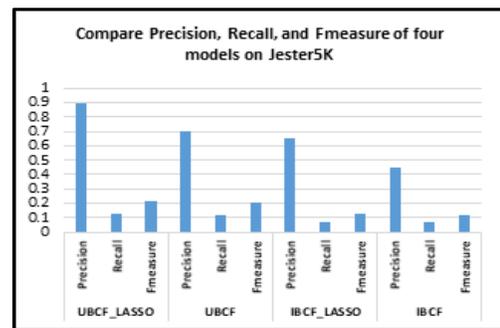

Fig. 7. Comparison Chart of Indicators: Precision, Recall, and Fmeasure of Four Models on Jester5K.

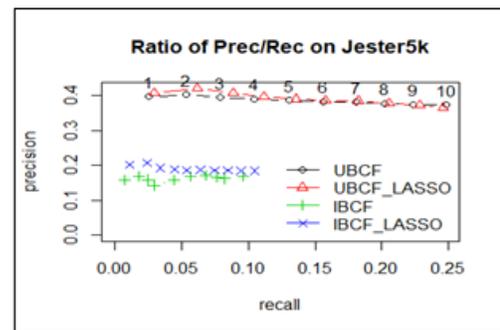

Fig. 8. Comparing the Prec / Rec Ratio of Four Models on Jester5K.

## VII. CONCLUSION

Collaborative filtering model is one of the effective technical solutions to provide customer support on e-Commerce sites. Recommended collaborative filtering models are mainly based on user or product similarity to make recommendations to online customers from rating data. However, these models always face the problem of sparse data on e-commerce sites such as new customers, new products, or too little information about customer reviews of products.

In this approach, an integration matrix between Lasso regression similarity and rating data similarity is constructed in a way that is appropriate to make predictions for new users. Experiments on two popular datasets (MovieLense and Jester5K) suggest that the proposed models provide the recommendation result comparable to significantly better accuracy.

Furthermore, while the accuracy of the traditional CFR models is very dependent on rating data, our model is more accurate than the traditional CFR models even when the number of ratings of users is very small.

# Face Age Estimation using Shortcut Identity Connection of Convolutional Neural Network

Shohel Pramanik, Dr. Hadi Affendy Bin Dahlan  
Information Science and Technology  
University Kebangsaan Malaysia  
Selangor, Malaysia

**Abstract**—Depletion of skin and muscle tone has a considerable impact on the appearance of the face, which is constantly evolving. Algorithms necessitate a large number of aging faces for this purpose. Another popular deep learning technique is convolutional neural networks. In a recent study, many computer vision and pattern recognition problems have been successfully tackled using it. But these methods have architectural issues (e.g., the training process) that have a negative impact on their age estimation performance. As a result, a whole new approach is proposed in this research to address the issue. Using a convolutional neural network framework and resnet50 architecture, researchers were able to detect the age of a human face. This proposed shortcut identity connection strategy, which enables age estimation from the face image, has improved the success of the resnet50 architecture. To be able to tell a person's age from a picture of their face, it was important to know the characteristics of aging. As a result, the rhetorical classification method, which employs the resnet50 structure, is used to shift the face aging levels to a probability level. All of the 50 layers in the proposed residual network have a residual block that connects them. As far as face-aging databases go, ImageNet and FG-NET are both good choices for the proposed age estimation process. In the training session, the experiment results are 2.27 and 2.38, based mostly on the mean absolute error. The test accuracy results for the ImageNet dataset are 81.75% with the FG-NET dataset and 57% with the ImageNet dataset.

**Keywords**—Shortcut identity connection; ImageNet; residual connection; face aging

## I. INTRODUCTION

There are numerous real-world applications for age estimation from facial photographs, including security monitoring, missing-person inquiries, entertainment, crime investigation, forensic art, cosmetology, biometrics, and facial recognition. Because of the rising interest in this topic among scientists, the automatic age estimate has attracted a large number of them. It is possible to define an automatic age estimate as either a predefined age range or an actual age.

Multiple ways have been investigated to depict age using facial photos to estimate it. Unfortunately, most of the techniques require a significant number of facial aging datasets and an excessive level of architectural fitness to be implemented. Due to their inaccuracies, these approaches take a long time to train and also lack robustness [12]. To train deep neural networks, researchers have turned to the ResNet framework, which was released last year. The method can

employ shortcut identity connections to avoid overfitting in this network's numerous layers. When used for image classification, ResNet is capable of achieving good performance in prediction [1].

The Shortcut Identity Connection of ResNet50, as shown in Fig. 1, is a convolutional neural network is used to estimate an individual's age. The age estimation problem may be solved using a minimal face aging dataset with the proposed approach. Overfitting architectural designs have been solved through shortcut identity connections. In addition, the input data size can be matched to the design using this technique. Different images are trained and tested on various datasets to establish a shortcut identity connection in the ResNet50 architecture. As a final step, the algorithm used the testing dataset and a live image taken by the webcam to estimate age using an estimator. Detailed explanations of the algorithm can be found in the third section.

When deep networks were seen to be converging, a degradation issue arises [1]. As a result of this, the gradients between neurons were completely wiped out [2]. No additional layers or overfitting will solve this gradient problem [1]. Active functions like the sigmoid active function and the tanh active function [3] are to blame for this.

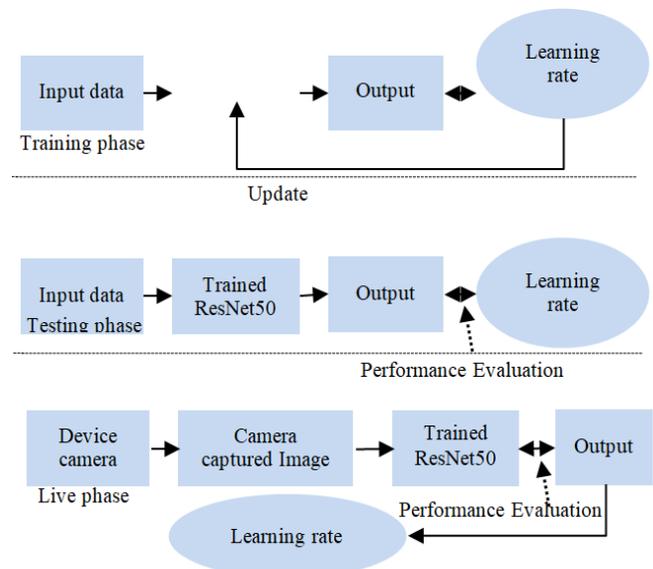

Fig. 1. Proposed Algorithm.

The following are the main points of this manuscript: The proposed shortcut identity connection method demonstrates the high capability of resnet50 by freezing layers from the structure; the presented method can accurately estimate the ages of global and regional people. The proposed age estimation process is immediate and uses an image taken directly by the device webcam.

## II. RELATED WORK

### A. Convolutional Neural Network (CNN)

Convolutional Neural Network (CNN) is a feed-forward artificial neural network approach [34]. Individual neurons are structured such that they can respond to the overlapping areas of the visual field. In 1968, Hubel and Wiesel [4] studied the cat's visual cortex and discovered that the cortex had a complex arrangement of neurons. In order to cover as much of the subregional visual field as possible, these neurons are placed in a grid-like pattern. It is these neurons that perform the filtering of the input image and work with respect to the natural face photo. Each layer of the CNN design uses a differential function to turn the input volume into the output volume. The architecture of CNN is divided into several separate tiers. Fig. 2 displays the CNN layers.

The work of CNN layers [13] has given below:

The convolution layer serves as the foundation upon which CNN is built, and it is the first step in the learning process. CNN parameters can calculate by multiplying each filter's width and height ( $w$  and  $h$ ), the preceding layer's filter ( $F$ ), and the current layer's filters ( $n$ ).  $P = (w \times h \times f) \times n$ .

During the training session, filters and parameters will learn. While processing the image classification, each filter generates an activation map. In the pooling layer, there are no parameters. The CNN pooling layer does not require any kind of learning. To avoid overfitting during training sessions, it is also beneficial to use the pooling layer. So, the pooling layer  $p$  parameter is zero.

A Fully Connected Layer is made up of feed-forward neural networks. The "Fully Connected Layer" is the network's final layer and is referred to as such because of its connectivity. An input is flattened from the final Pooling or Convolutional Layer. A fully connected layer has the most factors to consider when comparing it to other layers. The ideal parameters for a fully linked layer may be found easily because each neuron is connected to every other neuron in the system.

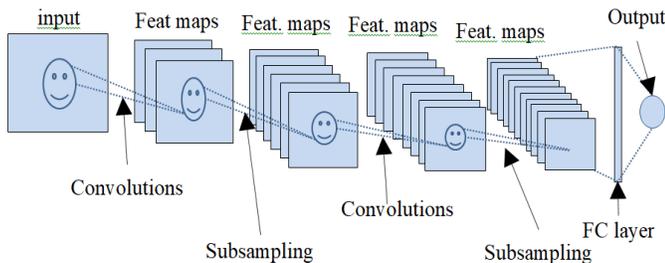

Fig. 2. Neural Networks are constructed using a Common Method known as Convolution. There are Several Separate Layers in CNN Topologies, Including an Input Layer, Convolution Layers, and a Fully Connected Layer.

The generated image is presented in the figure above in the top right corner (Fig. 2), is known as the "Feature Map" [31]. It's the number of confusing features. As a result, the input image information is reduced. When the number of confusing features is 2, the algorithm reduces the image. If the number of confusing features is 4, the algorithm further reduces the image, which makes it easier to process. The question is whether the filter function detector causes information loss. The higher the number in the feature map, the better the filtering process, which implies that the algorithm is not missing many features. Essentially, researchers create all of the feature maps that are required, as well as all of the filters that are required (e.g., edge detection, blur detection, bump detection). Using the Softmax function, the method can assure that all of the estimation will add up to 1. The cross-entropy function and the Softmax function are frequently used interchangeably [32]. After applying the Softmax function in CNN, the next step is to test the reliability of the model using the cross-entropy function to maximize the performance of the neural network [35]. Using the cross-entropy function has several advantages. One of the best features is that if the output value is much smaller than the actual value at the start of the back-propagation, the gradient descent will be very slow. Since Cross-Entropy uses the logarithm, it helps the network evaluate even the largest errors.

### B. Residual Network (ResNet)

VGG networks [5] encourage the use of simple residual networks. [5] In order to reduce layer complexity, the number of filters is doubled when the feature map's size is only half-complete [1]. Residual connections were introduced in [1], where they proposed theoretical and practical proof for the use of signal merging for image recognition. This is the original residual connection, and this is an improved version that decreases the computational cost of 11 convolutions (Fig. 3).

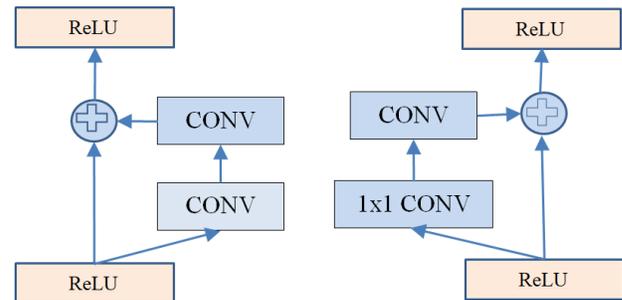

Fig. 3. Residual Connection.

The 50-layer of residual network architecture [1] detail has given below:

It is possible to get a stride size of 2 with a kernel size of  $7 \times 7$  and 64 unique kernels in the first convolution layer. With a stride length of two, which is the maximum pooling layer. As a result of the three levels being repeated three times, the network now contains nine layers after  $1 \times 1$ , 64 kernels, and  $3 \times 3$ , 64 kernels. By the time the procedure reaches the 12th layer, the model has a  $3 \times 3$ -layer kernel, a  $1 \times 1$ , 128-layer kernel, and a  $1 \times 1$ -layer kernel that has been replicated four times in total. There is one more layer in this level, making the total number of layers in the kernel  $1 \times 1 \times 1$ , 1024. There are

now a total of 18 tiers to pick from after the procedure's sixth iteration. It now has a total of nine levels of kernels:  $3 * 3$ , 512, and  $1 * 1$ , 2048. In the end, a Softmax function and a 1000-node connected layer reduce the algorithm to a single layer. So, this is a typical pool, no? The activation function and the maximum and the average pooling layer are not calculated. Adding all of the numbers together, they get a convolutional network with 50 layers:  $1 + 9 + 12 + 18 + 9 + 1$ .

Age estimation can be seen as both non-linear and non-category regression problems. In the current age estimation frameworks, the use of images of aging and age estimation modules is common. Shape and texture data from facial photos are commonly used in aging trait techniques. They fall under the categories of anthropometric models, AAM, AGES, age distribution, and appearance models. Regression methods or age-related institutional categories can be used to estimate an individual's age from this point onward. In the most recent research, categorical and regression methodologies are experienced jointly in the most recent research, resulting in a hybrid structure [29]. To create age estimates based solely on facial features, the robust multi-sample regression mastering rule set is also used [30]. Table I presents existing ways for estimating a person's age.

### C. Shortcut Identity Connection

Adding more layers in the architecture of a deep neural network allows it to better recognize multiple layers of features in an image. Due to over-exercise, additional layers may not always yield precise results. The problem can be alleviated by establishing a shortcut identity connection between residual blocks. The layer of the neural network where most accuracy will be achieved must be identified [36]. Excessive fitness reduces accuracy, so don't add any more layers after you've found the one with the highest accuracy. The "shortcut identity connection" refers to the identity link between the beginning residual block and the correct stage of a residual block. When

the shortcut identity connection is used, all remaining blocks in the architecture will be eliminated [33]. The residual building block [1] is defined as:

$$b = F(a, \{W_i\}) + a, \quad (1)$$

There are two levels here, a is input, and b is output level [37]. The function represents the remaining knowledge. According to Eqn. (1), the size of input a and F must be equal. Use a linear projection if the dimensions of the input image and F don't match up. This issue can solve with a shortcut identity connection if they aren't.

$$b = F(a, \{W_i\}) + W_c a, \quad (2)$$

The experiments in this paper involve varying dimensions of images to estimate age. The shortcut identity connection is effective for the degradation problem, and there is a need to match input dimensions. Age estimation from different dimensional input images can be robust in real-life experience.

### III. AGE ESTIMATION METHODOLOGY

The ResNet50 residual network is used in this paper to present a new age estimate approach called "age estimation using the shortcut identity connection of CNN" [33]. Data preprocessing, model creation or choosing a pre-made model, learning rate estimation, and model training are all part of the algorithm's process of determining age estimation. These parts work together to figure out how old you are.

#### A. Data Preprocessing

This module consists of input data from GitHub (ImageNet) and a loaded data set from the device (FG-NET dataset by Yanwei Fu). The model's expectations for data preprocessing are using ResNet50-selected auto normalization pixel values. Several steps are involved in the data preprocessing modules: acquiring the ImageNet data set, importing all libraries required for the ResNet50 model, identifying missing values, encoding the face aging data, splitting the dataset for the training phase, the testing phase, and the feature scaling.

There are several steps involved in data acquisition before the model may be built and developed. The algorithm needs to create a data set accurately, and then the algorithm uses a shortcut identity connection to match dimensions. A number of graphs and figures were created using the Matplotlib Python program for the experiment. In addition to importing datasets from multiple sources, and data preparation also requires the import of datasets. Setting the data set's current directory was required before import. For the experiment's training and testing phases, the algorithm needed data set splitting to calculate the mean absolute error (MAE), validation error, loss, and validation loss, as well as delete a particular row or column when more than 80% of the values were missing. When dividing a dataset in half, the ratio is 80:20. In the end, the data preparation module applies feature scaling. Within a particular range of values, the algorithm had to summarise several sorts of variables in a dataset. These things are very important in age estimation experiments of any significance: the epochs, loss functions, error functions, and validation functions for each epoch are very important as well.

**B. Model Creation**

The residual network has 50 layers in this experiment. In brackets, you'll see the residual building blocks (Table II). It takes 50 layers of the residual network to achieve 3.8 billion FLOPs per second [1].

The algorithm used shortcut identity connections for identity mapping to use different dimensional images and set up a freezing process to ignore layers from the model to avoid overfitting. To wrap up, the algorithm presents an alternative CNN design based on shortcut identity connections (Fig. 4).

**C. Estimate Learning Rate**

During these trials, the algorithm used the range of learning rates to estimate the optimal learning rate for the algorithm and data set under consideration. A maximum learning rate of 0.0001 has been employed in the one-cycle policy [6] ( $1 \times 10^{-4}$ ). Algorithm training sessions make use of the term "epoch term." There is a count of how many times the algorithm has been trained. A batch size of 512, ResNet50, and momentum equal to 0.9 was used, and the weight decrease was equivalent to  $1e-4$  [6]. Since it has a rate of learning close to 1, it can be put to good use. CIFAR10 and ResNet56's training loss, validation accuracy, and validation loss are illustrated in Fig. 5's characteristic plot (a). Fig. 5 shows the age estimation method's log scale of learning rate (b).

**D. Training Model**

In this experiment, the auto-fit method employed a learning rate schedule with an automatic initial stop on the plateau and a

reduction of the maximum learning rate [7]. The auto-fit strategy, when supplied with the fit\_onecycle parameter, reduces the learning rate of each cycle using cosine. To estimate age, the algorithm has used the Softmax image classifier with the ResNet50 model pre-trained on ImageNet.

TABLE II. 50 LAYERS OF THE RESIDUAL NETWORK

CNN layer name	Output size of layer	Layer

#### IV. EXPERIMENTS AND RESULTS

To obtain these results, the algorithm used the ImageNet and FG-NET datasets together. The experiments use a variety of epochs to evaluate the outcomes. Epoch specifies how many times the algorithm runs during the training process. Each sample of the training data set is only transmitted through the neural network once during a single epoch in a single neural network [33]. One epoch is made up of one or even more batches. The facial photos of Malaysian and Bangladeshi citizens are used to test the suggested approach. Images from the ImageNet and FG-NET databases are shown in Fig. 6. Another experiment was performed on the FG-NET database utilizing the ResNet50 design. To see how the shortcut identity connection worked, the algorithm used images of different sizes and resolutions.

A total of 21690 photos from the ImageNet collection were utilized to train the algorithm, and a further 2411 images that have been verified were used to conduct the testing. To obtain the most accurate results while using the fewest facial photos possible, we have sought to reduce the number of images used. The ImageNet data set can be used to estimate an age with an average accuracy of 81.75 percent and MAE of 2.27 in the training session (Fig. 7). The evaluation method of Mean Absolute Error (MAE) [8] is shown in Eqn. (3).

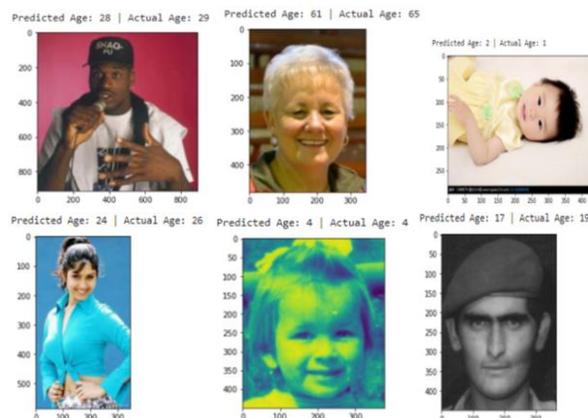

$$MAE = \sum_{i=1}^n |\hat{l}_i - l_i| / N_t, \quad (3)$$

Where:  $\hat{l}_i$  age is recognized,  $i$  is a testing sample, and the total number of testing samples is  $N_t$ .

Only 352 facial photos from the FG-NET database were used throughout the training period to test how this method worked with a smaller number of facial aging cases. Fig. 8 shows the FG-NET dataset age estimation accuracy [23]. In the

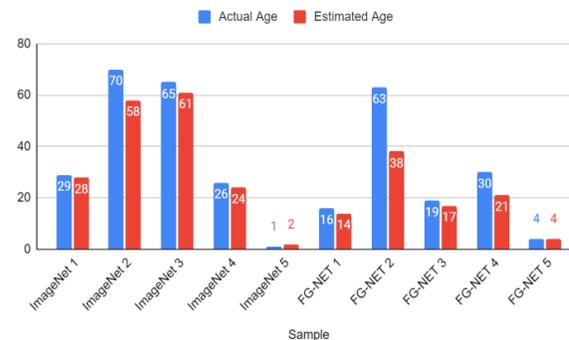

training session, MAE for the FG-NET dataset was 2.38. The accuracy rate is 57% across the experiment.

A parameter includes added to estimate age automatically from the camera-captured facial image. The system will automatically turn on the device's camera at the end of the training and testing session of the algorithm. It helps to capture the live facial image to estimate age. After capturing the photo, the estimator will estimate the age. The accuracy of the camera-captured image is 93.75%. A sample has been shown in Table III. Only images from the ImageNet database have been used in training to figure out how old people are from their live webcam captured images, so far.

## V. CONCLUSION AND FUTURE WORK

The proposed ResNet50-based CNN model for estimating age from a facial image has the best performance of any model that's already out there. Use the shortcut identity connection method to come up with a new CNN architectural design. Using different dimensional images and freezing many layers of CNN architecture, this method has been effectively implemented. The image is classified using the softmax classifier, and the positive value is normalized. Improved calculation speed and accuracy are two benefits of shortcut identity connection use in CNN systems. The proposed method achieves MAE 2.27 and MAE 2.38 using the ImageNet and FG-NET datasets. In the future, the algorithm will consider the proposed technique to determine gender and ethnicity and improve the accuracy of the age estimate method by adjusting the ResNet method. Age estimation thus relies on the capacity to classify face images. The proposed method can apply to small and big databases for facial image classification.

## ACKNOWLEDGMENT

I have my deepest gratitude to Dr. Hadi Affendy Bin Dahlan, the doctor who supervised me. Patience, time, and encouragement he has given me have been greatly appreciated. He taught me a lot about image processing and computer vision in particular. Hadi Affendy bin Dahlan, in particular, taught me a great deal about doing and writing a research report. I'd want to express my gratitude to the individuals who provided feedback on my review article, which allowed me to make the necessary corrections.

# Framework to Deploy Containers using Kubernetes and CI/CD Pipeline

Manish Kumar Abhishek, D. Rajeswara Rao, K. Subrahmanyam

Department of CSE  
Koneru Lakshmaiah Education Foundation  
Vaddeswaram, India

**Abstract**—Containers are continuously replacing the usage of virtual machines and gaining popularity in terms of scalability and agility in IT Industry. The key concept behind containers is Operating system based virtualization. In cloud, computing containers are getting deployed in terms of computing instances whereas in premises they are getting deployed using Docker as a part of CI/CD pipelines using Jenkin Server. When containers are going to be increased in number, its deployment and resource management is always a concern which is managed using the Kubernetes. Kubernetes is used to deploy and manage the containers in an autonomous manner and Rancher is used to manage the Kubernetes Cluster in an efficient manner. First Analysis is done for the scheduler, resource management which is used by Kubernetes to deploy the containers and proposed a framework which will automate the whole process using the helm-charts, ansible scripts from container deployment to the management of Kubernetes Cluster in a scalable manner. It is fully automated framework and can be used to deploy the scalable applications in form of containers as Docker images. CI/CD pipeline is also considered using Jenkin Server.

**Keywords**—Containers; Docker; Jenkin; Kubernetes; rancher; virtualization

## I. INTRODUCTION

In an agile environment, the application needs to be scalable, performant and highly available based on customer requirements and to achieve the same, containers are widely used in IT industry. The releases are so frequent in terms of delivery in cloud based SaaS (Software as a Service) environment. This is one of the main reasons containers are gaining popularity and used in cloud computing environments and High Performance Computing [1]. Containers are very lightweight in terms of application deployment as one whole package including its required libs, binaries and other dependencies, if any. When an application is split in terms of micro services, every feature is implemented as a micro service and going to be deployed using containers. As a whole Product, the entire application is split in terms of multiple micro services and to have scalability and high availability, every application has a fail back mechanism and to avail the same, each application is deployed with at least two containers. In case one is down another will be available to serve the request or both are used to distribute the workload. In result of this if one product has n numbers of application then need n multiply by two containers. The huge numbers of containers are going to be deployed and then needs to be managed. This requirement of managing high number of containers

deployment is always a concern. These containers are provisioned using the Docker images. Docker is an open source platform to bundle the services in form of containers. Using various components, the applications are bundled as Docker images. The required libraries, binaries and other dependencies are defined as a part of configuration in terms of Docker File. Docker file is converted in form of image and then deployed by running commands. Using commands, the image is deployed and the application starts running within container within few seconds. The complete lifecycle of the application revolves around the container lifecycle. Using Docker the state of application is also maintained via commit the container state as an image and tagging it with multiple versions accordingly. If at one point, application crashes, the committed state of container in form of image can be easily deployed again and application will start running with same state when it is committed. This is one of the reason containers provides fault-tolerance and high availability for applications. They are highly trending for application deployment and wherever micro services are getting designed. In comparison of virtual machines, more weightage has been given to the containers in cloud computing as well as in high performance computing. The overhead of application deployment is reduced as it runs on an operating system isolated layer which is portable without use of a hypervisor.

Kubernetes is used for cluster systems to support the container based application deployment. Containers where they are going to be deployed in known as “pod” and it manages thee multiple pod deployment across the physical servers, scaling out the application at run time with multiple workloads. It provides multiple services and tools which are widely available. It is used to avoid downtime of an application. If one container gets stopped or crashed, the another one needs to be up and running in next second. This is the behaviour which is handled easily by Kubernetes. It also offers service registry and load balancing. Multiple containers can reside within a pod to use its file systems and other services belong to a particular pod. The functional or dynamic programming where resource provisioning is so frequent in terms of milliseconds and containers are used, the deployment and its performance need to be monitored. For example: AWS Lambda where multiple user streams are generating the events which are processed by a lambda function. The whole process is executed by deploying a container and billed at 100ms interval of time. The container will be stopped as the function completes its execution. This container deployment, management, monitoring where lambda

function is hosted and its performance impacts the provider ability to facilitate the more efficient charging alternatives to the users to process the stream based applications.

Framework is proposed for deploying the containers using Kubernetes based on high performance and fully automated to process the requests which need multiple deployments of containers within few milliseconds. It will identify the required states associated with pods and containers. It can be further used as a configuration to monitor the resources and other details acquired from a Kubernetes Cluster deployment. Using this framework, individuals can plan the capacity support for applications scalability and can do the evaluation of containers and pods which can impact the application performance.

The structure of this paper is as follows: the second section is the analysis and related work; the third section describes the proposed design of framework using Jenkin server and CI/CD pipeline; the fourth section is the evaluation and results; and the fifth section is the conclusion and acknowledgement.

## II. ANALYSIS AND RELATED WORK

Hardware virtualization and operating system virtualization in terms of virtual machines and containers are always being a research topic from a performance perspective in terms of computing resources such as CPU, memory and storage workloads [2]. In spite of being so much analysis, it is found that many are not familiar or reluctant to use the formal methods. Cloud computing is using a minimal amount of work done on using the formal methods from a performance perspective [3]. Under [4], it is provided as a cyclic design based on particular functional algorithm specifications. Later, it went with the computing resource availability specifications holding the data, control and resources workflow. It was based on Petri Net model [5] capturing the details of functionalities and computing resources requirements involved in the running environment. It starts first with the analyses of the application deployment lifecycle and then understanding of the execution behaviour at run time. It combines the analyses with simulation and predicts the non-functional and functional requirements. Over a time of period, this model is enhanced with the inclusion of performance minimal and maximum boundaries. It allows the competition of resources consumption via formulating the model which is not considered in nude queued networks. The requirement of these models to work is the historical data which need to be feed in form of temporary data. The virtual machine performance has been evaluated in cloud computing environments [6]. Using [7], [8] the containers and virtual machines performance have been evaluated with multiple performance metrics. The few designed have been evaluated in past to manage the containers using Docker and Kubernetes but there is a limitation exists in research area around containers deployment and its management using the Kubernetes architecture. In [9], Containers using Docker performance results into a degradation of network and CPU based negligible performance impact in specified configurations. Kubernetes is not using fully nested-container strategy. It uses the partial one having pod concept where the same IP is used across the containers deployed within that pod. It uses multiple performance metrics for Pod start up and

REST API request-response time. Kubemark is used for the Kubernetes Cluster performance evaluation.

Kubernetes is not a traditional platform based system. It operates at container and offers flexibility, monitoring, scaling, load balancing and deployment of containers [10]. There is no limitation for application type with any amount of workload. It is used for containers not for source code deployment. Using its API, required specifications can be declared for the containers which eliminate the requirement of orchestration where steps are executed one by one in sequential order. It is holding a complete independent set of controlled processes which drives continuously the present state to the targeted one. How to reach from one point to another does not matter which make it easy to use extensible and resilient. It is formed using a set of worker machines known as nodes which are used to execute the application in containers and mainly hosts the pods. There is a control panel which is responsible to manager the worker nodes and pods in the Kubernetes Cluster including scheduling, start-up of the new pod, detecting and responding to the triggered events.

Kube-API server is used for the API which is the frontend of control panel and offers horizontal scalability. Fig. 1 shows the high level flow of container's deployment using the Kubernetes. Kube-Scheduler is used to select a node to the newly created pod to run on. For scheduling the node to the pod several factors need to be considered which includes resources requirements, specifications, deadline and infrastructure based policy constraints. There is also kube-controller manager which manages the different type of controllers. For example: Job Controller, Node Controller, Service Account & Token Controller and Endpoint Controller. etcd is used to store the info about the cluster in terms of key-value pair. For cloud based environment, it also offers cloud-controller manager which links the Kubernetes cluster to the cloud based API. Multiple components are also running on the nodes which manage the running pods. Kubelet and kube-proxy are among those components. Kubelet is an agent which runs on the node to make sure that containers are running fine in pod where kube-proxy manages the network rules to make the communication inside and outside of cluster. Containerd is one of the container runtime used by Kubernetes which is mainly holding the responsibility of running the containers [11]-[13]. Kubernetes monitors the container resources via saving the time-series based metrics in a centralised data base. It offers an UI in form Dashboard using which users can monitor the resources and can search on logging i.e. view the logged activity perform against the running application in container. The pod will live till the containers are running which are deployed inside it. Its lifecycle depends on the container lifecycle. The pod required to be waiting till the containers have been created. Using Object Nets [14]-[15] abstraction, pods and containers can be represented as System and Token Nets. To improvise the legibility, the creation part is hidden and apart from this, it is assumed that as long as resources are present, the scheduler is going to allocate a single node to a single pod. If the resource exhausted, the pods will reside in the waiting queue. The node represents the management of resources. For every node, there will be a token which identify the node and its available computing resources.

The allocated resources to a pod will be released based on the policy value i.e. “release” or “failure”. Containers creation will get started only when pod is going to be assigned to node. The pod will wait in waiting queue till containers creation will get over. Once all containers get created, pod will be moved to the running state. It will remain in same state till the time containers will not terminate. If any container gets terminated, pod will go in runningFailed state. If container gets restarted without any failure, pod will come back to running state and come to the success state once all containers finished without any failure. Fig. 2 shows the same behaviour. The different transition states are represented from TS1 to TS7. Table I elaborates all the transition states.

TABLE I. TIME BASED TRANSITION STATES IN THE MODEL

Transition States	Description
TS1	Creation time of a container.
TS2	Execution time of a container
TS3	Time until next failure
TS4, TS5	Time taken to restart a container
TS6, TS7	Successful termination of a container

### III. PROPOSED DESIGN

Here, the proposed framework is explained to deploy the containers using the Kubernetes cluster which is going to be managed by Rancher. The applications are bundled in form of a single entity as container which will get deployed on a pod. Multiple applications are considered based on different workloads and resource requirements. It consist multiple stages from building the application to its deployment. At first the application will be built and bundled in terms of a jar/war or based on application type. Secondly, Docker file will be created that will hold the multiple instructions, configurations required to execute the application. Once Docker file will be defined, Docker image will be created using the same; it will be tagged based on release version. Using the Jenkin server the application will be built as a part of CI/CD pipeline which will be responsible to take care of whole process from building the application till its execution. Helm Charts have been used in form of YAML files to deploy these container images. In these YAML files, multiple steps have been defined. For example: version, stages from checkout to deployment , repository from where it is needed to checkout the application source code, building the Docker image with name, Docker file, its tag, working directory and deployment details. Ansible scripts have been used to install the helm charts in an automated manner. Whenever the new version of application is available, using CI/CD pipeline; it will be checkout, built, converted into a Docker image and gets installed using the helm-charts via running the Kubernetes commands [16]. Fig. 3 shows the proposed architecture to deploy the containers using Kubernetes followed by CI/CD pipeline.

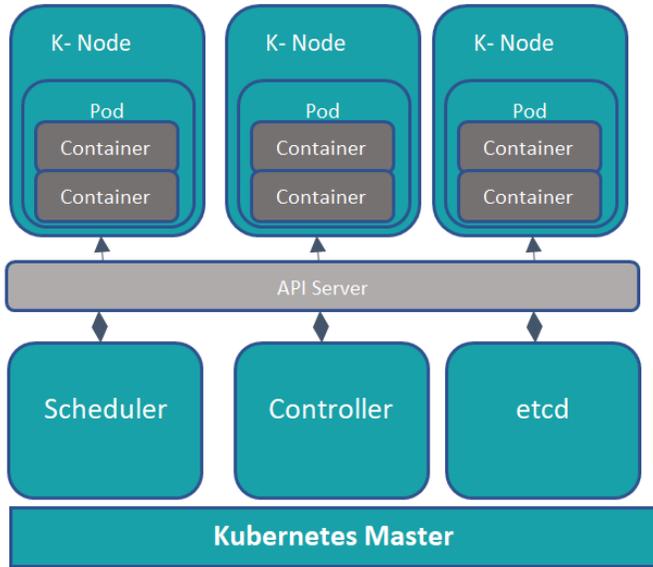

Fig. 1. Container Deployment using Kubernetes.

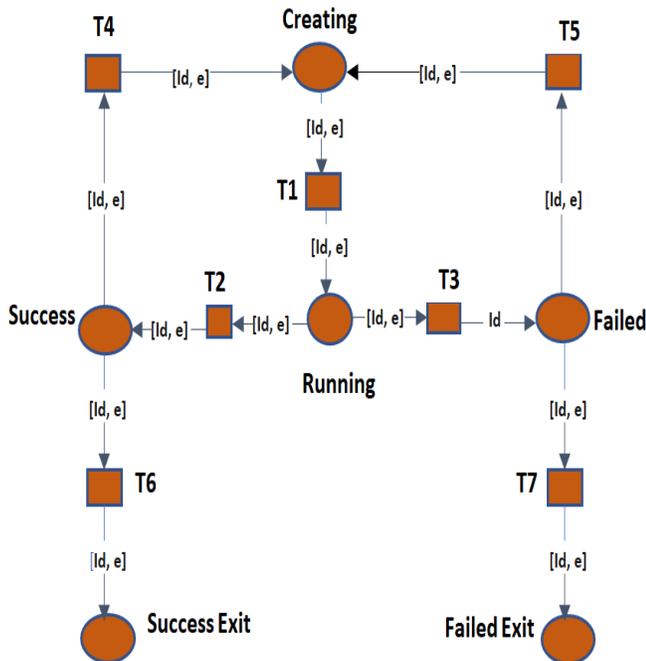

Fig. 2. Transition States Model.

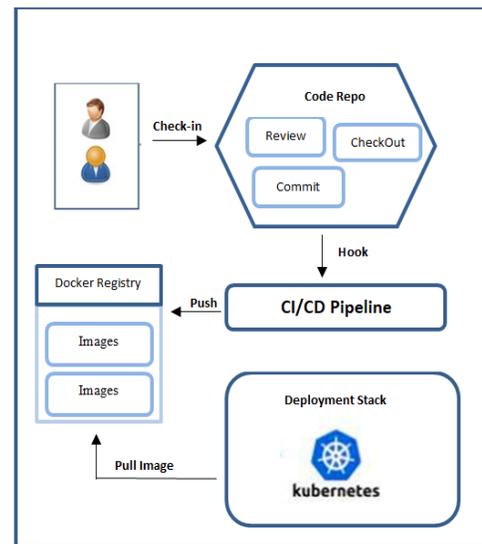

Fig. 3. Proposed Model using Kubernetes followed by CI/CD Pipeline.

### A. Jenkin Server

Jenkin Server is used to automate the whole process of check out the application source code, getting compiled, and bundled in appropriate package/build and its conversion to the Docker image and persist it to Docker registry. The main advantage of using the Jenkin server is facilitating the CI/CD pipeline [17] to deploy the containers in form of helm charts using Kubernetes Cluster. It is easily configurable and extendible. For every application, one pipeline is defined with respective set of instructions in Jenkin Server. It also helps us to check the error at run time by using its flexible UI. For Docker images and helm charts, leveraged its plugin architecture and found it really helpful at every stage of pipeline.

### B. Continuous Integration and Deployment (CI/CD)Pipeline

Jenkin Server is used for delivering and deploying the application as container in form Continuous Integration and deployment pipeline which is split into multiple stages. Main branch of source code is targeted to pull the source code. In the first stage of CI/CD pipeline [18], whenever the code will be pushed to the respective release branch, it will start building the application in terms of Docker image. The second pipeline will be created for the helm install. It will first setup the infrastructure in terms of database, ElasticSearch, Kafka, Zookeeper if any. After the infrastructure build, it will start pushing the helm packages and charts to respective node. The helm package will be extracted and start executing the YAML files using the ansible scripts. It will run the helm install commands to deploy the containers on pod. As a next stage of pipeline, it will check the health of container. If it is up and running, it will end the pipeline successfully else in case of failure, it will wait for some time as retry else will terminate the container and exists. The Kubernetes Cluster is responsible for the containers deployment but to manage the multiple Kubernetes Cluster health, Rancher Server is used [19]. It provides a Dashboard using which multiple Kubernetes Cluster are monitored and managed.

## IV. EVALUATION AND RESULT

Evaluation is carried out and benchmarked the overhead during the deployment of containers using Kubernetes with the consideration of following scenarios. (i) Multiple containers i.e. 17 in count are deployed within single pod. (ii) Multiple pods i.e. 4 in count and single container deployment per pod. These 4 pods are deployed on single physical host of 16 cores on Kubernetes node. Mean is represented by symbol ( $\mu_i$ ) and standard deviation is represented by symbol ( $\sigma_i$ ). For comparing the results it is equated like  $N_0$  which is the difference both means as  $\mu_1 - \mu_2 = 0$  and  $N_1$  is going to be the difference as:  $\mu_1 - \mu_2 \neq 0$ . TC represents the total number of containers.

For the CPU intensive benchmarking used the pov-ray 3.7 for the measurement of overhead over the pods. Kubernetes allows the containers CPU reservation based on Docker. Sharing of multiple CPUs is directly proportional to the Docker-based reservations. IN scenario (i), as there are multiple containers on a single pod, so it is going to be

distributed but in scenario (ii) where single container is deployed per pod, one container can consume the all CPU cores. Table II shows the results for same where execution time is linear. It is found that for the CPU usage, Kubernetes has introduced about 13% overhead. It is concluded that for CPU intensive applications instead of deploying single container per pod, multiple containers deployment on a single pod is recommended. Multiple containers are not resulting into the addition of any type of overhead. If application has the extensive tasks to do at the same time then deployment of application in terms of one replica is not recommendable.

For the I/O intensive, BZip is used for the measurement of overhead. During this experiment,  $N_0: \mu_1 - \mu_2 = 0$  is targeted. Table III shows the outcome of measured results of using the BZip for all 17 containers execution time during the compression of the UNIX kernel. It is found that I/O intensive applications are not impacting the deployment. The overhead is almost negligible even the file system is shared across all the deployed containers.

For the network benchmarking, used the iperf server [20] and client deployment on the pods. Server and client are on same physical machine. The containers are deployed in a pod is going to share the IP address in terms of network connection. The TCP based traffic has been monitored by running the tests for about 1 minute. Both the scenarios (i) and (ii) have been considered to find out the impact of network connection. Tables IV and V show the results for both scenarios where single container per pod and multiple container in a pod. It is found that for the running application more than 5 containers. It is concluded that group of few containers on a single pod is better than having higher number of containers deployed within a pod. This number can be fine-tuned based on workloads and application type.

TABLE II. POV-RAY FOR CPU INTENSIVE BASED APPLICATION

TC	Scenario 1		Scenario 2		$N_0?$
	$\mu_1$	$\sigma_1$	$\mu_2$	$\sigma_2$	
1	122.34	0.42	122.23	0.38	Yes
5	467.56	0.94	469.14	0.59	No
9	936.80	0.71	936.58	0.68	Yes
13	1411.66	1.57	1414.30	1.25	No
17	2360.22	1.14	2364.37	3.87	Yes

TABLE III. BZIP FOR INPUT / OUTPUT INTENSIVE BASED APPLICATION

TC	Scenario 1		Scenario 2		$N_0?$
	$\mu_1$	$\sigma_1$	$\mu_2$	$\sigma_2$	
1	15.04	0.15	14.97	0.23	Yes
5	15.93	0.14	15.916	0.15	Yes
9	18.19	1.40	18.88	0.53	Yes
13	21.73	1.42	20.33	1.09	Yes
17	35.34	2.67	34.58	0.98	Yes

TABLE IV. N/W BENCHMARKING USING C-PERF CLIENT FOR SCENARIO 1

1	1.88	0.05	1.88	Yes
5	9.82	0.08	2.19	Yes
9	16.95	0.12	2.04	Yes
13	17.18	0.20	1.16	No
17	18.17	1.35	2.19	No

## V. CONCLUSION

For containers deployment, Kubernetes is highly recommendable. Wherever there is a need to provision the high number of computing instances frequently within seconds, the overhead attached to the containers and resource allocation is a limitation. In this paper proposed a flexible, automated and performance based framework that can be used by developers or students in their labs to deploy the containers using Kubernetes. It can be used for any application release, capacity planning and for resource management. It is highly flexible in nature using the helm-charts. In this framework not only the deployment of containers are outlined but also focused on managing the Kubernetes cluster using the Rancher. The life cycle of container is also elaborated and pods internally. The CI/CD pipeline based on Jenkin Server is making this framework fully automated. It is not only offering the fault-tolerance but also support the horizontal scalability of an application in terms of containers. The fully automated framework is elastic in nature without any single manual interruptions.

## ACKNOWLEDGMENT

I am really thankful to the Koneru Lakshmaiah Education Foundation for allowing me to choose my research area as per my interest and my guide optimistic nature as well as other staff members who encouraged me to complete this research work.

**Abstract**—Standard classification algorithms often face a challenge of learning from imbalanced datasets. While several approaches have been employed in addressing this problem, methods that involve oversampling of minority samples remain more widely used in comparison to algorithmic modifications. Most variants of oversampling are derived from Synthetic Minority Oversampling Technique (SMOTE), which involves generation of synthetic minority samples along a point in the feature space between two minority class instances. The main reasons these variants produce different results lies in (1) the samples they use as initial selection / base samples and the nearest neighbors. (2) Variation in how they handle minority noises. Therefore, this paper presented different combinations of base and nearest neighbor's samples which never used before to monitor their effect in comparison to the standard oversampling techniques. Six methods; three combinations of Only Danger Oversampling (ODO) techniques, and three combinations of Danger Noise Oversampling (DNO) techniques are proposed. The ODO's and DNO's methods use different groups of samples as base and nearest neighbors. While the three ODO's methods do not consider the minority noises, the three DNO's include the minority noises in both the base and neighbor samples. The performances of the proposed methods are compared to that of several standard oversampling algorithms. We present experimental results demonstrating a significant improvement in the recall metric.

**Keywords**—Class imbalance; nearest neighbors; base samples; initial selection; SMOTE

## I. INTRODUCTION

One of the most challenging machine learning problems to both the academia and industry in the last couple of decades is one associated with learning from data that is unbalanced [1]. This problem is known to arise in both binary and multiclass classification tasks when data instances from one class, known as the majority class occur more frequently than instances of other classes, known as the minority classes [2]. This obvious disproportion in the distribution of data instances across classes leans the classifier towards significant bias to the majority class which in turn results in the misclassification of instances of other classes [3]. What makes the class imbalance problem more interesting is the fact that the minority class is often the

class of interest in most real-life application domain, thus, the cost of misclassifying the minority class is often higher than that of the majority class [4, 5]. For instance, given a machine learning fraud detection system, legitimate transactions occur more often than fraudulent ones, but the cost of misclassifying a fraudulent transaction as legitimate is greater than the opposite. Therefore, approaches to addressing class imbalance problem are aimed at increasing the accuracy and sensitivity of the classifier to the minority class.

The approaches to dealing with class imbalance problem can broadly be grouped into two categories [6]. The first category entails algorithmic creation/modification to improve learning of the minority class samples. The second category of approaches is the most popularly used category, data level methods, which resamples the data distribution to ensure balanced data distribution across the respective classes via oversampling, under-sampling or their hybrid combination.

This paper focuses on oversampling methods that involve the generation of synthetic data samples to augment the minority class. A leading oversampling method that serves as the basis for most of the recent oversampling methods is the Synthetic Minority Over-sampling Technique (SMOTE) algorithm [2]. SMOTE basically generates artificial samples along the length of the line joining neighboring minority class samples.

SMOTE has also inspired several approaches to counter the issue of class imbalance. It is standard benchmark for learning from imbalanced data [7]. Based on SMOTE, several techniques have been proposed in the literature, and these techniques have been categorized according to some properties include: (1) initial selection of instances to be oversampled (technically called base samples), (2) integration with Under-sampling as step in the technique, (3) type of interpolation, (4) operation with dimensionality changes, (5) adaptive generation of synthetic examples, (6) possibility of relabeling and (7) filtering of noisy generated instances.

Each SMOTE-based extension might have different properties from the aforementioned aspects. However, a large number of them use the three common aspects include: initial selection, type of interpolation (the common type is 'range

restricted'), and the adaptive generation of the new samples. This study, therefore, focuses on those three properties.

The most common standard technique that utilizes initial selection and the 'range restricted' interpolation aspects is SMOTE\_BORDERLINE [8]. This research, thus, started with adopting the same initial selection of instances to be oversampled in SMOTE-BORDERLINE. The common standard technique that uses adaptive generation of synthetic examples is ADASYN [9], and this is also adopted in this study to be used in our proposed techniques. The minority classes have been classified into three different groups namely safe, danger, and noise; according to its level of difficulty [8, 10-12].

Consequently, six new oversampling techniques, namely, ODO1, ODO2, ODO3, DNO1, DNO2, and DNO3 are proposed. For the ODO techniques, only the borderline examples (Danger group) of the minority class are oversampled, while in case of the DNO techniques, both the minority danger and minority noise examples are oversampled. The main difference between the three ODO methods lies in the criteria for choosing the nearest neighbors (NN) group. In ODO1, the NN is the minority class except the minority noises, while in ODO2; the NN is the same as the base example which are the borderline examples (minority danger). In ODO3, the NN group includes the whole classes except the minority noises.

Similarly, the main difference between the three DNO methods is the criteria for choosing the nearest neighbors. In DNO1, the NN is the minority class, while in DNO2, the NN are the same as the base examples which consist of the Danger and Noise examples. Lastly, in DNO3, the NN group consists of the whole classes (minority and majority).

Table I shows how each of the proposed methods differs from the standard techniques (SMOTE, Borderline1, Borderline2, and ADASYN). Moreover, in this study, three aspects are added for more clarification about the methods and they are: (1) Nearest Neighbor group, (2) 'how to choose from NN group' and (3) 'noise considered?'

Hence, the major contribution of this study includes the implementation of the proposed methods as well as a tabular overview showing the differences between the methods in details and more clarifications, and this includes the initial selection / base samples used, the NN groups, the method of NN selection, type of interpolation, adaptive generation, and the representation of the minority noises (noises considered?) as shown in Table I. The proposed oversampling techniques were experimentally analyzed using four classification algorithms and evaluation metrics across 15 publicly available datasets from Machine Learning Repositories. The performances of the proposed methods are compared to SMOTE, Borderline SMOTE and ADASYN oversampling methods. In addition, statistical analysis was also carried out using Friedman aligned and Holm's tests.

The organization of this article is as follows. An overview of pertinent studies and oversampling methods is provided in Section II while the procedure of the proposed methods is listed in Section III followed by the experimental design in

Section IV. The experimental results and conclusion are respectively presented in Sections V and VI.

## II. RELATED WORK

Given that this study focuses on oversampling through synthetic data generation which is a data level approach, a short review of related studies is presented here in this regard. References [7, 13, 14] are important articles for an in-depth review of imbalance resolution approaches. The most basic form of oversampling is known as Random Oversampling which involves random sampling of minority class samples with replacement till it matches the size of the majority class samples. A major drawback of this approach is high likelihood of overfitting that results from the exposure of the classifier to the same information.

An oversampling approach that sidesteps the challenges associated with basic random oversampling is SMOTE which involves synthetic data generation along the length of the line joining neighboring minority class samples. SMOTE generates synthetic samples for any minority class including minority noises which also participate as nearest neighbors. However, when the separation between majority and minority class clusters is not clear, noisy samples may be generated [2]. On the other hand, borderline-SMOTE methods [8] intend to prevent producing noisy samples by detecting the boundary instances between the majority and minority classes, which are then utilized to identify useful informative minority class samples. Although both SMOTE-Borderline1 and SMOTE-Borderline 2 do not generate any sample for minority noises, dealing with those noises as nearest neighbors may generate new samples located near the noises or overlap with them. The study in [9] aims to distribute the new synthetic samples according to the level of difficulties by making the most difficult samples have more new samples. However, this approach results in that minority noises will have the big portion of the new synthetic samples.

From the afore-highlighted, it is obvious that the methods vary in how they deal with the base and nearest neighbor's samples. Similarly, some of them give the minority noises the advantage of being more represented in the new samples while others ignore them completely. However, the use of other different groups is still lacking, therefore, using different sample groups of the base and nearest neighbors are needed.

## III. PROPOSED METHODS' PROCEDURE

Suppose that the whole training set is  $X$ , the minority class is  $P$  and the majority class is  $N$ , and  $P = \{p_1, p_2, \dots, p_{n_{\text{num}}}\}$ ,  $N = \{n_1, n_2, \dots, n_{n_{\text{num}}}\}$  Where  $p_{n_{\text{num}}}$  and  $n_{n_{\text{num}}}$  are the number of minority and majority examples. The detailed procedure of ODO1 explained in Fig. 1.

The difference between ODO1, ODO2, and ODO3 is the NN groups as we mentioned above. Additionally, the difference between ODO's techniques and DNO's techniques is that, in DNO's methods, minority noises are added to both base samples and NN samples as declared in Table I. Further, In situations where the NN is from the majority class, a random value between 0 and 0.5 will be multiplied by the difference between the base example and its nearest negative example as in SMOTE\_Borderline2 [8].

TABLE I. DIFFERENCES BETWEEN THE OVERSAMPLING METHODS

Method	Initial Selection/ Base samples	NN group	How to choose from neighbors	Type of interpolation	Adaptive generation	Noise considered?
SMOTE	Any from minority	The 5 NN all minority	Randomly	On the line between base and NN New sample= base + (rand(0,1)*diff)	-	Base →yes NN →yes
Borderline1	Minority_Danger (3,4)	the 5 NN (minority)	Randomly	New sample= base + (rand(0,1)*diff)	-	Base →NO NN →yes
Borderline2	Minority_Danger (3,4)	the 5 NN (minority + majority)	Randomly	(range restricted) If NN is minority New sample= base + (rand(0,1)*diff) If NN is majority New sample= base + (rand(0,0.5)*diff)	-	Base →No NN →yes
ADASYN	Minority (1,2,3,4,5)	the 5 NN all minority	Randomly	Weighted distribution New sample= base + (rand(0,1)*diff)	Weighted distribution	Base →yes NN →yes
ODO1	Minority_Danger (3,4)	the 5 NN (minority-noise)	Randomly	New sample= base + (rand(0,1)*diff)	Weighted distribution	Base →No NN →No
ODO2	Minority_Danger (3,4)	the 5 NN (minority Danger)	Randomly	New sample= base + (rand(0,1)*diff)	Weighted distribution	Base →No NN →No
ODO3	Minority_Danger (3,4)	the 5 NN (minority-noise) + majority	Randomly	(range restricted) If NN is minority New sample= base + (rand(0,1)*diff) If NN is majority New sample= base + (rand(0,0.5)*diff)	Weighted distribution	Base →No NN →No
DNO1	Minority_Danger and Noise (3,4,5)	the 5 NN (minority)	Randomly	New sample= base + (rand(0,1)*diff)	Weighted distribution	Base →Yes NN →Yes
DNO2	Minority_Danger and Noise (3,4,5)	the 5 NN (minority Danger and Noise)	Randomly	New sample= base + (rand(0,1)*diff)	Weighted distribution	Base →Yes NN →Yes
DNO3	Minority_Danger and Noise (3,4,5)	the 5 NN (minority + majority)	Randomly	(range restricted) If NN is minority New sample= base + (rand(0,1)*diff) If NN is majority New sample= base + (rand(0,0.5)*diff)	Weighted distribution	Base →Yes NN →Yes

#### IV. EXPERIMENTAL DESIGN

The performance of the proposed methods is evaluated using 15 benchmark imbalanced datasets of varying imbalance ratios (IR) from the Machine Learning Repositories (UCI, Kaggle, Keel, Datahub) and this is a common practice in class imbalance learning. Table II shows a summary of the 15 datasets. The performances of the proposed oversampling techniques were evaluated and compared with SMOTE, SMOTE\_Borderline1, SMOTE\_Borderline2, and ADASYN. Since accuracy has been shown in representative works as an insufficient evaluation metric for imbalanced datasets, Recall, and F1-measure are employed in this study. Additionally, the four classifiers considered for evaluation in this study are Decision Trees (DT) [15], Logistic Regression (LR) [16], RandomForest (RF) [17] and Support Vector Machine (SVM) [18].

For each combination of dataset, classifier and evaluation metric, an aligned ranking score is used to rank each oversampling method including the baseline. In addition to the 10 oversampling algorithms considered in this study, the performance of the classifiers on the original dataset without oversampling is also used as the baseline.

Thus, the best performing method has the biggest ranking score while the smallest ranking score indicates the worst performing method. Additionally, two statistical tests, Friedman aligned ranks and Holm, were also used to further establish the significance of our findings. While the Friedman aligned rank's test recognizes the difference in outcomes obtained from many attempts when the normality assumption may not hold, the Holm's test is a nonparametric t-test used to establish whether a control method outperforms comparative methods.

<b>Only Danger Oversampling (ODO1) algorithm:</b>
<b>Step 1.</b> Extract the $X_{\min}$ as the minority samples.
<b>Step 2.</b> Define $m_{\min}$ and $m_{\max}$ as the number of minority class examples and the number of majority class examples, respectively. Therefore, $m_{\min} \leq m_{\max}$ and $m_{\min} + m_{\max} = X$ .
<b>Step 3.</b> Calculate the degree of class imbalance: $d = m_{\min}/m_{\max}$ , where $d \in (0, 1]$ .
<b>Step 4.</b> Calculate the number of synthetic data examples that need to be generated for the minority class: $G = (m_{\max} - m_{\min}) \times \beta$ Where $\beta \in [0, 1]$ is a parameter used to specify the desired balance level after generation of the synthetic data. $\beta = 1$ means a fully balanced data set is created after the generalization process.
<b>Step 5.</b> Determine the three Minority groups (Noise, Danger, Safe)
<b>Step 6.</b> Now, we find the KNN (K=5) for each example $x_i$ in the danger group in the whole training dataset $X$ .
<b>Step 7.</b> calculate the ratio $r_i$ defined as: $r_i = \Delta_i/K$ , $i = 1, \dots, X_d$ . $X_d$ is the number of examples in Danger group. where $\Delta_i$ is the number of examples in the K nearest neighbors of $x_i$ that belong to the majority class, therefore $r_i \in [0, 1]$ .
<b>Step 8.</b> Normalize $r_i$ according to $r_i^{\hat{}} = r_i / \sum_{i=1}^{X_d} r_i$ , so that $r_i^{\hat{}}$ is a density distribution ( $\sum r_i^{\hat{}} = 1$ )
<b>Step 9.</b> Calculate the number of synthetic data examples that need to be generated for each minority_danger example $x_i$ : $g_i = r_i^{\hat{}} \times G$ where $G$ is the total number of synthetic data examples that need to be generated for the minority_danger class.
<b>Step 10.</b> Determine the minority group without noises $X_{\min\_no\_noise} = (X_{\min}) - (\text{Noise})$
<b>Step 11.</b> find the KNN (K=5) for each example $x_i$ in the danger group in the $X_{\min\_no\_noise}$ . In this step, we guarantee that we don't use any minority noise as a NN.
<b>Step 12.</b> For each minority_danger class data example $x_i$ , generate $g_i$ synthetic data examples according to the following steps:  Do the Loop from 1 to $g_i$ : (i) Choose a minority data example ( $x_{zi}$ ) randomly from the nearest neighbors for data $x_i$ . (ii) Generate the synthetic data example: $s_i = x_i + (x_{zi} - x_i) \times \lambda$ where $(x_{zi} - x_i)$ is the difference vector in n dimensional spaces, and $\lambda$ is a random number: $\lambda \in [0, 1]$ . End Loop

Fig. 1. ODO1 Algorithm.

To evaluate the performance of the classifiers on each dataset and method, a stratified k-fold cross validation experimental setup was applied with  $k = 5$ . Each oversampling method is performed on only the training portion dataset during k-fold CV and tested on their respective test folds [19]. The presented results represent the means validation performance. When the data you are using to train a machine learning algorithm happens to have the information you are trying to predict that is called Data leakage [20]. Therefore, to prevent leaking the data, the data preparation was performed within cross validation folds.

The hyperparameter tuning of the classifiers was done on the original datasets with no oversampling (baseline) and then the obtained optimal parameters are used when applying the

oversampling methods to have fairness with all techniques, while the various oversampling algorithms' hyperparameters were tuned using the default values, except an important parameter in this study that is k nearest neighbor which must be equal to 5 in all oversampling techniques since the proposed methods are built on this number of nearest neighbors. The classifiers and standard oversampling algorithms were implemented using Python modules Scikit-Learn [21] and Imbalanced-Learn [22].

## V. EXPERIMENTAL RESULT AND DISCUSSION

At first, in the favor of explaining more about the nature of work of the oversampling standard techniques and the proposed methods, this research visualized their generating of the new samples using a synthetic dataset as you can see in Fig. 2, in addition to the detail description in Table I.

On your imbalanced classification problem, you can choose to use precision or recall. The number of false positive errors will be reduced if precision is maximized, while the number of false negative errors will be reduced if recall is maximized. As a result, precision may be a better fit for classification problems where false positives are a concern. Alternately, recall may be more appropriate on classification problems when false negatives are more important [23]. With dataset such as Breast Cancer, the concern is the recall, therefore, try to reduce the False Negative (FN) as possible as can, while with dataset such as Spam mails dataset, the task will be more focus on precision since it is needed to reduce the False Positive (FP) the most. This study tries to improve the recall without hurting the precision too much.

For each combination of classifier and evaluation metric, the mean rankings of the oversampling approaches over data sets are shown in Table III. The Friedman aligned test is used to statistically confirm the conclusion and the results are shown in Table IV. As a result, the null hypothesis is rejected at a significance level of 0.05., i.e., the oversampling methods do not perform equally in mean rankings for all evaluation metrics.

Table V shows that our proposed method DNO3 is always the first or the second winner with all classifiers when the metric measure is the recall, therefore, DNO3 oversampler is used as a control method in the Holm's test to see if DNO3 result is a significant or not. The adjusted p-values are shown in Table VI.

DNO3 ranked as the best method among all techniques regarding the recall results, and then DNO1 coming as the second. By looking at the differences between the DNO1 and DNO3, the only difference is the NN samples. DNO3 will deal with all classes in the NN whether they are minority or majority class, while DNO1 will only consider the minority class in the NN. This shows the importance of considering both minority and majority classes in the nearest neighbors.

ODO3	<b>0.02908</b>	ODO1	0.50404	ODO2	<b>0.04196</b>	BL1	<b>0.03726</b>
ODO1	<b>0.04105</b>	SMOTE	0.50404	ODO3	0.05474	SMOTE	<b>0.04402</b>
BL1	0.09000	BL1	0.50404	SMOTE	0.12593	ODO2	0.05936
ADASYN	0.51162	ADASYN	1.00000	BL1	0.16331	BL2	0.10763
SMOTE	0.51693	ODO3	1.00000	BL2	1.00000	ODO3	0.51500
DNO2	1.00000	DNO2	1.00000	DNO2	1.00000	ADASYN	0.51500
BL2	1.00000	DNO1	1.00000	ADASYN	1.00000	DNO2	0.73831
DNO1	1.00000	BL2	1.00000	DNO1	1.00000	DNO1	0.73831

Among the common standard techniques (SMOTE, SMOTE\_BORDERLINE1 (BL1), SMOTE\_BORDERLINE2 (BL2), and ADASYN), the BL2 is the best in Recall results. Comparing SMOTE\_BORDERLINE2's structure with DNO3 shows the importance of considering the minority noise in the base samples since SMOTE\_BORDERLINE2 is not considering that, as well as the weighted distribution of the new samples used by DNO3 that creates more new samples for the most difficult samples which is not the way used in SMOTE\_BORDERLINE2.

From the above analysis this study depicts that there are three factors can affect the detection of the minority class; the first is that the minority's noises and danger samples which should be considered in the initial selection / base samples, and the second factor is that the minority noises, danger, and also the majority samples should be considered in the nearest neighbors samples, and last but not least is that the distribution of the new synthetic samples should be also weighted distributed so that the more difficult samples will be given more new synthetic samples. These factors can help reducing the false negative (FN) examples and this, in turn, increases the recall.

## VI. CONCLUSION

DNO'S techniques performances were the best in Recall, and specifically DNO3 that outperformed all standard techniques in recall metric. This study shows the importance of considering minority noises and danger samples whether as base samples or nearest neighbors' group. Furthermore, the majority class samples should be under concern in the nearest neighbors' group. Finally, the weighted distribution (adaptive generation) of the new samples can help to get better Recall

result. Taking everything into account, next work should consider not only the minority danger and minority noise groups, but also different groups of difficult minority samples including the minority safe samples.

# Social Group Optimization-based New Routing Approach for WMN's

Bhanu Sharma, Amar Singh  
School of Computer Applications  
Lovely Professional University  
Jalandhar, India

**Abstract**—Wireless Mesh Networks (WMNs) are hop-to-hop communication networks that are quickly deployable, dynamically self-organizing, self-configuring, self-healing, self-balancing, and self-aware. In WMNs, a node can leave or join the network at any time. Due to the mobile nature of nodes, the routes between source and destination can change frequently. Computing the shortest path under dynamic conditions for a given time constraint imposed due to node mobility can also be placed in the class of highly complex problems. However, as the network size grows, the performance of the nodes decreases. As a result, we require Soft Computing approaches to handle this problem. This article proposes a Social Group Optimization (SGO) based routing approach to wireless mesh networks. The proposed approach was implemented in MATLAB and tested on different dynamic nodes network scenarios. We compare the performance of the proposed approach with Ant Colony Optimization (ACO), Ad-hoc On-demand Distance Vector (AODV), Dynamic Source Routing (DSR), BAT, Biogeography-based optimization (BBO), and Firefly Algorithm based routing approaches. We observe that the proposed approach outperformed all other approaches on the more than 1000 node network scenarios.

**Keywords**—ACO; AODV; DSR; BAT; BBO; wireless mesh network; social group optimization

## I. INTRODUCTION

A mesh network is a rising era that can provide broadband Internet access, wi-fi nearby area coverage, and network connectivity to operators and customers at a low cost. Wireless Mesh Network is a network that consists of n number of nodes that help in communication within a network structure. Because of its characteristics like self-healing, fault-tolerant and self-organizing, WMNs make the communication process more reliable. There are three types of components in Wireless Mesh Network: Mesh Clients, Wireless Mesh Routers, and Wireless Mesh gateways. Mesh clients, also known as Wireless Mesh clients, are the end-user devices that access the network to run applications like email, games, tracking location, etc. Examples of these clients are mobile, laptops, smartphones, etc. They have limited resources, and sometimes they might not be connected to the network. Client WMNs consists of routers with no cabling connecting the nodes and can work using inbuilt radios in network nodes. Unlike traditional wireless access points, every node consists of inbuilt hardware gateways to connect it with neighbor nodes.

Routing in WMNs is a challenging issue due to the dynamic nature of networks. In WMNs, any node can move

anywhere without informing other nodes. Due to the mobile nature of nodes, the routes are frequently changing. Computing the shortest path under dynamic conditions for a given time constraint imposed due to node mobility can also be placed in the class of highly complex problems. So, for efficient communication, there is a need for routing approaches that can discover the new routes quickly before the network structure changes again. It is a well-known fact that the probability of finding the best solution is significantly less for the highly nonlinear and complex problems falling under the class of NP-hard or NP-complete problems. The computational cost for such cases may be so high that the best solutions may not be affordable. Under such circumstances, wherever best can be replaced with reasonable solutions, soft computing approaches perform better than their hard computing counterparts. Thus, suggesting that soft computing-based approaches to dynamic shortest path route evaluation shall provide better results than the hard computing-based approaches such as AODV, DSR, etc. The hard computing-based algorithms work well on WMNs with less than 1000 nodes. This article proposes a new soft computing-based routing approach for WMNs. The proposed approach works upon the social learning behavior of humans. The proposed algorithm worked very well on large nodes network scenarios.

We divide our paper into 5 sections. Section 1 of the paper presents the motivation for the paper. Section 2 discusses the overview of the SGO (Social Group Optimization) Algorithm. Section 3 presents the SGO based approach for shortest route evaluation in WMNs. Section 4 discusses the implementation and performance analysis of the proposed approach for WMNs. Section 5 concludes the paper.

## II. SOCIAL GROUP OPTIMIZATION ALGORITHM

Social Group optimization group is the nature-inspired computing approach that is based on the human decision-making process. This algorithm is based on peer learning and increasing an individual's knowledge. The SGO algorithm works in two phases: The Improving Phase and Acquiring Phase. Here each person in the group is considered as a candidate solution. Each candidate tends to acquire knowledge and possess to increase fitness value. On the other hand, the one with the highest expertise or the best person tries to distribute the knowledge among all the candidate solutions, resulting in upgrading the knowledge level of the entire group members.

### A. Improving Phase

In the improving Phase, each candidate solution communicates/interacts with the best person present in the group. As a result, an individual's knowledge shall upgrade with the help of the one with the highest fitness value. The pictorial representation of this Phase can be seen in Fig. 1.

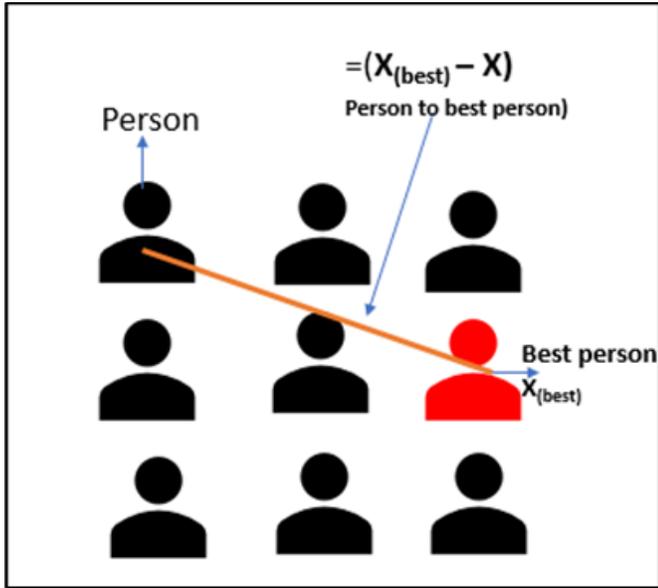

Fig. 1. Shows the Improving Phase Working.

$$X_{new} = cX + r(X_{best} - X) \quad (1)$$

The new solution computed with  $c$ , a self-introspection parameter, is here  $X_{new}$ ,  $r$  is the random number between  $(0,1)$ , and  $X$  is the previous solution.  $X_{best}$  represents the one with the highest fitness value. With  $(X_{best}, X)$ , the individual interacts with the best person in the group, which helps them enhance their expertise. The focus will be on the acquisition phase once the new solution has been produced. This entire process works in two steps: Improving and acquiring Phases. Previously the improving Phase has been discussed. Once the communication between the partner and the best person occurs, the algorithm moves to the next phase, i.e., acquiring.

### B. Acquiring Phase

Now this Phase works in two steps:

Step 1: Mutual interaction with the other partners in the group.

Step 2: Mutual Interaction with the other people in the group + considering the best person from Phase 1 (Fig. 2).

In the case of Step 1, each person interacts with other people in the group by using the following Eq 2:

$$Person\ to\ partner\ or\ peer = X - X_p \quad (2)$$

Where  $X$  is the person and  $X_p$  are their colleagues. In Step 2, communication will be done with the best person in the group. Here each member interacts with the best person only, which is calculated using the following Eq calculates. 3.

$$Person\ to\ Best\ person = (X_{best} - X) \quad (3)$$

Here  $X_{best}$  represents the person with the highest fitness value or with the best knowledge. Once the acquiring completes, each person's ability in the group is updated using the following Eq. 4.

$$X_{new} = X + r1(X - X_p) + r2(X_{best} - X) \quad (4)$$

With the help of these two steps, a new solution is generated by  $X_p$  (partner solution). The obtained solution could be used to solve different types of optimized problems. Here if the knowledge of the person  $X$  is greater than the partner  $X_p$ . The objective function for Maximization is given by equation 5. Similarly, if the knowledge of the person  $X$  is less than the partner  $X_p$ , then the objective function is given by following (Eq. 6)

$$X_{new} = X + r1(X - X_p) + r2(X_{best} - X) \quad (5)$$

*if*  $X > X_p$

$$X_{new} = X - r1(X - X_p) + r2(X_{best} - X) \quad (6)$$

*if*  $X < X_p$

and for the same condition, the objective function for Minimization is shown below in (Eq. 7 and Eq. 8)

$$X_{new} = X + r1(X - X_p) + r2(X_{best} - X) \quad (7)$$

*if*  $X < X_p$

$$X_{new} = X - r1(X - X_p) + r2(X_{best} - X) \quad (8)$$

*if*  $X > X_p$

## III. SOCIAL GROUP OPTIMIZATION-BASED DYNAMIC SHORTEST PATH ROUTE EVALUATION IN WIRELESS MESH NETWORK

This section proposes an SGO based approach for least-cost route evaluation in WMNs. Routing is the process of establishing a communication link between a source and a destination node. The cheapest path in WMNs is challenging to determine due to the dynamic nature of network nodes. Routing techniques for WMNs are often divided into two phases. The first Phase is the route discovery phase. The source nodes should discover the best route within the specific time frame. Once the route is discovered, data communication is

performed in the second Phase. In the second phase, source and destination nodes can communicate. Data transfer continues until a specified time interval or network structure changes.

When estimating a minimal or near-cost route, these dynamic scenarios and time constraints complicate the routing process. In most cases, the exact shortest path cannot be calculated, so the shortest path must be replaced with the least cost path so that the path can be served as an input to the existing dynamic environment [1]. Due to the complexity of this in Wireless Mesh Network, A soft computing approach is preferred over hard computing. Soft computing techniques provide an optimized route instead of the best route within a given time constraint.

In WMN's routing, matrices play a crucial role in path selection and route optimization. As defined in the literature, ETX [2] is termed as the "expected no of transmission nodes," which are required when transmitting the information from a source node to a destination node. To calculate ETX, each node spreads an inquiry packet which is having the number of received inquiries from every neighbor. The Route EXT sums up all the ETX links which come in between the route. With the help of source routing and ETX/ETT metrics, the Local On-Demand Link State (LOLS)[3] protocol executes the route-discovery process. WCETT was proposed [4] to minimize the number of nodes on the route of a flow that transmits information on the same channel. It is a combination of end-to-end delay and channel diversity. The MR-LQSR (Multi-Radio Link Quality Source Routing Protocol) [5] follows LQSR to work over multiple channels and interfaces with the help of the WCETT metric. ETT (Expected Transmission Time) [6] tackles the problem of low performance presented in ETX by considering the differences in link transmission rates. ETT adjusts ETX to different PHY rates and data-packet sizes. Apart from all these, we have some more metrics like Per-Hop Packet Pair Delay (PktPair)[7], Expected Transmission on a Path (ETOP) [8], Effective Number of Transmission (ENT)[9], and Modified Expected Number of Transmissions (mETX) [10], Metric of Interference and Channel Switching (MIC) [11], Bottleneck Link Capacity (BLC) path metric [12], cross-layer link quality and congestion aware (LQCA) metric [13]. A novel interference aware low overhead routing metric was proposed [14]. In our proposed approach we use the fuzzy-based integrated link cost (ILC) method [15].

Some more interesting study on Soft computed based WMN's can be seen in [16]-[20].

Integrated link cost (ILC) = f(throughput, delay, jitter, node residual energy)

### **Proposed SGO Approach in Routing in Wireless Mesh Network for Dynamic Optimal Cost Route Evaluation**

#### **Begin**

/\* SGO starts

Initialize the SGO parameter. Generate N populations each with randomly generated NC candidate Solutions, Dimension D of each population, termination criteria self-introspection parameter c.

**while!** = T C **do**

/\* TC is a termination criterion \*/

**for** i = 1: N **do**

Calculate ILC of every link of the network.

Using ILC to evaluate the fitness calculate the fitness value of each person in the population

Sort the ith populations from best to worst based on the values of ILC;

The best-fit individual of the ith population is chosen as the gbest of the person;

**End for**

Record the best route from amongst all available routes.

The best fit is called elite;

Initiate an improving Phase to update the knowledge of persons with the help of the best route

**for** i = 1: N **do**

Update the i<sup>th</sup> route by integrating it with the best route in populations.

**End for**

% Acquiring Phase

**Select a route 'r' randomly from the available population of routes**

**Compute fitness of 'r'**

**for** i = 1: N **do**

if r is better than the ith route

Update the i<sup>th</sup> route by integrating it with the 'r' route in populations.

**End for**

Compute fitness of the entire route population.

**Calculate the best fit route from the current population and call it temp\_fit**

**Update elite with temp\_fit (if required)**

**Stop**

#### IV. ARCHITECTURAL DETAILS OF VARIOUS CLIENT WMN SCENARIO

For implementation purposes, we consider different client WMN scenarios. The architectural detail of each scenario is shown in Table I.

TABLE I. NETWORK ARCHITECTURE OF CLIENT MESH NETWORK

No. of Nodes Area	Area(m×m)	Radio Range	Timing Constraint (in Seconds)
500	1000 *1000	250	1.3,1.5,1.7,2.1,2.3,2.5,2.7,3.1,3.3,3.5
1000	1000*1000	250	1.2,1.4,1.6,1.8,2.0,2.2,2.4,2.6,2.8,3.0
2000	2000*2000	250	2.0,2.2,2.4,2.6,2.8,3.0,3.2,3.4,3.6,3.8
3000	3000*3000	250	4.0,4.5,5.0,5.5,6.0,6.5,7.0,7.5,8.0,8.5
4000	4000*4000	250	5.0, 5.5, 6.0, 6.5, 7.0, 7.5, 8.0, 8.5, 9.0, 9.5, 10.0

#### V. RESULT AND DISCUSSION

To assess the appropriateness of the suggested SGO-based approach to route evaluation in WMNs, we implemented it in MATLAB along with 6 other algorithms and ran simulations using dynamic scenarios. We evaluated 500, 1000, 2000,3000, and 4000 node client WMN designs for simulation purposes. For simplicity, we have eliminated the findings from WMNs with up to 1000 nodes because the proposed SGO technique performs better on larger networks. Table I shows the architectural design of several Client WMN node scenarios.

##### A. Comparative Performance of 2000 Node Client Wireless Mesh Networks

The performance of the Social Group Optimization-based new routing approach for the Wireless Mesh Network approach is evaluated along with other 6 algorithms on the 2000 node client WMN scenario. We have considered 2.0, 2.2,2.4,2.6,2.8,3.0,3.2,3.4,3.6, and 3.8 seconds timing constrain for performance analysis purpose. For each timing constrain, we conducted 10 trials. For testing purposes, we conducted a total number of 100 trials.

The performance of each approach with different time intervals on the 2000 nodes scenario is presented in Table II. For all time limits and given trials, the results achieved by SGO based routing approach outperformed ACO, DSR, AODV, BAT, BBO, and Firefly algorithms 56 times out of 100 trials. The optimal route generated by Firefly is 32 times and BAT 8 times. BBO generated better results 4 times in some time constraints including equal optimal route cost with BAT, Firefly, and SGO. With the given timing constraints, no route was discovered by ACO, DSR, and AODV. For the time constraints 2.0, 2.6 3.4, and 3.8, BAT and BBO were able to discover routes but were unable to produce optimal route cost. For the time constraints 2.4,3.0, and 3.2 BAT, BBO, and Firefly generated similar route costs. SGO came out as a winning approach with the highest route discovery and minimal route cost in the entire analysis. Fig. 3 shows the pictorial representation of the best performance of SGO with the other 6 algorithms.

TABLE II. ARCHITECTURAL DETAILS OF 2000 NODES CLIENT WMN SCENARIOS

Time Constraints										
Algo	2.0	2.2	2.4	2.6	2.8	3.0	3.2	3.4	3.6	3.8
ACO	----	----	----	----	----	----	----	----	----	----
AODV	----	----	----	----	----	----	----	----	----	----
DSR	----	----	----	----	----	----	----	----	----	----
BBO	0	0	1+ A	0	0	1+ A	1+ A	0	1+ A	0
BAT	0	2	1+ A	0	2	1+ A	1+ A	0	1+ A	0
Firefly	4	3	2	3	4	1+ A	2	4	5	4
SGO	6	5	6	7	4	7	6	6	3	6

A=1 represents equal results generated

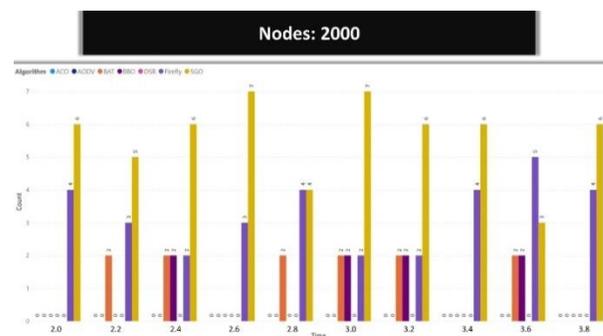

Fig. 3. Graphical Presentation of 2000 Nodes in Client Wireless Mesh Networks.

##### B. Comparative Performance of 3000 Node Client Wireless Mesh Networks

From Table III, it is observed that for time constraints of 4.0 seconds BAT and BBO produce minimum route cost and equal results for one time each, Firefly-based approach produced 3 times and SGO generated minimum cost route 5 times. Within time constraint 4.5 BBO and BAT and SGO produced enumerated equal best paths. For 5.0 seconds BAT, BBO and Firefly produced equal results once and generated minimal route path 1 time.

SGO on the other hand generated a minimal route cost path 7 times. For time constraints 6.0, 7.0,8.0, and 8.5 BBO and BAT-based approaches successfully discovered the route but did not produce the shortest path. For the same time constraints, the shortest path discovered by Firefly is 13 times and SGO is 22 times in total. Further, we observe that the overall performance of SGO based routing approach is much better than the other 6 approaches for each timing constraint. For a total of 100 trials, SGO produced a minimum cost path 55 times followed by Firefly 34 times, BAT 6 times, and BBO 5 times. For the given timing constraint all the algorithms except for AODV, ACO, and DSR have produced results. Fig.4 represents the histogram of the frequency of best performance for each timing constraint.

TABLE III. ARCHITECTURAL DETAILS OF 3000 NODES CLIENT WMN SCENARIOS

Time Constraints										
Algo	4.0	4.5	5.0	5.5	6.0	6.5	7.0	7.5	8.0	8.5
ACO	---	---	---	---	---	---	---	---	---	---
AODV	---	---	---	---	---	---	---	---	---	---
DSR	---	---	---	---	---	---	---	---	---	---
BBO	1+ A	1+ A	1+ A	1	0	0	0	1+ A	0	0
BAT	1+ A	1+ A	1+ A	1	0	1	0	1+ A	0	0
Firefly	3	2	1+ A	5+ A	7	3	4	2	2	5
SGO	5	6+ A	7	3+ A	3	6	6	6	8	5

A=1 represents equal results generated

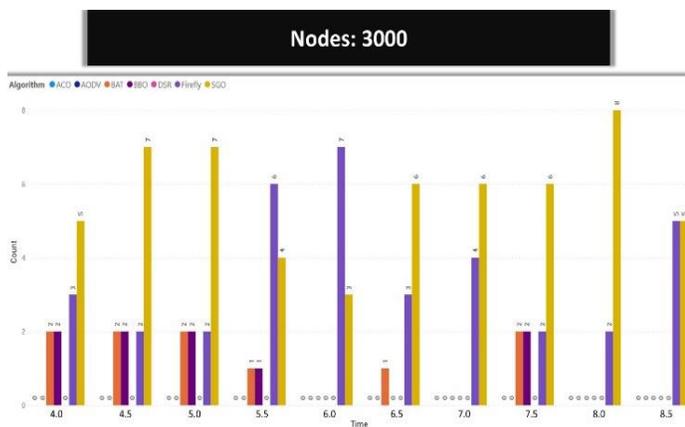

Fig. 4. Graphical Presentation of 3000 Nodes in Client Wireless Mesh Networks.

C. Comparative Performance of 4000 Node Client Wireless Mesh Networks

Table IV shows the architectural design of 4000 nodes of Client Wireless Mesh Network along with 6 algorithms in given time constraints of 5.0,5.5,6.0,6.5,7.0,7.5,8.0,8.5,9.0,9.5, and 10.0 seconds. During implementation and results analysis, SGO outperformed ACO, DSR, AODV, BAT, BBO, and Firefly. ACO, DSR, and AODV failed to identify the path as the number of nodes increased, suggesting that these two approaches cannot perform for bigger networks. For the time constraints 5.0,6.5,8.0 and 9.5 BBO, BAT and Firefly have produced equal minimal route cost paths for once. SGO in the same time constraints produced the best results 30 times. For a time constraint of 5.5 seconds, BBO and BAT were able to discover a route but did not produce the shortest path. On the other hand, the optimal path produced by SGO is 8 times and

Firefly 2 times for the same time intervals i.e. 5.5 seconds. For time constraints 6.5 and 7.0 seconds SGO discovered route 9 times, firefly 1 time each. BAT and BBO, on the other hand, were able to discover a route but not an optimal one. For a total of 100 trials, SGO outperforms 76 times, followed by Firefly 28 times, BAT 4 times, and BBO 1 time excluding the same route discovery cost. It illustrates how, as SGO is implemented in a larger network with greater time constraints, its performance improves, yielding the optimal shortest path.

Fig. 5 shows the graphical representation of the simulation results implemented using MATLAB.

TABLE IV. ARCHITECTURAL DETAILS OF 4000 NODES CLIENT WMN SCENARIOS

Time Constraints											
Algo	5.0	5.5	6.0	6.5	7.0	7.5	8.0	8.5	9.0	9.5	10.0
ACO	---	---	---	---	---	---	---	---	---	---	---
AODV	---	---	---	---	---	---	---	---	---	---	---
DSR	---	---	---	---	---	---	---	---	---	---	---
BBO	A	0	0	A	0	0	1+ A	0	0	A	A
BAT	1+ A	0	0	A	0	0	1+ A	0	0	1+ A	1+ A

VI. CONCLUSION

Wireless Mesh Network is dynamic because nodes are free to move in any direction. As the node's changes, the structure of the network also changes along with them. Due to network changes, there comes a high probability of route variation between source and destination. This route variation causes a loss of information between nodes and however it is difficult to get the optimized results in less time. Thus, there is a need for a

routing approach that can discover the optimum route quickly even if there is any fault in a specific path. To overcome this problem some soft computing-based approaches can be integrated into Wireless Mesh networks which can help to get optimal results within the given time constraints. This article proposes a new SGO based new Routing approach for wireless mesh networks. The proposed approach was tested and implemented in MATLAB on different network scenarios. The performance of the proposed approach was compared with 6 other algorithms (ACO, AODV, DSR, BAT, and Firefly) on the bases to calculate a minimal cost path. The result analysis shows that SGO based routing approach outperforms the other 6 algorithms on network architecture greater than 1000 nodes. Thus, with all the computational results and analysis, we conclude that SGO based routing approach is the best-suited dynamic near shortest path approach amongst all 6 algorithms discussed.

#### ACKNOWLEDGMENT

I would like to express my very great appreciation to Dr Amar Singh for their valuable and constructive suggestion during the planning and development of the research work. This paper and research behind it would not have been possible without their guidance. His enthusiasm and knowledge have always been an inspiration to me. I wish to acknowledge the help and support provided by Lovely Professional University and my colleagues.

# A New Combination Approach to CPU Scheduling based on Priority and Round-Robin Algorithms for Assigning a Priority to a Process and Eliminating Starvation

Hussain Mohammad Abu-Dalbouh

Department of Computer Science, College of Science and Arts, Qassim University, Unaizah, Saudi Arabia

**Abstract**—The main purpose of an operating system is to control a group of processes, through a method known as CPU scheduling. The performance and efficiency of multitasking operating systems are determined by the use of a CPU scheduling algorithm. Round-robin scheduling is the best solution for time-shared systems, but it is not ideal for real-time systems as it causes more context shifts, longer wait times, and slower turnaround times. Its performance is mostly determined by the time quantum. Processes cannot have priorities set for them. Round-robin scheduling does not give more critical work greater consideration, which may affect system performance in solving processes. On the other hand, a priority algorithm can resolve processes' priority levels. This means that each process has a priority assigned to it, and processes with highest priority are executed first. If which process should come first and the process waiting time in CPU are not considered, this can cause a starvation problem. In this paper, a new CPU scheduling algorithm called the mix PI-RR algorithm was developed. The proposed algorithm is based on a combination of round-robin (RR) and priority-based (PI) scheduling algorithms for determining which tasks run and which should be waiting. The disadvantages of both round-robin and priority CPU scheduling algorithms are addressed by this novel algorithm. When using the proposed mix PI-RR algorithm, the performance measures indicated improved CPU scheduling. Other processes should not be affected by the CPU's requirements. This algorithm helps the CPU to overcome some of the problems of both algorithms.

**Keywords**—Average turnaround time; average waiting time; utilization; performance measures; operating system; process

## I. INTRODUCTION

People can shop, learn, arrange appointments, play games, and more due to technological advancements such as mobile phones and computers. Because humans are typically unable to utilize and maintain these devices due to their complexity, operating systems have emerged to address these issues [1], [2]. They are best described as a link between the user and the computer hardware that makes managing and controlling the computer system easier. Both the user and the system benefit from the services provided by operating systems [3]. On the user side, they provide user interfaces and assist in the implementation of programs, file management, and information exchange with other computers, while on the system side, they allow multiple users to share resources and protect system resources [4], [5].

In a multitasking context, CPU scheduling is a critical duty for an operating system. A ready queue is maintained when more than one procedure needs to be executed. In a two-processor system, each processor has its own ready queue. The operating system chooses a process from a list of those in the ready queue, and assigns the CPU to it based on an algorithm [6], [7]. To ensure fairness and avoid hunger while allocating CPU to processes, close attention is essential. When making scheduling decisions, the aim is to keep the average waiting time, average turnaround time, and number of context flips as low as possible.

The operating system is in charge of managing the computer's hardware and software resources, as well as performing many functions. Processor scheduling is regarded as a fundamental task. All resources are scheduled before they are used, so they are available to processes when they are needed and at a new stage in the process life cycle [8], [9]. A short-term scheduler (STS) [10] selects a process from the ready queue for implementation, and scheduling is the essential function of the operating system in a computer system. These algorithms are used to schedule tasks in the CPU; each one outperforms the others in some performance metrics, and has its own set of benefits and drawbacks [11].

The job of a CPU scheduler is to select a process from a memory list of ready-to-run processes. In the following situations, the CPU scheduling choice for a scheduler must be made:

- Switch a process from running to ready state.
- Switch a process from waiting to ready state.
- Send a process to terminate state.

The success of the scheduler is decided by an algorithm. High-quality CPU scheduling algorithms rely on maximize usage rate, throughput, turnaround time, waiting time, and response time. In multi-processing systems, the user executes multiple applications at the same time, each of which contains multiple processes that require the CPU to complete its responsibilities, but only one process can acquire the CPU at a time. As a result, CPU scheduling is required, which allows one function to use the CPU while another waits for other resources, improving management reliability and efficiency [12]. One of the most significant components of the device is

the CPU. Because most operations rely on it, we must maximize its usage and throughput, while reducing turnaround time, waiting time, and response time. CPU scheduling techniques, which control how processes enter the CPU, can meet all of these requirements [13]. There are numerous scheduling algorithms, each of which is implemented in a unique way. The FCFS algorithm, for example, assigns the CPU to the first person who arrives. The SJF algorithm allocates the CPU to the shortest task. The round-robin algorithm assigns a time quantum to each process, calculates its working time in the CPU, then leaves the process and permits another to run. According to their priority, the priority algorithm [8] determines which processes are allowed to access the CPU. Many issues might arise during the execution of scheduling algorithms [14].

This paper proposes a mix priority and round-robin algorithm (mix PI-RR algorithm) for assigning a priority to a process and eliminating starvation. This algorithm has the optimal advantages of both priority and round-robin algorithms. The rest of this paper is organized as follows: Section II presents the literature review. In Section III, the proposed algorithm is discussed and a flowchart is presented. In Section IV, present the discussion and conclusion in the final section.

## II. LITERATURE REVIEW

To discover the best CPU algorithm for a given procedure, it is possible to compare the three CPU algorithms based on their waiting times. Each algorithm has been extensively tested and the outcomes compared. In [15], the researchers developed an improved round-robin scheduling approach based on the clustering algorithm, which combined the advantages of prioritizing short operations with low round-robin scheduling overheads to reduce the average waiting time and turnaround time. Using the k means technique, similar processes were clustered. These researchers employed the CPU scheduling approach in [16] to create a fast system with fewer resources. They were able to improve the algorithm's efficiency and reduce its runtime. The various scheduling algorithms were designed and implemented by them. In [17], the researchers recommended scheduling techniques to increase the operating system's real-time performance.

In [18], the round-robin scheduling algorithm's time quantum concerns were addressed. The researchers developed the smart job first dynamic round-robin technique. Using a dynamic time-quantum technique, the program required the CPU schedule to sort processes in ascending order based on burst time, assign system priority, and calculate a smart priority factor (SPF) for each process. The team created a simulator to evaluate the proposed algorithm.

In [19], the researchers released an enhanced version of the Fittest Job First Dynamic Round-Robin algorithm (FJFDRR), which incorporates the process arrival time as an algorithmic element that various queues handle. The suggested approach was compared against current scheduling algorithms in four test cases using the ATAT, AWT, AR, and CS metrics. Based on the number of processes provided, the statistics demonstrated that the suggested technique had the best appropriate context switch rate.

The researchers presented the Enhanced Round-Robin (ERR) algorithm in [20], which aims to increase CPU performance by reducing the average waiting time and turnaround time. In three separate scenarios, the suggested algorithm was compared to the RR and IRR algorithms. The findings revealed that this approach performed better by reducing the average WT and average TAT.

The researchers suggested the Modified Priority Preemptive Scheduling Technique as a novel CPU scheduling algorithm in [21]. Priority pre-scheduling is implemented in a cyclical manner by the algorithm. The results indicated that the novel technique handled the starving problem, while also improving the speed of the standard preemptive algorithm.

In [22], the researchers proposed an approach for managing loads and prioritizing selection of tasks.

The SJF algorithm must be used to rank jobs, followed by the RR algorithm for execution. The findings demonstrated that the ad hoc algorithm prioritizes higher priority jobs and executes them rapidly, while contextual switching is reduced for low priority processes, reducing the options between RR and SJF.

In the Cyber-Physical System, the researcher presented a scheduling strategy for high-priority random jobs [23]. A fog group is used in idle time to process the most recent available time and execution time before assigning the system to a random high-priority task. This method speeds up the dispatch of high-priority random jobs, allowing them to be performed more quickly.

A number of CPU scheduling algorithms have been developed in recent years to ensure predictable processor allocation. Often, the best features of each algorithm have been combined to create the ideal algorithm for a given situation. The upgraded round-robin (IRR) CPU scheduling algorithm, invented by Mishra, is an improved round-robin scheduler. It is comparable to round-robin (RR), but is a little better [24]. IRR chooses the first process from the ready queue and gives it the CPU for up to one QT. When a process completes its QT, it checks the remaining CPU burst time of the presently executing process.

## III. PROPOSED ALGORITHM

The round-robin algorithm does not consider the importance and significance of processes; it simply solves the queue, so the process order that the CPU performs causes a decrease in the CPU efficiency. The priority algorithm has some disadvantages because it solves the process priority for which process come first, so it performs the process with the highest priority and does not consider the arrival time or size of the process. It also ignores CPU bursts that can cause starvation. Therefore, this study created a mix of the two previous algorithms to decrease the disadvantages for the operating system environment. Mix PI-RR algorithm and flowchart of the proposed Mix PI-RR algorithm is shown in "Fig. 1 and 2".

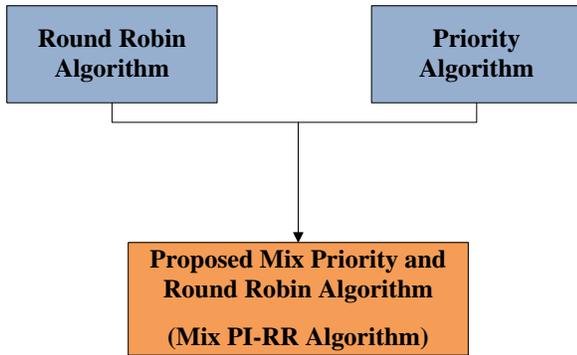

Fig. 1. Mix PI-RR Algorithm.

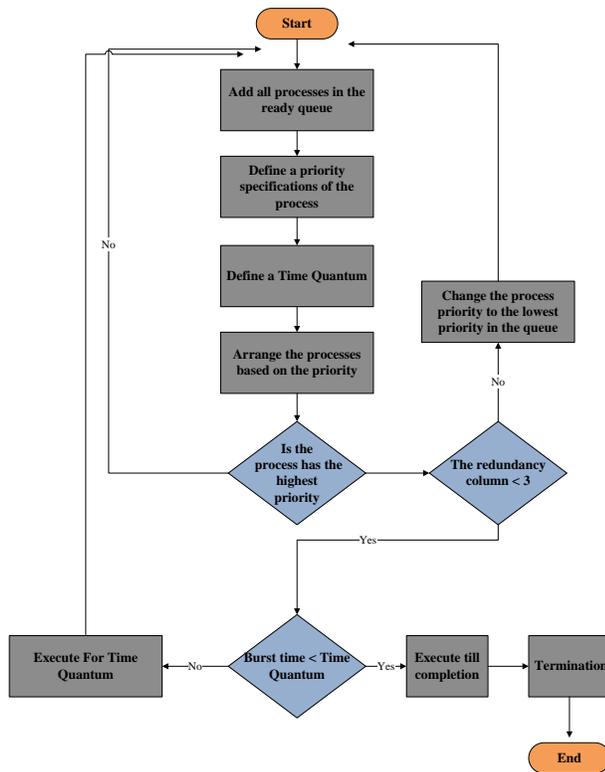

Fig. 2. Flowchart of the Proposed Mix PI-RR Algorithm.

The proposed algorithm adds two more columns to the original columns in the round-robin as follows:

**Priority column:** The CPU gives some processes higher priority than others. The number of times to repeat this is listed in the second column. If the procedure is prioritized three times then, in the central processing unit, the original priority is updated and the lowest priority is assigned. Following this, the processes will be carried out in accordance with the arrival time of the central processing unit (CPU). Finally, when the CPU receives the lowest priority process, the priority will be activated again. Then, it will be implemented three times before being assigned the lowest priority in the central processing unit (CPU).

**NOTE 1:** If more than one process had the same priority after a change, we looked at the redundancy column, and then we implemented the process with the fewest repetitions.

**NOTE 2:** If they were equal in the redundancy column, the arrival time to the central processing unit was taken. To break ties, processes with equal priority were completed on a FCFS basis.

**NOTE 3:** If a process was running and another process arrived with the highest priority, it did not interrupt the work of the process, but waited until the end of the quantum time.

#### IV. DISCUSSION

Preparing a successful proposal for a newly inspired algorithm in such a pure field is not a simple undertaking. Given the difficulties of this research topic, it was necessary to propose a new optimization technique with novel aspects. Apart from the innovation, the authors' findings were supported by a dataset and a comparison of some criteria between algorithms. As a result, the three samples from the literature were utilized as examples in this study, and the average TAT and average WT of both the proposed and presented algorithms were compared. The average TAT and average WT are examined and compared to the current round-robin scheduling algorithm in different cases. Some scenarios were demonstrated, the results of each iteration were studied, and the final outputs were compared using the round-robin algorithm to verify the quality and efficiency of the suggested mix PI-RR algorithm.

**Sample 1:** The first dataset, which contained seven processes, was used in this sample from the benchmark datasets used in the studies. In addition to explaining how the suggested algorithm works, this research developed a Gantt chart for the method. For the following collection of processes, Table I shows the length of the CPU-burst period in milliseconds. We assigned the time quantum as 3 ms for each process. Tables II and III show gantt chart of sample 1 and turnaround time and waiting time of sample 1, respectively.

Sample 3: For the following collection of processes, Table VII shows the length of the CPU-burst period in milliseconds. We assigned the time quantum as 5 ms for each process, which contained ten processes. Tables VIII and IX show gantt chart of sample 3 and turnaround time and waiting time of sample 3, respectively.

Scheduling is a fundamental operating system feature. Almost all computer resources are pre-programmed before they are used. One of the most important computer resources is the central processing unit (CPU). Its scheduling is crucial to the architecture of an operating system. Which processes run and which processes wait are determined by CPU scheduling. CPU

scheduling is critical because it has a significant impact on resource usage, system performance, and CPU efficiency. Process execution is made up of a cycle of CPU execution (CPU burst) and I/O wait (I/O burst), with CPU burst coming first, then I/O burst, then another I/O burst, and so on. The most recent CPU explosion ends with a system request to stop the process.

Due to their significant waiting time, long response time, large turnaround time, and low throughput, existing round-robin CPU scheduling algorithms cannot be used in real-time operating systems. Furthermore, existing priority CPU scheduling algorithms are inadequate for real-time operating systems since they create starvation, and do not take into consideration which processes come first and the time spent waiting for them to run in the CPU.

The proposed mix priority and round-robin algorithm (mix PI-RR algorithm) is an algorithm that obtains the optimal advantages of both priority and round-robin algorithms. Round-robin scheduling does not give any process priority or additional consideration based on other processes, and processes cannot have priorities set for them. Therefore, delayed execution of important processes may affect the performance of the whole system. On the other hand, in the priority algorithm, each process is assigned a priority. Processes with highest priority are executed first. However, this occurs without taking into account which process comes first and the time the process has been waiting in CPU to run, and this can cause starvation. Therefore, this paper introduced the mix PI-RR algorithm to assign a priority to important processes, without causing starvation.

The average waiting and turnaround times depend on the number of processes in the ready queue; as number of processes increases, time cost increases. In addition, long burst times of the processes increase the time cost. To emphasize the efficiency of the proposed algorithm, samples datasets varying in number and burst times of processes are used. The proposed mix PI-RR algorithm enhances CPU performance in general, the results revealed that wait time and turnaround time were reduced. Furthermore, the CPU algorithms enabled the user to obtain good results without increasing the time. Tables X and XI show the average turnaround time and average waiting time of the proposed mix PI-RR algorithm and current round-robin algorithm. As observed from the average turnaround time and average waiting time, the performance of the proposed mix PI-RR algorithm was better than the current round-robin algorithm. It is clearly observed that average turnaround time and average waiting time of the processes are optimum for proposed Mix PI-RR algorithm compared to round robin fundamental algorithm. The comparison between the proposed mix PI-RR algorithm and the current round-robin algorithm is shown in “Fig. 3 and 4”.

## V. CONCLUSION

The algorithm presented here outperforms several other algorithms; in general, it outperforms the RR and priority-based methods. No algorithm is ideal in every circumstance. It is impossible to watch a precise scheduling algorithm in action, yet precise performance can be viewed in real-time operating system operations. Several elements, such as changeable capacity, have a substantial impact on performance. This study introduced a real-time operating system and real-time tasks. We highlighted RR and priority drawbacks like high average turnaround, high context switching, high response time, high turnaround time, and low throughput, as well as the failure to take into account the process that should be first and how long processes have been waiting. After analyzing RR and priority algorithm’s performances and drawbacks, we proposed a new algorithm, named mix priority and round-robin (the mix PI-RR algorithm), which deals with the drawbacks of simple round-robin and priority algorithms. This new approach performed better than a simple RR and priority, by taking the best features of each algorithm and combining them to create the ideal algorithm for a given situation in terms of average waiting time and average turnaround time. This study justified the mix between priority and round-robin to help the CPU overcome indefinite blocking or starvation (leaving some lower priority processes waiting in CPU) in priority algorithms, and using queue up to solve the processes regardless of the importance and priority of the process for the CPU in the round-robin

algorithm. The results of this evaluation highlight ways in which instructional material should be clarified. It will be important for the proposed algorithm to be more efficient and effective than current CPU scheduling algorithms. Finally, further research is needed to compare it with other algorithms. In future work, simulations of CPU scheduling strategies are recommended. The most efficient way to evaluate a scheduling algorithm is to code it and include it in an operating system; then, the algorithm's correct working capabilities can be determined in real-time systems. Further research and studies in the future should be carried out to discover other scheduling algorithms that are optimal in certain situations and, hence, deliver the highest level of user satisfaction.

**Abstract**—This paper concentrates on proposing a newly effective control approach to ensure the balance of an inverted pendulum (IP) system consisting of a free-rotational rod and a small cart. The novel idea is to create an effective integration between a PD-like fuzzy logic architecture and a modified genetic algorithm (mGA). The mGA is executed with an appropriately fast optimization as an initial phase in dealing with optimizing scaling factors of the fuzzy logic controller. There are totally six meaningful scaling factors corresponding to two fuzzy logic controllers applied in the balance control system of the IP. These six scaling coefficients are highly significant to strongly affect control quality of the system applying such a PD-like fuzzy logic control methodology. Excellent results obtained in terms of numerical simulations compared with those of both the conventional PID and existed fuzzy logic counterparts as well as practical experiments implemented in a real IP topology verify the promising applicability of the new control methodology proposed in this study.

**Keywords**—mGA; inverted pendulum (IP); balance control; scaling factors; optimization

## I. INTRODUCTION

It should be obvious that controlling an inverted pendulum (IP) system to be balanced at a desirable position of the rod embedded in the model is one of the most traditional control problems [1-3]. This control approach is highly significant to a various number of nonlinear control strategies such as control of transport machines needing to balance things, robot technology, and even launch direction of missiles. Naturally, the IP system has been usually used to testify the applicability of new control strategies.

Recently, intelligent controllers, i.e. fuzzy logic – based regulators have been increasingly developed to replace with conventional counterparts such as PI (proportional integral) and PID (proportional – integral – derivative) in dealing with nonlinear and/or uncertain control systems [4-10]. Fuzzy logic technique has been considered to be highly suitable for these types of control plants due to its operation principle depends only on knowledge and experiences of experts to handle a system. Obviously, the better understanding of the system we have, the more effective operation of a control strategy based on fuzzy logic model we can obtain [11-13].

This work concentrates on applying fuzzy logic – based control strategy which was presented in [5] to design intelligent

controllers, carrying out the balance of an IP system. Since an IP system is a multi-input multi-output (MIMO) system and the balance control problem should be solved by suitable controllers, the PD-like fuzzy logic control methodology has been selected. Technically, such a fuzzy logic controller has two inputs, error and derivative of error, and one output. Corresponding to these inputs and output, there are three scaling factors which strongly affect control quality of the system need to be determined in an effective manner. This mission is able to be successfully executed by using an appropriate optimization method. Metaheuristic optimization techniques [14-18], such as GA and PSO, have been completely capable of dealing with the determination of three scaling factors.

When applying a number of aforementioned biology-inspired optimization techniques, e.g. GA, it should be clear this is a time-consuming procedure. To find an optimal solution corresponding to a set of scaling factors for the fuzzy logic controller effective for the IP's balancing control, this is a fact that the duration is frustrating to operators. The new contribution of the current paper is to find a possible way to reduce this time period. The authors propose a hybrid procedure to initialize the GA mechanism by means of a faster optimization technique [15], e.g. Salp Swarm Optimization Algorithm (SSOA). This optimization mechanism is used to initially create a set of closed-optimal parameters as first phase of the GA. It is denoted modified GA (mGA) procedure and will be used to determine scaling coefficients of the two controllers embedded in the balance control for the IP: cart's position and pendulum's rotational angle ones. Simulation processes and experiments in a real model will be implemented to demonstrate the feasibility and applicability of the control scheme proposed in this study.

The rest of this paper is organized as follows. Section II presents an overview of related works to the IP's balance control. Section III will briefly create a mathematical model of an IP system which is helpful to design balance control strategies. Next, Section IV focuses on proposing a novel GA technology modified from a typical one. A control strategy applying such a modified GA mechanism will also be provided in Section V for solving the IP's balancing problem. Section VI concentrates on testifying the control strategy proposed in both simulation and experiment scenarios. Eventually, the conclusion and future work raised from this study will also be provided in the last section.

## II. RELATED WORK

Studies on IP systems, especially on the balancing control problem, have been conducted by a lot of researchers around the world. In [1], the authors investigated several traditional control strategies i.e. PID, LQR, Pole placement and Fractional PID to control the position of the pendulum's rod as well as cart via a number of simulations implemented in MATLAB software. Reference [2] introduced a comprehensive illustration from the past to current approach of nonlinear control theory for the IP system, focusing on robust control methodology. The classical PID regulators had been used for a linear inverted pendulum system in cooperation with the GA mechanism which was embedded to tune PID's parameters [3]. In [19], the conventional PID, LQR together with MPC (model predictive controller) –based schemes were applied in dealing with the IP's balance control. The authors in [20] proposed a Sugeno - based fuzzy parallel distributed compensation regulator to control a nonlinear IP model with demonstration on MATLAB simulations. In almost reports conducted on the IP balance control, the control methodologies might not be sufficient in terms of their applicability and effectiveness concerning both theory and practice. It means that if the studies used conventional regulators such as PID and LQR, the control qualities were not good enough to ensure a high quality control system. In contrast, if the intelligent control approaches e.g. fuzzy logic – based schemes were applied, they had only been employed for the theoretical IP system testified by a proper software such as MATLAB. This work will be addressed by an idea of integration theoretical and practical IP topology. In addition, a novel hybrid intelligent control strategy using fuzzy logic technology integrated with a modified GA in comparison with conventional regulator as well as initial smart controllers will be proposed in this paper.

## III. A MATHEMATICAL MODEL OF THE IP SYSTEM

A dynamic model representing a typical inverted pendulum system is shown in Fig. 1. This model consists of two main parts, i.e. a cart and a pole. The cart is actually a wagon driven by a small DC motor. The pole looks like a rod attached to a weight of mass  $m$ . This pole can be freely rotated by a cart – mounted rotary joint. The system as drawn in Fig. 1 is manipulated by only one force  $F$  taken out by the DC motor.

In order to establish the dynamic model of the inverted pendulum system, taking the second Newton's law of motion the following equation can be obtained:

$$\begin{cases} (M + m)\ddot{x} - (ml \sin \theta)\dot{\theta}^2 + (ml \cos \theta)\ddot{\theta} = F \\ m\ddot{x} \cos \theta + ml\ddot{\theta} = mg \sin \theta \end{cases} \quad (1)$$

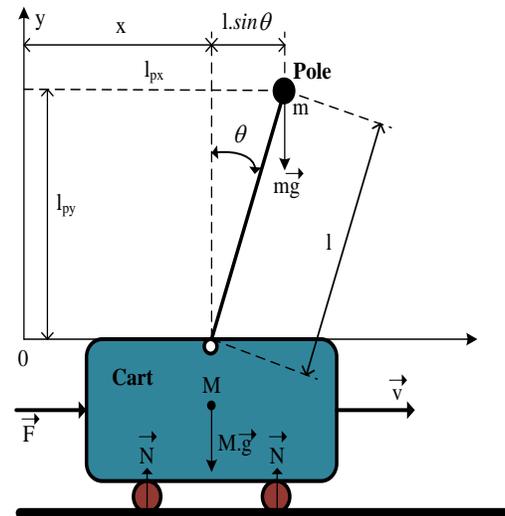

Fig. 1. The Typical Model of an Inverted Pendulum System.

Where  $F$  or  $u$  is the force of motion generated from the dc motor mounted on the cart. The fact that this force is only the control signal to keep the rod to be stable at the equilibrium. From (1), the following can be deduced:

$$\begin{cases} \ddot{x} = \frac{F + (ml \sin \theta)\dot{\theta}^2 - mg \cos \theta \sin \theta}{M + m \sin^2 \theta} \\ \ddot{\theta} = \frac{F \cos \theta - (M + m)g \sin \theta + ml(\sin \theta \cdot \cos \theta)\dot{\theta}}{ml \cos^2 \theta - (M + m)l} \end{cases} \quad (2)$$

The two equations indicated above are usually used to represent the dynamics of the IP system.

## IV. THE MODIFIED GENETIC ALGORITHM - MGA

Considered to be one of the most effective optimization techniques, the genetic algorithm (GA) has been applied for a huge number of optimization problems, including a significant layer of control issues. The balance control problem of the IP system is exactly suitable in using this optimization mechanism.

Typically, the conventional GA technique is presented in Fig. 2. The core idea for the GA came from the principles of biology relating to the theory of genetics and natural selection, an alternative name of the theory of natural evolution invented by Charles Darwin. This theory mainly focuses on a natural phenomenon in which the reproduction of the fittest individuals which are selected to replace the other ones must be implemented. The production of new generations, so-called offsprings, reflects the evolution of nature. Developed by John Holland and his colleagues, the GA has been inspired by step-by-step of the genetics. They consist of several main steps as shown in Fig. 3. Remember that the first step, normally defined as initialization of parameters for the GA mechanism, is highly important. If this phase is executed in a reasonable manner, it should be possible to dramatically reduce the duration of whole procedure.

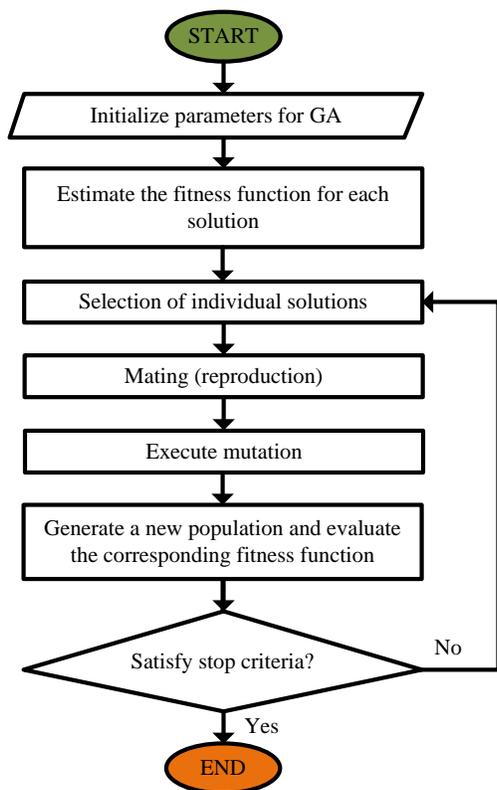

Fig. 2. The Flow Chart of a Conventional GA Technique.

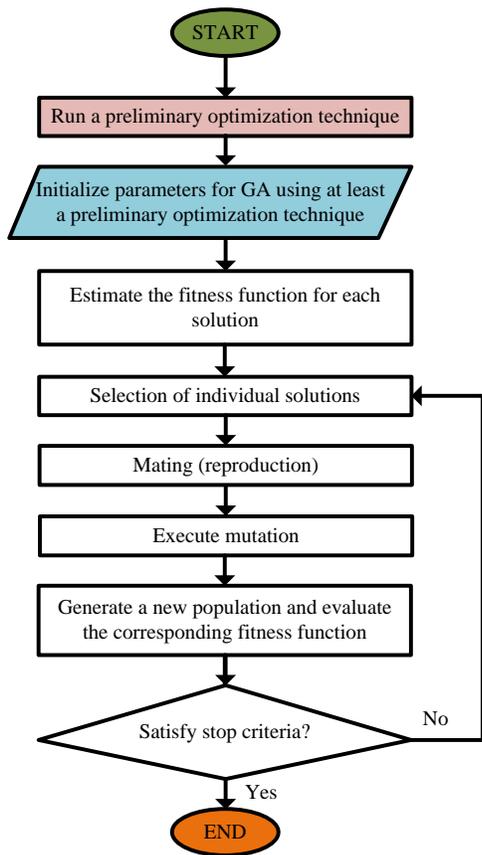

Fig. 3. The Flowchart of the Proposed Modified GA Technique.

In this paper, a modified GA (mGA) mechanism is proposed in order to minimize the period of time regarding the GA execution. An auxiliary phase is added as an initialization of parameters for the GA procedure. As shown in Fig. 3, the mGA is initialized by running a preliminary optimization mechanism. Such an optimization method aims to create initial parameters for the GA applying a possible optimization technique. A feasible method is selection of a faster optimization procedure, i.e. PSO (particle swarm optimization) and Salp Swarm Optimization Algorithm (SSOA) [15]. Theoretically, the PSO or SSOA is a local optimization technique may obtain faster execution time in comparison with the GA mechanism. This statement is also examined and confirmed by numerical simulation experiments. The mission of such a preliminary optimization technique in this aspect is to temporarily find a possible solution to the problem. The result obtained is a set of parameters which is near to local and/or global optimization point. From point of view, this idea can significantly minimize duration performing the GA procedure. Since the GA is a global optimization method, using a preliminary optimization technique to create initial parameters has a meaningful role, reducing significantly executed time. This feasible procedure also ensures the quality as well as convergent rate of the GA mechanism. The next section will verify the effectiveness of the proposed mechanism.

#### V. DESIGN OF AN MGA – BASED CONTROL STRATEGY TO BALANCING THE IP SYSTEM

The balance control of an IP system, considered to be a typical nonlinear control problem, can be successfully solved by applying intelligent controllers such as fuzzy logic regulators. This study is an extended work proposed in [5]. The authors integrate the fuzzy logic architectures presented in [5] with the mGA proposed in the previous section. The novel control methodology is described in Fig. 4.

As shown, the goals of the control issue are to bring the system back to the stable state within acceptable tolerances. This means both the position of the cart and the bias angle of the pole must be manipulated to ensure the balance of the IP system. It is noted that there is only one control signal,  $u$ , which is created from two controllers regarding two feedback parameters, i.e. position  $x$  and rotational angle  $\theta$ . Technically, this control signal must be fed to an actuator which is normally a DC motor. The control signal also needs to be limited because the motor can only operate within certain constraints of parameters such as power, voltage and current. In this work, a permitted range of voltage is applied to the control signal  $u$ .

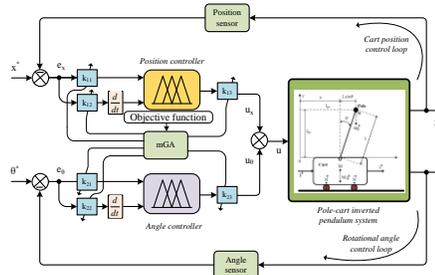

Fig. 4. Proposed Control Strategy for Balancing the IP System using mGA-based Fuzzy Logic Controllers.

The two controllers, position and angle regulators are employing the fuzzy logic architectures as presented in [5]. Since this is a nonlinear balance control problem, the PD-like fuzzy logic model is more suitable than the PI-based one. Remember that each of these PD-like fuzzy logic controllers has two inputs and one output. The two inputs are errors between desired and feedback signals. This study focuses on the vertical position of the pole, so that the desired value for the rotational angle is set to zero. In contrast, the setpoint corresponding to the desired position can be set at any value depending upon a particular control purpose. In this work, several references in accordance with the desired positions will be provided for verification via numerical simulations.

Each of two inputs and one output for an individual fuzzy logic controller as illustrated in Fig. 4 has a particular scaling factor. The fact that is each scaling factor in this aspect absolutely affects control quality of the system, leading to a mandatory requirement of determining it in a good enough manner. This is successfully implemented by means of a strong optimization technique. The modified GA proposed in the previous section is fully suitable in this perspective. Given a possible candidate of objective functions as indicated in the expression below, the proposed mGA can obtain the control quality as desired:

$$f_{obj} = \int (e_x^2(t) + \rho e_\theta^2(t)) dt \quad (3)$$

Where  $e_x(t)$  and  $e_\theta(t)$ , expressed in the following two equations, are position error and angle error, respectively.

$$e_x(t) = x^*(t) - x(t) \quad (4)$$

$$e_\theta(t) = \theta^*(t) - \theta(t) \quad (5)$$

The factor  $\rho$  added in (3) denotes the weighting coefficient for executing the optimization mechanism.

As shown in Fig. 4, there are totally 6 parameters with regard to 6 scaling factors of two fuzzy logic controllers need to be optimized. The new GA optimization technique proposed in the previous section is utilized to determine these scaling factors. The control performance will be testified in the next section through both numerical simulation processes and practical experiments.

## VI. NUMERICAL SIMULATIONS AND EXPERIMENTS

Performing numerical simulations on appropriate software as well as conducting experiments on real models is extremely necessary steps to prove the correctness and feasibility of the proposed control strategy. In this section, simulations applying MATLAB/Simulink will be executed at first to theoretically testify applicability of the new control methodology compared to those of conventional PID regulators [19] as well as fuzzy logic controllers [20]. Simulation parameters are given in Table I and Table II. Two PD-type fuzzy logic controllers used for the IP system have the same structures with the membership functions as well as sets of fuzzy rules. Fig. 5 describes membership functions for two inputs and one output of each fuzzy logic architecture, while Fig. 6 illustrates fuzzy rules in form of a 3-D graph. The rule base can be specifically found in

[6]. Applying the control methodology proposed in Section IV, after executing the mGA procedure, the optimal scaling factors obtained are indicated in Table III.

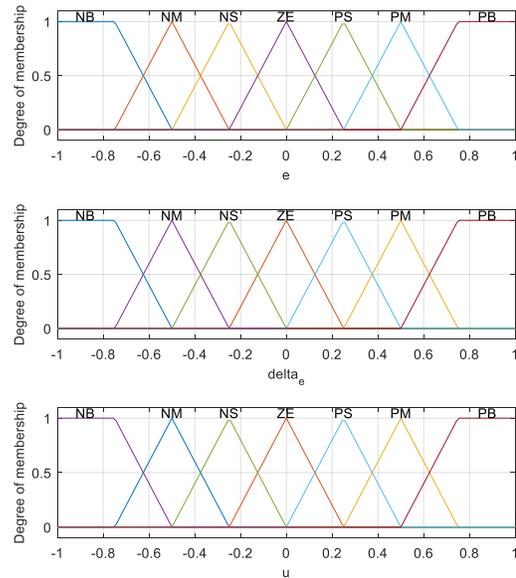

Fig. 5. Membership Functions of the PD – Like Fuzzy Logic Control Architecture.

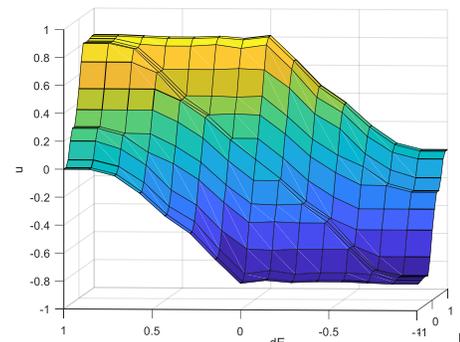

Fig. 6. A 3-D Illustration of the PD-Like Fuzzy Logic Model in Accordance with Rule base given in [6].

### A. Simulation Results using MATLAB / Simulink

With six optimal factors presented in Table III, to verify the feasibility of the proposed control scheme, this work assumes the following three scenarios:

- 1) *Scenario 1*: The desired position of the cart is kept to be constant at 0.1 (m).
- 2) *Scenario 2*: The desired position of the cart is varied in four levels, i.e. 0(m), 0.1(m), 0.3(m) and 0.2(m) at different time instants.
- 3) *Scenario 3*: This should be the most difficult case when the cart's position is supposed to periodically change in the form of a square pulse between 0.1(m) and 0.3 (m).

All three perspectives of desirable cart's positions are plotted in Fig. 7. The results concerning these simulation cases are shown in Fig. 8 to 11. It is noted that in each illustration, both position of the cart and deviated rotational angle are considered to ensure the balance of the system. Moreover, the proposed intelligent fuzzy control strategy is compared with widely-used conventional PID regulator – based schemes [19] and fuzzy logic controller – based counterparts [20] in each simulation scenario.

In the first simulation case, due to the simplest position of the cart when considered as reference of the control system, the settling times for both the angle and position are quite excellent as shown in Fig. 8. Obviously, these durations resulting from the proposed control strategy are much less than two seconds. The results of the conventional PID controllers [19] are apparently greater than three seconds. The control quality resulting from the proposed FLC is also better than that of the FLC presented in [20] as illustrated in Fig. 8. This description demonstrates more feasible performance of the new control strategy proposed in this study.

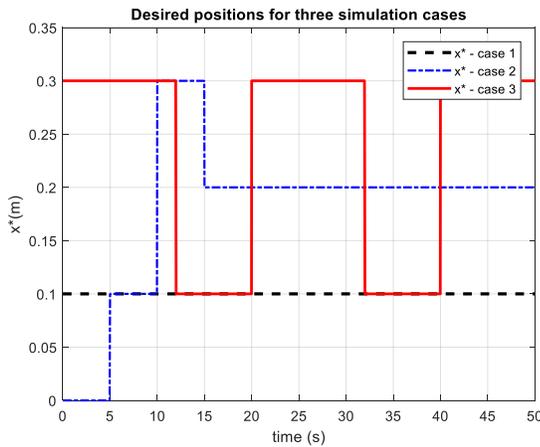

Fig. 7. Three Scenarios of Desirable Positions to the Cart.

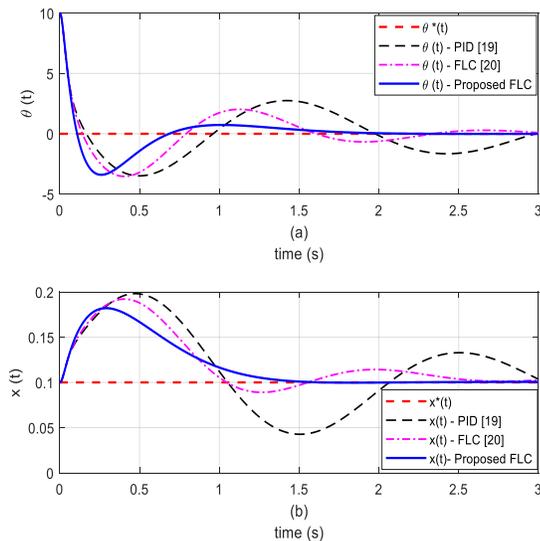

Fig. 8. Simulation Results for the First Scenario.

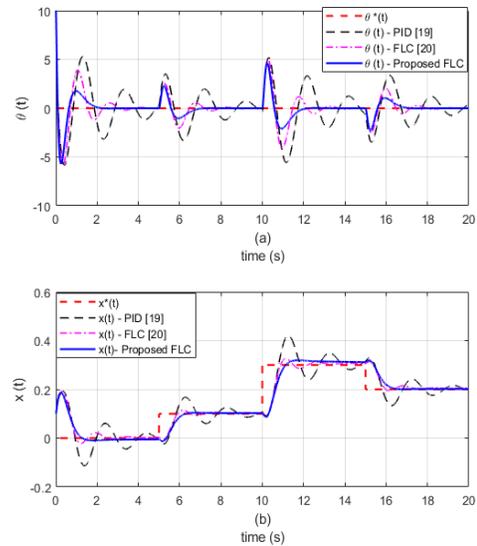

Fig. 9. Simulation Results for the Second Scenario.

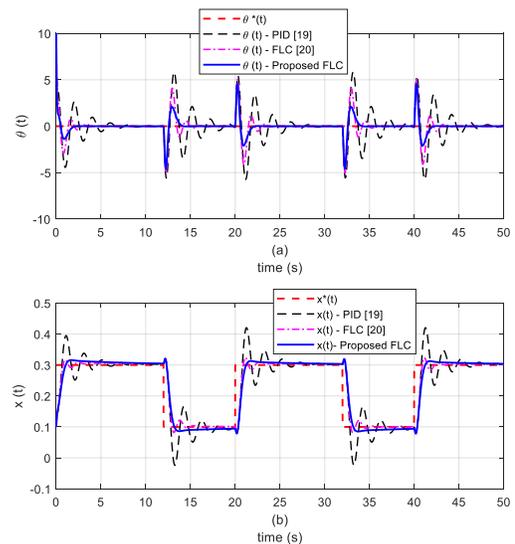

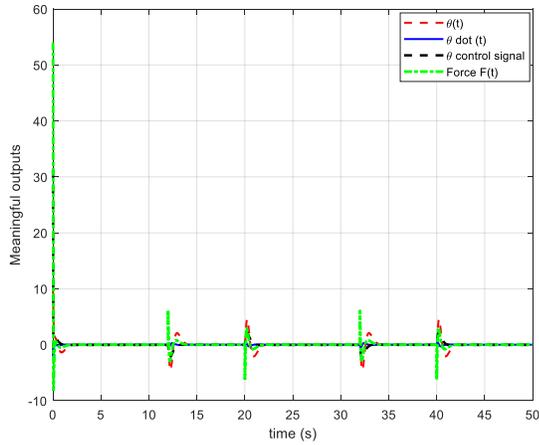

Fig. 10. Simulation Results for the Third Scenario.

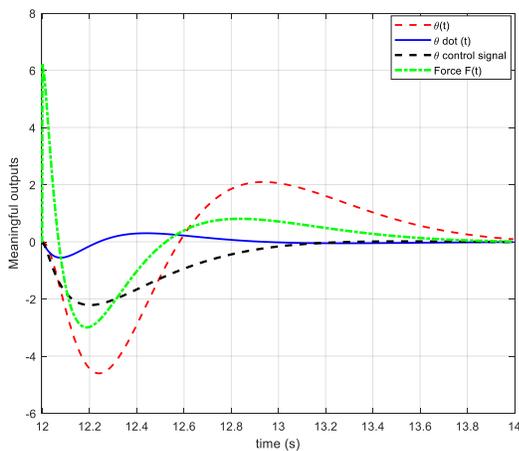

In the last two simulation scenarios as shown in Fig. 9 to 11 which are more complicated than the first case, it is clear that results of the proposed fuzzy logic controllers are still much better than those of the PID controllers [19] and FLC [20]. Even when the desired position  $x^*(t)$  changes periodically as illustrated in Fig. 10, the actual position of the cart is able to track well with good control performances outperforming the conventional PID counterpart. Remember that in this perspective, the deviation angle of the pendulum must be still balanced at the vertical axis, ensuring the original goal of the control problem. In addition to the deviation angle, Fig. 11 shows several control signals such as rotational acceleration, angle control signal, and control force  $F$  fed to a motion DC motor for the third simulation scenario. It should be obvious that these signals tend to be extinguished to zero values, ensuring a stable goal of vertical equilibrium for the pendulum.

### C. Practical Experiments

In an effort to examine the proposed control strategy, a practical IP system has successfully been built. Fig. 13 provides artwork for this practical prototype. With a set of optimal scaling factors obtained from the mGA as indicated in Table III, we address practical experiments on the IP model. Fig. 14 shows the real signals of both the position and angle of the IP system when considering the deviations of the position as presented if the previous simulation scenario. It was found that after transient period, both real signals, in form of transmitted into voltage values, are damped to be closed to zero, verifying the capability of the proposed control methodology.

(a) With Entire Simulation Time.

(b) An enlarged Part.

Fig. 11. Several Simulation Signals for the Third Simulation Scenario Applying the Proposed FLC.

### B. Simulation Results via Python Software

To make a more obvious view verifying control performance of the proposed control strategy, the authors have employed Python software to simulate the balance of the inverted pendulum system in a highly intuitive way as shown in Fig. 12.

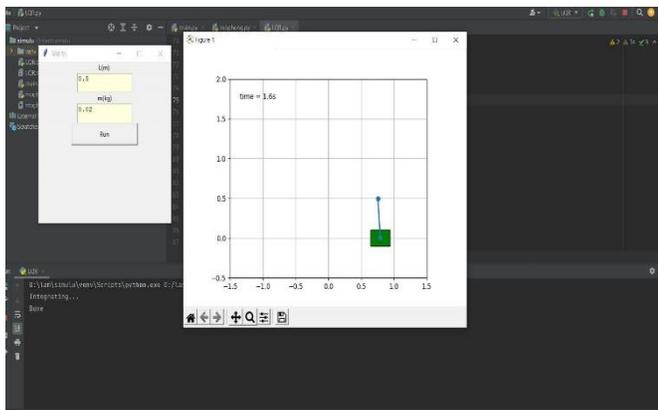

Fig. 12. Python – based Simulation Verifying Control Performances.

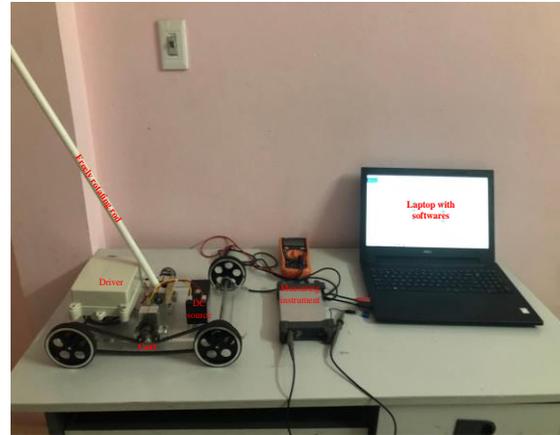

Fig. 13. The Real Model of the Inverted Pendulum System.

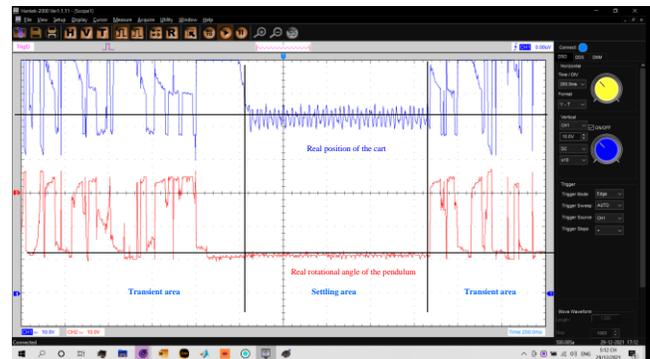

Fig. 14. Real Illustration of the Two Output Variables.

### VII. CONCLUSION AND FUTURE WORK

This study proposed a novel control strategy based on fuzzy logic architecture integrated with an mGA optimization technique to balance an IP system. The GA presented in this work used a faster optimization mechanism to accelerate global convergence, improving control quality of the system. Together with various simulation scenarios executed in MATLAB/Simulink platform, an actual IP system has also been built to demonstrate the efficiency of the control methodology proposed in this paper. Simulation results obtained by means of the proposed fuzzy logic control approach are much better than those of the conventional PID regulators as well as a single fuzzy logic controller, demonstrating the feasibility of this study. One direction to further improve this work as future work is to continue

optimizing membership functions of two fuzzy logic controllers as well as rule base sets. Technically, the mGA proposed will be completely able to carry out this mission. In this aspect, a promising intelligent fuzzy logic – based control strategy can be obtained in dealing with a huge number of complicated control problems, including the IP balancing issue.

APPENDIX

TABLE I. NOMENCLATURE

Symbol	Meaning	Value, [unit]
$M$	Mass of the cart	0.1 [kg]
$m$	Mass of the pole	0.02 [kg]
$l$	Length of the rod (mass omitted)	0.35 [m]
$x(t)$	Position of the cart	[m]
$\dot{x}(t)$	Velocity of the cart	[m/s]
$\ddot{x}(t)$	Acceleration of the cart	[m <sup>2</sup> /s]
$\theta(t)$	Pendulum angle (upright position)	[rad], [degree]
$\dot{\theta}(t)$	Rotational velocity of the pole	[rad/s]
$\ddot{\theta}(t)$	Rotational acceleration of the pole	[rad <sup>2</sup> /s]
$F$	Variable force exerted on the cart	[N]
k11, k12, k13	Scaling factors of the fuzzy logic – based position controller	N/A
k21, k22, k23	Scaling factors of the fuzzy logic – based angle controller	N/A

TABLE II. PARAMETERS TO EXECUTE THE MGA TECHNIQUE

No.	Symbol	Meaning	Value
1	$N_{max}$	Maximum value of generations	1000
2	$N_{pop}$	Population size	20
3	$N_{var}$	Number of variables	6
4	$H_c$	Upper constraint	100
5	$L_c$	Lower constraint	0
6	$cr$	Crossing factor	0.6
7	$mt$	Mutating factor	0.4

TABLE III. OPTIMAL SCALING FACTORS FOR TWO FUZZY LOGIC CONTROLLERS APPLYING MGA TECHNIQUE

Symbol	Type of controller
k11 = 12.154; k12 = 4.572; k13 = 1.245	Angle fuzzy logic controller
k21 = 6.798; k22 = 7.923; k23 = 0.865	Position fuzzy logic controller

# Application of Affective Computing in the Analysis of Advertising Jingles in the Political Context

**Abstract**—Affective computing is an emerging research area focused on the development of systems with the ability to recognize, process and simulate human emotions in order to improve a user's experience in an interactive system. One of the possible fields of application of affective computing is marketing and advertising, where the application of emotion analysis techniques on the opinions made by users in different contexts has been evidenced, being a challenge the analysis of different types of multimedia content, such as advertising jingles. Thus, in this article we propose as a contribution the development of an emotion analysis study on the advertising jingles of the main candidates for mayor of Cartagena-Colombia in the period 2020-2023. For the development of this study, the acoustic properties of arousal and valence present throughout the audio track of each advertising jingle were taken into consideration, in such a way that through these properties it is possible to classify an audio fragment into an emotion belonging to the circumflex model or Russell model. To perform the segmentation of the audio track and the extraction of the acoustic properties of arousal and valence, we developed the MUSEMAN tool, which allows determining the emotions fluctuation in the advertising jingle audio track.

**Keywords**—Affective computing; advertising jingles; emotion analysis; arousal; valence

## I. INTRODUCTION

One of the most effective means of promoting products, services and even political campaigns is advertising jingles. These are broadcast on radio networks, television channels, web portals and social networks in order to promote the use of a product or service or motivate the intention to vote for a candidate [1]. Given that advertising jingles comprise an audio component, it is possible to analyze the emotionality present during the audio track using the methods and techniques provided by affective computing [2]. Research in affective computing focuses on systems being able to interpret the emotional state of a human and obtain or provide an appropriate response in real time to the identified emotion [3]–[7], which can be used to improve the interaction of a user with a service, content, or specific product [8].

A common approach to detecting emotions in acoustic content is the circumflex model, or Russell's model, which proposes to represent emotional states in two dimensions [9]–[11]: The horizontal dimension (x-axis), called valence, expresses the degree of positivity or negativity of the emotion

(pleasure/displeasure), and the vertical dimension, called arousal, indicates the degree of excitement of the emotion (arousal-relaxation) [12]. Emotions can therefore be defined in regions within the emotional plane as a combination of valence and activation [13], [14]. In detecting emotions in music, the arousal value represents the intensity and activity in the course of an audio track, so that fast tracks and loud sounds will have a high arousal value, while tracks with a softer sound and slower tempo will have a low arousal value. Valence thus represents the acoustic property that describes the positivity present in an audio track, i.e. tracks with a positive valence are associated with emotions such as joy, euphoria, and happiness, while tracks with a negative valence correspond to emotions such as sadness, depression, or anger [15]. In this way, from the musical properties of arousal and valence of an audio track, by mapping them in the emotional plane it is possible to obtain the trigonometric angle and the emotion associated with the Russell model, thereby avoiding taxonomic ambiguity [16].

Based on the above and taking advantage of the advantages provided by the acoustic properties of arousal and valence, in this article we proposed as a contribution the development of a study based on emotion analysis on the advertising jingles of the candidates for mayor of Cartagena-Colombia for the period 2020-2023, in which the extraction and segmentation of the audio of each jingle was performed in order to obtain the emotion associated with each segment taking into account the Russell model and with the aim of obtaining the trace of emotions of each jingle. To carry out the above process, the MUSEMAN (Music Emotion Analyzer) tool was developed in Java language, which allows automating the above-mentioned analysis process using free libraries and technologies (FFmpeg, openEAR and JFreeChart). The FFMpeg tool allows the extraction and segmentation of the audio track into fragments of 5 seconds or less. The openEAR tool was used in the background and allows obtaining the acoustic variables of arousal and valence for a given audio fragment, which allow classifying each fragment in Russell's two-dimensional model. Finally, the JFreeChart library was used to generate the emotion trace graph for each jingle, as well as to generate the spider web graph with the distribution of emotions for each jingle. Thus, the present proposal has as a contribution with respect to other works of the state of the art the application of affective computing in the analysis of advertising jingles in the political context, as well as the automation of the process of analysis of emotions in multimedia audio contents. The

approach proposed in this article is intended to support content creators in the objective design of the emotions communicated in multimedia advertising content, in order to generate greater interest in the audience.

The article is organized as follows: Section 2 describes a set of related works that were taken into account for the development of the present research; Section 3 presents the materials and methods used for carrying out this research study; In Section 4, the results of the analysis performed on the advertising jingles of the candidates for mayor of Cartagena de Indias using the MUSEMAN tool, are presented; and finally, Section 5 reports the conclusions and future work derived from this research.

## II. RELATED WORK

In previous work, the following proposals are found. In 2021, Sánchez-Barragán et al. [17] propose a music content recommendation system, which has as input the affective profile of the user determined from the sentiment analysis of the comments made through the social network twitter. In 2020, Russo et al. [16] presented a system based on images of cochleograms for the detection of affective musical content, first using Russell's model in combination with a convolutional neural network to extract the relevant musical characteristics. In 2019, Chmulik et al. [12], evaluated different selected acoustic characteristics using Russell's model (2-D emotional model). For comparison, they applied two-dimensional cepstrum (TDC), MIRToolbox (Matlab), Linear Prediction (LP) analysis, on a support vector regression (SVR) model. Also in 2019, Panwar et al. [18], studied the impact of emotions transmitted by music broadcast by radio channels, by mapping a function to transform music from radio channels into emotions. For the above, Thayer's plane of arousal and valence was used [19] and a linear regression model was applied to predict the values of music on the emotional plane. In addition, the mapping of emotions was performed at different times in various cities in the United States, obtaining a window for marketing with music and thus directing the different advertising messages in specific slots. In 2019, García et al. [20], an emotion analysis study based on data mining was carried out on the tweets generated in Mexico related to the 2017 earthquake. In addition to detection of the primary emotions, the study sought to identify the evolution of emotions over time and the patterns of propagation by comparing two datasets, one containing tweets with the word "earthquake" and the other that included a mention of the emergency mechanisms. The study was able to conclude that the sentiments most widely propagated independent of the dataset were anger and joy. In 2019, Chanchí and Cordoba [2], a study of emotions and sentiments was carried out on the speech of the signing of the peace agreement. The analysis was performed by extracting the emotions during the audio track, making use of the arousal and valence variables in each subsegment of the track. Sentiment analysis was performed by studying the text of the speech through the service provided on the ParallelDots platform. This study was able to determine concordance between the motionality of the audio track and the polarity of the text of the speech. In 2018, Mäntylä et al. [21], a review of the literature was carried out on 6996 Scopus papers on the subject of sentiment analysis, making use of data mining

techniques. The study concluded that work carried out at the beginning of the 21st century was focused on studies of public opinion. However, the theme of sentiment analysis acquired a greater diffusion from 2004 with the evolution of the web and the content generated and published by users in this. According to the results of the study, sentiment analysis has currently been dispersed to different topics such as the analysis of opinions of products or services, analysis in social networks, reactions to disasters, voting intentions in elections, medicine, and engineering software. In 2013, Mosquera-Cabrera [22], an exploration of music as a phenomenon of psychological interest and its participation in the development of emotional experiences is carried out. Through the exploration of different sources, the authors make a description of works that integrate neuroscience, the study of higher psychological functions and musical stimuli to elucidate the mechanisms that allow defining the role of music in the manifestation of positive emotions. The work concludes that thanks to the benefits of music, it becomes a tool to support the human being in different settings, in which it seeks to positively influence personal, social, and intellectual development. In this sense, among the main benefits of music in human beings, the authors found: facilitating the expression of emotions, energizing the body and mind, relieving fears and anxieties, psychophysical relaxation, and decreased perception of pain.

From the review of previous works, it is possible to identify that at the level of affective computing, sentiment analysis techniques have been widely spread in the study of opinions made in contents belonging to social networks in different application contexts, being a challenge the application of affective computing in the analysis of multimedia advertising content. In this sense, within this article it was proposed as a contribution the application of affective computing techniques in the analysis of emotions on advertising multimedia content in the political context, taking advantage of the advantages provided by the acoustic variables of arousal and valence in the determination of emotions from Russell's two-dimensional model. Similarly, considering that the existence of automated tools for the analysis of emotions in multimedia content has not been evidenced, this article proposes an automated tool called MUSEMAN, which allows the segmentation and analysis of the audio tracks of advertising jingles to obtain the emotions transmitted in each multimedia content.

## III. MATERIALS AND METHODS

This section presents the jingles considered for the present study, as well as the conceptualization about the musical recognition of emotions and the methodology used for the conduction of the developed study.

### A. Jingles Considered

The present study was carried out considering the jingles published on social networks of the candidates who obtained the 6 highest votes in the elections of October 27, 2019; with William Dau, the winner, followed by William García, Yolanda Wong, Sergio Londoño, Fernando Araujo and Jesús Hernández. The jingles were obtained from YouTube and Facebook and transformed into audio and video formats using online encoding services. Table I shows the description of the

videos from which the audio tracks considered for the present study were taken.

### B. Music Emotion Recognition

Music emotions recognition (MER) uses several approaches: 1) The categorical one predicts an emotion using a classification with labels; 2) The dimensional approach establishes the emotions of a song, representing them on a dimensional plane with numerical values in X and Y [11], [19]; and 3) A dynamic process, to predict the emotion of each short segment of a song, thus obtaining the variation of musical emotion [23]. The steps followed to conduct a recognition of musical emotions may vary, depending on the classification process to be followed, but in general terms it can be summarized as follows [24]: 1) Speech acquisition the data is acquired and makes sure to have the corpus to use for the training datasets. 2) Noise removal - improving the quality of the data to be processed is vital for proper data processing, for this you can use filtering algorithms, spectral restoration and speech-structure based. 3) End point detection - the separation of non-speech sounds: recognition depends also on this separation being carried out; 4) Windowing - voice segments (word) are limited in a window, to help in the extraction of characteristics, for which the Mel frequency cepstral coefficient (MFCC) method is used; 5) Feature Extraction - the relevant characteristics for the prediction model to be built are selected, methods such as Hidden Markov Models and Vector Support Machines are used.

In the present work, the MUSEMAN tool was developed in the Java language, which allows the segmentation and extraction of the acoustic properties of arousal and valence associated with the segments of an audio track. These acoustic properties allow the classification of a certain audio segment within the circumflex model (Russell model) in such a way that the tool obtains the fluctuation of emotions throughout an audio track. Specifically, for the classification of emotions, the trigonometric angle  $\theta$  formed with respect to the x-axis is obtained according to Equation 1 [14]. The angle  $\theta$  obtained determines the quadrant and the emotion to which the analyzed audio segment belongs.

$$\theta = \arctan\left(\frac{arousal}{valence}\right) \quad (1)$$

The extraction of acoustic characteristics is carried out in the background by using the openEAR library [25], which comprises a set of tools with functionalities for the recognition of emotions, such as audio recording, feature extraction, classification, result evaluation and previously trained models. It is free software available under the GNU General Public License.

### C. Experimental Methodology

To carry out this work, Iterative Research Pattern – IRP [26] were used, which has four phases as presented in Fig. 1. Next, Table II shows the decomposition of each phase into activities.

The different activities of the methodology are presented in Table II.

TABLE I. STATISTICAL RESULTS OBTAINED

Id	Jingle	Description
1	<b>Title:</b> I'm with Dau - Let's save Cartagena. <b>Duration:</b> 38 seconds <b>Facebook ID:</b> 926585794379373	Commercial for the candidate William Dau. Without background music, images allusive to the city with a voice in the background talking about corruption and inviting to vote for a new option.
2	<b>Title:</b> Commercial William García Tirado for mayor of Cartagena. <b>Duration:</b> 30 seconds <b>Youtube ID:</b> zXKFsvAvnIg	Commercial for the candidate William García Tirado. Song adapted for the candidacy with the images of the candidate walking with the people through the streets of Cartagena.
3	<b>Title:</b> Yolanda Wong – The strength of our young people. <b>Duration:</b> 57 seconds <b>Youtube ID:</b> eTtIQJYs2Qw	Commercial for the candidate Yolanda Wong. Song adapted for the candidacy and choreography of young people in the historic center.
4	<b>Title:</b> Sergio Londoño – Gone are the days of getting it wrong. <b>Duration:</b> 59 seconds <b>Youtube ID:</b> NNalpG-R60A	Commercial for the candidate Sergio Londoño. Without background music, the candidate appears speaking about corruption in the city, about his government plans and inviting citizens to vote.
5	<b>Title:</b> Fernando Araujo - I will be the first person to police Cartagena. <b>Duration:</b> 20 seconds <b>Youtube ID:</b> CXhW6sKe7cU	Commercial for the candidate Fernando Araujo. Without background music, the candidate appears walking through the streets of Cartagena talking about his proposals.
6	<b>Title:</b> Jesús Hernández Amín <b>Duration:</b> 38 seconds. <b>Youtube ID:</b> hxidFtMPD-I	Commercial for the candidate Jesús Hernández Amín. Without background music, the candidate appears reflecting on the problems of Cartagena with images alluding to them.

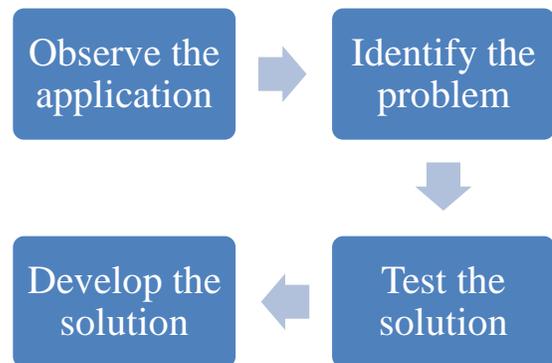

Fig. 1. Methodology Phases.

TABLE II. RESULTS OF DOMINANT POLARITIES

Phases	Activities description
Phase 1 - Observe	Activity 1.1: Review of the state of the art on Music Emotion Recognition  Activity 1.2: Definition of the model of emotions, an adaptation of Russell's model of emotions was defined, which is based on five emotions: happiness, excitement, sadness, anger and relaxation, taking into account the proposal presented in [15].
Phase 2 - Identify	Activity 2.1: Characterization of the improvements to be made to the adapted and improved from tool [27].  Activity 2.2: Definition of the architecture of the MUSEMAN tool.
Phase 3 - Develop	Activity 3.1: Design and development of the tool, based on the model defined, the MUSEMAN tool was designed and implemented in the Java language, which allows dividing an audio track into segments and obtaining, through the acoustic properties, the emotion associated with each audio segment.  Activity 3.2: Design and execution of unit and integration tests of the implemented features.
Phase 4 - Test	Activity 4.1: A study of the emotionality of the advertising jingles, emotional analysis was carried out on each of the audio tracks of the chosen advertising jingles, using the MUSEMAN tool.  Activity 4.2: Analysis of results, the analysis and discussion of the results is carried out, obtaining the main conclusions using the MUSEMAN tool.

IV. RESULTS

This section presents the software architecture of the MUSEMAN tool and the results of the emotion analysis on the selected advertising jingles using the proposed tool.

A. MUSEMAN Software Tool

This section describes the software architecture of the tool for the classification of emotions from analysis of the acoustic properties of arousal and valence, adapted and improved from [27]. In addition, the definitive interfaces of the MUSEMAN tool are presented. Fig. 2 outlines the functional architecture of the MUSEMAN tool, which was developed in the Java language and has three functional layers: View, Analysis and Storage.

In the view layer is the graphical interface of the tool, where the audio file to be analyzed is loaded, which can be in .mp3 or .wav format. Once the file has been loaded, the emotionality analysis begins from the analysis layer, in which the file is segmented into 5-second fragments with the help of the FFmpeg library, in such a way that temporary files are generated audio on the storage layer. As the audio fragments are generated, the acoustic properties of arousal and valence are obtained, making use of the free openEAR library. With the acoustic properties of arousal and valence obtained, it is

possible to classify each fragment within the circumflex model or Russell model, from obtaining the trigonometric angle formed by these two variables. In this work the model of emotions proposed in [14] was used, which has five emotions: happy, excited, angry, sad and relaxed, each of which have a coverage range of 72. As emotions are calculated, they are presented in the view layer and kept in the storage layer in a vector (time stamp and emotion), in such a way that the vector will have as many emotions as fragments are obtained from the loaded audio track. When the analysis process on the audio track has finished, it is possible to generate from the view layer a report with the results of the analysis in a csv file, consulting the emotions and the time stamps in the emotions vector. Additionally, when the report is generated, two types of graphs are also obtained: one that shows the fluctuation of emotions and their distribution along the track analyzed. These graphs were generated with the help of the Java JFreeChart library.

Fig. 3 presents the graphical interface of the MUSEMAN tool, which was developed in the Java language (using the swing library components) and has three tabs: "Emotions Analysis", "Emotions Trace" and "Emotions Distribution".

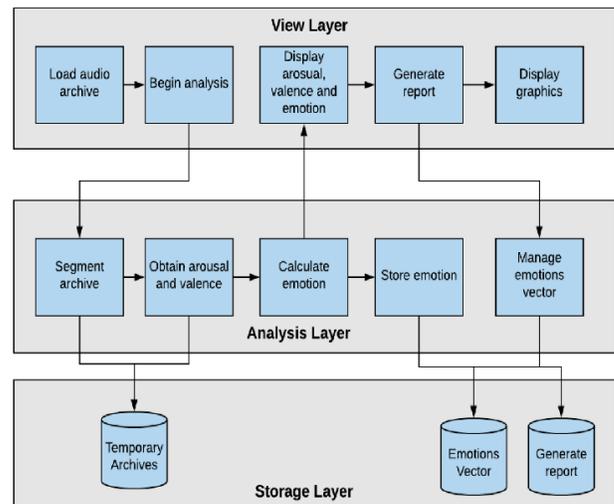

Fig. 2. Architecture of the MUSEMAN Software Tool.

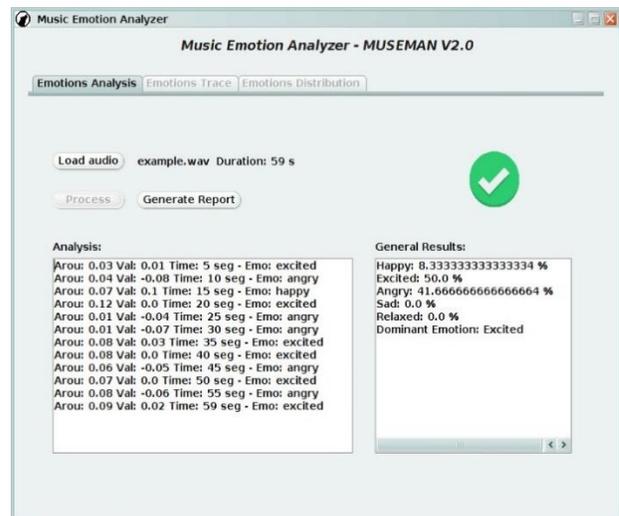

Fig. 3. Main Interface of the MUSEMAN Software Tool.

From Fig. 3, in the “Emotions Analysis” tab, the audio file is loaded using the “Load audio” button, then when pressing the “Process” button, the segmentation of the audio track starts (FFmpeg library), to obtain the variables arousal and valence (openEAR library), and calculate the emotion associated with each fragment. In the text area on the left, in Fig. 3, the value of the variables arousal and valence is displayed in real time, as well as the emotion of each 5-second segment throughout the audio track. When the analysis process is complete, the percentages for each emotion and the dominant emotion on the audio track are displayed in the text area on the right. Also in Fig. 3, it can be seen that, for the case of the loaded audio file, it is obtained that the “excited” emotion is the one with the highest percentage in the audio track with a value of 50%. In Fig. 3, the “Generate Report” button can be seen, with which a .csv file is obtained with the time stamp of each segment and the emotion corresponding to them. Once the report has been generated, in the tab “Trace Emotions” a graph is obtained that shows the fluctuation of emotions along the audio track, as can be seen in Fig. 4. This graph is made by using from the JFreeChart library.

In Fig. 4, the fluctuation of emotions in the course of the loaded audio track in Fig. 3 is shown, where it can be seen that the track fluctuates mostly between excited (2) and angry (3) emotions, with a shift towards happy emotion (1).

In Fig. 5 the “Emotions Distribution” tab of the MUSEMAN tool is shown, where a radial graph shows the distribution of emotions in the audio track, that is, the number of times an emotion is present in the audio. Thus, for example, it is observed that for the track loaded in Fig. 3, there are six instances corresponding to the excited emotion, five instances for the angry emotion and one instance associated with the happy emotion.

Finally, it is appropriate to specify that the tool requires the use of the FFmpeg and openEAR libraries in the background. It was therefore necessary to deploy the tool on the Linux operating system, in its Ubuntu distribution.

### B. Emotions Analysis Carried Out on Advertising Jingles

From the previously constructed tool presented, the analysis of the emotions on the audio associated with the advertising jingles of the candidates for mayor of Cartagena de Indias for the period 2020-2023 was carried out. From the audios associated with the videos presented in Table I and using the MUSEMAN tool, the graph of the fluctuation of emotions of the jingles of the candidates was obtained. In Fig. 6, it can be seen that the horizontal axis (x) shows the duration in seconds of the track, while the vertical axis (y) shows the emotions identified at a certain moment of the track: 1 happy, 2 excited, 3 angry, 4 sad, and 5 relaxed.

In Fig. 6, it can be seen that the horizontal axis (x) shows the duration in seconds of the track, while the vertical axis (y) shows the emotions identified at a certain moment of the track: 1 happy, 2 excited, 3 angry, 4 sad, and 5 relaxed. In Fig. 6 it can be seen that the jingles associated with:

- Candidates Araujo, García and Wong remain or broadcast their entire duration in an excited state (2).
- Candidate Dau spends half the time in the excited state (2) and alternates the rest of the time between happy (1), sad (4) and relaxed (5) emotions.
- Candidate Londoño is associated with the angry emotion (3) most of the time with two fluctuations towards the excited (2) and sad (4) states.
- Candidate Hernández remains most of the time in the sad state (4), with a fluctuation towards the relaxed state (5).

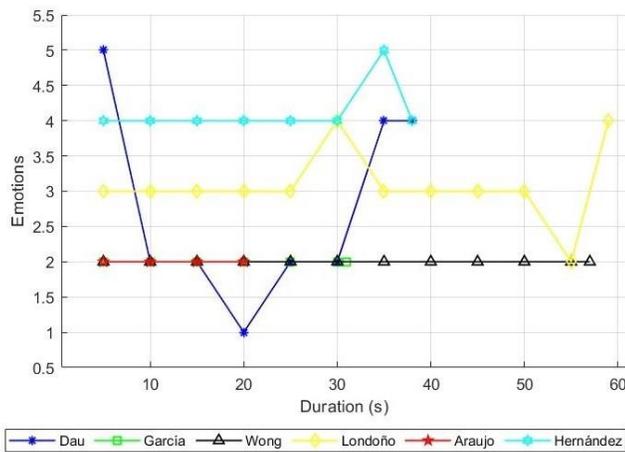

Fig. 6. Emotion Analysis Results.

The above results can be seen more clearly in Table III, which shows the way in which emotions are distributed as a percentage in each audio track.

Additionally, in Table III, it can be seen that the track of:

- Candidate Dau’s dominant emotion is the excited state (50%) with fluctuations towards happy, relaxed and sad states, taking into account that in a large part of the track there is an emphasis on some acts of corruption in the city, ending with an invitation to vote for the candidate.

TABLE III. RESULTS OF DOMINANT POLARITIES

Track	Percentage of distribution of emotions
1 - Dau	%Happy = 12.5 %Excited = 50 %Angry = 0 %Sad = 25 %Relaxed = 12.5
2 – García	%Happy = 0 %Excited = 100 %Angry = 0 %Sad = 0 %Relaxed = 0
3 – Wong	%Happy = 0 %Excited = 100 %Angry = 0 %Sad = 0 %Relaxed = 0
4 - Londoño	%Happy = 0 %Excited = 8.33 %Angry = 75 %Sad = 16.66 %Relaxed = 0
5 – Araujo	%Happy = 0 %Excited = 100 %Angry = 0 %Sad = 0 %Relaxed = 0
6 - Hernández	%Happy = 0 %Excited = 0 %Angry = 0 %Sad = 87.5 %Relaxed = 12.5

- For candidates García and Wong, the dominant emotion is associated with the excited or euphoric state (100%). This reflects that throughout the track the message is transmitted by the lyrics of a song with a high arousal level.
- For candidate Londoño, the dominant emotion is that of the angry state (75%) with fluctuations towards the excited and sad states. The above highlights that for most of the track the candidate denounces the acts of corruption of past administrations, ending with an invitation to vote for his proposals.
- Candidate Araujo has the excited state (100%) as the dominant emotion, explaining the fact that the candidate throughout the jingle is accompanied by people talking in a euphoric way about their proposals for change.
- Candidate Hernández’s dominant emotion is the sad state (87.5%) with a fluctuation towards the relaxed state, which is explained by the fact that for most of the track the candidate reflects on the situation of the city with a slow tone of voice and ending with the invitation to vote for his proposals.

## V. DISCUSSION OF THE RESULTS

In this article we presented as a contribution the application of affective computing techniques in the emotional analysis of advertising jingles in the political context, taking advantage of the benefits of multimedia content and specifically audio and music to communicate emotions. In this sense, the acoustic properties of arousal and valence were used to determine the emotion associated with an audio fragment belonging to a jingle in Russell’s two-dimensional model [11], [15]. Thus, the approach proposed in this work provides an objective contribution to the creators of advertising content for the design of the emotions to be communicated in an advertising jingle, enriching the traditional methods of content creation.

For the development of the proposal presented in this article, an automated tool was built for the analysis of emotions in advertising jingles called MUSEMAN, which allows the fragmentation of the audio of a jingle in segments of 5 seconds, to each of which the variable arousal and valence is determined, so that the tool allows to obtain statistically the percentage distribution of emotions in the jingle and graphically the variation of emotions over time. It is worth mentioning that in order to obtain the acoustic properties of each of the audio fragments; the proposed tool makes use of the openEar library in the background. Thus, with respect to other state-of-the-art proposals, including the openEar library itself, the MUSEMAN tool automates the process of analysis of advertising jingles, having as an added value the segmentation processes, as well as the statistical and graphic analysis of the emotions present in the analyzed jingle, which allows supporting content creators in the design of the emotions to be communicated in an advertising jingle.

One of the limitations of this study is that it focuses on the emotional analysis of advertising jingles in the political context from the analysis of acoustic variables, so that this study can be complemented in the future by analyzing the text

corresponding to the message expressed in the audio, for example by using sentiment analysis techniques, in order to determine the level of polarity of the message. Thus, a possible challenge in the analysis of emotions in advertising jingles could be the use of fuzzy logic based systems that receive as input the polarity values of the text and the emotionality of the audio to determine as output an enriched emotionality level for the analyzed jingle.

## VI. CONCLUSION

In this work, an analysis of emotions was carried out on the advertising jingles of the candidates for mayor of Cartagena de Indias for the period 2020-2023. The study was carried out from the analysis of the audios associated with each of the jingles, by determining the musical properties of arousal and valence at different moments of the audio track, in such a way that from these properties it was possible to establish an emotion in the plane of the circumplex, or Russell, model. This study intends to serve as a reference regarding the application of affective computing in the design of the messages and emotions transmitted in advertising jingles.

The approach proposed in this work represents a contribution to the state of the art regarding the application of affective computing in the analysis of commercial advertising jingles and in the political context, taking advantage of the benefits provided by the acoustic properties of arousal and valence, in terms of determining the emotions of an audio fragment according to Russell's model. In this sense, the study developed in this article was supported by a tool called MUSEMAN, which allows the automation of the process of analysis of emotions in acoustic multimedia content, through the segmentation of the advertising jingle analyzed in a set of fragments to each of which the associated emotion is determined from the acoustic properties of arousal and valence, in order to obtain the trace of emotions that make up the jingle. Thus, the tools and libraries considered in the proposed tool can serve as a reference for the extrapolation of this research in the analysis of multimedia content in other application areas.

The analysis of emotions from the study of musical properties such as arousal and valence corresponds to a non-subjective technique, since it depends on acoustic characteristics such as time, intensity, volume, rhythm, etc. This makes this method useful both for studying the design of the messages transmitted in advertising jingles and for analyzing the perception or level of user satisfaction.

The MUSEMAN tool proved to be adequate in terms of the analysis of the emotions present in an audio track, since it allows to carry out the segmentation processes, obtaining the arousal and valence properties, calculating the emotions associated with each segment, generating reports and display of follow-up and distribution graphs. In this sense, the MUSEMAN tool takes advantage of the advantages provided by the FFmpeg and openEAR libraries, acting in the background on the Linux operating system.

The study carried out showed that the candidates used different communication strategies in their advertising messages. On the one hand, three candidates transmitted the emotion of euphoria in their messages through the use of

adapted songs (García and Wong) and through the socialization of the proposals in the streets of Cartagena (Araujo). On the other hand, the three remaining candidates recounted stories with a reflection on the problems of corruption and the problem of inequality in the city, relying on emotions such as anger and sadness.

As a future work derived from the present research, we intend to complement and contrast the results obtained by applying sentiment and text analysis techniques to the messages included in the advertising jingles.

## ACKNOWLEDGMENT

The authors would like to thank the Universidad of Cartagena-Colombia and the Universidad of Cauca-Colombia for their support in the development of this research.

## Highlights

- Collection of several types of speech recordings of the vowels /a/, /e/, /i/, /o/ and /u/.
- The decomposition of each voice signal by DWT using the different types of wavelets.
- Extraction of the delta delta MFCC from all voice samples.
- Classification using decision tree classifier along with holdout scheme

## Graphical Abstract:

**Abstract**—To diagnose Parkinson's disease (PD), it is necessary to monitor the progression of symptoms. Unfortunately, diagnosis is often confirmed years after the onset of the disease. Communication problems are often the first symptoms that appear earlier in people with Parkinson's disease. In this study, we focus on the signal of speech to discriminate between people with and without PD, for this, we used a Spanish database that contains 50 records of which 28 are patients with Parkinson's disease and 22 are healthy people, these records contain five types of supported vowels (/a/, /e/, /i/, /o/ and /u/), The proposed treatment is based on the decomposition of each sample using Discrete Wavelet Transform (DWT) by testing several kinds of wavelets, then extracting the delta delta Mel Frequency Cepstral Coefficients (delta delta MFCC) from the decomposed signals, finally we apply the decision tree as a classifier, the purpose of this process is to determine which is the appropriate wavelet analyzer for each type of vowel to diagnose Parkinson's disease.

**Keywords**—Parkinson's disease; discrete wavelet transform; delta delta MFCC; decision tree classifier

## I. INTRODUCTION

Parkinson's disease is a severe health problem. According to the American Parkinson's Disease Association (APDA) [1], more than 10 million people worldwide are affected by Parkinson's disease. Due to the loss of certain groups of brain cells that produce neurotransmitters, including dopamine, causes symptoms such as impaired speech, movement, and sleep, as well as panic and anxiety attacks.

Speech disorders include reduced speech intensity, fluctuating fundamental frequency, and irregular speech articulation which are signs that appear early in people with Parkinson's disease, allowing many studies to use the speech signal for the identification of Parkinson's disease [2-5].

However, the speech signal is one of the most complex signals to characterize, which makes it difficult to develop a system to understand different diseases such as Parkinson's disease [6-8], Alzheimer's disease [9-11], and COVID 19 [12-15], etc. This complexity of the speech signal comes from a combination of several factors, the redundancy of the acoustic signal, the high inter-and intra-speaker variability, the effects

of coarticulation in continuous speech, and the recording conditions. To overcome these difficulties, many methods and mathematical models have been developed, including neural networks [16, 17], Support Vector Machines (SVM) [18, 19], stochastic Markov models, and in particular Hidden Markov Models (HMM) [20, 21].

These methods and models work from information extracted from the speech signal considered relevant. This extraction is performed by an acoustic analysis which leads to gathering this information under the term of the vector of acoustic parameters whose dimension and nature are determinant to reach good performances of the knowledge system of Parkinson's disease which is of interest to us in this article. The different types of acoustic parameters commonly cited in the literature are the coefficients: LPC [22], LPCC [23], LFCC [24], PLP [23], MFCC [6, 23], etc. Generally, the MFCC coefficients are the most used acoustic parameters in speech feature extraction [25-27].

However, for these systems of recognition of Parkinson's disease, research work has studied the improvement of the performance of this system by combining the MFCC coefficients with other types of acoustic parameters such as LPCC [28], PLP [28], energy [29], wavelets [29-31] and Empirical Mode Decomposition (EMD) [32].

In this study, far from static coefficients, for correct detection of Parkinson's disease through voice our contribution consists in proposing a new method of selection of relevant acoustic parameters based on the use of dynamic delta delta MFCC coefficients combined with wavelets, these differential coefficients referred as dynamic parameters provide useful information on the temporal trajectory of the speech signal. This information extracted by discrete wavelet transform and delta delta MFCC will be used in the classification block using a decision tree classifier. To evaluate the performance of this model we applied it to a database of five vowels (/a/, /e/, /i/, /o/, /u/), each vowel includes 28 people with Parkinson's disease and 22 are healthy people.

The structure of the rest of the article is as follows: section II concerns a definition of the methods used, section III presents a description of the process used and the results obtained, and finally the conclusion in section IV.

## II. METHOD

### A. Feature Extraction

For feature extraction, we are interested in the joint use of DWT and the second derivative of the MFCC (delta delta MFCC). This step allows extracting features that will be used by the decision tree classifier.

1) *Discrete wavelet transform*: For the discrete wavelet transform, it is the discrete version of the Continuous Wavelet Transform (CWT) that used Mallat's algorithm, it is based on the principle of multi-resolution that allows the separation of details and approximations of signals by using a pair of filters H and G that constitute respectively a low-pass filter and a high-pass filter.

With the high-pass filters, we obtain the coefficients of the discrete wavelet decomposition (the details), and with the low-pass filters, we obtain the approximation coefficients. This operation is applied again to the approximation, generating another detail and a new approximation as shown in Figure 1. There are several types of wavelets, in our case; we used the wavelets presented in the table I:

2) *Delta delta MFCC*: Temporal changes in the cepstrum play an important role in human perception and it is through the derivatives of MFCC coefficients that we can measure these changes.

TABLE I. WAVELET FAMILIES USED

Wavelets families	Wavelets
Daubechies	db1, db2, and db3
Coiflets	coif1, coif2, and coif3
Symplets	sym1, sym2, and sym3
Discrete Meyer	dmey

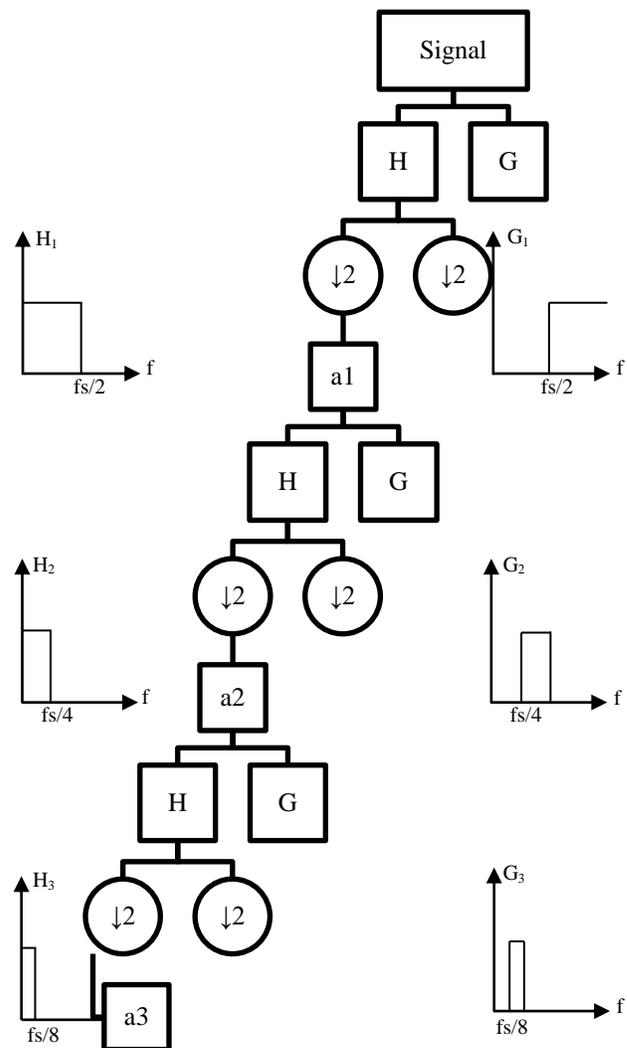

Fig. 1. Representation of the Mallat Algorithm for the Implementation of the DWT Decomposition, H is a Low Pass Filter and G is a High Pass Filter.

Usually, MFCC coefficients are referred to as static parameters, since they contain only the information about a given frame. To improve the frame representation, it is often proposed to introduce new parameters into the parameter vector. The reference [33] proposed the use of dynamic parameters that present cepstral transition information in the speech signal. In particular, it proposed second-order differential coefficients, also called delta delta coefficients, derived from cepstral coefficients. Let  $d_t$  be the first-order differential coefficient (delta MFCC) of frame  $t$ , then the corresponding second-order differential coefficient (delta delta MFCC)  $dd_t$  is calculated by the following formula:

$$dd_t = \frac{\sum_{n=1}^N n(d_{t+n} - d_{t-n})}{2 \sum_{n=1}^N n^2} \quad (1)$$

The coefficients delta delta MFCC, also called acceleration coefficients are obtained using the second derivative of static Mel Frequency Cepstral Coefficients (MFCC), the latter is a representation defined as the discrete cosine transform of the logarithm of the spectrum of the energy of the speech segment. The spectral energy is calculated by applying a bank of evenly spaced filters on a modified frequency scale, called the Mel scale. The Mel scale redistributes the frequencies in a non-linear scale that simulates human perception of sounds. Figure 2 illustrates the steps involved in obtaining the delta delta MFCC coefficients. Based on the results obtained in [26], we use only the first 12 delta delta MFCC coefficients.

### B. Feature Classification

1) *The decision tree classifier:* A decision tree is one of the most popular techniques in machine learning. Indeed, decision tree learning is part of supervised learning, it is generally a classifier presented in the form of a tree structure [34].

A decision tree consists of a set of rules allowing a segment of a data set into homogeneous groups. Each rule associates the conjunction of tests with the descriptive variables. The first vertex is called the root of the tree, the following variables, which correspond to non-terminal nodes, are segmentation variables; each branch corresponds to a modality of the variable considered at this level of the tree. This process is repeated on each node of the tree, the nodes that are not pure are segmented until pure leaves are obtained.

Here we try to classify a population of individuals containing healthy people and people with Parkinson's disease pronounce these five vowels (/a/, /e/, /i/, /o/, /u/) into two classes with respect to a label {1 (healthy), 0 (sick)} from the recordings. The decision tree-learning algorithm is described below:

---

### Algorithm 1: Decision tree

---

**Data:** a sample  $\Omega$  of  $m$  labeled records

**Initialization:** empty tree; current node: root; current sample:  $\Omega$

- Repeat
- Decide whether the current node is terminal
- If the current node is terminal then
- Label the current node with a leaf
- Otherwise
- Select a test and create the subtree
- End if
- Current node: a node not yet studied
- Current sample: sample reaching the current node
- Until a decision tree is produced

**Output:** decision tree

---

2) *Holdout method:* All classification results are obtained using the "holdout" method. This method is a commonly used practice for evaluating machine-learning models. It works by first dividing the data randomly into two parts; one of larger size is used for training and the other part is reserved for error rate estimation. Another version of this method, called "data shuffle", consists in repeating  $L$  times the random division of the data into two parts; one for training and the other for testing, and then calculating the average of the  $L$  estimates of the error rates evaluated on the test data parts. The advantage of this method is that all data are used for both training and testing. The holdout is a simple method to understand and generally results in a less biased model estimate than other methods.

To assess classifier performance, the following parameters are used:

$$\text{Accuracy} = \frac{\text{TN} + \text{TP}}{\text{TN} + \text{TP} + \text{FP} + \text{FN}} \quad (2)$$

$$\text{Sensitivity} = \frac{\text{TP}}{\text{TP} + \text{FN}} \quad (3)$$

$$\text{Specificity} = \frac{\text{TN}}{\text{TN} + \text{FP}} \quad (4)$$

Where TP: true positive; TN: true negative; FP: false positive; FN: false negative.

### III. METHODOLOGY AND RESULT

We have implemented our algorithm in Matlab version R2019a. The tests were performed on a PC with the following configuration:

CPU: Intel(R) Core(TM) i3-3110M CPU @ 2.40GHz  
Memory: 4,00 Go  
Operating System: Windows 10 64bit.

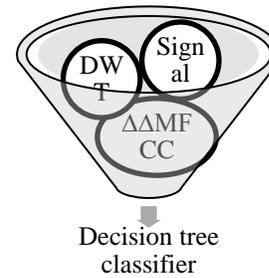

Fig. 3. The Process used to Diagnose Parkinson's Disease.

A. Data Collection

This study takes into account two subgroups of this group: the Healthy Control (HC) group with 22 speakers and the Parkinson's disease (PD) group with 28 speakers. All utterers included in this Italian corpus were registered in Bari (Puglia region), Italy. Each recording session took place in a controlled environment, taking into account factors such as room temperature, distance from the microphone, time of day, and having a conversation with the subject to warm up their vocal muscles. The sampling frequency was 16 kHz; more information is available in [35]. Table II includes the demographic information of the corpus.

B. Methodology

The objective of this part of Parkinson's disease detection is to design and experiment with a system based on extensive use of wavelet types combined with acceleration coefficients (delta delta MFCC) as features and the decision tree as a classifier, as illustrated in Figure 3.

For the feature selection and extraction domain, which is an important step in the recognition process of Parkinson's disease, we consider the use of the wavelet transform, which is a time and frequency analysis tool that allows obtaining variable temporal and frequency resolutions.

TABLE II. AGE DEMOGRAPHIC DATA FROM THE ITALIAN CORPUS, ARRANGED BY GENDER AND CLASS

	Female		Male		Total	
	PD	HC	PD	HC	PD	HC
Subjects	9	12	19	10	28	22
Age range	40-80	60-72	50-77	60-77	40-80	60-77

Our model for the diagnosis of Parkinson's disease will be applied to a corpus containing 28 subjects with Parkinson's disease and 22 healthy subjects for each vowel (/a/, /e/, /i/, /o/, /u/). It is based firstly on the decomposition of the signal into two sub-bands of approximate frequency and details by the use of a wide range of wavelets (Debauchies, Coiflets, Symlets, and Discrete Meyer) on the first seven scales.

Susceptible to better characterize our system, extracting the first 12 coefficients delta delta MFCC that are parameters widely used to encode the dynamic information of cepstral parameters. This extraction is only performed on the low-frequency band (approximation) for each type of wavelet and from the first scale up to the seventh scale.

The main objective of the feature selection step is its direct contribution to the performance of the overall system this step allowed us to extract the features that will be then used by the decision tree classifier with the cross-validation method "holdout" that serves to decompose the base of each vowel (/a/, /e/, /i/, /o/, /u/) into 80% as a learning base and the whole base as a test base.

C. Experiments and Results

In this part of our work, we implemented our Parkinson's disease detection system where we introduced the DWT method and the delta delta MFCC coefficients as a feature vector, we changed the wavelet types for each first seven scales, then we measured the impact of each of these changes on the Parkinson's disease recognition performance by the decision tree classifier performance evaluation metrics.

A comparative study between the extracted features based on delta delta MFCCs is performed to visualize the distinctive behavior of the subject with Parkinson's disease and the healthy subject for the five vowels. Figures 4-8 show the 12 delta delta MFCC coefficients as extracted features for a healthy person and a person with Parkinson's disease. The feature patterns are obtained from 50 speech samples for each vowel (/a/, /e/, /i/, /o/, /u/) from people with Parkinson's and healthy people. Almost all speech signals follow the same pattern. Figure 4 clearly distinguishes the variation in the speech pattern of a healthy person and a person with Parkinson's disease for the vowel /a/ based on the wavelet of discrete Meyer at scale 5 the latter is the one that gave us a better Accuracy. Figures 5, 6, 7, and 8 present the delta delta MFCC coefficients respectively for the vowels /e/, /i/, /o/, and /u/, we based on these wavelets with these scales respectively discrete Meyer at scale 5, Coiflets level 3 at scale 6, discrete Meyer at scale 7 and discrete Meyer at scale 6 because it is those that gave us

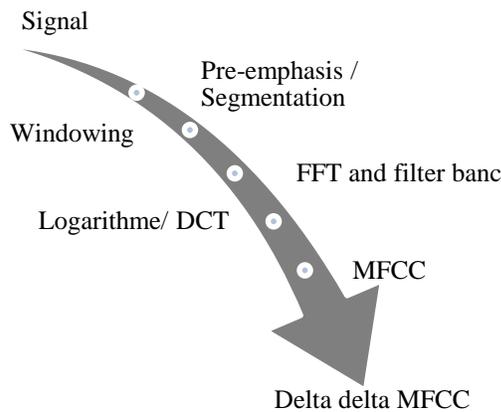

Fig. 2. Delta Delta MFCC Extraction Process.

important results that are displayed in Tables III, IV, V, VI, and VII a notable variation is observed between the healthy speech signal and that of Parkinson's disease. Thus, the proposed feature-based on delta delta MFCC can be a good marker for the prediction of Parkinson's disease.

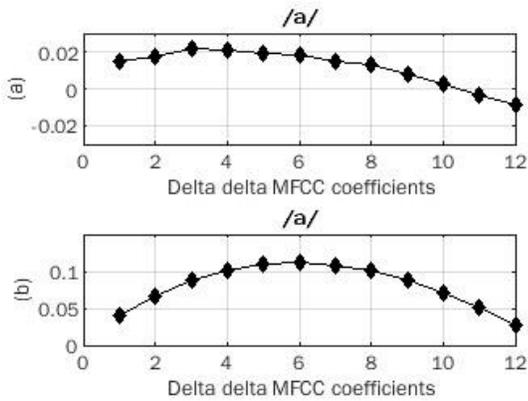

Fig. 4. Delta Delta Coefficients Extracted from the Vowel /a/ for: (a) Healthy Person, (b) Person with Parkinson's Disease.

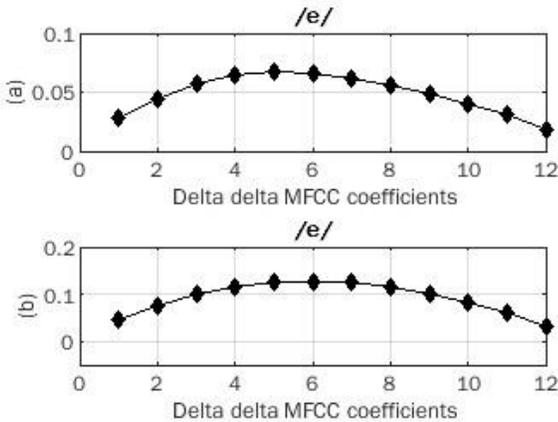

Fig. 5. Delta Delta Coefficients Extracted from the Vowel /e/ for: (a) Healthy Person, (b) Person with Parkinson's Disease.

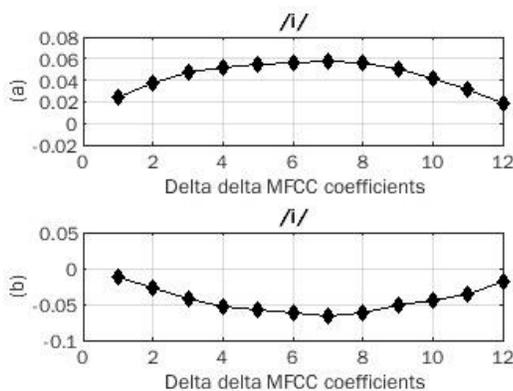

Fig. 6. Delta Delta Coefficients Extracted from the Vowel /i/ for: (a) Healthy Person, (b) Person with Parkinson's Disease.

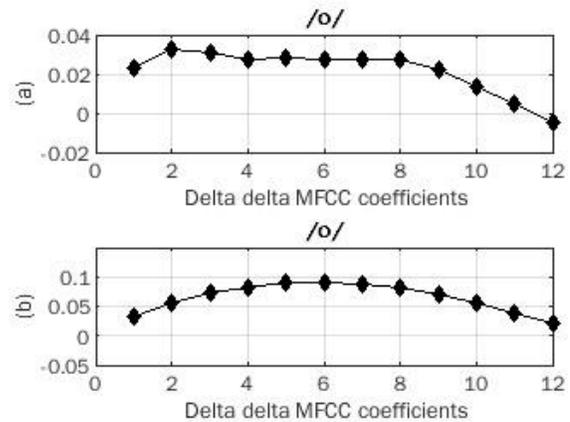

Fig. 7. Delta Delta Coefficients Extracted from the Vowel /o/ for: (a) Healthy Person, (b) Person with Parkinson's Disease.

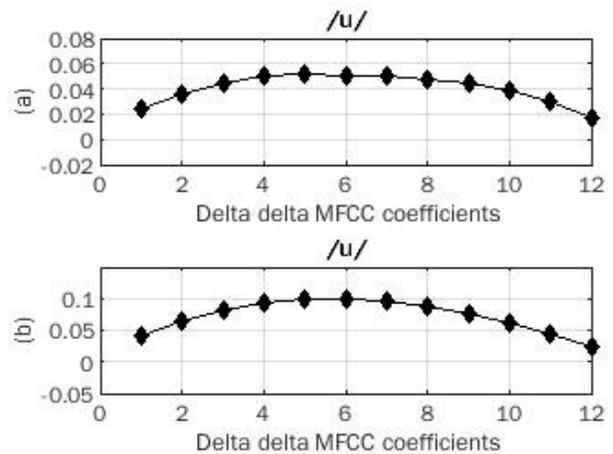

Fig. 8. Delta Delta Coefficients Extracted from the Vowel /u/ for: (a) Healthy Person, (b) Person with Parkinson's Disease.

The following tables show the different results obtained for the five vowels according to accuracy, specificity, and sensitivity.

For the vowel /a/, the results obtained in Table III show that the wavelet by using discrete Meyer at scale 5 offers better modeling for the classification of healthy people and people with Parkinson's disease with high accuracy of 97.5%. While for the vowel /e/, Table IV is still with the same wavelet, and on the same scale of 5, the best accuracy of 92.5% is achieved.

In contrast to the experiment for the vowel /i/, in Table V we register a slight performance low of the accuracy of 87,5% by using the wavelet of Coiflets level 3 at scale 6 and discrete Meyer at scale 7.

For the vowel /o/, according to the results shown in Table VI, we find that the wavelet of discrete Meyer at scale 7 gives accuracy up to 92,5% for the discrimination between healthy patients and patients with Parkinson's disease. For the vowel /u/, Table VII shows an important result with an accuracy of 90% by using the wavelet of discrete Meyer at scale 6.

In Table VIII we have listed, but not exhaustively, the different works on Parkinson's disease recognition systems. The performances are difficult to compare because they vary according to several elements such as the type of data, the choice of the learning models, the way the parameters are obtained, etc. In this section, we will compare our results with those of some works.

TABLE VIII. COMPARISON OF PERFORMANCE WITH RECENTLY PUBLISHED WORK

Study	Method	Accuracy
Zayrit et al [29]	DWT-genetic algorithm and SVM	91,18 (k-fold cross-validation)
Benba et al [26]	MFCC- MLP kernel of SVM	82,50 (LOSO)
Sakar et al [36]	KNN+SVM	55,00 (LOSO on training database) 68,45 (LOSO on the testing database)
Belhoussine drissi et al [30]	DWT-MFCC-SVM	86,84
Eskidere et al [37]	Random subspace classifier	74,17 (10-fold CV)
Li et al [38]	SVM+FS	82,5
Ali et al [39]	Multimodal approach	70
Ali et al. [40]	LDA-NN-GA	95,00
Proposed method.	DWT-delta delta MFCC- decision tree classifier	vowel /a/ 97,5

Zayrit et al [29] evaluated the /a/ vowel in the Turkish corpus by a vector of 21 prosodic features including LPC, ZCR, energy, Shannon entropy, and MFCC. The recognition accuracy of PD using the SVM classifier was around 91.18%. The researchers in [26] also conducted experiments using a Turkish corpus where the accuracy was 82.50%. This accuracy rate was shown for cepstral features applied with the SVM classifier. Sakar et al [36] reported a PD recognition accuracy of 68.45% using prosodic features in an SVM-based classification. They used the vowel /a/ from the Turkish corpus. Belhoussine drissi et al [30] reported a recognition accuracy of 86.84% for PD using cepstral features in an SVM-based classification. They used a database of 38 recordings, 18 of which were from healthy individuals and 20 from patients with Parkinson's disease from the Turkic corpus. References [37], [38], [39], and [40] extracted the spectral, and prosodic features used respectively Random subspace classifier, Support Vector Machines (SVM) as classifiers, Multimodal approach and LDA-NN-GA classifiers, they achieved recognition accuracy of PD respectively 74.17%, 82.5%, 70%, and 95%. In this article, the results show that the joint use of the wavelets and the delta delta MFCC coefficients as features brings a significantly important improvement to the performance of the Parkinson's disease diagnostic system with an accuracy of up to 97,5%.

#### IV. CONCLUSION

The work presented in this article is part of a project to recognize Parkinson's disease from the voice, in an educational context. The objective is to detect the state of each person if he/she is healthy or suffering from Parkinson's disease. To achieve this goal, we first proposed a comprehensive and

efficient system for automatic recognition of people's states from a Spanish corpus of the five sustained vowels (/a/, /e/, /i/, /o/, and /u/) produced by 28 subjects with Parkinson's disease and 22 healthy subjects. Our process starts with the transformation of the speech signals by several types of DWT based on the approximation of the first seven scales which will be injected into the delta delta MFCC block to extract the 12 coefficients at each time. These coefficients are applied in the classification using the decision tree classifier.

The results show that the proposed feature is superior, providing a maximum accuracy of 97.5% for the database that contains the vowel /a/. There is a significant improvement over recent studies. The complete study showed that the proposed combination of wavelets with delta delta MFCC could be used to effectively detect PD.

**Abstract**—These days, the Internet is subjected to a variety of attacks that can harm network devices or allow attackers to steal the most sensitive data from these devices. IoT environment provides new perspective and requirements for intrusion detection due to its heterogeneity. This paper proposes a newly developed Intrusion Detection System (IDS) that relies on machine learning and deep learning techniques to identify new attacks that existed systems fail to detect in such an IoT environment. The paper experiments consider the benchmark dataset ToN\_IoT that includes IoT services telemetry, Windows, Linux operating system, and network traffic. Feature selection is an important process that plays a key role in building an efficient IDS. A new feature selection module has been introduced to the IDS; it is based on the ReliefF algorithm which outputs the most essential features. These extracted features are fed into some selected machine learning and deep learning models. The proposed ReliefF-based IDSs are compared to the existed IDSs based correlation function. The proposed ReliefF-based IDSs model outperforms the previous IDSs based correlation function models. The Medium Neural Network model, Weighted KNN model, and Fine Gaussian SVM model have an accuracy of 98.39 %, 98.22 %, and 97.97 %, respectively.

**Keywords**—Intrusion detection systems (IDSs); TON IoT dataset; machine learning; deep learning; ReliefF

## I. INTRODUCTION

The Internet of Things (IoT) environment describes a network of physical objects that includes software, sensors, and other technologies to connect and transfer data with systems and devices on the Internet. IoT represents the interconnection of heterogeneous entities, where the term “entity” refers to a human being, a sensor, or possibly anything that can request or provide a service [1]. The Internet of Things (IoT) has become one of the most important technologies of the 21st century, so we need to protect data traveling between devices. IoT security is an ongoing research topic that's gaining increasing attention in governmental, industrial, and academic research. IoT security requirements are Confidentiality, Integrity, Availability, Authentication, and Authorization. There are multiple IDS systems that are used to protect networks from attacks, but some systems can't identify the newest attacks. We provide in this paper an intrusion detection system to detect attacks, the system is developed using deep learning and machine learning techniques with an efficient feature selection using the ReliefF algorithm. The proposed model is based on the Windows 10 subset of the ToN-IoT dataset. A comparison is carried out with the existed work which selects features from Windows 10 dataset using the correlation function.

In this paper, we focus on Windows 10 dataset as the windows 10 operating system is widely used in personal computers. This dataset contains new attacks for IIoT networks which can't be detected by traditional IDSs so this paper presents a new IDS system for IoT networks by using machine learning and deep learning algorithms. Many datasets have redundant or noisy data which may cause poor learning performance and consume time for training so the feature selection techniques are used to remove irrelevant and noisy attributes from the dataset. In this paper, we apply the ReliefF feature selection method on the windows 10 dataset.

The paper structure is as follows: Section II reviews the IDS backgrounds, Datasets, feature selection techniques, and Machine learning and deep learning algorithms. Section III discusses Related Works on IDS. The proposed model is explained in Section IV. Following that the Evaluation Metrics and Experimental Results are described in Section V. Finally, Section VI describes the conclusions of the future work.

## II. BACKGROUND

Intrusion detection systems (IDSs) are tools or software that can secure or defend your networks from intrusions. The purpose of IDS is to recognize various types of attacks and usage of the computer that cannot be known via firewalls. This is often very important to achieve a high level of protection versus action which compromises the availability, integrity, or confidentiality of a computer system [2]. IDS monitors network traffic for suspicious activities and issues alerts when such activities are detected. Some intrusion detection systems can do actions if anomalous traffic is detected such as blocking traffic sent from a suspicious IP address. IDS sometimes is classified based on its location; Host Intrusion Detection Systems (HIDS) and Network Intrusion Detection Systems (NIDS) [3]. HIDS monitors and analyzes host activities, application logs, system calls, and modifications that occur on system files to identify intrusions such as login to unprivileged data [4]. Network-based IDS monitors the network traffic by using techniques such as packet sniffing to collect network traffic and detect attacks such as DOS attacks or port scans [4]. There are two types of Network-based IDS Statistical anomaly IDS and Pattern matching IDS [3]. On the other hand, IDS is practically classified as signature-based IDS and anomaly-based IDS. Anomaly-based IDS is significantly used for detecting zero-day attacks. Efficient IDS development depends on selecting suitable machine learning or deep learning models as well as the feature selection technique in order to enhance the performance and reduce the computations.

Feature selection is an important step that plays a significant role in the development of an effective IDS. Feature selection is categorized into three methods like filter methods, wrapper methods, and embedded methods. The filter methods select the most discriminating features by data character. Features are ranked according to specific criteria and then the highest-ranked features are selected. There are many types of filter methods that have been used, such as ReliefF, F-statistic, mRMR, correlation, and information gain. Wrapper methods use the intended learning algorithm to evaluate the features. Examples of wrapper methods are Sequential forward selection and Sequential backward selection. Embedded methods perform feature selection in the model construction process examples of embedded methods are Elastic Net and Ridge Regression [5]. The most widely used feature selection methods are The ReliefF (Relief-F) [6], Correlation-Based Feature Selection [7, 8], and Information Gain Ratio-based feature selection [9, 10].

Various network datasets were prepared for the evaluation of IDS, such as KDDCUP99, NSLKDD [11], UNSW-NB15 [12], Ton-IoT, and ISCX [13].

There are several techniques of classification like decision trees, naïve Bayes (NB), neural networks (NN), support vector machines (SVM), Random Forest (RF), rule-based system, and nearest neighbor (KNN) [14,15]. Every algorithm utilizes learning methods to create a classification model. However, proper classification techniques should handle the training data and should be able to accurately identify a class of records that have not ever been seen before [4].

Deep Learning a branch of Machine Learning, has also begun to be widely used to implement IDS. There are many types of deep learning algorithms that can be used for intrusion detection systems such as recurrent neural network, deep belief network, Long Short Term Memory, restricted Boltzmann machine, deep auto-encoder, self-taught learning, convolutional neural network, deep migration learning, and replicator neural network [16, 17].

### III. RELATED WORK

There are lots of researches that use some methodologies and algorithms to overcome the most advanced attacks in the network. These researches trend to intrusion detection systems (IDSs) by using machine learning and deep learning algorithms with different feature selection methods to select the most important features from the datasets. The related works are explained in this section as follows:

Senthilnayaki Balakrishnan et al [18], the authors developed a new feature selection method based on Information Gain Ratio. They had named it an Optimal Feature Selection algorithm that could select an optimal number of features from the dataset. They used the KDD Cup dataset. They used Support Vector Machine and Rule-Based Classification algorithms to classify data as normal or as attacks data. The proposed feature selection and classification algorithms had achieved the best results.

S. Ramakrishnan et al. [19], the authors developed an IDS to detect attacks or normal data from the KDD Cup 99 dataset. They first selected the most important attributes by using the entropy-based feature selection method. The Fuzzy Control Language was used to classify data as normal or attack data. The results showed that the proposed system reduced the computational time and achieved high accuracy.

Peilun Wu et al. [20], in this paper, the authors developed an IDS system called Densely-ResNet. They selected the important attributes using the correlation function. The UNSW-NB15 was used to evaluate the performance of Densely-ResNet. The results showed that the Densely-ResNet had achieved high accuracy and reduced false alarm rate.

Shahid Latif et al. [21], the authors proposed an IDS that utilized a deep random neural network to protect IIoT systems. However, the system had been tested with the UNSW NB15 dataset. This dataset was used to observe its applicability or feasibility to IIoT. The results showed a better detection accuracy with a low false alarm rate.

Merna Gamal et al [14], the authors proposed a hybrid intrusion detection system using machine learning and deep learning techniques to benefit from the advantage of deep learning and machine learning. They used 10% of the KDDcup1999 dataset, and applied CNN to extract features from the KDDcup1999 dataset, then used machine learning techniques (SVM, KNN) to classify the data. The experiment results showed that the proposed model had achieved the best accuracy.

Prabhat Kumar et al [22], the authors developed an ensemble learning and fog-cloud architecture-driven cyberattack detection framework for IoMT networks. They used a ToN-IoT dataset that was collected from a large-scale and heterogeneous IoT network. Results showed that the proposed system could achieve high accuracy of 96.35%, a high detection rate of 99.98%, and a reduction in false alarm rate by 5.59%.

### IV. PROPOSED MODEL

This section provides our proposed model. We select features from windows 10 datasets using the ReliefF algorithm. We apply the ReliefF algorithm to remove irrelevant variables from Windows 10 dataset. Windows 10 dataset contains 125 attributes and two attributes one called "Label" whose values are (0 or 1), 0 for normal data and 1 for attack data, and "type" attribute contains normal data and seven attack categories (DDOS, DOS, Injection, MITM, Password, Scanning, and XSS). Before selecting features from the windows 10 dataset, we do preprocess on a dataset. The "type" feature refers to attack categories, these categories are converted from text data to numeric data from 2 to 8 respectively, and normal data are converted to 1. Fig. 1 shows the number of rows for each type of data in the dataset. Then we divide the dataset into training and testing data using holdout validation, 80 % of the dataset is training data and 20 % of the dataset is used as testing data.

No of rows	Type
4608	ddos
525	dos
612	injection
24871	normal
1269	xss
3628	password
447	scanning
15	mitm

Fig. 1. Number of Rows for each Type of Data.

The ReliefF algorithm is used to select features from the windows 10 dataset. After selecting features, we apply deep learning and machine learning techniques to classify the data as normal or attacks data. The Matlab tool and Machine Learning Toolbox (Classification Learner) are used to simulate algorithms such as KNN, SVM, and NN. We apply different types of KNN algorithm (such as Weighted KNN and Medium KNN), SVM (like Linear SVM and Fine Gaussian SVM), and Neural Network (like Medium NN and Bilayered NN). Also, we apply the LSTM algorithm to the dataset. Fig. 2 shows the flowchart of our proposed model.

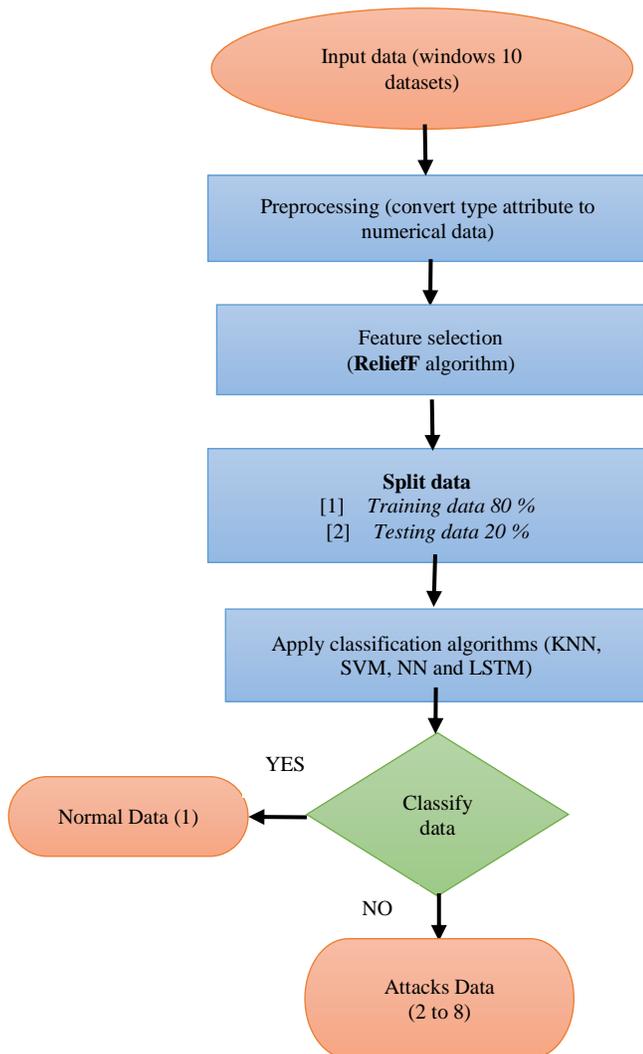

Fig. 2. Flowchart of Proposed Model.

## V. SIMULATION AND EXPERIMENTAL RESULTS

Experiments are carried out to examine the performance of the proposed model.

### A. Ton-IoT Datasets Description

Ton-IoT datasets were collected from Telemetry datasets of IoT services, Operating systems datasets of Windows and Linux, as well as datasets of Network traffic. The Windows datasets were generated using the virtual machines running Windows 7 and Windows 10 and incorporated the collections of data from multiple sources, including memory, process, processor, and hard drive of the systems. Windows 10 dataset contained 125 attributes and two attributes one called “Label” which values are (0 or 1), 0 for normal data and 1 for attack data, and the “type” attribute contained normal data and seven attack categories.

We apply our proposed model to Windows 10 dataset. We select features from it using the ReliefF algorithm then we apply deep learning and machine learning techniques to classify the data as normal or attack data. We divide the dataset using holdout validation as the following; 80 % of the dataset is used for training (28780 data sample records). 20 % of the dataset is used for testing (7195 data sample records).

### B. Simulation Environment Properties

The proposed system is implemented using Matlab 2021a, Classification learner App is set to apply imported and preprocessed instances of the dataset the processor unit (CPU) is Intel(R) Core(TM) i5-6200U CPU @ 2.30GHz 2.40 GHz, main memory(RAM) is 16.0 GB and the operating system is Windows 10 Pro.

### C. Evaluation Metrics

There are performance metrics are calculated to examine the model performance. These metrics are accuracy, recall, precision rate and, F1-Measure ought to be calculated for evaluation. These all performance metrics can be calculated by using a confusion matrix.

- Confusion matrix is a table or array that represents the performance of a classification model on testing data for which the true values are identified. Fig. 3 shows the confusion matrix.

**Confusion Matrix**

	Actually Positive (1)	Actually Negative (0)
Predicted Positive (1)	True Positives (TPs)	False Positives (FPs)
Predicted Negative (0)	False Negatives (FNs)	True Negatives (TNs)

Fig. 3. Confusion Matrix.

- Accuracy is the ratio of true detection over the whole instances.

$$accuracy = \frac{TP+TN}{totalSample} \quad (1)$$

- Recall is how often does it predict correctly. Also known as Sensitivity or True Positive Rate (TPR).

$$Recall = \frac{TP}{TP+FN} \quad (2)$$

- Precision indicates how often it is accurate when it is predicted to be accurate.

$$precision = \frac{TP}{TP + FP} \quad (3)$$

- F1-measure is the average of recall and precision weight. The mathematical representation of all measures can be deduced from the confusion matrix.

$$F - Measure = 2 * \frac{precision * Recall}{precision + Recall} \quad (4)$$

Area Under ROC Curve (AUC) is the performance metric for binary classification issues. AUC represents the work of the model for distinguishing between the negative classes and positive classes. An area of 1.0 acts as a model in which all predictions are made perfectly. An area of 0.5 acts as a model that is as good as random. The ROC can be classified into specificity and sensitivity.

#### D. Feature Selection

The paper in [23] selects features from Windows 7 and Windows 10 datasets using a correlation function that selects the most correlated features in datasets, and the authors suggest applying machine learning and deep learning algorithms to selected features. In our proposed model we suggest modifying the feature selection step, we apply the ReliefF algorithm to remove irrelevant variables from Windows 10 dataset. We compare our proposed model with the work implemented in the paper [23].

We use the ReliefF algorithm because it is a widely used filter-based feature selection method that finds the best feature subset by calculating the features' weights. The ReliefF algorithm's advantages are that more robust and can deal with incomplete and noisy data. It consumes less computational resources and is not limited to two-class problems, but it can work with multiple classes [6, 24]. The ReliefF algorithm first selects R samples randomly from the training set, and then it finds Near Hits in the same class, finds Near Miss in other classes, and updates each feature weight by rules. After repeating the above action m times, all feature weights will be obtained. The higher the feature weight is, the more useful the feature is for classification. The reverse is also true. The following steps are the pseudocode of the ReliefF algorithm:

#### Pseudocode for ReliefF Algorithm:

**Input:** a vector of attribute values and the class value for each training instance  
**Output:** the vector W of estimations of the attributes qualifies.

Step 1: put up all of the weights  $W[A] := 0.0$ ;  
 Step 2: **for**  $i := 1$  **to**  $m$  **do begin**  
 Step 3: randomly select an instance  $R_i$ ;  
 Step 4: find  $k$  nearest hits  $H_j$ ;  
 Step 5: **for** each class  $C \neq class(R_i)$  **do**  
 Step 6: from class  $C$  find  $k$  nearest misses  $M_j(C)$ ;  
 Step 7: **for**  $A := 1$  **to**  $a$  **do**

$$\text{Step 8: } W[A] := W[A] - \sum_{j=1}^K \frac{\text{diff}(A, Ri, Hi)}{m \cdot K} +$$

$$\text{Step 9: } \sum_{C \neq class(Ri)} \left[ \frac{P(C)}{1 - P(class(Ri))} \sum_{j=1}^K \frac{\text{diff}(A, Ri, Mj(C))}{m \cdot K} \right]$$

Step 10: **end;**

#### E. Result and Discussion

ReliefF algorithm estimates the weight of each feature and sorts features according to their weights. Fig. 4 shows the most important weights of 20 selected features, the highest feature weight is equal to 0.257.

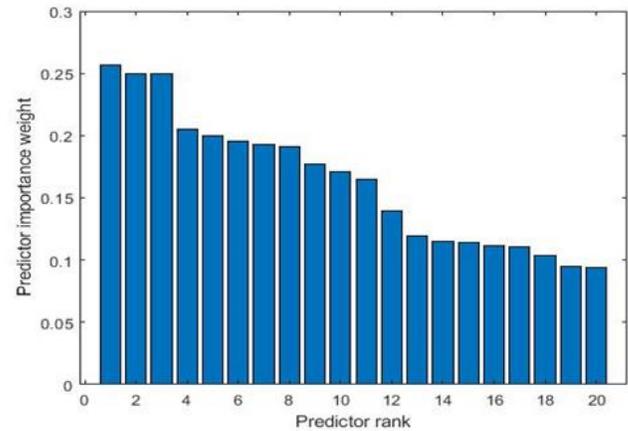

Fig. 4. Weights of Selected Features.

Tables I and II show features selected in the windows 10 dataset using the correlation function in [23] and features selected using the ReliefF algorithm in our proposed model, respectively. The selected features will be then used for training and testing machine learning and deep learning algorithms to evaluate their efficiency in classifying the dataset as normal or attacks data.

After selecting features, we apply deep learning and machine learning techniques to classify the data as normal or as attacks data. The algorithms applied are KNN, SVM, Neural Network, and LSTM. We apply different types of KNN algorithms (such as Weighted KNN and Medium KNN), SVM (like Linear SVM and Fine Gaussian SVM), and Neural Network (like Narrow NN and Bilayered NN). Table III shows the performance metrics of classification algorithms applied to the features selected in [23] in the windows 10 dataset. Table IV shows performance metrics of classification algorithms applied to the features selected using the ReliefF algorithm in windows 10 datasets.

TABLE I. FEATURES SELECTED FROM WINDOWS 10 DATASETS USING CORRELATION FUNCTION

Feature selection method	Selected Features
correlation function [23]	<ol style="list-style-type: none"> <li>1. Network I.Intel.R 82574L GNC.Current Bandwidth</li> <li>2. Network I.Intel.R 82574L GNC.Packets Sent Unicast.sec</li> <li>3. TABLE III. PERFORMANCE METRICS OF CLASSIFICATION ALGORITHMS IN FEATURES SELECTED USING CORRELATION FUNCTION IN [23]

Classification algorithm	Accuracy (%)	Precision	Recall	F_measure	AUC
Medium KNN Model	93.47	0.664	0.957	0.785	0.99
Weighted KNN Model	94.02	0.686	0.956	0.799	0.99
Linear SVM Model	75.48	0.006	0.006	0.006	0.97
Fine Gaussian SVM Model	91.22	0.594	0.926	0.724	0.99
Bilayered NN Model	92.23	0.622	0.956	0.753	0.99
Medium NN Model	94.12	0.689	0.962	0.803	0.99

TABLE IV. PERFORMANCE METRICS OF CLASSIFICATION ALGORITHMS IN FEATURES SELECTED USING THE RELIEF ALGORITHM IN THE PROPOSED MODEL

Classification algorithm	Accuracy (%)	Precision	Recall	F_measure	AUC
Medium KNN Model	98.15	0.994	0.979	0.987	0.99
Weighted KNN Model	98.22	0.991	0.983	0.987	0.99
Linear SVM Model	96.54	0.985	0.964	0.975	0.99
Fine Gaussian SVM Model	97.97	0.992	0.978	0.985	0.99
Bilayered NN Model	98.17	0.996	0.977	0.987	1.00
Medium NN Model	<b>98.39</b>	0.996	0.980	0.988	1.00

TABLE V. PERFORMANCE METRICS OF LSTM IN FEATURES SELECTED USING THE RELIEFF ALGORITHM AND CORRELATION FUNCTION

LSTM model	Accuracy	Precision	Recall	F_measure
Relieff algorithm	70 %	0.72	0.94	0.81
Correlation function	68.9 %	0.71	0.95	0.81

Long Short Term Memory algorithm (LSTM) is also applied to features of windows 10 which are selected from using the correlation function in the paper [23] and the Relieff algorithm in our proposed model. Table V shows the comparison of performance metrics of the LSTM model applied to the features selected using the correlation function in the paper [23] and the Relieff algorithm in our proposed model in windows 10 datasets.

The results showed that the accuracy of the LSTM model is 68.9 % of features selected from using the correlation function, and the accuracy of the LSTM model is 70 % of features selected from using the Relieff algorithm and the Precision is 0.72 in our proposed model unlike in the paper [23] is 0.71. This indicates that our proposed model has achieved the best results.

The results of Table III and Table IV showed that our proposed model has achieved the best results, as in our proposed model the Medium NN Model has best results than in results in the paper [23]. The accuracy of the Medium NN Model in our proposed model is 98.39 and the Precision is 0.996 unlike in the paper [23] the Medium NN Model has achieved 94.12% and Precision is 0.689. Also Weighted KNN Model and Bilayered NN Model accuracy is 98.22%, and 98.17%, respectively. Unlike in [23], the Weighted KNN Model and Bilayered NN Model accuracy is 94.02%, and 92.23%, respectively.

The accuracy of the Linear SVM algorithm in our proposed model is 96.54 %, but in paper [23] the accuracy is 75.48%. The reason this algorithm has achieved lower results than other machine learning algorithms is that this algorithm works more efficiently with two classes, but if it works with a dataset that has multiple classes may achieve low accuracy, and it isn't suitable for large datasets.

LSTM also has archived low accuracy as it doesn't work efficiently with a large number of samples. As the number of samples increases, the accuracy of LSTM tends to decrease. Figure 5 shows a graphical representation of the accuracy of algorithms applied to features selected from the windows 10 dataset. This comparison shows that our proposed model has achieved the best results than the results of [23].

Fig. 6 and 7 show the graphical representation of performance metrics of our proposed model and of [23], respectively.

Fig. 6 and 7 show that our proposed model has achieved high values of performance metrics against another work [23].

All results of our proposed model are better than the results of [23]. It indicates that the Relieff algorithm selects the most important features and it can work with multiple classes.

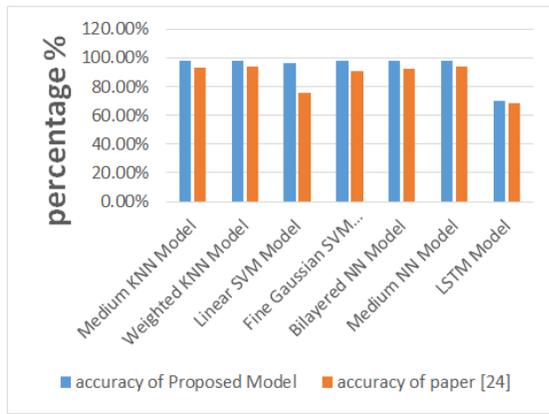

Fig. 5. Accuracy Comparison between Paper [23] and our Proposed Model.

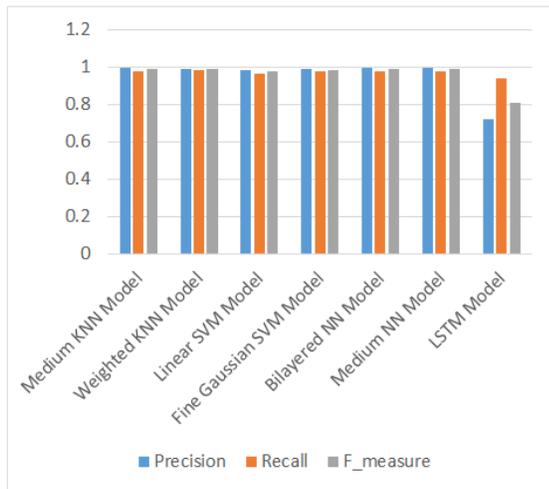

Fig. 6. Performance Metrics of our Proposed Model.

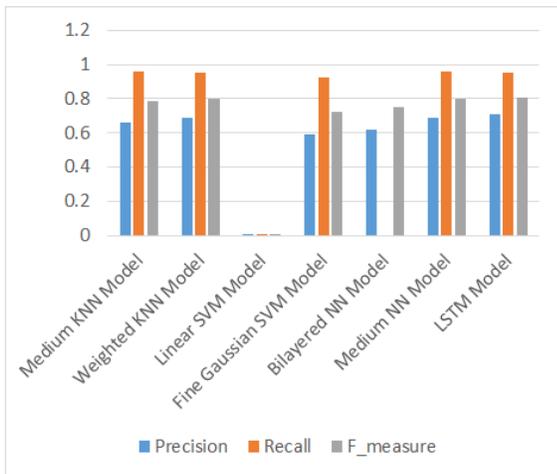

Fig. 7. Performance Metrics of Paper [23].

## VI. CONCLUSION

This paper has introduced an efficient IDS for the IoT environment. The paper uses the benchmark dataset ToN\_IoT which includes IoT telemetry data. ReliefF algorithm is proposed to efficiently select the most vital features to get more

enhanced performance and computations reduction. A comparison is carried out with the correlation function by applying machine learning and deep learning algorithms to the selected features from the windows 10 dataset. The proposed model has been applied to the windows 10 subset. The experimental results reveal that our proposed model has achieved better results than theirs. Our proposed model has high accuracy such as using Medium Neural Network, Weighted KNN, and Fine Gaussian SVM has 98.39 %, 98.22 %, and 97.97 % respectively. In the future, we will use Transfer Learning to enhance the accuracy of the Long Short Term Memory (LSTM) model.

**Abstract**—The elevated version of the Agricultural Traceability System dealing with food production holds utmost significance in not only assuring food insecure, smart contracts and agri-insurance to farmers but also guaranteeing insurance to them during natural disaster. The proposed and improved system for food cultivation traceability deals with agri-crops and farmers that hires the Blockchain technology guarantee at par safety, agreement, distributed ledger, immediate payment, decentralization and thereby achieving the goal of minimizing the cost incurred in the food processing system and building trust. Smart contracts play a pivot role in the field of agricultural insurance. Agricultural insurance based upon Blockchain comprises of major weather incidents and associated payouts enlisted on a smart contract, connected to the mobile wallets with timely weather updates notified by the field sensors and interrelated with data from proximity weather stations would enable prompt payout during any natural calamity such as flood or drought. A panel of advisers in the decentralized system which is professionally governed and managed by certain retired officers makes the traceability system more trustworthy. These professionals can offer wise suggestions to the planters aiding them to acquire productive outcome.

**Keywords**—Blockchain; distributed ledger; consensus; decentralized; stakeholders; agricultural insurance; payouts; trust-based farming system; food safety; panel of advisers; agri-supply chain

## I. INTRODUCTION

Food safety tends to be an over concerning matter which is seeking attention worldwide. Both the agricultural sector and food quality are of utmost necessity without doubt and it is crucial that the end-user receives a quality product. But without any centralized framework, this is infeasible to achieve. Usually, the food supply chain is quiet long as it involves various sub departments such as farming, producing, transporting and much more. There are many restrictions and formalities which becomes hindrances in addressing the challenges faced and fulfilling the needs of the end customer. Not only the end-users, farmers and transporters are of major concern but there exist other challenges too that can't be neglected. Factors or entities such as the stake holders, agricultural insurance, factory staff, wholesales shops as well as the retail shopkeepers are of significant importance in the process of food supply chain and involves many complications which must be closely observed as pointed out by [1].

The initial stage of food supply chain is Farming. If Unscientific farming methods and inefficient agricultural process are being practiced, it will hamper both the production and the quality. Also, the fertilized agricultural area will be affected and neglected by the farmers for carrying out further farming. Another underlying factor is the seed's quality that will be sowed in the field. In case of small-scale fields, the loss incurred due to poor quality of seed can still be handled. But fields that are in huge acres and caters to voluminous production cannot take any chance with the quality of the seed. Adopting unscientific means in treating and handling animal-farms can lead to severe diseases in animals and can transmit to humans like the avian flu. Also, if the feed and food are contaminated with chemicals, it can be risky and unsafe for the animals and any other products according to [2].

According to experts, the cost of production and transportation has an impact on the market value of the finished product [3]. Once the products are collected from the producers, the overall expenses and transportation overhead is computed and evaluated by the stakeholders which may not be so trustworthy. Such computations are bound to be altered and misleading because of varying fuel cost, bribe and corruption involved thus causing inflation. Due to such deeds, economy of the entire nation is at stake. After the stakeholders, the wholesale and retail keepers come into the picture where it is very likely that the market value of the product can increase further. Inflation affects the trading of food retailers leading to shutdown of stores, rise of independent retails power, polarization of store sizes and the targeting of market struggles as put forth by [4]. Apart from the cost, the food safety too gets hampered with such inflation. In other words, inflation is directly proportional to the loss incurred, higher the loss, higher will be the corruption and higher will be the inflation. Both the quality and quantity get affected right from the stockholders to retail shopkeepers as emphasized by [5].

The reason behind all the above prominent issues is the lack of a well-designed traceability framework comprising of all the departments. According to the concept, all individuals who are a part of the food supply chain, from the seed seller to the end user, must be catered to and accommodated. [6]. Missing upon any one entity or not abiding by the said criteria, development of any system will contract black holes thus becoming a failure and inefficient structure in the market. Hence, it is essential that every single department is taken into

consideration along with effective planning. The proposed system includes all the important departments that are essential in the formation of a complete food supply chain. That is starting from the Seed Seller → Farmer → Insurance Company → Government Panel → Producers → Distributors → Retailers and eventually the end-user.

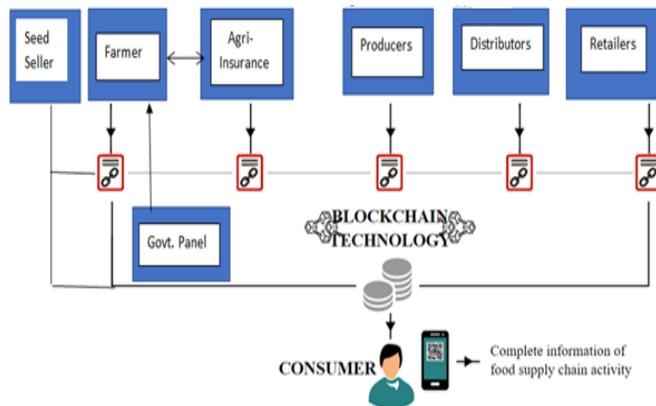

Fig. 1. Production Flow in Food Crops Supply Chain.

Fig. 1 shows the proposed system's production flow in food crops supply chain. The main goal of this article is to improve the agricultural traceability system for food production using Blockchain technology. The Blockchain technique is adopted to frame the above system as per [7] a Blockchain resembles a digital transaction ledger that is controlled using a network of various computing machines without involving the interference of any third party. Management of blocks in a Blockchain which represents individual transaction data files is accomplished using certain software platforms that enable data transmission, processing, storing and its representation in human understandable form. This technique works as per certain standard set of rules according to the consensus mechanisms (run by algorithms). In this form of a distributed consensus, a single authority is not designated as trustworthy but the responsibility is distributed across the entire network. There are various consensus mechanisms prevailing. Hash functions, or hashes, produces a digital fingerprint from the input data or referring an entire document. Similar to the human fingerprint that matches a single person, a digital fingerprint uniquely identifies a single data unit. Any minute alteration in the transaction data leads to totally dissimilar fingerprint. This makes the ledger highly secure against any tampering.

Every process that takes place along the food chain is there and then recorded to the Blockchain. This recorded information is indisputable and is willingly accepted by all the participants. Also, the recorded information is thoroughly verified by the stake holders of the agri-supply chain thus building an agreement amidst among the partakers. Every Block that is validated is then appended to the transaction chain to form a permanent record of the Blockchain. There are certain low-cost agricultural insurance schemes that offer social security to numerous farmers whose livelihood are severely impacted due to the natural calamities. Though such insurance schemes are beneficial, they are rarely availed by the poor farmers or rural

people. The potential benefits of the proposed system include profit to all the stakeholders involved in the agri-supply chain. When a transaction is created by a stakeholder, that gets stored in pending transactions and it gets added to the Blockchain once the miner validates the block.

In an agricultural supply chain, traceability of products involves collection, exchange and handling of critical information by determining the source and all the information communication taking place in food supply chain. This information is dynamic in nature as the crops are produced and directed through various middle man; hence following and tracing it becomes infeasible. Spoiled food and its consequences to community health enforce the essential policy tool of traceability for precise monitoring of food standard and protection. The prevailing tool employed in agri-supply chain for traceability confronts data fragmentation and centralized controls that degrade data modification as well as its management. For overcoming the above situation, improvised agricultural traceability system has been recommended that benefits food production and farmers using the effective means of Blockchain technology. Moreover, the control panel's timely and consistent advise pertaining to the crop's status proves to be utmost helpful to the farmers.

The present research aims towards revealing the working of Blockchain in efficiently tracing the agricultural products, make the transparency between all the participants higher and increase food safety in the food processing system for achieving at par efficiency and information sharing. Parameters such as weather, crops, irrigation and fertilizers for agricultural inputs form the dataset. The suggested method creates a Blockchain-based food production system that reduces transmission costs, improves efficiency, and increases security throughout the food supply chain. Security, distributed ledger, consensus, speedy settlement, and decentralization are just a few of the characteristics that have been improved. The SHA-256 (Secure Hash Algorithm) hashing technique is used to determine the hash for agricultural inputs. Agricultural insurance based on Blockchain, which includes major weather incidents and associated payouts enlisted on a smart contract, and which is connected to mobile wallets for timely weather updates notified by field sensors and interrelated with data from nearby weather stations, would be possible. When combined with data from nearby meteorological sensors, it would be possible to pay out quickly in the event of a natural disaster such as a flood or drought.

Compared to the other existing systems, the proposed work has the following advancements:

- The novelty of the proposed system has a module called Agri-Insurance, which is responsible for providing Insurance to farmers for buying seeds and timely payout is given to the farmers during natural calamities.
- The proposed system deals about the agricultural crops and farmers which uses Blockchain technology, that guarantees security, agreement, shared record, fast payment and decentralized network, that achieves the goal of minimizing cost incurred in the food processing system and building trust.

- All transactions are recorded in distributed shared ledger which associates to IPFS that ensures the transparent and traceable in supply chain.
- Blockchain based proof of delivery with automated payments is made to all parties using cryptocurrency by the smart contracts when crops and products are delivered.
- Government Panel gives wise suggestion to Farmers enabling them to increase the crop yield and to take fruitful decisions.

The entire work is classified into the following: Section 2 highlights the literature survey on Blockchain technique implemented in agricultural domain, Section 3 discusses the recommended technique by elaborating the performance of Blockchain in agricultural processing and uplifting the overall trust and security in the agri-food supply chain, Results and discussions are put forth in Section 4 and the conclusion is stated in Section 5 along with the future works.

## II. RELATED WORK

It is very well-known that the present agriculture system experiences many setbacks and the technique of Blockchain is the beacon of hope. Though implementing and making best use of this technique still remains ignorant to many. Whereas on the other hand the so called 'Blockchain onlookers' are vigilant against the restrictions and inadequacies of the Blockchain and accordingly apply it in real sense. Hence the need of the hour is to determine the relevant situations in businesses where the implementation of BCT can be revealed in its true sense.

Numerous organizations are seeking towards implying the transparency and fault tolerance of Blockchain technique for handling situations that involves multiple unreliable entities for the distribution of certain resources. In addition, the ceaseless advancement and performance of the Blockchain in various crypto-currencies has won trust of everyone. The agriculture and food supply chain depicts the highly significant domains as indicated by [2].

It has been more than ten years since the whitepaper "Bitcoin was launched. Introduced by a pseudonymous author, this Peer-to-Peer Electronic Cash System" became the very first crypto-currency that enabled trusted financial transactions without the involvement of any banks or financial institutions. The present research lays foundation for the advancement of Bitcoin according to [3]. This technology in collaboration with Blockchain cracked the issue related to double-spending wherein the digital tokens had drawbacks because of duplicate or erroneous computer files.

BCT employs a set of techniques holding a sound year of experience in information technology as well as in commercial domain. Some of them are: private and public key, hash functions, databases particularly the shared databases, agreement algorithms and decentralized systems as put forth by [4]. The prime aim in implementing these techniques is to gain database consistency and integrity with respect to a distributed decentralized database with either controlled or uncontrolled database nodes (such as Bitcoin).

Distributive storage is the best part of this technique. In other words, the information residing in the database resides not just on a single server but rather on innumerable computers spanned across any geographic location. Users that are a part of this network are permitted to access the current registry. Moreover, participants can independently carry out any transactions without the interference of any intermediaries such as the banks. According to the Blockchain system, all digital documents are combined into blocks that are encrypted before computer miners organize them in chronological order by mining - solving relevant mathematical techniques [5].

Blockchain has gained significant popularity in the agricultural system as it immensely benefits the market agents as put forth by [6] Manufacturers are not in favor of employing state-of-the-art or highly cost techniques since the end user just receives the final product and has to do nothing with the overall food supply chain or the cost incurred in every process. Also, this value does not become monetized. The aforementioned system assures to handle this issue effectively. The Blockchain technique attempts to minimize the intermediaries involved from producer to end user through the translucent fixation of all the data in the supply chain. Moreover, the technique helps in determining the buyers who are ready to pay additional amount for those products which are superior in quality and requires expensive techniques in their production as observed by [7].

Food processors confront lack of adequate information for validating the actual source of products (like in case of hormone-friendly chickens). The processor's products gain trust only if there is precise information related to its processing as well as its source. And, in order to do so, precise data of the complete cultivation procedure has to be obtained from every producers/farmers, according to [8]. In fact the manufacturers must be inspired by the Recyclers to brief about all the processing information willingly, albeit they do not share it. Herein lies the importance of the "Blockchain" which helps the manufacturers to share such information in a secure manner that has to be further precisely validated.

Agricultural supply chain must be equipped with proficient logistics management with consistent supervision of development of agricultural products for achieving the safety of the product. Issues pertaining to food security and also the spoiled food calls out the necessary of improvised traceability system for the entire food supply chain as ascertained by [8], [9]. Also, with the trading of agricultural products to different geographical locations, there must be keen tracking and conformance as per the country specific guidelines [10] [11]. In an agricultural supply chain, product's traceability comprises of information collection and its communication and management by determining its source accurately.

Mao et al. [12] has recommended the approach of consortium Blockchain for improvisation of food trading system. Towards this, a Practical Byzantine Fault Tolerance (PBFT) algorithm has been suggested for the optimization of buyers trading portfolio within the food supply chain. The proposed system is verified by Mao et al. by employing the consortium Blockchain.

The traceability system applied in the food and agricultural supply chain enables tracking and tracing of the products through their origin, mentions [13]. Previously, the conventional traceability system just needed the database technology for allowing the user to store entire information in it and the MySQL database was one such popular means. Though the database technique helps in tracking information but it suffers from human error while performing the data collection.

The research has put forth a popular Blockchain technique referred to as the Ethereum Blockchain, for implementing the traceability system. Using the web3 API, data from Ethereum Blockchain can be revealed. Unlike the critical data, data in the ledger can be viewed by anyone in the Ethereum network. Bigger the network size, higher will be the expense and time involved in generating the blocks. Another disadvantage of using a Blockchain database is the requirement of a specific set of commands for each Blockchain in order to query the information, as mentioned by [14]. That is, searching information in a conventional Blockchain database can be difficult.

For building the prevailing food traceability systems (or models), following were taken into consideration: (i) information and communication techniques along with RFID (Radio Frequency Identification) and NFC (Near Field Communication); (ii) DNA bar-coding as highlighted by [15]. These tools were responsible towards food tracing and tracking along with its identification and monitoring so as to preserve its quality and safety across the entire supply chain.

The food industry Blockchain needs a data platform with intense investment in generous IT elevation and infrastructure, covering the essentials like APIs for encrypting and recovering data, creating and maintaining ledger, storage, communications and much more. The block must be automatically generated by the ledgers via cultivation procedures. Governing and paying for such an IT framework is the point of concern as portrayed by [16].

There has been evaluation of various cases pertaining to the supply chain research literature, aiming towards comprehending the Blockchain impact on major supply chain parameters namely: transparency, cost, risk reduction, quality, trust, sustainability and flexibility. Blockchain significantly contributes in elevating transparency and accountability thus raising trust and cooperation amidst the supply chain members as surveyed by [17] for reviewing the implementation traits at an individual level, the UTAUT model can be employed across USA and India.

Allocating Blockchain distinct digital hashes for the products help to trace through the supply chain and also to determine their growth status, batch numbers and expiry dates. In addition, it helps in avoiding food wastage, enabling consumers to understand the environmental foot printing for the foods and guiding towards the distribution process of excess foods. This accurate food and transactions records helps in preventing any sort of fraud as well as determining the source for food borne illness. Moreover, the digital traits of these techniques can enable on-farm data sharing as reported by [18].

By incorporating the GPS directs every locality with respect to the distribution flow that enables traceability of products when encountered with an accident. The system is beneficial in the cold chain distribution, wherein if the temperature and humidity surpasses the given limit controlled on the smart contract, an alert is notified to the concerned personnel for regulating the delivery condition. Wu et al. offers the stakeholders with authenticated visibility of physical delivery process that draws recognition of goods transportation from the supplier to the customer as put forth by [19].

Generally, the stakeholders linked this system which exhibits high rating process to the customers. This could be smoothly achieved by the Blockchain technique by offering transparent, efficacy, confidentiality and also privacy amidst all the contestants. There lies immense scope and advancement for the organizations employing the Blockchain technique and the associated service applications. Irrespective of the overall Blockchain experience, the developers must inculcate at par measures against security risks right from designing to development according to [20].

Its quiet apparent that the agri-food system comprises of multiple stakeholders that desires seeks for superior and secured goods with maximum possible information, discussed by [21] There are chances that the issue of information asymmetry surfaces. According to the discussion, asymmetric information surfaces when the parties are partially intimated during the economic transaction thus preventing the distributions of resources that leads to failure in the marketplace.

The proposed traceability system ascertains to be more farmer friendly and gains popularity in contrast to the prevailing traceability systems. Farmers represent the backbone of the food supply chain and hence their presence is supreme most. The system targets towards offering unconditional and timely support to the farmers in a friendly manner so that maximum of them can benefit from it. Farming has been a keen interest and necessity of numerous people worldwide but the risks involved and lack of knowledge regarding the technique's add process involved, restrain them from doing so as elucidated by [22]. And hence the introduction of a rich experienced panel can uplift the vision and actions of farmers as well as of the entire market. In addition, the farmers can get immensely inspired to independently build their own business. The system would also guarantee better food quality and economical support from insurance agencies in case of any natural calamity, states [23]. The information can be encrypted using Advanced Encryption Algorithm [24].

### III. PROPOSED SYSTEM

#### A. Overview

There is proposal of an agriculture traceability system built for various stakeholders that are an integral part of a food supply chain. Towards this, a suitable trust-worthy framework has been built which emphasizes the food security and generating the revenue for every department which are involved. The system caters to and includes the primary entity of seed sellers to the final entity i.e., the end-user of the food supply chain. The centralized feature of the proposed system

ascertains the systematic flow of the chain and makes sure that the processes involved are completely scientific oriented. Upon the willingness of the farmer to take up agriculture and get connected to the system, an agreement is made with the insurance company. Various agriculture insurance companies precisely specify their insurance criteria and qualification to the concerned farmers based upon which the farmer can make the decision of selecting one specific company for the policy. This agreement forms the first stage in the system. By examining the consistent information uploaded by the farmer, the insurance company can keep a check on the farmer's land or crops. This information can be accessed by all the departments in the chain for checking the growth status. Next, comes the process of good breed seed selection. This being an essential and critical step since the further results highly depends on this. As the plant grows, the Blockchain technique is employed for managing the further stages. The smart contracts in the Blockchain are responsible for triggering alerts and events upon receiving any function calls as a transaction. This helps the relevant entities to consistently supervise, track and receive appropriate alerts in case of any disaster. Resultant, any natural calamity can be timely and effectively restored within the food supply chain. Fig. 2 clearly depicts the Blockchain based Agricultural Traceability System. The seeds sold to the farmers are allocated standardized identifiers using which digital connectivity and tracking of any transaction between the participating entities can be achieved. Algorithm 1 elaborates the complete registration process of a new farmer. The IPFS helps in recording the consistent and timely growth of the crop. All the captured images related to the crop's growth are time stamped and the smart contract is utilized for storing the IPFS hash of the file. The hash values are determined through the SHA-256. Cereals grown by the farmer are stored in the elevator only after verifying the right humidity, temperature, moisture, heat etc. The processor then buys the cereal for giving the final finish to the product. Thereafter, the finished product is purchased by the distributor for shipping it further to the buyers.

### B. Methodology

1) *Process of registration:* As aforesaid, the achievement of this system hinges around to how many farmers or agri-oriented people have been successfully associated with the proposed system. The suggested traceability system must inculcate and manage full fledged database involving all the participants. Hence, formal and precise registration with authentic information is necessary. As soon as a member request for joining, the database will be updated by the same. The credentials such as username and password are verified and based on its authenticity, a Blockchain is generated which is then allocated to the relevant member. It is assured that the farmer's information is kept confidential and just the relevant information about a specific farmer is made available to others. Only for the identification of the member's identity, personal information is made use of and its ascertained that there is no misuse or privacy breach of this information. For logging into the system, the farmer must use the valid credentials such as

the userid and password and upon exiting, it ensured that the page or account is logged out. This is made compulsory so that there is no misuse of the account. Algorithm 1 depicts the registration process of a new member.

2) *Agreementation:* The proposed system enables the farmers and insurance companies to carry out the business practices in coordination and a smooth manner. It cut downs the farmer's effort and time in identifying the apt insurance schemes and neither the insurance companies require to spend their energy and time in selling their policies. Based on the detail briefing given by the farmer of his plan, the insurance company put forth their norms and condition once the farmer's plan is verified. The farmer is free to make the policy selection according to his contentment. The centralized system acts as an evidence for the entire process taking place between the farmer and insurance company. Every single step gets recorded in the database as an evidence. This can be later useful, in case any conflicts or arguments emerges between the parties. The system is upartial against any member and it ensures that no conflicts takes place between them. That is, whether it be farmers, insurance company, processors or any department, all will be treated equally and can benefit from the system in a transparent manner. This helps in building a united, trustworthy and sturdy food supply chain. The system ascertains that, as and when the farmer intimates regarding a natural calamity, a notification or alert is triggered and transmitted to the relevant company. There is a consistent follow up by the system until the farmer receives the insured amount as per the terms and conditions. Hence, with this fail proof system, there is trusted and transparent relationship is established between all the participants. There may be cases or situations which may not comply with the given norms or conditions, in such scenarios the system automatically agrees or support the company policies rather than the client's plea. Hence, the system presents the whole agreement in a precise and transparent manner so that both the parties remain vigilant about the same.

3) *Seed selection:* Once the registration is completed and the contract is signed, the farmer needs to buy large bulk of good breed seed from the seed seller. This tends to be the most important decision since the entire crop production depends on the quality and fertility of the seed. The farmer gets to choose from the enlisted and registered seed companies present in the system. Algorithm 2 elaborates the process of seed selling by the relevant seed company. On signing up the initial contract, the smart contract verifies the farmer's registration and subsequently the payment for the seeds bought is done via Agri Insurance. That is the required money for purchasing the seeds is provided by the Agri Insurance to the farmers. If all goes well and successful, then the contract state becomes as Seed Request Submitted, the farmer state becomes Wait for Seeds and seed company state becomes Agree to Sell. This change of 'state' is notified and updated to all the participants in the supply chain. If not updated, then the state of contract reverts back to initial state thus terminating the transaction.

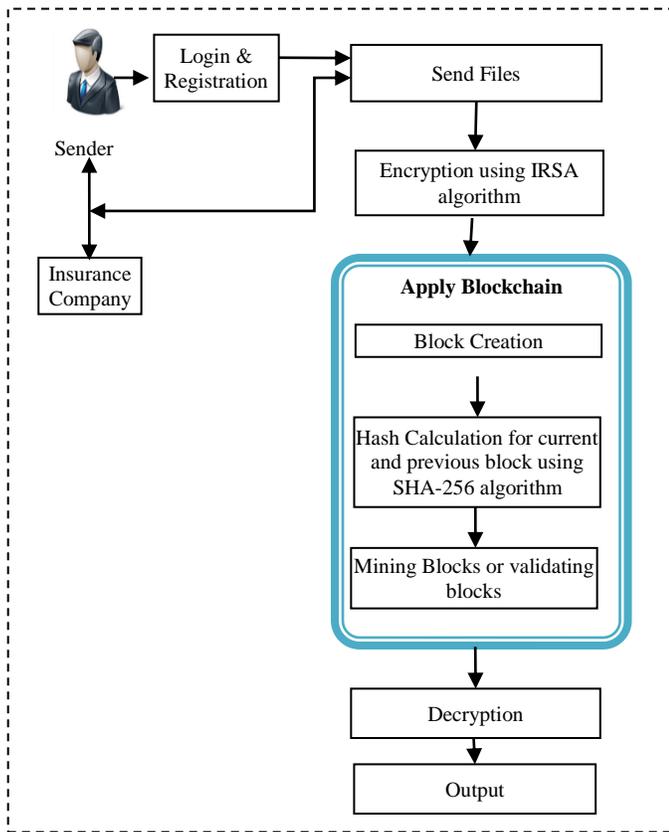

Fig. 2. Architecture Diagram for Blockchain based Agricultural Traceability System.

### Algorithm 1 New Farmer Registration

Inputs : Request for New Registration

Nodes of the current Blockchain network(N)

Outputs: Newly entered farmer f

Step 1:  $(K_{pub}, K_{pr}) = generatekeys()$

Step 2:  $uID \rightarrow create\ userID(); BlockchainAddress() + (K_{pub}, K_{pr})$

Step 3:  $Addr \rightarrow create\ BlockchainAddress() + (K_{pub}, K_{pr})$

Step 4:  $(uID, kpr) \rightarrow safelystore(uID, K_{pr})$

Step 5:  $Walt \rightarrow creates\ BlockchainWallet() + (K_{pub}, K_{pr})$

Step 6: for every node,  $n \in N$  loop

Step 7:  $distributeWallet(n, Walt)$

Step 8: end for

Step 9:  $u \leftarrow verifiedNewfarmer()$

### Algorithm 2: Selling Seed to Farmers

Step 1: Let  $G_1, G_2, \dots, G_n$  be the registered farmers,

Let  $t_1, t_2$  be the token of farmer and Seed Distributor respectively

Consider Quantity, SType, SBrand, SPrice

Step 5: Contract State is created

Step 6: Farmer State  $\rightarrow$  SeedsReq

Step 7: Seed Distributor State  $\rightarrow$  Ready

Step 8: Restricting access to only registered farmers i.e.  $g \in G$

Step 9: If farmers = G and SPrice = paid then

Step 10: Contract state  $\rightarrow$  SReqSubmitted

Step 11: Farmer State  $\rightarrow$  WaitforSeeds

Step 12: SDistributor State  $\rightarrow$  AgrreToSell

Step 13: Notification msg to state sale of seeds

Step 14: end

Step 15: Else

Step 16: Revert contract state and display an error msg

Step 17: End

4) *Blockchain technology*: Post seed trading process, the farmer enters the Blockchain or IPFS (Interplanetary File System) system. IPFS refers to a protocol within the Blockchain and depicts a P2P networks that facilitates file storage and transfer for a shared file structure. It grants users to accept host content and is based upon a decentralized system of user-operators, holding a segment of overall data. The IRSA algorithm is employed for encrypting the information sent by the farmer before it is stored. The information comprises of images pertaining to growth measurement, weather and soil reports which gets digitally recorded in the database.

In the Blockchain and IPFS system, every information whether it be data, reports or images, that are signed digital and attributes in a specific manner. The fields have installed cameras for capturing the images automatically which are then transmitted to the Blockchain where they get recorded. These cameras are specially crafted and provided to the farmers such that they cannot be tampered. Hence the images captured by them remain unaltered and authentic which can be trusted by all the entities in the Blockchain. Moreover, any illegitimate user is strictly prohibited from accessing this information.

In fact, the authorized user can also access just the permitted information. Data residing in the Blockchain is utilized for performing certain computations such as generating values for the observation including the hash value. These computed values are of utmost significance and directs if the farmer is following the correct method or not. Basically, there are two prime reasons for computing the hash value. First, for determining the growth rate, and second to track if the farmer is proceeding in the suggested and agreed manner. In case of any forgery or misconduct, penalties are imposed on the farmer which is being programmed automatically in the Blockchain. Hash value is computed using the SHA-256.

The food supply traceability system that incorporates smart contracts greatly aids in transmitting unimpeded information to all organisations in the supply chain without the involvement or control of any central authority. Each single transaction, right from seed selling, to the amount of crop produced and sold is recorded precisely which can be validated thoroughly. Like for instance, set quantity of cereal sold amidst the stakeholders with respect to the specified norms is not subject to change. Moreover, mixing of cereals with different quality is not allowed for selling. Since it is difficult to monitor the status of the field and crop growth, the IPFS helps in uploading the crop and land images periodically which can be verified and accepted by all.

For assuring elevated Quality Compliance, all the corresponding transactions amidst all the entities is traced. The sensors are highly equipped with the feature of sending consistent alerts pertaining to the crop and land status. The Blockchain technique prohibits modification of any info or alerts and permits the accessibility of information to all the authentic entities in a secure and decentralized way without the involvement of any central figure. Apparently, there can be cases of fraud by reporting misleading information by the stakeholders. Such data is automatically verified by the Blockchain whether it appears to be fraudulent or not. For guarding and preventing against such frauds, Blockchain can be programmed to nullify the supply chain process thereby imposing penalties on such stakeholders. By performing this precise and undoubted traceability s presented to the supply chain stakeholders.

5) *Support to the farmer:* While carrying out farming, the farmers need wise and effective suggestions from the system. Towards this, it is essential that the farmers upload timely and precise information and images pertaining to the crops. Certain essential factors that must be reported includes: growth of the crop, temperature, average rain measurement and soil components along with its percentage. As and when the values are fed by the farmer, the database must be updated. Using Algorithm 2, the transactions are mined and hash values are created. The database has a collection of information related to the crop. In addition, it has the fertilization requirement for the relevant crops at every level and in varying weather conditions. As the farmer updates regarding his crop, there are suggestions provided regarding the further stages. This enables the farmer to nourish its crop with the right amount of manure thus making the entire farming economical, Fig. 3.

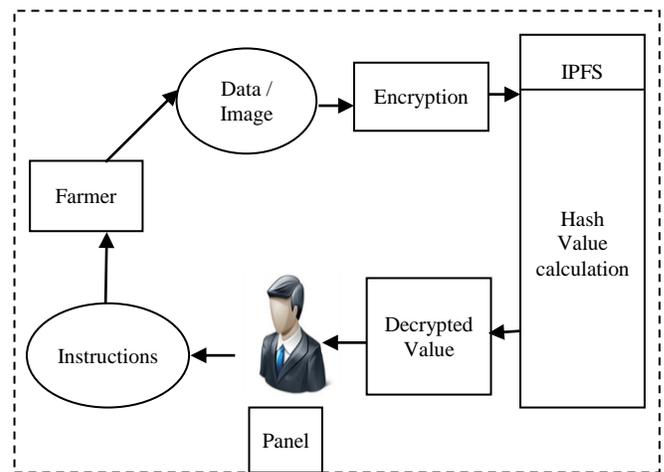

Fig. 3. Instruction Forming to the Farmer.

6) *Trade in the end:* After the farmer produces quality crop and there is completion of all the processes, the crop or the end product is ready for selling. Based upon the market value there can be negotiation in the price with the distributor and vice-versa. Each transaction taking place is recorded correspondingly in the system for performing subsequent processes. Upon completing the entire process, the farmer is eligible for selling their products to the distributors. The system even records the overall interaction and trading of the farmer with the distributor. Above all, the system empowers and attempts to fulfil the farmer's effort without being partial or biased in its protocol.

$$\text{Farmer Satisfaction Index} = p(pr, pg) * (100 - \sum(pd)/n)$$

Here  $p(pr, pg)$  depicts the relation of  $pr$  (pay-outs requisite),  $pg$  (pay-outs given) and also  $pd$  resembles its pay-out variations (that is the variation among the required pay-out with respect to crop loss and pay-out with respect to the design agreements),  $n$  shows the total years. Present key factor equivalently caters to under and over-payments that is inconsiderable for the development of key insurance.

Lately, the retailers have flourished their own business with in depth understanding of stock holders and the product they comply with. Only the registered retailers are granted accessibility with respect to these essential attributes provided namely: Manufacturing date of the goods, purchase date, and the number of products Sold. Verification is done against the fulfilment of accepted sales agreement and product payment. If verified and true then the transaction is executed by the contract and the state becomes.

The state of the retailer turns to ProdDelSuccessful. For ensuring the successful delivery of the product, the contract notifies the successful delivery to the retailer. In case of any failure, the contract state turns into SaleRequestDenied. Eventually, the customer-retailer purchase or transaction is traced. The end user or the customer depicts the final entity of the entire network. At the beginning, the art of customer is ReadyToBuy. The smart contract allows those Customers who have the essential product information such as the Customer token, Retailer token, Purchased date, Sales Id and Product Id.

Once the payment is done successfully, the contract state becomes ProdSoldToCust, and the customer state depicts SuccessfulPurchase. In case any sales failure occurs, the contract intimates everyone in the network.

IV. RESULT AND DISCUSSION

The proposed system is tested in Blockchain network. The entire system is written in Java. The test system depicts briefly in Table I. Two major indices of system performance are: information uploading time and information response time. Fig. 4 to 6 exhibits the system test results of the mentioned indices.

Fig. 4 clearly reveals that the information upload time gets impacted according to the interval of upload request interval. This upload request interval varies between 100 - 900 times per second and based upon that the upload information time witnesses a rise from nearly 7s to 47s. A genuine rise of 600 to 700 is observed with the upload period rising around 25s to 42s. This reason may be attributed to the limitation of consensus agreement in Blockchain, whereas the single block which possess the restriction of transactions.

Fig. 5 and 6 exhibits that outcome of response period impacted at regular interval of transaction request. Fig. 4 presents the information response period exceeding from 2ms to 5ms with respect to the rise in capacity of on-chain transaction data ranges 1G - 9G. According to Fig. 5, the information response period increases a bit from 2.2ms - 3.2ms, with respect to the transaction request rising from 1,000 to 9,000 per second with the on-chain transaction data fixed to 1G. This is due to the mode of data query and P2P networking.

V. SIMULATION RESULT

Online dataset are being utilized for the collection of data and JAVA environment is used for the development purpose. Also entire dataset along with the results generated is managed and stored with the help of MySQL. Attributes such as crop, temperature, wind speed, irrigation, fertilizers and rainfall are main attributes. Other attributes used are seeds area etc.

Fig. 7b depicts collection of dataset information taken from Internet dataset. The Dataset are assembled been pre-processed to get the desired output. The dataset uploaded is of weather information.

TABLE II. COMPARISON OF PROPOSED SYSTEM WITH EXISTING SYSTEMS

Attributes	Fine grained access [27]	Food Supply Chain [28]	Deep Reinforcement Learning [26]	Soybean Traceability [25]	Yield Estimation System [29]	Fruit and Vegetable Agricultural products [30]	Proposed System
Agri-Insurance	no	no	no	no	no	no	yes
Government Panel	no	no	no	no	no	no	yes
Product Traceability	yes	yes	yes	yes	no	yes	yes
Timely Payouts	yes	no	no	no	no	no	yes
Responsibility	yes	yes	yes	yes	yes	yes	yes
Integrity	yes	yes	yes	yes	yes	yes	yes
Recommendation	no	no	no	no	no	no	yes

The predominant attributes of the proposed agricultural traceability system for food production shown in Table II is expounded below:

1) *Agri-Insurance*: Insurance module is implemented in the agricultural traceability system for food production to provide insurance to the farmers to buy seeds as well as during natural calamities. Upon the willingness of the farmer to take up agriculture and get connected to the system, an agreement is made with Agri-Insurance. Natural calamities like flood, drought, earth quake, unpredictable weather or disaster, loss due to harvest, cyclone, the farmer can claim for the insurance. The system checks, when the farmer intimates regarding a natural calamity, a notification or alert is triggered and transmitted to the Agri-Insurance company. Agri-Insurance checks the timely weather incidents like rainfall, temperature, humidity, wind speed etc and associated payout enlisted on smart contract and enable prompt payment to the farmers.

2) *Government panel*: The farmers can get wise suggestion from the advisory board members or government panel. Which crop should be cultivated in a particular season to increase the crop yield and maximize the profit, type of fertilizers must be used, soil type, irrigation method. The farmers will be updated to adapt new methods and planting techniques. This panel members helps farmers understand their crops better and about soil and quality of seed, organic farming, crop rotation, the potentiality to examine soil nutrients to enhance better outcome.

3) *Product traceability*: Product Traceability helps the stake holders and farmers to track and trace the product in the supply chain management. When the end user scanning QR code, complete information about the product can be traced.

4) *Timely payouts*: The farmers can get financial assistance during disasters occurs to food crops. The insurance amount is processed and settled on time.

5) *Responsibility*: The proposed agri-supply system's stakeholders are integrated and de-centralized. All the transactions are transparent and secured so that the intruders are denied to hack the data from the supply chain system. Farmers registered in the Blockchain network, also accepted

agreement can buy seeds, cultivate, sell and trade at the end to customers. The proposed system guarantee profit to all departments involved in the supply chain network minimizing the cost required in processing the food and build trust among the stakeholders.

6) *Integrity*: The transaction data which is stored in Blockchain and the broadcasted to all the stakeholders are immutable and persistent and it cannot be changed, tampered or deleted. The transactions taking place are transparent that have facility to track and trace the food crops from the beginning of the supply chain till the consumer purchase the finished product.

7) *Recommendation*: The farmers are recommended to acquire better crop yield such as the appropriate irrigation method, utilization of organic manure and fertilizers, method for crop rotation, high yield variety seeds, temperature, water, rainfall, soil type, humidity, weather, wind.

The proposed agri-supply chain using Blockchain, helps the farmers to buy seeds from authorized seed seller. The farmers can use agri-insurance to buy seeds and also during natural calamities. The finished goods can be send to the distributors and retailers and finally to the end consumers. The government panel members are the advisors who give suggestions to the farmers to get better yield.

## VI. CONCLUSION AND FUTURE WORK

The Blockchain method has seen explosive growth in recent years. The Blockchain approach has seen a clear and considerable increase in the agriculture sphere. This technique makes strong promises about food safety since it stresses the traceability of an agricultural product's origins as well as the validation of agricultural inputs. There is a safeguard in place to prevent the source of contamination from being traced. The Blockchain based agri-supply chain system is designed to get profit for all entities involved in the network. Though the Blockchain professes to be unbiased, it assures that low-income farmers benefit from small payments through Agri-Insurance. In future, when the end-user scan the QR code, the farming operations, information about the product, traceability information and security information can be traced. Also, the price of Bitcoin can be forecasted using intelligence techniques.

**Abstract**—Blockchain already has gained popularity due to its highly secured network and same time enormous computational power consumption has become an undifferentiated debate among the users. A Blockchain network is reliable, secure, transparent, and immutable where the transactions cannot be reversed between sender and receiver. Blockchain technology is not only used for mining cryptocurrency, it has other applications in different sectors like agriculture, education, insurance, etc., but the noticeable concern is still energy consumption. On the other hand, there is a significant impact on the environment due to the use of excessive energy for mining cryptocurrency which releases more carbon dioxide (CO<sub>2</sub>) in nature. The Proof-of-Work (PoW) algorithm is used for mining ‘Bitcoin’ which is consumed enormous computational power. However, an alternative solution like Proof-of-Stake (PoS) consensus protocol has been proposed to use instead of the Proof-of-Work algorithm for mining cryptocurrencies which is capable to reduce the significant amount of energy consumption. Not only that, but the use of renewable energy can also be an alternate option to use the Proof-of-Work algorithm for mining cryptocurrencies which is environment friendly. This paper aims to highlight blockchain technology, the energy consumption and impact on the environment, energy reducing method by using PoS consensus protocol instead of using the PoW algorithm, and discussion with some recommendations.

**Keywords**—Blockchain; cryptocurrency; bitcoin; Proof-of-Work (PoW); Proof-of-Stake (PoS)

## I. INTRODUCTION

Blockchain already has gained popularity due to its highly secured network. Bitcoin is the first cryptocurrency that was introduced by the pseudonymous name Satoshi Nakamoto [1]. Blockchain technology was used to develop this cryptocurrency. Bitcoin is also called digital currency which is used for transacting the currencies between peer-to-peer (P2P) into the blockchain secured network without the intervention of a third part intermediary [2-3].

A Blockchain network is reliable, secure, transparent, and immutable where the transactions cannot be reversed between sender and receiver [4]. Another strong security feature cryptographic hashing algorithm is used to maintain the data integrity by applying the encryption and decryption method this algorithm is also used for joining the blocks in

chronological order and forming a chain [5-6]. Decentralization of data and storing the same in all existing nodes in the network is an important feature to provide data backup [7]. The distributed ledger is used for keeping all the information in different geographical locations where every user is capable to view the data [8]. Proof-of-Work (PoW) algorithm is a very strong, secured, and powerful mechanism that is used for mining a new block into the blockchain network and keeping the transaction records in this block permanently [9-10]. In the last couple of years, a few numbers of a consortium like r3 Corda, Hyperledger Fabric, Ethereum, etc. have been formed in the banking sectors where some of them are already doing the transactions for cross-border payment among themselves on a pilot basis [11-13]. The not only banking sector, other sectors like healthcare, education, insurance, agriculture, etc. are highly considered for keeping their information in this blockchain network with the consideration of security and transparency [14].

Though blockchain technology has several advantages, some significant challenges need to be addressed by the implementation. Power consumption is one of the major concerns for people across the globe [15]. Proof-of-Work is the powerful algorithm of blockchain technology to mine a new block into the blockchain network which consumes the maximum amount of power [16]. Due to the enormous consumption of power, there is a huge impact on the environment due to the emission of carbon dioxide. Maximum power generates from fossil fuels around the world which help to produce carbon dioxide and pollute the environment simultaneously [17-18]. This paper will briefly discuss the background and architecture of blockchain in section II, cryptocurrency mining procedure by using the PoW mechanism in section III, methods of reducing the impact of producing cryptocurrency mining power and other impacts as well in section IV, and finally, the paper will be concluded by section 5.

## II. BLOCKCHAIN BACKGROUND AND ARCHITECTURE

First, the blockchain concept was introduced in 1990. In 1992 the trusted data tempering protocol was ensured in the format of a chain that guarantees the privacy of data in the form of the integrity of the records [19]. Fig. 1 shows the history of blockchain technology.

\*Corresponding Author

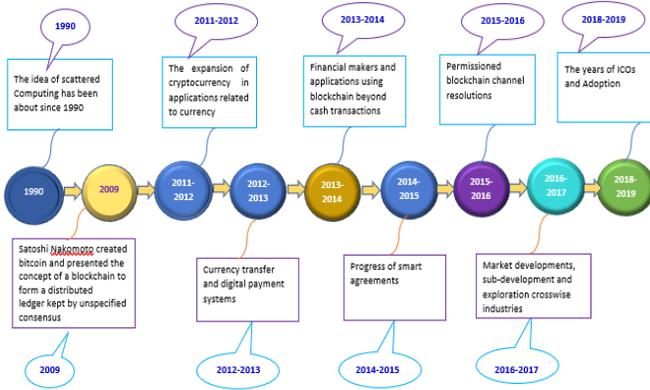

Fig. 1. A Brief Blockchain History [20].

The pseudonymous name Satoshi Nakamoto first introduced a new cryptocurrency called Bitcoin in 2009 for the peer-to-peer transaction into the blockchain network [1]. Gradually blockchain technology was becoming popular and more cryptocurrencies like Litecoin, Namecoin, and PPCoin were founded from 2011 to 2012 [21]. Some other remarkable cryptocurrencies Ripple, Dogecoin, and Stellar were introduced in the year 2012-2014 [22-23]. Another emerging cryptocurrency called Ethereum was came-up in the market by using a famous Ethereum blockchain network which was launched in 2015 [13]. Nowadays, there is a significant number of cryptocurrencies already have been introduced with their network infrastructures which are shown in Fig. 2. The maximum use of this blockchain technology and cryptocurrencies in the financial sectors. With consideration of the security, transparency, and reliability of this network, some other sectors like health care, insurance, education, energy, and agriculture have already started to implement blockchain-based applications in their companies in different countries around the world.

**A. Blockchain Architecture**

The architecture of blockchain is completely different from a traditional centralized database management system where the information is stored digitally in all the connected nodes in a decentralized manner rather than a centralized version [25]. All the blocks in the blockchain network are connected through a chain that a cryptographic algorithm uses to maintain security [26]. However, the block maintains three different parts data section, a hash of the present block, and the hash of the previous block. The useability of the blockchain network depends on the nature of the business aspect. The cryptocurrency blockchain keeps the transactional records in the nodes. Every time hash value will be changed if any new data will add or amended to the data in the blocks of the network [27]. The hash value is generated by using the hash function and it converts the data in a fixed format like 32 bits, 64 bits, 128 bits, 256 bits whatever may be the size of the input data [28]. It depends on the nature of the hash function. The previous block hash connects to the next block to form a blockchain network. The initial block is called the genesis

block where the hash value is 0 [29]. For example, in Fig. 3, a simple blockchain has been presented where the genesis block contains the 0 (zero) hash value for the initial, 7A4RFGY8 is the present block hash for block 1, 8GJI7RGY represents the block 2 hash, and so on where all the blocks have connected each other cryptographically. Due to this complex format, manipulation of records is almost impossible. To compromise any bit of information in the network, all the consequence hash values need to be changed in the entire network, and at least 51% of nodes to be agreed to make any amendment [30]. The distributed ledger is used to make transaction into the blockchain network which is an immutable ledger and help to resist the temperament of the data in the block [31].

**B. Data Signing and Verification Process**

The data signing and verification process is shown in Fig. 4. The plain text format data pass into the hash function and convert the data as the fixed hash format. The hash values are encrypted by using the private key of the sender and converted as a digital signature [32]. This digital signature is attached to the data and creates digitally signed data which send to the receiver.

On the other hand, after receiving the digitally signed data by the receiver, the receiver verifies the originality of the data. First, the receiver decrypts the encrypted data by using the signatory’s public key which helps to find the hash value [33]. Second, the receiver then passes the plain text data sent by the sender will pass through the hash function and get the hash value. The receiver will then check the integrity and originality of the data by matching both hash values [34].

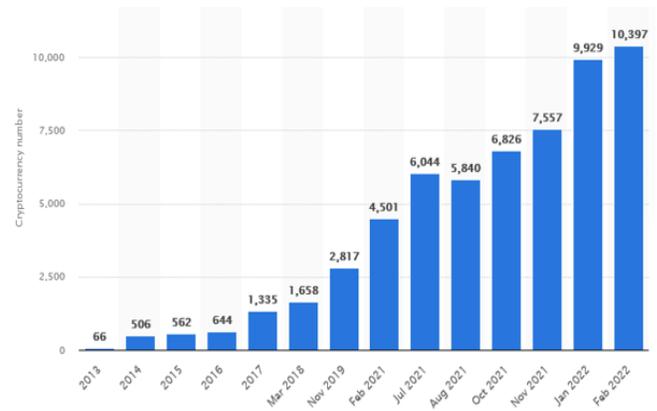

Fig. 2. Cryptocurrency Statistics [24].

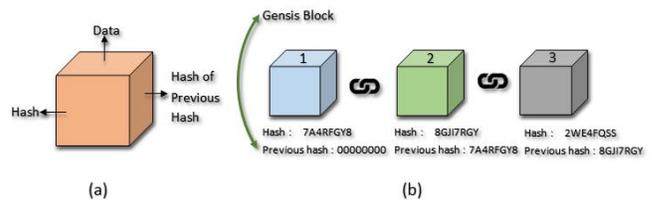

Fig. 3. Blockchain Structure.

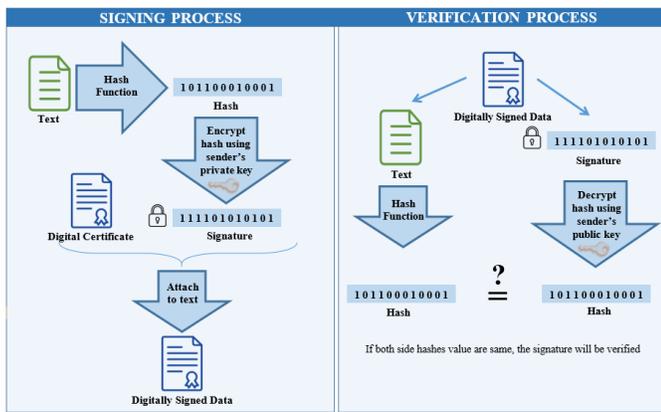

Fig. 4. Digital Data Certification Process in the Blockchain.

### C. Transaction Process into the Blockchain Network

There are a few steps that must follow for adding a transaction into the blockchain network which are shown in Fig. 5. Before transacting into the network, the authentication and authorization process needs to be done by using cryptographic keys and proof of work simultaneously [35]. As shown in Fig. 5, the transaction process describes the popular bitcoin network which runs in a public network where anyone can participate. Initially, the transaction initiator sends the transaction request into the public bitcoin network for authentication and adding the data into the network. The transaction requests all the nodes into the network for verification for the same [36]. Once the transaction is validated by the nodes, the block is then added to the blockchain network, and all the participants' nodes are rewarded by bitcoin for participating for proof of work [37]. After that, the transaction will be completed by updating the blockchain network. Private and public keys are used to validate the transactions where the private key is used for digitally signing the data and the public key is used for decrypting the data at the receiver end [38-39]. On the other hand, authorization is required to add the data into the block through a consensus mechanism which means the majority nodes need to be agreed to complete the transaction [40].

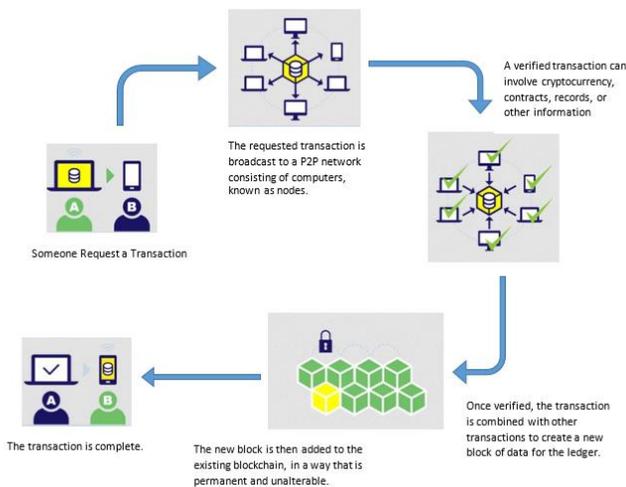

Fig. 5. Transaction Process in the Blockchain Network.

### III. ENERGY CONSUMPTION AND IMPACT OF BLOCKCHAIN

Though blockchain is a highly secured platform, energy consumption becomes very high especially when the mining process has occurred which is a big concern in the industry [41-42]. The validation for proof of work algorithm is a complex as well as trial and error process for matching with hash value [43]. For example, an average of ten minutes is required to mine a new block for the bitcoin miners. In terms of data security and integrity, it is highly recommended for using this technology where energy consumption is a big concern for different entities [44].

In an article has been published by Raynor de Best in February 2022, the total number of cryptocurrencies more than 10,000 shown in Fig. 2 which have been drastically increased from 2013 [45]. However, all these digital currencies are not active in the market. Different algorithms are used for mining these cryptocurrencies. Among the plenty of digital currencies, bitcoin is the most popular and useable cryptocurrency across the globe which consume an exorbitant amount of energy for mining bitcoin. There is an article written by Eugene Kim in September 2021 in business insider mentioned that approximately 0.5% electricity of total global electricity used for mining the bitcoin which is approximately more than 7 (seven) times the energy consumption by google per year [46]. The energy consumption for mining the bitcoin from 2017 to 2021 is presented in Table I, the electricity consumption rate has been significantly increased every year, and this consumption in the year 2021 is nearly 6 times that of 2017. From Table I, the number of bitcoins mining gradually decreased from 2017 to 2022. On the other hand, the usage of electricity for mining bitcoin gradually increased over the same period, and finally, bitcoin mining costs were increased.

On the other hand, the Ethereum blockchain uses much less electricity than the bitcoin blockchain for mining Ether tokens which is shown in Table II [47]. As per Table II, the total electricity of 145.39 TWh has been used to mine approximately 59.5 million ethers whereas 480.82 TWh electricity has been used to mine 2.83 million bitcoins only which is shown in Table I. The average mining cost for one bitcoin is USD 19,229, whereas the average mining cost for one ether is USD 217.52 only which is shown in Table III.

An article was published in "The New York Times" in September 2021, approximately 91-terawatt hours of electricity is consumed annually to mine bitcoin which is more than the used by Finland where the population is about 5.5 million [52]. The bitcoin mining electricity consumption was higher than the electricity consumption by Ireland in 2017 [53]. Bitcoin uses more electricity annually than Argentina [54]. on the other hand, the Cambridge University researchers said the bitcoin uses approximately 121.6 terawatt-hours (TWh) which is more than the electricity usage by Argentina (121TWh), 108.8 TWh used by Netherland, and the United Arab Emirates uses 113.20 TWh annually [55] that represent in Fig. 6. China is the highest electricity consumer for mining bitcoin in the world which is 71.70% and the remaining balance is approximately 28.3% uses by the rest of the world whereas USA and Russia are second and third which is shown in Fig. 7 [56]. David Vetter published an article in Forbes where he predicted that by 2024

China alone will use more power for mining cryptocurrency than Italy uses electricity annually [57].

TABLE I. ELECTRICITY CONSUMPTION FOR MINING BITCOIN FROM JAN 2017 TO OCT 2021

Year	Electricity uses by Bitcoin mining (TWh) [47]	Electricity uses growth (%)	No of Bitcoin mining ('000) [48]	Per Bitcoin electricity consumption (KWh)	Avg. retail electricity cost/KWh in USA (USD) [49]	Per Bitcoin mining cost (USD)
2017	36.68		700	52,400	0.1048	5,492
2018	45.81	24.89	680	67,367	0.1053	7,094
2019	73.12	59.62	680	107,529	0.1054	11,334
2020	77.78	6.37	460	114,382	0.1059	12,113
2021	177.43	128.12	330	537,667	0.1118	60,111
Total	410.82		2,830			

TABLE II. ELECTRICITY CONSUMPTION FOR MINING ETHER FROM MAY 2017 TO DEC 2021

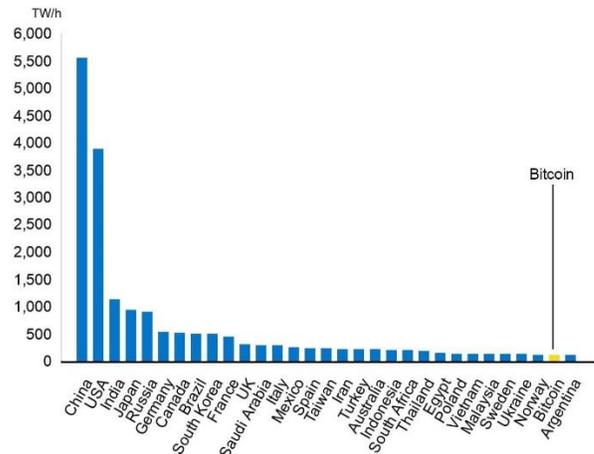

Year	Electricity uses by Ethereum (TWh) [50]	Electricity uses growth (%)	Approx. no of Ether mining ('000) [51]	Per Ether electricity consumption (KWh)	Avg. retail electricity cost/KWh in USA (USD) [49]	Per Ethereum mining cost (USD)
2017	9.56		9,000	1062	0.1048	111.30
2018	9.63	0.73	8,000	1204	0.1053	126.78
2019	8.14	15.47	10,000	814	0.1054	85.80
2020	14.64	79.85	15,000	976	0.1059	103.36
2021	103.42	606.42	17,500	5910	0.1118	660.34
Total	145.39		59,500			

TABLE III. MINING COST COMPARISON BETWEEN BITCOIN AND ETHER

Year	Per unit of Bitcoin mining cost (USD)	Ave. Bitcoin mining cost (USD)	Per unit of Ether mining cost (USD)	Ave. Ether mining cost (USD)
2017	5,492		111.30	
2018	7,094		126.78	
2019	11,334	19,229	85.80	217.52

2021	60,111		660.34	

**Bitcoin uses more energy than Argentina**

If Bitcoin was a country, it would be in the top 30 energy users worldwide

Source: University of Cambridge Bitcoin Electricity Consumption Index

Fig. 6. Bitcoin Mining Power Consumption Globally.

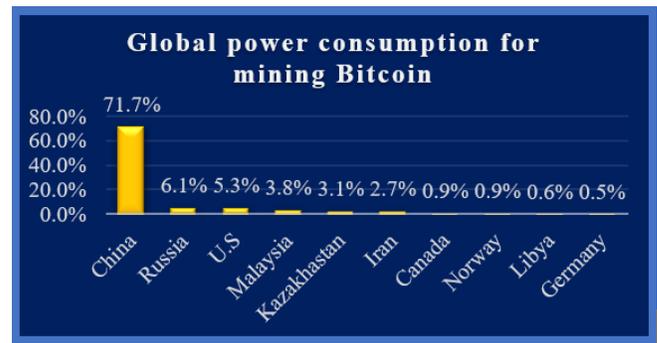

Fig. 7. Country-Wise Monthly Average Bitcoin Mining Computing Power.

However, the electricity consumption has been abruptly increased for mining bitcoin which is 177.43 TWh in 2021 as per Table I. Bitcoin mining needs 17MJ (megajoules) of power to generate an equivalent \$1 amount of bitcoin whereas gold mining takes 5MJ to produce an equivalent \$1 amount of gold [58]. On the other hand, there is a huge impact on the environment due to excessive use of electricity for mining bitcoin which releases more carbon dioxide (CO<sub>2</sub>) into nature. Since the long increase of CO<sub>2</sub> in the environment is one of the big concerns in the world, cryptocurrency mining is increasing day by day which might be a severe disaster for the environment [59-60]. It is not only helping to increase CO<sub>2</sub> in nature, and it helps for rising temperature in the environment [61]. Table IV represents the fossil CO<sub>2</sub> emission from 2017 to 2022 and it shows that the CO<sub>2</sub> emission was 0.16% in the year 2017 and it sharply increased to 0.80% in 2021 which is alarming for the environment in the future.

On the other hand, CO<sub>2</sub> emission by Ether is approximately half of the bitcoin mining, which is shown in Table V, where the CO<sub>2</sub> emission is 0.46% in 2021. The combined impact of emission CO<sub>2</sub> has become noticeable for the environment due to generate bitcoin and ether where 0.99 Giga Tone (Gt) extra

CO<sub>2</sub> has been added in the nature shown in Table V. Bitcoin and Ether are not only the cryptocurrencies in the world, there are more than 10 thousand cryptocurrencies have been created by different companies though all of them are not active commercially, it will be extremely alarming for the nature in future if all the cryptocurrencies will go for commercial production.

TABLE IV. CARBON DIOXIDE EMISSION FOR MINING OF BITCOIN

Year	Fossil CO <sub>2</sub> emission in nature (Gt) [62]	Global electricity consumption (TWh)	Electricity consumption by bitcoin mining (TWh)	Fossil CO <sub>2</sub> emission by bitcoin mining (Gt)	Fossil CO <sub>2</sub> emission by bitcoin mining (%)
2017	36.40	23,150	36.68	0.06	0.16

Fig. 8 represents the future prediction of electricity need for mining the bitcoin and Ether only which is drawn based on the bitcoin and Ether mining data from 2017 to 2021 where the electricity consumption will be increased by approximately more than 300 TWh in the year 2023 which can be higher than the annual consumption of many countries in the world.

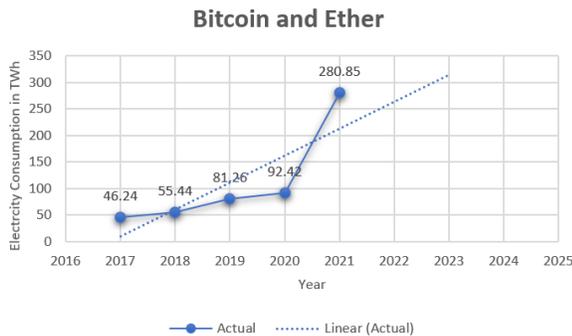

Fig. 8. Prediction of Electricity Consumption for Mining Bitcoin.

However, the proof-of-work algorithm is used to solve a complex mathematical problem for mining the bitcoin is the main concern for consumption of high energy [63-64]. It is an open public platform, and any participant can join the network and can be awarded by solving the mathematical puzzle. The PoW consensus algorithm is used to validate the transaction as well as generate the new blocks into the blockchain network [65-66]. The participants in the blockchain network send the transaction and all the transactions are gathered using the distributed ledger in the blocks through the validation process [67]. Though millions of participants compete to solve the puzzle, only a single participant will be declared a winner who can solve the cryptographic puzzle first, and this message will convey to all the users in the network [68]. So, the bitcoin mining power consumption is not so high concerning the winner [69]. But the participants those are not succeeded to solve the puzzle, their computers also use their power for the same which ultimately enormous amount of energy. The bitcoin mining process is shown in Fig. 9 where all the participants try to solve the complex mathematical puzzle to find out the nonce that can be matched with the target value [70]. To solve the mathematical puzzle, a large amount of computational power is required which depends on the issues are i) Hash function, ii) Integer factorization, and iii) Guided Tour Puzzle protocol.

- Hash Function: SHA-256 cryptographic hashing function is used for mining bitcoin where chunk amount data is used as input and bring it down the value in fixed format 256 bits [71]. Whatever the input, the out-hash value will be the same which fixes 256 bits or 64 bits hexadecimal value [72]. There is no simple way to get the hash value which depends on the lots of input data to needs to be used as the trial basis and it comes consumes huge computational power.
- Integer Factorial: It is used to secure the public key encryption process [73]. It is the way to represent the present whole number of the multiplication of two other numbers [74].
- Guided Tour Puzzle protocol: It works to protect the Denial of Service (DoS) attach to the blockchain network [75]. It also insists to focus on the nodes to compute the memory-bound puzzle which helps the users to use the abandoned computational power [76].

Presently, the blockchain network for bitcoin is growing faster, the users are facing more difficulties to solve the cryptographic puzzle and the algorithm needs more power to solve the same which tends to use more power for mining bitcoin.

Earlier, only a CPU was used for mining the bitcoin which is very slow and consumed more power to generate the bitcoin. To minimize the mining cost, special hardware called GPU is used for the same purpose. GPU is around 100 times faster than traditional CPU. Application Specific Integrated Circuit (ASIC) is another option that is also faster than GPU, CPU, and FPGA which is shown in Fig. 10.

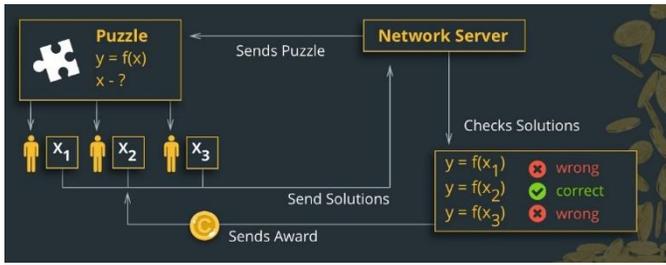

Fig. 9. Bitcoin Mining Process [77].

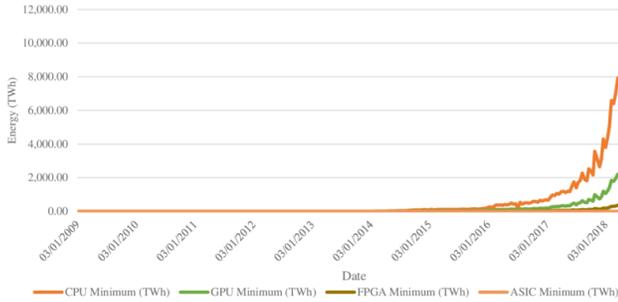

Fig. 10. Power Consumption by CPU, GPU, FPGA, ASIC [78].

IV. ENERGY REDUCING METHODS IN BLOCKCHAIN

Several layers consume the power for mining cryptocurrency, but the enormous power is used by the Proof-of-Work hashing algorithm. Here we have discussed the three methods A. Proof-of-Stake (Pos), B. Delegated Proof-of-Stake (DPoS), and C. Use of renewable energy. Method A and B will contribute to saving more energy for mining the cryptocurrency especially bitcoin which is used as an example. On the other hand, if the cryptocurrency network owners do not want to change the PoW algorithm, method iii) can be the alternative solution that is not capable to save energy for mining bitcoin, but it is environment friendly.

A. Proof-of-Stake (PoS)

PoS is a consensus algorithm that is the improved version of the PoW algorithm that may reduce the 99.5% power consumption for mining the cryptocurrency [79]. This algorithm does not depend on competition to generate a suitable hash among the users. The protocol determines the selector based on the ownership of the coin supply which replace the computational power and the transaction validation process will be done by this stakeholder. In Fig. 11, there is no miner is needed to validate the transaction. The participant's 33% stakeholder will be the validator of the transaction due to holding the maximum amount of stake in the network. The validators will not be rewarded for block validation and get the transaction fees only. Due to the single validator concept, the energy consumption is very low and there is no wastage of power. On the other hand, a successful miner for mining the bitcoin will be the gainer, the use of power by other miners should be considered a wastage of power. This wastage of power generates an excessive amount of carbon dioxide in the earth. If the PoS consensus algorithm was used instead of PoW for mining the bitcoin, a significant amount of power could be saved, and the CO<sub>2</sub> emission cloud is insignificant. As per Tables VI and VII, the carbon dioxide emission could be

minimized by 179.75 Giga tones and 180.06 Giga tones for mining bitcoin and Ether respectively from the year 2017 to 2021 by using the PoS algorithm instead of the PoW algorithm. So, the PoS consensus algorithm is much more efficient and cost-effective for mining bitcoin and ether, and at the same time, it is environmentally friendly as well [80].

TABLE VI. IMPACT OF PoS ON ELECTRICITY AND CO<sub>2</sub> TO MINE BITCOIN

Year	Electricity consumption for mining Bitcoin (TWh) using PoW	Electricity Requirement for mining Bitcoin (TWh) using PoS	Electricity saves (99.5%) by using PoS (TWh)	CO <sub>2</sub> emission in nature (Gt) using PoW	CO <sub>2</sub> emission for mining Bitcoin (Gt) using PoS	CO <sub>2</sub> emission saving by using PoS (Gt)	CO <sub>2</sub> emission saving (%) by using PoS
2017	36.68	0.18	36.50	36.40	0.06	36.34	99.84
2018	45.81	0.23	45.58	34.80	0.07	34.73	99.80
2019	73.12	0.37	72.75	36.70	0.11	36.59	99.70
2020	77.78	0.39	77.39	36.60	0.12	36.48	99.67
2021	177.43	0.89	176.54	35.90	0.29	35.61	99.19
Total	410.82	2.05	408.77	180.4	0.65	179.75	99.64

TABLE VII. IMPACT OF PoS ON ELECTRICITY AND CO<sub>2</sub> TO MINE ETHER

Year	Electricity consumption for mining Ether (TWh) using PoW	Electricity Requirement for mining Ether (TWh) using PoS	Electricity saves (99.5%) by using PoS (TWh)	CO <sub>2</sub> emission in nature (Gt) using PoW	CO <sub>2</sub> emission for mining Ether (Gt) using PoS	CO <sub>2</sub> emission saves by using PoS (Gt)	CO <sub>2</sub> emission saving (%) by using PoS
2017	9.56	0.05	9.51	36.40	0.02	36.37	99.95
2018	9.63	0.05	9.58	34.80	0.02	34.73	99.94
2019	8.14	0.04	8.10	36.70	0.01	36.62	99.97
2020	14.64	0.07	14.57	36.60	0.12	36.50	99.67
2021	103.42	0.52	102.90	35.90	0.17	35.73	99.53
Total	145.39	0.73	144.66	180.4	0.34	180.06	99.81

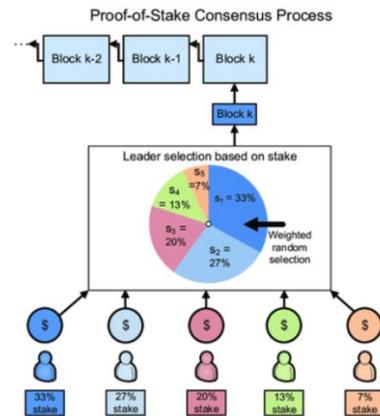

Fig. 11. Proof-of-Stake Consensus [80].

### B. Delegated Proof-of-Stake (DPoS)

There is another protocol called Delegated Proof-of Work (DPoS) is the evolution of the PoS algorithm where the users are required to keep in stake their coins for getting the validation power for the transaction. The users of the blockchain network need to provide the votes and elect the delegate for validating the next available block. A maximum of 20 to 100 delegates can be chosen to validate the new block and the delegates for one block cannot be the delegate for the next block where the delegates will be eligible to receive the transaction fees from that validated block [81]. In terms of power consumption, DPoS is almost the same as the PoS algorithm which can be a good choice to use this protocol instead of the PoW algorithm for mining bitcoin or other cryptocurrencies. A comparison among PoW, PoS, and DPoS has been provided in Table VIII.

TABLE VIII. COMPARISON OF POW, POS, AND DPOS

PoW	PoS	DPoS
i. Number of participants becomes very high for mining cryptocurrency. ii. Energy consumption volume is very high. iii. Transaction speed is slower than PoS and DPoS. iv. Transaction validation method is very comparative for receiving the reward	i. Number of the participant is one and depends on the stake of the coin. ii. No extra power is required except the single computer power. iii. Transaction speed is very higher than PoW. iv. Competition for validation of transaction is not required due to a single selected validator.	i. Number of participants is limited to between 10 to 100. ii. Less energy consumption than PoW iii. Transaction speed is very higher than PoW and PoS iv. Competition for validation of transaction is not required due to selected validators.

### C. Use of Renewable Energy

On the other hand, renewable energy may be the alternative option for mining cryptocurrency by using the same PoW algorithm. Though it will not save the electricity consumption rate, it will help to reduce the environmental pollution where the carbon dioxide emission will be zero. The largest bitcoin mining location in Dalian, China where the hash rate is 360,000 TH is used for mining 750 bitcoin every month and the average monthly cost is \$1,170,000, and the second-highest mining location in Moscow, Russia where the hash rate is used 38PH for mining 600 bitcoins in every month and the monthly cost is \$120,000 [82].

Renewable energy sources are preferable rather than non-renewable energy sources for mining cryptocurrency whereas IBM and Intel also prefer to use green energy for blockchain-based cryptocurrency transactions. Renewable power can be generated from different sources like solar, wind, water, etc. in different communities and the same can be distributed through blockchain applications by establishing a microgrid system. Power can be transmitted between peer-to-peer consumers into the blockchain network.

However, one of the main challenges to implementing blockchain technology is power consumption. So, the use of

the PoS consensus algorithm can be a better option instead of using the PoW algorithm to reduce the power consumption whereas the use of renewable energy for the PoW algorithm may be the alternative option.

### V. DISCUSSION AND RECOMMENDATION

The background and architecture of the blockchain technology, the energy consumption, and the impact of blockchain, energy reducing methods by applying blockchain applications have been discussed in detail in this review paper. To overcome the enormous energy consumption issues for mining cryptocurrencies and reduce the carbon dioxide emission in the environment, the following important recommendations can be addressed in the future.

- To minimize the consumption of computing power, the Proof-of-Stake (PoS) consensus algorithm is highly recommended to use instead of use Proof-of-Work (PoW) algorithm for mining cryptocurrencies.
- Electricity consumption can be minimized by approximately more than 99% by using the PoS consensus algorithm which will lead to saving the computation power cost of the end-users.
- A significant amount of CO<sub>2</sub> emission in the environment can be minimized by using the PoS algorithm instead of using PoW algorithm.
- Renewable energy sources are preferable rather than non-renewable energy sources for mining cryptocurrencies by using the PoW algorithm, though it will not help to reduce the computational power, it will help to minimize the CO<sub>2</sub> emission in nature.

### VI. CONCLUSION

Blockchain already has become one of the leading-edge technologies that provide the highest level of data security through using a cryptographic hashing algorithm where data tempering is almost impossible. Nowadays, the maximum application of this technology uses for mining cryptocurrency where bitcoin is the leader in the market. But the consumption of computing power is the major challenge to adopting this technology for mining cryptocurrency and other sectors. Due to the consumption of enormous energy, carbon dioxide emission becomes very high which ultimately pollutes the environment. An alternative solution like Proof-of-Stake consensus protocols has been proposed to use instead of the Proof-of-Work algorithm for mining cryptocurrencies. Not only that, but the use of renewable energy can also be an alternate option to use the Proof-of-Work algorithm for mining cryptocurrencies which is environment friendly. Blockchain technology might be more useful in different sectors if the high energy consumption is addressed properly which will be able to build a secure blockchain network and save the transactional cost as well.

**Abstract**—Currently, radiometric thermography image has been explored adequately as alternative advance Non-Destructive Testing (NDT) especially for early detection analysis in various applications. Systematic image calibration, higher spatial resolution and high degree order image processing, thermography imagery potential to be used in concrete structure defect detection. Therefore, this study is carried out to examine the defect on bridge pillar surface concrete using drone-based thermography sensor (7–13  $\mu\text{m}$ ). Close range remote sensing NDT based on drone platform and imagery segmentation analysis have been applied to interpret the crack line on two pillars at North-South Expressway Central Link (ELITE) Highway. As a result, thermography imagery segmentation and support by multispectral radiometric imagery (RGB) successfully to delineate the micro crack line on the bridge pillar concrete using K-means clustering method. Overall, this study successfully shows the higher order optional platform using drone and thermography sensor that potentially to be applied in forensic concrete structure defect detection for tall structure building.

**Keywords**—Defect; detection; bridge pillar; drone; thermography; close range remote sensing

## I. INTRODUCTION

Thermography that uses a mid-infrared band is the part of remote sensing that manages the acquisition, processing and interpretation of information procured essentially in the thermal infrared (TIR) area of the electromagnetic (EM) range. In thermography remote sensing, the radiations emitted from the target surface will be measured which differ from optical remote sensing where the reflected radiation from target surface is the one that will be measured and these measures will determine a body's radiant temperature that were determined by two variables, kinetic temperature and emissivity [1]. Current technology has allowed the concept of thermography remote sensing being adapted by the use of

drone or Unmanned Aerial Vehicle (UAV) as many compact thermal sensors were available. Nowadays, the thermal sensors are extensively utilized in different surface temperature and thermal emission measurements. The old-style issue on kinetic temperature and emissivity assurance through the force and its circulation over the wavelength region of close-range remote sensing can be explained not similar concept as the airborne or spaceborne thermal sensors. Concerning low altitude or drone-based sensors, the atmospheric impacts are insignificant, lab-level adjustment are progressively available, and theoretically the measurement of temperature are more accurate [2]. Close-range remote sensing imagery technology detection are believed to be a much more practical and more relevance approach to the work of detecting a surface that are not accessible by the remote sensing sensor.

Concrete structure surface defect come in quite few types with cracking and scaling being one of the most common defects. In order to detect defect of a certain structure or infrastructure, the methods that are considered as the most suitable are usually a Non-Destructive Testing (NDT) method because this method allows to avoid interfering with the asset's current state. The majority of NDT for structural elements, such as ultrasonic, magnetic field, and eddy current methods, are best suited for detecting flaws at depths of 5 to 100 cm and have two major drawbacks: they require physical contact with the tested object and scan images slowly [3]. Other method that would be very useful to the concrete structure defect detection is a LiDAR measurement method. LiDAR is a method for determining ranges by targeting an object with a laser and measuring the time for the reflected light that return to the receiver. As a result, LiDAR provides point cloud data, which is basically 3D geometric information that may be used to measure surface anomalies, by populating a surface with hundreds of laser points [4]. As it was mention

\*Corresponding Author

earlier, this study will incorporate a thermography imaging method which is also consider as part of NDT method. Thermography, commonly known as thermal scanning or infrared imaging, is a rapid and remote technology that is increasingly being utilized in conjunction with NDT methods [5,3]. Usually, defects produce an excessive heat during operation due to the excess current flow at the fault point results in power dissipation [6].

Nowadays the concept of infrared thermography (IRT) imagery was being utilized in many ways. Firefighters use them to see through smoke, find people and localize hotspots of fires. Law enforcement uses the technology to manage surveillance activities, locate and apprehend suspects, investigate crime scenes and conduct search and rescue operations. Power line maintenance technicians locate overheating joints and parts eliminate potential failures. Where thermal insulation becomes faulty, building construction technicians can see heat leaks to improve the efficiencies of cooling or heating. Physiological activities, such as fever, in human beings and other warm-blooded animals can also be monitored with thermographic imaging. IRT imagery have great thermal resolution capabilities, but they have a basic spatial resolution constraint [6]. This indicating that thermography imaging concept has proven its usefulness and other ways that this concept can be used is for the detection of defect on a concrete surface such as bridge pillar.

Surface temperature data can be collected using IRT method on which its data can detect the internal faults in concrete [7]. The work defect detection on a concrete surface can be carried out done by differentiating the temperature on its surface as thermography create an illusion of differences temperature for human to detect the difference in thermography imagery or in this case a defect on a concrete surface. The concept of thermography imagery in detecting the defect structure is when the thermographic camera detects the radiation emitted by an object as it was heated by sun or any sourced of heat. The thermography NDT image is mainly judged by analyzing the abnormal conditions of the temperature change law at the crack manifested that when the ambient temperature is lower than the object temperature, the cracks are shown as hot spots or regions in the thermal camera. While cracks would manifest themselves as cold spots when the region of interest is colder than the surrounding environment [8].

This project utilized a drone-based platform in which the thermal image acquired vertically to reconstruct a complete pillar structure. A thermal sensor mounted to the drone to capture the thermography image of the pillar surface. The acquired imagery then underwent in a vertical flight plan as in order to completely cover all the area of the pillar. Therefore, when this concept was applied on the maintenance work of the bridge pillar, a thermal sensor will be attached on a drone and thermography image of the pillar surface will be collected. From those images, the temperature of the pillar surface will be identified and the differences in temperature will produced an assessment that indicate there is something thermal hot spot with the concrete surface of the pillar hence, a defect is detected. This defect might result as the presence of cracked

on the surface of the concrete which needed to be inspected and immediate action can be performed to avoid any unwanted event.

## II. STUDY AREA

The research areas that explored are located at part of North-South Expressway Central Link (ELITE) Highways' bridge pillar, which is also known as Asian Highway 2 (AH2), situated near to Management and Science University (MSU) Shah Alam, Selangor, Malaysia (03°04'41.3"N,101°33'06"E) as shown in Fig. 1. This study focused on the crack detection of two pillars or piers of the highway bridge. The data acquisition that has been collected then processed and analyzed using the specific software to detect crack on bridge surface.

(a)

(b)

Fig. 1. The Study Area Located at Part of ELITE Highways Bridge near to MSU Shah Alam, Selangor. (a). Location Map (Source: Google Earth), (b). Concrete Pillar.

## III. AIM AND OBJECTIVE

The aim of this research is to study the performance of thermal imaging technique for detecting the defect of vertical concrete surface. In pursuit of the aim of this research, this study specifically addresses two objectives as follows:

- To demonstrate the vertical concrete surface defect detection technique using drone-based close-range thermography imagery.
- To detect the defect on bridge surface using segmentation method by utilizing thermal group of UAV remote sensing.

#### IV. METHODOLOGY

##### A. Close Range Thermography Imagery

Close range photogrammetry also known as terrestrial photogrammetry is a procedure in which photos are collected with relatively high convergent camera orientations around an entity, often facing towards the entity's center [9]. The concept of it refers to the imagery collected in a range less than 300 meters away from a study object. In this project, the close-range drone approach was utilized where the thermography imagery was acquired using a sensor carried by DJI Inspire 1. The drone is a commercial off-the-shelf (COTS) photography platform that is ready to maneuver right out the box. The drone is featured with an onboard color camera equipped with a lens and a stabilized gimbal, also a retractable landing gear that can be pulled up out of the view, giving the camera 360 degrees of view towards the world below without obstruction.

The reason to acquire and process the thermography imagery photogrammetrically was to produce thermal orthomosaic with ground resolution distance (GSD) below 10mm. Meanwhile, thermography lacks the image's features. The recorded details are based on temperature, limiting the success of image matching among overlapped photographs for orientation in photogrammetric software. For that reason, the normal color image was also acquired to assist the photogrammetric image orientation process.

The DJI FC350 camera and the FLIR Zenmuse XT (Table I) were used to capture the color and thermographic images, respectively. The former is an onboard camera for the DJI Inspire 1 drone system. It features a 12.4-megapixel effective pixel and a 20-millimeter lens. Additionally, the camera is detachable from the drone, allowing for the attachment of the former camera for thermographic imaging. The FLIR Zenmuse XT is designed to be mounted on the DJI Inspire 1, capturing images between 7.5 and 13.5 meters and storing them in 640 x 512 pixels image.

In a typical photogrammetric mapping project, the flight mission configures autonomous data collection in the open space area prior to the flight mission. The benefits of an autonomous flight mission include the drone maneuvering autonomously as a result of the GPS satellite signal assisting with flight direction and hovering. Additionally, the image can be captured automatically based on the coordinates of the configured camera station. The coordinates are then geotagged to the corresponding captured photo station to facilitate the point cloud construction process in photogrammetric software, as the exterior orientation parameter is available.

However, in this project, the drone was piloted manually because the data acquisition took place the beneath of bridge, where a tick concrete structure interfered with the GPS signal. Manually controlling the drone without locking the GPS signal was difficult in areas where the drone was uncontrollable due to turbulence. Additionally, the image was captured manually, as it was not necessary to preconfigure the flight planning. The image captured from a photogrammetric image block is made up of individual strips. The overlap of images was set to 80%. The camera-to-object distance was set

to 1.5m in order to obtain thermography images with a 10mm GSD.

##### B. Establishment of Control Point

Photogrammetric processing enables the estimation of an object's scale and orientation based on the image's exterior orientation parameter. However, because the work is being conducted in a tick structure environment, accurate geotagging of GPS signals on the image is compromised. As a result, the image's geotagged parameter did not accurately reflect the image's actual location on the ground.

Alternatively, the use of GCP can be used to resolve the determination of the constructed object's coordinates and scale. Additionally, GCPs are used to determine the exterior orientation parameter of an image by resecting the coordinate to the image point via a mathematical equation. With a precise exterior orientation for the image, light rays are projected to precisely and accurately model space from images. As a result, the 3D model of the object constructed has an accurate scale and orientation similar to that of the ground.

On the other hand, the thermal image's nature is to capture the object's heat/temperature. Thus, the thermal image does not contain a common GCP marker used in photogrammetry. The use of a thermal patch may be appropriate. However, the patch's coordinates cannot be precisely determined. For this project, the standard photogrammetric control point marker was designed based on the focal lens, sensor resolution, and camera-to-object distance of the respective camera. Ten markers were printed on A4-size paper and adhered to the surface of each pillar.

TABLE I. SPECIFICATION OF THE INSTRUMENT

Instrument	Specification
 DJI FC350	Total Pixels: 12.76M Effective Pixels: 12.4M Image Max Size: 4000x3000 ISO Range: 100-3200 (video) 100-1600 (photo) Electronic Shutter Speed: 8s — 1/8000s FOV: 94° Lens: 20mm
 FLIR Zenmuse XT	Spectral Band: 7.5 – 13.5 μm Thermal Resolution: 640 × 512 pixels Full frame rate: 30 Hz Field of view: 9mm lens (69°×56°)
 DJI Inspire 1	Flight autonomous: 20 minutes Payload: 1.7 kg

In this study, the location of markers on two pillars was set to the upper area as the focus point for thermography analysis and shown in Table II. Each marker's position was determined using the tacheometry technique using an arbitrary coordinate system consisting of a single baseline. The geometric control point coordinates of each pillar are shown in Table III and Table IV, respectively. The information from the GCPs was then used to create the thermography orthomosaic, as explained in the following section.

TABLE II. LOCATION OF CONTROL TARGETS

### C. Orthophoto Construction

After constructing the tie point cloud, a dense point cloud was generated. The distinction between a tie and a dense point cloud is that the former is used to determine the exterior orientation parameter by resecting the tie point. Meanwhile, the latter is used to transform each pixel in the image into three-dimensional space. From the dense point cloud, a variety of photogrammetric products such as a 3D model and orthomosaic can be generated. The thermographic orthomosaic in this work was created using the Pix4D mapper (academic version).

The process began with aligning the color images in Pix4D in order to create a tie point cloud and estimate the exterior orientation parameter for each image. The GCPs are then used to reorient the image via bundle adjustment and to scale the pillar's 3D point cloud for metric measurement. Following that, a dense 3D point cloud was generated and the coordinates of pillar features such as edges and contrast spots were extracted in order to align the thermography imagery. Due to high resolution of color image, the common features on overlapped images were seamlessly matched for tie point construction.

The thermal dataset was then sequentially inserted onto color photographs that had previously been aligned. The edges and contrast spots were marked as control points for the thermal point cloud. The coordinates for the control point were extracted from the object coordinates previously determined using the color image. This procedure enables the transformation of the constructed pillar's coordinates to the features visible on the thermographic image. When the thermal imagery was successfully aligned, the thermal image's dense point cloud was also generated. Following that, the thermal orthomosaic was created using the orthoplane function included with Pix4D Mapper. Fig. 2 to Fig. 5 has shown the process using Pix4D Mapper.

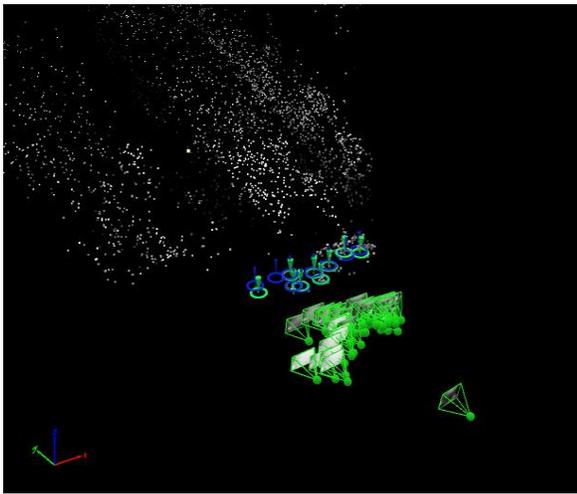

Fig. 2. Aligned Photographs in Pix4D Mapper.

Fig. 3. Dense Point Cloud.

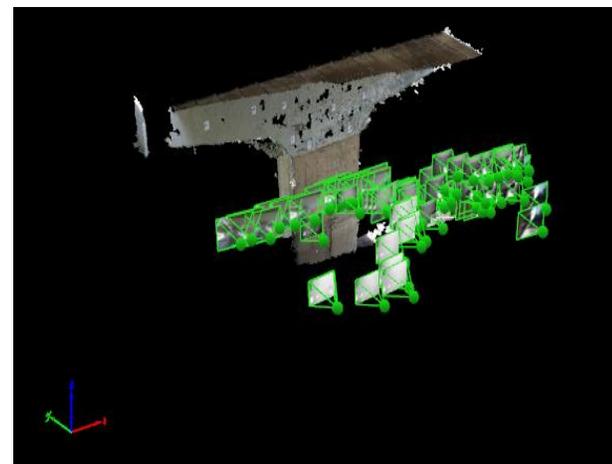

Fig. 4. Thermal Orthoplane for Mosaic Extraction Process.

Fig. 5. RGB Image Stitching. (a) 34A (b) 34B.

FLIR Tools+'s image stitching for thermal images is fairly simple, beginning with importing the images into the FLIR Tools+ workspace. FLIR Tool+ stitched together several smaller images into a larger one using panorama mode by analyzing each image to detect pixel patterns that match pixel patterns in other images. Fig. 6 shows the results of image stitching from a thermal image using the FLIR Tool+ software.

#### D. Image Enhancement and Segmentation

According to [10], there are many researchers has used the image processing technique to detect a crack or defect in a certain structure, for example [11] has proposed preprocessing, image segmentation and feature extraction, [12] have presented a detection method based on the use of acoustic emission and digital image correlation and [13] used Gabor filtering to presented a method for automatically detecting cracks in digital photographs. In this project the method used was the image enhancement and image segmentation.

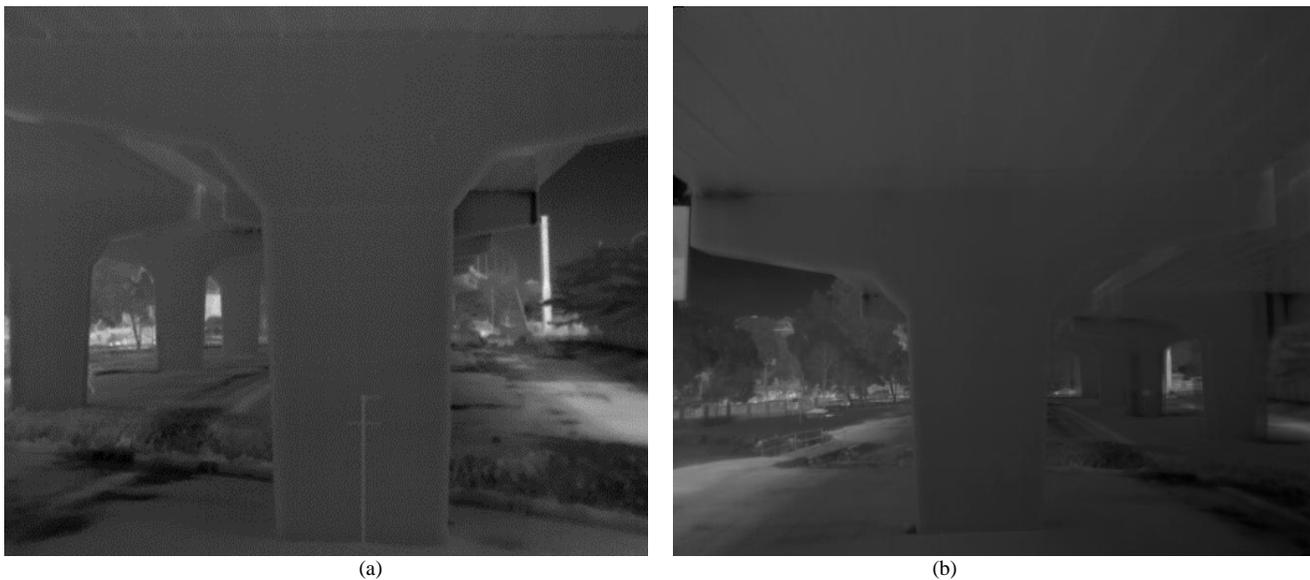

Fig. 6. Thermal Image Stitching. (a) 34A (b) 34B.

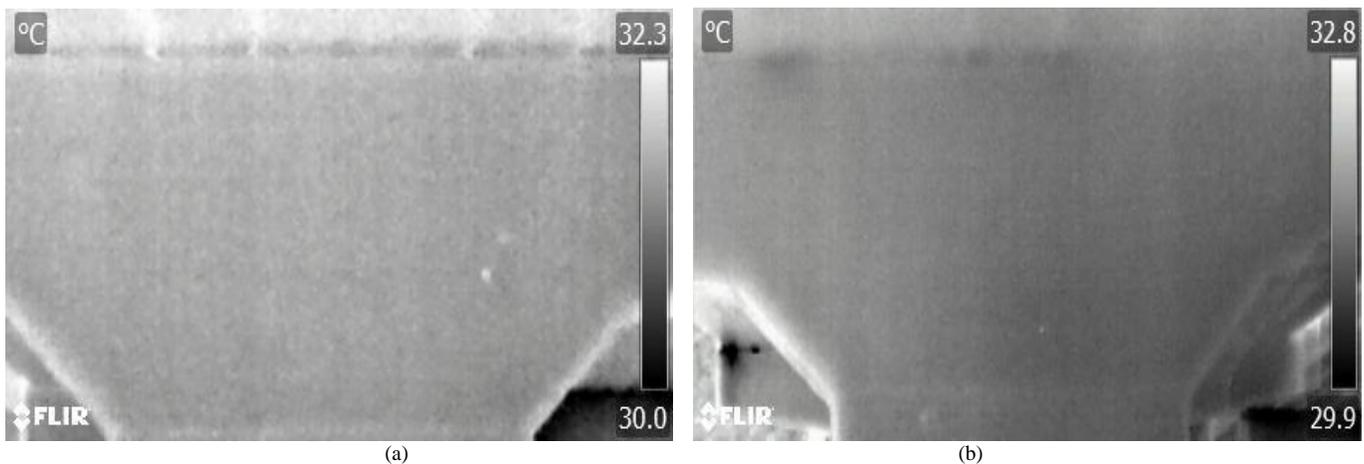

Fig. 7. Thermal Image Enhancement Result. (a) 34A (b) 34B.

For Image enhancement is the process of adjusting digital images so that the results are more suitable for display or further image analysis. Furthermore, Image enhancement is used to improve the perception of visual quality in an image as well as to provide better input for other computerised image processing processes [14]. This process allowed the user to remove noise, sharpen, or brighten an image thus, making it easier to identify key features on the image and for this case, is to detect the defect area. Using FLIR Tool+ software, the image enhancement process can simply be achieved by adjusting the image contrast between temperature. Fig. 7 below shows the result of image enhancement.

Image segmentation is the process of dividing an image into several segments in order to transform the image's interpretation into something more meaningful and easier to work with or being analyzed [15]. As for this project, the segmentation was used to identify a weak region on the pillar. For image segmentation, the k-means clustering method was implemented in both ENVI and Matlab software. When working with small datasets, K-means clustering performs

well because it can separate items in photographs and produce superior results. The ENVI software image segmentation process was carried out using the software's existing k-means clustering function, whereas the Matlab software required the implementation of a simple code, as shown below.

K-means clustering:

Matlab Programming Code:

To read an image into workspace:

```
I = imread('34a.jpg');
```

```
imshow(I)  
title('Original Image')
```

To segment the image into three regions using k-means clustering:

```
[L,Centers] = imsegkmeans(I,3);
```

```
B = labeloverlay(I,L);  
imshow(B)  
title('Segmented Image')
```

## V. RESULT AND ANALYSIS

To begin with, the enhanced image in Fig. 8 below shows that the quality of the thermal image has been improved as it has become brighter. These findings will make the image segmentation process more visible. The K-means clustering method of image segmentation divides the image into several predefined clusters and groups the different clusters with the same color to create the segmentation region. The segmented image in Fig. 8 shows that the results are quite similar, but the ENVI result appears to produce a much more detailed result. The segmentation process produced three distinct clusters, with the hottest area assuming to be the most affected area of defect.

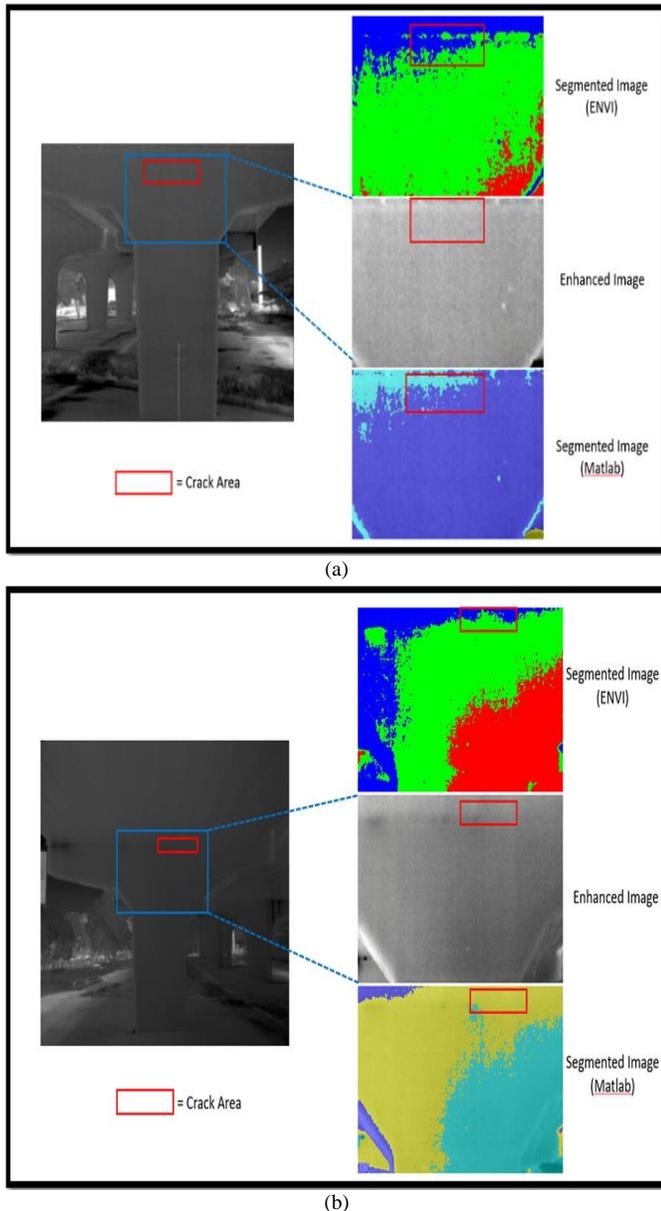

Fig. 8. Image Enhancement and K-Means Segmentation Results. (a) 34A (b) 34B.

Subsurface deficiencies in concrete heat up at faster rate than sound surface which means the hotter region on the concrete surface appear to be the weak region that could possibly be a crack. The algorithm cluster thermal image by extracting the hottest pixel is brightest blob for great contrast between defect and non-defect area. The output from the segmentation process on the enhance thermal image it can be seen that the hotter region falls in to the crack area but in the segmented image there are also other hotter region on the pillar that fall out of the crack area and this is indicating that area might also have defect or just another weaker spot.

## VI. DISCUSSION AND CONCLUSION

This study was successful in identifying a new method for detecting high concrete structure defects that was integrated with advances in aerial data acquisition and imagery processing. As is well known, the drone platform is very useful for acquiring low altitude aerial information using a camera or sensor payload. While the image processing system can produce good segmentation for various types of surfaces. It is a difficult task to create the 3D thermal image enhancement orthoplane where there is difficulty in stitching the homogenous structure surface such as to produce 3D bridge pillar. Another critical step is to use image processing system to determine the micro level of structure cracks from thermography image. As a result of this breakthrough, another advanced NDT process method for structure inspection is now available.

Furthermore, the capability of thermography imagery in dealing with the problem of defect detection on a concrete surface can be seen. This new method is quite useful and effective in that thermal imagery can be interpreted into other forms of imagery through the process of segmentation, providing a better initial view to solve the problem. Thermography imagery will always be an interesting NDT method for monitoring the health or condition of structures, not just concrete structures, but also other types of structures in a cost-effective manner. Sirca Jr and Adeli (2018) [16] state that this is due to the unique environmental constraints and the massive amount of data that must be processed, applying the thermography method of defect detection to large scale three-dimensional concrete structures such as power plant cooling towers and hydroelectric dams will remain be a challenge. This statement has surely been a reason to keep on studying and explore the potential of the thermography imagery in solving the structure defect problem.

In conclusion, the aim of this study in which to study the performance of thermal imaging technique for detecting the defect of bridge surface has been achieved as the final result of the study has shown a positive outcome. Furthermore. The objective which is to demonstrate concrete surface defect detection technique using UAV thermography imagery and to detect the defect on bridge pillar surface using segmentation method by utilizing thermal group of UAV remote sensing has also been achieved. This study has profoundly used the method of close-range UAV in collecting thermal which then the data were processed into a better form of imagery in order to conduct the segmentation process that produce a clear vision to the defect on the concrete surface.

#### ACKNOWLEDGMENT

The authors would like to express their profound gratitude to Faculty of Built Environment and Survey (FABU), Universiti Teknologi Malaysia (UTM) for all the support that been provided. The authors would also like to express their gratitude to PLUS Malaysia Berhad (PMB) for data collection and excellent technical assistance in this study, which was greatly appreciated. A special thanks also goes to Geolatitude Technology Sdn. Bhd., Johor, for providing drone technical expert assistance during field activities. Last but not least, the authors would like to express their gratitude to Center of Excellence, PMB for the research collaboration grant awarded under UTM CR DTD cost center no. R.J130000.7652.4C585 and FRGS grant with cost center no. R.J130000.7852.5F478.

School of Computer Sciences, Universiti Sains Malaysia, Penang, Malaysia<sup>6</sup>

**Abstract**—Many universities worldwide were forced to physically close campuses due to lockdown and resumed the in-person classes compliant with a stringent set of standards of procedures (SOPs) as Covid cases drop. This has profoundly disrupted the hands-on lab face-to-face learning process that is harder to be moved online. Virtual simulation lab could be the answer and its use in many courses has been extensively studied. However, it is relatively little studied when it comes to land surveying courses. The purpose of the study is to explore the learning effectiveness of virtual surveying field lab for blended open distance learning (ODL) students at Wawasan Open University (WOU) in the time of Covid-19. This study used a mixed-method that combines qualitative and quantitative approaches to get a fuller picture and deeper meaning of learning behavior while using descriptive and inferential statistical methods in SPSS platform. Respondents were selected using the purposive sampling method. Survey questionnaires were designed and distributed to students before and after lab simulation class. Instructors were interviewed after the lab simulation class. Students' learning results for the surveying course were compared with the past-year examination results at pre-Covid-19 times before the virtual simulator was introduced. Both qualitative and quantitative data set were collected and analyzed. The findings revealed that the virtual simulator has enhanced students' learning interest and efficiency for surveying course in a ODL setting. Both students and instructors have responded positively towards the virtual simulator learning experiences. Students' achievement in the final examination amid Covid-19 was better than pre-Covid-19 performance. It is recommended that the virtual simulator shouldn't be a replacement to physical instrument but as a complement.

## I. INTRODUCTION

The abrupt outbreak of Covid-19 pandemic has forced many universities worldwide to temporarily close physical campuses due to lockdown and shifted the in-person classes to online mode. However, the practical lab class that requires hands-on and is more difficult to be moved online has to be halted and to be adjourned to a much later time. Even if the hands-on lab is forcibly moved online, the hands-on lab most likely has to go hands-off, leaving out the hands-on experience whereby students passively watching the demonstration videos

from the instructors, that either live or pre-recorded. Like the other countries, Malaysia resorted to the extreme measures to curb the spread of the Covid-19, began to implement the unprecedented lockdown starting in March 2020 until May 2020 with the gradually eased lockdown restrictions. Universities in Malaysia, public and private, have not been spared from the impacts of the Covid-19, were ordered by the Higher Education Ministry to stay shut physically and to go fully online until end of 2020, with a few exceptions that let students who need to carry out practical laboratory work using specialized equipment to enter the campus, subjected to the stringent set of standard operating procedures (SOPs) [1]. In January 2021, following a second wave of Covid-19, much of the country again was into its second major lockdown. The whole nation was plunged back into a full lockdown in June 2021 as third wave hit. In virtue of the national vaccine rollout success, universities finally opened their campus doors to fully vaccinated students to return starting Oct 2021, but still with strict SOPs in place [2]. Admittedly, with many un-certainties and the ups and downs of repetitive lockdowns, the Covid-19 pandemic has indeed profoundly disrupted the whole educational system and in particular, the hands-on lab face-to-face learning process.

Nonetheless, the land surveying hands-on outdoor lab has faced its own unique challenges even before the Covid-19 pandemic [3-10]. The physical surveying instruments that are generally sensitive and delicate have to be handled with great care, but wear out despite years of good maintenance, and get expensive when replacing with more up-to-date or higher quality one. Insufficient quantity of the physical surveying instruments leads to the unequal access to the instruments when students are asked to practice in bigger groups. The practical session is further bounded by the location within the vicinity of the campus with the same terrain characteristics due to accessibility and safety issues; the unpleasant external environmental conditions like haze or rainy weather especially in this tropical climate zone; and the allotted time for the hands-on lab to cover fairly each surveying topics in the course syllabus. The demonstration on the operation of the surveying instruments from the instructors may not be seen clearly by the students in the field, particularly some detailed operation steps with tiny finger motion like setting up the instruments. After the demonstration, students are usually dispatched in groups to

carry out the fieldwork, often with little supervision, in the end, are asked to report their fieldwork results to the instructors and have no way to trace back their multi-steps process. All these factors have thrown wrenches to the learning process in getting students to familiarize with the use of modern surveying instruments and preparing them adequately for surveying work in the real world.

With these challenges in mind, virtual land surveying simulator seems like the perfect solution. But then in-depth study on the learning effectiveness of virtual surveying simulator should be conducted before incorporating it into the land surveying course curriculum. Although the use of virtual simulator has been extensively studied in many fields, but there have been relatively much lesser studies of its development and implementation when it comes to architecture-engineering-construction education, especially for land surveying courses, in an open distance education setting, to say the least [11-14]. Recognizing the value that comes after it, this study kicked off way before Covid-19. While working on the solution, this study proved to be very timely during the nationwide shutdown of on-campus teaching due to the Covid-19 surge. Therefore, the main objective of the study is to explore the learning effectiveness of virtual surveying field lab simulation for blended open distance learning (ODL) students at Wawasan Open University (WOU) in the time of Covid-19.

## II. LITERATURE REVIEW

Ever since the emerging of this new virtual reality technology, computer generated simulation has been exponentially increased its use in many education and training courses involving hands-on laboratories in wide spectrum of fields, in particular, dominating mainly in science, engineering and medical, leading the trend by renowned universities and institutions like Massachusetts Institute of Technology (MIT), Carnegie Mellon University, to name a few; and its application has been extensively studied in the literature review over the past decade, showing great deal of interest in this topic worldwide [15-19]. In architecture-engineering-construction (AEC) education, the underpinning VR technology has been adopted to support design, visualization, structural analysis, hazards recognition, safety training, decision-making, operational training of heavy equipment such as cranes; without facing the dire do-or-die consequences as in real construction project.

Several successful attempts to explore in-depth the virtual laboratory for construction surveying are deemed valuable and commendable. Using QuickTime VR technology, Ellis et al. (2006) implemented an interactive multi-media learning resources for leveling survey only and evaluated its application among undergraduate students in the School of the Built Environment at Leeds Metropolitan University [20]. Mills and Barber (2008) employed virtual interactive learning tool running on AJAX for traversing survey only at Newcastle University's School of Civil Engineering and Geosciences [4]. In addition to levelling and traversing, a virtual simulator for survey training, SimuSurvey and an improved version using XNA gaming platform, SimuSurvey X, were developed at the Department of Civil Engineering in National Taiwan University that cover other surveying topics as well [3, 6, 21].

In the College of Technology at Purdue University, a virtual learning environment was created and a pilot study with undergraduate students was conducted for one chaining module only in surveying fundamental course before extending to differential level surveying module. [7, 22] Gao and Wu (2017) designed an experimental virtual surveying system using VR modeling language for students in Henan University of Urban Construction. [8] León and Morales (2018) created interactive survey instructor (ISI) that was being used by the surveying engineering school from University of Costa Rica for teaching two modules only, differential leveling and traversing [23]. In response to the Covid-19 pan-demic, Tingerthal and Kaoni (2021) prepared a virtual laboratory centered on a series of interactive videos for students at Northern Arizona University, without the gamifying survey experience that allows students to operate virtual instruments [10]. Whereas Bolkas et al. (2021) presented surveying reality (SurReal) software solution that simulated the virtual reality environment and surveying level instrument in an immersive and interactive virtual laboratory based on levelling task only at Pennsylvania State University Wilkes-Barre campus [9].

Triumphantly, all the findings of these studies related to the virtual laboratory for construction surveying in recent decade bring forth positive results and reach a conclusion on the betterment of teaching and learning process with the use of virtual simulation laboratory for surveying when querying about participants' perception [3, 4, 7, 9, 10, 20, 22, 23]. The findings are equally exciting when measuring the performances of the students. Kuo et al. (2007) found that approximately two-third of the students were able to answer correctly the follow-up quizzes after simulator lab class [3]. Hazar and Nicoletta (2011) presented the students' average e-grade using with the simulator was 65% [7]. Hazar et al. (2014) saw an increase of declarative knowledge by 28% in a given written test and procedural knowledge by 30% in a field surveying exercise among students who used the simulator [22]. Gao and Wu (2017) acclaimed the success of the university in winning a total of 60 person-time awards of undergraduate surveying skill competitions at national and provincial level, owing to the great teaching effect of the simulator [8]. Tingerthal and Kaoni (2021) reported students who completed 19 or more out of the 23 practice quizzes that interleave in the virtual lab has achieved higher scores (average=93.3%) on the summative quiz at the end of the module than students who completed less (average=63.7%) [10].

However, it is relatively little studied on the development and implementation of the virtual simulator in the field of architecture-engineering-construction, particularly, the land surveying course, in comparison to the vast study of simulator in other fields. Most of the universities involved in the studies are conventional brick-and-mortar universities with surveying courses primarily taught in-person, while developing the virtual surveying simulator as a webpage that is hosted on the internet server [20, 4, 8, 10, 20] or downloadable on personal computers with low-end graphic cards [3, 7] or as a lightweight web application [23] or as a software installed on a stationary workstations in the campus that work faster than a personal computer [9]. It is therefore fewer studies when it comes to pedagogical implementation in an open distance education

setting in the pre Covid-19 era and also during the outbreak of Covid-19. This study is to answer the research question at the onset of the study whether the virtual surveying simulator has any effect on the learning interest and efficiency for open distance learning students amid Covid-19, that will help to fill the research gaps.

### III. RESEARCH METHODOLOGY

#### A. Research Setting

Basic surveying course is the basic major course within the undergraduate construction management program at Wawasan Open University (WOU). It is an introductory course to the fundamentals of construction surveying that comprises the basic principles and branches of surveying, the use of survey instruments such as auto level, theodolite, EDM, total station, etc. the various common methods of surveying procedures such as levelling, traversing, bearing etc.; and the applications of surveying in building construction. Students from main campus in Penang and four geographically apart study centers at different locations in Perak, Johor, Kuala Lumpur and Sarawak, are required to take this basic surveying course in the first year of their studies and to complete it in one semester. In year 2020, there were 208 active current undergraduate construction management program students and about 30 of them taking basic surveying course in each year cohort. These students were invited to participate in the virtual surveying field lab simulation class, along with 21 graduating students and 53 graduated students as well, so to compare between those with and without prior knowledge of surveying background.

#### B. Ecosystem Approach

Being an ODL university, WOU robust virtual learning spaces are naturally flexible and accessible to cater to students' online and remote learning experience as shown in Fig. 1, even despite the interruption brought about by Covid-19. Learning management system (LMS) at WOU uses MOODLE that delivers one stop service for students [24]. Through the LMS gateway, the surveying course page provides for students all the surveying materials at one place including surveying course materials, lab manual, lab procedures, demo videos and animations, quizzes, course assignments, past year exam papers, online forum, announcements, additional web resources, library learning resources etc. On the other hand, for instructors, it provides LMS analytic reports of users' access and views, customization, instructor supports, helpdesk etc. The online submission system (OAS) is where the students can submit, resubmit, apply submission extension, and view the grades and feedback of their written assignments whilst the instructors can assess the assignments, give comments, moderate and export the marks, approve students' request, set deadlines and mark allocation etc. However, there have been physical surveying field labs with practical training initially conducted on-campus that had to go online due to the nationwide shutdown of on-campus teaching. As such, the virtual surveying lab simulators that are available to students and instructors to install onto personal computers / laptops or to access it through local network remotely made it possible for online surveying lab classes to continue effectively.

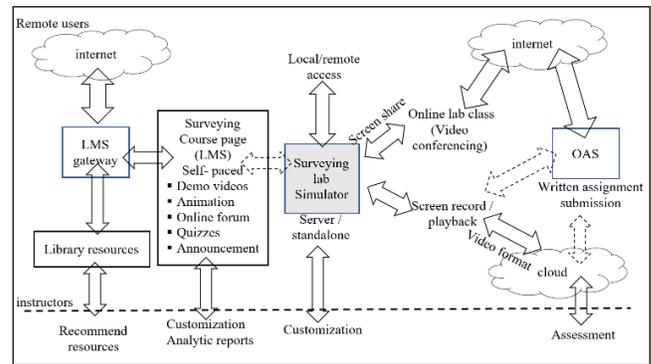

Fig. 1. Ecosystem of Virtual Learning Platforms for Surveying Courses.

#### C. Virtual Land Surveying Simulator

Amid the Covid-19 pandemic, virtual land surveying simulator was introduced for the first time to students before the physical surveying field lab class was conducted on WOU main campus and four regional learning centers, with the stringent SOPs in place such as masking, temperature screening, social distancing, MySejahtera scanning etc. After the first introduction, students would then access it remotely by downloading and installing the virtual simulator onto their own personal devices or to access it through local network, for their own practices. The virtual surveying simulator used in this study is SimuSurveyX, an improved version of a computer-based surveying simulator, SimuSurvey that was first developed by researchers from Department of Civil Engineering in National Taiwan University using OpenGL graphic library and the C# object-oriented programming (OOP) language [21]. A feasibility study on the original version of the virtual surveying simulator was conducted [3]. Following that the user interface of SimuSurvey was then redesigned by using user-centered design (UCD) approach [5]. The original version was further improvised by using XNA gaming platform. SimuSurveyX provides a virtual environment and simulates various surveying instrument and accessories for users' manipulation controlling like auto level, theodolite, total station, tripod, reflector prism, level staff and ranging rod. It covers five basic surveying training activities namely leveling, horizontal angle & vertical angle surveying, traversing and free mode surveying [6].

#### D. Sampling Method and Instrument

Prior to the virtual surveying field lab simulation classes with students, instructors attended the training workshop on the operation of the virtual surveying instrument through the scheduled meeting online. Pre and post survey questionnaires were de-signed and distributed to the students before and after the virtual surveying field lab classes. There were three sections in the pre-survey whereas there were two sections in the post-survey. The instructors who are also the subject experts were interviewed after the virtual lab classes as well. The total respondents who have responded voluntarily to participate in this study are 28 students and 7 instructors of WOU. Both students and instructors were identified and selected as the respondents using the purposive sampling method. During the virtual lab classes, instructors gave demonstration and guided the students for five virtual

surveying activities namely distance measurement, angle & direction measurement, levelling, traversing and calculation related to surveying, in order to achieve the learning objectives whereby students should be able to set up the virtual surveying instruments, to perform measurements using different virtual surveying instruments and to carry out calculation related to surveying.

*E. Data Collection and Analysis Procedures*

At the end of the virtual lab classes, students were asked to answer the quizzes related to the surveying activities and their answers were graded. As the basic surveying course is offered at WOU every academic year, students’ learning results for basic surveying course are tested again in the final examination at the end of the semester and these results were compared with the past year examination results at pre-Covid-19 times before the virtual surveying simulator was introduced. Mixed method combining qualitative and quantitative approaches is used in this study whereby the quantitative data set was collected and analyzed using descriptive and inferential statistical methods in Statistical Package for Social Sciences (SPSS v. 28) software platform while the qualitative data set was examined further to get a fuller picture and to perceive deeper meaning of students’ learning behavior, with the primary objective to explore the learning effectiveness of virtual land surveying field lab simulation for blended open distance learning (ODL) students at WOU in the time of COVID-19 pandemic.

**IV. RESULTS**

*A. Demographic Characteristics*

The virtual surveying field lab simulation class was planned for construction management program students in year 2020, there were 208 active current undergraduate, 21 graduating students and 53 graduated students invited to participate the study. A total of 28 students responded. Two anonymous pre and post survey questionnaires were designed in the form of binary yes or no questions, multiple choices, a 4-point Likert-type scale, as follows, 1=strongly disagree to 4=strongly agree, and open-ended questions whereby their other comments were also welcome. In the pre-survey questionnaires, there were three sections. The first section was to attain the background of students that include age, year of studies, prior knowledge in surveying courses, work and surveying experiences etc. Overall, we had a good balanced distribution among participants with diversified demographic and background characteristics (Table I).

*B. Pre-Survey*

The second section of the pre-survey questionnaires was to gauge students’ attitude towards conventional surveying course without virtual surveying simulator that comprises of three parts: students’ degree of interest in surveying course itself, their degree of interest in operation of physical surveying instrument and their challenges in handling the physical instrument. Students were asked to indicate their level of agreement with statements in this section. Using boxplot, Fig. 2 to 5 illustrates the students’ responses to the statements. Fig. 2 shows that students generally were keen in surveying course itself, for example, statement 1: I am very interested in the surveying course (median=3); statement 9: the surveying

course prepares me for the sub-sequent higher-level courses in my overall study (median=3); and statement 13: I think the surveying course is useful for my profession (median=3).

Fig. 3 shows that students mostly were keen in learning how to operate physical surveying instrument, for example, statement 1: I am very interested in the operation of physical surveying instrument (median=3); however, majority of the students disagree statement 14: operating physical surveying instrument is easy (median=2); and they are willing to spend more time to practice on how to operate physical surveying instrument after leaving lab class in statement 18 (median=3).

Fig. 4 shows that students faced many challenges in handling the physical surveying instrument, for example, statement 1: the physical surveying instrument is not enough for students to take turn to practice (median=3); statement 17: I want more interaction between instructors and students (median=3); statement 18: I need more guidance from instructor when I operate surveying instrument; and statement 20: I cannot understand without audio visual teaching aids used by instructor (median=3).

TABLE I. DEMOGRAPHIC CHARACTERISTICS OF PARTICIPANTS

Demographic characteristics		%
Age	20 – 34 years	50
	35 – 44 years	39
	45 – 54 years	11
Years of studies	Year 1 – 2	36
	Year 3 – 4	43
	Year 5 or more	14
	Graduated	7
Taken basic surveying course at WOU	Taking now	57
	Taken already	22
	Not taken	21
Taken land surveying course during diploma / technical / vocational studies	Yes	39
	No	61
Construction work experience	Less than 1 year	11
	1 – 5 years	36
	6 – 10 years	14
	More than 10 years	39
Surveying experience at workplace	Yes	43
	No	57

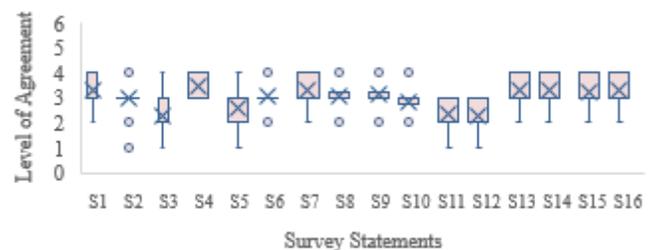

Fig. 2. Students’ Responses to Statements Regarding their Degree of Interest in Surveying Course.

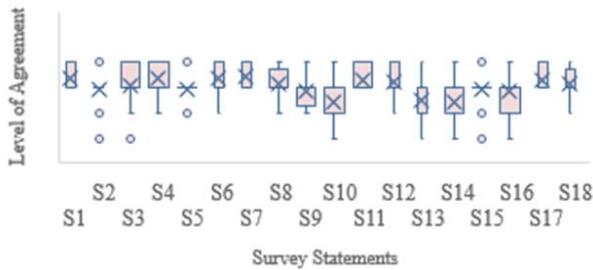

Fig. 3. Students' Responses to Statements Regarding their Degree of Interest in Operation of Physical Surveying Instrument.

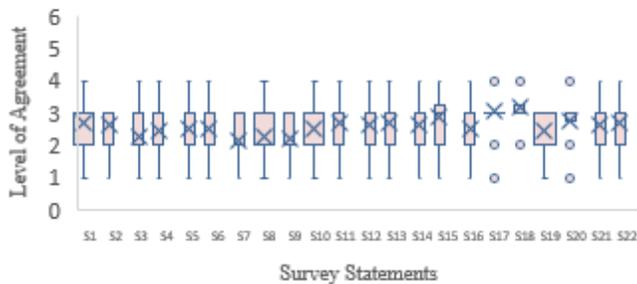

Fig. 4. Students' Responses to Statements Regarding their Challenges in Handling the Physical Surveying Instrument.

The third section of the pre-survey questionnaires was to gauge students' attitude towards unconventional surveying course with virtual surveying simulator that comprises of two parts: students' degree of interest in learning how to operate virtual surveying instrument and their readiness to run virtual simulator on their personal devices such as their device types, window version, graphic card, internet connection, etc. Fig. 5 shows in general students were keen in learning how to operate virtual surveying instrument, for example, statement 1: I am very interested in the operation of virtual surveying instrument (median=3) and they are willing to spend more time to practice on how to operate virtual surveying instrument after leaving lab class in statement 16 (median =3). All the students possessed personal devices either laptop or desktop with Windows 7 and above. 61% of their devices have graphic card. 75% of the students had stable internet connection access and 86% of them were comfortable to download and install virtual simulator on their own.

### C. Post Survey

Whereas in the post survey questionnaires, there were two sections in the post-survey. The first section was to find out if any changes of students' attitude towards unconventional surveying course with virtual surveying simulator after participating the virtual surveying field lab simulation classes. This section comprises of students' rating on self-efficacy, effectiveness of learning, instructors, virtual surveying activities, virtual surveying software, lab manual and exercise provided during the virtual lab simulation classes. Fig. 6 shows students' ratings and the students in general have responded positively towards the virtual surveying simulator learning experiences.

The second section of the post survey questionnaires was to determine students' preference between surveying course with and without virtual surveying simulator. Fig. 7 shows that majority of the students agreed the surveying course with virtual simulator is better, corresponding to the challenges with the physical instrument, for example, statement 1: virtual surveying instrument is better because every student can handle the surveying instrument at their desktop (median=3); statement 17: virtual simulator is better because there is more interaction between instructors and students (median=3); statement 18: virtual simulator is better because instructor could provide more guidance when I operate surveying instrument; and statement 20: virtual simulator is better because instructor could use it as audio visual teaching aids (median=3).

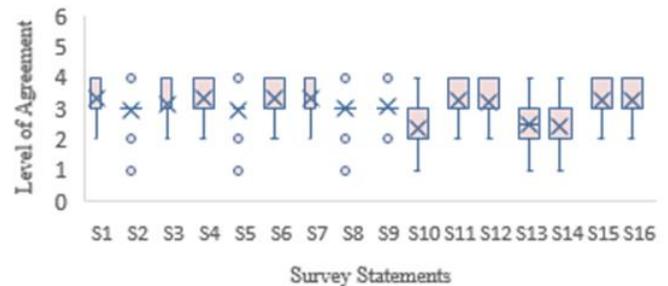

Fig. 5. Students' Responses to Statements Regarding their Degree of Interest in Operation of Virtual Surveying Instrument.

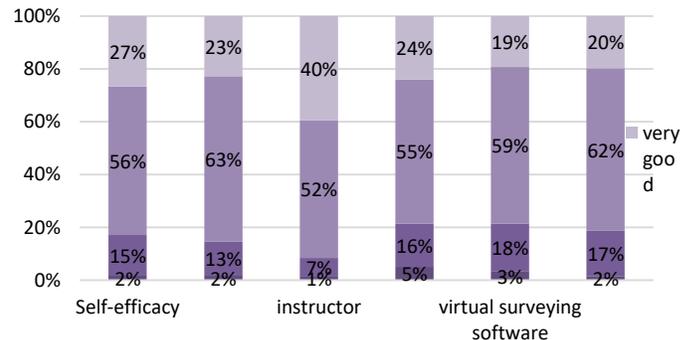

Fig. 6. Students' Rating on their Learning Experiences towards Surveying Simulator Lab Class.

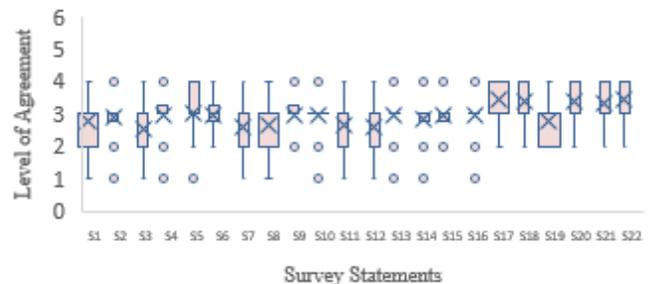

Fig. 7. Students' Response to their Preference between Surveying Course with and without Virtual Surveying Simulator.

#### D. Comparison between Pre and Post Survey

Students' level of agreement on 10 parallel survey statements each related to learning interest and learning efficiency in surveying respectively from both pre and post survey are compared. A parametric test i.e., student t test for dependent or paired t test was used to find out any statistically significant mean change in learning interest and learning efficiency of surveying following the virtual simulator lab class as sample size,  $n < 30$ . The distribution is normal after verifying with the Kolmogorov-Smirnov test as  $p\text{-value} > 0.05$ . The  $\text{mean} \pm \text{SD}$  of learning interest in surveying before surveying simulator lab class was  $30.86 \pm 2.965$ , and  $\text{mean} \pm \text{SD}$  after simulator lab class was  $32.21 \pm 3.985$ . There was significant mean change in learning interest of surveying after simulator class as  $p\text{-value} < 0.05$  ( $p = 0.022$ ) (Fig. 7). The  $\text{mean} \pm \text{SD}$  of learning efficiency in surveying before surveying simulator lab class was  $26.86 \pm 3.608$ , and  $\text{mean} \pm \text{SD}$  after simulator lab class was  $30.68 \pm 3.486$ . There was also significant mean change in learning efficiency of surveying after simulator class as  $p\text{-value} < 0.05$  ( $p = < 0.001$ ) (Fig. 8).

#### E. Direct Method

Besides reporting on the indirect method that captures students' perceptions of their learning experiences through survey questionnaire, a direct method involving an evaluation of students' quizzes in answering four different surveying topics upon completion of the virtual lab class (Fig. 9) and also the comparison of the year end final examination results of surveying course with the past year results before the introduction of virtual simulator (Fig. 10) were also employed in this study.

Fig. 9 illustrates that more than half of the students, i.e., 61% of them, passed their quizzes (average=44%), the lowest score for students who failed was 13% and the highest score was full mark, 100%. Majority of the students agreed that they had no difficulties in understanding the questions provided in the quizzes (median=3) and better understanding of the questions after carrying out the virtual surveying activities (median=3), but think they would be able to solve the questions if they have more time (median=3).

Fig. 10 depicts that the  $\text{mean} \pm \text{SD}$  score for group in year 2020 is higher at  $67.70 \pm 21.544$  as compared to year 2019 ( $\text{mean} \pm \text{SD} = 41.81 \pm 21.360$ ) and 2018 ( $\text{mean} \pm \text{SD} = 57.93 \pm 21.251$ ). One-way ANOVA analysis confirms that there is a statistically significant difference between the mean score for each group as the significance value is 0.000 ( $p = 0.000$ ), which is  $p\text{-value} < 0.05$ . The Tukey's HSD test i.e., the preferred test for conducting post hoc tests on a one-way ANOVA. The multiple (pair-wise) comparisons of scores between the groups shows that there is a statistically significant difference in the scores between year 2020 and 2019 ( $p = 0.000$ ) and between year 2019 and 2018 ( $p = 0.029$ ). However, there is no significant difference of the scores for year 2020 and 2018 ( $p = 0.198$ ). In short, this proves that the virtual simulator lab class introduced to the group in year 2020 helped the students scored better in their final examination as compared to the groups not introduced with the simulator lab class in year 2019 and 2018.

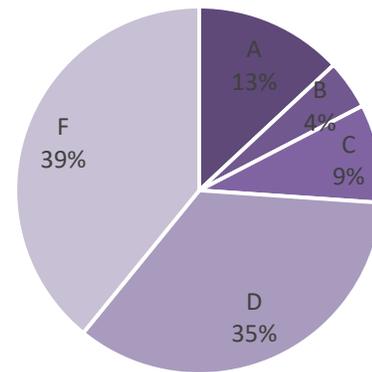

Fig. 9. Students' Quizzes Result at the End of the Simulator Class.

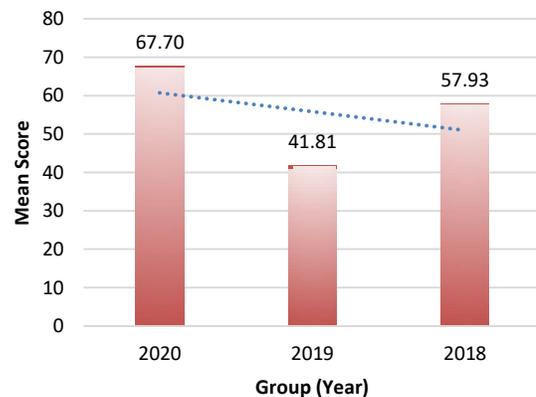

Fig. 10. Comparison of Mean Scores for Final Exam Results in Year 2020, 2019 and 2018.

#### F. Instructors' Rating

While the virtual simulator was received positively by the students, instructors were also asked to give their rating on students' learning experiences that comprises of learning interest, learning effectiveness, interaction between instructors and students, virtual surveying activities, virtual surveying software, lab manual and exercise provided, based on their observation during the virtual lab class. (Fig. 11) The instructors in general have responded positively towards the virtual surveying simulator learning experiences.

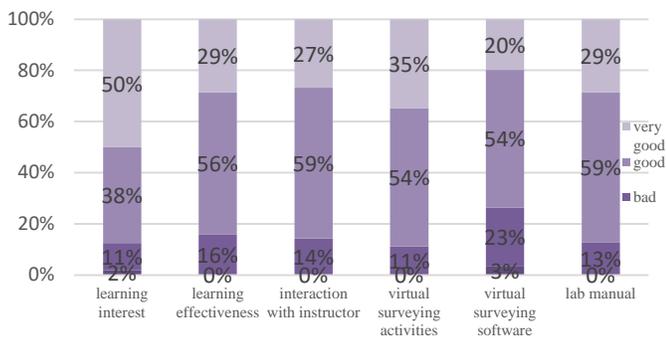

Fig. 11. Instructors' Rating on Students Learning Experiences towards Surveying Simulator Lab Class.

## V. DISCUSSION

The statistically significant and positive results from the study clearly answer the research questions posed at the onset of the study. It is hypothesized that the virtual land surveying simulator will enhance students' learning interest and learning efficiency for land surveying course in blended distance learning setting at Wawasan Open University (WOU) in the time of Covid-19 pandemic. The null hypothesis of this study, which is, virtual land surveying simulator will have no effect at all on the learning effectiveness has been rejected. This finding is established when comparisons are made in between pre and post survey statements related to learning interest and learning efficiency in surveying respectively; in between the indirect method reflecting students' perceptions of their learning experiences and the direct method evaluating students' performance through quizzes and year end final examination; and in between students' rating and instructors' rating towards surveying simulator lab class.

In order to explain the results obtained, the instructors' interview and observation gave some insights on the students' learning behavior. The instructors observed that during the simulator class students paid full attention to them, the interaction between them and students were good, eventually students could clearly understand the learning objective and were able to operate the virtual surveying instrument as instructed. They also commented that during the learning process, virtual surveying simulator helped students to understand some of the surveying theories and concepts that are abstract. The virtual surveying simulator allowed students to screen record the surveying activities history to the cloud / drive to share with the instructors in order to playback the recorded surveying activities to review students' learning problem and to provide constructive feedback.

It is found that the virtual surveying software is simple and easy to use, however, it is noted that there are some limitations with the software, for example some components of the virtual surveying instrument such as screws, knobs, buttons are not designed for students to manipulate, and some details of the virtual instrument operation procedure and interface are missing for students to learn. Students were not able to learn teamwork skills as they couldn't cooperate with the other course mate in a team to carry out the virtual surveying activities together. Despite those minor flaws, the instructors and students still perceived the virtual surveying simulator has

effectively enhanced the learning interest and efficiency in both surveying course and in physical surveying activities.

In an open distance learning (ODL) setting, when linking the demographic characteristics of the participants, it was found that ODL students whom were largely made up of working adults, mature in age, more computer savvy with technology readiness, have certain measures of exposures to surveying experiences at their workplace or have some prior knowledge in surveying by taking land surveying related courses during pre-university study, they were more interested and had positive attitude in surveying, physical surveying instrument and virtual surveying simulators, as  $p$ -value  $< 0.05$  ( $p = < 0.001$ ) using paired T-test. Their interests to discover more aspects of surveying were further enhanced with the virtual surveying simulator. Their surveying skills and understanding were reinforced through repeated practices and exercises using surveying simulator after classes.

Differing from the previous studies conducted by the conventional universities [3, 4, 7, 8, 9, 10, 20, 22, 8, 23], as an ODL university that offers blended or fully open distance learning delivery without regular face-to-face (F2F) contact in the physical classroom, WOU in this study adopted an ecosystem approach whereby the virtual land surveying lab simulator is part of that learning support system on 24x7 basis that comprises of online learning management system (LMS) and online assignment submission system (OAS) that provide students access to self-directed learning materials, online counselling and tutoring, electronic library resources, forum discussions etc. from anywhere remotely and at any time with personalized and self-paced learning experience. In assuring the quality of online teaching and learning, the quality assurance (QA) components are being integrated within the LMS of WOU [25]. Even during the Covid-19 lockdown, nationwide, the regional learning centers and offices in the urban cities that are equipped with physical libraries, laboratories, computer terminals and administrative support were closed temporarily, the interruption in learning and teaching process was able to be kept to a minimal level.

In this study, it is also recognized that virtual surveying simulator comes in handy especially amid pandemic outbreak, so that students could still carry out the surveying activities virtually, as the university couldn't get enough physical surveying instruments for students to keep their social distancing since the purchasing and maintenance cost of physical instruments is often expensive. This same sentiment is also echoed by other affected universities as well. Bolkas et al. (2021) pointed out that the Covid-19 pandemic has pushed universities to remote learning and opened the door to implement the novel desktop-based VR platform for surveying labs. [9] Tingerthal and Kaoni (2021) also expressed that the Covid-19 pandemic has forced the universities to pivot in the modality of online teaching and proposed the virtual surveying laboratory to incorporate even into a post Covid-19 curriculum. [10].

## VI. CONCLUSION

It is concluded that the virtual land surveying simulator has shown statistically significant and positive results in stimulating learning interests and enhancing effectiveness for

land surveying courses among blended open distance learning (ODL) students at Wawasan Open University (WOU) in the time of Covid-19 pandemic, solving many bottleneck problems associated with conventional surveying course. Both students and instructors have responded positively on the learning experiences towards the virtual surveying simulator lab class. Students' quizzes result at the end of the simulator class overall was satisfactory. Moreover, after the introduction of virtual surveying simulator, students' achievement in the year end final examination amid Covid-19 was better than pre-Covid-19 performance.

It is strongly recommended that the virtual surveying simulator should be added to the surveying field lab along with the physical surveying instrument, but never as a substitution to do away with the physical surveying instrument. It is suggested that the use of virtual surveying simulator in designing teaching activities as an effective visual teaching aid. More activities related to field of surveying should be added and at the same time students should be given more time to complete those surveying activities, at least a couple hours more. It is preferred that students first learn the physical surveying instrument to carry out the physical activities before learning the operation of the virtual surveying simulator to carry out the virtual surveying activities. Smaller class size is ideal for both physical and virtual surveying lab classes.

It will be still a long time before we could return to pre-Covid era and in the meantime, we will be living together with coronavirus in the new normal. Even in a post-Covid world, the landscape of education will never look the same anymore. More future work will focus on the immersive lab learning experiences with the promising use of virtual reality (VR), augmented reality (AR) and artificial intelligence (AI). And the virtual lab simulator could model after unmanned aerial vehicle / unmanned aircraft system (UAV/UAS) or known as drone, which keeps rising as a viable alternative to traditional land surveying. Greater samples size could be collected and more academic years could be monitored to compare the examination scores in the future research.

#### ACKNOWLEDGMENT

This study is supported by the Centre for Research & Innovation (CeRI) grant that sponsored the visiting scholar program to the Department of Civil Engineering, at National Taiwan University for the research collaboration on development of SimuSurveyX. We wish to express gratitude to Professor Patrick Shang-Hsien Hsieh and Professor Jen-Yu Han of National Taiwan University.

**Abstract**—The accurate approximation of pixel value for preserving image details at a high concentration of noise has led the researchers to improve filters performance. A few image restoration filters are effective at lower density noise. Filters are commonly deployed for cameras, image processing tasks, medical image analysis, guided media data transmission, and real-time machine learning. This article proposes a mathematical model for the exact pixel value estimation at a high noise density for RGB and Gray images. The mathematical model is implemented to fuse statistical reasoning on the optimized mask sizes while preserving image details. Different parameter returns from the median filter, the trimmed median filter, the trimmed mean filter, and mood analysis form a mathematical function. The filter iteratively selects different schemes to calculate pixel values at different noise densities with minimum image information. Different processing masks are analyzed to preserve local data at specific image locations correctly in high density. A robust estimator counts false approximation of pixel values as discontinued, identified, and removed. At the post smoothing process, the filter recovers the misclassification of noise-free pixel and blur effects in the image. The qualitative experiments show satisfactory results in storing the details of the image from any image. The performance of the fusion filter is verified with visual quality and performance analysis matrices such as the image enhancement factor, the similarity indicator and the noise ratio from the peak signal.

**Keywords**—Salt and pepper noise; median filter; statistical reasoning; performance analysis matrices; high-density noise; mood; trimmed median; trimmed mean; peak signal-to-noise ratio; image enhancement factor; structural similarity index

## I. INTRODUCTION

Some notable developments have attracted attention from the image processing industry to academia. Its research opportunities have been expanded due to the implementation of real-time applications in computer vision, digital image

acquisition, satellite image analysis, data transmission and medical image analysis [1]. Preprocessing a digital image for a real-time application is essential before deploying for any application. This article focuses on significant preprocessing work and recommends a statistics-based mathematical model to eliminate digital images' salt and pepper noise (SAPN). The previously proven filters have been discussed here: standard median filter (SMF)[2], an adaptive median filter (AMF) [3], decision-based filter (DBA) [4], and noise-adaptive fuzzy switching median filter (NAFSM)[5]. The most common disadvantage of denoising is that the image information is lost in higher noise density [6].

SMF has a fundamental mathematical structure and displays the best output on low-density noise removal [7]. A mask with a 3X3 size limits the processing ability to select noise-free pixels at high densities. Nevertheless, several recent additions to nonlinear filters have outgrown existing filter errors and reached a stage where they may be suitable for approved types of noise. Nonlinear methods such as trimmed media filters, noise adaptive fuzzy median filters [5], decision-based median filters [4] have become the norm for image analysis.

Related research indicates that the development of the filtering phase is gradual, and the opportunity motivates the researcher to strengthen the filters based on statistical reasoning. This article investigates the fusion of statistical logic to design an effective filter to remove noise from the highly damaged image.

Filters are loosely classified according to their ability to reduce the noise of any concentration: when retrieved, images begin to have jitter effects, noise type, recovery of image data, image type, and noise removal from pure black and white dot [8]. The adaptive median filter mask shows a different technique for selecting a noise-free pixel by extending the size

\*Corresponding Author

of  $2 \times 2$  but fails due to limited statistical analysis and displacement of the denoised pixels at high noise densities. The adaptive median filter fails to store local information properly, while the noise adaptive fuzzy switching median filter [9](NAFSM)[10] and the decision-based filter (DBA) [4] repeatedly replace the noisy pixels that are resulting blurred effect on the restored images. However, the output of any filter can be improved to a certain extent by giving more weight to a particular pixel based on the surrounding pixel intensity statistics [11][12][9] [13].

Statistical analysis for the improvements of AMF, DBA, NAFSM, and other filters was initiated. However, a proper mathematical model is not yet proposed. Instead, most researchers have suggested multiple-combined filters to eliminate high-density pulse noise from the grey and colour images, regardless of the image's black and white part, discussed in Section 2.3. And most of them are not defined as state-of-the-art filters, such as morphological-mean filter [14], decision-based asymmetric filter (DBUF) [15] and filter boundary discriminative noise detection [16]. Most of the improved filters have the following drawbacks:

1) Most advanced/hybrid filters replace noise pixels under certain predefined conditions. Eliminating high SAPN concentration confuses filters to replace noisy pixels.

2) Most recently improved decision-based filters use threshold concepts and retain high noise density (above 50% noise density) in the restoration process. A striking effect is included separately in the restored image. In comparison, such filters do not perform well in extracting features from the medical image.

3) Most sophisticated filters and derivatives of median-type filters repeatedly replace the noise pixels in recovered images, regardless of the pixels in the  $3 \times 3$  Mask.

A fusion-based statistical model performs iterative analysis on the different processing mask sizes for statistical analysis for image retrieval with improved visual quality from high-density SAPN. The filter iteratively selects the different mask sizes and performs comparative analysis based on neighbours pixels information and the non-local pixels information at  $11 \times 11$  Mask to understand the image texture. The proposed filter has the following distinctive features to overcome the limitations:

#### A. Optimization of Texture-based Accurate Pixel Classification

Misclassification of noise pixels at high densities is a significant limitation of most filters. Most recently enhanced hybrid filters such as decision-based filters, noise-adapted obscure medium filters, interpolation-based filters [17], morphological filters [18], inpainting-based filters [19] to classify noisy pixels at high noise density.

#### B. Optimization of Mask Sizes to Fuse Statistical Analysis into the Mathematical Model

A filtering mask plays a vital role in removing high-density noise from the image regardless of local information at high density. The image texture should be maintained from any shape of the processing mask when retrieving an image from corruption, and the mathematical model is inspired by proper image texture management. A recommended mask size is preferred from the recently proposed hybrid filters discussed in Section 2.3. Experiments already have identified the use of a  $3 \times 3$  mask as the best filtering option for removing low noise levels (<30 % noise) [20]. However, there are no optimal rules for determining the size of a mask that can be applied to a noise concentration. The algorithm provides a statistical, mathematical model that can repeatedly use different shapes of the Mask according to the noise density.

#### C. Statistical Reasoning to Identify Image Texture

The pixel intensity of the edges is identical to the details of the SAPN, which assumes it as the noise feature instead of evaluating edge information. The concept of axis based statistical analysis [6] is used here for edge detection based on the horizontal and vertical resolution in the Mask. The filter utilizes a primary mask at low density to identify the edges and noise-free pixels. But at high-density, different mask shapes are used repeatedly to reconstruct the edges, noise-free pixels, and non-local image details from corruption to image details.

#### D. Need for the Fusion of Statistical Model

Statistical analysis provides high visual quality and high efficiency of quantitative measurement with other popular filters. The quantitative measurements are the structural similarity index (SSIM) [21], the image enhancement factor (IEF) and the peak signal-to-noise ratio (PSNR) [22].

It provides a systematic decision rule for selecting processing mask size based on noise density. The rule-driven model allows multiple filters to work in an iterative process to estimate pixel intensity.

The above features distinguish from other existing filters in terms of retrieving an image from low and high noise concentrations. The model can be applied at the image preprocessing stage for image preparation for any application.

The rest of the paper is fourfold: It gives an overview of related literature, provides complete implementation methods of the proposed algorithm, performance analysis, and conclusion.

## II. LITERATURE REVIEW

#### A. Salt and Pepper Noise (SAPN)

Reconstruction of digital images from high-density salt and pepper sounds is induced by transmissions, faulty sensors, or analogue-to-digital converters. Noise is evenly distributed in the image where infected pixels are usually identical to their neighbours. A fixed number of pixels that change to 0 or 255 is found in the salt and pepper noise (SAPN).

**B. SAPN Detection Criteria for Existing and Hybrid Filters**

Algorithms such as Noise Adaptive Fuzzy Switching Media Filters, Decision-Based Algorithms, and Adaptive Media Filters are standard today, often showing noise on the pixel intensity rather than identifying the properties of the surrounding pixels. Thus, filters select 0 or 255 noise-free volumes as noise pixels, contributing to incorrect detection in the image. It affects the decision on the image recovered from the high noise in a severe case. A noisy image has the following features:

- 1) SAPN is evenly or randomly scattered and spread over distorted images with equal probability.
- 2) Noisy pixels are not distinguished from noise-free 0 or 255. Again, the pixel intensity in that vicinity can be 0 (or 255) in most cases.
- 3) The SAPN often distorts the black and white information in the grey or RGB images. The salt or pepper noise is assimilated in the image white or black detail and lost, respectively.

Problems with the above design are considered when improving the filter. But the use of weak statistical methods or multiple filters consistently provides a certain level of performance. Advanced logic-based mathematical models or machine learning methods can overcome current performance limitations. Fig. 1 provides a classification of filters based on noise concentration.

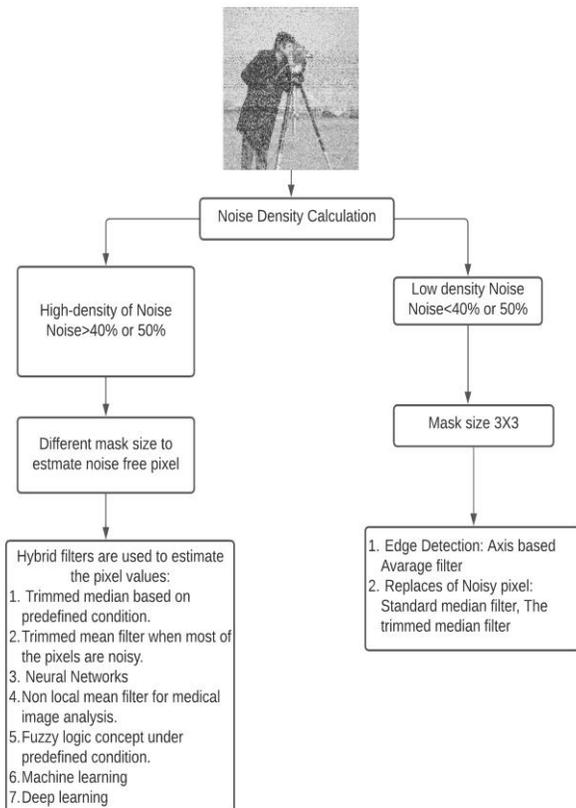

Fig. 1. Classification of Filters based on Noise Density.

**C. Statistical or Mathematical Model used in Recently Published Journals**

Recently published articles show that the most advanced filters are hybrid filter types, and a variety of filters act as a single algorithm applied to remove higher noise concentrations from images. The exact mathematical model for high-density pixel estimation has not yet been adequately defined. The statistical analysis of some recently published journals to identify trends in improving filters is summarized here in Table I. The table demonstrates the need to have an accurate mathematical model for eliminating noise at higher densities. Table I shows that filters for removing high-density noise are based on the systematic deployment of several filters in a single algorithm that improves the image quality at a certain level.

TABLE I. EXITING ALGORITHMS ACCURACIES

Filters	Statistical reasoning used for the filter design in recently published journals
The Axis-Based Filters[6]	The edges of the Mask are described with the aid of using a direct line passing via the primary pixel. Otherwise, its miles changed with the aid of using the expected value.
DBUTM Filter [23]	The mean of all four creaking neighbours replaces the noisy pels. If four neighbours aren't noisy, the corrupted pixel returns the unsymmetrical cut changed median value.
A CNN filter [24]	CNN model is used for denoising Salt and Pepper noise.
Modified cascaded filter[8]	The trimmed median value replaces the noisy pixel while other pixel values, 0 and 255, are present at a high noise density in the selected window.
Improved Switching Median Filter [25]	The median value selection is based on the 2nd and 8th pixels of the 3 × 3, where all the pixels are arranged in a matrix in ascending order. Also, the window means is calculated from a 4X4 window.
Minimum-maximum median filter[26]	Selecting the mask size is entirely based on the noise density of the current processing window. Noisy pixel is replaced by the last processing pixel or median value.
Min-Max Filter[27]	Min-max average pooling is used here to remove SAPN noise.
Neural network[28]	The proposed algorithm utilizes a denoising convolutional neural network at a high noise density.
Tropical algebra-based adaptive filter[29]	The filter deployed tropical algebra to illustrate the adaptive principles to do away with salt and pepper noise.
A two-stage filter[30]	The filter behaves like a conventional filter; however, the high-density noisy pixel is changed using the median of the most repetitive pixels.
FFDNet: CNN based Image Denoising [34]	Proposed a CNN model.
Adaptive Algorithm and Wavelet Transform [33]	Utilizes Adaptive filtering and Wavelet Transform

From Table I above, a summary of the most proposed hybrid filters between 2019 and 2021 can be summarized as follows:

- 1) The approximation of pixel intensity at high density is based on finding the noise-free pixel regardless of maintaining local features.
- 2) Install filters without comparing local information to different image properties at high density.
- 3) Sometimes pixel estimation relies on threshold value to estimate noisy pixels as noise-free.
- 4) Discontinuity of local pixels is not yet maintained at high density, which causes a blur effect in the image.

### III. METHODOLOGY

In this section, a fusion of statistically based filters is presented, broadly divided into four subdivisions: the estimation of noise density, pre-edge filtering, and statistical reasoning based on ambient pixel intensity (the main algorithm of the filter), and post-smoothing filter (Robust Statistics). The block diagram of the proposed filter is demonstrated in Fig. 2.

#### A. Estimation of the Noise Density

The noise concentration of the processing mask is calculated to start the filtering process because it is an integral part of statistical analysis. Sound density ( $n_d$ ) can be calculated using equations (1) and (2) [31].

$$Y_{(x,y)} = \begin{cases} 1, & q_{x,y} \in \{0,255\} \\ 0, & \text{Otherwise} \end{cases} \quad (1)$$

$$N_d = \frac{\sum_{y=1}^{x=R} \sum_{x=1}^{y=C} Y_{x,y}}{R \times C} \times 100\% \quad (2)$$

Where,  $q_{x,y}$  is the pixels of the noisy image, and R and C are the image dimension.

#### B. Filtration of the Edges of the Image Objects

At first, a 3X3 mask was taken to classify the contaminated pixels based on the horizontal and diagonal directions in the initial stage. If the pair of pixels in the horizontal or diagonal direction is the same, it is declared as the underlying processing pixel,  $q_{x,y}$  Noise-free. The matching figure is shown in equation 3 below:

$$q(x,y) = \begin{cases} q_{x+1,y+1}, & \text{if, } q_{x+1,y+1} = q_{x-1,y-1} \\ q_{x+1,y-1} & \text{if, } q_{x+1,y-1} = q_{x-1,y+1} \\ q_{x,y+1}, & \text{if, } q_{x,y+1} = q_{x,y-1} \\ q_{x,y} & \text{Trimmed Median} \end{cases} \quad (3)$$

It can be seen that the original values replace most of the pixels recovered in this process, and here the incorrect classification of pixels is reduced in a high density of noise.

This technique is considered when enough noise-free pixels are available to detect edges in the processing mask. Otherwise, the trimmed medium filter is placed in the processing mask. The block diagram of the vertical and horizontal edge detection scheme is given in Fig. 3.

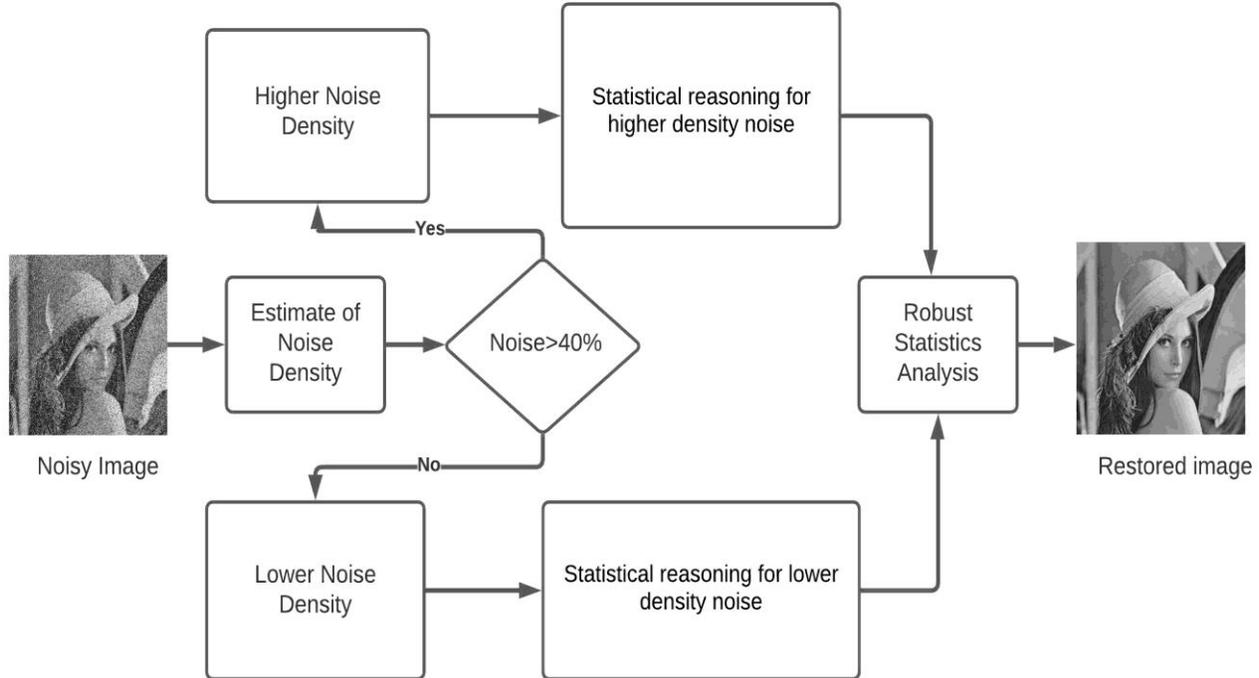

Fig. 2. Block Diagram of the Proposed Filter.

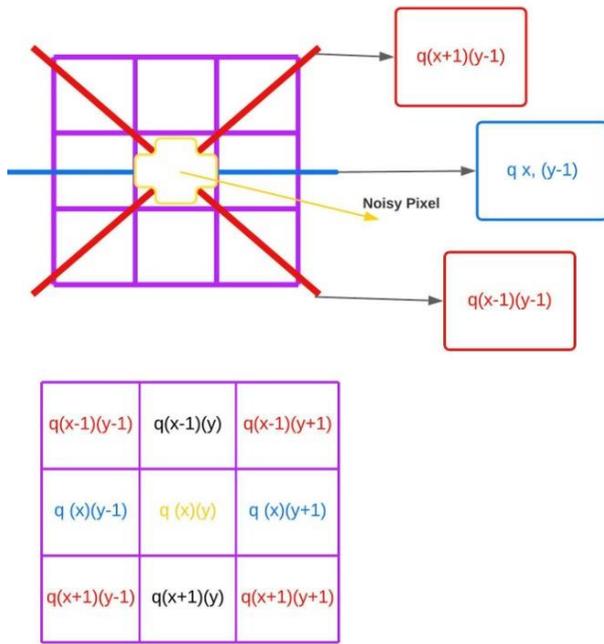

Fig. 3. Filtration of the Edges from the Image Objects.

### C. Statistical Reasoning based on Ambient Pixel Intensity

At higher noise concentrations, the filter utilizes 3X3, 9X9, and 11X11 masks, and at the lower noise <40% density, only a 3X3 mask is applicable to perform edge detection and noise elimination. The trimmed median value shows the best result after detecting edges at lower noise density. Mood value is estimated from the 11X11 Mask for the pure image black and white data. Statistical analysis from 3X3 and 9X9 masks offer a function to calculate the pixel intensity of distorted images as given in an equation (4).

$$U_{x,y} = (\alpha \times q_{x-1,y-1}) + (1.0 - \alpha)SMF(11 \times 11) \quad (4)$$

Here,

$$\alpha = \left( \frac{mood(3 \times 3 \text{ mask})}{9} \right),$$

$1 - q_{x,y} = \text{Last processed pixel}$ ,

$SMF(11 \times 11) = \text{Median value of } 9 \times 9 \text{ Mask}$ .

If the last processed pixel is,  $q_{x-1,y-1} = 0$  or  $255$ , and all the pixels at  $11 \times 11$  Mask is  $0$  or  $255$ , then the filter detects this image detail is pure black or white. Then the complete statistical equation is shown in (5).

$$q_{x,y} = \begin{cases} U_{x,y}, & \text{if } 1 - q_{x,y} \neq 0 \text{ or } 255, \text{ Noise} > 40\% \\ \text{Mood}(9 \times 9), & \text{Otherwise} \end{cases} \quad (5)$$

Tests show that PSNR values drop sharply when  $N_d > 40\%$ . Statistical analysis of decision-making is based on the SAPN density of the Mask is considered here. Fig. 4 shows the different mask size sizes required to estimate intensity value. The proposed filter iteratively use the filter and perform median, mood and probability analysis on image data.

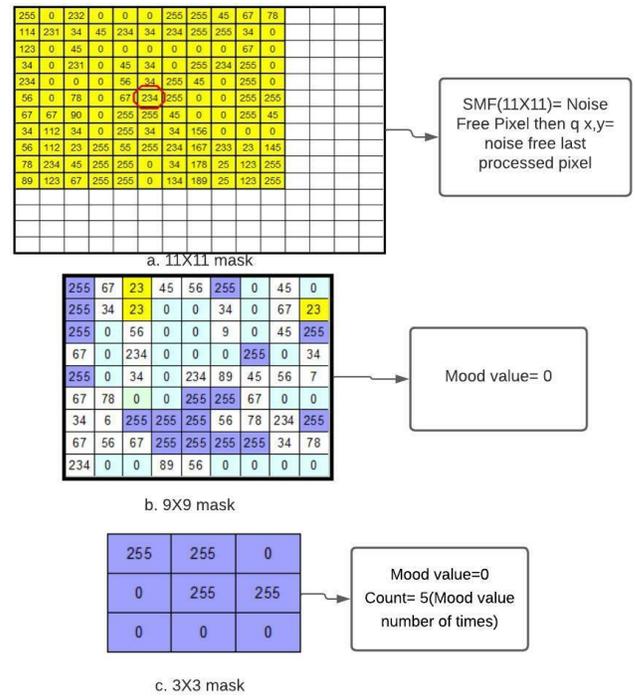

Fig. 4. Comparison Analysis on different Mask at Higher Density.

The need to select both masks of 9X9 and 11X11 is shown in a, b, and c of Fig. 5. The size of the Mask above 11X11 could not properly store local information. Thus, the statistical analysis is entirely dependent on  $3 \times 3$ ,  $9 \times 9$ , and  $11 \times 11$  masks. Experiment shows that, filter with size more than  $11 \times 11$  could not maintain the local image information at high density of noise. Fig. 5 visually demonstrates the trimmed median and the mood at e and f.

1) *Post-smoothing filter*: A smooth step has been added to the algorithm to improve the image quality further. The Robust Estimation is based on the principle that safety is more important than efficiency[32]. Here, the median is an estimator. Let  $q^1, q^2, q^3, \dots, q^n$  indicate a random pixel from that processing image.

Algorithm 1( Removal of higher density SAPN):

- 1:  $q_{x,y} \leftarrow \text{Input Noisy image}$
- 2: *if*  $N_d < 40 \ \&\& \ M_{3 \times 3}$
- 3:     { *if*  $Q_{xy} \leftarrow q(x,y)$  // Filtration of the edges
- 4:         else
- 5:              $Q_{xy} \leftarrow M_t(q_{x,y})$  // Trimmed Median
- 6:         }
- 7: *elseif*  $N_d > 40 \ \&\& \ (1 - q_{x,y}) \neq 0 \ || \ 255 \ \&\& \ M_{9 \times 9}$
- 8:      $Q_{xy} \leftarrow U_{x,y}$
- 9: *else*  $N_d = 100 \ \&\& \ M_{9 \times 9}$
- 10:      $Q_{xy} \leftarrow \text{Mood}(q_{x,y})$
11. Algorithm2  $\leftarrow Q_{xy}$

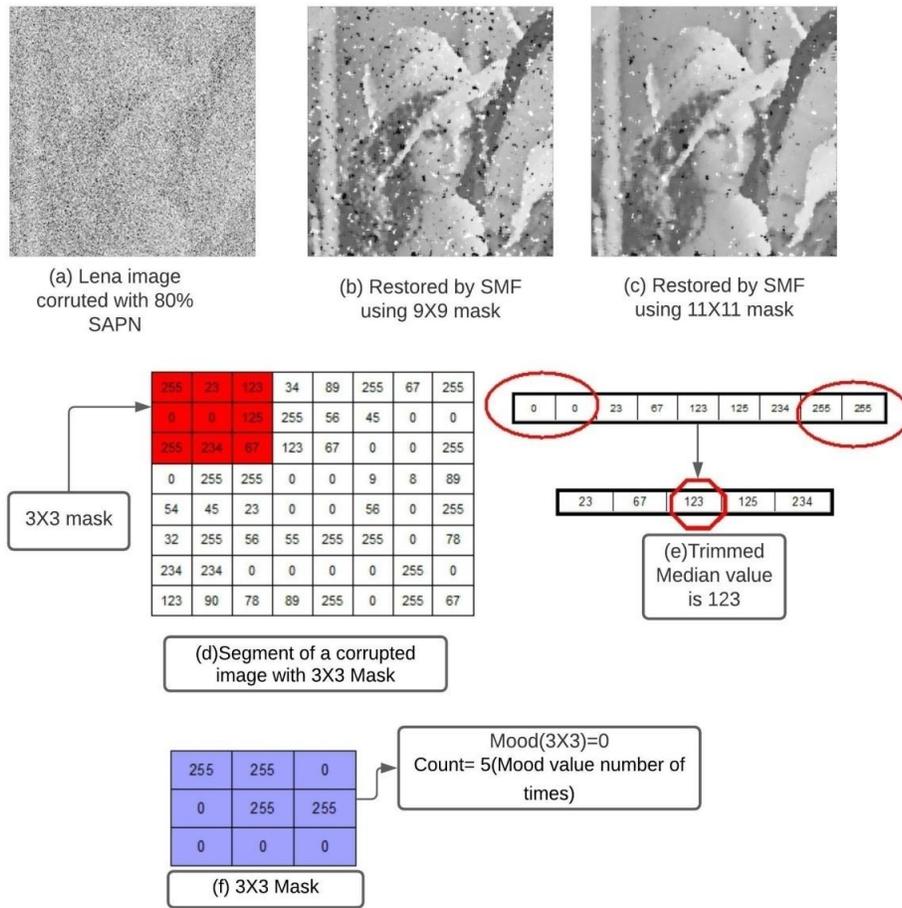

Fig. 5. Statistical Reasoning: (a) Lena Image Corrupted with 80% SAPN (b) Restored by SMF using  $9 \times 9$  Mask (c) Restored by SMF using  $11 \times 11$  Mask (d) the Segment of the Corrupted Image (e) the Trimmed Median (f) Mood Value.

U1 is the minor key of Qi, U2 is the following key in the sequence of Qi, and Un is the largest in the list (ascending order). The estimation of the new median, which removes pixel discontinuity in the image, is based on the L1 norm or Laplacian Distribution. The influence function is constant for the median, making the median an excellent and robust estimator. Robust Estimator is the M-estimators that are pretty good for distribution with outliers (scatter data value). The effects of robust estimators are compared in terms of influence function in the equation (6).

$$\varphi(q) = \begin{cases} 1 & q > 0 \\ -1 & q < 0 \end{cases} \quad (6)$$

Lorentz has an influence function of an estimator that tends to zero to increase the estimation distance and maximum value for the breakdown, which is used to the original pixel value from a corrupted image. The equations are given in (7) and (8).

$$P(q) = \log \frac{(1+x^2)}{2\sigma^2} \quad (7)$$

$$\varphi = \frac{2q}{2\sigma^2+q} \quad (8)$$

Robust estimation is applied to minimize pixel discontinuity of the corrupted image, which eliminates blur effects from the image. The SAPN is first identified based on this method's minimum (0) and maximum (255) values. It is considered noise-free if the current pixel is within the dynamic range 0 and 255. Otherwise, it is seen as a noise pixel and is replaced by a value determined by the following algorithm using the Lorentzian Estimator.

Algorithm 2( Robust Statistics):

- 1:  $Q_{x,y} \leftarrow$  Input preprocess image layer
- 2: if  $Q_{med} \leftarrow$  SAPN and Mask =  $3 \times 3$
- 3:  $P_{x,y} \leftarrow Q_{med} - Q_{xy}$
- 4: if  $P_{x,y} \leftarrow$  SAPN  
//calculate the robust influence function
- 5:  $\varphi(p) \leftarrow \frac{2p}{2\sigma^2+p^2}$
- 6:  $s1 \leftarrow \sum_{l \in L} \frac{Pixel(l) \times \varphi(x)}{p}$
- 7:  $s2 \leftarrow \sum_{l \in L} \frac{\varphi(x)}{p}$   
//Estimated pixel value
- 8:  $Q_{x,y} \leftarrow s1/s2;$
- 9:  $R_{x,y} \leftarrow$  Restored image

#### IV. RESULTS

The statistics model and popular filters are programmed in MATLAB 2014 and then simulated with the 14 benchmark images used in related journals to study filter performance. The evaluation task is to calculate a denoised image with a noise density in the medium to high range (40% to 90%). The denoised images are judged in terms of visual quality and performance analysis matrices.

##### A. Evaluating by Quantitative Comparison

The visual reports are taken from the simulation to judge the significance of the proposed filter in terms of visual quality. The famous benchmark data for image denoising are Fishing Boat, Baboon, Pepper, Barbara, Bubble, and Camera Man. The visual quality shows that SAPN can be extracted from any digital image by the proposed filter.

Fig. 6 to 11 visually compare the proposed filter and other existing filters. Benchmark datasets are corrupted with SAPN at different levels of noise concentration, and the same datasets are restored from the stated filters. Recovered images are visually compared, and it is seen that the proposed filter has the best performance in creating high-quality images. As in the case of Fig. 6 and 7, the images are restored from 70% and 90% of the SAPN where the images are visually compared to the proposed filter outperforms the other filters. The optimal suppression power at all levels of noise concentration is shown in Fig. 8 and 9. Furthermore, Fig. 10 shows that 50% of bubbles have been recovered from noise.

The proposed filter cannot correctly restore the image because some parts have too rough transitions. It should be noted that most sophisticated filters, such as SMF, AMF, DBA, and MDBUTMF, are weak in effectively detecting noise pixels when the noise pollution in the image is above 40%. The visual comparison shows that they often fail to classify the pixel as noise-free at higher noise density, causing a blurring effect on images. In this case, the proposed filter applied post smoothing statistical analysis to remove image artefacts and blurring effects. The proposed filter did not perform well in the bubble image of Fig. 8 but shows excellent performance in removing noise from the cameraman's images in Fig. 11. Fig. 6 to 11 visually compare the proposed filter and other existing filters. Benchmark datasets are corrupted with SAPN at different levels of noise concentration, and the same datasets are restored from the stated filters. Recovered images are visually compared, and it is seen that the proposed filter has the best performance in creating high-quality images. As in the case of Fig. 6 and 7, the images are restored from 70% and 90% of the SAPN where the images are visually compared to the proposed filter outperforms the other filters. The optimal suppression power at all levels of noise concentration is shown in Fig. 8 and 9. Furthermore, Fig. 10 shows that 50% of bubbles have been recovered from noise. The proposed filter cannot correctly restore the image because some parts have too rough transitions.

### B. Evaluating by Quantitative Comparison

In this article, the Peak Signal-to-Noise Ratio (PSNR), Mean Square Error (MSE), Image Enhancement Factor (IEF), and Structural Similarity Index (SSIM) are considered for quantitative analysis. The PSNR is defined as the ratio between the original image's strength and the denoised image's strength, and the mathematical equation is given in (9).

$$\text{Peak Signal to Noise Ratio} = 10 \log_{10} \frac{(\text{MAX} \times \text{MAX})}{\text{MSE}} \quad (9)$$

Here, MAX is the maximum gray level of the image, and the Mean Square Error (MSE) is defined in the equation (10).

$$\text{Mean Square Error} = \frac{1}{RC} \sum (P_{x,y} - Q_{x,y})^2 \quad (10)$$

The R and C is the dimension of the image,  $Q_{x,y}$  - original image and the  $P_{x,y}$  - restored image. Another parameter is used, the Image Enhancement Factor (IEF). The mathematical expression of IEF is given in the equation (11).

$$\text{Image Enhancement Factor} = \frac{\sum_{i=1}^M \sum_{j=1}^N (N_{ij} - R_{ij})^2}{\sum_{i=1}^M \sum_{j=1}^N (X_{ij} - R_{ij})^2} \quad (11)$$

Where  $R_{ij}$ ,  $X$  and  $N_{ij}$  denote the original image, denoised image, and corrupted image, respectively. The final parameter used to evaluate the proposed filter's performance is Structural Similarity Index. The mathematical expression is in an equation (12).

$$\text{SSIM}(x, y) = \frac{(2\mu_x\mu_y + c_1)(2\sigma_{x,y} + c_2)}{(\mu_x^2 + \mu_y^2 + c_1)(\sigma_x^2 + \sigma_y^2 + c_2)} \quad (12)$$

Here,  $\mu_x$  and  $\mu_y$  are the standard deviation used as an estimation of the signal contrast,  $\sigma_x$  and  $\sigma_y$  are the contrast comparison, and C1 and C2 are the constant value with a limit of 1.

### C. Experimental Results of Tabular Style for High Density of Noise for Baboon(Grey) and Lena(RGB) Images

Tables II and III summarize the IEF, PSNR, and SSIM values for the six filters in the Baboon Grayscale and Lena RGB images. The experimental clearly show that the proposed algorithm has the edge over reported filters. Sometimes the Proposed filter cannot deliver optimal results in specific embodiments if certain image parts have very rough transitions or an utterly smooth area. Nevertheless, the average improvement of the proposed filter is the best from existing filters at SAPN density varies from 50% to 90%.

This, the performance of PSNR is exceptionally good for the noise concentration > 70%. Even at SAPN concentrations up to 95%, the proposed algorithm provides a fair average value compared with other existing filters. At medium noise concentrations, the effectiveness of NAFSM manages to surpass the Proposed algorithm but still exceeds existing strategies.

#### D. Experimental Results of Graphical Style for Low Noise Concentration for Pepper Image

The performance of the proposed algorithm is tested with a pepper image, and the noise density varies from 10% to 40%. Restoration performance is quantitatively measured by metrics such as IEF, PSNR and SSIM, as shown in Fig. 12, 13 and 14. The SMF replaces the processing pixel by its median regardless of the type of pixel, which provides poor performance. However, the AMF [8] shows improved performance, but the loss of local image details is much more significant due to its adaptive nature. Predefined condition-based filters such as NAFSM and decision-based filters failed to retrieve images correctly.

The trimmed median filter always considers median values from the processing mask eliminating 0 and 255, which failed to store image edges and local information properly. Necessary features that may suppressed noise for filters should also be taken care of for image processing tasks. The mathematical model also focused on this described in low density. Tests show that the exact pixel estimate of the proposed filters in low-density noise is the highest of the popular filters.

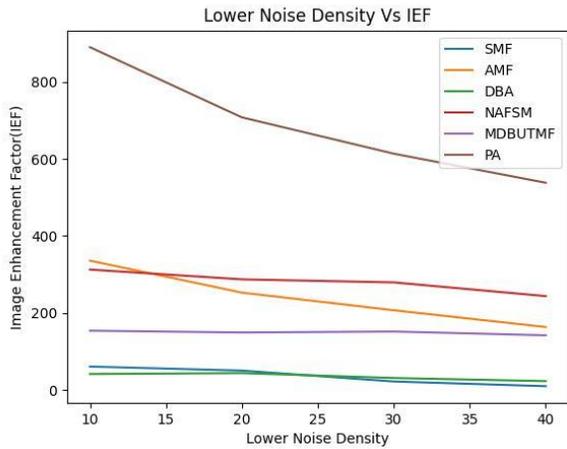

Fig. 12. Quantitative Analysis of Filters using IEF for Pepper Image.

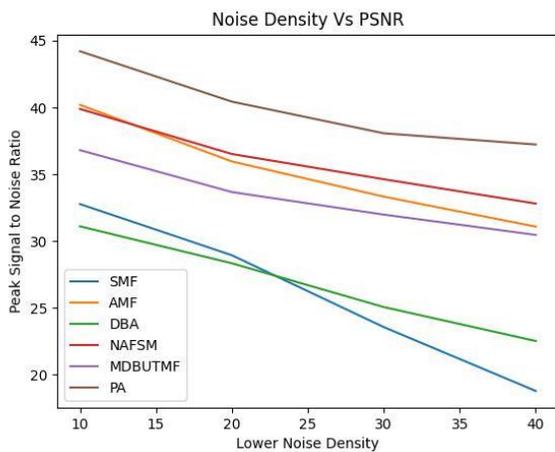

Fig. 13. Quantitative Analysis of Filters using PSNR for Pepper Image.

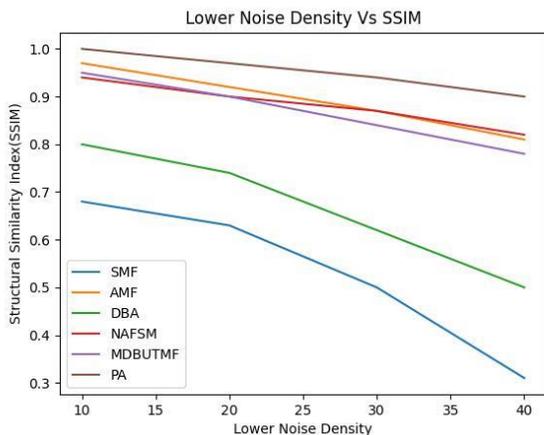

Fig. 14. Quantitative Analysis of Filters using SSIM for Pepper Image.

## V. CONCLUSION

In this article, a complete and relative study of some sophisticated filters evaluates their performance in high-density noise removal. A fusion filter has been developed to

deal with high-density noise. Statistical analysis was conducted on high-density noise, pixel estimation, data saving, white and black data identification of images, and removal of isolated pixels for data discontinuity without normalizing the image intensity. The proposed model provides the best results for noise removal at any concentration level. The main drawback of this filter is that the streaking effect occurs only when the high concentration of noise is removed from the pure black and white or medical images. Incorporating non-local statistical concepts into the proposed mathematical model could eliminate the streaking effect when removing high-density noise from medical images. The proposed algorithm can be placed on any digital devices as an image preprocessor.

**Abstract**—Infotainment system potentially contributes towards controlling accident fatalities in the era of Internet-of-Vehicles (IoV). Review of existing system is carried out to find that irrespective of various methods towards infotainment system, the quality of data being retrieved as well as issues associated with power and traffic congestion in vehicular communication is still an impending challenge. Therefore, this manuscript introduces a novel predictive scheme that offers enriched set of information from the environment to assists in decision making. Reinforcement learning is adopted for controlling traffic signal and power while the proposed system introduce augmented Long Short Term Memory scheme in order to predict the best possible traffic scenario for assisting the infotainment system to make a precise decision. The simulation is carried out for proposed system with existing learning schemes to find out proposed scheme offers better performance in every respect over challenging scene of an IoV.

**Keywords**—Infotainment system; internet-of-vehicle; reinforcement learning; decision making; power; long short term memory

## I. INTRODUCTION

The concept of vehicular communication system arrives from vehicular adhoc network two decades back in order to facilitate comfortable and safer driving experience [1]. However, owing to the complex structural implementation and various problems associated with such forms of adhoc network, a reliable and safer communication cannot be guaranteed. So, the most recent innovations of Internet-of-Things (IoT) have introduced an Internet-of-Vehicle (IoV) system that is mainly formed to minimize the event of fatal accidents on road [2]. This is carried out by installing IoT objects within the vehicle which is known to facilitate various functionalities. One such form of system which creates a bridge of communication between the vehicle and external entities is infotainment system [3][4]. The contribution of infotainment system is quite significant especially when deployed over an IoV with respect to essential data transmission [5]. It doesn't only pertain to data transmission based on real-time data, but it also carry out various analytical operation to judge the traffic system. This analyzed outcome is disseminated to drivers via infotainment system in order to ensure safer driving over road [6]. A study shows that out of all deaths happened in country of Sri Lanka, maximum of deaths were due to road accidents [7]. Among the road accidents, maximum of them occur during morning hours

of 9:00 AM to 10:00 AM and also during evening hours of 6:00 PM to 7:00 PM [8]. This clearly indicates that during rush hours, there will be more accidents and fatalities. Hence an efficient traffic management system is required to manage the traffic and avoid congestion and ultimately accidents. The travel time of the emergency vehicles is also an important factor. It is shown that risk of death due to cardiac arrest will increase by 95% during initial 3 hours of time. Hence, the travel time of emergency vehicles should be much lesser compared to travel time of ordinary vehicles. The infotainment system can be used to transfer vital information and entertainment information together. Since the Infotainment system is aware of GPS co-ordinates and health information of the vehicle, the same information can be used to perform several important tasks e.g. redirecting the driver to roads which have less traffic congestion with connected Infotainment system this can be used to manage entire city's traffic. CityFlow provides an excellent platform for simulating city's traffic and urban mobility in general [9]. The CityFlow platform is built in python and is 20 times faster than the other popular alternatives [10]. It is also found to be compatible with Reinforcement Learning (RL) techniques and hence it can be used along with RL agents. Reviews show that studies towards infotainment system and IoV still demands lot of improvisation that motivates to carry out proposed study.

The proposed study presents a unique computational framework of an infotainment system that is meant for data dissemination over congestion-free traffic using machine learning. The contributions of this study are: i) a unique traffic model is implemented for an IoV considering power consumption, ii) a better traffic management is presented to control power and traffic signaling operation in distributed manner applicable for an IoV operation, and, iii) an analytical model is built which is responsible for carrying predictive analysis of data dissemination for infotainment system with an effective decision making system considering the dynamicity of practical IoV environment. The organization of the manuscript is as follows: Section II discusses about existing investigation towards infotainment system followed by research problem highlights in Section III. Briefing of adopted research methodology is carried out in Section IV while an elaborated discussion about the system implementation is carried out in Section V. Discussion of Result analysis is carried out in Section VI while conclusive remarks of proposed contribution is carried out in Section VII.

## II. RELATED WORK

This section discusses about the existing studies being carried out towards IoV with a special emphasis towards infotainment system supportability. Recent studies towards IoV have been reviewed with respect to various methodologies and its effectiveness is studied.

The recent work carried out by Wu et al. [11] has constructed a hybrid communication system which mainly targets towards energy-efficient data transmission system using infotainment. The study also introduces a selection of cache nodes for all the intelligently connected vehicles. The limitation of the study is associated with non-inclusion of spatial complexity associated with streaming over such caching system. Adoption of machine learning towards communication system via infotainment system is carried out by Xu et al. [12] where a reinforcement learning algorithm has been used. The purpose is to encapsulate fluctuating patterns of channel condition in order to select a specific frame. The limitation of the study is that it emphasizes mainly on achieving throughput without consideration of vehicle density or emergency condition. Din et al. [13] have developed a caching system which assists in placing an appropriate content over the target vehicle. The limitation of this model is its non-consideration of uncertain traffic situation which could adversely affect the caching process. Vasudev et al. [14] have developed a unique communication system that emphasize over the mutual authentication scheme in vehicle-to-vehicle communication system. The limitation of this approach is that it uses cryptographic operation over a constraint device, which cannot be considered over a long run without performing any form of optimization of key management. Benarous et al. [15] have implemented a secure communication scheme in IoV where maintains privacy of location-based services utilized by the vehicles. The limitation of this scheme is that it doesn't present any identification system towards intruders and implementation is carried out considering known adversarial scenario.

A robust infotainment system over an IoV also demands an efficient resource management scheme as seen in work of Ni et al. [16]. The study uses allocation of resources as well as broadcasting of beacons over arbitrary access points for performing congestion control. However, the limitation of the study is that the model carry out the resource allocation without considering dynamic traffic scenario as well as it doesn't cater up any emergency services too during communication. Adoption of deep learning is witnessed in work of Chang et al. [17] where a model for accident detection system is developed. Upon detecting the collision, the information is transmitted to cloud-services which release notification. The limitation of the study is that its response time of notification completely depends upon the traffic and priority system, which may fail to cater up emergency transmission of accident notification. Silva et al. [18] have carried out a study towards social IoV system which uses conventional communication system in order to perform exchange of data among the vehicles. The paper concludes that there is still an unsolved problem associated with ethical guidelines about such communication in IoV. The work carried out by Sharma and Liu [19] have addressed the problem of misbehavior detection using machine learning in

IoV. The study has used supervised learning model for this purpose. The limitation of this work is it is applicable only for specific attack. The work carried out by Wang et al. [20] has developed a behavioral modelling that predicts the driving strategy for safer driving. However, this model completely lacks associating with traffic system in order to exchange such information using infotainment system.

The work presented by Qureshi et al. [21] has presented a mechanism of data propagation using clustering approach in IoV. The method calls for a selection of a cluster head using self-assessment approach as well as routing attributes for data exchange within one-hop nodes. The limitation of this paper is that it consumes too much time in clustering process and does leads to delay in case of heavy traffic in IoV. The work carried out by the Fu et al. [22] have presented a transcoding operation for multimedia streaming in IoV over fog computing. The study uses a reinforcement learning scheme which assists in optimizing the allocation of an appropriate resource for facilitating streaming in IoV. The limitation of this work is its it cannot be used for large stream of data in dense traffic. Mechanism of content caching is implemented in work of Xue et al. [23] where a dynamic programming has been used for minimizing the problem of content caching in data transmission of vehicular network. Irrespective of reduced delay, the study model suffers from poor scalability issues in presence of massive number of vehicle density as well as there is no scheme for prioritization of certain vehicle that seems quite impractical. Existing system has also witnessed modelling of task orchestration in vehicular network as reported in work of Sonmez et al. [24]. The study has used machine learning approach considering the success score of task completion. However, the limitation of the study is its non-inclusion of traffic-lights or centralized controlling system, without which the model is not practical to implement. Hong et al. [25] have presented a cost optimization based scheme using analytical framework in order to enhance the transmission time in IoV network. The model suffers from pitfall of using static threshold for cost, which is impractical in real-world traffic. The work carried out by Hou et al. [26] has used Q-learning-based strategy for content management in IoV. Although, the model is capable of making prediction for movement of vehicle, it doesn't have any inclusion of multiple path decision over urban traffic. Apart from these, there are various work carried out by Xia et al. [27], Su et al. [28], Ni et al. [29], and Heo et al [30] towards improving communication system with respect to infotainment system in an IoV.

Existing approaches discussed about offers a claim to better outcome; however, they are also associated with some significant issues. The next section outlines the research problems explored from this review.

## III. MOTIVATION FOR THE RESEARCH

- The traffic congestion is a daily day problem especially in a country like India. The traffic congestion can be easily mitigated with the existing infrastructures and roads. The issue is not of the infrastructure but of the poor management of the infrastructure. Hence an efficient system needs to be designed to manage all the infrastructure and get a better results for the same.

- The connected vehicles are no longer a dream of the future. With several car companies like Tesla and Morris Garage supporting the connected cars by default, the system does not require a hardware upgrade anymore. The computing power of the cars is more than the horsepower of themselves as of now. Since the computing power already exists in the car they only need a software update to support the smart Internet of Vehicle infrastructure now a days.
- The Road accidents due to congestion are a serious cause of the concern now a days. With the systems like autopilot from tesla and several other cutting edge technologies, it is possible to automatically redirect the city's traffic easily with the modern technological systems. And hence there is a scope for a system that can plan the city's traffic and redirect it to a suitable destination on the go.
- The heart attack and other serious emergencies must be addressed immediately. There is a limit to which people cooperate with the emergency vehicles. Green corridor is a very much common phenomenon in cities where an emergency vehicle is given zero traffic and fully allowed to pass through. This is traditionally done for VIP vehicles. However for the genuine emergency vehicles, people give way with understanding. This is possible to be modified based on traffic signal where the emergency vehicles can be made to reach destinations much faster that they are now.
- The Infotainment systems make the driving experience less of a hassle but more of an enjoyable experience. This can be achieved with the proposed study.
- More Focus on Navigation: Majority of existing studies towards infotainment system only focuses on route navigation, whereas infotainment system can also be used for various other forms of data transmission at same time. This requires a dedicated and congestion-free communication channel to be explored by the infotainment system in vehicles. Even if this concept is implemented within present state of implementation in infotainment system, it will significantly cause a serious bottleneck condition for the traffic among the vehicles.
- Less Emphasis towards Data Quality: In IoV system, there are numerous numbers and types of data being required to fulfill the process of data dissemination within an infotainment system. Although usage of mobile edge computing and cloud services makes the operation easier, but still there is a serious pitfalls of almost all the existing architecture of data transmission in IoV. This generates a massive set of traffic data which pertains to road attributes as well as vehicle attributes. Apart from this, there is also a need of multi-objective function to develop a model, which can extract only the productive traffic-related information within IoV system. Hence, ensuring data quality is quite a challenging scenario within current state of infotainment system.
- Uses of Sophisticated Technique: Existing system adopts sophisticated technique targeting for data transmission within vehicles ignoring the resource efficiency of the infotainment system. Adoption of machine learning demands higher training, which is again not much reported to be resource friendly for all implementation carried out in IoV till date.

#### IV. RESEARCH PROBLEM

After reviewing the existing system in infotainment system in IoV, following are the open end problems identified in proposed study:

- Restricted Coverage Issues in IoV: The conceptual definition of an IoV calls for an interconnected vehicles; however, they still have a dependencies towards a fixed infrastructure at one point. It could be in the form of a hotspots mounted on road or embedded within traffic signal in order to guide the vehicles for congestion free direction. However, the existing studies don't report to consider this coverage issue from Road Side Units (RSU) and mainly focus on vehicle to vehicle communication. This is incomplete implementation for any IoV system to assists the infotainment system within the vehicle.
- Non-inclusion for Density Monitoring: Majority of existing studies on IoV and infotainment system fixes the number of vehicles on specific route. However, in real-time, there are fair possibilities of either increase or decrease of such density over an uncertain instance of time. Without this consideration, the infotainment system will either faces congestion issue or face scarcity of information to undertake decision of data transmission.

Therefore, it can be seen that above mentioned issues do exist in present time of IoV deployment scenario. From practical viewpoint, this problem is much dominantly seen in a road network  $R_n$  with multiple junction point. It is because of the decision to find the optimal path owing to the problems identified in this section. Therefore, the prime problem formulation of the proposed system can be stated as follow:

$$R_n(S) \rightarrow [\text{opt}(r_i)] \approx A_i \quad (1)$$

In the above problem formulation, the core idea is to obtain a better form of road network  $R_n$  for all state attributes associated with intersection points. The idea is to optimize the set of reward  $r_i$  parameters for all the set of actions  $A_i$  considered in environment of IoV.

This problem is tackled by developing a computational framework that implements a conditional logic for vehicles considering its properties. Further reinforcement learning approach is used to redefine various state attributes that resolves the decision making problem further using LSTM attention network.

#### V. RESEARCH METHODOLOGY

The core aim of the proposed system is to design and develop a smart traffic system which is capable of facilitating

enriched information to the infotainment system embedded within the vehicle in IoV. Adopting an analytical research methodology, the proposed system make use of machine learning approach in a unique manner which assists in better decision making in the form of direction as well as seamless data transmission in IoV. The proposed system emphasizes more on data quality, where data is associated with both traffic and vehicles in order to assist the infotainment system to undertake correct decision of route formation and resource-efficient seamless data dissemination in IoV. The architecture developed for this notion is highlighted in Fig. 1 as follows:

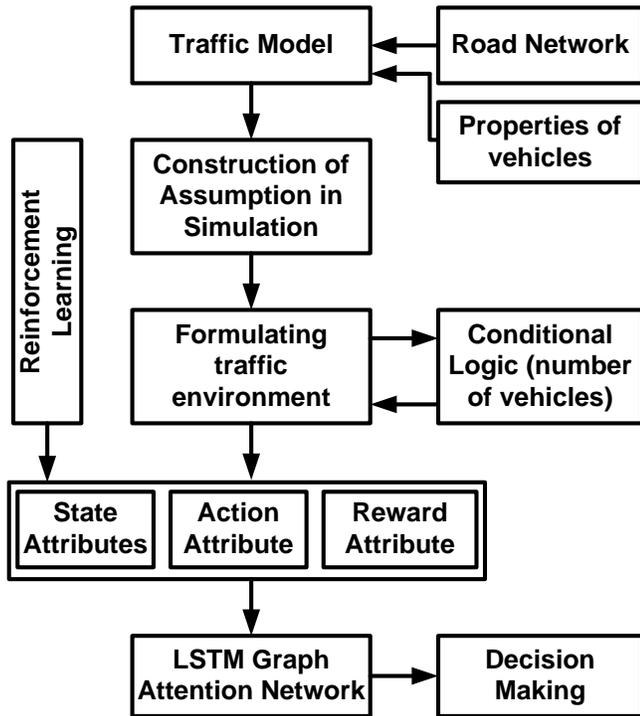

Fig. 1. Architecture of Proposed System.

According to Fig. 1, the proposed system develops a traffic model that mainly consists of formation of road network and properties of vehicle. The proposed modelling considers various attributes in order to develop the topology of traffic model. Further the proposed scheme also constructs assumption which is used for simulation study followed by considering all the essential challenges involved in developing this model. A traffic environment is formed where specific conditional logic is constructed. The proposed system makes use of reinforcement learning scheme which is used over framing up state attributes, action attributes, and reward attributes. Further, Long Short Term Memory (LSTM) graph attention network is utilized which is basically used for decision making towards opting for congestion free and reserving resources while performing vehicular communication in IoV. The next section elaborates further about the operation being carried out by each block towards infotainment system.

## VI. SYSTEM IMPLEMENTATION

In order to design an infotainment platform/scenario, it is required to realize that all vehicles in IoV are required to be

strongly interconnected with each other in order to make a seamless transmission. There might be some vehicles connected directly to internet via 4G/5G; however it is required to ensure that the connectivity is given to all vehicles in order to ensure transmission of vital data like traffic and emergency data. Before simulation of the infotainment system itself, the traffic and the congestion is needed to be simulated first and therefore the proposed system is simulated using standard CityFlow simulator [9]. This section discusses about the various aspects of the system implementation.

### A. Traffic Model

In order to simulate the traffic scenario, A road network  $R_n$  with 4 junctions as  $\{J_1, J_2, J_3, J_4\}$  is considered with three level of congestion as i) highly congested, ii) moderately congested, and iii) less congested. The model defines a vehicle  $V$  with characteristic elements from the set of properties viz. length, width, maximum positive acceleration, maximum negative acceleration, usual positive acceleration, usual negative acceleration, minimum gap, maximum speed, headway time. The brief highlights of these properties are as follows:

- Length refers to the length of vehicle including the luggage space and bumpers.
- Width of vehicle refers to physical width of the vehicle including mirrors.
- Maximum positive acceleration is the change in speed of the vehicle when accelerator is applied in full throttle.
- Maximum negative acceleration is change in speed of the vehicle when sudden break is applied.
- Typical positive acceleration is the usual acceleration of the vehicle.
- Typical negative acceleration is usual change in speed occurred when breaks are applied.
- Minimum gap is recommended gap that should be maintained between the vehicles.
- Maximum speed is top speed of the vehicle.
- Headway time is the time taken by the following vehicle to reach the position of leading vehicle.

### B. Assumptions on Traffic Simulation

The assumptions being considered while developing the proposed schema of infotainment are as follows:

- Everyone respects traffic rules and lane discipline.
- It is assumed that no mishaps happen like accidents.
- All roads are in good condition.
- There are no two wheelers and three wheelers. All the vehicles are assumed to be cars or emergency vehicles.
- Everyone tend to move at similar speeds.

Another, important properties defined for a vehicle are: {Interval, Start time, End time} with default values of {5.0, 0, -1} respectively. These values are considered using 5.0 Likert Scale which signifies 5 as highest and -1 as lowest score. The design process of the model defines a definite simulation time ( $T_s$ ). If the start time is equal to zero, it means that at the beginning of simulation, the vehicles will appear at their respective junction, however if the end time is equal to -1, it means that it is uncertain to say that when again a particular vehicle will re-appear on the same junction. Moreover, if the interval is defined say interval=5, it means that at every 5 units of time, that vehicle will re-appear on respective junction.

C. Challenges of Modelling

In the present study, the problem is being formulated as a Markov chain model. Each intersection in the system is controlled by an agent. The infotainment system which is present within the vehicle is an embedded system hence it only has a routing table to forward the information. Since all the information is encrypted only the end node can see the required information. SNR of the multimedia signals are noted at the cars and average SNR is calculated. SNR is calculated for 4 different types of data viz. i) text data, ii) video data, iii) audio data, and iv) security data.

D. Traffic Environment from CityFlow

The CityFlow simulator is used to generate the traffic data for three years’ time period. Apart from the traffic scenarios of junctions and vehicle characteristics, the program (simulator) also keep adding vehicles with random start time and end time parameters over the span of simulation. Hence, the number of vehicles on the roads keep increasing and creates a dynamic and uncertain stage of congestion. In addition the simulator is internally programmed to model seasonal traffic in such a way that the number of vehicles on the road will be comparatively lower in the month of July and august due to rainy season. The problem of mitigating the congestion, require information as in the Table I.

In the Table I, the parameter of MED is computed as following expression (1),

$$MED(S) = \begin{cases} S \left[ \frac{1}{2} \times (\sum_{j=1}^n V_j) \right] & \text{if number of vehicles are even} \\ \frac{S \left[ \frac{1}{2} \times (\sum_{j=1}^n V_j - 1) \right] + S \left[ \frac{1}{2} \times (\sum_{j=1}^n V_j + 1) \right]}{2} & \text{if number of vehicles are odd} \end{cases} \quad (1)$$

TABLE I. FORMULATION USED IN PROPOSED STUDY

Junction ID	Total number of vehicles	Speed	Congestion
{J1,J2,J3,J4, .. Jn}	$\sum_{j=1}^n V_j$	MED (S)	$\left( \frac{\sum_{j=1}^n V_j, speed = 0}{\sum_{j=1}^n V_j} \right) \times 100$

E. Formulating State Attribute

State is definitive term that represents the state of the particular intersection. Since it has multiple values, it is represented in form of a vector  $S$  as follows,

$$S = \{ \overline{S_1}, \overline{S_2}, \overline{S_3} \dots \overline{S_n} \}$$

$$\overline{S_i} = [L_q, P_i] \quad (2)$$

In the above expression (2), the variable  $L_q$  represents the average queue length of the intersection that is mathematically represented as follows,

$$L_q = \frac{1}{4} \sum_{i=1}^4 u_i \quad (3)$$

$u_i$  is the queue length of the individual road in the intersection.

F. Formulating Actions Attribute

Actions are execution attribute that Reinforcement Learning RL agent can perform on the environment. Since a single RL agent is assigned to an intersection, there are possibilities of  $n$  number of actions  $A$  as follows,

$$A = \{A_1, A_2, A_3 \dots A_n\}$$

$$A_i = [\overline{T}_v, P_i] \quad (4)$$

In the above expression (4), the variable  $P_i$  represents the power input of the base station. If the RL agent sets a higher power then the signal can be transmitted further and results in a higher useful information ratio. At the same time, it also results in higher overall power consumption. The first variable in expression (4) is represented as follows,

$$\overline{T}_i = [X_1, X_2, X_3, X_4] \quad (5)$$

In the above expression (5), the variable  $X_i$  represents the traffic signal. Since there are 4 signals in each intersection it is represented by  $X_1$  to  $X_4$  and its generalized form is as follows,

$$X_i \in \{R, Y, G\} \quad (6)$$

In the above expression (6), the variable R, Y, and G represents three different lights in the traffic signal. Red, Yellow and Green.

G. Formulating Reward Attribute

Reward  $r_i$  is a real number representing the overall performance of the system.

$$r_i = - \frac{\sum_{i=1}^4 u_i}{4} - P_i + \frac{\sum_{i=1}^N S_i}{N} \quad (7)$$

The RL system proposed in this study is programmed in such a way that both traffic congestion as well as information SNR are optimized. The information is passed through a software Defined Network (SDN) created by Mobile Adhoc Networks (MANET) by the vehicles. The parameters which are being optimized here are,

- Useful information ratio of 4 different types of data (varying preference) (MAX).
- Traffic congestion (Average queue length) (MIN).

- Average Travel time of the regular vehicles (MIN).
- Average Travel time of the emergency vehicles (Only ambulances are considered) (MIN).
- Overall Power consumption by the base stations (MIN).

#### H. Methodology for Implementing LGAT Neural Network

The proposed system implements a neural network in the form of regular Long Short-Term Memory LSTM itself; however, one of the hidden layers in this network is common for all the networks over the grid. This essentially makes each neural network to be aware of its surroundings. Hence this is named as LSTM Graph Attention Network (LGAT). LGAT has two parts involved in its module i.e. i) First part which is before the GAT layer and ii) second part is after the GAT layer. Before GAT layer rectified linear unit ReLU Activation function is used whereas after GAT layer, Sigmoid function is used. This is done since the output is always expected to be residing between 0 and 1. The power input of the base station is controlled by considering the input of the percentage of maximum power consumption. The traffic signals are always controlled by considering the input of 1 or 0 to each signal lamp with the one hot encoding strategy. The Adam optimizer is used to train the neural network and the loss function used here is MSE. It should be taken into special attention that MSE is used here instead of commonly used binary cross entropy. This is due to the fact that the network should output an analog value for power consumption in terms of percentage.

Fig. 2 shows the structure of the proposed LGAT neural network where the second hidden layer is the shared layer whose weights and biases are shared with all the other networks. The weight sharing mechanism here is very similar to that of the Siamese neural networks. The output layer contains 13 outputs 12 of which corresponds to the traffic signals and one corresponds to the base station input power percentage.

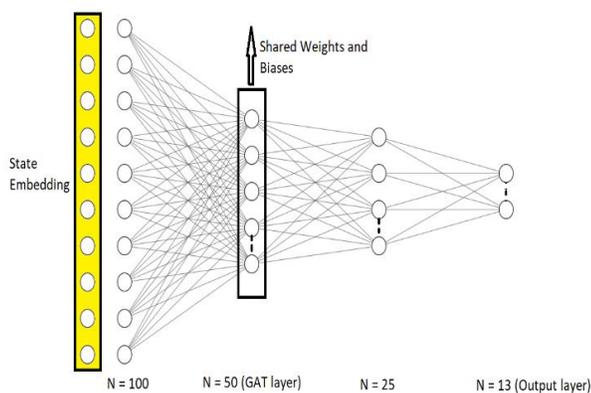

Fig. 2. Structure of Proposed Neural Network.

#### I. Training the Agent

The agent is trained for 4000 episodes in the study and the ANN shown here is trained for one epoch in every episode. Effectively the ANN is trained for 4000 epochs with dynamically changing data. However, since this is an LSTM network, the changing nature of the data is also learnt by the network. The central shared hidden layer enables multiple agents to cooperate with each other. Due to this cooperation the agents are able to produce a good output. Here, the competition behind agents must be avoided at all costs as that will result in selfish agents which may just shut down their base stations in order to save power.

### VII. RESULT ANALYSIS

This section discusses about results being obtained from the simulation study by implementing the proposed scheme discussed in prior section. The recommended hardware and software stack for training the agent are as follows.

- CPU: Intel Core I7 10th Generation.
- GPU: Nvidia GeForce RTX 2060.
- OS: Kali Linux 2021.
- C compiler: GCC 10.2.1.
- GPU C library: Nvidia CUDA 10.1.
- GPU python bridge: Nvidia CuDNN.
- Python: 3.8.2.
- TensorFlow: 2.5.0.

The above-mentioned stack is used in order to get the best results since the TensorFlow works better when it is executed on GPU. Above stack must be used in order to run TensorFlow over GPU. Table II highlights about the properties of vehicles considered for proposed scheme.

TABLE II. PROPERTIES OF A VEHICLE (V)

#	Property	Value	Units
1	Length	5	Feet
2	Width	2	Feet
3	Maximum Positive Acceleration	2	m/sec <sup>2</sup>
4	Maximum Negative Acceleration	4.5	- m/sec <sup>2</sup>
5	Typical Positive Acceleration	2	m/sec <sup>2</sup>
6	Typical Negative Acceleration	4.5	- m/sec <sup>2</sup>
7	Minimum Gap	2.5	Feet
8	Maximum Speed	16.67	m/sec
9	Headway Time	1.5	second

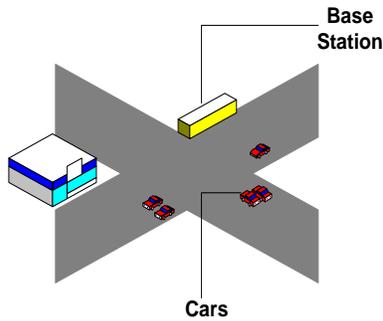

Fig. 3. Simulation Environment.

As it can be observed from Fig. 3 that the simulation is a set up in such a way that there is always a base station in every intersection. Fig. 4 exhibits the higher level overview of system implementation. It is powerful enough to transmit till next base station. However, since the signal strength of the base station can be controlled by the RL agent, the base station's power consumption will vary and the range also varies. If there are vehicles closer to each other, then it is enough if the base station transmits the signal to nearest car. That car can act as a repeater and transmit the message further to other cars. Hence if a particular junction is congested, then the base station may spend less amount of power to transmit the signal further.

The reward depends on both travel time and power consumption. Hence the agent is expected to optimize both of these parameters. The environment is built in such a way that it can support one agent per every intersection. Hence this is a multi-agent environment. Every agent can perform the optimization of power and congestion in their own intersections however, they are expected to co-operate with each other and optimize the entire city's power consumption and travel time of entire city in average.

There are several base stations are present in the city as well as vehicles act as relay to the signal. If the vehicles are far apart, then the base stations have to send signal far hence there will be more power consumption by the base stations. The system must optimize the over power consumption as well.

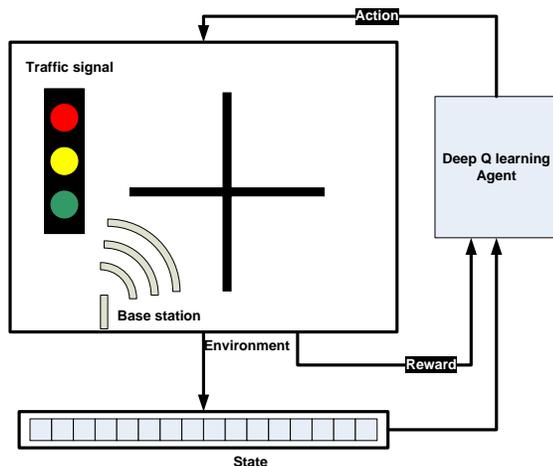

Fig. 4. Higher Level Overview of the System.

Following are the parameters which are being optimized

- Useful Information Ratio: Every vehicle needs to receive the information required for itself. More it acts as a relay, more the battery consumption and lower the bandwidth utilization for itself. Hence base station must provide higher power for better data transmission.
- Queue Length: Queue length is defined as the distance between front of the first stopped car in the intersection to the back of the last stopped car in the intersection (Feet). Traffic congestion is the average of all 4 incoming queue lengths in each intersection.
- Average Travel Time: Average travel time is nothing but average time taken by all cars to travel from source to destination (Entry intersection, Exit intersection). It is considered for Regular vehicles and Emergency vehicles.
- Overall Power Consumption: This is the sum of power consumed by all base stations in the city. The order in which the priority is given to the parameters viz. Travel time of Emergency vehicles, Congestion, Travel time of Regular vehicles, Useful info ratio for emergency data, Useful info ratio for text data, Useful info ratio for audio/video data, Power consumption Simulation parameters are set as following.

Fig. 5 highlights the consideration of 6X6 grid for proposed simulation with 36 intersections in total while there are two simulations done using this layout. Uniflow assumes that the traffic moves in a single direction during morning and opposite direction in the evening. Biflow assumes that the traffic moves in both directions during all times of the day.

Fig. 6 highlights the map to shows the area considered in Hangzhou junction of China. It contains total of 16 junctions and traffic is the real recorded traffic.

Fig. 7 highlights the map to shows the area considered in New York city that contains 196 junctions in total. The proposed system is assessed with existing system of learning-based model of vehicular network in IoV.

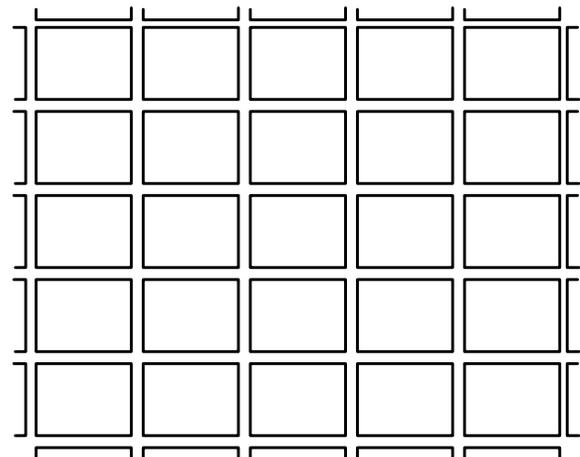

Fig. 5. 6X6 Grid for Simulation.

Fig. 6. Hangzhou Simulation Setup.

Fig. 7. New York Simulation Setup.

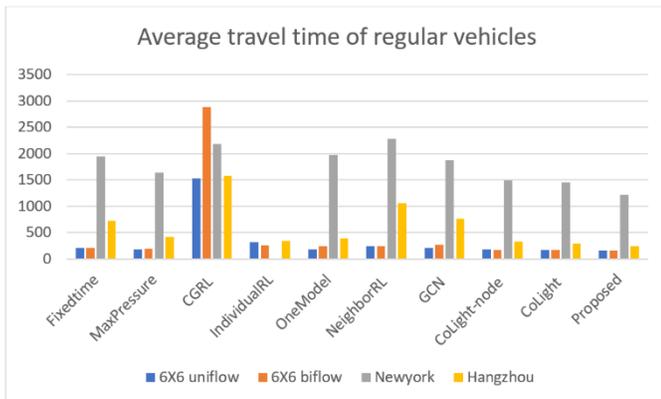

Fig. 8. Average Travel Time for Various Methods.

The above graph in Fig. 8 clearly indicates that the proposed method performs better for every scenario. As it can be observed, New York City is the most difficult scenario. For individual RL, data isn't available. The overall travel time is reduced because of the LGAT architecture. The vehicular traffic follows a particular pattern during the day. LGAT can learn the temporal patterns as well and be able to predict the future vehicular traffic.

An extra parameter which is considered in this study is that average travel time of emergency vehicles (Fig. 9) in which the proposed system is performing better compared to CoLight model. The performance is better in the proposed system since the LSTM layer is used. From Fig. 10, can be observed that the travel time of emergency vehicle is half of regular vehicles.

The graph in Fig. 11 shows that the overall power consumption is less for proposed method. This evidently shows that proposed system has better performance score when evaluated with existing CoLight model in perspective of different available dataset of data dissemination in vehicles of urban scenario.

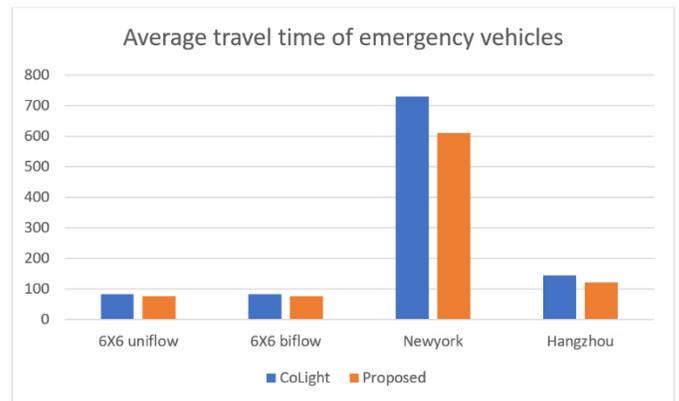

Fig. 9. Comparison of Travel Time for Emergency Vehicles.

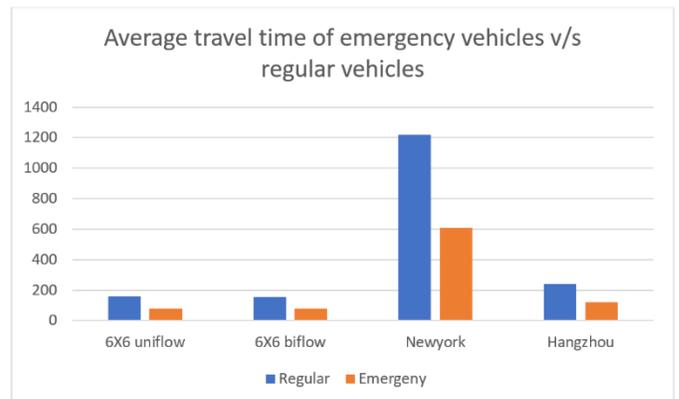

Fig. 10. Average Travel Time for Emergency Vehicle vs Regular Vehicle.

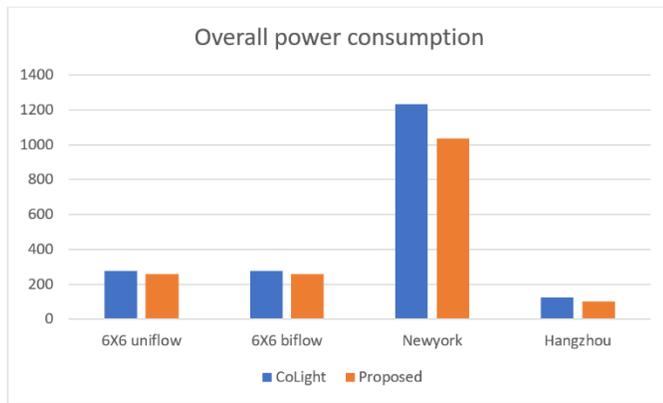

Fig. 11. Overall Power Consumption in MWH.

### VIII. CONCLUSION

This study presents a novel mechanism to manage the urban traffic system and prevents the congestion at the same time. The system can be used to redirect emergency vehicles to shorter paths where there is less congestion and reduce their travel time. The presented model considers the aspect of power consumption by the system. This is carried out in order to address the problem about infotainment system that not only consists of the in-vehicle system but also the sensors, gateways and signal repeaters. Such forms of devices consume a lot of power in order to make sure the quality information is transferred. The implementation of proposed study also optimizes the power consumption by the infotainment system and ensures overall transmission efficiency. The proposed system constructs an optimal environment for the city traffic management and its reward system so that the system rewards the agent based on both power consumption and the travel time. While the environment is a single environment, this is a multi-agent system. An RL agent is assigned at every intersection and they control the traffic signal and power input of the transmitter at the intersection. An agent will also be aware of actions and states of other agents through a novel neural network architecture proposed in this study, LGAT architecture. The proposed system implements an LGAT that is a special type of LSTM in which one of the layer's weights and biases are shared with all other agent's weights and biases. The neural network here uses the DQN architecture for RL. The DQN architecture means the NN takes the action as input and outputs Q values for all possible actions. Q values are nothing but the future rewards for the system. The system is trained over multiple episodes with a single epoch per episode. The proposed study considers several existing methods and considers various parameters to study the traffic. There are two synthetic environments and two realistic environments in this study. The two realistic environments are the traffic data from Network city and Hongzow junction from Hong Kong. The synthetic environment contains two different environments which are 6x6 uniflow and 6x6 Biflow.

# Internet of Things (IoT) Application for Management in Automotive Parts Manufacturing

Apiwat Krommuang, Opal Suwunnamek

King Mongkut's Institute of Technology Ladkrabang Business School  
King Mongkut's Institute of Technology Ladkrabang, Bangkok, Thailand

**Abstract**—Automotive parts manufacturing focuses on sustainable development manufacturing capabilities with future technology changes. Internet of Things (IoT) plays an important role in applying internet technology to machines and equipment in manufacturing processes for transformation towards Industry 4.0 as well as creating values added and higher competitive advantage for the sustainability of the industries. This research aims to study factors that influence decision-makers in selecting IoT applications for managing auto parts production and they consist of connectivity, telepresence, intelligence, security, and value including their fifteen sub-factors. In this research, The Fuzzy Analytic Network Process (FANP) is a Multiple Criteria Decision Making (MCDM) technique used to analyze, identify, and prioritize factors in selecting IoT applications for managing production processes. The questionnaire is designed based on the FANP technique to survey the importance of weight for each factor from executives of 88 auto parts manufacturers who authorize as the decision-makers for selecting IoT applications. The results have indicated that telepresence is the most important factor that will assist them in controlling production to guarantee that production capabilities meet the objective and connectivity is the second important factor that must ensure that IoT applications are compatible with their machinery and equipment can be controlled smoothly and precisely. Meanwhile, performance is the most important sub-factor and other sub-factors are ranked as functional orientation, data management, control, and compatibility respectively. Therefore, manufacturers can use this research as a criterion for selecting appropriate IoT applications for controlling their manufacturing for sustainable effectiveness.

**Keywords**—Internet of things; auto parts industry; FANP; MCDM; sustainable manufacturing

## I. INTRODUCTION

The Internet of Things (IoT) is admitted as one of the most essential areas of future technology and is gaining various attention from several industries. IoT is considered a key driver for industries to transform industry 3.0 to industry 4.0 [1]. It is also crucial for integrating manufacturing processes for the fourth industrial revolution [2]. The gap between the physical and digital worlds can be bridged by synchronizing the flow of information with the physical flow for greater supply chain integration [3]. This is because IoTs devices play a crucial role in driving businesses to create superior connectivity and progressive operations to increase their agility [4]. It is an integration of interconnected sensing and communication technology that enables equipment, machines, sensors, robots, and automatic actuators [5]. IoT is determined into three groups: People to people, people to machine/things,

Things/machine to things/machine, and Interacting through the internet [6]. The industrial internet of things is a concept based on the same principles as the IoT, but for connection machines in factories. The primary communication between machine-to-machine and automation based on the information exchanged between them [7]. Smart factory solutions are designed the enable sensors and connected edge devices to improve product quality and real-time factory operational efficiency. The potential to address the data captured and exchanged in real-time has multiplied [4]. Some devices are operating their functionality for progressive production, performance, and maintenance in the production [5] that can generate greater customer value through offered services. The efficacy can provide identifying, sensing, networking, and processing abilities for communicating with other devices and services through the internet.

Several organizations are searching for new technologies which can support their sustainable businesses [8] such as the Internet of Things (IoT), Big Data Analytics (BDA), Cloud Computing [5], and Blockchain (BC). Meanwhile, these new technologies can be used to support production and services in other sectors [9]. Besides, the mentioned technologies are currently applied in several industries for transforming towards Industry 4.0 which is a crucial industrial revolution in this century [10]. To improve supply chain structures and achieve sustainability, industry 4.0 becomes the most prominent solution in current manufacturing processes [11]. Therefore, industry 4.0 plays a critical role in bringing manufacturers to sustainable production [12]. Sustainable production covers important components such as production, process, and system which create value-added and sustainable growth for the business [13]. Therefore, this integration is a challenge for improving sustainable production in the future [14]. Moreover, Industry 4.0 also entails data exchange and autonomous systems, as well as manufacturing activities centered on the development of smart factories to respond to dynamic production [15]. Because the investment in IoT applications is expensive, decision-makers in selecting IoT applications in the auto parts production process confront a challenge in determining which relevant IoT apps should be chosen. Therefore, this study aims to answer this research question with the following objectives. 1) This research aims to study the influences of factors in selecting IoT applications in the auto parts industry, 2) the importance of each factor will be identified and prioritized, and 3) trends of decision-making for selecting IoT applications are studied for improving the management of the auto parts production. Thus, the first section of this article identifies factors that influence decision-

making in selecting IoT applications by reviewing relevant literature. Subsequently, quantitative research is conducted by surveying decision-makers in the auto parts industry with a questionnaire developed based on the Fuzzy Analytical Network approach (FANP). The next section defines and formulas of FANP are introduced, and it can effectively identify and prioritize factors in selecting IoT applications for the auto parts production. Finally, the results of data analysis by FANP express and indicate important factors that influence decision-makers in selecting IoT applications for auto parts production.

## II. LITERATURE REVIEW

### A. Connectivity

Currently, the Internet is the interconnection hub of smart devices and can create an intelligent network throughout the value chain to machines, products, and systems [16]. This consequence is the connection and interaction between people and machines which leads to more interconnected production systems [17], the connection of physical devices and machines, and the integration of applications to the software or database [18]. The information was gathered through the IoTs to enhance the productivity of business processes [19]. Therefore, it is the industrial processes to connectivity technologies for monitoring the production activities, inventory management, sales management, and after-sales services. Compatibility is the connectivity and automation of collaboration activities [20]. and accessibility in entering the network while providing the general ability to generate data [6]. Data exchange is supported by different networks and data is gathered from networks connecting equipment, production line, and sensor network. Standardization is an important prerequisite in digitization. [21]. The connection of any object to the Internet could be one of the standardization challenges and the success of the development of interoperable. Standardization also enables the optimization between functionality, costs, and quality of applications and solutions. The key IoT infrastructures can help customers in industries to transform businesses and services successfully [22]. The combination of numerous sensors in wireless technologies can communicate with the Internet infrastructure and can collect information for different industrial applications. It is converting compatible data to interoperability between internet devices, appliances, and objects.

### B. Telepresence

Telepresence can presentation where all employees can access their current operational status simultaneously, for convenient control and decision making by IoT applications. [21]. Thus, the services with the telepresence function would positively influence workers [23], and the performance of IoT devices in real-time from different locations at any time. Therefore, reliable telepresence helps consumers feel positive about their products and positive Internet experiences. The IoT System can improve management efficiency with more controllable and auditable management processes [24]. Synchronization of production systems between virtual and real systems depends on data from sensors and connected smart devices, and real-time data updates [25]. Connectivity

automation of collaboration activities enables synchronization through IoT-enabled productivity [20]. It focuses on the synchronization of the production process in optimizing the production requirements [26]. Time and energy can be saved by using an internet device to synchronize things or products during the work process. IoT monitoring with dynamic system analysis and event processing integrates between device and business [20]. Communication between machines and connected machines provides information about the status of controlling or monitoring systems [27]. For example, the area of condition monitoring, predictive maintenance, estimating the remaining lifetime of the components, making decisions about urgent, short-term, and real-time actions [28]. Smart process monitoring is realized by connecting cloud computing and services the machine tools [29]. Internet of Things (IoT) dynamically controls and makes decisions, as well as the real-time monitoring and controlling of the manufacturing process [30]. The smart factory uses self-controlled machines and automated robots that have the module of adaptive intelligence to take necessary actions depending on pre-defined instructions [31]. It has an automatic device control system to continuously monitor performance in real-time anytime and anywhere. This data of smart factories will be available to humans or systems for the monitoring, prediction, and control of the production systems [32].

### C. Intelligence

The intelligence of IoT is the capability to derive real-time data. The purpose of smart manufacturing into intelligence systems is to improve the positive production processes in all aspects [33]. Smart manufacturing information systems changed from digitization and networking to intelligence [34]. IoT applications must be embedded with intelligence to enhance devices that can monitor the environment, identify problems, communicate with each other, and potentially address problems without human assistance [35]. It more profoundly integrates manufacturing operations systems with communication, information, and intelligence technologies [36]. IoT devices are functional or personal assistants for organizations and are functions that control devices in real-time from different locations by connecting the internet devices of things to the employees [37]. Smart devices are focused on functional orientation, application, and analysis to be able to solve problems. The internet devices coordinate things, and function as personal assistants for the organization. Therefore, the service of this functional orientation will benefit employees. Challenges and applications of artificial intelligence are components of the concept of the Internet of Things. Relevant to Industry 4.0, it involves automation including artificial intelligence. The information system of smart manufacturing is based on the new technology of industrial artificial intelligence. Cloud Computing provides infrastructure, software, and platform as services [38]. Cloud computing and IoT are the main support technologies in Cloud manufacturing and can interact with each other in a cloud-based intelligent environment [39]. Therefore, cloud computing can continually access available data that requires manufacturing management applications and enables the effectiveness of processes.

#### D. Security

Security and privacy of sensitive data in Industrial IoT systems are necessary nowadays, and management trust is crucial for data security in IoT. [40]. Transparency, conflict of interests, data confidentiality, network security, and the safety of IoT devices are among the most important security and privacy problems. [41]. The security for industrial process measurement and control network and system security [42]. High-value industrial data can be harmed by a single click, potentially riskiness the entire process of industrial plants. Traceability and monitoring of systems are the results of real-time data management to prevent certain events or potential system failures [43]. As a result, higher-layer applications can avoid having to handle unneeded data and lower the danger of information privacy being compromised. Employees and businesses that share information between departments are protected by security, which encompasses information privacy, data management, and permission. [44]. It is the permission of employees and businesses when they communicate information, as well as a feature that allows an authorized user to search the database for specific information when needed. The ability to manage the information flow is known as data management. Information can be retrieved, integrated, and controlled using data management under the management service layer [43]. It is capable of handling large amounts of data and synchronizing operations in real-time.

#### E. Value

When connected devices can communicate with one another, the actual potential of the IoT for businesses may be completely realized. The connection of humans, parts, and systems creates self-guided, dynamic, real-time value-added interconnections across the value chain [45]. Several processes happen, and value is added to every process [46]. Improved product or service delivery, increased productivity, lower labor costs, lower energy usage, and a shorter build-to-order cycle are all examples of this benefit. There is also a need for Internet of Things integration in the operation of marketing activities, seasonal variations or market trends, and fluctuations in market demand or custom orders [28]. The benefits of the Internet of Things can be used to improve manufacturing processes and create new products. After receiving data from IoT devices, the organization can learn about some business concerns such as changes in client preferences or worker performance [34]. Similarly, The data, the convenience, and the ease with which it is collected and evaluated are the key drivers of this industrial revolution [47]. Using IoT devices or goods during the work process can help employees save time and energy [21]. [13]. It can also refer to services that help people manage their jobs more effectively and make quick judgments. The effectiveness of IoT enables stakeholders to make dynamic decisions based on real-time data [48]. It can manage the use of technology to fulfill company objectives [49]. The information could be utilized to assess different performance levels and provide statistical

analysis reports. Data on machine tools will improve as a result of increased machine use, which can be used to improve overall performance [50].

#### F. Factors Influence IoT Applications

IoT devices have been recognized as useful in a variety of situations and environments [51]. Furthermore, IoT could connect disparate networks while also addressing security concerns [52]. It is a technology and innovation that focuses on motion and environmental detection [53]. Therefore, the main purpose of IoT was to provide a that could accept, store, and transmit data over the Internet within computer devices including sensors, desktops, laptops, smartphones, and other electronic devices, some applications related to the IoT had provided value for consumers [54]. Moreover, these devices could potentially link to the Internet and keep track of personal and user data. The devices would then evaluate the data and make sensible recommendations to the users. From the literature review, IoT applications with references as the Table I and factors have been derived and reviewed to determine the factors that influence IoT applications for auto parts production as connectivity, telepresence, intelligence, security, and value which are shown in Fig. 1.

### III. MATERIALS AND METHODS

#### A. Data Collection

This study was based on the quantitative research principle by using the survey method for data collection. The population of auto parts manufacturers came from the automotive institute and the institute identified that there were 720 auto parts firms. Subsequently, the sample size for this research was 88 samples as Yamane's formula [55]. The research tool in this study was a questionnaire that was developed based on factors of connectivity, telepresence, intelligence, security, and value as the framework shown in Fig. 1.

After the questionnaire was developed completely, the research distributed the questionnaire to 88 respondents sampled by snowball method who were the decision-makers in implementing IoT in automotive part manufacturers. At the beginning of this survey, five experts the auto parts manufacturers, which had deployed IoT applications in the auto parts production, were identified and called in for asking their permission to answer the questionnaire.

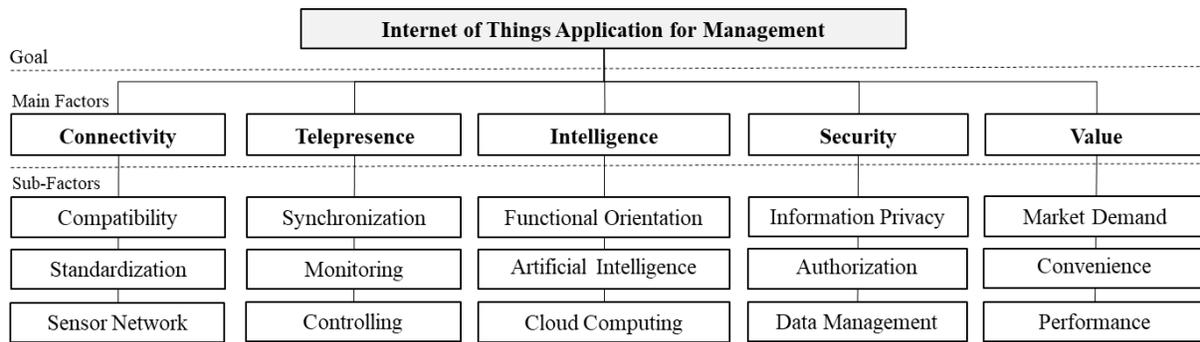

Fig. 1. Conceptual Framework of Internet of Things Application for Management.

### B. Analytic Network Process

The analytic hierarchy process (AHP) is a well-known multiple criteria decision-making (MCDM) method that has been widely used in a variety of decision-making situations. The principle of AHP is to distinguish problems in a linear top-bottom format as a hierarchy. While the upper levels of the constructed hierarchy are independent of all lower levels, and the components in each level are likewise independent. However, some decision-making problems cannot be structured as a hierarchy, or some components have relations to other components in the structure. Thus, the analytic network process had been developed to address the mentioned problems of AHP and deal with dependencies between criteria and alternatives [57]. The components in the same level can be functionally dependent and the lower levels can reversely affect the upper level in each component. [58]. The advantages of ANP for considering dependencies between criteria and alternatives are listed as follows [59].

- The approach can deal with various, and complicated criteria.
- It supports decision-makers to build a decision-making model and to study relationships in the matrix form.
- It can evaluate both quantitative and qualitative criteria with the pairwise comparison technique to identify the importance of criteria.

Therefore, ANP is the appropriate MCDM approach than AHP for identifying and prioritizing factors that influence decision-makers in selecting IoT applications because the dependencies between each main factor and its sub-factors will be analyzed.

### C. Fuzzy Analytic Network Process

1) *Fuzzy set theory*: To deal with situations involving uncertainty, imprecision, and vagueness, Zadeh (1965) created a fuzzy set theory. The capacity to represent ambiguous data is a major contribution of fuzzy set theory. [60]. The theory also permits mathematical operations and programming to be applied to the fuzzy domain. Generally, the fuzzy set is defined by a membership function, which represents the grade of any element  $x$  of  $X$  that has the partial membership to  $M$ . The value between zero and one determines the degree to

which an element belongs to a set. So an element  $x$  belongs to  $M$ ,  $\mu_M(x) = 1$  and  $\mu_M(x) = 0$  [56, 60, 61].

2) *Triangular fuzzy number*: A triangular fuzzy number (TFN) is presented as  $(l, m, u)$ , where  $l \leq m \leq u$ . The membership function  $\mu_M(x)$  of TFN is obtained by Equation (1).

$$\mu_M(x) = \begin{cases} (x - l)/(m - l) & l \leq x \leq m \\ (u - x)/(u - m) & m \leq x \leq u \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

The membership functions of triangular fuzzy numbers are used for the pairwise comparison of decision variables from “Very bad” to “Excellent”, and the middle preference values between them. The membership functions of TFNs,  $M_i = (m_{i1}, m_{i2}, m_{i3})$ , where  $i = 1, 2, \dots, n$  and  $m_{i1}, m_{i2}, m_{i3}$  are the lower, middle, and upper values of the fuzzy number  $M_i$ , respectively [56, 61]. According to the concept of extent analysis, each object is taken and extent analysis for each goal  $g_i$  is performed, respectively. Therefore, the  $m$  extent analysis values for each object are obtained as the following signs [61]:

$$M_{g_i}^1, M_{g_i}^2, \dots, M_{g_i}^m, i=1, 2, \dots, n \quad (2)$$

where  $M_{g_i}^j (j = 1, 2, \dots, m)$  are presented in triangular fuzzy numbers.

3) *Fuzzy analytic network process*: Fuzzy analytic network process (Fuzzy ANP) is a multiple criteria decision-making (MCDM) approach that uses both interdependences of criteria and inner dependences of criteria with the pairwise comparison matrix. The steps of Chang’s (1996) extent analysis can be given as follows [61, 62]. The value of fuzzy synthetic extent for the  $i^{\text{th}}$  object is defined as:

$$S_i = \sum_{j=1}^m M_{g_i}^j \otimes [\sum_{i=1}^n \sum_{j=1}^m M_{g_i}^j]^{-1} \quad (3)$$

To obtain  $\sum_{j=1}^m M_{g_i}^j$ , perform the fuzzy addition operation of  $m$  extent analysis values for a particular matrix such that:

$$\sum_{j=1}^m M_{g_i}^j = (\sum_{j=1}^m l_j, \sum_{j=1}^m m_j, \sum_{j=1}^m u_j) \quad (4)$$

And to obtain  $[\sum_{i=1}^n \sum_{j=1}^m M_{g_i}^j]^{-1}$ , perform the fuzzy addition operation of  $M_{g_i}^j (j = 1, 2, \dots, m)$  values such that:

$$\sum_{i=1}^n \sum_{j=1}^m M_{gi}^j = (\sum_{j=1}^m l_j, \sum_{j=1}^m m_j, \sum_{j=1}^m u_j) \quad (5)$$

Then the inverse of the vector in eq. (5) is calculated as follows:

$$[\sum_{i=1}^n \sum_{j=1}^m M_{gi}^j]^{-1} = \left( \frac{1}{\sum_{i=1}^n u_i}, \frac{1}{\sum_{i=1}^n m_i}, \frac{1}{\sum_{i=1}^n l_i} \right) \quad (6)$$

The degree of possibility of  $M_2 = (l_2, m_2, u_2) \geq M_1 = (l_1, m_1, u_1)$  is defined as:

$$V(M_2 \geq M_1) = \sup[\min(\mu_{M_1}(x), \mu_{M_2}(y))] \quad (7)$$

and can be equivalently expressed as follows:

$$V(M_2 \geq M_1) = \begin{cases} 1 & \text{if } m_2 \geq m_1, \\ 0 & \text{if } l_1 \geq u_2, \\ \frac{l_1 - u_2}{(m_2 - u_2) - (m_1 - l_1)} & \text{otherwise} \end{cases} \quad (8)$$

The degree of possibility for a convex fuzzy number is greater than  $k$  convex fuzzy numbers  $M_i (i = 1, 2, \dots, k)$  that can be defined by:

$$V(M \geq M_1, M_2, \dots, M_k) = \min V(M \geq M_i), \quad i = 1, 2, \dots, k \quad (9)$$

Assume that:

$$d(S_i) = \min V(S_i \geq S_k), \quad k = 1, 2, \dots, n; k \neq i \quad (10)$$

Then the weights vector is calculated by:

$$W' = (d(S_1), d(S_2), \dots, d(S_n))^T \quad (11)$$

And weight vectors are normalized as follows.

$$W = (d(A_1), d(A_2), \dots, d(A_n))^T \quad (12)$$

Where  $W$  is a real number, and  $A_i = (i = 1, 2, \dots, n)$  are  $n$  elements.

#### IV. RESULTS

This paper, Internet of Things application is divided into five categories consisting of Connectivity, Telepresence, Intelligence, Security and Value. Each category contains several IoT applications for management which are shown in Fig. 1. This study proposes the Internet of Things application for management related to the auto parts manufacturers in Thailand. This section can be divided into six steps to evaluate the industry. The first step is to determine the Internet of Things framework of main factors and sub-factors, which is performed using a questionnaire survey that uses the fuzzy ANP approach to calculate the weights of the factors and sub-factors. The application is based on the methods outlined in the preceding part and is explained step by step, along with the outcomes.

Step 1. Determine the fuzzy scale for the important weight of factors and sub-factors from a decision-maker with the responsibility for the Internet of Things application management in a company. Choose appropriate linguistic variables for the relative weight of the factors as defined by

Table II [61,72] prepare a pair-wise comparison to each factor from expert opinion by using the linguistic scale.

Step 2. Conduct the questionnaire survey for exploring internet of things application for management in practices by collecting data from 88 respondents in auto parts companies.

Step 3. Calculate the consistency ratio (CR) by Equation (13).

$$CR = \frac{CI}{RI} \quad (13)$$

When  $CI = \frac{(\lambda_{max} - n)}{(n-1)}$  and  $\lambda_{max} = \sum_{i=1}^n [\sum_{j=1}^n a_{ij} W_j]$ . The CR value should be lower than 0.1 which means the weights are determined by decision-makers have consistency. If the CR value is greater than 0.1, it expresses those weights determined to have no consistency. Therefore, the research should review the evaluation of main factors and sub-factors in the first step.

Step 4. Calculate the average fuzzy evaluation matrix from the questionnaire survey and the local weights of the main factors and sub-factors as shown in Tables III to VIII.

Step 5. Calculate the inner dependence weights and the dependencies among the factors that are considered the main factors as shown in Table IX.

Step 6. Calculate the global weights of sub-factors by multiplying the local weights of the sub-factors with the interdependent weights of main factors as shown in Table X.

From the results, the CR ratios of five main factors and fifteen sub-factors were lower than 0.1 which expressed weights determined by decision-makers of auto parts companies had consistency. In this study, the decision-makers made the pairwise comparison for main factors and sub-factors and they were analyzed by fuzzy ANP. The results indicated that telepresence was the most important factor with the interdependent weight at 22.9 percent. Next, connectivity was the second rank of the important factor with a weight of 20.5 percent. While value, security, and intelligence had interdependent weights at 19.7, 18.7, and 18.2 percent respectively.

For the importance of sub-factors, the results indicated that performance was the most important sub-factor that influenced the decision-makers with the global weight at 9.20 percent. The second rank was the functional orientation with a global weight of 8.80 percent, while data management, controlling, and compatibility had the global weights of 8.60, 8.30, and 8.28 percent respectively. For the least importance, the bottom five sub-factors had consisted of information privacy, cloud computing, authorization, artificial intelligence, and market demand with their global weights at 5.88, 5.41, 4.30, 3.91, and 2.84 percent respectively. Therefore, these sub-factors had less impact on the decision-maker during selection to apply IoT in their production management.

TABLE II. LINGUISTIC SCALE FOR RELATIVE WEIGHTS OF FACTORS

Risk Level	Triangular Fuzzy Scale	Triangular Fuzzy Reciprocal Scale
Just equal	(1, 1, 1)	(1, 1, 1)
Equally important	(1/2, 1, 3/2)	(2/3, 1, 2)
Weakly more important	(1, 3/2, 2)	(1/2, 2/3, 1)
Strongly more important	(3/2, 2, 5/2)	(2/5, 1/2, 2/3)
Very strongly more important	(2, 5/2, 3)	(1/3, 2/5, 1/2)
More important	(5/2, 3, 7/2)	(2/7, 1/3, 2/5)

## V. DISCUSSION

Results from this study have indicated that the importance level of each variable is different by the factor of telepresence is the most important because there is telepresence for considering proposed data in working units that are connected to IoT for tracking operations in the production process. The data should be presented in real-time to executives and employees to track circumstances in production more conveniently. Moreover, it has impacted the controlling, decision-making, and planning that is done more efficiently. The second factor is connectivity which is important for integrating the production process of auto parts to control processes connected. Furthermore, the connectivity is for processing and exchanging data with suppliers, production process, and warehouse management following Just-In-Time production for more flexibility and accuracy. For the performance factor, it can be connected to IoT which is important in controlling and tracking operations more quickly. The accuracy of data enhances forecasting and decision-making, as well as the ability to improve working units throughout the supply chain, following specified plans. The function orientation is a crucial part that must control flows of produced auto parts continuously throughout the process and lay down guidelines with relevant departments both inside and outside the organization. Besides, data that is connected to IoT can improve function orientation more efficiently. Finally, data management is for managing big data from IoT through a data center that relates to internal and external networks that enhance efficient operations in the production process of auto parts. However, the results can be discussed in detail for each factor as follows.

### A. Telepresence

The telepresence can consolidate and analyze data for presenting reports from several perspectives as requirements and scopes of each department such as the productivity report of each production line versus production plan or failure reports. The reports are for relevant departments can receive information and prepare for any case from the defined plan delayed. It can be summarized and proposed to executives as management dashboards on important issues for industrial management based on changing circumstances or needs. It can

also be used as information for each department to have a picture of their performance or service levels of others to improve their processes more efficiently [63], such as presenting information in the production process, auto parts approval data for delivery, notifying customers, or forecasting stock more precisely. Therefore, the presentation of data enables all relevant segments to evaluate and track actual production reports against targets in real-time.

1) *Controlling*: Operating processes following targets or defined plans is necessary to ensure continuity and accuracy in the production of auto parts for stable working throughout production operations, enabling dynamic control, and situational assessment for data analysis in decision-making more quickly and anywhere [30, 64]. Besides, controlling through several Programmable Logic Control (PLC) systems can deal with machines that have complex functions in the production line of various auto parts to ensure that operations are in line with the production plan. Therefore, it expresses that the automated control of the production system supports operations through the working steps, controlling robots to comply with requirements is for operating continuous production, such as plating and painting robots that are controlled to work relative to the movement of parts on production belts, or robots at the packing belts which must be controlled to operate accurately and precisely as the determined functions to meet the customer orders. Additionally, robots are controlled to weld joints of auto parts as specified standards as well as control interaction or transmission environments between devices.

2) *Synchronization*: The auto parts manufacturing process is for connecting data to work consistently throughout the supply chain, such as ordering, controlling, or transmitting data without any interruption in the working process. Therefore, all units must precisely synchronize data into the central operating system for a holistic view of all productions. As a result, management is more convenient and faster [25, 26]. Process synchronization can create balance in production lines and units because the production of auto parts includes the main production line for assembly parts and the second

production line for assembly sub-parts as well as parts from suppliers that are a part of the production.

3) *Monitoring*: The manufacturing process of auto parts is crucial due to the large number of components and suppliers in the supply chain. It can dynamically monitor and perform real-time analysis efficiently [20]. Therefore, applying the internet of things is to continuously monitor operations of each unit on the production line, such as monitoring the assembly process to track operations as planned, monitoring the operating systems for avoiding potential risks and system failures, or doing preventative maintenance for machines, etc.

#### B. Connectivity

Connectivity is a crucial integration in the production of auto parts for control of various stages to detect machines and equipment for the exchange of data in analytical processing [65]. Particularly, the auto parts industry produces parts with a Just-In-Time production system to meet the needs of the production line in terms of quantity, time, and quality. Therefore, data connections with suppliers have real-time access to various information, and coordination with suppliers is streamlined and accurate [66]. Enable efficient operation, such as planning production requirements and delivering raw material parts in due course, managing raw materials in warehouses to be alerted reducing raw material shortages, and reliability of the delivery of raw material parts, etc.

1) *Compatibility*: The Auto parts manufacturing process is for centralizing data of operational statuses quickly and up to date. Particularly, several parts produced from different suppliers need to be linked with the same platform [6], for example, linking customer production data to assemble a vehicle that lets suppliers know what materials to produce or order during what period. In a part of compatibility for quality inspection data of vehicle chassis parts, when it is compared to the customer-specified standards, assembling auto parts that must match the production plan according to the specified model. In case of the product does not meet standards, it will inform details of errors for revisions, etc.

2) *Sensor network*: Linking sensors to computer systems in the same network is to communicate with each other inside and outside the organization [22,67]. This method enables data transfer, controlling and tracking working statuses, or detecting errors that occur in the production process, such as errors from machines in the manufacture of auto parts or detecting parts that do not meet the standard or track statuses in the logistic process effectively. Besides, the sensor network can build trust by connecting external sensor networks to auto parts suppliers for coordination through the enterprise resource planning system (ERP) that allows data from suppliers to be centralized into the data center such as production planning, quality management of parts, purchasing and delivery statuses, disbursement of raw materials, etc. The logistic management in the transportation of auto parts that are linked to the sensor network can control and trace the services by connecting to the Global Positioning System (GPS).

Furthermore, it can check the driver's status and physical condition for safety and efficiency purposes.

3) *Standardization*: Standards for auto parts manufacturers must build confidence throughout the supply chain process [21]. Effective control under the same standards, such as standardized performance of parts, is created and delivered to both inside and outside involved units through the correct digital system as designed. It can be connected to various measurements to detect non-compliant auto parts, such as checking the coating standard of all standard vehicle parts in terms of thickness and shades. It must be precise checking because the color is very close, or the traceability process of auto parts (vehicles have a wide range of different models and parts, there must be standards for tracking the production process and sources), etc.

#### C. Value

Creating value in the auto parts manufacturing industry can create value-added through tracking, recording, and data processing. Exchange of information and display insights that enable more accurate and faster decision making by enabling organizations to dynamically recognize the device connection that can communicate [45] such as linking data from suppliers, production, logistic system, and services. It supports the ability of data analysis throughout the production process or can operate automated systems that are linked to production plans in the production process of auto parts. Therefore, costs have been reduced from removing wastes in the production and increasing value-added in operations. Moreover, decision-making and strategies can be appropriately operated from the quality data.

1) *Performance*: The basic need of the auto parts industry to operate. Using an appropriate production factor and reducing waste in the working process can be done. IoT is a tool that can support operations work more accurately and quickly as well as reduce waste of time and errors [50, 68]. Moreover, tracking devices and connecting data can help to produce quality auto parts that meet the customer's needs, data from IoT can evaluate performances in departments for improving their performances consistently.

2) *Convenience*: The access insights that are analyzed and processed, can be used in operating the quality production because IoT can create convenience in terms of data collection from resources [47, 65]. It can facilitate operators or executives in working such as convenience in tracking real-time performances of different product lines at the same time, convenience in tracking the shipment of auto parts from suppliers, and convenience in trust-building to the customers by enabling tracking of production information and services.

3) *Market demand*: The application in marketing helps auto parts manufacturers to get the correct data on customer needs [28, 34]. The auto parts can be adjusted to meet the customer's needs as well as quality standards or other requirements that the customers accept. Change circumstances and market volatility through devices and data networks can

exchange the data with customers in perspectives such as quality issues, customer complaints about quality issues, and production plans changing. It occurs from the data exchange in the same operating system including determining the delivery cycle to meet the just-in-time system or anticipating new products developed.

#### D. Security

Information security plays a crucial role which restricting access to only relevant data to prevent espionage from unauthorized persons [40, 69]. The auto parts industry because data in business operations must be kept confidentially for the highest benefit of the organization, particularly the auto parts industry has a large network of people involved. Therefore, permissions of data access and data management require a security system to prevent data leakage from employee or system errors such as production data, logistics data, customer service data, etc.

1) *Data management*: The auto parts industry where data collection is dynamically changing. Center data management must have the capability to deal with big data, filter standard data, and manage data more efficiently [70]. Therefore, it is necessary to have an efficient storage system for managing data formats, data display, and managing data as the operation characteristic to prevent failures of the system that may occur from various specifications or productions from different suppliers. Besides, failures can be occurred by capability data of different production lines, data of the automated system, or robots that need data characteristics in terms of the readable language by robots.

2) *Information privacy*: Information privacy is a challenge in the development and services of IoT solutions that require strict compliance with standards of data privacy, access statuses of using devices in production, encrypting, and controlling data under the security policy [43]. including reducing the risk of disclosure because the industry has more trade secrets such as production technology, product details, and features as well as developing new products in the future. The considered information privacy management is the controlling of connecting between devices in both internal and external organizations. Preventive management that maintains the confidentiality of process data in the supply chain access the secured cloud system in connecting production data.

3) *Authorization*: Data access in levels of departments is an important part that must be operated consistently with information privacy to avoid obstacles to access to information excluded the permission for practitioners to access self-information. In the industry, the cross-function team can work with other employees from other departments in terms of developing new products that should have the team from R&D, marketing, production, or suppliers. Therefore, people in the team should be able to access information about each other. Therefore, assigning permissions to temporarily grant access to the necessary information of other entities but there must be a controller of authority to access only specified data for preventing data security that may impact the total

production of auto parts such as standard parameters in the quality inspection or accessibility of trade secrets. The importance of accessing sensitive information can prevent problems or adverse events in the organization.

#### E. Intelligence

Intelligence is directly involved in the production of auto parts that uses IoT to interact between machine and machine, or machine and human to understand patterns or behaviors of wise operations. Furthermore, It can adjust production systems of auto parts to digital systems to increase their intelligence [24]. Such as intelligence in evaluation and analysis for the volume of produced auto parts in each production line and using data to measure performances as planned against the past data as well as forecasting its trend. Intelligence in simultaneous controlling complex machines and equipment in the main and second production lines is for the operations can be traced and controlled more efficiently.

1) *Functional orientation*: The auto parts production that can be applied to use IoT for providing information that is beneficial to operators can work accurately and make decisions efficiently. Furthermore, functional orientation for tracking auto parts from suppliers or customers can be connected to logistics processes for continuous monitoring [65]. This emphasizes the exact time of delivery according to the specified cycle [24]. The functional orientation has been used to align works and be an assistant for the organization in multi-tasks such as connecting ERPs in the supply chain, determining collaborative networks clearly, and set-up clear process flows. Besides, automated data recording with RFID can check the status of auto parts from suppliers and the production more effectively that expresses production data and quality of raw material for planning.

2) *Cloud computing*: The auto parts industry is a service that provides an external IT infrastructure for connecting software and platforms that can process big data from IoT to respond to intelligent processing that can access data anytime and anywhere. This can respond to the needs of customers and related parties more comprehensively [34,71]. Internal and external organizations under collaboration have a data center to access data conveniently such as the production report of auto parts through the organization's web browser and software and all data will be simultaneously kept on the service provider's server. Therefore, the user can access the system all time the most services are the type of web applications to support data-driven. When there is sufficient data for creating innovation in the manufacturing process of auto parts.

3) *Artificial intelligence*: Artificial Intelligence (AI) is a cutting-edge technology that has changed the way of working for the auto parts industry and has been involved with IoT directly. AI also helps to increase customer satisfaction by analyzing big data from the customer relationship management (CRM) system that supports continuous production and creates value-added for the organization [34, 71]. It supports the industry to operate with complex matters

more quickly such as quality inspection of auto parts by running a simulation of used auto parts in a real situation instead of real inspections that spends more time and resources than the simulation. Besides, it can propose the best alternative to the operators to consider and make decisions more precisely such as selecting the best route for transportation purposes or predicting possible incidents that may occur in the production line in advance. Moreover, AI can be developed into an intelligent operating system that can interact with humans, intelligent production that can predict or notify any incident in the production, and planning and inspection for auto parts to be stocked and utilize spaces in the warehouse more effectively. With another application, raw materials in the process can be scanned to trigger the automated reimbursement system to feed raw materials into the production line continuously and support the non-stop production. Therefore, the production data can be transferred to other departments such as planning, purchasing, production, and marketing departments to know the statuses in production at the same time and use the data to plan future operations more precisely.

## VI. CONCLUSION

In this research, five factors have been identified that influence the auto parts industry for applying Internet of Things (IoT) technology to integrate production management with connectivity, telepresence, intelligence, security, and value respectively. The study has revealed that telepresence is the most important factor for decision-makers of auto parts manufacturers in selecting IoT applications for managing production. While the importance of connectivity, value, security, and intelligence are prioritized in descending order respectively. For the importance of sub-factors, the top five ranks have consisted of performance, functional orientation, data management, controlling, and compatibility respectively which influence the auto parts manufacturers to decide for applying IoT. Meanwhile, information privacy, cloud computing, authorization, artificial intelligence, and market demand have less influence on decision-makers for selecting IoT to apply to their auto parts production. To the results of this study, auto parts manufacturers can make use of factors and sub-factors as selection criteria for procuring internet devices or relevant equipment to IoT to improve their production management as well as the firm's performances in terms of financial and production benefits.

In implications for management, this research benefits executive (Decision-makers) in auto parts manufacturers who are seeking IoT applications to improve production capabilities to increase value-added and competitive advantages. The first criteria that they need to consider when selecting IoT applications are telepresence. Telepresence will assist them in controlling production lines to guarantee that production capabilities meet the objective, and all data from each unit in the production lines should be integrated for daily performance monitoring and early detection of any events that could stop production. Connectivity is the second criterion that needs to consider for selecting IoT applications. Decision-makers must ensure that IoT applications are compatible with

their machinery and equipment so that they can be controlled smoothly and precisely, and they are also connected to the existing computer network. Moreover, considered IoT applications should have a standard that is both trustworthy and market acceptance. Next, the values that decision-makers should consider, are to improve performance in production, be convenient to use, and be desired by end-users. Therefore, if consumers can perceive the value and benefits of IoT applications, they will be more likely to accept them, and their obstacles to using them will be greatly lowered. Security is the next criterion to consider in the selection of IoT applications. To avoid the risk of data disclosure or leaking, IoT applications should have an efficient data storage system to manage sent data from devices, as well as a data privacy standard. Besides, data access should be set with authorization to avoid unauthorized access to personal information or commercial secrets. Finally, intelligence is considered the least important criteria for selecting IoT applications because most auto parts manufacturers in use manpower in production. Moreover, the industry still needs skilled manpower for producing high-quality auto parts. Intelligence may be necessary for the firms that are looking for cost reduction and automated processes. These firms want to expand their capacity and productivity to supply auto parts for large automotive firms with increased demand.

The auto parts manufacturers who have fully implemented and used IoT applications in their manufacturing lines are limited to very large enterprises, which is a limitation of this study. Therefore, small and medium-sized auto parts manufacturers may choose to integrate some IoT applications in their production as a way to save money. For future research, these factors in this study will be used as the selection criteria to evaluate and select appropriate IoT applications for managing auto parts production.

**Abstract**—Autism Spectrum Disorder (ASD), the non-uniform neurodevelopment condition that is characterized by the impairment of behaviour in communication and social interaction with some restricted their repetitive behaviour. Today, to measure the voltage created during brain activity is measured using electroencephalography (EEG). The wavelet transform is used for decomposing the time-frequency of the EEG signal. Feature Selection is the process that significantly reduces feature space dimensionality, while maintaining the right representation of their original data. In this work, metaheuristic algorithm is utilized for feature selection. The proposed feature selection is based on River Formation Dynamics (RFD) and a hybrid Greedy RFD is presented. Support Vector Machine (SVM) can be a concept consisting of a set of methods of supervised learning to analyze pattern recognition that is a successful tool in the analysis of regression and classification. Experimental results show the proposed Greedy RFD feature selection improves the performance of the classifiers and enhance the accuracy of classifying ASD.

**Keywords**—Autism spectrum disorder (ASD); electroencephalography (EEG); feature selection; River Formation Dynamics (RFD); Support Vector Machine (SVM); hybrid greedy RFD

## I. INTRODUCTION

All the existing medical conditions in human are recognised with the support of a medical professional [1]. But, owing to any variation in their physiological signals, the assessments can result in human error and are not similar while being met by a medical professional. Autism has been identified as a new spectrum disorder that can affect every individual in a different manner in different degrees. This is characterized by means of social deficits, poor communication, and repetitive behavioural patterns. Nevertheless, all problems with children that have a condition of Autism Spectrum Disorder (ASD) can contribute to this. Even though the ministry has been focusing on its early identification resulting in screening and intervention, there are some challenges faced. Different tools are available to diagnose the condition of ASD using this. Human brain have specific paths to send, receive and to interpret all information to bring about a response through its synaptic activation.. These pathways are known as sensory systems [2, 3].

The electroencephalogram (EEG) is a signal acquired from individuals that are scientifically and clinically sound. As a consequence, quantification has a vital role in the study of the human brain [4]. The frequency content and examination of

EEG signals, in particular, were identified as a preponderant approach to the knowledge extraction problem. These were used in the research of brain processes related to Motor Imagery (MI). It shows there were tremendous development in the Brain –computer Interface (BCI) technology, which aims to replace compromised human neuromuscular system capability. The majority of BCIs depend on physiologically well-defined EEG properties, such as oscillations in neural networks or their potentials generated by specific stimuli. Various methods that assess the energy of the signal that is dispersed in this frequency, which is t-f or t-s domains, dominated the extraction of EEG features. The Discrete Wavelet Transform (DWT) further decomposes this EEG segment into various sub-bands [5]. Different statistical features and entropy functions were used for the extraction of features from sub-bands.

Multi-variate relations in data can be captured using Machine learning techniques [6] and are very suitable for the detection distribution and subtle differences of certain found in data. Therefore, when compared to the other univariate approaches, the machine learning approach will be able to perform better in terms of classifying the EEG, especially in terms of conditions such as ASD [7, 8]. Therefore, they hold plenty of promise in bringing about knowledge improvement in diagnosing ASD. The Support Vector Machines (SVM) tends to have some merits like higher accuracy and not needing large numbers of training samples that avoid overfitting. Therefore, the SVM has now aroused plenty of concern among the neuroimaging research community [9]. GBM iteratively builds by combining prediction from several weak learners and achieves good performance [10]. In this work, greedy RFD has been investigated to classify the EEG and ASD.

The main contribution of this work is:

The features of EEG and the behavioural data is fused to achieve better accuracy in classifying ASD.

The River Formation Dynamics (RFD) metaheuristic is used for selecting features from the wavelet transforms.

The proposed Greedy RFD improves the performance of RFD.

## II. RELATED WORK

Sudirman et al [11] aimed to build a new sensory profile using the EEG bio-signal and its potential for distinguishing between various sensory responses. All EEG signals needed here were useful in identifying various emotional states like

super learning, light relaxation, and positive thinking. These were inside a frequency range falling between 8 and 12 Hertz. A total of 64 children were part of this research, and from among them, about 34 children were given vestibular sensory, taste, sound, and visual simulations. All raw EEG data had been filtered using an Independent Component Analysis (ICA), and wavelet transforms with the EEGLAB software. To build its sensory profile, standard deviations means and entropy approximation had been extracted from filtered EEG signals.

Herman et al [12] had performed a study which compares spectral signal representation like Power Spectral Density (PSD) techniques, continuous and discrete wavelets, atomic decompositions, and Time-Frequency (t-f) energy distributions. The main emphasis was on the identification of certain differentiated properties in the feature sets that represent EEG trials that are recorded at the time of imagination, that is, for the left-hand or the right-hand movement. Separating features can be quantified in an offline study by making use of the accuracy of classification based on a rate that is obtained using linear as well as non-linear classifiers. There are PSD approaches that demonstrate a consistent level of robustness along with effectiveness that is useful in certain distinctive spectral patterns. They are used to differentiate whether MI induced EEGs are belongs to left and right. The observation has been based on data analysis from a total of eleven subjects in two different sessions. Additionally, the capabilities of generalization of these classifiers found in their intersession performance have been discussed.

Cheong et al [13] studied the Discrete Wavelet Transform (DWT) for extraction of features from their EEG signals that were obtained based on a sensory response from children suffering from autism. For the purpose of this study, the DWT was used in order to decompose the filtered EEG signal into their components with a statistical DWT coefficient feature computed within the time domain. Such features were employed for training Multilayer Perceptron (MLP) based neural network for the classification of signals into three different classes based on the severity of autism (whether mild, moderate, or severe). The results of training in terms of accuracy had achieved about 92.3% with an MSE of 0.0362.

Fan et al [14] had proposed a data-driven method to design the RFD. Speaking technically, the RFD was constructed using threshold responses using receptive fields from many candidates based on their distinctiveness and their correlations. By means of employing two types of such receptive fields (rectangular pooling and Gaussian pooling), two different binary descriptors, the RFDR and RFDG, were chosen. The experiments of image matching experiments on the Patch Dataset and the Oxford Dataset proved that the RFD was able to outperform them, and its work was comparable to the float-valued descriptors at a short time. Experiments on object recognition proved that the RFDR and RFDG were able to show better performance than their competitors.

The human genome can be used to extract vast amounts of data. Autism is a type of neurobehavioral disorder in which a person's capacity to interact and communicate is impaired. It has a solid genetic foundation. There are various gene variants

linked to autism, and these changes can disrupt the functioning of the brain that begins before birth. Mutated genes are passed down from their immediate ancestors to their offspring, and this is a risk factor for autism. Reeta et al [15] had proposed another novel approach for ranking such diseased genes that are found in an autistic individual. This system will predict the autistic behaviour of individuals by means of comparing certain similarities among the genes of individuals and the diseased for training that is implemented by making use of the method known as the Naive Bayesian classification. For example, in case the DNA of an individual will be tested, and in case it is found that the DNA consists of certain diseased genes in the training set, autism may be predicted. The approach also makes the process of diagnosis of the condition simpler and earlier as well.

In Vaishali and Sasikala [16], the diagnosis dataset of the ASD will have 21 features that are obtained from the repository of the UCI machine learning, and this has been experimented with by using a swarm intelligence-based binary firefly feature selection wrapper by using the same, there was an identification made that about 10 features among a total of 21 ASD datasets were enough to distinguish between the patients that had ASD or did not. The obtained results, along with the proposed approach, were able to justify the new hypothesis by means of producing a certain amount of average accuracy within the range of about 92.12%-97.95% along with optimum feature subsets that were equal to the accuracy of the ASD.

In Alzubi et al [17], a hybrid mechanism to select feature which is more accurate was proposed to detect informative SNPs to be chosen for an optimal SNP subset. This method was based on the fusion of that of a filter and also a wrapper method along with the Conditional Mutual Information Maximization (CMIM) method and Support Vector Machine Recursive Feature Elimination (SVM-RFE). The proposed method's performance had been evaluated based on three different state-of-the-art methods, which are the Minimum Redundancy Maximum Relevance (mRMR), ReliefF, and the CMIM. It also used four classifiers which were the Naive Bayes (NB), SVM, Linear Discriminant Analysis (LDA), and the k Nearest Neighbors (kNN) on an ASD-SNP dataset that was obtained from the Gene Expression Omnibus and National Center for Biotechnology Information genomics data repository. The results of the experiment had demonstrated that the efficiency of this approach of feature selection outperformed other methods and achieved a classification accuracy of 89%.

### III. METHODOLOGY

Feature selection refers to a technique that was employed for pre-processing data, and this is preferable at the time of performing machine learning. Selection by mean is to choose attributes and variables within a dataset that is fit into a particular model and is tested for performance. The section further details the extraction of features by making use of the Wavelet Transform, Support Vector Machine, RFD, Greedy RFD, Naive Bayesian Classification, and K- Nearest Neighbours.

### A. Datasets

The techniques are evaluated using autism dataset obtained from King Abdulaziz University (KAU) Brain Computer Interface (BCI) Group. The EEG data is recorded using all the electrodes with 16 channels. This dataset had been filtered using a band-pass filter along with pass band frequency (0.1–60Hz) and a notch filter that had stop band frequency (60Hz) and at 256Hz frequency sampling is digitized. The recording time of EEG is varied from 12 to 40 minutes among autistic subjects up to 173 minutes, and from 5 to 27 minutes up to 148 minutes for normal subjects.

The behavioural dataset related to autism screening of toddlers containing features that is used for further analysis to determine autistic traits. Ten behavioural features is recorded with other individuals characteristics.

### B. Feature Extraction using Wavelet Transform (WT)

These wavelets were in use in the recent decade for different tasks of image processing. For the purpose of image compression, fractals compression, fractals, resolution enhancement, denoising, and image enhancement frequency domain and time analysis is used. The basic idea behind all of this is the analysis of the signal in accordance with the scale. The main advantages of such Wavelet transforms are that compared to the Fourier transforms that represent functions; there are some discontinuities with sharp peaks that help in the accurate deconstruction or reconstruction of non-periodic, non-stationary finite signals. The images based on wavelet, enhancement, de-noising, and so on had better performance owing to the properties of sparsity or multi-resolution structure. Wavelet transform also has the trait of multi-resolution analysis aside from the ability to express a local feature of this signal in the domain of time and frequency. Therefore, it is found to be fit to detect the flash state or the irregularity of the signal and in setting out the composition [18]. The wavelet  $\psi$  having a compact support and vanishing moment  $n$  is as in (1):

$$\int_{-\infty}^{+\infty} t^k \psi(t) dt = 0, \text{ for } 0 \leq k \leq n \quad (1)$$

This has another function  $\theta$  that has fast decay and is shown as (2).

$$\psi(t) = (-1)^n \frac{d^n \theta(t)}{dt^n} \quad (2)$$

Once this is done, the wavelet transform for signal  $f$  is given as in (3):

$$Wf(u, s) = s^n \frac{d^n}{du^n} (f * \bar{\theta}_s)(u) \quad (3)$$

Wherein,  $\bar{\theta}_s(t) = s^{-1/2} \theta(-t/s)$ , are the time and space coordinate and  $s$  the scale. The wavelet transforms  $Wf(u, s)$  is the  $n$ th order derivative of  $f$  that has  $\bar{\theta}_s$  on a domain proportional to  $s$ .

The most important frequencies of EEG exist between 0.1 to 30 Hz. The standard EEG clinical bands are the delta (0.1 to 3.5 Hz), theta (4 to 7.5 Hz), alpha (8 to 13 Hz), and beta (14 to 30 Hz) bands. A sample EEG image and corresponding alpha,

beta, delta and theta waveforms are shown in Fig. 1. 30Hz waves will termed as gamma waves.

In this work, the number of decomposition levels is taken as 5. Thus, the EEG signal is decomposed into D1-D5 details. As a result output coefficients of mean, standard deviation, variance, skewness and kurtosis feature vectors are used for classifying the signal.

### C. River Formation Dynamics (RFD) Feature Selection

The algorithm of River Formation Dynamics was earlier used in solving problems that are NP-hard to find paths within a graph [19]. Furthermore, the algorithm is also capable of optimizing the distance of the path and also considers certain other dependencies like restrictions to acceleration, velocity, pathfinding tasks, and so on, which are considered to be NP-hard problems [20]. The RFD algorithm can be depicted as given below. The actual amount of soil that is assigned to each of the nodes will drop as they keep moving and erode the paths or depositing the carried sediment (thereby increasing node altitude). The descending slope makes more dependence on the probability of deciding the next node, and which can be relative to the actual the node's altitude dissimilarity, the altitude of its adjacent node, and the drop position. The environment created in the early stages will be flat. This means that throughout the process, the nodes will have the same height, except in the case of a target node with a height of zero. There is a blotch placed at the starting node to navigate the entire site, which determines the optimal path. At every step there is another set of droplets are traversed in space sequentially and erosion is marked at the nodes traversed.

The nodes represent features, and the routes between them reflect the decision of the next feature when utilising RFD to optimise feature selection. The drop travelling through with the least number of nodes visited that meets the stopping requirement is used to find the best feature subset.

The first step will be the initialization of the nodes of the algorithm and define the set that is formed using the cell decomposition of the site. Every node here will possess all information, and in case it consists of an obstacle aside from additional data, the determination of the time that is required for traveling across the entire distance to its goal is considered. When there is a drop initialization there may be a suitable number of drops that are kept to the first node. After this, the algorithm will be executed until such time the last condition is met.

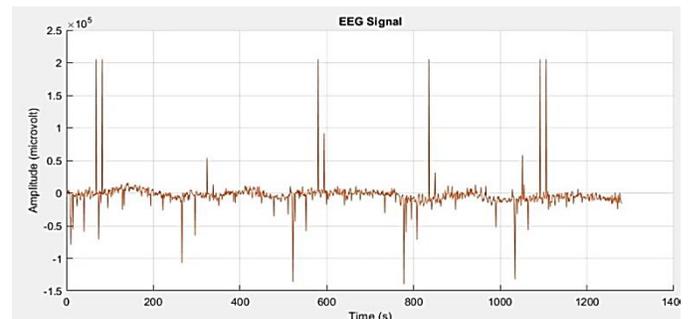

Fig. 1. Sample EEG Images.

The statements says that the drops were in the same path, and in addition to that, for reducing the time taken for computation, a upper limit on the actual number of iterations was introduced along with the condition that verifies whether the last n loops have improved the solution or not. Path analysis will involve identifying the right solution. For the purpose of discovering the best drop that can conduct any additional erosion, it has to be performed on travelled paths by means of reducing the altitude of the nodes. The final step will be to add some sediment to the nodes in order to overcome any circumstances in which all the altitudes are near 0, thus making the gradients can be ignored, which may destroy the paths formed. This will diminish slowly with each loop in the algorithm.

#### D. Proposed Greedy River Formation Dynamics Feature Selection

The Greedy algorithm is the one that can determine this problem by means of making a choice that appears to be the best at that moment. There are several problems of optimization that may be solved by means of using this algorithm, and some may not have an efficient solution. However, the Greedy algorithm can implement such a solution which is nearly optimal. The Greedy algorithm also reflects a problem-solving heuristic that makes a locally optimal choice in every stage, hoping to be able to find a global optimum. For most of these issues, the greedy strategy may not be able to produce an optimal solution, but it can bring about a locally optimal one that can approximate another globally optimal solution within a reasonable time frame.

```
Initialize Nodes(), Drops(), Greedy (D, n)
Solution <- 0
while (not endConditionMet())
  For i<-1 to n do {
    S<-Select (D)
    If (Feasible (solution, s)) then
      Solution <-Union (Solution, s)}
  Return solution
moveDrops()
analyzePaths()
erodePaths()
depositSediments()
end while
```

#### E. K- Nearest Neighbors (KNN)

Computing the closest distance between the neighbours is depicted as the K value, and for making use of this algorithm, a few other elements in the initial subject set, which is the K number (of nearest neighbours), is observed, and the K parameter and distance were considered.

These training tuples have been described in the form of n attributes. In this, every tuple will indicate the point within the n-dimensional space. So, all training tuples will be stored

within an n-dimensional pattern space. For a certain unknown tuple, the k-NN classifier will lookout for a pattern space in the k training tuples that are the closest to the unknown one. The k training tuples represent the k-nearest neighbours of this unknown tuple. "Closeness" has been defined as the distance metric like the Euclidean distance. Euclidean distance between that of two points or tuples will be  $X = (x_1, x_2, \dots, x_n)$  and  $Y = (y_1, y_2, \dots, y_n)$  is (4):

$$d(X, Y) = \sqrt{\sum_{i=1}^n (X_i - Y_i)^2} \quad (4)$$

The step by step process of K-NN algorithm is given below:

- Computing the distance between that of the new sample and all earlier samples that have been grouped in the form of clusters;
- Sorting the distance in increasing order to choose k samples having smaller distance values;
- Applying a voting principle and adding a new sample to the largest cluster of the k samples.

#### F. Naive Bayesian Classification

Naive Bayes' is very popular method in the categorization of the texts and in identifying documents of a certain type as to whether they are legitimate or spam. The Naive Bayes' Classifier can be very scalable and needs linear parameters in the variables (or predictors) for a learning problem. The probability models with strong assumptions of independence of Naive Bayes classification using diseased gene classification and is a conditional model.

$$P(C_k|x) = P(C_k) . P(x|C_k) P(x) \quad (5)$$

If there is a genetic instance that has to be classified and is represented by a vector  $x = (x_1, x_2, \dots, x_n)$  will represent n genes with assigned probabilities.  $P(C_k, x_1, \dots, x_n)$  It is for every possible k outcome or class  $C_k$ .

#### G. Support Vector Machine (SVM)

The SVM refers to a new form of supervised learning algorithm for rightly categorizing a target result that uses independent variables which is present inside the dataset. Another new SVM can be the maximum margin classifier, and this will further maximize any separation between the n classes of data. The SVMs are useful, especially when there is a boundary between the groups that are non-linear and owing to this feature, they are normally used for problems of classification where there is a distinction made between groups that are non-linear. The SVM algorithms are used for classifying individuals based on diagnosis, neuroimaging, genes, standardized assessments, and some more measurements [21]. The SVM classification algorithm makes use of training instances to predict other new ones using two different class label -1, 1. As per Fig. 1, a hyperplane is  $w^T x + b = 0$ , wherein,  $w \in R^n$  is orthogonal to a hyperplane and  $b \in R^n$  is constant. With training data D, equation (6) is derived:

$$D = \{(\vec{x}_i, \vec{y}_i) | \vec{x}_i \in R^m, \vec{y}_i \in \{-1, +1\}\}_{i=1}^n \quad (6)$$

In which  $x_i$  is the m-dimensional real vector,  $y_i$  the input vector class,  $x_i$  either -1 or +1. The SVM looks for a hyperplane to maximize the margin between two sample classes in D.

$$y_i(\bar{w}^T \vec{x} + b) \geq 1 \tag{7}$$

The aim of the SVM is to increase the distance between two different hyperplanes. One will compute the distance between both hyperplanes  $\frac{1}{\|\bar{w}\|}$ . The SVM training in a non-separable case will be solved with a problem of quadratic optimization as in Equation (8):

$$\begin{aligned} \text{minimize: } P(\bar{w}, b, \xi) &= \frac{1}{2} \|\bar{w}\|^2 + C \sum_{i=1}^n \xi_i \\ \text{subject to: } y(\bar{w} \cdot \phi(\vec{x}) + b) &\geq 1 - \xi_i, \xi_i \geq 0 \end{aligned} \tag{8}$$

#### H. Gradient Boosting Machine (GBM)

An ensemble technique, boosting will help to reduce the bias which is dependent and also generalized error in an ensemble. Another technique of boosting which will repeatedly combine 30 base (weak) learners that have low variance and high bias like the stumps in the decision tree. These base learners are combined to ensure ensemble bias, and this will reduce the variance remaining the same, thus reducing its net ensemble error. For every boosting step or iteration, the GBM will construct yet another new base learner to a negative gradient of the loss function with the observed data in order to ensure the focus of the new base learner is on the model and its weakness. This means a functional approximation for the model has been made by bringing about a consecutive improvement with the negative direction to the loss function [22].

Normally, the GBM algorithm will have better results in the case, for every iterative step, there can be an added decision tree and its contribution, which is reduced by using a parameter for shrinkage  $\alpha$  which is known as the rate of learning. The main idea behind this method of shrinkage in the GBM will be that it has more steps, and these small ones will result in better accuracy compared to a less number of larger steps. This parameter of learning  $\alpha$  will fall between 0 and 1, and the smaller the value, the more its accuracy.

For each iterative step, as opposed to making use of a complete training dataset, a randomly chosen (that does not have a replacement) subsample that will fit a decision tree will be used. If there are many observations a default fraction of this data will  $\frac{1}{2}=0.5$ . This means about half i.e.,50%) of the dataset can be used. Additionally, algorithms computation cost will be reduced by subsampling to the means of a factor that is equal to the subsampling factor [23] and improves the accuracy of Gradient boost machine model. The algorithm used for gradient boosting is as given below:

- Initialize the predictions with one simple decision tree.
- Calculate the residual – and this will be its (actual-prediction) value.
- Build a shallow decision tree to predict the residual based on independent values.

- Update its original prediction with another one multiplied by its rate of learning.
- Iterate the step 2 to 4 for certain number of times which should be equal to the tree count.

#### I. Proposed Greedy RFD GBM

The proposed Greedy RFD is used to optimize the GBM’s hyperparameters. The GBM model hyperparameter of number of trees, tree depth, learning rate, Minimum number of observations in terminal nodes is optimized using the Greedy RFD optimization algorithm. In the proposed Greedy RFD GBM, the initial solutions are created randomly. The range specified for number of trees is 1000 to 5000, tree depth 1 to 10, learning rate 0.05–0.3, Minimum number of observations in terminal nodes 5-15. The Root Mean Square Error (RMSE) is used as the objective function. On iterations of the Greedy RBF, the optimal set of GBM hyperparameters to classify ASD is obtained.

### IV. RESULT AND DISCUSSION

The techniques were evaluated for two scenarios, using features from EEG data only and using features from both EEG and behavioural data. In the latter, the features of EEG and the behavioural data is fused. In this section, the RFD feature methods with classifiers such as KNN, NB, SVM and GBM are evaluated. Section 4.1 presents the results for EEG data without feature fusion and section 4.2 the results for feature fusion.

#### A. Without Feature Fusion

Tables I to IV and Fig. 2 to 5 shows accuracy of the classification, precision, recall and F measure for both normal and ASD features.

TABLE I. CLASSIFICATION ACCURACY FOR GREEDY RFD-GREEDY RFD GBM WITHOUT FEATURE FUSION

Techniques Used	Classification Accuracy
RFD-KNN	92.31
RFD-NB	92.69
RFD-SVM	93.27
RFD-GBM	95.19
Greedy-RFD-GBM	95.58
Greedy RFD-Greedy RFD GBM	96.35

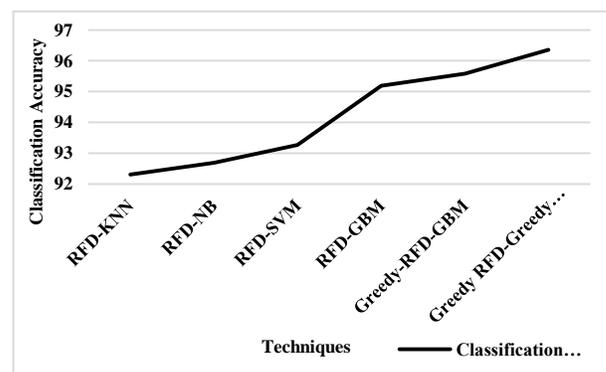

Fig. 2. Classification Accuracy for Greedy RFD-Greedy RFD GBM without Feature Fusion.

From Fig. 2, it can be observed that the Greedy RFD-Greedy RFD GBM has higher classification accuracy by 4.3%, by 3.9%, by 3.25%, by 1.21% and by 0.8% for RFD-KNN, RFD-NB, RFD-SVM, RFD-GBM and Greedy-RFD-GBM, respectively. The selection of optimal hyperparameters of GBM shows improved performance.

TABLE II. RECALL FOR GREEDY RFD-GREEDY RFD GBM WITHOUT FEATURE FUSION

Techniques Used	Recall for normal	Recall for ASD
RFD-KNN	0.9214	0.9237
RFD-NB	0.9286	0.9263
RFD-SVM	0.9357	0.9316
RFD-GBM	0.95	0.9526
Greedy-RFD-GBM	0.95	0.9579
Greedy RFD-Greedy RFD GBM	0.9571	0.9658

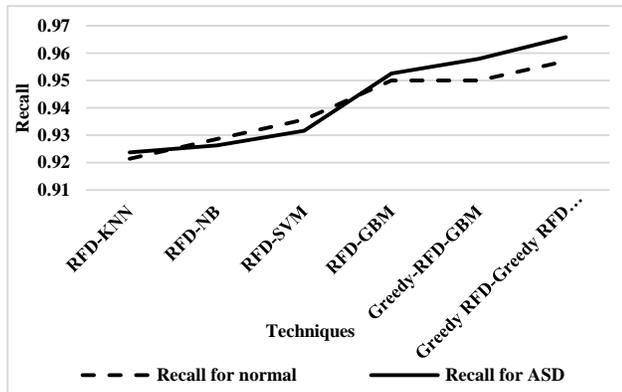

Fig. 3. Recall for Greedy RFD-Greedy RFD GBM without Feature Fusion.

From Fig. 3, it can be observed that the Greedy RFD-Greedy RFD GBM has higher recall by 3.8%, by 3.02%, by 2.26%, by 0.74% and by 0.74% for RFD-KNN, RFD-NB, RFD-SVM, RFD-GBM and Greedy-RFD-GBM, respectively, for normal. Similarly, the Greedy RFD-Greedy RFD GBM has higher recall by 4.46%, by 4.18%, by 3.6%, by 1.38% and by 0.82% for RFD-KNN, RFD-NB, RFD-SVM, RFD-GBM and Greedy-RFD-GBM, respectively for ASD. It is observed that the feature selection significantly improves the classification of the ASD. The proposed Greedy RFD feature selections achieves the best performance.

TABLE III. PRECISION FOR GREEDY RFD-GREEDY RFD GBM WITHOUT FEATURE FUSION

Techniques Used	Precision for normal	Precision for ASD
RFD-KNN	0.8165	0.9696
RFD-NB	0.8228	0.9724
RFD-SVM	0.8344	0.9752
RFD-GBM	0.8808	0.981
Greedy-RFD-GBM	0.8926	0.9811
Greedy RFD-Greedy RFD GBM	0.9116	0.9839

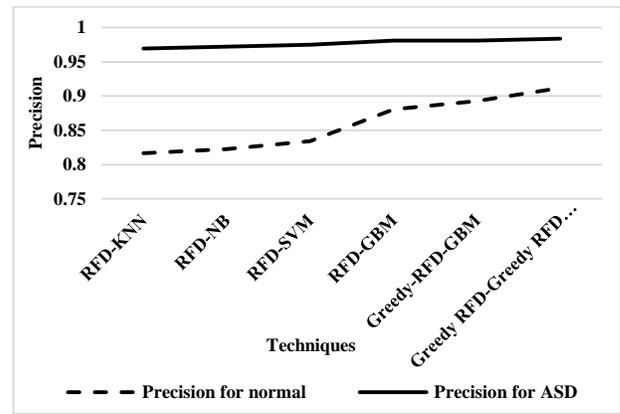

Fig. 4. Precision for Greedy RFD-Greedy RFD GBM without Feature Fusion.

From Fig. 4, it can be observed that the Greedy RFD-Greedy RFD GBM has higher Precision by 11%, by 10.24%, by 8.84%, by 3.44% and by 2.1% for RFD-KNN, RFD-NB, RFD-SVM, RFD-GBM and Greedy-RFD-GBM, respectively for normal. Similarly, the Greedy RFD-Greedy RFD GBM has higher Precision by 1.46%, by 1.2%, by 0.89%, by 0.3% and by 0.29% for RFD-KNN, RFD-NB, RFD-SVM, RFD-GBM and Greedy-RFD-GBM, respectively for ASD. The optimization of the feature selection and classifier hyperparameters has significant improvement in the performance. The proposed Greedy RFD is effective when compared to RFD.

TABLE IV. F MEASURE FOR GREEDY RFD-GREEDY RFD GBM WITHOUT FEATURE FUSION

Techniques Used	F measure Normal	F Measure ASD
RFD-KNN	0.8658	0.9461
RFD-NB	0.8725	0.9488
RFD-SVM	0.8822	0.9529
RFD-GBM	0.9141	0.9666
Greedy-RFD-GBM	0.9204	0.9694
Greedy RFD-Greedy RFD GBM	0.9338	0.9748

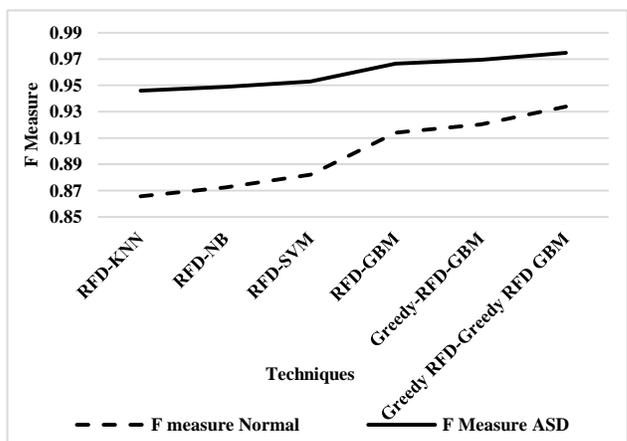

Fig. 5. F measure for Greedy RFD-Greedy RFD GBM without Feature Fusion.

From Fig. 5, it can be observed that the Greedy RFD-Greedy RFD GBM has a higher F measure by 7.6%, by 6.79%, by 5.68%, by 2.13% and by 1.45% for RFD-KNN, RFD-NB, RFD-SVM, RFD-GBM and Greedy-RFD-GBM respectively for normal. Similarly, the Greedy RFD-Greedy RFD GBM has higher F measure by 2.99%, by 2.7%, by 2.3%, by 0.84% and by 0.56% for RFD-KNN, RFD-NB, RFD-SVM, RFD-GBM and Greedy-RFD-GBM, respectively for ASD.

**B. After Feature Fusion**

Headings, The classification accuracy, recall, precision and F Measure for both normal and ASD features as shown in Table V to VIII and Fig. 6 to 9.

TABLE V. CLASSIFICATION ACCURACY FOR GREEDY RFD FEATURE SELECTION-GREEDY RFD GBM

Techniques	Classification accuracy
RFD-Feature Selection - KNN	94.08
RFD-Feature Selection -Naïve Bayes	94.64
RFD-Feature Selection - SVM	95.21
RFD Feature Selection - GBM	95.78
Greedy RFD feature selection GBM	96.56
Greedy RFD feature selection - Greedy RFD GBM	97.15

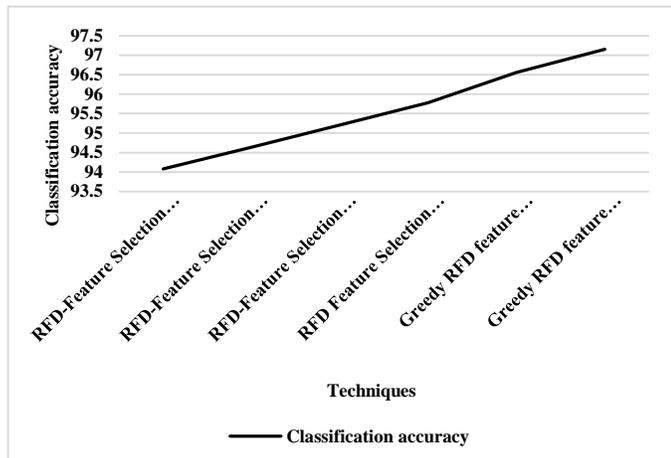

Fig. 6. Classification Accuracy for Greedy RFD Feature Selection-Greedy RFD GBM.

From Fig. 6, it can be observed that the Greedy RFD feature selection-Greedy RFD GBM has higher classification accuracy by 3.21% for RFD-feature selection-KNN, by 2.62% for RFD-feature selection-Naive Bayes, by 2.01% for RFD-feature selection-SVM, by 1.42% for RFD-feature selection-GBM and by 0.61% for Greedy RFD feature selection GBM, respectively.

From Fig. 7, it can be observed that the Greedy RFD feature selection-Greedy RFD GBM has higher recall for normal by 2.94% for RFD-feature selection-KNN, by 2.22% for RFD-feature selection-Naive Bayes, by 1.48% for RFD-feature selection-SVM, by 1.48% for RFD-feature selection-GBM and by 0.74% for Greedy RFD feature selection GBM respectively. The Greedy RFD feature selection-Greedy RFD GBM has higher recall for ASD by 3.3% for RFD-feature

selection-KNN, by 2.77% for RFD-feature selection-Naive Bayes, by 2.22% for RFD-feature selection-SVM, by 1.39% for RFD-feature selection-GBM and by 0.55% for Greedy RFD feature selection GBM, respectively.

From Fig. 8, it can be observed that the Greedy RFD feature selection-Greedy RFD GBM has higher precision for normal by 8.33% for RFD-feature selection-KNN, by 6.99% for RFD-feature selection-Naive Bayes, by 5.63% for RFD-feature selection-SVM, by 3.56% for RFD-feature selection-GBM and by 1.44% for Greedy RFD feature selection GBM, respectively. The Greedy RFD feature selection-Greedy RFD GBM has higher precision for ASD by 1.12% for RFD-feature selection-KNN, by 0.84% for RFD-feature selection-Naive Bayes, by 0.56% for RFD-feature selection-SVM, by 0.56% for RFD-feature selection-GBM and by 0.27% for Greedy RFD feature selection GBM, respectively.

TABLE VI. RECALL FOR GREEDY RFD FEATURE SELECTION-GREEDY RFD GBM

Techniques	Recall for Normal	Recall for ASD
RFD-Feature Selection - KNN	0.9348	0.9431
RFD-Feature Selection -Naïve Bayes	0.9416	0.9482

Techniques	F Measure for Normal	F Measure for ASD
RFD-Feature Selection - KNN	0.8958	0.9587
RFD-Feature Selection - Naïve Bayes	0.9052	0.9626
RFD-Feature Selection - SVM	0.9149	0.9666
RFD Feature Selection - GBM	0.9247	0.9707
Greedy RFD feature selection GBM	0.9381	0.9762
Greedy RFD feature selection - Greedy RFD GBM	0.9485	0.9802

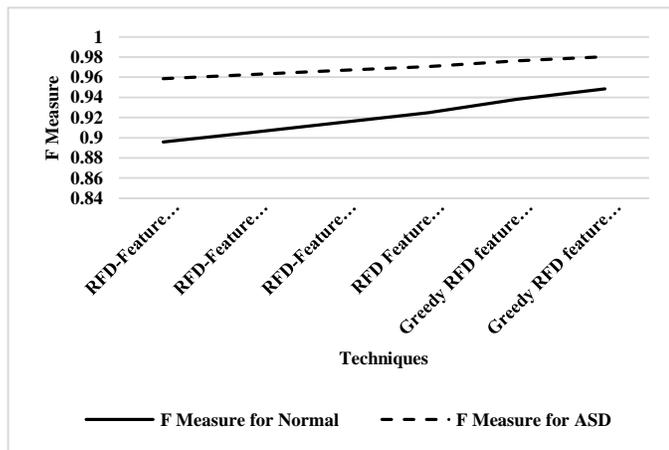

Fig. 9. F Measure for Greedy RFD Feature Selection-Greedy RFD GBM.

From Fig. 9, it can be observed that the Greedy RFD feature selection-Greedy RFD GBM has higher f measure for normal by 5.71% for RFD-feature selection-KNN, by 4.67% for RFD-feature selection-Naïve Bayes, by 3.61% for RFD-feature selection-SVM, by 2.54% for RFD-feature selection-GBM and by 1.09% for Greedy RFD feature selection GBM respectively. The Greedy RFD feature selection-Greedy RFD GBM has higher f measure for ASD by 2.22% for RFD-feature selection-KNN, by 1.82% for RFD-feature selection-Naïve Bayes, by 1.39% for RFD-feature selection-SVM, by 0.98% for RFD-feature selection-GBM and by 0.41% for Greedy RFD feature selection GBM, respectively.

It is observed that the feature fusion using EEG and behavioural data has higher classification of ASD of 97.15% when compared to 96.35% accuracy with only EEG data. Similarly, precision, recall and f measure achieved is better when feature fusion is used. Though the classification is enhanced, the sampling used is small. The proposed methods needs to be evaluated with larger dataset.

## V. CONCLUSION

Autism Spectrum Disorder (ASD) can be a lifelong condition that is quite serious and characterized by restricted but repetitive behaviour along with deficits in terms of communication or its reciprocal social interaction. The EEG and behavioural data is used for identifying the ASD. In this work, the wavelet transform is used to extract features from EEG. Features of the EEG and behavioural data is fused. Feature selection is achieved using proposed RFD and Greedy RFD algorithms. SVM can take a collection of input data to make a prediction where the binary class input will make the SVM a two-class linear classifier that is non-probabilistic. GBM iteratively builds by combining prediction from several weak learners. The hyperparameters of the GBM is optimized using Greedy RFD to improve the classification of the ASD. The results have proved that Greedy RFD-Greedy RFD GBM with fused features from both EEG and behavioural data had a better accuracy of classification than the RFD-KNN, RFD-NB, RFD-SVM, RFD-GBM, and the Greedy-RFD-GBM. The findings show that fusing of EEG and behavioural data does improve the classification of ASD. Future research can focus on evaluating the proposed methods using larger dataset.

**Abstract**—We present an optimized hybrid fuzzy Weighted k-Nearest Neighbor classification model in the presence of imbalanced data. More attention is placed on data points in the boundary area between two classes. Finding greater results in the general classification of imbalanced data for both the minority and the majority classes. The fuzzy weighted approach assigns large weights to small classes and small weights to large classes. It improves the classification performance for the minority class. Experimental results show a higher average performance than other relevant algorithms, e.g., the variants of kNN with SMOTE such as Weighted kNN alone and Fuzzy kNN alone. The results also signify that the proposed approach makes the overall solution more robust. At the same time, the overall classification performance on the complete dataset is also increased, thereby improving the overall solution.

**Keywords**—Imbalanced data; fuzzy weighted kNN; SMOTE; classification model; optimized hybrid kNN

## I. INTRODUCTION

In supervised learning, labeled training data is used to prepare certain classifiers and find the class name of the test data using that classifier [1]. The performance of such classifiers on balanced datasets is generally better than on imbalanced datasets. Hence, there is an increasing need to tackle the issue of class imbalance [2, 3]. The problem of class imbalance states that the number of instances in one class is slightly lower in these datasets than in the other classes [4]. On imbalanced datasets of the binary class, only one positive and one negative class is present. The positive and negative classes are the minor and the major classes, respectively.

In many classification problems, however, the more useful are the instances of the minor with lower instances [5]. Therefore, imbalance occurs whenever the class of interest is relatively rare and has a small number of instances compared to the majority class. In addition, relative to the cost of misclassifying the majority class, for example, the cost of misclassifying the minority class is very high; consider cancer versus non-cancer or fraud versus un-fraud [6]. Since the majority class is over-represented, it impacts the training of the classifier and hence the majority class has better accuracy than the minority class(es).

Although a variety of solutions to data imbalance have been developed, in some ways they have shortcomings. Some solutions consider adding, deleting or weighting the data in order to closely balance the data. Other solutions attempt to find some good pre-processing measures for solving such

particular problems in the training dataset that may restore balance between the majority and minority classes before performing classification [7, 8].

In general, existing class-imbalanced classification methods are divided into four categories: either manipulating or modifying the distribution of data by under- or over-sampling (data sampling), modifying in traditional classification existing algorithms to suit class imbalance (algorithmic modification), ensemble approaches [9], or cost-sensitive learning [10]. Therefore, data imbalance can be resolved by over-sampling the under-represented class or under-sampling the over-represented class. But both of these methods are not much scientific and suffer from various drawbacks. Therefore, we adopt the first and the second categories of sampling a dataset in the pre-processing phase and the modification of traditional classification algorithm. The data sampling methods focus on balancing the data, and the common strategies are to reduce the majority class examples (under-sampling) or to add new minority class examples to the data (oversampling) [8, 11].

Synthetic Minority Oversampling Technique (SMOTE) is one of the techniques used to balance imbalanced datasets. Researchers have widely adopted SMOTE due to its versatility and added value with respect to random over-sampling [8]. It reduces the possibilities of over-fitting by randomly resampling the data and generating new samples of the minority class by interpolating multiple samples of the minority class that lie together. Nearest neighbour rule can be used over here. The over-fitting dilemma is thereby eliminated and the decision space is more widespread for the minority class; meanwhile the decision space for the majority class is reduced. By operating in feature space, synthetic instances are created. Some drawbacks of SMOTE, however, are unavoidable because it synthesizes new instances without taking the majority class into account [8], which could lead to fuzzy boundaries between the positive and negative classes. Therefore, SMOTE technique has been proposed with various improvements and extensions that aim to eliminate its drawbacks.

In this paper, we combine a method of class weighting with SMOTE's over-sampling of the minority class to improve the classification accuracy of the minority class without sacrificing the accuracy of the majority class. The combination is performed in a simple classification model based on kNN algorithm [12, 13] which has the ability to accommodate enhancements and extensions [14]. It is the Hybrid Fuzzy weighted k Nearest Neighbor (HFwkNN) classifier introduced

in [15]. It is a weighted and fuzzy extension to kNN based on fuzzy set theory.

We optimize HFWkNN to deal with imbalanced datasets and find greater results in the general classification of imbalanced data for both the minority and the majority classes. It determines the fuzzy membership function in favor of the minority class and creates a fuzzy equivalent relationship between the unlabeled instance and its  $k$  closest neighbors. In other words, it takes into account the fuzziness of an instance's closest neighbors, which can decrease the disturbance of the majority class to the minority class. The advantages of the neighbor weighted  $K$  nearest neighbor method are combined with fuzzy logic, i.e., the assignment of large weights to small classes and small weights to large classes. Fuzzy classification tends to more adequately classify objects as it defines how much of an object belongs to a class.

As presented in [15], the hyperparameters  $\gamma$ ,  $\varepsilon$  and  $\varepsilon_{\min}$  are introduced in the membership function of HFWkNN to increase the accuracy score, improve the performance and handle the class-imbalance. Weight-assignment technique is developed and combined with SMOTE for the class membership function of the HFWkNN of each neighbor, which learns the class weight for each training sample, to process imbalanced data. The minority class samples are given a higher weight to let the classifier concentrate on them.

The rest of the paper is organized as follows. Section II briefly discusses some related work. Section III presents the classification model with the class-imbalanced data. Section IV presents the experimental results, analysis and evaluation of the model. Finally, Section V concludes the paper and suggests future work.

## II. RELATED WORK

There are quite a few innovative solutions and methods which have been proposed by researchers to tackle the problem of class imbalance in classification problems. These methods either oversample the minor class or under-sample the majority class [16]. That is why these methods are sometimes called as sampling techniques. Although these methods are popular, they suffer from the problem of impacting the original distribution of the data. Nevertheless, there are approaches which deal with the issue of class imbalance while not impacting the original structure of the data. such approaches can be utilized by many classifiers such as those based on kNN.

kNN is one of the most utilized and quite popular classification algorithms. It is used in various classification problems and is considered as one of the top 10 algorithms in data mining [14]. But the classic kNN algorithm is not equipped enough if the dataset is imbalanced. Hence, to tackle the issue of imbalanced dataset for kNN algorithm, researchers have proposed quite a few distance or similarity based classification algorithms like kENN [25] and CCW-kNN [17]. But these methods are good for numerical data points.

Weighted kNN proved to performs well on imbalanced datasets. Dubey et al. [18] proposed class based weighted approach for performing classification on imbalanced dataset. In this approach, the distribution of the nearest neighbour was analysed and used to calculate the weights. Classic kNN is

used to perform the initial classification and is used to get the respective weights for each of the classes in the classification problem. A hybrid approach was proposed by Patel et al. [19]. It tackles the class imbalance by assigning small weights to the majority class and large weights to the minority class. Tomasev and Mladeni\_c [20] explored the hubness effect which is related to kNN in high-dimensional datasets, where minority class instances lead to higher misclassification errors. With low or medium dimensional datasets, majority class instances lead to misclassification.

Fuzzy solutions have been used for dealing with imbalanced dataset problems. However, not much work has been done in this area. Liu et al. [21] proposed a fuzzy kNN approach for unequally distributed dataset. The dataset had strong relationships between attributes, instances and classes. The approach utilized assigning sized memberships, similarity calculations and integration as the main methods. Sometimes, addressing the problem of data leaks in a classification model may result in data imbalance [22]. Ramentol et al. [23] have dealt with imbalanced dataset in a fuzzy-rough ordered weighted average nearest neighbour algorithm for binary classification. Six weight vectors and some indiscernibility relations are used with these weight vectors. Han and Mao [24] proposed an approach which utilizes fuzzy and rough properties of nearest neighbours data. The approach minimized the biasness owing to a membership function resulting in an advantage to the minority class.

In our case, we deal with data imbalance using easy to compute neighbour weighted with fuzzy kNN. We use the fuzzy kNN algorithm [25] to keep some of the nearest neighbours and utilizes their respective distances as key values. These distances are important as they help in finding the respective membership of the data instances into classes. This approach is further enhanced and refined by utilizing weights of different classes which are based on their respective sizes. The proposed solution strives to resolve the class imbalance by finding the membership function of the imbalanced data. This membership function uses the hyperparameters  $\gamma$ ,  $\varepsilon$  and  $\varepsilon_{\min}$  which we introduced in the proposed solution to tune up the classifier as they determine fuzzy membership and therefore lead the classifier to handle data imbalance. The fuzzy membership function was originally proposed by Keller et al. [25]. In our model, in addition to hypermeterizing the membership function, we use SMOTE with weight assignment function to get the membership of instances into all of the respective classes. Next, we present the proposed classification model that deals with the class-imbalanced datasets.

## III. OPTIMIZING HYBRID FUZZY WEIGHTED KNN WITH IMBALANCED DATA

The Optimized HFWkNN for imbalanced data handles the classification problem on the class-imbalanced mixed type datasets. It is an improved version of kNN and it combines fuzzy logic with weights to give more optimal results of prediction. We have presented the Optimized HFWkNN in full detail in [15]. Next, we summarize it for the benefit of the optimization process with the presence of data imbalance.

HFWkNN, as presented in [15], has two stages. In the first stage, the  $k$  nearest neighbors of the train set are calculated

against itself. Once the neighbors are calculated, then the class memberships are calculated with the training set using Equation (1).

$$U_c(x_i) = \begin{cases} 0.51 + 0.49 \times \frac{n_c}{k} \times \varepsilon + \gamma & \text{if } x \in C \\ 0.49 \times \frac{n_c}{k} \times \varepsilon_{\min} + \gamma & \text{if } x \notin C \end{cases} \quad (1)$$

In the membership assignment, we introduce the hyperparameters  $\gamma$ ,  $\varepsilon$  and  $\varepsilon_{\min}$  in a fuzzy membership to handle the class-imbalanced issue.

In the second stage, for each instance of the test set the  $k$  closest in the train set is calculated, based on the values of  $k$ . The resulting class is decided using Equation (2) instead of majority voting performed by  $k$ NN algorithm.

$$U_c(x_i) = \frac{\sum_{j=1}^k (U_{cj}) \times 1 / \|x_i - x_j\|^{2/(m-1)}}{\sum_{j=1}^k 1 / \|x_i - x_j\|^{2/(m-1)}} \quad (2)$$

The final class is obtained as the class with the greatest combined votes as a result of Equation (3).

$$C(x) = \operatorname{argmax}_i (U_i(x)) \quad (3)$$

To increase the accuracy score, improve the performance and handle the class-imbalance issue in the data, the hyperparameters  $\gamma$ ,  $\varepsilon$  and  $\varepsilon_{\min}$  are introduced in the membership function of the proposed HFWkNN model [15]. These hyperparameters are optimized using two different methods which are grid search and random search. These two methods are turned into user defined parameterized callable functions to obtain the values of the three hyperparameters. They are based on the optimization process of the class weight parameter to find the weight for each class.

For instance, by using grid search, large weights are assigned to small classes and small weights are assigned to large classes to minimize the bias of the Optimized HFWkNN towards the majority class and avoid minority class. The following is the pseudocode of hyperparameter optimization procedure of HFWkNN using grid search method as we stated it in [27].

- Step 1:** **Initialize** the different parameters  $\gamma$ ,  $\varepsilon$  and  $\varepsilon_{\min}$ , with  $cv=5$
- Step 2:** **Creating** the search space. we input the domain and the algorithm selects the next value for each hyperparameter in an ordered sequence.
- Step 3:** **Generate** a model using grid search. (grid search technique will construct many versions of HFWkNN with all the possible combinations of hyperparameter  $\gamma$ ,  $\varepsilon$  and  $\varepsilon_{\min}$  values that are defined)
- Step 4:** **Train** the Model.
- Step 5:** **Train phase:** Once the neighbors are calculated, give each neighbor a weight as the inverse distance of its Euclidean distance from that training data, then find memberships of training data into each class using Equation (1). The parameters  $\gamma$ ,  $\varepsilon$  and  $\varepsilon_{\min}$  are introduced in the membership function to give it a weight in all classes. This is to minimize the bias of the classifier towards majority class and avoid minority class.

- Step 6:** **Test phase:** Once the neighbors are calculated, the predicted class is decided as shown in Equation (2) to define the degree of membership of  $x$  in each class  $c$ .  
 $i = 1, 2, 3, \dots, C$   
 $j = 1, 2, 3, \dots, k$   
 $C$  is the number of classes,  $k$  is the number of nearest neighbors and  $m$  is the parameter of fuzzy strength.
- Step 7:** The final class is obtained as the class with the greatest combined vote.  
Classifier assigns  $x$ , using Equation (3), as belonging to the class label whose fuzzy membership for  $x_i$  is maximum.
- Step 8:** **Calculate** the model accuracy and save the model configuration and accuracy.
- Step 9:** **Check** if stopping criteria is not complete (no. of iterations end) **Updating** parameter values and **Return** back to step 3.
- Step 10:** **Get** and **report** the optimal value of the parameters and position of the model with high accuracy. Output the settings that achieved the highest score in the validation procedure.

To treat class imbalance, we reduce the bias inherent in the learning procedure and increase the sampling weights for the minority class. The weight-assignment technique is introduced for the class membership function of each neighbor in HFWkNN. Therefore, it learns the class weight for each training sample to process imbalanced data. Weights are assigned to the selected samples according to their importance in the data. The minority class samples are given a higher weight to let the classifier concentrate on them. The minority class decision space is expanded to allow HFWkNN to have a higher prediction on unknown samples of minority class. It also avoids the overfitting problem. Furthermore, combining class weighting with over-sampling of the minority class using SMOTE improves the classification accuracy of minority data without sacrificing the accuracy of the majority class. SMOTE is used to pre-process the dataset.

This over sampling, SMOTE + Weighting assignment, strategy, can tune HFWkNN towards a certain performance measure of interest with only moderate computational overhead. Each observation is weighted based on the class to which it belongs. The effect of minority class observations is increased simply by a larger weight of these instances and vice versa for majority class observations. This is similar to sampling-based approaches. It takes advantage of two efficient techniques: SMOTE as it is used at the pre-processing phase and class weighting assignment which is used to adjust the class distributions of the imbalanced datasets and respectively weight the base classifiers. This proposed strategy (SMOTE with Weight Assignment) is shown in Fig. 1 and is summarized as follows:

1) SMOTE as a common general-purpose approach handles data imbalance of the dataset at the pre-processing phase of data processing.

2) We get the weights of the class weight parameter. It is based on the optimization process where we use grid search. Grid search assigns large weights to small classes and small weights to large classes. Such an assignment minimizes the bias of the classifier towards majority class and avoid minority class. The assignments of weights in such a manner assures a better classification performance and tackling of the imbalanced dataset.

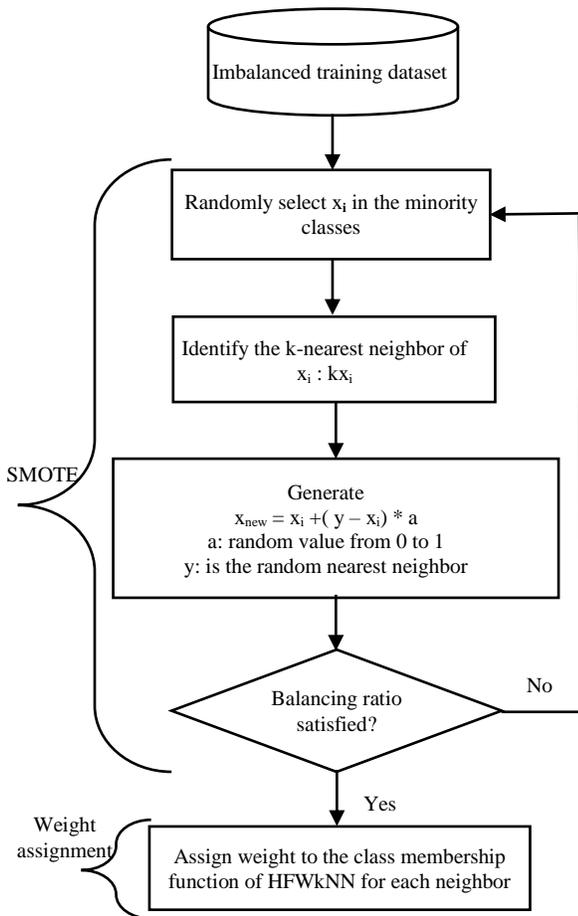

Fig. 1. SMOTE with Weight Assignment.

This strategy employs oversampling, weighting and strengthening. Notice that this improves the minority class samples in boundary region (or uncertain area). It extends the coverage space of minority class samples in boundary region and improves the confidence degree of decision rules without having much impact on the decision space of majority class. Hence the accuracy of HFWkNN is improved. Next, we present the conducted experiments on the optimized HFWkNN based on this strategy and their results.

#### IV. EXPERIMENTAL RESULTS

In order to verify the performance of the proposed model on benchmark datasets, we have used five datasets from UCI [26]. These datasets are known to be imbalanced by the unequal distribution of instances into classes. Haberman dataset describes the five year or greater survival of breast cancer patients and mostly contains patients who survive. Pima dataset collected originally from the National Institute of Diabetes and Digestive and Kidney Diseases.

The objective of the dataset is to diagnostically predict whether or not a patient has diabetes, based on certain diagnostic measurements included in the dataset. Ionosphere is a radar data collected by a system in Goose Bay, Labrador. Breast Cancer dataset is a classic and binary classification dataset. Readmission dataset represents 10 years of clinical care for diabetic patients at 130 US hospitals and integrated

delivery networks. It includes over 50 features representing patient and hospital outcomes.

Table I provides a summary of these datasets. They vary in the number of instances, number of attributes, class label ratio, and minority class percentage. Based on the minority class percentage, we can see that the datasets are highly imbalanced. For Haberman dataset only 26.5% of patients did not survive. For Pima dataset only 34.9% of patient has diabetes. While for Ionosphere dataset only 35.9% of records labeled as bad radar. For Breast Cancer dataset only 37.3% of patients belong to the malignant class. For Readmission dataset with respect to readmissions only 11% of patients have been readmitted within 30-days.

We compare our approach, the Optimized HFWkNN for imbalanced dataset with kNN, Weighted kNN (WkNN) and Fuzzy kNN (FkNN). We conducted a 5-fold cross validation for each dataset to evaluate the performance of all the 4 algorithms. We obtained and compared the results of Recall and F-value of minority class and the Area Under the ROC Curve (AUC) for each experiment. AUC indicates the overall classification performance and the AUC of a perfect classifier equals to 1, a bad one is less than 0.5. A good classification algorithm usually has a higher AUC.

In all our experiments, we set k to 3 since all the 4 classifiers are based on kNN. The cleaned data was randomized to avoid any selection bias and divided into two parts: 80:20 Training and Test data. This allowed us to train the model on 80% of the data and use an additional 20% to test the performance of the model. A 5-fold cross validation is used to avoid over-fitting on the training data in the evaluated models. The models are trained and evaluated using the same data to ensure fair performance comparison.

Tables II, III, and IV show the results of Recall, F-value of minority class and the Area Under the ROC Curve (AUC) measurements for all of the algorithms with the different datasets. Recall results in Table II indicate that the Optimized HFWkNN outperformed kNN, FkNN. It only outperformed WkNN in the case of the Readmission dataset.

This is due to two factors; first, the improvement occurred in the case of the Readmission dataset because it is larger and richer in terms of attributes than the other 4 datasets. Second, WkNN as it considered weights has shown better performance than kNN and FkNN since they do not consider weights. Nevertheless, the 3 algorithms outperformed the basic kNN since they are fuzzy and weighted.

TABLE I. SHORT DESCRIPTION OF THE DATASETS

Datasets	Number of instances	Number of attributes	Class labels (Minority: Majority)	Percent of the minority class
Haberman	306	3	2:1	26.5%
Pima	768	8	1:0	34.9%
Ionosphere	351	34	1:0	35.9%
Breast Cancer	570	8	1:0	37.3%
Readmission dataset	101,766	50	1:0	11.16%

TABLE II. RECALL RESULTS FOR THE OPTIMIZED HFWkNN IN COMPARISON WITH OTHER ALGORITHMS

Dataset	Recall			
	kNN	FkNN	WkNN	Optimized HFWkNN
Haberman	69%	73%	74%	74%
Pima	72%	75%	77%	77%
Ionosphere	82%	82%	83%	83%
Breast Cancer	87%	89%	89%	89%
Readmission dataset	75%	76%	74%	80%

The F-value results in Table III indicate that the Optimized HFWkNN outperformed kNN, FkNN and marginally outperformed them in the case of the Ionosphere dataset. This is due to the limited size and number of features in this dataset. Again, it outperformed WkNN in the case of the Readmission dataset due to two factors.

First, the improvement occurred in the case of the Readmission dataset because it is larger and richer in terms of classification-considered features than the other 4 datasets.

Second, WkNN, as it considered weights, has shown better performance than kNN and FkNN since they do not consider weights.

The AUC results in Table IV indicate that the Optimized HFWkNN has a high degree of class separability, i.e., it has high probability of distinguishing between classes. The results also indicate that HFWkNN outperformed kNN, FkNN and WkNN in its ability of class separability especially in the case of Ionosphere and Breast Cancer datasets. This is due to the limited number of classes in these two datasets.

TABLE III. F-VALUE RESULTS FOR THE OPTIMIZED HFWkNN IN COMPARISON WITH OTHER ALGORITHMS

Dataset	F-value			
	kNN	FkNN	WkNN	Optimized HFWkNN
Haberman	71%	76%	77%	77%
Pima	72%	75%	77%	77%
Ionosphere	83%	83%	84%	84%
Breast Cancer	87%	89%	89%	90%
Readmission dataset	75%	76%	74%	80%

TABLE IV. AUC RESULTS FOR THE OPTIMIZED HFWkNN IN COMPARISON WITH OTHER ALGORITHMS

Dataset	AUC			
	kNN	FkNN	WkNN	Optimized HFWkNN
Haberman	63%	67%	70%	70%
Pima	67%	70%	72%	72%
Ionosphere	85%	88%	88%	89%
Breast Cancer	87%	89%	89%	90%
Readmission dataset	76%	76%	74%	79%

The overall results of Recall, F-value and AUC show running the 4 models on the 5 datasets achieved better performance for the proposed Optimized HFWkNN than kNN, WkNN, and FkNN. It increases the classification performance of the minority class compared to the other 3 models. Its performance on the entire datasets is better than the other 3 models. Furthermore, these results indicate that kNN, in all cases has the lowest performance compared to FkNN, WkNN and our Optimized HFWkNN. Therefore, these extensions to kNN are justified and necessary.

It is worth mentioning again that the improvements of the Optimized HFWkNN over the other 3 models are due to combining SMOTE and class weighting assignment. SMOTE has succeeded in improving the accuracy of minority classes. Therefore, the Optimized HFWkNN was able to better model the minority class in the dataset by presenting not only the minority class instances, but also a broader representation of such instances. Such a representation resulted in improving the overall accuracy of the Optimized HFWkNN by concentrating on the minimal cases of the minority, positive classes as well as by properly modelling such classes.

Finally, since the Optimized HFWkNN is based on kNN, its complexity does not differ much from that of kNN which is  $O(n)$ . Taking the time of computing fuzzy membership grade of training and test samples using Equation (2) above, the time for testing fuzzy membership degree of all classes, and the time of SMOTE (although it is consumed once at the processing stage) and the time of class weighting assignment. These collective times add extra overhead but do not change the overall complexity of the model from that of kNN. Nevertheless, there still a need to perform a complete complexity analysis of HFWkNN.

## V. CONCLUSION

We have presented the Optimized HFWkNN classification model dealing with imbalanced datasets. The model has used three hyperparameters  $\gamma$ ,  $\epsilon$  and  $\epsilon_{min}$  that are introduced in the membership function to give it more general character and are tuned to give appropriate membership values for each class and help to balance the dataset. The model also has combined the method of class weighting with over-sampling of the minority class, SMOTE, to improve the classification accuracy of minority class without sacrificing the accuracy of the majority class. This has led to better results in the general classification of imbalanced data for both the minority and the majority.

Experimental results have shown higher average performance for the Optimized HFWkNN than kNN, Fuzzy kNN, and Weighted kNN. Results of Recall, F-value and AUC measurements for the different datasets are higher with the optimized HFWkNN model than the other 3 models. For example, Recall, F-value and AUC measurements with the Readmission dataset are 80%, 80% and 79% respectively, which are higher than those of the other 3 algorithms. These results also prove that the proposed model lead to better overall classification performance on the complete datasets than the other 3 algorithms.

The proposed model can be extended for multiclass and large size datasets with different strategies to construct the

fuzzy membership function in addition to the three hyperparameters  $\gamma$ ,  $\epsilon$  and  $\epsilon_{\min}$ . Although we have mentioned that the performance of the model is in line with that of kNN, the induced overhead due to computing and ranking fuzzy membership as well as the overhead due SMOTE and class weighting assignment need to be investigated. Finally, the model can be extended to other classification algorithms such SVM based on fuzzy similarities, weights and distances.

# SPKP: A Web-based Application System for Managing Mental Health in Higher Institution

Mohamad Fadli Zolkipli, Zahidah Mohamad Said, Massudi Mahmuiddin  
School of Computing, Universiti Utara Malaysia  
Kedah, Malaysia

**Abstract**—Client psychology profile is one of the methods used by UUM's Counselling Centre to analyze client psychological health conditions. This psychological profile is in a physical form which means the questions that need to be answered are on the paper. This psychology profile consists of three types of psychological modules whereby each module consists of questions related to psychology. The estimated time taken to answer this psychological profile is around 10 minutes. This physical form method may cause data to be lost and it will create issues when counselors want to retrieve the data back. This paper is aimed to develop Sistem Profil Kesejahteraan Psikologi (SPKP) for Counselling Centre of Universiti Utara Malaysia (UUM) in helping to know the client's psychological health before meeting up with the counselor. By focusing on analyzing Counselling Centre client's data, the basis of this web application system is to create a new space that will help Counselling Centre to improve the way they collect data, store data, and also improve their quality in time management whereby all those data can be collect, store, retrieve and analyze in a single click. By developing this system, Counselling Centre can monitor clients' psychological health before they meet up with the counselor.

**Keywords**—Psychology tests; psychology health; counselling; counselor

## I. INTRODUCTION

Conducting a psychological test is not something that people like to do. Further, the task of getting mental health checkups is quite time-consuming and sometimes people with mental health problems would not like to seek help from others. Even though counselors are like to accept people with open hands, there is still some gap between the client and the counselor. To make things harder, people with low self-esteem and anxiety would think multiple times before asking for people help. This is because, they might feel scared, ashamed, or even afraid of what other people would think about them after getting the mental health checkup. Psychological testing and assessment are a tools use by psychologist or counselor to test and measure a client's behavior to come out with a specific diagnosis and guide treatment. This test and assessment are being conduct for a wide variety of reasons. For example, children who is experiencing difficulty in school. The children may undergo aptitude testing or test for learning disabilities. This test can help a psychologist to understand more about the children condition. The test involves the use of questionnaires or checklist [1].

As time goes by, nowadays everything is just under the fingertip. What do you want to do, what do you want to search

for, what do you want to buy is all over the internet? There is no need for people to travel from one place to another just to buy their food and etc. For example, person A wants to buy cloth. He or she just needs to access any website that sells cloth and just buy it from there; Simple and easy, and also time-saving.

It is not that different from psychology. Before this, counselors conduct psychological tests through pen and paper tests. This method is good in terms of meeting the client directly face to face. However, as Covid-19 has taken over the world, the higher institution needs to stop operating face-to-face and change the teaching and learning method online. This means that UUM Counselling Centre also needs to stop operating. It also means that students are no longer able to conduct psychological test at UUM Counselling Centre. Moreover, the way UUM Counselling Centre conducts psychological tests is quite time consuming as they have 3 modules and each module consist of 10 to 20 questions which resulting in a lot of time consuming. Not only that, but the clients of UUM Counselling Centre also need to manually calculate the test results, and later on the test result would be kept in file storage rooms which might have resulted in the test reports might be lost and hard to retrieve.

Due to this problem, there is an urgent need for solutions that can manage the psychological tests efficiently. The emergence of digital technology in human life may open an opportunity for providing an effective way of managing the psychological health of people. Moreover, findings reveal that computer-based models outperform humans in a critical social-cognitive task: personality judgment [2]. It can be stated that, computer is more accurate in judging personality of person. Therefore, this paper is going to investigate the potential of computer as a platform to managing psychological health. This paper is aimed to develop Sistem Profil Kesejahteraan Psikologi (SPKP) for Counselling Centre of Universiti Utara Malaysia (UUM) in helping to know the student's psychological health before meeting up with the counselor. As a result, SPKP prototype of a web-based application for managing psychological health was developed and evaluated. The study contributes towards an understanding the system requirements for such web-based application and could be a reference model for developers and researchers to improve and managing psychological health. The next section describes the background and related studies. Next, the section describes the design and development of SPKP. The subsequent section explains the usability evaluation of SPKP. The last section in this paper concludes the study and lists the future works.

## II. BACKGROUND AND RELATED STUDIES

This section describes the background of psychological tests. Later, this section discusses the role of information technology in facilitating the creation and management of psychological tests. Although some students and staff found that doing psychological tests is easy and nothing to be worried about, in some cases, there are some students and staff who might have anxiety or depression or any related mental health problems that might find it is hard for them to conduct even one psychological test. Social stressors are amongst the most reliable forms of stress in humans and other species [3]. Accessing help, worries about confidentiality and trust, a preference for informal sources of help, and stigma are all barriers to obtaining help [4]. It is because of the stigma that, people who seek help from counselor or people who get medical treatment for mental health is crazy. Because of that, most people tend to just keep the problem to themselves and make their mental health worsen. The modern way of conducting psychological tests could make use of web-based applications where users use computers for managing their mental health. A detailed discussion of the concept and related studies are presented in the following paragraph of this section.

According to the World Health Organization, over 800,000 individuals commit suicide each year [5]. Latent components that are not observable in nature are evaluated using social and personality psychology exams. For instance, a self-report test could be created to assess belief in a just world, right-wing authoritarianism, or personality traits [6]. Sometimes, what we see is not the truth and we cannot differentiate between people with no mental illness and people with mental illness. Sometimes, people with health problems are more exposed on getting mental health problems too. Depression affects one out of every five individuals with coronary artery disease or heart failure, a rate that is at least three times higher than the overall population [7]. Because everyone is the same. The only way to differentiate is by conducting psychological tests. However, some people are not likely to conduct the tests because they feeling of ashamed and afraid would be called someone with mental health problems afterward. However, receiving psychological assistance is critical because it reduces the long-term detrimental impacts of mental illness [8]. Thus, seeking psychological help is very important in order to maintain a healthy mind.

The desire to be alone is a common behavior among people suffering from mental diseases. As a result of their seclusion, people with mental illnesses turn to social media sites like Twitter to freely discuss their illnesses [9]. However, sometimes the response received is not as expected. There are various reasons why online comments may be more detrimental than responses received in person [10]. When the discloser receives the desired response, requesting support in stigmatized situations is beneficial, but it comes with societal harms [11]. As a result, people feel scared and do not always reveal or seek help when they are in need.

Due to the Covid-19, the majority of the higher institution needs to stop operating as well as the UUM Counselling Centre. Currently, UUM Counselling Centre is conducting

psychological tests through pen and paper tests as shown in Fig. 1.

**SARINGAN STATUS KESIHATAN MENTAL 20 (SSKM 20)**

Untuk setiap soalnya yang berikut sila pilih satu jawapan yang mengambarkan pengalaman atau perasaan anda dengan paling tepat dan tandakan (%) di dalam kotak yang disediakan.

Di dalam tempoh satu bulan yang lepas pernahkah anda mempunyai pengalaman atau perasaan yang berikut:

Soalan	0 Tiada	1 Kadang- kadang	2 Kerap	3 Sentiasa
1. Sedih (atau susah hati)				
2. Mudah marah				
3. Tidak minat bercakap				
4. Kerap terjaga dari tidur				
5. Sakit-sakit badan/sendi				
6. Hilang minat pada perkara yang biasa diminati				
7. Menangis atau rasa hendak menangis				
8. Rasa sunyi				
9. Takut terhadap sesuatu objek atau keadaan				
10. Badan lemah, lesu atau tidak bertenaga				
11. Tidak suka bercampur dengan orang lain (menyendiri)				
12. Perasaan ingin mati				
13. Kurang daya ingatan atau mudah terlupe				
14. Otot tegang				
15. Keyakinan pada diri sendiri yang berlebihan				
16. Buah fikiran yang pantas, seolah berlumba-lumba				
17. Kurang yakin pada diri sendiri				
18. Rasa tiada jalan keluar				
19. Perasaan terlalu seronok				
20. Susah hendak menyesuaikan diri dengan keadaan				
<b>JUMLAH</b>				

Fig. 1. An Example of One of the Psychological Tests.

According to a senior psychology officer at UUM Counselling Centre, this method of conducting psychological tests is not efficient and a lot of times are needed just to conduct one test. This is because the client of UUM Counselling Centre needs to manually calculate the test result which required a lot of time to do so. Not only that, the test results would be kept manually in the files storage rooms which results in the test result might be lost and unretrieved. Moreover, this method is also not environmentally friendly as they need a lot of paper to print the psychological tests questions. It is because, to make one ton of paper, twelve trees, 540,000 gallons of water, and a variety of chemicals are required [12]. It means that this method is not environmentally friendly and it needs to be changed.

However, the method of conducting online psychological tests is not been widely discussed by the previous researchers. Therefore, only a few data can be collected to make a comparison between the two psychological tests method. Another method of conducting psychological tests is by using a mobile device as a platform for conducting psychological tests. Conducting psychological tests personally on mobile devices allows people to replay the tests as many times as needed. Not only that but they will also be received immediate feedback after conducting the tests [13]. Moreover, people with limitations such as handicapped and hard to moving from one place to another can easily use the system without worrying to

travel to the specific places just to conduct the psychological tests. SPKP is also good in terms of allowing users to conduct psychological tests multiple times. It is also can help students and staff in saving money and saving time where they no longer need to travel to UUM Counselling Centre just to conduct the psychological tests. Moreover, they can get the test results immediately after done answering the psychological tests questions. It shows that any method of psychological tests when being conducted online or computerized-based platform, will help in efficiency, flexibility, mobility, saving money, and saving time.

The future outcome of the mental health technology revolution depends on accelerating innovation and enhancing the path to adoption by challenging the normal ways of thinking [14]. The emergence of digital devices such as computer, tablets, and laptop has shed light on a more flexible and easier way of conducting psychological tests. A web-based psychological test is a new method that is going to be implemented by UUM Counselling Centre. This method is not only more efficient in a matter of time but also environmentally friendly. This means that by using this method people can also help to save the world from tree cutting and global warming. Therefore, there is a need for research and development of a web-based application for conducting psychological tests that could minimize the effort and time, especially for people who are afraid of seeking counselor help for their mental health. The study presented in this paper aims at designing and developing a web-based application that could help the users in conducting and managing psychological tests.

### III. METHODOLOGY OF THE STUDY

The methodology of development for this paper is Waterfall Model. The rationale why creates this paper using the Waterfall Model is because to relies on paper documentation, like technical specifications to define the scope of work clearly before it is started. Furthermore, the use of Waterfall Model is for ensuring that Counselling Centre deliverable meets expectations. Besides that, the Waterfall Model methodology has been chosen as a methodology to complete the system because it contains planning, analyzing, designing, implementation, testing, and maintenance as illustrated in Fig. 2. This system uses waterfall model as the methodology because this model works well for smaller papers where requirements are very well understood and phases are processed and completed one at a time [15].

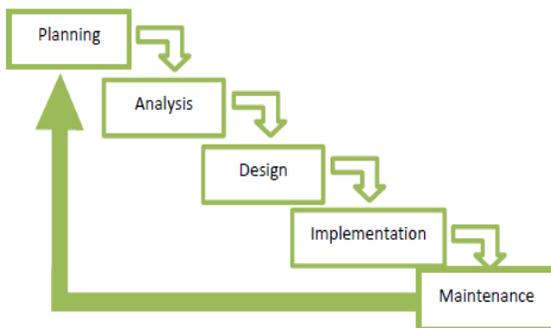

Fig. 2. The Phase of Waterfall Model [14].

- **Planning:** In the preliminary stage, planning begins with asking about problems that occur at the Counselling Centre. Student collects information about the new system that wanted to be developed by discussing with counselor and Counselling Centre's director. From the results of the discussion, student learn about what problems occur and face by Counselling Centre and to find solution to that problems. The goal of planning is to facilitate this system to be built smoothly. Therefore, the output in first phase is the problems faced by the Counselling Centre will be detected.
- **Analysis:** Students perform analysis by finding related work with the system to have more information about the current system by making a research at google scholar, to collect more info about similar system that related with SPKP more deeply to gather information and finalizing requirements with supervisor. It requires documentation time for paper technical proposals that need to be prepared. From there it must need to contact the client to ask what the client wants in the system. The output that will be gained from the analysis is student will be able to finalize system requirements and understand what the client wants in the system.
- **Design:** When requirements are known, a preliminary design or quick design for SPKP will be created. It is not a detailed design and includes only the important aspects of the system. Student will develop a prototype design which is low-fidelity prototype for a system to present for teachers and client. The output for design is to develop low-fidelity prototype for counselor to make sure they know how the system is going to function.
- **Implementation:** Student will implement it for the last time before officially present to the counselor and Counselling Centre's director. Lastly, all the related documents and final reports are then completed and submitted to the supervisor and the lecturer. The output that will be gained in implementation is the documents already completed and submitted to the supervisor and the lecturer.
- **Testing:** The paper development included software testing and user testing. A software testing is tested by the student intend to find syntax and logic error. The syntax and logic error on the system will be corrected and rebuild, this process ends until the system is robust. Then, the client can test the system in terms to evaluate usability, functionality, performance, and satisfaction. The evaluation result of the user testing recorded for future improvement and enhancement. The output that will get is the system must be tested until success in terms of usability, functionality, performance, and satisfaction.
- **Maintenance:** For the purpose of this paper, this maintenance phase will not be implemented. The software is operated to stay effective and relevant. It will be made to the initial software in order that will remains a workable solution that is free from bugs. The

output is the system must always be in a good condition without any failure, security system must be updated from time to time, ensuring high system quality and ease clients to key-in data and get their psychological report.

#### IV. DESIGN AND DEVELOPMENT OF SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI

This section describes the design and development of a web-based application for conducting and managing psychological tests. This section is divided into two sub-sections; (1) the requirements of the web-based application for conducting and managing psychological tests and (2) the prototype development of SPKP.

The Requirements of Sistem Profil Kesejahteraan Psikologi as followed:

A requirement gathering process was carried out using two methods that are interviewing UUM Counselling Centre's counselor and analyzing documents and web-based applications from the Internet that are related to psychological tests. The counselor was asked fewer questions primarily on the feature of the future developed web-based application of psychological tests. The example of the questions is, what are the characteristics of a web-based application of psychological tests that you would like to have, how would the interface design look like, and what are the things that you would like to put in the web-based application. The opinion was recorded, and the requirements were elicited.

For the secondary requirements gathering process, the documents were searched using Google Scholar by providing keywords primarily "psychological test", "mental health", "depression and anxiety", "digital world" and "global warming". The documents were analyzed to elicit the requirements for a web-based application that can conduct and manage psychological tests. Table I lists the requirements and their priority produced from the requirements gathering process. The requirements include new user registration, login to the system, answer submission, report viewing, and report managing.

The requirements presented in Table I were translated into the computer system functionality. The next process is visualizing and modelling the requirements of the web-based application using the appropriate modelling method and tools. In this work, the Unified Modelling Language (UML) was used to visualize and model the requirements. The models used in this work are two behavioral diagrams namely use case and activity diagrams, and a class diagram that represents the structural components of the app. Fig. 3 illustrates the use case diagram and the communications between the use cases and the actor for a web-based application that can be used conduct and manage psychological tests.

TABLE I. LIST OF REQUIREMENTS FOR CONDUCTING AND MANAGING PSYCHOLOGICAL TESTS

ID	Requirements Description	Priority
<b>1</b>	<b>Register</b>	
1.1	A new user must register before login to the system	Mandatory
1.2	System must display a page that allow user to key in their details: a) Name b) Role c) Email d) Password e) Confirm Password	Mandatory
1.3	The system must save all the information submitted by the user	Mandatory
1.4	User can cancel their registration by clicking the "Return to login" button if they want to	Optional
<b>2</b>	<b>Login</b>	
2.1	User must login into SPKP system by key in their email and password	Mandatory
2.2	If user entered incorrect email or password, the system will alert user with error message	Mandatory
2.3	If user forget his/her email or password, the user can click "forget password" button to reset it	Desirable
2.4	User can cancel their log in if they want to	Optional
<b>3</b>	<b>Submit answer</b>	
3.1	System must display a page that allow user to answer three psychological test questions	Mandatory
3.2	The system must save all the submitted answers	Mandatory
3.3	User can edit the answers before submit the answers if they want to	Optional
3.4	Once answers submitted, user can no longer edit the answers	Mandatory
<b>4</b>	<b>View report</b>	
4.1	The system should allow user to view their report result	Mandatory
4.2	User able to print the report result	Mandatory
<b>5</b>	<b>Manage report</b>	
5.1	The system must allow counsellor to view the report result	Mandatory
5.2	The system provide function for the counsellor to search for the specific client's report	Desirable
5.3	The system must allow counsellor to print the report results	Mandatory
5.4	The system should process all submitted answers and come out with the psychological test report results	Mandatory

The structural components of a web-based application for conducting and managing psychological tests are represented in a class diagram as illustrated in Fig. 4. The class diagram in Fig. 4 shows the attributes and operations of the web-based application.

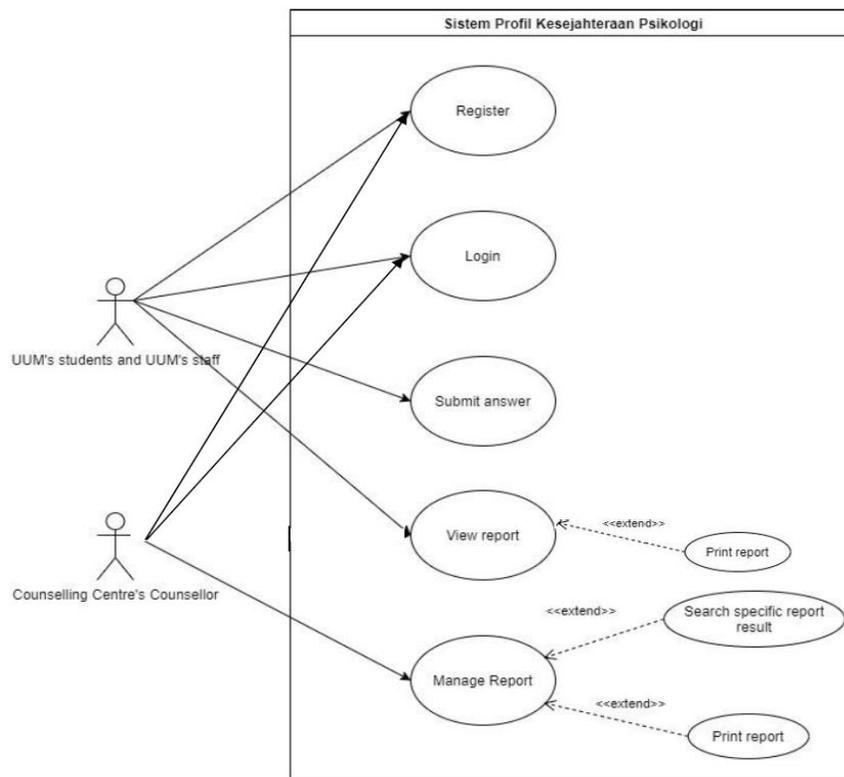

Fig. 3. The use Case Diagram of a Web-based Application for Conducting and Managing Psychological Tests.

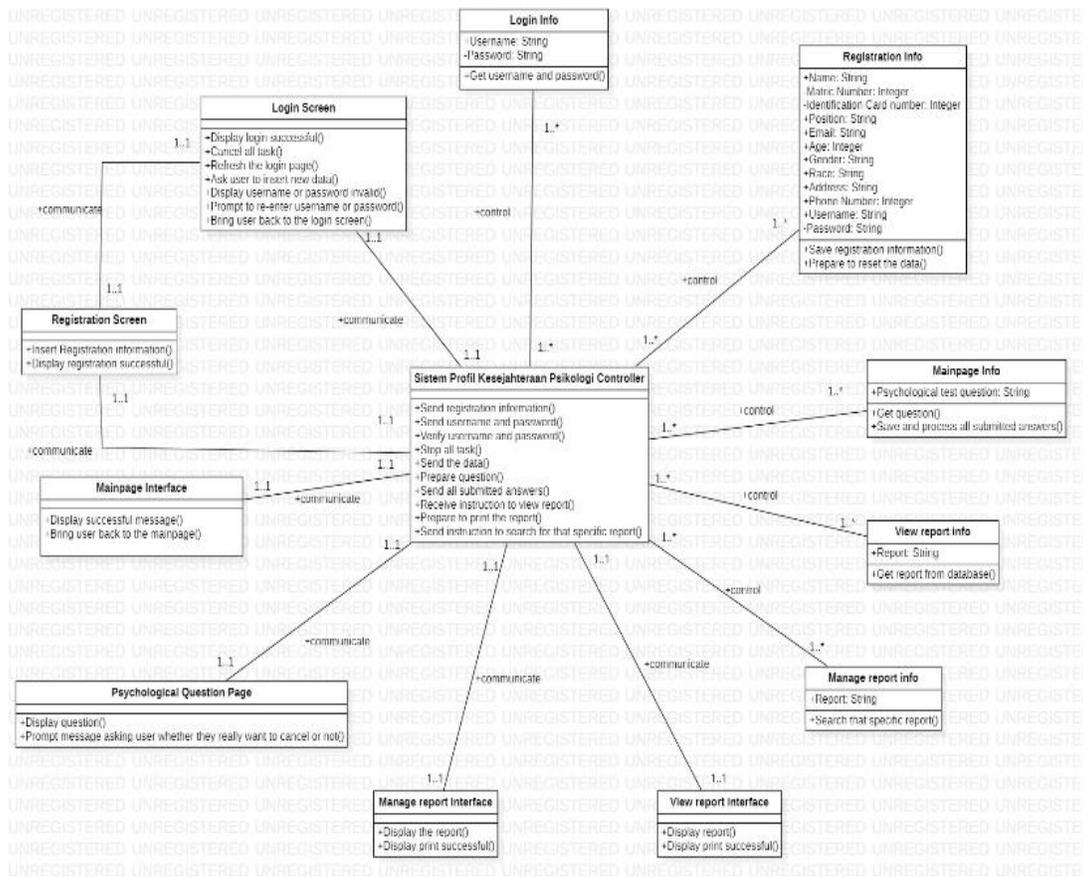

Fig. 4. The Class Diagram of a Web-based Application for Conducting and Managing Psychological Tests.

## V. THE SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI PROTOTYPE DEVELOPMENT

A prototype of a web-based application for managing mental health named SPKP was developed. It represents the requirements explained in the previous subsection. Software prototyping is a standard way of demonstrating the software requirements so that further comments and suggestions could be obtained from the users based on their experience in interacting with the prototype. The Visual Studio Code was used as the main platform to write the code for this system. Further, XAMPP was used to create the web server and phpMyAdmin as the database for the system. Print screen in Fig. 5 to 13 shows the selected interface of SPKP.

Fig. 5 interface shows the landing page of the system. This is the first interface user will see once they get into the system. This interface consists of four buttons on the left side which is the homepage or the landing page, about us, our counselor, and the login button. The about us button will bring the user to a new section where it will show information about what the counseling center does and its vision and mission. Our counselor button will list all counseling center's staff names, phone numbers, positions, and pictures. The last button is the login button for the user to log in to the system. The interface design is simple and easy for users to understand how to use it. There is no random button on the interface which might cause users to feel uncomfortable using the system.

Fig. 6 shows the login page of the system where users need to key in their email and password. Before login, the user needs to register first by clicking the register now hyperlink. If user forgot their password, they can reset the password back by clicking the click here hyperlink. The hyperlink is in the blue color so that users can easily see it and to make sure that users do not accidentally click it while using the system. The login button is in a red color box with white text so that it will enhance the button's look while the background color is black. This design will help users to recognize the button and know that the button is for login even without reading the text on it.

Fig. 7 shows the registration page of the system. Users need to register into the system by keying in their details such as name, matric no/ staff no, phone no, email address, and password. The interface design of the registration page is similar to the login page to keep the consistent look of the design. Hence, the design will not confuse the user whether the system is the same system or a different system if the interface design keeps on changing. All user needs to register or else they are not allowed to access the system.

Fig. 8 shows the main page of the system by user view. This interface can only be viewed by the students and the staff. The background layout is in pastel color to keep a calm atmosphere for the user while using the system. The interface has three columns representing three psychological tests modules which are the SSOSH test in a blue column, the SSKM test in a green column, and the D.A.S.S test in a red column. The reason why each column is in a different color is to differentiate between the modules. It means that regular users can easily recognize which column is for what psychological tests. Users can choose to answer which modules

to get the psychological test results. On the left side of the interface, there are three options in white text in a grey color layout which are home, report, and profile. Once the user finished answering the psychological tests questions, the user can view the results and the history of the results of the previous tests by clicking the report button. User also can edit their details such as passwords by clicking the profile button. The reason why the grey layout is on the left side is to put a systematic look at the interface.

Fig. 5. The Landing Page of the System.

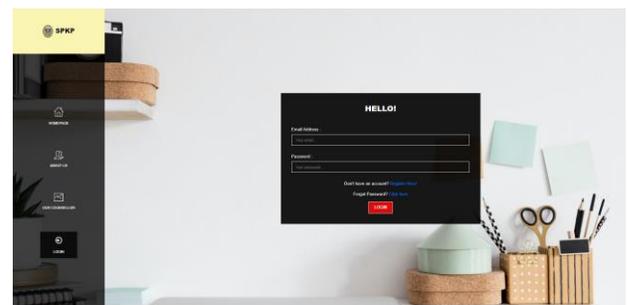

Fig. 6. The Login Page of the System.

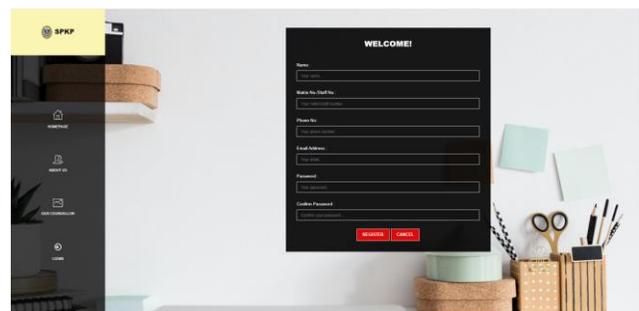

Fig. 7. The Registration Page of the System.

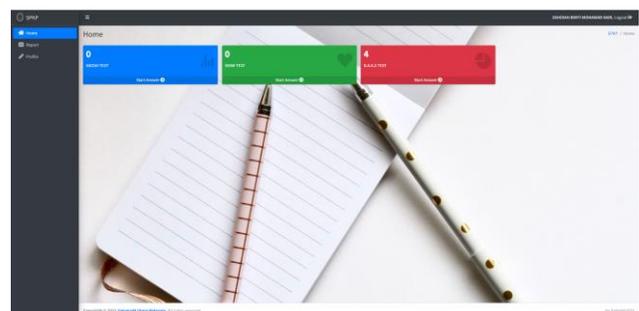

Fig. 8. The User Mainpage of the System.

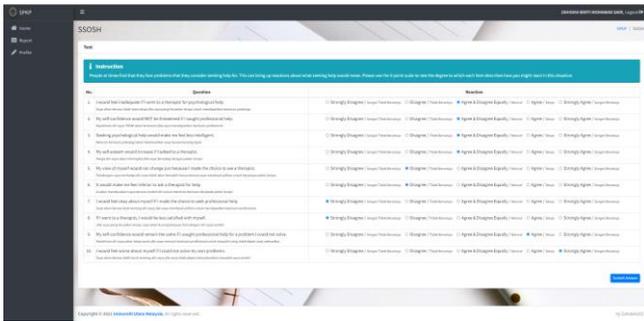

Fig. 9. The Interface for SSOSH Psychological Test Question.

Fig. 9 shows the interface of one of the psychological tests question which is the SSOSH test. This test consists of 10 questions. The questions are aligned in a box to create a systematic and nice look whereas the user can easily see all questions at once. The user does not need to click the next button just to see the next question. All question is compulsory to be answered or else the user cannot click the submit answer button. The reasons are to make sure the result that they will get is reliable and correct.

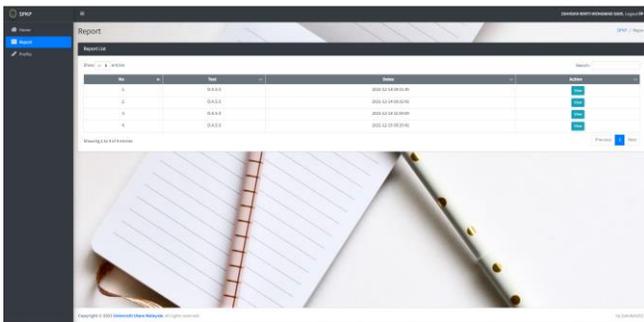

Fig. 10. The Interface for Psychological Test Report Result. (User).

Fig. 10 shows the interface of the test report result. The interface will list down all report results history. Not only that, but the user also can search for the specific report results by inserting particular report results keywords in the search box at the top right of the interface. The search box is at the top right so that users can easily see it.

Fig. 11 shows the main page of the system from the counselor's view. This interface consists of four columns which are the SSOSH test result in a blue column, the SSKM test result in a green column, the D.A.S.S test result in a red column, and user registration in a yellow column. Three columns are just the same as the user view side, only that there are no questions in it but instead there are report results of psychological tests of the users. The user registration column which is the yellow column, that column consists of a list of all registered user info such as their name and registration date. The interface design between the users and counselor view is not that different to keep the consistent looks and image of the system.

Fig. 12 and Fig. 13 show the interface for psychological test results from the counselor's view. The counselor can view all report results of all users by clicking the report button. The counselor also can search for the specific report results of the user by inserting the name or matric no/ staff no of the user in

the search box at the top right of the interface. The counselor can also print out the report result by clicking the view button which is in turquoise color and then clicking the print button which is in blue color.

## VI. EVALUATION OF SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI

### A. The Evaluation Setting

A usability evaluation was conducted on 30 respondents, consisting of students from Universiti Utara Malaysia. The respondents were approached randomly by sending out the Google form consisting of the questionnaire through WhatsApp. However, the respondents can choose to answer or ignore the questionnaire as there is no coercion. The instruments used for the evaluation were the SPKP web-based application and post-task questionnaire. The post-task questionnaire was adapted from [16] which consists of 33 items in four sections. Section A asked the respondents' demographic information while Section B, C, and D asked the

respondent's opinions about SPKP web-based application on a five-point Likert scale where one represents strongly disagree, and five represents strongly agree. The respondents performed the following step-by-step procedure for the evaluation: (1) read and signed a consent form, (2) interacted with SPKP web-based application as stated in the experiment procedure, and (3) answered the post-task questionnaire.

### B. The Respondents' Demographic Information

Analysis of the respondents' demographic information revealed that 70% of them were female and 30% of them were male. 86.7% of them were aged between 21 to 25 years old, 10% of them were 26 to 35 years old and 1% of them were 16 to 20 years old. It is also revealed that 83.3% of them once did

the psychological tests while the remaining 16.7% have never done it before.

### C. The Usability of Sistem Profil Kesejahteraan Psikologi

An analysis was conducted on the respondents' responses in Sections B, C, and D of the post-task questionnaire. The section measures the respondents' perception of SPKP's usefulness and ease of use. It also measured the respondents' satisfaction with SPKP. Tables II, III, and IV reported the frequency and average of the responses. The respondents rated four or five of the post-task scales for the three aspects of usability. None of the respondents rated one or two. Only a few rated neutral.

TABLE II. THE RESPONDENTS' RESPONSE ON THE USEFULNESS OF SYSTEM PROFILE KESEJAHTERAAN PSIKOLOGI

The post-task questionnaire items:	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	Average
SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI enhances my effectiveness on managing my mental health condition	0 (0%)	0 (0%)	0 (0%)	2 (6.7%)	28 (93.3%)	4.93
I can register an account in SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI without any error	0 (0%)	0 (0%)	0 (0%)	3 (10%)	27 (90%)	4.90
I can login the system with registered email and password	0 (0%)	0 (0%)	1 (3.3%)	11 (36.7%)	18 (60%)	4.57
The search button can function well	0 (0%)	0 (0%)	0 (0%)	10 (33.3%)	20 (66.7%)	4.67
I can answer all psychological test without any problem	0 (0%)	0 (0%)	2 (6.7%)	7 (23.3%)	21 (70%)	4.63
The report result that I got after answering all psychological test question are as expected	0 (0%)	0 (0%)	1 (3.3%)	8 (26.7%)	21 (70%)	4.67
It saves my time when I use this system to manage my mental health condition	0 (0%)	0 (0%)	1 (3.3%)	8 (26.7%)	21 (70%)	4.67
SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI meets my needs	0 (0%)	0 (0%)	1 (3.3%)	9 (30%)	20 (66.7%)	4.63
SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI is useful in overall	0 (0%)	0 (0%)	0 (0%)	6 (20%)	24 (80%)	4.80

TABLE III. THE RESPONDENTS' RESPONSE ON THE EASE OF USE OF SYSTEM PROFILE KESEJAHTERAAN PSIKOLOGI

The post-task questionnaire items:	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	Average
SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI is easy to use	0 (0%)	0 (0%)	0 (0%)	5 (16.7%)	25 (83.3%)	4.83
SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI is user friendly	0 (0%)	0 (0%)	0 (0%)	8 (26.7%)	22 (73.3%)	4.73
SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI is flexible	0 (0%)	0 (0%)	0 (0%)	12 (40%)	18 (60%)	4.60
SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI is easy to learn how to use it	0 (0%)	0 (0%)	1 (3.3%)	3 (10%)	26 (86.7%)	4.83
I can use SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI without written instruction	0 (0%)	0 (0%)	0 (0%)	7 (23.3%)	23 (76.7%)	4.77
I can easily remember how to use SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI	0 (0%)	0 (0%)	1 (3.3%)	2 (6.7%)	27 (90%)	4.87
I didn't notice any inconsistencies as I use SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI	0 (0%)	0 (0%)	0 (0%)	10 (33.3%)	20 (66.7%)	4.67
My interaction with the system would be clear and understandable	0 (0%)	0 (0%)	0 (0%)	9 (30%)	21 (70%)	4.70
I can use SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI successfully every time	0 (0%)	0 (0%)	0 (0%)	7 (23.3%)	23 (76.7%)	4.77

TABLE IV. THE RESPONDENTS' RESPONSE ON THEIR SATISFACTION OF SYSTEM PROFILE KESEJAHTERAAN PSIKOLOGI

The post-task questionnaire items:	Strongly disagree	Disagree	Neutral	Agree	Strongly agree	Average
I am satisfied with SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI	0 (0%)	0 (0%)	1 (3.3%)	3 (10%)	26 (86.7%)	4.83
I would recommend SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI to my friends	0 (0%)	0 (0%)	0 (0%)	7 (23.3%)	23 (76.7%)	4.77
SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI works the way I want it to work	0 (0%)	0 (0%)	1 (3.3%)	8 (26.7%)	21 (70%)	4.67
I feel I need to have SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI account in my PC/ Laptop	0 (0%)	0 (0%)	3 (10%)	8 (26.7%)	19 (63.3%)	4.53
SISTEM PROFIL KESEJAHTERAAN PSIKOLOGI is wonderful and pleasant to use	0 (0%)	0 (0%)	0 (0%)	7 (23.3%)	23 (76.7%)	4.77

The outcomes of the evaluation suggested that SPKP is useful and easy to use. Further, 86.7% of the respondents responded that they satisfied with the SPKP. 10% of them agree while 1% choose neutral. Analysis of the respondents' feedback about the specific features offered by SPKP shows that most of the respondents agree that the registration, login, search, and buttons were straightforward and useful with 80% of the respondents strongly agree with the statement that SPKP is useful in overall. Meanwhile, 20% of the respondents choose to agree with the statement. They also perceived that SPKP could help them in save their time in managing their mental health with 70% of the respondents strongly agree while 26.7% agree with the statement. However, there is 3.3% of the respondents unsure about the question. In terms of the user interface, the respondents reported that SPKP was easy to use without the need for written instruction and they can easily remember the way of using the web-based application system with 76.7% and 90% of the respondents respectively choose to strongly agree with the statements. Further, the respondents satisfied with the appearance of the web-based application and intended to recommend the web-based application to other.

## VII. DISCUSSION

It has been agreed that the advantages of SPKP are widely acknowledged by UUM students. According to the result that we get from the questionnaire conducted among UUM students, it shows that majority of the students agree that SPKP is useful and easy to use compared to the current method where the students need to go physically to the UUM Counselling Centre just to get their mental health tested. This current method is not efficient and consumes a lot of money and time. As we know, the majority of the students do not have any income and some of them were busy with study life. Hence, most of them tend to ignore any mental health problems like depression and stress. By the time they realize they need help, it was too late. According to a series of researches, suicidal people do not always identify that they have an issue or symptoms that could benefit from expert help. According to a poll of 165 college students at high risk of suicide who had not sought professional help, 66% of these students believed that counseling was unnecessary [17]. Therefore, there is a need for a new method that will benefit them in terms of managing their mental health condition.

Overall, among 30 respondents 80% of them agree that SPKP is useful overall in managing their mental health

conditions. This finding was conducted during the Covid-19 pandemic whereby the majority of the students and the staff were staying at home. Thus, conducting psychological tests physically at UUM Counselling Centre is impossible. By developing the system, they no longer need to worry about the Covid-19 pandemic whereby they can easily conduct their psychological tests tested anywhere and anytime they want. This system provides flexibility to them.

In order to attract user attention to using the system, the interface design of the system must need to be attractive, simple, and easy to use. A well-designed user interface can reduce training time, performance speed, error rates, user satisfaction, and the user's long-term retention of operations knowledge [18]. Based on the questionnaire conducted, 86% of the respondents stated that they feel satisfied with the system. However, there are some limitations to be considered while analyzing the study results. First, the sampling technique is only restricted to people with laptops or personal computers only as the system is a web-based application. Second, the research topic itself is not widely discussed and there are only a few related researches that can be used for this paper. Lastly, time is also one of the limitations faced while conducting this research.

Despite the limitations, this study provides the data of a web-based application system for managing mental health in higher institutions for future research. Questionnaires have been found as an effective way of assessing problems related to mental health and this becomes a method of conducting research during the Covid-19 pandemic. Results will make researchers be able to make decisions on what number of rating scale points to use for their survey and questionnaire [19]. Thus, the result of the questionnaire can be used for future research.

However, there is a need for improvements in certain areas such as the web-based application can be changed to a mobile application. Thus, there will be more people to receive the benefits of the system. It is because not every student is coming from a well-off family, so there are a few of them who cannot afford in buying a laptop or personal computer and only depends on a mobile phone. They couldn't afford a laptop, in part because they thought they'd used up all of their lending alternatives and, in part, because they didn't want to take out additional debt [20]. Hence, improving the web-based to the mobile applications can be a good idea.

### VIII. CONCLUSION AND FUTURE WORK

This paper described the design and development of a web-based application for conducting and managing psychological tests. In the end, the SPKP system is able to be developed, and hope that the system can really perform the work that it is supposed to do such as collecting, storing, retrieving, and calculating the result of the psychological tests for the UUM Counselling Centre. There are many aspects of psychological tests that can be studied. However, there are a few limitations while conducting this research where there is limited access to the data and there are also only a few previous research studies on the topic. Time is also one of the limitations we faced while conducting this research. In the future, we plan to expand the functionality of SPKP by making it available as a mobile application. Past studies suggested that psychological tests are a method conducted to know someone's mental health condition. However, some issues mentioned in the paper show that there is a need for improvement in a specific area so that the psychological tests can be conducted with ease. We also plan on making the web-based application responsive on multiple interfaces so that it will enhance user satisfaction when using the web-based application. It could also be extended into a recommender system which could suggest the counselor that is available at the moment in case the clients need further intervention without the need on making the appointment first.

### ACKNOWLEDGMENT

The authors would like to thank to all School of Computing of Universiti Utara Malaysia members who involved in this study. This study was conducted for the purpose of Undergraduate Final Year Project. This work was supported by Universiti Utara Malaysia.

**Abstract**—Cancer is a major health issue that affects individuals all over the world. This disease has claimed the lives of many people, and will continue to do so in the future. Breast cancer has recently surpassed cervical cancer as the most frequent cancer among women in both industrialized and developing countries and it is now the second leading cause of cancer mortality among women. A high number of women die each year as a result of this disease. Breast cancer is significantly easier to treat if caught early. This paper introduces a decision tree-based data mining technique for breast cancer early detection with highest accuracy, which helps patients to recover. Breast cancers are classed as benign (unable to penetrate surrounding tissue) or malignant (able to infiltrate adjacent tissue) breast growths. Two tests were included in the review. The primary study uses 10 breast cancer samples from the Kaggle archive, whereas the follow-up study uses 286 breast cancer samples from the same pool. The Decision Tree's accuracy in the first trial was 100%, while it was 97.9% in the follow-up inquiry. These findings justify the use of the proposed machine learning-based Decision Tree classifier in pre-evaluating patients for triage and decision-making prior to the availability of data.

**Keywords**—Data mining; decision tree; classifier; breast cancer

## I. INTRODUCTION

A huge number of cells make up the human body, each with its own unmistakable reason. Cancer is characterized as the uncontrolled proliferation of any of these cells. Cells partition and create uncontrolled, bringing about a cancer, which is an abnormal mass of tissue. Growth cells increase and infiltrate the stomach related, neurological, and circulatory frameworks, interfering with normal body capacities. Although not all growths are malignant [1].

Cancer is classed based on the sort of cell that is afflicted, and there are more than 200 distinct varieties of cancer. Breast cancer is the subject of this review. Breast cancer is the most continuous type of cancer in ladies and it is considered as a major cause of death from all cancers, especially among ladies [2]. There are no established methods for avoiding breast cancer at this time. Figuring out how to recognize breast cancer at an early stage, then again, will assist with peopling who are affected. Breast cancer fixes chances can be enhanced assuming that the disease is diagnosed early. Provided that breast cancer is diagnosed early can it be avoided and safeguarded. Among the several evaluating strategies for

classifying breast cancer, digital mammography is the most generally used [3].

Breast cancer survival rates have worked on considerably lately, regarding to the enhanced screening and treatment decisions. As a result of the advancements in data assortment and storage advances, medical organizations and hospitals may now store massive amounts of data associated with their medical records, including meds and disease indications. Data mining is the method involved with obtaining helpful information from large amounts of data utilizing complex algorithms. Medical data have broadened the applicability and potentials of these strategies [4]. Anticipating the result of a disease is a challenging task. Data mining strategies are regularly used to work on the expectation fragment. Large volumes of medical data may now be gathered and made available to medical research bunches using automated approaches. Thus, data mining apparatuses for finding patterns and correlations among countless variables are turning out to be increasingly normal, allowing for the forecast of ailment results based on recently gathered data [5]. However, most of the previous studies suffer from lack of accuracy in diagnose of this disease.

To fill in this gap, recognize and classify breast cancer at an early stage with high accuracy is very important in order to help patients to recover from this disease. Thus, this paper classified the breast cancer dataset by utilizing Decision Tree classification technique in WEKA. The breast cancer dataset is isolated and classified into categories based on features, performance, and different factors. Fig. 1 shows the entire interaction stream of the suggested paradigm.

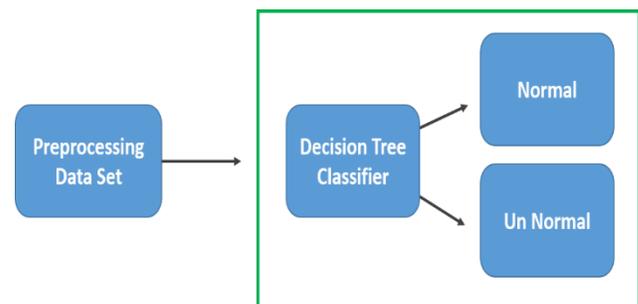

Fig. 1. Block Diagram of the Proposed Approach.

The classifier receives profound characteristics from the completely linked layer. The decision tree classifier makes use of these characteristics. After that, the characterization is complete, and all arrangement properties are defined. The suggested approach might be used to assess images of breast cancer.

The rest of this paper is organized as follows: Section 2 presents the mostly related works. Section 3 explains how decision tree can be used in the proposed paradigm. Section 4 discusses the experimental results. Finally, we conclude the paper in Section 5.

## II. RELATED WORK

Poomani and Porkodi conducted a study that aims to get the best classifier, by comparing different learning techniques [6]. The findings of their investigation reveal that the most elevated accuracy is found in the J48 classifier, which returns 0.979 with the least mistake rate of 0.9587 of all the classification methods. Their findings demonstrate that the combination of MLP and J48 classifiers with features determination Prognosis Breast Cancer (PCA) is better than different classifiers. In the Wisconsin Prognosis Breast Cancer WPBC dataset, their discoveries showed that the combination of IBK, J48, SMO, and MLP performs effectively. Saabithet et al. Compare numerous breast cancer data sets in, their research [7]. The extent of exactness with and without features selection techniques for breast cancer data was estimated utilizing classification algorithms like J48, MLP, and Rough. They conclude that the characteristic decision technique is the most reliable signifier process for enhancing the exactness of various categorization techniques, achieving the least Mean Standard Error (MSE) and the most elevated Recipient Operating Characteristics (ROC) to recognize breast cancer disease.

Peter et al. in [8] used two data mining approaches to quantify breast cancer gambles in Nigerian patients using the naïve Bayes algorithm and the J48 decision trees algorithms in their review exertion. The effectiveness of both categorization algorithms was evaluated to figure out which model was the most capable and beneficial. S. Syed Shajahaan, et al. [9] Compare DM approaches to model breast cancer data in a review. They took a gander at how to utilize decision trees to foresee the presence of breast cancer, as well as how to quantify the performance of conservative administered learning algorithms utilizing CART, C4.5, ID3, and Naive Byes. The ID3 random tree was demonstrated to be impressive with the most elevated accuracy in the investigations.

This study [10] compares the performance of the J48, AD Tree, BF Tree, and regression trees (CART) algorithms based on classification accuracy, using several accuracy measurements, for example, FP rate, TP rate, Recall, Precision, ROC Area, and F-measure. Decision trees are common and easy-to-understand structures from which rules may be obtained. Just the numerical values of explicit attributes in the breast cancer data are examined all through the implementation phase. The J48 classifier has the highest accuracy of close to 100%, while the CART algorithm has a 96 percent accuracy, the AD Tree algorithm has a 97 percent accuracy, and the BF Tree algorithm has a 98 percent accuracy. According to the classification findings of the four algorithms, it is obviously

shown that J48 beats the other three techniques for the predetermined data set.

In [13], they proposed utilizing gene expression data to classify triple negative and non-triple negative breast cancer patients using a machine learning (ML) technique. The Support Vector Machine approach, out of the four ML algorithms tested, was able to classify breast cancer more accurately into triple negative and non-triple negative breast cancer and had less misclassification errors than the other three.

Epimack et. al [14] presented a computer-aided diagnostic (CAD) system that generates an optimum algorithm automatically which use 13 of the 185 features available to teach machine learning. To distinguish between malignant and benign tumors, researchers deployed five machine learning classifiers. For 10-fold cross-validation, the experimental findings indicated Bayesian optimization with a tree-structured Parzen estimator based on a machine learning classifier.

## III. DECISION TREE LEARNING AS A PROPOSED TECHNIQUE

Breast cancer classification was considered in many recent researches [13][14] using most of machine and deep learning techniques, because such classification is very important to be accurate as much as possible since it is related with most of women lives.

A decision tree is described as a classifier using a recursive split of the instance space. It generates a predictive model that connects node observations to inferences about the desired value of the nodes. The leaf in a tree structure represents the class.

Labels and branches represent the attributes that lead to the class labels. Fig. 2 is an illustrative example of a binary decision tree [11].

The proposed technique comprises constructing a prediction model for detecting whether a tumor is benign or malignant based on various characteristics associated with a given medical record using a decision tree data mining methodology. A decision tree is an excellent tool for classification and prediction in the case of Breast Cancer diagnosis. A number of decision tree approaches are available to categorize the data. Following data pre-processing (in CSV format), WEKA (Java Toolkit for Different Data Mining Techniques) is used to apply the Decision tree algorithm to the dataset, and the data is classed as benign or malignant based on the decision tree's final conclusion. Fig. 3 depicts the flow of the research that was utilized to create the model.

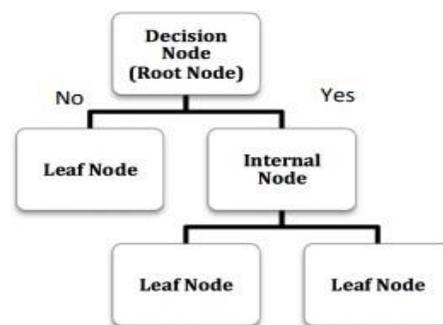

Fig. 2. Illustrated Example of Binary Decision Tree.

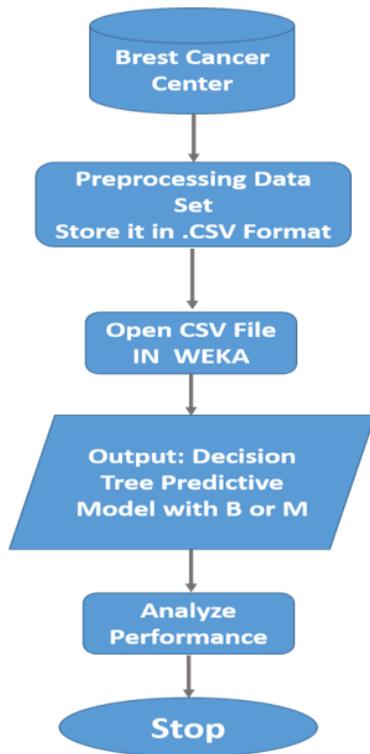

Fig. 3. Example of Binary Decision Tree.

The algorithm is carried out according to the following steps:

- 1) Collect datasets on breast cancer.
- 2) Pre-processing data in for performing the Decision Tree data mining approach (Benign, Malignant).
- 3) Data that has been pre-processed is submitted to the WEKA toolbox for analysis.
- 4) Implement the Decision Tree algorithm, which generates a decision tree with leaf nodes as class labels (benign and malignant).
- 5) New patient diagnoses are made by cross-referencing new attribute values in the decision tree and continuing the route until the leaf node is reached, which indicates whether the tumor is benign or malignant.

#### IV. EXPERIMENTAL STUDIES

##### A. Dataset

The CSV (Comma Separated Value) format was utilized in this study. Breast cancer data is supplied in CSV format via sex, age, menopause, tumor- size, inv-nodes, node-caps, deg-malig, breast, and breast-quad, irradiate, Class. These records were prepared in an Excel spreadsheet and saved as a CSV file, then uploaded to WEKA which accepted this format. In breast cancer data two types of properties, benign and malignant. In this study, these data are used and analyzed.

##### B. Experimental Results

The major goal of this paper is to evaluate the effectiveness of the breast cancer classification algorithms depending on a variety of input factors. They are analyzed using a Decision Tree algorithm. For the performance evaluation, the WEKA application is employed. Two setoff experiments are used to test each classifier. The first experiment has 10 samples. While the second one has 286 samples. This involves categorizing pre-processing based on all of the values of the attributes that have been taken. This paper compares the accuracy of categorization in the Decision Tree algorithm. The analysis of precision, FT Rate, and TP Rate is also performed. The following are the numerous formulas used to calculate various metrics. Precision P is calculated using the Formula (1) where TP = True Positive Rate, which is the proportion of expected positive instances, and FP = False Positive Rate, which is the part of the anticipated false positive cases:

$$Precision P = TP / (TP + FP) \quad (1)$$

The proportion of positive instances that were accurately detected has been described as True Positive Rate (TPR), Sensitivity, or Recall. Formula (2) will be used to calculate it:

$$Recall = TP / (TP + FN). \text{ Where } FN = \text{False Negative Rate} \quad (2)$$

$$Accuracy = (TP + TN) / (TP + TN + FP + FN) \quad (3)$$

The accuracy in (3) will be computed as the fraction of the total number of correct predictions, where TN = True Negative. The calculation of an average of the recall and precision measures for retrieving information, which called as F-Measure as shown in Formula (4).

$$F = (2 * Recall * Precision) / (Precision + Recall) \quad (4)$$

1) *First experimental results:* The first experiment has 10 samples of breast cancer [12]. Tables I to VI show the results of algorithms and compared with them.

Table I shows the summary of accuracy for proposed technique. Where the number of samples is 10.

Table II illustrates all the measures that used to evaluate the proposed method in details. We can see the proposed technique.

TABLE I. SUMMARY ACCURACY OF DECISION TREE ALGORITHM

Total Number of Instances	10	
Correctly Classified Instances	10	100%
Incorrectly Classified Instances	0	0%
Kappa statistic	1	
Mean absolute error	0.1429	
Root mean squared error	0.1429

Root relative squared error	28.5714 %	

TABLE II. METRICS RESULTS ACHIEVED BY DECISION TREE ALGORITHM

	TP Rate	FP Rate	Precision	Recall	F-Measure	MCC	ROC Area	PRC Area	Class
	1.000	1.000	1.000	1.000	1.000	1.000	1.000	1.000	0
	1.000	1.000	1.000	1.000	1.000	1.000	1.000	1.000	1
Weighted Avg.	1.000	1.000	1.000	1.000	1.000	1.000	1.000	1.000	

TABLE III. CONFUSION MATRIX OF DECISION TREE ALGORITHM

a	b	classified as
5	0	a = 0
0	5	b = 1

Table III shows the confusion matrix.

Table IV shows the summary of accuracy in a Random Forest algorithm, where the number of samples is 10.

Table V shows the values of the using measures to evaluate Random Forest algorithm classification.

TABLE IV. SUMMARY ACCURACY OF RANDOM FOREST ALGORITHM

<b>Total Number of Instances</b>	<b>10</b>	
Correctly Classified Instances	5	50 %
Incorrectly Classified Instances	5	50 %
Kappa statistic	0	
Mean absolute error	0.5	
Root mean squared error	0.5	
Relative absolute error	100 %	
Root relative squared error	100 %	

TABLE V. METRICS RESULTS ACHIEVED BY RANDOM FOREST ALGORITHM

	TP Rate	FP Rate	Precision	Recall	F-Measure	MCC	ROC Area	PRC Area	Class
	1.000	1.000	0.500	1.000	0.667	0.352	0.500	0.500	0
	0.000	0.000	0.000	0.000	0.200	0.352	0.500	0.500	1
Weighted Avg.	0.500	0.500	0.250	0.500	0.516	0.352	0.500	0.500	

TABLE VI. CONFUSION MATRIX OF RANDOM FOREST ALGORITHM

a	b	classified as
5	0	a = 0
5	0	b = 1

The results that attained from Tables I to VI illustrate the loss and accuracy throughout training and validation. Based on the results, it is clear that the maximum training and validation accuracy is seen in the Decision Tree architecture, with a loss rate of 0%. The Random Forest, on the other hand, achieves the lowest training and validation accuracy of 50% and a loss of 50% at iterations 100. Fig. 4 and Fig. 5 show that the loss values of decision tree equal to zero.

2) *Second experimental results:* When used large number of samples [12], the accuracy will be change as the Tables VII, VIII and IX. The classification of the attributes (age, menopause, tumor-size, inv-nodes, node-caps, deg-malig, breast, breast-quad, irradiat, Class) can be shown in the Fig. 6.

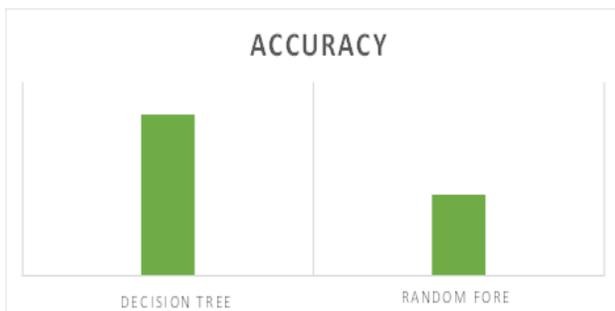

Fig. 4. Accuracy Comparison of Algorithms.

Fig. 5. Loose Comparison of Algorithms.

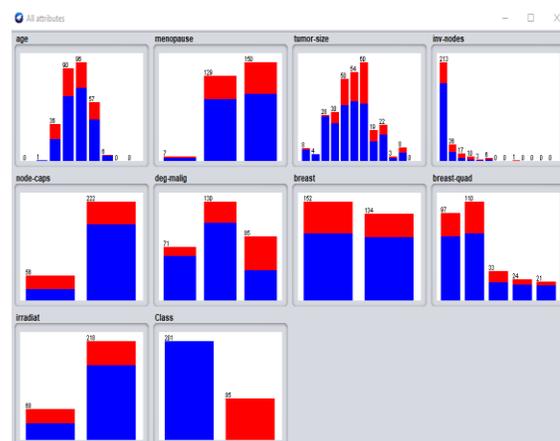

Fig. 6. Attribute Classification.

Table VII shows the accuracy summary in the Decision Tree algorithm, where the number of samples is 286.

Table VIII shows all measures values that were used to evaluate classification in studied methods.

TABLE VII. SUMMARY ACCURACY OF DECISION TREE ALGORITHM

<b>Total Number of Instances</b>	<b>286</b>	
Correctly Classified Instances	280	97.9021%
Incorrectly Classified Instances	6	2.0979%
Kappa statistic	0.9491	
Mean absolute error	0.0221	
Root mean squared error	0.1052	
Relative absolute error	5.2937 %	
Root relative squared error	23.0237 %	

TABLE VIII. DETAILED ACCURACY BY CLASS OF DECISION TREE ALGORITHM

	<b>TP Rate</b>	<b>FP Rate</b>	<b>Precision</b>	<b>Recall</b>	<b>F-Measure</b>	<b>MCC</b>	<b>ROC Area</b>	<b>PRC Area</b>	<b>Class</b>
	0.995	0.059	0.976	0.995	0.985	0.950	0.999	0.999	0
	0.941	0.005	0.988	0.941	0.964	0.950	0.999	0.996	1
Weighted Avg.	0.979	0.043	0.979	0.979	0.979	0.950	0.999	0.998	

TABLE IX. CONFUSION MATRIX OF DECISION TREE ALGORITHM

<b>a</b>	<b>b</b>	<b>classified as</b>
200	1	a = 0
5	80	b = 1

The results obtained from the Tables VII to IX demonstrate the loss and accuracy during the training and validation stages. The maximum training and validation accuracy are observed for Decision Tree architecture 97.9021% and loss is 2.0979%. These results show that the proposed technique is active in all cases. Fig. 6 illustrates the classification depending on attributes.

### V. CONCLUSION

This study demonstrates the use of decision trees to represent actual breast cancer diagnosis for local and systemic treatment, as well as additional strategies that may be employed. The study assesses the performance of the Decision Tree algorithm in terms of classification accuracy, using several accuracy metrics such as the F-measure, ROC Area, Precision, Recall, TP rate, and FP rate. Decision trees are well-known and simple to comprehend structures from that rule may be derived. The studied model's efficacy is demonstrated by experimental findings. For the detection of breast cancer, the effectiveness of the decision tree approach was evaluated and explored. Throughout the implementation phase, only the numerical values of particular breast cancer features are assessed. The experimental findings reveal that the Decision Tree classifier has a 100% accuracy rate, while the Random Forest method only has a 50% accuracy rate. The performance of Decision Tree is superior than the other method for the specified dataset on the basis of the four algorithms' categorization results.

**Abstract**—Indonesia has natural diversity in the form of tropical rain forests, the sea, flora, and fauna. Information technology adaptation is needed considering its development and use is getting higher, especially during the pandemic and post-pandemic periods. Through information technology in the form of E-books based on local wisdom, an attitude of caring for the environment grows. This research aims to combine information technology, environmental-based science learning, and local wisdom in growing students' environmental care character. Through the use of e-books based on Google's website as information technology in implementing a green science learning model that is oriented to local wisdom. This study develops and validates an e-book based on local wisdom through the ADDIE research design. The results of the analysis and discussion are that the development of an e-book based on Google's website with a green science model oriented to local wisdom is declared valid and feasible to use with an average percentage of 90.74% from the three experts. Then the results of student responses also showed a positive response from students with a percentage of 90.29%. The application of google site-based e-books in the green science model oriented to local wisdom in learning can increase the growth of environmental care characters for junior high school students as evidenced by the results of multiple regression analysis of significance 0.00 below 0.05.

**Keywords**—e-Book; Google site; green science learning model; local wisdom; environmental care character

## I. INTRODUCTION

In the new normal era after being released from the pandemic, Indonesia began to rise and begin to be able to adapt to the pandemic environment. Likewise, education was also affected by the pandemic which eventually adopted technology and information as a solution in the learning process. Adaptation in digital learning is beneficial in pandemic learning because it can reduce the spread of the coronavirus [1]. Layali et al in their research argue that E-learning can be positively accepted in learning during a pandemic [2]. In addition to the pandemic, Indonesia has experienced a decline in culture and care for the environment because people cannot leave their homes so cultural activities do not run effectively. Research conducted by Yanuarita & Haryati [3] took samples in socio-cultural conditions in Indonesia which showed a negative impact during this pandemic. Meanwhile, Indonesia is a country that is rich in cultural diversity. This culture has been passed down from generation to generation by the ancestors

until now. If these problems are not addressed, Indonesia can lose its original culture and education can also have an impact.

Local culture or local wisdom is also essentially the foundation of the philosophy of education in Indonesia as a filter in an outside culture that enters through electronic media. This local wisdom can also shape the character of discipline, honesty, cooperation, responsibility, environmental care, and tolerance [4]. This local wisdom can be developed and integrated into the educational curriculum [5]. Even in the research of Ratminingsih et al [6], learning media integrated with the local culture can increase students' basic competence in learning. In social life, local wisdom is ingrained and becomes a guide in determining a decision. The local wisdom can be expressed in the form of learning models or learning tools. Local wisdom is associated with scientific and rational real life. Local wisdom also has a relationship with the environment or nature so that local wisdom in learning is more contextual.

The green science learning model is a learning model that contains the characteristics of the learning model according to Arends [7]. The characteristics of the model include the underlying theory, learning objectives, syntax, and classroom management. The green science learning-oriented model is a learning model that is based on the environment. Environmental-based learning was first initiated by Jan Ligthart in 1859. The next figure who moved environment-based learning was J.J Rousseau. The learning idea is to bring students to real situations within the main learning environment. Piaget [8] supports this by stating that children's thinking in the formal operational period is no longer centered on what is seen, but can think of a hypothesis. Besides being able to have an impact on student character, the green science learning model also requires learning media and, books/student worksheets as an aid in learning.

Previous research on educational technology in general regarding the use of technology in learning has not discussed integration into aspects of local wisdom. For example in research Sindi et al [9] stated that today's education, especially in pandemic conditions, applies technology and information in the classroom because it includes kinesthetic, visual, and auditory aspects. Learning media in education in the digitalization era is now applying technology and information as mandatory. Constraints in digital learning are concentration

in learning, interaction in activities, and decreased motivation, but information technology-based learning can still find a place if it is packaged interactively and innovatively to generate enthusiasm for learning [10]. It is indeed needed in the development of learning media in technology because in the digital era there are now many programs that are used. According to Xin & Singh [11], the transformation in educational technology is now available in various platforms that can be used, such as e-learning, e-books, learning management systems, and evaluation systems learning. e-Books are part of the learning media in the form of interactive electronic-based textbooks for access [12], [13], [14].

The difference and the novelty of the research carried out is the development of e-books made into google sites for easy access, e-book content containing local wisdom-based science learning models in growing environmental care characters. The choice of developing an e-book makes it easier for students to access and use it because it can be used with electronic media [15]. The use of the google site is easier in design, development, and implementation, especially free and unpaid aid, which can be used by all groups. The cultural element is local wisdom in green science learning as character building. So to combine the components of technology, teaching, and culture, it is developed, integrated, and implemented to grow the character of caring for the environment.

## II. METHOD

### A. The Research Model

The research was conducted using a research and development (R&D) research model. The development procedure used refers to the ADDIE development model. Branch [16] describes the ADDIE model development procedure including analysis, design, development, implementation, and evaluation steps. The procedure for developing the ADDIE model in this study can be explained through the flow chart in Fig. 1 below:

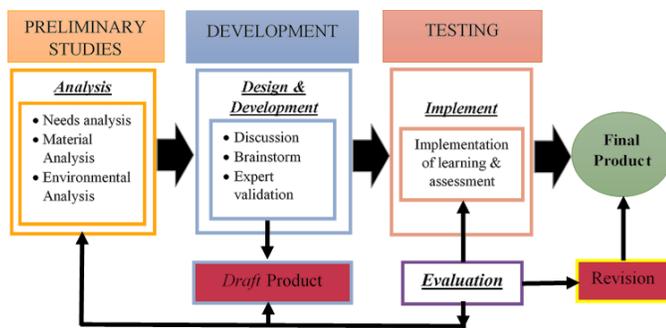

Fig. 1. ADDIE Model Development Flow.

Following Fig. 1 shows the stages of development to implementation. The analysis phase contains an analysis of needs in learning, especially during a pandemic and online learning. Regarding the need for technology and information in learning, these component examining into learning materials that can be linked to culture and environment in learning natural sciences. The Design and Develop stage is a follow-up to the analysis stage, which requires learning media that combines technology, local culture, and green

science learning model learning in growing the character of caring for the environment. The selection of e-books through the Google site as a development product with the contents of the green science learning model based on local wisdom foster a caring character for the environment. The developed learning media products are then tested for feasibility and discussed with the Experts in the Group Discussion Forum.

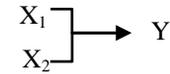

Fig. 2. Product Implementation Paradigm.

Product development results are implemented in learning to be tested using quantitative analysis. According to Fig. 2,  $X_1$  is the independent variable. The first independent variable is the development of e-books based on google sites,  $X_2$  is also the independent variable is a green science learning model based on local wisdom, and  $Y$  is the dependent variable is the character of environmental care. This is followed by the evaluation stage of the implementation of the e-book based on the Google site as a development product with the contents of the green science learning model based on local wisdom to cultivate the character of caring for the environment, questionnaires, and student responses.

### B. Research Sample and Instrument

To implement and evaluate product development, a sample of 32 students was taken at Bumiayu Junior High School, Brebes Regency, Indonesia to collect response data.

Evaluation of the application of student worksheets was taken using a questionnaire and student responses. The student response instrument using student worksheets also uses a response questionnaire. Both instruments use a Likert scale of 1-4 with a description of a score of 1 is not good, a score of 2 being quite good, a score of 3 being good, and a score of 4 being very good.

### C. Data Analysis

The feasibility test data is used to determine the feasibility of the product that has been developed through expert validation, which consists of 3 experts including material experts, technology media, and models. Furthermore, implementation is carried out to students to determine student responses using student worksheets. Taking expert validation sheets and student response questionnaires through qualitative data which is converted into quantitative data with a Likert scale of 1-4. Furthermore, the data is analyzed and considered feasible if it is declared valid using descriptive analysis. Based on the following equation (1):

$$P = \frac{\sum x}{\sum x^i} \times 100\% \quad (1)$$

Info :

$P$  : percentage of expert/practitioner validity.

$\sum x$  : total number of respondents' answers.

$\sum x^i$  : the total number of ideal scores in one item.

The data is then converted based on the validity conversion which can be seen in Table I.

TABLE I. VALIDITY CONVERSION GUIDELINES

Score Range (%)	Category
90 – 100	Very valid
75 – 89	Valid
65 – 74	Quite valid
55 – 64	Less valid
0 – 54	Invalid

The data from the implementation of the use of e-books based on google sites in the local wisdom-oriented green science learning model were analyzed through multiple regression tests. Multiple regression test aims to determine the effect of the use of e-books through Google sites in the local wisdom-based green science learning model on the character of environmental care. By using the IBM SPSS 25 application in multiple regression tests with the following hypothesis:

$H_0$  The variable of e-books based on google sites in the local wisdom-oriented green science learning model affects the character of caring for the environment.

$H_a$  Variable e-books based on google sites in the green science learning model oriented to local wisdom do not affect the character of caring for the environment.

The multiple linear regression equation used for data analysis on Eq. (2).

$$Y = a + b_1X_1 + b_2X_2 \quad (2)$$

According to equation (2), the values of  $X_1$  and  $X_2$  are independent variables of the study with  $Y$  as the dependent variable. Where  $a$  is a constant coefficient,  $b_1$  is a variable coefficient of  $X_1$  and  $b_2$  is a variable coefficient of  $X_2$  which is obtained from the results of data analysis.

The result of the multiple regression test is interpreted that the significance value of the SPSS calculation results is less than the degree of freedom, which is 5% (Sig. < 0.05), then the hypothesis  $H_0$  is accepted. This means that there is an influence on the use of e-books based on Google sites in the green science learning model oriented to local wisdom on the character of caring for the environment. Conversely, if the significance value is more than 5% (Sig. > 0.05), then there is no effect, meaning that  $H_0$  is rejected.

### III. RESULT AND DISCUSSION

The findings and discussions were carried out by developing an e-book of local wisdom oriented towards green science learning through the ADDIE design. The development of this e-book product was validated by several experts to test its feasibility. Then it was tested and evaluated on improving the attitude of caring for the environment in junior high school students. the ADDIE development process is produced as follows:

#### A. Analysis Stage

The analysis stage is carried out by analyzing needs, materials, and the environment. At this stage, as complete information as possible is extracted to obtain everything needed to proceed to the next stage. The analysis phase is carried out by direct observation of students, teachers, curriculum, and the school environment. The needs, material, and environmental analysis stages are carried out by analyzing essential learning materials and learning media so that they can be used in learning that relates to these myths and fosters an attitude of caring for the environment. The results of observations for the analysis of needs, materials, and the environment in the development of learning media, the following is a description of the analysis:

TABLE II. DESCRIPTION OF THE ANALYSIS STAGE

No.	Aspects analyzed	Analysis Results
1.	Need analysis	Innovative natural science learning based on technology without losing cultural and environmental values. By using an e-book-based Student Worksheet in which students interact in learning activities.
2.	Material Analysis	Natural science learning has themes and materials that can be related to cultures such as mythical culture and the environment. All of Indonesia has a wide variety of cultures and nature because it is an archipelagic country.
3.	Environmental Analysis	The education sector can contribute to environmental sustainability. Students are taught indirectly through learning in nature.

Table II shows the need for learning that combines learning about natural science, culture, and technology to develop e-books based on Google sites in a green science model oriented to local wisdom to foster an attitude of caring for the environment.

#### B. Design and Development Stage

The next stage is product development, namely from product drafts according to Fig. 3. The use of google sites is easy to use in the process of making e-books, without using complicated web coding, you can create good website features.

Fig. 3. Product Draft Start Page View.

Fig. 4. E-book Display in a Smartphone.

Even by using the Google websites that we have designed, they can be accessed in the form of a smartphone display as shown in Fig. 4. The goal is to facilitate access so that students can use it anywhere and anytime.

The feasibility test of the product development draft from Fig. 3 and Fig. 4 was carried out through a Forum Group Discussion (FGD) between product makers and experts who assessed the feasibility of the product. Each expert who participated in the FGD provided an assessment and suggestion for the product. The results of the e-book validation questionnaire based on Google sites in the local wisdom-oriented green science model from the Learning Model Experts obtained scores according to Table III.

Following Table III, the total score is 31, and the conversion score is 86.11%, so it is included in the Valid category. From the two scores, according to experts, the product model is valid and suitable for use in learning. Suggestions from model experts are to realize the application of e-books in the learning of green science models oriented to local wisdom with student activities in the environment.

The results of the e-book validation questionnaire based on google sites in the local wisdom-oriented green science model from the Material Experts obtained scores according to Table IV.

Based on Table IV, the total score of 32 is calculated, and conversion score is 88.89, so it is included in the Valid category. From the two scores, according to the expert, the product material is valid and feasible to be implemented or applied in learning. Suggestions from material experts for product development, namely the learning theme is made to foster an attitude of caring for the environment.

TABLE III. MODEL EXPERT VALIDATION SCORE

No.	Assessment Indicators	Score	Percentage Conversion Score	Category
1.	Products are presented systematically	4	100	Very Valid
2.	Each technology-based activity presented has a clear purpose	4	100	Very Valid
3.	The activities presented can foster conceptual understanding, environmental care attitudes, and observation skills	4	100	Very Valid
4.	The product provides sufficient answer space	3	75	Valid
5.	Use of google sites	3	75	Valid
6.	The language used is following the level of students' cognitive development	3	75	Valid
7.	The language used is communicative	3	75	Valid
8.	The sentences used are clear and easy to understand	3	75	Valid
9.	Clarity of instructions or directions	4	100	Very Valid
total score		31	86,11	Valid

TABLE IV. MATERIAL EXPERT VALIDATION SCORE

No.	Assessment Indicators	Score	Percentage Conversion Score	Category
1.	Products are presented systematically	4	100	Very Valid
2.	Each technology-based activity presented has a clear purpose	4	100	Very Valid
3.	The activities presented can foster conceptual understanding, environmental care attitudes, and observation skills	3	75	Valid
4.	The product provides sufficient answer space	4	100	Very Valid
5.	Use of google sites	3	75	Valid
6.	The language used is following the level of students' cognitive development	3	75	Valid
7.	The language used is communicative	4	100	Very Valid
8.	The sentences used are clear and easy to understand	3	75	Valid
9.	Clarity of instructions or directions	4	100	Very Valid
total score		32	88,89	Valid

The results of the questionnaire validation assessment of e-books based on google sites in the local wisdom-oriented green science model from Media Technology and Information Experts obtained scores according to Table V.

TABLE V. MEDIA TECHNOLOGY AND INFORMATION EXPERT VALIDATION SCORE

No.	Assessment Indicators	Score	Percentage Conversion Score	Category
1.	Products are presented systematically	4	100	Very Valid
2.	Each technology-based activity presented has a clear purpose	4	100	Very Valid
3.	The activities presented can foster conceptual understanding, environmental care attitudes, and observation skills	3	75	Valid
4.	The product provides sufficient answer space	4	100	Very Valid
5.	Use of google sites	4	100	Very Valid
6.	The language used is following the level of students' cognitive development	4	100	Very Valid
7.	The language used is communicative	4	100	Very Valid
8.	The sentences used are clear and easy to understand	4	100	Very Valid
9.	Clarity of instructions or directions	4	100	Very Valid
total score		35	97.22	Very Valid

Based on Table V, the total score is 35 and the result of the calculation of the conversion score is 97.22, so it is included in the Very Valid category. From the two scores, according to the Media Technology Expert, the product is very valid and feasible to be implemented or applied in learning.

Nine assessment indicators in validating e-books based on Google sites in a local wisdom-oriented green science model, each measuring the feasibility of several aspects. These indicators become the basis for the assessment of experts. Based on the scores obtained from the three experts, then the scores of the three experts on average obtained a score of 90.74% which means that the student worksheets are very valid and can be applied to local wisdom-oriented green science learning models.

The expert's assessment of the product is suitable for use in learning, the comments of the experts support technology as a means of learning media by combining culture. Due to the pandemic conditions that force people not to leave the house, learning is now adapting to online-based learning [17]. Through this e-book, students can be helped in re-learning the material because the content can be accessed anytime and anywhere. Expert comments regarding the development of e-books based on google sites which are implemented in a local wisdom-oriented green science learning model must be applied in learning to find out how it affects students.

### C. Implementation and Evaluation Stage

The implementation phase through the use of the product in grade 7 junior high school students as many as 32 students. The implementation is carried out by bringing students to open natural locations, precisely at Telaga Ranjeng in Brebes

Regency, Central Java Province, Indonesia according to Fig. 5. This activity is carried out by integrating technology, namely e-books based on Google sites that can be accessed via smartphone applications.

Fig. 5. Students Conduct Learning Activities at Ranjeng Lake.

Students are asked to carry out activities according to the instructions on the student worksheets in the e-book while at Telaga Ranjeng as shown in Fig. 5. Student activities continue to apply the health protocol when interacting with the environment and the community around Telaga Ranjeng. The teacher only directs and guides in activities and explains learning material. After the students carried out the activity, a response questionnaire was distributed to find out the student's responses to the student worksheet. From the results of the student response questionnaires obtained in Table VI.

TABLE VI. STUDENT RESPONSE QUESTIONNAIRE RESULTS

No.	Response Indicator	Total Score of Respondents	Percentage Conversion Score	Category
1	The e-book presented is interesting and based on information technology	120	93.75	Very Valid
2	Each activity presented has a clear purpose	102	79.68	Valid
3	Activities related to environmental care	104	81.25	Valid
4	Clarity of description of local wisdom	122	95.31	Very Valid
5	The clarity of local wisdom, namely the myth of Telaga Ranjeng in science learning	123	96.09	Very Valid
6	Accuracy of presentation of material with learning objectives	120	93.75	Very Valid
7	Environmental awareness in learning	123	96.09	Very Valid
8	The suitability of the material with google sites-based technology media	107	83.59	Valid
9	Use of standard and clear language	100	78.12	Valid
10	The language used is communicative	119	92.96	Very Valid
11	The sentences used are clear and easy to understand	124	96.87	Very Valid
12	Ease of use	123	96.09	Very Valid
TOTAL		1387	90.29	Very Valid

Based on Table VI, the percentage score of student responses to student worksheets is 90.29%, indicating that students after using and carrying out activities on the student worksheets have a positive response. Judging from direct observation, students enjoy and have fun during learning. Enjoy the learning process based on technology, environment, and local wisdom. During the learning activities, students were supervised and observed to collect data on the environmental care characters that grew in junior high school students. The environmental care character data were analyzed through multiple regression tests to determine the effect of the independent variable ( $X_1$  &  $X_2$ ) on the dependent variable (Y).

The results of the partial variable test in multiple regression analysis are to determine the effect of each/partial of the independent variables ( $X_1$  &  $X_2$ ) on the dependent variable (Y) obtained following Table VII using SPSS 25 software.

TABLE VII. THE RESULTS OF THE REGRESSION ANALYSIS OF EACH INDEPENDENT VARIABLE ON THE DEPENDENT VARIABLE

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	21,984	13,142		1,673	0,105
	X1	,430	,118	,496	3,634	0,001
	X2	,368	,123	,409	2,994	0,006

a. Dependent Variable: Y

Based on Table VII in row  $X_1$  obtained the value of Sig. 0,001 is smaller than the value of the degree of freedom, which is 0,05 ( $0,00 < 0,05$ ). Supported by the value of t-count SPSS analysis results in Table VII in row  $X_1$  get a value of 3.634 which is greater than the t-table that is 2,045 ( $3,634 > 2,045$ ). The significance interpretation and t-test analysis show that the  $X_1$  variable is the use of e-books based on google sites which affects the Y variable of caring for the environment.

This shows that the independent variable of e-books based on google sites can influence the development of environmental care characters for junior high school students. Through e-books based on Google sites in a green science model oriented to local wisdom, students are allowed to cultivate themselves individually with group collaboration. Research, by Harjono et al [18] stated that e-books by adding interaction features by adding student activities, videos, and animations helped in strengthening students' concepts. Alqahtani et.al [19] also in their research on the effectiveness of e-learning during a pandemic, the current e-learning needed must prioritize different individual learning and provide control to students in learning. Through interactive activities carried out in e-book content based on Google sites in a local wisdom-oriented green science model, students are invited to interact fully in learning activities.

The second independent variable analysis, seen in Table VII rows  $X_2$ , obtained the value of Sig. 0,006 is smaller than the value of the degree of freedom, which is 0,05 ( $0,006 < 0,05$ ). Supported by the t-count row  $X_2$ , the result of the SPSS Table VII analysis is 2,994, the value is greater than the t table is 2,045 ( $2,994 > 2,045$ ). The significance interpretation and t-test analysis showed that the variable  $X_2$

was the implementation of the local wisdom-oriented green science model which affected the Y variable for the environmental care character. The green science model itself applies the concept of environmental-based natural science learning, coupled with an Indonesian local wisdom oriented that is obedient and protects the environment in its application. The research of Sera et al [20], explains that local wisdom knowledge is considered very relevant to modern ecological principles so that it can be used in environmental or natural management. Ismawati [21] also stated that through local wisdom, we can instill environmental care with trusted habits and cultures. Christiawan [22] through strong local wisdom in an area can control the exploitation of nature, including forests. So, through learning the green science model oriented to local wisdom, students get to know environmental care by getting to know the culture that is embraced around them.

Then the results of the analysis of two independent variables ( $X_1$  &  $X_2$ ) on the dependent variable (Y). Data from e-books based on Google sites in a local wisdom-oriented green science model that is carried out to foster an attitude of caring for the environment. Based on multiple regression analysis using SPSS 25 software according to Table VIII.

TABLE VIII. THE RESULTS OF THE ANALYSIS OF MULTIPLE REGRESSION

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	194,897	2	97,449	12,928	0,000 <sup>b</sup>
	Residual	218,603	29	7,538		
	Total	413,500	31			

a. Dependent Variable: Y

b. Predictors: (Constant), X2, X1

Based on Table VIII in column Sig. shows a value of 0,000 when compared to the value of the degree of freedom of 0,05, the value is smaller ( $0,000 < 0,05$ ). It is confirmed that the calculated F value is 12,928 which is greater than the F table value, which is 3,32 ( $F_{count} > F_{table}$ ). Following the significant value and F value, a decision was made that the accepted hypothesis is that there is a simultaneous influence on the use of e-books based on google sites ( $X_1$ ) in the green science model oriented to local wisdom ( $X_2$ ) there is a simultaneous influence on environmental care characteristics (Y).

e-Books based on Google sites in the green science model are oriented towards local wisdom to foster an attitude of caring for the environment, basically instilling in junior high school students to protect the environment, ecosystem management, and conservation. Due to the effects of a pandemic that does not allow students to go out for activities, as a result, they form a character who is indifferent to the environment [23]. Combining technology, and green science learning, namely learning natural sciences based on the environment and local culture can grow the character of caring for the environment. It is evident from the results of the SPSS analysis in Table VIII which shows the simultaneous effect on increasing the character of caring for the environment by using e-books based on google sites in a local wisdom-oriented green science model.

This can also be applied in learning in other schools so that students have a sense of concern for their environment. The values contained in local wisdom are closer and closer because they are part of everyday life so they are easy to understand. According to Glasson et al [24] and Ilhami et al [25] also stated that learning that links local content will deepen the material and increase the community's sense of care for environmental sustainability. According to Uge et al [26], it is explained that local wisdom is rarely used properly, especially in learning it can have an impact on environmental sustainability. Sofyan et al. [27] also support local wisdom that is applied in learning, through modules based on local wisdom students can learn about the culture and the environment.

#### IV. CONCLUSION

The conclusion from the data analysis and discussion shows the success of combining information technology, green science learning and local wisdom through the development of e-books. The success of e-book development is shown by the percentage of the three experts, namely 90.74%, indicating that the e-book based on Google sites in a local wisdom-oriented green science model is declared valid and feasible to use. Activities and the use of student worksheets and from direct observation students enjoy and have fun during learning. The implementation also shows the results of multiple regression analysis of Sig.  $0.000 < 0.05$ , which means that the development of an e-book based on Google sites in a local wisdom-oriented green science model influences and fosters an attitude of caring for the environment.

#### V. RECOMMENDATIONS FOR FURTHER RESEARCH

Indonesia has a diversity of cultures and rich natural resources so it is necessary to introduce students so that they know about culture and the environment as well as learn. It takes learning to link culture and the environment both in media, models, teaching materials, and other learning materials

**Abstract**—In the sphere of IoT, one of the most significant issues is quality of service (QoS), which is critical for both developers and customers. As a result, IoT platform developers are working to enhance models that will meet consumer expectations in terms of IoT services meeting their expected specified levels of quality. The multidimensional architecture of the IoT platform, combined with the ambiguous mindset of consumers' thinking, makes QoS evaluation a difficult process. As a result, this study seeks to solve these issues and proposes a new paradigm for assessing QoS in IoT ecosystems. The proposed approach evaluates QoS in two steps, with the goal of assessing QoS at all levels. To address the issue of uncertainty, the metric values and QoS were represented using a fuzzy logic method. The model correctly estimated the QoS for 50 services in the dataset, and the results show that 16 services are classed as high quality, while 25 are rated as medium quality and the rest rated as low quality.

**Keywords**—IoT; internet of things; QoS; quality of services; fuzzy logic; evaluate; assess

## I. INTRODUCTION

The IoT service is a key component in IoT ecosystems and is actually considered to be the backbone of it. Obviously, service plays a crucial role in any IoT platform as it is always the center of attention for both providers and consumers, for after all, it is the source from which both ends of the equation are potentially going to benefit. In general, the concept of services as defined by [1] is the commercial transaction between two parties in which one party allows another to access specific resources. Recent years have witnessed a significant development in IoT market, in turn, the number of IoT services have increased rapidly. This rapid increase in IoT services has been on the rise due to the dramatic increase in the number of devices, that are considered the main source of IoT services. There is no unanimous opinion on the number of things that will connect to the Internet [2]. According to most surveys undertaken by reputable companies such as Gartner, HIS Markit, and Ericson, the number of internet-connected devices will reach nearly 30 to 50 billion in 2021. (excluding smartphones, tablets, and computers) [3]. However, according to a recent estimate which conducted by [4], the number of linked devices worldwide will approach 75 billion by 2025. This reported big jump in the number of devices gives an indication of the massive number of IoT services that we will have and underpins the projection of a significant increase in the number of IoT services in the near future.

This consequential growth in IoT market motivates huge number of consumers to adopt IoT services. However, one of the big challenges that face most of the consumers is how to find the services fulfilling their specific requirements among massive numbers of services that have similar functionality but different in non-functional attributes. Therefore, the IoT developers endeavor to develop IoT platforms that would allow consumers to have access to services meeting their requirements. One of the most requirements most consumers seek and are concerned with is the quality of Services (QoS). According to [5], QoS is the overall performance of a telecommunication system, computer network, or IoT platform, explicitly, the performance perceived by network or platform users, and there are numerous metrics used to measure performance. As QoS is a key metric in measuring the performance of IoT platforms, many researches have been conducted with the view to tackling the issue of QoS in terms of QoS metrics and assessment methods. Researcher in [6] addressed the challenge of how to meet the consumers QoS-based demand whereas [7] discussed the problem of how to calculate the aggregate QoS of a composite service.

As we have noticed, QoS has significant impact on IoT performance. Hence, many researches have been developed in order to address the all issues related to the QoS in IoT platforms. QoS assessment is one of the most challenging issues that must be taken into consideration in any IoT platform, for more explanation, to develop a convenient IoT platform that would allow consumers to get the services with the desirable level of quality, it is necessary first to have a convenient approach for assessment of the QoS. However, developing an assessment approach for QoS in IoT is a rather challenging task for several reasons including: initially, the architecture of IoT platforms is made up of many layers and each layer has a conspicuous impact on the QoS. Thus, firstly, we assume that assessment the QoS for one layer and ignore the other layers will give a result that doesn't express the QoS for all IoT platform, secondly, calculate the QoS for all layers but deal with each result of layer individually also will affect the final result of QoS for IoT platform. On the other side, the non-functional attributes (QoS metrics) are represented in numerical values, in contrast, humans always think in inexact ways in their daily life, and used linguistic terms such as Short/tall, close/far, and hot/cold. Therefore, we assume that the way of representing the metrics of QoS has a great impact in the final results.

The goal of this work is to address the issues raised above by offering a new method for assessing QoS in IoT ecosystems. The suggested model examines QoS in two steps, with the goal of computing QoS at the all layers. To address the uncertainty issue, we employed the fuzzy logic approach to describe metric values and compute QoS.

## II. BACKGROUND

### A. IoT Service Profile

The IoT service profile consists mainly of three models: Service profile, service model and service grounding, Fig. 1.

1) *Service model*: This model addresses the functional component of services at a high level; it specifies what a service does and is mostly used for service discovery [8].

2) *Service profile*: Mainly used for service selection. The goal of this section is to aid service selection by semantically describing the service's non-functionality. There are several QoS attributes that used to specify the non-functional of services such as: accuracy, reliability, security, reputation etc..

3) *Service grounding*: This section contains information about the message format and transfer protocol that are required for service invocation. Some models, for example, employ WSDL to deliver messages over common network protocols [9].

### B. IoT Architecture from QoS Prospective

Form QoS prospective, IoT architecture made up of three layers, the perception layer, the network layer and the application layer, Fig. 2. In the perception layer we find the IoT devices from which services publish. The network layer represents the medium communication used to transfer services such as WiFi, ZigBee. The application layer is the interface where the end users access the services. Each layer has its own QoS metrics and based on these metrics the quality of services will be computed.

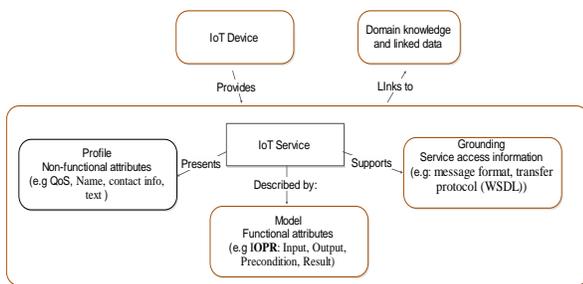

Fig. 1. Shows IoT Service Profile.

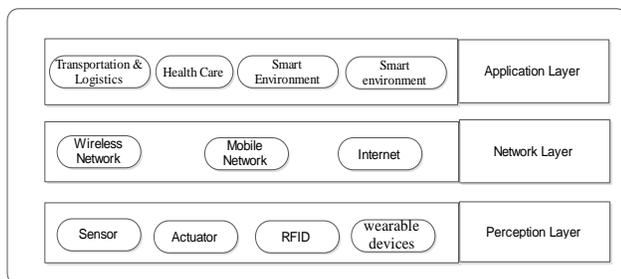

Fig. 2. Architecture in IoT from QoS Prospective.

1) *QoS of Perception Layer*: This layer is the backbone of the IoT and it is described as the five sense organs of IoT ecosystems [10]. In this layer we find the IoT devices. These can be the edge devices such as sensors, actuators, RFID, cameras, GPS, wearable devices that interact with their environment. Several QoS metrics can be defined under this layer and they include:

a) *Accuracy*: Accuracy is one of the parameters that play vital role in QoS. Accuracy of sensor as defined by [11] is the greatest uncertainty between a sensor's actual value and the standard value defined at output settings.

b) *Precision*: Precision refers to the sensors' capacity to measure the deviation in the output obtained when the same signal is measured repeatedly under the same conditions [11].

c) *Reliability*: Reliability provides a high degree of trust and trustworthiness during the operation of IoT systems [12]. The reliability also reflects the ability of systems to recover and self-configure in the changing environment.

d) *Sensor Time Constant ( $\tau$ )*: A sensor constant time is defined as the time required for the sensor reading/output to reach to 63.2% of its total step change in measurement" [13].

e) *Response Time*: It is defined as the time taken by the sensors to change its output state with the change in input parameters. The Sensors that have low response time are more desirable for any application [11].

2) *QoS of Network Layer*: Network layer connects the IoT devices to other smart objects, servers, and network devices, it is considered as an intermediate between the application layer and perception layer [14] [15]. Several QoS metrics can be defined under this layer and they include:

a) *Bandwidth*: Represents the measured amount of data that transmitted over network at a given period of time. For accessing, the ones with a high available bandwidth are preferred for accessing [11].

b) *Reliability*: If the packet arrives at its destination without any loss or security breach, the service is considered reliable. [15].

c) *Availability*: Availability represented as the percentage of time, in a specific time interval, during which network components such as (a server, cloud service, or other machine) can be used for the task that it was mainly designed and created for [16] [17].

d) *Security*: There is an increasing demand for security among the IoT users. Most of the users want to ensure that the network used to provide IoT services is secure and the information provided will be treated confidentially [18].

3) *QoS of Application (Cloud) Layer*: It is responsible of providing the user with application-specific services. or what the user interacts with [19]. Several QoS metrics which can be defined under this layer and they include:

a) *Price*: The price of getting services in IoT is one of the metrics that reflects the QoS.

b) *Reputation*: Reputation of IoT services is measured based on the individual's experience and reviews. Many

services selection approaches are customized based on the preferences [20].

c) *Availability*: As in sensor layer the availability also used as metric of QoS in application layer. It can be defined as a probability ratio that the service is operational and accessible when selected [21].

### III. RELATED WORK

The non-functional or QoS attributes are the key criteria when IoT end users need to select specific service to perform specific task. Therefore, it is important to develop an approach that allows providers of services to evaluate the QoS before making them available for the end users. Recently, many researches have been developed in order to improve tools to calculate or assess the QoS.

A study conducted by [22] investigated the problem of how to find the best service providers that offer smart parking services. The researchers identified 25 parameters that play a vital role in identifying the QoS in such a service. In [23], investigated the most suitable QoS criteria for optimal services selection problem in composition and classify them to the negative and positive criteria. In order to develop a good services evaluation model for IoT environment, a model based on multi-objective decision making (MODM) is proposed by [24]. The parameters that used to assess the QoS are: battery energy cost RE, CPU cost RC, memory usage RM, user-friendly RU and network bandwidth usage RB. The result obtained showed that this model successfully evaluated the QoS. A model based on fuzzy logic is developed by [25] in order to propose an assessment method to evaluate the level of QoS in IoT. The authors used execution time and reliability as the measurement metrics to the QoS. Fuzzy Logic Estimating Level (FLEL) estimates the QoS level by performing many tests. To evaluate the model, the researchers compares the proposed model with the existing model such as a Randomization Test (RT) and the estimating method by a Single Test in Steps (STS), and the result revealed that the efficiency of the FLEL is close to the STS and RT or even higher through the comparison of Average Paased Times APTs. in [26], a model developed to assess the QoS in IoT network layer. The parameters used in this study are end to end delay, energy consumption, energy fairness, jitter, throughput, routing load, packet delivery ratio and normalized routing overhead. The QoS of each parameter is evaluated by testing the performance of each parameter by increasing and decreasing the number of nodes in IoT network. The result obtained showed that, as the number of nodes grows, the performance of QoS measures such as end-to-end delay, energy consumption, energy fairness, routing load, and normalized routing overhead improves.

In [27], a model for evaluating QoS is developed based on five attributes. The attributes are classified in two categories: positive attributes (reliability, reputation, security) and negative attributes (cost, response time). To compute the QoS, the weight for each attribute is identified based on users' preferences, then the QoS is aggregated for negative and positive attribute separately using tow aggregation formulas.

To improve the services selection, [28] developed QoS model based on three components of IoT (things, communication and computing). The model provides description to the services in all three components. The aim of this study is to improve the services selection by considering the QoS in the three mentioned components. Evaluation of the quality of services in the proposed model passes through three steps: first the QoS parameters will be identified; secondly, the weight of each QoS parameter is calculated using Analytic Hierarchy Process (AHP) method. In the last steps the IoT services are ranked by using Order Preference by Similarity to Ideal Solution (TOPSIS). To validate the model, it compared with AHP, the evaluation showed that execution time taken by AHP- TOPSIS is less that than the time taken AHP.

A QoS model was established by [21] in order to compute QoS in the application layer. The main goal of this study is to tackle the issues of selecting the ideal service among similar functionally identical services and varied non-functionality needs. They classified the QoS factors into two categories: the first one is Business Quality Type (BQT), which assesses the quality of services from a business view point, the factors in this type like Reputation and Execution Price. The second type is System Quality Type (SQT). This type relates to the processing time of system and used factors such as Reliability, Availability and Response Time.

As we have seen, though the assessment of QoS in IoT ecosystems has been addressed by many researchers, however, some of the adopted solution developed based one specific layer and ignore the other layers. Moreover, most of the proposed solution did not consider the fuzziness of the QoS attributes. Therefore, in this paper is going to address all these issues by proposing new approach for computing the QoS in IoT ecosystems.

### IV. ASSESSMENT QoS MODEL

In this research our assessment QoS model is based on a new approach. The model is based on three-layers IoT architecture as shown in Fig. 2. We used the fuzzy logic system to assess the QoS in each layer. The assessment of QoS performed in two stages (Fig. 3).

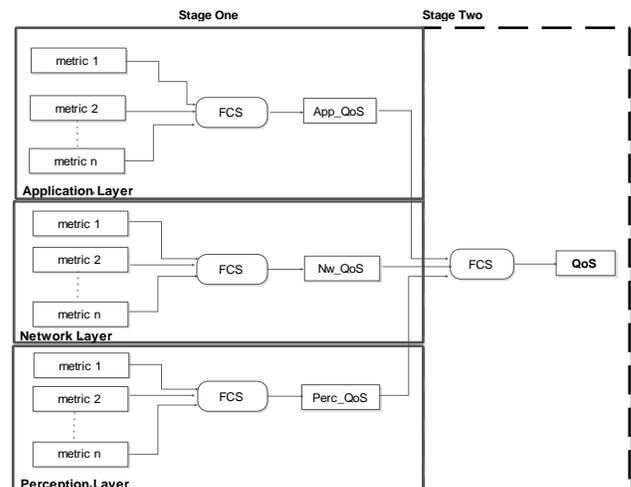

Fig. 3. Show the Two Fuzzy Stages of Assessment QoS for IoT Services.

In the first stage we have three FCSs which assess the QoS in perception layer, network layer and application layer. The metrics of each layer represent the inputs of the FCS. The result of this stage is three outputs named Perc\_QoS, Nw\_QoS and App\_QoS, which represent the QoS of perception layer, network layer and application layer, respectively.

In the second stage the Perc\_QoS, Nw\_QoS and App\_QoS obtained from first stage will be inputs of the FCS of the second stage. The result of this stage is the QoS which represents the final output of the system. The methodology that we used to perform the two stages mentioned is fuzzy control system which based on Lotfi A. Zadeh's fuzzy logic theory, which was developed in the 1960s to offer mathematical rules and functions that allowed natural language queries. The general idea behind the Fuzzy Logic is to mimic the way humans think [29], which tends to think in approximate rather than precise terms [30]. In other word, fuzzy logic is a method for describing and processing vague information that is commonly used by humans in their daily lives. Unlike traditional propositional logic, fuzzy logic assigns numeric values between 0 and 1 to each proposition in order to reflects uncertainty [31]. It is possible to calculate the degree to which an item belongs using fuzzy sets. For example, if a person is.83 tall, they are considered "rather tall." Fuzzy logic determines the shades of gray between black and white and true and false. The fuzzy logic control system typically consists of three major components, which are as follows:

(1) fuzzifier (2) inference rules and (3) defuzzifier. These components represent the sequences processes of the fuzzy logic controller (Fig. 4).

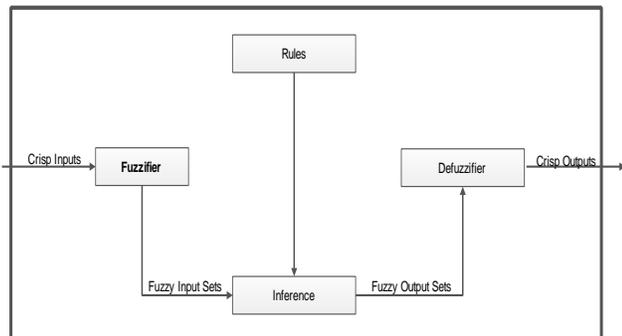

Fig. 4. Shows Fuzzy Logic Control System Architecture [32].

### A. Fuzzification

This is the first step in developing FCS which explains the process of converting a set of crisp data into a set of linguistic variables using the membership functions (fuzzy sets) [33]. Fuzzification is a useful tool for dealing with vague and uncertain information, which can be objective or subjective. The membership function chart can be drawn in a variety of ways, including triangles, trapezoids, bell curves, or any other shape that accurately represents the distribution of information inside the system. A triangular fuzzy number is represented by a triplet (a, b, c), as shown in Fig. 5, and the membership function is calculated by equation (1):

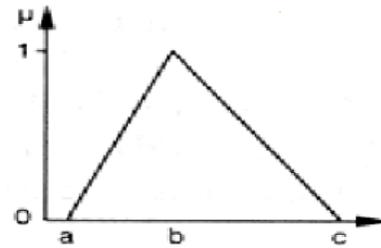

Fig. 5. Shows a Triangular Fuzzy Shape [34].

$$\mu(x) = \begin{cases} \frac{x-a}{b-a} & a \leq x \leq b \\ \frac{c-x}{c-b} & b \leq x \leq c \\ 0 & \text{otherwise} \end{cases} \quad (1)$$

A trapezoids fuzzy number is defined by four variables (a, b, c, d), as shown in Fig. 6, and the membership function is calculated by Equation (2):

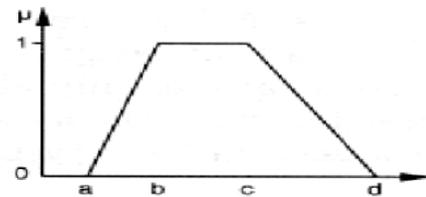

Fig. 6. Shows a Trapezoid Fuzzy Shape [35].

$$\mu(x) = \begin{cases} \frac{x-a}{b-a} & a \leq x \leq b \\ 1 & b \leq x \leq c \\ \frac{d-x}{d-c} & c \leq x \leq d \end{cases} \quad (2)$$

### B. Inference Mechanism

This is the main intelligent control of this system. Forming the rules base doesn't has systemic tools that can be used as standard in developing the fuzzy logic controller [30]. As a controller designed as expert system, thus, developing the rule base depend on intuitive knowledge and the experience.

### C. Defuzzification

After examining the fuzzy rules, the defuzzification component of fuzzy logic converts the fuzzy data values into real-world data values, and these real-world data values are determined by the defuzzification method. Different methods are used for defuzzification process such Center of Gravity (SOG), Weighted Average method, Mean of Maxima (MOM) and Smallest of Maxima (SOM). These methods are set by the controller designer.

## V. IMPLEMENTATION AND RESULTS

Based on the above definition and steps of developing FCS, we used Fuzzy Logic Designer in MATLAB to develop the proposed model. Our purpose of this research is to assess the QoS of IoT service in all layers. As shown in Fig. 3, the calculation of QoS will be performed in two stages:

A. Stage One

In this stage we develop three FCSs for the three layers. For straightforwardness we selected two metrics in each layer to represent inputs for FCS. Upcoming in this we will describe in details the steps of building the FCS for the three layers:

1) *Fuzzification*: For each layer we choose two QoS metrics to represent the inputs of the FCS. For example, we choose price and reputation for application layer, bandwidth and reliability for network layer and accuracy and response time for perception layer. Then we identified the fuzzy set of each input and outputs in each layer as showed in Table I and Table II.

We used triangular and trapezoid shapes to represent the fuzzy set for all inputs and outputs in the three layers.

2) *The rule base*: The inputs identified in the fuzzification step will be applied to a set of IF/then control rules in this step. The results of this step are combined to produce a set of fuzzy outputs. In our proposed model we have 2 inputs for each layer, and each input has 3 fuzzy sets, as showed in the Table I. Therefore, the number of control rules that we need will be based on the equation (3) below:

$$\text{Number of control rules} = n^m \tag{3}$$

where n = the number of fuzzy sets and m = the number of inputs.

By applying the above rule, number of control rules =  $3^2 = 9$  rules (for each FCS).

In this paper we used (And) as conjunction operator to form the rules as showed below:

If (metric1 is membership function1) and (metric2 is membership function2) then (output is output membership function).

TABLE I. SHOWS THE FUZZY SETS FOR INPUTS

Layer	Input Parameters	Fuzzy set	Universe of Discourse
Application Layer	Price	Cheap, medium, Expensive	0 – 15
	Reputation	Low, Medium, High	0 – 100
Network Layer	Bandwidth	Low, Medium, High	0-100
	Reliability	Low, Medium, High	0-100
Perception Layer	Accuracy	Low, Medium, High	0-100
	Response time	Fast, Medium, Slow	0-1

TABLE II. SHOWS THE FUZZY SETS FOR OUTPUTS

Output Parameters	Fuzzy set	Universe of Discourse
App_QoS	Low, Medium, High	0 -10
Nw_QoS	Low, Medium, High	0 -10
Perc_QoS	Low, Medium, High	0 -10

3) *The defuzzification*: Since the outputs from the previous step still fuzzy and uncertain, a defuzzification process is needed. The function of the defuzzification is to convert back the linguistic variable obtained from the previous step into numerical value in order to make the fuzzy output suitable to use in real application [36]. we used the MOM fuzzification method in order to get the results. From this step we received three outputs which represent the QoS for IoT services in perception layer, network layer and application layer, these outputs are Perc\_QoS, Nw\_QoS and App\_QoS respectively.

B. Result of Stage One

To test the new model, we used the random function in MATLAB to generate a data set of 50 services. By applying the model to this stage, the model successfully calculates the QoS for all 50 services in perception layer, network layer and application layer. The Table III shows random samples of results obtained in this stage.

TABLE III. SHOWS SAMPLE OF RESULTS OF STAGE ONE

Service_ID	App_QoS	Nw_QoS	Perc_QoS
1	5.00	5.10	5.10
5	5.00	5.10	3.50
8	8.50	8.50	4.20
9	5.00	8.50	5.10
10	1.10	5.10	0.10
11	5.00	1.40	7.50
12	5.00	8.50	5.10
13	1.30	8.50	0.10
16	1.10	1.40	7.60
17	5.00	5.10	0.10
21	1.40	1.10	3.20
24	1.10	8.50	5.10
31	5.00	1.50	3.90
33	8.50	0.80	7.40
35	5.00	5.10	7.90
50	8.50	8.50	0.10

C. Stage Two

The FCS for this stage is based on the outputs of the FCSs of stage one. As we mentioned before, we received three outputs from the FCSs of stage one, which are: App\_QoS, Nw\_QoS and Perc\_QoS. These outputs will be the inputs of the FCS for this stage. To develop the FCS, we follow the same steps as in the first stage.

1) *Fuzzification*: In this step we identified the fuzzy set of the inputs parameters as shows in Table IV.

The result of this stage is one output which represents the QoS. And as the purpose of this research is to assess the Quality of IoT service and put it into three categories (high quality, medium quality and low quality), we identified the fuzzy set of the output based on these categories, Table V.

TABLE IV. SHOWS THE MEMBERSHIP FUNCTION FOR INPUTS

Inputs Parameters	Fuzzy set	Universe of Discourse
App_QoS	Low, Medium, High	0 –100
Nw_QoS	Low, Medium, High	0 –100
Perc_QoS	Low, Medium, High	0-100

TABLE V. SHOWS THE MEMBERSHIP FUNCTION FOR OUTPUTS OF FCS FOR STAGE TWO

Outputs Parameters	Fuzzy set	Universe of Discourse
QoS	Low, Medium, High	0 –10

We used triangular and trapezoid shapes to represent the fuzzy set for all inputs and output in FCS Fig. 7(a-b-c-d).

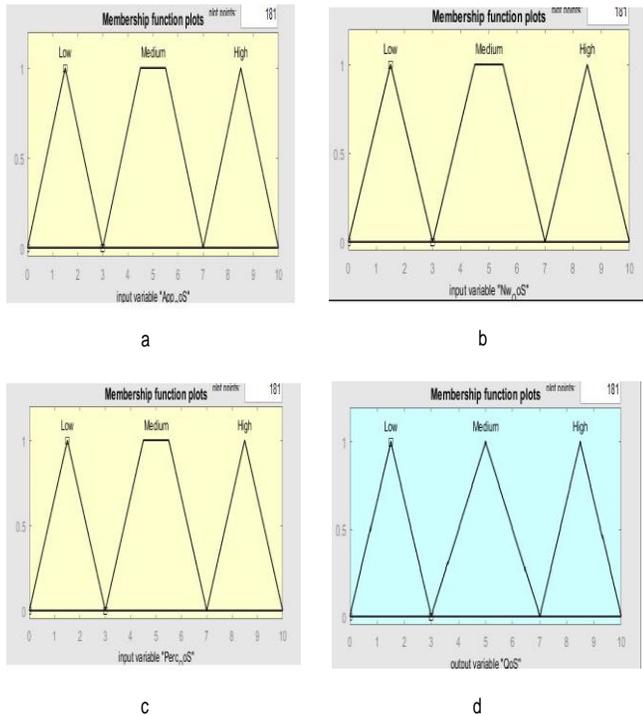

Fig. 7. Shows the Representation Fuzzy Set for Inputs and Output.

2) *The rule base:* As we have 3 inputs and 3 fuzzy set for each input, and referred to the equation (3), the number of the rules will be  $= 3^3 = 27$  rules.

3) *The defuzzification:* We received from the previous step the output which represents the QoS. To convert the fuzzy output to crisp form, we used MOM defuzzification method.

#### D. Result of Stage Two

The result obtained from stage one has become the dataset for stage two. By applying the dataset in this stage, the model successfully calculates the QoS for all 50 services which are based on the three layers. Table VI shows the final result we obtained and which represents QoS of some of the targeted services.

TABLE VI. SHOWS QoS OF SOME OF SERVICES

Service_ID	App_QoS	Nw_QoS	Perc_QoS	QoS
1	5.00	5.10	5.10	5.00
5	5.00	5.10	3.50	5.00
8	8.50	8.50	4.20	8.50
9	5.00	8.50	5.10	8.50
10	1.10	5.10	0.10	1.50
11	5.00	1.40	7.50	5.00
12	5.00	8.50	5.10	8.50
13	1.30	8.50	0.10	1.50
16	1.10	1.40	7.60	1.50
17	5.00	5.10	0.10	5.00
21	1.40	1.10	3.20	1.50
24	1.10	8.50	5.10	5.00
31	5.00	1.50	3.90	5.00
33	8.50	0.80	7.40	8.50
35	5.00	5.10	7.90	8.50
50	8.50	8.50	0.10	8.50

## VI. DISCUSSION

Through two stages our model calculated the QoS for 50 services. In the first stage the model calculated the QoS for all services in perception layer, network layer and application layer. Then in the next stage the model used the results of the first stage to calculate the QoS for all targeted services. Unlike other approaches which calculate QoS by focusing on some layers and ignore the other layers, or calculate the QoS in all layers but deal with each layer separately, our model evaluated the QoS in three layers and combined the results of all layers in order to get the final result which represents the QoS for all targeted services.

Based on the final result obtained and reference to the range of fuzzy set of QoS parameters that we identified earlier in the FLC Fig. 7(d), we have successfully classified the all services into three categories: high quality services, medium quality services and low quality services. Based on this classification: the number of high quality services is 16, the number of the medium quality services is 25 and the number of the low quality services is 9.

Our findings show that our model was able to calculate the QoS for all services in the dataset. As a result, the model will be of great assistance to service providers by providing them with convenient tools that allow them to accurately assess QoS before delivering it to end users. In addition, the model enables end users to request services using linguistic terms rather than numerical values. When compared to existing models such as AHP-TOPSIS, our developed model is more flexible while AHP-TOPSIS is very restricted because the end user is required to use numerical values to identify the weight of each metric. To explain this point, for example suppose that we have a user need an IoT services with a medium quality. In AHP-TOPSIS the user must use numeric value as the model does not support fuzziness. The user has to say (“I need a service with

quality = 55”), but if there is no service with exact number in registry, the system will replies “null”, maybe in registry there are services with medium quality = 56 or 54, But because the AHP- TOPSIS model is very restricted, the other services will not be recommended to the end user. In our model we have solved this problem by using fuzzy logic technique. Instead of use numbers, end user just has to say (“I need a service with a medium quality”), immediately the model will recommend 25 services that match the user requirement.

To validate the model, we compare its execution time with AHP-TOPSIS. AHP-TOPSIS took 0.0386 second to rank 50 services, whereas our model took 0.2274 second to assess QoS for 50 services. This slight increase in execution time in our developed model is due to the model calculating QoS across all layers and then aggregating the results to obtain the final results.

## VII. CONCLUSION

Delivering a service that meets certain standards of quality demanded by end users in the realm of IoT has clearly piqued the interest of many academics. As a result, it is essential to first build a model that allows IoT service providers to measure QoS before making them available to users. We solved this issue in this research by building a novel model that allows us to calculate QoS for all targeted services. The main contribution of this model lies in the evaluation of QoS in IoT platforms at the level of three layers. Moreover, the model used the fuzzy logic system in order to support the uncertainty thinking of humans. Over all, the model provides IoT services providers with a convenient tool which allows them to evaluate QoS for all available services. In future work, firstly we will try to improve the performance of the model, then we will use the results obtained from this model to develop a selection model that would allow IoT service consumers to select the kind of services meeting the levels of Quality they anticipate and look for.

**Abstract**—Hypertension is currently rising steadily among the world population. The first level of screening to know whether one is suffering from hypertension is essential as this lays the foundation for the actual diagnosis. This research details the user interface design and usability evaluation of the hypertension management guideline. The proposed mobile application prototype assists people in screening themselves with regards to hypertension based on symptoms. This prototype also acts as a sharing platform for hypertension patients to help them share their concerns and advice within the related online community. The eye-tracker experiment was used to support the visual strategy of the prototype design. In studying the usability of the mobile application, an experiment carried out with two groups of people, of which one group of people have hypertension. In contrast, the other group of people do not have hypertension. An independent-samples t-test conducted to compare the user performance scores using the proposed prototype. Based on the usability study, both user groups understood and used the applications with ease. However, the findings revealed there was a significant difference in overall scores for hypertension patients and non-hypertension patients. The findings of this study could help software developer design an effective application for hypertension guideline tool for monitoring health and well-being.

## I. INTRODUCTION

High blood pressure (hypertension) is not usually something that one can feel or notice. It does not give any symptoms ahead or apparent signs. The only way to know that one is suffering from high blood pressure is to have it measured [1-2]. Recently in 2015, a survey was conducted by National Health and Morbidity concerning hypertension. Based on the overall prevalence of hypertension, 30.3% hypertension-related disease is among adults of 18 years and above in Malaysia. Apart from age, hypertension patients are also categorized based on the grouping of areas. In rural areas, the prevalence of people suffering from hypertension is 33.5% compared to an urban area with a percentage of 29.3%. Other findings from the survey are that the overall percentage prevalence of people suffering from hypertension according to their gender is lower among females with 29.7% whereas higher among males with 30.8%. The survey result provides the observation that hypertension diseases can attack anyone regardless of their age, gender, and even their place [3]. This evidence directs that hypertension is a severe and dangerous

disease and should be firmly dealt with as it can also lead to death.

The information gathered helps to conduct an in-depth study which in turn helps in creating an application that can help hypertension patients [4]. Various difference methods have used to build a related mobile app [5-9]. However, based on previous studies, it is found that most related applications provide guidance that is too general and less helpful for patients with different symptoms. In this study, a user-centred approach is adopted in designing Hypertension Management Guideline mobile app for helping the hypertensive patients. Interviews were conducted with hypertension patients as used in Jolles et al. [10] to get to know more about the hypertension disease and how they handled the condition. Also, two different groups of people were invited, one group that suffers from hypertension disease and another group that does not suffer from hypertension disease. This study also used the visual strategy with an eye tracker in order to find out the pattern behaviour of the selected users looking at the proposed mobile app design. The proposed framework also supports a simpler user interaction through the user interface. In the following section, the brief description of Hypertension Management Guideline mobile app prototype is developed as MYHpGuide and the methods used to complete this study are discussed.

The rest of the article is structured as follows. Section 2 details the recent literatures of the prototypes used for self-diagnosis of hypertension; Section 3 illustrates the materials and methods used for the development of proposed prototype design; Section 4 describes the prototype design and user experimental results; and finally, Section 5 concludes the paper.

## II. RELATED WORK

In this technology era, people are quite advanced and prefer to self-diagnose their ailments with the help of the World Wide Web before visiting the doctors. In the case of hypertension, self-screening helps the patients to measure their blood pressure, symptoms, and diagnose their disease [11].

Carrera et al. [12] offer a user-friendly high blood pressure (HBP) app to monitor hypertensive patients. The HBP app called BP control is an Android and IOS app which allows the hypertensive patients to communicate their blood pressure measurements with their clinician, thus providing monitoring

\*Corresponding Author.

and diagnosis. Cruz et al., [13] propose a mobile application called HeartBeat+ for recording and monitoring blood pressure readings for hypertensive patients. It provides an easy way for self-monitoring. The application is a combination of a mobile application for patients and web applications for the clinician to monitor the status of their patients. The web application keeps track of the vital records of the patient, charts of the previous readings, medical history, allergies, habits, and medications. The mobile application can be used by hypertensive patients to feed and monitor their vital signs, daily activities, medications, and food intake. In turn, it helps in identifying what triggers the patients' high blood pressure every time.

Alvarez et al., [14] provide a hypertension prevention method in the lower economic region of Peru with information and communication technology. In this paper, a mobile application called Wondershare-MobileGo is used, which provides a record of the blood pressure of the patients in real-time. Some of the papers also focus on using smartwatch along with smartphone and mobile applications for blood pressure monitoring [15]. Schaeffer et al., [16] present a prototype in his paper that combines an Android application called Lifestyle App, a smartphone, and a smartwatch which all integrated with a Server Lifestyle. The data input from the smartwatch and the smartphone application integrates with the server which lets to several abstract concepts of connection and communication between different devices, which facilitates the development of better lifestyle for patients based on the blood pressure measurement and daily activities.

Meanwhile, Pulgarin et al., [17] study presents the integration of a physical arterial blood pressure monitor with a web server with the help of WIFI interconnection module. They use a wrist blood pressure monitor that measures the heart rate, systolic, and diastolic pressure data, which in turn stores the measured data in an EEPROM storage memory with I2C connectivity, integrates with a Wi-Fi interconnection module to enable communication with the server [18]. The major drawback of conventional hypertension management system is its higher cost of purchasing and system maintenance.

### III. MATERIALS AND METHODS

The overview of the design, development and evaluation phase of the proposed model is illustrated in Fig. 1.

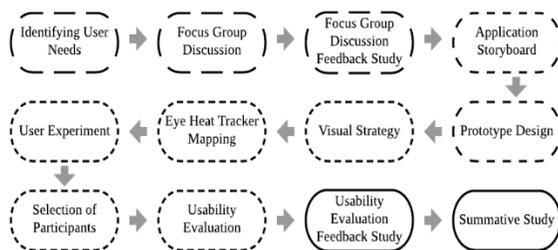

Fig. 1. Overview of the Design, Development and Evaluation Process. Milestones: Application Discussion Study (Rough Dotted), Concept Development (Medium Dotted), Visual Strategy and usability Evaluation (Dense Dotted), and Summative Evaluation (Solid Line).

#### A. Identifying User Needs

An experiment was carried out to identify the user needs on the proposed prototype applications. Two main user groups were involved in this experiment. The first group comprises of hypertension patients who have experience with other hypertension applications previously, and the second group includes non-hypertension patients. To gain information and in-depth understanding of hypertension disease, a focus group discussion was conducted from the perspectives of hypertension patients. Each talk was audio recorded. A survey was also conducted with a set of questionnaires with other people on their requirements of the related applications.

#### B. Prototype Design

Low fidelity prototype has been designed based on the findings of identifying user requirements experiment and Gestalt Principle [19]. Also, the visual strategy is used by conducting eye tracker experiment for the proposed prototype screen and layout design. The proposed prototype design was also tested using an eye tracker device and software called Tobbi Pro. The device detected the movement of the user's eye during the testing of the application's user interface [20]. The device is linked to the software and generates a heat map based on the user's eyes focus during the testing of the user interface.

#### C. User Experiment

Ten participants are chosen for the usability study of MYHpGuide mobile application. Those who are non-hypertension patients were eager to take part to know more about this application. After the testing, the participants need to give their opinion about the app. Smartphones and laptops were used as a platform to do the testing. The instructions were given to each participant on how to use the proposed prototype mobile application. Below are the tasks that assigned to the participants for the experiment:

Task1: Use the search bar and select headache symptom

Task2: Browse and select headache symptom guidelines

Task3: Bookmark, like and share headache symptom guidelines

Task4: Give feedback on headache symptom guidelines by typing "The guidelines were very helpful" on the feedback box for bulleted list.

### IV. RESULTS AND DISCUSSION

#### A. Identifying user Needs

The results from the interview indicate that most hypertension and non-hypertension patients come from various age ranges for both men and women. Thus, it is concluded that the proposed application design and directions should not be complicated and rather be friendly to the user so that the application is accessible among adults and elderly users. The main component is consisting of sets of guidelines to manage hypertension disease. The priority of proposed system feature and functionality of hypertension management guideline application is divided by hypertension and non-hypertension patients. Table I shows the percentages of hypertension and non-hypertension group who have chosen each component.

TABLE I. PRIORITIES OF NON-HYPERTENSION AND HYPERTENSION ON HYPERTENSION MANAGEMENT GUIDELINE APPLICATION COMPONENTS

Component of Self-care Application	Hypertension (%)	Non-Hypertension (%)
Self-Monitoring	100	100
Diet	70	86
Exercises	80	80
Personal Data	75	90
Activities Planning	55	70
Goal Setting	90	97
Online Education	45	88
Forum	39	80
Social Support	98	80
Alert / Reminder	56	88
Coaching	60	70
Meditation	89	77
Reward System	45	56

**B. Prototype Design**

Our proposed prototype is MYHpGuide application, as shown in Fig. 2(a), a hypertension management guideline application on a smart phone that designed specifically for patients diagnosed with hypertension. It has a database of hypertension guideline management for a patient to refer. Other than that, user can also like, share, save and give feedback for any guideline that they want as illustrated in Fig. 2(b).

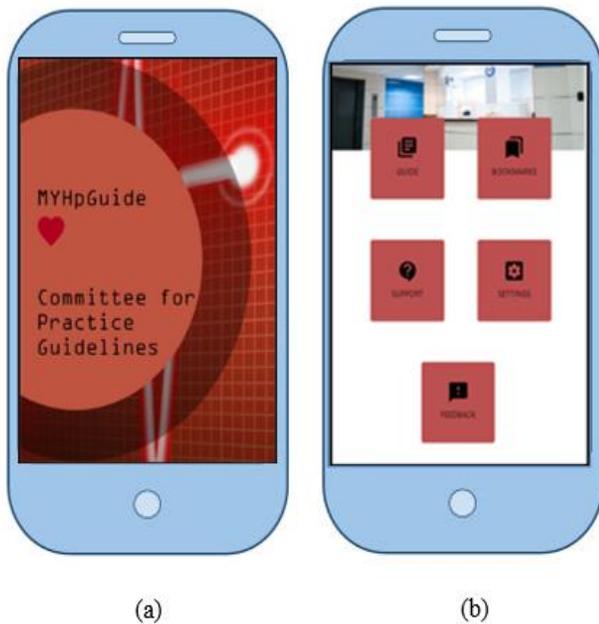

Fig. 2. Front Page (a) and Main Menu of MYHpGuide Application (b).

The task given to participants is to take note of the time in which they complete a task, their understanding of the tasks and tracking their eyes to understand their point of focus. These parameters were noted for both the participating groups.

In the first task, participants need to type "headache" as a symptom in the search box, as shown in Fig. 3 below. Participants can also browse through the symptoms already shown in the app and can choose the headache symptom and or choose any other additional symptoms as per their need. However, some participants were confused about attempting the first task, as most thought that they can only choose the symptoms shown in the list and not type in.

In the second task, the participants need to browse the headache symptom guidelines and select the proper guidelines, as shown in Fig. 3 (Task 1). A list of hypertension guidelines regarding the headache symptom is shown in a list (Task 2). The list view of guidelines shows the title and a short description of the guideline, including the number of people who have read it. In the third task, the participants need to bookmark, like or share the headache symptom guidelines. The application allows the participants to like and share the guidelines if the participants think that the guidelines are helpful. A bookmark button provided so the participants can save the guidelines for future use. The final task for the participants was that the users could give feedback for the guideline that they choose. A feedback box was provided for the users to share their thoughts and comments regarding the guidelines.

**C. Visual Strategy**

The primary purpose of the visual strategy in the usability study was to identify the suitable user interface design. The group conducted the visual strategy by using the eye tracker test. In the Color mapping result, the region where the eye focused longer represented with an increasing degree of a warmer colour. For the front page, Fig. 4 shows the logo of the apps had the warmest tone because it had the most observation from the test by the users.

Other than that, the result for the guideline page shows that the author's name had the warmest tone because the users were inquisitive about the author app, as shown in Fig. 5.

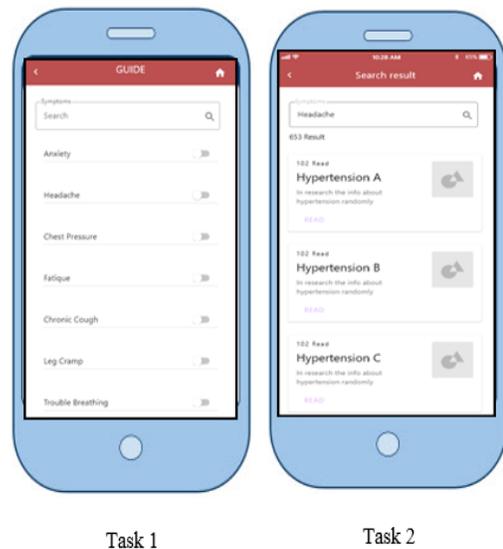

Fig. 3. Type on the Search or Select Symptom on Task1 and Browse all the Guide shown based on the Symptom Task 2.

Fig. 4. Heat Map for Front Page of MYHpGuide Apps.

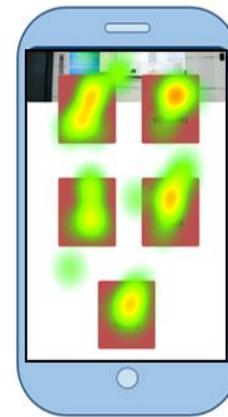

Fig. 6. Heat Map for Guideline of MYHpGuide Apps.

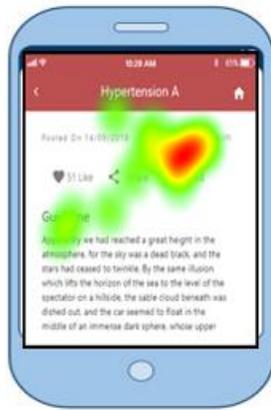

Fig. 5. Heat Map for Guideline of MYHpGuide Apps.

Lastly, Fig. 6 shows the result of the guideline system main menu. The results show that the users were more keenly observing the logo of each menu as all the logos had the warmest tone, especially for bookmarks and guideline menu logo.

#### D. User Experimental Results

An independent-samples t-test conducted to compare the performance scores for hypertension patients and non-hypertension patients. There was a significant difference in scores for hypertension patients ( $M=3.33$ ,  $SD=0.08$ ) and non-hypertension patients [ $M=4.08$ ,  $SD=0.33$ ];  $t(8)=-5.41$ ,  $p<0.01$ ]. The magnitude of the differences in the means is (eta squared=0.079). Based on the result, all participants successfully managed to complete all the task given. Table II shows the result of user performance. For task 1, 2, 3 and 4, the time difference between the users spending their time on the application was not too big between the two groups. All the data have been recorded in Table II as shown, the time users spend using the application (minutes) with the task given to two groups of hypertension patients and are non-hypertension patients are provided. The result shows that the mean difference between hypertension patients ( $m=3.3333$ ) and non-hypertension patients ( $m=4.0750$ ) is approximately 7 second apart. When compared with all the tasks, the value may seem significant, but in real life situation, the 7-second difference is not that big and noticeable.

TABLE II. USER PERFORMANCE RESULTS

TASK	The Time Users Spend Using the Hypertension Management Guideline Mobile Application (minute)									
	P1	P2	P3	P4	P5	P6	P7	P8	P9	P10
	(HP)	(NHP)	(HP)	(HP)	(NHP)	(HP)	(HP)	(NHP)	(NHP)	(HP)
Task 1	0.8	0.6	0.5	0.7	0.6	0.7	0.4	0.9	0.8	0.5
Task 2	1.0	1.3	0.8	0.7	1.2	0.9	0.8	0.9	1.5	0.5
Task 3	0.5	0.8	0.7	0.8	0.9	0.8	1.0	0.7	0.6	0.9
Task 4	1.1	1.2	1.3	1.2	1.6	1.0	1.0	1.2	1.5	1.4
<b>TOTAL TIME</b>	3.4	3.9	3.3	3.4	4.3	3.4	3.2	3.7	4.4	3.3
<b>RESULT</b>										
Type of Participant	Amount of Participant				Mean		Std. Deviation			
Hypertension Patient (HP)	6				3.3333		0.08165			
Non-Hypertension Patient (HP)	4				4.0750		0.33040			

However, it still shows the difference between the performances of the two-user group to complete the task. The standard deviation of hypertension patients overall time taken to complete all tasks is more prominent (SD: 0.33040) than non-hypertension patients (SD: 0.08165). It proves that, in using the hypertension guideline management application, non-hypertension patients take more time than hypertension patients.

Usability testing result was analyzed; both groups can complete all given tasks successfully. In using the MYHpGuide application, non-hypertension patients take more time than hypertension patients to complete all task. An independent-samples t-test showed that there was a significant difference in time taken to complete all the tasks between hypertension patients and non for non-hypertension patients. This result may be due to the lack of experience of non-hypertension patients with hypertension symptoms and related terminology. Compared to non-hypertension users, patients with hypertension are using the proposed apps efficiently, and they took a shorter time to complete all task given because they already familiar and have some experienced with various hypertension symptoms.

The result from the eye tracker test shows that users focused more on visual content (e.g., icons and graphics) compared to words. It can also be concluded that user's eye is more focus on symbols rather than texts because users maybe need to identify and analyze the logo meaning. Other than that, the eye tracker test results also show that users may be more interested in looking at the name of the author's guideline because of their curiosity (see Fig. 5(B)).

It can also be concluded that the eye heat tracker test used on the visual strategy for the proposed design is sufficient to prove the understanding of the target user on the user interface features and the structure of the proposed application. Other than that, the result also shows the design strength and weakness that have on the user interface design, which can guide us to improve the user interface design of related applications.

## V. CONCLUSION

The ability of user-centered design in considering the user's needs, devise a plan to meet them, and direct the elderly person's perspective to a positive attitude, has made it plays a significant role throughout the design phase of mobile application for hypertension management guideline. The result shows that the app presented in this paper has a higher engagement of user interaction with the features present in the user interface. Based on the heat map, it can be concluded that the visual engagement with icon and graphic has higher interaction and ease of use for the user. It is also observed that the hypertension group users spend less time on each task as they usually use other similar apps and are experienced with this, while the other non-hypertension group users take more time to get to know each feature in the app. The reported usability evaluation demonstrates that hypertension user performs positively with ease. The app can assist them and provide considerable benefit with the interaction with other similar hypertension user. This study could help in designing an effective application for hypertension guideline and

innovative tool for monitoring health and well-being during daily life activities.

## ACKNOWLEDGMENT

We want to thank VicubeLab for providing infrastructure for usability testing and eye heat tracker session. The authors also wish to thank the Ministry of Higher Education Malaysia for funding this study under Fundamental Research Grant Scheme (FRGS/1/2019/ICT04/UTM/02/8) with Grant No – 4L809, Universiti Teknologi Malaysia.

**Abstract**—Handwritten character recognition is the most critical and challenging area of research in image processing. A computer's ability to detect handwriting input from various original sources, such as paper documents, images, touch screens, and other online and offline devices, may be classified as this recognition. Identifying handwriting in Indian languages like Hindi, Tamil, Telugu, and Kannada has gotten less attention than in other languages like English and Asian dialects like Japanese and Chinese. Adaptive Moment Estimation (ADAM), Root Mean Square Propagation (RMSProp) and Stochastic Gradient Descent (SGD) optimization methods employed in a Convolution Neural Network (CNN) have produced good recognition, accuracy, and training and classification times for Telugu handwritten character recognition. It's possible to overcome the limitations of classic machine learning methods using CNN. We used numerous handwritten Telugu guninthalu as input to construct our own data set used in our proposed model. Comparatively, the RMSprop optimizer outperforms ADAM and SGD optimizer by 94.26%.

**Keywords**—Character recognition; Adam; RMSProp; SGD; CNN

## I. INTRODUCTION

In today's world, the internet is brimming with images and video representations, providing sufficient opportunity for building numerous research applications for image and video analysis [1] to educate people about more complex material and techniques. With the rise of Artificial Neural Networks, machine learning has advanced significantly in recent years (ANN). These ideas enhance the model's capabilities beyond machine-learning tasks and other domains. Convolutional neural network (CNN) architecture has been considered as one of the most inventive. Using CNN in image processing became clearer and more beneficial as ANN performance deteriorated in object recognition and image classification. As better CNN became accessible, research using CNN in image processing domains grew dramatically [2-4]. CNNs have had a lot of success in various domains, including computer vision, natural language processing, and speech recognition.

One of the most widely used machine learning models is CNN which has been expanded to handle a wide range of visual image applications, item classification, and audio identification challenges by applying mathematical representations. Multi-layer network structure that may be learned and consists of several layers [5]. Raw pixel values may be utilized as input to the network instead of feature vectors, which are often employed in machine learning. Even though there are many different kinds of CNNs (fig.1), they always have the same basic structure: a convolutional layer, a pooling layer, and an entirely connected layer.

1) *Convolution layer*: Images are filtered using this tool, which identifies characteristics that are used to identify matching spots during testing. Enlarged images need a convolution procedure with minimum parameters. With a filter or kernel, the input data is transformed into a feature map for use by CNN.

2) *Pooling layer*: This layer receives the extracted characteristics. It reduces bigger images while keeping the most critical data. It keeps the maximum value from each window by preserving the best fit value. This function shrinks the picture spatially to minimize the number of parameters and computations in the model. Max Pooling is a typical strategy in pooling. It selects the greatest element from the feature map covered by the filter.

3) *Fully connected layer*: High-level filtered images are fed in and categorized using labels in the final layer. Every neuron in this layer is related to the one below it. Layers of convolution and pooling are common in most designs.

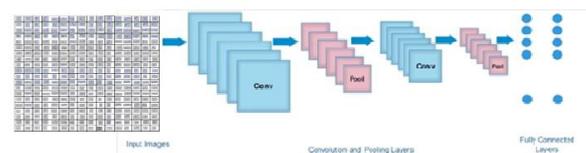

Fig. 1. Layers CNN.

## II. LITERATURE REVIEW

CNN performs well in various applications, inspiring academics to work on it in key fields such as natural language processing (NLP), image classification and face recognition, predictive analytics, and so on. P.V. Ramana Murthy et al. [6] built a model that recognizes online handwritten Telugu letters for various domains and companies, yielding a model with 98.3 per cent accuracy, exceeding their expectations. P. Sujatha et al. [7] used CNN architecture to identify a few deep learning strategies for detecting Telugu and Hindi scripts. They also developed a new architecture for identifying low-level textual properties of handwritten characters. Buddharaju Revathi et al. [8] also conducted a survey on Optical Character Recognition (OCR) for the Telugu language, demonstrating the progress of processing the characters stage by stage and performing operations such as segmentation and processing, which resulted in higher accuracy.

B. Hari Kumar et al. [9] used data from several sources to conduct script identification in Telugu. Konkimalla Chandra Prakash et al. [10] used CNN for Telugu script recognition. They supplied a list of Telugu typefaces, a client-server solution for the algorithm's online deployment, and deep learning-based OCR techniques in their study. The segmentation method can be improved so that each character, along with its guninatham and vattu, is segmented. Chirag I Patel et al. [11] developed a technique for identifying characters in a given digitalized text and reading the changing effects of the Models utilizing ANN by employing a back growing neural network to improve script identification accuracy. A.Ram Bharadwaj et al. [12] built a model for Telugu text extraction and recognition using CNN and a recurrent neural network (RNN) with their own data set, achieving an accuracy of 81% by selecting 100 random words from the validation set.

## III. PROPOSED METHOD

In image-based classification, the CNN architecture is a popular choice. To distinguish features like edges and forms, CNNs apply a range of filters composed of trainable parameters to an image. These high-level filters often utilize weights learned from the spatial attributes of each subsequent level to capture an image's spatial properties. For this design, parameters named as Hyper Parameters are employed. These parameters may influence both the network architecture and training before the training begins.

Hyper Parameters used for building the network are:

- Count the number of hidden layers: the layers between input and output.
- To prevent overfitting, dropouts are employed.
- The activation function is used to add some nonlinearity.
- Learning Rate: It specifies the rate at which the network's parameters are updated.
- Momentum: It keeps things from oscillations.

- One complete prediction cycle of a neural network is one epoch.

Batch Size: The number of subsamples sent to the network.

Fig. 2 [13] depicts the suggested model's implementation stages.

To speed up CNN model training, all of the images in the build data set were categorized, reduced to 70 by 70 pixels, transformed to greyscale, and saved in .npz format. Telugu Guninthalu dataset was trained using three hidden layers of a CNN and tested on it. The network consists of three convolutional layers, two Maxpooling layers, and a fully connected layer. The first hidden layer is a Convolution2D layer. A Maxpooling layer with a pool size of 22 was then employed, along with 256 filters, each with a kernel size of 33 and a stride of 1. A layer of padding has been added to the design to keep the original input size.

Each of the 256 convolution filters in the second convolution layer has a kernel size of 33, followed by a Maxpooling layer of 22. New features have been added to the algorithm, including an additional 256-filter convolution layer and a Maxpooling layer of pool size 22. The two-dimensional matrix data is first transformed into a one-dimensional vector using a Flatten layer before the fully connected layers are generated. Next, we used a totally corresponding layer with the activation of ReLu in it. Dropout, a regularization layer, is set to randomly eliminate 20% of the layer neurons to prevent overfitting.

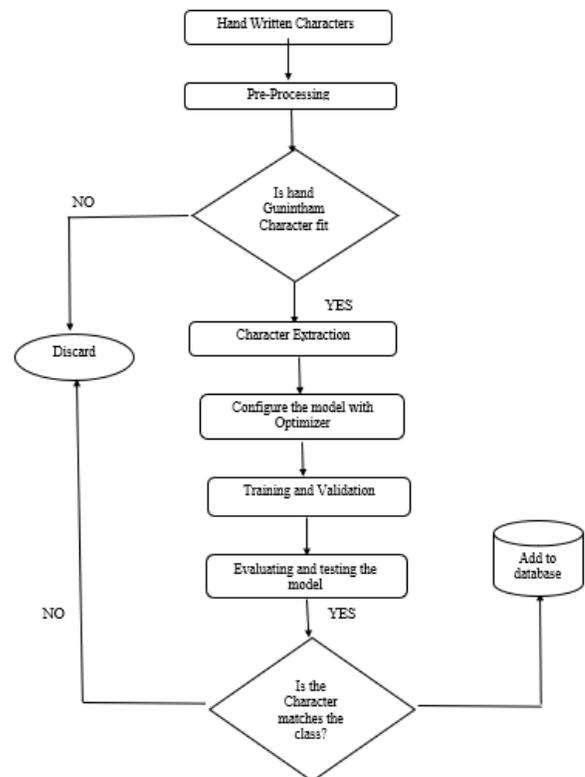

Fig. 2. Process Flow.

At long last, a sigmoid activation function is added to the 16-neuron output layer. An essential part of CNN is the activation function; it determines the output of a neuron concerning a set of inputs. The activation function is used to introduce nonlinearity into the model. A CNN model's performance is improved by selecting the appropriate activation function. The ReLu and Sigmoid activation functions are used in the suggested model.

1) *Rectified Linear Unit (ReLU)*: It's a biologically and mathematically sound activation function [14]. If the input is negative, ReLu returns 0, if the input is positive; it returns the value itself (Eq 1). ReLu's max operation calculates more quickly than other activation functions. For many kinds of neural networks, it is the default activation function.

$$f(x) = \max(0, x) \quad (1)$$

If we are doing a matrix-vector product, this is often done element by element to get the desired outcome. Nonlinearity is vital for CNN since every layer in the network contributes to it.

2) *Sigmoid*: Eq 2 indicates that it is a probabilistic strategy for decision-making with a range of 0 to 1. We used this activation function to forecast an output since it would be more accurate.

$$f(x) = 1 / (1 + e^{-x}) \quad (2)$$

It's beneficial for models that forecast probability as a result. Because the probability of anything spans between 0 and 1, a differentiable sigmoid function is the best option. As a result, this function yields the curve's slope at any two locations.

Training and validation errors were calculated after each cycle. The training is completed when the number of epochs in training and validation hasn't changed considerably. On the test set, faults in training and validation were discovered, and the network was approximated. It is vital to utilize optimizers in order to improve accuracy and decrease mistakes. Optimizers alter the weight settings in order to minimize the loss function. To get the greatest possible design, we considered a set of priorities or limitations. Adaptive Moment Estimation (Adam), Root Mean Square Propagation (RMSprop) and Stochastic Gradient Descent (SGD) were used in the proposed model.

3) *Adaptive Moment Estimation (Adam)*: Using Adam, an adaptive learning rate technique, individual learning rates are calculated. The exponentially declining average of the preceding squared gradient is stored, and the value of previous historical gradients is preserved, much as momentum. It may also be used to replace stochastic gradient descent systems when updating the network weights in training data. Equations

3 and 4 are used to derive the gradients, which are then used to estimate the moments using exponentially moving averages. Where  $m_t$  and  $v_t$  are moving averages,  $g$  is gradient,  $\beta_1$ ,  $\beta_2$ , and second moment of gradients are gradient forgetting features, and index  $t$  is the current training iteration.

$$m_t = \beta_1 m_{t-1} + (1 - \beta_1) g_t \quad (3)$$

$$v_t = \beta_2 v_{t-1} + (1 - \beta_2) g_t^2 \quad (4)$$

The recommended Adam configuration parameters [15] of  $\beta_1=0.9$  and  $\beta_2=0.999$ .

4) *Root Mean Square Propagation (RMSprop)*: This approach is similar to a gradient descent with the momentum that confines oscillations to the vertical plane. Thus, increasing the learning rate enables the algorithm to make considerable horizontal jumps toward rapid convergence. The magnitude of recent gradient descents is used to normalize the gradient. Selecting alternative learning rates for each parameter causes the pace of learning to be automatically changed. The parameters are updated using Eq. 5, 6, where  $g_t$  is the gradient at time  $t$ ,  $v_t$  is the exponential average of squares of gradients, and  $\eta$  is the learning rate, which is set at 0.001.

$$v_t = \rho v_{t-1} + (1 - \rho) g_t^2 \quad (5)$$

$$\Delta \omega_t = - \frac{\eta}{\sqrt{v_t + \epsilon}} g_t \quad (6)$$

5) *Stochastic gradient descent*: Stochastic Gradient Descent (SGD) is a simple yet efficient optimization algorithm used to find the parameters/coefficients of functions that minimize a cost function. In other words, it is used for discriminative learning of linear classifiers under convex loss functions such as SVM and Logistic regression.

$$E(w, b) = \frac{1}{n} \sum_{i=1}^n L(y_i, f(x_i)) + \alpha R(w) \quad (7)$$

## IV. EXPERIMENTAL RESULTS

### A. Data Set

Due to the lack of publicly available training data for Telugu characters, we had to construct our own dataset. There is an initial gathering of people's handwritten Telugu guninthalu in various formats and scanning them into precise symbols. Fig. 3 shows a scanned copy of a handwritten guninthalu both online and offline. There are 16 characters in each of the 21 guninthalu, for a total of 275520 handwritten characters.

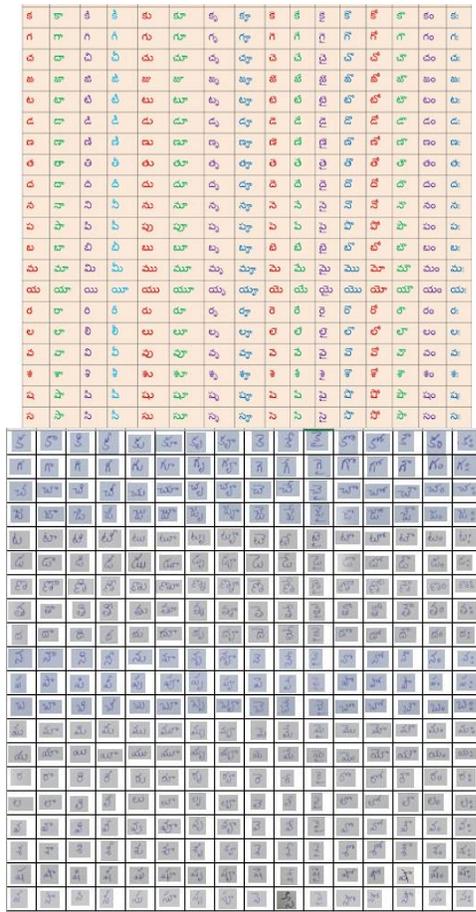

Fig. 3. Notations used in the Model (Both Online and Offline).

V. REQUIREMENTS

The backend engine for the recommended model is Tensor Flow 2.2. CNN was implemented using the built-in dataset. These tests were run on a 64-bit operating system with an Intel i7-4770 CPU running at 4.00GHz and 16GB of RAM.

A. Results

The suggested model is applied to the pre-existing data set in the system. This research aims to develop a system for recognizing handwritten characters in Telugu, which makes extensive use of classification. Table I displays the model's layer-by-layer attributes. The proposed network will handle a total of 1,986,640 parameters.

Metrics including recall, precision, and accuracy [16] are used to assess the proposed system.

- Positive patterns that can be correctly anticipated from the totality of other positive patterns are "predicted with precision".

$$Precision = \frac{true\ positives}{true\ positives + false\ positives}$$

- Recall computes the fraction of positive patterns that are appropriately classified.

$$Recall = \frac{true\ positives}{true\ positives + false\ negatives}$$

- In order to measure the model's classification accuracy, the percentage of accurate predictions is calculated. The formula provided may be used to figure this out.

$$Accuracy = \frac{true\ positives + true\ negatives}{true\ examples}$$

Tables II to V illustrate the results of different optimizers such as Adam, SGD and RMSprop with all the performance metrics. When compared to Adam, and SGD the RMSprop optimizer generated superior results. When RMSprop is employed, the learning rate is enhanced since it takes huge horizontal steps and converges faster. The loss function quantifies how close the network's predicted output and given ground truth labels are through forward propagation. The confusion matrices of different optimizers are shown in Fig. 4 to 6.

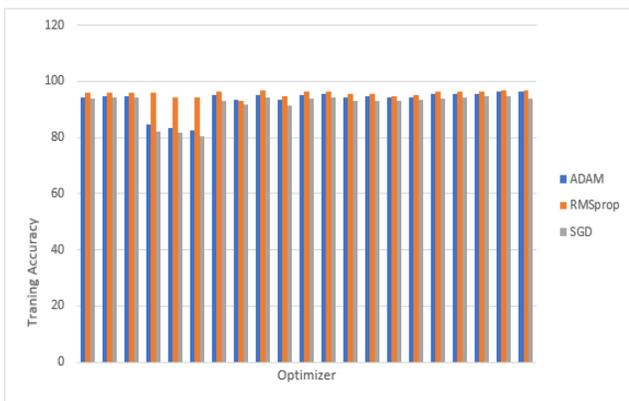

Fig. 7. Training Accuracy with ADAM, RMSprop & SGD Optimizer on 21 Guninthalu.

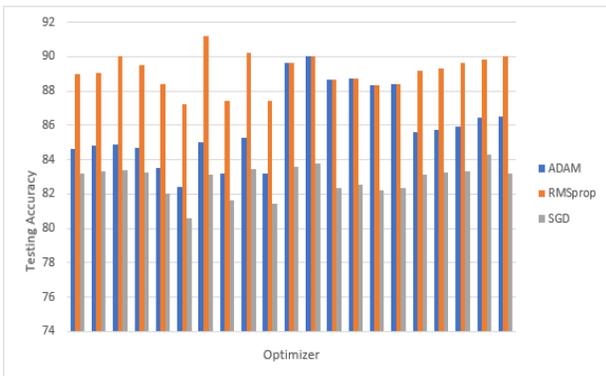

Fig. 8. Testing Accuracy with ADAM, RMSprop & SGD Optimizer on 21 Guninthalu.

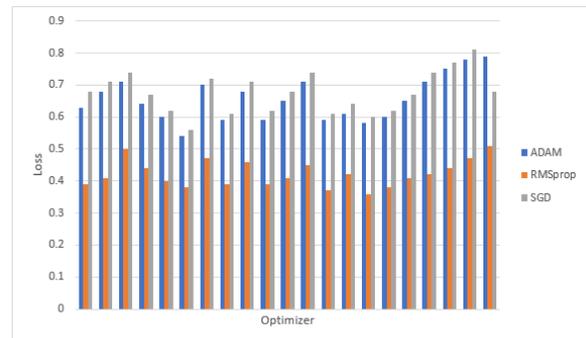

Fig. 9. Loss with ADAM, RMSprop & SGD Optimizer on 21 Guninthalu.

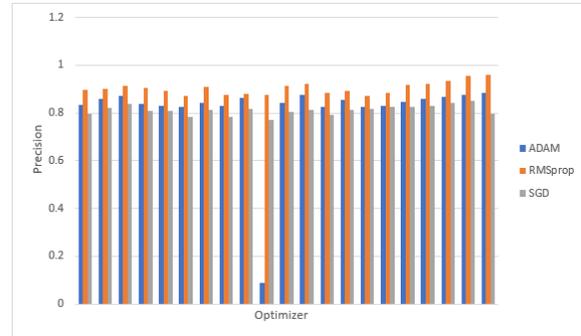

Fig. 10. Precision with ADAM, RMSprop & SGD Optimizer on 21 Guninthalu.

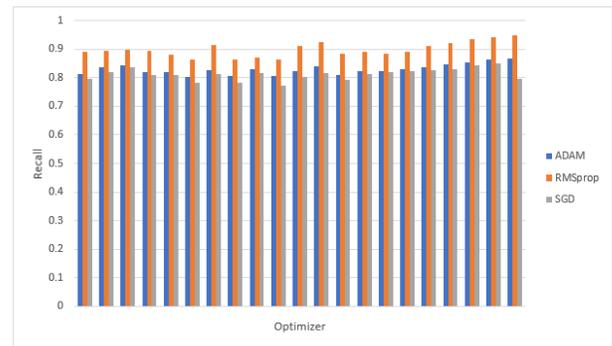

Fig. 11. Recall with ADAM, RMSprop & SGD Optimizer on 21 Guninthalu.

The training, testing accuracy, loss, precision, and recall with Adam optimizer, RMSprop optimizer, and SDG optimizer are shown in Fig. 7 to 11. The results show that the RMSprop optimizer has a higher testing accuracy than the ADAM and SGD optimizers. The mean values acquired with all the guninthalu are used to determine the overall training, testing accuracy, precision, and recall. Tables III to VI shows that when compared to ADAM and SGD optimizers, the RMSprop optimizer performs well on all guninthalu.

There are 820 different handwritten characters for each guninthalu used to train the model. Each of the 21 guninthalu contains 16 characters, for a total of  $21 \times 16 \times 820 = 275520$  handwritten characters, which are used to train the model as shown in Table VII. After training, the model is checked using a 20% data mean and 55104 characters. Accuracy, Precision, Loss, and Recall are used to evaluate the model after it has been evaluated on 55104 data points.

**B. Augmentation**

Data augmentation is a method of artificially creating fresh training data from existing data. This is performed by transforming examples from the training data into fresh and unique training examples using domain-specific techniques.

**C. Dropout**

Dropout is a technique for preventing overfitting in a model. Dropout operates by setting the outgoing edges of hidden units at random. As the augmentation factor is increased, the validation accuracy improves. The test accuracy increased to 90.12 with ADAM optimizer, 94.26 with RMSprop, and 86.72 with SGD optimizer after data augmentation as shown in Fig. 12 to 14.

**VI. CONCLUSION**

With CNN, our goal is to improve the quality of handwritten Telugu guninatham identification. The contributions of Adam, RMSprop, and SGD were critical in improving the model's accuracy and performance. The dropout and activation functions ReLu and Sigmoid are used to prevent overfitting. In CNN models, RMSprop optimizer outperformed Adam and SGD in terms of accuracy. This model might be adjusted to enhance the identification of handwritten Telugu characters. In the future, we want to continue experimenting with new approaches to improve the identification of Telugu handwritten guninthalu.

**Abstract**—Information security is a crucial issue and needs to be addressed efficiently. Encryption of the original information is used to ensure privacy during exchange of information. In GSM (Global System for Mobile) standard, once the voice traffic initiates after signaling, encryption comes into the picture to ensure privacy during the call, after authentication. Here in this process, the plaintext is encrypted in to cipher-text using stream ciphers. For stronger security, strong ciphers with strong randomness are required. Linear Feedback Shift Registers (LFSRs) based A5 algorithm family is used for encryption in GSM. There are many shortcomings of this cipher and with these, privacy can't be assured. Some ways are proposed in this paper to ensure better security by enhancing the randomness of the generated bit stream being used for encryption. These are incorporation of user's current location, reuse of already generated 32 bit SRES during authentication process and conversion of linear FSRs into nonlinear FSRs. Statistical Test Suite NIST is used to test the various properties of random bit stream and an attempt has been made to achieve better randomness, hence more security.

**Keywords**—Security; encryption; A5/1 stream cipher; randomness; NIST test suite

## I. INTRODUCTION

Although with the advancement of technology, many vulnerabilities of security threats of GSM have been addressed in EDGE, 3G (HSPA/HSDPA) & 4G (LTE) but this is still relevant as large number of people use GSM specially in rural areas. In addition to this, stream ciphers are used in many other wireless applications like modems / routers, smart appliances & security devices. Few algorithms like A3, A8 & A5 are used in GSM for authentication & encryption process over  $A_{bis}$  air interface between user mobile (MS) and base station (BS). The details of inputs, outputs & use of these algorithms are described in Table I. Here the SRES is Signed Response of 32 bits,  $K_c$  is a 64 bits Cipher Key and RAND is a 128 bits random number. Fig. 1 shows that the combination of  $K_c$ , RAND and SRES is called "Triplet".

A5 is mainly responsible for encryption as shown in Fig. 2. Here by using Cipher Key  $K_c$  of 64 bits along with TDMA Frame number  $F_n$ , a 228 bits pseudo random number PRAN is generated which is XORed with 228 bits plain-text in bit-by-bit manner to get cipher-text. This cipher form of information after encryption is finally transmitted over the air interface between the user mobile station & base station.

Two stage security, i.e. "Authentication" & "Encryption" is implemented in GSM. Initially, the access of the network resources is granted to any new or existing subscriber on its request after authentication process on every location update.

During this "Authentication Process", the core network challenges MS and in response to this, MS sends SRES. This is matched with the SRES available with itself and grants the access on matching only as described in Fig. 3. After getting the access of the network, the encryption process takes place to ensure the privacy during the call. Here in this process, the plaintext is encrypted in to cipher-text using stream ciphers of A5/1 algorithm. In the same way, decryption occurs at the other end to reconstruct the original information.

As the transmission of information is bursty in nature in GSM, the 114 bit frame sequence in downlink (BS to MS) & the same way a 114 bit frame sequence in uplink (MS to BS) is transmitted every 4.6 milliseconds.  $K_c$  is produced and mixed with a publically known TDMA frame number  $F_n$  for each frame for every new voice call.

The configuration of A5 was never shared by the ETSI [1]. Although, it got reverse engineered & became available to all. Many crypto attacks occurred by cryptanalysts to reveal the internal structure of this algorithm and hackers & intruders managed to decrypt the transmitted information by users. Golic [2, 3] presented the functional design in the year 1994 and later Marc Briceno [4] revealed the entire design by reverse engineering in the year 1999 [15,16,17,19,20].

TABLE I. ALGORITHMS USED FOR INFORMATION SECURITY IN GSM

Algorithm	Inputs	Output	Purpose
A3	$K_i$ (128 Bits)	SRES (32 Bits)	Authentication Process
	RAND (128 Bits)		
A8	$K_i$ (128 Bits)	$K_c$ (64 Bits)	Cipher Key Generation ( $K_c$ )
	RAND (128 Bits)		
A5	$K_c$ (64 Bits)	Cipher Text (228 Bits)	Encryption Process (Voice & Data)
	TDMA Frame No. (22 Bits)		
	Plain Text (228 Bits)		

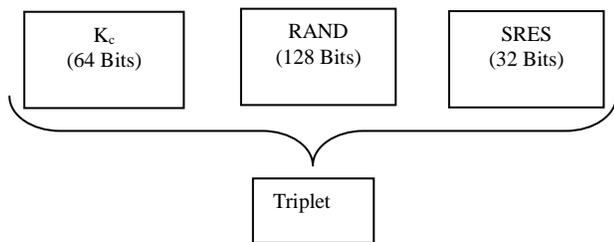

Fig. 1. Triplet Details.

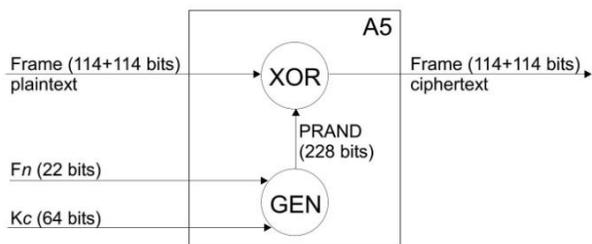

Fig. 2. Encryption by A5/1 in GSM.

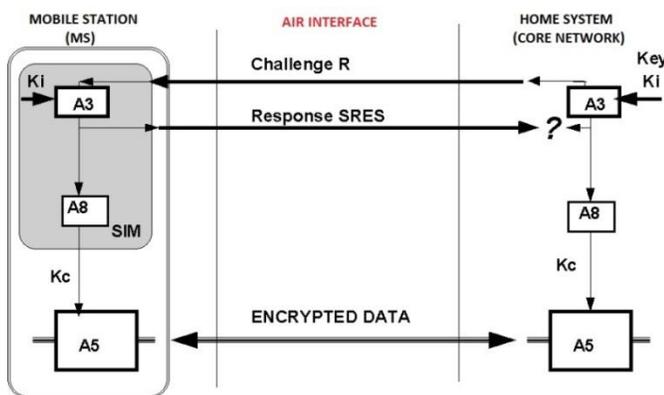

Fig. 3. Authentication and Encryption Process.

Biryukov, Wagner and Shamir [6], Ekdahl and Johansson [10], Dunkelman and Biham [5], Maximov & team [11] and Barkan [14] contributed lot. Contribution of Andrew Rukhin et al [8], N. Komminos [9], Basar Kasim [12, 13] is also remarkable. Very recently, Darshana Upadhyay, Priyanka Sharma & Sharada Valiveti [18], Sattar B. Sadkhan [21,24,26] & Nagendar Yerukala [27] made some modifications by changing of feedback taps in A5/1 stream cipher to improve the randomization property to make it robust to attacks [22,23].

Many cryptanalysts proved that due to weaknesses of this stream cipher, information security can be compromised in GSM [25, 28, 29]. These weaknesses are:

- 1) Weak Linear Complexity (LC).
- 2) Poor clocking system (Majority Function Rule).
- 3) Clocking period is too short.
- 4) Poor clocking taps selection.
- 5) Collision issue.

Using an improved clocking system with a combinational function of high correlation immunity and high algebraic degree, the security can be increased [6, 11].

Logisim simulator (primarily developed by Dr. Carl Burch) is used to realize the structure of the proposed A5/1 algorithm and its randomness parameters are analyzed by NIST Suite [7]. Brief description about the internal structure of A5/1 is given in Section II, modifications are proposed in Section III, observations and randomness analysis is given in Section IV and Section V concludes the results.

## II. INTERNAL STRUCTURE OF A5/1

It has three Linear Feedback Shift Registers (LFSRs) of different bit lengths to generate a pseudo random binary stream. The total bit length of this cipher is 64 bits in which LFSR-1 (R1) has 19 bits, LFSR-2 (R2) has 22 bits, and LFSR-3 (R3) has 23 bits as depicted in Fig. 4.

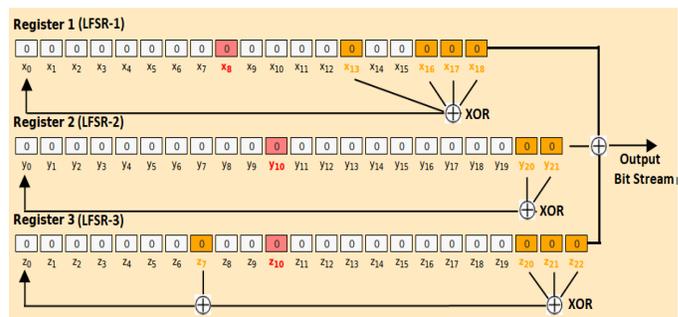

Fig. 4. Internal Design of A5/1.

Following its own feedback polynomial, periodic bit sequence is generated by these registers. The feedback bit positions are predefined at 13, 16, 17, 18 and 20, 21 and 7, 20, 21, 22 for R1, R2 and R3, respectively.

Similarly, the single clocking taps of these registers are also predefined at tap 8, 10, and 10 for R1, R2 and R3, respectively. Bit length, clocking bit, tap bits and primitive polynomial are shown in Table II.

TABLE II. INFORMATION TABLE FOR LFSRS

LFSR	Length (in bits)	Clocking Bit	Tap Bits	Primitive Feedback Polynomials
R1	19	8	13, 16, 17, 18	$x^{19}+x^{18}+x^{17}+x^{14}+1$
R2	22	10	20, 21	$x^{22}+x^{21}+1$
R3	23	10	7, 20, 21, 22	$x^{23}+x^{22}+x^{21}+x^8+1$

TABLE III. MAJORITY RULE TRUTH TABLE

Clocking Bit			Majority Function	Clocked LFSR		
R1	R2	R3		R1	R2	R3
0	0	0	0	Yes	Yes	Yes
0	0	1	0	Yes	Yes	No
0	1	0	0	Yes	No	Yes
0	1	1	1	No	Yes	Yes
1	0	0	0	No	Yes	Yes
1	0	1	1	Yes	No	Yes
1	1	0	1	Yes	Yes	No
1	1	1	1	Yes	Yes	Yes

The clocking mechanism of each register is decided by Majority Rule as shown in the truth table Table III below. For each cycle, only those registers will be clocked and updated whose clocking bit values have majority. The majority value  $m$  is decided by  $m = maj(C1, C2, C3)$ , here  $C1, C2$  and  $C3$  are the clocking bits of all three registers.

In simple words, “at least two out of three” is the majority rule i.e. the majority among these bits. If two or more clocking bits are 1, the majority value  $m$  will be 1, and similarly if two or more are 0, the majority value  $m$  will be 0.

Thus, in this mechanism, two or more, whose clocking bit is the equal to  $m$ , will be clocked at each clock cycle. Every register has the clocking probability of 0.75 and non-clocking probability of 0.25. The majority rule function can be realized using logic gates as shown below in Fig. 5 (Logisim simulator).

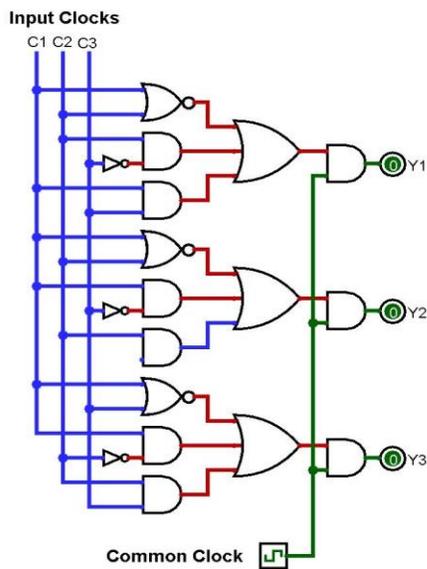

Fig. 5. Realization Majority Function in Logisim.

All three registers are reset by setting a zero value. In next 86 cycles,  $K_c$  and  $F_n$  are loaded bit by bit with regular clocking. The output ignored during initial stage of the first 100 clock cycles and during this period the irregular clocking continues for all three LFSRs as per the majority rule. Now the required random bit stream of 228 bits is obtained for 228 clock cycles [28]. The same steps are repeated for the next frame.

### III. PROPOSED CIPHER

To overcome some of the problems mentioned above in previous section, the following schemes / modifications are proposed to increase the randomness:

1) *MOD-I*: Here in this scheme as shown in Fig. 6, the nonlinearity is introduced in the feedback path of the shift registers by adding universal gates. Thus, the LFSRs have been converted into NLFSRs. By this, the randomness of the generated bit stream will be improved.

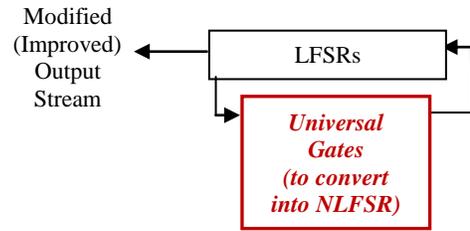

Fig. 6. Proposed MOD-I Scheme.

Polynomial equations of this MOD-I scheme will have the impact of NAND and NOR logic gates in it.

2) *MOD-II*: Here in this scheme, the 32 bit SRES is reused in the feedback path of the shift registers, which is already generated during the authentication process by A3 algorithm, as shown in Fig. 7. The SRES is XOR'ed in the feedback unit of LFSR through a NAND gate on bit by bit basis. This scheme reuses the output of another algorithm, hence increases the randomness of the cipher key.

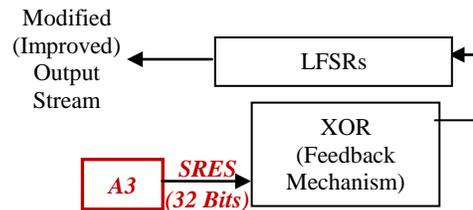

Fig. 7. Proposed MOD-II Scheme.

3) *MOD-III*: The user location is mixed with the bit stream generated using XOR (only last 32 bits). This works as a key feature as generally users have different locations and intruders cannot crack it easily. This is very important proposal, because the location of each individual user is not known to intruders and many times dynamic in nature. The CGI changes with the movement of the user and this makes the bit stream more complex. The idea is shown in Fig. 8.

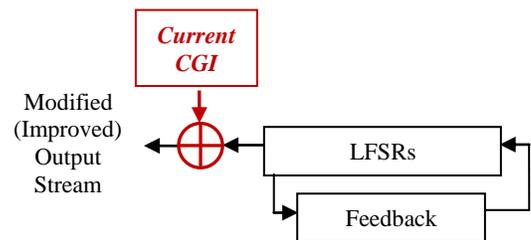

Fig. 8. Proposed MOD-III Scheme.

4) *MOD-C*: In this, all the above three modifications are combined to get the simultaneous impact of all above modifications.

The idea of combining all three modifications is shown in Fig. 9.

The proposed A5/1 cipher is realized and simulated in Logisim as shown in Fig. 10.

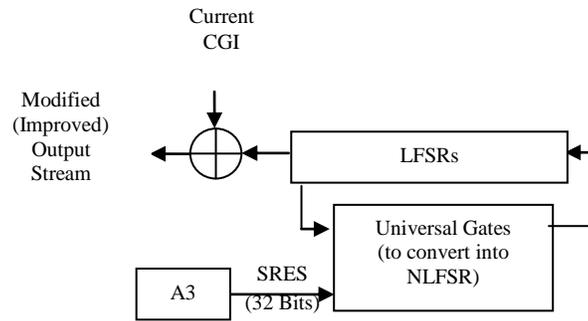

Fig. 9. Proposed Scheme of MOD-C.

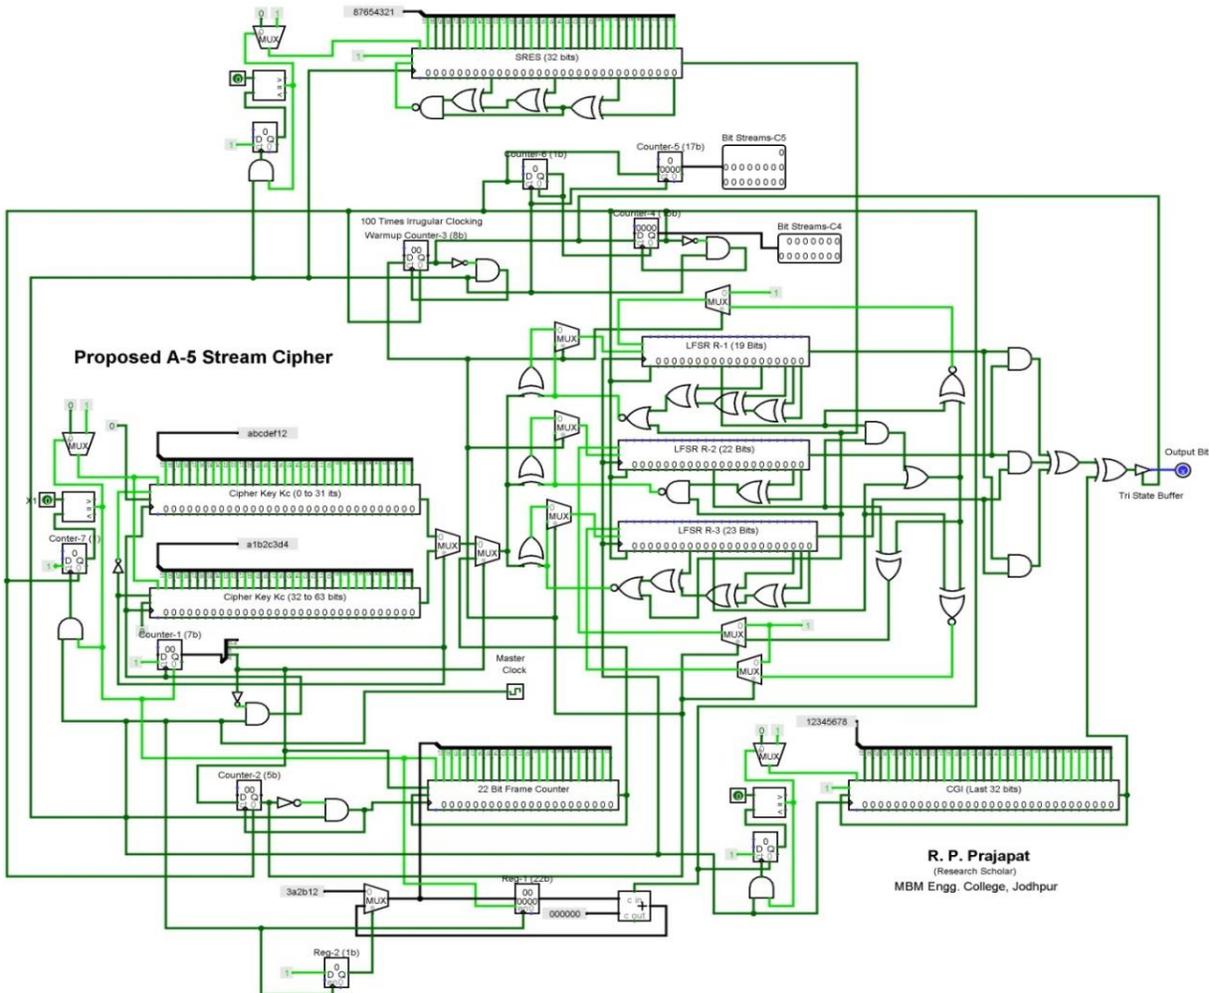

Fig. 10. Proposed Scheme of MOD-C in Logisim.

#### IV. OBSERVATIONS AND RANDOMNESS ANALYSIS

In a broader sense, the randomness of a data set is the lack of predictability, i.e. more uncertainty or more entropy. If a data set has more randomness means it has more encryption capability, hence more security. Such tests are carried out to check recognizable or repetitive patterns in any data set under test. Randomness is related to the theory of information entropy, probability, and chance. Entropy is a measuring tool for randomness.

NIST Suite is a statistical test suite based on Linux operating system and is used for statistical parameters testing of the output bit stream of both the actual and proposed scheme of A5/1 cipher. This test suite is also used in various cryptographic applications [7]. Performance comparison has also been done between these two with respect to various parameters. Following are the main tests which were carried out for the randomness test:

1) *The frequency test (monobit & within a block)*: It tests the balance of 0's and 1's in the bit stream. The equilibrium between 0's and 1's should be maintained for a perfectly random data set. Therefore, the probability of availability of 0's and 1's should be close to 0.5 [7].

2) *The cumulative sums test (cusums)*: It tests the randomness of a sequence of 0's and 1's which are called "random walks" or "partial sequences". It tells that the sum of the partial sequences is too large or too small [7].

3) *The runs test*: It analyzes the occurrence of similar patterns that are separated by different patterns [7].

4) *The DFT (spectral) test*: It finds out the patterns which are periodic in nature in a random bit sequence. The repetitive or periodic patterns close to each other are detected in this test [7].

5) *The serial test*: It detects the pair or patterns like 00, 01, 10, 11, 100 & 101 etc and checks the balances with its complimentary pair/pattern [7].

6) *The linear complexity test*: It is directly related to the bit length of the LFSRs used to generate the random bit stream [7].

The P-value parameter is defined for all these tests in NIST suite. It shows the probability of a bit stream of being random in nature. For an ideal random bit set, this P-value is 1 and if it is 0, then the bit stream is completely nonrandom. Thus, a higher value or close to 1 is desirable.

Different sizes of data (up to 10,000 blocks of 114 bit i.e. 10,000 x 114 = 10,00,000 consecutive bits) are used during the statistical tests both for the actual and proposed cipher [28]. The observations of different tests conducted upon the generated bit stream are as follows:

As the LFSRs of the actual cipher have been converted into NLFSRs in MOD-I scheme, we see a slight increase in the P-values of various tests. The 32 bit SRES is reused in feedback path of the shift registers in MOD-II and again slight increment in the P-values of various tests. As the last 32 bits of current location (CGI) of the user incorporated in output bit stream the slight increment in the P-values of various tests can be observed I MOD-III. Because all proposed modifications are implemented here simultaneously in MOD-C, a huge increase in the P-values of various tests can be observed.

The details of observations of different sizes of the data set are also provided in Table V for this MOD-C scheme.

TABLE IV. OBSERVATIONS OF THE PROPOSED SCHEMES

Test Parameter	Actual A5/1 (P-Value)	Proposed MOD-I Scheme (P-Value)	Proposed MOD-II Scheme (P-Value)	Proposed MOD-III Scheme (P-Value)	Proposed MOD-C Scheme (P-Value)
Frequency	0.46	0.55	0.58	0.57	0.77
Block Frequency	0.82	0.87	0.87	0.86	0.92
Cumulative Sum	0.44	0.61	0.62	0.64	0.80
Runs	0.90	0.91	0.92	0.91	0.94

Average		0.46	0.79	0.81	0.90	0.42	0.78	0.85	0.91	0.93	0.97	0.94	0.97	0.76	0.86

## V. CONCLUSION

The improvements in P-values of various tests of all four modifications (MOD-I, MOD-II, MOD-III & MOD-C) have been described in different tables of previous section. Based on these test results, it is stated that there is slight improvement in the randomness of generated bit stream of all three MODs but when all MODs are combined simultaneously in MOD-C a huge improvement can be observed in the P-values of Cumulative Sum test, Frequency test and most importantly in Linear Complexity test. There is a good balance between 0's and 1's (results of Frequency test), better random walks (results of Cumulative test), less occurrence of similar patterns and that too are well separated by different patterns (results of Run tests), low periodic patterns (results of DFT test) and enhanced entropy (results of Linear Complexity test) in random bit stream generated by proposed cipher.

An effort is made in this paper to improve the randomness by making three modifications MOD-I, II, & III and then comparing the NIST test results. These modifications are the incorporation of nonlinearity I feedback path of LFSRs, reusing the SRES of A3, and inclusion of current CGI of the user, respectively to improve the entropy. After that, all three modifications are implemented simultaneously in a combined manner to achieve better results. These are the major improvements and contributions in the proposed cipher scheme.

The weakness issues mentioned in early part of this paper are addressed significantly by these proposed schemes. Simulation & testing results confirmed it.

The test results of MOD-C scheme for different data sizes as shown in Table V and depicted in graphical form in Fig. 11 above. The P-values of all the tests of proposed A5/1 have been increased by a significant value in comparison with the original A5/1 cipher. For better randomness, higher P-values are desired and better randomness means stronger encryption and enhanced security. Therefore, as per the observations and test results, it is concluded that the proposed scheme of cipher is having better security against the cryptographic attacks with respect to the actual A5/1 cipher due to increased randomness (at the cost of slight increment in hardware).

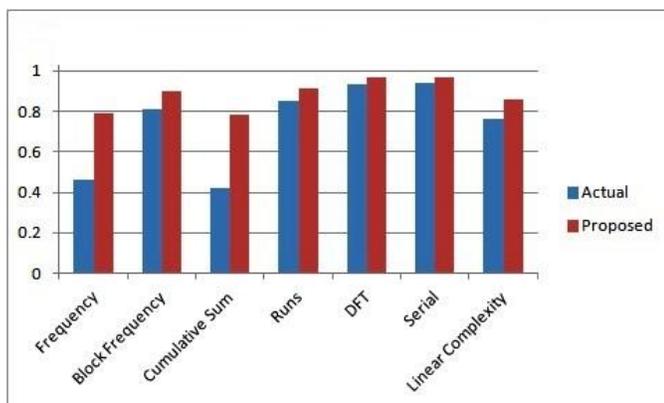

Fig. 11. Comparative Analysis of Test results of MOD-C Scheme.

**Abstract**—Agriculture and modern farming is one of the fields where IoT and automation can have a great impact. Maintaining healthy plants and monitoring their environment in order to identify or detect diseases is essential in order to maintain a maximum crop yield. The implementation of current high rocketing technologies including artificial intelligence (AI), machine learning, and deep learning has proved to be extremely important in modern agriculture as a method of advanced image analysis domain. Artificial intelligence adds time efficiency and the possibility of identifying plant diseases, in addition to monitoring and controlling the environmental conditions in farms. Several studies showed that machine learning and deep learning technologies can detect plant diseases upon analyzing plant leaves with great accuracy and sensitivity. In this study, considering the worth of machine learning for disease detection, we present a convolutional neural network VGG-16 model to detect plant diseases, to allow farmers to make timely actions with respect to treatment without further delay. To carry this out, 19 different classes of plants diseases were chosen, where 15,915 plant leaf images (both diseased and healthy leaves) were acquired from the Plant Village dataset for training and testing. Based on the experimental results, the proposed model is able to achieve an accuracy of about 95.2% with the testing loss being only 0.4418. The proposed model provides a clear direction toward a deep learning-based plant disease detection to apply on a large scale in future.

**Keywords**—Machine learning; VGG-16; disease detection; convolutional networks; Plant Village; modern farming

## I. INTRODUCTION

Agriculture has always been a basic human need ever since humans' existence as plants were a primary source of food. Even nowadays, agriculture is still considered an essential food resource and is the center of several aspects in humans' lives [1]. As a matter of fact, agriculture serves as the pillar of economy in many countries regardless of their developmental stages. The various domains that show the importance of agriculture include the fact that agriculture is a main source of livelihood where approximately 70% of the population depends on plants and their cultivation for livelihood. This great percentage reflects on agriculture being the most important resource that can actually stand a chance in the face of the rapidly increasing population [2].

One of the most critical challenges that face agriculture and affects it trade is plant diseases and how to timely detect them and deal with them to improve the health of crops. By definition, plant disease in a type of natural problems that

occur in plants affecting their overall growth and might lead to plant death in extreme cases. Plant diseases can occur throughout the different stages of plant development including seed development, seedling, and seedling growth [3]. When diseased, plants go through different mechanical, morphological, and biochemical changes [4, 5]. Truthfully, there are two main types of plant stress classified as biotic stress represented by living creatures that interact with plants in a way that negatively affects their growth [6] such as bacteria, viruses, or fungi [7], or abiotic stress represented by the collection of non-living factors or the environmental factors. Fig. 1 illustrates the collection of factors that contribute to plant diseases.

Typically, the commonly used approach for farmers, scientists, and even breeders, to detect and identify plant disease was the manual inspection of plants. Of course, this process requires expertise and knowledge for the proper detection. With time, manual inspection became tiresome and time consuming and not as quite efficient especially when large amounts of plants needed to be inspected. Another factor that proves the inefficiency of manual inspection is the similar conditions that might be caused by different pathogens that might look alike in their effect on the plant [6].

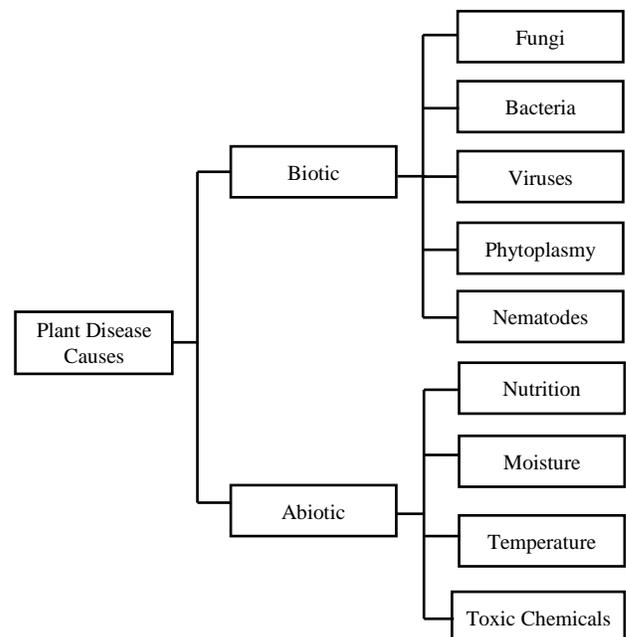

Fig. 1. Plant Disease Causes Detailed as Biotic and Abiotic Factors.

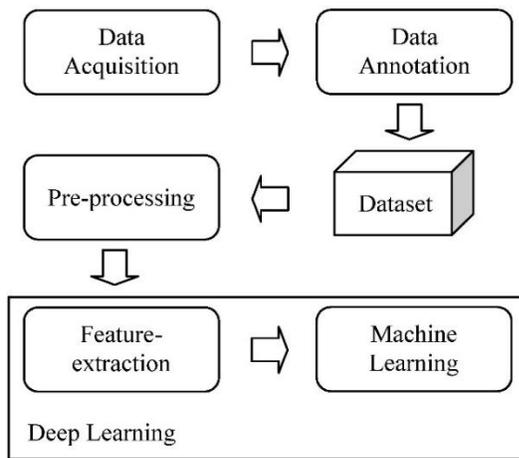

Fig. 2. Steps in the Implementation of Machine Learning Models in Plant Disease Detection.

For this reason, humans needed a better suited technique that can deliver effective plant detection results in less time.

Technology and the rise of both deep and machine learning came as a benefit in various fields, most importantly medicine. Nonetheless, advanced technological approaches can also be implemented for the purpose of detecting diseases in plants. Thus, machine learning and deep learning approaches can be considered non-destructive disease detection methods since they are based on image-processing techniques, as opposed to destructive serology or molecular methods [8]. However, for these techniques to work, the disease must have already caused a visible change in the plant, particularly in the leaf area or stem [9].

Artificial intelligence, computer vision and machine learning utilizations can greatly enhance the process of plant disease detection, and is already applied in multiple research papers [10]. Such technologies are capable of not only detecting the presence of a disease, but it is also possible to determine its severity, and to classify exactly which kind of disease is present in a given plant sample [11].

Based on their depth, the plant disease detection methods can be divided into shallow architectures and deep architectures. Basic machine learning methods like Random Forest (RF), Support Vector Machine (SVM), Naïve Bayes (NB), and K-Nearest Neighbor (KNN) rely on specific design intended for features such that good features and patterns must be recognized. These specific features include hue saturation value (HSV), Histogram of Oriented gradient (HOG), linear binary pattern (LBP), and red-green-blue RGB color features [12]. In machine learning, according to the complexity of the classifier, the more data is required for its training in order to achieve satisfactory results. The Fig. 2 illustrates the general flow of the implementation of machine learning techniques in detecting plant diseases. Initially, the data is acquired and labeled according to disease classes or healthy class. A specific dataset is then created for the model, where the input images can be pre-processed before feature extraction can take place. Machine learning algorithms are capable of recognizing the changes in features upon comparison, and thus determining the output as diseased or healthy [13].

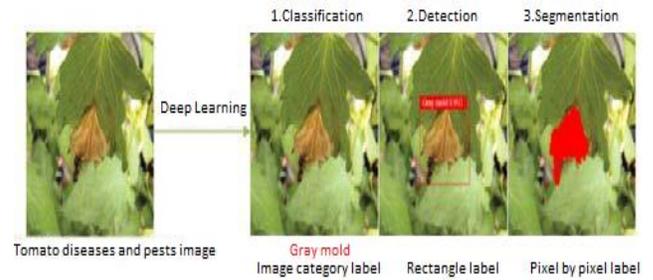

Fig. 3. Plant Disease Detection Phases through Deep Learning.

On the other hand, deep architectures like CNN (Convolutional Neural Networks) have also been heavily used in studies that are concerned with plant disease detection. These deep architectures differ from the shallow ones by not requiring hand-designed features since deep learning algorithms are able to learn the features themselves. Thus, deep learning approaches undergo three basic stages in detecting plant diseases (see Fig. 3): classification, detection, and segmentation [14].

After SVM machine learning approach was the most commonly used one for so long, approximately after the year 2015 CNN replaced SVM as the most popular ML technique for detection of diseases. CNN is considered state-of-the-art model that has been used in plant disease detection nowadays, especially since this task requires dealing with image data applications [13].

CNN can execute tasks such as classification of images, segmentation, object detection, and recognition. In their structure, CNNs are made up of artificial neural networks where tens and even hundreds of layers are used [15, 16]. CNNs is made up of an input layer, several convolutional layers, along with pooling layers in between them, and finally full connection layer in addition to activation function layers, and output layer. There exist several forms of CNN architectures like VGG-16, Inception-V3, ResNet50, and AlexNet. However, CNN architectures need large data numbers which is often considered as a challenge [17-19].

Since agriculture is essential there's a need to provide methods that enhance the agricultural methods in terms of planting, monitoring crop environment, detecting plant disease, and even harvesting. These important details led to significant research to be conducted and several papers to be published with the purpose of providing solutions to these agricultural challenges. This study proposes a model based on CNN, namely VGG-16 architecture in order to detect and classify a total of 19 plant conditions (several crop types and diseases) with the best accuracy possible.

Our contributions in this study can be summed up as follows:

1) Updating a large dataset based on Plant Village. The dataset comprises 15 thousand images of plant leaves which are captured on the field, which means that they are photographed within their surroundings, and thus it is efficient in terms of not needing to isolate the plant for disease detection.

2) Implementing the proposed VGG-16 model which is an effective convolutional neural network architecture, and it achieves a great accuracy. Our proposed model is capable of scanning through thousands of leaf images in order to identify if a plant has a certain type of disease based on its leaf image. The proposed model achieves a great accuracy of detection among 19 different disease classes in a short period of time, and it doesn't require a long time in training either.

The arrangement of the current paper is as follows: section two is a description of some of the published similar studies about ML and DL in plant disease detection. Section three describes the proposed methodology including the dataset and the proposed model. Results are provided and compared theoretically with some of existing techniques in section four, while section five concludes the article by sharing the future research intentions.

## II. RELATED WORK

A large number of studies have been performed and published about the detection of diseases in plants, especially since disease detection and classification can help in treating the diseased plant. The more technology emerges, the more it will be implemented in the agricultural field, one of the reasons being the continuous enhancement of already existing machine learning and deep learning methods that identify and classify plant diseases. This section describes five studies conducted in this regard.

The study by Ashwin et al. [20] discussed the development of a machine learning approach for the detection of diseases in Soybean plant in Mazandaran province in Iran. The study aimed to illustrate the importance of incorporating physiological features as well as the morphological features in realizing the diseases presence in a plant. The dataset used by the authors contains two randomly chosen subsets one for the healthy soybean plants (negative) and one for the diseased soybean plants (positive), which makes up to 2,500 images total. These images were collected from 10 different regions in the Mazandaran province. Several features were selected based on one-way ANOVA F1-score which include stem length, root length, number of pods per plant, empty pods per plants and seed oil content. Six different machine learning techniques with ten-fold cross validation and internal cross validation, which are the binary Logistic Regression, Multilayer Perceptron with Adam optimization, Random Forest, Gradient Tree Boosting (GBT), and Support Vector Machine. These ML techniques are evaluated based on confusion matrix, precision, F1-score, AUC, etc. Out of the six techniques, GBT achieved the best results of 96.79% accuracy, 96.68% F1-score, and 97% sensitivity and specificity depending on 21 features. The same technique achieved similar results (96.13%) depending on 12 morphological features.

Xian et al. [21] relied on a supervised machine learning termed Extreme Learning Machine "ELM" to determine the presence or absence of tomato diseases. The developed system was based on analyzing tomato leaves; the whole dataset was acquired from Kaggle, specifically the Plant Village dataset. The dataset comprises 10 classes, which makes a total of 1,000 images. The model is a feed forward neural network made up

of several hidden nodes with weights that connect and the complete neural network has no iterations. Image pre-processing is done on the images in the dataset including image resizing, segmentation, color space conversion, and HSV. A scatter plot of HSV is done on the resized image of tomato late blight, where a mask can be performed on the segmented image. 7,000 images of tomato leaves were selected for training (70%) whereas 3,000 were selected for testing (30%). The features HSV histogram, Haralick textures, and Colour Moments were selected and the labels were transformed into numerical values via the One Hot Encoding method. In the ELM model, using 1024 neurons and Sigmoid activation function yielded the best disease detection accuracy of 84.94%. When compared to Decision Tree model, ELM achieves better overall accuracies, 77.8% vs. 84.94%, respectively, in all of the 10 classes. On the other hand, SVM is slightly better in terms of accuracy (91.43%) when compared with this ELM model.

In their paper discussing plant disease detection, Bedi et al. [22] proposed a detection model based on convolutional auto encoder "CAE" and CNN as two parts of a hybrid system. The system was implemented on leaf images of peach plants specifically, but it can also be used to spot diseases in other plants. The dataset consists of two different classes healthy peach leaves (2160) and diseased leaves with bacterial spots (2297) which sums up 4457 images in total. 70% of the images in the dataset were used for training the system whereas the remaining 30% were kept for testing the detection performance. After gathering the data into the dataset, the usual pre-processing procedures are performed on the images. The next step is the training of the CAE model and getting compressed domain representations of leaf images from which, a CNN model will be trained afterwards. Upon testing, new leaf images will be used as input and their respective compressed representations will be compared for the CNN to determine if the leaf is healthy or not based on whether a defect is found. The CAE network was made up of 14 layers while the hybrid system was made up of 17 total layers through concatenating layers of the CAE with the CNN layers. Adam optimizer and binary cross entropy were used on the proposed system, where parameters such as NRMSE loss and accuracy measures were used for evaluation. As a result, the testing NRMSE loss was 0.0607, the testing accuracy reached 98.38%, and the F1-score was 98.36%.

Jeyalakshmi et al. [23] developed an approach based on machine learning for classification of diseases of potato and grape crops depending on their leaf images. The dataset was acquired from Pant Village dataset, consisting of 1000 healthy leaf images, as well as 2000 images of diseased potato leaves, and 3270 of diseased grape leaves. In the potato subset, there exist three different classes, while there are four classes in the grape leaves subset. From each RGB leaf images, the background was removed through using "enhanced GrabCut algorithm". Several features were selected from the images such as the intensities of red, green and blue, weighted mean and weighted standard deviation (belonging to histogram features), and texture features including contrast, entropy, etc. After that, the features were normalized and fed into several classifiers, namely KNN, Naïve Bayes, and SVM. It was observed that the number of features (ranging between 7 and

13) affects the accuracy of detection such that the higher the number of features, the better the accuracy. For instance, the highest accuracies were achieved by KNN at 94% considering 13 features, and 96.8% by SVM similarly in potato crops. On the other hand, in grape crops, SVM was superior achieving 96.02% accuracy with respect to 13 features.

Lamba et al. [24] published a paper discussing the implementation of several machine learning algorithms as well as deep learning techniques to properly detect diseases in crops. The images comprising the dataset are from Kaggle and rice dataset. In fact, four different datasets are created which are: the rice dataset containing 120 images, the pepper dataset containing 1,994 images, potato dataset containing 2,152 images, and tomato dataset containing 16,072 images. As usual, the images are pre-processed accordingly, and then auto-color correlogram filter is applied as an additional pre-processing step. After that, classification took place through machine learning techniques, or through deep learning methods with various activation functions to assess the overall performances. With respect to machine learning, fifteen different algorithms were tested including bayes net, random forest, and iterative optimized classifier to name a few. On the other hand, in the deep learning method, different activation functions were used including SoftMax, Softsign, ReLu, etc. The evaluation of performance was done relying on confusion matrix, specificity, F1-score, and accuracy. As a matter of fact, each of the models (ML and DL) was implemented on each one of the four datasets. In Pepper dataset, random forest and DL-Softsign achieved the best results as ML and DL techniques respectively. In rice dataset, random forest and DL-Softmax achieved the best results. SVM and DL-Softsign were responsible for the better results in the tomato dataset, and SVM and DL-Hard-tanh outperformed the rest in the potato dataset. In conclusion, from the large set of experiments, the

authors concluded that in binary classification, DL with Softsign is the best, whereas Softmax is better suited for multi-class classifications. Table I compares between these similar systems.

From the analysis of these previous studies, a group of limitations can be seen, as most of the studies focus on detecting the diseases in one type of crops. On the other hand, logically, most farms are interested in growing more than one crop, especially if the farmer is using these crops for the local market, whereas in some cases a field might be planted with one specific type of crop which is grown for a huge demand and can be used for exportation and national trade. However, the aim is to create a model that can be used by the various farmers, whether they have a small farm growing multiple crops, or they had large farms with more than one type of crop. For this reason, we chose to take into consideration a group of plants to be analyzed and to train our model to detect their diseases respectively. Furthermore, the second aim is to create a reliable model which achieves very accurate results with minimal loss and minimal false detection (both false positive and false negative), for this reason the majority of the studies focus on CNN models for the disease detection class. Similarly, our chosen CNN architecture in VGG-16 still stands as one of the best computer vision models. VGG provides better results while having smaller convolutional layers since it doesn't rely on a large number of hyper-parameters, yet it has several 3x3 filters with stride 1, and max layers and padding with stride 2 that are distributed throughout the architecture. In addition, the VGG16 model not only perform image recognition and detection, but it is also capable of localization, meaning that in our case and objectives, the model can be improved to detect the exact location of the classified disease on the plant leaf.

### III. IMPLEMENTATION OF THE MODEL

In order to maintain constant care of plants in any farm, especially a vertical farm, you need to constantly keep a close eye on the crops and their leaves as well as their stems and all the surrounding conditions. Of course, detecting plant diseases from looking into plant leaves manually takes a lot of time and effort from the farmer, which is why automation could be a game changer in the field of plant disease detection. Computational techniques can be applied such that the images of the plants are being taken and analyzed or screened for diseases in a time efficient manner, without facing human effort or human error challenges.

In this project, we implement several deep learning technologies in order to classify the diseases in crops. Among machine learning techniques, deep learning is an interesting area since it can easily recognize patterns and perform complicated procedures, which makes it suitable for the disease classification task. In deep learning, deep neural networks are created, among which is the CNN, short for Convolutional Neural Networks, that can easily analyze images upon training. In our project, VGG-16 was selected to be the CNN classifier of different plant diseases.

#### A. Dataset

The chosen dataset for our study is the Plant Village dataset which contains numerous images of plant diseases totaling for 15,915 images. From these images, the dataset is divided into nineteen different classes, each class resembles a disease, and these classes do not overlap, meaning that a single image only belongs to one class and cannot simultaneously belong to two or more classes.

The nineteen classes include tomato, grape, apple, tomato, and corn diseases as well as healthy classes. The Fig. 4 and Fig. 6 demonstrate in detail the different classes and to which crop they belong.

The number of images per class varies between the classes, as shown in the Fig. 5. After the data had been selected, they

are collected in a csv file, where each image is labeled with a path that indicates the health conditions of the crop within the image.

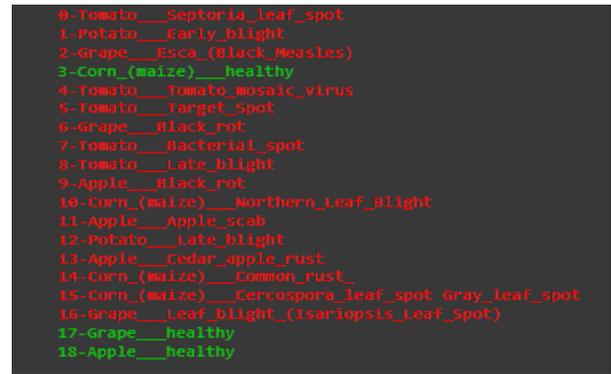

Fig. 4. Crop Disease Classes in Plant Village Dataset-1.

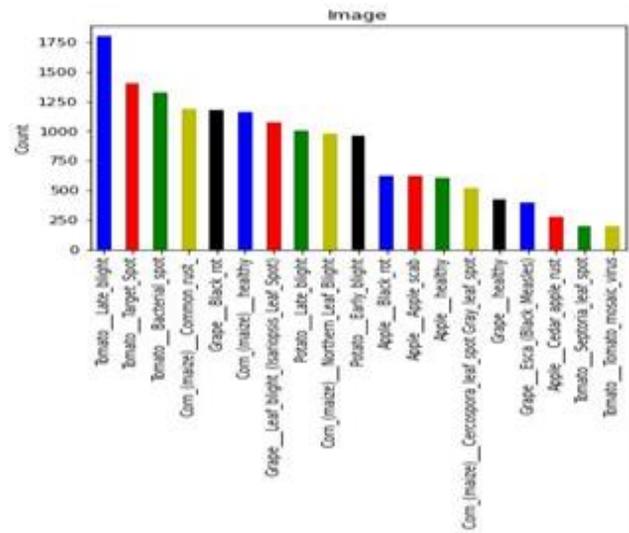

Fig. 5. Distribution of Images in Plant Village Dataset into Nineteen different Classes.

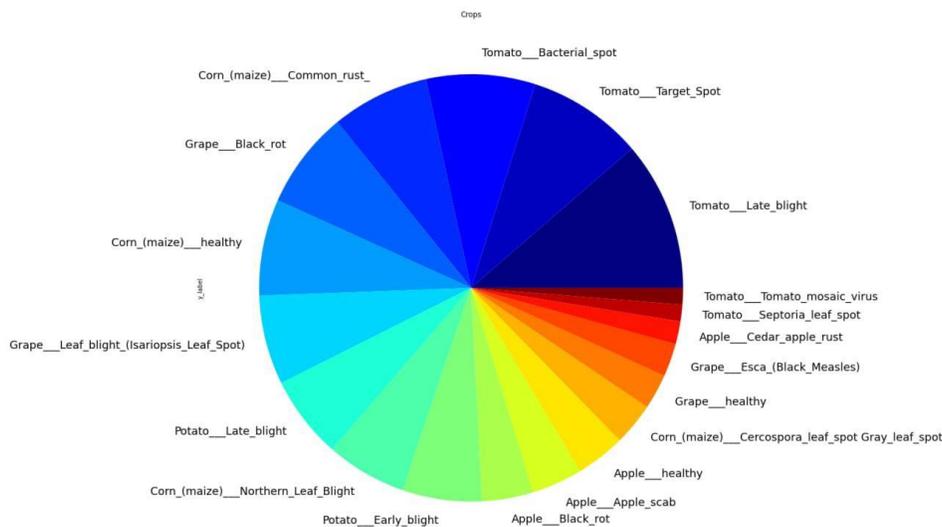

Fig. 6. Crop Disease Classes in Plant Village Dataset-2.

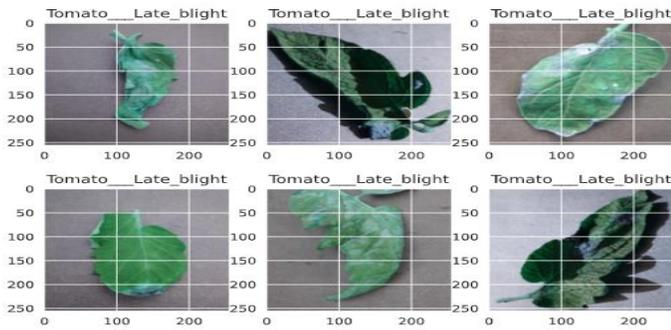

Fig. 7. Leaves with Diseases.

The Fig. 7 illustrates some images of the tomato late blight class which refers to a disease in the tomato crop.

In order for the data to be convenient for our chosen model, all the text value had to be converted into numeric values that are suitable for the model. Moreover, the majority of dataset’s images (80%) were utilized in the training procedure, and the rest 20% were kept for testing.

**B. Proposed Model**

VGG-16 is one of the most commonly used CNN architecture, especially since it works well with the ImageNet, which is large project utilized for visual object recognition procedures and it is considered one of the best models to be proposed so far due to its extreme usefulness in the image classification’s field in the deep learning domain. Initially, this model was created by Karen Simonyan and Andrew Zisserman in 2014, where they developed in during their work in Oxford University titled “Very Deep Convolutional Networks for Large-Scale Image Recognition”. In fact, “V” means Visual,” G” Geometry while “G” stands for research group who contributed in the development of this Convolutional Neural Network model, whereas the number 16 refers to the neural network layer’s number. ImageNet is so large that it contains more than fourteen million images distributed over thousand classes. This architecture is one of the top 5 models in terms of performance achievement in the ImageNet dataset, where its accuracy reached 92.7%. As an approach for the AlexNet enhancement, this architecture was submitted to ImageNet.

Large Scale Visual Recognition Challenge (ILSVRC), where this model has replaced the large kernel-sized filters of numbers 11 and 5 in both first and second convolutional layer, respectively by a multiple three × three kernel-sized filters consecutively. Moreover, the training of this model was trained by utilizing NVIDIA Titan Black GPUs for several weeks.

**C. VGG-16 Architecture and Training Procedure**

The training Procedure is made up of three consecutive steps as shown in Fig. 8:

- Preparing the images.
- Classifying the photos.
- Printing the decision.

**Image Processing:** The input of the convnets is 224 × 224 RGB image with a fixed size where the value of each pixel is subtracted from the RGB mean value of the training image.

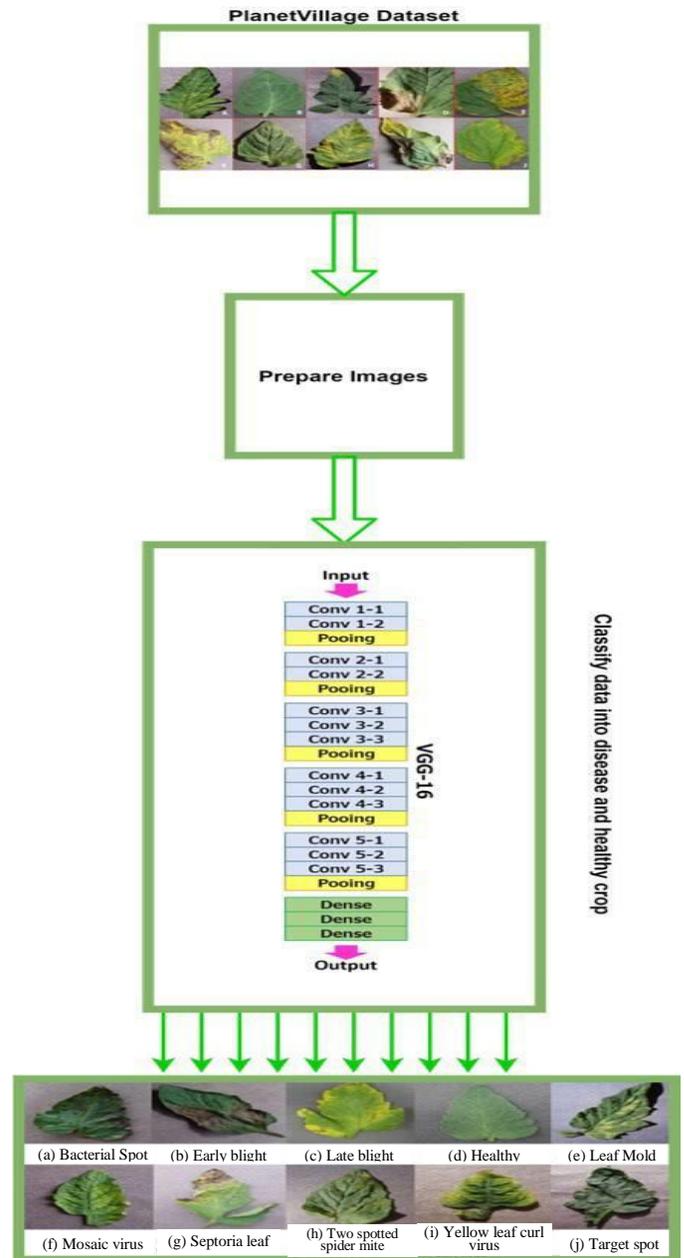

Fig. 8. Training Steps.

**Classifying the data:** The proposed model is made up of thirteen convolution layers, two batch normalization layers, along with five max-pooling layers and three full connection layers.

The processed image passes through several convolutional layers that contains filters that are characterized by a receptive field of size 3 × 3 for capturing the notions of left and right, up and down along with the center. Despite its small size of the mentioned filter, this filter is accompanied by the same efficiency as that of a receptive field of size 7 × 7 due to its deep characteristics such as including more nonlinearities and lesser parameters. In addition to that, a 1x1 convolution filter was used as an input channel’s linear transformation in a certain configuration. On the other hand, both spatial padding

and the convolution stride are fixed to 1 pixel for  $3 \times 3$  convolutional layers, in which the spatial resolution's preservation becomes easy to occur. Also, spatial pooling is easier in case of a five max-pooling layers' addition after some of the convolutional layers and the Max-pooling layer takes place over a  $2 \times 2$ -pixel window, with stride 2.

In addition to that, a total of three varying FC (Fully Connected) layers in depths are fixed behind a group of convolutional layers, where the first two FC layers is made up of 4096 channels per FC layer, and the third performs 1000-way ILSVRC classification and is made up of 1000 channels for each class. Finally, the final layer is the soft-max layer, it's important to say the Fully Connected Layer's configuration does not vary among different networks.

The architecture of the VGG-16 model is portrayed in details in the Fig. 9.

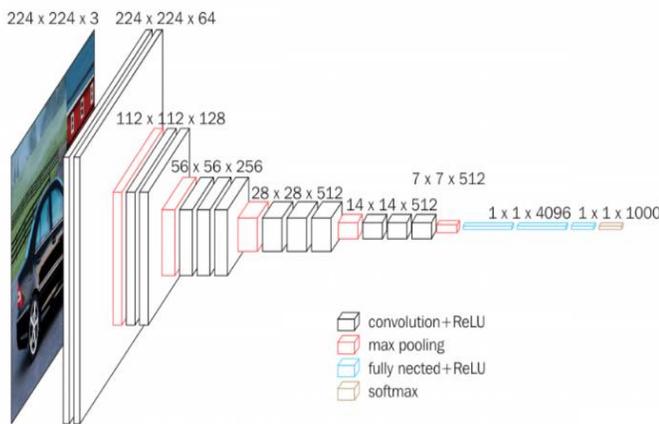

Fig. 9. VGG-16 Detailed Architecture showing the Various Layer and their Positioning.

#### D. Activation Function Used

Two activation Functions were used for our model training where the Softmax activation and the ReLU function.

The ReLU function was used at the fully connected layers, where the ReLU or "Rectified Linear Unit" is one of the popular activation functions used in Neural Networks and specifically in Convolutional Neural Networks and is defined as in (1):

$$y = \max(0, x) \quad (1)$$

Moreover, the Softmax activation function is used for the output layers and this activation function is a type of logistic regression that is able of normalizing the inputted vector to a new vector where its probability distribution is equal to 1 and it is defined as in (2):

$$\sigma(\vec{a})_i = \frac{e^{z_i}}{\sum_{j=1}^K e^{z_j}} \quad (2)$$

#### E. Loss Functions used

In the machine learning domain, the cost functions tend to optimize the model in the training procedure and the aim of the training procedure is to minimize the loss function and the model obtained is better as much as we tend to minimize this

loss function. Therefore, one of the most important loss functions is the Cross Entropy Loss Function where it is used for Classification model's optimization and the complete understanding of this loss function depends on the Softmax activation function understanding. Moreover, in our project, the Sparse Categorical Cross Entropy is used for training our model where it has the same loss function as that of the cross entropy as in (3):

$$Loss = - \sum_{i=1}^{output\ size} y_i \log \hat{y}_i \quad (3)$$

However, the truth labelling procedure is what differs between the two loss functions, where in the case of a one hot encoded true labels ([1,0,0], [0,1,0] and [0,0,1] in 3 classification problem) the categorical cross entropy is used, while the cross entropy is used in the case of an integer truth labels coding ([1],[2],[3]).

#### F. Accuracy Calculation

The accuracy of the model is calculated as in (4):

$$Accuracy = \frac{True\ Positive}{True\ Positive + True\ Negative} \times 100 \quad (4)$$

### IV. RESULTS

The performance of our proposed model was assessed in terms of Loss Function and Accuracy, which was measured during the training/validation step as well as during the testing step. The Fig. 10 shows the performance during the training phase.

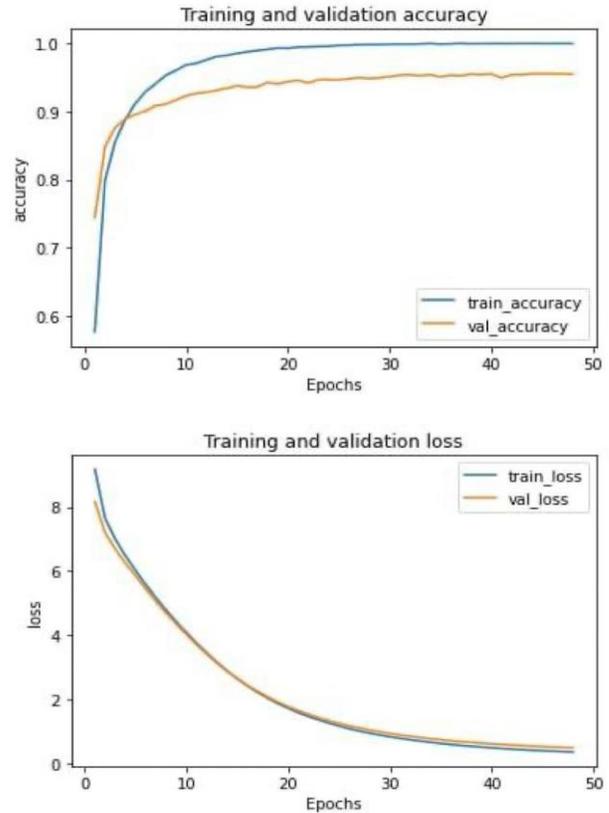

Fig. 10. The Performance of Proposed Model in Terms of Training and Validation Loss and Accuracy.

In the testing phase, the proposed VGG-16 model achieves the 93.5% accuracy, taking into consideration that the model performs classification on 19 different classes. The performance of our model is excellent for detecting diseases automatically from plant images. On the test set, which is excellent accuracy for classifying 19 items of plant images where the Test loss has reached 0.44 while the Test accuracy has reached 0.95. Moreover, the test accuracy was also computed for each of the 19 cases as well as the estimated distribution for the prediction and probability is shown in the Fig. 11 and Fig. 12.

A. Discussion

In the light of these results, and taking into consideration all of the parameters such as the big dataset and the variety of used crops, we can compare our results with those of similar studies that also used VGG networks for plant disease detection. For instance, the study by Iftikhar Ahmad implemented the VGG-16 model among others for the detection of diseases that infect tomato leaves, where the VGG16 network achieved a 76.2% accuracy by using feature extraction on augmented field dataset of 15 thousand images, and 84% accuracy for VGG16 when using parameter tuning [25]. Another study also used VGG and achieved an accuracy of 95.32% when using the Plant Village dataset of 4062 grape leaf images [26]. Narayani Patil and his colleagues also used VGG-16 networks for detection of plant diseases, and it achieved 97.53 % accuracy [27]. Finally, a pretrained VGG-16 model achieved an accuracy of 94.3% compared to 96.5% for the fine-tuned VGG-16 while using the Plant Village dataset but only for tomato leaves [28]. Taking into consideration that in our model we used a large dataset and multiple crops, it can be concluded that our VGG-16 model performed better in terms of accuracy than these studies.

Increasing agricultural movement is becoming more and more important by the day due to the rapid increase in population which increases the food demand, and ultimately means the need for more crops. Maintaining crop health is a very important field, since growing the plants in their ideal conditions leads to better yield which comes with greater benefits. New technologies are invested in the agricultural domain to take care of the wellbeing of plants.

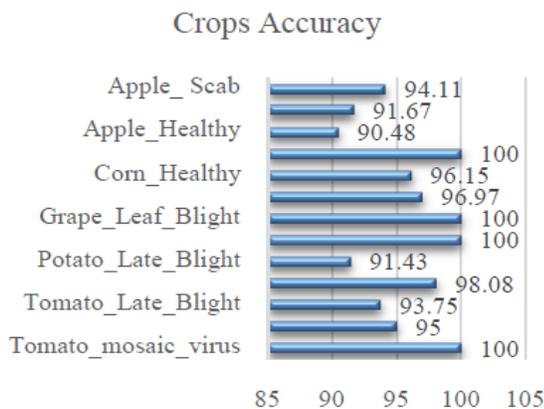

Fig. 11. Crops Accuracy.

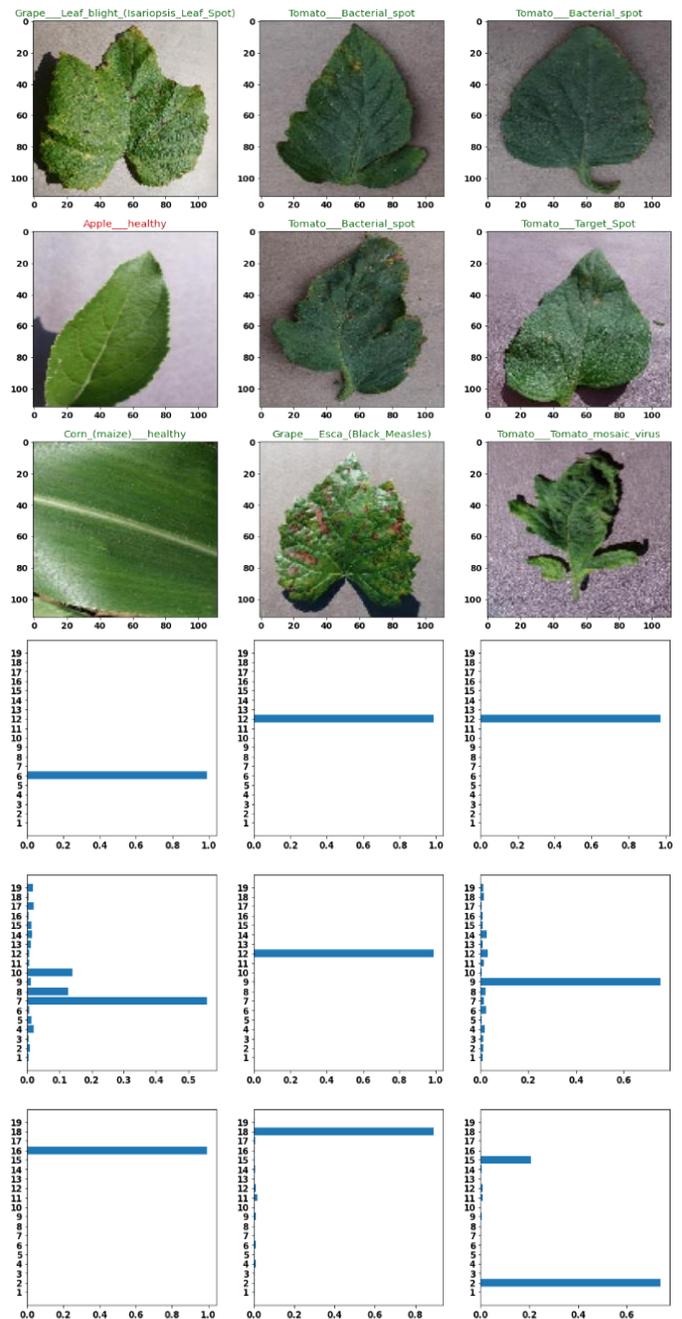

Fig. 12. Probability Estimated Distribution.

One of the domains where technology can have a large impact is the detection of plant diseases. Machine learning and deep learning are often implemented in systems for this specific purpose especially since ML techniques have an important image processing capability.

V. CONCLUSION

In this study, we proposed a system for the detection of plant diseases through analyzing leaf images of plants to determine not only if they are healthy or diseased, but rather to classify which kind of disease exists in each crop type. Our

model is based on a VGG-16 architecture that classifies 19 classes of plant diseases, according to the data acquired from the Plant Village dataset. The model was able to achieve a 95.2% accuracy with a loss of 0.4418.

Despite achieving a high accuracy with a low loss, our model faces some limitations since the input images must have certain illumination conditions and a complex background behind them due to the fact that they are collected from actual leaves from planted plants. These conditions pose as a challenge for any model used for plant disease detection and they can be considered as areas for improvement when designing or trying to enhance the existing model. Furthermore, in the future studies, our efforts will be focused on achieving more precise disease detection, particularly through training our machine learning model to identify the exact location of the disease on each leaf, especially if more than one disease is detected in one plant leaf. In addition to that, the plant disease dataset can be further increased to take into consideration even more plant diseases and to incorporate additional crop types. Moreover, we can consider some advanced methods to increase the accuracy of processing of leaf images by applying technologies like Faster region-based convolutional neural network (Faster R-CNN), which is a unified network designed for object recognition. Faster R-CNN creates a network that proposes a region for the detection which is then fed to the developed model for training, and after that according to the features, the optimal detection region is selected for classification purposes. Another method that can be implemented is the You Only Look Once YOLO technology which presents a very fast detection in real time with approximately 45 frames for second. Another technique similar to YOLO is the Single Shot Detector (SSD) which provides a fast detection of objects from a single frame. SSD achieves its high accuracy by producing detection at different scales and separates between the predictions by aspect ratio.

Computer Science Department, School of Computer Science, Bina Nusantara University, Jakarta, Indonesia 11480<sup>1,3,4</sup>  
Tokyo Institute of Technology, Yokohama 226-8502, Japan<sup>2</sup>

**Abstract**—This research aims to create a model, analyze the factors that influence the COVID-19 mortality rate in Indonesia. There are five independent variables and one dependent variable used in the research. The independent variables used are the percentage of poor people, the percentage of households using shared toilet facilities, the percentage of households using wood as the main fuel for cooking, the percentage of the population whose drinking water source comes from pumped water and the percentage of population who have health insurance from private insurance. While the dependent variable used is the Annual Parasite incidence COVID-19. The results obtained are as follows. First, a Zero-Inflated Negative Binomial regression model was obtained for the case of COVID-19 morbidity where this model could overcome overdispersion and excess zero values in observations. Second, there are 4 independent variables that have a significant effect on the count model and there is no independent variable that has a significant effect on the Zero inflation model. Third, a web application is produced that can display the Zero-Inflated Negative Binomial regression model (ZINB).

**Keywords**—Mortality rate; overdispersion; zero-inflated negative binomial; Poisson regression; correlation

## I. INTRODUCTION

Health is very important for every human being. With a healthy body, the soul will be good, and the mind will be in balance. Having a healthy body and soul can support human activities without any obstacles. Steps that need to be taken to maintain health include exercising, getting appropriate nutrition coverage and guarding yourself from habits that damage the body. Public awareness is needed to carry out a healthy lifestyle to avoid disease. COVID-19 has become a health emergency in the past one month since the first case in Indonesia was reported in Depok in March 2020. The problem that Indonesia is currently facing is that the government is still not effective in conducting testing and COVID-19 cases and there is no enforcement of rules regarding social distancing and mobility [1].

Research on the analysis of factors that influence COVID-19 in Indonesia is carried out using several different methods. The Zero-Inflated method used by the researcher in this research is the Zero-Inflated Negative Binomial method. This research was conducted to model the COVID-19 mortality rate using the web-based Zero-Inflated Negative Binomial method. The Zero-Inflated Negative Binomial method is used because

there is overdispersion in the Poisson regression model and the data used has an excessive value of 0 [2]. Overdispersion is a condition where the value of the variance is greater than the average [3]. One of the causes of overdispersion is the number of observations that are zero in the dependent variable or variable Y. Zero-Inflated Negative Binomial Regression (ZINB) is a model formed from a mixed distribution of Poisson gamma [3]. If  $y_i$  is a discrete independent random variable with  $i = 1, 2, n$  the null value of the observation is assumed to appear in two appropriate ways for separate states. The first state called zero state occurs with probability  $\pi_i$  and produces only zero observations, while the second state is called Negative Binomial state occurs with probability  $(1 - \pi_i)$  and has a Negative Binomial distribution with mean  $\mu$ , with  $0 \leq \pi_i \leq 1$  [4]. Estimated ZINB regression parameters using the Maximum Likelihood Estimation (MLE) method with the EM (Expectation Maximization) and Newton Raphson Algorithm procedures [5]. This method is usually used to estimate the parameters of a model whose density function is known.

The use of the Zero-Inflated Negative Binomial (ZINB) method has been carried out by several researchers [6][7][8]. In research conducted concluded that the ZINB regression model is more appropriate to be used to model data on the number of maternal deaths in Bali Province which contains many zero values and experiences overdispersion [9]. In another research conducted and concluded that the Poisson regression model does not meet the overdispersion hypothesis, so another model is used, the proposed model is the Zero-Inflated Poisson (ZIP) model, but there is still overdispersion on the ZIP models [10].

To overcome this problem, the ZINB model and the hurdle negative binomial (HNB) model are used [11]. The Akaike Information Criterion (AIC) value of the ZINB model is lower than the value of the HNB model [12]. This shows that the ZINB model is best used in data on the incidence of diphtheria in Indonesia [13]. The HNB model can control zero values and overdispersion, just like the ZINB model [14]. However, in the data on the incidence of diphtheria in Indonesia, the ZINB model is more suitable to control the value and over-dispersion of the data concludes that the appropriate model for the frequency of traveling during the last six months in South Tapanuli regency, North Sumatra, for the March 2016 period is the Zero-Inflated Negative Binomial model [15].

The independent variables used in this research were the percentage of poor population, the percentage of households using shared toilet facilities, the percentage of the population whose drinking water source came from pump water and the percentage of the population who had health insurance from private insurance. The dependent variable used in this research is the COVID-19 mortality rate. Based on the data obtained, there are areas where the COVID-19 mortality rate is zero. This causes the data used to be overdispersion or the average value and variance are different. Therefore, the formulation of the problem in this research is:

- 1) Create a Zero-Inflated Negative Binomial model for the COVID-19 mortality rate in Indonesia.
- 2) Analyzing the Factors Affecting the COVID-19 mortality rate in Indonesia.

## II. MATERIALS AND METHODS

### A. Research Variable

The type of data used in this research is secondary data. The variables used in this research consisted of the dependent variable and the independent variable (can be seen in Table I). Measurement scale of the variables is ratio.

TABLE I. EXPLANATION OF THE VARIABLES USED

Variable Name	Variable type.	Definition
COVID-19 mortality rate	Dependent	API is the morbidity rate per 1000 population at risk in one year.
Percentage of poor people	Independent	Population whose average monthly per capita expenditure is below the poverty line. The unit used is Percent (%).
Percentage of households that use shared toilet facilities	Independent	MCK stands for bathing, washing, and toileting is one of the public facilities that are shared by several families for the purpose of bathing, washing, and defecating in certain residential locations which are considered to have a fairly dense population and low level of economic capacity. The unit used is Percent (%).
Percentage of households that use wood as the main fuel for cooking	Independent	Until now, household energy needs in rural areas are still supported by firewood and agricultural waste. In rural areas, especially in remote areas, people still use more than 60% of their energy needs from firewood or biomass. The unit used is Percent (%).
Percentage of population whose drinking water source comes from pumped water	Independent	Pump water is water that comes from pumping from a water source in the ground, then distributed into existing water pipes in the house or in the water tank. The unit used is Percent (%).
Percentage of population who have health insurance from private insurance.	Independent	Health Insurance is an insurance that provides insurance to the insured to replace any medical expenses which include hospital treatment costs, surgery costs and drug costs. The unit used is Percent (%).

### B. Research Steps

The data analysis technique used in this research is descriptive analysis, Poisson regression and Zero-Inflated Negative Binomial. The following is a more detailed explanation of the steps taken by researchers in completing this research.

- 1) Perform secondary data collection.
- 2) Perform data processing so that the data used.
- 3) Determine the type of variable from each variable used.

Conducting descriptive analysis by calculating the Mean, Median and standard deviation values. In addition, it determines the maximum and minimum values of each variable.

The following is an explanation of the steps taken by researchers in making this Zero-Inflated Negative Binomial model (can be seen in Fig. 1):

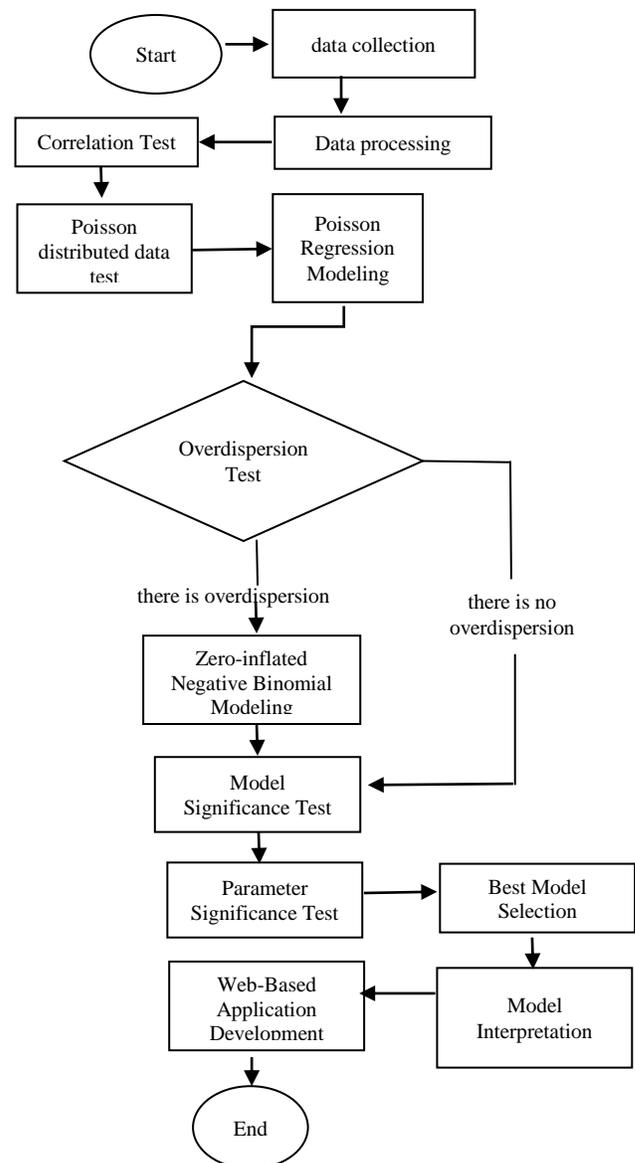

Fig. 1. Flowchart of Research Steps.

1) Perform the Spearman rank correlation test to find out whether there is a relationship between the dependent variable and the independent variable with the following steps:

- Specifies  $H_0$  and  $H_1$ .
- Calculate  $\rho_{count}$  according to equation.

Equation (1) if there is no the same rank.

$$\rho_{calculate} = 1 - \frac{6 \sum d^2}{n(n^2-1)} \quad (1)$$

Equation (2) If there is the same rank.

$$\rho_{calculate} = \frac{\frac{\sum(R_x - \bar{R}_x)(R_y - \bar{R}_y)}{n}}{\sqrt{\frac{\sum(R_x - \bar{R}_x)^2}{n}} \sqrt{\frac{\sum(R_y - \bar{R}_y)^2}{n}}} \quad (2)$$

- $\rho_{count}$  =Spearman Correlation Coefficient.
- $d$  = Rank difference for each data.
- $n$  = Number of Samples or data.
- $R_x$ = Rating for each data on Variable X.
- $\bar{R}_x$  = Average Rating for each data on Variable X.
- $R_y$ = Rank for each data on Variable Y.
- $\bar{R}_y$  =Average Rating for each data on variable Y.
  - $H_0$ :  $\rho = 0$  which means there is no correlation between variables X and Y.
  - $H_1$  :  $\rho \neq 0$  which means there is a correlation between the variables X and Y.
- Determine the  $\rho_{(table)}$ .
- Comparing the value of  $\rho_{count}$  with the value of  $-\rho_{(table)}$ .
- Draw conclusions based on the results of the comparison.

2) Determine the estimated regression coefficient by using the Maximum Likelihood Estimation method and Newton Raphson iteration [16].

3) Create a Poisson Regression model using Equation (3).

$$\ln \hat{\mu}_i = \hat{\beta}_0 + \sum_{j=1}^p \hat{\beta}_j x_{ij}, i = 1, 2, \dots, n \text{ and } j = 1, 2, \dots, p \quad (3)$$

4) where the coefficients used are the coefficients obtained in step 3.

5) Create a Poisson Regression model using Equation (3).

$$\ln \hat{\mu}_i = \hat{\beta}_0 + \sum_{j=1}^p \hat{\beta}_j x_{ij}, i = 1, 2, \dots, n \text{ and } j = 1, 2, \dots, p \quad (3)$$

where the coefficients used are the coefficients obtained in step 3.

6) Perform the Overdispersion test on Poisson regression with the following steps [17]:

- Specifies  $H_0$  and  $H_1$ .
- Determine the value of Deviance ( $\theta_1$ ) and Pearson Chi-Squared ( $\theta_2$ ).
- Compares the values of  $\theta_1$  and  $\theta_2$  with 1.
- Draw conclusions based on the results of the comparison.

7) If Overdispersion is found, then the model made is Zero Inflated Negative Binomial.

### C. Analyzing

After the previous steps have been taken, the steps taken to analyze the factors that influence the COVID-19 mortality rate are as follows:

1) Determine the estimated regression coefficient by using the Maximum Likelihood Estimation method and Newton Raphson iteration.

2) Create a Zero-Inflated Negative Binomial model using Equations (4).

$$\text{logit } \hat{\pi}_i = \hat{\gamma}_0 + \sum_{j=1}^p \hat{\gamma}_j x_{ij}, i = 1, 2, \dots, n \text{ and } j = 1, 2, \dots, p \quad (4)$$

$p$  : number of independent variables.

$n$  : number of observations.

$\hat{\beta}$ : estimated ZINB regression model parameters.

$\hat{\gamma}$ : estimated ZINB regression model parameters.

3) Conducting the test simultaneously with the following steps:

a) Specifies  $H_0$  and  $H_1$ .

b) Calculating the value of the G test statistic according to Equation (5).

$$W = \left( \frac{\hat{\beta}_j}{SE(\hat{\beta}_j)} \right)^2 \quad (5)$$

The test criteria is reject  $H_0$  if  $W > t(\frac{\alpha}{2}; n - 1)$ . Denial  $H_0$  at the level of significance  $\alpha$  means that a certain j-th independent variable has a significant contribution to the dependent variable Y.

c) Determining the value  $X_{(\alpha, n-k-1)}^2$ .

d) Comparing the value of the G test statistic with the value of  $X_{(\alpha, n-k-1)}^2$ .

e) Drawing conclusions based on comparison results.

4) Conduct a parameter significance test for each of the independent variables in the former model to find out which variables influence the COVID-19 mortality rate. The test steps are as follows:

- a) Specifies  $H_0$  and  $H_1$ .
  - b) Calculating the value of the Wald test statistic according to Equation (5).
  - c) Looking for value  $t(\frac{\alpha}{2}; n - 1)$ .
  - d) Comparing the statistical value of the Wald test of each independent variable with the value of  $t(\frac{\alpha}{2}; n - 1)$ .
  - e) Determining the independent variables that affect the dependent variable based on the comparison results.
- 5) Choose the best model based on Akaike Information Criterion (AIC) based on Equation (6).

$$AIC = 2k - 2 \ln(\hat{L}) \tag{6}$$

$k$  = Number of parameter estimates in the model  $\hat{L}$ = The maximum value of the model Likelihood function

- 6) Make an interpretation of the model that has been made.

### III. RESULT AND DISCUSSION

In this research, a web-based application was made. Users must register their personal data first as a complete account. After the account has been successfully created, the user will be directed to the Login page to input the registered Username and Password. If the Username and Password match, the User can access the features contained in the application. After successful login, the user will be directed to the home menu. In the home menu there is a Navigation bar that contains the features found in the application. Users can see the results of predictions of mortality rates that have been done before or Users can make new interpretations of COVID-19 mortality rates based on existing variables. After the user has finished using the application, the user can log out of the account by pressing the logout button. Use cases in this research can be seen in Fig. 2.

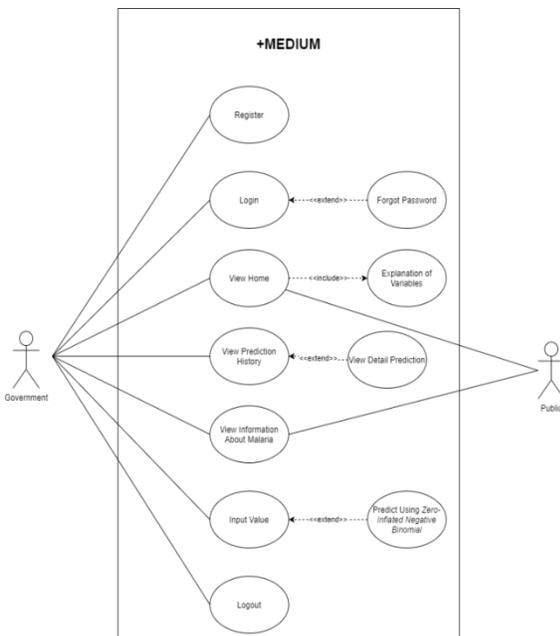

Fig. 2. Use Case.

### A. Correlation Analysis

The independent variables tested were the percentage of poor people ( $X_1$ ), the percentage of households using shared toilet facilities ( $X_2$ ), the percentage of households using wood as the main fuel for cooking ( $X_3$ ), the percentage of the population whose drinking water source came from pumps ( $X_4$ ), the percentage of the population who had health insurance from Private Insurance ( $X_5$ ), Area Height ( $X_6$ ), Number of Hospitals ( $X_7$ ), Number of Doctors ( $X_8$ ) and Percentage of Households with Ground Floor ( $X_9$ ). For example, the correlation value of  $X_1$  and  $Y$  is  $-0.4570287$ , then the interpretation of the correlation value is that the relationship between the percentage of the poor and the COVID-19 mortality rate is in the moderate category and contradicts each other where if the percentage of the poor increases, then the mortality rate will decrease (can be seen in Table II).

Based on Table I, the correlation value of several independent variables is greater than  $(0.05,29)$  which means that several independent variables have a significant effect on the dependent variable. The influential variable is Percentage of poor people ( $X_1$ ), the percentage of households using shared toilet facilities ( $X_2$ ), the percentage of households using wood as the main fuel for cooking ( $X_3$ ), the percentage of the population whose drinking water source came from pumps ( $X_4$ ), and the percentage of the population who had health insurance from Private Insurance ( $X_5$ ). Therefore, the variables Area Height ( $X_6$ ), Number of Hospitals ( $X_7$ ), Number of Doctors ( $X_8$ ) and Percentage of Households with Ground Floor ( $X_9$ ) are excluded from the modeling to be carried out.

### B. Poisson Distributed Data Test

From the test, the results of the  $D_n$  test statistic value of  $0.4286$ . These results were compared with the statistical value of the Kolmogorov-Smirnov test  $(0.05;7)$  which was worth  $0.48343$ . Because the statistical value of the  $D_n$  test is smaller than the statistical value of the Kolmogorov-Smirnov test, it can be concluded that  $H_0$  failed to reject or the data came from a population that followed the Poisson distribution. Based on the conclusion, the regression model that will be made is Poisson regression modeling.

TABLE II. SPEARMAN CORRELATION TEST

Variabl e	$\rho$	Direction	$\rho(0.05,29)$	Conclusio n
$X_1$	0.4570287	Negative	0.368	There is a relationshi p
$X_2$	0.435146	Positive	0.368	There is a relationshi p
$X_3$	0.3951663	Negative	0.368	There is a relationship
$X_4$	0.4761548	Positive	0.368	There is a relationshi p
$X_5$	0.4286245	Positive	0.368	There is a relationshi p
$X_6$	0.29007756 9	Negative	0.368	No connection
$X_7$	0.29205161 4	Positive	0.368	No connection
$X_8$	0.14653836 3	Positive	0.368	No connection
$X_9$	0.19619172 8	Negative	0.368	No connection

TABLE III. POISSON REGRESSION MODELING RESULTS

Variable	Coefficient	Standard Error	Test Statistic Value	Conclusion
Intercept	3.772434	0.318566	11.842	Significant
X <sub>1</sub>	-0.004478	0.013024	- 0.344	Not Significant
X <sub>2</sub>	0.078039	0.021383	3.650	Significant
X <sub>3</sub>	-0.034350	0.003827	- 8.975	Significant
X <sub>4</sub>	0.085689	0.011711	7.317	Significant
X <sub>5</sub>	-1.014189	0.201304	- 5.038	Significant

Table III shows the coefficient values, standard error, test statistics and conclusions from each Poisson regression variable. The influential variable is Percentage of poor people (X<sub>1</sub>), the percentage of households using shared toilet facilities (X<sub>2</sub>), the percentage of households using wood as the main fuel for cooking (X<sub>3</sub>), the percentage of the population whose drinking water source came from pumps (X<sub>4</sub>), and the percentage of the population who had health insurance from

Private Insurance (X<sub>5</sub>). The model formed based on the values shown in Table III is as follows:

$$\ln \hat{\mu}_i = 3.772434 - 0.004478 * X_1 + 0.078039 * X_2 - 0.034350 * X_3 + 0.085689 * X_4 - 1.014189 * X_5$$

C. Zero-Inflated Negative Binomial Modeling

The Zero-Inflated Negative Binomial (ZINB) regression model is a regression model that can be used to model data with the dependent variable having a Poisson distribution, many observations that are zero in the dependent variable and overdispersion occurs.

Table IV displays the coefficient values, Standard error, test statistics, and conclusions from each of the Zero-Inflated Negative Binomial regression variables. Based on the table, it is known that the percentage of the population who has health insurance from private insurance does not have a significant effect on both models. So that the Zero-Inflated Negative Binomial modeling was carried out without using the variable Percentage of the population who had health insurance from private insurance. The results of modeling can be seen in Table V.

TABLE IV. RESULTS OF THE ZERO-INFLATED NEGATIVE BINOMIAL REGRESSION MODEL

Variable	Coefficient	Standard Error	Wald Test Statistic Value	Conclusion
β <sub>0</sub>	2.26342	0.33687	6.719	Significant
β <sub>1</sub>	0.48196	0.06754	7.136	Significant Influence on the Dependent Variable for the Count Model.
β <sub>2</sub>	0.12367	0.05760	2.147	Significant Influence on the Dependent Variable for the Count Model.
β <sub>3</sub>	-0.24037	0.04078	-5.894	Significant Influence on the Dependent Variable for the Count Model.
β <sub>4</sub>	0.13436	0.02281	5.891	Significant Influence on the Dependent Variable for the Count Model.
β <sub>5</sub>	-0.49147	0.48896	-1.005	No Significant Effect on the Dependent Variable for the Count Model.
γ <sub>0</sub>	-15.2554	5294.8945	-0.003	Not Significant
γ <sub>1</sub>	2.0205	709.9964	0.003	No Significant Effect on the Dependent Variable for the Zero-Inflation Model.
γ <sub>2</sub>	-13.0143	3093.7702	-0.004	No Significant Effect on the Dependent Variable for the Zero-Inflation Model.
γ <sub>3</sub>	-0.2961	287.7473	-0.001	No Significant Effect on the Dependent Variable for the Zero-Inflation Model.
γ <sub>4</sub>	-1.2309	2178.5769	-0.001	No Significant Effect on the Dependent Variable for the Zero-Inflation Model.
γ <sub>5</sub>	34.4325	8887.1670	0.004	No Significant Effect on the Dependent Variable for the Zero-Inflation Model.

TABLE V. ZERO-INFLATED NEGATIVE BINOMIAL MODELING RESULTS WITHOUT VARIABLE PERCENTAGE OF POPULATION WHO HAVE HEALTH INSURANCE FROM PRIVATE INSURANCE

Variable	Coefficient	Standard Error	Wald Test Statistic Value	Conclusion
β <sub>0</sub>	2.13703	0.32859	6.504	Significant
β <sub>1</sub>	0.52405	0.06850	7.650	Significant Influence on the Dependent Variable for the Count Model.
β <sub>2</sub>	0.14371	0.05981	2.403	Significant Influence on the Dependent Variable for the Count Model.
β <sub>3</sub>	-0.26860	0.04007	-6.704	Significant Influence on the Dependent Variable for the Count Model.
β <sub>4</sub>	0.15242	0.01937	7.870	Significant Influence on the Dependent Variable for the Count Model.
γ <sub>0</sub>	-27.395	24062.983	-0.001	Not Significant
γ <sub>1</sub>	7.081	2213.102	0.003	No Significant Effect on the Dependent Variable for the Zero-Inflation Model.
γ <sub>2</sub>	-17.144	697.278	-0.025	No Significant Effect on the Dependent Variable for the Zero-Inflation Model.
γ <sub>3</sub>	-2.119	617.880	-0.003	No Significant Effect on the Dependent Variable for the Zero-Inflation Model.
γ <sub>4</sub>	-9.382	2751.073	-0.003	No Significant Effect on the Dependent Variable for the Zero-Inflation Model.

The model formed can be as follows:

a) Count Model Coefficient

$$\hat{\mu} = \exp(2.13703 + 0.52405 * X_1 + 0.14371 * X_2 - 0.26860 * X_3 + 0.15242 * X_4)$$

b) Zero-Inflation Model Coefficient

$$\hat{\pi} = \frac{\exp(-27.395 + 7.081 * X_1 - 17.144 * X_2 - 2.119 * X_3 - 9.382 * X_4)}{1 + \exp(-27.395 + 7.081 * X_1 - 17.144 * X_2 - 2.119 * X_3 - 9.382 * X_4)}$$

#### D. Best Model Selection

The best model selection is done by looking at the AIC (Akaike Information Criterion) value. The selection of the best model is done by comparing the 2 models that have been formed, namely the Poisson Regression model and the Zero-Inflated Negative Binomial Model. The AIC values of the two models can be seen in Table VI.

TABLE VI. COMPARISON OF AIC VALUES

Regression Model	AIC Values
Regresi Poisson	817.4561
Zero-Inflated Negative Binomial (Full Model)	65.1253
Zero-Inflated Negative Binomial (Without $X_5$ )	62.1329

The AIC value in Table VI shows that the lowest AIC value is the Zero-Inflated Negative Binomial model without a Variable Percentage of the population who has health insurance from private insurance. These variables were excluded because they had no significant effect on the Count Model and Zero-Inflation Model. Therefore, the Zero-Inflated Negative Binomial modeling was carried out without using the Variable Percentage of the population who had health insurance from private insurance.

#### E. Model Interpretation

The ZINB model is used to deal with overdispersion in the Poisson Regression model. The ZINB model is divided into two components, namely the count model for and the zero inflation model for. The interpretation of the model formed from ZINB is based on the odd ratio value as seen from the exp ( $\beta$ ) value.

1) The interpretation of the count model coefficient is as follows :

a) The constant is 2.13703, meaning that if the variables are Percentage of poor people  $X_1$ , Percentage of households using shared MCK facilities ( $X_2$ ), Percentage of households using wood as the main fuel for cooking ( $X_3$ ), and Percentage of population whose drinking water source comes from Pump Water ( $X_4$ ), is zero, then the COVID-19 mortality rate is worth  $\exp(2.13703) = 8.474232$ .

b) The coefficient of  $X_2$  is 0.52405, meaning that every 1 percent increase in the percentage of poor people ( $X_2$ ), will increase the COVID-19 mortality rate by  $\exp(0.52405) =$

1.688854 times the original COVID-19 mortality rate, if other variables are constant.

c) The coefficient of  $X_3$  is -0.26860, meaning that every 1 percent increase in the percentage of households that use wood as the main fuel for cooking ( $X_3$ ), it will reduce the COVID-19 mortality rate by  $\exp(-0.26860) = 0.764449$  times the original COVID-19 mortality rate, if the variable is else constant value.

d) The  $X_4$  coefficient is 0.15242, meaning that every 1 percent increase in the Percentage of the Population whose drinking water source comes from Pump Water ( $X_4$ ) will increase the COVID-19 mortality rate by  $\exp(0.15242) = 1.164649$  times the original COVID-19 mortality rate, if other variables are constant.

2) The interpretation of the zero inflation model coefficient is as follows:

a) The constant is -27.395, meaning that if the variables are Percentage of poor people ( $X_1$ ), Percentage of households using shared MCK facilities ( $X_2$ ), Percentage of households using wood as the main fuel for cooking ( $X_3$ ), and Percentage of population whose drinking water source comes from from the Air Pump ( $X_4$ ), is zero, then the value of the COVID-19 mortality rate is  $\exp(-27.395) = 1.266E-12$ .

b) The coefficient of  $X_1$  is 7.081, meaning that every 1 percent increase in the percentage of poor people ( $X_1$ ), will increase the chance of the COVID-19 mortality rate to zero by  $\exp(7.081) = 1189,157$  times, if other variables are constant.

c) The coefficient of  $X_2$  is -17,144, meaning that every 1 percent increase in the percentage of households using shared MCK facilities ( $X_2$ ), will reduce the chance of the COVID-19 mortality rate to zero by  $\exp(-17,144) = 3.58E-08$  times, if other variables are constant.

d) The coefficient of  $X_3$  is -2.119, meaning that every 1 percent increase in the percentage of households that use wood as the main fuel for cooking ( $X_3$ ), it will reduce the chance of the COVID-19 mortality rate to zero by  $\exp(-2.119) = 0.1201$  times, if other variables are worth constant.

e) The coefficient of  $X_4$ , is -9.382, meaning that every 1 percent increase in the Percentage of the Population whose drinking water source comes from Pump Water ( $X_4$ ) will reduce the chance of the COVID-19 mortality rate to zero by  $\exp(-9.382) = 8.42E-05$  times, if other variables are worth constant.

#### F. Parameter Significance Test Results

Based on Table VII, it can be concluded that in the count model there are 4 variables that have a significant effect on the COVID-19 mortality rate. In the zero-inflation model, there are no independent variables that affect the COVID-19 mortality rate. Based on the two models, it can be concluded that the variables used are not appropriate for the zero-inflation model.

TABLE VII. PARAMETER SIGNIFICANCE TEST RESULTS

Variable Name	Count Model Coefficient	Zero-Inflation Coefficient
Percentage of poor people ( $X_1$ )	Significant	Not significant
Percentage of households using shared toilet facilities ( $X_2$ )	Significant	Not significant
Percentage of households using wood as the main fuel for cooking ( $X_3$ )	Significant	Not significant
Percentage of Population whose drinking water source comes from Pump Water ( $X_4$ )	Significant	Not significant

#### IV. CONCLUSION

The conclusions obtained from this research are as follows the factors that influence the COVID-19 mortality rate in the count model are percentage of poor people ( $X_1$ ), the percentage of households using shared toilet facilities ( $X_2$ ), the percentage of households using wood as the main fuel for cooking ( $X_3$ ), and the percentage of the population whose drinking water source came from pumps ( $X_4$ ). In the Zero-Inflation model, there are no factors that affect the COVID-19 mortality rate. so that the ZINB regression model used is the count model. Third, based on the evaluation of user satisfaction, the designed application has been able to help predict COVID-19 mortality and assist in providing information and insight to the public about COVID-19.

# Automatic Healthy Sperm Head Detection using Deep Learning

Ahmad Abdelaziz Mashaal<sup>1</sup>, Mohamed A. A. Eldosoky<sup>2</sup>, Lamia Nabil Mahdy<sup>3</sup>, Kadry Ali Ezzat<sup>4</sup>

Biomedical Engineering Department, Faculty of Engineering, Helwan University, Cairo, Egypt<sup>1,2</sup>  
Biomedical Engineering Department, Higher Technological Institute, 10<sup>th</sup> of Ramadan City, Egypt<sup>3,4</sup>

**Abstract**—Infertility is one of the diseases in which researchers are interested. Infertility disease is a global health concern, and andrologists are constantly looking for more advanced solutions for this disease. The intracytoplasmic sperm injection (ICSI) process is considered as one of the most common procedures for achieving fertilization. Sperm selection is performed using visual assessment which is dependent upon the skills of the laboratory technicians and as such prone to human errors. Therefore, an automatic detection system is needed for quick and more accurate results. This study utilizes a deep learning technique for the classification of heads of human sperms which indicate the healthy human sperms. The Convolutional Neural Network (CNN) model of visual Geometry Group of 16 layers (VGG16) was used for classification, and it is one of the best architectures used for image classification. The dataset consists of 1200 images of human sperm heads divided into healthy and unhealthy. Here, the VGG16 model is fine-tuned and achieved an accuracy of 97.92% and a sensitivity of 98.82%. Moreover, it achieved an F1 score of 98.53%. The model is an effective and real-time system for detecting healthy sperms that can be injected into eggs for achieving successful fertilization. This model quickly recognizes healthy sperms and makes the sperm selection process more accurate and easier for the andrologists.

**Keywords**—Infertility; sperm morphology; deep learning; human sperm head; healthy sperms

## I. INTRODUCTION

The inability of couples to achieve pregnancy after 1 year of regular coition is known as infertility [1]. Infertility is the problem of most couples around the world, about 30-40% of them related with male factor abnormalities [2]. The most important role in the intracytoplasmic sperm injection method is the selection of the best sperms that can be injected into the oocytes. Embryologists select the best sperm depending on the morphology of sperms by visual assessment. This process is time-consuming and so tiring compared to machine learning approaches [3]. Machine learning depends on manual extraction of features such as head area, length, and width of sperms [4]–[6]. The human sperms are composed of head, midpiece and tail. The head of human sperm contains the deoxyribonucleic acid which carries the genetic instructions needed for reproduction. The midpiece part has the mitochondria to supply the tail with energy required for movement. The tail part provides the sperm with motility required for its movement to oocytes for fertilization [34]. The tip of head contains acrosome which secretes enzymes that are useful for penetration and make the penetration process easier for human sperms.

Intracytoplasmic sperm injection (ICSI) process is considered as an optimum choice with male infertility diseases. ICSI process is done when the sperm count is low, and it is also preferable when the sperms have low motility according to the semen analysis. In Vitro Fertilization (IVF) process is different from ICSI since the fertilization is performed by the sperms themselves in the test tube without injection with any needles after keeping the human sperms with oocytes inside one tube [35]. Intrauterine Insemination (IUI) process is less costly in which the semen is injected directly into the uterine cavity and this method increases the success rate of pregnancy with some cases [34].

The rest sections of this paper is organized as follows: Section 2 discusses the literature review. Section 3 describes the methodology, dataset, and explanation of preprocessing stages in detail. Section 4 explains the proposed model for healthy sperm detection. Section 5 shows and discuss the results of this proposed model. Section 6 concludes the paper and mentions the scope of future work.

## II. LITERATURE REVIEW

There are several researches about automatic detection of the best sperms used for the intracytoplasmic sperm injection process using machine learning and deep learning. In one of these studies, J Riordon et al. improved a model for classification of sperms using VGG16 using versatile dataset with accuracy reached 94.1% [9]. Javadi et al. proposed a method for sperm evaluation with 3 labels which are acrosome, head and vacuole [10]. Mirroshandel et al. improved automatic detection algorithm for human sperm images with accuracy reached 93.2% with tail and neck [11]. Revollo, Natalia V., et al. improved an automatic system for human sperm head detection using machine learning techniques in which the sperms were labeled manually achieving an accuracy of 92% [36]. Bijar et al. proposed a model for segmentation of different parts of sperms with high accuracy [12]. Erfan Miahi et al. developed a neural architecture search based on genetic algorithm for detection of different parts of human sperm with an accuracy of 91.66% and 77.33% in the vacuole and head abnormality detection, respectively [37]. Prabakaran, L., and A. Raghunathan. proposed a convolutional neural network for abnormal sperm detection based on morphology achieving an accuracy of 98.99% [38].

There are some researchers who used K-nearest neighbor and principal component for sperm analysis [7]. Several researches have proven the relationship between ICSI success

and the morphology of the sperm head [8]. In some studies, stained sperms were used, and they are not useful for the intracytoplasmic sperm injection (ICSI) process, but this method has the advantage of detecting healthy sperms easily and it is more suitable for low quality and noisy images [14].

There are also many researchers used versatile types of deep learning architectures; liu et al. used AlexNet architecture for classification of human sperms [13]. McCallum et al. improved a VGG16 model for detecting the best sperms of highest integrity of DNA [14]. Ghasemian et al. proposed a model for recognition of sperm abnormality with low computation time [15]. Some studies used segmentation procedures, shaker et al. proposed a method for detection and segmentation of human sperms achieving accuracy of 92% for sperm head segmentation [16]. Urbano et al. presented a model for tracking of human sperms [17]. Mirsky et al. developed a system for healthy and unhealthy sperm detection based on morphology using machine learning with precision of 90% [18]. Thirumalaraju et al. presented a deep learning model with accuracy of 89% in recognition of good sperms [19]. These algorithms could automate the process of sperm recognition with its types [14]. For computer vision tasks, there are many algorithms for transfer learning performed by researchers to find out the best processes for the image classifiers [22], [23]. The design of the neural network affects the accuracy of the classification, depending also on the type of dataset. Baker et al. used reinforcement learning in designing neural network architectures [24], zoph et al. also updated a neural network architecture using reinforcement learning [25]. Zoph et al. used versatile methods for producing the best architectures for classification of images and proposed learning architectures for image recognition [21].

Mathematical morphology is so important for sperm recognition and detection of healthy and unhealthy sperms. Rodríguez et al. used Lambertian model and sperm cell segmentation based on mathematical morphology [28]. There are several research studies that are interested in counting the sperms using versatile methods. One of these works is the method of Susrama, I. G., K. E. Purnama, and M. H. Purnomo, which proposed a model for human sperm concentration and number using Otsu's threshold obtaining an accuracy of 91% [29]. There are some models for processing microscopic videos for detecting the motility of sperms [30]. It is helpful for tracking of the spermatozoa through the videos and this analysis is needed for motility assessment. Boumaza et al. improved an automatic system for concentration assessment based on decision trees machine learning [31]. Ilhan et al. presented an approach for analyzing spermogram tests with high correlation with visual assessment results and proposed an algorithm for motile sperm detection [32]. Lv, Qixian, et al. proposed an algorithm for automatic segmentation of sperm head based on the U-Net network [39]. Chandra, Satish, et al. utilized different deep learning models, and both ResNet50 and VGG19 models achieved an accuracy of 71%, 87.33%, 73% for acrosome, vacuole and head label, respectively [40].

The intracytoplasmic morphologically selected sperm injection (IMSI) usually is done using magnification of 10,000 and it has the property of motile spermatozoa selection properly [26]. Several researches demonstrated the effectiveness of IMSI over ICSI process due to the power of magnification of IMSI process and many factors that differ from patient to another. So, IMSI process in some cases showed clinically significant difference [26]. There are many factors that influence the success of intracytoplasmic sperm injection process, the World Health Organization (WHO) defined the criteria of reference values for the characteristics of semen. The reference volume of semen is 1.5 mL, reference sperm count is 15 million per mL and minimum total motility of 40% [27], [34]. The abnormalities of sperm heads can cause failure of fertilization, and then failure of ICSI process [8].

### III. MATERIAL AND METHODS

#### A. Sperm Head Dataset

The Dataset used is freely available for public, collected from Hannam Fertility Centre in Canada and utilized by McCallum et al [14]. Some processing work was done on dataset before using, and then the dataset has been classified into healthy and unhealthy human sperm heads with the help of andrologists as shown some of dataset in Fig. 2. Google Colab in python is mainly used for implementing this paper with the aid of MATLAB program. Dataset is partitioned into training set, test set and validation set. The dataset consists of 1200 images of size 150x150 pixels and partitioned as 720 images for training, 240 images for test purpose and 240 images for validation purpose, as represented in Fig. 1, and Table I.

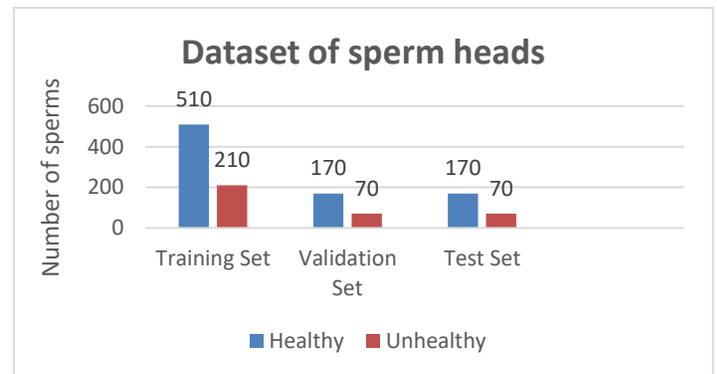

Fig. 1. Overview of Sperm Head Dataset with Healthy and Unhealthy Classes.

TABLE I. PARTITIONING OF DATASET

Dataset Partitions	Number of Images	Percentage
Training Dataset	720	60%
Validation Dataset	240	20%
Test Dataset	240	20%
Total Dataset	1200	100%

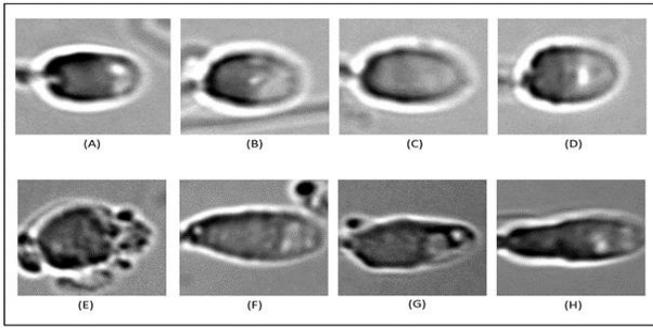

Fig. 2. A Selection of Sperm Head Dataset. (A), (B), (C), (D) Healthy Sperm Head Images. (E), (F), (G), (H) Unhealthy Sperm Head Images.

### B. Image Preprocessing

Preprocessing of images is an important step for image enhancement (e.g., noise removal), the median filter is used for this purpose [33] as represented in Fig. 3. Image resizing also is necessary in the preprocessing steps. Dataset images were scaled up to 224x224 pixels according to VGG16 requirements. Image resizing has an important role in image processing technique to enlarge or reduce the dataset. Image interpolation can be divided into two different ways, both image down sampling and image up sampling are necessary when resizing the dataset for matching the requirements of the deep learning model and differ according to each model and the field of study.

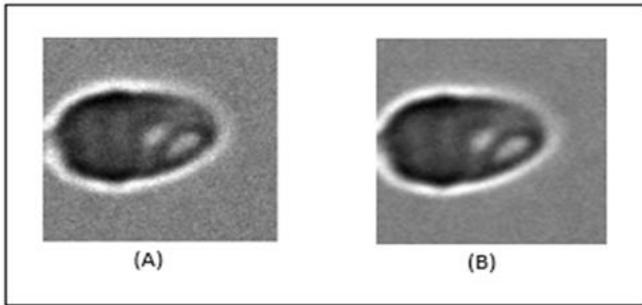

Fig. 3. Preprocessing of Input Images. (A) Noisy Image before Preprocessing. (B) Image after Applying Median Filter for Noise Removal.

The main preprocessing methods used after denoising process are explained as the following.

1) *Otsu's thresholding process*: In this technique, the thresholding on grayscale image is processed. Otsu's method is used to perform automatic image thresholding by obtaining the image histogram and computing the threshold value (t) then the image pixels is replaced into white or black depending on the value of the threshold (t) [29]. The image pixels whose saturation is greater the threshold is replaced into white and image pixels whose saturation is lower than the threshold is replaced into black color. It searches for the threshold that reduces the intra-class variance as shown.

$$\sigma_{\omega}^2(t) = \omega_0(t)\sigma_0^2(t) + \omega_1(t)\sigma_1^2(t) \quad (1)$$

where  $\sigma_{\omega}^2$  is the intra-class variance,  $\omega_0$  and  $\omega_1$  are the probabilities of the two classes separated by a threshold (t) and  $\sigma_0^2$  and  $\sigma_1^2$  are the variances of these two classes.

This method is considered as one of segmentation techniques in image processing and this algorithm can be described as the following.

#### Otsu's thresholding algorithm:

- a) Given grayscale image.
- b) Calculate the histogram of this image.
- c) Computing the probabilities of each intensity level
- d) Set up initial  $\omega_i$  and  $\mu_i$  at  $t = 0$
- e) Calculate  $\omega_i$  and  $\mu_i$  at all possible thresholds. ( $t = 1, t = 2, \dots$  till the maximum intensity)
- f) Calculate  $\sigma_b^2(t)$  as the following equation:

$$\sigma_b^2(t) = \sigma^2 - \sigma_{\omega}^2(t) = \omega_0(t)\omega_1(t)[\mu_0(t) - \mu_1(t)]^2 \quad (2)$$

where  $\sigma_b^2$  is the inter-class variance,  $\omega$  is the class probabilities and  $\mu$  is the class means.

- g) Choose the best threshold value for optimum results corresponding to the maximum  $\sigma_b^2(t)$  and apply this threshold to image [29].

2) *Area opening method*: Area opening technique is used for removal of objects with area smaller than a specified parameter from the foreground of binary images [33]. Mathematically, opening a set A by a structuring element B can be given by the following equation.

$$A \circ B = (A \ominus B) \oplus B \quad (3)$$

where the symbol  $\ominus$  denotes to erosion and  $\oplus$  denotes to dilation.

Area opening technique is utilized for removing vacuoles that may appear in the head of sperms in order not to affect the accuracy of the classifier of the proposed model as shown in Fig. 4, and this method contributes to get high accuracy.

3) *Image complement process*: The complement of a black and white image is converting the zeros to ones and ones to zeros [33]. Image complement is performed for getting white sperm head and black background as shown in Fig. 5. The image complement is used as a final step before training in which data augmentation is done through.

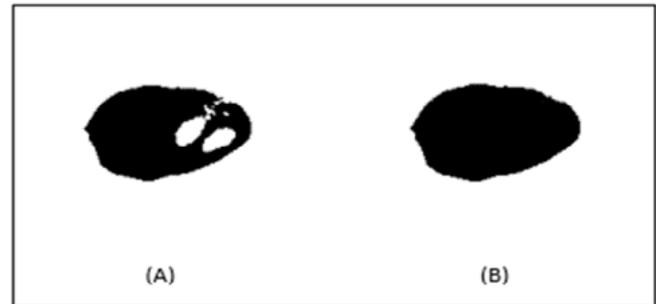

Fig. 4. Area Opening of Input Images. (A) Image after Applying Otsu's Thresholding Segmentation Method and before Applying Area Opening. (B) Image after Applying Area Opening for Removing Vacuoles in Sperm Head.

Fig. 5. Image Complement of Input Images. (A) Image after Applying Area Opening Process. (B) Image after the Complement Process.

4) *Data augmentation*: Image data augmentation is a technique used to increase the dataset by modifying images. Image data augmentation is performed only on training dataset. This is done by using ImageDataGenerator that is provided by Keras deep learning library. ImageDataGenerator class is used for augmentation of images with some parameters of image augmentation (e.g., shift, zoom and rotation) as represented in Table II. Some of these modifications for each parameter and its effect on the original images are shown in Fig. 6.

TABLE II. PARAMETERS OF DATA AUGMENTATION

Parameters	Values
Rescale	1./255
Width shift range	0.2
Height shift range	0.2
Horizontal flip	True
Zoom	0.25
Rotation	-30°
Image fill	"Nearest"

#### IV. PROPOSED HEALTHY SPERM HEAD DETECTION MODEL

The deep learning architecture VGG16 is a convolutional neural network model proposed by Simonyan et al. [20] and pre-trained on ImageNet. The size of the input image of this architecture is fixed 224x224x3 then the image is passed through a stack of convolutional layers and the filter used of size 3x3 [9]. At first it has two convolution layers with pooling layer then another two convolution layers with pooling followed by three convolution layers with pooling repeated three times and finally three layers of fully connected (FC) attached with the output layer (e.g., sigmoid function) as shown in Fig. 7. In this proposed model, new layers are considered. Flatten layer, dense, dropout, dense and dropout layer are added respectively, and then dense layer with sigmoid activation function is used as represented in Fig. 8.

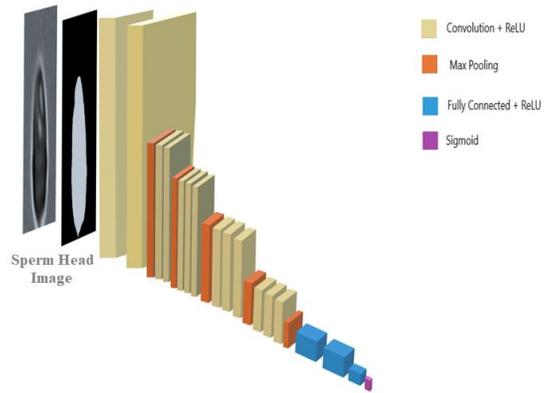

Fig. 7. General Representation of VGG16 Architecture.

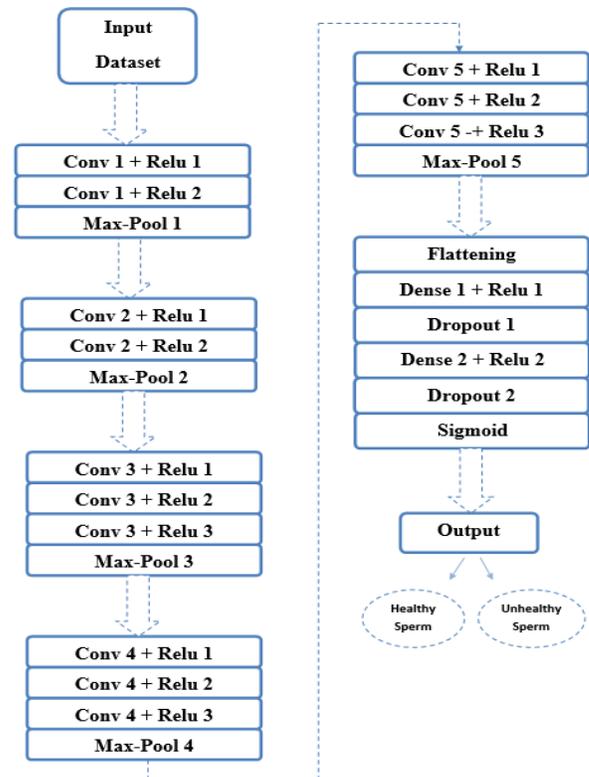

Fig. 8. Fine-Tuned Proposed Model for Healthy Sperm Head Detection.

The features of sperm head were extracted by convolutional layers, each convolutional layer has the same size of kernels [10]. Given an image H of size  $(u, v)$ , the convolution can be estimated as follows,

$$G(u, v) = (H * Q)(u, v) = \sum_x \sum_z M(u - X, v - Z)Q(x, z) \quad (4)$$

where Q is the convolution kernel of size x, G is the feature map of the output, H is the feature map of the input and  $(u, v)$  is the size of image.

In this proposed model, binary cross entropy loss function is performed since we have only 2 output categories, binary cross entropy loss function is used during adjusting the weights of the model, and then the loss can be minimized [10], this function is effective for optimizing the model and it is represented as the following formula.

$$E = -\frac{1}{n} \sum_{i=1}^n [y_i \cdot \log(\hat{y}_i) + (1 - y_i) \cdot \log(1 - \hat{y}_i)] \quad (5)$$

where n is the number of scalar values in the model output,  $y_i$  is the true label,  $\hat{y}_i$  is the predicted label.

The proposed algorithm demonstrated its effectiveness in classification of healthy and unhealthy sperm head then detecting the best healthy sperm head which indicates the best healthy sperm that can be used for successful fertilization as proved in andrology [34]. The main steps of the convolution and the VGG16 algorithm can be summarized as the following.

**1) Steps of Convolution algorithm are:**

- a) The first step is to multiply the filter with the region of the input image of the same size using the convolution formula.
- b) Each element is multiplied with an element in the corresponding location then the results will be summed and give one output value.
- c) Repeating these steps by sliding the filter across the image until getting the final output.

**2) Main steps of VGG16 algorithm are:**

- a) 2D Convolution as previously described.
- b) Max Pooling. This operation is used for down sampling feature maps by calculating the maximum value in each patch of a feature map.
- c) Flattening, converting pooled feature map to a one-dimensional array (vector).
- d) Dense layer. It's a layer that consists of neurons that detect input from neurons that's in the previous layers.
- e) Dropout Layer. Used to prevent a model from overfitting.
- f) Activation function that finally used for defining the output [10]. In the last layer, the sigmoid function is used for the classification of sperms healthy or unhealthy. The sigmoid function is expressed as the following,

$$S(x) = \frac{1}{1 + e^{-x}} \quad (6)$$

where  $S(x)$  is the sigmoid function of a variable x

In this paper, the best sperms could be recognized using this proposed model. At the first, the dataset was uploaded. The preprocessing steps were done to be handled by VGG16 and they were effective in this process. The noises in the image were removed using median filter, the sperm heads were segmented using Otsu's thresholding process, area opening was implemented for removing objects in the heads, the images were complemented, and then the model training and evaluation were done. Consequently, any image can be inserted after preprocessing for detection as shown in the proposed model flowchart in Fig. 9. There are also preprocessing steps should be done to the input images.

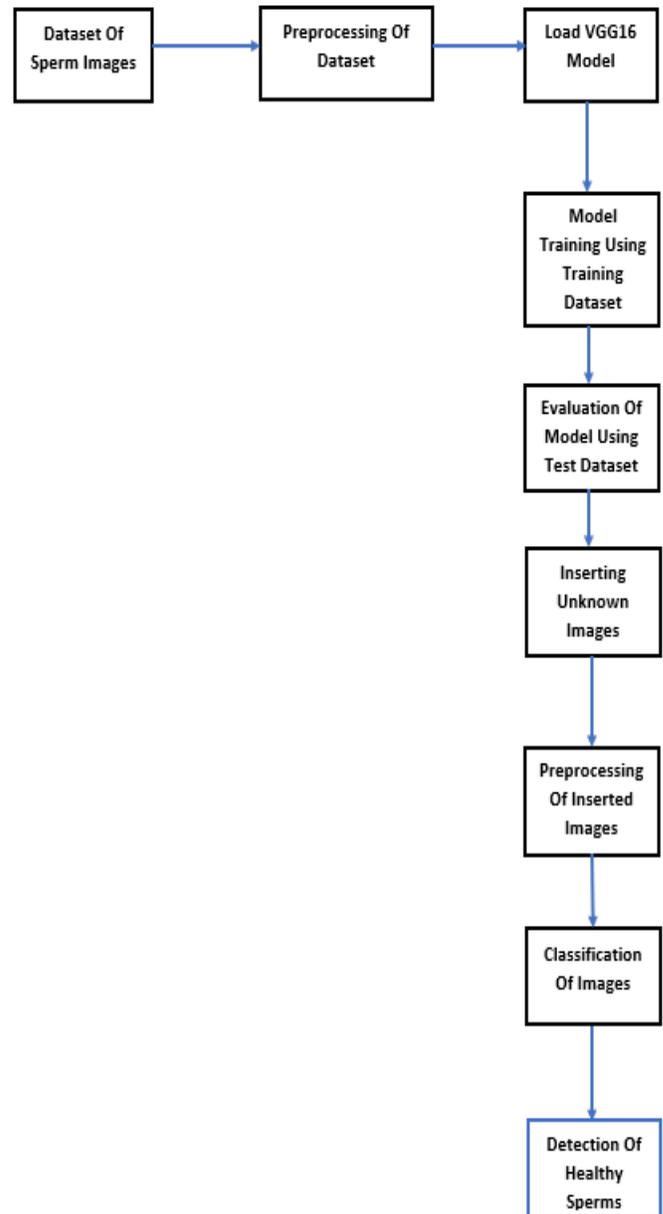

Fig. 9. Flowchart of the Proposed Model for Healthy Sperm Detection.

V. RESULTS AND DISCUSSION

The proposed model for classification of sperm heads is effective after using 1200 images of healthy and unhealthy sperm heads resulting in high accuracy. This proposed model is trained on a large dataset, and it is a real time system for andrologists for classification of healthy and unhealthy sperms. In Fig. 10, the results of the proposed model are shown for 4 unknown images of healthy and unhealthy sperm heads which are detected accurately. In this study, the median filter demonstrated the effectiveness of image denoising. Otsu’s thresholding process is done for segmentation then area opening technique is done and both have proved their success with the dataset. The accuracy of model reaches 97.92%, sensitivity equals 98.82%, precision equals 98.25%, specificity equals 95.71% and F1 Score equals 98.53% as shown in Table IV. The following formulas [7]–[11] respectively represents Accuracy, Sensitivity, Precision, Specificity and F1 Score. The following confusion matrix shows the values of True Positive (TP), True Negative (TN), False Positive (FP) and False Negative (FN) [11]. The confusion matrix of our study is shown in Table III with 168 true positive and 67 true negative. The performance of our model is shown in Fig. 11 with high training and validation accuracy after training with 200 epochs respectively reached 99.51% and 98.48%. The training and validation loss respectively reached 0.9817 and 1.4251.

TABLE III. THE CONFUSION MATRIX ON THE TEST SET

		Predicted	
		Healthy	Unhealthy
Actual	Healthy	TP = 168	FN = 2
	Unhealthy	FP = 3	TN = 67

$$Accuracy = \frac{TN+TP}{TN+TP+FP+FN} \tag{7}$$

$$Sensitivity = \frac{TP}{TP+FN} \tag{8}$$

$$Precision = \frac{TP}{TP+FP} \tag{9}$$

$$Specificity = \frac{TN}{TN+FP} \tag{10}$$

$$F1\ Score = \frac{2 * Precision * Sensitivity}{(Precision+Sensitivity)} \tag{11}$$

TABLE IV. EVALUATION PARAMETERS FOR THE PROPOSED MODEL

Classifier	Accuracy	Sensitivity	Precision	Specificity	F1 Score
Proposed Method	97.92%	98.82%	98.25%	95.71%	98.53%

## VI. CONCLUSION AND FUTURE WORK

In conclusion, the best sperms required for the ICSI process can be selected using the proposed deep learning model. Laboratory specialists always look for simple and precise methods for healthy sperm recognition for injection into oocytes process. This paper proposed a deep learning method based on VGG16 and its results have been approved by the andrologists. In this article, deep learning approach demonstrated the effectiveness of healthy sperm detection rather than machine learning. The fine-tuned VGG16 model resulting in high accuracy of 97.92% and this is one of the main advantages of this proposed model compared to the results of other models in literature review section. The VGG16 transfer learning model has proven its computationally efficiency for sperm head recognition. Assisted reproductive technology (ART) is necessary for finding more tools for the detection of the best sperms for increasing fertilization, pregnancy, and live birth rates. This proposed approach demonstrated its advantages of getting rapid results with high accuracy for detecting the healthy sperm heads which indicate to the healthy sperms that can be used in the intracytoplasmic sperm injection process.

For future work, different deep learning architectures can be used with a comparative study among them with using versatile dataset for better and more accurate evaluation. Taking another part of sperm into consideration with different preprocessing methods can be useful.

**Abstract**—With the rapid growth and widespread implementation of Internet-of-Things (IoT) technology, Radio Frequency Identification (RFID) has become a vital supporting technology to enable it. Various researchers have studied the design of digital or analog blocks for RFID readers. However, most of these works did not provide a comprehensive design methodology. Hence, the motivation of this study is to full fill the research gap. This paper proposes a comprehensive design and testing methodology for the Ultrahigh Frequency (UHF) RFID passive tag baseband processor at the register transfer (RTL). A complete design procedure of each block from state diagram to schematic level is presented; it comprises several blocks, *i.e.*, transmitter, receiver, Cyclic Redundancy Check (CRC), command processing, and Pseudorandom Number Generator (PRNG). Each block produces low latency (<400 ns). Two CRCs were applied to this system for different purpose: CRC-5 and CRC-16. To perform multi-parameter combinations of as many as 1344 combinations (including timing parameter, query respond, state transition, and BLF), a Universal Verification Methodology (UVM)-based test is conducted. The simulation results reveal that the proposed RFID baseband processor passes all the testing scenarios using UVM (version 1.1d). Moreover, we also implemented the proposed design on the FPGA board (ALTERA DE2-115). The system consumes 976 logic elements and 173.14 mW of total power dissipation (*i.e.*, 0.13 mW of dynamic power dissipation, 98.6 mW of static power dissipation, and 74.34 mW of I/O dissipation), which is reasonably low. This demonstrates that our design is synthesizable and ready to be processed further. All system design and test criteria were conducted following the EPC Gen-2 standard. The developed chip can be a solution for various kinds of RFID chip-based IoT applications.

**Keywords**—UHF RFID passive tag; baseband processor; register transfer level; universal verification methodology; Internet-of-things enabler; FPGA

## I. INTRODUCTION

Within the last few decades, automatic identification system has become an essential part of industrial applications, such as logistics, retails, and manufacturing [1]–[4]. Now,

with the rise of the Internet of Things (IoT), the use of Radio Frequency Identification (RFID) technology has a crucial role [5]. The RFID has been applied in various fields, *e.g.*, smart agriculture, smart homes, health care, medicines, transportation sector, payment, environment monitoring, disaster warning, or even telepresence for distant objects monitoring [6]–[13]. RFID is a communications technology that uses electromagnetic fields to detect tags attached to objects wirelessly. RFID technology is preferred over other identification or wireless communication technologies due to its various advantages, including bigger information storage capacity, more comprehensive coverage, better security system, more affordable price, and a universal standard. RFID is usually designed under the EPC Gen-2 standard, then adopted into the ISO 18000-6C standard. Even though the typical reading distance of an RFID tag is relatively long, about 6 meters, most of the tags are passive, which means that they do not have a self-powered source [14]. Instead, it solely relies on a converted power obtained from the RF signal sent by the reader. The analog circuit part is responsible for this power conversion or generation. The tag will then use the generated power, especially the baseband processor, to run the whole system. The RFID tag design has been finalized and matures in the industry for many years. With the detailed technical description in the Gen-2 tag standard, it is effortless to come up with a Register-Transfer Level (RTL) design. However, further observation and exploration are still an exciting topic by many researchers worldwide to fulfill numerous requirements of the recent issues and use cases [15]–[18], such as IoT applications based on-chip technology.

Flourishing along with the emergence of IoT technology, various research projects have been conducted related to RFID tags or readers, including the analog and digital circuit building blocks. The baseband processor is part of the digital block. Most research on UHF RFID baseband processors explores low power/energy-efficient design. For example, Wei et al. [19] proposed a low-power baseband processor using several techniques, including low operating frequency clock, clock gating, and asynchronous design. Using these

techniques, they can achieve a low power consumption baseband processor as low as 2.7  $\mu\text{W}$ . Similarly, Lee et al. [20] also proposed a low-power baseband processor. To achieve a low power consumption, they use numerous techniques, including the lowest possible clock frequency, latch-based clock gating, variable clock frequencies, and resource combining and sharing between blocks. Their design achieves a rather high-power consumption, 29.2  $\mu\text{W}$ . However, this is due to their circuit also including the analog part. Despite their advanced circuit design, they did not provide a comprehensive design and testing methodology for the baseband processor. Ismail et al. [21] presented a comprehensive baseband processor design methodology, including the Finite State Machine (FSM). However, they did not describe the command processor design and the system test. Moreover, the testing only showed the signal encoding and decoding test results. There is no other parameter for the tests was shown. Indeed, to perform many test parameters, an additional test technique or tool is needed so that a large number of test combinations can be efficiently performed. Su et al. [22] proposed a novel automatic verification strategy for a UHF RFID baseband processor. Using their verification, they could perform a set of 2700 commands testing in total. In detail, the verification or test included several command responses tests, e.g., Ready, Arbitrate, Reply, Acknowledge, and random command test. Li et al. proposed an RFID tag IC that is fabricated on 0.13  $\mu\text{m}$  CMOS technology. They achieved low power consumption: 4.8  $\mu\text{W}$  for reading operations and 11.5  $\mu\text{W}$  for writing operations [23]. Bhanushali, et al., successfully realized a digital UHF RFID Tag IC compatible with EPC Gen2 standard applied on 55 nm CMOS technology [16]. However, in their work, no comprehensive design methodology was provided. Design, implementation, verification methodology, and testing techniques is one set discussion that essential to be reported [24]; this will gain benefit, such as it can provide insights to early the designers/engineers who want to follow the proposed design.

This work presents a comprehensive and systematic RTL design and testing methodology specifically for UHF RFID passive tag baseband processors to fill the research gap. The baseband processor design includes receiver, transmitter, and command processing block. Before designing the schematic, the state diagram of each block is investigated to ensure all possible states are included. Then, each block and the design of the integrated block is tested based on the EPC Gen-2 standard to verify and ensure the functionality of the design. The latency of each block is also calculated. For the testing, numerous tests are performed, including query command, timing parameter, state transition, and Backscattering Link Frequency (BLF) test. To conduct the tests efficiently, a Universal Verification Methodology (UVM) is used as the test methodology. Using this UVM, a set of tests, as many as 1344 test combinations, was conducted, and thus, a rigorous parameter test was able to be performed. Additionally, the RTL design is also implemented on the FPGA development board to show the practicability of the design for future real chip implementation. Having this comprehensive RTL design and methodology, a more reliable baseband processor design can be realized. The developed chip can further be a strong candidate for IoT applications.

Our main contribution is providing a comprehensive RTL design and testing methodology. It includes each block's state diagram and schematic design, comprising a receiver, transmitter, command processing, Pseudorandom Number Generator (PRNG), Cyclic Redundancy Check (CRC), and their corresponding functional tests. In addition, the integrated system test is performed using UVM to perform the tests efficiently. The rest of this paper is organized as follows. To provide a short technical background and point out the distinct contributions, a description of related works is elaborated in Section I. The details of system design, starting from each block to its integration, are provided in Section II. Section III shows the testing results of the design, including an integrated system test using UVM, the implementation design, and the test of the baseband processor RTL design on the FPGA board. Lastly, Section IV provides the conclusion of this work.

## II. METHODOLOGY

The structure of the proposed RFID tag system is depicted in Fig. 1. The digital block has three inputs (i.e., data, clock signal, and voltage source) and one output (backscattering data). The digital block is the baseband processor itself; it comprises five blocks: receiver (PIE decoder and data buffer), command processor, transmitter (Miller encoder, FM0 encoder, and frame generator), CRC (CRC-5 and CRC-16), BLF generator, and PRNG block. Each block will be described in detail as follows.

### A. Receiver Block

The receiver block comprises three main components, i.e., Pulse Interval Encoding (PIE) decoder, data buffer or command parser, and BLF generator. In Fig. 2, the PIE decoder and data buffer are combined and represented as a "logic block." When a data signal comes from an RF demodulator, the data will be processed and interpreted by the PIE decoder by using Counter and Logic blocks. Those interpreted data are then stored in the data buffer and transmitted to command processing. The command parser will then separate the reader commands stored in Memory. Besides storing the data, the data buffer will also separate the query command to obtain Miller index (M) and Divide Ratio (DR) parameters. These two parameters are essential for the RFID system since M is used to determine which encoder to be used; either FM0 or DR is used to determine the value of BLF [25].

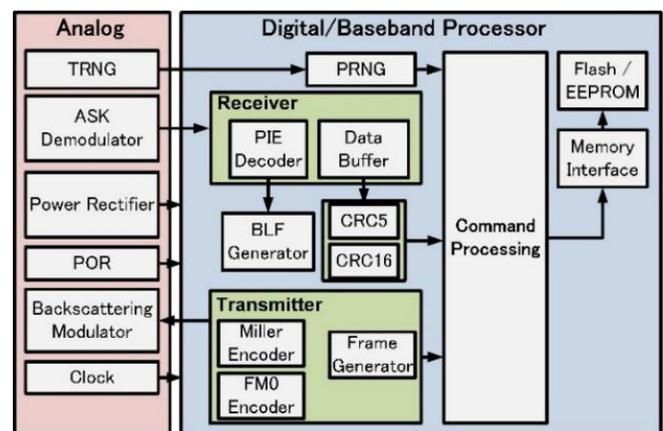

Fig. 1. Block Diagram of RFID Tag System.

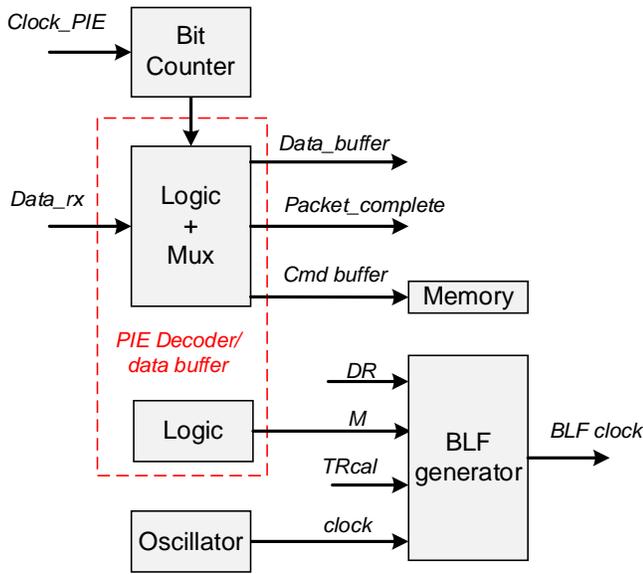

Fig. 2. Schematic of the Receiver Block.

Before designing the PIE decoder, the FSM should be determined first. PIE decoder consists of two state machines: PIE counter and data packet structure states. The PIE counter state machine detects the symbol of the bit logic state, either high or low, and then gives a corresponding instruction to the counter. As shown in Fig. 3(a), after the transition from logic low to logic high, the counter counts a full symbol until the end. Afterward, it begins to reset the counter when a new symbol comes. Meanwhile, the data packet structure state machine extracts the query parameters. The data packet structure sent by the reader includes delimiter, data-0, Reader-to-tag calibration (RTcal), Tag-to-reader calibration (TRcal), and data. In detail, the delimiter is a timing parameter with a constant value of 12.5  $\mu$ s, ensuring that the tag can receive data from the reader even at the longest possible data-0. Data-0 is data that contains all binary 0. RTcal is a sum of the duration of symbols one and zero, used to determine the bit rate of the reader's transmitter. TRcal is a timing parameter used along with the DR parameter to determine the value of BLF. However, not every command has a TRcal. The TRcal will exit only if the symbol value is less than RTcal. This data packet structure state machine is illustrated in Fig. 3(b).

To decode the PIE symbol correctly, a 16-bit counter is used; this counter calculates the length of the PIE symbol. Afterward, the result is then compared to the calibration value in the preamble. According to the EPC Gen-2 standard, the counter requires at least 324 kHz of sampling clock since the minimum interval length between “0,” and “1” symbols is 3.1  $\mu$ s. In our design, the counter accommodates a clock input up to 16 MHz without causing the overflow to the longest possible TRcal symbol. The schematic structure of the PIE decoder is shown in Fig. 4. Data buffer and BLF generator are represented as “logic blocks.” The logic and mux block are responsible for separating a command from its accompanying parameters, whereas another logic block is to extract DR and M values. These DR, M, and TRcal values are then used to determine the BLF value (Eq. 1),

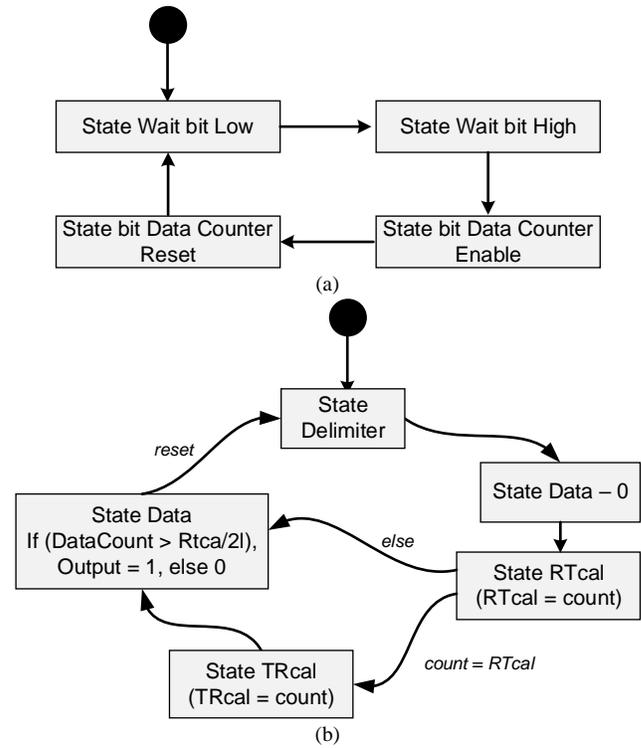

Fig. 3. (a) State Diagram of PIE Counter; (b) State Diagram of PIE Data Packet Structure.

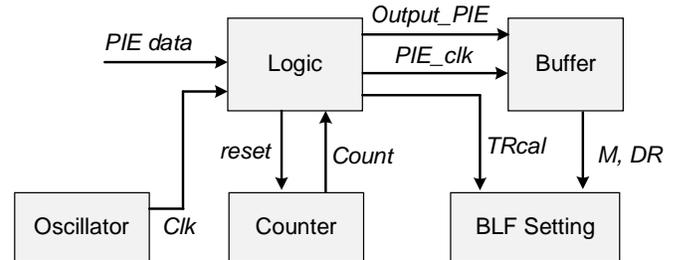

Fig. 4. Schematic Design of PIE Decoder.

$$BLF = \frac{DR}{TRcal} \quad (1)$$

The DR parameter has a value of either 8 or 64/3, depending on the parameter set in the query command. TRcal is calculated by the tag using oscillator frequency clock ( $f_0$ ) as a counter, and thus written as in Eq. 2, where TRcount defines the TRcal counts obtained from the receiver counter,

$$TRcount = TRcal \times f_0 \quad (2)$$

### B. Transmitter Block

The transmitter block (Fig. 5) comprises five inputs from the command processing block: (1) data input (PC\_EPC); (2) M carrier signal, which is used to determine the encoding type; (3) TRext for deciding the use of pilot tone in the preamble; (4) CRC; and (5) Tx\_enable signal. These inputs are processed in the frame generator, which is responsible for choosing the encoder type and inserting preamble and termination signals. In this study, the design of the transmitter block is focused on FM0 and Miller Encoder only.

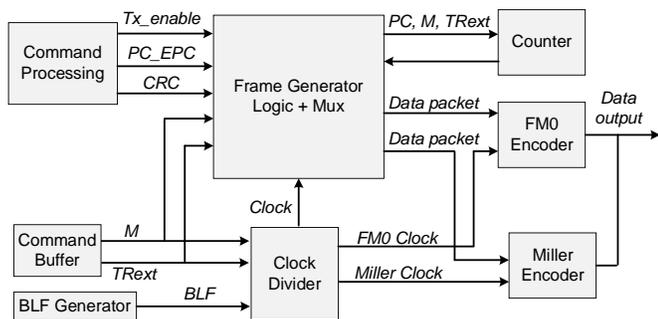

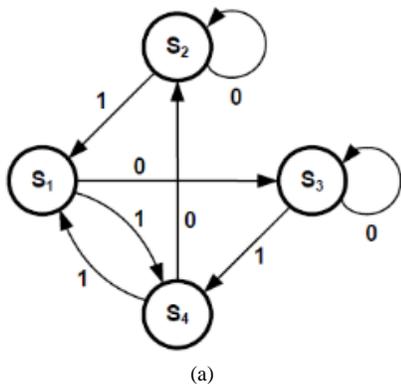

Fig. 5. Schematic of the Transmitter Block.

The default operation mode for data transmission from the tag uses FM0 Encoding. In transmitting the data, the tag changes the backscatter status in each symbol edge. Based on EPC Gen-2 standard, data transmission must be terminated with a dummy binary symbol “1” followed by a “low” state. The change of FM0 binary value determines the next sequential binary value, and therefore there are four states in total, as depicted in Fig. 6(a). The schematic design of this FM0 Encoding using the state machine model in Verilog is shown in Fig. 6(b). A Miller Modulated Signal (MMS) encoding is also added to the transmitted signal to avoid interference noise and be more flexible in managing the data rate. Any FM0 encoded signal will be encoded with an MMS subcarrier signal with a particular M value. The M value

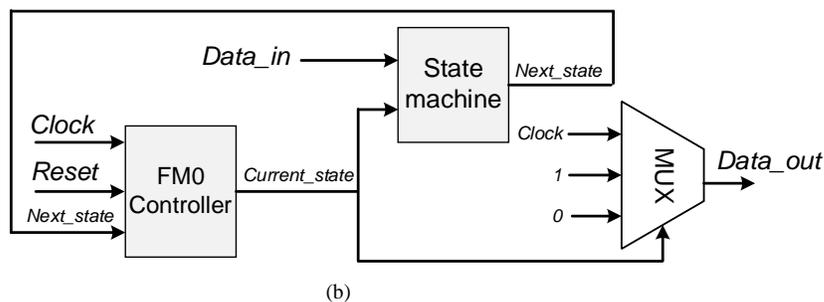

represents how many clock cycles MMS encodes the FM0 signal. The higher the M value, the slower the data rate. In the Miller encoder, the binary symbol “1” (a state transition) is inserted in the middle of the symbol. In contrast, the binary symbol “0” (no state transition) is in the middle of the symbol.

Moreover, there is no state transition in symbol transition, except when the binary symbols “0” meet consecutively. Furthermore, the encoding results are multiplied by the M value, where M is either 2, 4, or 8. The state diagram for this Miller encoding is represented in Fig. 7(a), while the Verilog schematic design is shown in Fig. 7(b).

The command processing is a block responsible for controlling the transition between EPC Gen-2 states and determining the tag response according to the reader commands. The command processor has two crucial logic functions to manage: slot logic as the anti-collision protocol and session logic. The schematic of the command processor block is depicted in Fig. 8(a). The state diagram for the command processing block is depicted in Fig. 8(b). The RFID transponder tag consists of seven states: Ready, Arbitrate, Reply, Acknowledged, Open, Secured, and Killed. When the tag is powered, it stands by in the Ready state until the Query command is received. The tag will then enter one of the two following states: 1) The tag changes to the slot state if a suitable session exists, or 2) The tag changes to the Arbitrate state if the slot value does not equal zero.

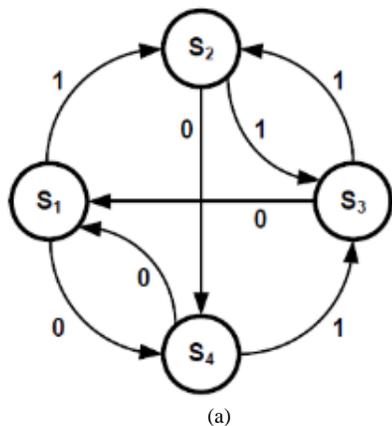

(a)

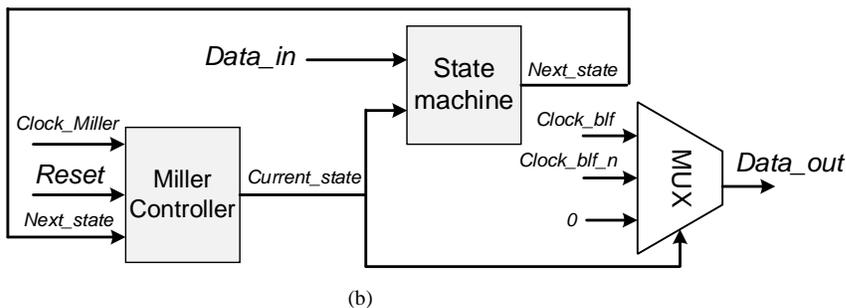

(b)

Fig. 6. (a) State diagram of FM0 encoding [26]; (b) Schematic design of FM0 encoder

(a)

(b)

Fig. 7. (a) State Diagram of Miller Encoding [26]; (b) Schematic Design of Miller Encoder.

The anti-collision protocol is applied within the Arbitrate state, and the tag's state will be held until the slot value equals zero. At this hold state, there are three command query options for the reader: (1) reduce slot number using QueryRep command; (2) change slot masking using QueryAdj, or (3) repeat the Query command. Once the slot has zero value, the tag will enter the Reply state and send a 16-bit random number (RN16). Afterward, the tag will wait for a response from the reader and enter one of the following states: 1) return to the Ready state if the received command query is an invalid session, or 2) return to the Arbitrate state if the received command query matches the valid session. If the reader correctly receives RN16, the reader will send an acknowledgment signal along with the previously received RN16. If the number matches the sent number, the tag will send the EPC value to the reader and change the session state from A to B or vice versa. Otherwise, the tag will return to the Arbitrate state. Additional blocks, i.e., CRC and PRNG, are required to make the system works correctly and adequately. For the CRC block, we employed two CRCs as suggested by the EPC Gen-2 standard: CRC-16 and CRC-5.

CRC-5 is used when inventory mode is started or when the reader gives the Query command. CRC-16 is used when the reader sends command select, Req-RN, NAK, Read, Kill, and Lock. The CRC-5 has a specification in the form of polynomial  $x^5 + x^3 + 1$  [27], residue 000002, Preset 010012, and length 5 bits. The CRC-5 is implemented using a register flip-flop and XOR circuit in our design.

In this design, the value of preset 010012 is inserted into the register flip flop. Input data will then enter one by one according to the clock signal. CRC-5 check will return pass/successful if the value in the register output is 000002. On the other hand, CRC-16 has a specification in polynomial  $x^{16} + x^{12} + x^5 + 1$  [28], residue 1D0Fh, Preset FFFFh, and

length 16 bits. The same with the CRC-5 implementation, the CRC-16 uses a register flip flop and XOR circuit. The difference is that CRC-16 has more flip-flops compared to CRC-5. In this design, in the beginning, the FFFFh preset value is inserted into the register flip flop. Input data will then enter one by one according to the clock signal. The CRC-16 check will return pass/successful if the value in the register output is 1D0Fh.

C. Pseudo Random Generator Number (PRNG)

The PRNG block commonly generates a 16-bit random value. This random value will determine the slot value in the tag according to the Q value received by the tag. The most recent advancement of a hardware implementation for a security system employs the physical variation in an integrated circuit; it can be called Physically Unclonable Functions (PUF), as presented in [29], [30]. However, the system becomes complicated, so it is not preferred for RFID applications. Instead of PUF, this study employs the Linear Feedback Shift Register (LFSR) for the PRNG block to obtain a uniform output distribution. LFSR uses registers or flip-flops [31] whose input is based on linear functions from the previous state, which is implemented using the XOR function. The LFSR uses polynomial  $1 + x^{11} + x^{13} + x^{14} + x^{16}$ . This polynomial selection is based on the study by [32].

D. Baseband Processor

The overview of the baseband processor is depicted in Fig. 9. It works through the following steps: (1) the receiver sends input to command processing in the form of decoded data buffer along with a package complete flag as an indicator that input data has been received; (2) at the same time, the receiver also sends BLF and query parameters to the transmitter; (3) command processing then sends the reply data to the transmitter, transmitting the data back to the reader.

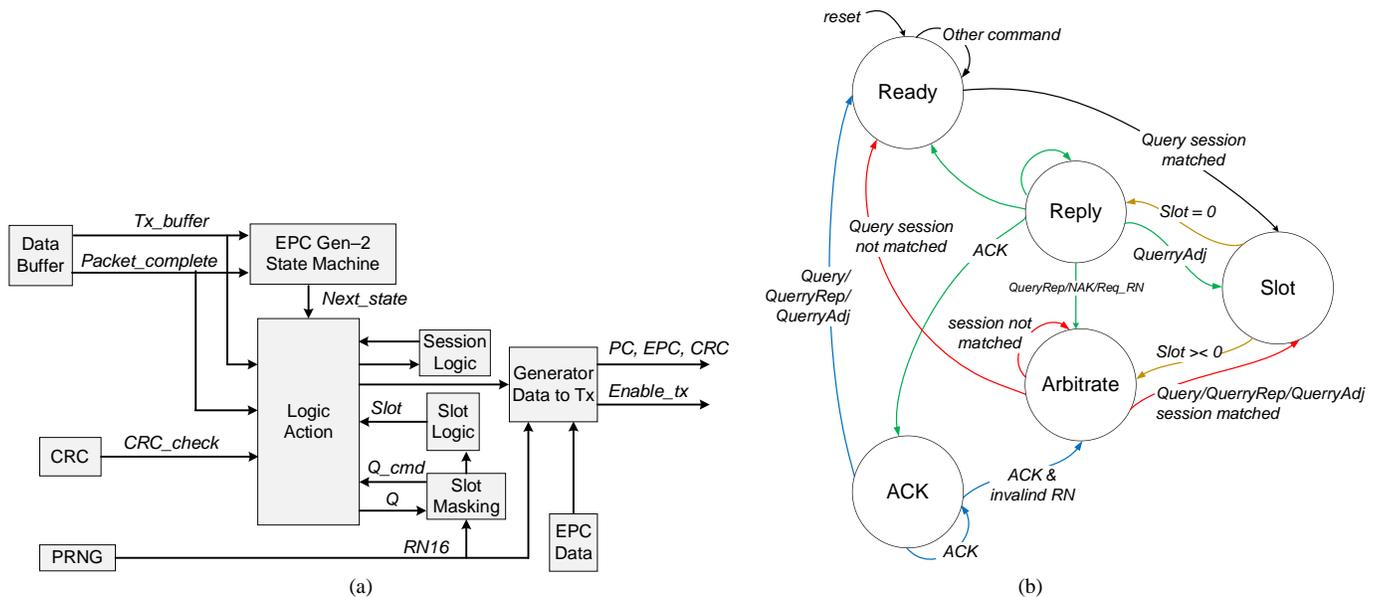

Fig. 8. (a) Schematic of Command Processing; (b) State Diagram of Command Processing Block.

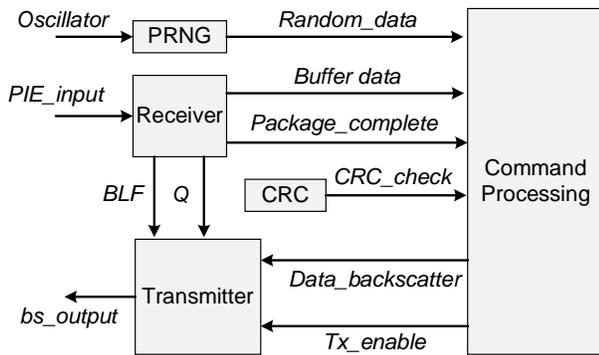

Fig. 9. Schematic of UHF RFID Tag baseband Processor.

### III. RESULT AND DISCUSSION

In this section, we evaluate our design by testing each block that contains the receiver, transmitter, and command processing block. Also, we verify the entire system by implementing the UVM. In this test, we use a reader that fulfills the ISO8000-6C standard and evaluates our proposed design by confirming the RFID reader and tag data. The test was conducted on an RTL simulation.

#### A. Receiver Block

We first tested the PIE decoder block on the receiver side. The central controller is the PIE state machine. When the enable counter is active at the delimiter state, the state machine will check whether the delimiter value is 12.5  $\mu$ s or not. Then, there are two possible states: data-0 and TRcal. Both are used as a comparison to determine the logic value “1” or “0”. Next is TRcal state, which is used to obtain the TRcal value. Finally, this TRcal will be used as a parameter to produce the desired BLF value. After the PIE block has been tested, the whole receiver block (including the PIE encoding, command buffer, and BLF generator) is evaluated. The value of PIE\_output, originating from the PIE decoder, is stored in the data buffer module. It is then transmitted to command processing and the packet\_complete signal, indicating the packet’s end. The data buffer module will also perform a command filter/parser. The command filter/parser will extract the query parameter used by the BLF generator module. The BLF module will only work to reduce dynamic power consumption if it receives a signal from a transmitter. The optimum throughput speed can be obtained using this receiver architecture, which only produces the latency of two-oscillator clock cycles. In our design, an internal 8 MHz oscillator is used, which causes a latency of 250 ns. However, this latency is insignificant compared to the whole system, and it can be neglected.

#### B. Transmitter Block

The FM0 and Miller encoder blocks are tested well on an RTL simulation. When the value of enable\_FM0 is “1”, the FM0 encoder module becomes active. The input data from the frame generator will enter the state machine, and the next state will be determined. The FM0 controller module will provide input to the multiplexer in the form of data\_selector to select the output of fm0\_data. This FM0 encoder architecture design

has a latency of one cycle fm0\_clock that depends on the BLF value. Hence, the latency in the FM0 module is defined as Eq. 3,

$$FM0\_latency = \frac{TRcal}{DR} \quad (3)$$

In testing the Miller encoder block, the subcarrier encoding with  $M = 2$  is conducted. The test result shows that the working principle of the circuit is similar to the FM0 encoder module, where the data\_selector output from the controller determines the Miller encoder data output. The main difference is in the clock that it uses. In the FM0 encoder module, the FM0 clock has the same value as the BLF clock, whereas, in the Miller encoder, the Miller clock value depends on the  $M$  value. For instance, the Miller encoder latency depends on the BLF and  $M$  values, as defined in Eq. 4.

$$Miller\_latency = \frac{TRcal}{DR \times M} \quad (4)$$

We also tested the whole transmitter block. Input data from command processing in PC/EPC/RN16 data and tx\_enable signals are processed by the frame generator and sent serially to the encoder module. Depending on the PC’s value, counters, preamble, data, and CRC will activate. In this test, the FM0 and TRext are set to “0”. Thus, the value of fm0\_enable becomes “1”, activating the FM0 encoder module. Furthermore, clock for BLF and  $M$  value determine the clock value of each encoder module. Simulation reveals the latency of the transmitter block depends on the encoder type. The FM0 encoder has low latency. Nevertheless, when miller encoding with  $M = 8$  is used, the latency becomes significant, as inferred in Eq. 5, where Tx\_latency denotes the latency of the transmitter block and clk\_osc defines the oscillator clock.

$$Tx\_latency = \left(2 \times clk\_osc + \frac{TRcal}{DR}\right) + \left(\frac{TRcal}{DR \times M}\right) \quad (5)$$

#### C. Command Processing Block

The complete testing sequence of the command processing module has been verified carefully. It is tested from the query command is received until the tag sends the EPC code. When the receiver module receives a packet, it will send a signal to indicate that the packet is complete, and thus the command processing will make a response accordingly. Finally, the CRC module checks whether the command query has a valid CRC value or not. The latency of this command processing is three oscillator clock cycles. 16 MHz of the internal oscillator is used in this design, which produces a latency of 375 ns; this latency is not significant.

#### D. Full System Test

The entire system is simulated and tested using UVM, specifically the Coverage Driven Verification (CDV) approach. The UVM is version 1.1d and implemented using Synopsys VCS 2014.10 on the EDA playground application. The testing diagram using UVM is illustrated in Fig 10(a). We used a reader that already fulfills the ISO 18000-6C standard requirement for the whole system test as a master. The reader has simple instructions and is intended only to identify the EPC value of the tag.

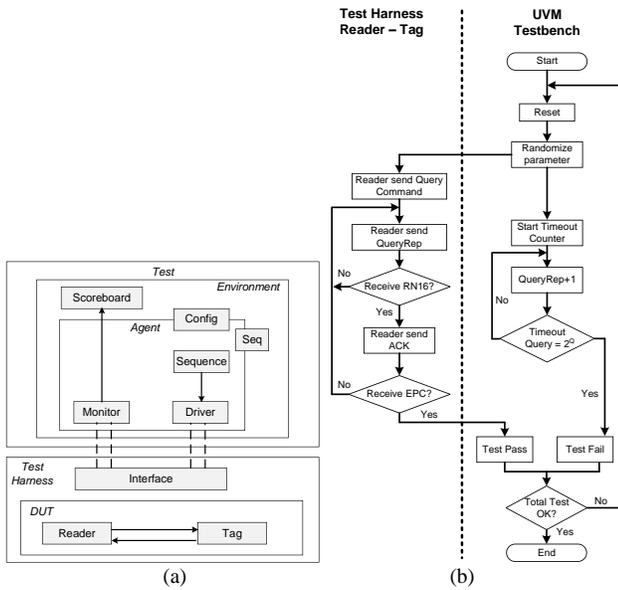

Fig. 10. (a) Full System Testing Diagram using UVM; (b) Flowchart of the System Testing using UVM.

In general, the test is conducted based on the following sequences: (1) after a reset signal is given to the reader, it sends the Query command to the tag; (2) the reader will continuously send QueryRep in order to have the tag reduces the slot value until zero and until the tag sends 16-bit random number (RN16) to the reader; (3) using “ACK” command, RN16 will be transmitted back to the tag, after which the reader will wait for EPC value from the tag. The test session is considered to be finished once the reader receives the EPC value from the tag. The flowchart of the testing sequences is illustrated in Fig. 10(b). The functional system test is intended to check both timing and query parameters to be used by the reader and the command response of the tag. Four available techniques are chosen depending on the dataset size, testing type, and specification. The techniques can obtain those parameters, i.e., constrained random test, direct test, coverage test, and edge corner test. A timeout program is also set up in the test to anticipate a situation when the tag does not send any response that makes the reader unable to obtain the EPC value. The timeout value depends on the Q value, where Q denotes

the query parameter used to determine the tag’s random slot, and 2Q can find the total timeout of UVM (UVM\_timeout).

1) *Query parameter test*: A query command is an inventory command that the reader first sends. The tag should be able to accept and process all possible combinations of query parameters (including Q, T<sub>RExt</sub>, DR, and encoding). The query parameter test is conducted using constrained random and coverage tests. The coverage tests all possible combinations to generate the parameters, which amounts to 512 combinations. While a random test is conducted to identify possible errors caused by a state transition. All these possible combinations are summarized in Table I. Based on the tests results shown in Table II, the design 100% passes all the test combinations.

2) *Timing parameter test*: The timing parameter is conducted using the edge corner and constrained random tests. The edge corner test is conducted only on the smallest and biggest possible value of Tari, PW, RTcal, and TRcal parameters, resulting in 16 combinations. Meanwhile, the constrained random test is conducted by setting the parameters within certain limits, i.e., 6.25 μs to 25 μs for Tari, then 2.5Tari to 3Tari for RTcal, and 1.1RTcal to 3RTcal for TRcal. The test results are shown in Table II. It shows that the design passes all the testing combinations of the timing parameter test.

3) *State transition test*: An RFID tag design must be able to respond according to specifications based on the command it receives from a reader. The RFID tag has four states in our design: ready, reply, arbitrate, and acknowledge. On the other hand, there are six commands from the reader that the tag must recognize: query, queryrep, queryadj, select, ACK, and NAK. The command response test is conducted using direct testing. The result is summarized in Table III.

4) *BLF Test*: The BLF test is conducted using 16 MHz of frequency sampling. Based on the specification regulated in ISO 18000-6C, the deviations in each parameter must be kept below 2.5%. Based on the test results shown in Table II and Table IV, the deviations of the parameters are all below 2.5%; thus, all tests are 100% passed. Further test will follow a procedure from [33].

TABLE I. QUERY COMMAND COMBINATIONS

	Command	DR	M	T <sub>RExt</sub>	Sel	Session	Target	Q	CRC-5
#of bits	4	-	2	1	2	-	1	4	5
Description	1000	0 :DR=8 1:DR=64/3	00:M=1 01:M=2 10:M=4 11:M=8	00: No. Pilot 01:Use Pilot	00:All 01:All 10:~SL 11:SL	00:M=1 01:M=2 10:M=4 11:M=8	0:A 1:B	0-15	-

TABLE II. SUMMARY OF SYSTEM TESTING RESULTS USING UVM

Testing Parameter	Testing technique	#of Combination	Result
Query Parameter	Coverage Test	512	100% pass
	Random Test	500	100% pass
Timing Parameter	Edge Corner Test	16	100% pass
	Random Test	300	100% pass
BLF	Direct Test	16	100% pass

### A. Implementation

The baseband processor is implemented on the Altera DE2-115 FPGA development board. The board uses Cyclone EP4CE115 chip, which has 114,480 logic elements, 3,9 Mbits RAM, 266 multipliers [34], and a Nios II soft-processor. Moreover, the board is also equipped with several interfaces such as Ethernet, RS232, PS2, and USB. The implementation diagram of the baseband processor and the reader in the DE2-115 board is depicted in Fig. 11. The implemented system comprises two blocks: the processing system and programmable logic. The processing system comprises a Nios II soft-processor and memory-on-chip, while the programmable logic comprises the RFID tag baseband processor and the reader. The programmable logic is connected to the Avalon interface through the PIO. The Nios II soft-processor sends input in the form of EPC data to the tag and timing and query parameters to the reader. It will monitor the outputs in the form of protocol status, EPC data, and *TRcal*. The result is displayed on a host computer connected to Nios

II through the UART JTAG interface. The RTL design synthesis is performed using Altera Quartus® software. Firstly, the implemented design is tested for its system communication. Then, the test process and results are monitored and displayed on the Nios II console. The DE2 communicates with the host PC via the JTAG interface.

As the test program is run, Nios II will initialize the parameters by giving the corresponding input to the reader. Afterward, Nios II will monitor any changes in the protocol status since it indicates the exchange data process or status between the reader and tag. Every communication from the reader is displayed on the Nios II console. There are three stages of communication between reader and tag. In the first stage, after Nios II initialization, the reader will send data in the form of the Query command, then followed by the QueryRep command. In the second stage, the reader receives a reply from the tag in the form of RN16. Then, the reader will return the RN16 along with the ACK command. Finally, the reader receives the EPC value from the tag in the last stage.

These three stages of communication and their testing result are shown in Fig. 12. It can be seen that the implemented design is successful in performing all stages of communication, and the reader can also successfully receive the EPC value from the tag. The synthesis result is presented in Table V and Table VI. The design uses 976 logic elements and 939 combination functions, consisting of 573 (4-input functions), 213 (3-input functions), and 153 (2-or-less-input functions). From 976 logic inputs available, 119 are used in arithmetic mode, and the other 373 are registers. As for the submodules, the command processor uses 346 logic elements, while the transmitter and receiver use 328 and 265 logic elements, respectively.

The power consumption is calculated using Powerplay analysis provided by Quartus, as shown in Fig. 13. A Powerplay is a standard tool used by various scholars to analyze the power consumption of the designed chip [35]–[37]. Based on the analysis result, the proposed chip consumes 173.14 mW with the following details: 0.13 mW from dynamic power dissipation, 98.6 mW from static power dissipation, and 74.34 mW from I/O dissipation. The power consumption is relatively low and it can also answer one of various challenges in RFID tag chip design, which is low-power allowing with low-cost [38]. This data is expected to transfer the design into a specific chip dedicated to IoT application, specially targeted for a low-power application case that requires RFID to operate.

The RFID tag design made is a digital block from a complete transponder tag. The phase for developing RFID tags is to integrate digital blocks with analog parts such as antennas, modulators, and voltage regulators. The design of the RFID tag made is an initial study that focuses on a digital block architecture that can accommodate the ISO 18000-6C standard. The development space for digital blocks is still vast, including design optimization so that a tag design can be obtained that has a smaller size and more efficient in consuming the power.

#### IV. CONCLUSION

This study has designed a baseband processor design for UHF RFID passive tag. The baseband processor consists of several blocks, *i.e.*, receiver, transmitter, command processing, CRC (CRC-5 and CRC-16), and PRNG. A detailed RTL design and testing methodology of the baseband processor was also presented. All the design and testing criteria were constructed compliant with the EPC Gen-2 standard. Each block showed a low latency (below 400 ns), which is negligible to the whole system. Using the UVM testing method, 1344 parameter combinations were conducted on the whole system design. The results reveal that it passed all the testing scenarios by the UVM, including query parameter, timing parameter, state transition, and BLF test. Moreover, the design was also successfully implemented on an FPGA board (Altera DE2-115). The implemented system used 976 logic elements and consumed 173.14 mW of power dissipation. This comprehensive RFID design and testing methodology allow a more reliable RFID baseband processor design to be realized, leading to a higher yield of other real chip fabrication processes. The results show that it can be used to enable a chip-based, low-power IoT Application. Future work will focus on the chipset design and tap-out the design.

**Abstract**—Diversified systems hosted on cloud infrastructure have to work increasingly on physical servers. Cloud applications running on physical machines require diverse resources. The resource requirements of cloud applications are fluctuating based on the resource intensity of the applications. The multi-tenancy of Cloud servers can be achieved based on effective resource utilization. The optimum resource utilization, maximum service level agreement, and minimization of interference are the major objectives to be achieved. Using live Virtual Machine (VM) migration techniques cloud resources can be utilized efficiently. But the migrated VMs can interfere with the ongoing applications on the targeted server which may lead to the service level agreement violation (SLAV) and performance degradation. To resolve this issue, understanding the current state of cloud hosts before the allocation of newly migrated VM is necessary. This paper presents Interference Attentive Genetic Algorithm (IAGA) based VM allocation strategy to achieve the aforementioned objectives. The proposed IAGA policy has outperformed existing policies for quantifiable performance metrics such as energy consumed by cloud systems, count of hosts shut down, average SLAV, and count of VM migrations.

**Keywords**—Cloud computing; interference; VM allocation; SLA violation; resource utilization

## I. INTRODUCTION

The term Cloud is buzzing technology that can be viewed as the provision of services over the Internet as per the demand of the users. The changeover of large organizations from the traditional Capital Expenditure (CapEx) model to the Operating expenses (OpEx) model supports the reality that the Cloud environment is one of the majority capable technologies in the dated digital era. The escalating number of cloud service consumers has amplified the challenges faced by the Cloud Service Providers (CSPs) to provide the requested services with high availability and reliability of the services. The virtualization technique provides the CSPs to meet these challenges. The main basis of the cloud environment is virtualization.

In virtualized scenarios, the hardware resources of every host also called Physical Machine (PM) are imitated to be independently running entities that are represented as a virtual machine (VM). In the host machine, the cloud service request from the user is managed by the VM to fulfill the computational resource demands such as the size of the memory, computing duration, CPU cycles, network bandwidth, etc. Various cloud systems may support such as the size of the memory, computing duration, CPU cycles,

network bandwidth, etc. Various cloud systems may support such virtualizations, in different ways such as operating system-level virtualization, and virtualization based on type-I and type-II [1].

As and when the demand for any VMs' resource increases that particular set of VMs, in the running state, needs to be migrated and accommodated to the new host or physical machine. This entire procedure is known as live VM migration. The VM allocation is the sub-process of the full-stack live VM migration process. Once the migration decision is made by the virtual machine monitor of a particular host, the host needs to look for a new physical machine by keeping various constraints in an account. Such constraints include uninterrupted resource sharing of the existing VMs host with the migrated host after allocation.

The performance of the overall host should not be regretted because of the resource claim of newly migrated VMs and the SLA of the applications hosted on the migrated VMs should not be violated. An interference-aware technique of VM allocation is a must to achieve the aforementioned objectives. This paper discusses an Interference Attentive Genetic Algorithm-based VM allocation policy named IAGA. It is designed to achieve interference minimization by allocating the migratable VMs to the best-suited PM while maintaining high SLA and optimized resource utilization of cloud hosts.

In general, this research article aims to:

- 1) Discuss the state-of-art current trends in VM allocation policies.
- 2) The involvement of Genetic Algorithms in cloud service delivery.
- 3) Mathematical model, design constraints, and algorithm design of proposed technique for VM allocation using the genetic algorithm to address resource interferences.
- 4) Experimental result analysis of the proposed approach with the existing approaches.

The structure of the paper is as follows: Section 2 discusses the state-of-the-art and the details of genetic algorithm variants used by various researchers. Section 3 gives elaboration on the proposed system model along with the mathematical model, design constraints, and algorithm design. Section 4 talks about the experimental scenario and achieved results. Section 5 concludes the paper and the possible future extension of the proposed research.

## II. STATE-OF-THE-ART

VM allocation is the major decision involved in the live VM migration procedure which raises many concerns such as proper resource utilization, increased throughput, SLA maintenance, energy consumption minimization, etc. Various optimization techniques have been applied by the researchers. According to Christina et al, VM allocation is a multi-objective constrained optimization NP-Hard problem [2].

Yuzhe et al proposed a system for optimizing VM allocation techniques in uncertain cloud environments based on the user requirements. The authors considered the optimization perspective of energy consumption for the data center for VMs with no special needs. For the remaining Virtual machines, the present throughput of the hosts and the service consumer's bandwidth requirements are considered in the allocation process of Virtual machines. They designed a VM allocation system to significantly improve multiple objectives such as proper resource utilization, minimization of PMs used, and minimization of energy consumption by taking into consideration the cost of data transmission between VMs [3].

As per Jenn-Wei et al, without considering the VM interference in the VM placement requirement, the Quality of Service (QoS) requirements of the cloud application executing in VMs may be violated. The authors have considered three factors in the proposed VM placement policy: (i) Resource demand of virtual machines (ii) The QoS of cloud applications (iii) The VM interference. As per the authors' point of view, it is difficult to accommodate all the aforementioned factors in the VM placement policy. Authors have named research problem as IAVMP – Interference Aware VM Placement problem. They have formulated an integer linear programming model to solve IAVMP as an NP-complete problem [4].

Sasmitha et al considered a single parameter optimization technique to achieve the goal of cloud service consumers or cloud service providers. In realism, the user and service provider have opposing goals. This objective could be used to guide the selection of cloud hosts. They proposed an Efficient Multi-optimization Resource Allocation (eMRA) model using optimization techniques to achieve the goals of cloud service consumers and data centers in the proposed work. SGO (Social Group Optimization) technique is proposed to improve user requests by taking into account related parameters for allocation. Similarly, Particle Swarm Optimization (PSO) is being used to improve data center lists that are fitting for optimized user requests. To design the model that separates the proposed design model from other existing works, the eMRA considers distinct related parameters of cloud service consumer request, cloud host, and network. The eMRA technique is simulated using CloudAnalyst, and the authors researched ten distinct scenarios using three different CloudAnalyst broker policies [5].

S. Savitha et al. presented a perceptive priority-aware VM allocation strategy called the P-PAVA algorithm which determines an application's priority and also resource needs. Using an ML-based prediction model, the system assigns applications based on one's priority. Moreover, parallelization has been used before conveying various workloads to reduce

the overhead of the allocation algorithm. To accomplish this, the algorithm uses the first fit technique as a baseline for user request allocation with a low priority norm. P-PAVA outshines the state-of-the-art algorithm for VM allocation for priority-aware applications on a variety of indicators such as average response time, execution time, and power consumption [6].

Garg R. et al. developed a virtual machine allocation policy to evaluate the behavior of commonly used heuristic allocation policies. To substantiate the logistic comparison, a policy that implements a bin-packing approach in Virtual machine allocation has been developed. The implemented research problem has been rigorously tested using a diverse range of workload data sets and experimental configurations. The performance of these algorithms is also evaluated with varying threshold and VM selection policies. Experimental results indicate that policies that take into account the server's power and computing capacity perform much better in almost all scenarios [7].

Jitendra et al. created an Intelligent SLA-aware and Energy Minimization VM allocation approach that uses the Emperor Penguin Optimization (EPO) algorithm. In a heterogeneous cloud environment, the system could indeed allocate virtual machines based on power usage. The proposed method has illustrated its appropriateness for virtual machines in the data center by making comparisons of it to the Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and Binary Gravity Search Algorithm (BGSA). The outcomes of the proposed system have been evaluated by using the JAVA simulation platform. The investigation results reveal that the improved EPO-based system is very effective in limiting energy consumption, SLA Violations (SLAV), and the advancement of QoS requirements to provide desirable cloud services [8].

Rahimi Zadeh et al. [9] proposed an interference-aware and joint profit scheduling scheme (PIAS) to proficiently consolidate Virtual machines on the physical machine that hosts multi-tier application workloads in Infrastructure-as-a-Service (IaaS). For consolidating VMs, the PIAS policy took into account resource usage, costs and profits of power consumption, service level agreements (SLAs), and operational interference of VMs along with the number of transferred memory pages during live VM migration. The functioning behavior patterns of VMs are examined in this work. Furthermore, an optimization problem is presented to achieve maximum cloud service provider profit while reducing the overall cost of application workload executions.

From the various literature [11-15], it is clear that the impact of the interference is unavoidable to achieve high SLA. Recently also many researchers have developed VM migration techniques by keeping the different objectives in the center. CMIG – is a Concurrency-aware Migration System [10]. Rachael et al [11] used an intelligent approach to minimize interference and energy consumption. Anu et al [12] addressed interference minimization in the proposed system Interference Aware Live Migration (IALM). Babu et al [13] have designed an interference-aware system that has automatic scaling support to handle sudden load drift with precise prediction and

minimum VM migration. Chao et al have addressed the interference awareness during the migration process to mitigate cache-based side challenge attacks in the cloud [14]. Yiling et al have proposed the live migration technique which applies to software-defined networks with awareness of interference and topology [15].

Neha et al [38], proposed an optimized VM allocation scheme called Resource Aware Provisioning (RAP). For the VM allocation criteria, the authors considered better energy efficiency and a fixed upper threshold value. RAP is working with the static upper threshold and the authors have not considered all types of required resources for different applications running inside VMs. The limitation of the RAP is that it has not taken the future resource type intensity into the consideration while choosing the PM for VM allocation. For example if one of the newly migrated VM starts grabbing more CPU cycles and if the PM is about to reach the upper threshold then any proactive steps are not taken by the authors. Only the energy consumption has been considered as a major parameter for the VM allocation which is not

sufficient for the optimized VM allocation approach because interference minimization is an unavoidable parameter that has not been considered by RAP.

Genetic Algorithms have been applied significantly during the current era to achieve the optimized solution to various research problems. It has been observed from various works of literature that the involvement of genetic algorithms and variants has given improved results in the various cloud computing-related research problem solutions. The genetic algorithms have been applied to address the cloud security related issues [16-18], to achieve optimum solutions in the Internet of Things (IoT) service placement in fog computing environment cloud computing [19], and to leverage the fog computing frameworks the human activity recognition has been achieved through deep genetic algorithm [20].

Genetic algorithms are considerably being used for a better cloud service experience. The list of the Genetic algorithm and its variants applied in recent research trends by various researchers [21-32] for better cloud service is presented in Table I.

### III. PROPOSED SYSTEM

This section represents the proposed system architecture, mathematical model, design constraints, and algorithm design.

A Genetic Algorithm (GA) is a well-known meta-heuristic algorithm that is inspired by the biological evolution process [40]. In nature, GA mimics the Darwinian theory of the survival of the fittest. GA's fundamental components are chromosome representation, fitness, selection, and biologically inspired operators [40]. Chromosomes can be thought of as points in the solution space. These are processed by iteratively replacing the population with genetic operators. The fitness function is used to assign a value to each of the population's chromosomes [39].

In selection operation, chromosomes are chosen for further processing based on achieved fitness value. In the crossover operator, a random convergence point is chosen and the subsequences between chromosomes are changed to produce offspring [40].

For the proposed research problem the chromosomes are considered as the PMs to allocate the migrated VMs. The fitness function is designed by considering the total resource capacity of the server.

Crossover is performed to choose the best PMs by keeping the future resource demands of the VMs hosted on that PM. The following section discusses the proposed architecture, design constraints, mathematical model of the research problem, and ultimately the algorithm design presented thereof.

#### A. Proposed System Architecture

Fig. 1 depicts the system architecture of the proposed VM

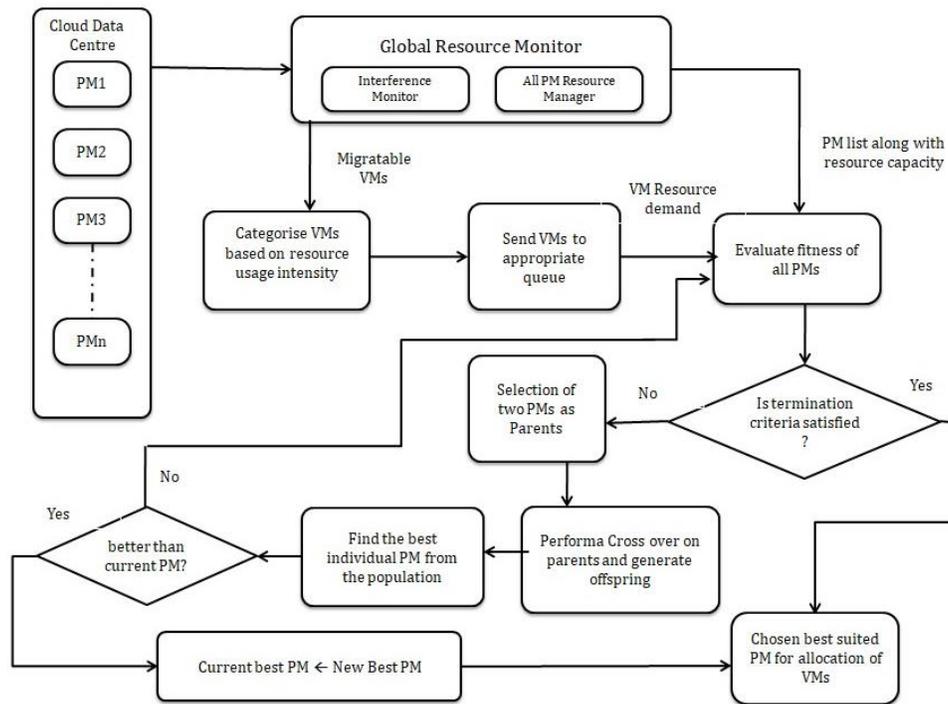

Fig. 1. Proposed System Architecture.

allocation system. In the cloud environment, all the PMs resource usage will be monitored especially at the time when that PM is the candidate to be chosen for the accommodation of a new set of migratable VMs. A genetic algorithm is applied in the proposed system to choose the best suitable PM to allocate migratable VMs.

In the proposed architecture, the major components are:

- Local Resource Monitor.
- Local Interference Monitor.
- Global Interference Monitor.
- Historical Resource Usage.
- Resource Usage-based VM Categorization System.

The local resource monitor keeps track of resource usage based on the resource intensity type and the local interference monitor observes the interference by considering SLA. From the study of existing systems, it is clear that during live VM migration, allocation of optimum resources and SLA management is the major objective. To achieve this research objective the proposed system must be clear about the available resource capacity of the chosen PM for the allocation of migratable VMs. The candidate PMs mostly has varying resource capabilities. The used resource amount of PMs depends on the hosted applications running on the VMs of that server. Based on this scenario the application need or VM resource intensity can be categorized as:

- CPU intensive VMs.
- Memory intensive VMs and.
- Network bandwidth-intensive VM.

It is necessary to allocate the VMs based on the available resource type intensity of the PM. So in the proposed design the interference monitor categorizes VMs and aligns them to the appropriate queue before allocation using a resource usage-based VM categorization system. Categorization is performed based on the prediction carried out using historical resource usage. The global resource monitor keeps track of all the PM resource usage states and lists of migratable VMs selected by the overloaded PM in case of excessive resource usage. Ultimately the decision support system takes care of the migration process to the chosen destination PM. The list of chosen PMs and migratable VM list will be given as input to apply the genetic algorithm. The strength of the proposed solution is the fitness function evaluated for all the PMs. The fitness function is discussed in Section III C.

### B. Proposed Mathematical Model

Let V be the set of n migratable VMs.

$$V = \{VM_1, VM_2, VM_3, \dots, VM_n\}$$

where n = number of migratable VM.

Let P be the set of PMs in the cloud environment.

$$P = \{PM_1, PM_2, PM_3, \dots, PM_m\}.$$

where m = number of PMs in set P.

Logically overall performance degradation due to the VM migration interferences on PM denoted by MI can be calculated as the total of co-location interference that occurred because of the resource share claim of newly migrated VMs known as co-location interference MIC and network interference is migration network time MNW.

So, for PM the total interference

$$MIC_i = CI_i + MNW_i \quad (1)$$

Based on the resource interference taxonomy provided in [33] the performance degradation due to the co-location interference is the total of CPU contention interference, memory consumption interference, and network bandwidth contention interference. Here co-location interference is denoted by CI. So, for  $i^{th}$  PM the co-location interference can be defined as:

$$CI_i = M_c + M_m + M_{nb} \quad (2)$$

Where

$M_c$  is CPU contention time.

$M_m$  is memory contention time, and

$M_{nb}$  is network bandwidth contention time.

The CPU contention time  $M_c$  is the ratio of  $C_{dem}$  CPU cycles in demand and  $C_{avl}$  available CPU cycles that can be allotted.  $M_c$  can be represented as:

$$M_c = C_{dem} / C_{avl} \quad (3)$$

The severity of the performance degradation increases if the ratio increases. The demand for the CPU cycles  $C_{dem}$  can be defined as the sum of the CPU cycles being used by VMs

in execution  $C_e$  and the waited CPU cycles by the VMs in the waiting queue  $C_{que}$ .

$$C_{dem} = C_e + C_{que} \quad (4)$$

Therefore, the overall performance degradation of  $i^{th}$  PM due to the network interference and co-location interference can be thought of as under:

$$I_i \approx f(CI_n, MNW_k)$$

So,

$$I_i = a \cdot CI_n + b \cdot MNW_k \quad (5)$$

where a and b are constants that are used to regulate the values.

### C. Proposed System Design Constraints

At the time of VM allocation policy design, for k number of PM used from the P set of available physical machines and V set of migratable VMs there are certain design constraints (DC) that are mandatory to be considered:

1) *Design Constraint 1:* Each VM has to be allocated to one and only one physical machine

$$V = \bigcup_{P_k \in P} V_k$$

2) *Design Constraint 2:* To minimize the co-location interference, the requested resources such as CPU cycles, network bandwidth, and memory should not exceed the total capacity of the server.

$$\sum_{i=1}^n V_i^{CPU} \leq \sum_{k=1}^m P_k^{CPU}$$

$$\sum_{i=1}^n V_i^{mem} \leq \sum_{k=1}^m P_k^{mem}$$

$$\sum_{i=1}^n V_i^{bw} \leq \sum_{k=1}^m P_k^{bw}$$

Where,

$V_i^{cpu}$  = CPU contention of  $i^{th}$  VM

$P_i^{cpu}$  = CPU contention of  $i^{th}$  PM

$V_i^{mem}$  = memory contention of  $i^{th}$  VM

$P_i^{mem}$  = memory contention of  $i^{th}$  PM

$V_i^{bw}$  = network bandwidth of  $i^{th}$  VM

$P_i^{bw}$  = network contention of  $i^{th}$  PM

3) *Design Constraint 3:* The total allocation capacity of the server for  $i^{th}$  PM to proceed with the new allocation is defined by SC:

$$SC = \sum_{P_i \in P} u_i^{cpu} + \sum_{P_i \in P} u_i^{mem} + \sum_{P_i \in P} u_i^{bw} \quad (6)$$

where,

$u_i^{cpu}$  is unused CPU cycles from the total CPU cycles of  $i^{th}$  PM consider it as x.

$u_i^{mem}$  is unused memory from the total memory of  $i^{th}$  PM consider it as y.

$u_i^{bw}$  is unused network bandwidth from the total network bandwidth of  $i^{th}$  PM consider it as z.

A genetic algorithm [34] is a method of an arbitrarily defined searching method with improved optimization and autonomic implied parallelism. GA can be used to automatically govern the search direction using probability, as well as to acquire and instruct the optimum searching space [35, 36]. Considering the advantages of the genetic algorithm mentioned in [34, 35, 36], the proposed algorithm employs an interference attentive genetic algorithm-based VM allocation strategy for live VM migration in a computing environment.

This method calculates resource usage in advance by taking historical data and current states into account, which will have an impact on the entire cloud system. By considering the above-described design constraints a genetic algorithm-based Interference Attentive VM allocation algorithm has been designed.

This research solution focuses on the total resource capacity of the server denoted as server capacity SC before allocating VMs to it.

As per design constraint number 3, there is a need to reduce the sum deviating from SC i.e.  $|x + y + z - SC|$  should be zero. Hence the fitness can be considered as the inverse of  $|x + y + z - SC|$ .

So,

$$f(x) = 1 \div |x + y + z - SC| \quad (7)$$

where

$$f(x) \in [0, 1]$$

In the proposed solution fitness function is the driving factor for VM allocation. The fitness function is designed by considering total server capacity which considers unused CPU cycles, memory, and bandwidth. Before allocation, the migrated VM demand and available server capacity are being evaluated for choosing the optimal solution to the VM allocation problem. The interconnections of the applied solution mathematically prove that the proposed fitness function will reduce the interference raised by migratable VMs.

#### D. Proposed Algorithm

The section discusses the proposed algorithm design. The VM allocation to the PM should be based on the probability of fitness value of a particular PM's resource utilization described in equation (7).

The design of the IAGA – Interference Attentive Genetic Algorithm-based VM allocation policy is in the direction of achieving the aforementioned research objective while simultaneously keeping discussed design constraints in mind. There are various strategies for finding the best genes for step 6.

The fitness ratio-based selection algorithm is used in this research. The calculation of the fitness value for each PM in the present PM population has been derived first and then kept for the individual PM with the highest score in the next generation. After that for allocation, every PM probability of the accommodation based on the fitness ratio is calculated.

---

**Algorithm:** Proposed VM allocation policy

**Input** PM: PM list, VM: Migratable VM list

**Output** P: best suitable PM for allocation of migratable VMs

**Procedure:**

```
For all the PMs in the list initialize the random population
  Categorize VMs into different categories based on the resource intensity as well the prior history of resource utilization
  Send VM to the appropriate queue
Evaluate fitness based on utilization of resources for each PM based on eq. (7)
While termination condition (! = generation count) do
  Parents ← select two parent individuals from the PM list according to the fitness value.
  For each parent1, parent2 do
    Offspring1, offspring2 ← Crossover (parent1, parent2)
    Apply mutation on generated offspring
    Find the best individual in the PM population
    If the best individual in the population is better then
      current best individual PM ← new best individual PM
  End If
End For
End While
Return best-suited PM
```

---

### E. Performance Metrics

Quantitative parameters such as energy consumption, amount of VM migrations, amount of host shutdowns, and average service level agreement violations are all properly considered. The following are explanations of the aforementioned performance matrices:

- **Energy Consumption:** The sum of energy consumed by each host during the overloading, underloading, and migration procedures.
- **The number of VM migrations:** The number of VMs migrated from one host to another during the allocation procedure while migrating.
- **The number of host shutdowns:** The number of host shutdowns performed during the migration process to minimize energy consumption as much as possible.
- **Average Service Level Agreement Violation (SLAV):** The average value of quantitative service level agreement violation due to migration and/or interference across all VMs.

### IV. EXPERIMENTAL SETUP AND RESULT DISCUSSION

The live VM migration can be considered as the whole process of host overload or underload detection, choosing the VMs for the migration and placing these VM in the target host. The term VM allocation policies are interchangeably used with PM selection policies. From the various literature discussed here, it is clear that while allocating the host to the migratable VMs different researchers have kept different research goals into consideration. Some of the common goals are energy minimization and SLA maximization. The major diverse effect of the live VM migration is the interference which has been considered by very few researchers. For the VM allocation strategy, one of the major goals should be the proactive strategy about the co-location interferences that may occur after the allocation VMs to the targeted PM along with optimum resource allocation to the ongoing VMs and newly migrated VMs. High SLA can be achieved if the resource allocation is as per the promised amount. The resource allocation could be proper if the newly migrated VMs are not exceeding their share by creating trouble for ongoing VMs. The interference awareness is the novel approach applied to the VM allocation policy to achieve multiple aforementioned research objectives.

To implement and test the proposed system the CloudSim simulator has been used. The CloudSim toolkit, developed by Rajkumar Buyya et al., was used for the experimental implementation [37], and then after the CloudSim is being used as a low-cost simulation environment for cloud-based research projects. It is an open-source simulation tool that most researchers use to simulate the cloud environment. The workload dataset compiled by PlanetLab has been used in the experimentation. The workloads used in this investigation are 20110303, 20110325, and 20110420. PlanetLab workloads are also included in the CloudSim simulator package.

Certain algorithms for VM allocation and VM selection approaches are also available in the CloudSim tool kit. Virtual machine allocation policies such as Static Threshold – THR, Median Absolute Deviation – MAD, Inter-Quartile Range – IQR, Local Regression – LR, and Local Robust Regression – LRR are given in the simulator. There are certain policies for VM selection, which include Maximum Correlation – MC, Minimum Migration Time – MMT, and Random Selection – RS. These are the benchmark algorithms used by many researchers for the comparisons of proposed systems.

LR and MAD VM allocation policies have been considered in the experiment. VM selection policies, MMT, MU, and RS have been used. The validation of the proposed system Interference Attentive Genetic Algorithm IAGA has been carried out against these policies. Workloads have been applied in various configurations of VM allocation and host overload detection policies. The evaluation has incorporated the IAGA policy and studied the imperial results of the aforementioned experiment scenarios. The proposed algorithm was also compared to Neha et al [38] RAP VM allocation policy.

The VM allocation approach applied in RAP is based on the static upper threshold whereas in the modern cloud application the workload fluctuates based on the high and the low number of user requests for a particular cloud application. Due to this, the static threshold will not lead to the appropriate resource utilization. The proposed VM allocation system is developed using a genetic algorithm.

A genetic algorithm is an adaptive heuristic search-based solution that presents the intelligent utilization of search space to solve the optimization problem. From the graphs, it is proved that for the dynamic workload-based cloud systems, the adaptive solution performs better than the static threshold-based policy for the VM allocation problem.

So the given experiments study the effect of the applied genetic algorithm for searching for the best suitable PM for the available list of candidate PMs. So the existing VM allocation policies have been modified to proceed further with the Genetic algorithm principles. The behavior of the system under study has been observed by various combinations specified in the result graphs.

Fig. 2, Fig. 3, and Fig. 4 show the number of hosts shut down for mentioned workloads. The resultant graph indicates that the count of hosts shutdowns is less in IAGA. Less number of host shutdowns will reduce the downtime for the ongoing application on the cloud host. This will lead toward the goal of SLA maximization. It can be observed in Fig. 5, Fig. 6, and Fig. 7, that the IAGA reduces energy consumption by the PMs. Fig. 8, Fig. 9, and Fig. 10 show the number of VM migrations. Average SAL violations achieved through experimentation have been presented in Fig. 11, Fig. 12, and Fig. 13. The results show that the SLA violation is lower for the proposed approach IAGA to ensure more effective service to cloud service consumers compared to the existing policies.

## V. CONCLUSION AND FUTURE WORK

The movement of VMs across the system for proper resource utilization is one of the solutions that may result in outlays and service interruptions, resulting in a drop in service quality by affecting SLA. The data centers in a cloud environment require a large number of VMs to run continuously with a high SLA demand. Proposed research experimentation focuses on interference attentive VM allocation. The main challenge of the proposed research work was to strike a balance between effective server resource utilization and the preservation of cloud resources while adhering to SLA constraints with minimized interference effects. The fitness function is a critical component of the proposed method for reducing interferences in Infrastructure as a Service (IaaS) Cloud data centers as it helps the proposed algorithm to find the best optimum PM from all the candidate PMs for the allocation of migratable VMs. One of the most inescapable principles of cloud computing systems that should be pursued is the principle of service quality. As a result, in proposed work concentrated on cloud computing systems competence characteristics such as the current state of PM computing resources specifically resource usage and demand queue to ensure the expected quality of service with minimal interferences from newly moved VMs during live VM migration. To improve the efficiency of the traditional algorithms, a Genetic Algorithm has been applied for VM allocation; the paper proposes a VM allocation policy to address the reduced number of VM migrations, reduced energy consumption, and low SLA violations. The promising results obtained from the proposed approach reveal that the genetic algorithm can be efficiently applied in real data centers to achieve interference minimizations. Furthermore, as the energy consumption decreases, it can also be used in green data centers. The proposed system has achieved the research objectives with a noticeable improvement compared to the existing approaches. The proposed research solution is useful to the cloud service provider to enhance the SLA and achieve satisfactory resource allocation by using the cloud server capacity at the optimum level. As of now, the proposed approach has been tested in the Cloud simulation environment. In the future, this approach could be extended by implanting it in a real cloud environment, the behavior of which could be studied and could be validated for other workloads and/or live streaming applications.

**Abstract**—The main objective of this work is to enhance the prediction of the Freezing of Gait (FoG) episodes for patients with Parkinson's Disease (PD). Thus, this paper proposes a hybrid deep learning approach that considers FoG prediction as an unsupervised multiclass classification problem with 3 classes: namely, normal walking, pre-FoG, and FoG events. The proposed hybrid approach Deep Conv-LSTM is based on the use of Convolutional Neural Network layers (CNN) and Long Short-Term Memory (LSTM) units with spectrogram images generated based on angular axes features instead of the normal principle-axes features as the model input. Experimental results showed that the proposed approach achieved an average accuracy of 94.55% for FoG episodes early detection using Daphnet and Opportunity publicly available benchmark datasets. Furthermore, the proposed approach achieved an accuracy of 93.5% for FoG events prediction using the Daphnet dataset with the subject independent mode. Thus, the significance of this study is to investigate and validate the impact of using hybrid deep learning method for improving FoG episodes prediction.

**Keywords**—Freezing of Gait (FoG); Parkinson's disease (PD); angular axes features; spectrogram; convolutional neural network (CNN); long short-term memory (LSTM)

## I. INTRODUCTION

Parkinson's Disease (PD) is a disorder that affects the patient's nerves, which are recognized by low levels in the brain's dopamine. Also, PD is the second most common symptom after Alzheimer's disease [1]. Low levels of dopamine lead the patients to the inability to control their body motion or activity. PD can affect the patients by two kinds of symptoms, motor, and non-motor symptoms, the motor symptoms, or cardinal symptoms, which are related to the movement in general, including resting tremor, stepping slowness (bradykinesia), postural instability (issues in balance), and Freezing of Gait (FoG). Non-motor or dopamine-non-responsive including cognitive weakness, sleeping behavior problems, sense of smell loss, difficulty defecation, talking and swallowing problems, and other related side effects to the human's sensory [2].

FoG is a side effect and one of the main symptoms for patients with both advanced and early PD stages. It is one of the most debilitating motor symptoms in patients with PD as it may lead to falls and a loss of independence. FoG can occur in the arms (which affects the writing ability), face (which affects the patient's vision), and leg (which results during gait

initiation by a series of short steps with tremors on lower limbs, turning, or walking towards a particular goal) [2].

FoG could be seen in different forms like 1) A complete FoG cycle 2) Freezing with knee-trembling 3) Walking with very short steps. For some patients, there is a brief trembling of the feet in place followed by short steps, while others experience total immobility and are unable to move it all for a few moments.

The main objective of this study is to predict FoG episodes based on a hybrid deep learning approach using time-series episodes windowing and relay on the use of angular axes feature to help in predicting FoG episodes with their different occurrence cases as mentioned previously. The baseline model has experimented with the proposed one (Conv-LSTM), a model based on the use of a deep convolutional neural network (CNN). This model is also implemented for detecting/predicting FoG episodes. The developed models in this paper have been tested with both Daphnet and Opportunity benchmark datasets.

Accordingly, the main contributions of this paper are summarized in the following points:

- Updating the publicly available Daphnet dataset through adding a new label (3) that specifies the pre-FoG episodes prediction.
- Developing a deep learning (CNN-LSTM) hybrid approach for handling the problem of FoG episodes prediction in patients with PD.
- Investigating subject-dependent spectrograms for predicting FoG episodes.
- Testing and validating the performance of the proposed approach through implementing multiple experiments using the benchmark datasets.

The remainder of this paper is organized as follows. Section II presents a review of the state-of-the-art related work employing different deep learning algorithms for predicting/detecting FoG episodes based on different approaches. Section III presents an overview of the main structure of the proposed approach. Results and discussion are presented in Section IV. Conclusions and future work are highlighted in Section V.

## II. RELATED WORK

Relevant state-of-the-art studies addressing FoG detection and prediction are described in this section.

The authors of [4] developed an approach to predict FoG for patients with PD using a deep learning model based on the Recurrent Neural Network (RNN) and Long Short-Term Memory networks (LSTMs). The achieved results were 94.7% with 1-second prediction, 82.9% with 3 seconds prediction, and 68.1% with 5 seconds prediction.

Also, the authors in [5] aimed to detect FoG based on the use of the DL approach, the data was collected from one wrist based on linear and angular acceleration. The collected data was fed into a CNN model with 10-fold cross-validation and Leave-one-out-subject-out (LOSO) Cross-Validation. The achieved results were 83% and 86% for sensitivity and specificity, respectively when using LOSO-CV. When using the 10-fold CV the achieved results were 88% and 90% for sensitivity and specificity, respectively.

For capturing long-range dependencies in variable-length input sequences, the authors in [6] used a Deep Recurrent Neural Network (DRNN) for building recognition models that can fulfill the paper's purpose. The proposed algorithms like cascaded, unidirectional, and bidirectional architectures are based on LSTM DRNNs. By using Unidirectional DRNN for the UCI dataset, the results were 96.7%, 96.8%, 96.7%, and 0.96. By using Unidirectional DRNN for the USC-HAD dataset, the results were 97.8%, 97.4.0%, 97.4%, and 0.97. By using Bidirectional DRNN for Opportunity dataset, the results were 92.5%, 86.7%, 83.5% and 0.92. Using the Cascaded DRNN for the Daphnet dataset, the results were 94.1%, 84.7%, 78.9%, and 0.93. Using the Cascaded DRNN for the Skoda dataset, the results were 92.6%, 93.0%, 92.6%, and 0.92. All datasets were measured with accuracy, average precision, average recall, and f1 score, respectively.

The author in [7] sought to detect FoG episodes from the data signal for the subject in/dependent with a 3D accelerometer. The proposed model implemented on patients in the daphnet dataset was based on the RNN LSTM model with three accelerometer sensors. The overall results were 80% and 79% for specificity and sensitivity, respectively when using all features (statistical and frequency domain features) with sensor and subject independent. When using only the statistical features the results were 89% and 34% for specificity and sensitivity, respectively with sensor and subject independent. The achieved results when using the frequency domain features were 80% and 77% for specificity and sensitivity, respectively with sensor and subject independent. They also implement a baseline model using the Random Forest classifier for comparing the achievements of each model. The results showed that the proposed RNN LSTM model outperforms the baseline model (RF classifier).

In [8], the authors developed a system for FoG detection that is based on CNN from a 2D acceleration signal. The average results for the subject independent were 80.7%, 69.29%, and 90.6% for accuracy, precision, and specificity, respectively. Moreover, the author in [9] proposed a hybrid deep learning algorithm for detecting FoG episodes. Their first model was based on the use of convolutional layers with LSTM units. The achieved results were 87.8% accuracy, 88.1% sensitivity, 89.1% specificity, and 88.4% geometric mean. The second model was based on convolutional layers with GRU (Gated Recurrent Unit). The results achieved were 85.4% accuracy, 94.8% sensitivity, 84.7% specificity, and 89.5% geometric mean.

The goal of the authors in [10] was to detect FoG using four types of feature sets with a DNN with 4-sec windowing. A model of CNN with MLP layers was introduced. It contains two convolutional layers with a max-pooling layer for feature extraction and with three fully connected layers for classification. The achieved sensitivity was 93.1% and 75% for specificity.

Furthermore, the authors in [19] used deep learning approaches and image processing techniques to detect FOG. The presented approach was based on the use of 1D-ConvNet. The results were 88.6% for sensitivity and 78% for specificity.

The aim of the study proposed in [20] was to detect FOG episodes in PD patients with a proposed model that consists of eight layered of 1D-ConvNet using two activation functions (sigmoid and hyperbolic). Down-sampling and low pass filter are used for data preprocessing. The achieved results were 89% for accuracy, 91.9% for sensitivity, and 89.5% for, specificity, respectively.

The purpose of the approach proposed in [21] was to detect FOG episodes using CNN based on two types of features, namely time and frequency domain features with 2.5 s windowing. The features were extracted from a tri-axil accelerometer and gyroscope sensors from a smartphone located in the patient's trouser pocket. Results were 91.8%, 93.8%, and 90.1% for F1-score, sensitivity, and specificity, respectively.

The main objective of this study is to investigate the impact of using deep feature learning based on angular axes spectrogram images and different windowing mechanisms through a hybrid deep learning approach for improving FoG episodes prediction.

## III. PROPOSED APPROACH

The proposed approach section is divided into four stages, starting with dataset acquisition, data preparation, going through deep learning features, and ending with the classification, as illustrated in Fig. 1.

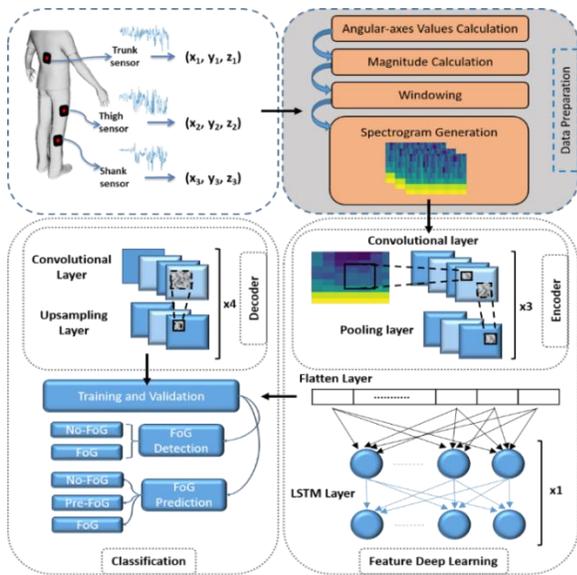

Fig. 1. Structure of the Proposed Hybrid FoG Prediction Model.

### A. Dataset Acquisition

To train and validate the proposed models, two benchmark datasets are considered; namely the Daphnet and the Opportunity datasets of FoG time-series data.

1) *The Daphnet dataset*, which is available publicly from the UCI Machine Learning Repository [11], has been used for validating the proposed approach. The dataset was collected from a total of 10 PD volunteers patients, where 8 subjects have experienced FoG while performing several walking tasks in the lab. The Shank (ankle), the thigh (above the knee), and the trunk (lower back) of each subject were used to place a three-wearable tri-axial accelerometer for data recording [3]. From Fig. 3, which presents the same portions for ankle, knee, and trunk sensors of the walking, pre-FoG, and FoG signals it can be observed that the existence of the signal spacing when there are pre-FoG or FoG samples. The original data samples have been labeled as 0 for describing out-of-experiment events, 1 for describing no-FoG events, and 2 for describing FoG events. Sessions with a duration between 20 and 30 minutes are accomplished by the subjects in the Daphnet dataset to represent different characteristics of daily walking [11].

2) *The opportunity dataset*, which contains recordings that are collected from 12 subjects using 15 networked sensor systems with 72 sensors [12]. For each subject, 6 different runs were recorded 5 of them were the Activity of Daily Living (ADL) the remaining was a drill run. For this study, the activity recognition subset of the opportunity dataset was used. Only 4 subjects with ADL runs were used, which corresponds to recordings of three tri-axial accelerometer placements namely, hip, above the right knee (RKN<sup>^</sup>), and below the right knee (RKN<sub>-</sub>).

### B. Data Preparation

Originally the validation Daphnet dataset doesn't contain samples with label 3 corresponding to pre-FoG events. For featuring the pre-FoG episodes with a new label as shown in Fig. 2, all samples with the same label (unified labels) for a specific window time before label 2

have been converted into label 3. Therefore, for the FoG prediction problem, a multi-class classification has been handled with the proposed approach. This method is used only for prediction implementations, but for the detection implementations, labels 1 and 2 only are used. Subjects four and ten have not experienced any Freezing of Gait episodes while performing several walking tasks. As previously mentioned in the data description section, the Daphnet dataset consists of ten PD subjects; the data of the two previous subjects and all records with zero labeling have been neglected. The data preparation phase has consisted of four steps, as follows:

1) *Angular axes values calculation*: The angular axes features [13], or axes of rotation, provide a combination of three rotations about different axes to represent the 3D orientation of an object. Because of the need to focus on the patient's rotation and orientation the reliance on the accelerometer features will not be efficient. Motions are dominated by rotations; therefore, it is needed to avoid the use of accelerometers and use a gyroscope sensor [14].

For the angular-axes calculation  $x$ ,  $y$ , and  $z$  of the principle-axes from the three sensors have been used to calculate the angular axes features (Roll, Pitch, and Yaw). As shown in equations (1), (2), and (3) details of calculating the angular values, Roll ( $r$ ), Pitch ( $p$ ), and Yaw ( $y$ ), about the  $x$ ,  $y$ , and  $z$  axes, respectively, where  $\Pi = 3.14$  is constant.

$$Roll = 180 * \arctan(y/\sqrt{x^2 + z^2})/\pi \quad (1)$$

$$Pitch = 180 * \arctan(x/\sqrt{y^2 + z^2})/\pi \quad (2)$$

$$Yaw = 180 * \arctan(z/\sqrt{x^2 + y^2})/\pi \quad (3)$$

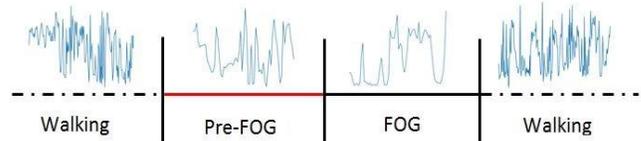

Fig. 2. An Example Signal Pattern for Accelerometer Signal Categories.

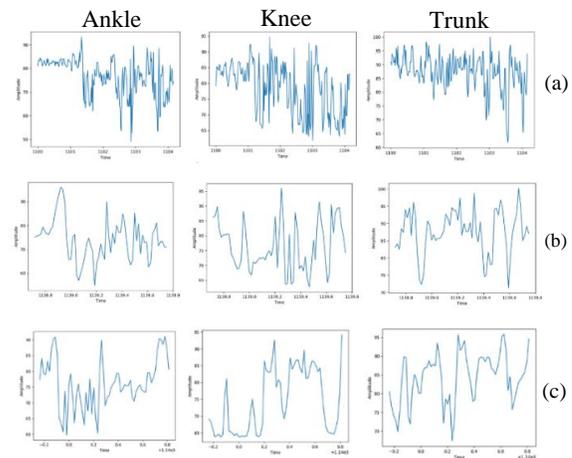

Fig. 3. Portion of Walking (a), pre-FoG (b) and FoG (c) Signals for Ankle, Knee and Trunk Sensor.

2) *Magnitude calculation*: After converting the principle-axes into angular axes, the magnitude of the obtained values has been calculated from each record of the three angular axes features values, according to equation (4), where  $s$  refers to the used ankle's (shank), knee's (lower thigh), or trunk's (lower back) sensor.

$$\text{Magnitude} = \sqrt{(r_s^2 + p_s^2 + y_s^2)} \quad (4)$$

3) *Windowing*: From each sensor, all the calculated magnitudes are divided into two overlapping windowing sizes, namely fixed and dynamic sizing based on the data labels. This paper presents two different schemes for selecting the best slicing technique and for testing various windowing mechanisms. Method 1 (scheme 1): The first method is adopting a 1 sec. window size, each window contains 76 samples, and each sample is 15 milliseconds [3]. Method 2 (scheme 2): On the other hand, a partially overlapping windowing method of dynamic-sized windows based on the data labels [3].

4) *Spectrogram generation*: Because other signals like nonstationary or non-periodic frequencies differ in time, in this step the information about the time domain and the frequency domain of real-life signals are needed, which is better computed from time-frequency analysis [15]. One of the basic visual tools for displaying the time-frequency analysis information is the spectrogram. The spectrogram is a 2D map, the vertical axis represents the frequency, and the horizontal axis represents the time of the signal. For spectrogram-based CNN, the amplitude provides a 2D array of successive segments used as an input feature for the spectrogram-based CNN. The spectrogram parameters are window size, noverlap, nfft (length of the FFT), and fs (sampling frequency). The input to the spectrogram is a signal data  $x$  and the output will be a matrix of 2D array  $q$ . The output  $q$  will have  $(\text{nfft}/2+1)$  rows if  $\text{nfft}$  is even and  $(\text{nfft}+1)/2$  rows if  $\text{nfft}$  is odd. For columns, will be  $(\text{the length of } q - \text{noverlap}) / (\text{length}(\text{window-noverlap}))$  [16].

Fig. 4 presents the 3D accelerometer axes spectrograms for FoG activity on the three sensors, namely the ankle, knee, and trunk. The time in milliseconds is presented on the x-axis and the frequency in Hz is presented on the y-axis, each row presents one of the axes, namely x, y, and z, respectively. The same portion of data is used for all sensors (ankle, knee, and trunk). It is visualized also from the figure areas with darker colors means that for a specific time and frequency point, the color of the image will be darker with a lower amplitude. Similarly, the color will be lighter with high magnitude.

It can be also observed that the most effective sensor placement is the trunk sensor, the readings from this sensor are better than the ankle and the knee sensors placements. It can be observed the lighter areas emitted from the trunk sensor, which means that those areas have a high frequency of FoG activity with high severity of FoG in the same area.

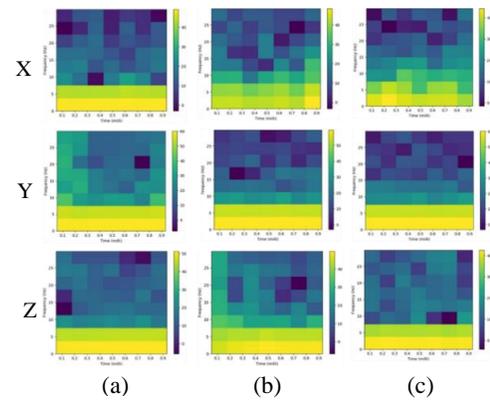

Fig. 4. Samples for each Axis (X, Y, and Z) for FoG Activity on the Ankle (a), Knee (b) and Trunk (c) Sensor.

### C. Deep Learning Features

For the proposed approach (Conv-LSTM), with the use of three Convolutional layers, which receive and extract features from spectrogram images with intermediate three max-pooling layers (encoder) as shown in Fig. 1. The encoder in the network compresses or down-samples the input into a fewer number of bits. The space represented by these fewer numbers of bits is often called the latent space, at this point, the input has compressed to the maximum. A convolution layer tries to extract higher-level features by replacing data for each pixel with a value computed from the pixels. From Fig. 1 it can be observed how features are extracted from each Conv-LSTM layer, clarifying, and discussing the use of intermediate LSTM layers, which are used for the feature deep learning phase, and CNN layers that are used for classification.

It can be also observed how features are extracted from each Conv-LSTM layer after extracting features from spectrograms, by using an intermediate LSTM layer that is used to receive the output of the last convolutional layer. To do so, the flatten layer is used because convolutional layers output a shape of four dimensions whereas the LSTM layer needs a three-dimension input. Like the proposed approach, the baseline 2D CNN approach also used the encoder as a feature extractor with three convolutional layers and three max-pooling layers, but without using any LSTM layer.

CNN is a class of deep, feed-forward AI neural networks that are used in Image & video recognition/classification, Video to Text (seq. to seq.), and Image Question Answering. A CNN consists of an input and output layer as well as multiple hidden layers. Typically, a CNN's hidden layers consist of Convolutional layers, pooling layers, and fully connected layers. Typically, a CNN is used mostly for image and video recognition, classification, video to text, and image question answering applications. CNN learns useful features from data itself dispenses the use of the hand-crafted features and instead depends on learning features that the network automatically extracted. So, it is a combination of a feature extractor and a classifier. Mainly the CNN contains convolutional, pooling, fully connected layers, and soft-max [17], [18].

- Convolutional layer is responsible for extracting useful features automatically by learning and knowing the best features by selecting the highest weights of each neuron in each convolutional layer.
- Max-pooling layer is used to reduce the size of the feature map, which results in having a smaller number of parameters and computations.
- Up-sampling layer is a backward stride convolution and performed for end-to-end backpropagation learning from the pixel-wise loss
- Fully connected layer means that all the input neurons in each layer are connected to the previous layer.
- Soft-max layer acts like a classifier in which many probabilities were proposed from each class and the class with the highest probability was predicted.

LSTM layer, Fig. 5 magnifying the steps of how the LSTM network works. The first step is to decide what information will be thrown away from the cell state. This decision is made by the sigmoid layer ( $\sigma$ ), which is called the "forget gate layer", it looks at  $x_t$  (current input) and  $h(t-1)$  (output of the last LSTM unit) and outputs a number between 0 and 1 for each number in the cell state  $c(t-1)$  (memory of the last LSTM unit). 1 means "keep the previous" result and don't forget it while 0 means "don't keep the previous result" and forget it. For simplicity, if it is needed to predict the next word based on all the previous ones, the cell state might include the gender of the present subject so that the correct pronouns can be used. But when a new subject came up, the previous gender of the old subject needs to be forgotten.

In the next step, a decision as to what new information will be stored in the cell state is taken in two steps. First, a decision for which values will be updated is taken by a sigmoid layer called the "input gate layer". Next, a tanh layer creates a vector of new values  $c_t$  (new updated memory). The next step is to combine the previous two outputs from each layer to create the updated cell state. For simplicity going back to the example, here adding the gender of the new subject to the cell state by replacing it with the old one that was forgotten is needed.

Finally, the  $h_t$  (output) is based on the value stored in the cell state. First running a sigmoid layer that decides, which parts of the cell state will be going to be output is needed. Then, go through the tanh layer and multiply ( $\times$ ) the output of each layer.

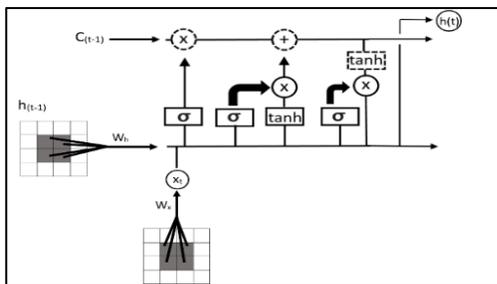

Fig. 5. Presents an Illustration of the Proposed Hybrid Model.

As the problem is based on unsupervised learning, the use of an Auto-Encoder mechanism is taking place as it has the option to not use dense layers, it can use the convolutional layers itself to learn, which is better for video, image, and series data. The encoder compresses or down-samples the input into a fewer number of bits, the space represented by these fewer bits is often called the latent space or bottleneck. At a maximum level, the input at a particular point is compressed that's why it can be also called the "maximum point of compression". The decoder is the reverse of the encoder, and its importance lies in rebuilding the original image with the highest possible quality.

#### D. Classification

For the proposed model, both datasets are divided into sub-datasets, one for training and the other for validation using a k-fold cross-validation method applied for both training and validation. A hybrid deep learning structure is used as shown in Table I, the hybridization here is based on three convolutional layers with intermediate max-pooling layers, a flatten layer, three LSTM layers for feature deep learning, and four convolutional layers with intermediate up-sampling layers for classification. Convolutional layers as mentioned previously learn features automatically in each layer, so it doesn't need any hand-crafted features, and the reason is that the deep architecture, which includes multiple layers allows those layers to be stacked. So, this deep architecture can characterize the prominence of signals on different scales. In each convolutional layer, each neuron carries the maximum weight (the maximum weight means a better result) from the input layer and if a neuron was for example in the third layer it takes the output of the previous layer as its input. The convolutional layer's network has its output as a convolution fully connected neural network instead of matrix multiplication.

The structure of the baseline model (Deep 2D CNN) model was fed with spectrogram images as model input. The same as the proposed model, a baseline model consists of three convolutional layers with intermediate max-pooling layers for feature deep learning and four convolutional layers with intermediate up-sampling but without flatten and LSTM layers.

#### IV. RESULT AND DISCUSSION

This section discusses different models' results used in this paper to reach the best approach that effectively influences predicting FoG episodes. Also presents and discusses the experimental outcomes of using the proposed hybrid deep learning scheme for FoG episodes prediction. Both datasets are divided 80% for training with a random dividing and 20% for validation. The implementation consists of two phases using the Daphnet dataset:

- Working on the original dataset applying all sensors and each sensor apart (Ankle, Knee, and Trunk).
- Working on the original dataset after applying the proposed angular axes features for in/dependent subjects using all sensors and each sensor apart (Ankle, Knee, and Trunk).

The performance measurements as shown in equations (5), (6), (7), (8), and (9) are the accuracy, precision, recall, F-measure, and Specificity.

$$Accuracy = \frac{tp+tn}{tp+fn+fp+tn} \quad (5)$$

$$Precision = \frac{tp}{tp+fp} \quad (6)$$

$$Recall = \frac{tp}{tp+fn} \quad (7)$$

$$F - measure = 2 \frac{precision*recall}{precision+recall} \quad (8)$$

$$Specificity = \frac{TN}{(TN+FP)} \quad (9)$$

#### A. Daphnet Dataset Results

In subject-independent FoG prediction, from Table II and Table III it can be observed that the results derived from sensor independent are almost the same as the results when using only data from the trunk sensor (sensor dependent). But for overall performance, using sensor independent is better than using sensor dependent. It was also observed that using a windowing with 1-second achieves a better performance than using a windowing with 4-seconds. Another enhancement is for using angular axes features over principle-axes. For the 2D CNN model, same as the hybrid Conv-LSTM model; the trunk sensor outperforms other sensors, and angular axes features achieve better performance. Using 1-second windowing records an enhancement against using 4-seconds windowing and better overall performance is achieved when using sensors independent over-dependent sensors. In addition, for the 2D CNN model, from Table IV and Table V it can be observed that using only CNN without LSTM the model achieves better results than using a hybrid structure of CNN with LSTM.

The results show that the implemented deep 2D CNN model achieves the highest accuracy against the proposed one, it can be observed in Fig. 7. It also emphasizes that the use of the angular axes features is much better than the principle-axes. For subject-independent and sensor dependent with 1-second (67 samples) windowing the two implemented models namely, 2D CNN and hybrid deep Conv-LSTM achieves an increase in the performance using angular axes against principle-axes by 2.7%, and 2.8% using ankle sensor for the two models respectively. And for the knee sensor the performance increased by 2.6%, and 2% for the two models, respectively. The enhancement in the trunk sensor is 3.3%, and 2.5% for the two models, respectively. When using sensor independent the angular axes features achieve an enhancement of 3.8%, and 2.2% for the two models, respectively, over the principle-axes.

Implementing subject independent with sensor dependent for FoG prediction with a 4-seconds (268 samples) windowing technique, the results as shown in Fig. 7 clarifies that using a bigger windowing technique negatively affects the performance. When using 1-second windowing against 4-seconds windowing with angular axes features from Fig. 6 and Fig. 7, the performance increases by 9% and 4.3% for the ankle sensor with 2D CNN, hybrid deep Conv-LSTM, respectively. On the knee sensor, the enhancement is 6.5%

using the 2D CNN model and 4.4% using the hybrid Conv-LSTM model. The enhancement using trunk sensor is 4.8% and 3.7 for the two models, respectively. Finally, using sensor independent achieves increasing in the performance by 5.6% and 3.8% for the two models, respectively.

Applying the 4-seconds windowing technique using angular axes features outperforms using principle-axes as shown in Fig. 7. The enhancement on the ankle sensor is 2.3% and 5.6% for 2D CNN, and hybrid deep Conv-LSTM respectively. On the knee sensor, the enhancement increased by 3.1% and 3.6% for the two models, respectively. The performance using the trunk sensor increases by 2.6% and 2.8%. When applying sensor independent with angular axes features the performance against the use of principle-axes increased by 2.8% and 3.1% for the two models, respectively.

The implementation of Subject-independent FoG detection for deep learning models with sensor dependent from Table VI emphasized that the trunk sensor outperforms other sensors, and angular axes features achieve better performance against principle-axes. Also, using 1-second windowing achieves an enhancement over using the 4-second windowing. It has been observed from Table VI and Table VII that a better overall performance is achieved when using sensors independent over-dependent sensors. When comparing results of prediction with detection, it can be observed that FoG prediction outperforms FoG detection for both 2D CNN and hybrid deep Conv-LSTM models. In addition, from Table VIII and Table IX the results ensure that the 2D CNN model structure is better than the hybrid Conv-LSTM model structure.

Detecting FoG episodes for subject-independent and sensor dependent with 1-second (67 samples) windowing as shown in Fig. 8 when applying angular axes features outperforms using principle-axes. The enhancement on the ankle sensor is 2.6% and 3% for the 2D CNN and hybrid deep Conv-LSTM models, respectively. Furthermore, the enhancement on the knee sensor is 0.5% and 2.5% for the two models, respectively. The performance increased also when using the trunk sensor, the enhancement is 1% and 2.9%. An enhancement using angular axes features with sensor independent by 1.6% and 1.3%. Applying the 4-seconds windowing technique using angular axes features outperforms using principle-axes as shown in Fig. 9. The enhancement on the ankle sensor is 3.7% and 4.9% for 2D CNN, and hybrid deep Conv-LSTM, respectively. On the knee sensor, the enhancement increased by 3.3% and 3.5% for the two models, respectively. The performance using the trunk sensor increased by 4% and 3.2%. An enhancement is achieved when applying sensor independent with angular axes features by 2.9% and 3.4% for the two models, respectively against the use of principle-axes.

An enhancement can be observed in Fig. 8 and 9 when using angular axes features with 1-second, which equals 67 samples against 4-seconds (268 samples) windowing. The enhancement on the ankle sensor increased by 4.6% using the 2D CNN model and 4.3% using the hybrid deep Conv-LSTM model. On the knee sensor, the enhancement is 3.5% using the 2D CNN model and 4.9% using the hybrid deep Conv-LSTM

model. The enhancement on the trunk sensor achieves 5% using the 2D CNN model and 3.2% using the hybrid deep Conv- LSTM model. The implementation of the sensor independent has also increased the performance by 4.7% using the 2D CNN model and 4.3% using the hybrid deep Conv-LSTM model.

B. Opportunity Dataset Results

Results for sensor dependent, Table X shows that using angular axes features outperforms using principle-axes, as the Conv-LSTM model achieved an enhancement of 4.3%, 2.6%, and 2.4% for upper knee, hip, and lower knee sensors, respectively. Sensor-dependent results for 2D CNN, Table XI ensure also that the use of angular axes features results are better than principal axes. The results increased by 3.1%, 1.6%, and 1.2% for upper knee, hip, and lower knee sensors, respectively. For the independent sensor using angular axes features outperform the results from principle-axes with an enhancement by 3.5% and 4.1% for Conv-LSTM and 2D CNN models, respectively as shown in Table XII. From Table X and Table XI, it can be observed that the hip sensor outperforms other sensors and the performance of the 2D CNN model achieves results better than the Conv-LSTM model. Table XIII presents different deep learning models and features for the related work compared with the proposed models. Two different models are proposed for deep learning implementation, the first one is a combination of a convolutional neural network layer for 2D spectrograms images and LSTM recurrent units (Conv-LSTM). The second model used CNN also with 2D spectrogram images. Both models are implemented under the use of angular axes features instead of principle-axes. The best F-measure achieved by the proposed related work algorithms using the same Daphnet dataset was 80% on the other hand, the Conv-LSTM model achieves 95.1% F-measure and the CNN model achieves 98.1% F-measure. The enhancement here is 15.1% and 18.1% for Conv-LSTM and CNN models, respectively.

## V. CONCLUSION AND FUTURE WORK

In this paper, a hybrid model of 2D convolutional layers with LSTM layers (Conv-LSTM) was proposed with the use of spectrograms as an input for the model and another baseline model was 2D CNN. The developed models are implemented

using angular axes features and principle-axes sensor data readings. In this paper, two windowing methodologies are tested and applied for the Daphnet dataset. The two methodologies are a window of 67 samples, which is equivalent to 1-second, and a window of 268 samples, which

is equivalent to 4 seconds. The paper aimed to predict the FoG episodes, the most approach that achieves this aim was the use of the CNN approach for both Daphnet and Opportunity datasets as shown in Fig. 6 and Table XII, followed by adopting the hybrid Conv-LSTM approach. Several observed enhancements are achieved. First, the enhancement was achieved when using angular axes features over principle-axes. Second, using 1-second windowing against 4 seconds achieves better performance. Deep learning algorithms for predicting pre-FoG episodes, results from Table II and Table III for the Conv-LSTM model, Table IV and Table V for the CNN model ensure on using angular axes features outperforms the use of principle-axes. Deep learning results for detecting FoG episodes from Tables VI and VIII for the Conv-LSTM model and Tables VIII and IX for the CNN model also clarify that the use of the angular axes features is better than the principle-axes. In addition, the prediction results for both Conv-LSTM and 2D CNN models are better than the detection results.

Deep learning algorithms are implemented with the use of an early stopping approach to avoid the model's overfitting. All training sets are implemented for 15 epochs and 15 folds in each epoch for both datasets. It also emphasizes that the maximum number of epochs the model reached was 14 epochs, the minimum number was 2 epochs and the average number of epochs lasting in each fold was 6 epochs. The best result achieved from deep learning models was 97.6% and 93.5% for 2D CNN and hybrid Conv-LSTM respectively for the subject and sensor independent. It can be also observed that patient 8 was the subject with almost the best accuracy in subject dependent, as the patient recorded a score of 4 out of 5 on the Hoehn and Yahr (H&Y) scale, which is considered the highest score among the other 10 patients in the Daphnet dataset.

For future work, various challenges could be considered in the domain of predicting the FoG episodes via pre-fog behavior detection as well as predicting FoG severity. Working on new feature fusion sets. Build our dataset to experiment with different algorithms and features and to be compared with other datasets.

**Abstract**—Emotions are the essential parts that convey meaning to the interlocutors during social interactions. Hence, recognising emotions is paramount in building a good and natural affective system that can naturally interact with the human interlocutors. However, recognising emotions from social interactions require temporal information in order to classify the emotions correctly. This research aims to propose an architecture that extracts temporal information using the Temporal model of Convolutional Neural Network (CNN) and combined with the Long Short Term Memory (LSTM) architecture from the Speech modality. Several combinations and settings of the architectures were explored and presented in the paper. The results show that the best classifier achieved by the model trained with four layers of CNN combined with one layer of Bidirectional LSTM. Furthermore, the model was trained with an augmented training dataset with seven times more data than the original training dataset. The best model resulted in 94.25%, 57.07%, 0.2577 and 1.1678 for training accuracy, validation accuracy, training loss and validation loss, respectively. Moreover, Neutral (Calm) and Happy are the easiest classes to be recognised, while Angry is the hardest to be classified.

**Keywords**—Emotions recognition; speech modality; temporal information; affective system

## I. INTRODUCTION

Emotions are one of the essential communication factors during the social interactions. They provide additional meanings to verbal communication. Most of the conversation meaning can be captured mostly via non-verbal channels (e.g. speech prosody, body gestures and facial expressions) [1], [2], [3]. Hence, capturing emotions during social interactions between interlocutors is essential to building a system that can interact with humans effectively, efficiently, and naturally. Several efforts have been made to build models that can automatically classify emotions from non-verbal cues in the conversation. Some researchers aim to model the emotions classifier from image or video modality (e.g. Facial Expression Recognition and Hand and Body Gesture). The others use speech and text modality to recognise emotions from the conversation. Generally, the emotions are classified into six basic emotions plus neutral [4]. Recognising emotions from the conversation is a cumbersome task to a social ignorant computer [3]. Several problems exist in building good emotions classifier model from social conversation. First is the dataset; most datasets exist to model the emotions recognition are not balanced in the emotions class. This is due to not all emotions being expressed equally. The second problem is that not all

the emotions recognition models have good performance to recognise emotions from the conversation. The results depend on the implemented machine or deep learning algorithms, the dataset used, pre-processing applied, and the modality used (video, image, text or speech). This research proposes and explores several deep learning architectures based on Temporal Convolutional Neural Networks (CNN) and Long Short Term Memory (LSTM) to extract features and classify emotions from speech. Most of the emotions recognition required temporal information to improve the model performance. Hence, this research proposes a combination of Temporal CNN to extract the features from the speech signals with LSTM to extract the features further and classify the emotions. The results have shown that MODEL-5 achieved the best model with the training accuracy score of 99.92%, validation accuracy of 78.22%, training loss of 0.0144 and validation loss of 0.8432. The rest of the sections in this paper are organised as follows: The next section illustrates the related work and state of art of emotions recognition from speech. The next section, Emotions Recognition from Speech, demonstrates the proposed framework to model emotions recognition from speech signals. The details of the experiment's settings are also shown in this section. The results are comprehensively presented and discussed in section Results and Discussion. Finally, the last section demonstrates the conclusion and future research direction of this research.

## II. RELATED WORK

### A. Emotion Detection / Recognition

Emotions are one of the essential parts of social interactions. Emotions convey more than 80% meanings during the social interactions between interlocutors [2], [1]. Hence, detecting or recognising emotions is a paramount task to build a good and natural affective system. Emotion Detection / Recognition is a classification method that can bring up an important feature, namely the emotion contained in an input used for various uses [5]. The input used consists of various forms such as: speech [6], text [7] and visual [8], [9] cues. Most emotions detection/recognition tasks implement machine or deep learning (e.g. convolutional based, attention-based, recurrent based and transformer-based) to model the detector or recogniser. Analysing emotions can help in various fields, one of which is human and computer interaction which can later make computers better decisions for their users. Some research regarding emotion detection has many variations,

such as: Sarcasm Detection [10], Mood Prediction [11] and Personality Detection [12].

### B. Speech Emotion Recognition

Speech Emotion Recognition (SER) is a method for mapping the features of a speech into the emotions contained in the speech. SER is not a new field of study [13]. However, along with the development of technologies, several methodological developments can be applied to SER. Thus, making research in the SER field more varied and complex to achieve more optimal results. SER usually utilises a classification algorithm to map input in a speech to output in the form of emotion classification. In general, the pipeline for SER is data pre-processing, features extraction and model training + evaluation. The data pre-processing generally involves data augmentation as well as data framing and windowing. Features extraction techniques are implemented to the data after the data is being pre-processed. The features can be extracted in the form of Spectral features, Prosodic features and the combination of both Spectral and Prosodic features. Finally, the features are then trained and evaluated using machine (or deep) learning algorithms.

### C. Convolutional Neural Network in Speech Emotion Recognition

Although CNN is well-designed for Image Recognition it could be extended to Natural Language Processing and Speech Processing [14][15][16] Research regarding CNN for Speech Emotion Recognition conducted in 2016 [17] and 2018 [18] using RECOLA datasets [19]. by combining Convolutional Neural Network and Long Short-Term Memory which resulted in an outperformed model compared to traditional approaches on signal processing techniques. Then in 2017 [6] conducted research regarding Speech Emotion Recognition using Deep Convolutional Neural Network (DCNN) and Discriminant. Temporal Pyramid Matching (DTPM) to classify speaker's emotion resulting in a good model for automatic feature learning on speech emotion recognition tasks. The research concludes that DCNN is not only effective for image recognition but also in Speech Emotion Recognition. In 2020 [20] conducted research about CNN based Framework for Enhancing Audio Signal Processing for Speech Emotion Recognition proposing a framework that utilises a discriminative CNN using spectrogram which according to the author, the spectrogram has many features that texts or phonemes cannot represent.

## III. EMOTIONS RECOGNITION FROM SPEECH

This research proposes the five best architectures by combining Temporal Convolutional Neural Network (CNN) and Long Short Term Memory (LSTM) to extract and classify emotions from speech signals. The dataset used in this research is The Ryerson Audio-Visual Database of Emotional Speech and Song (RAVDESS) [21]. The dataset contains more than 7000 audio files of emotional speech acted by twenty-four professional actors. This research only uses the emotional song dataset, where there are 920 audio data files and four basic emotions (i.e. Angry, Fear, Happy and Sad) plus Neutral. The RAVDESS dataset encodes the audio information (e.g. label and gender) in the filename. Hence, some text sub-string

methods were applied to extract the label of the files. In this research, gender information is not used. Moreover, several pre-processing techniques were implemented to the dataset to enhance the quality of the dataset. First, the sample rate of the dataset was set to 16 *KHz*, and to normalise the speech time, the signal audio was padded to a maximum of 3 seconds. The dataset was split into two sets of data train and test with the ratio of 80%:20% (736:184). Moreover, the training data then were augmented to improve the quality of the data. This research proposed two settings of the data augmentation: seven times of the training data (5,152) and three times of the training data (2,208). Table I illustrates the emotions class distribution on each augmentation setting. The column Train Aug 1 denotes the augmentation with three times of the training data, while column Train Aug 2 refers to the augmentation with seven times of the training data. The dataset has an imbalanced dataset, where the Sad class is the majority class, and the Angry class is the minority class. Fig. 1 illustrates the example of the speech signal. The X-axis indicates the time is second (*s*), while the Y-axis indicates the amplitude of the signals in Decibel (*dB*). The left side of the image illustrates the original speech signal and the right side of the image demonstrates the augmented speech signal with noise.

TABLE I. DATASET DISTRIBUTION

No	Label	Train Aug 1	Train Aug 2	Test
1	SAD	465	1120	46
2	NEUTRAL	450	1036	39
3	HAPPY	444	1015	39
4	FEAR	441	1015	36
5	ANGRY	408	966	24
6	TOTAL	2,208	5,152	184

Feature extraction methods using Short-time Fourier Transform (STFT) and Mel Frequencies were applied to generate the Mel-Spectrogram representation on each audio file. The features were extracted using several parameters, such as: the hop length of 512, the window of 256. To normalise the features, all the vector then padded with zeros up to 2,048 to match the Fast Fourier Transform input. The next step was to generate Mel-Spectrogram from the Mel frequencies generated from Mel bins of 128 and the maximum frequency of 4.0 *KHz*. Finally, the features were framed with a window step of 128 and a window size of 64. Fig. 1 and Fig. 2 illustrate the examples of the Mel Spectrogram features visualisation from a happy female audio (left side of the image) and a happy male audio (right side of the image). The features extracted are then used in training with the proposed architectures. There are five best architectures proposed in this research.

Fig. 3 demonstrates the blueprint of the proposed architectures. The architecture blueprint consists of four parts: the CNN block, The Flatten layer, the LSTM block and the Softmax Layer. The Temporal CNN block consists of one temporal convolutional layer (3x3 filter), one batch normalisation layer, one Exponential Linear Unit (ELU) activation layer, one Max Pooling layer (3x3 filter) and one Dropout layer. The CNN block can have two to four blocks of layers in the proposed architecture (see Table II). The Flatten layer aims to flatten all the extracted layers with temporal features. Moreover, the LSTM block consists of 128 units of LSTM layers. The LSTM block has one to two LSTM layers plus one bi-directional layer in the proposed architecture (see Table II). Finally, the

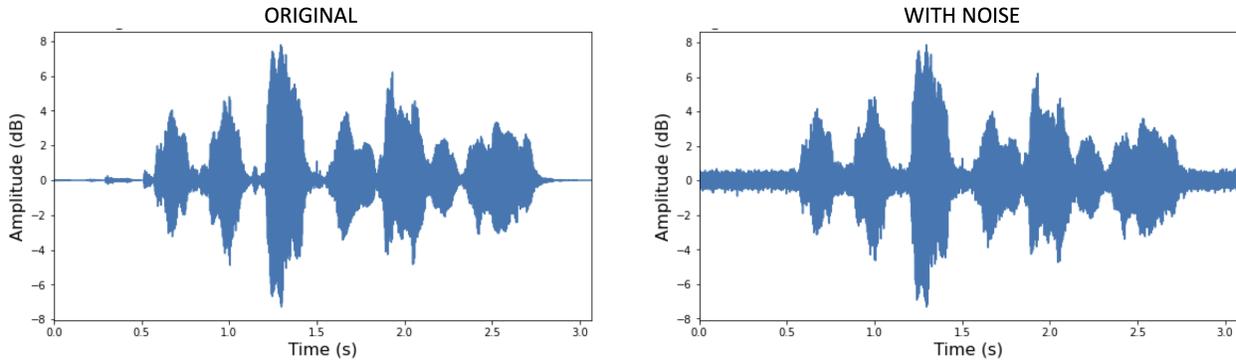

Fig. 1. Speech Signals: Original (left), Augmented with Noise (right).

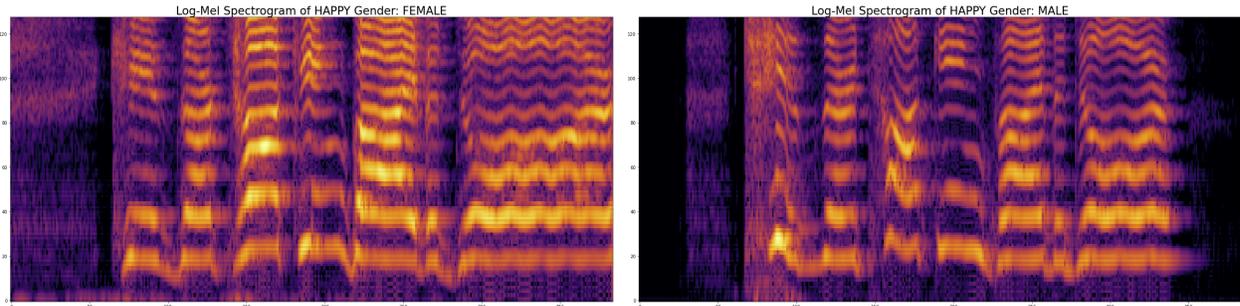

Fig. 2. Mel Spectrogram Features: Happy Female (left), Happy Male (right).

features extracted then are classified in the Softmax activation layer. Table II shows the overall settings of the proposed architectures. The CNN column indicated the number of the CNN blocks (e.g. 2 indicates that there are two blocks of CNN layers in the model), while the LSTM column shows the number of the LSTM blocks, where the asterisk mark (\*) indicates a Bidirectional LSTM layer. The Dropout implemented in this research is between 0.3 to 0.4. Finally, the column Aug indicates the augmented training dataset used, and three indicates three times the original training dataset and seven indicates seven times the original training dataset.

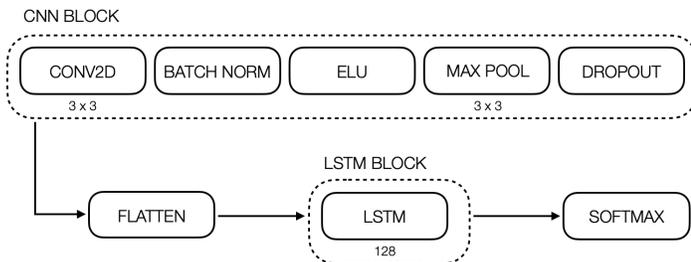

Fig. 3. Proposed Architecture.

#### IV. RESULTS AND DISCUSSION

Five architectures with two settings of augmentation data were explored in this research. The architectures combine Temporal CNN and LSTM (or Bidirectional LSTM) to extract and classify the emotions. Fig. 3 illustrates the baseline of the proposed architectures and Table II demonstrates the proposed

TABLE II. PROPOSED ARCHITECTURE SETTINGS

NO.	NAME	CNN	LSTM	DROPOUT	AUG
1	MODEL-1	2	1	0.3	3
2	MODEL-2	2	1	0.4	3
3	MODEL-3	2	2	0.3	3
4	MODEL-4	3	1*	0.3	7
5	MODEL-5	4	1*	0.3	7

architecture settings. This research explores several settings of deep learning architectures and results in the five best architectures that provide the best results. The best result was achieved by the MODEL-5 that consisted of four CNN blocks combined with one bidirectional LSTM layer with a dropout value of 0.3. MODEL-5 also implemented data augmentation seven times bigger than the original training data. The MODEL-5 provides 99.92% and 78.22% of training accuracy and validation accuracy scores, respectively. Moreover, the MODEL-5 provides 0.0144 and 0.8432 of training loss and validation loss, respectively. The dropout value of 0.4 did not significantly improve the model compared to the dropout value of 0.3.

TABLE III. OVERALL RESULTS

NO.	NAME	Train Acc	Val Acc	Train Loss	Val Loss
1	MODEL-1	98.73%	58.15%	0.1396	1.1680
2	MODEL-2	94.25%	57.07%	0.2577	1.1678
3	MODEL-3	96.01%	55.98%	0.2098	1.2720
4	MODEL-4	98.84%	69.85%	0.0625	0.9312
5	MODEL-5	<b>99.92%</b>	<b>78.22%</b>	<b>0.0144</b>	<b>0.8432</b>

Table III illustrates the overall results of the experiments.

The results have shown that the models trained with seven times training data augmentation perform better than the models trained with three times training data augmentation. Overall, there are no significant differences in the training accuracy score of models trained with three times training data augmentation compared to the models trained with seven times training data augmentation. However, the seven times training data augmentation model provides higher validation accuracy and lower validation loss. Moreover, the models trained with three times training data augmentation suffer from over-fitting despite batch normalisation and dropout were applied to the CNN and LSTM architectures. MODEL-1 that implemented 2 CNN blocks and 1 LSTM block with 0.3 dropouts trained with three times training data augmentation resulted in 98.73%, 58.15%, 0.1396 and 1.1680 in training accuracy, validation accuracy, training loss and validation loss, respectively. Moreover, MODEL-4 implemented three blocks CNN, one bidirectional LSTM with dropout value of 0.3 and trained with seven times training data augmentation resulted in 98.84%, 69.85%, 0.0625 and 0.9312 in training accuracy, validation accuracy, training loss and validation loss, respectively. Training with two layers of LSTM did not improve the validation accuracy, albeit two layers of LSTM improved the training accuracy. The results show that the model trained with two layers CNN and one layer LSTM (MODEL-2) provides 94.25%, 57.07%, 0.2577 and 1.1678 for training accuracy, validation accuracy, training loss and validation loss, respectively. Moreover, the model trained with two layers CNN and two layers LSTM (MODEL-3) provides 96/01%, 55.98%, 0.2098 and 1.2720 for training accuracy, validation accuracy, training loss and validation loss, respectively. Fig. 4 illustrates the confusion matrix for each classes in the best model (i.e. MODEL-5). The result shows that Neutral (Calm) and Happy emotions are the easiest emotions to classify from the given speech dataset. Moreover, the Angry emotion is the hardest emotion to classify compared to the other classes. The Angry emotion is also mostly miss-classified as the false positive in the other classes. Most likely, it is due to the number of the Angry class in both the training and testing dataset. Finally, the Adam and SGD optimiser do not provide a significant difference to the training accuracy, validation accuracy, training loss and validation loss.

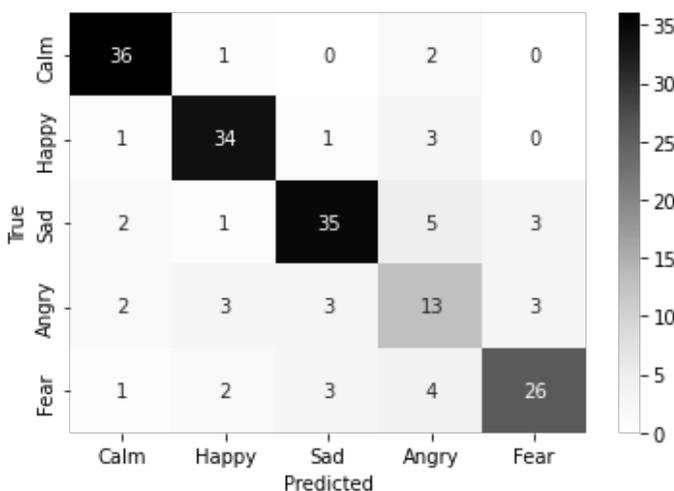

Fig. 4. Confusion Matrix for MODEL-5.

## V. CONCLUSION AND FUTURE WORK

Five settings of architectures with the combination of CNN and LSTM (or Bidirectional LSTM), number of dropouts and the data augmentation settings were explored in this research. The architectures were implemented to train the emotions recognition models using The Ryerson Audio-Visual Database of Emotional Speech and Song (RAVDESS) dataset. The dataset was pre-processed and augmented with two data augmentation settings (i.e. three times and seven times of the original data). The results show that the best model was achieved by MODEL-2, which provides 94.25%, 57.07%, 0.2577 and 1.1678 for training accuracy, validation accuracy, training loss and validation loss, respectively. Moreover, Neutral (Calm) and Happy emotions are the easiest emotions to classify from the given speech dataset, while the Angry emotion is the hardest emotion to classify compared to the other classes. This is due to the number of data in the Angry class in both the training and testing dataset.

For future direction research, more combinations of the architectures, such as the attention architectures and Transformer based architectures, will be explored to increase the recogniser model performances. Moreover, the multi-modal features can also be explored to increase the accuracy and tackle the over-fitting problem. Furthermore, the features from videos (e.g. facial expressions and body gestures), speech and text, can be explored to build a better model for emotion recognition. Finally, the emotions recogniser model that has been trained can be implemented to the more complex affective system such as virtual humans, where recognising emotions can be one of the tools to extract non-verbal meanings from the human interlocutors.

**Abstract**—Biometric authentication is becoming more prevalent as it allows consumers to authenticate themselves without entering a physical address or a personal identification number. Thus, a simple finger gesture or a glance at a camera can still prove one's identity. In this review, we explain in detail how the concept of authentication and the various types of biometric techniques is used for user identification. Then, we discuss the various ways these techniques can be combined to create a truly multimodal authentication system. For a more organized approach, our overview is classified into two main categories based on human biometric traits. First, the physiological traits include fingerprint, facial, iris/retina, hand, and finger-vein. Second, the behavioral traits includes voice, signature, and keystroke recognition systems. Finally, we offer a comprehensive comparison of selected methods and techniques and focus on three criteria: algorithms, merits, and drawbacks. Based on this comparison, we provide insight into our future research in iris recognition, by which we combine several artificial intelligence algorithms to develop our system.

**Keywords**—Biometric authentication; physiological traits; behavioral traits; facial recognition; iris recognition; voice recognition; signature

## I. INTRODUCTION

Authentication is a security function that involves providing and checking the proof of the person's identity, the message sender, the software, the logical server, or the device. Different identification methods have been proposed for exchanging safety-related information [1], [2], [3], [4], faced with the logical evolution of international regulations; new technological solutions are gradually being implemented. Among these technologies, biometrics is the most relevant technology to reliably and rapidly identify and authenticate a person, based on their unique biological characteristics.

Biometric authentication uses a person's biological characteristics to verify their identity and ensure secure access to an electronic system. The biometric technologies are based on how each person can be identified distinctly through one or more biological characteristics, such as fingerprint, hand morphology, retina and iris, voice, DNA, or signatures. In general, biometrics can be classified into two categories: physiological traits, and behavioral traits, as shown in Fig. 1. Biometric authentication is the application of these biometric technologies to identify a person as part of a user validation process to access a system.

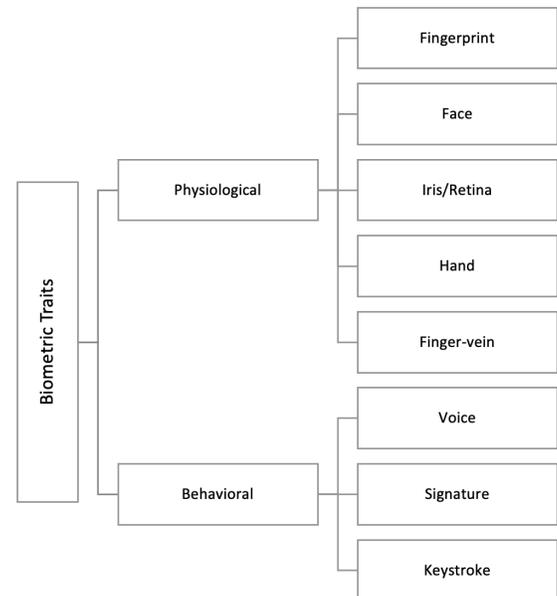

Fig. 1. Classification of Biometric Traits.

The motivations and potential benefits that drive our research are the convenient use of this approach in different systems around the world. Our future project involves using iris recognition methods in airports for fast and accurate authentication. The objective is to identify the human iris and link the data together by using artificial intelligence (AI) techniques to extract a passenger's information, such as flight number, dedicated gate, seat number, departure and arrival times, travel bag weight, how many kilos are reserved for travel bags, vaccination status, and chronic disease diagnosis (e.g., diabetes, high blood pressure).

Because different types of information can be extracted from the human iris, from our point of view, we believe the following methods better fit for our future work. (1) The edge detection algorithm is used to localize the iris and select the most important features. The system can then be segmented

and localized by using the fuzzy algorithms and the edge detection. (2) statistical features extraction methods are then used to extract the characteristics of human iris. (3) The feature space is then divided into classes, and the extracted features are trained parallel to partition the features into these classes using Principal component analysis (PCA). (4) The Support vector machines (SVMs) algorithm is then used to classify the new images in the database according to their classes to pinpoint the traveler's identity.

In this work, we present a review of biometric authentication methods and techniques that ease the way people interact with systems and how their identity influences governmental and private systems. Section III introduces physiological biometrics, and the behavioural biometrics are presented in Section IV. In these sections, we briefly discuss and list the most common biometrics, such as the facial, iris, fingerprint, voice, and signature recognition techniques. We also depict, the typical design steps of each system and its applications to provide a thorough description.

## II. BIOMETRICS RECOGNITION SYSTEMS

Biometric technologies are used to secure a wide range of electronic communications or to connect to a computer or smartphone. Biometric authentication systems compare the human biometric data to be authenticated with the biometric database. If the two samples are matched, the authentication is then confirmed and access is granted. This process is sometimes part of a multifactor authentication system. Thus, the smartphone user can connect using their secret code such as a personal identification number [PIN] and add an iris scan. Generally, biometric identifiers are classified into physiological or behavioral characteristics; see Fig. 1.

Human biometrics are related to the various physiological characteristics of the human body such as fingerprints, facial features, iris, retina recognition, and DNA. Behavioral biometrics are related to a behavioral pattern, like the rhythm of a person typing, or how they use their fingers or look at the camera.

## III. PHYSIOLOGICAL BIOMETRICS

Physiological or static biometrics use physical characteristics, such as fingerprint or facial recognition, etc. to unlock cell phones, log into bank accounts, or complete transactions. However, the main types of static biometrics used to verify a person's identity are fingerprint recognition, facial recognition, iris recognition, etc.

### A. Fingerprint Recognition

The fingerprint is one of the oldest forms of biometric authentication, and mobile platforms use this technology widely. It was originally popularized by Apple's Touch ID. A fingerprint reader analyzes a person's fingerprint and compares it to the finger's stored digital pattern during authentication. Fingerprint recognition may change if the finger is wet or dirty. An attacker cannot replicate a person's fingerprint because of its vividness; however, it can be used to create a 3D model or a fake image.

Fingerprint authentication is based on the concordance between the registration or signature file obtained during

enrollment and the file obtained during authentication. Several methods are used to recognize fingerprints, such as locating minutiae and processing textures. The process of extracting minutiae involves using the template comparing to the image digitization and minutiae extraction, as shown in Fig. 2.

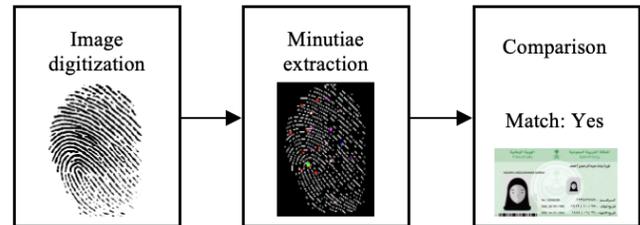

Fig. 2. Fingerprint Authentication Process: (1) Image Digitization, (2) Minutiae Extraction and (3) Comparison to the Templates.

The image digitization step consists of digitizing the fingerprint, filtering unnecessary features (e.g., scars), and determining information useful to the system. To detect the endpoints and crossing points of ridges, known as minutiae, a fingerprint skeleton is created using complex algorithms in order to make each line of the imprint, with a length from 5 to 8 pixels and a thickness of 1 pixel. Fig. 3 shows the creation of a fingerprint skeleton.

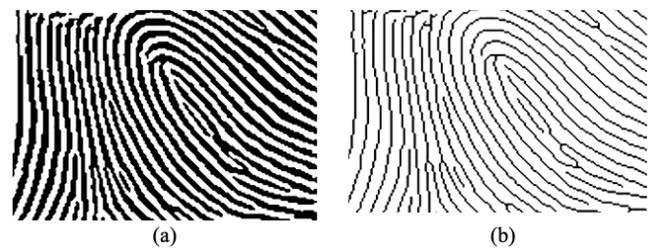

Fig. 3. Fingerprint Skeleton Creation.

The minutiae allows the extraction step to determine the signature of the fingerprint using different algorithms. The template used to characterize the fingerprint is based on a minimum number ranging from 12 to 14 minutiae, although this number can be higher as needed to establish a reliable comparison. In fact, it is possible to identify one fingerprint among several million fingerprints with this minimum of correctly identified and localized minutiae.

Finally, the comparison of two minutiae's, corresponding to two fingers to be compared, constitutes the identity verification system. To determine whether two minutiae's extracted from two images correspond to the same fingerprint, it is necessary to adopt a comparison system that is insensitive to any translations, rotations, or deformations, which systematically affect the fingerprints. From two extracted minutiae's, the system should be able to give a similarity or correspondence index of 0% if the fingerprints are totally different, and 100% if the fingerprints are from the same image.

Fingerprint recognition algorithms are sensitive to the image quality. The pretreatment step is therefore necessary before

performing the following steps. The quality of fingerprint images depends on several factors, such as contact with the probe, quality of the probe, and depth of ridges/bifurcations. Generally, preprocessing consists of smoothing, contrast enhancement, spatial/frequency domain filtering. Today, several techniques are used to solve the problems associated with fingerprints recognition.

A comprehensive overview of the patterns and techniques used in fingerprint recognition depends on the minutiae-based technique. [5]. Peralta, et al. [6] described the various aspects of fingerprint authentication and identification with respect to the minutiae-based matching algorithm. Fingerprint authentication utilizing minutiae extraction technique are discussed by Sharma, et al. [7] who covered all related systems and processes. Unimodal and multi-modal biometrics techniques were summarised by Delac and Grgic [8] including pros and cons for each model.

### B. Facial Recognition

facial recognition is a technique used to identify/verify human identity based on their facial features. facial recognition can be performed from photos or video recordings. To develop a system with robust facial recognition, four steps are taken under consideration: (1) facial detection, (2) feature extraction, and (3) feature classification, and (4) feature matching. The face detection step involves identifying the human face in the image, and the feature extraction step involves extracting the feature vectors for the identified facial. The feature extraction step is considered the most crucial step in the facial recognition process. The results can then be compared and classified according to a certain criterion to identify the features of the image. These steps are illustrated in Fig. 4.

There are three major approaches to automatic face recognition by computer: global feature approach (facial-based recognition), local feature approach (constituent-based recognition), and hybrid approaches.

1) *Global methods:* The global approach is commonly used to identify facials using the entire image without taking into account the a face's local physiological features, such as the eyes and mouth.

The global algorithms are based on statistical properties and are usually quick to implement. However, they are sensitive to various factors such as lighting conditions and facial expression. Some of these algorithms are principal component analysis (PCA), linear discriminant analysis (LDA), support vector machine (SVM), and neural network (NN).

In this context, Sugandi, et al. [9] have proposed a facial recognition method based on PCA and backpropagation NN. Each facial image in the training is represented exactly by a linear combination of eigenfaces. This method is performed in three stages. In the first step, facial detection is performed using Haar-like features. In the second step, the authors use the AdaBoost learning algorithm to select the most important features. Finally, the backpropagation NN is used for the recognition process. In their work, the authors demonstrated that using 5 data facial images with each data are taken 100 times than usual, the experimental result showed the satisfactory result with 87.5% recognition rate.

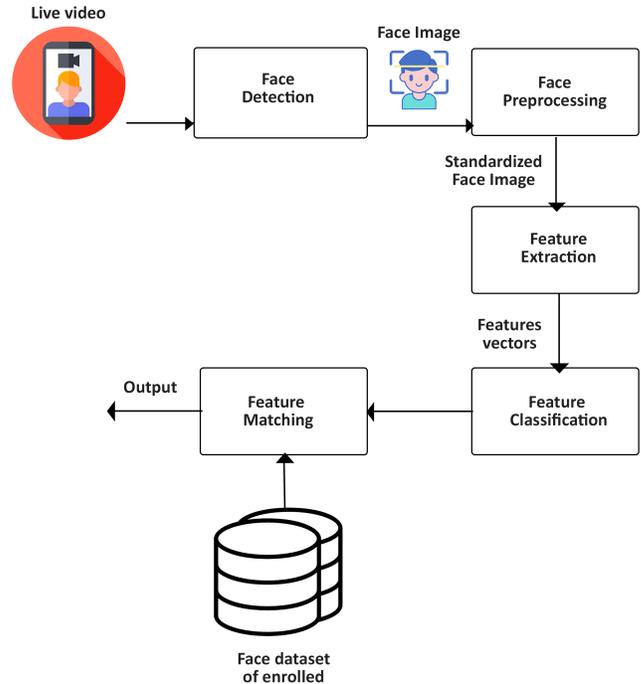

Fig. 4. Facial Recognition Structural Steps: (1) Facial Detection, (2) Feature Extraction and (3) Facial Recognition.

A study conducted by Anusha, et al. [10] showed that the weight of the image when compared with the test images can be used to identify the facials. With the same objective, Shen, et al. [11] proposed a method that uses both the, (1) PCA algorithm to get the feature space of the training set and then trains to identify the projected facial and (2) Fisher linear discriminant (FLD) algorithm to obtain the fusion feature space and then to train and recognize the projected facial in the feature space. Their study proved that the algorithm based on the FLD and PCA features can outperform the existing facial recognition methods.

Luabibi, et al. [12] proposed a four-phase approach for facial recognition. The first step is the localization of the facials, and the second involves extracting the features, and the third one is the classification, and the fourth phase is the back propagation algorithm to identify the facials.

The LDA method is a numerical technique that can be used to classify and improve the data representation. The resulting combinations are usually used as linear classifiers. This algorithm cuts each facial into a linear combination before classifying it. The resulting sets of new dimensions are called fisherfaces after the LDA method. Due to its complexity, the LDA algorithm is not as effective as other methods.

Bhattacharyya, et al. [13] proposed a method that involves grouping images of the same class and different classes. The resulting set of facials is then classified according to the closest training images. The study's results revealed that the proposed algorithm is significantly better than the existing methods. Lu, et al. [14] combined both the direct LDA and Fractional LDA techniques, and algorithms can be used for small sample sizes.

It can also classify the facials according to the closest training images. Results of the experiments on two databases supported the effectiveness of the proposed algorithm.

SVM's are commonly used in machine learning to solve problems related to discrimination and regression. Although they are not as efficient as some of the most popular algorithms, their potential is still very promising. In their study, Jin, et al. [15] proposed an algorithm based on a modified SVM learning scheme that uses the SVM and particle swarm optimization techniques. The results of the experiments showed that the proposed method has better accuracy than the existing methods.

In addition, Jose, et al. [16] presented a review of the techniques used for 2D facial recognition using the SVM technique. The authors analyzed the recognition results according to the techniques used to extract information such as facial features, pattern classifiers, and databases. A new method that uses the SVM algorithm to detect the facials in grayscale images was presented by Ignas et al. [17]. They then identified the faces using the sizes and positions of the eyes and lips.

Also, Javed [18] used the PCA and SVM to build for building a facial recognition model. The authors [19] presented an overview of the effective use of machine learning, particularly regarding using SVMs in facial recognition. Therefore, the authors give an extensive survey of facial recognition and its applications.

Artificial Neural Networks (ANNs) are systems comprising of several interconnected processing units. They can perform various computational tasks based on the input data. In computer vision, an NN is composed of several processing units known as neurons. These components can learn and adapt to different tasks in order to classify the data.

Deep learning (DL) is an AI method that learns by itself. It is inspired by the human brain. The goal of DL is to learn and recognize different words and facials in an image. For example, DL can detect the letters in text before recognizing a face. In their work, Hassan, et al. [20] detailed the various approaches used in facial recognition and provided a thorough analysis of their results. They also introduced hybrid algorithms that can be used for extracting and classifying facial features.

Convolutional Neural Networks (CNNs) are commonly used in facial recognition. They are typically complex and require a high amount of processing power and storage space to perform their intended applications. In this area, Liu, et al. [21] tried to improve the performance of CNNs by introducing a block called the squeeze-and-excitation algorithm. The proposed algorithm has fewer parameters and can be more suitable for various applications.

2) *Local methods:* These are also called the geometrical, local characteristics, or analytical methods. This approach involves in applying transformations in specific places of the image, most often around the characteristic points (i.e., corners of the eyes, mouth, and nose). Attention is given to small local details, and the approach avoids the noise generated by aspects such as hair, eyeglasses, hats, and beards.

However, the difficulty of these methods arises when it taking into consideration several views of the facial and the

lack of precision in the extraction phase of the points, which constitute their major drawback. Specifically, the methods start by extracting the local facial features such as the nose, eyes, and mouth; and the method then use their geometry and/or appearance as input to the classifier. Hence, we can distinguish two practices:

- The first practice is based on the extraction of entire regions of the facial; it is often implemented with a global facial recognition approach.
- The second practice extracts particular points from different characteristic regions of the facial, such as the corners of the eyes, mouth, and nose.

Among these approaches, we can list the hidden Markov model (HMM) and the elastic bunch graph matching algorithm (EBGM). An HMM is a statistical model in which the modeled system is assumed a Markov process with unknown parameters. Unlike a classic Markov chain, where the transitions have taken are unknown to the user but the states of execution are known, in an HMM, the states of execution are unknown to the user. HMMs are currently among the most widespread models of form recognition. They then were established in speech recognition and written recognition.. However, when using HMMs, the structure of the facial is considered as distinct regions, described by characteristic vectors.

In this context, Alhadi, et al. [22] studied three different methods to extract feature vectors from HMMs: discrete cosine transform, discrete wavelet transform, and PCA. The results of the experiments revealed that combining these methods improved the models' recognition performance. In addition, a state-of-art HMM model applied to facial recognition problems in the review [23]. In this work, the authors have presented the evolution of HMM use from the early 1990s to the present day; this makes it easier for new researchers to understand and adopt the HMMs more easily for facial recognition.

In 1997, Wiskott, et al. [24] proposed a graph matching algorithm commonly used in computer vision. This algorithm makes it possible to recognize objects in an image by using a graphic representation extracted from other images. This approach extracts a set of characteristics using a data structure called a packet graph [25]. Furthermore, Jaiswal [26] presented a method for recognizing human facials that uses the concept of a graph matching algorithm known as EBGM. The proposed method achieves high recognition rates for both the facial and the image graphs.

3) *Hybrid methods:* Hybrid methods pair the advantages of global and local methods by combining the detection of geometric (or structural) characteristics with the extraction of local characteristics. They make it possible to increase the stability of the recognition performance during changes in pose, lighting, and facial expressions. Local feature analysis and Gabor wavelet extracted features (such as EBGM) are typical hybrid algorithms [27], [28], [29].

### C. Iris / Retina Recognition

The ability to identify the facial using the iris is one of the most accurate and secure methods for biometric identification. Unlike the hands and facial, the iris is a protected internal

organ and is therefore less, and therefore less likely to be damaged. The user must fix a digital camera that scans the iris of a person from a distance of 30 to 60 cm and directly acquires iris drawing. Then, this drawing is compared to a computerized personal identification file to identify the person.

An iris recognition system is a type of biometric system that uses images of human irises to identify people. It features two main processes: localization and segmentation. Images of the iris are determine and analyzed to extract its biometric signature. However, the image processing operations are divided into four stages: localization, segmentation, encoding, and classification. The diagram in Fig. 5 shows the methodology steps and sequential processing of the proposed iris recognition system.

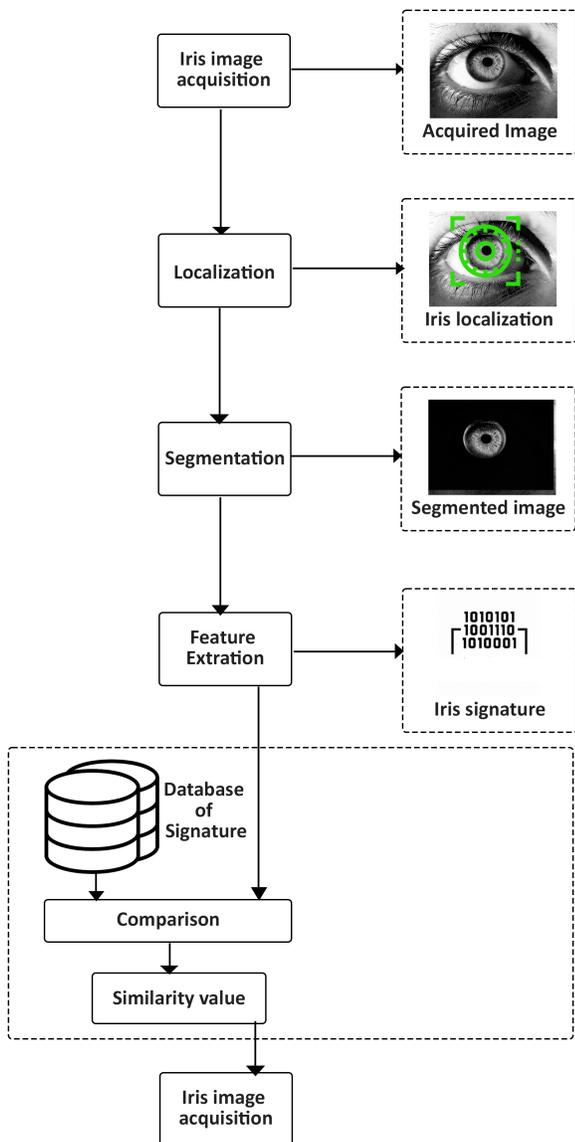

Fig. 5. The Architecture of the Iris Recognition System which Include; (1) Image Acquisition, (2) Iris Localization, (3) Segmentation and (4) Feature Extraction.

1) *Iris Recognition:* A new approach for the recognition of the human iris was developed by Fernando, et al. [30]. It uses the SIFT feature transformation to extract the characteristic features and then matches two images. Experiments with the BioSec database show that the SIFT approach achieves better performance than the existing matching methods.

A novel approach for deep learning that aims to improve the accuracy of the recognition of the iris using a more simplified framework was presented by wang and Kumar [31]. It utilizes residual network learning and dilated convolutional kernels to improve the training process. An unsupervised network approach can greatly simplify the network and provide better performance than state-of-the-art algorithms for iris recognition. It also eliminates the need for upsampling and downsampling layers. The results of our experiments demonstrate the applicability of our approach to improve the accuracy of iris recognition.

Furthermore, a new generalizability method for the recognition of the iris is introduced by Adamović, et al. [32], which performed on the two CASIA databases. The results of the experiments demonstrated the system performs as expected. The generalizability method can significantly reduce the computational costs of the system, which in turn makes the method suitable for practical applications. The goal is to achieve a classification accuracy of almost perfect. The method also eliminates the possibility of generating an image from a template.

2) *Retina Recognition:* The retina is a region of the eye that consists of four layers of cells. The arrangement of these cells is unique and provides a high level of recognition. This technology is well-suited for high-security applications because it can achieve a recognition rate of around 90% compared to other methods. The idea for retinal identification and unique vascular pattern was first introduced by two ophthalmologists, Dr Carleton Simon and Dr. Isodore Goldstein in 1935 [33].

A new method for retina recognition based on a fractal dimension was also presented by Sukumaran, et al. [34]. The authors of the study compared the accuracy of this technology with the commercially available ones. The experimental results of the method revealed that it produces high accuracy and low computational cost.

With the same objective, Tuama and George [35] proposed a personal identification system using the vascular diagram of the human retina. This system is composed of four stages. First, the preprocessing technique is used to extract the retinal image from the background and to remove noisy areas from the retinal image. Then, wavelet transforms 2D and adaptive thresholding were used to extract the blood vessels. Next, the system performs feature extraction and filtration. Finally, the matching step is used for the retina recognition. Experimental results on three publicly available databases (DRIVE, STARE, and VARIA) have demonstrated that the proposed method is better than several existing techniques.

#### IV. BEHAVIORAL BIOMETRICS

Behavioral biometrics analyze a person's unique habits and movements to create a behavioral pattern. Like static biometrics, behavioral biometrics adds another layer of security to

verify a person's identity. Accordingly, this technology uses motion sensors and AI to identify unique behaviors, such as how a phone is held. These technologies are widely regarded as the last frontier in security [36], [37].

### A. Keystroke Dynamics Recognition

Stroke rhythm analyzes a person's typing rhythm on digital devices (e.g., smartphones) to create a form of human digital footprint or signatures. Gaines, et al. [38] first proposed this technology when they created the first automated dynamic keystroke recognition systems [39]. Major contributions have notably evaluated the fuzzy logic [40], NNs, [41], [42], and different pattern recognition techniques (e.g., Bayes classifier) [43], [44].

### B. Signature Recognition

The recognition of a signature can be accomplished by analyzing a large number of discriminative variables: (i) global characteristics such as writing time or the number of touches on the tablet with the pen, and/or (ii) local characteristics such as the position of certain curvatures or the instantaneous speed. A pressure-sensitive pencil-shaped reader and a digital tablet usually acquire a signature.

Developing a robust facial recognition system involves three basic steps: (1) preprocessing, (2) feature extraction, and (3) signature matching and classification. Before the algorithm can be used for facial recognition, the preprocessing step involves removing background noise and refining on the signature. The signature recognition system architecture is presented in Fig. 6. Feature extraction is the next step in the recognition process. It involves extracting the various features of the human signature, such as the Walsh coefficient, grid, and texture. The signature recognition step matches the various features of the human signature to template signature databases.

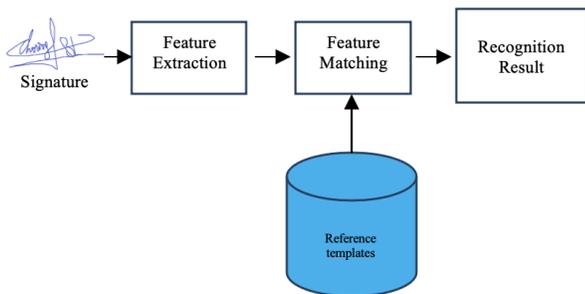

Fig. 6. Signature Recognition System Architecture that begins with Feature Extraction, then Matches these Features with a Reference Template and Finally Obtains the Recognition Result.

The best-known comparison techniques use a HMM [45], or a dynamic programming approach [46], [47]. The International Graphonomic Society (IGS) research community, particularly the Scribens team, proposed the most important contribution to handwritten signature verification [48]. In this area, Jain, et al. [46] proposed to use a new measure of dissimilarity based on the alignment of characteristic vector

sequences by dynamic time warping. This technique represents the most recent work in manual signature verification

### C. Voice Recognition

Voice recognition is a process that uses the sounds produced by a person's vocal tract and the shape of their nose, mouth, and larynx to identify their voice. Analyzing a person's voice is a strong authentication method, but illness (e.g., the common cold, bronchitis) and background noise can distort the voice and disrupt authentication. The architecture of an automatic voice recognition system is represented in Fig. 7.

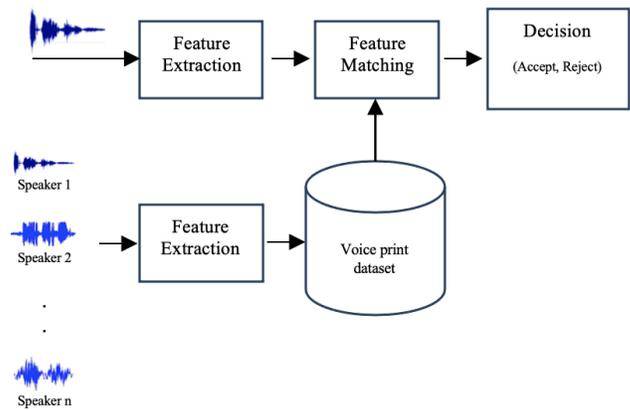

Fig. 7. Voice Recognition System Architecture that Includes Feature Extraction, Feature Matching and Decision-making based on the Voice Print Dataset.

However, the applications of speech recognition are diverse and each system has its own architecture and operation mode. In 1987, the Worlds of Wonder Company first marketed speech recognition via a doll named Julie [49]. For its voice recognition algorithm, Texas Instruments used a digital signal processing system that could recognize eight different sentences.

In addition, voice recognition has been studied for many years to help people with disabilities [50], [49], [51]. People without mobility can control an electric wheelchair through voice commands [52].

## V. DISCUSSION AND COMPARISON

In this section, we provide a summary and discussion of the review and outline different methods of biometric authentication. We select and compare some of these methods and observe each method's algorithms, advantages and disadvantages. The study of limitations is key to improving in the future work, and we must highlight them to build our own methodology.

It is crucial to acknowledge that each method is not excluded from the others. These techniques can be combined with one another or used in different parts of the whole process to achieve the desired realism.

To explore each technique and compare these methods, we established criteria to recognize the major differences and how

they affect the final outcome. The major differences in aim, accuracy, and robustness among methods make concluding the compression challenging.

Therefore, based on the information provided in each study we attempted to distill the most useful information to write this section. We believe this effort will be helpful as a future reference for our work and that of others regarding usability, performance and more. Thus, the criteria are as follows:

- **Method.** The fundamental calculations and algorithms essential for the system's methodology and structure.
- **Merit.** The advantages the system provides, including the accuracy of the result under the previous criteria.
- **Drawbacks.** The system's limitations based on the required data, assumptions, and outcomes. Future work usually starts by discussing and discovering these drawbacks and then attempting to solve them.

We could cover more criteria, but doing so requires insight into and evaluation of each system, which is outside the scope of the current review. We might approximate for the time and effort for the rendering and processing, but the result would be untrustworthy without any quantitative data.

An overview of these criteria to compare the previous methods from selected papers are presented in Table I. These papers were chosen based on two factors: (1) significance in their field, (2) ability to offer insights for our future work.

## VI. OPEN PROBLEM AND PROPOSED METHODOLOGY

Biometric identification is a process that uses sensors to measure a person's biological characteristics. The data these devices collect then can be compared to information stored in a database. In addition to fingerprints and eyes, biometrics such as facial recognition and hand geometry have been studied and used. Eye biometrics offer the highest level of accuracy and individuality.

Iris recognition is a biometric technique that allows recognition of a person by observing their iris. Generally, the iris recognition system includes a series of steps: (i) image acquisition; (ii) iris preprocessing, including localization and segmentation; (iii) feature extraction; and (iv) matching and classification. The diagram in Fig. 8 shows the methodology steps and sequential processing of the proposed iris recognition system.

For passenger identification at an airport, we propose an iris recognition system that performs the feature extraction method and the PCA algorithm to extract and select the most important statistical features of the human iris. In addition, this system performs a supervised classification process using the SVM algorithm to identify a person's identity. The proposed system will be applied to a collection of human iris databases, such as the CASIA iris database.

This system consists of two main phases: the preprocessing phase and the classification phase. In the preprocessing phase, the system will acquire the required human iris image. The iris's features will be processed to obtain information using the statistical feature extraction method. Next, these features

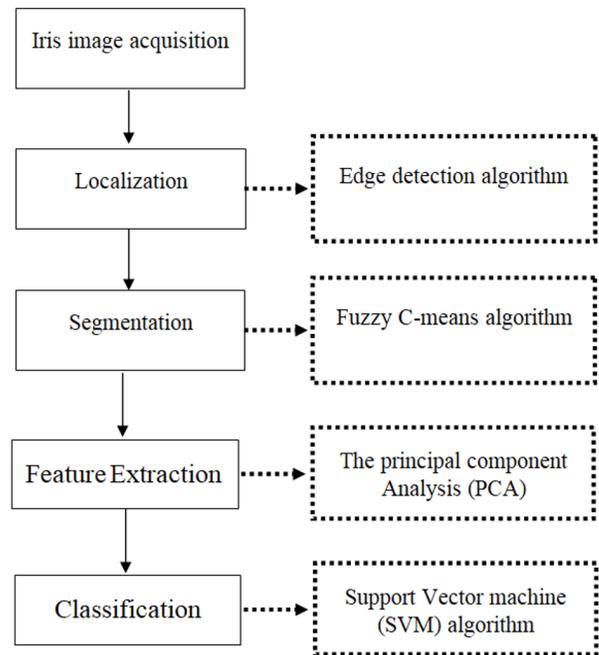

Fig. 8. Methodology Steps for Our Future Implementation in Iris Recognition System.

will be refined using the PCA reduction technique and will be the input to the SVM algorithm for classifying human iris.

Once the iris's image is acquired, image-processing techniques are used to extract the iris, construct biometric signature, and finally find its identity. However, the acquired image must have a minimum resolution and quality to ensure the characteristics necessary for representation and identification have been obtained. Therefore, efficient segmentation of these regions is necessary.

Iris localization is one of the most important steps in an iris recognition system because it determines the matching accuracy. This step mainly localizes the boundaries of the iris, which are the inner and outer boundaries of the iris and upper and lower eyelids. To do this, edge detection techniques can be used to localize the iris in the original image. After acquiring the image, the iris should be isolated. As a first step, a series of image enhancement operations such as filtering, contrast enhancement, and histogram equalization type can be applied. The goal is to enhance the quality of the image and then apply iris segmentation operations.

The processing set necessary to extract the iris from its environment defines the iris segmentation: pupil, sclera, eyelids, eyelashes, and specular reflections. This is the most difficult step in the recognition system because it affects the system's performance.

Segmentation approaches are based on detection by fuzzy algorithms such as the fuzzy c-means algorithm. In this step, the iris is segmented in details. The encoding consists of extracting the iris's most discriminating and relevant characteristics, which are required for its identification.

To do this, the statistical features are extracted from the iris

TABLE I. COMPARISON OF PREVIOUS METHODS FROM THE SELECTED PAPERS THAT WE COVERED FOCUSING ON THREE CRITERIA: ALGORITHMS, MERIT AND DRAWBACKS

Research	Method	Merit	Drawbacks
<b>PHYSIOLOGICAL BIOMETRICS</b>			
<b>Fingerprint Recognition Methods</b>			
Borra, et al. [5]	-Minutiae based approach. -Pattern recognition. -Wavelet.	High accuracy rate.	-No noisy/encrypted images, -Slow performance due to three levels of split texture -Fails to determine real humans sometimes.
Peralta, et al. [6]	-Minutiae-based local matching -Correlation-based matching -Indexing	-Simplicity -Distortion tolerance.	Expensive computation, slow and depend on the skin situation.
Sharma, [7]	Minutiae based matching.	Widely used and familiar.	Affected with wet or dry skin.
Delac, et al. [8]	-Unimodal biometric systems -Multimodal biometric system.	Reliability due to use the combination of different biometric strength.	-Noisy Scanned data. Difficulty in the data gained from humans. -Biometric sign can expose to forgery.
<b>Facial Recognition</b>			
Budiet, et al. [9]	-PCA -Back Propagation Neural Network.	-No Correlated Features, -High Performance, -Reduce Overfitting, -Improved Visualization, -No user action: not very intrusive, No physical contact.	Independent variables become less interpretable, -Data standardization is must before PCA, -Information Loss.
Anusha, et al. [10]	PCA	-Not intrusive, done from a distance, -Inexpensive technique. -Several characteristic features	-More suited for authentication than for identification purposes. -User perceptions and civil liberty.
Shen, et al. [11]	-PCA -FLD .	-Reduced Overfitting. -Improved Visualization.	-Data standardization before PCA. -Information Loss.
Morooj, et al. [12]	-PCA -Backpropagation NN	-Removes Correlated Features. -Improves Algorithm Performance	-Independent variables become less interpretable, -Information Loss
Bhattacharyya, et al. [13]	LDA	-Objective evaluation. -small set of features for classification purposes. -Overcomes the limitation of PCA by applying the linear discriminant criterion.	-Singular within-class scatter matrix due to small size sample. -Difficulty differentiating identical twins. Sensitive to changes such as beard and glasses.
Jin, et al. [15]	-PSO -SVM	Effective in high dimensional spaces.	-Not suitable for large data sets. -Premature convergence of PSO leading to stagnate in local optimum. -Environmentally sensitive technology.
Jose, et al. [16]	SVM	Effective in high dimensional spaces.	Not suitable for large data sets.
Ignas, et al. [17]	-SVM -Gaussian kernel for grayscale.	Effective in high dimensional spaces	-Not suitable for large data sets. -No Noisy data. -No Overlapped classes.
Mahnoor, [18]	-PCA -SVM	Effective in high dimensional spaces	-Not suitable for large data sets. -No Noisy data. -No Overlapped classes.
Jaiswal, et al. [26]	EBGM.	Insensitive to lighting variation -Rigid, and deformable matching.	More complicate procedure.
<b>Iris/Retina Recognition</b>			
Fernando, et al. [53]	SIFT	- Stable in lighting and perspective variations. -Locality. -Resistant to occlusion and crowding -No prior segmentation. - Distinctiveness. -Quantity, generate many features.	-Complicated Mathematically. .High computation cost. .Not effective for low powered devices.
Poursaberi, et al. [54]	-Wavelet-based texture Hamming distance of minimum and harmonic mean	-Efficiency: close to real-time performance. -Extendable -Robust High accuracy. -Iris does not change over time	-Acquiring an image requires proper alignment and positioning. -Result affected by pupil size change.
Félix, al. [55]	Facial key-point detection, Integro-differential operator (IDO) Mathematical morphology	-No intimate contact with the reader. -More robust than voices.	-Hard to use. -Difficulty integrating with other systems
Vahid, al. [56]	Pattern Recognition Approach.	-Higher average for matching performance. -Convenient for people who wear glasses. -Low chances of a false positive.	-The eye position can be problematic. -Expensive specialized devices.
Sukumaran, et al. [57]	Fractal dimension using box counting Pattern Recognition Approach	-Most reliable biometric technology -Unique data points	-Serious health risk, infrared light beam. -Very large false rejection rate
Saba, et al. [58]	-Vascular diagram of the human retina -Pattern Recognition Approach	-Very accurate. -Impossible to forge a retina. -Low error rate. -Low false rejection rate -Low false acceptance rate.	-Inconvenient for people who wear eyeglasses. -Uncomfortable for some users. -Retina biometric devices.
<b>BEHAVIORAL BIOMETRICS</b>			
<b>Keystroke Dynamics Recognition</b>			
Gaines, et al. [38]	Examine the probability distribution of time to pressed/relaxed each key while typing on keyboard.	-Ergonomic. -Uniqueness. -Low Implementation and Deployment Cost. -Transparency and Noninvasiveness. -Increase Password Strength and Lifespan. -Replication Prevention -Additional Security. -Continuous Monitoring and Authentication	-Person's physical condition is important. -Lower Accuracy. -Lower Permanence .

			Signature recognition	
Jain, et al.[46]	Behavioral biometrics based on person's handwriting		-Ergonomic. -Highly resistant to impostors. -Enrollment is intuitive and fast. -Fast response -Low storage needed. -Native language don't matter. -Little time of verification.	-Depend on the emotional state. -Difficult to use. -Large template. -High Cost -Vary over time.
			Voice recognition	
Simpson, et al. [52]	Arduino, HM2007 Voice recognition module and Motors.		-More natural and easier- -Faster than typing -Can be done over the phone- No specialized equipment -Not intrusive, Low computing power	-Not reliable. Sensitivity to environment variations.

image, and the linear dimensionality reduction technique PCA is used to refine the features. Therefore, the iris encoding process constitutes representing the iris's signature. The encoding or feature extraction step is unique for each iris, regardless of dimensional variations or rotations created during the iris acquisition. This information then will be used to classify the iris.

## VII. CONCLUSION AND FUTURE WORK

Biometrics involves studying physical characteristics to identify human. With information technology and digitization, these techniques have undergone major development. Generally, biometrics can be applied to individuals who have voluntarily shared information with the biometric system, which must control them based on characteristics such as their fingerprint or voice. This step represents the enrollment procedure. This biometric information is then transformed into a digital file called a signature or template, using a specific algorithm that retains and encrypts the characteristic elements of the digitized image. This signature is then archived and compared with the person's characteristics during the control.

In this paper, we presented a detailed review of biometric systems and compared them to find the best methods and algorithms for our future work. We summarized the notion of authentication and authentication technologies and focused on biometric authentication methods. In addition, we briefly discussed the most common biometrics (i.e., face, iris, voice, signature, and fingerprint recognition techniques) and the different ways to combine them to obtain multimodal systems. Finally, we presented the typical design steps of each system and biometric applications. Consequently, the process automation, particularly the measure of characteristics such as the iris, the shape of the face or hand, the voice, the speed of typing or pressing keys, the dynamics of signature represent some challenges that can be develop in the authentication system.

After collecting all this information, we will present a hybrid approach that combines SVM-based classification and AI techniques to perform advanced iris recognition. The first step involves developing an edge detection algorithm that selects the most important features. The fuzzy and edge detection algorithms are then used to segment and localize the system. The extracted features are then divided into classes using the PCA algorithm. The proposed methodology will be used to identify passengers at an airport in our future work.

**Abstract**—Protecting data privacy is of extremely importance for users who outsource their data to a third-party in cloud computing. Although there exist plenty of research work on data privacy protection, the problem of protecting user's preference information has received less attention. In this paper, we consider the problem of how to prevent user preference information leakage from the third-party when processing ranked queries. We propose two algorithms to solve the problem, where the first one is based on distortion of preference vector and the second one is based on homomorphic encryption. We conduct extensive experiments to verify effectiveness of our approaches.

**Keywords**—Preference privacy; distortion; homomorphic encryption

## I. INTRODUCTION

Ranked queries are useful in many real world applications for users to express their tastes in queries, such that the returned query results are the most preferable ones than the other records in database. Currently, there are two kinds of approaches to capturing user's preferences, that is, the quantitative approach [1] and qualitative approach [2]. In the paper, we focus on quantitative approach for modeling user preference.

Given a relational database  $D = \{A_1, A_2, \dots, A_d\}$  with numerical attribute  $A_i$ ,  $i = 1, \dots, d$ , i.e., a linear function  $q = \omega_1 * A_1 + \omega_2 * A_2 + \dots + \omega_d * A_d$ , where  $\omega_1, \omega_2, \dots, \omega_d$  are non-negative weights given by the user as preferences toward the corresponding attributes, and  $\omega_1 + \omega_2 + \dots + \omega_d = 1$ . Upon receiving a user ranked query  $q$ , for each record  $r_i \in D$  the server computes its preference score as  $Score(i) = \sum_{j=1}^d \omega_j * r_i.A_j$ ,  $j = 1, \dots, d$ , and returns to the user the top  $k$  records with the highest scores.

Although there are extensive research work on processing ranked queries, the privacy issue of user preferences so far has not received attention. There is no doubt that user's preference is a strong and direct link to his/her identity, which the user wants to keep in private, otherwise the information may be utilized by an adversary to against he/she. Thus, one may want to hide his/her preference embedded in the ranked query in order to protect privacy. To illustrate, we give two examples below.

**Example 1.** Consider a user looking for a second-hand car at a website running by a car dealer. The dealer maintains a used car database, recording for all the cars the features such as Make, Model, Year, MPG (miles per gallon), Mileage, and Price, etc. The user may care more about some of the features, such as MPG, mileage, and Year, and want to find a suitable car for him with the lowest price. By collecting and observing user's queries with preferred features, the dealer knows that the

user strongly favors MPG. So the dealer may want to increase a bit the prices of the cars with favorable MPG, such that he is expected to profit more from the user. To have the edge over the car dealer while making a deal, the user wishes to hide his preferences during the querying process.

**Example 2.** Consider a customer searching for financial information of NYSE-listed companies, through websites such as Yahoo! finance or Google finance. By giving preferences on attributes such as cash flow, P/E (price-to-earnings) ratio, ROA (return on assets) ratio, and debt ratio, the customer intends to search through query interface the favorable companies, based on which he/she may make buy or sale decision for his/her investment portfolio management. On the other hand, a curious adversary may sniff the search results of the customer at the server side and extract the preferable attributes, which may be used to infer the possible investment of the customer. Since customer's portfolio information is critical for him/her to stand up to the fierce business competition, he/she may strongly oppose the exposure of his/her preferences to anyone else.

**Problem Statement:** Our model includes the user and the service provider (the server). The server maintains a database  $D$  and processes users' queries with difference preference on the attributes of  $D$ . We assume that the server is semi-honest, that is, the server correctly performs the query processing and returns the results, but he is curious and tries to find out the user's preferences. Each user composes his ranked query as a weight vector  $f = \{\omega_1, \omega_2, \dots, \omega_d\}$  on attributes of  $D$ , and submits it to the server for processing. Our objective is to prevent the server from knowing the exact preferences, i.e., the weight vector of the user, without deteriorating the query processing efficiency and accuracy.

The contributions of this paper are as follows:

- We consider the problem of protecting user's preferences in ranked queries, which is of great importance in many real world applications.
- We propose a simple strategy to distort user's true preferences, and give a test to the strategy.
- To strengthen the privacy level, we devise another algorithm based on homomorphic encryption to protect user's preference.
- We conduct extensive experiments to verify effectiveness of the proposed approaches.

## II. BACKGROUND

### A. Preliminaries

**Ranked query.** Ranked query [3] is very useful in many real-world applications. It is a powerful technology to simulate

users' personalized information needs, which has attracted great attention of researchers all over the world. It allows users to express their preferences for queries and specify the specific weight of each query limit, so that the returned query results meet the needs of users better than other data records in the database. At present, there are two methods to describe user preferences, namely qualitative method and quantitative method.

The qualitative method [2] usually uses the preference formula to evaluate which data tuple is more favorable over the others, i.e. determining the partial order relationship between tuples. The quantitative method [1] defines a preference function to express the user's preference for different data attributes, and then finds the data records that best meet the user's needs from the database according to the preference function, that is, measured by specific values. For example, given a hotel dataset containing three dimensions  $D = \{d_1, d_2, d_3\}$ , where  $d_1$  represents price,  $d_2$  represents score,  $d_3$  represents distance, preference function is defined as  $f = \omega_1 * d_1 + \omega_2 * d_2 + \omega_3 * d_3$  according to user preference  $f = \{\omega_1, \omega_2, \omega_3\}$ . The highest score is the most desirable.

In practical applications, ranked query is often directly related to other problems, such as skyline computing [4] and top-k query [5], [6]. Combining multiple queries can usually get the results you want most quickly.

**Top-k query.** Top-k query [7], [8] refers to returning the best  $k$  data records according to an objective function. It is widely used in many fields, such as e-commerce, recommendation system, search engine and so on. When the Top-k query is associated with the preference problem, it will calculate the score of each data record according to the preference function given by the user, and then return the  $k$  objects with the smallest (or largest) scores.

The concept of Top-k query has been around for many years and is widely used in real life. So far, many algorithms for Top-k query have been proposed, which can be roughly divided into three categories. The first is index based algorithm [9], [10]. Its main idea is to divide the whole data set into multiple layers according to the division rules, then index and mark each layer, and finally retrieve layer by layer according to the index order to return the best  $k$  results, such as Onion algorithm [11]. The second is the Top-k query algorithm based on view [12]. This kind of algorithm first calculates the scores corresponding to each tuple according to the preference function provided by the user and arranges them in order. The view contains the identifier and score of tuples. After these preparations, it finally returns the Top-k query results. The third is the Top-k query algorithm based on ordered list [13], [14], which is realized by using multiple column files.

## B. Related Work

**Skyline query.** Skyline query problem [4], [15], [16] is a popular technology for processing user preferences and Top-k query. It is used to select a series of objects that meet user preferences and are not dominated by other objects. Given a dataset  $D$  with  $d$ -dimensions  $\{d_1, d_2, \dots, d_d\}$  and  $n$  objects  $\{A_1, A_2, \dots, A_n\}$ , where  $A_i.d_j$  denotes the  $j$ -th dimension value of object  $A_i$ . The definition of dominance and skyline are as follows:

**Dominance:** An object  $A_i \in D$  is said to dominate another object  $A_j \in D$ , denoted as  $A_i \prec A_j$ , if  $A_i.d_r \leq A_j.d_r (1 \leq r \leq d)$  for all  $d$  dimensions and  $A_i.d_t < A_j.d_t (1 \leq t \leq d)$  for at least one attribute. We call such  $A_i$  as *dominant object* and such  $A_j$  as *dominated object* between  $A_i$  and  $A_j$ .

**Skyline:** An object  $A_i$  is said to be a skyline object of  $D$ , if and only if there is no such object  $A_j \in D (j \neq i)$  that dominates  $A_i$ . The skyline of  $D$  is the set of skyline objects in  $D$ .

At present, there are mainly two kinds of methods for skyline query processing. The first kind of methods do not need to preprocess the data set, but retrieve the query by scanning the whole database at least once, such as block nested loop (BNL), divide and conquer, etc. BNL algorithm [17] adopts the most straightforward method, that is, a point  $p$  is compared with each other point to decide whether it is dominated by other points, so as to determine whether the point is part of the skyline. Divide and conquer algorithm [17] divides the universe into several regions, calculates the skyline in each region, and produces the final skyline from the regional skylines. Therefore, the performance of this kind of methods is low because of scanning the whole database.

The second [18] is to reduce the query cost by using the index structure, such as nearest neighbor(NN), branch and bound skyline(BBS), etc. NN and BBS find the skyline by using an R-tree. NN algorithm [19] divides the data space iteratively based on the nearest object in the space, and prunes the dominant object quickly and effectively. However, BBS algorithm [20] uses heap to realize progressive search without redundant query in subspace. Obviously, the difference is that NN issues multiple NN queries [21], whereas BBS performs only a single traversal of the tree. It has been proved [22] that BBS is I/O optimal; that is, it accesses the least number of disk pages among all algorithms based on R-trees (including NN).

**Homomorphic encryption(HE).** Homomorphic cryptographic system [23], [24] is a public-key cryptosystem that can provide user with the ability to directly perform algebraic operations on ciphertext without decrypting the ciphertext.

Given two messages  $m_1$  and  $m_2$ , suppose a homomorphic cryptographic system encrypts them, using public key  $\mathcal{PK}$ , to ciphertexts  $C_1 = E(\mathcal{PK}, m_1)$  and  $C_2 = E(\mathcal{PK}, m_2)$ . Without knowing the corresponding secret key, one can compute  $E(\mathcal{PK}, m_1 + m_2)$ , i.e., the ciphertext of the addition of  $m_1$  and  $m_2$ , by simply multiplying the two ciphertexts  $C_1 \times C_2$ . This property is called additive homomorphisms. Similarly, a cryptographic system is multiplicatively homomorphic if one can derive  $E(\mathcal{PK}, m_1 \times m_2)$  from  $C_1$  and  $C_2$  directly.

The concept of homomorphic encryption [25], [26] is proposed to directly perform operations in the encryption domain, that is, the results obtained by decrypting the operations performed in the ciphertext domain are consistent with those obtained by performing the same operations in the plaintext domain. However, most existing homomorphic encryption schemes only support accurate computing operations in some discrete spaces, so these schemes can not be applied to tasks requiring floating-point or real number computing. For example, in the bit-wise encryption scheme, the integer is first converted into binary, and then encrypted by bit. The

addition and multiplication operations are also based on bits. This scheme cannot be applied to floating-point numbers. For the word-wise encryption scheme, multiple numbers can be encrypted in a single ciphertext, but the rounding operation is difficult to evaluate because it is not expressed as a decimal polynomial.

After Regev [27] introduced the learning with errors (LWE) problem, approximate homomorphic encryption was proposed one after another. Since the key of the method based on LWE problem is realized through matrix, its efficiency will decrease rapidly with the increase of security parameters. Then the ring-LWE problem [28] is proposed. The key of the encryption scheme based on this problem is expressed by several polynomials, which greatly reduces the size of the key and speeds up the encryption and decryption operations. The scheme based on RLWE problem include BFV [26], BGV [29] and HEAAN [30]. BFV and BGV encryption scheme only support accurate computing operations on integers.

However, HEAAN scheme can encrypt floating-point numbers. And the goal of this scheme is efficient approximate calculation on HE. Its main idea is to add a noise to the plaintext number that can reflect important information, so that the addition and multiplication operations of encrypted messages can be approximately calculated. In HEAAN encryption scheme, its decryption structure of the form  $(c, sk) = m + e \pmod{q}$  where  $e$  is a small error inserted to guarantee the security. In addition, HEAAN also provides a rescaling operation to remove the error of the least significant bit, which ensures that the length of the error bit increases linearly in proportion to the number of levels consumed, rather than exponentially. The efficiency of HEAAN [30] has been proved in many practical applications, and is still being improved by better bootstrapping algorithms [31], [32]. Therefore, considering that the data used in this paper are floating-point numbers, HEAAN homomorphic encryption scheme will be adopted.

**Approximate Algorithm for Comparison Function.** Logical operation has always been a difficult point in HE. Bit-wise FHEs encrypt data in a bit-by-bit manner. They support fast logical operations, such as comparison. But they can not support floating point encryption. On the contrary, word-wise FHEs, which store messages as their word-sized numbers, support high-speed arithmetic operations between messages. Therefore, in order to calculate the comparison function, an approximate form of the comparison function is proposed by using polynomials.

Cheon et al. [33] first proposed a new identity  $comp(a, b) = \lim_{k \rightarrow \infty} a^k / (a^k + b^k)$ , and showed that the identity can be computed by an iterative algorithm. Because of the iterative feature, this algorithm is slow in HE implementation. Then, they proposed a new comparison methods SIMD [34], using composite polynomial approximation on the sign function, which is equivalent to the comparison function. That is, repeated compositions of  $(2n+1)$ -degree polynomial  $f_n(x)$  and  $g_n(x)$  output the approximate value of the sign function.

We denote the approximate comparison for two inputs  $x, y$  by  $(x > y)$  or  $(y < x)$ . According to the conclusion of [34], given iteration numbers  $d_f$  and  $d_g$ ,  $(x > y)$  is computed as follows

$$(x > y) := (f_n^{d_f} \circ g_n^{d_g}(x - y) + 1)/2 \quad (1)$$

TABLE I. AN EXAMPLE DATABASE

Record	$A_1$	$A_2$
$r_1$	1.4	4.4
$r_2$	2.5	2.9
$r_3$	3.5	1.0
$r_4$	3.3	4.1
$r_5$	4.2	2.8
$r_6$	1.9	2.3

Here  $f_d$  means  $f \circ f \circ \dots \circ f$ , i.e., the operation is performed  $d$  times.

### III. OUR APPROACHES FOR PREFERENCE PROTECTION

Ranked queries are complementary to traditional SQL query semantics. The preferences expressed by the user are considered as *soft constraints* of the queries, whereas the hit-or-miss query conditions, e.g.,  $\leq$ ,  $>$ , and  $\neq$ , are known as *hard constraints* [1], [2], [35]. To evaluate a ranked query  $q$ , the server computes the sum of the linear combination of attributes of the records, based on the user preference vector  $f = \{\omega_1, \omega_2, \dots, \omega_d\}$  (note we use vector and weight interchangeably), then returns to the user the top-k objects with the highest sum.

Table I gives an example of a toy database with 2 attributes  $A_1$  and  $A_2$ . Suppose the user expresses in a query his preference as  $f = \{0.4, 0.6\}$ , and wants to pull top 3 favorable records from the server. Starting from the first record  $r_1$ , the server computes its preference score  $score(r_1) = 0.4 * 1.4 + 0.6 * 4.4 = 3.2$ , and the scores of the rest records. Among the computed scores  $\{3.2, 2.7, 2, 3.8, 3.4, 2.1\}$ ,  $r_1, r_4$ , and  $r_5$  are the top 3 records with highest scores and they are returned as result to the user. As this example shows, there is no protection for user queries, which means that the server can easily obtain the preference information of a user. In this section, we propose two approaches to prevent leakage of user preference, which are described below.

#### A. The First Approach

Our first approach is called PD, which is based on preference distortion. So far in the model we assume that there is no encryption involved, i.e., the user queries and database content are all in plaintext. We defer discussion of the case in which encryption is employed in the next section.

Our strategy to protect user's true preference is simple, and goes as follows. Instead of directly submitting to the server the true preference vector  $f$ , the user distorts  $f$  by randomly adding to or subtracting from the components of  $f$  a small number, then sends the modified preference vector to the server. Specifically, given a preference vector  $f = \{\omega_1, \omega_2, \dots, \omega_d\}$ , we transform  $f$  into a new vector  $f' = \{\omega'_1, \omega'_2, \dots, \omega'_d\}$ , such that  $\omega'_i \in [0, 1]$  and  $\sum_i^d \omega'_i = 1$ . Suppose the increment/decrement added to component  $\omega_i$  of  $f$  is  $\delta_i$ , based on the relation  $\omega'_i = \omega_i + \delta_i$  we can easily verify the following equation

$$\delta_1 + \delta_2 + \dots + \delta_d = 0 \quad (2)$$

where  $-\omega_i \leq \delta_i \leq 1 - \omega_i$ .

We outline the preference distortion in Algorithm 1. We generate  $d$  random numbers, and normalize them to maintain

the convex property. These random numbers are sorted in descending order, such that the relative preference relation among attributes is maintained. For example, we are given a vector  $f = \{0.3, 0.5, 0.2\}$ , and the generated random numbers are  $R = \{0.4, 0.2, 0.8\}$ . After normalization and sorting, we get  $R = \{0.6, 0.3, 0.1\}$ , from which we get the distorted vector  $f' = \{0.3, 0.6, 0.1\}$ , and the increment/decrement vector  $\Delta = \{0, 0.1, -0.1\}$ . It is obvious that after distortion, the new vector still preserves the relative preference relation among attributes as in the original vector, but the actual value of preference weights have been changed.

---

**Algorithm 1: Preference Distortion**

---

**input :** Preference vector  $f = \{\omega_1, \omega_2, \dots, \omega_d\}$   
**output:** Distorted preference vector  $f'$

- 1  $R' = \Delta = f' = \emptyset$ ;
- 2 Generate a set  $R$  of  $d$  random numbers;
- 3 **for**  $\forall rand_i \in R$  **do**
- 4      $rand'_i = \frac{rand_i}{\sum_j rand_j}$ ;
- 5     Insert  $rand'_i$  into  $R'$ ;
- 6 **end**
- 7 Sort  $R'$  in descending order;
- 8  $count = \text{len}(f)$ ;
- 9  $j = 1$ ;
- 10 **while**  $count > 0$  **do**
- 11      $i =$  the index of the greatest weight in  $f$ ;
- 12      $\omega'_i = rand'_j$ ;
- 13      $\delta_i = \omega'_i - \omega_i$ ;
- 14      $f[\text{index}] = 0$ ;
- 15     Insert  $\omega'_i$  and  $\delta_i$  into  $f'$  and  $\Delta$ , respectively;
- 16      $count = count - 1$ ;
- 17      $j = j + 1$ ;
- 18 **end**
- 19 Return  $f'$ ;

---

Having obtained the distorted vector  $f'$ , the user sends it to the server for processing, where at the server side the query processing is just as the same as before and the query results and scores are sent back to the user. Since the scores do not reflect the true values for the original preference vector, the user has to revert the scores returned by the server. Consider the score of a record  $r_i$  with respect to  $f'$ ,  $score(i) = f' \cdot r_i$ , which can be represented as

$$(\omega_1 + \delta_1 \times r_i.a_1 + \omega_2 + \delta_2 \times r_i.a_2 + \dots + \omega_d + \delta_d \times r_i.a_d)$$

After re-arrangement of the above formula we have

$$(\omega_1 \times r_i.a_1 + \dots + \omega_d \times r_i.a_d) + (\delta_1 \times r_i.a_1 + \dots + \delta_d \times r_i.a_d)$$

It is clear that the first parenthesized part is the correct score with respect to  $f$ , and the second part is the noise artificially added by the distorted vector  $f'$ . Thus, the user computes the noise for each  $r_i$  of the return top  $k$  records by multiplying  $\Delta$  with  $r_i$ , and then subtracting the noise from the returned score. After the reverting procedure, the user re-orders the resulting records according to the restored scores. We summarize the reverting procedure in Algorithm 2.

The algorithm of preference distortion is simple and efficient for protecting user preferences, however it may introduce

---

**Algorithm 2: Score Reverting**

---

**input :** Query result set  $S$ , and the set  $Score$   
**output:** The restored score set  $Score'$

- 1  $Score = \emptyset$ ;
- 2 **for**  $Score(i) \in Score$  **do**
- 3      $Noise = \delta_1 \times r_i.a_1 + \dots + \delta_d \times r_i.a_d$ ;
- 4      $Score'(i) = Score(i) - Noise$ ;
- 5     Insert  $Score'(i)$  into  $Score'$ ;
- 6 **end**
- 7 Sort the records in  $S$  according to  $Score'$ ;
- 8 Return  $Score'$ ;

---

false negative and false positive query result, as we will show in the next section.

**Security Discussion.** When the user sends the preference vector to the server for query, even if the preference vector is disturbed, the server may predict the user's real vector according to the returned top  $k$  result, that is, the higher the precision, the higher the probability of being predicted. It is known that the weight of the user preference vector is a decimal between  $[0,1]$ , and the server cannot know the specific decimal places of each weight in the real vector. Obviously, the top  $k$  result corresponding to the vector in a small range is the same. Therefore, when the server predicts the user preference vector according to the top  $k$  query results, there are countless possibilities in the case of uncertain decimal places of each weight in the vector. Especially when the dimension is higher and the number of decimal places is more, there is a lower probability of being predicted by the server.

**B. The Second Approach**

To further strengthen the privacy level of user's preferences, in this section we propose the second approach called HE, which is based on homomorphic encryption.

Considering that the attributes of a record are floating-point numbers, and HEAAN [30] scheme is selected as the encryption scheme. Assume the secret/public key pair of HEAAN homomorphic encryption system is  $\langle SK, PK \rangle$ . The user encrypts his plaintext preference weights  $f = \{\omega_1, \omega_2, \dots, \omega_d\}$  by using the public key  $PK$ , which gives the encrypted weights  $E(f) = \{E(\omega_1), E(\omega_2), \dots, E(\omega_d)\}$  (see Algorithm 3).

---

**Algorithm 3: Preference Encryption**

---

**input :** Preference vector  $f$ , the public key of CKKS encryption system  $PK$   
**output:** Encrypted preference vector  $E(f)$

- 1  $E(f) = \emptyset$ ;
- 2 **for**  $\forall \omega_i \in f$  **do**
- 3      $E(\omega_i) = \langle \omega_i, PK \rangle$ ;
- 4     Insert  $E(\omega_i)$  into  $E(f)$ ;
- 5 **end**
- 6 Return  $E(f)$ ;

---

After the preference vector encryption operation is completed, the next step is to perform the linear weighted summation operation on the data records in the data set, and select the  $k$  results with the top scores through comparison.

The comparison operation of ciphertext is realized by SIMD [34] scheme. In order to reduce the computational consumption of encryption, we consider that the server first performs  $K$ -Skyband operation on the dataset  $D$ , and then only calculates and compares the data records in the  $K$ -Skyband dataset. Similar to  $K$  nearest-neighbor queries, a  $K$ -Skyband [22] query reports the set of points which are dominated by at most  $K - 1$  points. The definition of  $K$ -Skyband is as follows.

**$K$ -Skyband:** An object  $A_i \in D$  is said to be a  $K$ -Skyband object of  $D$ , if  $A_i$  is dominated by at most  $K - 1$  objects in  $D$ .

As can be seen from the definition,  $K$ -Skyband [22] is a variant of skyline, in which  $K$  can be regarded as the thickness of skyline; the case  $K = 0$  corresponds to a conventional skyline. Thus, we implement  $K$ -Skyband by modifying the BBS algorithm. Based on this, the specific process of query is shown in algorithm 4.

---

**Algorithm 4:** Query Evaluation

---

**input :** Encrypted preference vector  $E(f)$   
**output:** Result records and their encrypted scores  
1  $Score = \emptyset$ ;  
2 Compute the set  $Band_k$  of  $k$ -skyband points of  $D$ ;  
3 **for**  $\forall r_i \in Band_k$  **do**  
4      $E(score(i)) = \sum_{\forall a_j \in r_i} E(\omega_j) * a_j$ ;  
5     Insert  $E(score(i))$  into  $Score$ , and compare;  
6 **end**  
7 Send  $Score$  and  $Band_k$  to the user;

---

**Security Discussion.** This scheme encrypts the preference vector. The IND-CPA security nature of FHE scheme ensures that any opponent with the result homomorphic operation between ciphertext and ciphertext cannot extract any information of the message in the ciphertext, our HE method is secure based on the security of FHE, because the server can only access the ciphertext. There is no information leak of user preference.

#### IV. EXPERIMENTAL RESULTS

In this section we conduct extensive experiments to evaluate performance of the proposed two approaches, and all experiments are conducted on a PC running Ubuntu 18.04.2 LTS. We discuss experiment settings below.

**Dataset.** We use synthetic datasets of three data distributions, namely, independent (uniform), correlation and anti-correlation, with dimensionality  $d$  varying in the range [2,5] and cardinality  $N$  in the range [1k,20k], respectively.

**Performance Indicators.** For our first approach PD, since it is an approximate method, we focus on precision and recall indicator, i.e., how many real results can be found for PD. On the other hand, for our second approach HE, since it is an exact method, i.e., HE can find all the correct results, we employ running time as the performance indicator for the HE approach. The precision and recall indicator is defined as

$$precision = \frac{TP}{TP + FP} \quad (3)$$

$$recall = \frac{TP}{TP + FN} \quad (4)$$

where  $TP$  indicates that the number of positive query results retrieved,  $FP$  indicates the number of points which the retrieved positive ones are actually negative,  $FN$  indicates the number of points which it has not been retrieved but they are actually positive. Each precision and each recall result is the average of 10 trails.

Suppose  $Q(x)$  is defined as the number of data points in area  $x$ . Based on the premise of Top-k preference query in this paper, it is easy to obtain

$$Q(TP) + Q(FP) = k$$

and

$$Q(TP) + Q(FN) = k$$

then  $Q(FP) = Q(FN)$ . Therefore, the results of precision and recall are the same.

##### A. Effect of Dimensionality $d$

We vary data dimensionality  $d$  from 2 to 5. As shown in Fig. 1, the cardinality  $N$  is  $10k$  and  $K$  is 50. And it can be seen that the average precision and recall results of datasets with independent (uniform), correlation and anti-correlation distribution are basically stable and were not affected by the dimensionality. It is obvious that the average precision and recall results of correlation data set are the highest, while that of anti-correlation are poor.

##### B. Effect of $K$

In order to study the effect of  $K$  we carried out experiments when  $K = 10, 20, 50, 100$ . Fig. 2 shows the precision and recall corresponding to each case. Obviously, the query results are not affected by the  $K$  value.

##### C. Effect of Cardinality $N$

Fig. 3 shows the precision and recall results when the cardinality  $N$  in the range [1k,20k]. It can be clearly seen that the precision and recall values of the three types of datasets tend to be stable.

In conclusion, our proposed distortion algorithm has little relationship with the size of  $K$ , data dimension and data set cardinality. Thus, the disturbance scheme is practical and will not be affected by other factors. In addition, it can be clearly seen that it has a good precision and recall result in correlation datasets but poor in anti-correlation datasets.

##### D. Discussion

From the above experimental results, it can be obviously seen that precisions are float up and down. That is due to the existence of false negative and false positive points, and the number of them is uncertain.

For ease of discussion, we use the example database in Table I, and assume the data space range for attribute  $A_1, A_2$  are  $x = [0, U_x], y = [0, U_y]$ , respectively, and  $k = 3$  for the returned top  $k$  results. Now consider an original vector  $f = \{\omega_1, \omega_2\}$  and the corresponding transformed vector  $f' = \{\omega'_1, \omega'_2\}$ . After examining each vector against the records in  $D$ , the qualified records (represented as data points in 2-D space) are highlighted in Fig. 4(A). Specifically, the top 3 records with

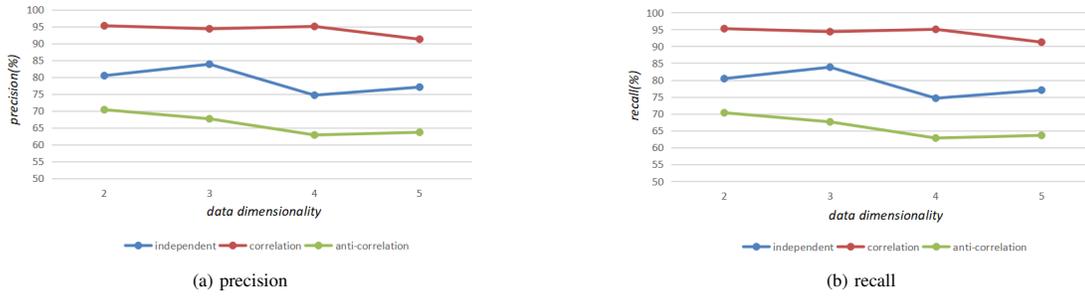

Fig. 1. Precision & Recall on a Dataset with Top-50 Query, 10k Records and Varying Dimensionality  $d$ .

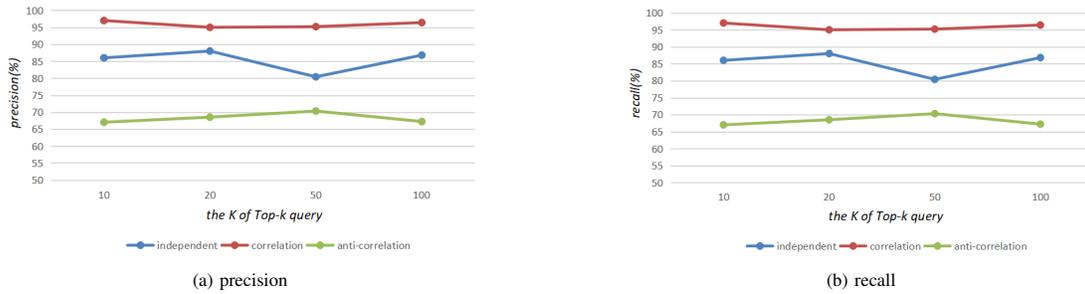

Fig. 2. Precision & Recall on a Dataset of 10k Records in 3D Versus  $K$ .

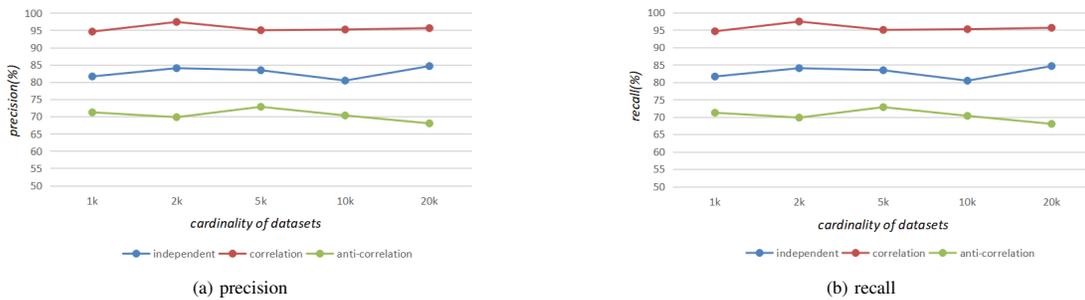

Fig. 3. Precision & Recall on a Dataset with Top-50 Query and Varying Cardinality  $N$ .

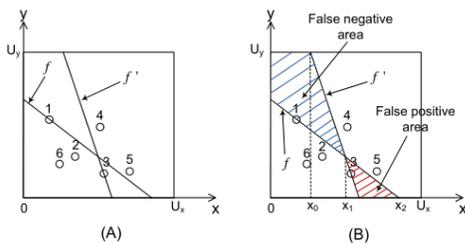

Fig. 4. Original and Distorted Ranked Queries.

To evaluate the original and distorted preference vector, one has to quantify the number of false positive and negative results. As depicted in Fig.4(B), it is clear that the larger striped area (denoted by  $FN$ ) contains false negative points, and the smaller striped area (denoted by  $FP$ ) false positive points. The area of  $FN$  and  $FP$  can be easily calculated by computing the following integrals.

$$FN = \int_0^{x_0} (U_y - f)dx + \int_{x_0}^{x_1} (f' - f)dx \quad (5)$$

$$FP = \int_{x_1}^{x_2} (f - f')dx \quad (6)$$

respect to the original vector  $f$  include  $r_4, r_5, r_1$ , whereas the answers for distorted vector  $f'$  are  $r_4, r_5$  and  $r_3$ . There is a false positive result,  $r_3$ , and a false negative  $r_1$ , due to the weight distortion.

Under the assumption of uniform distribution of the data records in  $D$ , we can estimate the number of false negative and false positive results as  $N*FN$  and  $N*FP$  respectively, where  $N$  is the cardinality of  $D$ . On the other hand, the computation of the  $FP$  and  $FN$  becomes complicated in the case of high

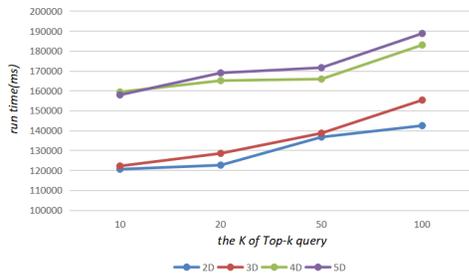

Fig. 5. Running Time on a Dataset by Varying  $K$ .

dimensional data. However, one may resort to techniques such as Monte Carlo method to approximate the integral in high-dimensional case. This is a future direction of our work.

### E. Performance of HE Approach

For HEAN, we fix the dimension  $N = 2^{17}$ ,  $\Delta = 2^{40}$ , and hamming weight  $h = 128$  and the secret key is chosen from the ring with ternary secret distribution, i.e., all nonzero coefficients of secret key are  $\pm 1$ . For SIMD, we employ the approximate comparison method where  $f_n$  and  $g_n$  are chosen by  $n = 3$ , where

$$f_3(x) = (35x - 35x^3 + 21x^5 - 5x^7)/2^4 \quad (7)$$

$$g_3(x) = (4589x - 16577x^3 + 25614x^5 - 12860x^7)/2^{10} \quad (8)$$

We conduct experiments with different  $k$  and dimensionality  $d$  varying in the range  $[2,5]$ , and report the corresponding running time. Fig. 5 shows the running time when  $k = 10, 20, 50, 100$  with  $10k$  objects.

When  $K$  in  $K$ -Skyband is large, the data to be calculated decreases relatively, but the running time still increases steadily with the increase of dimensionality.

## V. CONCLUSION

In order to protect user preference privacy information, we propose two approaches to solve the problem of user preference privacy protection in ranked queries. The first method, called PD, hides the user's real preference information by introducing perturbation to the user ranked query vector. This scheme will lead to a slight degradation in precision in the query results. Moreover, the experiment results also show that PD achieves the best performance on dataset with correlation distribution, whereas it performs relatively poor on dataset with anti-correlation distribution. Therefore, PD is suitable for real-time ranked query processing scenarios with less accurate requirement for the query result. In order to get exact query result, a homomorphic encryption-based method called HE is proposed to encrypt the preference vector, which enables the third-party server to process ranked query by calculating the ciphertext, so as to fully protect the privacy of user preference.

## ACKNOWLEDGMENT

We would like to thank the anonymous reviewers for reviewing this paper. This work is supported in part by National Natural Science Foundation of China (Grant No. 61972177),

Science Plan of Yunfu city (Grant No. 2021020302), Guangdong China. Rong Tang and Xinyu Yu contribute equally to this paper.

# Towards Security Awareness of Mobile Applications using Semantic-based Sentiment Analysis

Ahmed Alzhrani, Abdulmjeed Alatawi, Bandar Alsharari, Umar Albalawi, Mohammed Mustafa  
College of Computing and Information Technology, University of Tabuk, Tabuk, 71491, Saudi Arabia  
Industrial Innovation and Robotics Center, University of Tabuk, KSA, Tabuk, 71491, Saudi Arabia

**Abstract**—With the rapid increase of smartphones and the growing interest in their applications, e.g., Google Play Apps, it becomes necessary to analyze users' reviews whether they are expressed as ratings or comments. This is because recent studies reported that users' reviews could provide us with useful clues and valuable features that can help in understanding the broad opinion about some applications in term of security awareness. Several techniques have been developed for this crucial task and significant progress have been achieved such as Semantic and Sentiment Analysis, Topic Modelling, and Clustering. The majority of the existing methods are mainly based on representing reviews' words in a Bag-Of-Words vector space with String-matched approaches without considering the common polysemy and synonymy problems of words. This is true due to the fact that users who make use of these applications are often from a diverse background and thus, different vocabulary. This paper proposes a new approach to classifying security opinions about applications from users' reviews while considering special features of synonymous and polysemous words. To achieve this task, the proposed model makes use of word embedding, topic modelling, Bi-LSTM, and n-grams approach. For the proposed model, a new dataset is built that contains reviews about 18 popular applications. The application's selection was primarily governed by making the dataset diverse in its domain. The experiment results showed that the proposed ensemble model which combines the prediction of the extracted features, which in turn captures synonymy, polysemy, and dependency of words is significantly useful, and it achieves better results with an accuracy approaching 90% compared to the use of each technique separately. The model could contribute in preventing mobile users from unsafe applications.

**Keywords**—Security awareness; semantic analysis; sentiment analysis; mobile applications; topic modelling; clustering

## I. INTRODUCTION

The history of smartphones dates to the 1980s; however, the revolution in the industry came when the first iPhone was introduced in the market. This revolution has completely changed the life of humanity and how people interact; and what seemed like a distinct dream has become a tangible reality. After 2007, users felt the power within their hands, with smartphones becoming an integral part of every life. Today, there are close to six billion smartphone users, which amounts to over 70% of the world population. It is estimated that access to smartphones would reach over 7.5 billion in the next five years [1], as shown in Fig. 1. Smartphones are also expected to affect all aspects of life on earth in the coming years. Smartphones have evolved over the last decade and have come a long way from being a prized possession to an ultimate necessity. When IBM introduced the first smartphone,

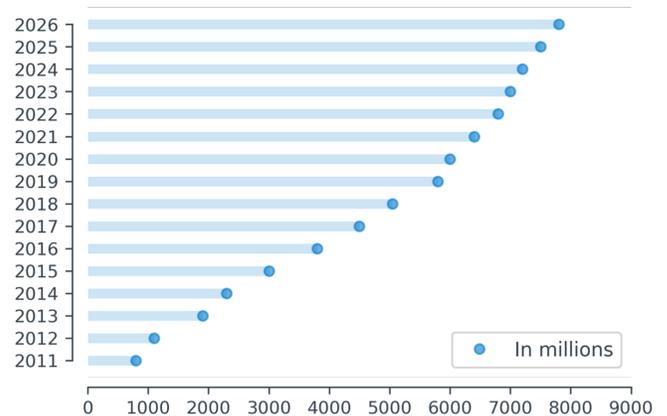

Fig. 1. Number of Smartphone Users.

it was more about the touchscreen, email, fax, and notes than anything fancy or smart power in hand. The first smartphone was never that powerful and looked like it would take ages to reach the common people. It was in the year 2007, however, when the first iPhone was introduced, and it captured the market by storm. It possessed a number of features, including the capacity to play music and capture images, not to mention that it was priced at something that people could think to own [2].

Today, the 'New Generation' of smartphones have increasingly become more innovative and eye-catching. During the current pandemic (COVID-19), smartphone users have increased [3]. While in lockdown, such users have befittingly found solace in these gadgets, allowing them to stay connected with their families, gain access to information, and use them to join work platforms, such as Teams and Zoom, in addition to other users. Many companies started producing smartphones and application distribution platforms. For example, Samsung entered the market strongly and distinctively in 2009 through the Android operating system and has since been continuously developing its famously known application store 'Google Play' (GP). There are millions of different smartphone apps that are emerging as the number of users increases and technology develops. In 2017, the Google Play store had approximately 3.5 million apps [4], as shown in Fig. 2.

One of the advantages of the applications is that they allow users to review and evaluate. Therefore, any application downloaded by any of the operating systems can get

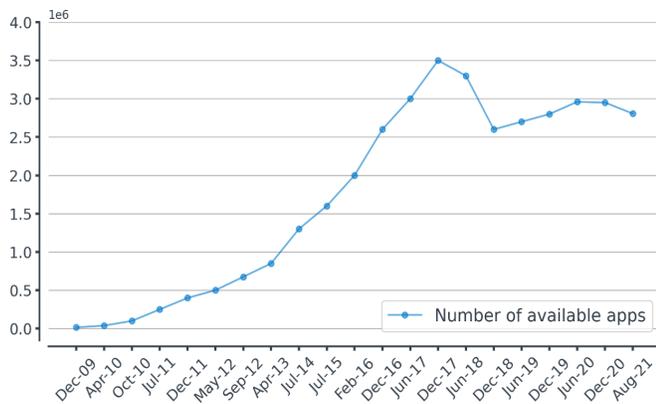

Fig. 2. Number of Available Applications in Google Play.

reviewed by its users, which lets others know about the app's benefits, drawbacks, or any security issues. User reviews and ratings are some of the most critical factors in determining whether or not an app will survive and prosper in the market. Furthermore, data scraping can be used with these reviews to benefit from them or to provide information. According to a survey published in 2018 [5], 94% of buyers avoided a business after reading unfavorable reviews about it online. Interestingly, 80% of clients would avoid doing business with a company if it had less than four stars, which is also relevant to the app industry. Hence, it is crucial to take app reviews into consideration. Through the advancements in new apps, software, and technologies, IT security is forced into continuously being upgraded to prevent it from breaching privacy. With so many apps, as well as social media platforms available to communicate and express ideas freely, technology has aided an explosion of data in recent years. This has created a loophole through which smartphone users' personal information can be easily accessed, raising larger security concerns and difficulties.

Smartphones invading human life has produced multiple apps that are related to almost everything a user does in their routine life, indicating that the user of a smartphone is never alone and always being watched by someone or the other. Today, there are apps developed for everything: job-hunting, reading books, watching movies, or anything else throughout the day [6]. These apps give their users the freedom and ease to complete the requirements ranging from simple data collection or information gathering to entertainment or any further assistance. According to [7], the number of individuals using mobile banking applications has surpassed two billion, accounting for around 40% of the global adult population. A few fact checks of the security issues in these apps [8] are as follows:

- In the second quarter of 2018, mobile applications and mobile browsers accounted for 71% of all fraud transactions.
- In 2018, tools and leisure applications accounted for 54% of malicious mobile apps.
- The United States accounted for 25% of all mobile malware incidence, India for 23%, and China for only

3 %.

Modern mobile operating systems include a variety of security features. Installed apps can only access files in their own sandbox folders by default, with user privileges preventing them from changing system files. However, mistakes made by developers while designing and coding for mobile applications leave security vulnerabilities that adversaries may exploit. A lack of multi-factor authentication is one of the most frequent risks to mobile app security. Without this protection, a hacker only needs a tiny amount of personal information to access the data.

The rest of this paper is organized as follows: The Background and related works are described in Section II. The database collection of this paper is summarized in Section III. Section IV discusses the datasets analysis. In Section V, the proposed model is discussed. Section VI illustrates the experiment results, while Section VII concludes the paper and briefly discusses areas of future work.

## II. BACKGROUND AND RELATED WORK

Several methods and techniques have been proposed in the literature for the task of how to extract sentiments in user's review texts. Some of these methods were built on top of supervised learning, in which a large set of data is being labelled, whereas others were based on unsupervised learning. However, the common theme among the provided studies is how to extract useful features that can help in identifying sentiments or opinions. Besides the use of conventional classification techniques that are based on the traditional frequency of both positive and negative words, the utilized approaches for feature extraction that are related to this study can be informally categorized into three main categories, these are Sentiment-based, Semantic-based and Topic-based techniques. Next section discusses each of which in more detail.

### A. Sentiment-Based Analysis

Prior studies have proposed various sentiment analysis approaches. The authors [9] used text mining to summarize user evaluations and extract key features from Android app reviews. They then utilized a natural language processing (NLP) technique to write rules. They used SAS® Enterprise MinerTM 7.1 to summarize reviews and pull-out features, and SAS® Sentiment Analysis Studio 12.1 is utilized to perform sentiment analysis. Reviews from two Apps from two different categories were used in the experiment; namely: "Where is my Perry" from "Brain & Puzzle" category and "Beautiful widgets" from "Personalization" category. Data was gathered from the Google Play Android App Store. Textual reviews with rich content were collected from the App Store website. Six hundred reviews were extracted, A corpus of 500 reviews was used for text mining, constructing sentiment models, and developing sentiment rules, while a testing dataset of 100 reviews was used. Each textual review is categorized into a positive or negative directories based on overall ratings depending on the 5-star rating scale used by Google Play. Rule based models were applied to the testing datasets. The NLP rule-based model outperformed the SAS® Sentiment Analysis Studio 12.1 default statistical model in predicting sentiment

in test data. In analyzing customer sentiment, NLP rule-based models give deeper insights than statistical models.

In the research [10], A series of comparison studies were carried out using classification algorithms to classify emotions. Review length and feature representation. The experiments were carried out on over 1400000 mobile app reviews based on four characteristics: 1) short average length; 2) large span of length; 3) power-law distribution; 4) Significant difference in polarity. This research makes a comparison between two classification techniques; namely: Support Vector Machine (SVM) and Naïve Bayes. The experimental results stated that: 1) Bayesian method is proved to perform better than the SVM on the classification link; 2) N-Gram is applied (N=2) for the best result on feature representation after the Chinese word segmentation; 3) Feature extraction process can improve the sentiment classification accuracy when reviews have more than 150 words; 4) Short reviews are more easily classifiable than long ones.

Zhang et al. [11] built a novel system for named MoSa (Mobile Sentiment Analysis) for data analysis. The proposed system employs algorithms for detecting and analyzing different types of application big data, such as news comments. They proposed a sentiment analysis approach relying on a mixed sentiment dictionary and new algorithms for calculating comment sentiment scores and categorizing comment sentiment tendencies. The mixed sentiment dictionary is more effective at classifying short texts according to experimental data. The average word length should be less than 2.3 when utilizing a sentiment dictionary to analyze brief texts. They also suggest certain unique statistical models that describe public behavior. In doing so, they discovered that standard deviation is a better indicator of public sentiment than other statistics.

The study [12] proposed a security-related and evidence-based ranking scheme, called SERS. This approach is utilizing the principles of Subjective Logic operations, theory of evidence, Sentiment Analysis techniques, Static taint analysis, and NLP. SERS achieves a holistic rank ordering of related apps and generates insights linked to apps available on the Google Play Store, in both structured and unstructured contexts. They tested their method on publicly available apps from the Google Play Store and compared their results to common ranking methods like average star ratings.

The review paper [13] focuses on the sentiment analysis (SA) for users' review of mobile apps to extract user requirements for developing new apps or improving existing ones, i.e., requirements evolution. They have investigated the approaches employed in the literature during the years 2009 to 2015 to answer the following research questions: 1) "Are there any publications about using SA of mobile app users' reviews for requirements evolution?", 2) "What are the methods used?", and 3) "What are the tools used?". Results demonstrate the value of using SA to analyze user reviews and reports, automated methods, and tools for evaluating reviews with features and sentiments.

The research published by Rizk et al. [14] utilized the naïve Bayes method and LDA algorithm for determining the customer sentiment on mobile banking apps and what aspects need to be maintained or improved in the app. The data used for the experiment were collected from the user reviews

on Google Play store. Data were manually labelled and two classes (positive and negative) were generated. Naïve Bayes is utilized for the sentiment analysis process, LDA is used for the process of topic modelling. The experiment's findings revealed that the Naive Bayes approach had a high level of accuracy, recall, and precision. The value of  $k=5$ , which equals 86 % accuracy, 93 % recall, and 92 % precision, has the highest accuracy, recall, and precision. The most common topics in negative classes, according to the LDA method, are OTP code delivery constraints, application login problems, and network connection issues. The most often common topics in positives classes, on the other hand, were ease, simplicity, and helpfulness.

Lavanya et al. [15] proposed an opinion mining algorithm utilizing the word alignment model for extracting opinion targets and opinion words from online reviews extracted from Twitter. The proposed project aimed to design opinion words and opinion target predicting algorithms that mine user reviews posted on Twitter to analyze the market status of a particular product. The results of the experiments show that the proposed method achieves higher accuracy in a more efficient manner. Furthermore, the project's ultimate goal is to create possible consumer-oriented items such as mobile phones, laptops, and so on.

The study [16] has merged three techniques; namely, 1) Sentiment analysis (SA), 2) NLP and 3) Text Analysis (TA), to classify the reviews of mobile apps into categories related to software maintenance and evolution. This study provides a high-level taxonomy of sentences' categories included in user reviews that are related to the maintenance and evolution of mobile applications. Moreover, it provides a novel approach using NLP techniques to extract the user Intentions expressed in user reviews. The study's findings revealed that combining NLP, TA, and SA methods allows app developers to discover meaningful phrases with higher precision (75.2%) and recall (74.2%) than utilizing each methodology separately. The authors also demonstrated that increasing the size of the training set improves accuracy and recall in specific setups. They also discovered that a classifier that is trained using both structure (NLP) and sentiment (SA) characteristics performs considerably better than the one that is just trained with text (TA) features.

## B. Semantic-based Analysis

The authors [17] proposed a framework for automatically analyzing the differences and similarities between app reviews from the Google Play Store and tweets based on the semantics of the words. They demonstrated that the framework can automatically identify similarities and differences using statistical tests and human expert review. This system may be used instead of the costly and unreliable crowd sources (due to the evaluation of non-experts). By filtering similar and different issues, it can decrease redundant information and group the main points. The results of multiple experiments, which were compared to expert evaluation, showed that it may be used to find similarities and differences between extracted topics, n-grams, and user comments.

Yadav et al. [18] proposed a novel framework that employs Word2Vec word embeddings to incorporate semantics into

app user feedback analysis. They use Google Play, Store and Twitter as a case study to see if their method can detect similar/different comments in the two well-studied types of bug reports and feature requests in the literature. Statistical analysis and human expert evaluation both validated the result. The result demonstrated that this approach could measure the semantic differences between users' comments in both groups automatically. The framework may be used to create intelligent tools that combine user input from various platforms while also allowing for automated analysis of reviews.

### C. Topic Modelling and Clustering

The authors [19] conducted a study employing machine learning techniques to compare national cybersecurity strategies (NCSs) for different nations. Topic modeling and clustering methods were utilized to investigate the similarity and differences between NCSs and to identify the underlying topics that are appearing in them. A total of 60 NCSs developed between 2003 and 2016 were gathered and examined. They discovered that membership in international intuitions could be a determinant factor for NCS harmonization and integration using institutional theories. The study indicated that quantitative analytical methods such as LDA and clustering can be used to acquire a wider picture and insights during the formation of NCS while analyzing qualitative data such as textual policies strategies, and legislations. The clustering method's results assisted us in gaining a better understanding of the overall similarities between NCSs. The findings suggested that members of a group such as NATO or other like-minded allies have established more integrated and coordinated NCS.

Moubayed et al. [20] introduced a tool that summaries, categorizes, and models such data sets, as well as a search engine that allows users to query the model created from the data. The tool is based on a technique known as probabilistic topic modeling, which goes beyond document lexical analysis to model the intricate relationships between words, documents, and abstract concepts. It will help academics query the papers' underlying models and access the library of documents, allowing them to be sorted thematically. LDAVis, a third-party tool, is also included to provide a more in-depth understanding of the LDA model's inner structure. The tool has simple and intuitive navigation features that display the words inside a subject as well as the relationships between topic and words. This is a very useful tool for security experts to assess the quality of the created model and fine-tune the search queries they provide to the search engine.

### D. Analyzing the Current State of the Research in Users' Reviews (Security)

To build a well-designed architecture, firstly existing studies are analyzed briefly, in terms of whether the used model can capture the unique characteristics of English language that often present in reviews. The main four features are whether they are covered by the described studies or not. These features are synonymy, polysemy, contextual information inside text, hidden and latent variables in texts, and word dependency. Table I briefly discusses the outcomes and the main shortcomings in each of the listed studies.

## III. DATABASE COLLECTION

Existing corpora are either distributed under some license policy (not accessible) or they do not suite this study, which is the classification of English reviews for some of the most popular applications from a security perspective. For this reason, we decided to collect our own corpus with an eye to make it public for researchers in the near future. English reviews were crawled by making use of a quantitative approach from the mobile app metadata of Google Play Store during the period of January 2021 to September 2021. In particular, several tools including the most popular Google Play Scraper are used for this purpose. Accordingly, a Python application is built based on the API of Google Play Scraper. One of the elegant features of Google Play Store is that it does not require any dependencies. In the process, however, a list of some popular keywords in security and cryptography domains was prepared by an expert in the field. Examples for the employed tokens include words like cryptography, confidentiality, breach, crack, etc.

Recently, the research [21] showed that racing game applications are often downloaded by users and their reviews are frequently reviewed. The same study also showed that education apps are the most dominant in Google Store. Motivated by the arguments and with an eye on analyzing security in several domains, six categories have been chosen in the most popular domains and from which the majority of the applications are often downloaded. These are games, finance, education, shopping, entertainment, and social media. The domains were specified from mobile app metadata.

This study focus is concentrated around 18 common and well-known applications, each of which is under a specific category. In particular, in each domain, three applications are chosen among the top popular ones. The intended period was from 2013 to 2021. Given these constrains, about 250435 reviews are collected. Due to the messy theme of the raw reviews (and before the features were extracted), the data was firstly gone through various preprocessing. The main of this processing is to populate text into a standard and canonical form and thus, it can be analyzed. Those preprocessing steps are as follows:

- 1) Awkward Reviews: the data was filtered to remove awkward reviews and those were in mixed languages (i.e., English and French) and emojis.
- 2) Punctuation Marks and Symbols: to have clean text, all punctuations, marks, and symbols were eliminated.
- 3) Normalization: texts were normalized, trimmed, and cases folded, started with removing stopwords. Stopwords are often eliminated to compress corpus size. Additionally, they are non useful and of little importance because they are present approximately in the majority of the reviews. However, since the data had many misspelled words, a list of additional awkward stopwords is identified that were removed during this cleaning phase. For example, the phrase doesn't (does not) has been removed.
- 4) Porter Stemmer: After that, the texts in the dataset were stemmed using Porter stemmer. Porter stemmer is a light stemmer that can chop off the suffixes to render different forms from a single stem.

TABLE I. THE COMPARISON STUDY OF SENTIMENT AND SEMANTIC-BASED ANALYSIS

References	Contribution	Approach	Potential shortcoming
[9]	A sentiment feature-based model that combines text mining techniques with NLP. In particular, the learned features were automatically used to extract keywords.	Text clustering techniques from text mining plus Part-Of- Speech (POS) in NLP.	- weighting method used for clustering was based on simple Frequency. - Contextual information was not exploited. - Dataset size was relatively small. - POS needs large data to correctly identify sentiment in reviews. - The impact of stopwords removal was not investigated.
[13]	Investigating the importance of employing sentiment analysis techniques in providing a picture about the mobile applications.	A general review paper.	- No empirical analysis for the employed approaches and techniques. - The tools that were covered by the study were not assessed.
[14]	Identifying the weaknesses and strengths in mobile banking apps through the analysis of topics in users' reviews comparing results to those obtained through Naive Bayes classifier.	Latent Dirichlet Allocation (LDA) topic model.	- Neither Hidden Topic Markov Model (HTMM) nor N-gram language models were used in the study. - Additionally, the use of LDA is not a good option when dealing with short texts, especially those with messy nature like reviews. In such cases, the use of NMF is the most adequate approach.
[15]	An opinion mining algorithm was proposed to extract opinion words and target opinion from Some online reviews extracted.	The IBM-1 alignment model, which is originally used for translation task in NLP.	IBM model needs a considerable large amount of parallel data to extract lexical weights. However, a small size of sentences were used in the study.
[16]	Classify the reviews of mobile apps into groups related to software maintenance and evolution.	Sentiment analysis, NLP, Text Analysis.	The study needs to be extended to a larger number and variety of apps.
[18]	Integrating users' reviews and feedback about specific application(s) from different platforms.	Google's word2vec Pre-trained word embedding model.	- Topicality has not been modeled in the developed approach. - Dependency of words in text was not investigated and thus, words were handled as if they were independent inside the texts.
[20]	Building a topic-based (semantic-based) search engine to tackle the change in security threats.	Latent Dirichlet Allocation (LDA) topic model.	Bag-Of-Words topic modelling does not consider Markovian relations between topics. Neither HTMM nor N-gram language models were used in the study. Thus, topics may be incoherent.

TABLE II. DISTRIBUTION OF COLLECTED REVIEWS IN DIFFERENT APPLICATIONS AND DOMAINS NORMALIZATION PROCESSES

Following this, the extracted reviews were stored into a CSV format file containing their corresponding metadata. After the above normalization processes, Table II illustrates the distributions and the total number of reviews of each application with its category. For Training phase, the dataset needs to be labeled. Accordingly, we decided to classify the sentiments of the review texts into three main categories (Positive, negative and Neutral). The word neutral means the review is actually not related, but it was collected because of one of its constituent words is on the keywords list. One might ask why to eliminate such reviews. After a deep discussion, we decided to keep them so as to mimic what actually happening in the real world. From that perspective, a human judgment process was conducted to label the reviews in one of the three aforementioned classes. Fig. 3 shows the distributions of the three classes according to category.

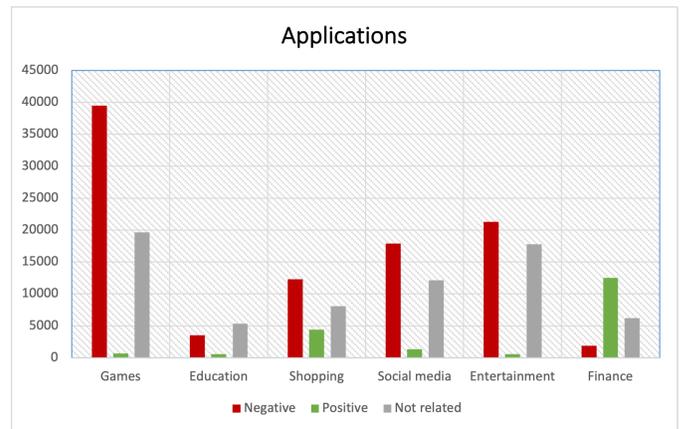

Fig. 3. The Distribution of the Three Classes According to Category.

#### IV. DATASETS ANALYSIS

At first, the distribution of labelled classes from two prospective: users' ratings and the class labelling is investigated. In all reviews that were collected from different domains, the user's rating is of 1 to 5 stars. Fig. 4 plots the distribution of different ratings using a pie chart. In the figure, it is obvious that the higher rating for all applications together is found to be of user rating level 1.

This indicates that the overall satisfaction in terms of the selected is high. However, users' ratings may not be perfect. Therefore, the correlation between human labelled classes and these users' rating levels is studied. In particular, exploring whether the sentiment polarity is correlated with users' ratings. Therefore, the ratings levels is categorized as shown in Table III. In the same table, the total number of different review categories plus labelling on the same categories, are also provided.

From Table III, it is evident that the distribution between the two types of labelling (users' rating vs. our labelling)

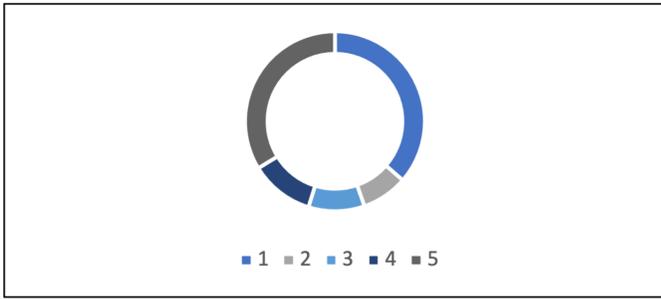

Fig. 4. The Destruction of the users' Ratings for All Categories Together.

TABLE III. THE CATEGORIZED LABELS FOR USERS' RATING AND OUR LABELLING

Rating	Categorized Label	Users' Rating Class	Our Labelling
$\geq 4$	Positive	73774	17216
$\equiv 3$	Natural	86357	66406
$\leq 2$	negative	17005	93514

are significantly inconsistent and extremely varied. We cannot claim that the labelling is perfect, but it has been judged by the same team, unlike the users' ratings, which are judged by a large number of users, and thus, we can claim that the labelling (human labelling for distinguishing purposes) is better than the identified classes of human labels. This is an important conclusion because often researchers attempt to avoid the boring and time-consuming process of labelling. Therefore, unless the ratings are checked statistically, we cannot depend on users' ratings, which are very subjective among a large number of users.

Fig. 5 shows the correlation between the two identified types of labels (Human labelling vs user-rating labels) using HeatMap. It is clear that the two types of ratings are highly uncorrelated. This is an indication for the fact that users' ratings are not aligned with human judgment labelled about reviews. The conclusion is aligned with Table III. Next step is to analyze why there are many unrelated reviews. We went through several reviews, not related to the study but they were crawled. From the proposed analysis, it is showing that the main problem for this phenomenon is the polysemy of words. Polysemy means a single word that have different meanings. For example, the word apple in the information technology domain has a very different meaning from its meaning in the agriculture domain. In the former field, it is likely related to apple phone, whereas in the latter, it refers to fruits. This polysemy nature of words in English texts cannot be disambiguated unless contextual information (topicality) and homonyms inside the texts are captured. There are many topical model and approaches that can be utilized to mitigate this problem, e.g., Latent Dirichlet Analysis (LDA), Words' Embeddings, and BERTopic (Bidirectional Encoder Representations of Transformers).

Nevertheless, the use of such models may not resolve this problematic phenomenon and the availability of contextual information is doubtful. This is because texts in reviews are often too short with relatively weak co-occurrence associations among words. As a consequent result, the texts may not be interpreted (even the hidden topics are captured) due to lack

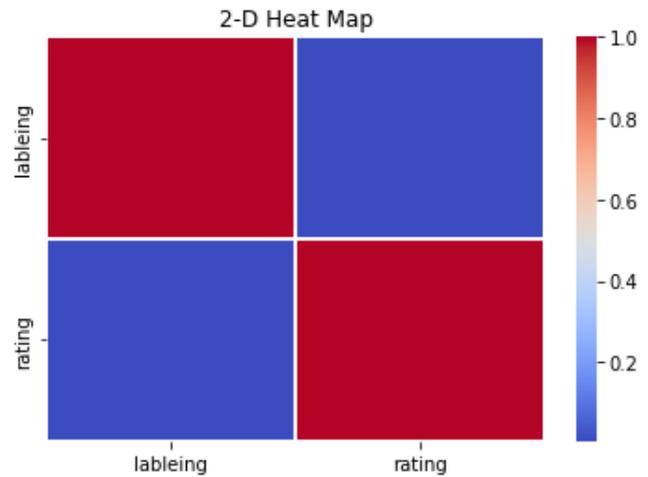

Fig. 5. The Destruction of the users' Ratings and Human Judgment Labeling.

of contextual semantics and topicality. This is one of the main targets for this research, to extract some useful features based on hidden and contextual information in reviews' texts. In Fig. 3, it is also evident that the probability distribution of the collected reviews is imbalanced. This bias can easily make the proposed model, as it will be described later, biased towards a specific category and/or classes. For this reason, in the experiments, a random up-sampling is implemented for each category to be aligned with the main category in the dataset.

## V. PROPOSED MODEL

### A. Motivation

Traditional approaches for representing texts in documents/reviews/tweets attempt to create some degree of association between words and documents (reviews in this case) to build some co-occurrence word-document matrix to standard weighting schemes for normalized and stemmed words. In such models, the order of words does not have any impact on the entire process, known as Bag-Of-Words (BOW) model. The main drawback that may occur here is that the model does not reveal the structural semantics among words and the hidden meanings of the entire context inside text. This means that the linguistic contexts of words are only eliminated due to their frequency in each document and among documents within an unordered set of words.

The problem here is that words in human language are polysemous by their nature. The term polysemy means a single word which can have several meanings and senses. On the other hand, synonymy is very prevalent in natural human languages. Synonymy refers to the opposite in which different words may have the same meaning. It is evident that traditional techniques for representing words are limited towards problematic synonymy and polysemy; and susceptible to mismatching problems. Synonyms and polysemy cannot be adequately captured unless three main features in the texts are considered:

- 1) How to represent words? it is a essential question. In traditional approaches, words are represented using

standard TF\*IDF weighting. In such a case, it cannot be predicted the best word from its surrounding text.

- 2) Capturing hidden topics and latent semantics and variables. Discovering such hidden structures is extremely valuable because more functions (more than classification or clustering technique) can be utilized for different purposes.
- 3) Capturing the dependence between texts' words. This means that the order is a matter here. This is not an easy task, because the dependency can be captured bidirectionally (in a forward or backward direction). This is because human usually does not begin their thoughts from scratch, there are always some dependencies that are represented inside text. For example, individual words can be understood according to their previous and next words.

### B. The Proposed Architecture

Inspired by the arguments above, the proposed model is a carefully designed architecture that can predict reviews while considering their contextual information, ordering and hidden topics. In a brief description as shown in Fig. 6, the proposed model uses:

- 1) Traditional n-grams TF\*IDF, which is the n-gram occurrence of a "n-word" phrase. In this case, it will capture which words are more likely to occur in reviews and which words are more likely occur together.
- 2) Distributional Representation: the proposed model will use word embeddings. The latter allows us the next representation of words that can understand their meanings.
- 3) Bi-Directional Long-Short Term Memory (Bi-LSTM), which is a Recurrent Neural Network (RNN) model used to capture dependencies inside texts.
- 4) For topic modelling, the proposed model will use the Non-Negative Matrix Factorization (NMF). NMF is a model used to find hidden and latent topics, which generate text according to some hidden topic distribution. One main feature of the NMF is its ability to handle short texts as those present in reviews.

## VI. EXPERIMENTAL RESULTS

Down-sample technique is used to balance the distributions across different classes in the dataset. Accordingly, the labelling classes with the highest frequencies were down sampled to the lowest one. The outputs were then merged and then randomly sampled together (shuffled) resulting into 17829 for each class instead of 91283, 17829, and 68024 for negative, positive, and neutral classes, respectively. Following this, the dataset was split into training, testing, and validation partitions with 80%, 10%, and 10% of the entire dataset, respectively, as illustrated in Table IV.

### A. Traditional N-Gram (TF-IDF) Model

The model starts to create various features with word n-grams model with n [1, 3]. Hence, the entire reviews were

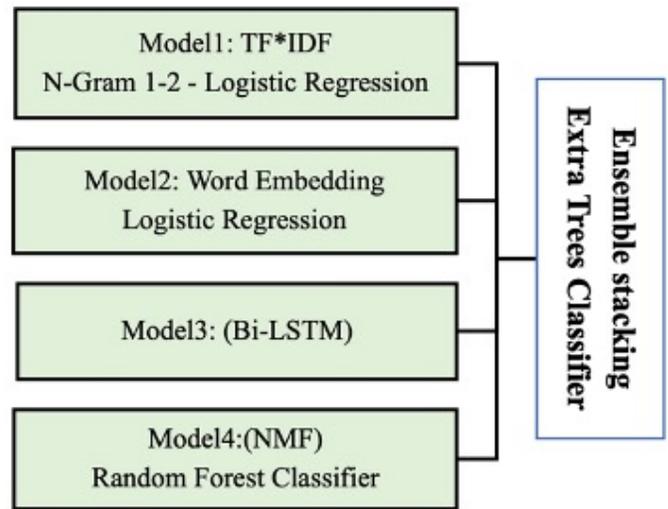

Fig. 6. The Proposed Ensemble Stacking Model.

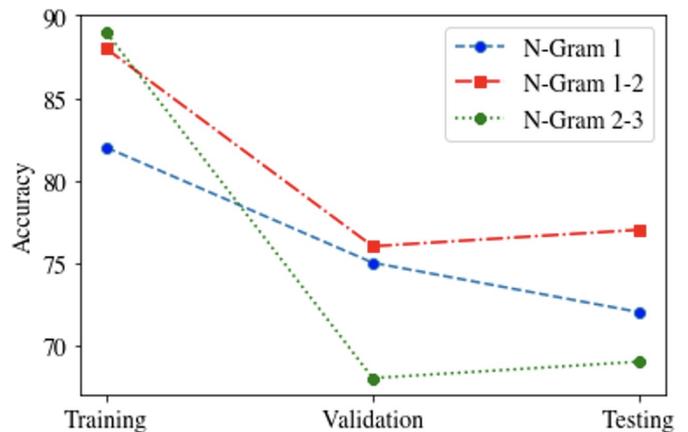

Fig. 7. The Accuracy of Logistic Regression Classifier with n-grams-based Features.

converted into a Bag-Of-Words model. Since the number of n-grams was found to be extremely high, the model tries to use top k-grams with k to be determined empirically. Following this, the features were fed to four different classifiers one by one, these are Logistic Regression, Naive Bayes, Decision Tree and Random Forest. The best result was achieved by employing the bigrams model on the top 296633 features with the logistic regression model. In particular, the overall accuracy performance was found to be 88%, 76%, and 77% for training, validation, and testing datasets. Fig. 7 plots the accuracy for different n-grams.

### B. Word Embedding Model

In the second run of the experiments, the model extracts features using the word2vec skip gram pretrained model of distributional representation of reviews' words. Hence, the embedding of each word in each review is extracted from the pretrained model and the average of all embeddings of the voter words is computed for each review. In the experiments, 300 features were used for each word. The computed vectors

TABLE IV. DISTRIBUTION OF COLLECTED REVIEWS IN DIFFERENT APPLICATIONS OF THEIR DOMAINS AFTER BEING BALANCED

Category	Application	# of Reviews	After balancing process			
			All	Negative	Positive	Natural

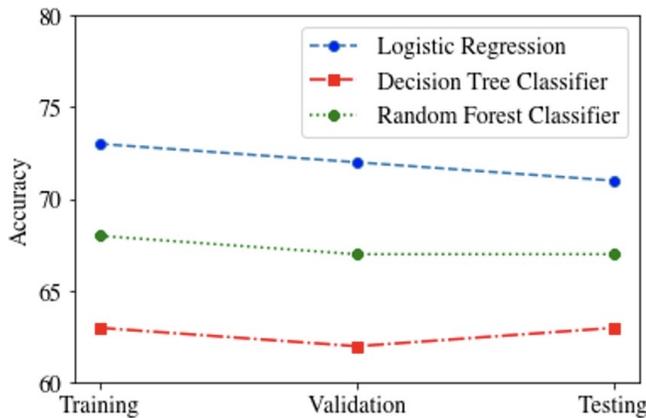

Fig. 8. The Accuracy of the Three used Classifier Word Embedding Model.

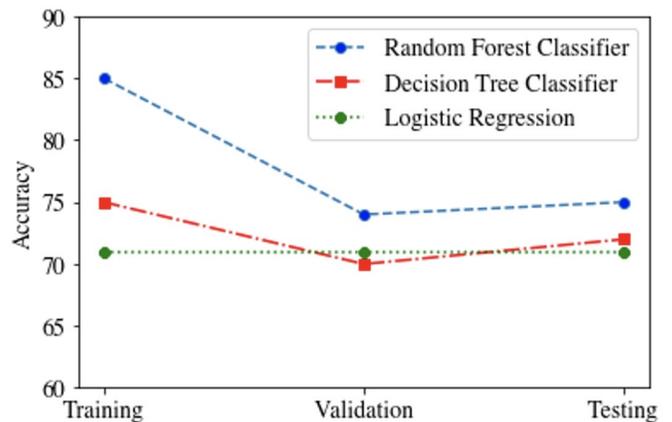

Fig. 9. The Accuracy of the used Classifiers with NMF Topic Modelling Features.

are then fed to logistic regression, decision tree and random forest classifier. Logistic regression classifier also obtains the best accuracy 73%, compared to decision tree and random forest, which both result in almost similar results - 72% and 71%, respectively. The Fig. 8 shows the results of words' embedding using the three classifiers.

### C. Bi-Directional Long-Short Term Memory (LSTM) Model

The fundamental concept of LSTM is the feedback connection. At first, the model tokenizes the corpus with a maximum unique word = 25000 words out of +26000 words in the whole corpus, then fitted the tokenizer to the train dataset, and transform all datasets. After that, it pads the tokenized dataset to keep all records with the same length and only needed and effective maximum sequence length which equals 120 features. After that, the model builds the Bi-LSTM architecture, train the Recurrent Neural Network (RNN) model on the padded training dataset, and evaluate the RNN through prediction accuracy. The best model is a simple Bi-LSTM NN with 1 embedding, 1 bidirectional layer, 1 dense layer with dropout 30% with 120 features the maximum sequence length used in the padding step with accuracy 85%, 77% and 78% for training, validation and testing datasets.

### D. Non-Negative Matrix Factorization (NMF) Model

In the forth experiment, the model extracts hidden topics that cause the texts in review to occur. For this purpose, it uses NMF. NMF is an unsupervised model that has the ability to discover such latent variables from a large amount of data and the end product is a probability distribution for every topic over words and how likely a word belongs to each topic is also extracted as a distribution over topics. One accredited feature of NMF is that the model has shown to be more effective - compared to other topic models - when it is used for short texts, as those present in reviews. From that prospective, the frequency of the words were extracted using the countvectorizer. the model attempted a different number of hidden topics and empirically concluded that the best number of topics to be extracted is 150. Results, which are plotted in Fig. 9, show that the best result by this method is obtained when a random forest classifier was used with an accuracy approaching 86% in the training dataset and 75% in the testing dataset.

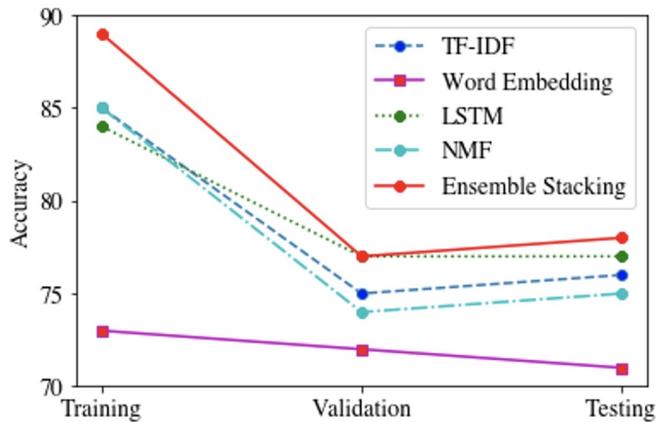

Fig. 10. The Accuracy of the Models Compared to the Proposed Ensemble Model.

### E. Ensemble Stacking Model

In the final set of the experiments there is an ensemble model that employs predictions of the base model that created to build a new model. Therefore, instead of averaging all extracted features from different models, we used the prediction output to feed the ensemble stacking model. Accordingly, the parameters of the model were estimated, and the results showed that the accuracy was increased significantly (it almost approaches 89%) compared to the base models. Fig. 10 plots the accuracy of all models when they were compared to the proposed ensemble model.

## VII. CONCLUSION

Several methods and techniques have been developed for the vital problem of extracting and classifying sentiment inside users' reviews of mobile applications. The problem is challenging because in human language, users can express their thoughts in different vocabularies and words, which are synonymous and polysemous by their nature. In particular, polysemy, in which a single word can have several senses, is significantly difficult. Additionally, texts convey contextual information that cannot be captured using conventional techniques like word-document matrices. In other words, words often tend to be generated according to some hidden topic distributions and they are also dependent inside text.

Inspired by these arguments, this paper attempts to contribute to security threat control by classifying automatically mobile applications based on their accompanied reviews. Accordingly, the proposed model combined the words embedding' features that are extracted from reviews of approximately 18 applications with hidden contextual information inside their texts, which were extracted using NMF topic model. However, to capture the dependency among words, the proposed model employed the use of Bi-LSTM in which the text will be analyzed in both forward and backward directions. We also add another type of features, which are those extracted from word embeddings as the belief is that similar words tend to occur in similar texts.

For the experiment, we built the dataset and the reported experiments showed that the proposed model outperforms

traditional models for classifying user reviews and it is able to capture the announced features in review text. In particular, the proposed model accuracy is above 89% and the improvement compared to the proposed base model is significantly high. The experiments showed that NMF model topic model is able to capture hidden topics inside short texts of users' reviews. On the other hand, both Bi-LSTM and word embeddings are extremely useful for handling synonymous and polysemous words.

In the future, we are going to investigate the impact of stemming in improving model performance. In addition, it is really interesting to look into the effect of the dataset word embedding, therefore we plan to train the model using the dataset instead of employing pretrained word embedding models. We are also going to expand the model to Arabic reviews. the latter language is rich in its vocabulary and the use of synonymy and polysemy is widespread.

**Abstract**—To build a competitive global view from multiple views which will represent all the views within a class label is the primary objective of this work. The first phase involves the extraction of spatio temporal features from videos of skeletal sign language using a 3D convolutional neural network. In phase two, the extracted spatio temporal features are ensembled into a latent low dimensional subspace for embedding in the global view. This is achieved by learning the weights of the linear combination of Laplacian eigenmaps of multiple views. Subsequently, the constructed global view is applied as training data for sign language recognition.

**Keywords**—Laplacian eigenmaps; 3D convolutional networks; sign language recognition; multi view; skeletal data

## I. INTRODUCTION

Sign Language Recognition (SLR) is extremely coordinated movements of hands captured through sensors as 1/2/3D data and translated into text or voice by a machine learning interface [1]. Sign language is a communication medium for hearing impaired people which consists of hand movements and finger shapes that operate independently or collaboratively with respect to upper body parts. SLR is considered an extension of human action recognition (HAR) [2]. Automated HAR or SLR is accomplished through machine learning approaches on multi modal datasets such as RGB, Depth and skeletal information in image, video and data formats. The RGB and depth formats provide appearance information whereas the skeletal joint data exclusively models pose details. Although SL knowledge representation is largely modelled in RGB video formats, it is bottlenecked by motion blurring and spatial resolution of fingers with respect to the frame size. Therefore, the skeletal data has obtained wide acceptance for human action or sign language recognition problems. The 3D skeletal data has been used as vectorized, image and RGB video formats for recognition.

However, the pattern identification process on skeletal 3D video data for building a real time application is a supremely challenging task. Traditional models employed vectorized 3D data for recognition with deep neural networks(DNN) [3]. Above all the DNN models on 3D skeletal action data, long short-term memory (LSTM) [4] networks have shown greater reliability and robustness for HAR tasks. Similarly, 3D skeletal SLR on vectorized data was successfully designed and experimented with color coded Spatio-Temporal features [5]. Singularly, most of these methods presented results related

to cross view testing with poor performance as these models received only single view training. As a result, the above methods failed to generalize on building a real time engine for HAR or SLR.

Meanwhile, the above problem is finding solutions in the form of multi view training on Deep Learning Models. Though multi view processing of video data is having 2 decades of research history, it has gained extensive attention in the last few years due to the progress in deep learning approaches. Earlier DNN proposed were constructed with multiple streams feeding into individual views independently whose Softmax scores are fused for getting a final recognition score. Later, learning approaches have trained multiple CNNs for each view and then learned the concatenated features in the dense layers. This approach has allowed for multiple views to share features across classes. Specifically, this process does not restrict the features that were not significant in the decision making. Additionally, the view specific features that play a major role in articulating the desired outcome are ignored.

To overcome the above challenges, we propose to learn a global synthesized target view by linearly combining the independent multiple views as suggested in [6]. However, these intra class independent views have shown to exhibit unequal similarities with other views which biases the result towards the false positives. Hence, to overcome this uniformity across views that influence the target class, we propose higher order Laplacian eigenmaps from [7]. This enables the target feature reconstruction to have a complete non uniform distribution across the multiple independent views. Consequently, we learn a nonuniform linear combination of weights on independent views which can be generalized for any target view. Finally, the synthesized target view features of all classes are classified using standard deep learning architectures. The proposed methodology called multi view spatio temporal feature embedding (MVSTFE) is illustrated in the following Fig. 1.

The proposed MVSTFE is investigated on our 3D skeletal video datasets of sign language (KLEF3DSL\_2Dskeletal) [8] and four other multiview action datasets NTU RGB-D [9], SBU Kinect Interaction [10], KLYoga3D [11] and KL3D\_MVaction [12]. The performance of the proposed deep networks was tested for the proposed method against the state-of-the-art on datasets. The remaining paper is clustered into four sections. The second section highlights the key historical aspects associated with multi view learning, sign language

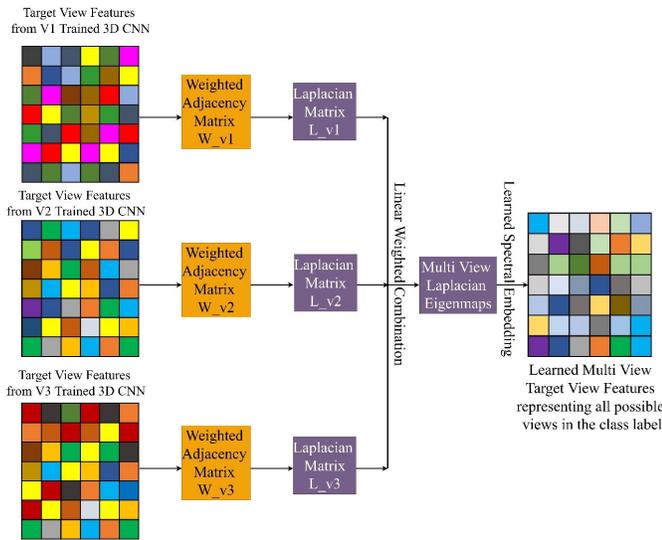

Fig. 1. Illustration of the Proposed Multi View Spatio Temporal Feature Embedding on Skeletal Sign Language Video Data.

recognition and deep networks. The methodology is packaged in the third section and the obtained results for experimentation with analysis are presented in section four. Finally, conclusions were drawn from the analytical insights gained on the overall performance of the proposed models.

## II. LITERATURE REVIEW

This section of the paper dwells on the advantages and disadvantages of the previous methods of sign language and action recognition in multiple views. Additionally, it also discusses the current models in deep metric learning.

With the advent of deep learning frameworks, the 2D video based SLR has become powerful with the option of feature learning rather than feature extraction. A large contingent of them is available for perusal [13]. The accuracies reported by these methods are not reproducible or they simply fail to generalize on the video quality or the signer. This has motivated researchers towards higher dimensional data such as RGB D or 3D skeletal representations. Multi modal video sequences that are fed into multiple streams of a CNN are predominantly researched which have shown evidence of exceptional performances in real time for sign (action) recognition applications [14]. The recognition accuracies were better than the single modal datasets. However, the training requires higher computing powers, and the datasets are captured with special devices making it an unfeasible deployable solution.

Eventually, to develop a real time SLR or HAR system, it is intuitive to learn multi views across datasets. This has initiated action recognition research to move in the direction of developing view-based learning algorithms [15], [16]. Multi view HAR has evolved through research using dictionary learning [17], neural networks with adaptable views [18], convolutional neural networks [19] and deep attention models [20], to name a few. However, the most widely researched and acknowledged models are from deep learning networks. Moreover, visual attention models with deep CNNs have established themselves as a formidable solution to multi view learning [21]. Despite

their success, attention models are specific to a particular view and the view specific features are to be fused accordingly for classification by the dense layers. The fusion mechanisms ensemble the view specific features into a multi view feature vector that has failed to capture the variations in multi view data [22].

Primarily multiview approaches were classified as multi-view learning and view invariant models. In multiview learning, the video input is considered as a time series of data frames in different views which are learned independently by the classifier [23], [24]. Most of the methods used low level observable features for generating discriminative features [17]. Subsequently, multiple training methods were employed for each of the views to find a set of consistent features between a pair of views [25], [26]. The algorithms are used for finding relationships between views canonical correlation analysis(CCA) [27] and projection matrices [28]. Extending to the above methods are matrix factorization [29] and low rank constrained matrix factorization [30] for capturing view similarities. All these models have shown good performance on instances where the number of views were limited and require extensive computational power for deployment.

Alternatively, view invariant models developed linear descriptors to transfer information between views. Accordingly, these models consider target views as a linear combination of views within a class label [6], [7]. Subsequently, the weight vectors are computed by applying optimization in Laplacian space. Moreover, these works assume that all views contribute equally to the target view features. However, in sign language recognition with video data from multiple source views it is difficult to impose the above assumption in real time. To overcome the disadvantage of equal contribution by all views to the target view, we propose to learn these contributions in the Laplacian space using deep learning.

The following points make the proposed method unique from the existing ones:

- 1) To design an unequal linear view combiner to extract target view features.
- 2) To construct highly discriminative Spatio-Temporal features in the Laplacian space.
- 3) To reconstruct learned target vectors into a Spatio-Temporal feature representation with 3D CNNs.

In order to find an appropriate solution for multiview problems, the following objectives are being formulated:

- 1) To design an unequally contributing linear view combiner to identify the linear combinations.
- 2) To learn the mapping function for generating a singularly trainable view invariant Spatio-Temporal feature.
- 3) To initiate anyone view testing model. We call our proposed model multi view spatio temporal feature embedding (MVSTFE).

## III. MULTI VIEW SPATIO TEMPORAL FEATURE EMBEDDING (MVSTFE)

This section describes the proposed multi view spatio temporal feature embedding model for multi view sign language

recognition on skeletal video datasets. First, a cluster of 3D CNNs is trained independently on individual views for all classes in the dataset. Secondly, a target view is selected randomly which is referenced on the pre trained 3D CNNs for feature extraction. The extracted features from independent view streams are learned by compiling Laplacian eigenmaps to construct a combined target view. This combined target view features will represent a linear combination of Laplacian eigen maps from multiple views generating a highly discriminative feature for all views of the target view class. Finally, these learned target view features will be used for training any deep classifier for sign or action recognition.

#### A. Independent View 3D CNN Model

The primary step in the process of multi view sign language recognition is to design and train a 3D convolutional neural network (3D CNN). The 3D CNN takes input as the skeletal video sequences as input for supervised training. The number

of 3D CNN streams are equal to the number of source views available for training. The 3D CNN architecture used in this work is shown in Fig. 2. The model has 4 pairs of 3D convolutional layers with one set of batch normalization and maximum pooling layers after each pair respectively. The input of the network is a 2D skeletal video sequence of size  $256 \times 256 \times 3$  with 100 frames. The features at the end of the convolutional layers are flattened and inputted to two fully connected layers with the last layers being Softmax.

Let  $X^{vc} = (x_v = \{S_v\} \forall v = 1 \text{ to } V, c = 1 \text{ to } C)$  be the RGB skeletal video sequences in  $V$  views with  $V \in R^3$ . The 3D CNN model will extract the features  $f^v$  from  $x_v$  with view specific labels  $y_v$  using the trainable parameters  $\theta_{3D}$  by optimizing a loss function  $L$  on the overall multi view dataset as

$$\theta_{3D} = \arg \min_{\theta_{3D}} L(\theta_{3D}; x_v, y_v) \quad (1)$$

For classification tasks, we need a global loss function to

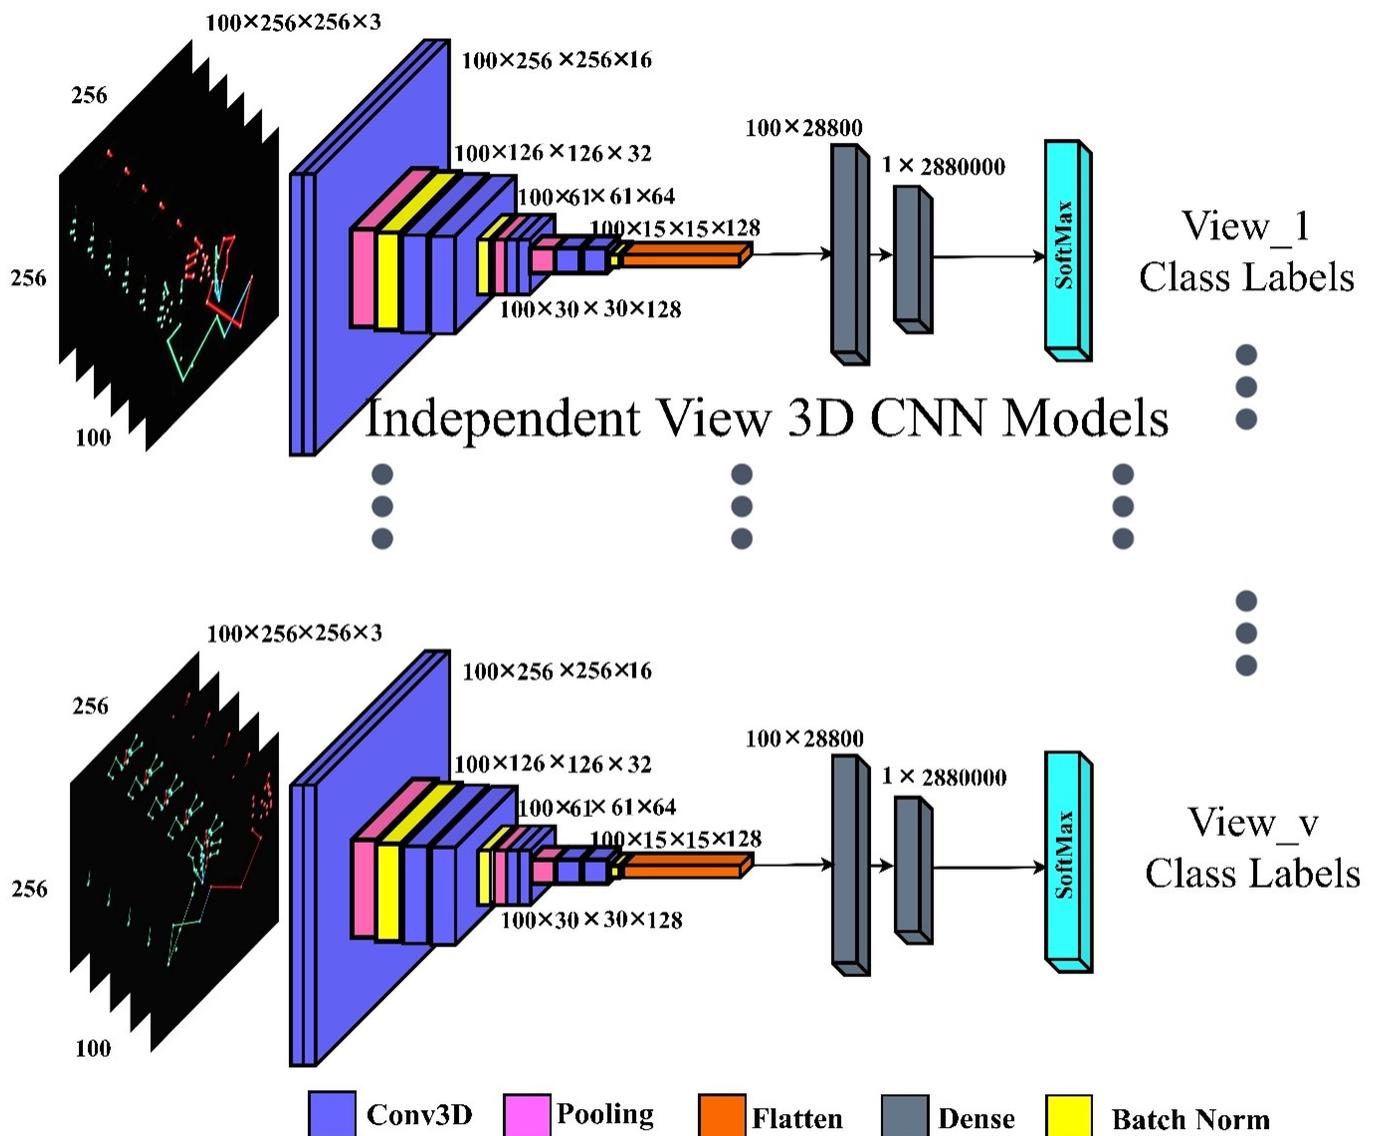

Fig. 2. 3D CNN Architecture for Training Multiple Views Independently across All Classes.

discriminate the classes with the help of SoftMax layers. The class label prediction is computed on the embedding space using the cross-entropy loss functional defined as

$$l_{CrossEnt} = - \sum_{i=1}^C (y_i \log(\hat{y}_i) + (1 - y_i) \log(1 - \hat{y}_i)) \quad (2)$$

The  $l_{CrossEnt}$  is the loss function for training the network. The  $(\hat{y}_i)$  is the predicted label and  $y_i$  is the actual. The C defines the total number of classes in the dataset. Each stream in the network is view independent with the specifications as shown in Fig. 2. Consequently, weight and biases are initialized using unit variance zero mean Gaussian random variable. The filter sizes in all 3D CNN layers is fixed at  $3 \times 3 \times 3$ . Moreover, the learning rate is dynamically controlled with 10% decrease rate from the previous valued whenever the loss became constant across 10 epochs. The initial learning rate was selected as 0.0001. Stochastic gradient descent optimizer is applied to update the wights and biases in the network. This trained network will be used to extract spatio temporal features from a target view which are further used to construct a combined view features. These constructed view features have the ability to represent all the views within a class label.

### B. Combined View Feature Generation

Given a sign class in a specific target view  $x_{vt}$  as input the trained model  $\theta_{3D}$ , the output features  $f_v$  at the end of dense layers are represented as

$$\{f_v\}_{v=\{1,V\}} = \sum_{i=1}^I \sum_{j=1}^J x_v(i,j) * K(k-i, k-j) \forall k \in \text{kernel size} \quad (3)$$

The features extraction network is shown in Fig. 3. The network consists of four pairs of convolutional layers with rectified linear activations followed by a  $2 \times 2$  window maximum pooling layer. The strides of the kernels in convolution layers is one and that of maximum pooling is two. After maximum pooling a batch normalization layer is added to standardize the inputs to the deeper layers. Finally, two fully connected layers are added to learn on the feature extracted in the convolutional layers. Subsequently, the spatial features at the output of dense layers are concatenated along the frames to generate a complete spatio temporal feature matrix representing the 2D skeletal video sequence. Altogether, V streams operate independently in the network generating view specific class features  $F^{cv} = \{f_{ic}\} \forall i = 1 \text{ to } V \in R^{g \times N}$ , Where  $g$  is the dimensionality of the features and  $N$  is the number of frames. The model is trained with categorical cross entropy loss with stochastic gradient descent optimizer on the entire dataset. The trained model  $\theta_{3D}$  is applied on all the input video frames to extract the feature samples as

$$F^{cv} = \widetilde{\theta_{3D}}(w, b) \times x_{vt}^c \forall V \ \& \ C \in R^{g \times N} \quad (4)$$

The spatio temporal feature matrix  $F^{cv}$  consists of the target view features inferred from independently trained views across all classes. The objective is to generate a feature matrix that will represent all views in a class as a linear combination of the extracted features. Traditionally, this is achieved by considering the all the mixing coefficients are equally distributed across all views. However, equally distribution of information across all views has produced ambiguous recognition accuracies. To overcome this, non-uniform distribution is proposed [7] with Laplacian eigenmaps. In this work, we incorporate the process of spectral embedding using Laplacian eigenmaps to calculate the mixing coefficients of the linear combination.

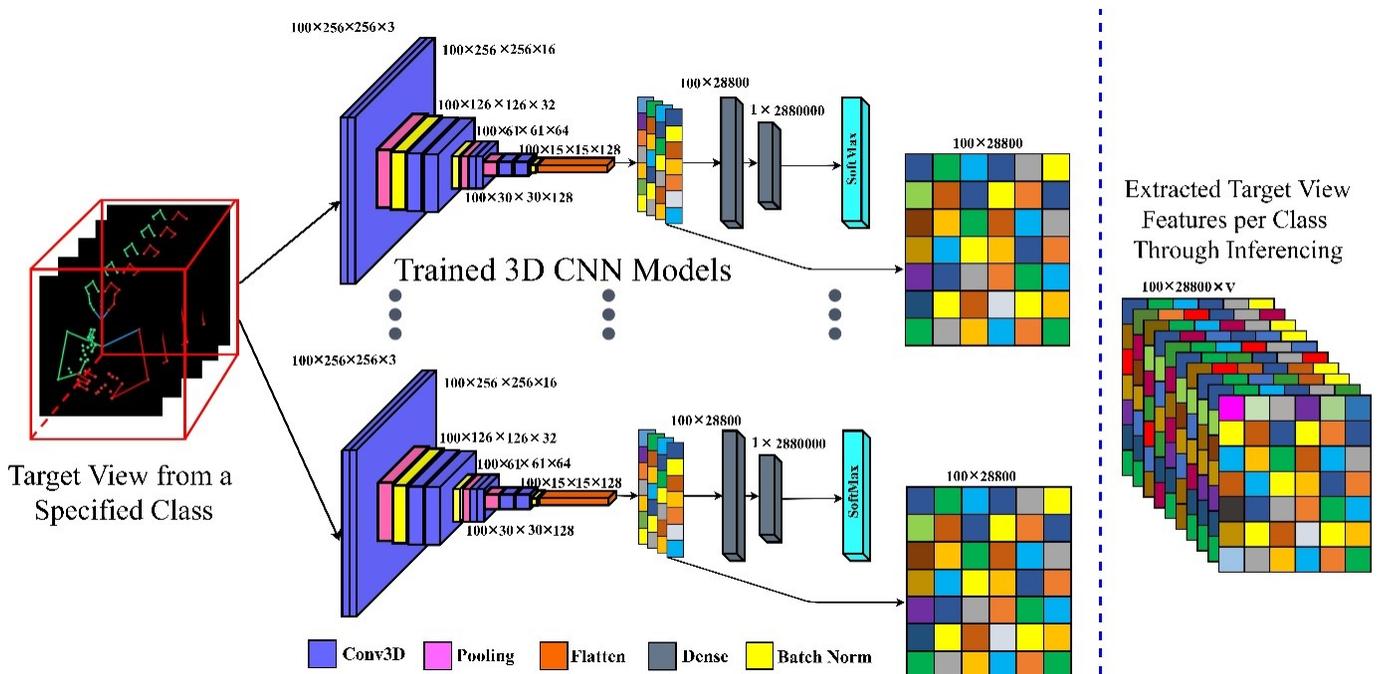

Fig. 3. The Inferring Process on Trained 3D CNN Model with Features Extracted from Multiple Layers in the Network.

### C. Constructing the Non-uniform View Linear Combiner

Given a set of spatio temporal target view features  $F^{cv} \in R^{d \times V}$  from a particular class label  $y_{i \in C}$  with  $V$  views, these views can be linearly combined with coefficients as

$$F_{Comb}^{cv} = \sum_{i=1}^V \lambda^i F^{cv(i)} \quad (5)$$

Where,  $V$  is the total number of source views and  $d$  is the feature matrix dimensionality.  $F_{Comb}^{cv}$  is the combined feature representation of the target feature. The mixing coefficients  $\lambda^i \forall i = 1$  to  $V$  is the weighted combination. The constraint on the mixing coefficient is

$$\sum_{i=1}^V \lambda^i = 1, \lambda^i > 0 \quad (6)$$

The intent in the above representation is to generate a global view that is compatible with all the views in the class. Mostly, the coefficient  $\lambda^i$  is considered as the average  $1/V$  across all the views. However, in reality, the views that are in close proximity with the target view contribute more than  $1/V$ . Consequently, the obtained linearly combined global view features are least compatible for representing all the views in a class. This problem is solved by evaluating the mixing coefficients of individual views with the help of cost function derived using Laplacian eigenmaps [7].

First, the target features are arranged a  $V$  data matrices  $F = \{F^{cv} \in R^d\}_{v=1}^V \forall d = R^{g \times N \times V}$  as shown in the output of Fig. 3. The objective is to calculate a set of mixing coefficients  $\lambda = \{\lambda^i\}_{i=1}^V$ . We start by initializing  $\lambda = [\frac{1}{V}, \dots, \frac{1}{V}]$ . Subsequently, set the  $g \times N$  feature points obtained from trained network in the  $t^{th}$  target view.

To compute the combined target view embedding features, we subsequently compute the weighted adjacency matrix  $A^t$  on the target features and the Laplacian matrix  $L^i$  of the individual views with  $i \in (1, 2, \dots, V)$ . Consequently, the global Laplacian  $L^G$  of the entire target view class is computed as a linear combination of initial weights. The spectral encoding,  $Y^G$  can be computed from eigen value decomposition of  $L^G$  as a Laplacian eigen map. Accordingly, select the smallest eigen values other than the zeroth one, reconstruct the spectral encoding  $Y^{G*}$ . Using the reconstructed spectral encoding  $Y^{G*}$  and  $Y^G$ , update the mixing coefficients of the linear combination  $\lambda^i$ . Optimize till the distance between the reconstructed and the original spectral encoding are less than a set experimental threshold.

### D. Construction of Laplacian Eigenmaps and Spectral Embedding

Given the feature data points in the  $t^{th}$  target view  $\{F^{cv} \in R^d\}_{v=1}^V$  with  $g \times N$  data points, we first compute the adjacency matrix  $A^t$  as

$$[A^t]_{i,j} = e^{-\left(\frac{\|F^{ci} - F^{cj}\|_2}{\sigma}\right)^2} \quad \forall F^{ci} \ \& \ F^{cj} \ \text{are associated} \quad (7)$$

Where,  $A^t$  is a symmetric matrix of size  $gN \times gN$ . The value of  $\sigma$  is selected as 2. The adjacency matrix establishes a link

between the target features extracted from trained CNN in Fig. 2 in all views. If the distance between the features is small, the value in the  $(i, j)^{th}$  position tends towards 1 and vice versa. Consequently,  $A^t$  establishes a relationship between the features points formed by a set of  $d$  data points in multiple views.

Subsequently, to compute a single view feature combination from multiple target view features Laplacian eigenmaps were used from [30]. Laplacian eigenmaps reduces the data by projecting data on a different spectral view without compromising on the relationships between the feature points. Accordingly, the spectral encoding  $Y^{G*}$  can be computed by minimizing the cost function defined as

$$f(Y^G) = \sum_{i,j \in \{\forall gN\}} \|y_i^G - y_j^G\|^2 [A^t]_{i,j} \quad (8)$$

The above representation gives the difference between two embedding features in multiple views modulated by their association values in adjacency matrix. If the feature points in multiple views are in close proximity, the adjacency matrix value is large, thus contributing more to cost function. As a result of this, similar data points are preserved in the spectral embedding from different views. Eventually, the solution to the optimization is transformed into a minimization problem as described in [30] as

$$Y^{G*} = \arg \min_{Y^{G^T} D Y^G = 1, Y^{G^T} D 1 = 0} \text{tr} \left( (Y^G)^T L^G Y^G \right) \quad (9)$$

The global laplacian matrix  $L^G$  is computed as  $L^G = D - A^t$ , where  $D$  gives the degree of connectivity in the data as  $[D]_{i,i} = \sum_{j=1}^{gN} [A^t]_{i,j}$ . Computing  $Y^{G*}$  in (9) is equivalent to finding eigen vectors of  $Y^{G*}$  as  $L^G Y^{G*} = \alpha D Y^{G*}$ . The spectral embedding  $Y^{G*}$  can also be calculated by simply computing the eigen values of  $L^G$ . Finally, the laplacian eigen maps  $L^G$  and spectral embedding  $Y^{G*}$  are used to compute the cost function to find the mixing coefficients as

$$\lambda^i = \frac{\text{tr} \left( (Y^G)^T L^i Y^{G*} \right)}{\sum_{i=1}^V \text{tr} \left( (Y^G)^T L^i Y^{G*} \right)} \quad (10)$$

Overall, the convergence of (10) can be decided based on the  $l_2$  norm between iterations as

$$\sqrt{\sum_{i=1}^V (\lambda_k^i - \lambda_{k-1}^i)^2} < \delta \quad (11)$$

Here,  $\lambda_k^i$  is the value of mixing coefficients at  $k^{th}$  iteration and  $\lambda_{k-1}^i$  is the value at  $(k-1)^{th}$  iteration. The constant  $\delta$  is a user defined parameter less than 1. Eventually, the value of  $\lambda^i$  will be different from  $\frac{1}{V}$  where multiple views are contributing differently to the target view. Finally, by multiplying the obtained mixing coefficients with target features from different views, we obtain a global view feature that closely relates to the target view features. Furthermore, the resulting single view target view feature is highly discriminative across classes and has found have close proximity with all the views from within a class label. The following section describes the datasets and

experiments conducted to ascertain the performance of the proposed method.

#### IV. EXPERIMENTATION

The proposed view invariant method, Deep Metric Encoder Decoder (DMED) was trained and tested on multi view skeletal sign (action) video datasets in multiple ratios. We present a one – to – one, one – to – many, many – to – one and many – to – many cross view training and testing approaches on DMED. Further, we compare the results of our approach with other state – of – the – art multi view methods. Finally, multiple CNNs architecture’s for classification were tested to check the robustness of the proposed feature extraction process in generating view invariant features.

##### A. Skeletal Video Datasets and Evaluation Metrics

The multi view sign language dataset KLEF3DSL\_2Dskeletal with  $V = 15$  views, 200 classes is generated at KL Biomechanics and Vision Computing Research Centre using 3D motion capture technology [8]. Further, the proposed model is evaluated on multi view benchmark skeletal action datasets such as NTU RGB-D [9], SBU Kinect Interaction [10], KLYoga3D [11] and KL3D\_MVaction [12]. A small subset of data sample from KLEF3DSL\_2Dskeletal is presented in Fig. 4 for a sign basketball. In this work we are limiting our views to 15 due to computational constraints. The training testing ratios are kept constant across all networks and datasets. The selected train test ratios are one – to – one and one – to – many. The remaining views were also evaluated but are not presented here as they have not produced any noticeable performance changes when compared to the selected ones. Since there are no multi view sign language datasets, we evaluated our model on multi view benchmark action datasets. Despite the availability of huge classes in action datasets, we selected only 40 action classes for training with 15 views from each class for maintaining uniformity during comparison. In some cases, unavailability of views has prompted us to generate random views by altering the viewing angles of joints. Here, the evaluation is performed independent of the type of view in which the action is recorded. Fig. 5(a), (b) and (c) shows samples from NTU RGB-D, KL3D\_MVaction and KLYoga3D dataset respectively. We used mean recognition accuracy (mRA) for performance evaluations.

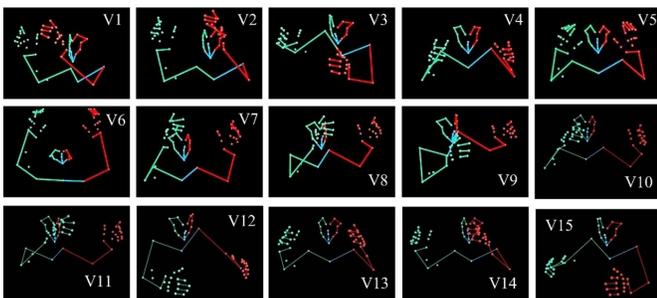

Fig. 4. KLEF3DSL\_2Dskeletal Sign Language Video Dataset. A Sample Frame in 15 Different Views from the Skeletal Video Sign “Basketball”.

The first 3D CNN network in Fig. 2 extracts the features from skeletal sign (action) video datasets. The network in Fig. 2 is trained on all the available views with similar hyper parameters except for the learning rate and number of epochs. The learning rate for KLEF3DSL\_2Dskeletal sign language video dataset is 0.001 and it was 0.005 for all other action datasets. However, the KLYoga3D was trained on a learning rate of 0.0001 for 200 epochs due to large number of skeletal joints. The remaining datasets were trained for 150 epochs. The maximum recognition accuracy achieved during training was around 0.973 for KLEF3DSL\_2Dskeletal sign language, 0.942 for NTU RGB-D, 0.845 for SBU Kinect Interaction, 0.902 for KLYoga3D and 0.985 for KL3D\_MVaction datasets respectively. Consequently, these individual view trained 3D CNN streams will be inferenced for all dataset samples to generate global view features which represent all views within a class label.

To accomplish the proposed objectives of MVSTFE, we select a target view from each class for inferencing on the trained 3D CNN in Fig. 2 as shown in Fig. 3. The output of Fig. 3 are the features extracted from each of the individual views for the inputted target view. These target view features are combined using the non – uniform linear combiner by computing the value of linear combination value  $\lambda^i$  using spectral embedding of Laplacian eigenmaps. The hyperparameter ( $\delta$ ) for MVSTFE on KLEF3DSL\_2Dskeletal ( $\delta = 0.54$ ), NTU RGB-D ( $\delta = 0.71$ ), SBU Kinect Interaction ( $\delta = 0.94$ ), KLYoga3D ( $\delta = 0.83$ ) and KL3D\_MVaction ( $\delta = 0.57$ ) is selected iteratively. Finally, the generated combined view target features are used for classification. Specifically, to test the robustness of the features in the classification process, we standardized it by training and inferencing on benchmark CNN architectures. However, these architectures are miniaturized in layers and depth to source the feature inputs of size  $100 \times 100$ . Moreover, the regular 2D Convolutional layers in these models were replaced with 3D layers. This has been done to directly extract spatio temporal features from the network. To demonstrate the actual usefulness of these view invariant features, which resulted in the formulation of multiple performance evaluation procedures on the classifier as presented in the following sections.

##### B. One – to – One Classifier Performance Evaluation

The one – to – one cross view recognition experiment is conducted by training the classifier in Fig. 6. with one view global target feature representing all views and inferencing on a different views. Specifically, the key aspect of this experiment is to test the robustness of the generated view invariant features in estimating a class label based on its constituent views on which it is formulated. To demonstrate this, we designed a CNN network inspired from VGG-16 with 6 convolutional layers, 3 maximum pooling, one flatten and 2 dense layers. The network is trained with the generated view invariant features in each class and tested with view specific features. Consequently, we selected the learning rate of 0.01 for this network with categorical cross entropy loss and Adam optimizer. Subsequently, the above procedure is repeated for all datasets with the same hyper parameters. Furthermore, three benchmark architectures such as Inception – V4, GoogleNet and ResNet – 50 were trained and tested. However, vanishing gradients and overfitting problem were eliminated by re-designing the

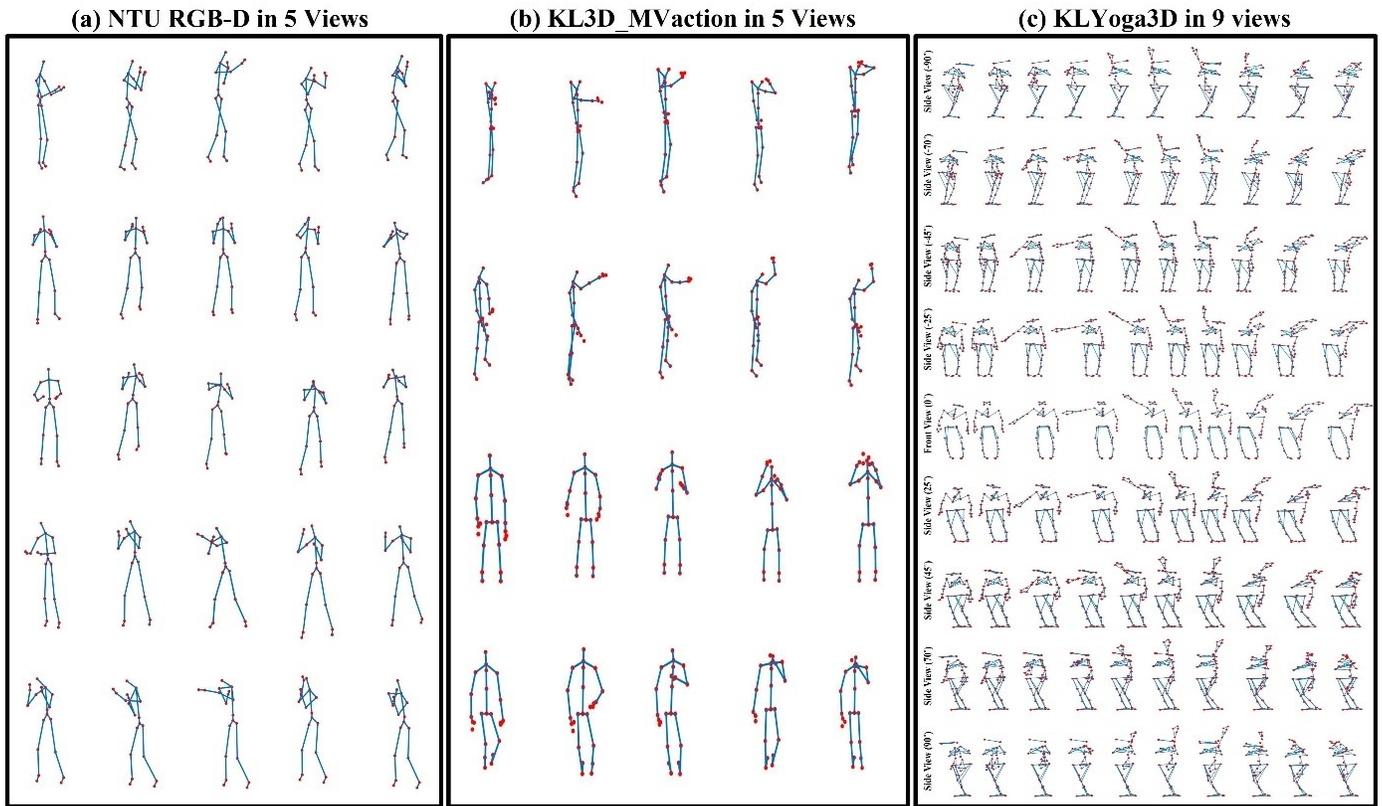

Fig. 5. Multi View Benchmark Action Datasets for Model Evaluation.

architectures with only half the layers than the original models. On the other hand, the structure of the original models were preserved to achieve highest performance. Eventually, mRA is computed during inferencing and the 10-fold maximum value is presented in Table I for all the datasets.

After examining the mRA in Table I, it is evident that all the models perform well on test views that have more visual information when compared to views with overlapping joints. The outcomes from Table I also suggests that the view target global features have shown to reduce false positives in all

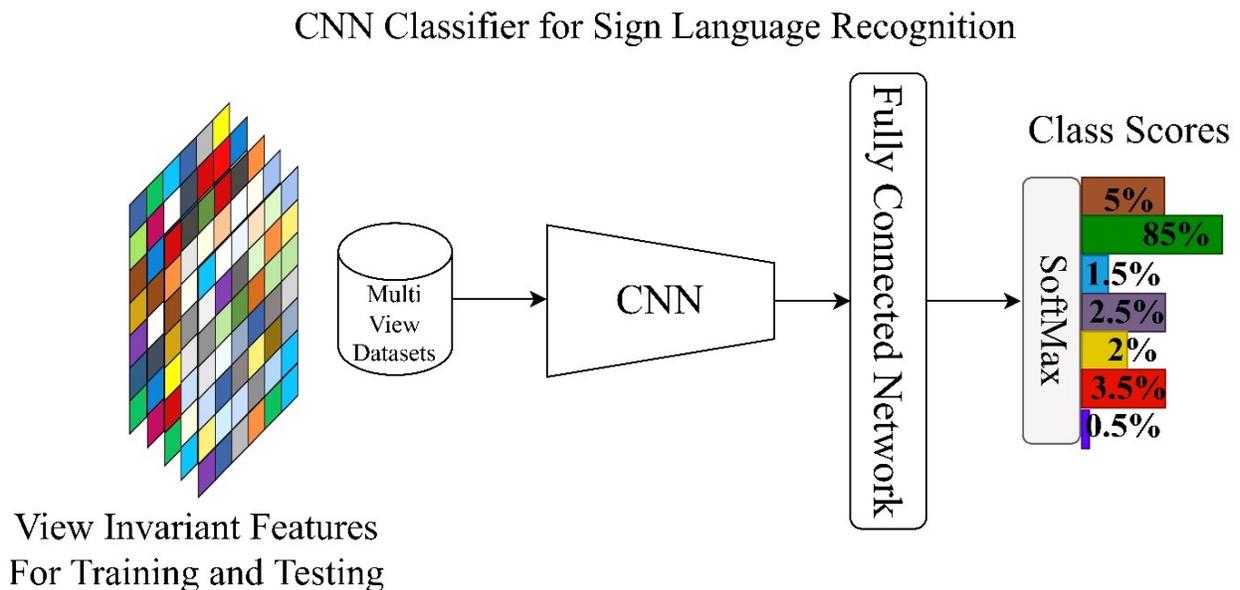

Fig. 6. CNN Architecture for Classification.

TABLE I. ONE – TO – ONE PERFORMANCE EVALUATION OF THE SELECTED CLASSIFIERS ON SKELETAL VIDEO DATASETS TRAINED WITH THE ONE VIEW OF TARGET VIEW FEATURE AND TESTED WITH ALL SPECIFIC VIEW FEATURES. THE PERFORMANCE OF THE CLASSIFIER IS MEASURED USING mRA

classes. Moreover, the proposed work also highlights the used of any single view for testing as against the previous models, where all views are required as input. Consequently, it will be interesting to test the many – to – one cross view performance, where the models are trained with view specific features and tested with only one target view invariant feature.

### C. Many – to – One Classifier Performance Evaluation

Here, we train the classifiers with all the views and test it only one target view feature. Table II shows mRA values for multiple sets of training views. The results in Table II show that the performance of the MVSTFE model has increased when trained with multiple view features. On the other hand, Inception – V4 has shown to outperform all other classifiers used for experimentation due to the fact that it contains multiple attention layers for selecting maximally contributing vectors.

### D. Comparisons against other View Invariant Generation Techniques

The previous models applied spectral clustering with matrix factorization [28], auto – weighted spectral clustering [7] and multi view temporal ensemble [6] are designed to generate complimentary views and correspondingly reconstructing a global view. Additionally, the number of views used in these models is comparatively lower than our proposed work. Increasing the number of views in the above models will increase the computational complexity, which was reduced in MVSTFE. Table III presents the comparisons of the above multi view recognition methods with MVSTFE.

### E. Validation of MVSTFE with State – of – the – Art Multi View Methods

Historical validation of the proposed MVSTFE is performed by comparing it with state – of – the – art multi view methods in Table IV. The methods selected for comparison have applied some kind of deep learning algorithms

for generation and classification of view video data. Since the data used in these methods were different, we recreated these models from scratch as given in their respective manuscripts. All the experiments were conducted on the benchmark skeletal datasets used in this work with one – to – one train – test pattern. We presented our best result obtained from inception V4 classifier in this comparison. However, the hyper parameters for the comparison networks was adopted from our Inception V4. The proposed MVSTFE has outperformed the existing models as can be seen in Table IV.

## V. CONCLUSION

This work proposed a deep learning based spectral embedding method for generating a single global view from a set of multi view features. We trained a 3D CNN on each of the available views and inferring on a target view video data to extract features. Eventually, these target features are combined linearly by calculating the mixing coefficients for making a global feature representation for all possible views. Consequently, the mixing coefficients are computed using spectral embedding in Laplacian eigen space which preserves proximity between views within the class label. Experimentation has shown that the proposed MVSTEF on 2D video based skeletal sign language dataset and the benchmark action

datasets has outperformed the previous multiview baseline models.

**Abstract**—Human activity recognition has become so widespread in recent times. Due to the modern advancements of technology, it has become an important solution to many problems in various fields such as medicine, industry, and sports. And this subject got the attention of a lot of researchers. Along with problems like wasted time in maintenance centers, we proposed a system that extracts worker poses from videos by using pose classification. In this paper, we have tested two algorithms to detect worker activity. This system aims to detect and classify positive and negative worker's activities in car maintenance centers such as (changing the tire, changing oil, using the phone, standing without work). We have conducted two experiments, the first experiment was for comparison between algorithms to determine the most accurate algorithm in recognizing the activities performed. The experiment was done using two different algorithms (1 dollar recognizer and Fast Dynamic time warping) on 3 participants in a controlled area. The one-dollar recognizer has achieved a 97% accuracy compared to the fastDTW with 86%. The second experiment was conducted to measure the performance of a one-dollar algorithm with different participants. The results show that a 1 dollar recognizer achieved an accuracy of 94.2% when tested on 420 different videos.

**Keywords**—Machine learning; human activity recognition; pose identification; industry analysis

## I. INTRODUCTION

Human activity recognition has gained importance in recent years because of its applications in various fields like health, security and surveillance, entertainment, and intelligent environments. Human activity recognition accounted a lot of researches in different approaches, like wearable devices [1][2][3][4][5], object-tagged[6][7][8], and device-free [9][10][11], to acknowledge human activities. Wasted time has become a prominent problem in various fields of work, and this problem affects the percentage of products and services required in our daily lives. The survey provided by Salary.com [12] found that 89% of workers admitted to wasting time at work every day. The survey showed that 61% claim to waste between 30 minutes to an hour a day. While this may not seem like much, it can add up to 5 hours a week or 260 hours a year/per employee. Maintenance places and factories are the most vulnerable to this issue. The survey depend heavily on human activity, which harms production rates and disrupts many required services. The field of car maintenance has become an important field in our daily life, and car workshops have spread greatly in the recent period, but difficulties have begun to appear inside the maintenance centers. The problem is that workers waste a lot of time while working by doing some negative activities. Fig. 1 shows a worker who uses the

phone at work. Moreover, there are a lot of negative activities such as (eating, drinking, talking to others, standing without work...). Besides, it is difficult to have an employee responsible for monitoring the worker for no less than 12 hours.

Fig. 1. A Negative Wasting Time Activity (using Mobile while being in Work).

The maintenance workshop could have dozens of activities some of them are consider positive and other consider negative. However, some activities look very similar such as shown in Fig. 2(a) and Fig. 2(b). The posture of changing oil activity looks very similar in motion trajectory to engine rebuild activity.

(a) Changing oil

(b) Engine rebuild

Fig. 2. A Sample for Positive Activity in Workshop.

The proposed system works by taking an input of recording videos of the worker's activities inside the maintenance center. The video is classified to determine the number of activities the worker performed such as (Changing the oil, changing the tire, or using the phone... Etc.). The classification was done by taking the path (x, y) of the important points in the skeleton

as shown in Fig.3, Fig. 4 and comparing them with the points that were taken from the collector of the data set. The system can determine the type of activities that the worker performed in the video.

Fig. 3. Worker Changing Oil.

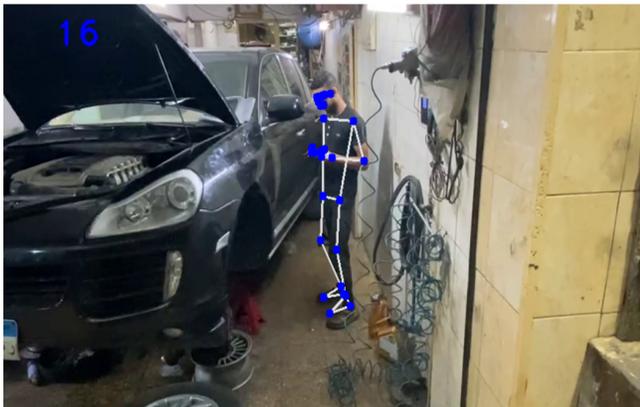

Fig. 4. Worker use Mobile.

The main contribution of this paper is to create a human activity recognition system that extract worker poses from the videos by using pose classification. The system used a dollar recognizer (1\$) to detect worker positive and negative activities in maintenance workshop. As a result of the presence of many maintenance workshops, a problem occurred which is many workers neglect their work resulting in the occurrence of negative activities. Therefore, this paper is needed to detect the positive and negative activities and differentiate between them without the need for a person to monitor these activities and depend on the computer as an alternative. The purpose of this paper as well as to facilitate the reduction of the waste time done by each worker so they can be more productive. Moreover, positive activity is detected to reward the committed workers and to evaluate the performance of the workers in general.

## II. RELATED WORK

Due to the popularity of human activity recognition systems and with the rapid advancement of computer technology, lots of research efforts were dedicated to this subject. Congcong Liu et al. [6], has proposed a activity recognition

method that can identify abnormal human activity recognition in surveillance video using a combination of Bayes Classifier and CNN (Convolution Neural Network) to detect the activities and also use KTH dataset as the input of Bayes Classifier and CNN. Another system that is able to recognize human activity is proposed by Bagate et al. [1], which identifies the activity using RGB-D sensors that is developed with deep learning model CNN (Convolution Neural Network) and using knight depth camera for capturing 3-D skeleton data. For Human detection and Motion tracking, Sandar et al. [8], used frame wise displacement and recognition is based on the skeletal model with the deep learning framework to understand human behavior in the indoor and outdoor environment. And in the field of Human activity recognition by sensors, Murat et al. [13], automatically identifies human activity using joint coordinates skeletons and uses two types of deep learning to make classification and use data set of multiple people in the images. Song et al. [5], propose (1D) Convolution Neural Network (CNN) -based method for recognizing the activities using collected accelerometer data from smartphones and this method gave high accuracy of 92.71. And using wearable devices, Tahera et al. [2], used the eSense accelerometer sensor to detect the matching of activity between the head and the mouth, from this collected data some activities of the head and mouth were identified and using the machine learning and deep learning for data classification. Nitin et al. [14], propose to use the TCN (temporal Convolutional Network) to recognize the activities because it better than other deep learning methods , it has strong ability to capture long-term dependencies. Godwin et al. [9], combined gyroscope sensors with accelerometers to detect human activity and perform analysis and recognition using ANN (artificial neural networks). Tsokov et al. [15], use of the 1D synaptic neural network (CNN) with accelerometer data to make recognition of human activity more accurate.

Isah et al. [3] collected hip motion from the different waist mounted sensors, and convert each signal into spectrum image and use them as input to the CNN (Convolution Neural Network). Nacer et al. [16], use entropy point estimate for 1D heat map to separate between human maps and animal maps to give high accuracy in human activity recognition. Selçuk et al. [10] used a novel design to reduce the number of sensors used for human activity recognition and detection by using (EMD) empirical mode decomposition. And Jiewen et al. [4], identified and interacted by focusing on two wearable cameras and the interactive activities that involve only two people. Peter Washington et al. [11], addressed the topic of identifying human activity in the treatment of autism and grouped movements with a handheld camera and used the classifier CNN (Convolution Neural Network) for detecting headbanging in home videos. Hristov et al. [17]proposed a method that classifies human activity by using 3D skeleton data and normalizing it beforehand and it was represented in 2 forms. They applied this method to the UTMHAD dataset, the system has achieved a 92.4% accuracy rate. Heilym et al. [18] was opposed to the idea of wearing devices and sensors to determine human activities and pointed out that these devices could cause inconvenience to the bearer and could give false results if used in crowded places, so he relied on the camera and determining the activity through the human skeleton features. Salahuddin Saddar et al. [19]have an objective which is to compare some machine learning algorithms

TABLE I. COMPARISON WITH SIMILAR SYSTEMS

Paper	Activities	Algorithms	Methods	Area	Accuracy
[7]	stopping the furnace operating checking the solid fuel tank checking the gear motor and auger tightening the mounting screws of the gear motor	CNN CNN+SVM Yolov3	Image classification	controlled area	95.7%
[22]	grab tools hammers nail wrench use screwdriver	CNN	Image classification	controlled area	87%
This paper	changing tire changing oil use mobile stand without work	one-dollar Fastdtw	Pose classification	uncontrolled area	95%

that were used in human activity recognition such as (SVM, Decision Trees, Random Forests, XGBoost). They tested these algorithms with measurement sensor data that was recently released from the LARA dataset. The XGBoost has achieved the best accuracy with a rate of 78.6%. Ismael et al. [20] took the topic of identifying human activity in terms of reducing aggressive actions inside prisons and on the streets to reduce aggression and used "handcrafted/learned" as a hybrid feature framework that gave it very high accuracy rates. Yusuf Erkan et al. [21] used depth sensor to classify 27 different activities and by using long-short term memory, they analyzed skeleton data. It has achieved an accuracy rate 93%. Halikowski et al. [7], presented a system for monitoring activities inside the factory using (CNN, CNN+SVM, Yolov3) algorithms. They used some activities such as (stopping the furnace operating, checking the solid fuel tank, checking the gear motor and auger, tightening the mounting screws of the gear motor) and achieved an accuracy 94%. The work presented utilize deep learning for extracting features without considering human post estimation. Zhaozheng et al. [22] presented a system for detecting activities in smart manufacturing. They used some activities (grab tools, hammer nail, wrench use, rest lever, screwdriver). They captured these activities using IMU and sEMG signals obtained from a MYO armband. They extract feature using a convolutional neural network (CNN) model. The CNN model is evaluated on this data set and achieves 98% and 87% recognition accuracy in the half-half and leave-one-out experiments. All of the previous explained the importance of identifying human activity in solving some problems in various fields. Alghyaline et al. [23] has proposed system that detects different actions in the street such as (walking, running, stopping). They measure the movement type by using three different techniques which are (Yolo, Kalman filter, Homography). The method was tested by CCTV camera and BEHAVE dataset, it has achieved an accuracy of 96.9% for the Behave dataset and achieved 88.4% for the dataset that was collected by CCTV camera. Arzani et al. [24] proposed a structural prediction strategy proposed by this system to recognize the simple and complex actions by using probabilistic graphical models (PGMs). These activities require various model parametrization to be spanned, category-switching scheme is used to deal with this parametrization. Three datasets were used to cover the two action types which are (CAD-60, UT-Kinect, and Florence 3-D). This system could recognize simple and complex activities while the previous systems focused on only one type of these two. The system proposed by Archana et al. [25] recognized human activity with Resnet and 3D CNN without using the LSTM- attention model as the 3D CNN

is achieved by modifying the 2D Resnet in order to achieve better accuracy, so that the development of detecting, and recognizing real-time human motion has been achieved. The system proposed by Zheng Dong et al. [26] resolves the issue of incomplete feature extraction by a new framework called CapsGaNNet which proposed multi-feature extraction, and gated recurrent units (GRU) with attention mechanisms. The constructed dataset was a daily and aggressive activity dataset (DAAD). Moreover, the paper approved that CapsGaNNet has efficiently improved the accuracy of recognition. Radhika V. et al. [27] proposed a system that used Random Forest Algorithm (RFA) to recognize human activity using Smartphones. RFA algorithm has different decision trees that is used in classification of the dataset. There were four various evaluation parameters used to measure the performance of the system such as F1 score, accuracy, precision, and sensitivity. The accuracy of the system achieved 98.34%. The system proposed by Navita et al. [28] detects the activity of aged people using the Internet of Things (IoT) monitoring model to monitor the activity of their health state. The SVM has attained 98.03%. The proposed system by Yin Tang et al. [29], a new CNN model that used hierarchical-split (HS) for a huge number of varieties in human activity recognition. Each one feature layer uses multi-scale feature representation by capturing a wide range of receptive fields of human activities. The proposed HS model can achieve high recognition performance compared to similar models complexities. The system achieved 94.10% SOTA accuracy on human activity recognition dataset. The proposed system by Maciej A. Noras et al. [30] discussed the topic of far-field electric field sensors, which accompany different physical events. The determination of activities in the proximity of the sensor is done by field signature signals. Moreover, the paper provided enhancements for electric field sensor usage and signal processing in human and animal motion recognition, perimeter monitoring, moving objects recognition, and electric power faults detection.

Table I shows a comparison between our system and different systems. The first system, Halikowski et al. [7] proposed this system to measure the performance of the worker in the factory, they recognized four different activities which are (stopping the furnace operating, checking the solid fuel tank, checking the gear motor and auger, tightening the mounting screws of the gear motor) in a controlled area using image classification method. They used more than one algorithm such as ( CNN, CNN+SVM, Yolov3), their system has achieved a 95.7% accuracy rate. The second system which is proposed by Zhaozheng et al. [22] was used for qualification and evaluation of the workers. They also used

image classification to detect four activities which are (grab tools, hammer nail, wrench use, rest lever, screwdriver) in a controlled area, and they achieved an accuracy rate of 87%. Our system was proposed to detect the activities of the worker inside the car maintenance center and differentiate between the negative and the positive activities. To help the workshop owner in measuring the worker performance, the system has used the pose classification method to detect four different activities which are (changing oil, changing tire, use mobile, stand without work). The system was used in an uncontrolled area and on different body characteristics such as (height and weight).

### III. PROPOSED SYSTEM

We presented a method that recognized and classified human activity in car workshops performed and captured from videos. It differentiated between the positive activities and the negative activities based on a comparison between input video and dataset stored in the templates. The proposed system used mediapipe for collecting key points of the skeletal joints and used the one-dollar and Fastdtw algorithms to classify the poses.

Fig. 5 shows the system overview, the system has two different way to input which is videos or live camera. The processing part starts with face recognition to differentiate between the workers because there is a large number of workers in the maintenance center. Then the mediapipe starts to extract the poses by calculating the path of each point in the skeleton. The mediapipe can extract 32 points, but this system focuses on extracting five important points which are (shoulder, elbow, wrist, hip, knee). The path of points was saved in a file to be ready for classification by the algorithms. The algorithms start to match these points with the points stored in the data set and send the results to the database to create a report that the managers and workshop owners can see.

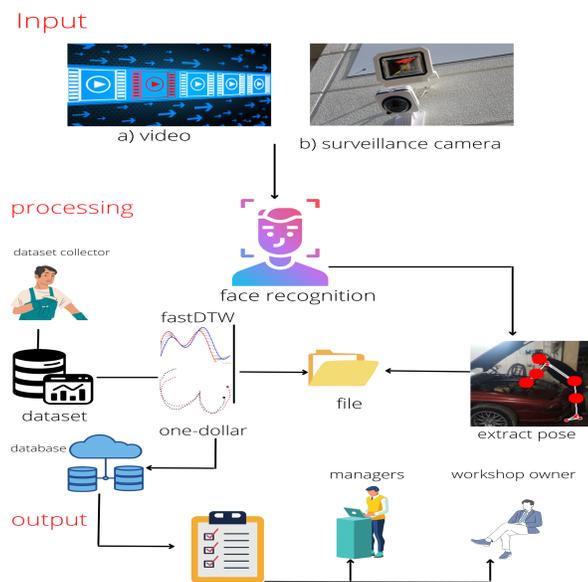

Fig. 5. System Overview.

The dataset was collected by recording videos of a specialist in the activities of the worker inside the maintenance

workshop. These videos were entered into the mediapipe and OpenCV to extract the human pose from the videos showing the path of each point during the video. Each list of points has been saved in a file contains the points and the name of the activity. With the aid of a partner in the industry, we managed to collect 560 videos including the four activities which are (changing tires, changing oil, using a mobile, and standing without work), to start testing them and in order to have a huge number of data to help in testing.

#### A. FastDTW Algorithm

Fast Dynamic Temporal Warping (FastDTW) is a time series alignment algorithm that was initially designed for speech recognition. Its goal is to align two sequences of feature vectors by warping the time axis iteratively until an optimal match is discovered. The two sequences can be placed on the sides of a grid, one on top of the other, with the Y time-series axis on the top and the X time-series axis on the left. In each cell, a distance metric can be set, comparing the relevant elements of the two sequences. Path is detected through the grid by determining the best match alignment between the two sequences which are "I", and "j", and results in the minimum overall distance between each cell. Finding all different routes possibilities through the grid and computing the total distance regarding each one is the process for computing this total distance (D) as mentioned in Equation 1. The total distance is calculated by dividing the sum of the distances between individual items on the path by the weighting function's sum. This is achieved by making an equal number of points in each of the two series, then calculating the Euclidean distance between the first and each subsequent point in the first series.

$$D(i, j) = |t(i) - r(j)| + \min \begin{cases} D(i-1, j) \\ D(i-1, j-1) \\ D(i, j-1) \end{cases} \quad (1)$$

#### B. 1 Dollar Algorithm

The one-dollar is a geometric template matcher, the previously stored templates (T) are compared to the candidate strokes (C) resulting in the match that is the closest in 2-D Euclidean space as mentioned in Equation 2. Thus, we have exactly N points that will allow us to calculate the distance between C[k] to T[k] in which k= 1 to N. The most used pairwise point comparisons in the one-dollar algorithm are scale, rotation, and position invariant. One-dollar cannot differentiate between gestures whose identities rely on special orientations, ratios, and locations. One-dollar algorithm does not contain usage of time, as a result, gestures cannot be separated with respect to the speed.

$$d_i = \frac{\sum_{K=1}^N \sqrt{(C[K_x] - T_i[K_x])^2 + (C[K_y] - T_i[K_y])^2}}{N} \quad (2)$$

#### IV. EXPERIMENT

##### A. Experiment 1

The objective from conducted this experiment was to find out the most accurate algorithm in determining the activity performed by the worker inside the maintenance center. Besides, how it is estimated to differentiate between positive and negative activities.

This experiment was conducted on 3 participants by recording 3 video streams with a duration of 7 minutes for each video. The system has 84 videos of four different activities, including the positive and the negative activities in the different sequences. Each activity was repeated 7 times in each video 4 from the right side and 3 from the left side. The input to our system is split videos for each sequence of activities, the duration is 25 seconds for each video. consequently, After that, the videos were inserted into the system and extracted the important points in the skeleton to determine the path of each point (the X-coordinate and the Y-coordinate) using mediapipe, and save them in a file to be ready to be tested by the algorithms. The system calculated the accuracy of each algorithm in identifying and distinguishing between activities.

In this experiment, we were able to choose the best algorithm by testing each one of them separately, the one-dollar recognizer was able to give the best accuracy rate of 97% regarding the following activities: (changing tires, changing oil, using mobile, and standing without work). The rate of the fastDtw algorithm was 86% in the same previously mentioned activities as shown in Table II.

TABLE II. THE RESULTS OF EXPERIMENT 1

Algorithms	Activites	Accuracy
One-dollar	changing tire changing oil use mobile stand without work	97%
Fastdtw	changing tire changing oil use mobile stand without work	86%

##### B. Experiment 2

This experiment was conducted to measure the performance of one-dollar algorithm with an increase in the number of participants.

We asked 15 participants to do a sequence of activities in different stream videos. The scenario of the activities was changing tire, use mobile, changing oil, stand without work and it was changeable from one to another. The average duration of the activity in the video was 30 seconds, Each activity was repeated 7 times 4 from the right side and 3 from the left side. The average age of the participants ranged from 19 to 23 years, and the characteristics of the body were also different. Afterwards, the videos were entered into the system, and the system was able to extract 420 videos for a range of different activities in uncontrolled environments. Through this experiment, we were able to measure the accuracy of the system in identifying activities in different conditions.

In this experiment, with large number of participants, experts in the field of mechanics, as well as workers from

maintenance centers, the system was able to extract 420 videos, and the one-dollar algorithm started the stage of identifying activities. It achieved an accuracy rate of 94.2%.

##### C. Discussion

After the two experiments have been done, there's a discussion to explain why these results appear in both. The first experiment was to determine the most accurate algorithm, and the result was that one dollar was more accurate than the fastdtw, which is because the One dollar recognizer has been built over fast dynamic time warping (fastDTW), and both can determine path differences between two trajectories. But the difference between them is that one dollar recognizer reduces the noise in orientation by taking the angles into its calculations, which gives preference to one dollar in the accuracy ratios. The second experiment was to test the performance of the one-dollar algorithm in determining the activity of a large number of participants. The results showed that there was a significant difference in accuracy ratios between the activities. The activity of changing the tire was more subtle because this activity differed from the other activities in the motion trajectory, and the activity of using mobile and standing without work had high accuracy, but there were few similarities between them. The oil change activity has a similar motion trajectory with the two activities (use mobile, standing without work), which reduced its accuracy as shown in Fig. 6.

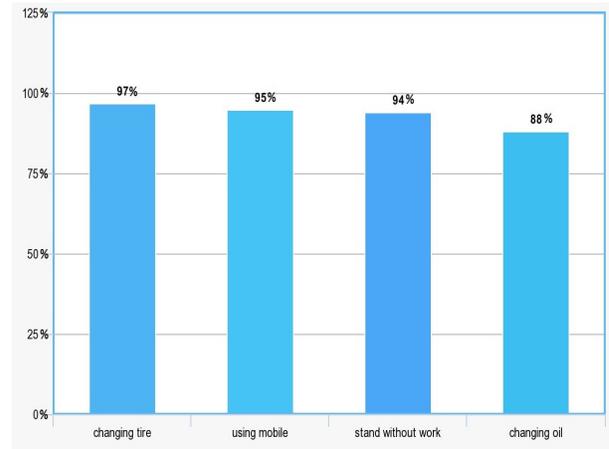

Fig. 6. The Results of the Activities.

The aim of this paper was achieved by using the method of pose classification to extract the pose points from the input video, after extracting the points, a one-dollar algorithm is used to match the extracted points with the collected dataset. As a result, we detect the activities and classify them whether they are positive activities or negative activities. We tested the previous method on 18 participants to prove the accuracy of the mentioned method which reached 94.2%.

#### V. CONCLUSION AND FUTURE WORK

In this paper, we proposed a human activity recognition system in a car workshop that would help maintenance center owners to identify positive or negative worker activities correctly and efficiently. Our system used pose classification to extract workers poses and used two different algorithms to

detect the activities. The system achieved an accuracy rate of 94.2% using this method. However, we are confident that the accuracy of this system will improve with more test videos and that we will increase the activities on which the experiment was conducted in the future. Our future work focus on calculating the wasted time of each worker. Besides, solving problems such as obstacles (engine hood) that appear while identifying activities and affecting the accuracy of the system.

**Abstract**— The Internet of Things (IoT), currently, is one of the most interesting technology trends. IoT is the foundation and driving force for the development of other scientific fields based on its ability to connect things and the huge amount of data it collects. The IoT Platform is considered the backbone of every IoT architecture that not only allows the transfer of data between user and device but also the feed of high-level applications such as big data or deep learning. As a result, the optimal design of the IoT Platform is a very important issue, which should be carefully considered in many aspects. Although the IoT is applied in multiple domains, there are three indispensable features including (a) data collections, (b) devices and users management, and (c) remote device control. These functions usually come with some requirements, for example, security, high-speed transmission, low energy consumption, reliable data exchange, and scalable systems. In this paper, we propose the IoT Platform, called BMP (Broker-less and Microservice Platform) designed according to microservice and broker-less architecture combined with gRPC protocol to meet the requirements of the three features mentioned above. Our IoT Platform addresses five issues: (1) address the limited processing capacity of devices, (2) reduce energy consumption, (3) speed up transmission rate and enhance the accuracy of the data exchange, (4) improve security mechanisms, and (5) improve the scalability of the system. Moreover, we describe the evaluation to prove the effectiveness of the BMP (i.e., proof-of-concept) in three scenarios. Finally, a source code of the BMP is publicized on the GitHub repository to engage further reproducibility and improvement.

**Keywords**—Internet of Things (IoT); gRPC; Single Sign-On; Broker-Less; Kafka; Microservice; Role-based Access Control (RBAC)

## I. INTRODUCTION

The application fields of the Internet of Thing (IoT), currently, are increasingly diverse including smart cities, healthcare, supply chains, industry, agriculture. According to [1], there will be approximately 75.44 billion IoT connected devices in 2025. Iot Platform is an intermediary system that acts as an “adhesive layer” to connect devices with users. There are many architectures outlined to optimize the IoT system, including 5-layer architecture in order from low to high: Things, Connect, Collect, Learn and Do introduced in book [2]. This architecture facilitates it easy to separate each specific group of roles required of an IoT Platform. The fields of application of the current IoT are varied, it is challenging to use a specific architecture suitable for every practical application. However, we generally draw features that are indispensable for an IoT system, namely, i) data collection; ii) device and user management; and iii) remote device control.

These three features are the Things, Connect and Collect layers, respectively [2].

The **Things layer** are the group of physical devices that directly collect data or perform an action based on a control command from the user. The device is usually limited in power, processing and bandwidth [3]. So, the most important requirement of the **Things layer** is balanced between processing capabilities and power consumption of devices (1).

The **Connect layer** is responsible for transmitting data. So, this layer is determined by transmission protocols which are suitable for the hardware and network processing capabilities of the devices in the **Things layer**. So, the most important requirement of the **Connect layer** is to ensure fast transmission speed and reliable transmission (2).

The **Collect layer** is responsible for gathering data from devices and users. The information can be very sensitive since it relates to user privacy, especially medical or financial IoT applications. So, the most important requirement of the **Collect layer** is a security mechanism (3).

In addition, the system scalability and resilience should be concerned as important factors in IoT platform design (4).

There are five popular IoT protocols namely Hypertext Transfer Protocol (HTTP), Constrained Application Protocol (CoAP), Extensible Messaging and Presence Protocol (XMPP), Advanced Message Queuing Protocol (AMQP), and Message Queuing Telemetry Protocol (MQTT) [4].

**Regarding to limited processing ability and power consumption (1):** There are many studies comparing the advantages and disadvantages of the above-mentioned protocols [1], [5], but for the communication in constrained networks bandwidth, MQTT and CoAP are proposed to be used [6]. Furthermore, regarding energy consumption, MQTT is lower than CoAP [7], so MQTT is the most favorite protocol used by developers [8].

**Regarding to transmission rate (2):** MQTT is twice as fast as CoAP [9]. MQTT has three levels of Quality-of-Service (QoS) from 0 to 2. Selecting these QoS levels is a trade-off between the reliability of packet transmission (rate of loss on the link), transmission rate, and energy consumption. The transmission rate of QoS-0 is the fastest, but this has the lowest reliability [10]; whereas, the opposite is the QoS-2. On the one hand, the energy consumption of the QoS-0 level is only about 50% of the QoS-2 level [11].

**Regarding to security mechanism (3):** MQTT has many limitations [10]. Scenarios that attack the Integrity, Availability, and Authentication and Authorization mechanisms of MQTT are outlined in [12].

**Regarding to system scalability and resilience (4):** MQTT protocol is used in popular IoT frameworks including well-known companies (e.g. IBM, Amazon and Microsoft) [13]. The MQTT protocol uses a pub/sub architecture [14], with the MQTT broker at the center. The MQTT subscriber (client), connects to the broker and sends messages to topics. Brokers rely on topic to route the packet, meaning that subscribers who subscribe a topic will receive all messages sent to that topic. This easily leads to a single point failure [15] error at the central broker location. In addition, MQTT is created for transmission purposes. Therefore, MQTT broker does not provide message storage as well as guarantee the order of messages when it reaches the receiver [16]. This is also an important issue to be considered as the weakness of the system using MQTT.

Addressing the MQTT issues, the aim of this paper is to propose a new IoT platform, called BMP, built on broker-less and microservice architecture. We used gRPC protocol to build the broker-less architecture at the **Collect layer** and **Connect layer** for gateway devices. This architecture provides a peer-to-peer communication between sender and receiver in BMP instead of using a central broker to coordinate topic-based messages. Collected messages will be sent to the message queue (Kafka) which provides a caching message mechanism to reduce lost messages when system error occurs. Furthermore, the microservice architecture ensures fault tolerance, scaling horizontally, availability, and carrying capacity of the BMP [17]. Moreover, we define a management model to manage the components in the BMP including users, devices, and communication channels. The management model is built on the RBAC (role-based access control) model combined with the single sign-on and the user organization to achieve authentication and authorization. To engage further reproducibility or improvement in this topic, finally, we share the completely code solution which is publicized on the our Github.

The rest of the paper is organized as follows. In Section 2 we provide knowledge about the technology used in the paper. Section 3 discusses related work. We introduce our IoT Platform and describe the proof-of-concept in Sections 4 and 5, respectively. Section 6, we discuss our test results. Finally, we summarize the paper and provide the potential directions for future work.

## II. BACKGROUND

### A. gRPC

The gRPC<sup>2</sup> is an open-source framework developed by Google for implementing RPC (Remote Procedure Calls) API via HTTP/2. The gRPC provides a new reality for RPC by making it interoperable, modern, and efficient using technologies such as Protocol buffers and HTTP/2. HTTP/1.1 protocol was born in 1997. With each request sent from the client to the server, a TCP connection is created. Connection processing must go through a three-way handshake. This takes a lot

of time. In addition, the headers in each request are plain text with lots of data fields and are not compressed and the headers usually have the same data. Therefore, the header occupies a significant size and is duplicated many times in the requests, leading to consuming a lot of bandwidth. HTTP/2 protocol was born in 2015 created by Google to overcome the above problems. HTTP/2 protocol supports multiplexing so it is possible to send multiple requests in parallel on an established TCP connection. This reduces bandwidth suitable for devices with limited hardware. Protocol buffers are a popular technology for data structures developed and used in communication between google services. The developer will define the data structure in the *.proto* file. The Protoc compiler then compiles the *.proto* file into any language it supports. At runtime, the data is compressed and normalized to binary. The gRPC is fully compatible with embedded devices [18]. This protocol provides four communication types including unary, server-streaming, client-streaming, and bidirectional streaming [19]. In Unary, the client sends a request, then the server sends back a response. In server-streaming, the client sends a request to the server, then the server sends back multiple responses on the same TCP connection. The order of messages for each stream is guaranteed to be the same between client and server. In client-streaming, the client sends multiple requests to the server, then the server sends back only one response to the client on the same TCP connection. In bidirectional-streaming, the client sends multiple requests to the server, then the server sends back multiple responses on the same TCP connection without waiting for response time.

### B. Kafka Message Queue

Kafka<sup>3</sup> is a distributed messaging system. It can transfer a vast number of messages in real-time. When the receiver has not received the message, this message is still stored on the message queue and the disk. This feature allows reducing lost messages when a system error occurs. The structure of Kafka includes the following main components [20]: producer, topic, partitions, consumer, broker, and zookeeper. A producer can be any application that publishes messages to a topic. A topic is a category or feed name where the record is published. The topics are divided into different segments, which are called partitions. A consumer can be any application that subscribes to a topic and consumes messages. Kafka cluster is a set of servers, each of which is called a broker. Zookeeper used to manage and arrange brokers. Kafka-Pixy<sup>4</sup> is a dual API (gRPC and REST) proxy for Kafka with automatic consumer group control. In this paper, we use Kafka-pixy open source to communicate between Kafka message queue and other microservice in BMP by gRPC protocol. Detailed source code can be found at the link<sup>5,6</sup>.

### C. Oauth and Single Sign-On

Oauth version 2.0<sup>7</sup> stands for Open with Authentication or Authorization. OAuth was born to solve the above problem and beyond, this is an authentication method that helps applications

<sup>3</sup><https://kafka.apache.org/>

<sup>4</sup><https://github.com/mailgun/kafka-pixy>

<sup>5</sup><https://github.com/thanhlam2110/Kafka-gRPC-Producer>

<sup>6</sup><https://github.com/thanhlam2110/Kafka-gRPC-Consumer>

<sup>7</sup><https://oauth.net/2/>

<sup>2</sup><https://grpc.io/>

to share resources without sharing username and password information.

Single Sign-On (SSO) is a mechanism that allows users to access many websites and applications without simply logging in once. Once identified in an application A, it will also be identified in application B without repeating the login operation. This feature is suitable for IoT applications because a user can be a customer of many different IoT service providers [21]. In this paper, we use open source CAS Apereo which is modified by us to implement SSO service and OAuth protocol. Detailed source code can be found at the link<sup>8</sup>

#### D. Microservice Architecture

Microservices are an approach to developing an application using a set of small services, a service that will run its own process independently, usually an HTTP resource API. This modern architecture allows for the creation of larger, more complex, and scalable applications [22]. Applications using the microservice architecture are very easy to maintain because the modules are completely separate from each other. It also provides high reliability since a service failure does not affect other services at all [23]. The microservice architecture is also easily extensible. The only weakness of the microservice architecture is the complex deployment process [24].

### III. RELATED WORK

#### A. Broker-less Architecture in IoT

Lu et al. in [25] described a solution to collect the data while meeting the confidentiality requirements via fog computing-enhanced IoT devices. They used a one-way hash string to authenticate IoT devices, then applied the Chinese Remainder Theorem to aggregate data generated by different IoT devices. They also took advantage of Uniform Paired Encryption to provide data security. Some interests of the proposed solution include i) fault tolerance, ii) solving heterogeneity problems in partial mode. Moreover, Lam et al. [26], [27] applied the broker-less architecture in their IoT platforms. However, their resolution applied a common privacy rule, differential privacy, to all IoT devices causing unintentional amounts of sensitive data to be accepted. Applying the access control model can solve this drawback [28], [29], where only authorized objects can accessed data [30], [31].

Furthermore, in the industrial environments, some research directions have applied IoT based on decentralized architecture to meet the requirements for specific system. For example, in [32], the authors focused on the varying IoT protocols in a distributed control platform by concentrating on the times and limits of the transit for different parameter options. Standardized system configuration exploits the embedded Raspberry Pi development board with open source protocol implementation for efficacy measurement, including scalability effectiveness with various data consumers in an automated network chemical. Leveraging the on-board computing resources of distributed embedded systems in the edge computing paradigm for industrial automation was argued in [33].

#### B. IoT Platform based on Microservice

The microservices architecture is introduced to address the traditional monolithic issues. For example, microservices architecture was introduced to fill this gap [34]. This article focuses on summarizing prior work that used the microservices benefits in designing their architecture rather than detailing how it works and the direction of development.

For the framework, Amazon offers AWS IoT Greengrass<sup>1</sup> as a solution to migrate analytics capabilities directly to edge devices (e.g., smartphones). Microsoft Azure provides similar functionality to Azure Stream Analytics on IoT Edge<sup>2</sup>, enabling users to use near-real-time analytic functionalities by using Azure Stream Analytics on IoT-applied devices. However, these frameworks neither provide any functionality to move Lambda calculation to and fro between cloud edge devices nor mix with exterior stream processing engines.

For the application, Lam et al. [35], [36], [37] applied microservice architecture to define the healthcare and IoT-Platform applications. In addition, Maia and associates [38] presented IRRISENS, which is designed based on microservices architectures used in agricultural environments to sense soil, crop, and atmospheric parameters.

### IV. BMP ARCHITECTURE

The BMP is designed according to microservice architecture, and broker-less architecture including **Thing layer**, **User layer**, **Edge layer** and **Cloud layer**, as shown in Fig. 1:

The **Thing layer** is the group of sensor or physical devices. These devices are responsible for measuring environmental parameters such as humidity, temperature or patient health parameters, etc. depending on the IoT application.

In each of these devices, we implement two services i) collection data service (client) and ii) control service (client). The former is responsible for streaming data collected from the environment according to a predetermined collection data server (server) in the IoT Platform. This data streaming is only performed when the client is authenticated and checked the things' role by the Single Sign-On service. The latter receives control commands from the control service (server) through the message queue system. The **Edge layer** including gateway devices. The Edge layer includes gateway devices. In each gateway, we implement two services: *collect data service client-side (CDC)* and *control service client-side (CSC)*. The CDC receives data from devices in the **Thing layer**, then sends it to the **Cloud layer**. The CSC receives control commands from **User layer** throughout **Cloud layer**.

The **User layer** is the groups of users, with different roles, registered to use IoT services. Users can control and monitor the device state by using the control service and the collect data service, in turn. This is performed after passing at the authentication phase and verifying at the authorization phase by the Single Sign-On service and RBAC model, respectively. Besides, users can manage device information ( for instance, create, delete, disable, active, or manage) their child users

<sup>8</sup><https://github.com/thanhlam2110/cas-overlay-template>

<sup>1</sup><https://docs.osgi.org/specification/osgi.cmpn/7.0.0/service.event.html>

<sup>2</sup><https://maven.apache.org/>

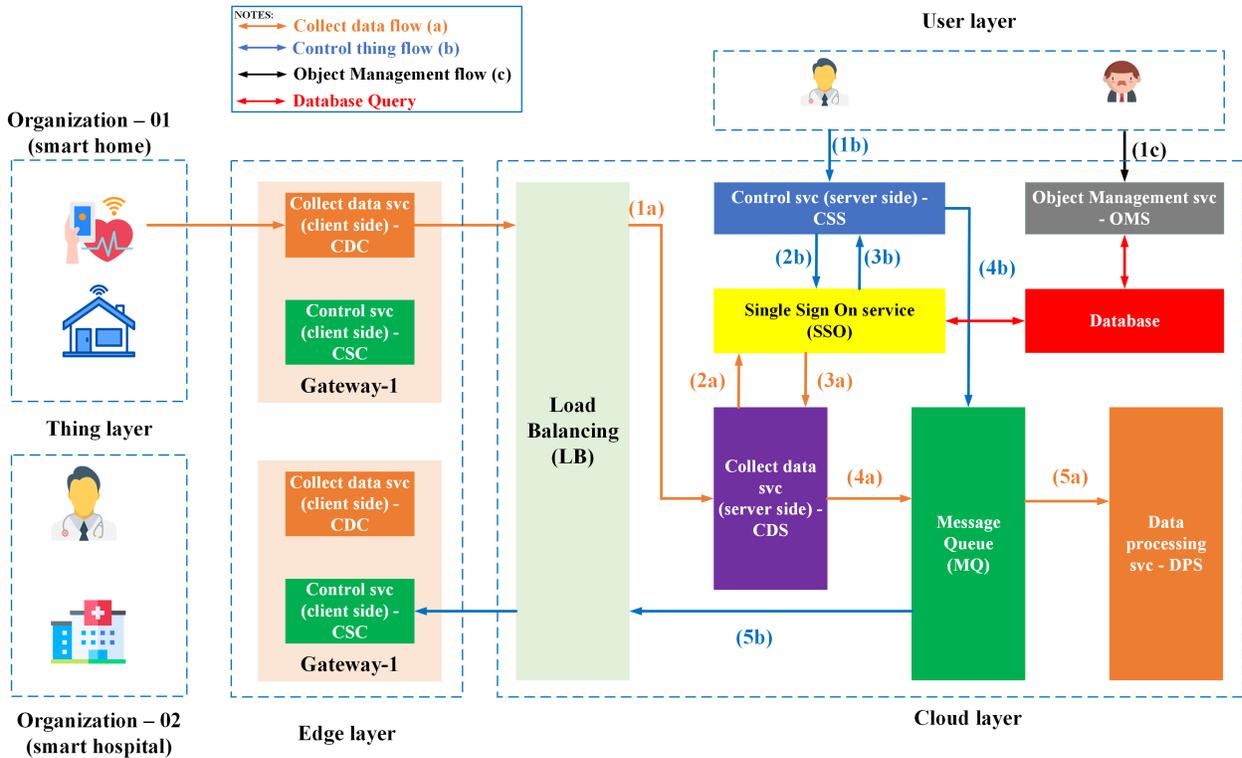

Fig. 1. BMP Platform Architecture.

(register, disable, active) through the Object Management service. Furthermore, users can create management information about devices and communication channels. This information is metadata and stored in a database helps users easily manage their devices and be aware clearly of where they send your messages. For example, user A can create/delete/update his device and communication channel information. Moreover, users are organized hierarchically according to a tree model so high-level users (aka *parent-user*) can manage low-level users (aka *child-user*). For example, user A (high-level) can enable or disable user B's status (low-level). If user B is disabled, user B can not interact with BMP. This feature is similar to the company model with user A as manager role and user B as staff role. In addition to the user and things layer services, the IoT platform has a Load balancing service to balance the load for the whole system. Besides, the Message Queue service is responsible for routing control packets from user to things and data collected from the things layer. Message Queue also stores messages going through the IoT Platform, ensuring that it could receive messages after recovery even the service fails. Data processing service analyzes data in-depth level.

The **Cloud layer** is the main processing part of BMP including *load balancing (LB)*, *collect data service server-side (CDS)*, *control service server-side (CSS)*, *single sign-on service (SSO)*, *message queue (MQ)*, *object management service (OMS)*, *data processing service (DPS)*, and *database (DB)*. The *LB* is responsible for distributing incoming traffic to ensure the **Cloud layer** is not overloaded. The *CDS* receives messages from *CDC*. These messages include OAuth access token and data collected from the **Thing layer**. The access token is verified by the *SSO*. If the access token is valid

the data will be sent to the *MQ*, otherwise, the data will be discarded. The *CSS* receives messages from users in the **User layer**. These messages include an OAuth access token and control command. Similarly, the access token is verified by the *SSO*. If the access token is valid the control command will be sent to the *MQ*, otherwise, the control command will be discarded. Thanks to gRPC's multiplexing feature and client-stream method, we only need to establish an http/2 connection between *CSC* and *CSS* or *CDC* and *CDS* to send the access token and a bunch of data at the same time. This helps to reduce system bandwidth as well as power consumption on the gateway. The *MQ* is responsible for distributing data to the *DPS* for deeper analysis or the *DB* for storage and control commands to the *CSC* in the **Edge layer**.

## V. IMPLEMENTATION

In this paper, we have implemented the services outlined in the proposal section including: single-sign on service (SSO)<sup>9</sup>, collect data service (CDC and CDS)<sup>10</sup>, and object management service (OMS)<sup>11</sup>. The model for the development and interaction between the symbolic services in Fig. 1 is as follows: (1a-5a) the collect data flow, (1b-5b) the control thing flow, and (1c) the object management thread.

The **collect data flow** details are shown in Fig. 2. The **Things layer** collects data from sensors and periodically sends them back to the gateway at the **Edge layer** (sending data periodically to help save energy). The *CDC* on gateway creates

<sup>9</sup><https://github.com/thanhlam2110/iccs-ss0-service>

<sup>10</sup><https://github.com/thanhlam2110/iccs-collect-data-svc>

<sup>11</sup><https://github.com/thanhlam2110/iccs-object-management-svc>

a single gRPC connection to both send access token, thing-id and streaming data to CDS - *process 1a* in Fig. 1. This is the multiplexing feature of the gRPC protocol, which was introduced in section 2.1. So the data sent from CDC to CDS is the combination of *access token*, *thing-id*, and *collected data from sensor*. Next, the CDS sends the *access token* and *thing-id* to the SSO service (process 2a) to verify access token and check role, the test result is returned (process 3a). If the token is authenticated and the role is verified, CDS will stream the bulk of *collected data* to MQ (process 4a), whereas the CDS will drop all data and return the error to CDC. MQ will distribute data to DPS for in-depth analysis (process 5a).

The **control thing flow** details are shown in Fig. 3. The user creates a single gRPC connection to both send the access token, things-id and control command to the CSS (process 1b). The CSS sends the *access token* and *thing-id* to the SSO service to verify access token and check role. Role-based access control integrated on SSO service uses user-id (get from check access token process) and thing-id to verify the device which the user wants to control belongs to the user or not ( process 2b). Next, the check result is returned to the CSS (process 3b), if it is valid, the control command will be sent to the MQ (process 4b). The CSC on gateway subscribes to the channel ( aka Kafka topic) on the MQ which is created by the user to be dedicated to receive control commands. When the MQ receives the control command, the CSC also receives it. (process 5b).

The **object management flow** provides APIs for users to interact with the database. The Single Sign On service will also use the data stored here to authenticate and verify the roles of users and things. We implement RBAC combined with Single Sign-On to provide role-based authentication and authorization for Things and Users. However, the concepts of users' roles and things' roles are somewhat different.

We define the users' role including permissions that affect their devices and child users.

*About users' role on their child user*, a parent user can create/delete/enable/ disable child user. For example, user A can create management information for user B who is the visitor to user A's house. In this case, user A is the *parent-user* and user B is the *child-user* of A. With management information, user B is allowed to control some devices in user A smart home. When user B leaves, user A deletes user B's information, which means user B can not interact with user A's smart home. We implement the user management by the model tree with the *child-user* has an attribute *user\_parent\_id* field equal to the *parent-user's* username. This organization user model allows BMP to be flexibly applied to the business of implementing hierarchical user management.

*About users' role on their devices*, the user can create/delete management information, enable/disable, or assign/unassign (to another user) their devices. For example, user A can choose some devices that user B can not control when user B visits user A's house by unassigning these devices to user B. To do this, we provide APIs that allow user-id and thing-id mapping. Then, SSO will check this information when a user wants to control devices. In addition, OMS also provides APIs for users to create/delete communication channels management information. This channel information allows users to assign

their devices to send and receive messages on it. This function helps users be aware clearly where they share data.

## VI. EVALUATION

The BMP design is based on microservice and broker-less architecture. To evaluate BMP, we deploy the **Cloud layer** on the Amazon EC2<sup>10</sup> platform with each service equivalent to a virtual machine with 1GB RAM and 1 vCPU configuration. For the gateway, we deploy CDC and CSC on the Raspberry Pi 3 model B<sup>11</sup> module with CPU quad-core, 1.2 GHz and 1GB RAM.

In this paper, we perform three test scenarios to evaluate BMP with aspects transmission rate, power consumption, and security mechanism.

**Scenario 1:** We measure the Round Trip Time (RTT) from when CDC streams *data* until it is received by the message queue. In addition, we also look at the error rate (number of messages lost per total number of messages). We assume the *data* in this test case is *data = access token + string*, with *string = "hello number" + for (i=1; i<=number\_of\_messages;i++)*. Measured results are shown in Table I.

The test results are quite good as we only deploy the evaluation on low-configuration servers. All messages are received in full and in order. By using gRPC which allows sending multiple messages on one connection, we achieve very fast transfer speed while still satisfy the whole process of checking and validating before streaming data as described in Section 5.

**Scenario 2:** We measure CPU and RAM usage to evaluate power consumption when streaming *data*. We use the htop<sup>12</sup> tool, a tool that allows real-time monitoring of system processes. Similarly test scenario 1, We assume the *data* in this test case is *data = access token + string*, with *string = "hello number" + for (i=1; i<=number\_of\_messages;i++)*.

As a result in Table II, at the no-load and 10000 messages levels, we recorded the value as 0, which means that the resource usage of the services is shallow (no-load) or takes place in a concise time (10000 messages); therefore, the measuring tool hardly records any change in resource usage. For the high load case (50000-100000 messages), the result shows that the resource consumption is very low. Furthermore, in practice, it is not always the thing that streams a large amount of data like in this scenario. This shows that our adoption of gRPC to the IoT Platform gives outstanding results, suitable for devices with low hardware.

**Scenario 3:** We capture the message that is transmitted between sender and receiver to analyze security risk. We use Wireshark<sup>3</sup> to capture the transmitted message. Wireshark is network packet analyzer software. Its job is to capture all network packets and then display the data of that packet in the most detail. We set up the test scenario to compare the security mechanism between MQTT and gRPC protocol. We use Wireshark to capture messages that are transmitted between the

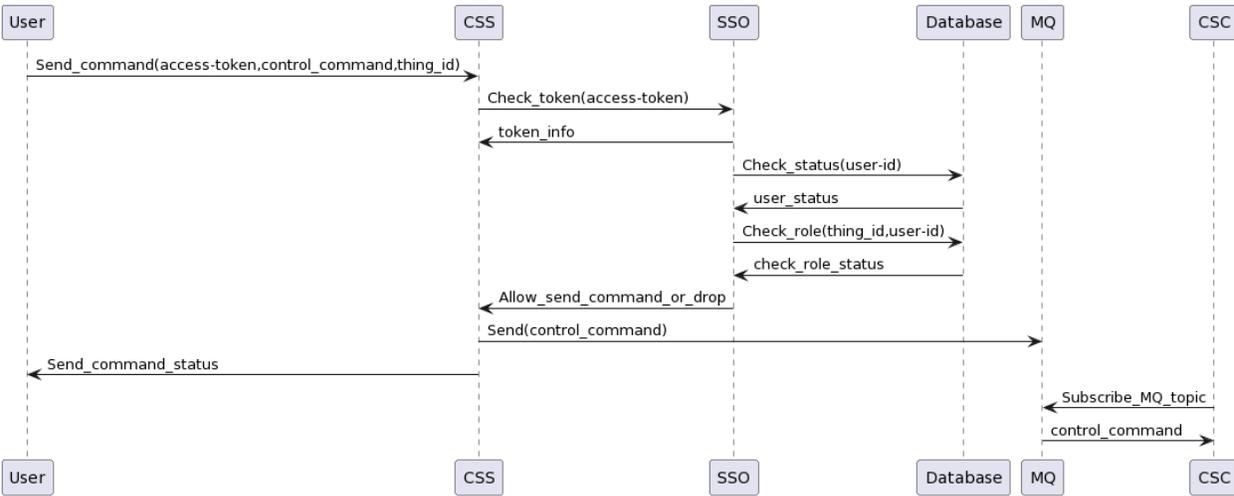

Fig. 3. The Control Flow.

TABLE I. THE RESULT OF THE FIRST SCENARIO

Number of messages	100	1000	5000	10000	50000
RTT (s)	1.5	4.07	14.79	27.05	138.02
Error (%)	0	0	0	0	0

sender and receiver and then analyze these messages. The test model is shown in Fig. 4.

The analyzed message result of MQTT and gRPC protocol is shown in Fig. 5 and Fig. 6, respectively.

According to Fig. 5 and Fig. 6, while MQTT protocol easily gets topic information as well as message content, in this case MQTT topic is "thanh-lam" and message is "Hello Thanh Lam", gRPC protocol provides packet encryption. This result proves that the gRPC protocol has a better security mechanism than the MQTT protocol.

## VII. CONCLUSION

In this paper, we propose the IoT Platform, called BMP, using the broker-less and microservice architecture. The broker-less architecture helps our IoT Platform reduce a single point of failure in comparison with brokering architecture. Furthermore, microservice architecture helps BMP easily scale out, reducing downtime when errors occur. The combination of broker-less and microservice architecture also helps 3rd parties easily integrate with BMP. Third-party developers only need to call the API and don't make major changes to the

TABLE II. THE RESULT OF THE SECOND SCENARIO

Number of messages		No load	10000	50000	100000
Raspberry Pi	CPU	0	0	0.3%	0.7%

BMP's architecture. Moreover, we chose gRPC as the main protocol for BMP because of its advantage in privacy, power consumption, speed, and reliable transmission in comparison with MQTT. In addition, the gRPC protocol works peer-to-peer which is suitable for broker-less implementation. BMP also provides authentication and authorization mechanisms for users, devices, and communication channels thanks to the combination of single sign-on (SSO) and role-based access control (RBAC). The BMP allows users to manage their devices and channels to aim at users clearly aware when they share data. The hierarchical organization of users as a tree model helps enhance flexibility. In the future, we will focus on the decentralized identity for IoT users and devices by applying blockchain.

**Abstract**—A denial-of-service (DoS) attack is a coordinated attack by many endpoints, such as computers or networks. These attacks are often performed by a botnet, a network of malware-infected computers controlled by an attacker. The endpoints are instructed to send traffic to a particular target, overwhelming it and preventing legitimate users from accessing its services. In this project, we used a CNN-LSTM network to detect and classify DoS intrusion attacks. Attacks detection is considered a classification problem; the main aim is to clarify the attack as Flooding, Blackhole, Normal, TDMA, or Grayhole. This research study uses a computer-generated wireless sensor network-detection system dataset. The wireless sensor network environment was simulated using network simulator NS-2 based on the LEACH routing protocol to gather data from the network and preprocessed to produce 23 features classifying the state of the respective sensor and simulate five forms of Denial of Service (DoS) attacks. The developed CNN-LSTM model is further evaluated on 25 epochs with accuracy, Precision score, and Recall score of 0.944, 0.959, and 0.922, respectively, all on a scale of 0-1.

**Keywords**—Denial of Service (DoS); Wireless Sensor Networks (WSN); Convolutional Neural Network (CNN); Long Short-Term Memory (LSTM)

## I. INTRODUCTION

Wireless Sensor Networks is regarded as one of the prominent research topics. The technology is an ideal solution for numerous applications in various fields like telecommunication, military, healthcare, research, and agriculture, amongst others [1]. Aziz et al. [2] reported the application of wireless sensor networks in detecting natural disasters such as earthquakes, flooding, or volcanoes. The widespread WSNs usage has introduced many security threats in the implementation and deployment phase. Wireless sensor networks are susceptible to different attacks due to unique constraints like storage capacity, restricted processing power, and battery power capacity.

People worldwide rely on networking systems to bring new ideas and answers to their issues and help them meet their basic requirements. New and most often used technological innovations include sensors that allow users to receive remote data and utilize it for their specific purpose. Sensors are being used by Internet of Things (IoT) devices [28], which are becoming more popular. Recently researchers' intention over Wireless Sensors Network (WSN) increased, and several research publications have been added over the research repositories. Despite the advantages of WSN, several security loopholes can be exploited to receive DoS attacks. While using WSN applications, users can face several types of security

threats that can cause data breaches [29]. Researchers have been attempting to develop new security solutions in order to prevent DoS attacks from succeeding in their endeavors. Several technological advancements have helped develop novel approaches to infiltrate and prevent such attacks. Still, deep learning has brought about the most effective approaches for preventing such security risks and DoS attacks [30].

DoS attacks are attacks on a service (network or application) that overload the service and prevent it from delivering services to the rest of the network or application's users. When a DoS assault is launched, it floods your site or the supporting infrastructure with a large amount of traffic from various sources, often preventing access to the site for the duration of the attack. Cloudflare, for example, is one of the services that provide DoS protection for websites. When it comes to defending against DoS attacks, it might be pretty challenging. Because it is coming at you from all over the Internet and all over the globe, there is almost no way to block the transmission of that deluge of illicit material. You have no control over it. Fortunately, specific DoS attacks may be detected and blocked upstream from the target (with the assistance of the ISP/backbone that hosts the target/victim). In contrast, others transmit data indistinguishable from a genuine user [20].

With limited resources, inadequate infrastructure, and a massive quantity of WSN use on our hands, we were forced to deal with a slew of security challenges. Assaults on the World Wide Web (WSN) are commonly targeted by Distributed Denial of Service (DoS) attacks. DoS attacks may be identified and avoided by several security measures that have been put in place by researchers, but preventing them is not a straightforward task. In order to safeguard WSN against such assaults, researchers are deploying dependable and easy-to-use security measures based on deep learning techniques.

This study investigates the defense mechanism for denial-of-service attacks in wireless sensor networks. The results of this deep learning technique were evaluated on a specialized wireless sensor network dataset called WSN-DS, having numerous normal and numerous attack circumstances to authenticate their efficiency in detecting Denial of Service attacks. The denial of service attacks can take place at any of the layers of the TCP/IP protocol stack [3],[4]. Presented in Table I are the different types of denial of service attacks available in each layer of the TCP/IP protocol stack. However, there is a range of DoS attacks that exist at each layer.

TABLE I. DoS ATTACKS ON TCP/IP PROTOCOL STACK [5]

Protocol Layer	Attacks
Physical Layer	Droplet Attack
	Jamming
	Node Tampering and Obliteration
Data Link Layer	Denial of Sleep
	Power Exhaustion
	Unfairness
Network Layer	Wormhole
	Blackhole
	Homing
	Spoofing, routing control traffic, replaying
	Misdirection
	Selective Forwarding
	Acknowledge Spoofing
Transport Layer	Sybil
	Desynchronization Attack
	SYN Flood
Application Layer	Overwhelming Sensors
	Reprogramming
	Path-based DoS

## II. LITERATURE REVIEW

In recent years, there has been a rise in published studies on Wireless Sensors Networks (WSN). Despite the benefits of WSN, it is vulnerable to DoS assaults because of several security flaws. Users using WSN services may be exposed to various security risks, some of which may result in data breaches. DoS attacks are becoming more common, and researchers prevent them from succeeding. There have been several technological breakthroughs that have made it easier to penetrate and protect against these assaults. However, the most successful techniques to avoid such security threats and DoS assaults have been developed using deep learning.

Numerous studies have detected and classified attacks in overall security architecture and wireless sensor network attacks. The study presented by Alsheikh [6] discussed different algorithms, applications, and strategies of machine learning in a wireless sensor network. The study also highlighted some notable challenges facing the performance of wireless sensor networks, such as quality of service (QoS), query processing, security, energy awareness, and event identification, though the study only highlights the qualitative evaluation of this work.

In the work of Gundunz et al. [5], a survey of machine learning solutions for identifying denial of attacks was presented. This study reviewed the DoS discrepancy available at each layer of the TCP/IP protocol stack and concentrated on the network layer attacks.

Sudar et al. [20] proposed an ML model in SDN to identify DoS attacks in KDD99 dataset. They have used SVM and Decision tree algorithm to detect the attacks due to its accurate classification and less complexity. They claimed that the proposed algorithm (SVM) gives a good performance level of 80%.

Anomaly detection in big data analytics addressed by [21]. based on a big data analytics framework, in which the authors handled structured and unstructured data streams and batch processing techniques. The authors used the WIDE backbone dataset gathered in real time. They recognized 5 types of

attacks, which are DoS attacks, HTTP flashcrowd attacks, flooding attacks, abnormal UDP and TCP using machine learning. The attack was identified by using 5 supervised machine learning techniques: Decision Trees (DT), Naïve Bayes (NB), Neural Networks (NN), Support Vector Machines (SVM) and Random Forest (RF).

Almomani et al. [22] used eight different machine learning models in detecting DoS attacks which are: Naive Bayes (NB), Decision Trees (DT), Random Forests (RF), Support Vector Machine (SVM), J48, Artificial Neural Networks (ANN), K-Nearest Neighbor (KNN) and Bayesian Networks (BN). They used the WSN-DS dataset for their experiment and performed feature selection based on expert survey. The authors reported that the Random Forest algorithm achieved the best results with a True positive of 99.7% accuracy, out-performing the ANN model with a True positive of 98.3%.

In [23], the authors have proposed a method provides two level of security, they have implemented suspicious detection module In the first level of security, and they imposed machine learning based C4.5 decision tree model in the second level. First inbound traffic is handled by a suspicious data detection engine. If traffic is suspected to be an attack based on entropy values, a temporary alert is generated and sent to OpenFlow switches the controller to save that particular flow. This module facilitates early detection of attacks This module results once again through Level 2 security. This module provides results by analyzing additional characteristics of the traffic. The output of this module is considered the final result. This module helps detect attacks with a low false positive rate. If it is an attack, this module sends an alert to drop packets and remove the flow from the flow table. By using these two levels authors can help for early detection of DoS attack with low false alarm rate.

Wu et al. [24] proposed a CNN+RNN hierarchical neural network, which they named LuNet. It consists of multiple layers of CNN and RNN, both networks learn together from their input data. Their proposed model was tested on the NSL-KDD and UNSW-NB15 datasets [25]. They performed binary and multi-class classification and achieved maximum accuracies of 99.36% and 99.05%, respectively. Both results are in the NSL-KDD dataset.

This research [27] aims to evaluate the effectiveness of machine learning classification algorithms in detecting flooding, grey hole, and black hole distributed denial of service attacks in wireless sensor networks. We conducted our review using a WSN-based dataset, referred to as WSN-DS, and took the accuracy and speediness measures into account. The results show that the J48 approach is the most accurate and fastest way for identifying grey hole and black hole attacks. At the same time, the Random Tree method is the most accurate and fastest method for detecting flooding assaults. The J48 approach is the most efficient for speed, requiring an average of 0.54 seconds of processing time per sample.

## III. SECURITY OBJECTIVES IN WIRELESS SENSOR NETWORKS (WSNs)

In wireless sensor networks, the security objectives are essential aspects of WSNs that must be addressed to avoid security compromise of any kind. There has been an ever-growing application of WSNs in penetrating security environments;

nodes are the network interface through which the attack nodes destroy the network. Routing is regarded as a trust-based process within nodes; the process serves as a good platform for attackers to disrupt the network. Security investigations in networks are carried out individually; thereby, networks are usually designed without pre-planning and are employed for a short period. Therefore, it is imperative to implement countermeasures to secure the wireless sensor networks from security attacks.

DoS is one of the most common attacks in wireless sensor networks. Figure 1 presents the wireless sensor networks with denial of service attacks. One profound effect of DoS involves refraining the radio from switching into sleep mode and draining the system battery completely. In the normal operating conditions, operating situations, the energy consumption ratio in the sensor reduces the battery capacity in months, while DoS reduces the battery in days by keeping the transmitter system incorporated in the sensor nodes [7],[8] and [9].

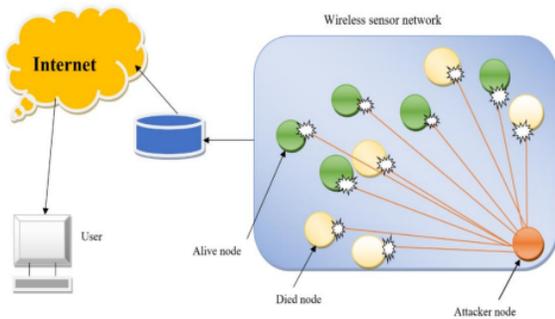

Fig. 1. WSNs with DoS Attack [10].

The security goals are based on the well-known triangle of CIA, namely confidentiality, integrity, and availability of information safety, and this describes what they represent in wireless sensor networks [11].

#### A. Confidentiality

In wireless sensor networks, the two most critical requirements are security and efficiency. There are several applications of WSNs, namely medical, military, research, agriculture, environmental monitoring and others. It is essential to avoid data leakage from sensor networks to neighbouring networks to avoid data confidentiality breaches. Securing the confidentiality of data is essential in protecting the data from attacks like spying [12]. The standard security measure in concealing confidential data is encryption before data transmission with a secret key acknowledged only by a particular receiver. Secure communication channels are established between source and sink, and other secure channels are triggered later if required [13].

#### B. Integrity

Wireless sensor nodes are susceptible to different security attacks threatening the reliability of the data, mainly in the interruption of the flow of information or data fraud [14]. In Sensor networks, transmitted data is considered by nodes to choose the right moves; this further confirms the importance

of data integrity. There are two main parts of transmitted data, namely, updated or deleted. To secure data information, data transmitted from the node should arrive at the destination without an alteration in the transmission. The most suitable means of providing data integrity is wireless sensor networks are by checking the data at the receiver end [15].

#### C. Availability

Wireless sensor network nodes should continue operating excellently and not disturbed even when attacked. The implementation of sensors ensures the accessibility of authorized when the data is needed. Information gathered from wireless sensor networks is essential only if the correct user gain access to it at the appropriate time. It is known that WSNs is used in numerous fields, loss of information may lead to damaging consequences. In all the attacks, the most common attack intended at data availability is a denial-of-service attack [16]. The CNN-LSTM model was trained using 10 and 25

### IV. METHODOLOGY

This section covers the steps involved in the data acquisition process, attack detection and classification process, algorithms used, and model design for the research. The block diagram is presented in Figure 2 for the proposed system, which used a CNN-LSTM network to detect and classify intrusion attacks. The model layer explanation, dataset properties, data process, model training, and many other methodologies are discussed in this section. After this stage comes to the main model development stage, then the inference stage, where the performance evaluation for the model was determined.

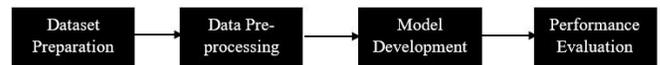

Fig. 2. Block Diagram of the Proposed Intrusion Detection Model.

#### A. DataSet

This research study uses a computer-generated wireless sensor network-detection system dataset developed by Almani et al. [17]. The wireless sensor network environment was simulated using network simulator NS-2 based on the LEACH routing protocol to gather data from the network and preprocessed to produce 23 features classifying the state of the respective sensor and simulate five forms of Denial of Service (DoS) attacks, namely; Flooding, Blackhole, Normal, TDMA, and Grayhole. WSN dataset was gathered as an intrusion detection dataset tailored towards machine learning and deep learning techniques to identify and classify Denial of Service attacks. 365788 occurrences of records were extracted; it has 19 different attributes. The simulation parameters of the WSN dataset is presented in Table II.

TABLE II. WSN DATASET PARAMETERS [17].

Parameter	Value
Cluster Number	5
Location of the Sink	(50, 175)
Packet header size	25 bytes
Data packet size	500 bytes
Network area dimension	100m×100m
Routing protocol	LEACH
Simulation time	3600s
Nodes number	100 nodes

The WSN dataset has the following data points; Normal has 332040, Grayscale has 13909, Blackhole has 10049, TDMA has 6633, and flooding has 3157 data points.

### B. DoS attacks types Description

DoS attacks types are described below [26]:

- 1) Black Hole attacks: the attacker plays the CH role. Then the attacker will keep dropping packets and not forwarding them to the sink node.
- 2) Grayhole attacks: the attacker advertising itself as a CH for other nodes. After the forged CH receives packets it selectively or randomly discarding packets, therefore it will prevent the legitimate packets to be delivered.
- 3) Flooding attacks: flooding attacks targeting LEACH protocol by sending a large number to the sensor to advertise itself as an advertising CH. This will lead to consuming energy, memory, and network traffic.
- 4) Scheduling attack: It occurs during the setup phase when CHs set up TDMA schedules for the data transmission time slots. The attacker will change the behavior of the TDMA schedule from broadcast to unicast to assign all nodes the same time slot to send data. This will cause a packet collision which leads to data loss.

### C. Data Preprocessing

WSN dataset has been employed for testing and assessing intrusion detection techniques. It possesses a good understanding of different intrusion behaviours. Figure 3 presents the importing procedure of the WSN dataset; the dataset was imported to SQL server to implement different statistical measurements values such as occurrences distribution, classes of attacks, and percentage of the occurrences.

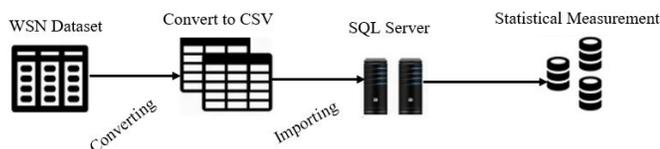

Fig. 3. Importing Procedure of WSN Dataset.

### D. Data Split

The dataset was split into two sections: A training set dedicated to training the detection algorithm and a testing set that is completely hidden from the training process. The two subsets use the 80:20 approaches. 80% of the total dataset is used for the training and validation set, while 20% is used for the test set.

## V. MODEL DESIGN AND DEVELOPMENT

To detect the intrusion attacks within the WSN dataset, a neural network that uses multi-layers that are interlinked together was used. The model used an eight-layered neural network structure to implement this study. These numerous layer neural networks used the same activation function (ReLU). The multiple layer networks learn over the input data using a selected kernel filter to extract essential features seen as necessary in the intrusion detection system. The developed model has one last layer, the dense layer; softmax activation function was considered for this layer due to its capability to hand classification of multi-classes. The summary of the developed CNN-LSTM model is illustrated in Table III and Table IV.

TABLE III. SUMMARY OF THE CNN MODEL PARAMETERS

Layer(type)	Output Shape	Param #
conv1d (Conv 1D)	(None, 18, 64)	256
conv1d (Conv 1D)	(None, 18, 64)	12352
max_pooling1d (MaxPooling1D)	(None, 9, 64)	0
flatten (Flatten)	(None, 576)	0
dense (Dense)	(None, 64)	36928
dropout (Dropout)	(None, 64)	0
dense_1 (Dense)	(None, 5)	325

TABLE IV. SUMMARY OF THE CNN-LSTM MODEL PARAMETERS

Layer(type)	Output Shape	Param #
conv1d_2 (Conv 1D)	(None, 18, 64)	256
conv1d_3 (Conv 1D)	(None, 18, 64)	12352
max_pooling1d_1 (MaxPooling1D)	(None, 9, 64)	0
conv1d_4 (Conv 1D)	(None, 9, 128)	24704
conv1d_5 (Conv 1D)	(None, 9, 128)	49280
max_pooling1d_2 (MaxPooling1D)	(None, 4, 128)	0
conv1d_6 (Conv 1D)	(None, 4, 256)	98560
conv1d_7 (Conv 1D)	(None, 4, 256)	196864
max_pooling1d_3 (MaxPooling1D)	(None, 2, 256)	0
lstm (LSTM)	(None, 70)	91560
Dropout_1 (Dropout)	(None, 70)	0
dense_2 (Dense)	(None, 5)	355

### A. Model Architecture

This section describes the steps taken in achieving the intrusion detection technique. The model takes in an input having an unknown type of attack; the second step involves processing the input data by converting it to an acceptable model format. Then the model carries out a detection process by comparing the features of the present input attack data with the learned features of different kinds of attacks it has been

trained with. If the model refuses to detect an attack, the system will return to step 2. If the model detects an attack, then the classification process takes place to ascertain the actual type of attack.

### B. Model Hyperparameter Setting

The model hyperparameters are a set of values well-defined to improve the training process of the developed model and its general performance.

The model hyperparameters acknowledged in this study include activation function, epoch, learning rate, verbose, patience, optimization technique, and loss function, as presented in Table V.

These hyperparameters are set at optimal values after many rounds of random search to enhance model optimization. The number of the epoch is the number of times the training data is exposed to the model while training; it is the total number of iterations the whole training data passes through the developed model.

The CNN-LSTM model was trained using 10 and 25 epochs. Activation function was introduced into the model training to incorporate non-linearity effects into the developed model due to the non-linear type of data used. The two activation function used for this study is the softmax function and Rectifier Linear Unit (ReLU).

The softmax function is employed as an activation function in the output layer; it was the selected activation function in the output layer due to its excellent performance when used as a classifier.

Conversely, ReLU is an element-wise activation function; it is fast and straightforward to implement. Also, ReLU is computationally efficient to compute than other kinds of activation functions.

An exponential decay where the learning rate reduces exponentially, a learning rate of 0.001 was optimal for this study.

TABLE V. MODEL HYPERPARAMETER

Hyperparameter	Value
Epoch	10, 25
Activation Function	ReLU, Softmax
Loss Function	Categorical Cross Entropy (CCE)
Optimization algorithm	Adam
Learning rate	0.001
Verbose	1

### C. Model Optimization

These are processes employed in ensuring the developed model reach a consistent and efficient level to achieve peak performance.

The adaptive moment estimation (Adam) is the optimizer used to minimize the loss function in this work. Adam is an efficient stochastic optimization that only requires a first-order gradient with its memory requirements. Adam was selected as

the preferred choice of optimizer due to requiring a stationary objective.

Categorical Cross-Entropy (CCE) was employed in this study to ensure a better classification process in the CNN-LSTM model. CCE was selected for this work due to its improved choice for cost function, and Ho and Wookey [18] described CCE mathematically using Equation (1).

$$J_{CCE} = -\frac{1}{M} \sum_{K=1}^K \sum_{m=1}^M W_K \times Y_m^k \times \log(h_{\Theta}(x_m, k)) \quad (1)$$

where M represent the number of training examples,  $W_K$  represent the weight for class k,  $Y_m^k$  represent the target label for training example m for class k, K represent the number of classes,  $x_m$  represent the input for training example m,  $h_{\Theta}$  represent the model with neural network weights  $\Theta$ .

### D. Model Implementation and Environment

The study was implemented using Python 3.7.7. Python language was selected as there is a lot of support from an active community for image classification using TensorFlow with Keras [19]. The study was started and completed on a laptop running on core i7, 8GB DDR RAM, a web IDE for Python (Google Colab) with Windows 10 operating system.

### E. Performance Evaluation Metrics

The developed model was evaluated using various performance metrics. The assessment metrics used to estimate the model's performance include precision, accuracy, recall, and f1-score.

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

$$F1 - Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (4)$$

where TP is the True Positives, TN is the True Negatives, FP is the False Positives, FN False Negatives.

## VI. THE EXPERIMENTAL RESULTS

This section describes the implementation of the intrusion detection model of all classes of attack on the network using the CNN-LSTM model. All the research details, results, and discussion of each experiment are presented. The results of the experiment are shown in different graphs and tables.

### A. Detection of Attacks using the Collected Dataset

Attacks detection is considered a classification problem; the main aim is to clarify the attack as Flooding, Blackhole, Normal, TDMA, or Grayhole. Presented in Table VI are the classes of attacks in the dataset and their percentage distribution. Figure 4 presents the graphical representation of all the five kinds of attacks present in the dataset and their distribution.

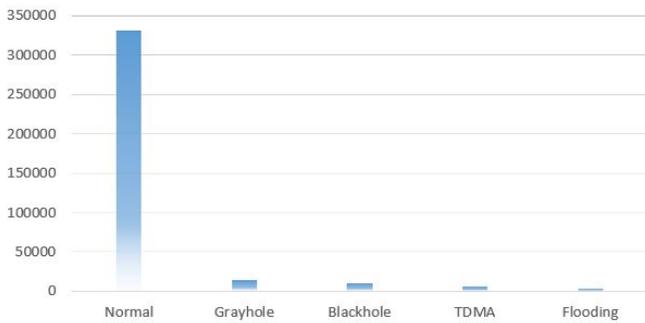

Fig. 4. WSN Dataset Distribution.

TABLE VI. DoS ATTACKS AND PERCENTAGE DISTRIBUTION

S/N	DoS Attacks	Distribution%
1	Normal	90.774
2	Grayhole	3.802
3	Blackhole	2.747
4	TDMA	1.813
5	Flooding	0.863

### B. Intrusion Detection Model

The WSN dataset was used to train the CNN-LSTM model. The developed model gives a promising outcome in the attack detection process. The model successfully classifies the given attacks with a training accuracy of 91% on ten epochs and 97% on 25 epochs using a learning rate of 0.001.

The softmax activation function was selected in the output layer of this model due to its capability to handle multi-classification excellently well. The execution time achieved by the CNN-LSTM model on 10 and 25 epochs was 805 and 1103 secs, respectively.

### C. Training Phase

During this phase, the training set was employed to train the intrusion detection model. The developed CNN-LSTM model recorded a training loss of 41.7%, training accuracy of 91.07%, validation loss of 47.01% and validation accuracy of 89.44% on 10 epochs, as illustrated in Figures 5 and 6.

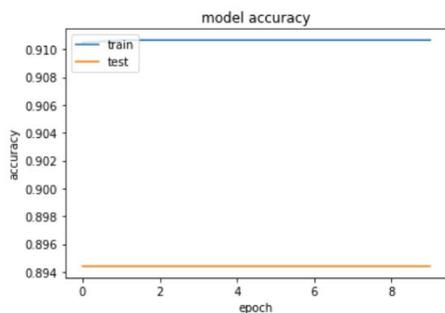

Fig. 5. Snippet of Model Training Accuracy with 10 Epochs.

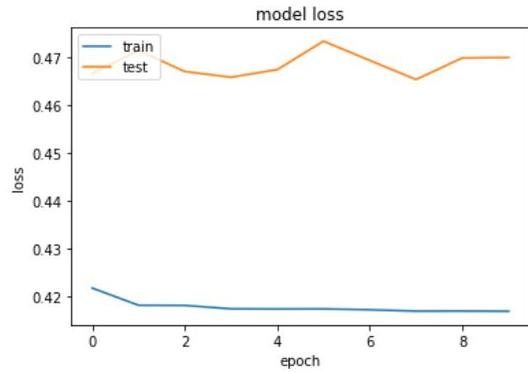

Fig. 6. Snippet of Model Training Loss with 10 Epochs.

The developed CNN-LSTM model recorded a training loss of 8.91%, training accuracy of 96.57%, validation loss of 11.47% and validation accuracy of 94.36% on 25 epochs, as illustrated in Figures 7 and 8.

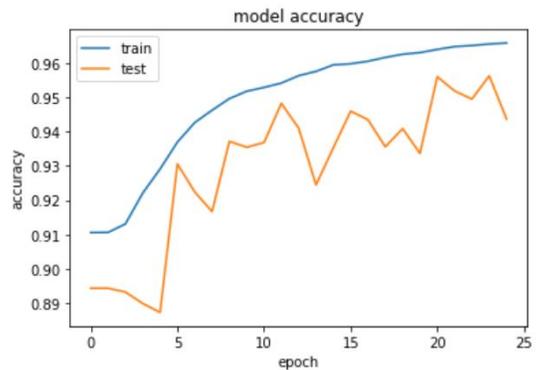

Fig. 7. Snippet of Model Training Accuracy with 25 Epochs.

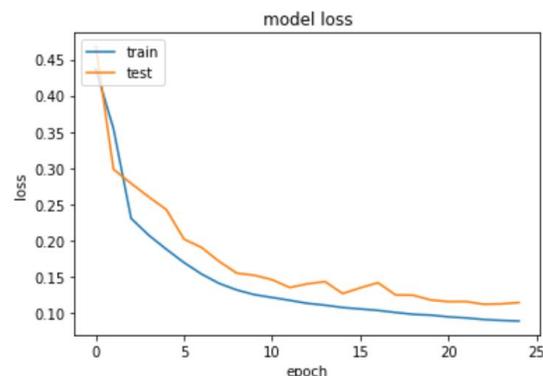

Fig. 8. Snippet of Model Training Loss with 25 Epochs.

### D. Performance Evaluation of the Intrusion Model

The entire test set of the overall dataset was tested on the intrusion detection model. The test samples for each attack class were randomly selected. The CNN-LSTM intrusion detection model is evaluated to give the accuracy, Precision score, and Recall score of 0.89, 0.894, and 0.894, respectively,

on ten epochs, all on a scale of 0-1. The developed CNN-LSTM model is further evaluated on 25 epochs with accuracy, Precision score, and Recall score of 0.944, 0.959, and 0.922, respectively, all on a scale of 0-1.

## VII. CONCLUSION

Intrusion Detection System is an essential tool used in cyber-security to determine and track intrusion attacks. The rising development of information technology lately has further increased the usage of computer networks for several applications such as finance, business, industry, health and other various aspects of human life. Therefore, developing and deploying secure and reliable networks are critical to information technology administrators. This rapid development of information technology has produced several threats to building a robust and reliable network. There are many kinds of attacks threatening the confidentiality, integrity, and availability of computer networks. Some of these are Flooding, Blackhole, Normal, TDMA, or Grayhole, and they are regarded as harmful attacks.

The DOS attacks are the most common harmful attacks that temporarily denies several services of the end-users, consume computer and network resources. To avoid DoS attacks on computer networks, it is very important to detect and identify the actual type of attacks invading the network. This study developed a neural network model that detects the type of attack affecting the overall system network.

Wireless Sensor Networks Dataset (WSN) having five types of attacks was used in this study. The CNN-LSTM learning model was trained over 10 and 25 epochs with a 0.001 learning rate to ideally detect and classify the attacks. The overall learning algorithm registered a training accuracy of 96.57%; the detection model detected the five kinds of attacks available successfully. The CNN-LSTM intrusion detection model is evaluated to give the accuracy, Precision score, and Recall score of 0.89, 0.894, and 0.894, respectively, on ten training epochs, all on a scale of 0-1. The developed CNN-LSTM model is further evaluated on 25 training epochs with accuracy, Precision score, and Recall score of 0.944, 0.959, and 0.922, respectively, all on a scale of 0-1. The model has successfully extracted essential features of the five kinds of attacks considered.

This study is suitable for detecting intrusion attacks of computer networks, thereby enabling a secured environment for the system's proper functioning.

**Abstract**—Cyberattacks are on the rise, making technology companies increasingly prone to data theft. Recent research has focused on constructing cognitive models for traffic anomaly detection in a communication network. Many of these experiments resulted in data packets recorded by technologies like Wireshark. These datasets provide high-dimensional data relating to benign and malicious data packets. Recent research has mostly focused on developing machine learning, and deep learning systems to detect attack data packets in a network. Also, machine learning algorithms are currently trained to detect only known threats. However, with the growth of new cyberattacks and zero-day attacks, current algorithms are unable to detect unknown attacks. This research focuses on detecting rare attacks using transfer learning from a dataset of known attacks. Deep learning outperforms explicit statistical modelling approaches by at least 21% for the dataset used. A preliminary survey of candidate deep learning architectures has been performed before testing for transferability and proposes a Convolutional Neural Network architecture that is 99.65% accurate in classifying attack data packets. The suggested CNN architecture trained with a known attack and then tested its performance on unknown attacks to assess transferability. For this model to extract sufficient information for transferability, the training samples must have more information. Only 20% of the dataset represents current threat data. Several strategies, such as innovative synthetic dataset-based training and bootstrapped dataset training, have been developed to overcome small training sets. A subset of training attacks is determined to optimise learning potential. This study finds training-testing attack pairings with good learning transferability. The most robust and stable relationships are found in DoS attack training-testing pairings. This study also presents model generalisation hypotheses. The dataset features and attack characteristics were analysed using the Recursive Feature Elimination (RFE) algorithm to validate the results.

**Keywords**—Transfer learning; convolutional neural network; intrusion detection system; cyber security; machine learning and deep learning

## I. INTRODUCTION

A neural network uses knowledge learned from previous training to improve generalization on another similar task in transfer learning. The primary goal of this study is to leverage learning transferability to select attacks from the training dataset that causes the model to generalize for other attacks, which can be extended to rare attacks.

In computer networks that employ machine learning algorithms for network security, it is difficult to provide guarantees

about the kind of attacks that the network can expect to see and is susceptible to, especially with the rise in the number of novel attacks. Current machine learning algorithms are usually trained to detect a set of known attacks or learn from attacks performed in the past. Therefore, it is hard to predict the range of attacks against which the employed machine learning algorithm is robust. In the literature, there is proof of concept for both classical ML and DL approaches for anomaly detection [1].

Transferability studies can help us understand the range of attacks against which the system is actually robust based on the attacks that the algorithm has been trained to detect and how those attacks enable the model to generalize for other attacks. This is especially useful when the trained model is able to generalize to unknown attacks without being trained on them explicitly because this provides a more extensive range of attacks that the network may be secure against attacks. Studying these attack correlations indicates the attacks that the model can detect and the accuracy of these unknown attacks. This helps us evaluate the risks of what the model can predict if the observed correlations are consistent and what kind of protection the algorithm provides at what computational cost. Transferability studies could discover that the model scales to other different attacks it has learned to detect without being trained on them explicitly. It assures detection for an even broader range of attacks than the ones it has seen. For groups of similar attacks or correlated attacks, transfer learning enables us to find representative attacks from that group. This helps us to train the model with a smaller number of attacks yet achieve the same level of security as it would have if trained with all the attacks in the group.

The increasing machine learning applications have also seen deep learning models going into hardware chips. The advantage of transferability is that we could identify smaller training sets yet make the model generalize well for a broader range of attacks. This decreases training times, making the process of training computationally efficient and having lower memory requirements. This is important, especially if this algorithm is deployed on a resource-constrained device while performing at par with a model trained on a full training set.

Increasing research in this domain has led to an increase in network traffic datasets. Some of the common datasets used are CAIDA 2007, DARPA 98, KDD 99, CSE-CIC-IDS 2018, and UNSW-NB15, to name a few. This work uses the traffic

dataset CICIDS 2017 for training the proposed model. Traffic monitoring software like Wireshark has been used for logging and monitoring network traffic packets for creating these datasets. While these datasets provide a complete description of network packets, they have a high dimensional feature space. In a preliminary study of a potentially suitable neural network, a model has been developed to extract meaningful data from high dimensional training data and a limited number of attack data packets. After identifying a suitable network, the work focuses on attack correlations and comparisons for why training the model with one attack scales for another and if these correlations are symmetric or asymmetric. This study describes the work's contributions in three sections: first, Developing a DNN architecture; second, Testing the proposed architecture for transferability and third, hypothesis for attack correlations.

**Developing a DNN architecture:** A comparative study of a Hidden Markov Model has been carried out as a statistical modelling-based approach and a candidate Convolutional LSTM Deep Neural Network (CLDNN) architecture and shows that the deep learning approach scales better for the used dataset. Further, deep learning models have been explored for the classification task. The proposed model's candidate DNN architectures include a Convolutional LSTM Deep Neural Network (CLDNN), Convolutional Neural Network with BGRU recurrent layers, and One Class Neural Networks (OCNN), and a Convolutional Neural Network (CNN). The performance of these models has been evaluated when trained and tested on all attacks in the dataset. Also, the learning transferability has been evaluated. All the above architectures had overall accuracies of above 90%; however, this dataset is highly unbalanced, with a majority of the dataset consisting of benign data packets. The models are able to detect benign attack packets with high accuracy, thereby boosting the overall accuracy of the models. Therefore, a major criterion for architecture selection is not the overall accuracy but the percentage of attack data packets it is able to classify correctly. Attack transferability has been studied with some of these architectures; however, none of the candidate models other than the proposed architecture showed very strong correlations between training-testing attack pairs. The proposed architecture is the model that shows maximum attack data classification accuracy for the multi-class classification problem. This architecture is able to perform deep feature extraction using flow-based features not only for adequately sampled attacks but also for severely underrepresented attacks.

**Testing the proposed architecture for transferability:** Attack transferability has been tested with the proposed model architecture by training the model with one kind of attack from the training dataset and testing it on another attack. The entire dataset consists of 20% of attack data that are further divided into fourteen categories of attacks. Therefore, the representation of each attack class is low. For learning transferability, the model requires a larger number of attack data packets. Two techniques have been used to increase the number of attack data packets to address this problem: 1) Using SMOTE generated data and 2) Using a bootstrapped dataset. A Synthetic Minority Oversampling Technique (SMOTE) was used for the first method to generate more attack data packets in each attack class synthetically. For the second method, the original attack data is resampled, shuffled and added to the training dataset to match the number of benign data packets.

Furthermore, exploring the possibility that the model may exhibit higher testing accuracies for a particular attack if it is trained with a subset of other attacks in the dataset. An attack boosting algorithm is employed to select a subset of attacks from the training dataset to maximize the classification accuracy when tested on a particular attack. **Hypotheses for correlated attacks:** The study of attack correlations reveals training testing attack pairs that exhibit strong correlations with each other. A hypothesis has been proposed for these observed attack correlations. The attack characteristics have been studied and important features to validate the hypotheses. The Recursive Feature Elimination (RFE) algorithm is used to identify the dominant features for learning. This not only reduces the dimensionality of the training data but also reduces training times. This study makes inferences about the properties of the features selected and the number of features selected for a pair of correlated attacks. This results in identifying usable attacks in this dataset for transfer learning and explaining why they scale for certain attacks.

## II. BACKGROUND AND RELATED WORK

The dataset used is the Canadian Institute of Cybersecurity Intrusion Detection Systems dataset: CICIDS 2017. Overall, the dataset consists of 8 separate CSV files, with data corresponding to attacks simulated in 8 sessions included. The entire dataset consists of data corresponding to 14 types of attacks and benign traffic. The dataset describes 78 flow features. 80% of the data entries are benign data, and 20% of the dataset consists of attack data. The dataset was created by simulating 14 different types of attacks that are shown below in Table I.

TABLE I. DATASET COMPOSITION

Classes	Attack	Percentage of data
0	BENIGN	80.3
1	Botnet	0.069
2	DDoS	4.52
3	DoS GoldenEye	0.36
4	DoS Hulk	8.16
5	DoS Slowhttptest	0.19
6	DoS Slowloris	0.2
7	FTP-Patator	0.28
8	Heartbleed	0.00038
9	Infiltration	0.0012
10	PortScan	5.61
11	SSH-Patator	0.2
12	Web Attack Brute Force	0.053
13	Web Attack SQL Injection	0.00074
14	Web Attack XSS	0.023

An attacker gains control of several machines and servers connected to the internet and uses these servers to carry out cyberattacks against a target. Due to multiple synchronized attacking machines, the attack data volumes are huge, thereby facilitating a strong attack against the target machine. Botnets are often used to carry out DDoS attacks. Denial of Service (DoS) attacks are attacks aimed at making a server unresponsive to the requests of legitimate users. They usually work by sending enormous traffic, thereby flooding the server and hitting its resource pool by requesting resources or sending obfuscated data that make the server unavailable to real requests.

**Distributed Denial of Service (DDoS)** attacks are DoS attacks conducted by different servers at once on a victim server. These servers have different IP addresses, thus making

it difficult to track down one single IP address for attacker identification, which makes it hard to mitigate the attack. In the case of flooding attacks, the volume of data generated to flood the victim server is larger, making the DoS attack strong and harder to terminate[2]. DoS: A goldenEye is an attack tool that identifies vulnerabilities in a target server. It explores the capability of victim servers to form multiple HTTP connections, thereby using up all possible connections on that server. This attack can be operated as a distributed attack as well. DoS GoldenEye uses Keep-Alive headers and Caching Control options to keep the connection alive, preventing the target server from shutting down the connections and making the server unresponsive to non-attack requests.

**DoS: HULK** is HTTP Unbearable Load King attack. A flooding attack floods the target servers with a large volume of HTTP requests, requesting data or resources or sending unclear HTTP packets. This floods the target machine with HTTP data packets, and the load is unbearable for the server, which makes the server unreachable.

DoS: Slowhttptest and DoS: Slowloris are attack tools for carrying out Slow HTTP attacks. **Slow HTTP attacks** form multiple connections with the target server and try to keep the connections open. Some slow HTTP attacks keep the connection open by declaring a large amount of data to be sent and sending the data at very large intervals of time, almost equal to the timeout period. However, the server cannot close the connection, and the connection does not take time out. This keeps all available connections alive and keeps the server from responding to legitimate requests. Slow HTTP attacks can be made using Slow Header attacks, where the packet header arrives at large intervals or Slow Body attacks, where the body of the data arrives very slowly.

**Brute Force attacks** are targeted towards gaining access to authentication keys by trying all possible combinations of the key. File Transfer Protocol is a network protocol that can be used to transfer files. Users connect to the server using an FTP client using the username and password authentication. Brute Force FTP attacks are an attack on the username and password. Brute Force SSH gains access to valid login credentials to authenticate SSH access to a server by trying all possible combinations.

**Heartbleed** could be classified as a protocol based attack where the attack utilizes a packet header field required for the transport layer security protocol that causes a machine to dump out its entire memory, including confidential and protected data. It does so without leaving traces in the target machine, making it undetectable. In an infiltration attack, the attacker gains access to a protected network or system and finds vulnerabilities in the machines or devices connected to the network. After identifying vulnerabilities, the attacker attacks the machine or device to steal private information.

In an **Port Scan attacks**, the attacker scans the ports of the target server and sends requests to a range of ports on the target server. The attacker finds an active port on the server and exploits a known vulnerability of that service to attack the target server.

**Web Attacks** identify weaknesses in web applications to gain access to private or protected data. These weaknesses could be exploited using data entry or using injection attacks

where malicious scripts are injected into data entries of otherwise harmless websites or by using brute force. For example, for a web application that uses an underlying SQL database and has an option for user inputs, malicious inputs could be given that cause the database to dump out confidential information. DDoS attacks are also a kind of web attack.

It can be observed from Table 1 the CICIDS 2017 dataset is highly unbalanced, with 80% of the dataset consisting of benign data and 20% of the dataset consisting of attack data packets. The attack data is further divided unequally into fourteen different types of attacks. Because of the unequal division, certain attack classes have a very sparse representation, for example, just 11 or 36 data packets throughout the entire dataset. This makes it difficult to generate realistic synthetic data to augment the number of data packets and limits model learning even when using a bootstrapped dataset for these classes of attacks. Therefore, when the proposed architecture has been tested for attack transferability. It eliminates those classes of attacks that cannot use for the transferability of learning.

In the literature, there are different machine learning techniques that deal with intrusion detection using flow characteristics. Alkassabeh et al. explore MLP, Naive-Bayes, and Random Forest classification algorithms for Distributed Denial of Service attack detection and show that MLP achieves the highest accuracy [3]. Lopez et al. presents a study of machine learning techniques for traffic anomaly detection and proves that a Random Forest-based decision classifier is the best model for anomaly detection, and a Dense Neural Network is a good classifier for some types of DDoS attacks with methods to boost a number of attack samples of underrepresented attack types [1]. Vinayakumar et al. carry out a comprehensive study of DNNs and Machine Learning classifiers that learn abstract and high dimensional data representation using the KDDCup99 dataset and test their model performance on other datasets, such as NSL-KDD, UNSW-NB15, Kyoto, WSN-DS, and CICIDS 2017. They also propose a hybrid DNN framework which can be deployed in real-time to monitor network traffic and events to detect possible network attacks [4]. Sharafaldin et al. generate a dataset consisting of benign and seven types of attack data. They also evaluate the performance of machine learning algorithms to identify the best subset of features for certain types of attacks [5]. Ferrag et al. analyze RNNs, DNNs, restricted Boltzmann machines, Deep Belief Networks, CNNs, Deep Boltzmann machines and deep autoencoders for traffic data classification using the CSE-CIC-IDS2018 dataset and the Bot-IoT dataset [6].

To find out about an undiscovered attack, researchers have chosen TL-based IDS more. Zhao et al. [7] proposed an algorithm that used the NSL-KDD dataset for binary classification mapped the source and target domains into the latent space K. In their method, the R2L attack was found by looking at DoS data from the source domain. The same author made their TL even better in their next work by adding clusters [8]. They found that 500 data points are enough to train the NSL-KDD dataset well. It was shown by Taghiyarrenani et al. [9] that transfer learning can work even if the source and target data are different from each other. They were able to tell the difference between normal traffic and traffic that wasn't normal. Their results were better when the source domain had a lot of labels

and the target domain didn't have as many labels.

Wu et al. [10] also used a CNN to pass on knowledge learned from one dataset to another. When they researched, the UNSW-NB15 dataset was used as the source data, and the NSL-KDD dataset was considered the target data. As the datasets were different, they used two CNNs in their method. Afterwards, a fully connected layer used the data to make the final classification for the data from NSL-KDD. Singla et al. [11] found that transfer learning can help when there isn't enough training data to learn new attacks. Their approach isn't very different from what [10] had done. They used binary classification to look for a specific attack in the UNSW-NB15 dataset. They used the remainder of the attacks using the same dataset as the original domain. With the normal DNN, they found that it did better when there was less training data for their transfer learning-based approach.

In 2020, Masum et al. [12] used the same computer vision algorithms on IDS that they used on PCs. As image processing needs two-dimensional data, they turned the intrusions dataset into two-dimensional data, and then used VGG-16 [13] to look for intrusions. However, they were able to get about 95% accuracy, which some people might think isn't enough for the real world because other algorithms have been able to get more than 95% accuracy in the past. The reason could be that the features that were made with VGG-16 might be better for image processing than intrusion detection. Second, Dhillon et al. [14] have shown how TL can be used in real-time. A CNN-LSTM algorithm was made. Then, they moved their model to a new place where they could use data that wasn't there to figure out whether it was an attack or not. Research done by them shows that there is no difference between the space for features and the space for labels in both fields. They were able to speed up their research by using TL.

Vijayakumar, Alazab et al. [15] evaluated the performance of CNN for intrusion detection. CNN was investigated in their work both directly and in combination with RNN, LSTM, and GRU algorithms. CNN and recurrent algorithms were found to perform nearly identically when used together. Even though they could get good outcomes, the computational power required by their approach was excessive.

### III. METHODOLOGIES

#### A. Hidden Markov Models: A Statistical Modeling based Approach

HMM is a Markov Model in which the process being modelled is a Markov Process. Markov models are used to model processes that change stochastically. This study considers that the phenomenon being modelled is a first-order Markov Process where the next state of the phenomenon is only dependent on the current state of the phenomenon. This is called the Markovian Property. If  $q_t$  represents the state of a model at time instant  $t$ , then the conditional probability of its next state will be as given:

$$P(q_t = S_i | q_{t-1} = S_j, q_{t-2} = S_k, \dots) = P(q_t = S_i | q_{t-1} = S_j)$$

Where  $S_i$  is the current state and  $S_j, S_k$  represents the past states.

In HMM problem, the observations are the features corresponding to a data sample. Forty flow features from the dataset are taken for each data sample and are fed to each HMM as 40 observations. Each CSV file in the dataset is treated as a separate dataset. The performance of HMMs has been evaluated on 2 class and 4 class classification problems. In those cases, 2 HMMs and 4 HMMs have been used, respectively, for training. Observations are taken at a time from the testing dataset, and each model is tested with the  $T$  observations. The model that generates the highest probability  $P(O|\lambda)$  implies that the set of observations  $O$  belongs to that HMM and class.

Computation of  $P(O|\lambda)$  using hidden states. Let  $Q$  be the set of hidden states:

$$O = O_1, O_2, O_3, \dots, O_T \text{ where } T = 40.$$

$$\sum_Q \frac{P(O|\lambda)}{P(O|Q, \lambda)P(Q|\lambda)} = P(O_1, O_2, O_3, \dots, O_T|\lambda) =$$

Where  $Q$  is the set of all possible hidden states, the complexity is of the order  $O(2TN^T)$  for a general system with  $N$  states and  $T$  observations to compute  $P(O|\lambda)$  using the method above. A forward-backwards algorithm is used to compute the same quantity. This reduces the computational complexity to  $O(N^2T)$ .

#### B. Neural Network Architectures

Deep Neural Network architectures have been tested to identify the best architecture to use to study attack correlations. The first two architectures that have been tested are a CLDNN and CNN with BGRU layers. These neural networks are part of a class of neural networks called CRNN, which is CNN with Recurrent Layers. Convolutional layers have been used because they capture spatial features from the dataset and gated RNNs to capture temporal patterns in the sequence. Bidirectional GRUs capture temporal patterns not only forward in time but also backward in time. In addition, the performance of a One Class Neural Network (OCNN) has been evaluated as it is good for minority data detection in large datasets. Finally, the performance of a Convolutional Neural Network without Recurrent layers has been evaluated.

1) **CLDNN**: The Convolutional LSTM Deep Neural Network architecture has 6 hidden layers. The first layer is a convolutional layer with 256 feature maps, a (1, 3) convolution kernel and 20% dropout. The second hidden layer is a convolutional layer with 256 feature maps and a (2, 3) convolution kernel. The third layer is a convolutional layer with 80 feature maps and a (1, 3) kernel with 20% dropout. The fourth hidden layer is a convolutional layer with 80 feature maps and a (1, 3) kernel. The fifth hidden layer is an LSTM layer with 50 cells. The sixth hidden layer is a fully-connected layer with 128 neurons. The CLDNN architecture has shown in Table II. All hidden layers have Rectified Linear Unit(ReLU) activation as:

$$g(x) = \max(0, x)$$

This architecture was used to evaluate its performance on i) The multi-class classification problem when it is trained with all classes of data and tested on all classes of data and ii) The two-class classification problem when it is trained with

one class of data and tested on all other classes of data. For the multi-class classification problem, the output layer has 15 output classes. For the two-class classification problem, the output layer has two output classes. In both implementations, the output layer has softmax activation. Softmax activation can be given as:

$$\sigma_i(z) = \frac{e^{z_i}}{\sum_{j=1}^J e^{z_j}}, \text{ where } J \text{ is the total number of classes}$$

TABLE II. CLDNN ARCHITECTURE

CLDNN Architecture
Conv2D 1x3x256, ReLU, Dropout(rate=0.2)
Conv2D 1x3x80, ReLU, Dropout(rate=0.2)
Conv2D 2x3x256, ReLU
Conv2D 1x3x64, ReLU
LSTM 50
Dense, 128, ReLU
Dense, 2, Softmax

All 78 features are used for training. For the two-class classification problem, the model has been trained on one kind of attack and evaluates its performance when tested on all the other attacks. In this case, all benign data is labelled zero, and all attack data is labelled one. For the multi-class classification problem, the model is trained with all 15 classes of data. The total dataset is divided into a fifty-fifty split; 50% of the data is used for training, and 50% of the data is used for testing. The loss function used is Categorical CrossEntropy, and the optimizer is Adam. The batch size is 1024. This model is trained for 50 epochs. The categorical CrossEntropy loss function is given by:  $L_{CE} = -\frac{1}{N} \sum_i t_i \log(p_i)$ .

where  $t_i$  is the true label of the  $i^{th}$  data point,  $p_i$  is the predicted probability of the data point belonging to class  $t_i$  and  $N$  is the batch size.

2) **CNN with BGRU layers and CNN with stacked BGRU layers:** Gated Recurrent Units are different from traditional RNNs without gates as they are able to control the amount of previous data to carry over to the next iteration using hidden states. GRUs usually have a reset gate and update gate as opposed to a forget gate, input gate and output gate as in LSTMs. This makes training the model with GRUs faster than using LSTMs. BGRUs have connections that go backwards in time, enabling them to capture temporal patterns backwards and forward in time. The CNN with Bidirectional Gated Recurrent Units and Stacked Bidirectional Gated Recurrent Units architecture is the same as the architecture of the CLDNN used, except in these architectures, there are BGRU and stacked-BGRU layers in place of the LSTM layer. Each BGRU layer has 50 cells. For a stacked-BGRU approach, there are two BGRU layers consecutively with 50 cells in each layer. Each model is trained for 150 epochs, with a batch size of 1024. The loss function used is mean squared error, and the optimizer used is RMSProp. Table III and Table IV are the architectures of these two DNNs.

3) **One Class Neural Networks:** One Class Neural Networks (OCNN) are used for anomaly detection in complex datasets that require highly non-linear decision boundaries. The loss function of OCNNs is derived from the loss function of OC-SVMs. In an OC-SVM, for input data  $X$  with  $N$  input samples  $\{X_i\}_{i=1}^N$ . A  $\phi(X_n)$  is a reproducing kernel Hilbert

space that is a mapping from the input space to feature space. All the input data points are labelled one, and the only negative point is the origin. A hyperplane separates the origin from the mapped  $\phi(X_n)$ s. The hyperplane in the feature space is given by  $f(X_n) = w^T \phi(X_n) - r$ .  $v$  is the parameter to control the trade-off between maximizing the distance and the number of data points falsely classified as positive.  $r$  is the hyperplane bias. An OCNN has a feedforward neural network with one hidden layer and one output node. Here,  $w$  is the scalar output from the hidden to the output layer, and  $V$  is the weight matrix from the input to the hidden layer. The hidden layer has a linear or sigmoidal activation given by  $g(\cdot)$ .

The optimization problem for OCNNs is:

$$\min_{w, v, r} \frac{1}{2} \|w\|_2^2 + \frac{1}{2} \|V\|_2^F + \frac{1}{v} \cdot \frac{1}{N} \sum_{n=1}^N \max(0, r - \langle w, g(VX_n) \rangle) - r \quad (1)$$

$(w, V)$  are updated using normal backpropagation. The model is trained using important features extracted from an auto-encoder instead of using the raw data. The OCNN algorithm is implemented by Chalapathy et al. [16]. The performance metrics have been calculated by True Positive Rate (TPR), False Positive Rate and (FPR)ROC curve.

4) **CNN:** The Convolutional Deep Neural Network architecture consists 5 hidden layers. The first hidden layer is a Convolutional layer with 256 feature maps and a (1, 3) convolution kernel. The second hidden layer is a convolutional layer with 256 feature maps and a (2, 3) convolution kernel. The third hidden layer is a convolutional layer with 256 feature maps and a (1, 3) convolution kernel and a dropout of 20%. The fourth hidden layer is a convolutional layer with 80 feature maps and a (1, 3) convolution kernel. The fifth hidden layer is a fully-connected layer with 128 neurons. The output layer has 2 output nodes and sigmoid activation. Layers 1,4 and 5 have ReLU activation and layers 2 and 3 have Leaky ReLU activation with  $\alpha = 0.3$ . All 78 features from the dataset were used for training. This model's performance is evaluated on the multi-class classification problem. The architecture of CNN has shown in Table V. The model is trained on 70% of data and tested on 30% of the data. 10% of the training data is used as validation data. The model is trained for 100 epochs. The

activation function used is Leaky ReLU and Sigmoid. The loss function used is Binary Cross-Entropy(BCE).

### C. Attack Correlations

**Base Architecture Trained on Original Dataset:** This section studies the transferability of learning using the proposed base architecture, training the CNN architecture with one attack, and testing on all the other attacks. A two-class classification problem has been considered to implement this. All attack data has been labelled as one class and all benign data as another class. The model has been trained on benign data and attack data corresponding to the attack whose transferability has to study. As seen in Table I, attacks like Attack 8 (HeartBleed), Attack 9 (Infiltration) and Attack 13 (Web Attack: SQL Injection) are severely underrepresented in the dataset. A synthetic and bootstrapped dataset has been discussed to address this problem. In this section, the models are trained with only the original dataset. In confusion matrices in the results section, Attacks 8, 9, and 13 are not included as there are not enough original samples in the dataset for transferability in learning. The model is trained for 20 epochs for each attack, the loss function used is Binary CrossEntropy, and the optimizer used is Adam.

**Base Architecture Trained on Synthetic and Bootstrapped Dataset:** The CICIDS 2017 dataset is unbalanced, with 80% of the data samples being benign data packets and 20% of the data samples belonging to attack data. The total attack data is further divided into fourteen classes of attacks; thus, each class is severely underrepresented in the dataset, which is not ideal for learning. The main goal of this section is to test the model for strong and consistent attack correlations when it is trained with a greater number of samples from the minority attack classes.

**Synthetic Minority Oversampling Technique (SMOTE):** More attack data has been generated per class using Synthetic Minority Oversampling Technique (SMOTE). SMOTE selects examples that are close to each other in the feature space. This technique selects one point from the minority attack class and uses K nearest neighbours algorithm to find the K nearest data points around the randomly chosen point. The number K is chosen based on how much minority classes have to oversample. In this implementation, 5 nearest neighbours have been chosen. It then randomly selects one neighbour point out of the K neighbours and creates a synthetic data point on the line joining the two selected points. Using this technique, specific regions have been identified in the feature space that can generate more samples belonging to a certain class of data. The number of attack packets generated using this technique is used to match the number of benign data packets in the dataset. This process is repeated for each attack. The model trained with this dataset is tested on: 1) SMOTE generated

benign data and real attack data for evaluation of accuracy when tested on a synthetically generated benign dataset and 2) Real benign data and real attack data as this scenario best emulates a real-life scenario.

**Bootstrapped Dataset:** Another technique used to create a balanced training dataset is for every attack that the model is trained with, the attack data is resampled to match the number of benign data packets. This training dataset is bootstrapped dataset. This process is used to replicate attack data corresponding to all attacks. The base architecture is trained with this enhanced dataset and tested on real attack data. During training, it is validated on 20% of the attack data. During training with the SMOTE dataset as well as a bootstrapped dataset, the model is trained for 20 epochs per training attack, the loss function used is Binary CrossEntropy, and the optimizer is Adam.

**Attack Boosting Algorithm:** The previous sections explore transferability in learning when the model is trained with a single attack and tested on other attacks. This section aims to identify a subset of training attacks that can be used to train the model to cause it to scale for other attacks. The possibility of the model scaling for a certain test attack has been explored when trained with a combination of training attacks (that do not include the testing attack). The aim was to observe consistent and strong off-diagonal correlations and identify training attacks. To do this, the attack boosting algorithm has been used as outlined in Algorithm 1. 50% of the set is used only as training data for selecting the training attacks, and the model performance is evaluated on the remaining 50% of the set that serves as the validation data. The testing data consists of the attack for which we want to select a subset of training attacks along with benign data. The loss function used is Binary CrossEntropy, and the optimizer used is Adam.

D. Hypothesis for Attack Correlations

In this section, we propose hypotheses for observing the correlations as in Fig. 5.2. In doing so, we use the Recursive Feature Elimination Algorithm [17] to identify the important and dominant features for model learning. We propose hypotheses based on the number of important features selected by the algorithm as well as the properties of the attacks and features selected.

Recursive Feature Elimination is a feature selection algorithm used to identify the important features. A different ML algorithm is used to identify important features in a given feature set and wrapped by the RFE algorithm to do so. This ML algorithm at the core of the wrapper does not have to be the same as the classifier used for the classification task at hand, and it can be other algorithms like Decision Trees, Random Forests, to name a few. RFE provides us with a subset of the entire feature set that is important for learning. This is especially important for datasets with a large number of features to identify the important features for learning and to reduce training times significantly. RFE works by recursively training the model with reduced features and removing features without which the model performs with higher accuracy. RFE also ranks the features in order of importance. The top n features can be selected based on this algorithm.

The CICIDS 2017 dataset has 78 features, a relatively large number of features. The main goal is to identify a smaller subset of features that are important for the learning and scalability of the proposed model and speed up training times. Two implementations of the RFE algorithm have been done in the proposed model. A single attack has been selected from all the attacks for the first implementation. The RFE algorithm is used to identify features that the classifier uses to separate from the benign data. This process has been repeated for all attacks in the dataset in order to identify the common features between attacks to validate the proposed hypotheses. The second implementation involves taking two correlated attacks (as observed in Figure 5) and using the RFE algorithm to identify the number of features that the classifier uses to differentiate both attacks from benign data. The Decision Tree Classifier has been used as the core model for RFE. The training data for both these implementations contain the attack and benign data.

IV. RESULT AND DISCUSSION

A. Comparison between HMM Performance and CLDNN Performance

To observe if the statistical modelling-based approach scales better than the deep learning approach, the performance of the HMM compared with a candidate CLDNN model (Table VI). It has been observed that the CLDNN model is able to achieve an overall accuracy of 99.69% for 2 classes of data and 99.57% for 4 classes of data. In contrast, the HMM model is only 78.7% accurate for 2 classes of data and 50.8% accurate for 4 classes of data. This could be because not all the attacks in the dataset are multi-stage attacks that correspond to the hidden states of the HMMs. The performance of the HMM model deteriorates as the number of classes in the dataset is increases.

TABLE VI. HMM vs CLDNN

Number of Classes of data in dataset	HMM accuracy	CLDNN accuracy
2 Classes	78.7%	99.69%
4 Classes	50.8%	99.57%

Table VI concluded that the deep learning approach shows more promise for the multi-class classification problem. Therefore, more deep learning architectures have been explored in the following sections to identify the best architecture to study attack transferability patterns. The next section gives the architecture details of the used candidate CLDNN model.

B. Result of the Neural Network Architectures

1) **Result of the CLDNN Architecture on the Multi-class Classification Problem:** An attack accuracy metric is used to evaluate the performance of a model other than the overall accuracy metric [18]. This metric was used because the number of benign packets is much larger than the attack data. A gross misclassification of the attack data packets does not diminish the overall accuracy considerably. A more accurate metric of performance evaluation would be the percentage of correctly classified attack data. Therefore, the attack accuracy is defined as the ratio of the number of correctly classified attack packets in a class to the total number of attack packets in that class. This is also called true positive rate more generally.

$$Attack\ Accuracy = \frac{Number\ of\ correctly\ classified\ attack\ packets\ in\ class\ i}{Total\ number\ of\ attack\ packet\ packets\ in\ class\ i}$$

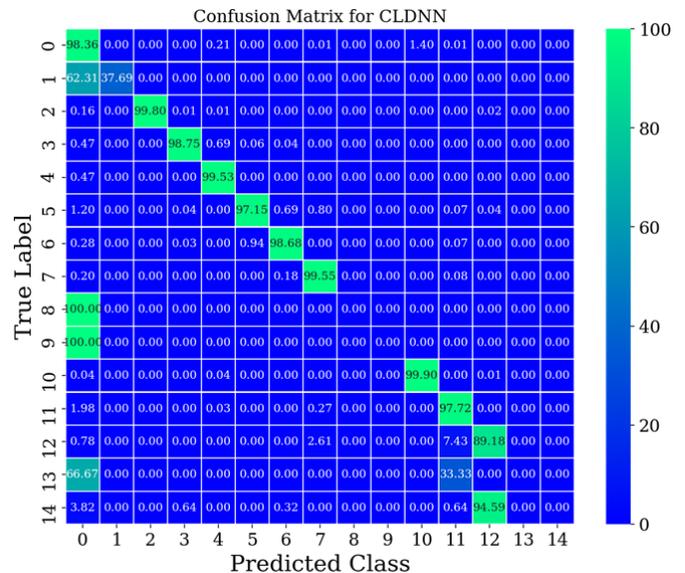

Fig. 1. Attack Accuracy for CLDNN Multi-class Classification Problem.

Fig. 1 is the confusion matrix of the performance of this CLDNN architecture. The labels on the Y-axis of the matrix indicate the true labels of the testing data. The labels on the X-axis of the matrix indicate the predicted labels of the testing data. A model with good performance observed high accuracy along the diagonal of the confusion matrix, which indicates that the model correctly classifies the attack with which it is trained with high accuracy. It has been observed that the proposed CLDNN architecture achieves an overall accuracy

of 98.53%. For most classes, the model is able to classify the attacks correctly. However, it can be observed that although the model is being trained on data from Attacks 8 (HeartBleed), 9 (Infiltration), and 13 (Web Attacks: SQL Injection), it is not able to classify them with a good attack accuracy correctly. This is mainly because Attacks 8, 9 and 13 are significantly underrepresented in the dataset. It could also be that there are not a lot of dominant features that influence the learning of the model. In addition, it is also a possibility that the important features do not have a large variance in their distribution. This makes it hard for the model to learn patterns to differentiate between the data classes.

**2) Result of the CLDNN Architecture on the Two-class Classification Problem:** Fig. 2 is the confusion matrix for the two-class classification problem. In this confusion matrix, the labels on the Y-axis indicate the attack with which the model has been trained. The labels on the X-axis represent the class of attack that the model is tested on. A model trained on one attack is tested on all other attacks for transferability. More off, the diagonal correlations are preferred for a model that exhibits attack transferability. High classification accuracies on the diagonal represent the model’s performance when it is trained and tested on the same attack. However, to observe transferability in learning, it will be best to observe high accuracies when the model is tested on an attack class that it has not been trained on. It can be observed that training this CLDNN model with one attack does not correlate to any other attack. Most of the correlations observed are on the diagonal of the confusion matrix, which means the model only performs well when tested on the training attack. It exhibits low transferability; for example, when the model is trained with Attack 12, it can identify attacks in class 14 with 91.87% accuracy. It does not exhibit other strong off the diagonal correlations. Therefore, it has been concluded from these results that the transferability of learning cannot be tested using this architecture.

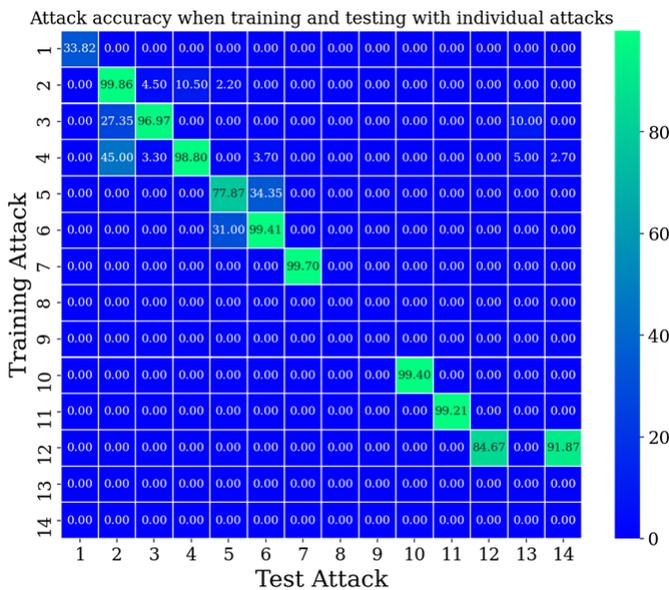

Fig. 2. Attack Accuracy for CLDNN for Two-class Classification Problem.

**3) Results on CNN with BGRU Layers and CNN with Stacked BGRU Layers:** These results present a comparative study of the performance of the CLDNN, CNN with BGRU layer and CNN with stacked BGRU layers for select attacks for the two-class classification problem. The performance of a CNN has also been evaluated with a BGRU layer with 10 cells. The attack accuracy was evaluated when tested on each attack. All the entries are attack accuracies in terms of percentages.

TABLE VII. COMPARISON OF PERFORMANCE OF LSTM, BGRU AND STACKED BGRU ARCHITECTURES ON ALL TESTING ATTACKS WHEN TRAINED WITH ATTACK 4(DOS:HULK).

Stacked BGRU	0	30.7	96.5	0	0	0	0	0	0	0	0	0	0	0

TABLE X. COMPARISON OF PERFORMANCE OF LSTM, BGRU AND STACKED BGRU ARCHITECTURES ON ALL TESTING ATTACKS WHEN TRAINED WITH ATTACK 5(DoS:SLOWHTTPTEST).

Testing Attack	1	2	3	4	5	6	7	8	9	10	11	12	13	14
LSTM	0	0	0	0	77.87	34.35	0	0	0	0	0	0	0	0
BGR (10)	0	3.2	0	0	98.83	35.9	0	0	0	0	0	0	0	0
BGRU (50)	0	0	0	0	76	34.16	0	0	0	0	0	0	0	0
Stacked BGRU	0	0	0	0	90.56	34.7	0	0	0	0	0	0	0	0

From Tables VII, VIII, IX, X, and XI, the models yield high accuracies only when tested on the training attack. Small correlations can be studied, for example, when the models are trained with Attack 5 (DoS: Slowhttpstest) and tested on Attack 6 (DoS: Slowloris) and vice versa. However, the prediction accuracies are still low (about 28%-35%), which is insufficient to

TABLE XI. COMPARISON OF PERFORMANCE OF LSTM, BGRU AND STACKED BGRU ARCHITECTURES ON ALL TESTING ATTACKS WHEN TRAINED WITH ATTACK 6(DoS:LOWLORIS)

Testing Attacks	1	2	3	4	5	6	7	8	9	10	11	12	13	14
LSTM	0	0	0	0	31	99.41	0	0	0	0	0	0	0	0

BGRU (50)	0	0	0	0	31.13	98.24	0	0	0	0	0	0	0	0
Stacked BGRU	0	0	0	0	28.91	98.24	31	0	0	0	0	0	0	0

conclude that those attacks have a strong correlation. It can also tell from Table 4.4 that training the model with Attack 4 (DoS: HULK) has the potential to scale for Attack 2(DDoS) and Attack 3 (DoS: Hulk), but this model only detects those attacks with 31%-47% accuracy. This comparative study concludes that the architectures explored so far do not exhibit very strong attack transferability. The next section will explore another deep learning architecture, a One Class Neural Network and evaluate its performance for anomaly detection.

C. Results of One Class

The implementations are the implementation by Chalapathy et al. [16][19]. The raw data is passed through an autoencoder to find important features. It is then passed through a one-layer NN, and the function it optimizes is given by equation 1. For the CICIDS dataset, the model AUROCs were computed for different seed values.

From Table XII, it can observe that the model performs as good as random guessing in 30% of the runs, marginally better than random guessing in 60% of the runs and worse than random guessing in 10% of the runs. On average, it achieves an AUROC of 0.55. Therefore, It concluded from the AUROC values that this model cannot detect anomalies with high accuracy and would not be suitable for the two-class classification task at hand. The performance of a Convolutional Deep Neural Network has been evaluated in the next section.

D. Result of CNN Architecture on Multi-class Classification Problem

The overall accuracy of the CNN is 99.65%, whereas the CLDNN achieved an overall accuracy of 98.53%. In the confusion matrix, the diagonal elements represent the percentage of data in each class correctly classified. It has been observed from the confusion matrix that the model is able to classify Attack 8 (HeartBleed) correctly and Attack 9

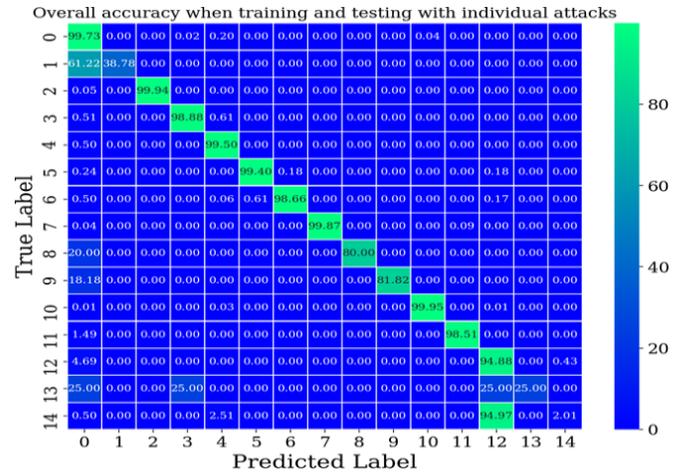

Fig. 3. Results of CNN Architecture on Multi-class Classification Problem.

(Infiltration), that have 11 and 36 data packets in the dataset up to 80% and 81.82% accuracy. Thus, this model can learn the important features from a high dimensional feature set. It concludes that this architecture has performed the best and is the best architecture for studying attack transferability. This architecture does not have recurrent layers, speeding up training time while increasing classification accuracy by 1.12%. This is our proposed base architecture.

E. Results of Attack Correlations

1) Results of Base Architecture Trained on Original Dataset: Fig. 4 represents the overall accuracy of the base architecture. Figure 5 is the confusion matrix for when the base architecture is tested for the two-class classification task. The diagonal elements are placeholders as they indicate the performance of the model when tested on the training attack. From Fig. 3, it has been observed that the model performs with high accuracies when trained and tested on the same attack. Observed Correlations have been shown in Table XIII. It observes transferability in the off-diagonal elements as:

- 1) Training with DoS:Golden Eye(Attack 3) scales for DDoS attacks(Attack 2), DoS:HULK(Attack 4), DoS:Slowhttptest(Attack 5) and DoS:Slowloris(Attack 6).
- 2) Training with DDoS Attack (Attack 2) scales for DoS:HULK(Attack 4) and vice versa.
- 3) Training with DoS:Slowhttptest(Attack 5) scales for DoS:GoldenEye(Attack 3) and DoS:Slowloris(Attack 6).
- 4) Training with DoS:Slowloris(Attack 6) scales for DoS:GoldenEye(Attack 3), DoS:HULK(Attack 4) and DoS:Slowhttptest(Attack5).

TABLE XIII. OBSERVED CORRELATIONS

Training Attack	Correlated Attacks
DDoS(2)	DoS:HULK(4)
DoS:GoldenEye (3)	DDoS(2),DoS:Hulk(4),DoS:Slowhttptest(5),DoS:Slowloris(6)
DoS:Hulk(4)	DDoS(2)
DoS:Slowhttptest(5)	DoS:GoldenEye(3),DoS:Slowloris(6)
DoS:Slowloris(6)	DoS:GoldenEye(3),DoS:HULK(4),DoS:Slowhttptest(5)

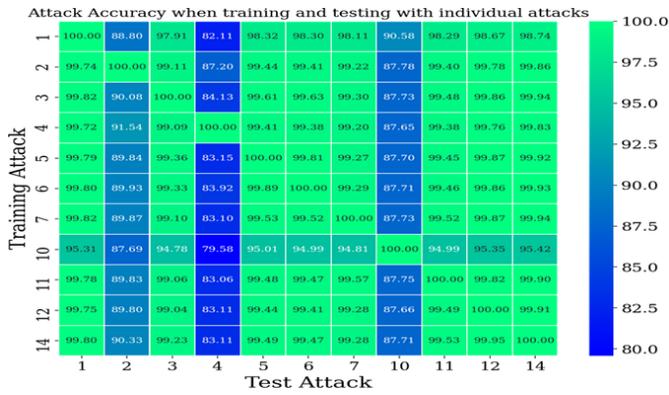

Fig. 4. Overall Accuracy for the Base Architecture for the Two-class Classification Problem.

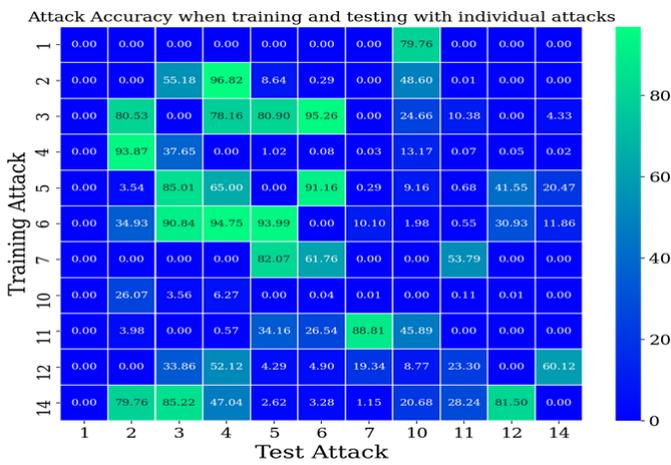

Fig. 5. Attack Accuracy for the Base Architecture for the Two-class Classification Problem.

2) **Results of Base Architecture Trained on Synthetic and Bootstrapped Dataset:** Fig. 6, Fig. 7 and Fig. 8 are the confusion matrices of the base architecture when trained on the SMOTE dataset and bootstrapped dataset and tested on SMOTE and real attack data. From Fig. 5, it can observe that most of the attack pairs that showed a correlation when the model was trained with the original training data also showed correlations when the model was being trained with synthetic and bootstrapped data. Like the previous section, the diagonal elements in the confusion matrices are placeholders as they represent the accuracies when training and testing on the same attack that already observed scales well with accuracies above 90% from Fig. 3.

3) **Results of Attack Boosting Algorithm:** As observed from Table XIV, the algorithm chooses Attack 11 (Brute Force: SSH Patator) as the selected training attack when tested on Attack 6 (Slowloris). This produces a very low PR. In Fig. 5, it can observe that training the model with Attack 3 (DoS: GoldenEye) alone yields a true positive accuracy of 95.26% and Attack 5 (DoS: Slowhttpstest) alone yields a true positive accuracy of 91.16% when tested on Attack 6 (DoS: Slowloris). Table XV can observe a Positive Rate of 0.877 when the model was trained on Attack 11 data and tested on Attack 6. However,

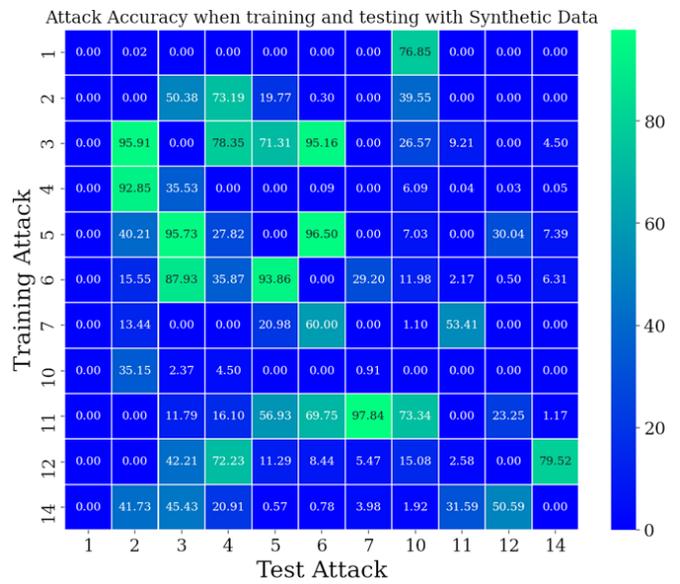

Fig. 6. Confusion Matrix for Base Architecture Trained on SMOTE Generated Attack Data and Tested on SMOTE Generated Benign Data and Real Attack Data.

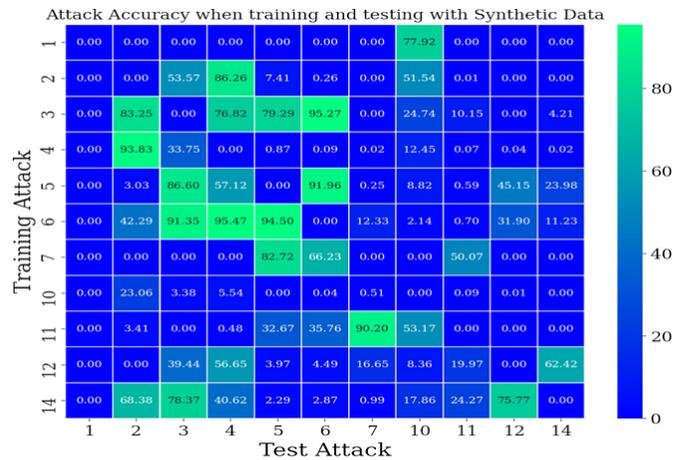

Fig. 7. Confusion Matrix for Base Architecture Trained on SMOTE Generated Attack Data and Tested on Real Benign Data and Real Attack Data.

this does not outperform the model's performance, which was trained with a single attack. From Table XIV can also be observed that the selected attacks for Attack 1 cannot correctly classify Attack 1. The selected attack for testing attack Attack 2 also achieves a low PR. From Figure 5, it can observe that training the model with attack data corresponding to only Attack 3 or Attack 4 yields true positive accuracies of 80.53% and 93.87% when tested on Attack 2. The selected attacks for Attack 3 cannot detect attack data packets; however, training the model with Attack 5 or Attack 6 yields a true positive accuracy of 85.01% and 90.84% when tested on attack 3 (as seen in Fig. 5).

Comparing the positive rates from Tables XIV and XV with Fig. 5, it concludes that training with one kind of attack scales better than training with a subset of attacks. Therefore, this algorithm has not been employed to further study attack

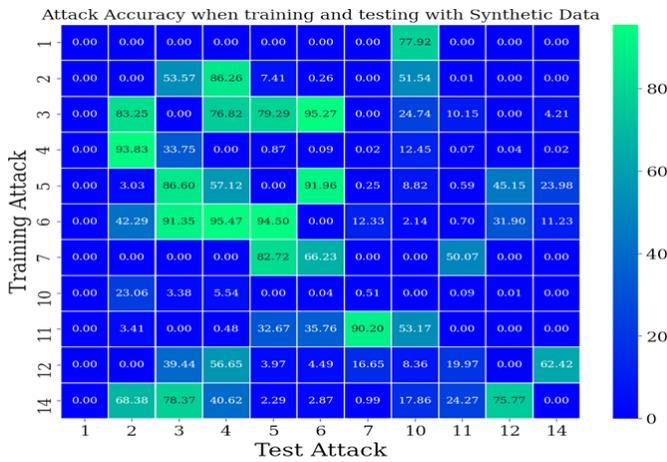

Fig. 8. Confusion Matrix for Base Architecture Trained on Bootstrapped Attack Data and Tested on Real Benign Data and Real Attack Data.

TABLE XIV. ATTACK BOOSTING ALGORITHM ON SELECTED ATTACKS

Test Attack	Selected Attacks	Accuracy	PR	NR	Weighted Acc.
1	10,7	92.75%	0.0	0.99	49.88%

11	99.54%	0.877	0.995	93.6%

correlations.

This study of attack correlations has concluded that the correlations observed in Fig. 5 are the only strong and consistent correlations that exist. The model exhibits the same correlations even when trained with a larger number of samples from the minority attack data classes using synthetic and bootstrapped datasets. Fig. 6, Fig. 7 and Fig. 8 indicate the same correlations as Fig. 5 when the model is trained with the augmented datasets. The next section discusses these observed correlations with the proposed hypothesis.

### F. Results of Hypothesis for Attack Correlations

Table XVI shows the number of features selected for select attack pairs. For attack pairs like (3,2), (3,6) and (3,4) that are correlated, as seen in Fig. 5, Fig. 6, Fig. 7 and Fig. 8, the algorithm selects only 4, 6 and 6 features out of a total of 78 features in the dataset. For uncorrelated attacks like (3,7), the number of features selected by the algorithm is 24, which is considerably higher than correlated attacks. Similarly, for (3,1), which are also uncorrelated, 21 features are selected. This forms the base for the hypotheses. Some selected features from correlated attacks have also been observed in Table XVII. In order to strengthen the hypothesis, Some of the features listed in Table XVII have been used.

**Hypothesis 1:** Fig. 5 shows that training the base architecture with Dos: GoldenEye(Attack 3) attack causes it to

TABLE XVI. NUMBER OF FEATURES SELECTED FOR SELECT ATTACK PAIRS BY RFE ALGORITHM

Attack(s)	N Features Selected
(3,2)	6
(3,6)	9
(3,4)	6
(4,6)	11
(3,7)	24
(3,1)	21

TABLE XVII. FEATURES SELECTED BY RFE FOR SELECT TRAINING-TESTING ATTACK PAIRS

Select Attack Pairs	Selected Features
(3,2)	Destination Port, Total Length of Fwd Packets, Subflow Fwd Packets, Sub- flow Fwd Bytes, Subflow Bwd Packets, Init Win bytes forward
(3,4)	Destination Port, Bwd Packet Length Std, Flow IAT Mean, Packet Length Mean, Init Win bytes forward, Idle Min
(6,4)	Destination Port, Total Length of Bwd Packets, Bwd Packet Length Std, Flow IAT Mean, Flow IAT Std, Bwd IAT Mean, Bwd IAT Std, Packet Length Mean, Bwd Avg Bulk Rate, Subflow Fwd Packets, Init Win bytes forward, Init Win bytes backward, Active Mean, Active Std

perform well on Slow HTTP Attacks like Attack 5 and Attack 6 that, are Slow HTTP Attacks performed with Slowloris and Slowhttptest attack tools and vice versa. We hypothesize that this is because Attacks 3, 5, and 6 are very similar in the way they are performed.

Training with DoS: slowHTTPpattack simulated with Slowhttptest scales well for Slowloris and vice versa as they are essentially the same attack but simulated using different tools. In Slow HTTP attacks, the attacker opens multiple HTTP connections with the target machine and keeps them open by sending packet headers or bodies slowly, thereby keeping all available connections occupied, making the target unavailable to legitimate requests. Since Attack 5 and Attack 6 are both the same kind of attack, it is possible for the model to learn attacking trends.

DoS: A goldenEye is an attack tool that explores vulnerabilities in the target; it tests how susceptible a target is to a DoS attack. DoS: GoldenEye opens multiple HTTP connections with the target server and keeps those connections open with keep-alive headers and caching control options. The connections cannot be closed, making the server unavailable to other HTTP requests. Slow HTTP attacks also open multiple HTTP connections with the target and keep open connections by sending large volumes of data at a slow rate, thereby making the target unavailable to other users. Whether it's for the keep-alive header or data being received slowly, the target is unable to close these connections. The same applies to Slowloris/Slowhttptest testing tools. This implies that although DoS: GoldenEye is not a Slow HTTP attack, it operates similar to Slow HTTP attacks. This could explain why training with DoS: GoldenEye Scales for both the Slow HTTP attacks.

**Hypothesis 2:** It has been observed from Figure 5 that training the model with attack data from DoS: HULK (Attack 4) causes it to scale for DDoS attacks (Attack 2) and vice versa. Training with Distributed Denial of Service attacks scales for DoS: HULK attack because the DDoS training attack was generated with Low Orbit Ion Cannon that simulated UDP, TCP or HTTP flooding attacks by sending enormous traffic

volume to the target machine. DoS: HTTP Unbearable Load King is a flooding attack where the target is flooded with HTTP data packets, sending GET requests and hitting its resource pool. Both these attacks are flooding attacks that may cause them to scale for each other.

**Hypothesis 3:** Fig. 5 shows that training the model with DoS: GoldenEye (Attack 3) causes the model to scale for DDoS (Attack 2) and DoS: HULK (Attack 4); however, this observed correlation does not apply the other way around. Similarly, training the model with DoS: Slowloris (Attack 6) causes it to scale for DoS: HULK (Attack 4) but not vice versa. The focus was on these asymmetric comparisons in this hypothesis. To explain this, it has been hypothesized that correlated attacks will have few dominant features selected by the algorithm, which may explain the correlations between the attacks. In contrast, the uncorrelated attacks will have many features selected by the RFE algorithm, indicating that there are not many dominant features that are important for learning which could explain the low correlations. This can be strengthened by the results in Table XVI for Attack pairs (3,2), (3,4), and (3,6) that have 6, 6 and 9 features selected by the algorithm. Each of these attack pairs is correlated. However, for uncorrelated attacks like (3,7) and (3,1), the RFE algorithm selects 24 and 21 features which are considerably more.

In addition to these hypotheses, some features observed from the selected feature list from Table XVII provide validation for our hypotheses. For example, in addition to DoS: GoldenEye and DDoS attacks having only a few features selected in their reduced feature set, the features selected as indicated in Table XVII are Subflow Fwd packets, Subflow Fwd bytes, Subflow Bwd packets. Subflow Fwd packets are the average number of packets in a sub-flow in the forward direction. Subflow Fwd bytes is the average number of bytes in a subflow in the forward direction, Subflow Bwd packet is the average number of bytes in a subflow in the backward direction. Subflows in the forward and backward direction are usually associated with distributed systems which point to these two attacks being distributed attacks. DoS: The GoldenEye attack tool can be used as a distributed attack as well by specifying the number of workers while simulating the attack. This provides further explanation for generalization.

Similarly, to study the correlation between DoS: GoldenEye, DoS: Slowhttptest, DoS: Slowloris and DoS: HULK, the RFE algorithm chooses features Inter-Arrival Time, Bytes Sent in the Forward Direction, Bytes sent in the Backward Directions in the Initial Window which is coherent with the hypotheses for symmetric comparisons.

## V. CONCLUSION

The deep learning approach shows that it generalizes well for this dataset in comparison to explicit statistical modelling-based methods. After evaluating the performance of several candidate DNN architectures like CLDNN, CNN with BGRU, OCNN and CNN, a CNN architecture has been proposed with the highest accuracy in the multi-class classification problem (Fig. 3). Further, this architecture has been used to study attack transferability and observe its performance in Fig. 5. Training attacks have been identified, for which the model generalizes well on certain testing attacks. The problem of underrepresented attacks in the dataset has been addressed using synthetic

and bootstrapped dataset based training methods. Fig. 6, Fig. 7 and Fig. 8 show that it can observe the same attack correlations as in Fig. 5 for the performance of the model trained on the SMOTE dataset and bootstrapped datasets. This confirms our identification of training-testing pairs of attacks that exhibit attack transferability.

Furthermore, this study proposes hypotheses for the observed correlations. A Reduced Feature Elimination Algorithm has been used to strengthen the hypotheses. The relationship between the number of features chosen and the training-testing attack pairs can be observed in Table XVI. Table XVII lists feature selected by the algorithm for selected attacks coherent with the proposed hypotheses.

This work validates the hypotheses with features from the RFE algorithm. Future work could validate these hypotheses using transferability in learning for different datasets, for example, DARPA 2009 IDD, KDDCup99, NSL-KDD, UNSW-NB15, and WSN- DS. Future work could also analyze specific or selected features trends in studying attack correlations. It is interesting to observe from Fig. 5 that it only observed correlations in attacks that are different types of DoS attacks. It did not observe correlations from other kinds of attacks, for example, Attack 1 (Botnets), Attack 7 (Brute Force: FTP-Patator), Attack 8 (Heartbleed), Attack 9 (Infiltration) and Attack 13 (Web Attack: SQL Injection). Future research can focus on identifying attributes that could help the model scale for these attacks and testing for transferability of learning for these attacks. Future work could also focus on attack detection when there is more than one attack being performed simultaneously.

## ACKNOWLEDGMENT

This work was supported by the Research Center of Computer Science and Engineering, PES Institute of Technology & Management, Shivamogga. The research centre is recognized by Visvesvaraya Technological University (VTU). The authors are grateful to all of those with whom we have had the pleasure to work during this work. Each of my Research Committee members has provided me with extensive personal and professional guidance and taught me a great deal about scientific research and life in general.

**Abstract**—Intrusion Detection Systems(IDS) are vital for computer networks as they protect against attacks that lead to privacy breaches and data leaks. Over the years, researchers have formulated IDS using machine learning (ML) and/or deep learning(DL) to detect network anomalies and identify attacks. Network Intrusion Detection Systems (NIDS) within corporate networks is a form of security that detects and generates an alarm for any cyberattacks. In both academia and industry, the concept of deploying a NIDS has been studied and adopted. The majority of NIDS research, on the other hand, has focused on detecting threats that emerge from outside of a wired connection. In addition, the NIDSs recognize Wi-Fi and wired networks alike. The Wi-Fi network's accessible connectivity distinguishes this from the wired network. A wired connection is highly resistant to many insider threats that could occur on a Wi-Fi router. A conventional view to developing NIDSs may miss malicious activities. This paper aims to design a multi-level NIDS for Wi-Fi predominant networks to identify both organizational Wi-Fi networks malicious activity and standard network malicious activity. Wi-Fi devices are common on campuses and businesses, and they are incorporated into the fixed wired network at the gateway. Wi-Fi networks are the primary target for this implementation; however, they are also designed to function in wired environments. For the Multi-Level NIDS, the proposed model used an ensemble learning method that pools the strengths of multiple weak learners into a single strong learner.

**Keywords**—Machine learning; ensemble learning; intrusion detection system; Wi-Fi security

## I. INTRODUCTION

When discussing modern technology, the dominating subject of conversations is the Internet and its continual progress. More specifically, how easy it has become to obtain access to it. This is why the number of Internet users has spiked up. Moreover, Internet applications in various industries have increased, providing a wider range of services. As a result, a considerable amount of information is to the users' disposition. Nevertheless, this information is available as well to the skilled network adversaries.

The 2022 Global Digital suite has reported that Internet users have reached 4.6 billion, as shown in Figure 1 [1]. At the beginning of the COVID-19 pandemic, one of the most talked-about stories was how much the world relied on the internet, especially as countries went into lockdown. Although the fluctuations in restrictions on movement over the last two

years, the most recent data show that people are actually spending more time than ever before using connected technology. 5.3 billion people will be online by 2023, according to a report cited by the source. Over the period of 2018 to 2023, compound annual growth is 6%. A growth rate of 7.7 % from 2018 is expected in 2019 when there will be an additional 300 million internet users. It is also revealed that the contribution to this accelerated number of people accessing the Internet can be attributed to the facilities now at the disposition to a large number of customers in relation to more affordable devices and mobile data plans. From all these devices owned by two-thirds of inhabitants of the world, around half of them are considered smart, which only means they have access to content provided by the Internet.

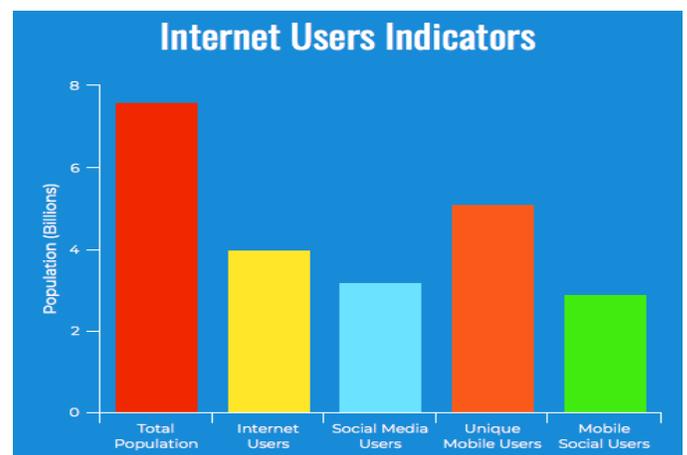

Fig. 1. Internet and Social Media Accessibility Statis [1].

**The Internet Stack:** The Internet protocol stack needs to be exposed to demonstrate the risks involved in blindly putting the trust in modern data transmission and management, which depicts the layers that describe the phases through which the data traverses between the communicating parties. Each layer fulfils its purpose and integrates with the others to provide the data transmission service. In Fig. 2, each layer could be explored as to its own world; nevertheless, this work aims to expose their main role in exchanging information, their characteristics, and the weaknesses that attackers commonly target at the highest level of the stack, application layer, which

interacts directly with the users and programs. Right below appears the Transport layer that offers services to network applications. The network layer makes communication possible by facilitating Network addressing and routing. The Data Link layer is responsible for data transmission between devices belonging to the same Network. Finally, the physical layer refers to the actual hardware employed for the transmission. Knowing these layers' functionality helps us understand that network attacks performed in different layers should be studied in a different fashion. In this initial stage of development of the NIDS, the focus was to set, Network, and Data Link layers. Studying, thoroughly these layers help us become more familiar with scenarios in which cyber-attackers exploit weaknesses. More specifically, it has been determined what classes of attacks involving breaching in the mentioned layers will be part of the study.

Layer #	Layer Name	Protocol	Protocol Data Unit	Addressing
5	Application	HTTP, SMTP, etc...	Messages	n/a
4	Transport	TCP/UDP	Segments/ Datagrams	Port #s
3	Network or Internet	IP	Packets	IP Address
2	Data Link	Ethernet, Wi-Fi	Frames	MAC Address
1	Physical	10 Base T, 802.11	Bits	n/a

Fig. 2. A Depiction of the 5 Layers of the Internet Stack Described by [2].

**Classes of Network Attacks:** The objective of flooding attacks is usually to generate a denial of service effect on the victim. Flooding attacks overwhelm the communication service with a considerable amount of traffic, which most of the time results in the collapse of an already established communication between client and server. Another network attack taken into account is the impersonation attack. Here, the intruder's ultimate goal is to falsify the identity of a trusted entity to obtain sensitive data. The third and last attack to be considered in the analysis of network attacks in this research is an injection attack. This class of attack attempts to introduce maliciously input to a particular network, machine, or program. This action can result in several consequences ranging from denial of service to data theft [3]. Providing details regarding these attacks, their mechanism, and how they relate to the characteristics of the link layer in wireless networks is key in discovering the effective implementation of an IDS. Enlightening research work regarding Wi-Fi network attacks makes available a public dataset that was created with the special purpose of the analysis of IDSs. This dataset is called the AWID dataset [4]. The background research made as part of the generation of this dataset provided basic network attack information and specifications for types and classes of attacks, which are very popular among network attackers.

**Machine Learning in Network Security:** After an overview of how the network attacks were performed and the data was collected, it presented the approach taken to develop the IDS, which is ML. Nowadays, ML has become a very popular technology used in several fields, including information technology. Modern research has leaned toward this technology and has demonstrated that it is one of the most effective approaches to develop a model that can be trained to scan network traffic and detect if a network attack is being held [5]. Even though this technology appears to be emerging,

research continues to evolve rapidly and makes available more efficient techniques. In recent years, it has become very popular to design learning models in an ensemble fashion as the combination of several ML models causes every model to help each other in correcting weaknesses. Therefore, the ensemble model will present an improved performance compared to the performance of each model considered alone. The outcome of including ensemble learning in network security is a great benefit since the ability to more accurately distinguish between normal and malicious traffic can prevent the compromise of sensitive data by its unauthorized use, misuse, or abuse [6] in any instance where the situation may happen.

It is critical as well to highlight that the technology of ML provides a precise way in which the effectiveness of a model can be measured. Most ML packages normally provide accuracy, which is considered in classifying if the network traffic is in a normal state or an attack is present, which becomes of great importance. Nevertheless, several other metrics can present deeper information about how effectively the model detects intruders. For example, logarithmic cost, F1 score, mean absolute error or mean squared error, among many others. These metrics are as important as accuracy and, in some cases, probably even more, especially when the samples of one class are imbalanced compared to the other class samples [7]. This is exactly the case of data describing a network attack. In a realistic network, it is very unlikely that an attack is being held, so if a network is monitored for a certain amount of time, the time frame of the network operating in a normal state is extremely larger than the time frame of the network while it was the victim of a network attack. Therefore, if an IDS classifies all network traffic as normal traffic, it will obtain an accuracy very high because the very few instances where it classified the network behaviour incorrectly were attacks. This result is clearly misleading and strongly suggests that in the case of IDS development, there needs to be included as many precision metrics as possible.

During last year, considering up to the 10 most disrupting events regarding cyberattacks, they compromised 5 million records with sensitive credit information in the mildest of these events up to breaching 1 billion records in the worst case [8]. It can be stated that organizational data breaches generate a greater concern about the safety of personal data. The study of a wireless network that simulates more the personal network setup does not restrict the findings to benefit these types of networks. Even though security levels may vary from a personal wireless network to an organizational one, the principles followed to compromise a network are the same. However, network communication is not just one type in an organization as they are traditionally in a personal network. Therefore, it is a more significant benefit to study the development of an IDS capable of scanning the behaviour of a network with a structure that combines wired and wireless networks. Even though the data, which was previously exposed, is comprehensive and provides a considerable amount of data to develop an effective model, it lacks the combination of different types of networks that, as mentioned before, are more common in the organization. An experimental setup that includes these requirements is necessary to simulate the performance of an IDS against network threats presented in this network architecture. The result of the combination of these two different types of networks is the motivation for the

development of an IDS capable of scanning and analyzing not only wireless traffic but also Ethernet traffic. The inclusion of wired networks allows this research to include attacks in this type of network. Wireless packets provide very useful information in their headers pertaining to the link layer, which is one of the layers said to be focused on. Moreover, there is also a demonstration of how much information, probably more than it is needed, is present in packets at the link layer in the AWID dataset previously exposed. This dataset contains 155 different characteristics, called attributes, that can be displayed for each Wi-Fi frame.

So far, it has been referring to the unit of measure for network traffic as a frame for wireless connection. A different way of analyzing the traffic for the layers above the Link layer is employed. A unit flow is used, a condensed structure that describes network traffic characteristics in aggregation. Attacks against a wired network in the link layer are not as common as attacks to the higher layers, where several varieties of techniques are designed to create breaches. Therefore, an expected characteristic of an IDS that analyzes wired traffic is that it should detect only high-layer layer attacks. Also, it is necessary to take into account that wireless networks can be victims of the same type of attacks for the higher layers; nevertheless, wireless traffic is very well known to be the target of link-layer attacks as this network is open to all devices within range. For this reason, another component in the section of intrusion detection that should exist in the IDS is the capability of analyzing Wi-Fi frames and performing the respective data processing to detect either in wired network attacks or wireless attacks. Moreover, another component should focus its analysis on link-layer attacks and perform its analysis and attack detection on wireless frames.

Network attacks that are performed either in the wired or wireless environment are commonly studied from a perspective that is leaned towards the type of attack, whether it is flooding, impersonation, or injection type. Or more focused on the network's structure, whether it is a home network set up or enterprise network set up; or it can stress more the Internet layer that the intruder aims at, whether the network layer or link-layer as discussed in the preceding paragraph. All these perspectives are critical for a comprehensive study of cybersecurity, but this work proposes the consideration of all the mentioned factors from the standpoint of subjects that already are members of the network and exploit this privilege to trespass security barriers. This particular scenario is referred to as internal network attacks, and it is considered the most preferred scenario for network intruders to put into practice their malicious techniques. A study has demonstrated that 74% of security incidents resulted from the extended enterprise level. Of this 74%, 42% represent actual inadvertent employees. A total of 74% is reached considering, besides employees, customers, and suppliers, entities that are known to the company. The remaining 26% is attributed to parties unknown to the organization. Insider attacks are not a current issue. Another study refers to a survey made to United States security personnel, where insider incidents were cited 59% of the time [9].

## II. RELATED WORK

This section briefly reviews the literature for the current work, where researchers present the design and implementation of NIDS.

### A. Wi-Fi Focused Research

Kolias et al. [4] extensively studied the attacks against Wi-Fi networks and categorized them. The contribution that proves to be the highlight of this research is the introduction of the Aegean Wi-Fi Intrusion Detection (AWID) dataset. In addition, this work also included the processing and analysis of the dataset. The dataset was fed into several ML algorithms. There are several characteristics that made this work stand out from similar research made in the field. The authors provided a wide overview of attacks being performed in the 802.11 standards in general. They constructed the dataset with well-supported assumptions, which is what makes this work recognized. This work also excelled at exposing a complete analysis of normal 802.11 network traffic containing normal network traffic behaviour and behaviour that describes a network attack. For the study of Wi-Fi IDSs, this dataset became a pillar, providing a format that is easy to distribute and very high-quality content as it is composed of real traces. The authors achieved the best accuracy using the J48 algorithm. They reported a 96.20% detection rate with all the features in the dataset and 96.26% with 20 features. Alotaibi et al. [10] attempted to improve the accuracy by applying the majority voting technique in which several ML algorithms were used with the AWID dataset, and then voting was performed on their results for the final prediction. Another singularity proposed in this work is the use of a technique based on the ensemble method of Extra Trees, which improves performance and is used for feature selection. The proposed solution was based on the combination of several machine-learning algorithms to learn patterns for different network behaviours. The initial procedure where patterns are constructed is called the offline stage. It was then followed by the online stage, where the classification of network attacks actually occurs. Before the intrusion detection, a filtering process was placed where all unnecessary features were disposed to leave only those that contribute to the classification. This work used the similar ensemble algorithms that have been used in this work, the combination of machine-learning algorithms, with a different approach and features. The participating algorithms used were Bagging, Random Forest(RF), and Extra Trees. Although these ML algorithms were used for the classification task, the Majority Voting, the voting technique employed, is what finally determined the classification output. The authors clearly specified that the voting technique was used particularly to improve the accuracy. As desired by the authors, it outperformed the result from Kolias et al. and reported an accuracy of 96.32%.

The literature review also found studies that make use of the DL approach. In [11], the author used DL for feature extraction, leaving the classification task to a Stacked-Auto encoder (SAE) classifier. The author mentioned that it is the first work considering this approach for IEEE 802.11 networks. The author presented the implementation of the neural network structure used for this classification problem. The neural network was composed of several layers. The first 3 layers were placed in the neural network to learn what features were

the most useful to determine patterns. These patterns aided in classifying network traffic behaviour as an attack. The author used an emerging option to be employed as the activation function, which is the Rectified Linear Unit (ReLU) function as an alternative to the traditionally used Sigmoid function for the DL models. This process was performed, as stated, to provide a self-learning characteristic to this classification model only to determine or "learn" the most effective features to be considered for the actual classification. Later on, the author came to expose the type of classifier used for the actual anomaly detection, which is the Softmax Regression, a classifier capable of handling multi-class classification. An accuracy of 98.66% was obtained after the mentioned techniques were applied. However, information in relation to data preparation was very limited. More than half of the features in the AWID dataset contain missing values. It's also worth noting that there are a variety of features in the dataset, including hexadecimal characters and numerical values. Because of this, the dataset pre-processing is essential before using it in a model. The lack of attention to data preparation has been noted in the literature. On the other hand, this study shows that the data preparation for this work was meticulous.

### *B. Research Focused on Ensemble Models and Multi-level Intrusion Detection*

Zaman et al. [12] proposed a more detailed perspective of network traffic analysis for intrusion detection. In this work, the authors focused on the different layers of the Internet stack. They proposed four different solutions that correspond to attacks analyzed from the perspective of the 4 upper layers in the Internet Stack. The IDSs are categorized as follows: Application Layer IDS, Transport Layer IDS, Network Layer IDS, and Link Layer IDS. The authors claimed that the results of this approach demonstrate improvement in system performance and scalability. For the task of feature selection, the authors employed Fuzzy Enhanced Support Vector Decision Function. As a result, the highest accuracy reported was 99.84% for the Transport layer IDS, which used Neural Networks for classification. Considering all layers, the best accuracy was 99.41% using a Neural Network classifier.

Zainal et al. [13] proposed an approach where classifiers with different learning paradigms are combined into a single Ensemble model. The paradigms employed are Linear Genetic Programming, Adaptive Neural Fuzzy Inference System, and RF. The authors' objective is to enhance the precision and lower the false alarm rate in IDS. Two principal steps were exposed in this work. First, select relevant features. Second, developing an ensemble model composed of classifiers with different learning paradigms. They demonstrated that the performance of the ensemble model surpassed the performance of the three models used separately for all types of attacks.

Li et al. [14] presented the use of Rough Set Theory and Quantum Genetic Algorithm for attribute reduction and as a method of classification. The author mentioned that attributes from network packets were reduced using the Quantum Genetic Algorithm. They used rough Set Theory to implement a rough meta-learning classification strategy. This strategy combined multiple rough learning methods. After the experiment, the author demonstrated that the detection rate was noticeably improved when Ensemble-Rough Classifiers were used versus

the use of Single-Rough classifiers. Particularly, the detection rate increased from 76.86% to 86.25% for DoS attacks.

Wang et al. [15] propose the use of ensemble learning by using a Bayesian Network and Random Tree as base classifiers. These algorithms were combined with meta-learning algorithms using "Random Committee". Then, voting was performed for the classification task. In this work, the authors mentioned that the KDDcup99 dataset was used. One of the main objectives of this work was tackling the unbalanced nature of this dataset using ensemble learning. The model is evaluated using receiver operating characteristic (ROC) curves. The authors computed the area under the ROC curves (AUC) for more specific results. In the results, it was found that the ensemble model outperforms the single based models.

In [16], Nenekazi et al. uncover the issue of researchers not being able to determine the performance of an ensemble-based NIDS until after it is implemented. This work is based on the study of average information gain, which determines performance. This average information gain is associated with the features. Adaboost, the weak ensemble classifier, is used to obtain the average information gain. The NSL KDD dataset was used, and accuracy was the metric considered to measure performance in this work. The author demonstrates that average information gain lies in the range of 0.045651 and 0.25615 when accuracy will reach as much as 90%. A gradient boosted machine was used by Tama and Rhee [17] to increase the detection accuracy of anomaly-based IDS. Gradient boosted machine's best results are achieved by a grid search of input parameters. Rezvy et al. [18] used the AWID dataset that they used in [19]. They combined autoencoder frameworks with feed-forward neural networks. 99% of the time, their model can classify everything correctly. Faik Kerem Ors et al. [20] have developed a ML-based Wi-Fi IDS to protect IoT devices better. A single multi-class classifier operating on encrypted data from the Wireless Data Link Layer demonstrates that the benign traffic and six types of IoT attacks can be identified with an overall accuracy of 96%.

## III. METHODOLOGY

The proposed installation of NIDS for the Wi-Fi network is shown in Fig. 3. The NIDS for the Wi-Fi network will receive Wi-Fi frames from the NIDS sensors for intrusion detection. As the NIDS is implemented using a ML approach, the model needs to train and validate it before deployment using the existing Wi-Fi frames dataset; it is the AWID dataset in this case. An overview of the various ensemble algorithms employed in the model development process is also offered here. Next, the algorithms will be applied to training data to identify the best one, and their evaluation of test data has been discussed in detail. Fig. 3 depicts the NIDS implementation process.

### *A. Datasets*

The AWID Wi-Fi intrusion data was gathered in a typical Wi-Fi network environment. All of the devices connected to the Wi-Fi network were connected to a single access point for the Internet connection. A single intruder machine launched the attacks. Wi-Fi frames were captured using a computer in monitor mode. It was equipped with high processing capabilities to be able to capture a large number of frames at a

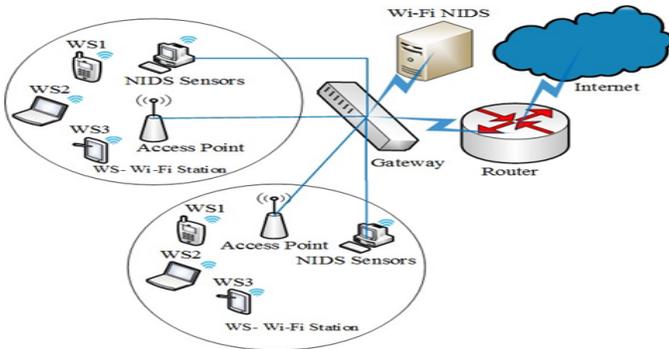

Fig. 3. An IDS Integrated with Infrastructure Wi-Fi Network.

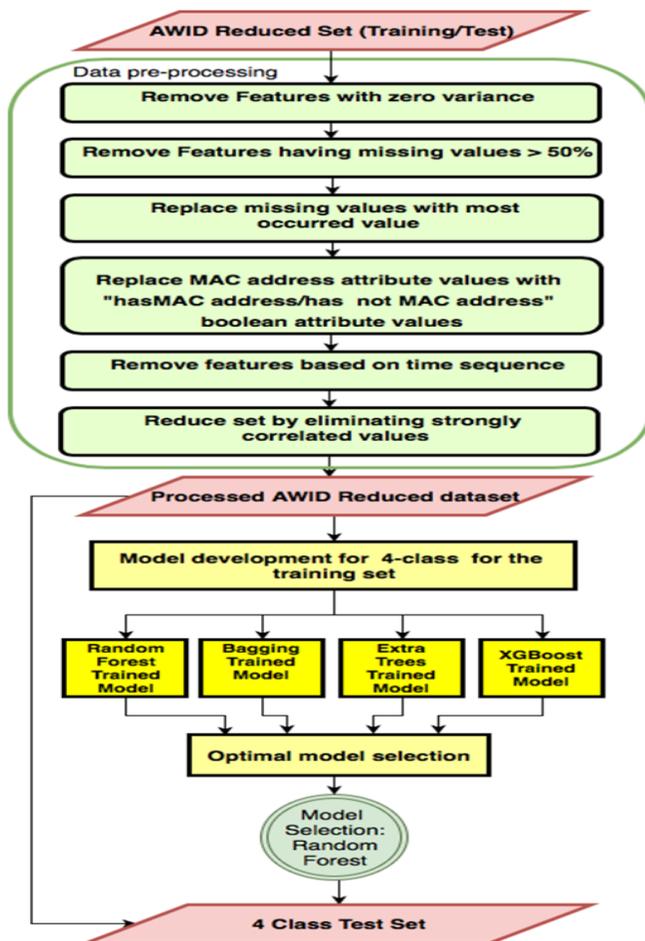

Fig. 4. Proposed IDS Model for Wif-Fi.

very high speed. All these equipment for the experimental setup had a variety of hardware, operating systems, and other characteristics. Furthermore, to maintain the data capturing as realistic as possible, mobile devices, such as smartphones and tablets, were kept in constant motion, laptops experienced sporadic movement, and the desktop and the smart TV were kept in fixed locations during the experiment. The Wi-Fi frames were collected for around five days to release different datasets version, discussed below, for the intrusion detection. Both threat-class and threat-specific versions of the AWID

dataset are available. Every record in the dataset is classified as either flooding, impersonation, injection attacks or normal. The identical information is labelled with threat specific class for 17 different Wi-Fi threats or benign. Many devices can use this available enormous or small version of this data format. In total, there are four AWID datasets available. The threat-class version of the dataset is used in this work. Table I shows the distribution of the records in the dataset. The AWID dataset has an imbalanced allocation, with more than 90% of the records in train and test sets being normal. As it can be seen, there is a significant difference in features and labels between large and small sets. The smaller dataset was collected separately from the larger dataset using various methods and techniques. As a result, there is no connection between them other than the sheer number of features and labels. Each record in the AWID dataset is a Wi-Fi frame with 155 features. These features represent various header fields values in each captured frame. They can define some traffic patterns helpful to detect intrusions. Nevertheless, some features may represent noise due to the raw state of the dataset. Control, management, and data frames are also included in Wi-Fi frames. Therefore, not every feature will apply to every frame. Therefore, some records may have missing values for those features.

TABLE I. TRAFFIC RECORDS DISTRIBUTION FOR THE TRAINING AND TEST SETS IN THE REDUCED AWID DATASET [10]

	Training %	Testing %
Normal	1633190 (91%)	530785 (92.2%)
Flooding	48483 (2.6%)	8096 (1.3%)
Injection	65377 (3.5%)	16684 (2.8%)
Impersonation	48521(2.6%)	20078 (3.1%)
Total	1795565(100%)	575643 (100%)

### B. Preparation of Data

In the AWID dataset description, some values of the features in each record may represent noise for the intrusion detection task or maybe missing values. As a result, pre-processing the dataset is absolutely necessary. The dataset contains 154 features for each record and one target class (a total of 155 features). Features with zero variance, i.e., features whose value was the same across all records, have been eliminated. The AWID dataset description contained 27 features, some of which may represent noise or missing values for the intrusion detection task; because of this, preparing the dataset is a must. Each record in the dataset has 154 features and a single target class (a total of 155 features). A feature that had the same value in all data was eliminated because it had zero variance. Statistically, 27 characteristics have been found that had no statistical variation. Attributes with less than half of their values were removed. Following these steps, there are now 36 features in Table II. It was necessary to replace an attribute's incomplete data with its most common value. Access points and receivers have MAC addresses of 29, 30, 31, 32, and 33 for Wi-Fi adapters. They constantly adapt to the changing needs of the machine. The values of all of these features were changed to indicate whether or not the device had an address. Features 0, 1, 2, 3, and 13 were omitted because this deployment does not make use of time series. In order to achieve success, prediction is handled on an independent record basis. Considering that this feature was a combination of Features 20 and 21, it was omitted from the final product.

Feature 35 was also left out due to the fact that it indicates the sequence identifier.

TABLE II. AFTER PRE-PROCESSING FEATURES REMAINED IN THE AWID DATASETS

No.	Features name	Definitions
0	frame.time epoch	Time of epoch
1	frame.time delta	Time delta from previous captured frame
2	frame.time delta displayed	Time delta from previous displayed frame
3	frame.time relative	Time since reference or first frame
4	<i>frame.len</i>	<i>Frame length</i>
5	frame.cap len	Frame length stored into the capture file
6	<i>radiotap.length</i>	<i>Header length</i>
7	radiotap.present.tsft	TSFT
8	radiotap.present.flags	Flags
9	radiotap.present.channel	Channel
10	radiotap.present.dbm antsignal	dB Antenna Signal
11	radiotap.present.antenna	Antenna
12	radiotap.present.rxflags	RX flags
13	radiotap.mactime	MAC timestamp
14	<i>radiotap.datarate</i>	<i>Data rate (Mb/s)</i>
15	<i>radiotap.channel.freq</i>	<i>Channel frequency</i>
16	<i>radiotap.channel.type.cck</i>	<i>Complementary Code Keying</i>
17	radiotap.channel.type.ofdm	Orthogonal Frequency-Division Multiplexing
18	<i>radiotap.dbm antsignal</i>	<i>Antenna signal</i>
19	wlan.fc.type subtype	Type/Sub-type
20	<i>wlan.fc.type</i>	<i>Type</i>
21	<i>wlan.fc.subtype</i>	<i>Sub-type</i>
22	<i>wlan.fc.ds</i>	<i>DS status</i>
23	<i>wlan.fc.frag</i>	<i>More Fragments</i>
24	<i>wlan.fc.retry</i>	<i>Retry</i>
25	<i>wlan.fc.pwrmtg</i>	<i>Power Management</i>
26	<i>wlan.fc.moredata</i>	<i>More Data</i>
27	<i>wlan.fc.protected</i>	<i>Protected flag</i>
28	<i>wlan.duration</i>	<i>Duration</i>
29	<i>wlan.ra</i>	<i>Receiver address</i>
30	<i>wlan.da</i>	<i>Destination address</i>
31	wlan.seq	Sequence id
32	wlan.sa	Source address
33	wlan.bssid	BSS Id
34	<i>wlan.frag</i>	<i>Fragment number</i>
35	wlan.ta	Transmitter address

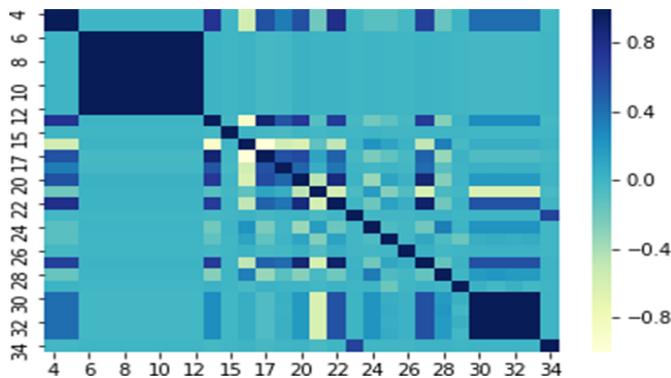

Fig. 5. Features Correlation Heat Map.

Finally, the correlation between the attributes has been calculated after following these steps.. It has been discovered that a few of the characteristics are strongly linked to each other. Fig. 5 depicts the feature correlation heat map. A strong positive correlation can be seen in the figure between the features numbered 4, 5, 6, 7, 8, 9, 10, 11, and 12, as well as 30, 31, 32, and 33, where the corresponding correlation value is 1. A strong negative correlation exists between features 16 and 17, with a correlation value of -1. One feature has been chosen from that group and discarded the rest for each group.

There were four features that were chosen from the groups: Features 4, 6, 30, and 16. Thus the model came up with a new list of 18 features after going through all of these steps. Table II displays these features in italic type.

### C. Ensemble Algorithms

An ensemble model is a technique that utilizes various algorithms or combines them to enhance the strength and efficiency of any of the components' algorithms. Syarif et al. (2012) [21] proposed that the benefit of ensemble methods is that they can be adjusted more appropriately than single models in any modifications in the controlled data stream.

1) *Bagging*: Unlike Boosting, the Bagging algorithm can be used for both classification and regression. In 1996, Leo Breiman developed the Bagging algorithm, which is also known as Bootstrap aggregating (Breiman, 1996) [22]. It was developed to improve the algorithm accuracy by producing diverse models and then combining them to produce the final model. Breiman's experiments indicated that Bagging could improve the efficiency of inconsistent learners but reduce the efficiency of a steady one when it was first established (Breiman, 1996) [22]. Changing the training data in the unstable learner can significantly impact the hypothesis it generates (Dietterich, 2002) [23]. The experimental results reveal that Bagging works better than Boosting and Randomization in the presence of noise (Dietterich, 2000b) [24].

2) *Random Forest*: It is a decision tree-based variation of bagging. A decision tree's learning ability allows RF to extract precise information considering all aspects. This results in a precise performance. But it can also lead to excessive variation and over-fitting. Together with the bagging algorithm's principles, this strategy could fix the issue. Bagging in RF creates random subsets of data. RF validates that samples from one subset have less correlation than samples from other subsets. Each subgroup has a decision tree. A decision tree's training subset is used to classify data. Finally, the most common occurrence from each decision tree is picked as the overall classification output. The fact that RF randomly chooses a portion of features from each decision tree's feature set increases performance over bagging.

3) *Extra Trees*: The RF algorithm has a lot in common with this technique. Decision trees are at the heart of both approaches. When comparing it to RF, the main distinction is that it adds more randomness. Random features are scoured for each decision tree, and the locally best feature/split combination is computed. A random number is chosen for the split in ET, unlike RF. Over-fitting is less likely with this approach, which broadens the application of the algorithm.

4) *XGBoost*: The Gradient Boosting (GB) technique is effectively implemented in XGBoost. Multiple weak learners are sequentially used in the GB. Each learner focuses on those samples that the previous learner misclassified in the sequence during the training process. The GB consists in minimizing a cost function. The cost function describes the difference between an actual value and the approximation corresponding to the actual value. The minimization problem is tackled with derivatives, and the objective is to find the fastest descent in the difference between the actual value and the approximation. One of the main concerns in the use of

GB is time. Even though this algorithm is well-known for its ability to learn, the performance comes at the expense of considerable computational resources. These problems led to the creation of a set of tools called XGBoost that can help with the computational load of GB.

#### D. Implementation of Multi-Level NIDS

Fig. 6 shows a Wi-Fi dominant campus network prototype for the proposed ML-NIDS implementation with a connected Gateway switch. The Gateway switch has several Ethernet ports. Wi-Fi access points (AP) and other switches for local sub-networks can be connected using these ports. A monitoring node (installed with IDS in the figure) captures Wi-Fi frames for the traffic outgoing from or incoming to the wireless network. The NIDS receives the packets for wired stations as well. Besides data, a network packet or frame consists of several headers corresponding to the different layers implemented in the network software stack of a wired or wireless station. These layers include application, transport, network, and data-link layers arranged in a top-down manner in the TCP/IP stack.

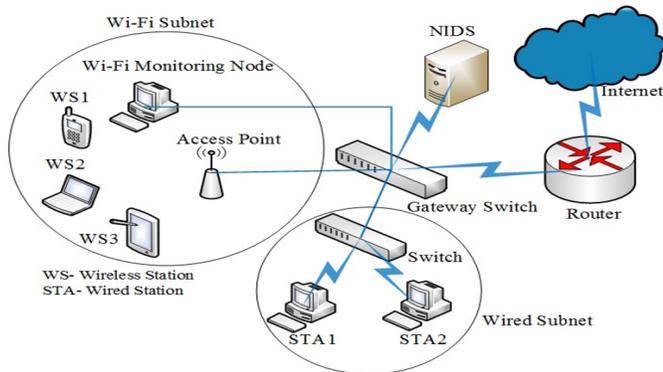

Fig. 6. Proposed IDS Model for Wif-Fi.

The NIDS processes data-link layer header fields in the case of a Wi-Fi frame and extract features to detect any internal attacks specific to Wi-Fi. The NIDS then processes header fields of network, transport, and application layers of Wi-Fi frame or wired packet and extracts features to detect generic network attacks. The functionality of the ML-NIDS is shown as a flow chart depicted in Fig. 7.

#### E. Obtaining Attack Traffic for ML-NIDS Implementation

A publicly available dataset has been selected, which contains captures of network traffic through an Ethernet connection for attacks and normal network behaviour. CTU University in the Czech Republic provides this dataset. Overall, it consists of 13 captures of normal traffic networks mixed with attacks. It is also available as separate captures, normal and attacks traffic behaviour. One particular CTU dataset has been selected that captured network traffic during a malware attack launched using an Ethernet connection. The model also used another dataset from [25] for normal traffic and DoS attacks. From the experiment mentioned, network traffic has been captured using tcpdump during the time when the attacks were launched. Since the length of the time captured was not too long, it has

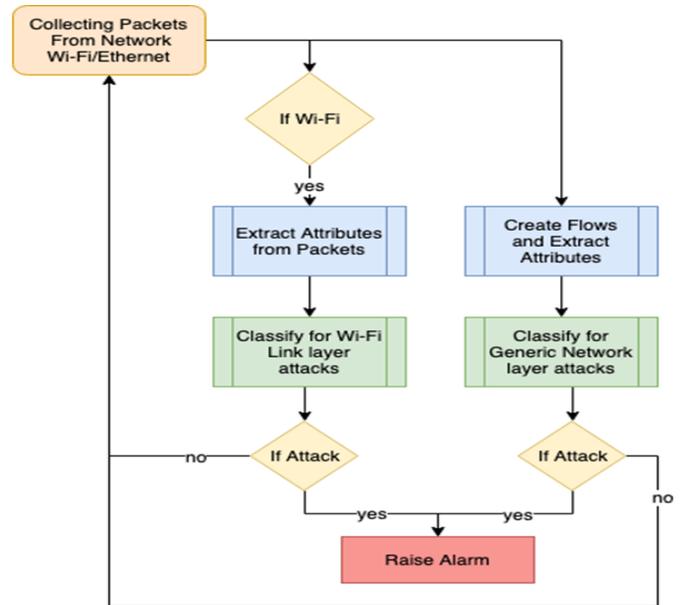

Fig. 7. Flowchart Demonstrating the Functioning of Multi-Level NIDS.

been decided that these captures were not useful for model training purposes. Therefore, these captures have been kept for testing. In this manner, it is possible to determine how the model would perform if an unrelated dataset is used for testing. Data Preparation and Features Extraction

In order to use the data for the ML-NIDS development, the raw data obtained is needed to prepare. All raw data manipulated in this study is in the PCAP format. To extract information for these files, "scapy" tool has been used. Scapy is a library that permits the manipulation of packets to extract their information in the python programming language. The manner in which information is extracted from the captured file to develop an intrusion detection model varies from the way proposed for a wireless network in this same study. This section will refer to the concept of flow to present a procedure that focuses more on finding meaningful information from the dataset used. A flow is a sequence of packets that share similar characteristics in their headers. Flows are commonly used to resolve performance issues. Because of the great amount of information they contain, using flows is the primary manner in which traffic network is represented for analysis. The features were derived by expressing statistical values describing characteristics such as direction (incoming/outgoing), size, flags, among many others. After that scapy was used to extract the features, it continued to process the data further to see if there was an opportunity to reduce the number of features. To determine what redundant features were redundant, their correlation and removed those highly correlated features. The heat map shown in Fig. 8 depicts the correlation status of all 68 features.

A threshold of 95% has been set, so from a group of features 95% correlated, only one feature has been kept. This process reduced the number of features from 68 to 37. A similar correlation heat map shown in Fig. 9 displays the correlation status of the 37 remaining features.

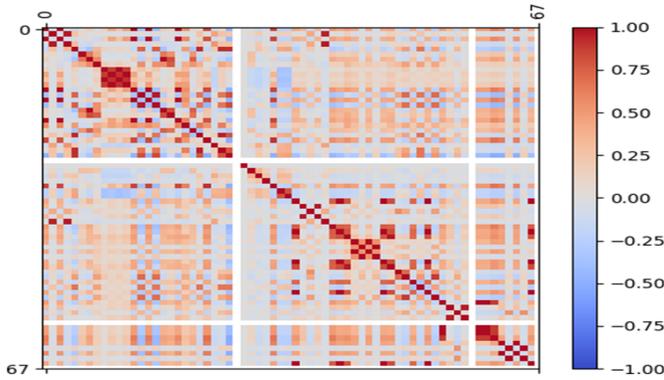

Fig. 8. Heat Map of Correlation between Original Features.

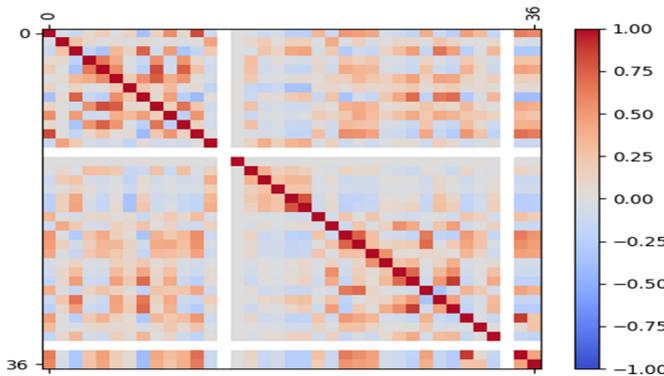

Fig. 9. Heat Map of Correlation between Features after Reduction of Features.

#### F. Ensemble Machine Learning Model Development

After the datasets were processed and converted into a format that can be used to train the NIDS model, the ML model was implemented. RF, Bagging, Extra Trees, and XGBoost were used as ensemble ML classification algorithms [27]. Training the models has been started with the dataset containing all 68 original features. Afterwards, the model was trained with the reduced 37 feature dataset. In the training process has been performed with 10 cross-validations and calculated the metrics: Accuracy, F1-score, Precision, and Recall.

It has been decided to include these metrics due to the nature of network behaviour. In a typical network, attacks are not something that happens very often. Therefore, it captures where a network attack was present; the number of packets involved in the attack will be considerably less than the number of packets involved in normal network activity.

For this reason, datasets containing network attacks are very unbalanced. In these cases, accuracy can be a deceiving metric to measure the performance of a NIDS. The other considered metrics can help us better understand the performance of a model trained and tested with very unbalanced datasets. This implementation corresponds to the second module of the Multi-Level NIDS. Therefore, the functionality of this system is organized in the flow chart shown in Fig. 7. The monitor node collects the data, and if the packets come from a Wi-Fi connection, they are first analyzed to determine if there

is a Link Layer attack present. Regardless of the type of connection, Wi-Fi or Ethernet, all packets are analyzed to determine if an attack at the network layer or above is present.

#### IV. RESULT AND DISCUSSION

Models for the AWID training dataset were developed using the ensemble method depicted in Fig. 4. Models are built using sci-kit-learn, a Python-based ML tool. The models for each algorithm were developed using a 10-fold cross-validation process. The best model was chosen by averaging the accuracy of all of the algorithms, each using a distinct set of random states. Each algorithm's classification accuracy is shown in Table III. The most accurate model was the RF one. This NIDS model for the Wi-Fi network has been used as the last model for testing the dataset.

TABLE III. ACCURACY OF ENSEMBLE ALGORITHMS

Ensemble Technique	Accu%
Bagging	98.967
ExtraTrees	99.018
RF	99.097
XGBoost	98.944

This work evaluated the prediction results of different experiments using the test scores produced from the confusion matrix [26]. The confusion matrix is a two-dimensional matrix that represents the correlation of true conditions and predictive results shown in Table IV. TP describes the number

TABLE IV. CONFUSION MATRIX

	Positive Prediction	Negative Prediction
Positive Condition	True Positive (TP)	False Negative (FN)
Negative Condition	False Positive (FP)	True Negative (TN)

of abnormal samples being accurately classified. TN defines the number of normal samples being accurately classified. FP specifies the number of normal samples being falsely classified as abnormal samples. FN specifies the number of abnormal samples being falsely classified as normal samples. Various test scores were calculated using the confusion matrix in this work: Accuracy, Precision, Recall, and F1 Score.

$$Accuracy(Accu) = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

$$Precision = \frac{TP}{TP + FP} \quad (2)$$

$$Recall = \frac{TP}{TP + FN} \quad (3)$$

$$F1Score = \frac{2 * Recall * Precision}{Recall + Precision} \quad (4)$$

The RF model was 95.873% accurate in classifying the records. Fig. 10 depicts the model's confusion matrix. Each of the traffic classes has its own set of average values for precision, recall, and f1-score has shown in Fig. 11. Due to its f1-score of 0.13, the RF model's impersonation attack performance was poor. Fig. 10 shows that most impersonation threats are classified as injection threats. The model has an f1-score of 0.95 and intermediate accuracy, recall, and F1-score of

0.96. The majority of the impersonation assault records were classed as "normal" even though the accuracy was slightly lower than that of [4] and [10]. In this regard, the proposed RF model outperforms theirs because it classifies the impersonation attack as a different type of attack. In addition, [4] reported a lower f1-score than the proposed model in this work. The model has an f1-score of 0.95 and intermediate accuracy, recall, and F1-score of 0.96. If flooding, impersonation, and injection threats are considered the sole attacks, it can map the confusion matrix of Fig. 10 to Fig. 12. When it comes to determining if the information is either malicious or benign, the model obtained 99.996% accuracy. To put it another way, in this context, [4] and [10] were both 96.28% and 96.28% accurate when it came to this question.

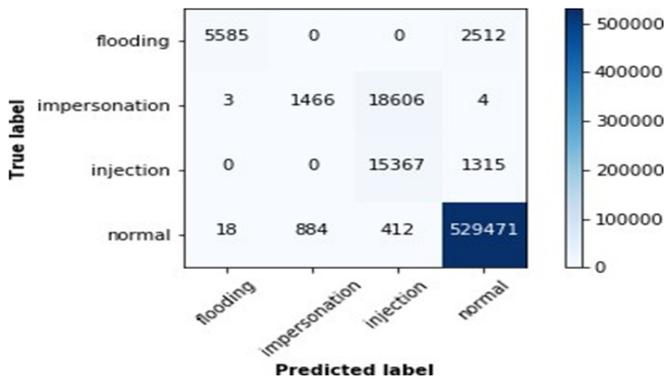

Fig. 10. Confusion Matrix for the 4-class Classification Model.

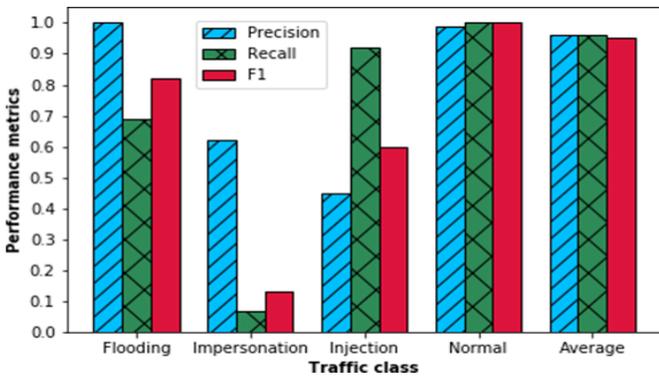

Fig. 11. Performance Metrics for Each Class.

The performance metrics were recorded after training the four mentioned ensemble models with the datasets before reducing the number of features. These are exposed in Table V. As shown, RF leads all 4 algorithms in all 4 metrics with an accuracy of 99.96%, F1-Score of 99.90%, the precision of 99.92, and recall of 99.89%.

TABLE V. CLASSIFICATION PERFORMANCE ON THE TRAINING DATASET

Algorithm	Accu	F1 Score	Precision	Recall
Random Forest	99.96	99.90	99.92	99.89
Bagging	99.94	99.87	99.89	99.87
Extra Trees	99.94	99.87	99.90	99.85
XGBoost	99.91	99.85	99.90	99.80

From the efficiency point of view, the training times RF is

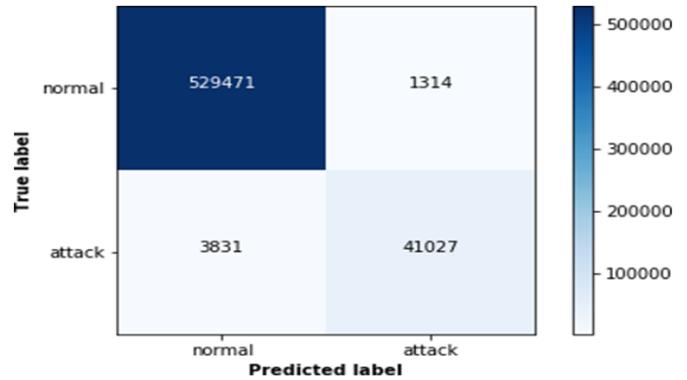

Fig. 12. 4-Class to 2-Class Confusion Matrix Conversion.

the second fastest model with 24.86 seconds after Extra Trees with a training time of 14.39 seconds. Bagging took longer to train with 59.12 seconds, and the second slowest was XGBoost with 31.83 seconds.

After decreasing the number of features, the same models were trained and the metrics recorded are shown in Table VI. Here it can be seen that Bagging and XGBoost performed very similarly. Both with an accuracy of 99.96%, F1 Score of 99.90%, and precision of 99.85%. Bagging lightly surpasses XGBoost in recall with a 99.85% versus 99.83%. The rest of the models score similar but slightly lower metrics.

TABLE VI. CLASSIFICATION ACCURACY ON THE TRAINING DATASET AFTER FEATURE REDUCTION

Algorithm	Accuracy	F1 Score	Precision	Recall
Random Forest	99.95	99.89	99.98	99.85
Bagging	99.96	99.90	99.98	99.85
Extra Trees	99.95	99.89	99.97	99.83
XGBoost	99.96	99.90	99.98	99.83

In training time, the fastest model once again was Extra Trees with 13.03 seconds of training time, followed by XGBoost with 18.89 seconds. RF took 20.44 seconds for training, and the Bagging model trained in 36.33 seconds. The performance metrics improved after the feature reduction and model efficiency increased. The Bagging model improved significantly in performance and efficiency. Therefore, it has been decided to select it to perform the classification task for the NIDS. This model has been tested against three different test sets. The first one was generated with the training set but separated before the training process. The second one was obtained from CTU University. This set is not related in any form to the CTU dataset used to create the training set. The third is network attack capture obtained from our experiment performed in the isolated network previously introduced. The proposed model started with the test set separated from the training set before the training process. After running the bagging model for classification, it was found that for all four metrics, this model obtained a perfect performance score. This exceptional result could have been caused due to the fact that this test set was generated together with the set used to train the model. Even though they were separated before the training process, they still share very similar characteristics. The confusion matrix shown in Fig. 13 exposes the classification output of the model when tested with the mentioned set.

Then the model was tested with the additional malware capture obtained from CTU. After testing the model with this dataset, the results were as follows: 99.79% for accuracy, f1-score of 99.89%, perfect precision score, and 99.79% for recall. The entire dataset was a malware attack, so it can be observed that very few records were misclassified. In the confusion matrix in Fig. 14, the classification report has been presented for this set. In the same confusion matrix, it can also see that almost all records were classified as attacks. This outcome was expected since the entire test set was a capture of a malware attack. Since the miss-classified records were very few, it is hard to identify them in the confusion matrix. At last, the model was tested against a dataset generated during the experiment mentioned previously. The duration of the attacks launched was not very long and did not generate as many records as desired. Therefore, this network attack capture has been combined with normal traffic and balanced it to be composed of 10% network attack traffic and 90% normal network traffic.

The results reflected perfect performance for this small test set for all metrics considered. Performance with this test is displayed in the confusion matrix shown in Fig. 15

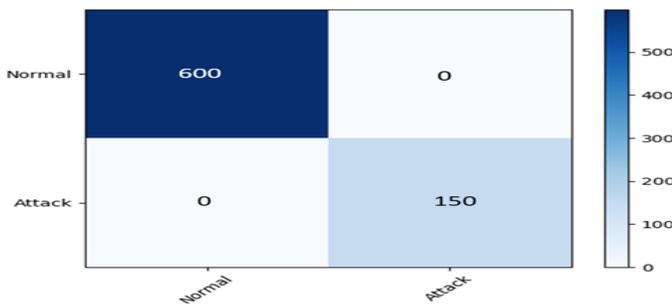

Fig. 13. Confusion Matrix for 1st Test Set.

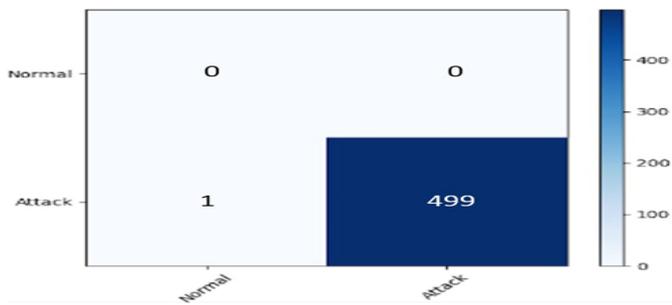

Fig. 14. Confusion Matrix for 2nd Test Set.

## V. CONCLUSION

A NIDS has been implemented to detect generic network attacks and Wi-Fi specific attacks. The most useful features selection techniques have been applied to select the features from the datasets to achieve precise and efficient performances. Ensemble ML models have been applied to classify network traffic as either normal traffic or malicious network traffic. The Ensemble ML models have been implemented separately to analyse Wi-Fi specific attacks and generic network attacks. RF for Link Layer Attacks and Bagging for Network Layer

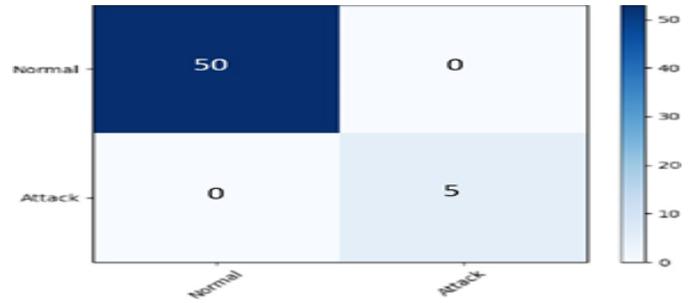

Fig. 15. Confusion Matrix for Test Set Obtained from Experiment.

attacks were the best performing models. It is worth highlighting that the models performed well accuracy, performance measure, F1 score, precision, and recall. As mentioned, these additional metrics gave a more trustworthy judgment of the performance of the models against several imbalanced test sets of different nature. For Link Layer attacks, the accuracy obtained for two-class detection was 99.106%. A perfect score has been obtained for Network Layer attacks for two test sets. It performed well for the test separated from the training set before the training process with an accuracy of 99.79%, F1 score of 99.89%, perfect precision score, and 99.79% for recall. This work demonstrated that careful attribute selection improves efficiency and speeds up the training and classification process. Attribute selection also helps the model consider useful information that directly affects how records are classified. Thus, ignoring as much noise as possible, the model performs more precisely. The objective of this work is not just to operate a wireless network but to emulate an organization network environment where Ethernet connections are considered an important component. It is important to mention that this work planned to analyze generic network attacks for Ethernet connections. The packets must collect for two specific reasons; first, to gather information for the NIDS implementation. Second, for the existing system to capture the packets in real-time.

The proposed work has many branches through which it can be expanded and improved in future. The following are a few considerations for upgrading this work to enhance its functionality:

- One of the most significant challenges faced in this study was generating a larger original dataset for training. Even though it was possible to set up the desired infrastructure and launch several network attacks, the model was not able to collect massive network captures of a wider variety of attacks. Therefore, the model considers obtaining more penetration tools to launch a wider variety of network attacks as future work. These tools can help generate a more trustworthy dataset.
- Another consideration is to provide this ensemble-based multi-level intrusion detection service from the cloud. It has become popular in delivering cloud-based services that can be considered this feature as one of the key upgrades. This can be viewed as a key upgrade because computational resources are expensive, and for data processing tasks, hardware

requirements are high. By providing this cloud-based service, it can become more accessible for anyone without the hardware resources needed for efficiently processing network data.

- An additional tool that should be considered for future work is using Big Data tools for implementation. Network data is considerably large and could be viewed as the perfect scenario for using Big Data tools such as Apache Spark or Hadoop to provide a distributed approach for tasks such as reading, filtering, and so forth. These tools also offer Machine-Learning libraries that can be used to implement ensemble models.

**Abstract**—Powered by advancements in information and Internet technologies, there has been a rapid development in network-based applications. Meanwhile, it is recognized that more attention needs to be paid to the issue of cybersecurity. The security of the network environment plays a vital role in the stable functioning of society. Cybersecurity research has become more active lately. Researchers have proposed several approaches to protect the network. Among them, a broadly practised approach is the intrusion detection system (IDS). This work suggested the potential value of reinforcement learning in building intrusion detection systems at the packet-level. A novel embedding approach has been proposed, namely image embedding, to encode the network traffics. Utilizing image encoding and raw network traffic, which are difficult to tackle by machine learning models, can be converted to images. Thus, the experiments applied convolutional neural networks. In addition, packets embedded in images are arranged in time order. In this way, it can integrate flow statistics with packet information and convert intrusion detection tasks to image-associated tasks. In this experiment, a Deep Q-Learning algorithm was selected for the ensemble with 1D-CNN and CNN and designed a training module and an interaction module. Experiments results indicate that the proposed RL-image-based approach can attain high performance on raw DDoS traffic provided by DDoS2019 and outperforms other traditional deep learning approaches.

## I. INTRODUCTION

Network is the substantial underpinning for developing a modernized economy. The progression of all professions and trades, including business, scientific research, entertainment as well as education, requires the assistance of a reliable and secure network system. However, numerous network security problems have also emerged, causing tremendous damage to individuals or the collective. For example, in April 2020, World Health Organization (WHO) announced that it had encountered an increased number of cyber-attacks, with about 450 email addresses and passwords of WHO and thousands of related staff exposed. If the network infrastructure is damaged and destroyed, not only will personal information be leaked, but the whole society will be thrown into chaos. Therefore, cybersecurity research is crucial for the successful and stable development of society.

Seeing the rapid development and the success of artificial intelligence (AI) attained in research areas such as computer vision, natural language processing and robotics, an increasing number of network engineers and researchers have started

exploring the applications of artificial intelligence techniques in cybersecurity. As mentioned above, conventional intrusion detection systems rely on user-defined filtering rules under which the matched network traffic will be filtered. However, this filtering method has severe defects. Firstly, it is difficult to set up faultless filtering rules, even if experts specify the rules. In the face of tremendous network traffic and a huge variety of attacks, limited artificial rules cannot cover the characteristics of these different types of network traffic. Secondly, from hackers' perspective, rules are formulated by people, so hackers can easily figure out the pattern of those rules by certain tests. Hence, it is straightforward for them to launch attacks that can bypass those rules. Thirdly, the update of rules is inefficient. Because malicious network attacks are evolving quickly, intrusion detection systems also require frequent updates and upgrades to detect these attacks. However, it is time-consuming and laborious to determine what kind of outdated rules should be discarded and to lay down pivotal regulations.

Employing artificial intelligence approaches in intrusion detection systems can mitigate the problems mentioned earlier [1][2][3][4]. The filter rules are rendered automatically when using a machine learning-based model as the IDS to detect malicious network attacks. Machine learning models, such as deep neural networks (DNNs) [5], can efficiently learn representative features of different network attacks and then implement classification or detection; hence, manual rules are not required anymore. Because neural networks are a type of black box to everyone, hackers cannot acquire what kind of patterns and relationships are captured by the neural networks. Therefore, it is harder for hackers to launch novel attacks that bypass detection.

Reinforcement learning research [6] has been booming in recent years. Incorporating deep neural networks (DNNs), reinforcement learning algorithms outperform in many fields in comparison to traditional deep learning approaches, such as games, recommendation systems and many scientific fields. Some well-known reinforcement learning algorithms, including Deep Q-Learning (DQN) [7] and Proximal Policy Optimization (PPO) [8], have already been widely used in many areas. AlphaGo is one of the most representative achievements of RL in games. In addition, many enterprises, such as YouTube, Alibaba [9], etc. are exploring novel RL based recommendation techniques. Also, RL has found many great applications and research value in various engineering fields. Studies [10] use deep reinforcement learning algorithms to solve the low-level control problem of autonomous underwater

vehicles (AUVs). Many researchers [11] apply reinforcement learning algorithms, especially PPO, to control unmanned aerial vehicles (UAVs). These successful applications demonstrate that reinforcement learning is at the stage of rapid growth. Motivated by the importance of the cybersecurity issue and the promising results of RL in many applications, a study has been conducted in this paper using reinforcement learning. Policy gradient methods, such as Asynchronous Advantage Actor-Critic (A3C), Trust Region Optimization (TRPO), and Proximal Policy Optimization (PPO), are widely applied in RL in devising game agents, including both discrete-action and continuous-action games. Among these methods, PPO stands out by achieving high scores in many testbeds, such as Atari games and MuJoCo [12]. The core innovation of PPO is the clipped surrogate objective. However, studies [13][14][15][16] indicate that the high achievements of PPO result from some additional code-level optimizations, instead of its key idea in a clipped surrogate objective. Thus, further understanding of these code-level optimizations is essential for applying PPO to tackle more problems, such as intrusion detection.

Reinforcement learning and intrusion detection are remarkably compatible in many aspects. Reinforcement learning algorithms are used for solving Markov problems [17]. Essentially, network flow is a special dynamic process type that a Markov process can model. Besides, when deciding on the current state, the RL agent can consider foresighted states by introducing discount factors when calculating the cumulative reward. This is also conducive to intrusion detection. The network flow consists of a sequence of different packets. When the current packet is examined, those packets behind it in the same flow can also provide useful information. Treat a packet as a state by using the cumulative reward with the discount factor, and reinforcement learning algorithms can be employed to take the features of future packets into account.

Furthermore, intrusion detection can be considered a special game. Hence, it is feasible to formulate and solve the intrusion detection problem in the reinforcement learning framework. Motivated by these pertinent aspects, this work attempt to study how to improve the performance of intrusion detection by using Deep Reinforcement Learning based Ensemble methods.

## II. BACKGROUND AND RELATED WORK

As an important method of machine learning, reinforcement learning (RL) is based on agents learning strategies to maximize returns or achieve specific goals while exploring and interacting with the environment. The basic framework of reinforcement learning is shown in Fig. 1. In general, a reinforcement learning framework consists of an agent and the interaction environment. The agent sends actions to the environment, and then the environment moves to a new state and generates rewards, which are sent back to the agent for the next step. The state represents the observation of the environment, and the rewards evaluate the outcome of the current action.

Similar to the controller in a control system, the agent is responsible for taking actions and interacting with the environment. An agent is controlled by its policy. As shown in Table I, the policy function takes the states/observations as the

input and generates the action for the agent at the current step. In the actual implementation, deep neural networks (DNNs) are commonly employed to realize the policy function.

TABLE I. THE EXPLANATION OF POLICY

Input	Output	Transformation	Function
State	Action	Action = Function (State)	Deep Neural Networks

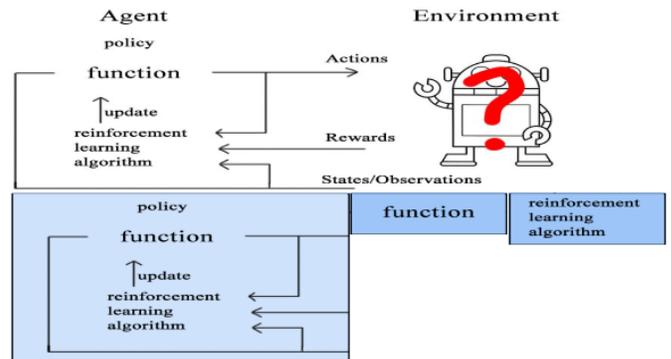

Fig. 1. Reinforcement Learning Framework.

In many cases, it is required to define the reward feedback rules manually. The rewards are used for updating the policy. After the policy is updated, it takes the current state as the input to issue new actions. In short, the policy can be considered a function that maps states to actions and is subject to changes according to rewards, as shown in Table I. The objective of RL is to learn the optimal policy for the agent to take the best action at each step.

**RL Algorithms:** In Fig. 2 some frequently used reinforcement learning algorithms are shown. A policy can be optimized by directly learning an actor or indirectly learning a critic instead. According to different learning targets, reinforcement learning algorithms can be divided into three main categories: policy-based algorithms, such as Proximal Policy Optimization (PPO) [8] and Trust Region Policy Optimization (TRPO); value-based algorithms, such as Q-Learning [18]; policy and value based algorithms, such as Actor-Critic (A2C) [19] and Asynchronous Advantage Actor-Critic (A3C) [20]. Policy-based algorithms train an actor who makes decisions directly while value-based algorithms train a critic who can evaluate current decisions. Policy and value-based algorithms utilize both the critic and the actor to train the agent.

Fig. 2. Classification of Reinforcement Learning Algorithms.

Another important classification basis is the type of actions

taken by the agent. In real implementation, actions can be either discrete or continuous. For example, the actions taken in Atari games are transferred to discrete values, but in MuJoCo games [12] actions are transferred to continuous values or vectors. In addition, Q-Learning is employed in the discrete domain. PPO and TRPO are suitable for both discrete domain and continuous domain. Deep Deterministic Policy Gradient (DDPG) [21] and Soft Actor-Critic (SAC) [22] are specifically devised for the continuous domain.

**Q-Learning:** Q-Learning [18] is a widely used model free value-based reinforcement learning algorithm, and it always works in the discrete domain. In this algorithm, the Q function  $Q(s, a)$  works as the critic, which is devised to evaluate the quality of the action taken in the current state. Its value, also called the Q-value, is updated by the equation (1):

$$Q^{new}(s_i, a_i) \leftarrow \underbrace{Q(s_i, a_i)}_{\text{CurrentValue}} + \underbrace{\alpha}_{\text{LearningStep}} \underbrace{(r_i + \gamma \max_a Q(s_{i+1}, a_{i+1}) - Q(s_i, a_i))}_{\text{TD Learning}} \quad (1)$$

The equation (1) demonstrates the idea of the temporal difference (TD) learning, which relies on the one-step bootstrapping technique [23] to update the values. Once updated, Q values are stored in a tabular form. The Q value is being updated until it stops changing or only changes slightly. After learning the Q values of all existing state and action pairs, the optimal policy can be generated under the following rule using equation (2):

$$a = \operatorname{argmax}_a Q(s, a) \quad (2)$$

Deep Q-Learning (DQN) [7] is an advanced version of Q-Learning, where deep neural networks (DNNs) are introduced to estimate Q values. Although Q-Learning is powerful and widely adopted, it can only estimate the Q values of existing state and action pairs that appeared during training. It is almost impossible for a problem with a large state space to store each value into a tabular form. Incorporating Q-Learning with DNNs can solve the problem. The deep neural network can estimate the Q values by using a state-action pair as the input. Even if the state-action pair has never appeared in the training stage, the deep neural network can still output an appropriate value. Compared with traditional tabular Q-Learning method, the generality of DQN is superior. DQN has several improved versions, such as Double DQN [24] and Dueling DQN [25]. DQN and its improved versions have been successfully applied in the game control. Researchers [7] have employed a variant of DQN to play seven Atari 2600 from the Arcade Learning Environment. The state is the game screen in the image form and thus convolutional neural networks (CNNs) are adopted to estimate the Q values. Experience replay is proposed to reduce the correlation among the training data. Results show that DQN outperforms almost all previous approaches when playing Atari games, including Sarsa [6] and human experts. However, in many cases, Q values tend to be overestimated by DQN. To handle this problem, Double DQN [24] is proposed. Studies [24] compare the DQN with the Double DQN on Atari games and find that the Double DQN can generate much more appropriate Q values while DQN always overestimates them, and this is the reason why Double DQN outperforms DQN in most Atari games.

**Policy Gradient:** Policy gradient method is a policy-based reinforcement learning technique that can be applied in both discrete and continuous domains. Policy gradient methods can directly optimize the parameterized policies  $\pi_{\theta}$  by maximizing the long-term cumulative reward  $E_{\pi}[G_i]$  based on the gradient ascent approach. The policy gradient method has many advantages over other reinforcement learning algorithms. It can make the policies' convergence more greedy over time autonomously. Furthermore, compared to Q-Learning and its variants, the policy gradient method can work effectively in continuous control problems. The policy gradient estimator can be expressed in the following form:

$$\hat{g} = \hat{E} \pi_{\theta} [\nabla \lg \pi_{\theta}(a_i | s_i) \hat{\psi}_i] \quad (3)$$

The equation (3) where  $\pi_{\theta}$  is a parameterized policy with respect to parameter  $\theta$ ,  $\hat{\psi}_i$  is a function related to rewards and  $E \hat{\pi}_{\theta}$  is the mean over a finite batch of samples collected under  $\pi_{\theta}$ . As shown in Table II, there are several expressions of  $\hat{\psi}_i$  adopted by different policy based algorithms. Specially, the advantage function and the TD-error are widely applied. Compared to the average reward, the average function measures how much reward can be gained by taking the action  $a_i$  in the current state  $s_i$ , compared to the average reward. As shown in Table III, the TD-error calculates the difference between the estimated accumulative reward to be received starting at given time step  $i$  and the actual accumulative reward received starting at step  $i$ , and the algorithm acts to reduce such error.

TABLE II. MULTIPLE EXPRESSIONS OF  $\hat{\psi}$

Expression	Explanation
$\sum_{i=0}^{\infty} r_i$	total reward after taking $a_i$
$\sum_{i=0}^{\infty} r_i^i$	add a baseline (constant)
$\sum_{i=0}^{\infty} r_i^i - b$	state-action value function
$Q^{\pi}(s_i, a_i)$	advantage function
$Q^{\pi}(s_i, a_i) - V^{\pi}(s_{i+1}) - V_{s_i}^{\pi}$	TD error

TABLE III. TD-ERROR

Expression	Explanation
$r_i$	instant reward at step $i$
$V^{\pi}(s_{i+1})$	estimated accumulative reward starting at step $i + 1$
$r_i + V^{\pi}(s_{i+1})$	actual accumulative reward starting at step $i$
$V^{\pi}(s_i)$	estimated accumulative reward starting at step $i$

Several RL algorithms are developed from the policy gradient method, including the well-known Trust Region Policy Optimization (TRPO) and Proximal Policy Optimization (PPO), which have been successfully implemented in many areas. PPO has been extensively applied to game AI research and solving control problems. PPO is an off-policy reinforcement learning algorithm applicable to continuous and discrete environments. The core idea of PPO is the clipped surrogate objective. PPO not only attains high scores in test-beds like Atari and MuJoCo [12], but also solves complex problems such as DOTA [25][26] and Glory of Kings [27]. The well-known StarCraft agent AlphaStar [28] and Mahjong agent Suphx [29] are also trained with PPO. Additionally PPO has also been exploited to solve control problems, such as unmanned aerial vehicles (UAVs) control [11] and an autonomous underwater vehicles (AUVs) control [10].

**Packet-level and Flow-level Intrusion Detection:** Packet-level and flow-level analyses are two fundamental methods for designing intrusion detection systems. In the packet-level intrusion detection, messages and headers transported by network packets are primarily extracted for detecting malignant traffics [1, 2]. In flow-level intrusion detection, the traffic flow characteristics, which usually contains numerous packets, are extracted for detecting attacks [3, 4].

Packet-level intrusion detection systems analyze and extract features from the network packet data through transmissions for intrusion detection. As shown in Table IV, a network packet travels across five layers, including an application layer, a transportation layer, a network layer, an Ethernet layer and a physical layer (not considered in the paper). A packet structure consists of messages generated in the application layer and three headers generated in the remaining three layers. The content of messages generated in the application layer is different with respect to different protocols. For example, HTTP generates special HTTP request messages. Different headers carry different knowledge. In the transportation layer, TCP and UDP are two most common protocols with TCP and UDP headers as the most common ones in this layer. IP is the most common protocol in the network layer with the IP header. Similarly, in the Ethernet layer, an Ethernet header is generated. The knowledge carried inside headers is called field.

TABLE IV. NETWORK LAYERS AND PACKET STRUCTURE

Layer	Main Protocol	Packet Structure
Application Layer	FTP HTTP	Messages
Transportation Layer	TCP UDP	TCP/UDP Header+Messages
Network Layer	IP	IP Header+TCP/UDP Header +Messages
Ethernet Layer (Data Link Layer)	Ethernet	Ethernet Header + IP Header + TCP/UDP Header + Messages
Physical Layer	Not Considered	Not Considered

Packet-level and flow-level techniques approach the intrusion detection problem from two different directions. Packet-level research studies the data knowledge carried inside packets but ignores the relationship among different packets. On the contrary, flow-level research focuses on flow knowledge and attempts to capture the relationship among packets, but ignores data transported inside a packet. Both approaches have their advantages and disadvantages [30], so this study attempts to combine the packet-level approach with the flow-level one and build a more robust intrusion detection system.

**ML-Based Intrusion Detection:** In recent years, machine learning algorithms are broadly adopted in cybersecurity studies [1–4]. Some well-known machine learning algorithms, such as Random Forest (RF) [31], support vector machine (SVM) [32], and deep neural networks (DNNs), have shown promising results in the area of cybersecurity. In the work, the focus was on supervised learning-based approaches, such as deep neural networks. Table V shows the fundamental supervised learning-based intrusion detection framework. The entire intrusion detection procedure can be divided into two stages: training stage and detection stage.

In step 1, feature engineering is first conducted on the network traffics for the training stage. It is important to design appropriate features of traffics to improve the performances of intrusion detection systems. In flow-based research, certain

TABLE V. INTRUSION DETECTION FRAMEWORK

Step	Training	Detection
0	Collect Network for Training	Collect Network for Detection
1	Feature Engineering	Feature Extraction
2	Data Preprocessing	Data Preprocessing
3	Train AI Models	Monitored by IDS
4	Apply AI Model as IDS	Evaluate Detection Results

standard flow-level features have already been given for most datasets available online, so the feature engineering step is not mandatory. However, for the packet-based research, it is often necessary to conduct feature engineering and extract features from raw network traffics. In this case, the quality of features is the key to the successful application of the intrusion detection system.

In step 2, data preprocessing is necessary for both flow-level and packet-level re- search. The features always contain three different value types: continuous value, categorical value, and discrete value. In order for the features to be processed by machine learning models, we need to transform the categorical and discrete values into certain suitable formats.

In step 3, an appropriate machine learning model need to be select. This step is of great importance to the final performance of the IDS. The most suitable model has been selected according to different rules with respect to different tasks. For example, if the input data is image, convolutional neural networks (CNNs) [33] are often the optimal choice. If it is time series data, the 1D-CNN [34] and the long-Short Term Memory (LSTM) network can be chosen. Afterward the training of the model and tuning of hyperparameters has been performed. Finally in step 4, the optimal model as the intrusion detection system has been applied.

For the detection stage, it was able to extract features engineered at the training stage from raw network traffics and conduct data preprocessing on these features. Subsequently, the pre-processing data was fed into the trained intrusion detection system. In order to evaluate the quality of the IDS, proper metrics for the machine learning model, such as the accuracy, precision, recall and F1 measures, etc. need to adopt.

**TCP/IP Model and Packet Switches:** This section introduces how a packet traverses from the source host to the destination host. Furthermore, important knowledge carried by the packets through the entire transmission trip has been introduced in details. Fig. 3 [35] shows a classical TCP/IP network model and the path of a packet traveling from the source host to the destination host. The TCP/IP model consists of an application layer, a transportation layer, a network layer, a data link layer (Ethernet layer) and a physical layer. The physical layer is not considered in this work. The packet transmission procedure [35] from a client side such as a browser has been explained.

First of all, the client launches an HTTP request in the application layer. The client creates a socket and sends the HTTP request message to the transportation layer through the socket. Both TCP and UDP protocols operate in the transportation layer, and HTTP can launch the TCP connection for transportation. After receiving HTTP messages from the application layer, the transportation layer creates a logic TCP connection with the transportation layer of the server through

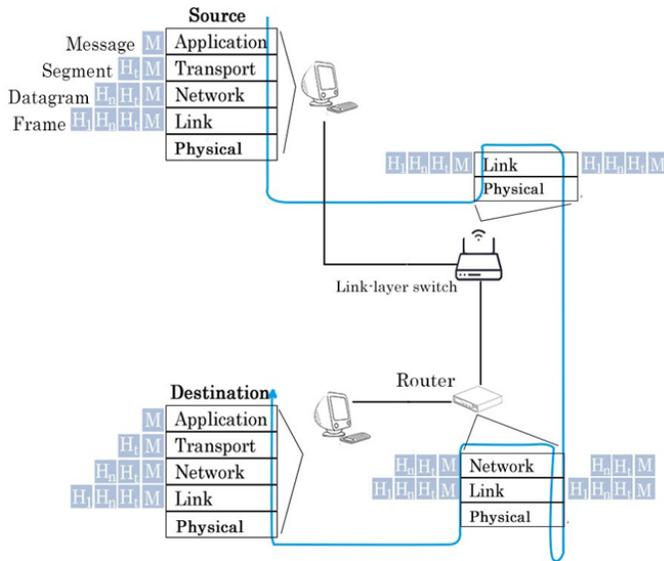

Fig. 3. TCP/IP Model and Packet Switches. M Represents the Application Messages Generated in the Application Layer.  $H_t$ ,  $H_n$ ,  $H_l$  Represent Transportation Layer Header, Network Layer Header and Data Link Layer Header, respectively.

three-way handshaking. Then, the transportation layer generates a TCP header ( $H_t$ ), and adds it to the message, composing a TCP segment. The most important knowledge carried in the TCP header is the source port and destination port. The port identifies the application process, and different ports are bound with different application protocols. In this case, HTTP is bound with the port 80. Subsequently, the TCP segment is sent to the network layer for routing and forwarding. After receiving the TCP segment from the transportation layer, the network layer generates and adds an IP header ( $H_n$ ) to the TCP segment, composing the IP datagram. The most important knowledge transported in the IP header is the source and destination IP addresses. IP address indicates the packet trip's start and end network address. Then, the IP datagram is sent to the data link layer. In addition to IP protocol, ICMP and ARP protocols also operate in the network layer. In most cases, Ethernet protocol is used in the data link layer, so the data link layer is also named the Ethernet layer. After receiving the IP datagram, the data link layer generates and adds an Ethernet header ( $H_l$ ) to the IP segment, composing the Ethernet frame. Finally, the frame is sent to the server-side. Similarly, receiving a packet on the server-side is the reverse of sending a packet as described in the above. In general, this work has taken advantage of the quintuple, i.e. source IP address, destination IP address, source port, destination port, and the transportation protocol, to distinguish between multiple packet transmissions. In the following experiments, it has been attempted to adopt these properties to split network traffics.

**Packet Headers and Fields:** The knowledge transported by packet headers will be extracted for packet-level intrusion detection. The application layer generates application messages, and the remaining three layers generate special headers. A packet header consists of different type of fields to store the most representative knowledge of each layer. Table VI lists some common headers and fields. Taking the TCP header as an example, a TCP header consists of various fields, including

source and destination port, sequence number, acknowledgment number, review window, header length, options and flag. The successful operation of TCP protocol requires the support of these filed knowledge [35]. Since fields store the most essential knowledge of headers, it is natural to adopt fields knowledge to establish a stable intrusion detection system. Fields are stored in the binary form in bytes, and in the following study, we use this property to transfer fields into pixels.

TABLE VI. HEADERS AND FIELDS

Header	Field
IP Header	Version Number, Header Length, Type of Service, Datagram Length, Identifier, Flags, Fragmentation Offset, Time-to-Live, Protocol, Header Checksum, Source and Destination IP, Options
TCP Header	Source and Destination Port, Sequence Number, Acknowledgement Number, Receive Window, Header Length, Options, Flag
UDP Header	Source and Destination Port, Length, Checksum
Ethernet Header	Source and Destination Address, Type, CRC, Preamble

Packet headers and application messages are recorded in 'pcap' (packet capture) files, which can be acquired by 'wireshark' [36], a commonly used network analysis tool. In the experiment, after selecting the network card of the network device on 'wireshark', it can automatically capture all the packets (Ethernet frames) traveling through the network card in chronological order and record these packets in 'pcap' files in a hexadecimal format. 'Pyshark' can be used to read packets from 'pcap' files. The DDoS2019 package, which contains raw 'pcap' files for the packet-level IDS research, has been adopted in this case study.

**Convolutional Neural Networks:** Convolutional neural networks (CNNs) [33] are feed-forward neural networks with a deep structure facilitating convolutional computations. It is one of the most representative algorithms of deep learning. CNN is widely applied in computer vision, such as image classification [37][38]. The name of CNN indicates that the network utilizes the convolution operation extensively. A basic CNN consists of convolutional layers, pooling layers and fully connected layers. CNN gains in popularity because of its affine invariance property, which is achieved by receptive field, shared weights and pooling.

A convolutional layer conducts feature extraction on images with convolution kernels, through which the receptive field and shared weights can be employed. The receptive field signifies that a neuron in the CNN is required to sense information of a part of the image, which can considerably reduce the number of parameters connected to a neuron. This is beneficial considering that the local correlation of an image is relatively stronger. By shared weights, different neurons can share the same convolution kernels, further reducing the number of parameters required for training. As shown in Fig. 4(b), a kernel (feature detector) performs the image's convolution operation to extract image features. Different kernels can extract different type of features. The output of the convolutional layer is called the feature map. Notably, one kernel generates one feature map.

A pooling layer can reduce the dimensionality of the data. As a general rule, the pooling layer is sandwiched between continuous convolutional layers, and it can compress

the amount of data/parameters and prevent over-fitting. This work adopted two pooling methods, the maximum pooling and the average pooling, to perform down-sampling on each feature map.

The other commonly used CNN is 1D-CNN [34]. 1D-CNN is especially efficient when extracting essential features from shorter and fixed-length segments of the overall data set, and when the feature within the segment is not of high relevance. Accordingly, 1D-CNN is good for analyzing sensor time-series data [39]. There are two main differences between the 1D-CNN and the CNN. First, the input dimensions are different, and second, the convolution kernel traverses the input data in different ways, as shown in Fig. 4. As displayed in Fig. 4(a), assuming that the input is a sentence, each word can be transferred into a vector by word embedding approaches. The convolution kernel can be treated as the feature detector. The feature detector in 1D-CNN always covers the whole word, and scans from the start position to the final position. For example, in Fig. 4(a), the height of the detector is 2, and it moves from the top to the bottom with the step of 1. As shown in Fig. 4(b), the input is a batch of 2D images with respect to CNN. Using a square window, the convolution kernel slides horizontally and vertically across the image. As shown in Fig. 4(b), the feature detector operates in a 2x2 window.

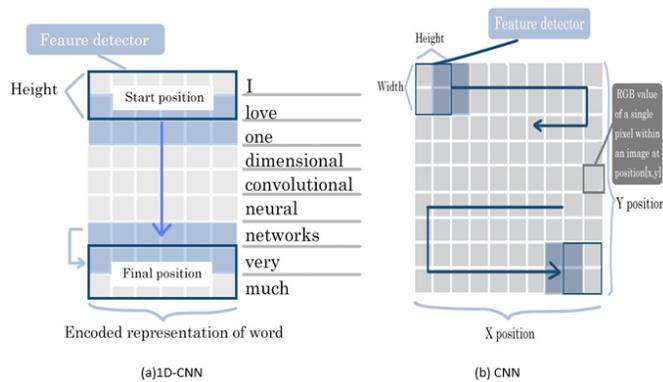

Fig. 4. Convolutional Operation Comparison. (a): 1D-CNN Convolutional Operation Example. (b): CNN Convolutional Operation Example.

Packet-level approaches, combined with machine learning algorithms and deep neural networks, have already been broadly applied in various areas of cybersecurity, including intrusion detection, traffic classification, etc.

In studies [1], an LSTM-based IDS is designed for detecting malicious traffics in raw network traffics at packet-level. The fields carried by packet headers are extracted and processed for experiments. They treat a field, such as IP version in the IP header, and TCP source port in the TCP header, as a word. A packet represents a sentence which consists of these fields (words). Researchers in this field have given a novel word embedding approach. They have produced a dictionary to map these words into integers. In this manner, one can transfer fields knowledge into 64-dimension vectors in the integer format. After implementing data extraction and word embedding, a 3-layer LSTM model with dropout layers is established for detection. Studies [2] also employ packet-level knowledge for detecting malicious traffics in IoT environment.

Similarly, they conduct feature extraction on raw traffic flow. Field information is extracted from separated packets and each field represents a feature. The authors concentrate on header fields, including frame, IP and TCP/UDP associated information and exploit one-hot encoding to encode those categorical features. After implementing feature extraction and data preprocessing, they design a three-layer fully connected neural network with the sparse cross-entropy loss function for multi-class classification.

### III. METHODOLOGY

#### A. Methods and Procedures

The novel intrusion detection framework proposed at packet-level is shown in Table VII. The framework consists of two major modules and several sub-modules. The preprocessing module is devised for data transformation and feature engineering. The reinforcement learning module is devised for training the intrusion detection system with RL approaches. This module further comprises a training module and an interaction module. An additional anomaly detection module is deployed to detect those attacks which are blind to the training module. Each module has been introduced in the following sections in details.

TABLE VII. INTRUSION DETECTION FRAMEWORK AT PACKET-LEVEL

Module	Sub-Module	Function
Data Preprocessing	None	Data Transformation and Feature Engineering
Reinforcement Learning	Interaction Training	Collect batch data and store in replay buffer <sup>1</sup> Train the RL agent with batch data
Anomaly Detection	None	Detect attacks blind to the training module

#### B. The Data Preprocessing Module

Motivated by the extensively used embedding approaches such as word2vec, a novel embedding method has been proposed, namely the image embedding for the RL based IDS developed in this work. Several designated transformations are performed in this method to convert the network packets into images. Table VIII show the main steps of the data preprocessing module. In the following, these steps have been explained in details.

TABLE VIII. THE DATA PREPROCESSING MODULE AT PACKET-LEVEL

Step	Process (Input → Method → Output)
1	Raw Network Traffic → Session-based Rule → Separated Sessions
2	Separated Sessions → Image Embedding → Session Images
3	Session Images → Labeling with Log Files → Images and Label
4	Images and Label → Normalization → Applicable Dataset

In step 1, the vast network traffic recorded in the 'pcap' files has been split into separated and small traffic files according to specific rules, such as the session-based and flow-based partition rules. The difference between a session and a flow is shown in Table IX. The packet transmission directions in the same session can be opposite, but the directions must be the same in the same flow. The common rule of session-based and flow-based partition is that if two packets share the same 5-tuple knowledge (source IP, source port, destination IP, destination port, transportation protocol), these packets will be categorized in the same way session or flow. As

explained previously, such 5-tuple knowledge determines the travel route of a packet, thus, this rule is used for flow or session categorization. A session or a flow always contains numerous packets. In this experiments, the session-based rule for partition has been used. After partition, several separated sessions stored in 'pcap' files can be obtained; each session contains various packets recorded in the order of capture time.

TABLE IX. PERFORMANCES OF DIFFERENT DISCOUNT VALUES ON FOUR AGENTS

<b>Source</b>	<b>Flow I</b>	<b>Destination</b>
IP 1	Packet 4, Packet 3, Packet 2, Packet 1	IP 2
Port 1	←(one direction)	Port 2
TCP or UDP Connection		
<b>Destination</b>	<b>Flow II</b>	<b>Source</b>
IP 1	Packet 4, Packet 3, Packet 2, Packet 1	IP 2
Port 1	→ (one direction)	Port 2
TCP or UDP Connection		
<b>Source/Des</b>	<b>Session I</b>	<b>Des./Source</b>
IP 1	Packet 4, Packet 3, Packet 2, Packet 1	IP 2
Port 1	↔(bi-direction)	Port 2
TCP or UDP Connection		

In step 2, image embedding is conducted on these separated sessions. The structure of a network packet can be found in Fig. 5(a). Generally, a network packet consists of an Ethernet header, a TCP or UDP header, an IP header and application messages. Only fields stored in packet headers has been extracted in this work.

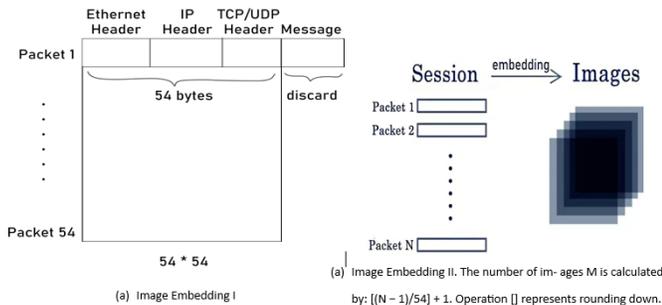

Fig. 5. Procedure of Image Embedding. (a): Transfer Packets to an Image. (b): Transfer a Session to a Batch of Images.

Application messages have been discarded because the length of a packet header is fixed, while the length of the application messages is not. The fixed embedding length is conducive to image embedding since the input image's size can be fixed. The whole procedure of image embedding is shown in Fig. 5. The fields transported by the packets are stored in bytes, so they can be converted to base 10 form with a range of 0 to 255, and one byte represents one pixel. Hence one packet represents a line of an image. With simple calculations, it has been found that the total length of a packet header is 54 bytes. Thus, the standard image format with a fixed size of 54x54 has been chosen, meaning that an image consists of only 54 packets. Some sessions may contain more than 54 packets, in this case, more images can be used to embed the extra packets. If the remaining packets are less than 54, the missing parts have been filled in with zeros. Packets are embedded in the order in which they are captured. This way, session knowledge into the packet-level experiments can be attached.

In step 3, after conducting image embedding, each session

has been labeled by matching the time stamp given in the log file provided by the raw dataset. In step 4, the normalization has been performed on these images by dividing 255. All pixels of images are then normalized into [0, 1] from [0, 255].

### C. The Reinforcement Learning Module

Before developing a reinforcement learning module, it is necessary to first transfer the intrusion detection problem into an RL-based problem. For this purpose, the intrusion detection problem has been compared to the Atari games studied in [12], considering intrusion detection as a special game. The comparison is shown in Table X.

TABLE X. COMPARISON BETWEEN ATARI GAME AND THE INTRUSION DETECTION GAME

RL	Atari	IDS	IDS Space
State	Image(s)	Image	Images in dataset
Action	Game Operation	Prediction	Label Space {0, 1, 2...}
Reward	Game Feedback	Reward Mechanism	{+1, -1}
Episode	Game Round	Session	-
Agent	Game User	Classifier	-

Sessions identified in an intrusion detection game correspond to game rounds in an Atari Game. When the agent is playing the game, it takes the following trajectory:

$$s_0, a_1, r_1, s_1, a_2, r_2 \dots s_t$$

where  $s$  represents the game screen,  $a$  represents the game operation and  $r$  represents the game reward. The game agent repeats until it reaches the terminated state  $s_t$  (game over) of an episode. Similarly, the intrusion detection agent can also take the above trajectory until it reaches the session's end (last image). The state is the game screen (in image format) in the Atari games, and in intrusion detection, the state is also an image after conducting image embedding on the sessions. The action space of Atari games contains game operations, which can be expressed as discrete numbers, e.g. 0 (one step left), 1 (one step right), 2 (one step up), etc. The action space of the intrusion detection game contains the types of the traffic class, which can also be expressed as discrete numbers like 0 (normal), 1 (attack 1), 2 (attack 2), etc. However, the reward system is different for the above two problems. Game developers have devised the reward mechanism of Atari games. For the intrusion detection problem, the reward system has to design carefully. After conducting the research it has found that the reward scale has a significant impact on the performance of reinforcement learning algorithms. Thus, inspired by reward clip for the code-level optimization implemented in the Atari game agent, the following reward feedback rule has been designed: if the prediction made by the agent is correct, the reward is 1; otherwise, the reward is -1. PPO is the main algorithm used for solving the discrete problem. Deep Q-Learning algorithm has been applied, rather than PPO. Deep Q-Learning is also an excellent choice for solving discrete problems, and it is much easier to implement compared to PPO. A comparison case study has been shown that the Deep Q-Learning outperforms policy gradient methods in the intrusion detection task.

After identifying these essential reinforcement learning ingredients, designing a reinforcement learning module has been started. Convolutional neural networks (CNNs) are chosen as

the network structure of the intrusion detection agent since the input states are images. It should be noted that, contrasting to Atari games and other computer vision tasks, 1D-CNN is also appropriate in this intrusion detection system. One reason is that session images have been treated as a type of time-series data since packets embedded in the image are arranged in chronological order according to the capture time. Most importantly, as shown in Table XI, the intrusion detection problem is similar to the language model, where 1D-CNN is widely applied. Generally, sentences consist of different words and have different lengths. Similarly, a packet can be treated as a word, and a session can be treated as a sentence. When dealing with language tasks, advantage of word2vec approaches has been taken to conduct data preprocessing, while this IDS used the proposed image embedding to conduct data preprocessing for packets. Due to the above, this work is motivated to adopt the 1D-CNN in this experiment for the proposed IDS. The main structure of the two RL agents, i.e. DQN-CNN and DQN-1D-CNN, is shown in Fig. 6. The RL agents' input

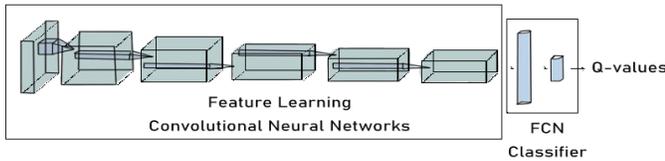

Fig. 6. Main Structure of Two Reinforcement Learning Agents DQN-CNN and DQN- 1D-CNN. For DQN-CNN, the Structure of the Feature Learning Part is CNN. For DQN-1D-CNN, the Structure of the Feature Learning Part is 1D-CNN.

states ( $s$ ) are a finite batch of images. CNN and 1D-CNN are applied for feature extraction on DQN-CNN and DQN-1D-CNN, respectively. An additional fully connected layer is deployed for final classification and detection. The output is Q-values of the current states, and the prediction/action ( $a$ ) is decided based on Eqn. (2) with the Q-values. As discussed above, the RL module in the IDS has two sub-modules, the interaction module and the training module. The complete procedure of the interaction module is shown in Algorithm 1. In the beginning, a session from the dataset has been sampled randomly. A session contains numerous images, and each image represents a states. If the current image is not the last image in the session, it store  $s$ ,  $r$ ,  $s_{-}$  and  $a$  into the replay buffer and continue. If the current image is the last one, the model stores  $s$ ,  $r$ , and  $a$  into the replay buffer and randomly samples another dataset session. The complete procedure of the training module is shown in Fig. 7. As mentioned above, Deep Q-Learning algorithm is employed in this experiments. Two networks (the Update and the Target) operate together to achieve the approximate regression. The functionality of the target network is to improve the training stability by fixing the regression target in  $N$  steps. The structure of the update network is the same as the agent introduced in Fig. 6. The target network copies the structure from the update network and is initialized with the parameters of the update network. The update network is updated through back propagation, and the target network is updated by copying the parameters from the update network every  $N$  times.

The training module and the interaction module work alternately. For example, once the replay buffer is full, training

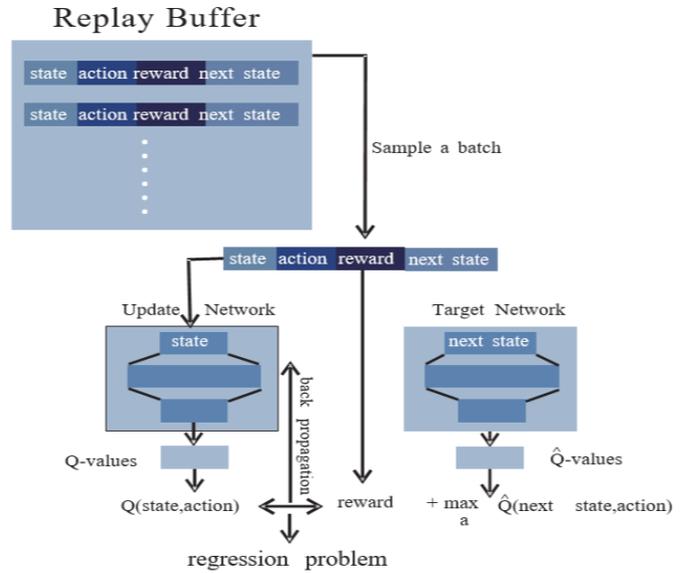

Fig. 7. Deep Q-Learning Training Module. Update Network is Updated through Back Propagation. Target Network is Initialized with the Parameters of Update Network, and Updates are made every  $N$  Times through Copying the Parameters from Update Network. The Mean Squared Error (MSE) is used as the Objective Function for the Approximate Regression Problem.

is started for several iterations. After training, the new agent can be used to interact with the environment and store the new data into the replay buffer and remove the old data. The complete pack-level IDS algorithm including both the interaction module and training module is shown in Algorithm 2.

**Algorithm 1 – Interaction Module**

```

Require: Start Interacting
1:for interaction process do
2:   Randomly sample a session and get its label
3:   Take first image in the session as current state  $s$ 
4:   Feed  $s$  into agent and obtain action (prediction)
5:   Feed  $a$  and label into reward mechanism, get reward  $r$ 
6:   for each episode do
7:     if Last image in the session then
8:       Store ( $s$ ,  $r$ ,  $a$ , None) into replay buffer
9:       break
10:    else
11:      Take next image in the session as next state  $s_{-}$ 
12:      Store ( $s$ ,  $r$ ,  $a$ ,  $s_{-}$ ) into replay buffer
13:      Set  $s = s_{-}$ 
14:    end if
15:  end for
16:end for

```

**D. The Additional Anomaly Detection Module**

An anomaly detection model has been employed to detect attacks blind to the training set, by considering them as an anomaly class. This is important to a robust intrusion detection system because it is impossible to include all types of attacks in the training set. As shown in Fig. 8, a confidence score

**Algorithm 2** – Deep Q-Learning Framework for Detection at Packet-level

**Require:** Extract sessions from raw traffic file  
 Split sessions based on session-based rule  
 Conduct image embedding on each session  
 Initialize Q-function Q for agent, target Q-function  $\hat{Q} = Q$   
 1: **for** each episode: **do**  
 2: Randomly choose a session from the dataset.  
 3: **for** each image within session,  $t \in [0, N]$  *do*  
 4: Given image  $s_t$ , take action at based on Q  
 5: Compare at with true label, obtain reward  $r_t$  and  $\bar{r}_t$   
 6: Derive next state  $s_{t+1}$  :the image behind current state  
 7: Store  $s_t, a_t, r_t, s_{t+1}$  into agent replay buffer  
 6: **end for**  
 7: Sample a batch  $s_t, a_t, r_t, s_{t+1}$  from agent replay buffer  
 8: Target  $y = r_t + \gamma \max_a \hat{Q}(s_{t+1}, a)$   
 9: Update Q through back propagation to make  $Q(s_t, a_t)$  close to y  
 10: Every C steps reset  $\hat{Q} = Q$   
 11: **end for**

TABLE XI. COMPARISON BETWEEN THE INTRUSION DETECTION SYSTEM AND THE LANGUAGE MODEL

	IDS	Language Model
Input	Session	Sentence
Element	Packet	Word
Embedding	Image Embedding	Word2vec
Input Format	[batch, len, dim]	[batch, Len, Dim]

has been outputted and set a threshold  $\gamma$  manually. In the experiment, a Softmax layer has been added at the end of the agent and view the output of the Softmax layer (Q-values) as the confidence score of each class. As shown in Eqn. (4), if all confidence scores are smaller than  $\gamma$ , the input will be determined as the 'anomaly' attack. Conversely, the class that belongs to the max confidence score is the expected detection result.

$$f(s) = \begin{cases} \underset{a}{\arg \max} Q(s,a) \text{ if } \max_{\alpha \in \alpha} Q(s,a) \leq \lambda \\ anomaly \text{ if } \max_{\alpha \in \alpha} Q(s,a) \leq \lambda \end{cases} \dots \quad (4)$$

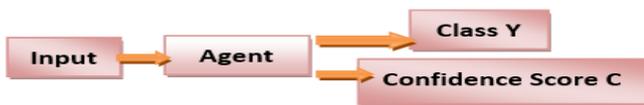

Fig. 8. The Work Flow of Anomaly Detection Model.

**E. Dataset**

DDoS2019 dataset has been selected as the major dataset for packet-level experiments. DDoS2019 is a relatively new dataset [40] which is collected for DDoS and packet-level research. The dataset details have been shown in Table XII. The distributed denial of service (DDoS) attack denotes that multiple attackers in different locations simultaneously attack one or more targets. One attacker takes control of multiple machines in different locations and uses them to attack victims simultaneously. The originating points of the attack are

distributed in different places in DDoS attacks, and there can be multiple attackers. DDoS attacks can cause great damages to the society. Various types of DDoS attacks pose huge challenges for intrusion detection systems. The images after image embedding has shown in Fig. 9. In such circumstances, DDoS2019 was collected to facilitate the DDoS research. Eight traffic types are collected in the training set: Normal, PortMap, Net- BIOS, LDAP, MSSQL, UDP, UDP-Lag, SYN. These are multiple types of DDoS attacks which have come up frequently in recent years. DDoS2019 is a balanced and sufficient dataset. Each attack contains at least 10000 samples. The test set contains 12 types of traffic. In addition to the eight types collected in the training set, other four types have been included: NTP, DNS, WebDDoS, TFTP. These additional attacks put forward higher requirements to the generality of the intrusion detection system because they are blind to our intrusion detection system at the training stage. For this problem, an anomaly detection model has been deployed to detect these four additional attacks, by considering them as an anomaly class.

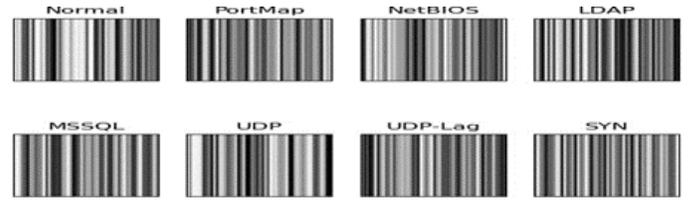

Fig. 9. Images after Image Embedding for each Class.

TABLE XII. DATASET DETAILS

Traffic Class	Session	Max Session Len	Average Session Len	Image
Normal (0)	20000	786	71	31256
PortMap (1)	20000	687	54	25258
NetBIOS (2)	20000	556	69	29564
LDAP (3)	20000	456	34	23102

SYN (7)	20000	563	60	27610

**IV. RESULT AND DISCUSSION**

**A. Evaluation Metrics**

Four metrics, including the accuracy, precision, recall and F1 score has been adapted to evaluate the intrusion detection system.

The definition of these four metrics [41][42] is shown in Table XIII and Table XIV. These evaluation metrics are regularly used in two-class classification problems. When calculating TP, FP, FN and TN with respect to each traffic class, the current class as the positive one, and the remaining classes as the negative one use to consider. With the assistance of these machine learning metrics, this intrusion detection system can be evaluated comprehensively.

**B. Experimental Results**

Deep Q-Learning algorithm combined with CNN and 1D-CNN for this IDS experiments has been used. In this IDS, two agents based on DQN-CNN and DQN-1D-CNN has been

TABLE XIII. CONFUSION MATRIX

Predicted	Actual	
	Positive	Negative
Positive	True Positive (TP)	False Positive (FP)
Negative	False Negative (FN)	True Negative (TN)

TABLE XIV. EVALUATION METRICS

Metric	Calculation
Accuracy	$(TP+TN)/(TP+FP+FN+TN)$
Precision	$TP/(TP+FP)$
Recall	$TP/(TP+FN)$
F1	$(2*Recall*Precision)/(Recall+Precision)$

devise. As a comparison, the model devises another two agents PG-CNN and PG-1D-CNN, which are trained with policy gradient methods. The sessions are extracted from raw network traffic data in 'pcap' files and split according to the session-based rule. The dataset is split in a ratio of 4:1 (16000 sessions for training and 4000 sessions for validation). During the partition, it has been ensured that the session length distribution of the training set and validation set is consistent, thus the image ratio can also reach approximately 4:1. After partition, the statistics of the dataset is shown in Table XV.

TABLE XV. TRAINING AND VALIDATION SET DETAILS

Traffic Class	Training Images	Validation Images
Normal	25012	6256
PortMap	20200	5058
NetBIOS	23652	5912
LDAP	18019	5083
MSSQL	22986	4709
UDP	19159	6051
UDP-Lag	19552	5198
SYN	22640	4970

Experiments are conducted on the computer configured as RTX2070, i5-9600k and 32GB Memory. Three discount values  $\gamma$ , including 0.1, 0.5 and 0.9 on four agents have been compared. The value of accuracy averaged used over each class on validation set to evaluate the performance and select the optimal discount value. The experiment results are shown in Table XVI. It has been noticed that when  $\gamma$  equals to 0.1, all of the four agents attain the highest performance. With regard to reinforcement learning algorithms, DQN-1D-CNN slightly outperforms PG-1D-CNN over all discount factors, and DQN-CNN also marginally outperforms PG-CNN over all discount factors. Meanwhile, it is observed that PG-based agents are more sensitive to discount factors. Overall results indicate that Deep Q-Learning is a relatively better algorithm than policy gradient methods in our experiments. Hence in the following case studies, it has been assumed that the discount value is fixed as 0.1, and mainly adopt Deep Q-Learning algorithms for the agent.

Detailed experiment results of DQN-1D-CNN with discount value  $\gamma$  equal to 0.1 are shown in Table XVII. The table shows that the proposed detection system can reach high accuracy at 98.78%. 100% of normal traffic can be detected with respect to each class. The detection rate (Recall) of MSSQL is the least among all eight types, but still reaching 97.30%. Table XVIII lists the validation results of DQN-CNN. It is seen that the performance of DQN-CNN is slightly worse

TABLE XVI. PERFORMANCES OF DIFFERENT DISCOUNT VALUES ON FOUR AGENTS

Discount Factor	Val Acc (DQN-1D-CNN)	Val Acc (DQN-CNN)
0.1*	98.78%	96.07%
0.5	95.21%	93.22%
0.9	87.12%	86.24%
Discount Factor	Val Acc (PG-1D-CNN)	Val Acc (PG-CNN)
0.1	96.17%	96.03%
0.5	90.15%	87.12%
0.9	79.68%	70.69%

than that of DQN-1D-CNN, but still reach a high accuracy at 96.07%. The experimental results prove that both DQN-1D-CNN and DQN-CNN can perform well when dealing with image tasks. In addition, in this experiment, the image can also be readily treated as the time series data, and DQN-1D-CNN can perform much better. The test set details has been shown in Table XIX. Afterwards the proposed DQN-1D-CNN agent has been evaluated on the test set. In this stage, it is required to set another important hyperparameter:  $\lambda$ .  $\lambda$  controls the detection performance of (unknown) anomaly traffic. The known eight types of attacks have been treated as the negative class, and the anomaly traffic as the positive class. We use precision and recall to evaluate the performances and select the optimal  $\lambda$ . Results are shown in Table XX. As  $\lambda$  is increasing, the precision decreases, which means that an increasing volume of network traffic is classified as the anomaly type. Conversely, as  $\lambda$  is increasing, the recall is also increasing, meaning that an increasing amount of anomaly traffic is detected. The value of  $\lambda$  can be determined based on actual requirements of the intrusion detection system. In this experiment, the  $\lambda$  is fixed as 0.7, which is a trade-off between 0.5 and 0.9. Finally, the intrusion detection system is evaluated on the test set with  $\gamma = 0.1$  and  $\lambda = 0.7$ . Results are shown in Table XXI. Due to the existence of anomaly traffic, the general accuracy has declined greatly to 84.27% compared with the validation accuracy at 96.07%. With respect to all classes, the DQN-1D-CNN agent can attain relatively high performances on those known types. With regard to anomaly types, although these anomaly types are completely blind to this system, 71.05% of them can still be detected.

TABLE XVII. VALIDATION RESULTS OF DQN-1D-CNN WITH DISCOUNT VALUE  $\gamma = 0.1$ . THE COMPUTATION TIME FOR DETECTION IS 0.112s

Traffic Class	Accuracy <sup>1</sup>	Precision	Recall	F1 Score
Normal	98.78%	99.32%	100%	99.66%
PortMap	98.78%	98.04%	98.95%	98.49%
NetBIOS	98.78%	98.87%	99.26%	99.06%
LDAP	98.78%	98.85%	98.37%	98.61%
MSSQL	98.78%	98.47%	97.30%	97.86%
UDP	98.78%	98.95%	99.62%	99.28%
UDP-Lag	98.78%	98.02%	98.31%	98.61%
SYN	98.78%	98.64%	97.83%	98.23%
Average	98.78%	98.65%	98.71%	98.73%

<sup>1</sup>According to the calculation formula displayed in Table XIV, accuracy is the general metric of a intrusion detection system, so the accuracy value of each category is the same, and it represents the overall accuracy of the system.

### C. Comparison with Deep Learning Approaches

The performance of the proposed approach has been compared with traditional 1D-CNN and CNN approaches (without

the reinforcement learning framework). The performances using two metrics. The first one is the detection rate (Recall), which measures how many attacks are correctly detected. The other is the false alarm rate, which measures how many normal traffics are classified as malignant types. Anomaly attacks are excluded in this experiment. Results are shown in Table XXII. It can be seen that traditional deep learning methods can also achieve relatively high performances on the test set, which supports that image embedding is a useful data preprocessing approach for network traffic analysis. Most importantly, the proposed RL-based approach still outperforms these traditional approaches in detecting and false alarm rates without increasing the computation time.

TABLE XXII. COMPARISON WITH DEEP LEARNING APPROACHES (ANOMALY TYPES IN THE TEST SET ARE EXCLUDED)

Approach	Detection Rate	False Alarm	Detection Time
ID-CNN	92.12%	5.12%	0.096s

<b>DQN-1D-CNN*</b>	<b>97.69%</b>	<b>0.12%</b>	0.101s
DQN-CNN	95.14%	3.50%	<b>0.079s</b>

## V. CONCLUSION

First of all, a novel image embedding approach has been designed. Using image embedding, raw traffic files can be transferred to images, which are generally difficult to process by artificial intelligence techniques. This is significant because many artificial intelligence techniques can achieve high performance on image tasks. In addition, those packets classified in the same session are arranged in the chronic order of the capture time. This way the image-based task can be extended to the time-series based task, where supplementary AI techniques such as 1D-CNN and LSTM, can also be applied. Secondly, Markov process has been used to model the dynamic process of network session. Therefore, a reinforcement learning framework can be devised to train the system. Introducing discount value  $\gamma$ , it can make the agent consider more farsighted information. This property is also important to the intrusion detection problem. Assuming that the model encounter a malignant flow, if agent is forced to consider more farsighted, the agent can detect the intrusion earlier. Thirdly, an additional anomaly detection system has been designed to detect those unknown attacks, and propose the idea of the confidence score. This anomaly detection module makes it possible to detect some unknown and novel attacks. It is crucial because the real network environment is complicated and ever changed, and hackers will continue to launch novel attacks which are blind to intrusion detection systems. The experimental results show that, with the assistance of CNN, 1D-CNN and reinforcement learning algorithms, the intrusion detection system can attain high detection rate and maintain low false alarm rate.

More research can be done in the future based on this reinforcement learning framework. Firstly, GAN can be introduced into the reinforcement learning framework. Since the traffic data into images already have been transformed, GAN can be used to generate some novel flows or sessions. Furthermore, GAN can use to simulate a dynamic network environment for interaction. Secondly, a more robust and high-accuracy anomaly detection system can be devised. In this experiment, the Q-value has been treated as the confidence score. Nevertheless, it is difficult to adjust the value of  $\lambda$ . One possibility is to train the agent to learn the confidence score by itself.

**Abstract**—Applying data mining for improving the outcomes of the educational process has become one of the most significant areas of research. The most important corner stone in the educational process is students' performance. Therefore, early prediction of students' performance aims to assist at-risk students by providing appropriate and early support and intervention. The objective of this paper is to propose an enhanced predictive model for students' performance prediction. Selecting the most important features is a crucial indicator for the academic institutions to make an appropriate intervention to help students with poor performance and the top influencing features were selected in feature selection step besides the dimensionality reduction and build an efficient predictive model. DB-Scan clustering technique is applied to enhance the proposed predictive model performance in the preprocessing step. Various classification techniques are used such as Decision Tree, Logistic regression, Naïve Bayes, Random Forest, and Multilayer Perceptron. Moreover ensemble method is used to solve the trade-off between the bias and the variance and there are two proposed ensemble methods through the experiments to be compared. The proposed model is an ensemble classifier of Multilayer Perceptron, Decision Tree, and Random Forest classifiers. The proposed model achieves an accuracy of 83.16%.

**Keywords**—Educational data mining; students' performance; classification; feature selection; machine learning

## I. INTRODUCTION

Educational systems contain massive data about students' behavior, enrollment of students, results, and attendance that could be analyzed to improve outcomes of the educational process [1]. Therefore, Educational Data Mining (EDM) has become a necessity to discover knowledge that helps decision makers to improve the educational process [2]. EDM can reduce the drop-out rate by providing the academic institutions with knowledge to be able to develop appropriate strategies. It can also provide a timely decision to help students who are vulnerable to failure. Data mining deals with the educational field to identify and evaluate several important learning indicators from the data [3].

Students' performance prediction is one of the most challenging and interesting topics of EDM research [4]. It helps instructors to track their students' performance to identify those at-risk [12]. Research on students' performance prediction is useful to identify the features, behaviors and hidden relations that affect the students' performance [6][11]. Many organizations, such as Accreditation Council for Business

Schools and Programs (ACBSP) and Accreditation Board for Engineering and Technology (ABET) evaluate the educational programs quality based on the learning outcomes [7]. There are two research perspectives, the first one is to find the features that affect the performance of students. The second one is to find an effective methodology to predict students' performance [4]. It is very crucial to apply the feature selection to discover high influence features that need to be improved the dropout rate and enhance student performance [5]. Machine learning is applied to discover hidden patterns and the relations between the features in addition to the prediction of at-risk students [20].

The massive growth of the educational data gives the education institutes the opportunity to apply data mining techniques to extract useful and hidden information for predicting students' academic performance effectively [22]. Therefore, the objective of this paper is to propose an enhanced predictive model for accurate prediction of students' performance. Various machine learning techniques were experimented. For enhancing the predictive model, we applied DB-Scan clustering technique and feature selection approach. Experimental results proved the effectiveness of the proposed model. The following sections of the paper are organized as follows: Section II presents the related work in page 1 and 2, Section III introduces the methodology in page 2, experiments and results are discussed in Section IV in page 2, 3, and 4, and finally conclusion is stated in Section V in page 5.

## II. RELATED WORK

Predicting learning outcomes and especially students' performance became very important in the overall learning and educational process. Francis et al. achieved an accuracy of 75.47% using a hybrid data mining technique to predict weak students [8]. (Pojon, 2017) compared various machine learning techniques such as Decision Tree, Linear Regression, and Naïve Bayes classifiers [13]. The experiments were conducted on two datasets. Experiments have shown that models with clustering and classification techniques achieve better results in predicting students' performance. The accuracy achieved using classification and regression trees (CART) algorithm were of 93% and 78%.

Lau et al. built a prediction model for students' performance using neural networks technique. The model contains two hidden-layers and the output layer with 11 features as

input. The prediction model achieved precision of 84.8% [10]. Xing et al. conducted a prediction model using deep learning approach based on the perspective of predicting temporal drop-out for improving the online learning. The proposed model achieved an accuracy of 90.8% and 96.1%, after the 1st week and the 7th week, respectively [21]. Divyabharathi et al. constructed a predictive model using Naïve Bayes classification technique to detect and prevent performance academic risk based on the students' data, and they achieved an accuracy of 94% [22]. Raihana et al. applied classification based on the academic performance as well as the quality of life that were psychological health, physical health, social relationship, environment, and the overall life quality. They used support vector machine (SVM) algorithm and achieved an accuracy of 73.33%. The experiments revealed that students, who achieved good academic performance, were psychologically healthy, physically healthy, have good social relationship, were in a good environment and have good overall life quality [23]. Uzel et al. experimented various machine learning predictors such as Decision Tree, Naïve Bayes, Random Forest, Multilayer Perceptron, and Ensemble method. They also applied Apriori technique to discover the hidden patterns from the data. They achieved the accuracy of 80.6% for the classification by the voting method classifier[19].

Sana et al. showed that there are many features and factors that affect the final students' performance significantly such as the number of student's absence days and the involvement of parents with students in the learning process. The accuracy of 78.1% was achieved by their approach using Artificial Neural Network (ANN) algorithm with highly ranked features [18].

Comparative results of some related works are shown in Table I.

TABLE I. COMPARATIVE RESULTS OF RELATED WORK

Ref.	Algorithm	Accuracy	Dataset
[8]	Hybrid Data Mining Approach	75.47%	480 records and 16 features
[10]	Neural Networks	84.8%	1000 records
[13]	CART	78%	480 records and 16 features
[18]	ANN	78.1%	480 records and 16 features
[19]	Voting Classifier	80.6%	480 records and 16 features
[21]	Deep Learning	96.1%	3617 records and 13 features
[22]	Naïve Bayes	94%	500 records and 8 features
[23]	SVM	73.33%	60 records and 26 features

There are many studies that focus either on finding hidden patterns, discovering relation between features, or enhancing the accuracy. However there is a lack in making a comprehensive work that combines enhancing the preprocessing step, finding the top influencing features, and proposing a predictive model to enhance the performance based on different measures to check the model's stability from different perspectives and show the variations of results to get insights from the experiments. Therefore the performance of prediction models in the previous studies needs to be enhanced to help at-risk students to improve their performance and help the academic institutions to make an appropriate intervention to assist the students with poor performance. Therefore, in this study we propose a predictive model to face these limitations and improve students' performance prediction.

### III. METHODOLOGY

The purpose of this paper is to propose a predictive model for students' performance prediction. This is achieved by exploring various classification techniques, besides the ensemble method that solves the trade-off between the bias and variance, to investigate which one would achieve the best performance. Moreover, DB-Scan was used in preprocessing for outlier detection and features selection was used to enhance the predictive model of students' performance. The proposed model is shown in Fig. 1. The following subsections describe the proposed model.

Fig. 1. The Proposed Model.

#### A. Preprocessing

Pre-processing is an essential process for any data set. It includes data cleaning and transformation. We pre-processed the dataset through three steps. Firstly, data was converted from nominal to numerical values. Secondly, some features were reshaped to be within a certain range using standardization method. Finally, DB-Scan clustering methodology was applied for outlier detection, as it had a great efficiency in [16].

#### B. Feature Selection

Feature selection aims to select the most important and influencing features in the dataset. Also, it is very important for dimensions' reduction before implementing the prediction and classification methods. It works by selecting the best features that contribute most to the target variable based on univariate statistical tests.

We used the SelectKBest technique [15]. SelectKBest technique selects the first k features with the highest score values based on the Chi-Square test, for comparing the actual and predicted results, as a score function [14] using equation (1).

$$X^2 = \sum(O_i - E_i)^2 / E_i \quad (1)$$

where  $O_i$  and  $E_i$  are the actual and expected values, respectively.

#### C. Classification

For classification, we designed two different Ensemble models. One consists of Multilayer Perceptron (MLP), Random Forest (RF) and Decision Tree (DT), the other consists of RF, Logistic regression (LR) and DT.

### IV. EXPERIMENTS AND RESULTS

To evaluate how the proposed models will perform in predicting the students' performance, several evaluation measures were used on a Learning Management System (LMS) dataset through several experiments as follows in page 3:

A. Dataset

The dataset is collected from a Learning Management System (LMS) [24]. It contains 480 records of students' data in various educational levels with 16 features. The features were categorized as follows:

- Academic features: Section id, Semester, Educational stages, Viewing announcements, Grade levels, Topic, Discussion groups, Visited resources, Raised hand, and Student absence days.
- Personal features: Gender, Parent responsible for student, Parent answering survey, and Parent school satisfaction.
- Demographic features: Nationality and Place of birth.

We pre-processed the dataset through two steps. Firstly, we converted the data from nominal to numerical values for the features: Section Id, Semester, Educational stages, Grade levels, Topic, Discussion groups, Gender, Parent responsible for student, Parent answering survey, Parent school satisfaction, Nationality, Place of birth, and Student absence days.

Secondly, the following features: Viewing announcements, Discussion, Visited resources, and Raised hand, were reshaped to be within a certain range using standardization method. Fig. 2 shows a sample of the dataset's features and instances.

gender	Nationality	PlaceOfBirth	StageID	GradeID	SectionID	Topic	Semester	Relation	raisedhands	VisitedResources	AnnouncementsView	Discussion	ParentAnsweringSurvey	ParentSchoolSatisfaction	StudentAbsenceDays	
470	0	11	5	1	5	0	8	0	0	0.81	0.88867	0.87751	0.48193	0	1	0
471	0	11	5	1	5	0	8	1	0	0.78	0.82083	0.76810	0.53082	0	1	0
472	0	11	11	1	5	0	11	0	0	0.80	0.81978	0.79502	0.68373	0	1	0
473	0	11	11	1	5	0	11	1	0	0.85	0.88888	0.89522	0.74082	0	1	0
474	1	5	5	1	5	0	10	0	0	0.02	0.07077	0.04816	0.07429	1	0	1
475	1	5	5	1	5	0	10	1	0	0.05	0.04664	0.09120	0.07429	1	0	1
476	1	5	5	1	5	0	11	0	0	0.50	0.77778	0.74267	0.27593	1	0	0
477	1	5	5	1	5	0	11	1	0	0.55	0.74743	0.26502	0.28714	1	0	0
478	1	5	5	1	5	0	8	0	0	0.30	0.17171	0.74267	0.57429	1	0	1
479	1	5	5	1	5	0	8	1	0	0.55	0.74743	0.24684	0.62349	1	0	1

Fig. 2. Sample of the Dataset Features and Instances.

B. Experiment Environment

Anaconda Navigator [17] was used to simplify the packages management and deployment. The implementation language was Python using pandas, numpy, and sklearn libraries. The experiments were performed on a machine with 2.60 GHz processor, 16 GB memory, and Windows 10 64-bit operating system. All the experiments were performed using the 10-fold cross validation [9].

C. Evaluation Measures

The accuracy measure is used for the evaluation of each model using equation (2).

$$\text{Accuracy} = (\text{TP} + \text{TN}) / (\text{TP} + \text{TN} + \text{FP} + \text{FN}) \quad (2)$$

It indicates a proportion of correctly predicted observation to the total observations, where: TP = True positive, FP = False positive, TN = True negative and FN = False negative.

Moreover, Precision, Recall, and F1-Score measures are used for the evaluation of each model using equations (3), (4), and (5) respectively.

$$\text{Precision} = (\text{TP}) / (\text{TP} + \text{FP}) \quad (3)$$

$$\text{Recall} = (\text{TP}) / (\text{TP} + \text{FN}) \quad (4)$$

$$\text{F1-Score} = 2 \times (\text{Precision} \times \text{Recall}) / (\text{Precision} + \text{Recall}) \quad (5)$$

D. Experiments

According to dataset features, the performance indicator was the success levels that were classified to three categories:

- Low-Level contains 127 of the data instances.
- Middle-Level contains 211 of the data instances.
- High-Level contains 142 of the data instances.

To evaluate our ensemble methods, several experiments were conducted. First, we studied the effect of using the DB-Scan as a preprocessing step as shown in the methodology section.

A comparison of our first and second ensemble classifiers' performance results before and after Applying DB-Scan in terms of accuracy, Precision, Recall, and F1-Score measures is shown in Table II.

TABLE II. PERFORMANCE OF OUR FIRST AND SECOND ENSEMBLE METHODS BEFORE AND AFTER DB-SCAN

Method	Accuracy	Precision	Recall	F1-Score
Our First Ensemble (MLP, RF, DT) (Before DB-Scan)	79.17%	79.2%	81.3%	80.1%
Our First Ensemble (MLP, RF, DT) (After DB-Scan)	83.16%	84.1%	83.3%	83.6%
Our Second Ensemble (RF, DT, LR) (Before DB-Scan)	78.125%	78.2%	80.6%	79.2%
Our Second Ensemble (RF, DT, LR) (After DB-Scan)	80.0%	80.7%	80.8%	80.7%

A comparison of classifiers' performance showing the evaluation results in terms of accuracy, Precision, Recall, and F1-Score measures after applying the DB-Scan algorithm as well as the evaluation of these classifiers using all the data without applying the DB-Scan clustering technique, and these comparison's results are shown in Table II.

Second experiment as shown in Table III is designed to evaluate our two ensemble models comparable to the Naïve Bayes, DT and MLP models. Evaluation is done using the accuracy, precision, recall and F1-Score.

In addition to assess the accuracy of our proposed models, we compared our work with the results of [18]. We compared our two ensemble models using the given evaluation measures.

The experiments in table IV show that our first ensemble model achieved better performance in terms of different evaluation measures than [18] and our second ensemble model.

TABLE III. PERFORMANCE OF OUR FIRST AND SECOND ENSEMBLE METHODS AS WELL AS NAÏVE BAYES, DECISION TREE, AND MLP CLASSIFIERS

Method	Accuracy	Precision	Recall	F1-Score
Naive Bayes	81.05%	81.2%	83.1%	81.6%
Decision Tree	77.89%	78.7%	78.0%	78.2%
MLP	80.0%	81.2%	80.0%	80.5%
Our First Ensemble (MLP, RF, DT)	83.16%	84.1%	83.3%	83.6%
Our Second Ensemble (RF, DT, LR)	80.0%	80.7%	80.8%	80.7%

TABLE IV. PERFORMANCE OF OUR FIRST AND SECOND ENSEMBLE METHODS BESIDES [18]

Method	Accuracy	Precision	Recall	F1-Score
[18]	78.1%	78.6%	78.9%	78.8%
Our First Ensemble (MLP, RF, DT)	83.16%	84.1%	83.3%	83.6%
Our Second Ensemble (RF, DT, LR)	80.0%	80.7%	80.8%	80.7%

Finally, to study the feature selection technique, the SelectKBest technique is applied based on chi-square test for feature selection approach for selecting the most influencing features to be involved in the model building phase. It works by selecting the best features that contribute most to the target variable based on univariate statistical tests.

The experiments were implemented using the top 10 and 5 features besides all the features from the dataset to be used in the classification.

Table V shows a comparison of models' performance in terms of accuracy measure using all the features of dataset, top 10, and top 5 features of the dataset correlated to the target.

TABLE V. PERFORMANCE ACCURACY WITH VARIOUS NUMBER OF SELECTED BEST FEATURES

Method	All Features	Top 10 Features	Top 5 Features
Naive Bayes	81.05%	80.0%	64.21%
Decision Tree	77.89%	68.42%	66.32%
MLP	80.0%	81.05%	68.42%
Our First Ensemble (MLP, RF, DT)	83.16%	78.95%	65.26%
Our Second Ensemble (RF, DT, LR)	80.0%	75.79%	65.26%

According to Fig. 3, the accuracy corresponding to each number of top K features is measured and plotted for selecting the best number of features in feature selection stage and the best accuracy can be achieved by using only the top correlated 9 features to the target that is the accuracy when we used all the features.

Table VI shows a comparison of models' building time in milliseconds using all the features of dataset, top 10, and top five features of the dataset correlated to the target. The results showed that the difference between models' building time is very small. Therefore building models using all the features

Testing Accuracy (y-axis) vs Top K Important Features (x-axis)

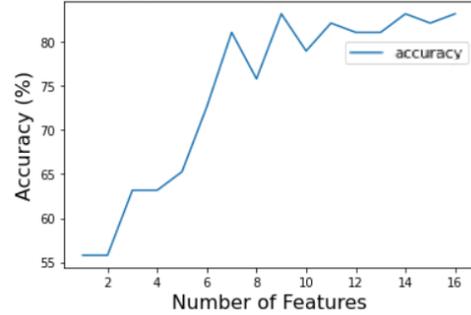

Fig. 3. Features' Selection Graph.

is the best choice. Moreover Fig. 4 shows the bar-chart graph representation of the results of Table VI.

TABLE VI. COMPARISON BETWEEN MODELS' BUILDING TIME IN MILLISECONDS WITH VARIOUS NUMBER OF SELECTED BEST FEATURES

Method	All Features	Top 10 Features	Top 5 Features
Naive Bayes	8.026	7.947	6.952
Decision Tree	10.121	9.091	8.285
MLP	145.065	162.463	155.802
Our First Ensemble (MLP, RF, DT)	217.56	231.273	207.702
Our Second Ensemble (RF, DT, LR)	127.004	142.911	110.764

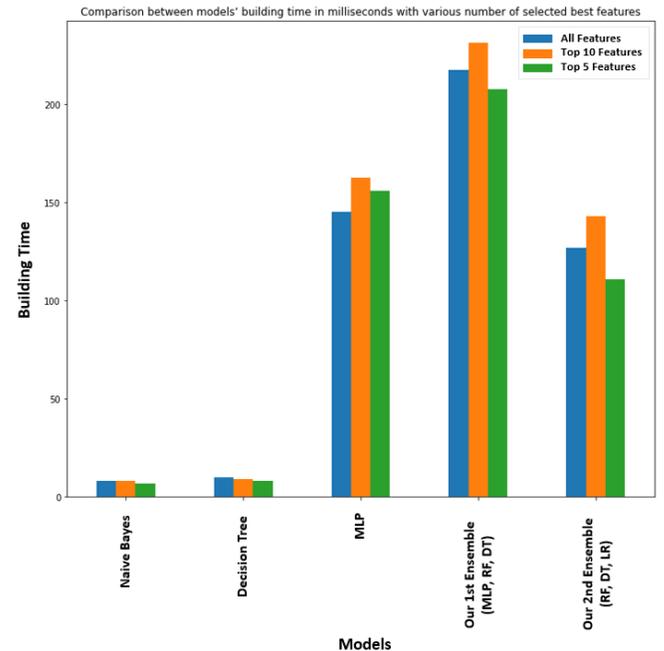

Fig. 4. Models' Building Time Graph.

## V. CONCLUSION

One of the essential objectives of educational data mining is to accurately predict students who are vulnerable to drop-

out for providing them with more support and the suitable intervention. EDM helps the academic institutions to make an appropriate intervention to assist those students enhance their performance. In this paper, we proposed an enhanced predictive model for students' performance to improve the prediction accuracy. We applied various machine learning techniques for predicting the students' performance. Additionally, DB-Scan clustering algorithm and feature selection steps have been exploited, for choosing the significant features. Our first ensemble method has achieved an accuracy of 83.16%, 78.95%, and 65.26% using all the features, the top 10 influencing features, and the top 5 influencing features, respectively. The proposed predictive model outperformed previous work using the same dataset from the learning management system. Applying DB-Scan clustering technique as a preprocessing step has a great effect on enhancing the predictive model performance and the distribution of results as seen in the confusion matrix of each predictive model. For future work, we intend to apply the proposed predictive approach to various datasets, experiment different feature selection techniques, and implement alternatives for DB-Scan clustering technique.

**Abstract**—The breakthroughs in securing speaker verification systems have been challenging and yet are explored by many researchers over the past five years. The compromise in security of these systems is due to naturally sounding synthetic speech and handiness of the recording devices. For developing a spoof detection system, the back-end classifier plays an integral role in differentiating spoofed speech from genuine speech. This work conducts the experimental analysis and comparison of up-to-date optimization techniques for a modified form of Convolutional Neural Network (CNN) architecture which is Light CNN (LCNN). The network is standardized by exploring various optimizers such as Adaptive moment estimation, and other adaptive algorithms, Root Mean Square propagation and Stochastic Gradient Descent (SGD) algorithms for spoof detection task. Furthermore, the activation functions and learning rates are also tested to investigate the hyperparameter configuration for faster convergence and improving the training accuracy. The counter measure systems are trained and validated on ASV spoof 2019 dataset with Logical (LA) and Physical Access (PA) attack data. The experimental results show optimizers perform better for LA attack in contrast to PA attack. Additionally, the lowest Equal Error Rate (EER) of 9.07 is obtained for softmax activation with SGD with momentum wrt LA attack and 9.951 for SGD with nestrov wrt PA attack.

**Keywords**—*Spoof detection; speech synthesis; voice conversion; convolutional neural networks; optimizers; gradient descent algorithm; spoofed speech; automatic speaker verification*

## I. INTRODUCTION

The uniqueness of voice makes it a popular choice as a biometric for securing smart-phones, telephonic-verification for banking, online-shopping and interestingly, voice-based logins. This also requires the voice biometric based systems to be resilient to unauthentic access in the form of spoofing attacks. The Automatic Speaker Verification (ASV) systems are thriving to make the voice-based applications secured through countermeasures or spoof detection algorithms. These spoof detection systems are embedded in the ASV pipeline as standalone or as a sub-part of the security stream. Apparently, the spoofing attacks may be categorized as synthetic or replay attacks. The synthetic speech (SS) is generated by means of Voice Conversion (VC) or Text-to-Speech (TTS) generators. The replay speech is acquired through careful filtering of the target speech through a recording device. Apart from this category, the spoofing attacks may be direct or Physical Access (PA) attacks and indirect or Logical Access (LA) attacks. The former requires physical space i.e., microphone while the

latter is conducted by direct injection of speech, exempting the sensor involvement. Lately, there is rise in spoofing attacks on the ASV systems due to impeccable quality of synthetic speech generators and cheaper high-end recording devices. Yet, these attacks are not preventable, but they can be detected by building countermeasures ensuring the safety of the ASV framework.

## II. RELATED LITERATURE

The robustness of a spoof detection system depends on its internal building blocks which includes the feature extraction and classification. During the training mode, the input speech is processed to reduce redundancy in data and filter out the required information from the speech, that is, naturality and speaker specific content. These unique features are then trained using appropriate machine learning algorithm to get a training rule or trained model. Consequently, in the testing mode the appropriate features are extracted from the test samples and fed to the trained model following which the samples are categorized as genuine or spoofed. For building a model, the number of samples and types of attacks must be considered in a dataset as they will help boost the validation accuracy. The datasets available for PA attacks are Red Dots [1], VoicePA [2] and ASV spoof 2017 [3] while for LA attack, SAS [4] and ASV spoof 2015 are popular. The ASV spoof 2019 [5], [6] has all three kind of attacks samples including synthetic and replay speech. Hence, it is chosen over all other datasets for developing an anti-spoofing algorithm.

With regards to capturing human and synthetic traits from the speech, the glottal excitation and source-filter parameters have been extracted along with prosodic features. The Linear Prediction Co-efficient (LPC) [7], Linear Prediction-Residual parameters [8] and Line Frequency Cepstral Co-efficient (LFCC) [9] based spectral features are found to represent speech quite profoundly. Additionally, the perceptual parameters have also been explored as they have similarity with human perceptual filter bank. The Mel Frequency Cepstral Co-efficient (MFCC), Constant Q-factor Cepstral Co-efficient (CQCC) [10] and Cochlear Filter Cepstral Coefficients with Instantaneous Frequency (CFCCIF) [9] are successfully tested perceptual features for LA attack. The Constant Q transform (CQT) unlike the standard Fourier Transform has irregular frequency bins that allows it to maintain a constant Q-factor

throughout the spectrum [11]. This promotes evident discrimination within the spectrum as spoofing related characteristics are revealed distinctly. Hence, considering the efficiency of CQT parameters, we are using these as the feature extraction technique.

In addition, the classification techniques have also caught attention of researchers for building a robust spoof detection system. Usually, the Gaussian Mixture Models (GMM) and Universal Background Models (UBM) are employed as they perform well with almost all the feature extraction techniques [8]. Yet, the main shortcoming of this arrangement is that the GMM and UBM are trained independently making them unaware of each other's learning rule. To overcome this shortcoming, the GMM and Support Vector Machines (SVM) were explored as they were more versatile and performed better than the GMM-UBM duo [12]. Additionally, the GMM classifier is limited to perform better with features of low dimensionality [13]. Furthermore, the Deep Learning models have been investigated and perform comparatively well in contrast to the shallow models [14]. Of course, they require a lot of labelled data for the training but also fail to capture temporal information simultaneously. This lead to exploring other deep models like Convolutional Neural Networks (CNN) [15], Recurrent Neural Networks (RNN) [16], Long Short-Term Memory (LSTM) [17], Gated Recurrent Units (GRU)[15] and Generated Adversarial Networks (GAN) [10]. In [16], [18], CNN-RNN are combined to explore effectiveness of both models individually. Thus, the CNNs are used when spatial learning is of importance while in case of temporal learning, RNNs and its variants are used. Moreover, the CNNs are powerful in handling large amount data at the cost of high training time and large number of parameters. To overcome this, the Light-CNN (LCNN) architecture is introduced to avoid repetition in the parameters and ultimately improve training resources [19]. The LCNN based fusion architecture achieved best results in the ASV spoof 2017 challenge with lower EER for replay attack [10]. Then onwards, LCNN gained popularity and has been tried for synthetic speech detection as well [20]. Following which, in the ASV spoof 2019 challenge, an improved version of this architecture with angular-softmax was presented for both LA and PA attack [21]. The major highlight of the LCNN is its ability to achieve generality for variation in data distribution such as recording conditions, noisy speech, speaker variations, etc [19]. This is possible by endowing in optimization of these networks. This leads to wider range of applications of the network along with impeccable theoretical proofs. Even though the optimization algorithms have been existing for more than two decades, through continuous refinement for highly complex networks with large data size, a defined reassessment of these state-of-the-art optimizers is the need of the day. In spite of the popularity of LCNNs, according to author's knowledge, there is no significant work found in optimizing the LCNN for spoof detection task. Moreover, tuning of the hyperparameters improves the performance of the network with faster convergence. This work also dedicates its attention to various activation functions as they hold a crucial role in deciding the category of the unknown test sample which ultimately contributes to lower model loss and increase performance accuracy. Also, a precise choice of activation might prove to enhance the training time by making the network learn complex patterns

easily. Different combinations of learning rates, activations and optimizers have been investigated in this work to determine most suitable model parameters for spoof detection task. Thus, the objectives of this work can be summarized as following:

- i An extensive comparison of various optimizers is performed using ASVspoof 2019 dataset for LA and PA attacks. The common optimizers compared include Adaptive moment estimation (Adam), Adaptive-gradient (Adagrad), Adaptive-delta (Adadelta), Nesterov Accelerated Adam (Nadam), Root Mean Square Propagation (RMSprop), Stochastic Gradient Descent (SGD), SGD with nesterov accelerated gradient (NAG) and momentum. This unravels certain unexpected results as against the usual classification problem where the RMS prop performs equally well with the gradients and delta versions of Adam.
- ii Exploring activation functions popularly used in training the transfer function are compared with variations in optimizers to suit the spoof detection application for the LCNN framework. These activations include Softmax, Rectified Linear Unit (ReLU) and Logistic function.
- iii The experimental results are compared with state-of-the-art softmax-Adam optimizer and evaluated using Equal Error Rate (EER) along with Receiver Operating Characteristics (ROC) Curve.

The article is arranged as follows: Section III ASV based spoof detection framework and Section IV describes the LCNN architecture and hyperparameter testing. The Section V includes the experimental results and discussion while Section VI is the Conclusion of the work.

### III. SPOOF DETECTION SYSTEM

The proposed spoof detection framework is portrayed in Fig. 1 showing two phases of operation. The training phase is also called enrolment phase where known authentic speaker samples are enrolled along with spoofed speech samples. Initially, the CQT features are extracted to obtain a spectrographic representation of speech [22]. The two dimensional spectrogram along with their labels is then fed to the LCNN architecture to obtain the trained speaker model using a loss function. Furthermore, in the testing phase, the unknown test samples which are a mixture of genuine and spoof speaker samples, are represented using CQT features. This feature set is then tested using LCNN classifier and categorized as spoof or genuine. The CQT based features extraction and LCNN classifier are explained in following sub-Sections III-A and III-B.

#### A. Front-end CQT Features

The CQT features were introduced few decades ago as an alternative to short-time Fourier transform (STFT) [22]. The STFT being a filtering technique for a long spectrum broken down into shorter windows leads to an increasing Q-factor towards higher frequencies. This is exactly opposite to the human speech perception model where the Q-factor is found to be constant from 500Hz to 20kHz. Thus, STFT fails to represent the human perception model and CQT is preferred.

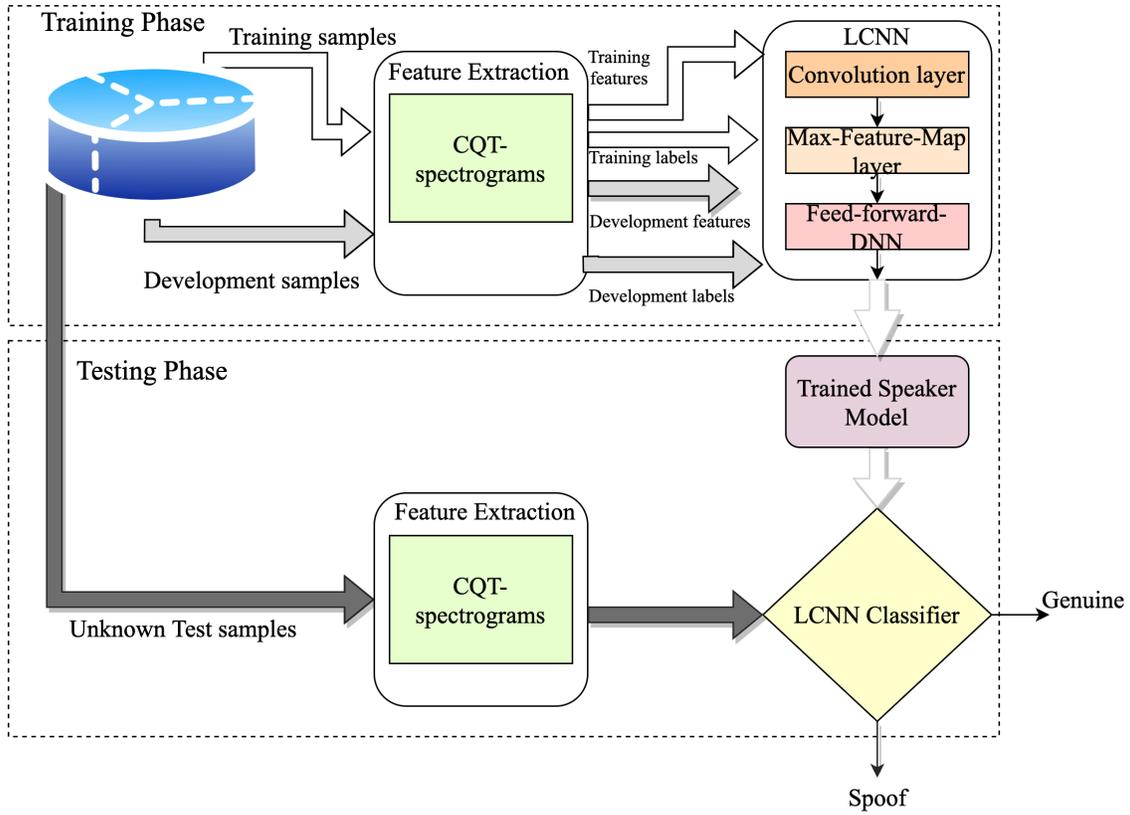

Fig. 1. Proposed Spoof Detection System.

The CQT based features,  $C(i, m)$  are computed as shown in Eq. 1.

$$C(i, m) = \sum_{k=m-[M_i/2]}^{k=m+[M_i/2]} s(k)z_i^*(k - m + M_i/2) \quad (1)$$

Where,  $i = 1$  to  $I$ , is the index of frequency bins,  $M_i$  is window length which is a variable and  $z_i^*$  is complex conjugate of basis. Hence, at lower frequencies, a high resolution is obtained wrt frequencies and at higher frequencies, high temporal resolution is possible. Thus overcoming the shortcoming of STFT with fixed time-frequency resolutions [21], [23].

### B. Back-end LCNN Classifier

The LCNN are popular due to their reduction in network parameters with nearly similar error rates as the CNNs [19]. In this work, we have employed a compact version of LCNN structure [21] using the Maximum Feature Mapping activation (MFM) layer. It is based on the Max-out activation which has the ability to choose the right features for problem solving purposes. The combination of MFM and multiple Batch Normalization (BN) layers form a LCNN structure with dense layer at end that wraps up the overall output from the previous layers. Also, after alternate MFM layer, a max pooling layer is added which picks out max value out a patch of feature map rather than input feature map. A more detailed information can be found in Section IV.

### IV. LCNN STRUCTURE AND HYPERPARAMETER TUNING

The conventional CNN uses activation function in the convolution layer, typically ReLU [15]. The CNN with MFM activation triggers two neurons and ignores one (in case of 2/1 MFM). This is termed as competitive relationship; hence MFM acts as a fine feature selection algorithm embed inside a CNN. The LCNN network used in this work has nine MFM-convolution, 4 max Pooling, 7 BN layers and 2 Fully Connected (FC) layers as shown in Fig. 2.

The BN layer is appended after every convolution layer as it leads to faster convergence and improved accuracy. For an input convolution layer,  $v^k \in R^{h \times w}$ , where  $k = \{1, 2, \dots, 2K\}$ ,  $w$  is spatial width while  $h$  is spatial height. The MFM activation is given as shown in Eq. 2.

$$\hat{v}_{a,b}^m = \max(v_{a,b}^m, v_{a,b}^{m+K}) \quad (2)$$

Where  $2K$  is number of channels specific to input layer,  $m$ ,  $a$  and  $b$  are indices for channel, width and height respectively. Therefore, the output dimension is  $R^{h \times w \times K}$  and the gradients are calculated as shown in Eq. 3 and Eq. 4.

$$\frac{\delta \hat{v}_{a,b}^m}{\delta v_{a,b}^m} = \begin{cases} 1, & \text{if } v_{a,b}^m \geq v_{a,b}^{m+K} \\ 0, & \text{elsewhere} \end{cases} \quad (3)$$

$$\frac{\delta \hat{v}_{a,b}^m}{\delta v_{a,b}^{m+K}} = \begin{cases} 0, & \text{if } v_{a,b}^m \geq v_{a,b}^{m+K} \\ 1, & \text{elsewhere} \end{cases} \quad (4)$$

TABLE I. VARIOUS OPTIMIZERS WITH THE UPDATE RULE

Optimizer	Update Rule	Description
Adam	$\Theta_{s+1} = \Theta_s - \frac{\alpha}{\sqrt{v_s}} \hat{m}_s$	$s$ = time step, $\alpha$ = learning parameter, $\Theta_s$ = model parameters, $m_s$ and $v_s$ are decaying average gradients of past gradients and square of the gradients respectively.
Adadelata	$\Theta_{s+1} = \Theta_s + \Delta\Theta$ $\Delta\Theta = \frac{RMS[\Delta\Theta]_{s-1}}{RMS[g]_s} g_s$	$g_s$ = gradient of objective function
Adagrad	$g_{s,i} = \nabla_{\Theta} J(\Theta_{s,i})$ $\Theta_{s+1,i} = \Theta_{s,i} - \alpha g_{s,i}$	$J(\Theta_{s,i})$ = objective function $i$ = individual parameter
SGD	$\Theta = \Theta - \alpha \nabla_{\Theta} J(\Theta; T^i; O^i)$	$T^i = i^{th}$ training sample $O^i = i^{th}$ label
SGD with momentum	$\Theta = \Theta - v_s$ $v_s = \sigma v_{s-1} + \alpha \nabla_{\Theta} J(\Theta)$	$\sigma$ = momentum factor
SGD with NAG	$\Theta = \Theta - v_s$ $v_s = \sigma v_{s-1} + \alpha \nabla_{\Theta} J(\Theta - \sigma v_{s-1})$	$v_{s-1}$ = square of the previous decaying gradient
Nadam	$\Theta_{s+1} = \Theta_s - m_s$ $m_s = \sigma v_{s-1} + \alpha g_{s,i}$	$\alpha$ = learning rate $\Theta_{s+1}$ = future model parameter
RMSprop	$\Theta_{s+1} = \Theta_s - \frac{\alpha}{\sqrt{E(g^2)_s + \rho}} g_s$	$E(g^2)_s$ = running average at time step $s$ , $\rho$ = smoothing term

TABLE II. DETAILS OF ASV SPOOF 2019 DATASET

	Logical Access		Physical Access	
	Genuine	Spoofed	Genuine	Spoofed
Training Set	2580	22800	5,400	48,600
Development Set	2548	22296	5,400	24,300
Total	5128	45096	10800	72900
	50224		83500	
133724 Samples				

Apparently, half the information bearing neurons are acquired by 2/1 MFM activation. Thus, implying 50% reduction in comparison to conventional CNN architecture. This is due to the element-wise maximum computation for all the feature channels. Hence, leading to sparser connections.

Additionally, this work experiments with different renowned optimizers to calculate the loss function including SGD, with momentum and NAG, Adaptive gradient techniques such as Adam, Adadelata, Adagrad and RMSprop optimizers [24]. Furthermore, we experimented by changing the activation functions from state-of-the-art softmax-Adam optimizer [20] based LCNN architecture to ReLU and logistic activations. The aim to try out various optimizers and activations is to investigate the appropriate combination of individual optimization algorithms with respective activation functions. Many parameters have different working scenarios to perform best and this gives the reason to explore other optimizers and activations specific to spoof detection scenario.

### A. Gradient Optimization Algorithms

The optimization of hyper-parameters is an essential step in training any Deep Learning framework. In this work, we have tested various gradient optimizers for overcoming the challenges of tuning learning rate, slow convergence, over-fitting of the model and lower accuracy. The SGD algorithms are derived from Gradient descent optimizers with noisy stochastic convergence at each iteration for a particular sample [25]. This implies that it can capture generality without the network to complete the training on the entire training set. On the other hand, the SGD algorithms might experience overshooting due to improper choice of learning rate. A small value of learning rate leads to slow convergence while a big value might lead to no convergence at all. To overcome this issue, momentum, NAG and adaptive optimizers are investigated. The momentum increases the speed of convergence towards steeper direction as against less steeper ones. The typical value of momentum is 0.9 [25]. Additionally, the NAG with momentum stores future gradients to speed-up the convergence by improving the learning rate to higher or lower values accordingly.

Apart from momentum and NAG, a vivid way of improving the performance of gradient optimizers is through adaptive gradient techniques. The AdaGrad [26] is one such optimizer that makes larger updates for not so frequent parameters while small updates for frequent ones. This also leads to accumulation of past gradients ultimately leading to a zero learning rate. In contrast to Adagrad, the Adadelata [26] uses a fixed

TABLE III. EXPERIMENTAL RESULTS FOR LA AND PA ATTACK VARIOUS OPTIMIZERS AND ACTIVATION FUNCTIONS

Type of System	Type of Attack		PA			LA		
	Activation	Optimizer	Epochs	Learning rate	EER	Epochs	Learning rate	EER

		Nadam	100	0.0001	15.779	100	0.0001	18.275
		RMSprop	100	0.00001	<b>11.317</b>	100	0.00001	19.893

window to refrain from past gradient accumulation. Similarly, the RMSprop tries to fix the past gradient issue by averaging the square of the gradients. Furthermore, the Adam optimizer estimates learning rate for every parameter value. It is a fusion of RMSprop with momentum. Additionally, the amalgam of Adam with NAG is Nadam optimizer [25]. Further, we have applied an Early stopping condition by tracking the validation error with some patience to see if it is experiencing any changes; if not then, training is halted. Table I summarizes the update rule for all the discussed optimizers.

### B. Activation Functions

The basis of any neural network to function the intended way is through activation. The activation functions lead the input to the output that speeds-up the training for capturing complex nature of the patterns within the input data. Usually the softmax and arg-softmax activations have been used in the LCNN architectures [21]. In this work, we have considered the combination of softmax, ReLU and logistic activation function to observe the loss characteristics with the chosen optimizers. The ReLU activation has been a popular choice amongst larger CNN as it overcomes the issue of vanishing gradients but at the same time experiences the dead neuron issue. While the logistic function is useful for binary classification tasks. The softmax is an extension of logistic activation as it works for multi-class problem [26].

## V. EXPERIMENTAL RESULTS AND DISCUSSION

The performance of these optimizers is measured using the Equal Error Rate (EER) [27] and the ROC curve is plotted

to check goodness of the classification algorithm signifying the Area Under Curve (AUC) value [28]. The EER must be ideally as low as possible. The system is trained and evaluated using the ASV spoof 2019 dataset that has synthetic (TTS and VC) and replay speech samples along with genuine speaker samples. There are 20 speakers (male and 12 female) including more than one hundred thousand samples with LA and PA attacks. This is currently the only large scale dataset with all three attack types and genuine samples. Also, in this work the development dataset is used for validation purposes. The test data or evaluation data has a lot of variation in environment conditions for replay speech and synthesizers of synthetic speech. Thus ensuring an unbiased testing scenario. Table II shows the details of ASV spoof 2019 dataset. Table III shows the EER along for various optimizers and activation functions for both the attacks while Fig. 3 and Fig. 4 portrays the ROC curve for individual activations and optimizers for LA and PA, respectively.

From Table III, the efficiency of sigmoid and softmax are similar in contrast to ReLU where it fails to capture generality in both the kind of attacks. The EER for ReLU is almost 50 for most of the optimizers implying that gradient is stuck in local minima rather than global minima. Additionally, the improper scaling of weights in ReLU function leads to loss of actual data being considered. The sigmoid and softmax are related as the latter is just an extension for multi-class problems. This results in similar performance by both the activations. Further, the spoofed samples have multiple types of attack generated from various VC and TTS sources. Hence, the softmax gives slightly better EER of 9.005 for LA and 9.951 for PA attack. Infact, the softmax is observed to converge faster with as low

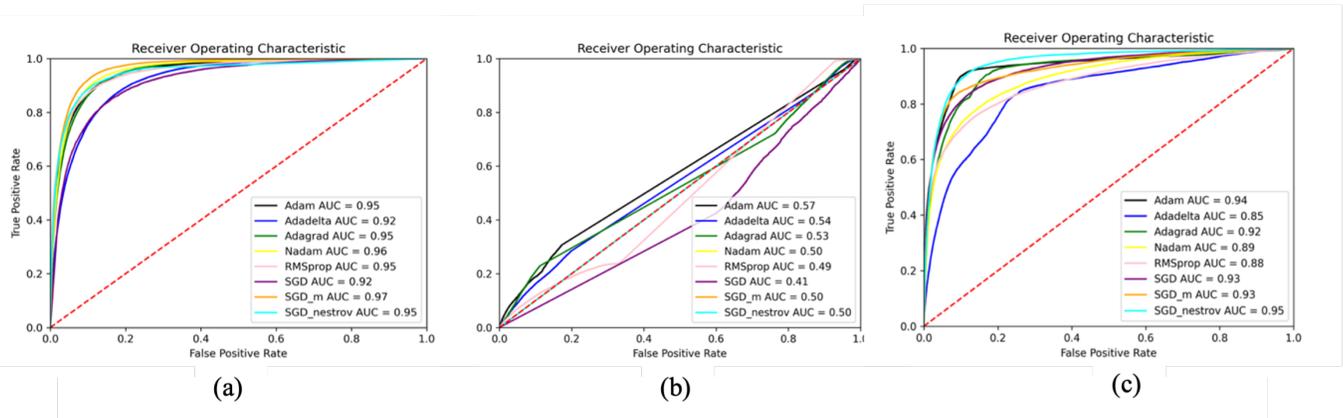

Fig. 3. ROC Curve for Various Activations and Optimizers for LA Attack (a) Softmax (b) ReLU (c) Sigmoid.

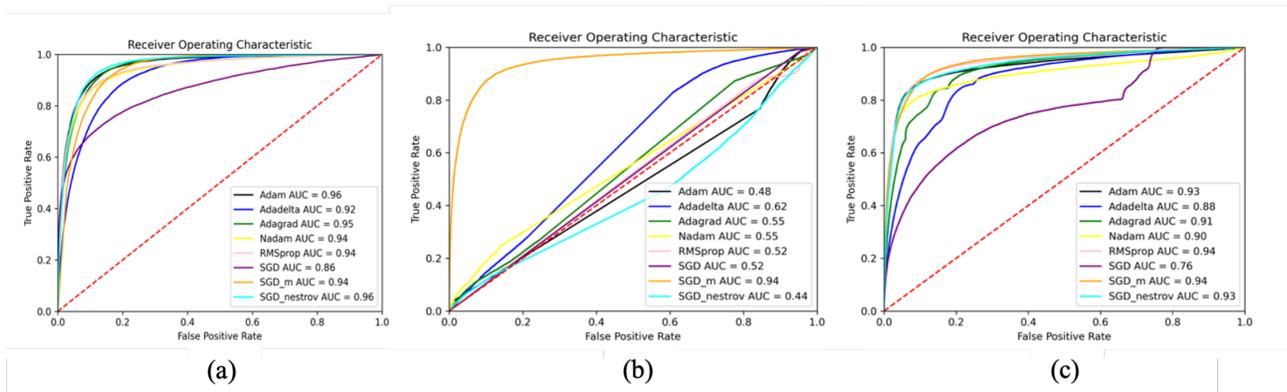

Fig. 4. ROC Curve for Various Activations and Optimizers for PA Attack (a) Softmax (b) ReLU (c) Sigmoid.

as 50 epochs for Adam and Adagrad for LA attack only.

In case of optimizer efficiency, Adam, RMSprop, SGD with momentum and NAG lead in EER for all the activations. The test condition comprise of noise in the dataset, hence RMSProp is the obvious performer for sigmoid activation with EER of 11.317. The SGD optimizer performs inconsistently with large variations in EER ranging from 14.379 to 30.070. This is due to lack of convergence and difficulty in adapting to convex problems. Thus as oppose to the SGD optimizer, the SGD with momentum and NAG are found to have a lower EER for both attacks. Hence, they are suitable for capturing generality like in the spoof detection task. The Adam optimizer performs consistently well with EER ranging from 10.015 to 11.949. So, it may be explored where generality is not of critical importance. Adadelata and Adagrad are not the shining performers but Adagrad gives a 0.3% improvement in EER than Adadelata; yet they perform poorly in comparison to Adam. The Nadam performs well for softmax optimizer while its performance worsens with increase in EER for sigmoid activation. The overall choice of activation will be softmax with any optimizer from the ones leading. Also, the EER for LA attack is lower than PA attack. Thus, the network efficiency is explicitly achieved for LA attack.

To confirm the performance of various optimizers the Receiver Operating Characteristics (ROC) curve with AUC are

shown in Fig. 3 and Fig. 4 for LA and PA attack respectively. The required value of AUC is between 0 and 1 with values closer to 1 implying a good classifier. The Fig. 3(a) shows ROC for softmax function where all the optimizers perform well. The SGD with mometum has exceptional AUC of 0.97. In Fig. 3(b), none of the optimizers are able to form a learning rule in case of ReLU activation implying the the ReLU classifiers are not suitable for spoof detection task. The Fig. 3(c) confirms that the Adam and SGD with NAG have same AUC of 0.95 which is best amongst the other optimizers for sigmoid activation. Simiarly for PA attack, from Fig. 4(a) the ROC for softmax function shows all the optimizers perform well except SGD which has AUC of 0.86, while in Fig. 4(b), no significant efficiency is observed for ReLU activation. Lastly, Fig. 4(c), in case of sigmoid activation, the RMSprop and SGD momentum have same AUC of 0.94 which are better amongst the rest of the optimizers.

## VI. CONCLUSION

The goal of conducting this study was proving that initialization of the network prior to training and tuning of parameters during the training improves the network accuracy. Thus in this work, a comprehensive comparison of various optimizers was carried out on LA and PA attack data. The rationale for conducting such a study was to signify the role of optimizers in classifying the test samples accurately.

Moreover, the activation functions were also considered in this comparative work to highlight their role based on nature of input—output data. The softmax and sigmoid prove to be better as against the ReLU function in the LA attack. Also, the networks converged faster with less number of epochs for Adam optimizers. In case of PA attack, the softmax function performed not so well and so did the ReLU function; while sigmoid showed significant improvement in accuracy in comparison to the other two. Further, it was evidently found that the RMSprop performed consistently well amongst all the others; while the SGD with momentum performed better than SGD but not so well against SGD with NAG. On the whole, the choice of optimizer, learning rate and activation affect the accuracy of the training network and thus the overall performance of the spoof detection system. In future, this work may be extended to experimenting with more activations like leaky-ReLU, Exponential linear unit and parametric ReLU; while optimizers such as AMSGrad may be explored to solve the issues of current adaptive algorithms.

**Abstract**—Social media content in regional languages is expanding from day to day. People use different social media platforms to express their suggestions and thoughts in their native languages. Sentiment Analysis (SA) is the known procedure for identifying the hidden sentiment present in the sentences for categorizing it as positive, negative, or neutral. The SA of Indian languages is challenging due to the unavailability of benchmark datasets and lexical resources. The analysis has been done using lexicon, Machine Learning (ML), and Deep Learning (DL) techniques. In this work, the baseline models and hybrid models of Deep Neural Network (DNN) architecture have been used for the classification of Malayalam tweets as positive, negative and neutral. Since, sentiment-tagged dataset for Malayalam is not readily available, the analysis has been done on the manually created dataset and translated Kaggle dataset. The hybrid models used in this study combine Convolutional Neural Networks (CNN) with variants of Recurrent Neural Networks (RNN). The RNN models are Long Short-Term Memory (LSTM), Bidirectional LSTM (Bi-LSTM) and Gated Recurrent Unit (GRU). All these hybrid models improve the performance of Sentiment Classification (SC) compared to baseline models LSTM, Bi-LSTM and GRU.

**Keywords**—Bi-LSTM; CNN; NLP; Malayalam; Twitter

## I. INTRODUCTION

Sentiment Analysis (SA) is one of the inevitable research domains in Natural Language Processing (NLP), ML and Linguistics. The public express their opinion about products, events, movies, political concerns, ideas, interests, and so on using various social media platforms like Facebook, Twitter, Blogs, and so forth. SA has a significant role in the automatic identification of sentiment hidden in the text [1]. SA classifies the text as positive, negative, or neutral based on the sentiment. SA has been done at different levels like sentence, document, and aspect levels. Since the Tweets are short messages with 280 characters long, sentence-level analysis is most suitable for SA of Tweets.

In the southern state of India, Malayalam is a prominent language spoken by Keralites and also in union territories like Lakshadweep and Puducherry. Most people in Kerala prefer Malayalam to express their opinion, ideas, comments, etc. The majority of youth in Kerala are using Twitter for expressing opinions. Thus the number of tweets is tremendously increasing over time. The Government has initiated the automation of regional languages such as automatic speech recognition, language translation, and character recognition to support the public. The policies made by Government can be modified or

changed based on the opinion expressed by the people through social media platforms. Hence, the automation of SA of Malayalam is essential. SA of Indian languages has initiated in the year 2010. The first work in Indian languages reported for the Hindi language [3]. Research work on SA of Malayalam is at the beginning stage due to the lack of benchmark datasets and lexical resources. So far, only few works have been done on Malayalam based on ML, DL, and lexicon-based approaches [29]-[36]. Further important applications are in the field of business analytics, movie reviews, stock market prediction, and so forth.

Hinton et al. proposed different deep learning architectures [2]. The DL models are extensively applied in image processing, NLP, SA, and so on. The most generally used DL models are CNN, RNN, LSTM, and GRU.

The main objective of this study is to enhance the performance of the system and reduce computational costs. In order to achieve this, we extracted the best features by finetuning the hyperparameters and modeled the combined architecture of CNN and the variants of RNN. As a result, the sentiment classification accuracy is improved. In this paper, two different datasets have been analyzed using baseline models and hybrid models of DL architectures. The analysis shows that hybrid models performed better in SA of Malayalam tweets than baseline models.

Word embedding has a significant impact on text processing. Word embedding is the process of converting words or sentences into numerical vectors. These word vectors lie in different dimensions like 32, 64, 128, 300, etc. The words in the same context appear to lie near the same vector space. The word embedding is created either during the training process of embedding layers in the neural network or by using a pre-trained model. The available word embedding models are word2vec [4], BERT [5], fastText [6], etc. The pre-trained model available for the Malayalam language is fastText and BERT. Since the pre-trained model has not performed well in our dataset, the word vectors are formed during the training phase of the embedding layer. The contributions of this study are mentioned below:

- Two different datasets have been created for SA of Malayalam Tweets. Dataset I contains 6304 tweets, where 2907 are positive and 3397 are negative. The Dataset II includes 170000 tweets, among which 66357 are positive, 52798 are negative, and 50845 are neutral.

- Different DL methods like LSTM, Bi-LSTM and GRU have been applied for SA of tweets.
- Novel hybrid DL architectures have been developed by combining both CNN and variants of RNN models for the effective implementation of sentiment classification of Malayalam Tweets.

In the subsequent sections, Section II briefs the related works using hybrid deep learning models and SA of Malayalam language, whereas Section III is the proposed methodology of SA. Section IV describes the novel hybrid models. Section V is the experimental setup followed by results and discussion. Section VI concludes the work.

## II. RELATED WORK

The hybrid architecture combines different ML and DL algorithms for feature extraction and sentiment classification of datasets. The various works done using hybrid models are discussed as follows.

DL models are widely used in the analysis of social media content [7][8][9][10][11]. Hassan et al. [12] and Hedge et al. [13] proved that CNN and LSTM performed well in the analysis of short text messages. The recent study shows that the DL models such as CNN and RNN performed well in SA [7][8][14][15][16]. CNN combined with RNN shows potential improvement in the accuracy of SA of English [17]. Srinidhi et al. proposed the LSTM model combined with SVM for SC of IMDb dataset [18]. A similar architecture CNN combined with SVM was proposed by Akhtar et al. for SC of Hindi dataset [19]. SA on reviews/comments from e-commerce sites was proposed by Vo et al. using the hybrid architecture LSTM-CNN model [20]. The same model was proposed by Rehman et al. for SA of movie reviews [21]. All the above-mentioned works have been used single architecture for SC. Multiple DL models, CNN, LSTM and hybrid model CNN-LSTM was proposed by Kastrati et al. [22]. Facebook comments related to the COVID-19 pandemic were tested using this model. Pre-trained models like fastText and BERT were utilized for word embedding [23]. The same hybrid model was used for SC of IMDb dataset, social media content and SMS spam detection for Arabic and English Messages [24][25]. The CNN-LSTM with fastText word embedding was proposed by Ombabi et al. [26]. SVM was used at the final layer for SC. A hybrid model CNN and Bi-LSTM were proposed for sentiment and emotions analysis of Chinese product reviews [27]. Pandey et al. proposed a hybrid DL model merged with CNN and Bi-LSTM for SA of Tweets [10]. Dang et al. suggested multiple hybrid DL models with CNN, LSTM, and SVM for the classification of tweets and review datasets [14]. Salur et al. proposed hybrid DL architecture for SC of Turkish dataset [28]. Both CNN and LSTM models were combined for feature extraction and have obtained better accuracy compared to baseline models. The works are done in Malayalam language using rule-based, lexicon-based, Fuzzy logic, ML, and DL methods are shown in Table I. All the works have been done on the dataset which is created by corresponding authors on different domains like a movie review, novel, Tweets, etc. Preprocessing is an important step in SA, which depends on the domain of the dataset. All the works in Malayalam have been used as a single model for SC. Here, we have used hybrid architecture which extracts

better features and has shown potential improvement in the SA tasks. The proposed hybrid DL models and their evaluation are explained in consecutive sections.

## III. PROPOSED METHODOLOGY

In the previous works, lexicon-based, ML approaches like NB, SVM and RF, DL models like RNN, CNN, LSTM, BiLSTM and GRU have been applied for SA of Malayalam tweets [37][38][39]. Considering the significance of hybrid models in SA, three different hybrid architectures are developed in this work. As the first step of implementation, two different sentiment-tagged Malayalam datasets has been created. The pre-processing steps eliminate unnecessary information from the retrieved text. After that the feature vector is formed during the training phase of embedding layer. The feature vector is given to baseline as well as hybrid DL models. The sigmoid activation function for Dataset I and softmax for Dataset II are applied at the output layer in the baseline models and SVM is applied in the hybrid models. The proposed methodology for SC is shown in Fig. 1.

### A. Dataset

Dataset I is created by retrieving Malayalam tweets using sentiment-oriented words [38]. Dataset II is created by translating the Kaggle dataset existing in English to Malayalam by using the Google document translator. The sample dataset is shown in Fig. 2. The sentiment distribution of the Dataset I and Dataset II are shown in Fig. 3 and Fig. 4, respectively. In Dataset I, 0 and 1 represents negative and positive sentiments, whereas, in the Dataset II, 0, 1, and 2 represent neutral, positive, and negative sentiment. The length of sentences under each category of Dataset I and Dataset II are shown in Fig. 5 and Fig. 6, respectively.

### B. Preprocessing

The performance of the system has been improved by removing unnecessary information from the text. The following steps have been performed as part of data cleaning.

- Hyperlinks: Most of the tweets contain brief sentences followed by hyperlinks that do not provide meaningful information for SA. Hence all the hyperlinks have been removed from the corpus.
- Punctuations and Special Characters: Removed punctuations like :, ', ... etc. and special characters like @, \$, #, etc. from the text.
- Stop Words: Stop words are often occurring in the input sentence, but are less information-oriented. Hence they are removed to reduce the vocabulary size.

Data cleaning has been done using regular expressions in Python language. Negative sentences are labeled with 0 and positive are labeled with 1. Preprocessing is an essential step in reducing the vocabulary size and removing unwanted information. Hyperlinks, special characters, punctuations, digits, foreign languages, etc. are removed by using the regular expression before extracting the features. Vocabulary is created by tokenizing the sentence based on Unicode standards within the range of 0D00–0D7F, which is shown in Fig. 7. Tokenized

TABLE I. SA OF MALAYALAM

Author	Domain with Size of Dataset	Preprocessing	Features	Classification Method	Accuracy
Mohandas et al. (2012) [29]	Novel	POS tagging	Tokens	SO-PMI-IR	63 %
Nair et al. (2014) [30]	Movie Review	Sandhi Splitter	Tokens, Negation	Rule Based	85 %
Anagha M et al.(2014) [31]	Movie Review	POS tagging	Wordnet	Lexicon	93.6 %
Anagha M et al. (2015) [32]	Movie Review	POS tagging	TnT tagger	Fuzzy Logic	91.6 %
Nair et al. (2015) [33]	Movie Review (30,000 tokens)	POS tagging	Tokens, Negation Intensifier	CRF, SVM	SVM: 91 %
Kumar et al. 2017 [34]	Tweets (12822)	Removing hyperlinks and punctuations	word embedding with different dimensions	LSTM, CNN	98.24 %
Rahul et al. (2018) [35]	Social Media	Removing hyperlinks and punctuations	POS tagging Positive and Negative Intensifier Negation	CRF, SVM	SVM: 52.75 %
Kumar et al. (2019) [36]	Tweets	Removing hyperlinks and punctuations	word embedding with different dimensions	RKS-RBF, LSTM CNN	86.5 % 89.3 %

TABLE II. DATASET 1

Dataset I	
Sentiment	Number of Tweets
Positive	2907
Negative	3397
Total	6304

TABLE III. DATASET 2

Dataset II	
Sentiment	Number of Tweets
Positive	66357
Negative	52798
Neutral	50845
Total	170000

corpus is converted to a sequence of integers with variable length records and is represented in Fig. 8. The variable-

length record is converted to fixed-length by zero-padding which is shown in Fig. 9. Word vector is formed during the training phase of embedding layer which takes embedding dimension, vocabulary size and maximum length of sentence as parameters. Embedding dimension takes different values like 64, 128 and 300, but it shows better performance when the dimension is set to 300. The 300 dimensional word vector is shown in Fig. 10.

#### IV. HYBRID ARCHITECTURE

In the related study, different hybrid models combined with CNN and LSTM show better results in SA of English languages. Here, we have used three different hybrid architectures for SA of Malayalam tweets. The word vector is created during the training phase of the embedding layer and then given to CNN and various RNN models. The features extracted by the CNN and RNN models are merged and corresponding output

Dataset I		
1	കലഹം നാലാംക്ലാസ്സുകാരൻ മൂന്നാംക്ലാസ്സുകാരനെ മണ്ണെണ്ണയൊഴിച്ചു തീകൊളുത്തു. (Riot A fourth-grader burned to death with kerosene)	0
2	അണലിയുടെ കടിയിൽ ചികിത്സയിൽ കഴിയുന്ന വാവ സുരേഷിന്റെ ആരോഗ്യനില അതീവ ഗുരുതരം. (Vava Suresh is in serious condition after being bitten by a viper)	0
3	എഴുന്നള്ളലുണ്ട് ഒരുപാട് വെള്ളവും ഏറ്റവുമിഷ്ടമുള്ളൊരു പാലും കേട്ടാൽ ശാരീരികവും മാനസികവുമായി ഉന്മേഷം ലഭിക്കും. (Getting up and drink a glass of water and listening to a favorite song will refresh you physically and mentally)	1
4	മൺസൂൺ നന്നായി പെയ്യുന്നു എന്നുള്ളത് വളരെ ശുഭകരമായ ഒരു വാർത്തയാണ്. (The good news is that the monsoon is getting better)	1
Dataset II		
1	ദൈവം നാളെ ഇന്ത്യയെ അനുഗ്രഹിക്കട്ടെ മോദി പ്രധാനമന്ത്രിയാകും (God bless India tomorrow Modi will be the Prime Minister)	0
2	മോഡിസ് ഇപ്പോൾ ഉപയോഗിക്കുന്ന അതേ വാക്കുകൾ ഇതിൽ നിന്ന് മാറ്റുന്നു (It replaces the same words that Modi now uses)	0
3	ആവേശമുണർത്തുന്ന ട്രെയിലർ ഗംഭീരമായ ശ്രമം കാത്തിരിക്കുന്നു നന്നായി കാണുക കഠിനമായ ചോദ്യങ്ങൾ ചോദിക്കുന്നു ജനാധിപത്യം ശരിക്കും സംരക്ഷിച്ചു മോദി രാജ് എല്ലാ ആശംസകളും ( Exciting trailer awaits great effort Watch well Ask tough questions Democracy is really protected Modi Raj All the best)	1
4	വിദേശ രാജ്യങ്ങളിലെ ഇന്ത്യൻ വംശജരെ മാനുഷമായ ജീവിതം നയിക്കാൻ സഹായിച്ച മികച്ച നയതന്ത്ര മോദി അതാണ്. (Modi is the best diplomat who has helped Indians in foreign countries lead a dignified life.)	1
5	ജിഎസി പോലെ മോഡി കാലഘട്ടത്തിൽ ഉണ്ടാക്കിയ ബാങ്ക് അക്കൗണ്ടുകൾ നീക്കം ചെയ്യുന്നില്ല ആരാണ് ഈ വിധിയിൽ പദ്ധതിക്ക് പണം നൽകുന്നത്. (Bank accounts created during the Modi era will not be removed like GST Who pays for this stupid scheme.)	2
6	വോട്ട് തേടുന്ന ഒരാളെ നിങ്ങൾ കാണുമ്പോഴൊപ്പം മോദിക്കെതിരെ അക്രമത്തിന് പേരിടിക്കുന്ന ക്യാറോഹിതനായ ഗൗഡയ്ക്ക് ശക്തമായ അടി നൽകുക. (Whenever you see someone seeking votes, give a strong blow to Gowda, who is accused of inciting violence against Modi.)	2

Fig. 10. Word Embedding.

layer [9]. The convolutional layer uses filters for extracting important attributes from the data. Different filters are utilized for various applications with distinct kernel sizes. Kernel size represents the n-gram representation. ReLU is the commonly used activation function in convolutional layers. The pooling layer consolidates the output from the convolutional layer by selecting optimal data from the previous layer. Thus, reducing the dimension of feature vectors. The final layer of CNN is a fully connected neural network. LSTM consists of different elements, including an input gate, forget gate, memory cell, hidden state and an output gate [40]. LSTM removes long-term dependency but keeps some useful information. Bi-LSTM [41] creates the exact copy of LSTM in a backward direction also. The output of both forward and backward LSTM hidden states are combined at each step. GRU [42] is the simplified model of LSTM by removing the output gate. Thus, it reduces the complexity involved in LSTM architecture.

#### A. Evaluation Measures

The model is evaluated for making standard metrics like Precision, Recall, F1-score, and Accuracy using the confusion matrix [43]. The evaluation measures are formulated using the following equations.

$$\begin{aligned} \text{Precision (positive classification)} &= \frac{TP}{TP+FP} \\ \text{Precision (negative classification)} &= \frac{TN}{TN+FN} \\ \text{Recall (positive classification)} &= \frac{TP}{TP+FN} \\ \text{Recall (negative classification)} &= \frac{TN}{TN+FP} \end{aligned}$$

Where,  $TP$  represents true positive,  $TN$ : true negative,  $FP$ : false positive, and  $FN$ : false negative.

$$\text{F1-score} = \frac{2 * \text{precision} * \text{recall}}{\text{precision} + \text{recall}}$$

Accuracy is measured based on how many sentences are correctly classified among total sentences.

$$\text{Accuracy} = \frac{TN+TP}{TP+TN+FP+FN}$$

#### B. Proposed Hybrid Architecture

The details of the proposed hybrid models are given as follows:

#### Algorithm 1: HYBRID MODEL OF CNN AND LSTM

```
1 Input: S // S is a corpus which consists a set of
  sentences  $S_1, S_2, \dots, S_n$ 
2 Output: Y // Labelled as 0 or 1 for Dataset I and 0, 1
  or 2 for Dataset II
3 for each sentence  $S_i$  in S do
4  $W_i = \text{Embedding}(S_i)$  // Word vector in 300
  dimensional space
5 end
6 for each  $W_i$  do
7  $C_i = \text{CNN}(W_i)$ 
8  $L_i = \text{LSTM}(W_i)$ 
9 end
10 for each  $C_i$  and  $L_i$  do
11  $O_i = \text{Dense}(C_i, L_i)$ 
12 end
13 for each  $O_i$  do
14  $Y_i = \text{LinearSVM}(O_i)$  // Linear SVM used as output
  layer activation function
15 end
```

#### Algorithm 2: HYBRID MODEL OF CNN AND Bi-LSTM

```
1 Input: S // S is a corpus which consists a set of
  sentences  $S_1, S_2, \dots, S_n$ 
2 Output: Y // Labelled as 0 or 1 for Dataset I and 0, 1
  or 2 for Dataset II
3 for each sentence  $S_i$  in S do
4  $W_i = \text{Embedding}(S_i)$  // Word vector in 300
  dimensional space
5 end
6 for each  $W_i$  do
7  $C_i = \text{CNN}(W_i)$ 
8  $B_i = \text{BiLSTM}(W_i)$ 
9 end
10 for each  $C_i$  and  $G_i$  do
11  $O_i = \text{Dense}(C_i, B_i)$ 
12 end
13 for each  $O_i$  do
14  $Y_i = \text{LinearSVM}(O_i)$  // Linear SVM used as output
  layer activation function
15 end
```

1) *Model I*: Model 1 combines both CNN and LSTM. The word vector is given to CNN and LSTM parallelly. Filter size and kernel size of CNN are 32 and 2 respectively. The LSTM has 50 neurons. The merged output is given to a dense layer with 20 neurons. Further, the output is given to the linear SVM. SVM classifies the Dataset I as positive or negative, whereas Dataset II as positive, negative or neutral. The pseudo-code representation of Model I is shown in Algorithm 1.

2) *Model II*: The second hybrid architecture combines both CNN and Bi-LSTM model. All the other layers are the same as in Model I. The pseudo-code representation of Model II is shown in Algorithm 2.

3) *Model III*: The third hybrid model combines both CNN and GRU. The merged output is given to the dense layer,

**Algorithm 3: HYBRID MODEL OF CNN AND GRU**

```

1 Input: S // S is a corpus which consists a set of
  sentences  $S_1, S_2, \dots, S_n$ 
2 Output: Y // Labelled as 0 or 1 for Dataset I and 0, 1
  or 2 for Dataset II
3 for each sentence  $S_i$  in S do
4  $W_i = Embedding(S_i)$  // Word vector in 300
  dimensional space
5 end
6 for each  $W_i$  do
7  $C_i = CNN(W_i)$ 
8  $G_i = GRU(W_i)$ 
9 end
10 for each  $C_i$  and  $G_i$  do
11  $O_i = Dense(C_i, G_i)$ 
12 end
13 for each  $O_i$  do
14  $Y_i = LinearSVM(O_i)$  // Linear SVM used as output
  layer activation function
15 end

```

followed by linear SVM. The pseudo-code representation of Model III is shown in Algorithm 3.

V. EXPERIMENTAL RESULTS AND DISCUSSION

The implementation of this work is carried out using Google Colab [46] with Keras [44] and TensorFlow [45] libraries. The three different baseline DNN models (LSTM, BiLSTM, GRU) and three hybrid models (CNN+LSTM, CNN+BiLSTM, CNN+GRU) are applied to two different datasets for SC. The dataset is split into 80:20 where 80% dataset is used for training while 20% is used for testing. For Dataset I, the vocabulary size is set to 8353 and for Dataset II, the vocabulary size is set to 58846 by removing the foreign words and least frequent words present in the text. The maximum sequence length of Dataset I is 32 and of Dataset II is 151. Table II represents the optimal value of hyperparameters chosen during the training phase of both baseline and hybrid models on Dataset I. The percentage of rightly classified and wrongly classified datasets are shown in Fig. 11 and Fig. 12. respectively. The confusion matrices of hybrid models like CNN+LSTM, CNN+Bi-LSTM, and CNN+GRU for Dataset I are shown in Fig. 11(a), Fig. 11(b), and Fig. 11(c), and for Dataset II is shown in Fig. 12(a), Fig. 12(b) and Fig. 12(c) respectively. Precision, Recall, F1-score and accuracy are used as evaluation measures. Table III represents the evaluation measures on Dataset I. Table IV represents the loss and accuracy of training, validation and test dataset. The optimal value of hyperparameters on Dataset II is depicted in Table V. Table VI is the evaluation measures on Dataset II. Table VII represents the loss and accuracy of training, validation and test dataset of Dataset II. Table IV and Table VII show that the CNN + GRU got better prediction accuracy of 87.23% for Dataset I and CNN + BiLSTM got an accuracy of 74% for Dataset II. The model architecture for CNN + GRU for Dataset I and CNN + BiLSTM for Dataset II are shown in Fig. 13 and Fig. 14, respectively. The bar chart shown in Fig. 15 and Fig. 16 compares the accuracy of baseline models with hybrid models for Dataset I and Dataset

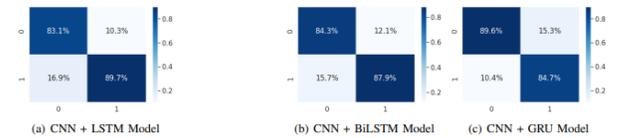

Fig. 11. Confusion Matrices of Hybrid Models on Dataset I.

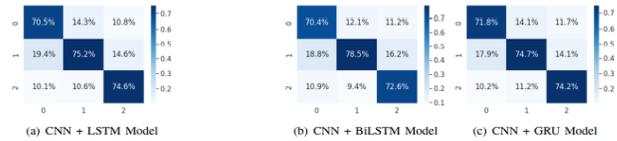

Fig. 12. Confusion Matrices of Hybrid Models on Dataset II.

II.

Discussion: Twitter is the most prominent platform for expressing opinions and suggestions about daily phenomena. Hence, tweets are considered for the SA. Both the baseline and hybrid DL models classified Dataset I as positive or negative and Dataset II as positive, negative and neutral. The best model is selected based on the accuracy of test dataset. The study of literature shows that the hybrid model performed well compared with baseline models for English and some Indian languages. This study analyzes that the hybrid models also show better prediction accuracy for the Malayalam language. Since the pre-trained vector fastText is not performed well on our datasets, the word embedding vector is created during the training phase of the embedding layer. After experimenting with various dimensions, the word vector is mapped to a 300-dimensional space for better prediction. Hybrid models improved the performance by nearly 2% to 3% compared with

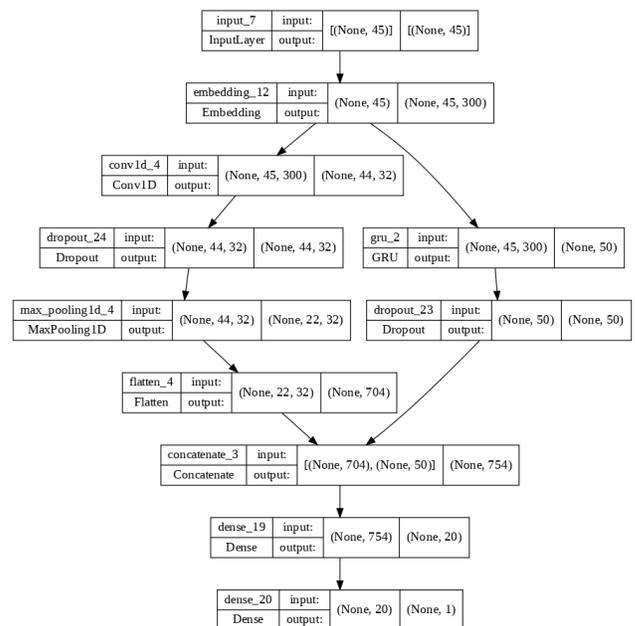

Fig. 13. Hybrid Architecture of CNN + GRU for Dataset I.

TABLE IV. VALUES OF HYPERPARAMETERS ON DATASET I

Model	Embedding Dimension	Number of Neurons in Dense Layer	Dropout	Optimizer	Kernel Size	Filter Size / Number of Neurons	Output Layer Activation Function	Loss Function
LSTM	300	20	0.4	Adam		50	sigmoid	binary_crossentropy
Bi-LSTM	300	20	0.4	Adam		50	sigmoid	binary_crossentropy
GRU	300	20	0.4	Adam		50	sigmoid	binary_crossentropy

TABLE V. EVALUATION MEASURES ON DATASET I

Model	Sentiment	Precision	Recall	F1-Score	Support
LSTM	Positive	0.84	0.78	0.81	581
	Negative	0.82	0.87	0.85	680
Bi-LSTM	Positive	0.80	0.87	0.83	581
	Negative	0.88	0.81	0.84	680
GRU	Positive	0.85	0.80	0.82	581
	Negative	0.83	0.88	0.86	680
CNN + LSTM	Positive	0.90	0.78	0.83	581
	Negative	0.83	0.92	0.87	680
CNN + Bi-LSTM	Positive	0.88	0.80	0.84	581
	Negative	0.84	0.91	0.87	680
CNN + GRU	Positive	0.85	0.88	0.86	581
	Negative	0.90	0.86	0.88	680

TABLE VI. TRAINING, VALIDATION AND TEST DATA ACCURACY OF DATASET I

Model	Training Loss	Training Accuracy	Validation Loss	Validation Accuracy	Test Loss	Test Accuracy
LSTM	0.0892	0.9586	0.4433	0.8571	0.5120	0.831
Bi-LSTM	0.1359	0.9482	0.3740	0.8552	0.4126	0.838
GRU	0.2068	0.9167	0.3659	0.8373	0.3217	0.8410
CNN + LSTM	0.1078	0.9548	0.5915	0.8373	0.4169	0.8572
CNN + BiLSTM	0.1146	0.9473	0.5917	0.833	0.4288	0.858
CNN + GRU	0.1191	0.9486	0.4917	0.8472	0.4414	0.8723

baseline models for Dataset I and 1% to 2% for Dataset II. The combined architecture of DNN models extracts better features rather than a single model. CNN extracts the local features and variants of RNN extracts the long-term features from the text data. The hyperparameters like the number of neurons in LSTM, BiLSTM and GRU are set to 50 for Dataset I and 100 for Dataset II after several trials with varying neurons. The number of neurons at dense layer is selected as 20 for both datasets. The sigmoid activation function is used at the output layer for Dataset I and Softmax for Dataset II. But, for both datasets, LinearSVM is selected as the best activation function for hybrid models. The loss function binary\_crossentropy, categorical\_crossentropy and squared\_hinge are applied for sigmoid, softmax and SVM activation functions. Adam optimizer is used for all the models. For small dataset, GRU performed well and for large dataset Bi-LSTM shows better accuracy in baseline models. Therefore, the combined architecture of CNN and GRU got better prediction accuracy for Dataset I and CNN + BiLSTM shows better accuracy for Dataset II.

## VI. CONCLUSION

The expeditious growth of social media content in regional languages have led to the importance of SA in native languages. The advancement of ML and DL models has improved the performance of NLP applications. Since general people in Kerala use their native language to express their suggestions and opinions in social media platforms like Twitter, Facebook,

etc. The automation of SA in Malayalam is essential for analysis. Also, DL models like LSTM, BiLSTM and GRU prevail over other methods of SC of text datasets. This paper proposes SA of Malayalam tweets using hybrid DNN models. Three different baseline DNN models, namely, LSTM, BiLSTM, GRU and further hybrid models combined with CNN and variants of RNN, including LSTM, Bi-LSTM and GRU, have been used for SC of tweets as positive, negative, or neutral. The experiments were conducted on two different datasets. Hybrid DL models performed well in both datasets. The combined architecture of CNN and the variants of RNN extract the best features compared to a single model. The word vector is formed during the training phase and mapped into a 300-dimensional vector space to achieve semantically similar words in the same space. Among the hybrid models, CNN + GRU shows the highest accuracy of 87.23 % for Dataset I and CNN + BiLSTM show better performance for Dataset II with an accuracy of 74%.

The major challenge was lack of benchmark datasets and lexical resources in Malayalam language. Hence, SA was done only on two different datasets, which is insufficient to standardize the results. Future work is aimed to develop

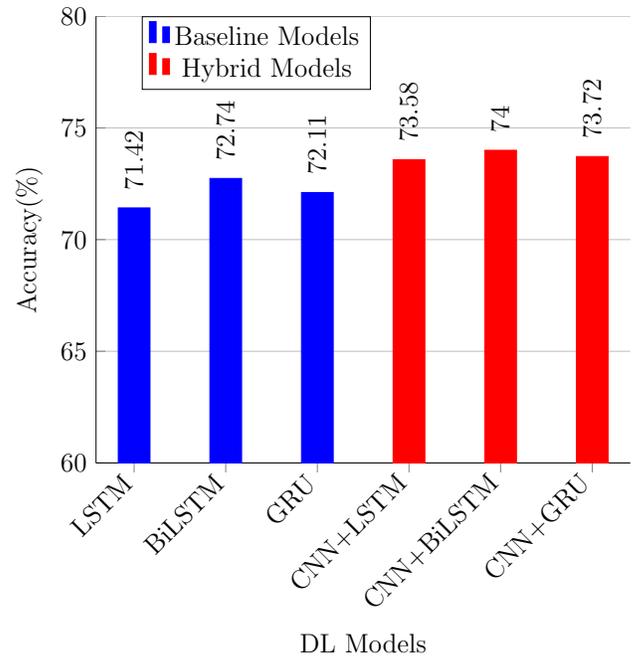

Fig. 16. Comparing Accuracy of DL Models on Dataset II.

benchmark datasets to achieve standardization of text analysis in Malayalam language.

**Abstract**—IoT is becoming a hot spot area of technological innovations and economic development promises for many industries and services. This new paradigm shift affects all the enterprise architecture layers from infrastructure to business. Business Process Management (BPM) is a field among others that is affected by this new technology. To assist data and events explosion resulting, among others, from IoT, data analytic processes combined with event processing techniques, examine large data sets to uncover hidden patterns, unknown correlations between collected events, either at a very technical level (incident/anomaly detection, predictive maintenance) or at business level (customer preferences, market trends, revenue opportunities) to provide improved operational efficiency, better customer service and competitive advantages over rival organizations. In order to capitalize the business value of data and events generated by IoT sensors, IoT, Data Analytics and BPM need to meet in the middle. In this paper, we propose an end-to-end IoT-BPM integration architecture (IoDEP: IoT-Data-Event-Process) for a proactive business process incident management. A case study is presented and the obtained results from our experimentations demonstrate the benefit of our approach and allowed us to confirm the efficiency of our assumptions.

## I. INTRODUCTION

Nowadays, Business Process Management (BPM) is a well-established discipline in both academia and industry. It is considered as a powerful solution that helps organisations adapt to strategic, tactical and operational changes and gain more visibility and control over their business processes, so that they can continuously improve and optimise their activities and resources. Organizations use Business Process Management systems as an activity-based workflow manager that allow them to track the optimized functioning of their activities in order to gain in terms of agility, efficiency and performance. This method is mainly based on the concept of business processes. A business process is the structure of activities and actions as they occur in the real world. It defines all the possible paths in the real process and the rules that determine the path to follow and the actions to perform.

In most cases, business processes are isolated either from each other or from the organization's external ecosystem.

Thus they don't benefit from the different added values that could be created from sensor data for example, and the useful knowledge that could be extracted from event logs and historical data from previous executions. Further, BPM works in a reactive way [1] which is not sufficient when facing new radical or incremental changes. Early anticipation is crucial to either avoid the occurrence of the problem or respond to it quickly, with no latency, and in an efficient way. This lack of proactivity and predictability is remarkable in three main steps of the BPM life cycle [2] [3]: the design and redesign step, the implementation step, and the execution step. To address this problem, proactive-oriented concepts start to be used in the BPM glossary such as proactive business process management [1] [4], process forecasting or future-oriented BPM [3] and context-aware business processes [5]. Therefore, switching from a reactive to a proactive and adaptable business processes becomes mandatory for every organization. With this new digitization of industrial processes, comes also the age of assistance, which mean that companies should be focused on customers, in order to offer a personalized and adaptable services, and even predict their needs in almost real time. Dealing with such a continuous changing environment requires an intelligent, adaptive and flexible business processes. As a result of all these new changes, organizations nowadays find that the traditional BPM systems present several limitations [6]. In the literature, different approaches have been proposed to improve business process by applying diverse techniques and technologies such as recommended systems [7] [8], Ontologies [9], data analysis, data mining and process mining [10] [11], complex event processing [1] [12], Ubiquitous Computing [13], Internet of things - IoT [14] [15], just to name few.

Processes are executed within application systems belonging to the real world, where humans, cooperative computer systems and even physical objects are involved. In fact, connected objects are becoming progressively more prominent in the business process execution environment. IoT represents the inter-networking of physical objects [16] (also referred to as "things", "connected devices", "smart devices", "ubiquitous devices"), vehicles and other items embedded with sensors, electronics, actuators, and network connectivity that enable these "things" to collect and exchange data when interacting and sensing their environment. At the execution level, Busi-

ness processes can be classified into Person-to-Person (P2P), Person-to-Application (P2A), and Application-to-Application (A2A) processes [2]. Recently with the emergence of these IoT devices, new Business process interactions are emerging such as Person-to-Thing, Thing-to-person, and Thing-to-Thing due to the advent of Internet of things (IoT) technologies [17]. However, IoT-BPM integration is still at its infant age. Most of the current research work on BPM-IoT integration, propose new approaches that target a specific aspect of the BPM life-cycle. For example, updating business process models by enriching business process model and notation (BPMN) with new elements that correspond to IoT domain and that can explicitly define IoT devices within a business process [18], improving resource Optimization and monitoring and task execution via IoT context-specific knowledge provisioning [19], improving business process execution via an IoT-aware business process execution that exploits IoT for BPM by providing IoT data in a process-aware way [20], or proposing an architecture for IoT-BPM integration in order to cope with the issues and limitations raised by the recent case studies in both industry or academia.

In this paper, we focus on how to improve BPM through IoT integration via an end-to-end architecture. This integration will help us to proactively manage the business process instances, that are launched by different IoT devices, based on their priority level. Although academia and industry have taken an interest in this integration, there is still a lot of research work to be done in order to propose effective methodologies, design patterns and architectures to ensure efficient and smooth integration and communication between the IoT domain and BPM.

In the literature, several research works are paving the way for BPM and IoT combination and integration, in order to optimize BPM using IoT and allow BPM to benefit from this new advanced technology. To go into more detail about our proposal related to IoT-BPM integration/Communication, it is appropriate to ask some research questions in order to define our problem in more concrete way.

- **Q01** : What is the state-of-the art regarding the integration/communication between IoT and BPM?
- **Q02** : What design strategy or methodology can we follow in order to achieve a successful integration/communication between IoT and BPM?
- **Q03** : What are the encountered issues when integrating IoT and BPM?
- **Q04** : And given that data and event are the common points between IoT and BPM, to what extent can the functionalities offered by data analysis and complex event processing be exploited for an end-to-end IoT-BPM architecture?

The reminder of this paper is organized as follow. Section 2 presents our context of work, illustrated with a real-life scenario. Section 3 overviews BPM, IoT and the integration of these two technologies. In Section 4, we present in more details our approach. In Sections 5, 6 and 7 we present an overview of our proposed IoDEP architecture from different perspectives. In Section 8 we describe the implementation of our approach (via an initial block validation), and we discuss

and evaluate our results. And finally, we conclude our paper and present some future perspectives in Section 9.

## II. CONTEXT AND MOTIVATING SCENARIO

In this section, we present a real-life scenario to illustrate our problematic and highlight the challenges we are trying to solve with the proposed approach.

The case study of our research work belongs to silver economy domain, which is a new industrial sector officially launched in 2013 in France. The aim is to create personalized services and new technologies to improve disability-free life expectancy and to help dependent elderly people as well as their care-givers on a day-to-day basis. Most countries all over the world live the demographic transition of aging population. According to the united nations, the number of people with 80+ years old will triple between 2015 (126.4 millions) and 2050 (446.6 millions). If we take France as an example, in 2015 the number of people with more than 60 years old is 12 thousands, which represents 18% of the French population and they will represent more than 1/3 of the population by 2060<sup>1</sup>. Since the demographic change is becoming a global phenomenon, several companies are focusing on developing products and services to create age-friendly societies.

The risk of diseases, loss of capacity and falls increase with age. Losing physical capacities due to age or some kind of accidents can lead to serious falls of elderly people and those falls can have adverse repercussions. In fact, The physical consequences of a fall differ from one individual to another. They can represent a decrease in mobility and an increase in daily life activities dependency. Falls have also some psychological consequences such as a loss of self-confidence, which can accelerate functional capacities decline. Falls among seniors result in a significant number of hospitalizations, with hip fractures being the main cause. Besides, falls are the leading cause of injury-related death.

Several studies have been conducted in the field of silver economy, in order to determine a standard definition of a fall and the number of falls over a specific period to consider an old person as a repetitive case. In [25] [21] [22] [23][24] a fall represents “an unintentional change in position resulting in coming to rest at a lower level or on the ground”. To characterize the repetitive aspect of a fall, we must determine the number of falls and the time interval between falls. As we can see in Table I, the majority of published studies consider at least two falls to retain repetitive character, with an interval between two falls ranging from 6 to 12 months on average. Quick intervention after a fall, using a fall detector for example, could avoid 26 % of hospitalizations, i.e. 160 M Euros and 9,400 deaths per year. There are several solutions for Fall Detection such as:

- **Passive Solutions**: where the senior must press a beeper to notify in case of an incident.
- **Active solutions**: these solutions require the use of sensors (Accelerometer, biological signals) or environmental detectors (presence, ground, doors...). In case of a particular variation of the signals, the device triggers an alert.

<sup>1</sup><https://www.insee.fr/fr/accueil>

TABLE I. REPETITIVENESS ASPECT OF A FALL

References	Data Collected	Participants	Study plan	Falls repetition
[21]	Questionnaire A follow-up period of one year Postal questionnaire	N = 730 Age $\geq$ 55 years	Transversal	Yes $\geq$ 2/12 months
[22]	A follow-up period of one year Telephone questionnaire	N = 1660 Age $\geq$ 70 years	Transversal	Yes $\geq$ 2/12 months
[23]	Interval : 6 weeks A follow-up period of 36 weeks	N = 311 Age $\geq$ 70 years	Observational cohort	Yes $\geq$ 2/9 months
[24]	A follow-up period of 3 years Participants report their falls weekly on a fall calendar Phone contact in case the person is incapable of filling in his calendar	N = 1365 Age $>$ 65 years	Observational cohort	Yes $\geq$ 2/6 months
[25]	Participants interviews Retrospective (12 months)	N = 377 Age =78 $\pm$ 3 years	Transversal	Yes $\geq$ 2/12 months

- Video-surveillance Solutions: the camera sensor analyzes the senior's behavior and triggers the alert accordingly.

Some of these solutions (bracelets, presence detectors, active floors...) are "blind". This means that they do not allow to know if a fall is a serious one or not, based on the received alert. Only the image delivered by the video fall detectors, allows us to remove doubt about the incident and therefore avoid unnecessary interventions and therefore minimize the overall cost of the service. Predicting and preventing falls among elderly, is the main objective of our case study, in fact to apply our approach, we will use a data set and a business process model from a Video surveillance company. This company edits an automatic falls detection system for elderly people and offers a 24/7 automatic alert solution and a quick rescue without the intervention of the person in danger.

Fig. 1 depicts our incident management process, using BPMN, which aims to manage falls alerts from detection to assistance and resolution. This incident management process is based on an analysis in real-time of alerts received from 24/7 streaming cameras (IoT devices) for detecting elderly people's falls. Waiting too long (sometimes even for few minutes) can be so risky as it can complicate the situation and also it can be so painful for the person. That is why a quick rescue is mandatory to assist the person after a fall or an incident. To achieve this prompt intervention, smart video surveillance cameras are installed at client's home or patients rooms at geriatric services. These devices detect suspicious scenes that may be a fall or an incident, take a picture of the scene and then send automatically an alert to the video-surveillance center. This received alert is handled by a human agent, who qualify the alerts into four categories, as described below, and after that he/she determines whether an assistance action is necessary or not according to the criticality level of the alert. That is why, each alert received requires a quite vigilant treatment, in order to be sure of its category, because the margin of error in this type of system must be very small, as those falls, in case of a delayed intervention or an incorrect qualification, may have an adverse impact on the person concerned: 1) False alerts (level 0): Empty place. 2) False alerts (level 1): Active person. 3) Alerts with average level (level 2): Seated person. 4) High level alerts (level 3): Person lying down.

Video-surveillance systems have proven their efficiency, as

they can detect hundreds of falls and risky situations and then assist the person in danger in less than five minutes. However, these ambient cameras videos generates a lot of false alerts, triggered by an active person or a moving curtains for example, that are send to the back-office alert workflow management system. Given that the human agent handles the received alerts in a first in first out (FIFO) order, sometimes true and critical alerts may stay on a waiting list for few minutes until the agent handles all the false alerts or less critical ones that were received before the true one, as the incoming events are intercepted, queued and launch the process instances . So if we do not integrate a mechanism to help the human intelligence by prioritizing the event generated by a (very) serious case, high latency will induce delays that can be disruptive, depending on the severity of the case.

### III. BACKGROUND AND LITERATURE OVERVIEW

In the literature, several research works are focusing on combining BPM and IoT. We start this section with a general BPM and IoT background. Then we present a literature Overview about BPM and IoT integration.

#### A. Introduction to Internet of things

Smart objects swept in our life to facilitate it in so many ways and in different domains such as transportation, health care, hospitalization, civil protection, smart home, smart cities, emergency, and individual automation. From smart phones to new smart objects that interact not only with people but with other machines (Machine to machine communication). The concept of the "Internet of Things" first emerged in a presentation by K. Ashton, on the connection of Radio Frequency Identification (RFID) to the supply chain of Procter and Gamble in 1999. Since then, IoT has been exploding and invading our daily lives in different aspects (smart phones, smart door locks, self-driving smart cars, smart cameras, smart medical devices, etc.). This new technology started to thrive right after the development of the web in the 1990's and mobile Internet in the 2010's. The internet of things (IoT) is growing by leaps and bounds. It is made up of billions of smart devices that use wireless technology to communicate with each other and with us. IoT infrastructures can range from connected, instrumented devices providing data to intelligent, standalone systems. IoT enables "a world where things can automatically

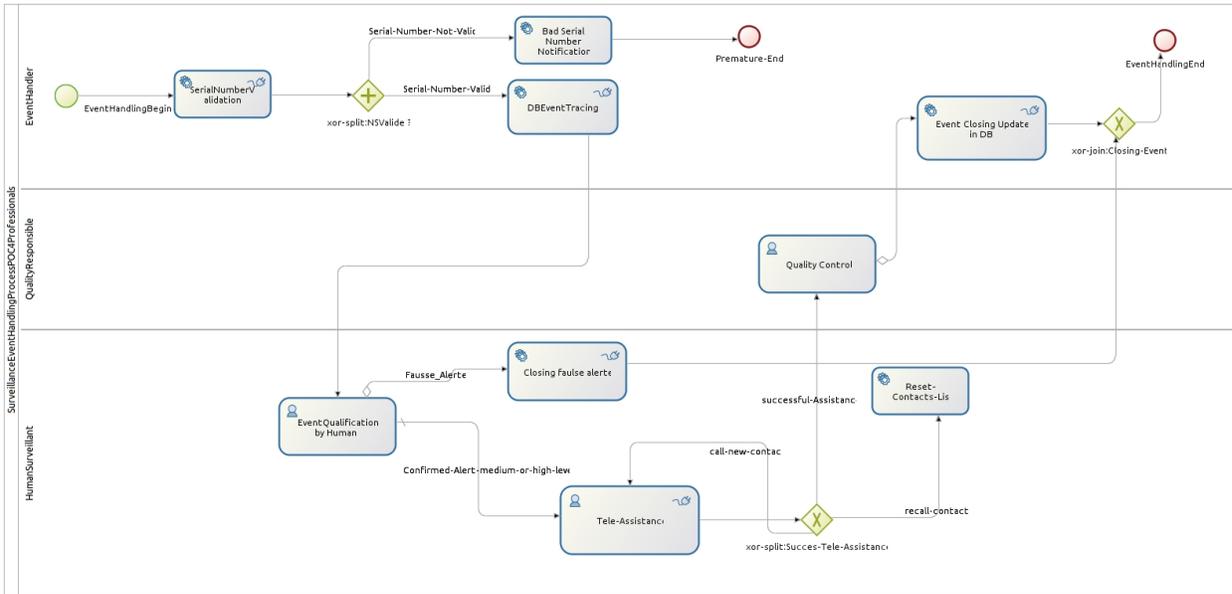

Fig. 1. Motivating Scenario: Qualification and Assessment of the Risk Level of Incidents Process.

communicate to computers and each other providing services to the benefit of the human kind” [26].

Connected devices collect data by sensing their environment, and exchange data with other devices and humans. All devices (things) act locally within their environment. Whereas, the IoT allows them to be remotely monitored via existing network infrastructures, including the Internet [19]. IoT contribute to continuously feeding “big” data to every node [27]. Besides, the evolution of the IoT invokes significant opportunities for private data exchange enabling new business models across heterogeneous networks [28]. However, it cannot generate value. That is why, it is necessary to couple it with other technologies to transform this huge amount of data into useful knowledge, in order to make meaningful decisions.

### B. Introduction to Business Process Management

The Process approach has been increasingly adopted by companies since the 1980s, leading to a new organizational model and a new way of operating in different organizations. Faced with a changing and competitive environment, traditional approaches that treat the company as a closed environment are no longer appropriate. Indeed, the process approach is a systemic approach that aims to transform the hierarchical and vertical structure of an organization into a transverse structure whose ultimate goal is the satisfaction of external and internal customers. It is a method of analysis and modeling intended to ensure collaborative work in order to control and improve the efficiency and smooth running of an organization.

This method is mainly based on the concept of business processes. A business process is the structure of activities and actions as they occur in the real world. It defines all the possible paths in the real process and the rules that determine the path to follow and the actions to perform [29]. The International Standards Organization (ISO) defines

processes as a set of interrelated or interacting activities that transform inputs into outputs elements. For Harrington in [30], he presents business processes as an activity or set of activities that uses an input, adds some value to it, and delivers it as an output to an internal or external customer. Dumas et al [31] represent a business process as a collection of inter-related events, activities, and decision points that involve a number of actors and objects, which collectively lead to an outcome that is of value to a customer. All these definitions and many others present business processes as a set of activities and tasks that exploit the different resources (human and/or machine) of the organization to achieve one or more objectives previously defined, in order to satisfy an internal or external customer. Each business process is attached to a single enterprise, but in some cases it may interact with other business processes belonging either to the same organization or to other organizations. In order to achieve its objectives and ensure efficient performance, the organization must subject its business processes to a continuous improvement mechanism. This mechanism represents the BPM life-cycle [31]. In fact, BPM life cycle is about discovery, modeling/(re)designing, executing, analysis and monitoring of business processes in a perpetual repetition in order to optimize and automate these processes as much as possible, and also to accommodate the ever-changing business requirements.

Business processes therefore occupy a very important place in the field of information systems, because they play a core role within every organization. Moreover, the performance level of any organization is indirectly linked to the efficiency of its processes and the quality of their models. In fact, a proper management of business processes within an organization can have a very positive impact on the efficiency and smooth running of its activities, as it allows this organization to have a clear vision of its objectives in order to better meet the requirements of competitiveness that are constantly increasing.

BPM provides already different methods and solutions to

manage and analyse data and events. Among these methods we have Business Process Intelligence (BPI). In fact BPI systems provides solutions to enhance decision making throughout a wide range of business activities, by analysing, predicting, monitoring, controlling and optimizing business processes [32]. Although, BPI has proven to be efficient for post-execution prediction of future process behavior, it is unable to manage and process huge amounts of real-time data and events that are generated from different sources [33]. This becomes more difficult when integrating IoT devices in a BPM architecture. Another solution provided by the BPM field, when dealing with real-time event data is Business activity monitoring (BAM). In fact, BAM is used in order to analyse data related to activities that have been executed. It complements ex-post analysis of process execution by continuously identifying specific situations at run-time and responding to them by triggering specific actions [34]. However, this technology remains less effective in use cases that includes IoT generated events. The limitations of traditional BAM in IoT case studies can be seen from two aspects: prediction and proactivity. The first aspect is manifested in the complex event correlation identification [35]. In fact, by sensing their environment, IoT devices generates a massive volume of event data that need to be processed and analyzed in order to extract useful information and to detect (complex) event patterns in real-time. However, traditional BAM does not provide rule-based engines. This limitation becomes more apparent when the events are generated from diverse data sources, because BAM lacks flexibility in integrating multiple heterogeneous data sources [33] [36] [37]. The second aspect is linked to the absence of proactivity in BAM solutions. In fact, using BAM in a reactive way is no longer sufficient, especially when we have this huge amount of real life data and events.

In business environment where every single event is important and need to be processed, Event Driven Architecture (EDA) needs to be adopted. Now with the emergence of IoT, events are becoming increasingly important for the current information systems (SI), especially for organizations that integrate IoT devices and sensors in their business operations (video surveillance, Health care, ...). EDA is the successor of service Oriented Architecture (SOA). The idea behind this paradigm is that everything is an event, all the different components of this architecture interact with each other by events. In this architecture each component is either an event consumer or an event provider. Event consumers subscribe to an intermediate event handler, and providers publish to that handler. When the event handler receives an event from a providers, the handler forwards it to the consumer [38]. The difference between EDA and SOA is that SOA is based on the "request/response" concept where the consumer of the service sends a request to the producer, and the producer sends a response that contains either the result or feedback. While EDA is based on the "publish/subscribe" concept where the communication pattern between the consumer and the provider is reversed. So in this architecture consumers do not start the communication channel, but they receive the events published by the event providers, which means that the communication is made in an unidirectional way [39].

The main interest of the EDA is to manage real-time process events and data in an efficient way. This message-driven architecture enables the introduction of a higher level

of event processing using the Complex Event Processing (CEP) engine. CEP is used to exploit and correlate large event streams generated by heterogeneous data sources in order to produce useful information.

### C. Event-Driven Business Process Management

Although, IoT is becoming the hot spot area of technological innovations and economic development promises for many industries and services, it still at its infant age, as we have seen previously. During the last years, both academic and industrial world have been interested in this field and its integration with other domains. However, there is still a lot of research work to do to propose methodologies, design models and architectures in order to ensure an efficient and smooth integration and bidirectional communication between IoT field and BPM. Dealing with event in BPM field is not recent. Event-Driven Business Process Management (EDBPM) concept represents an enhancement of Business Process Management, by including other concepts such as SOA (Service Oriented Architecture), EDA (Event Driven Architecture), SaaS (Software as a Service), BAM (Business Activity Monitoring) and CEP (Complex Event Processing) [40]. This concept was first used in 2003 in a white paper of Bruce Silver Associates in connection with the FileNet P8-BPM platform [41]. The idea behind EDBPM was limited to a single event processing, because the concept of CEP was not well known back then. So early applications of EDBPM was mainly focused on business process monitoring and on Key Performance Indicators (KPIs), or metrics measurement [42]. Despite the fact that the concept of CEP was used for the first time in 2002 by David Luckham in his book "the power of events" [43]. It was until 2007 that an integration of CEP in BPM field has been considered for the first time [44]. The integration of CEP technology within BPM is then known as EDBPM.

Recently, the EDBPM research area has been growing significantly again due to the omnipresence of IoT devices. We find applications that integrate IoT, CEP and (ED)BPM in several research area and business sectors such as Health-care, logistics, manufacturing, banking, smart cities/homes, cultural heritage, agriculture, etc. ([45], [46]). Hence the interest to propose an architecture that integrates all these technologies side by side, in order to achieve a proactive event/instance management.

### D. Integration BPM with IoT: Literature Overview

During the last years, both academic and industrial world have been interested in this field and its integration with other fields. However, there is still a lot of research work to do to propose methodologies, design models and architectures in order to ensure an efficient and smooth integration and bidirectional communication between IoT and BPM.

We discuss this related work from two perspectives. The first perspective is the impact of IoT on business process. The second one is the different problems and difficulties encountered when we try to integrate IoT and BPM.

1) *How IoT Can Impact Business Process?:* The alignment of IoT and BPM is the focus of several research works. However, this alignment comes with various challenges that

TABLE II. BUSINESS PROCESS RELATED LIMITATIONS, ADDRESSED VIA IOT INTEGRATION

BPM Limitations	BPM Life-cycle phases				References
	Process modeling	Process analysis	Process execution	Process monitoring	
Physical surrounding	X		X		[18] [47] [48]
Context-insensitivity			X		[47] [20] [49] [50] [51]
Data-input			X		[51] [16] [20] [47]
Models complexity	X		X		[51]
Transparency				X	[51]
Latency			X		[51]
Event-logs quality		X			[51] [52]
Context-awareness	X	X	X	X	[53] [54]
Knowledge feedback loop	X	X	X	X	[55] [56]

need to be tackled. Both technologies will affect and of course benefit from each other [19] [51]. However, in this paper, we focus only on the influence / benefit of IoT on BPM.

The integration of IoT can provide several benefits for BPM. Besides, it can also address some business process related limitations. Among these limitations we have:

- **Physical surrounding:** Business processes have no access (or limited access) to physical surrounding, as they operate in a cyber surrounding. Taking into consideration the physical surrounding at modeling phase can lead to correct resolution and execution of business processes [18] [47] [48].
- **Context-insensitivity:** Business processes are insensitive to context, they are considered as blind and stateless, which mean that in each business process execution we do not take into consideration neither the results from last process instances nor the context (a context-aware business processes execution). So they need to know the conditions and situations in which IoT operates, given that IoT is by default context sensitive through devices/sensors [47] [20] [49] [50] [51].
- **Data-input:** Business processes have no direct access to data generated by different devices and sensors. This data could be exploited to BP execution to progress via taking actions (e.g., IoT-based trigger events/alerts, IoT-based decisions...) [51] [16] [20] [47].
- **Models complexity:** Integrating IoT technology can reduce the complexity of process models (for example, replace elements or patterns, ...). It Can also extend and enrich process models. As a result, we have more precise process definitions that accurately reflect the operational reality [51].
- **Transparency:** Integrating IoT technology enhances business process monitoring by increasing BP transparency through data provided by IoT sensors [51].
- **Latency:** The incorporation of IoT technology can ultimately lead activity run time reduction and significant latency that can result in an overall performance enhancement [51].
- **Event-logs quality:** IoT sensors produce a huge amount of data that enrich process event logs. Given that event logs are the fuel of process mining technology enriched event logs provide enriched process models [51] [52].

Table (II) summarises and classifies these Business process related limitations according to the different phases of BPM life-Cycle.

2) *Problems Encountered in IoT/BPM Integration* : The integration of IoT with BPM certainly contributes to business process improvement. However, this integration comes with several issues and challenges. In [57], authors present the challenges that need to be addressed in Business Process Management Systems (BPMS) to achieve an efficient integration of IoT, such as the absence of direct interaction between the business layer and the edge network, or the problem of complex and inflexible business process models due to a lack of standardization and interoperability when modeling IoT elements and components in BPM. The unexploited potential of extracted data from sensing environment represents a challenging issue when integrating IoT with BPM [58]. Security and data privacy represent another level of IoT/BPM integration concerns [19]. Many other challenges exist and need to be tackled when dealing with an IoT and BPM integration and alignment, these challenges have been summarized by C.Janiesch et.al in their manifesto [19].

In this article, we focus mostly on the challenges linked to event processing and also learning aspect withing an IoT-BPM architecture. The next section details this proposed approach.

#### IV. PROPOSED APPROACH

Event-driven business process management is mainly adapted in organizations that have a real-time based activities which involved some sensors or some IoT devices that collect data and generate new events by sensing their environment [55]. However, a real-time system must have three main characteristics to ensure better functioning inside any organization [59]: 1) *High availability*, 2) *Low latency* and 3) *Horizontal scalability*. Those three characteristics are mandatory to achieve a real-time and efficient scheduling and event management in BPM.

So in order to ensure a (near) real-time priority-based business process instances management, we resort to an integration of four concepts: IoT (to sense the environment), CEP (to detect situations of interest since it is considered as the standard course for real-time analysis and situation detection [60]), Machine Learning (to analyse our data, find patterns in it and then make predictions, to facilitate decision making), and BPM (to manage our business processes). The idea behind this integrated quaternary of technologies (see Fig. 2) is: 1) to accompany data an event explosion resulting from IoT, 2) to

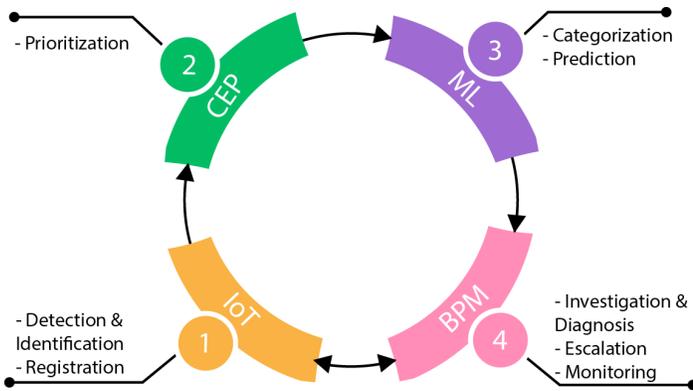

Fig. 2. Quaternity View of BPM, IoT, Machine Learning and CEP.

examine large data sets in order to uncover hidden patterns, unknown correlations between collected events, either at a very technical level (incident/anomaly detection, predictive maintenance) or at business level (customer preferences, market trends, revenue opportunities) 3) to capitalize business value from data generated by IoT sensors, 4) to provide improved operational efficiency, better customer service, competitive advantages over rival organizations.

To turn this conceptual integrated quaternity of technologies into a concrete reality, we propose an end-to-end IoT-BPM architecture (IoDEP: IoT-Data-Event-Process). This integration architecture follows Haze Architecture and Cascading Analytics [61], incarnated by a DIKW (Data Information Knowledge Wisdom) discovery pattern crossing the architecture from device then Fog/Edge to the cloud, and a learning feedback loop that feeds forward insight to adjust either Fog/Edge or device algorithms [55]. IoT-BPM integration involves bi-directional communication. It is possible to acquire data/event from sensors (e.g., monitor and control IoT devices) to manage business process instances and to send instructions to those devices (e.g., reset, adjustment or shut them down). One of the requirement of our proposed architecture is scalability without imposing an architecture redesign. That is the reason behind using Haze Architecture and Cascading architecture as it ensures fluidity and dynamism.

#### A. Research Design / Modeling Methodology

As we said previously, in order to handle the challenges faced by BPM when dealing with IoT objects, IoT and BPM need to meet in the middle. The Incorporation of two heavy paradigms such as IoT and BPM generates, with no doubt, a modeling methodology issue. This issue becomes more complicated when this integration involves other technologies (CEP and ML in this case). There are three types of modeling methodologies: - The Top-down approach, - The Bottom-up approach, - and the Meet-in-the-middle approach. We propose in this article a meet-in-the-middle approach, to facilitate the integration of IoT and BPM. In fact, The meet in the middle approach is considered as a method of refinement going alternately from top to bottom to bottom to top. The combination of deductive and inductive iterative sprints in this approach allows both re-use/mutualization and disruptive thinking. In this paper, we propose an integration of IoT and BPM via

an end-to-end architecture aiming to provide a meet-in-the-middle environment capable to capture data and event from IoT sensors, when they are sensing their environment, create actionable and useful knowledge, and allow this knowledge to be used in the business layer through business processes.

#### B. Functional Requirements

Business processes are supposed to be smoothly executed under different business situations and context. This constantly changing environment, requires having business processes that can easily be adapted to the appropriate action taken. However, without being coupled to other technology, business processes are still deficient regarding the critical ability to provide assistance to their users [62] due to a lack of two important aspect:

- **Context-awareness:** The emergence or even the omnipresence of IoT solutions in different businesses forces organizations to adapt their processes to a high level of connectivity. Context-awareness is a fundamental characteristic of ubiquitous computing [53], and it is the key to benefit from sensors collected raw data, as it allows to store contextual information related to these raw data and to decide which data should be processed, in order to facilitate the interpretation [54] especially at the level of business processes.
- **Knowledge feedback loop:** Traditional BPM systems present different limits, as they do not facilitate the use of knowledge extracted/generated from data by business processes after their execution. As a result, tremendous amount of data and event data that are constantly collected within the organization is not exploited to improve business processes. As a matter of fact, these data represent for enterprises a real engine of growth. However, a large amount of raw data is not valuable; data must go through a whole process to extract value from it [63]. The analysis of huge data helps organizations to extract information and then knowledge, because the real value is in how organizations will use that data and turn their organization into an information-centric company that relies on insights derived from data analyses for their decision-making.

To accompany data an events explosion resulting, among others, from IoT, data analytic processes combined with event processing techniques, examine large data sets to uncover hidden patterns, unknown correlations between collected events, either at a very technical level (incident/anomaly detection, predictive maintenance) or at business level (customer preferences, market trends, revenue opportunities) to provide improved operational efficiency, better customer service, competitive advantages over rival organizations. In order to capitalize business value of data and events generated by IoT sensors and business process execution, IoT and BPM need to meet in the middle, as we said previously. One critical use case for IoT is to warn organizations when a product or service is at risk. Early detection is essential to either remedy the issue before it becomes a real problem or quickly do cleanup when failure

hits<sup>2</sup>.

Supervision and incident management processes, especially in health-care domain, are considered as an event-driven business process. The instances of these processes are: In some cases, launched by IoT generated events ('Big' data push paradigm: i.e. data is triggering processes). In order to handle incident management in IoT-BPM architecture, Information Technology and Infrastructure Library (ITIL) repository has been considered. In fact, according to ITIL V3 [64], incident management processes are composed of the following functions:

- **Detection / Identification:** Detect the incident and identification of first elements of classification.
- **Registration:** Record basic details of the incident and propagate the incident alert as necessary.
- **Categorization:** Categorize incidents, Assign impact and urgency, and thereby define priority and match against known errors and problems.
- **Prioritization:** The incident is prioritized for better utilization of the resources and the Support Staff time
- **Investigation and Diagnosis:** Assess the incident details, Collect and analyse all related information, and resolve, (including any work around) or route to online support.
- **Escalation:** Escalate (functionally or hierarchically) where/when necessary.
- **Resolution and recovery:** Resolve the incident and take recovery actions.
- **Closure:** When the Incident has been resolved, the system should ensure that details of the action taken to resolve the incident are concise and readable, classification is complete and accurate according to root cause, resolution/action is achieved.

Beside incident management process, IoT-BPM Architecture integrates additional features to target highest IoT maturity levels. Among those features, we have:

- **Monitoring and Communication:** All information, metrics, and key performance indicators applicable to the incident are assessed, recorded and reported (time spent on the incident, support actors, date and time of closure, number and type of reoccurring incidents, average time to achieve incident resolution, percentage of incidents resolved at first line support that meet the Service Level Agreement, etc.).
- **Prediction:** Predicting an incident before happening, will enable anticipatory incident management. This may help avoiding the incident by actioning problem management, or at least, this moves the predicted incident resolution closer to the incident detection insuring proactive incident management. Thus, by collecting and combining connected devices/sensors data with historical context data, IoT-BPM Architecture could provide a wide variety of ad hoc, proactive and anticipatory incident, anomaly, and problem management.

Fig. 3 represents these functional requirements according to each layer of our proposed architecture.

## V. OVERVIEW OF THE LAYERED ARCHITECTURE

This section provides a high level overview about the different layers of our proposed IoDEP architecture.

Fig. 4 presents the layers of our architecture. In fact, the purpose of this layered architecture is to meet the requirements detailed in the previous section. Our proposed architecture requires five layers (see Fig. 4). IoT sensing layer or Edge Layer, IoT sensor data acquisition Layer, Detection, identification and registration Layer, Categorization and Prioritization Layer, and Cloud layer. In the following we will present a detailed explanation of each layer of this architecture.

### A. The Edge Layer

This layer concerns all IoT sensors and devices, each one of these have a precise role depending on their environment, location and the purpose behind using them, such

<sup>2</sup><https://www.informationweek.com/big-data-analytics/when-internet-of-things-meets-big-data>

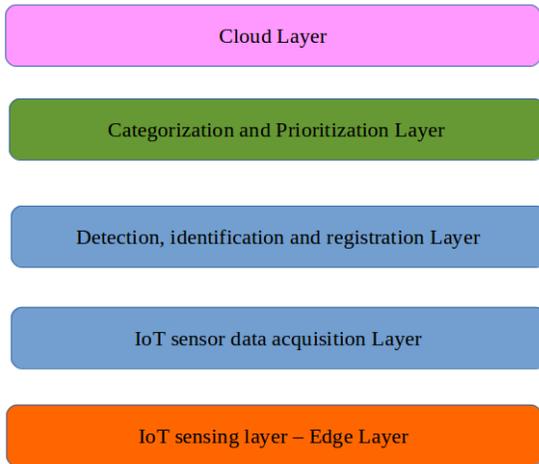

Fig. 4. The Architecture Layers.

as hospital, home, geriatric services, retail store, facilities. IoT devices collect data and generate new events by sensing their environment, after that those events could launch specific business process instances according to the particularities of the detected situation.

As we have seen before, early detection is essential to either remedy the issue before it becomes a real problem or quickly do cleanup when failure hits [65]. The time lapse between sensing the environment and sending a notification, a message or a signal is very critical. In fact, latency is one of the most challenging requirements for connected IoT devices. One of the most effective solution to reduce this lapse of time, is putting some computing on the device or at least bringing computing near the device (edge computing). Pushing data to the edge eliminates long-distance data transmissions to the cloud, which reduces network congestion and latency. Edge nodes are endowed with full detection capabilities. In fact, these nodes implements several advanced algorithms for image processing and interpretation ([66], [67]). However, this is out of scope of this paper. These algorithms allow the automatic detection and qualification of risky events, following these steps:

- **Image Qualification:** This step allows to qualify the captured image of the camera. Several types of errors are identified at this stage (Error of recovery of the image, Image of incorrect size ...).
- **Movement detection:** This step allows to identify the movements captured by the image, and then render the behaviors of these movements. Mathematical features are identified and extracted from the images and videos. Their exploitation allows to model the behaviors and the events.
- **Movement tracking:** This step consists of tracking objects in their attention zones. Tracking their evolution allows to recognize an abnormal event or behavior and to make a decision.
- **Decision:** At this step a decision about launching an alert or not is taking, based on the results of the

previous steps.

- **Pre-qualification:** This step is reinforced with the learning feed back loop [55], by learning from past decisions, mainly false alerts. This final step will consider and exploit the overall context to correct future risk assessments.

At the end of these steps, the detected alerts/events are sent to the cloud. Intercepted events are queued in order to be qualified by a human resource.

### B. The Fog Layer

When dealing with IoT devices and sensors, the cloud by itself cannot connect, process and analyze data from thousands and millions of objects and devices of different type and nature spread out over vast areas. To overcome this issue, Fog layer was introduced by Cisco in 2012, in order to offload the cloud through the injection of smart devices at the network layer to provide limited computational resources at the edge of the device layer [68]. Fog computing and edge computing seem similar since they both consist of bringing intelligence and processing closer to data creation. However, the location of the intelligence, processing and computing power is the key difference between these two layers. Generally, intelligence and computing power are placed in devices such as Smart Cameras with embedded vision software (used in our case study). While in the fog layer intelligence and computing facilities are placed at the local area network (LAN).

In our proposed architecture, the fog layer is dedicated to real-time stream processing with CEP as we can see in Fig. 6.

a) *Complex Event Processing - CEP:* An event is a record of an activity in a system [69] and it represents any change that occurs or will occur in this system, whereas a complex event is a set of events that are related to each other by aggregation, causality or time [70].

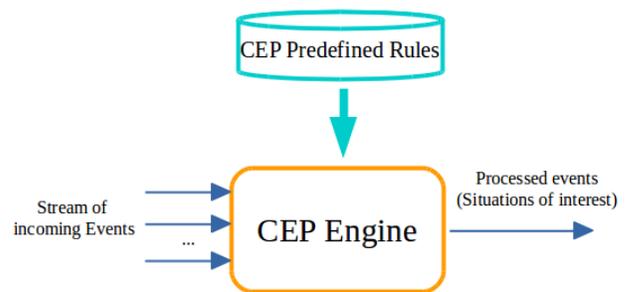

Fig. 5. CEP Basic Architecture.

Complex event processing is a widely used technology, it becomes an increasingly active research field [71] especially with the popularity of publish/subscribe systems in 1997 [72] as stated in [1]. Complex Event Processing (CEP) represents a set of methods, techniques, and tools for processing events while they occur [73]. It aims to process and analyze events generated from different sources in order to extract useful information [74]. CEP is widely used to detect and deal with different business anomalies, threats and opportunities [74] by analyzing event streams instead of traditional static data

stored in databases. CEP engines provide the scalability and the (near) real-time processing to filter, to combine and to extract actionable knowledge, known as situation of interest, from a stream of events (see Fig. 5).

Complex situation of interest can be easily expressed using CEP engines and rules. For example, in our case study, queries such as: *prioritize a case if the patient has some particular needs (Wheelchair, walker, etc.) or trigger an alert if the patient is a recidivist faller.*

The combination between CEP and BPM is not recent. In fact, it has been widely used to control and monitor business processes in real time in order to improve the effectiveness of business operations by keeping track of what is happening now and raising awareness of issues as soon as they can be detected [75]. CEP helps to monitor not only process instances and activities during run time, but also different events that are related to business process but not necessarily generated from the process instances [76]. Several approaches and solutions based on the integration of CEP with BPM have been proposed for run time or design time ([77], [78], [79]) just to name a few.

The starting point of this incident management approach is the real time analysis of the incoming generated events, using CEP engine to detect the events with the highest priority withing all the incoming ones, that will launch our business process different instances. And based on this estimated priority we can schedule those instances. In fact, the business process instances triggered by those events will then have the highest priority to be assigned to the available human resources. In order to process the incoming events and then detect meaningful patterns concerning the important situation of interest (which represent for us the events with the highest priority), CEP engine needs a set of rules that are determined in advance. A rule for us in this approach represents a condition (IF...THEN ...) that characterizes the event source (the different sources that generate each event). So in the processing step, whenever a condition is satisfied by the event, the priority of this event increases.

CEP strength relies basically on concept of rules and operators. CEP engines are mainly based on a set of rules provided by a rule engine. A rule engine represents a part of a CEP engine that generates rule models. These rules are used in order to create and/or modify business logic in a Business Process Management System (BPMS) [80] for example. CEP rules are based on CEP operators. Among these operators we have: *aggregation operators, sequencing operators, logic operators, single-item operators, windowing operators, and flow management operators.* Those rules are, in most of the time, manually predefined by domain experts, and after that implemented in CEP systems such as Esper, Siddhi, FlinkCEP<sup>3</sup>, or Oracle. Since defining these rules manually can be error prone and time consuming, there are many recent approaches that propose an automatic CEP rules learning and generation [1] [81] [74]. However, the automatic CEP rules learning and generation is out of the scope of this paper, because the main purpose of this paper it to pave the way for the use of CEP in order to achieve a real-time analysis of incoming events in order to detect situations of interest, about

the priority of the business process instances that need to be executed.

### C. The Cloud Layer

Both fog and edge computing are extensions of cloud networks. The majority of enterprises are already familiar with cloud since it is the de facto standard in most industries. The concept of "cloud" was used in several contexts in the 1990s, but only in 2006 when it became associated with offering services over the internet [82]. Cloud computing is "a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction." [83]. Cloud layer facilitates storing and accessing data and programs over the internet (as a service) rather than on servers of the enterprise as we can see in Fig. 6. In fact, it offers the ability to drastically outgrow an organization's normally available storage, without having to host any additional servers. In our IoDEP architecture, Data and intelligence are pushed through layers from edge to cloud in order to be analysed and processed. The knowledge produced goes through a learning feedback-loop that feeds forward insight to adjust either Fog/Edge or device algorithms. To produce this knowledge, we use machine learning algorithm. In the following, we introduce this technology and present in more details the algorithm used in our approach.

*a) Machine Learning:* Integrating IoT in a BPM environment generates several challenges, among these challenges, we have the huge amount of data and event data that are continuously gathered. Data and event data are the key to get a better understanding of the functioning of business processes. This data represent for enterprises a real engine of growth. However, a large amount of raw data is not valuable; data must go through a whole process to extract value from it. In fact, pre-processing and exploring data before using it help to get correct assumptions and insights in order to make correct predictions and finally take correct and accurate actions and decisions such as instances scheduling, resources management, or business process models redesign. The analysis of this huge generated data helps organizations to extract information and then knowledge, because the real value is in how organizations will use that data and turn their organization into an "information-centric company that relies on insights derived from data analyses for their decision-making"<sup>4</sup>. Hence integrating data analysis techniques, process mining, data mining, machine learning algorithms or even deep learning in each step of business process life cycle is very crucial for the process improvement. In our approach, we have chosen to exploit the machine learning algorithms in order to enhance one aspect of business process life-cycle, which is the instance management.

Machine learning is a branch of the artificial intelligence research domain. Using mathematical methods, Machine learning enables systems to learn from data and generate knowledge from experience. With time and more experience, the system can learn and improve and sharpen a model that can be used to predict outcomes of questions using previous learning

<sup>3</sup><https://nightlies.apache.org/flink/flink-docs-release-1.14/docs/libs/cep/>

<sup>4</sup><https://datafloq.com/read/3vs-sufficient-describe-big-data/>

[84]. Machine learning algorithms are organized into different categories based on the learning type: supervised learning, unsupervised learning, semi-supervised learning, Reinforcement learning, and Transduction learning. Supervised learning and unsupervised learning algorithms are the most used in real world problems. They can be further grouped into different categories that we can find in real world machine learning problems. However, the choice of the appropriate algorithm depends on your case study, the type of data manipulated, and the purpose of your analysis.

The first step of our approach aims to ensure an efficient acquisition, filtering, and analyzing incident/event data generated by IoT devices. The second step consists on scoring the generated events from IoT devices, based on the result of the first step, using unsupervised machine learning algorithm. We opted for clustering algorithms to discover groups in our dataset, in order to achieve a categorization of the event sources that trigger our process instances. We choose K-means clustering algorithms, which is a partitioning technique used to analyse data based on the distance between different data points in the input dataset. This algorithm was described by Hartigan in 1975. The idea behind K-means algorithm is to divide a dataset composed of  $M$  data points in  $N$  dimensions into  $K$  clusters, in such a way that the within-clusters sum of squares is minimized [85]. The most complicated part of this algorithm is the determination of the right value of  $K$  which represents the number of clusters. In the literature, we can find several methods for selecting the most optimal number of clusters for this algorithm such as: The Elbow method [86]: The Average Silhouette method [87], or the GAP statistic method [88]. When applying K-means algorithm in our approach, we have used the Elbow method to determine the value of  $K$ . The basic steps of K-means algorithm are shown in the following pseudo-code:

---

**Algorithm 1** K-Means Clustering Algorithm

---

**Input:**

$S = s_1, s_2, \dots, s_m$  // list of data points (list of sources which generate the different events)

$K$  // Number of clusters

- 1: choose  $K$  Random data points from  $S$  as initial clusters centroids
- 2: **repeat**
- 3: Assign each data point  $s_i$  to the cluster which has the closest centroids.
- 4: Calculate the new centroids of each cluster.
- 5: **until** Convergence //no more changes for centroids

**Output:** Set of  $K$  clusters

---

We tested several criteria such as the frequency of falls or total number of falls, in order to have the most representative clustering for our data. We apply K-means algorithm on a set of events sources in order to classify those sources on different clusters using a score that we calculate for each event's source (a patient in our case) based on the frequency of previously generated events and their criticality value given previously by the agents (human resources) in the qualification step.

## VI. OVERVIEW OF THE FRONT-END AND BACK-END OF THE ARCHITECTURE

From a front-end and back-end perspective, our architecture can be seen as follows (see Fig. 3):

The IoDEP Front-end architecture is composed of two parts:

- **Connected Device/Sensor Processing and Analytics:** insure acquisition of incident data, and incident data filtering and Simple classifier.
- **Fog/Edge Processing and Analytics:** insure the following functionalities:
  - 1) **incident data processing:** Detection of anomaly incident.
  - 2) **incident data analytics:** Pattern recognition/correlation/scoring (advanced supervised time-based analysis algorithms here need smaller training set but may need more performance resources like GPU).
  - 3) **incident data routing:** Transmission of the anomaly information through an Edge Spooler.

The IoDEP Architecture Back-End is represented by several components insuring cloud side processing and analytic of incident management:

- **Cloud Data Processing and Analytics:** Ensure the following functionalities:
  - 1) **incident data routing:** Transmission of the anomaly information to the relevant back end processing and analytics system – ESB/CEP.
  - 2) **incident data analytics and intelligence:** Extraction, cleaning and annotation, Integration, aggregation and representation, Modelling and analysis Pattern recognition/correlation/scoring (more sophisticated supervised machine learning algorithms (e.g. deep learning) may here need big training sets) (Big Data).
  - 3) **incident data processing:** Anomaly Human Processes (Human qualification of the anomaly information) and Enterprise Business Processes (BPMS based on Big Data analytics), and Interpretation: Through on Reporting incident KPI Scoreboards based on (Data Warehousing and Data visualisation).

## VII. APPLICATION ARCHITECTURE OVERVIEW

In this section, we present a concrete application of our architecture (see Fig. 6). The content of the Edge layer can differ from one case study to another. For our case study, IoT devices were represented by smart cameras that detect the falls of patients. In other context, these devices and sensors could be either Smart locks, Fire and smoke alarms, or smart wristband, etc.

Our Fog layer represents the real-time stream processing layer using CEP technologies. We propose the use of Apache Flink framework as it facilitates complex event processing

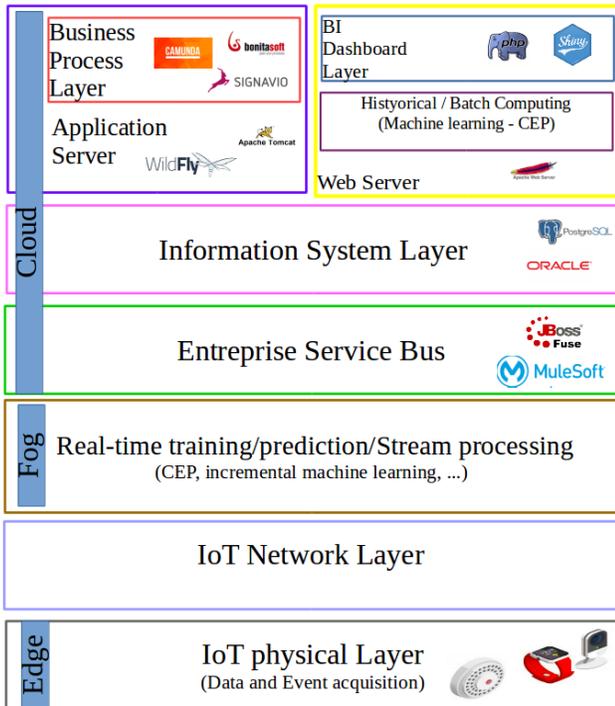

Fig. 6. IoDEP Applicative Architecture.

for real time analysis. Our choice is based on the benchmark that we have conducted. The Enterprise Service Bus layer represents a message broker. It is an integration solution implementing a totally distributed architecture where the applications or services to be integrated are distributed on different machines or information systems, and its role is to ensure communication and interoperability between these different applications whatever their communication protocols. ESB is mostly adapted to asynchronous communications, publish/subscribe messaging, and message queues. Solutions such as Mule ESB, PÉtALS, JBoss ESB, Glassfish ESB, or Apache Camel, could be used in this architecture. Historical data in our architecture are stored in a PostgreSQL database. However other Data Base Management System (DBMS) can be used. For the Business Process Layer, several Business Process management Systems can be used such as Bonitasoft<sup>5</sup> (that we have used in our case), Signavio, or Camunda. As an application server, solutions such as Apache Tomcat, or WildFly can be used in this architecture. As a web server to distribute web content, examples such as Apache web Server, can be integrated in this architecture. And finally, for communicating results a BI Dashboard layer, interactive Dashboards can be build using PHP, or Shiny R package given that we have used R language in our experiments.

### VIII. EXPERIMENTS AND RESULTS

We opted for a block validation in order to conduct an initial validation of the efficiency of our IoEDP architecture.

#### Experimental settings:

We worked with a dataset of patients falls (from 01-02-2016 to 12-06-2017), this dataset contains 238228 observations generated by 81 patients. The historical data in this dataset are gathered from our incident management process past instances, and they are partitioned as follows: 89312 alerts are of level 0 (low), 148466 of level 1 (average), 275 of level 2 (serious) and 175 of level 3 (very serious). Since that the serious and very serious alerts are the most important in our study, we have applied our clustering algorithms on these two levels only.

The dataset was stored in a PostgreSQL database and all analyses and algorithms implementation were conducted using R and different R packages<sup>6</sup>, such as: (tidyverse, RPostgreSQL, ggplot2, dplyr, caret, ...). And All our experiments were conducted on an Intel(R) Core(TM) i5- 540M2.53GHz. All data have been anonymized.

#### Experimental results for K-means:

As we have seen before, to determine the value of  $K$ , which represents the number of clusters, we have used the Elbow method (see Fig. 7).

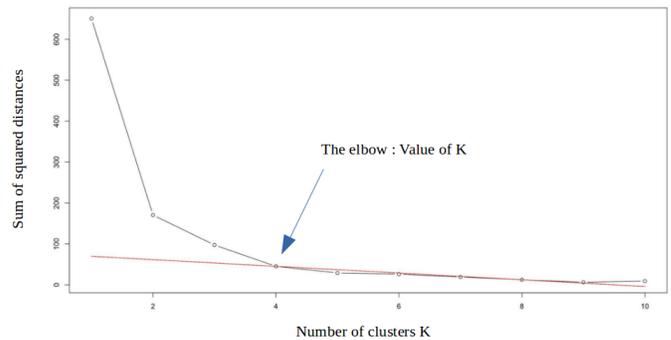

Fig. 7. Elbow Method - Sum of Squared Distances.

The plot represents the variation of the sum of squares with the number of classes. We notice that the most adequate number of clusters would be 4, since this point corresponds to an inflection point and the sum of squares seems to stabilize from this point on.

As we can see in Fig. 8, patients used in this clustering are divided into 4 clusters: patients with fewer than 8 falls (the blue cluster), 9 to 12 (the green cluster), 13 to 18 (the red cluster) and more than 24 falls (the black cluster). These latter represent the most critical cases. As we have seen before, The clustering algorithm helps us to categorize our event sources. In the following we will present some experimental results that proves the interest of integrating CEP into the IoDEP architecture, in order to manage the event that will trigger the process instances.

#### Experimental results for CEP integration:

The purpose of this series of experiments is to show the interest of integrating CEP in the IoT-BPM architecture. So we will compare two solutions. *Solution 1* represents incident management in our architecture without the integration of CEP, and *Solution 2* represents the integration of CEP in the architecture.

<sup>5</sup><https://fr.bonitasoft.com/>

<sup>6</sup><https://www.tidyverse.org/>

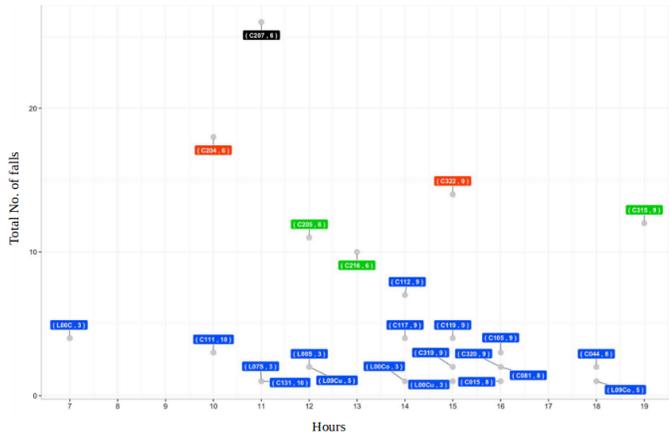

Fig. 8. Clustering with K-means.

**CEP Rules:**

Based on the context of our case study, we have defined some rules that help us to estimate the priority level of the incoming event. To define those rules we take into consideration the available information about the patient, his/her past incidents (falls) and the cluster to which this patient (event source) belongs. Taking into consideration the results of our clustering (detailed in the beginning of this section), we tried to manually define some rules. So basically we come up with the following rules:

- **IF** the event source belongs to cluster 4 (the critical cluster) **THEN** the new event generated by this source might be serious.
- **IF** The patient has some particular needs (Wheelchair, walker, etc.) **THEN** the new event generated by this source might be serious.
- **IF** The last event generated by this patient within one month was a serious or very serious alert **THEN** the new event generated by this source might be serious.

**CEP Message broker:**

As we have seen before, in order to manage the different incoming events within a CEP solution, we need a message broker. In this experiment, we have chosen RabbitMQ<sup>7</sup>. It is an open source message broker, lightweight and easy to deploy.

**Global Schema of Event-pattern detection with CEP solution:**

Fig. 9 illustrates our first attempt to integrate CEP engine in our IoT-BPM architecture.

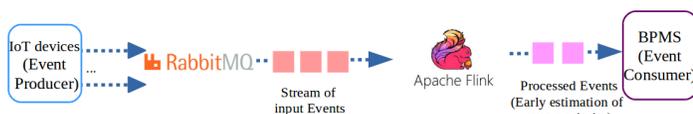

Fig. 9. Priority-based Event Management with CEP.

The different modules of this architecture operate as follows:

- **Event Producer:** Events in this approach are mostly generated by some sensors or some IoT devices by sensing their environment (Smart cameras).
- **Lightweight Message Broker:** To manage the amounts of events received and that need to be processed by the CEP engine, we use a message broker that ensure the communication between the source and the target based on a publish/subscribe mechanism. This asynchronous mechanism implemented by message brokers allows source and target messages to be completely decoupled. Besides the message brokers can as well store the messages locally until they can be processed by the target element. That is why we have chosen RabbitMQ.
- **CEP engine:** Flink CEP is used in this case to filter and process incoming events based on the predefined rules, in order to detect the events with highest priority among the incoming stream of events.
- **Event consumer:** It represents in this approach a business process management system (BPMS) where the processes are managed, executed and monitored.

In our experiment for both solutions, we have simulated several event streams with different total number of events (100, 200, 300, 400, 500) (generated from the historical events in our data set). Our objective is to compare the evolution of the computation time of both solutions (as described in the following tables) as a response to increasing the number of input events (non-concurrent access (see Table III and Table IV) and concurrent access (see Table V and Table VI)). Besides, in both solutions we have used the results of the clustering step.

**Non-Concurrent Access (NCA):**

TABLE III. COMPUTATION TIME (SEC) FOR SOLUTION 1 - NCA

Total event number	Computation time (sec) - Solution 1
100	19.0
200	19.45
300	25.48
400	31.3
500	37.4

TABLE IV. COMPUTATION TIME (SEC) FOR SOLUTION 2 - NCA

Total event number	Computation time (sec) - Solution 2
100	22.07
200	32.14
300	44.25
400	55.6
500	70.62

**Concurrent Access (CA) :**

As we can see in Fig. 10, solution 1 presents better results comparing to solution 2 when we have a non-concurrent access of the incoming events. However, when we have a concurrent access, the CEP-based approach (solution 2) presents better results, especially when we increase the number of incoming events (see Fig. 11).

<sup>7</sup><https://www.rabbitmq.com/>

TABLE V. COMPUTATION TIME (SEC) FOR SOLUTION 1 - CA

Total event number	Computation time (sec) - Solution 1
200	48
400	72.1
600	108

TABLE VI. COMPUTATION TIME (SEC) FOR SOLUTION 2 - CA

Total event number	Computation time (sec) - Solution 2
200	27
400	34
600	60.3

Although solution 1 seems to be more efficient at low input events volumes, the CEP solution can perform better especially if implemented in an effective IoT architecture with 'Big' Data requirements.

For incident management systems providing a balance between (near) real-time event processing and scalability, it is very important to achieve an efficient and optimized business process instances scheduling and event management in BPM. Moreover, in real cases, we deal in most of the time with concurrent access of incoming events. So this confirms the efficiency of our assumptions that CEP can provide better results when integrated to an IoT-BPM architecture, and it can also provide better results comparing to traditional approaches for business process instances scheduling. Those initial results are encouraging to implement the entire end-to-end IoDEP architecture.

Interested readers can check the complete solution that we have implemented from GitHub<sup>8</sup>.

### IX. CONCLUSIONS AND PERSPECTIVES

Integrating IoT and BPM as a step towards an improved process management that benefits from data and event power, is possible via an integrated architecture (IoDEP). The idea behind this architecture is to manage data and events at the same time via an integration approach that includes four concepts: IoT (to sense the environment), CEP (to detect situations of interest since it is considered as the standard course for real-time analysis and situation detection), Machine Learning (to analyse our data, find patterns in it and then make predictions, to facilitate decision making), and BPM (to manage our business processes instances).

We introduced in this article the reason behind using machine learning algorithms and CEP techniques in our IoT-BPM communication approach. In fact, this bi-directional communication is established through event in one direction and data in another direction. That is why conducting a data analysis approach with event management can facilitate this communication/integration. Moreover, we have presented the different functionalities proposed by this architecture and also the different requirements that should be addressed. Throughout the different overviews of our proposed architecture, we argue that our approach is generic and can be used in multivariate settings, and most importantly in normal and strict environments where time and priority matter.

<sup>8</sup>[https://github.com/Abir-IA/CEPFlink\\_EventManagement](https://github.com/Abir-IA/CEPFlink_EventManagement)

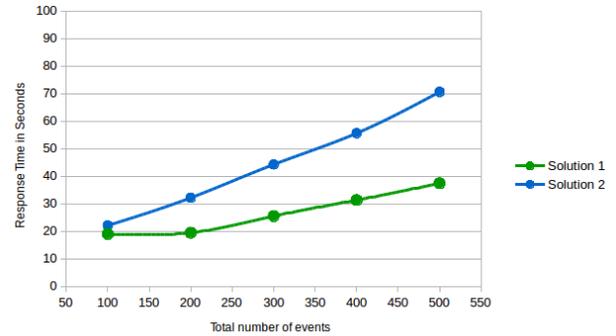

Fig. 10. Input Events with Non-concurrent Access.

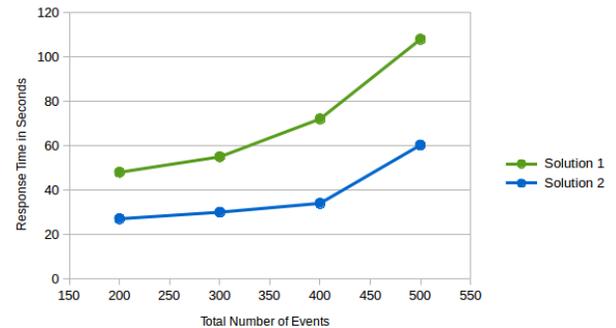

Fig. 11. Input Events with Concurrent Access.

Fully implementing this architecture, extending to test more machine learning algorithms, and exploring the automatic CEP rules learning in order to enrich the business rules engine for proactive event processing and process instances execution, are all plans to realize on our future schedule.

# Route Planning using Wireless Sensor Network for Garbage Collection in COVID-19 Pandemic

Javier E. Ramirez, Caleb M. Santiago, Angelica Kamiyama  
Systems Engineering Department,  
University of Lima, Lima 15023, Peru

**Abstract**—Garbage collection is a responsibility faced by all cities and, if not properly carried out, can generate greater costs or sanitary problems. Considering the sanitary situation due to the COVID-19 pandemic, it is necessary to take sanitary safety measures to prevent its spread. The challenge of the present work is to provide an efficient and effective solution that guarantees a garbage collection that optimizes the use of resources and prioritizes the attention to garbage containers located in or near contagion risk zones. To this end, this research proposes the integration of a basic garbage monitoring system, consisting of a wireless sensor network, and a route planning system that implements the decomposition of the Vehicle Routing problem into the subproblems of clustering and sequencing of containers using the K-Means and Ant Colony algorithms. For the monitoring of garbage, a significant reduction in the measurement error of waste level in the containers was achieved compared to other authors. About route planning, adequate error ranges were obtained in the calculation of the optimal values of distance traveled and travel time indicators with respect to an exhaustive enumeration of routes.

**Keywords**—K-Means; ant colony optimization; route planning; vehicle routing problem; garbage collection; wireless sensor network

## I. INTRODUCTION

Garbage collection is one of the most complex tasks of urban governments. Often, this task requires that collection vehicles travel along a specific route and manually check all the garbage containers along that route to empty them if necessary. The selection of routes followed by the vehicles is usually done at the discretion of the drivers which causes inefficient use of resources [1]. In general, there is no permanent monitoring of the containers to alert them about their possible overflow to avoid potential sanitation problems. In Peru, on average more than seven million tons of garbage are generated annually, of which about 50% comes from the capital city [2]. In addition, the city of Lima is ranked seventh with the highest traffic congestion worldwide [3]. Since March 2020, Peru has been in a state of health emergency due to the COVID-19 pandemic whose infection and mortality rates, as of January 2022, were 11.64% with respect to the number of tests and 7.22% with respect to the level of infected people in the whole country, respectively. Metropolitan Lima has a case fatality rate of 6.89% with respect to the number of people infected by coronavirus nationwide [4]. Waste collection costs in Peru are close to one billion soles annually, in addition to the work of thousands of operators, and the employment of hundreds of fleets of vehicles [5]. It is important to have an efficient waste collection service capable of dealing with the current health situation. Otherwise, the inefficient use of

resources by the municipalities will continue, as well as the increase in the contagion and mortality rate due to the spread of the pandemic. This article presents a solution to the problem of optimizing the garbage collection, considering not only the associated costs but also the impact on public health; it will focus on minimizing collection costs, but at the same time guaranteeing timely attention to the containers by not allowing them to overflow. In this way, by saving collection costs, more resources can be allocated to other municipal processes, meanwhile contributing to the containment of the pandemic and additionally having a positive impact on the environment. It will be assumed that the containers belong to the municipality and it is possible to insert wireless sensors in the containers. This solution includes two systems, the first is a basic monitoring system composed of a network of wireless sensors to detect the volume and level of decomposition of garbage in the containers, with which it will be possible to alert about the imminent overflow of the containers. This monitoring system feeds into a route planning system that uses a heuristic approach to determine the optimal routes for the collection trucks, i.e. the most economical routes. In this solution, preferential attention will be given to containers located in contagion risk zones<sup>1</sup> as follows: for the contents of a container to be emptied, its contents must exceed a certain threshold; for containers located in an contagion risk zone or close to one, this threshold is lower. In section two, related work is reviewed. In section three, the solution methodology is explained. The results and discussion are presented in sections four and five, respectively. In the last sections, conclusions are formulated and future work is proposed.

## II. RELATED WORK

### A. Waste Monitoring Sensors

An efficient garbage collection process requires knowing the current status of the garbage containers, which can be achieved through the use of different sensors and image processing methods, for which it is necessary to take into account the measurement range, accuracy, sensitivity, consistency, energy consumption, ease, and cost of the device [8]. Several solutions for this process use different sensors such as infrared [9] or ultrasound (HC-SR04) to determine the amount of stored waste, load cells to calculate the weight of the container [10], humidity sensors (DHT11), temperature sensors (LM35) for detecting the presence of fire [11], gas sensors (QS-01) for air quality monitoring [12], and tilt sensors (Itead) to detect possible container overturning. Among these reviewed works,

<sup>1</sup>A contagion risk zone refers to an area facing a health emergency and having a high rate of population density and/or mobility over time [6], [7].

several issues are reported that impact on the quality of the information, such as the angle of measurement and the position of the sensors inside the container, this issue can be solved by using high cost devices to reduce the percentage error in the measurement; therefore, a horizontal measurement is proposed to reduce the percentage error in the measurement through the use of low cost sensors, the mentioned served as motivation to seek to address these challenges evidenced in the research of other authors. Container status information needs to be sent and stored in a database for further analysis and monitoring. There are multiple data transmission techniques, e.g. the use of the Ethernet SPI module via network cable [13], as well as low-power communication technologies such as LoRa, which provides a long transmission range over long distances [14], and ZigBee, which improves data transfer speed [12]. However, these solutions generate a bottleneck by centralizing the sending of information. Another solution is a GSM transmission sensor, which allows data to be sent via SMS to a telephone number [9]. Finally, the NodeMCU device with a built-in Wi-Fi module allows each node of the sensor network to operate independently in data transmission [15]. Container status information can be used in the design of collection truck routes.

## B. Route Optimization

The determination of adequate garbage collection routes is crucial for efficient service. This is a combinatorial optimization problem known as the Vehicle Routing Problem (VRP); it is an extension of the classical traveling salesman problem, where multiple vehicles travel through a network, starting from and returning to an origin. Its objective is to find optimal routes for multiple vehicles visiting a set of locations [16]. The VRP is a difficult problem to solve exactly, but it can also be solved with approximate methods [17]. The exact method guarantees the computation of an optimal solution but can be computationally inefficient with large numbers of nodes to visit, while the approximate method can provide a good quality solution in a reasonable time, independent of the number of nodes [18]. Route planning can be approached with the mathematical programming method whose objective is to maximize or minimize an outcome by choosing the values of real or integer decision variables [1]. For example, [19] developed a mixed-integer linear programming model that integrates a continuous perspective, using formulas to provide asymptotic estimates of routing costs, with a discrete perspective, through an iterative stochastic approximation procedure. To solve capacitated vehicle routing problems, when vehicles do not necessarily return to the starting point at the end of their trip, a model was proposed through the use of LINGO and the Branch and Bound technique to obtain the optimal routing [20]. Regarding approximate methods, [21] propose an approach based on NSGA-III, a multi-objective evolutionary algorithm taking into consideration indicators such as distance, travel time, and the number of traffic lights, to find multiple solutions to different levels of traffic congestion. Likewise, [22] seeks to address the problems related to the adequate provision of garbage collection services, through the use of a heuristic model based on the Pagerank web ranking algorithm, which is complemented by the application of constructive heuristics to the entire system. Meanwhile [23] apply the Ant Colony Algorithm (ACO) adapted to a set of routes to search for

those that consume the least amount of energy, in addition to a Pareto solution that is deployed to find the optimized route in terms of energy and distance. On the other hand, [24] proposes a hybrid metaheuristic algorithm called GACO that adopts the path construction procedure of the ACO algorithm and incorporates the crossover and mutation operations used in the genetic algorithm to improve the local and global search for the solution. Some authors employ the strategy of decomposing the routing problem into two subproblems, the grouping of nodes into clusters or groups and the sequencing of nodes in each cluster. For example, [16] uses the Modified Capacity K-Means algorithms to group the new garbage cans concerning their distance and demand, and Variable Neighborhood Search to reorder the collection sequence of the garbage cans. In his work [25] uses the K-Means algorithm to group the garbage cans to form small clusters and the ACO algorithm to calculate the sequencing of the garbage cans in each cluster.

1) *Clustering Problem: K-Means Algorithm:* The clustering problem consists of gathering objects into groups or clusters according to some measure of similarity so that objects must be homogeneous within a group and heterogeneous in other groups [26]. Clustering techniques are used in various disciplines such as software engineering, statistics, data mining, image analysis, machine learning, web clustering engines, and text mining [27]. Among these techniques is the K-Means algorithm, which is widely used as an unsupervised learning technique [28]. This technique starts with the random selection of several centroids, where the centroid is defined as a point equidistant from the objects that belong to that group, each object is assigned to the nearest centroid, then the centroid in each group is recalculated as well as the distances of the objects to the new centroids, and new centroids are assigned again until the function  $F$ , called inertia, shown in the following expression, stabilizes [27], [29].

$$F = \sum_{k=1}^K \sum_{i \in C_k} \|x_i - m_k\|^2 \quad (1)$$

Notation:

- $K$ : Number of groups.
- $C_k$ : Partitioning of group  $k$  (set of objects that compose it).
- $x_i$ : Object data  $i$  for partition  $C_k$ .
- $m_k$ : Centroid of group  $k$ .

One method to compute the number of groups to be formed is the Elbow method, which evaluates the inertia shown in expression (1) so that, if you add another group, the inertia does not improve significantly [30]. Researcher in [31] argue that the choice of the number of groups will be determined at the point of highest curvature after multiple iterations.

2) *Sequencing Problem: Ant Colony Optimization:* Metaheuristics are defined as an iterative process that guides heuristics to explore and exploit the search space, are not specific to a particular problem, and can be applied to a wide variety of optimization problems [18]. Among these techniques is the Ant Colony Method (ACO), which is a development paradigm used to solve optimization problems, inspired by the behavior of the ant colony [17], [32]: to reach the food source, ants

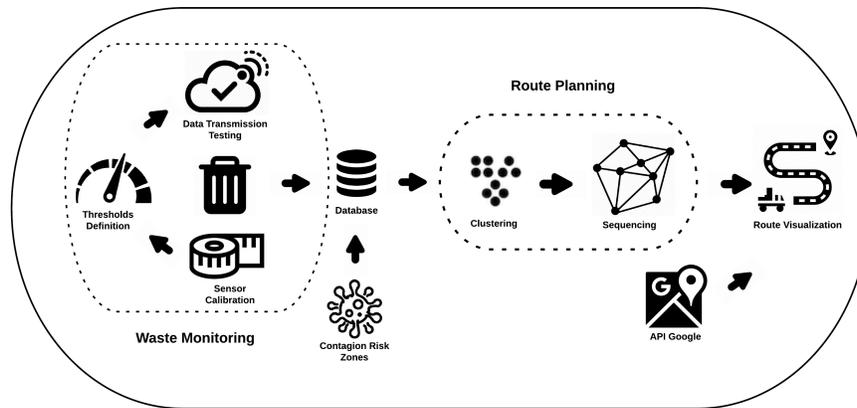

Fig. 1. Solution Diagram.

are guided by pheromone information, which is a substance that ants leave on the path as they pass through it, with ants preferring to follow the paths with the highest amount of pheromones. Artificial ants start at nodes chosen according to some initialization rule. Each ant incrementally builds a path by applying a state transition rule [33]. For this path to be visited by more ants, the local pheromone update rule is applied each time an ant crosses an arc in which, a pheromone level is calculated based on the total number of nodes and the visibility to the nearest node which are affected by a decay parameter will be added. Finally, when the ants complete their path, the global pheromone update rule is applied, this change is only performed on the best of the constructed paths. Since the Routing Problem can be solved with exact methods or with approximate methods, many authors have compared both types of methods in terms of computational efficiency. In [34], an exact solution method using the LINGO software and the Clark & Wright metaheuristic algorithm were compared, registering a processing time of 611 hours and 0.14 seconds respectively, which shows the higher computational efficiency of the latter. In the same way, [35] performed a comparison between the results obtained by applying exact methods using the LINGO program and the Simulated Annealing algorithm where vehicles must reach a customer before their competitors. For large instances, the former was not able to obtain an optimal solution in a reasonable time, while the latter achieved a quality result in an acceptable processing time. On the other hand, in [33], to minimize resources and provide efficient management of the garbage collection process focused on a vehicle routing problem with stochastic demand, a solution based on ant colony optimization was implemented and compared with the simulated annealing algorithm under different values of vehicle capacity. The results indicated that the former showed better performance for all ranges and sizes of the problem, and even has an additional advantage over the latter and the genetic algorithm because it can adapt the model to parameter changes in real-time. In this literature review, no published papers have been found that report solutions to the garbage collection problem that combine the advantages of sensors to monitor the containers and the effectiveness of existing methods that solve the vehicle routing problem. In this paper, a solution with such characteristics is proposed and will be described in the next section.

### III. METHODOLOGY

As explained in the previous section, this work proposes the implementation of a network of sensors that record and transfer the information from the containers through wireless links to a digital repository. This network would consist of low cost and ease of use ultrasound sensors for waste monitoring to measure the level of waste, as well as gas sensors to identify those containers with a higher level of biodegradable waste; for data transmission, the NodeMCU device was selected to work with each container independently to avoid bottlenecks, which ensures greater availability of the monitoring system. For route planning, the use of approximate methods was chosen, through a decomposition scheme and making use of the K-means algorithm and the Ant Colony algorithm to obtain adequate solutions in an acceptable processing time. Fig. 1 shows the outline of the solution to the problem of the garbage collection consisting of two components, Waste Monitoring, and Route Planning. Therefore, the framework is composed of two stages, the first one corresponds to the implementation of the smart container, that is, the container provided with ultrasound and gas sensors that allow monitoring of the volume and CO<sub>2</sub> concentration of the waste inside. This implementation involves sensor calibration, the definition of thresholds, and data transmission tests. The information obtained by the wireless sensor network, the location of the waste bins, and contagion risk zone will be stored in a database for later use. In the second stage, the Route Planner is implemented using a heuristic approach that decomposes the vehicle routing problem into the subproblems of container clustering and container sequencing. For clustering, the Elbow method and the K-Means algorithm will be used to obtain the appropriate number of container clusters and their distribution, respectively. On the other hand, sequencing will be implemented using the Ant Colony algorithm. Finally, the routes will be visualized on a map using Google Maps API Directions application.

#### A. Waste Monitoring

To obtain quality data, it is necessary to calibrate the sensors. To do this, the values obtained by the devices must be sampled, then the least-squares method is applied to obtain the linear relationship between the values provided by the sensors and the real values, obtaining the coefficients to calculate the

waste and CO2 levels. Thresholds must be defined to identify the containers to be collected. In the works reviewed, the so-called vertical measurement is used in which a waste level sensor is used; in this work, the horizontal measurement of the waste level will be carried out by inserting four waste level sensors which will be placed horizontally inside the container and, depending on the dimensions of the container, the low, medium and high thresholds will be defined. For the contents of a container to be emptied, it must exceed the high threshold, but if the container is in an contagion risk zone or sufficiently close to an area at risk, it will be sufficient for it to exceed the medium threshold. On the other hand, for the gas sensor, taking into account the CO2 concentration standards in the air, a value between 250 and 400 particles per million (ppm) represents adequate air quality. Values between 400 and 1000 ppm define a reduction in air quality being able to perceive unpleasant odors and possible discomfort. And a value higher than 1000 ppm represents a critical state capable of generating serious problems in air quality and serious diseases in the locations where it is perceived [36]. Therefore, the threshold for CO2 concentration is 1000 ppm, i.e., any container exceeding this threshold will be emptied. Finally, to send data, a series of tests must be performed to confirm the transmission of information from the NodeMCU device to a database through a wireless connection to the Internet, to effectively analyze and monitor the status of the garbage containers.

### B. Route Planning

1) *Clustering*: Previously, based on the data obtained by the Waste Monitoring system, the containers that will be identified will be emptied; a container will be attended only if its content exceeds at least one of the established thresholds. Subsequently, the K-Means algorithm will be applied to group these containers to be served in  $K$  clusters, based on the distances between them. The algorithm is as follows:

- 1) Randomly select  $K$  centroids
- 2) Repeat while there are new centroid assignments
  - a) Repeat for each node
    - i) Find the nearest centroid
    - ii) Assign the node to the cluster of that centroid
  - End repeat
  - b) Repeat for each cluster  $k \leftarrow 1$  to  $K$ 
    - i) New centroid  $\leftarrow$  "Average of the elements assigned to the cluster"
  - End repeat
- End repeat

2) *Sequencing*: After grouping the containers, the routes or sequences of attention of the containers in each of the groups or clusters will be defined using the Ant Colony metaheuristic. The corresponding algorithm to build a route for each cluster is shown below [37].

- 1) Initialize parameters and pheromone level in each arc
- 2) Repeat while the iteration limit is not exceeded
  - a) Repeat until each ant has built a solution
    - i) Repeat for each ant  $k$ 
      - A) Choose the next node by applying the state transition rule

- B) Apply local pheromone update rule
- End repeat
- End repeat
- b) Update the best solution
- c) Apply global pheromone update rule
- End repeat

In this algorithm, during the construction of a route, the ant  $k$  currently positioned at node  $i$ , moves to a node  $n$  according to the following state transition rule: A random variable  $q$  between 0 and 1 is evaluated, and if  $q > q_0$  then it is chosen to the next node  $n$ , through a biased scan of the arcs, based on expression (2), otherwise, a probabilistic random proportional rule is applied that uses the best weight, product of the pheromone level and the visibility in the arc, to move to a next node  $n$ , provided that it belongs to  $N_i^k$ , described in expression (3) [28].

$$p_{in}^k = \frac{(\tau_{in})^\alpha * (\eta_{in})^\beta}{\sum_{l \in N_i^k} (\tau_{il})^\alpha * (\eta_{il})^\beta} \quad (2)$$

$$n = \arg \max_{j \in N_i^k} \{(\tau_{ij}) * (\eta_{ij})^\beta\} \quad (3)$$

Notation:

- $\tau_{in}$ , represents the level of pheromones in the arc  $(i, n)$ .
- $\eta_{in}$ , represents visibility (inverse of distance/cost) in the arc  $(i, n)$ .
- $N_i^k$ , represents the list of previously unvisited nodes that the ant  $k$ , positioned at node  $i$ , can access.

## IV. RESULTS

The San Borja district of the city of Lima was selected as a test case for the experimentation since it had 74 underground containers, which are suitable for inserting the monitoring sensors since they are not exposed to the environment or the public [38]. However, due to the impossibility of experimenting with real containers, due to the health situation of the pandemic, a dataset (waste level) of 32 containers, generated by an Australian government project and applied to Wyndham City Council, was used [39]. Therefore, 32 of the 74 containers in the district of San Borja were randomly selected and assigned the data from the dataset. As for the contagion risk zones the "Peru en tus Manos" application was used to determine the exact locations with confirmed cases of COVID-19. Using the Google Maps API Distance Matrix application, the distances between the containers and between the areas at risk of infection and the containers were obtained.

### A. Smart Container

1) *Waste Level Sensor*: First, an algorithm was developed to calculate the distance between the objects and the ultrasonic sensor, a cylindrical test container, 34 cm high and 20 cm in diameter, was experimented with, and a sample of 84 values measured both real and by the sensor was taken, as shown in Fig. 2 the relationship between these values is approximately a linear function ( $y = a * x + b$ ). Subsequently, the least-squares

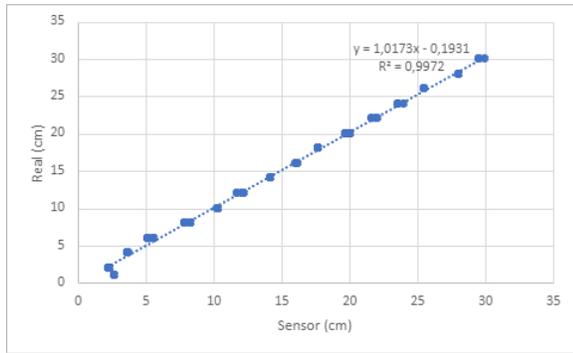

Fig. 2. Relationship Between Sensor Measurement and Real Measurement.

method was applied to obtain the values of the coefficients  $a$  and  $b$  of this function. Table I shows the results of the application of the developed algorithm and the Ultrasonic 1 [40] and Ultrasonic 2 [41]. In Table I it can be seen that the percentage error of the algorithm developed is 0.1%, while the library errors are 0.14% y 0.13% respectively, which shows that the algorithm developed provides a better approximation to the real distance. For experimental purposes, four ultrasonic sensors, a gas sensor, a NodeMCU device, and a portable battery were incorporated into the test container to monitor the level and decomposition of waste. The distribution of the ultrasound sensors was set horizontally about the dimensions of the garbage bin, i.e., for the low level at 3 cm from the base, for the medium level two sensors were placed at  $1/3$  and  $3/5$  of the height of the garbage can, finally, for the high level at 5 cm below the height of the garbage can alert the collection action before the garbage can overflow. As shown in the left container in Fig. 3, the sensors are distributed on the sides of the container according to the defined thresholds. Likewise, the present solution called horizontal measurement

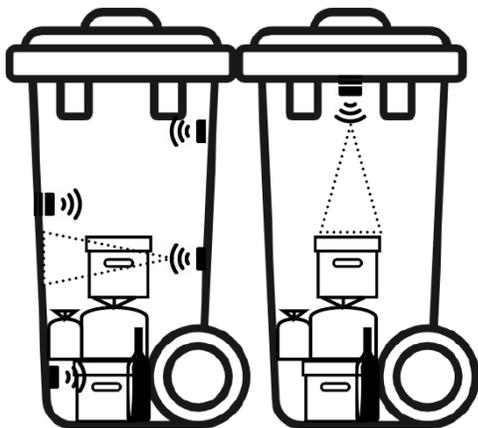

Fig. 3. Horizontal and Vertical Measurement of Container Contents.

was compared with the classic vertical measurement proposed by other authors [42]. In the right container in Fig. 3, a sensor located in the lid of the container can be seen to perform the vertical measurement. The results are shown in Table II, where the real measurement indicates the different levels of waste inside the container, symbolized by L, M, and H (low, medium, and high) respectively; the real location refers to the position

in which the waste is distributed, which can be in the center, to one side or uniformly, symbolized by C, L, and U, respectively. Finally, the horizontal and vertical measurements are the waste levels obtained by the sensors for the respective methods. According to Table II, the horizontal measurement reduces the number of erroneous results by 23%; the errors in the vertical measurement are generated because the value H or M can be obtained instead of M or L respectively since the waste is not necessarily uniformly distributed within the garbage bin. For example, in Fig. 3, the horizontal measurement would give the value B (low level of waste), while the vertical measurement would give M, when in fact it is L. It can be stated that with horizontal measurement better results are achieved than with vertical measurement. Moreover, adequate results are achieved by using low-cost sensors.

2) *CO2 Level Sensor*: A preheating stage was performed for 24 hours to establish the appropriate environmental conditions and eliminate excess impurities or humidity in the sensor [43]. Next, the sensor output resistance ( $R_s$ ) was measured over five minutes to obtain an average equivalent of 13480.265, which will be the final value of  $R_s$ . Then, the CO2 gas values specified in the sensor datasheet were used, obtaining an exponential function ( $y = a * x^b$ ), shown in Figure 4, where  $x = R_s/R_o$ , where  $R_o$  is the initial resistance. Subsequently, the least-squares method was applied, obtaining the values of the coefficients  $a$  and  $b$ , so that  $y = 114.308 * (R_s/21285.605)^{-2.829}$ . Table III shows the

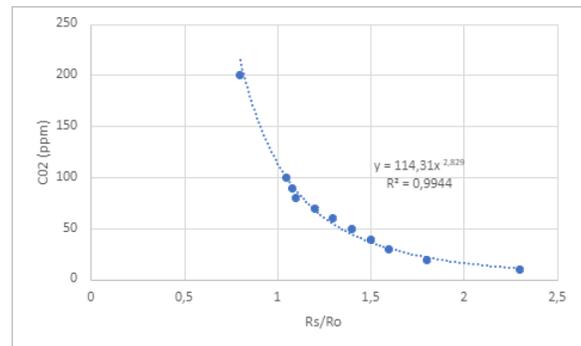

Fig. 4. CO2 Gas Measurement Curve.

average values obtained with the algorithm developed and with the MQ135 Library [44] for three scenarios: Scenario 1 refers to a container with organic waste, in Scenario 2 a container with non-organic waste was used and in Scenario 3 an empty container was used. While in scenarios 1 and 2 the variations of the results are 10.76% and 12.98% respectively, in scenario 3 a significant difference of 35.14% is observed. However, the average concentration of CO2 in free air is between 250 and 400 ppm [36], so when comparing the results in this scenario, it can be verified that the algorithm yields adequate values that are in this range.

## B. Route Planning

1) *Clustering*: With respect to the sample of 32 containers indicated above, only 12 exceeded the corresponding thresholds to be served. The Elbow method was used to determine the appropriate number of clusters to use in the clustering. Fig. 5 shows the plot of the inertia function concerning the

number of clusters where a sharp change in slope, similar to that of an arm and its elbow, is observed between two and three clusters, given that in the following numbers of clusters no substantial improvement in inertia is observed. Therefore, the 12 trash containers will be gathered in two clusters (which also coincides with the Municipal Tax Ordinance of San Borja [45]). Using the K-means algorithm, a group of the 12 garbage

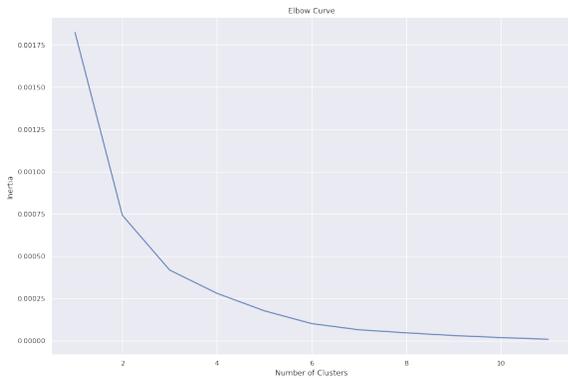

Fig. 5. Elbow Curve.

cans into two clusters of 6 garbage cans each was obtained as shown in Fig. 6. In each cluster, one more node appears which is the centroid, which is not an element of the cluster but is calculated as the average of the cluster elements.

2) Sequencing: 5000 iterations of the Ant Colony algorithm was run to find the best sequence of containers to serve, by optimizing each of the following two indicators: distance traveled and travel time separately, and for each of the two groups. Table IV shows the values obtained for each indicator in each group: the minimum travel distance to empty all the containers in group 1, starting from the Lurin depot and finally returning to the same depot is 101.122 kilometers, which requires the collection vehicle to be used for a time of 2.11 hours with a fuel cost of 61.4821 soles, calculated as the

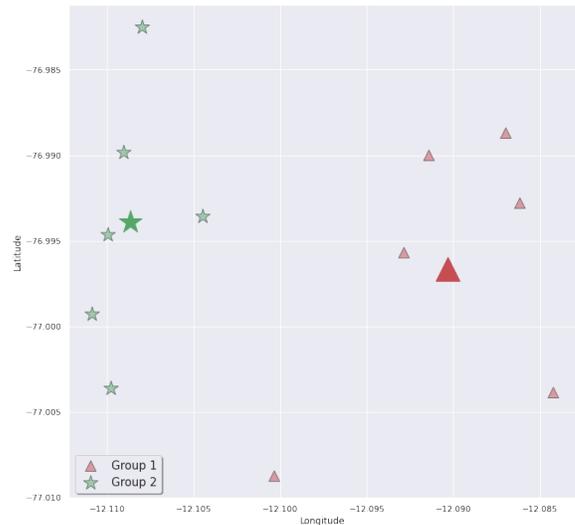

Fig. 6. Container Clustering.

product of the travel time and the unit cost of fuel. Likewise for group 2 with its corresponding indicators. Fig. 7 shows the

TABLE IV. ROUTE PLANNING INDICATORS

Indicator	Group 1	Group 2
Distance traveled (km)	101.122	97.015
Fuel cost (S/.)	61.482	58.985
Travel time (Hs)	2.11	2.12

sequence in which the containers of group 1 are visited by the collection truck that starts its route in the garbage depot located in the district of Lurin, being container A and F the first and the last to be emptied. To visualize this route, various tools provided by Google Maps, such as API Directions, markers, etc. were used.

V. DISCUSSION

To evaluate the results obtained by the proposed solution, we proceeded to the exhaustive enumeration (EE) of the routes for each of the two groups of 6 containers each that were obtained in the clustering phase, which allowed us to calculate the corresponding optimal values of the 2 indicators distance traveled and travel time, shown in Table V. Two additional scenarios were evaluated, scenario 2 with two groups of 8

TABLE V. OPTIMIZATION BY ACO AND EE FOR EACH GROUP AND EACH SCENARIO

Indicator	Distance traveled (km)						Travel time (Hs)					
	1		2		3		1		2		3	
	1	2	1	2	1	2	1	2	1	2	1	2
EE Optimal Value	100.807	96.830	97.971	98.608	98.440	97.831	2.03	1.99	2.12	1.87	1.93	2.11
ACO Optimal Value	101.122	97.015	98.361	98.608	99.097	97.831	2.11	2.12	2.18	1.87	1.99	2.11
Error (%)	0.31	0.19	0.40	0	0.67	0	3.84	6.70	2.43	0	2.43	0

TABLE VI. OPTIMIZATION BY ACO AND EE FOR ALL CONTAINERS AND EACH SCENARIO

Indicator	Total distance traveled (km)			Total vehicle usage time (Hs)			Total travel time (Hs)		
	1	2	3	1	2	3	1	2	3
EE Optimal Value	197.637	196.579	196.271	4.02	3.99	4.03	2.03	2.12	2.11
ACO Optimal Value	198.137	196.969	196.928	4.23	4.04	4.10	2.12	2.18	2.11
Error (%)	0.253	0.198	0.335	5.25	1.29	1.70	4.38	2.43	0

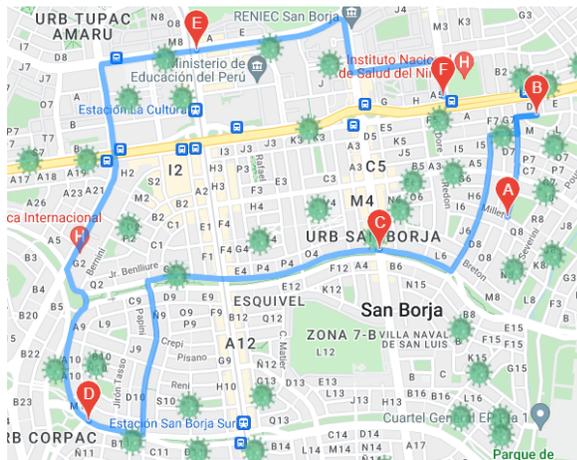

Fig. 7. Route for Group 1.

and 4 containers, and scenario 3 with two groups of 7 and 5 containers respectively. In scenario 1, 0.31% and 0.19% error was obtained in the results obtained by the ant colony algorithm (ACO) with respect to the exhaustive enumeration (EE) results about the distance traveled indicator for group 1 and 2, respectively, while for the travel time indicator, errors of 3.84% and 6.70% were obtained for group 1 and 2. Lower percentages error were observed in scenarios 2 and 3 for the distance traveled indicator. These results are evidence of the quality of the solutions computed by the ACO metaheuristic and are reported in a multitude of papers, some of which were referred to in section 2. Although acceptable results have been obtained for each of the two groups, it is necessary to evaluate the integrated solution that covered all 12 containers, analyzing the indicators of total distance traveled, total vehicle use time, and total travel time (time taken for the garbage collection process); the three indicators are referred to the set of all containers and in the same three scenarios defined in the previous analysis. The indicators are shown in Table VI as well as the percentages error. A fourth indicator would be the fuel cost indicator, however; as it is directly related to the distance indicator, it will have the same percentage error. In scenario 1 we noticed that the optimal ACO value of the total travel distance (and fuel costs), has an error of 0.253% with respect to the EE Optimal Value, while for the indicators of time of use of the collection vehicles and total travel time the

errors were 5.25% and 4.38%, respectively. Improvements in the percentages error can be seen in the other scenarios.

## VI. CONCLUSION

Taking into account the limitations of the experimentation due to the sanitary situation, and the quality of the results obtained, it can be affirmed that the objective of presenting a solution that optimizes the resources used in the collection of solid waste, keeping in mind the impact on public health, has been adequately fulfilled. On the one hand, the use of wireless sensors allows efficient monitoring of waste and contamination levels inside a container, since it is no longer necessary to check the garbage bins in situ to know the state they are in. Better quality data was obtained with the algorithms developed than with the standard libraries, as a lower percentage error was achieved in the measurement of waste and contamination levels. Likewise, evidence was found that through the horizontal measurement, the number of erroneous results generated by the vertical measurement is reduced, since not only the maximum level is considering when the waste is not uniformly distributed within the containers. In summary, by using low-cost devices, adequate results have been obtained. On the other hand, the low percentage error obtained with the model based on the K-Means algorithm and the Ant Colony metaheuristic evidences the quality of the results concerning parameters such as container location, location of contagion risk zones, fuel cost, thresholds for waste level and contamination inside the container, etc. The implementation of Route Planning using a heuristic approach guarantees its scalability by providing adequate results using a reasonable execution time. Moreover, by integrating the basic Waste Monitoring system with the Route Planning system, a continuous flow of information has been established to ensure traceability of results. This integration allows for agile planning of garbage collection since route planning is based on online information. Finally, the integrated system can be transformed into an online system, i.e., while the garbage collection is in progress, a container not scheduled to be collected might exceed one of the alert thresholds. In this case, the remaining containers to be collected would be rescheduled.

## VII. FUTURE WORK

Future work includes the incorporation of special sensors in the smart container to monitor the humidity and temperature inside the containers since the speed of sound and

the concentration of carbon dioxide (CO<sub>2</sub>) are sensitive to these variables. To preserve the energy and mobility of the smart container, it recommends using an independent long-life battery (LIPO), as well as a library that is characterized by setting the ESP8266 microcontroller in sleep mode to reduce the battery consumption and guarantee a long lifetime for the smart container. The proposed solution can be transformed into an online system through real-time route planning so that if any container not scheduled to be collected reaches a monitoring threshold during the route of the collection trucks, it will be integrated into the most convenient collection route. This will provide more timely attention. The proposed route planning model is essentially a Vehicle Routing model (VRP). This model could be made more realistic by taking into account other parameters that affect actual waste collection problems, e.g. number of vehicles, vehicle capacity, time windows, etc. Its application to larger cases is recommended due to the scalability of the Route Planning model.

**Abstract**—Malware, a short name for malicious software is an emerging cyber threat. Various researchers have proposed ways to build advanced malware detectors that can mitigate threat actors and enable effective cybersecurity decisions in the past. Recent research implements malware detectors based on visualized images of malware executable files. In this framework, a malware binary is converted into an image, and by extracting image features and applying machine learning methods, the malware is identified based on image similarity. In this research work, we implement the Image visualization-based malware detection method and conduct an empirical analysis of various learners for selecting a candidate learning classifier that can provide better prediction performance. We evaluate our framework using the following malware datasets, Search And RetrieveVal of Malware (SARVAM), Xue-dataset, and Canadian Institutes for Cyber Security (CIC) datasets. Our experiments include the following learning algorithms, Linear Regression, Random Forest, K-Nearest Neighbor (KNN), Classification and Decision Tree (CART), Support Vector Machine (SVM), Multi-Layer Perceptron (MLP), and deep learning-based Convolutional Neural Network (CNN). This image-visualization-based method proves to be effective in terms of prediction accuracy. Some conclusions emerge from our initial study and find that a Convolutional Neural Network (CNN) algorithm provides relatively better performance when used against SARvAM and various malware datasets. The CNN model achieved a high performance of F1-score and accuracy in the binary classification task reaching 95.70% and 99.50%, consecutively. The model in the multi-classification task achieved of 95.96% and 99.30% (F1-score and accuracy) for detecting malware types. We find that the KNN model outperforms other traditional classifiers.

## I. INTRODUCTION

Malware attacks are continuously evolving, and the spread of malware is ubiquitous and unstoppable. Attackers spread the malware through the Internet, email, and social media for the primary purpose of harming computers with a fraudulent intention. Typically, malware is an umbrella name for a set of malicious software, including viruses, worms, Trojan horses, spyware, etc. and are created to cause extensive damage to either data or systems or gain unauthorized access to a system or network. Cisco's recent cyber security threat report explores how cybercriminals exploited by building coordinated multi-step attacks using the following four types of attacks: crypto mining, phishing, Trojans, and Ransomware. These attacks received ten times more queries than any other type of attack. Building advanced software defense methods to mitigate the

spread of malware is an absolute necessity. Malware detection is a process of detecting the presence of malware on a host system or identifying whether a particular program file is malicious or not malicious, i.e., benign [1]. The malware detectors play a crucial role in building early warning systems to thwart any attacks and prevent hackers from using computer systems during the zero-day attack period.

In the past, various research works built a plethora of malware detection methods that address techniques to implement advanced malware detectors. Nevertheless, malware authors continuously innovate new ways to penetrate the defense mechanism. A vast amount of research work exists that formulates the signature-based, behavioral-based, and machine learning-based malware detection approaches [2], [3], [4], [5], [6]. In a signature-based detection, each file is analyzed, assigned a signature or hash (a unique alphanumeric way to identify malware), and then added to the signature database, where it's used for comparison in subsequent malware incidents. This technique identifies specific patterns in the application to determine whether the file is malicious by verifying against a known set of signatures for matching patterns. These patterns can be syntactic, e.g., the sequence of instructions, or semantic-based, e.g., control or data flow properties. One of the critical aspects of any malware detection system is identifying whether a file is malicious or benign. The signature-based detection is a simple and widely used method built as AV (Antivirus) and malware detectors. A behavioral-based technique implements a dynamic environment where malware binaries are executed in a sandbox machine to extract the run-time characteristics to identify the malware. In a static or code analysis-based malware detection technique, the malware can be classified by using the code structure of the malicious code, e.g., use of control Flow Graphs (CFG) to identify the malware. The static method is the process of analyzing malware/binary without executing it. Its main objective is to extract useful information from the malware code structure, and it helps us get an idea of the type of malware and what the malware can do.

Signature-based approaches allow security analysts to identify the malicious component quickly, and so they are widely used by several commercial anti-virus (AV) companies. However, this technique's primary disadvantage is that they require a trained security analyst to manually write appropriate signatures that can be used to detect each malware family and load them in a signature database for run-time access. Unfortunately, this manual effort is error-prone and as well as time-consuming. Also, storing the whole world of signature-

learning is a daunting task [7], [8], [9], [10]. Besides, when the malware mutates, the original stored signatures of malware become obsolete and unable to successfully detect the newly mutated malware due to the polymorphic and metamorphic methods that implement code obfuscation [11].

In contrast to signature-based detection, the machine learning-based (ML) technique aims to address this limitation of manual intervention and introduce automation by implementing a set of ML-based malware classifiers. Machine learning algorithms in the classification of malware rely on features extracted from binary files or a disassembled assembly code by using either the static code analysis techniques or dynamic analysis techniques where malware behavioral characteristics are studied during run-time and at the point of execution. This information is helpful for future analysis as it will allow us to analyze the sample efficiently. These techniques extract various features from the malicious samples and use standard machine learning algorithms to learn a classifier that labels the sample as either benign or malicious. However, there are still some challenges such as processing a large amount of malware, learning high-dimensional vectors, high storage usage, and low scalability in learning. Traditional approaches to malware detection using automatic classification are facing some limitations. The first one concerns feature extraction: static approaches are hindered by code obfuscation techniques, while dynamic methods are time-consuming, and evasion techniques often impede the correct execution of the code. The second limitation regards the building of the prediction models: the completeness of a training dataset may degrade over time as the malware authors evolve new techniques or can not be sufficient for some malware families or instances [12]. In addition, many malware runs independent of the operating system and executes its malicious code even before loads, running malicious.

The rest of the paper is organized as follows. Section II discusses related work. Our proposed framework are introduced in Section III. In Section IV, the framework's experiments are described. Discussion are covered in great details in Section V. Finally, the paper is concluded in Section VI.

## II. RELATED WORK

This section includes the relevant research associated with this project work comprising visualizing malware binaries and Machine-Learning (ML) based malware detection approaches. Malware detection has been widely practiced in the past decade. The detection approaches depend primarily on the following techniques: static - that relies on analyzing the code structure, call flow graphs of malware, the dynamic technique that addresses the behavioral characteristics of malware at run time execution in a sandbox environment during zero-day attack period [13]. Nataraj et al. [14] implemented the first framework on visualizing and classifying malware using image processing techniques. In their work, malware binaries are visualized as gray-scale images and observed that malware from the same families exhibited similarity in texture and layout. The authors conducted experiments on over 9,458 samples from 25 families of malware using image visualization and texture analysis. Nataraj et al. [15] also extended the approach to have malware binaries are represented as signals or images, and signal processing-based features are

used to characterize malware. Han et al. [16] implemented visualization of malware images and performed a similarity calculation between images of malware variants. In this new classification method, they proposed a new classifier by first converting malware into gray-scale images and then applied a histogram similarity measurement to study the similarity of gray-scale image entropy maps. Han et al. [17] proposed a new malware family classification method that converts malware binary files into images and entropy graphs. Xue et al. [18] built a homology-based malware analysis using an ensemble of learning methods. Xue used gray-scale images, RGB color images, opcode sequences, and system flow graph-based image visualization methods and used Convolutional Neural Networks (CNNs) as base learners to perform bagging ensemble learning that extract features from malware images. Liu et al. [19] proposed an automatic malware classification and a new malware detection scheme using a clustering-based machine learning method. They implemented a new malware detection using Opcode n-gram based gray-scale images and feature extraction with Shared Nearest Neighbor (SNN)-based clustering algorithm on discovering new malware. Fu et al. [20] proposed visualizing malware using color images and extracted global texture and color features from the images for classification. A series of unique byte sequences are extracted from code and data sections of malware and using simhash functions converted to local features. K-Nearest Neighbors, SVM, and Random Forest methods are used to classify the malware. Makandar et al. [21] implemented malware classification methods that apply image processing techniques that use image textures-based features extraction from visualized malware binaries. Multi-resolution and wavelets are used to build effective texture feature vectors using Gabor Wavelet, GIST, and Discrete Wavelet Transform. They proposed using Support Vector Machine (SVM) based multi-class malware image classification. Singh et al. [22] implemented a CNN-based deep-network in building visualization-based malware detection methods. The use of ensemble learning techniques in malware detection is not new. Zhang et al. [23] implemented malicious code detection using multiple classifiers fusion and is not strictly dependent on specific malicious code. Menahem et al. [24] improved the prediction performance of malware detectors by combining the results of the individual classifiers into one final result to achieve overall higher detection accuracy. Recent research by [25] implemented an ensemble classification scheme of using both binary and multi-class classification as part of implementing intrusion detection solutions. There exists incomplete knowledge of class examples present during the training time. Scheirer et al. [26] introduced the open-set-based recognition method for a computer vision problem. The open-set classifiers are expected to detect all unknown classes present during testing but are not known to the model during training time. Open-set recognition describes the scenario in such a way that new classes (unknown unknown classes) unseen in training appear in testing, and requires the classifiers not only to accurately classify the *known classes*, but also to effectively deal with the *unknown* ones. In a malware survey paper, Rudd et al. [13] identified the following six flawed assumptions to use an open-set based malware detection instead of a closed-set one: intrusions are closed-set, anomalies imply class labels, static models are sufficient, no feature space transformation is required, model interpretation is optional, and class distributions are Gaussian. Henrydoss et al. [27]

implemented an open-set-recognition-based intrusion detection scheme.

Han et al. implemented a feature extraction method of malware binary using texture fingerprints index structure. This method achieves the highest accuracy of 85.77 %. Han et al., proposed a malware visualization method that uses both the static and dynamic code analysis technique with RGB color images. Using RGB image Opcode is generated from the malware by executing it, converting that opcode sequence into images for classification. The accuracy of this method yielded 98.96%. Wang et al. [28] addressed the problem of using small training sets. Opcode sequence extracted from the malware binary file was converted to an image and then normalized by histograms. Dilated and eroded PCA is applied to extract features for SVM-enabled classification. Tobiyama et al. [29], Kolosonjaji B et al. [30], Zhao et al.[23] implemented deep learning techniques CNN to classify malware images and achieve a prediction accuracy of 96%, 85.6%, and 96.7% respectively. These experiments were performed on a few malware samples, and these techniques are not evaluated against larger datasets. Liu et al., Azia Makandar et al., Huang et al. implemented malware classification based-on image analysis using multiple features, e.g., use of binary files, opcode sequences, and API call sequences, and resulted in an accuracy of 98.9%, 98.8%, and 99.51%. These methods used an advanced feature set ranging from 4000 to 50000 feature sets. Huang et al. [31], provided the state of the art classification performance evaluated against a large dataset that contains a training set of 4.5 million and a testing set of 2 million samples.

### III. FRAMEWORK

#### A. Malware Analysis using Image Visualization

Traditional malware detection methods are based on static and dynamic analysis techniques. The static analysis technique involves analyzing the disassembled code of a malware file. The dynamic code analysis and run-time-based methods use malware behavioral characteristics at the point of execution in a sandbox test environment. We adopt an image-visualization-based technique to implement malware detectors in this work. Basically, instead of detecting the malware binary as is where we convert them into an image and use computer vision techniques to recognize the image and detect the appropriate malware family. Visualizing malware is a new type of malware detection method. Using image processing is a simple but very effective method [14] of malware detection. Nataraj et al. [14] propose the initial framework of malware analysis using an image visualization-based malware detection technique. This method converts a malware binary into an image, using image processing techniques, and extract image features, e.g., texture and layout. Then a machine-learning-based image detector is used to identify the malware family that is solely based on malware images that exhibit similar behaviors. Fig. 1 depicts a detailed architecture and framework of the image-visualization based malware detection method. Firstly, malware binaries are converted or visualized as gray-scale images. They observe that for many malware families, images belonging to the same family aims to have similar image layout and texture. This is based on the assumption that most of the malware authors use an existing malware and modify the source code to create new

malware. It has been observed that the Image visualization-based malware detection methods [19], [20], [18] yield a comparable detection performance in comparison to the regular static and dynamic malware detection technique [32], [33].

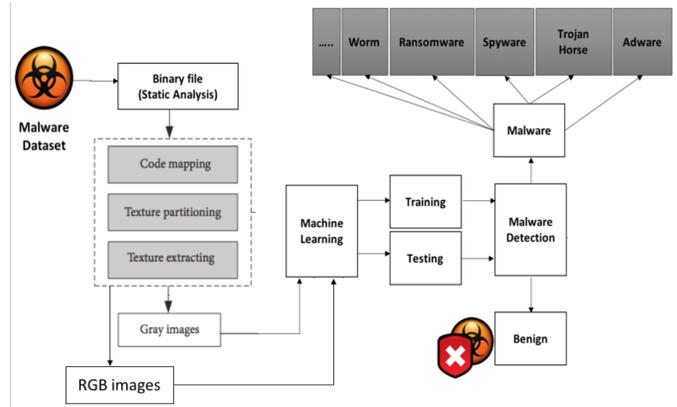

Fig. 1. Malware Detection Framework using Visualization Architecture.

The following covers the types of malware visualization methods: Gray-scale image visualization, RGB color image visualization-based methods that are widely used in the previous research works [19], [20], [18]. Also, using the malware binary file and other code analysis techniques like Opcode visualization and System Flow Graph (SFG) are also utilized [18]. As shown in Fig. 1 and Fig. 2, the system uses gray-scale and RGB color images of malware and computes the feature vector, i.e., fingerprint, to identify a malware binary. This fingerprint captures the structural, visual similarity between malware variants. The Opcode and SFG methods are out of scope for this work.

#### B. Gray-Scale Image Generation

In Fig. 2, a malware binary executable file is converted into a gray-scale image. A malware binary is converted to a vector of 8-bit unsigned integers and then organized into a two-dimensional (2D) array. This 2D data is visualized as a gray-scale image in the range [0,255] where 0 is black, and 255 denotes white. The image's width is fixed, and the height is allowed to vary according to the malware binary file size. Nataraj et al. recommend image widths for different file sizes based on empirical observations. We use their code base for converting and feature extraction for the Gray-scale image visualization prior to applying our proposed learning classifiers.

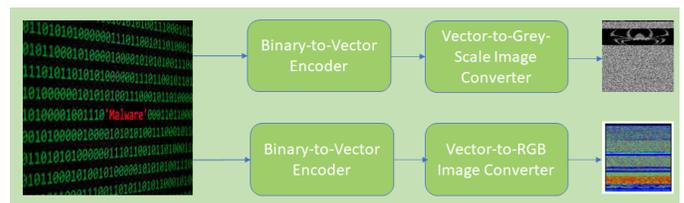

Fig. 2. Malware to Image Converter.

### C. RGB-Color Image Generation

In Fig. 2, a malware binary executable file is converted into a RGB, color image. A malware binary is converted into a vector of 24 bits binary data (8-bit represents red color, 8-bit represents the green color, and 8-bit represents blue color) unsigned integers and then organized into a 2D array. This 2D data is visualized as a color image [0,255] where 0 is black, and 255 denotes white. The image's width is fixed, and the height varies according to the malware binary file size.

### D. Malware Feature Extractor (MFE)

In this work, we conduct the malware detection approach using various machine learning algorithms on the features of the visualized image of the malware executable. We learn from the extensive research on signal and image processing techniques that implement compact signature extraction methods. The learning algorithms used in this work use image features extracted from these binaries. We consider techniques from the signal and image processing where compact structure extraction methods have been extensively studied. The image processing for content-based image retrieval has been extensively explored by Manjunath et al. [34], and scene classification by Olivia et al. [35] and Torralba et al. [36]. Manjunath et al.[34] propose image processing using texture information for browsing and retrieval of large image data. It uses the Gabor wavelet features for texture analysis and supports a comprehensive experimental evaluation. The Gabor features provide the best pattern retrieval accuracy [34]. We adopted a similar malware feature extraction method formulated using the GIST-based image features. The GIST method uses texture and spatial layout of an image [14], [37], [38]. Refer Fig.3 for the design details of the Malware Feature Extractor. Nataraj et al. founded the following feature extraction technique. Typically, a smaller resized or reshaped version of the image is used to compute the features [36]. Firstly, the binary executable file is converted to a discrete 1-dimensional signal by numerically coding every byte value as an 8-bit number that ranges from 0~255. Then the signal is "reshaped" to a 2-dimensional gray-scale image with "d" being the width and "h" being the height of the reshaped image. During reshaping, the width "d'" and the height "h'" are fixed depending on the number of bytes in the binary. The horizontally adjacent pixels in the image correspond to the adjacent bytes in the binary. The vertically adjacent pixels are associated with the bytes spaced by a multiple width of "d'" in the binary. Then the image is passed through various filters that capture both the short-range and long-range correlations in the image. The localized statistics are obtained by dividing the filtered images into non-overlapping sub-blocks from these filtered images and computing the average value on those blocks. This is called sub-block averaging. A compact signature is formed by concatenating the averages computed from all the filters. Typically, the features are extracted from the image's smaller "resized" version.

The feature computation details are explained below. The image on which the feature needs to be extracted is defined using  $(I(x, y))$ . The GIST descriptor id computed by filtering the image through a bank of Gabor filters that are band-pass filters whose responses are Gaussian functions modulated with a complex sinusoid. The filter response  $t(x, y)$  and the Fourier Transformed version  $T(u, v)$  are defined by the

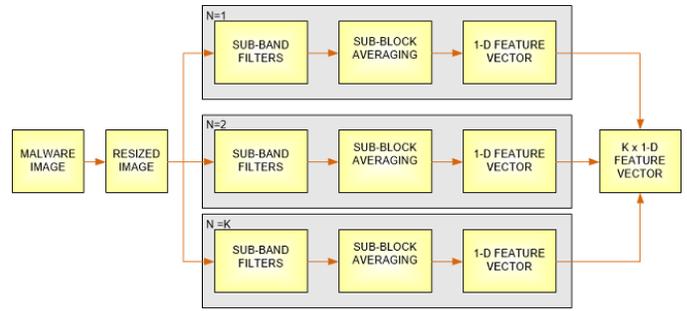

Fig. 3. Malware Feature Extractor.

following equations: Filter Response (FR) equation 1 and Fourier Transform of FR equation 2.

$$t(x, y) = \frac{1}{(2\pi\sigma_x\sigma_y)} \exp\left[-\frac{1}{2}\left(\frac{x^2}{\sigma_x^2} + \frac{y^2}{\sigma_y^2}\right)\right] \quad (1)$$

$$T(u, v) = \exp\left[-\frac{1}{2}\left(\frac{(u-w)^2}{\sigma_u^2} + \frac{v^2}{\sigma_v^2}\right)\right] \quad (2)$$

A filter bank, i.e., a block of filters, is created by rotating orientation and scaling the basic filter response function  $t(x, y)$ , resulting in a set of similar filters. Let  $S$  be the number of scales and  $O$  be the number of orientations per scale in a decomposed multi-resolution image. An image is filtered using "k" such filters to derive "k'" filtered images. To conduct our experiment, we select the number of filters,  $k = 20$  with a number of scales  $S = 3$  and in which the first two scales have 8 orientations ( $O=8$ ), and the last one has four orientations, i.e.,  $O = 4$ . Each filtered image is further divided into  $B \cdot B$  sub-blocks, and the average value of a sub-block is computed and stored as a vector of length "L" where  $L = B^2$ . Using this above method, "k'" vectors of length "L" are created per image. These vectors are then concatenated to form a  $kL$ -dim feature vector called GIST. We choose a  $B$  value of 4 to obtain a 320-dimensional feature vector in our work. When computing GIST descriptors, there is a key pre-processing step involved, that is, to reduce the image size to a square of dimensions  $S \times S$ . In our work we choose a value of  $S = 64$ . An optimal value of  $S$  to be used in the computation because larger the value of  $S$  increased the computational complexity. Because of the sub-band averaging, this higher  $S$  - vale does not significantly affect and strengthen the signature.

### E. Machine Learning Approaches

We have explored a few learning classifiers to evaluate a better performing algorithm for implementing the malware detection function using virtualized images as part of this work. This section describes the theory and implementation of the machine learning algorithms that we used in this study: Naïve Bayes Classifier (NBC), Support Vector Machines (SVMs), Random Forests, k-Nearest Neighbours (KNN), CART, and MLP. As a note, all of the ML classifiers were trained on normalized data.

## F. Evaluation Methods

The evaluation of machine learning classifiers is critical when studying the learning models and their performance. To evaluate the performance of the classifier models, we have used similar evaluation measures that are adopted in most of the previous research experiments that involve learning-based malware detection using visualized images of malware binaries. It covers the prediction accuracy and F1-score under varying conditions of input parameters. Most of the time, we use classification accuracy to measure the performance of machine learning models, and we have also used confusion matrices to compare the prediction accuracy and failures.

$$Accuracy = \frac{TP + TN}{TP + FP + TN + FN} \quad (3)$$

$$Precision(P) = \frac{TP}{TP + FP} \quad (4)$$

$$Recall(R) = \frac{TP}{TP + FN} \quad (5)$$

$$F1 - score = \frac{2 * Precision * Recall}{Precision + Recall} \quad (6)$$

In the above equations, TP, TN, FN, FN, and FP are true positives, true negatives, false positives, and false negatives. We use F1-score as the primary performance indicator to evaluate all the classifier models used in our experiments. F1 score is a single metric that combines both precision and recall. The precision or True Positive Rate (TPR) is a way to look at the accuracy of positive predictions performed by a classifier and can be defined as follows: precision =  $TP/(TP + FP)$  where the True Positives (TP) is the number of true positives, i.e., correct prediction of a positive sample, and the False Positives (FP), i.e., the wrong prediction. But precision is used with another parameter called recall. Recall is defined by  $TP/(TP + FN)$ .

We have also used a confusion matrix table to study the performance of classifiers. The confusion matrix is a table with rows and columns that report false positives, false negatives, true positives, and true negatives. This allows a more detailed analysis than the mere proportion of correct classifications, i.e., prediction accuracy.

## IV. EXPERIMENTS

Our experiments include the following three step approach. Firstly, we convert the malware binaries into images. Secondly, we perform feature extraction using the GIST-enabled MFE. Finally, we perform the malware classification using the following machine learning methods: Linear Regression, Random Forest, KNN, CART, SVM, and MLP, CNN. We evaluate on the following three malware datasets; SARVAM [14] (25 malware families), Xue et al. [18] (10 malware families), and CIC [39] (six malware categories). These experiments leverage gray-scale image features and RGB Color image features to build models of different classifiers and evaluate their performances.

## A. Datasets Summary

Fig. 4 shows malware families and categories distributions across all datasets. SARVAM dataset contains 9,339 instances broken into 25 malware families. The families distribution of malware are unbalanced with majority instances belonging to a family called *Allapple.A* as seen Fig. 4(a). In Xue et al. dataset, there are 10 malware families distributed in 5,314 instances. Fig. 4(b) presents malware family distribution with almost 20% of *Backdoor.Win32.Bifrose* as the top family. CIC is the smallest dataset which contains 439 instances and broken into six categories with a lot of families. This data shows that *Scareware* category includes the most instances among the families and *Botnet* includes the least instances as noticed in Fig. 4(c). Last, the benign dataset includes 1,024 instances collected from different sources and combined as one dataset. Finally, our experiments for the gray-scale images include all datasets while the RGB color images were just included for Xue and CIC datasets. We have not included the RGB color images as part of experiments and used only the gray-scale images due to unavailability of the original executable files of SARVAM dataset.

## B. Models Setup

Our experiments are conducted in two phases. The first phase focuses on identifying malware from benign as binary classification tasks. The second phase involves a multi-class classification that identifies the individual malware family. We evaluate seven classification algorithms and compare between them based on four performance metrics stated above. Due to the limitation of datasets sizes, we used 10-fold cross-validation mechanism to train and test the classification algorithm. The second phase aims to detect the family or the category of malware as a multi-classification task using the most effective classification algorithm in the previous phase. This task is evaluated by confusion matrix in order to see how the actual unbalanced malware families and categories are truly and falsely predicted. Both phases were consecutively built to compare the results of gray-scale images and RGB color images.

## C. Binary Classification Performance

In this phase, we compare the performance results of the seven classifiers as described in Fig. 5 and Table I. This task aims to predict malware instances from benign instances. Each instance includes 320-dimensional feature vector with the class types. The total elements of the feature vector are broken into 960 (320x3) elements. We firstly measure the accuracy of each fold (using 10-fold cross-validation) in each classifier. We depicted the accuracy results for the folds through their quarterlies in the box plots as seen in Fig. 5. We found that K-Nearest Neighbors classifier outperform others in the accuracy results across all datasets, while support vector machines and Naïve Bayes classifiers perform closely low in most cases.

In a more nuanced view, the performance of binary classification for malware and benign can be described through four following metrics: average accuracy, precision, recall and F1-score as seen in Table I. Whilst recall denotes the ability to locate every relevant instance in classification datasets, precision denotes the number of data points a classifier classifies

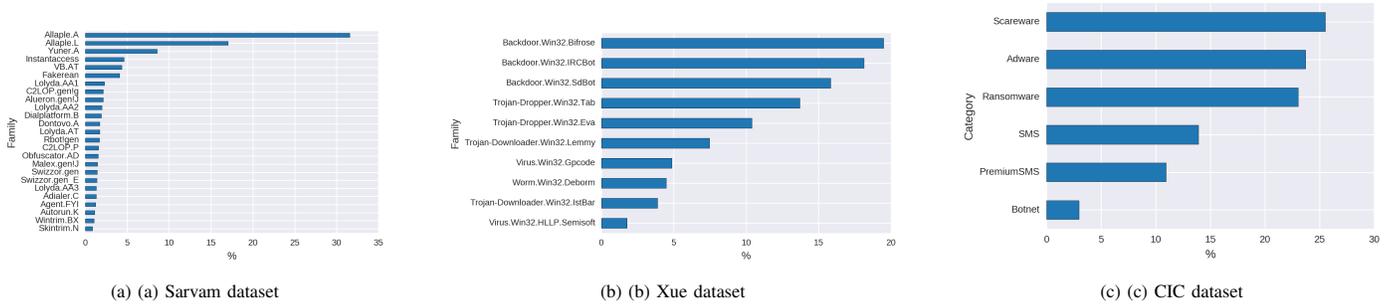

Fig. 4. Malware Families and Categories Distribution over All Datasets.

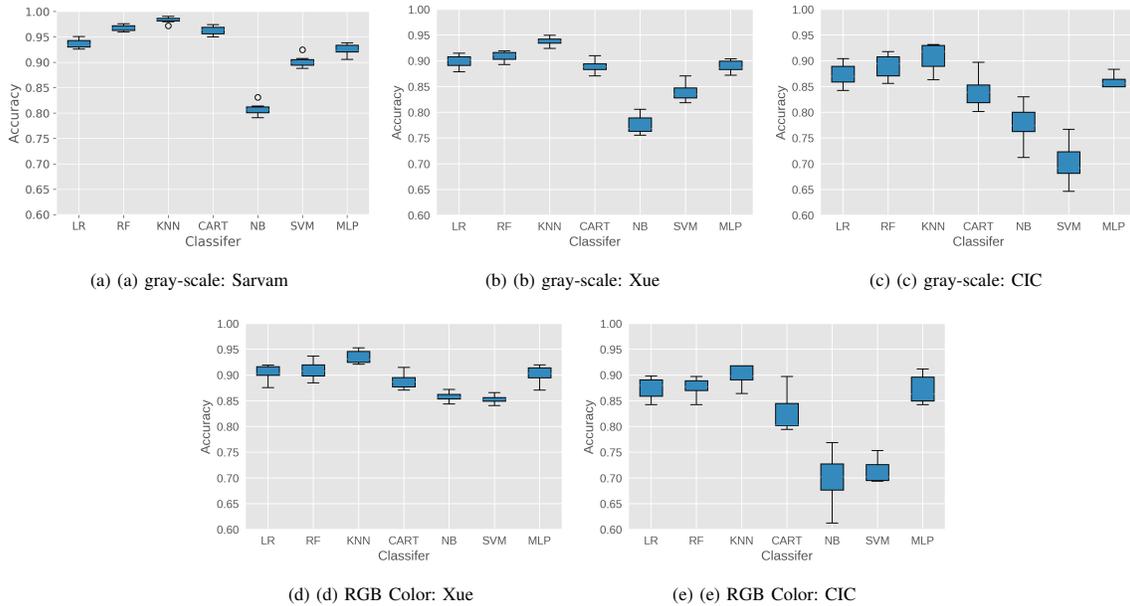

Fig. 5. Comparison of Seven Classifiers 10-fold CV Accuracy Results for Predicting Malware and Benign.

as relevant where it really is relevant. There is a compromise in these two evaluation metrics to maximize, when increasing the recall, the model decreases the precision. In case we want to find an optimum balance of recall and precision, we use the F1-score to combine measurements for both metrics. We applied these performance metrics per class to evaluate the instance type (belonging to either malware and benign).

The K-Nearest Neighbor classifier (KNN) achieved in the average accuracy about 98.27%, 93.83%, and 91.05%

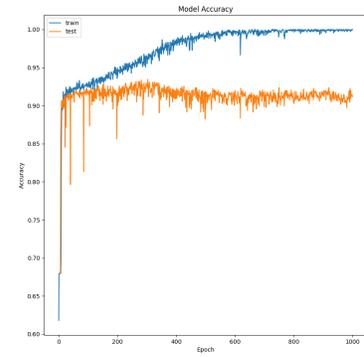

for the gray-scale images of SARVAM, Xue, CIC datasets respectively, irrespective of the instance types, i.e., malware or benign. It also achieved similar performance using the RGB color images of the two datasets, i.e., Xue and CIC. While the average accuracy metric cannot evaluate the performance of benign and malware separately, the performance of KNN vary across datasets. For the Xue dataset, F1-score on both gray-scale and RGB color images achieves closely better results in detecting malware (96.48% and 96.23%) than other classifiers except CNN classifier. While KNN F1-score for both gray-

(f) Gray-scale: All datasets

Fig. 6. Binary-classification CNN Accuracy Models based on Epochs.

scale and RGB color images in detecting benign achieves better results than others (78.87% and 78.14%), it performs low compared to SARVAM dataset. Conversely, KNN model in CIC dataset can be accurately detecting more benign instances than malware instances for both gray-scale and RGB color images as clearly seen in the F1-score results for both benign (93.45% and 92.92%) and malware (86.17% and 84.92%).

While the tree-based classifiers especially Random Forest (RF) perform well in this classification domain in SARVAM dataset, Decision Tree (CART) results underperform the logistic regression (LR) in the remaining datasets. The performance of these classifiers across datasets follows the same pattern of KNN when comparing F1-score results for detecting malware and benign. In other words, the classifiers' performance for detecting more instances of malware than benign were seen in SARVAM and Xue datasets. In contrast, the results in CIC dataset show that classifiers can detect more benign instances than malware.

The Multilayer Perceptron (MLP) classifier performance results are seen in the median position and they can be improved over all datasets. They are close to the performance results in the logistic regression classifier.

Support Vector Machine classifier (SVM) usually fails to detect the minority class. This means it can learn only one class that reflects the majority. For example, benign instances

are considered of the minority class in SARVAM and Xue datasets, and the F1-score results are either zero or below 10, and vice versa. In addition, Naïve Bayes classifier achieves the lowest results in all metrics over all datasets.

The Convolutional Neural Network classifier (CNN) achieved in the average accuracy about 99.50%, 94.83%, and 91.17% for the gray-scale images of SARVAM, Xue, CIC datasets respectively, irrespective of the instance types, i.e., malware or benign. It also achieves similar performances using the RGB color images of the two datasets, i.e., Xue and CIC. Specifically, CNN F1-score (where there is a balance of precision and recall) in SARVAM dataset achieves higher results for malware instances than benign instances because of their falling off in their recall scores. This means that some instances of benign are predicted to be malware. In contrast, the high precision scores reflect that classifier correctly predicts the majority instances of each type, whether benign or malware. For the Xue dataset, F1-score on both gray-scale and RGB color images achieves closely better results in detecting malware (96.93% and 97.31%) than all other classifiers and F1-score for both gray-scale and RGB color images in detecting benign achieves better results than others (83.73% and 85.40%). In contrast, CNN model of CIC dataset can be accurately detecting more benign instances than malware instances for both gray-scale and RGB color images as clearly seen in the F1-score results for both benign (93.31%

and 95.05%) and malware (86.98% and 91.53%). Finally, the results show that the CNN classifier is the best algorithm to be used in the second phase of classification task. Binary-classification CNN accuracy models based on 1000 Epochs are shown in Fig. 6(a), (b), (c), (d), (e), and (f).

#### D. Multi-classification Performance

After evaluating binary classification tasks in the first phase, we selected the best classification algorithm that performs well in all metrics among all datasets to be used in this phase. Thus, we aim in this phase to measure the performance of the KNN classification task on identifying the individual malware family or category. Due to the variation in naming malware families on each datasets, we separately evaluated the model performance for each dataset. We chose the confusion matrix as a performance metric in order to see how the actual unbalanced malware families and categories are truly and falsely predicted. It also depicts where the model is confusing classes and mislabeling one as another.

The performance results of the KNN models for malware families are reflected in a confusion matrix as shown in Fig. 7, where the ordinate and abscissa are the number of the malware family or category. The abscissa indicates the actual malware family and the ordinate indicates the predicted malware family. The color gray patches in the figure indicate the similarity between the predicted instances and the actual instances under specific family or category. According to the ribbon on the right, the more dark the color is to the top, the higher the similarity is, and less dark it is to the bottom, the lower the similarity is.

In SARVAM dataset (available only for gray-scale images), the KNN model achieves a large probability of true positives over the majority of malware families depicted in the dark color of the right diagonal in Fig. 7(a). In the other hand, there are few families misclassified. For example, the figure shows that lot of instances of “*Swissor.gen*” malware are falsely predicted as “*Swissor.gen E*” malware (42%) and vice versa (34%). It seems the features vector of both malware families showing same patterns and have identical sequences of codes. Similarly, many “*C2LOP.P*” malware instances are misclassified by the model as “*C2LOP.gen!g*”. This indicates that the model is biased toward the malware family that contains more instances and have identical sequences of codes with the other family. In other words, when a false prediction occurs, the predicted family is likely to belong to the same family series.

While the Xue dataset for the gray-scale images and the RGB color images are evaluated separately, the performance results of true positives and false positives are compatibly approximate among malware families as seen in Fig. 7(b) and Fig. 7(d). The KNN model for detecting malware family for this dataset achieves lower performance in the confusion matrix than for the SARVAM dataset. In addition, non malware families exceed 89% of the true positives of the total instances. For the CIC dataset, the KNN model also does not achieve a good results (Fig. 7(c) and Fig. 7(e)) compared to the models built for the other datasets.

We also train and test a model for multi-classification using CNN. For the SARVAM dataset, accuracy on gray-scale

images achieves closely better results in detecting malware 99.30% than all other classifiers as shown in Fig. 8(a) and Fig. 9(a). For the Xue dataset, accuracy on both gray-scale and RGB color images achieves better results in detecting malware (87.79% and 88.09%) than all other classifiers as shown in Fig. 8(b) and (d) and Fig. 9(b) and (d). For the CIC dataset, accuracy on both gray-scale and RGB color images achieves better results in detecting malware (78.51% and 85.93%) than all other classifiers as shown in Fig. 8(c) and (e) and Fig. 9(c) and (e)

TABLE II. MODEL GENERALIZATION: TESTING THE MODEL ON UNSEEN DATA TO PREDICT MALWARE AND BENIGN USING KNN AND CNN

Accuracy	Classes	Precision	Recall	F1-Score
97.10% (KNN)	Benign	89.66%	61.54%	72.98%
	Malware	97.44%	99.52%	98.47%
97.56% (CNN)	Benign	82.4%	77.81%	80.18%
	Malware	98.5%	98.9%	98.7%

#### E. Deep Learning Experiments using CNN

We also conducted deep learning experiments on visualized malware images using the Convolutional Neural Networks (CNN). After we generate grayscale and RGB images from Binary malware or benign executable files, we construct the CNN which has 24 layers (excluding the input layer), including 8 convolutional layers, 5 pooling layers, 6 dropout layers, 3 full-connection layers, and an output layer. All the convolutional layers use a  $3 \times 3$  convolution kernel with a step size of 1; the number of convolution kernels in the eight layers are 8, 16, 32, 32, 64, 64, 128, and 256. Because the size of the feature map does not change when the feature map passes through a convolutional layer, a 1-pixel edge fill is performed on each input feature map in the convolution layer. We use all max pooling layers with a  $2 \times 2$  sliding window and a step size of 2 as shown in Fig. 10. Because the last fully-connected layer of the CNN requires that the input feature maps should be the same size, the general CNN network structure needs to preprocess the image to unify the image size. We use a dropout regularization layer with 0.25 and 0.5 after each pair of convolutional and pooling layers to prevent CNN network overfitting. We also use ReLU and softmax activation functions for multi malware classification and sigmoid for binary malware classification.

#### F. Multi-class Open-Set Recognition Performance

Most of the malware detectors used today fall under the category of closed-set assumption. In a closed-set operation, the data for training and testing are drawn from the same label space and from the same distribution. A large database containing malware signatures are used and signature vectors received are compared against the database leading to a binary classification scheme of malicious or benign files. If there is a new malware, i.e., the training and testing distributions are different, all these methods from closed-set detection will fail. One possible approach that can be extended from our empirical study is to use the Open-set recognition based approach to implement malware detection technique using visualized malware images.

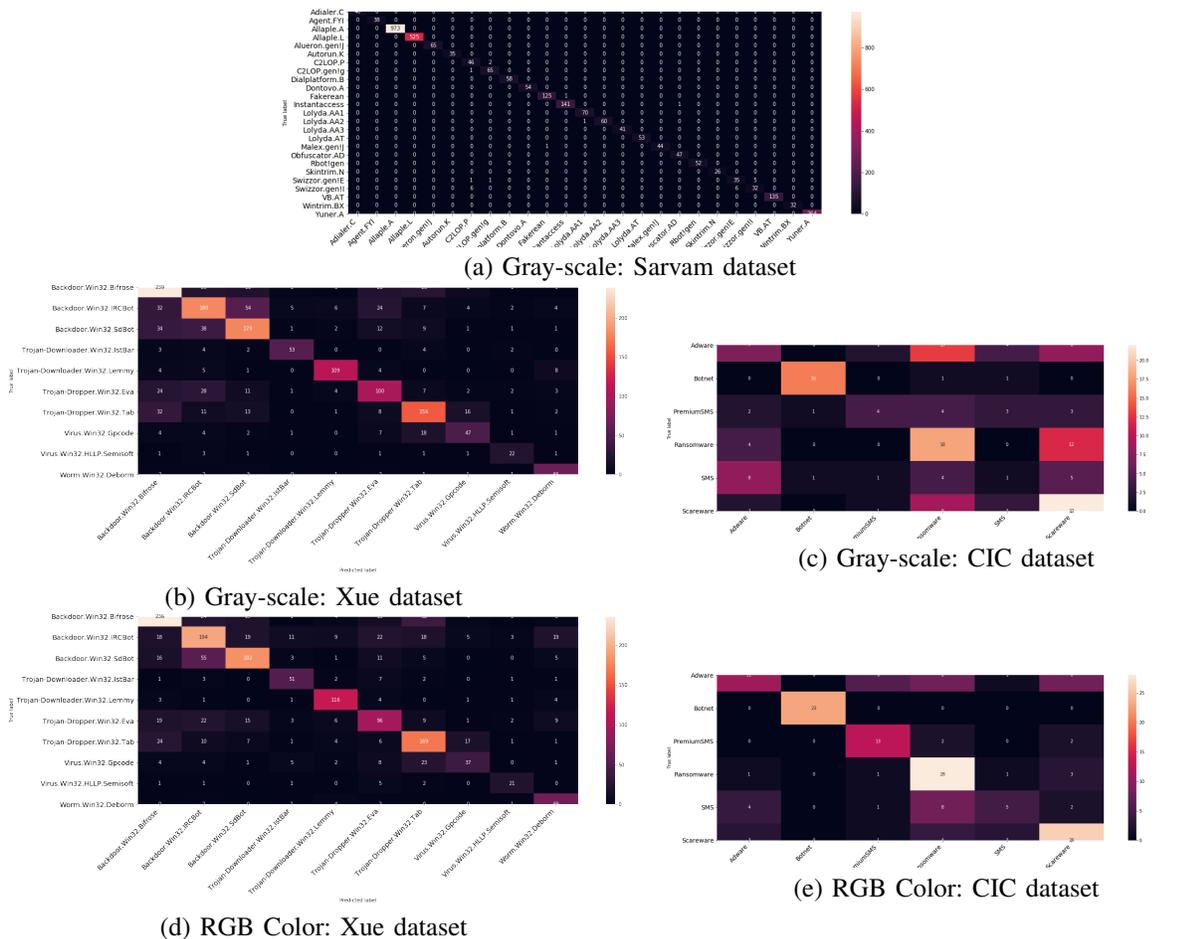

Fig. 8. Multi-classification Confusion Matrix of the CNN Classifier to Detect Malware Family and Category over Three Datasets.

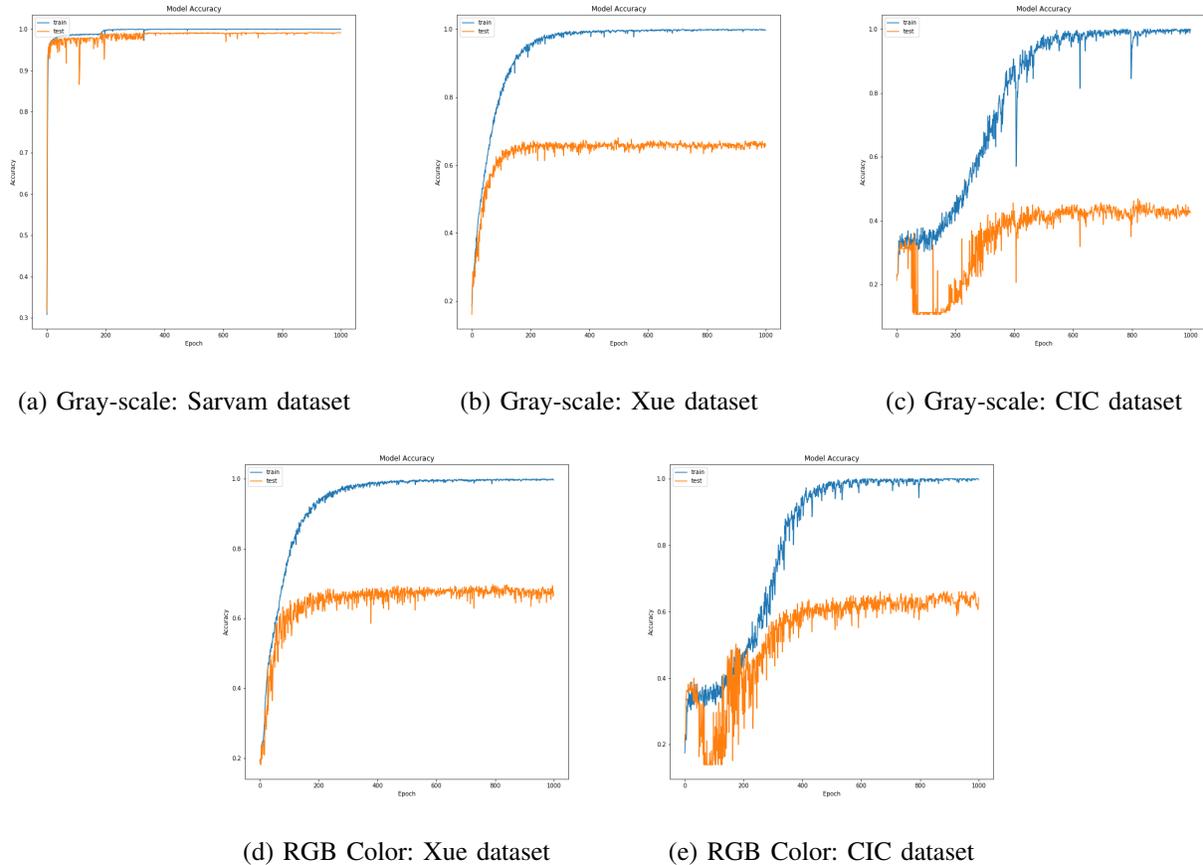

Fig. 9. Multi-classification CNN Accuracy Models based on Epochs.

### G. Model Generalization

Unlike other works, we built a generalized KNN and CNN models using 66.67% of the three datasets for the binary classification task. Then, we tested the model on the remaining combined datasets (33.33%) as unseen data. Our splitting mechanism applies the stratified sampling method to avoid the bias toward a majority class. This approach is more solid for evaluating the performance of the model. Moreover, combining datasets from independent sources will examine whether the model can be generalized for any cases. Table II shows the performance of the models tested on unseen instances of benign (338) and malware (4,981). In general, the models achieves above 97% of the accuracy where it is better detecting malware than benign. To investigate the model in depth, let us assume that malware cases are positive and benign cases are negative. The models were tested on 4,981 malware cases and 338 benign cases as unseen cases. The model of KNN predicted correctly more than 4,000 malware instances as true positive cases while there are 24 malware instances predicted as benign. In the other side, the model of KNN predicted truly 208 benign instances while the remaining are predicted as malware. The model of CNN predicted correctly more than 4,000 malware instances as true positive cases while there are 55 malware instances predicted as benign. In the other side, the model of CNN predicted truly 263 benign instances while the remaining was predicted as malware.

### V. DISCUSSION

In this section, we discuss the experimental results and their broader implications. Addressing the malware problem is an ongoing research area. We studied the impact of using both the gray-scale and RGB color images in the malware visualization method. We implemented binary and multi-class classification using both gray-scale imaging and RGB-color images. In our study, we find that converting the binary files to either gray-scale images or RGB color images does not impact the performance results. Hence, focusing on a new approach in feature generation and extraction is required. Using new visualization techniques like Speeded Up Robust Features(SURF), Histogram of Oriented Gradients (HOG), Local Binary Patterns (LBP), and Scale Invariant Feature Transform (SIFT) might better support and enhance the malware detection model [40] but subject to evaluation. In this work, we have included only the GIST-based Image visualization technique for malware detection. Any other visualization and non-visualization-based discussion are out of our work's scope. Nataraj et al. [14], [37], [15]'s original setup included 9,458 samples from 25 malware families with gray-scale image conversion and GIST-based feature extraction. Their approach achieved a classification accuracy score of 98 %. While our results align with the performance results, we extended the framework to include data not only from SARVAM [14] (25 malware families), but also from Xue et al. [18] (10 malware families), and CIC [39]

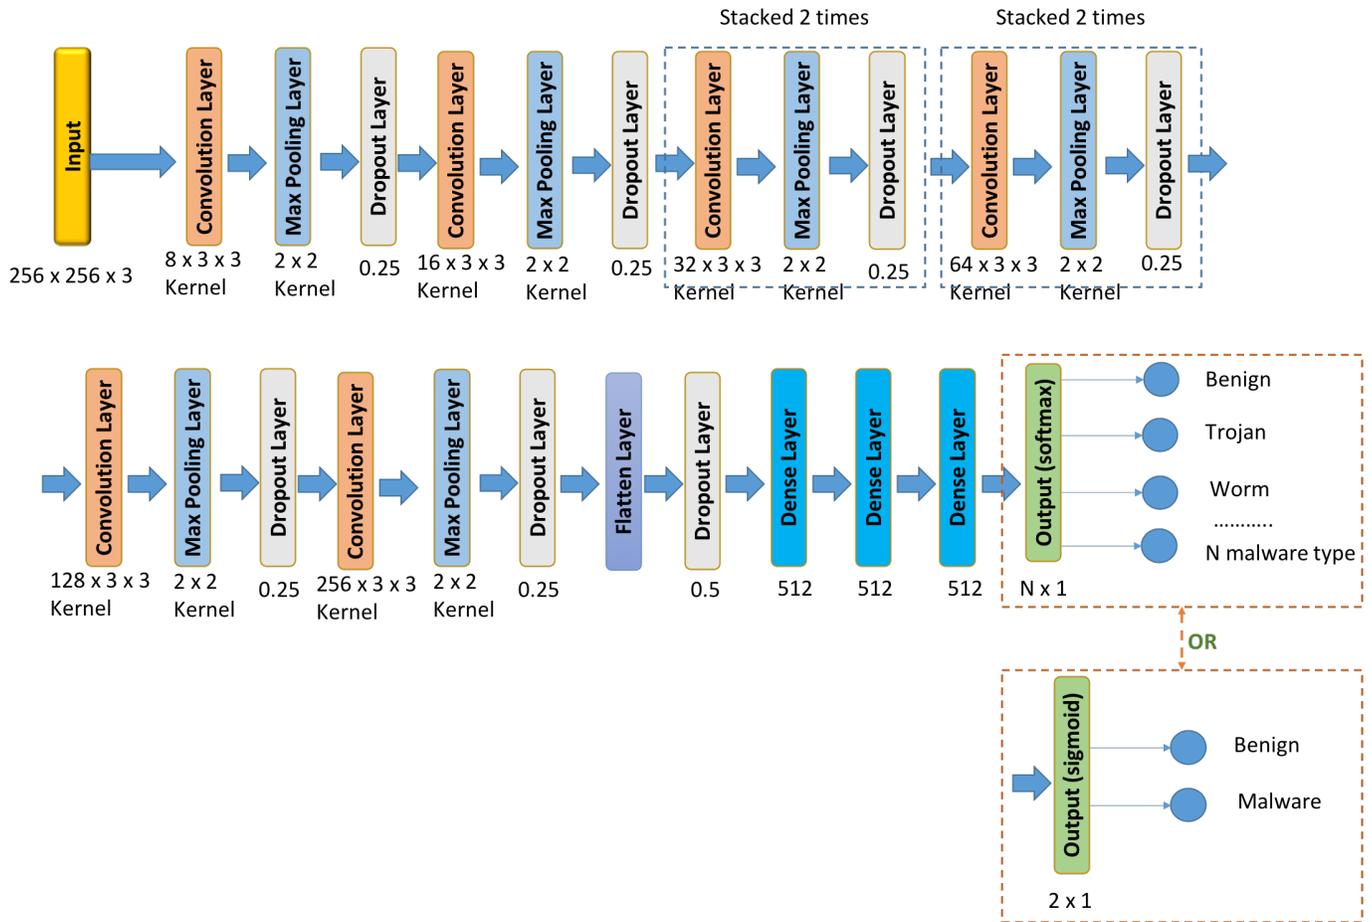

Fig. 10. Convolutional Neural Networks Architecture for Malware Classification.

(6 malware families). In addition, we evaluated the proposed design using various machine learning algorithms i.e. Linear Regression, Random Forest, KNN, CART, SVM. We also have evaluated using CNN-based deep learning technique and MLP. In our setup, we consider the idea of using both the binary and multi-class classifiers that provide handlers to extend the design to an open-set and ensemble-based learners.

Our approach is producing a comparable performance to the above-mentioned classifiers. Even though the datasets used in these classifiers are SARVAM and other datasets, our statistical T-TEST on F1-scores are not statistically significantly different.

## VI. CONCLUSION

In this work, we implement the computer visualization-based technique to build ML-based malware detection. We employ a GIST-based approach to extract malware image features from both the gray-scale and color images of malware binary samples. To study the prediction performance, we empirically analyze various machine learning algorithms. Our experimental study includes the following learning algorithms: linear regression, random forest, k-NN, CART, SVM, and MLP, and a CNN-based deep learning model and selects a candidate learning classifier that can yield better prediction performances. We evaluate our approach using the following malware datasets

SARVAM, PhD-thesis, and CIC. In comparison to traditional malware detectors, the visualization-based approach provides a significant performance enhancement. Our study observes that the CNN-based deep-learning model yields significantly better performance when tested against the various malware datasets listed above. Malware authors constantly innovate new methods for implementing sophisticated attacks that make the malware detection as an active research area. Our approach provides a path forward to implement an innovative malware detector. Nevertheless, this research work needs to be verified against various new malware datasets to be more effective. In the future, we would like to extend our research to benchmark datasets and as well conduct a large-scale evaluation.

**Abstract**—Eye movement analysis has gained significant attention from the eye-tracking research community, particularly for real-time applications. Eye movement prediction is predominantly required for the improvement of sensor lag. The previously introduced eye-movement approaches focused on classifying eye movements into two categories: saccades and non-saccades. Although these approaches are practical and relatively simple, they confuse fixations and smooth pursuit by putting them up within the non-saccadic category. Moreover, Eye movement analysis has been integrated into different applications, including psychology, neuroscience, human attention analysis, industrial engineering, marketing, advertising, etc. This paper introduces a low-cost eye-movement analysis system using Convolutional Neural Network (CCN) techniques and the Kalman filter to estimate and analyze eye position. The experiment results reveal that the proposed system can accurately classify and predict eye movements and detect pupil position in frames, notwithstanding the face tracking and detection. Additionally, the obtained results revealed that the overall performance of the proposed system is more efficient and effective comparing to Recurrent Neural Network (RNN).

**Keywords**—Eye Movement Classification; Eye Movement Prediction; Convolutional Neural Network (CNN); Recurrent Neural Network (RNN)

## I. INTRODUCTION

For a few decades, eye movement analysis has attained significant attention in the Human-Computer Interaction community. Various researchers have proposed using different technologies and algorithms to perform an automatic analysis for the position and direction of human eyes, helping different applications perform some analytics. The research community of eye movement analysis is growing owing to its capabilities of facilitating various tasks. One of these most useful is to detect someone's interest by determining the eye movement position and pupil size at a certain time. The analysis of eye movement has been commonly used in a variety of applications and different research areas, including visual systems [1], [2], [3], neuroscience and psychology [4], healthcare and psycholinguistics [5], user experience and interaction [6], consumer research, professional performance, and marketing [7], clinical research, economy, and education [8], software engineering, and product design [9], virtual reality [10], and transportation [11].

One of the main significant features of this research is to provide a method that can be exploited to accurately and objectively record and analyze human visual behavior. It would be incredible to request people glance over the supermarket

aisles to remember how many minutes they looked at every item or what advertisements they noticed most [12], [13]. Analyzing human eye movements enables researchers to study the movements of a participant's eyes during various activities, which provides insightfulness into the cognitive processes and understanding the common behavior of human behavior. Besides, it can show different things, including the methods of social interaction and learning patterns. It also helps researchers to screen typical nervous growth and perceptual disabilities. Furthermore, analyzing eye movements helps people clarify their thoughts [14], [15].

Eye movement analysis is referred to as the process of determining either the gaze point or the eye movement relative to the head position. In other words, Eye movement analysis classifies eye positions and eye movements by providing informative details about such movements. Eye movement analysis systems are widely utilized in various research fields, such as psychology, visual system, marketing, psycholinguistics, product design, and human-computer interaction. They are also ever-increasingly exploited for assistive and rehabilitative applications. Besides, along with eye movement analysis, it is required to estimate a noise-reduced signal's open eye movement position. Therefore, signal smoothing is obligatory to minimize the eye tracker's limited accuracy, and prediction is desirable to reduce the sampling lag of tracking systems. The eye movement prediction is meaningfully connected to distributed systems where instantaneous data of eye movements are required to be propagated over the network—the best example of this is Collaborative Virtual Environment (CVE) [10], [16].

There are numerous fields in which eye movement analysis could be applied extensively. Here to mention a few:

- **Scientific Research:** Studying visual behavior helps research obtain significant insightfulness into nervous growth, learning patterns, and cognitive impairments or diseases, such as people with Parkinson, Alzheimer, schizophrenia, brain injury, depression, autism, etc. In the same way, eye movement analysis can identify dyslexia and other learning or reading difficulties [17][18].
- **Market Research:** Eye movement analysis provides detailed and impartial information about the behavior of consumers and helps carry out decision-making processes. It enables brand owners and market researchers to detect consumers' behavior when observing and

choosing a product. It enables them to figure out what the most products naturally attracted the customers and the most product they ignored. Unlike questionnaires or surveys, eye movement analysis provides detailed, trustworthy behavior critical for branding, advertising, and packaging [16].

- Human Performance: Eye movement analysis and prediction can provide good insight into the ways of performing tasks and implementing processes implemented. It is used to identify risks, streamline training, operational inefficiencies, time efficiencies, and productivity improvement. Likewise, in sports and coaching, eye movement analysis can be used to improve performance by identifying skills and setting up strategies. It gives a unique insight into actions and tasks carried out hurriedly and often unconscious [19].

This paper introduces an eye-movement analysis and prediction system using a combination of the Kalman Filter and a convolutional neural network Network (CCN) to analyze the eye movement signal's instantaneous classification and predict forthcoming eye movement positions. Furthermore, using a numerical interpolation of the eye movement positions, the Kalman filter is utilized to provide a more useful interaction between the proposed system and the end-user. The contributions of this paper are as follows:

- Developing a real-time eye-movement analysis system using deep learning techniques, such as Convolutional Neural Network (CNN) and Kalman filter, which provides an accurate estimation for eye movements.
- Developing a cost-efficient eye-movement analysis and prediction system, which uses easy powerful deep learning-based calibration technique to predict eye movement and predict the eye movements based on the output of the deep learning technique.
- Designing hardware modules which are inexpensive based on a web camera and Arduino board.
- Conducting a quantitative evaluation of the performance for the implemented eye-movement analysis and prediction system.

The remainder of this paper is organized as follows: Section II presents state-of-the-art approaches related to the proposed system. Section III introduces the architecture of the proposed system. Section IV elaborates the evaluation of the proposed system and discusses the obtained results. Finally, Section VI concludes this work.

## II. RELATED WORK

Video/image-based eye movement analysis is classified into eye detection, eye position interpretation, and eye-tracking. It is critical to determine the eye model parameters from the image data in eye detection and tracking. The identification of the eye model can be made based on the eye region intensity distribution, the shape of the iris and eye, the pose of the head, etc. The authors in [20] and [21] present an excellent review of state-of-the-art image/video-based eye movement detection and tracking methods. As the authors stated, the eye detection models are categorized into the following classes:

- Eye-feature-based model;
- Eye-shape-based model;
- Eye-appearance-based model;
- Hybrid model.

### A. Eye-shape-based Models

The approaches based on this model detect the eye by contouring the pupil and iris and the eyelids' shape. Various eye-movement tracking applications use an elliptical model to prototype the eye, iris, and pupil's external shape. In these models, the model-fitting and voting-based methods are employed to calculate the elliptical model parameters. The authors in [22] exploited a voting-based method to contour the iris as an ellipse. They then applied horizontal scanning for the eye region to detect the iris center. At the horizontal line center, the pupil is located. The authors in [23] used ellipse to model the shape of the iris. Then, eye detection is carried out using spatio-temporal information. Because of the area darkness of the iris, the direction of the vertical and horizontal gradients will be outward from the iris center. Accordingly, a proposed voting-based method is used to find the iris center. At each edge point, an extrapolated line is delineated in the opposite direction of the gradient lines. The iris center is determined by the area where the largest number of lines are passing. In [24], the authors proposed a thresholding and contouring method to measure the radius of the iris. Other authors in [25] also used an ellipse to model the iris. Their model is built using RANSAC optimization and Expectation Maximization. In [26], the authors proposed an alternative ellipse fitting algorithm. They suppose that the contour points of the iris lay on an ellipse, and the contour points are applied to determine the ellipse parameters by a least-square fitting method. To obtain the sub-pixel level accuracy, the authors also introduced a sub-pixel edge detection approach. In [27] eye shape-based algorithm is proposed. The proposed algorithm utilizes a weakly supervised eye landmarks detection algorithm along with object detection and recurrent learning modules. The proposed algorithm can augment training data effectively and our specific format data consist of supervised and weakly supervised samples.

### B. Feature-based Models

The main goal of feature-based models is to detect local features, such as the pupil, limbus, etc., for localizing and modeling the eye parameters [20]. The authors in [28] tried to determine the region between the eyes rather than locating the local features. Their method is known as the "between-the-eyes" region. The idea behind this method is that the region between the eyes is brighter than the two sides. As both eyes are located on this region's sides, it contains the forehead and nose. Therefore, it is easier to be tracked, and both eyes can be detected by localizing both sides. In [29], the authors used the color of the skin to determine the face region. After that, in the detected skin area, both eyes are localized using four Gabor wavelets (linear filtering) to localize the eyes and non-linear filtering to detect the corners of both eyes. A feature-based gaze patterns recognition method is proposed in [30]. The proposed method used an eye tracker to collect data. Furthermore, Long Short-Term Memory (LSTM) technique is employed in this work for eye movements recognition.

### C. Appearance-based Models

These models are image template-based models. However, these models are single image-based templates and limited by the head pose changes and eye movements. If the head pose changes, these models fail. Also, these models are limited if there is a change in rotations and scales. Therefore, they need many different training datasets of eye areas to collect various eye orientations and states, and head poses in various illumination environments. A classifier is then modeled based on the pixel information of the given training datasets. Several authors introduced modified versions of feature-based models presented in [29] and [31] for eye detection and feature extractions. In [32] a human-computer interaction model is proposed based on medical staff eye movement. The Appearance-Based model is used such that the medical staff used their eye movements to control the robot during the operations time.

### D. Hybrid Models

Hybrid models are based on the three models introduced above. The authors in [33] and [34] use the appearance-based model as the combination of appearance and shape-based models by [20]. They also combined expectation-maximization for accurate estimation of the head poses and particle filtering for tracking the iris movements [21]. They used the distribution of face color and eye region for eye detection and tracking. In [35], the authors used image color information for face region detection. A hybrid eye movement recognition method is proposed in [36]. The proposed method aims to solve the inaccurate positioning problem of the initial position of the shape model in the process of eyelid matching by using machine learning. In addition, this method developed the algorithm by combining the AK-EYE model based on the combination of the ASM algorithm and Kalman filtering to create a local feature model for each feature point.

Similarly, the authors in [28] and [37] employed the same approach. After the face region detection, the detected face region is partitioned into smaller regions to find the eyes' region using thresholding and edge information. The template matching is then used for eye tracking. After the skin region detection, the detection of the face region is modeled as a face mirror-symmetry and ellipse. Besides, infrared illumination is also used for eye tracking, using more than one camera to capture IR images. If the light source is near the camera's optical axis, the light reflection from the pupil is used to detect the eye region. Accordingly, the pupil will be a brighter area in the image. Conversely, if the light source is far from the camera's optical axis, the pupil will appear as a darker area.

Different techniques for eye movement locating and measuring were proposed. Eye movement analysis is the process of locating the eye and measuring the eye movements. There are various methods and techniques used for eye-movement analysis. These techniques are divided into four classes:

- Scleral Search Coil (SSC)
- Infrared Oculography (IOG)
- Electrooculography (EOG)
- Video Oculography (VOG)

### E. Scleral Search Coil Technique (SSC)

As stated in [38], the SSC and Videoculography (VOG) techniques are primarily used for 3D eye-movement measurement. The authors proposed a method aiming to compare the accuracy of SSCS and VOG. Accordingly, the obtained results showed that VOG showed better accuracy than SSCS. Another Scleral Search Coil System was presented in [39]. The main goal is to investigate the effects of the Scleral Search Coils placement on the eyes saccades' kinematics. To that end, saccades of the human eye were recorded with an infrared video system while wearing coils. The results were compared with results while no coils were worn. According to [40], the SSC technique is suitable for animal studies, where coil lenses can be surgically implanted, leaving no peripheral to interfere with or damage. However, the SSC technique has several limitations. It can only be worn for a short period (approximately 30 minutes), and the eye cornea is required to be anesthetized. Even though it usually causes mild discomfort throughout and after the experimental sessions. The mounted annulus results in corneal dryness and vision blurring. The accuracy can be degraded by the annulus slippage on the eyes.

### F. Infrared Oculography (IOG)

This technique relies on the strength of infrared light reflected sclera to detect and localize the eye position using light beams generated by a pair of glasses. In this technique, a reference point, known as a glint or corneal reflection, is involved using an infrared light source when solving the sensitivity issue of head movements. It has been commonly used by various techniques, such as low pass filtering [41], K-means [42], Euclidean distance [43], random sample consensus [44], etc. The authors in [45] proposed a method based on a combination of IOG and Electromyography (EMG) techniques. The obtained result demonstrated that there is a robust linear correlation between time courses and amplitudes of EMG-and-IOG-recorded startle.

### G. Electrooculography (EOG)

As stated in [46], electrooculography (EOG) is an electrophysiologic test measuring the existing resting electrical potential between the Bruch's membrane and cornea. The mean transepithelial voltage of bovine Retinal pigment epithelium is 6 millivolts (mV). According to [47], the detection of saccades within raw mobile electrooculography (EOG) data includes complex algorithms processing data collected when seated static tasks. For dynamic tasks, the data processing is relatively infrequent and sophisticated, especially in the elders or people who have Parkinson's disease. EOG is an applicable and low-priced technique used in the field of human-computer interaction. This technique uses sensors attached to the eyes' surrounding area to obtain an electric field during eye rotation by measuring skin fluctuations. The eye movements are recorded unconnectedly employing electrodes.

Nevertheless, the recorded signal can be subjected to alteration without eye movements. Even if EOG is practicable, it is not widely used. To put it another way, the EOG is limited to medical applications and laboratories. Various approaches have employed this technique to perform different tasks [46][47]. The authors in [47] introduced a new method by employing a

differential electrooculography (EOG) signal using a fixation curve (DOSbFC) to eliminate baseline noise and drift based on a new electrode positioning scheme. The authors experimented with EOG eyeglasses and a new detection protocol for long-term step-by-step eye movement detection. The proposed DOSbFC computes the difference values of accumulated EOG signals between the initial eye movement and fixation time. It allows long-term eye movement detection with high accuracy and only needs a single calibration.

H. Video Oculography (VOG)

The primary methods for three-dimensional eye movement measurement are the scleral search coil system (SSCS) and Video Oculography (VOG) [48]. The authors proposed a method to evaluate the accuracy of SSCS and VOG. The obtained results revealed that VOG recorded better accuracy than SSCS. Another scleral search coil system was presented in [49]. The proposed method investigates the extent to which scleral search coils' placement onto the eyes influences saccades' kinematics. The saccades were recorded using an infrared video system. Simultaneously, The coils were worn, and the main-sequence properties were compared with recordings without coils mounted on the eyes. According to [50], the VOG technique is the most widely used technique for currently eye-movement tracking systems.

III. PROPOSED SYSTEM ARCHITECTURE

This section presents the general architecture and detailed components of the proposed system, which focuses on the analysis, classification, and prediction of eye movements. For the classification and prediction of eye movements, eye detection is the first step to be performed. The eye-detection step requires the head pose estimation for proper eye detection. Then, it is followed by finding the pupil to determine the iris center. The eye movement classification uses the positional eye data for the separation of eye movements: saccades, fixations, and smooth pursuit, which is a highly challenging task. Finally, the future eye movement prediction is carried out based on the classification of eye movements and head pose estimation.

A. System Components

The main task of this paper is to construct a system for eye movement analysis and prediction. The system's practical aspect includes incorporating all the components given in detail in the following sections. Thus, the system comprises the following components, as shown in Fig. 1. As illustrated by Fig. 1, the proposed system comprises the following components:

- Hardware components
- Software components.

B. Hardware Components

The hardware component is one of the essential parts of the proposed system. It is considered as the data frame source. The hardware component consists of sub-components: webcam and Arduino Uno board. In this section, the details of each sub-component are articulated. Fig. 2. shows a general connection view of the hardware components and the system. While Fig. 3 represents the real-world implementation of the system described in Fig. 2.

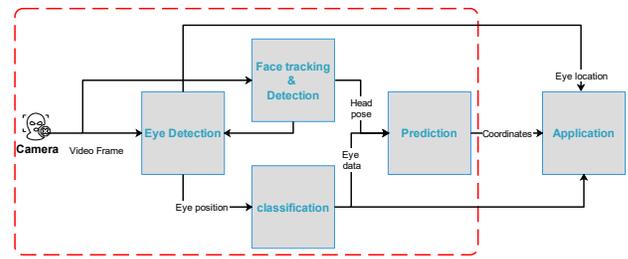

Fig. 1. The Proposed System's Architecture.

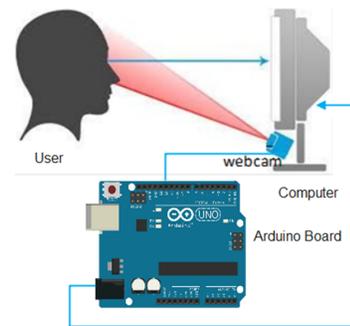

Fig. 2. Hardware Connection.

C. Software Components

The software module is responsible for performing different tasks and consists of the following sub-modules:

- Eye Detection,
- Face Tracking & detection,
- Eye Movement classification, and
- Prediction.

The detailed procedure of each module is given below.

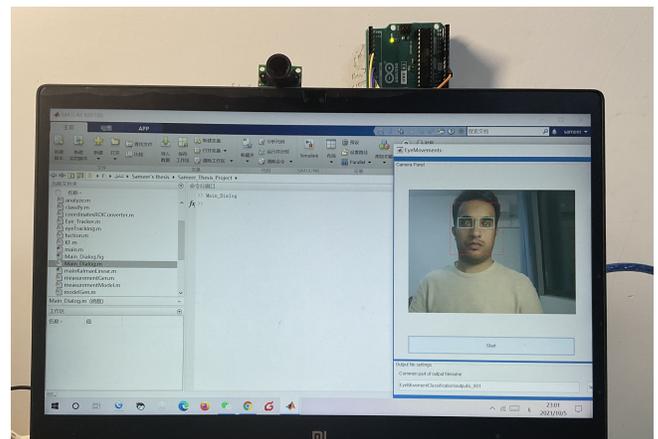

Fig. 3. Software Components.

1) *Eye Detection*: This component's main task is to detect the eyes on the face and determine the pupils' position. For eye detection, face region detection is the first task to be performed based on the head pose provided by the Head Pose Estimation module. The next step is to detect the eyes region and then detect the iris region.

a) *Eye Region Detection*: After face region detection, a feature-based method is applied sequentially to determine the regions of the left eye and the right eye. The gradient is calculated for each video frame based on the detected face box to accomplish this objective. Then, a horizontal projection is applied to calculate video frame gradient. In this application, the eye regions are located in the upper face part, characterized by the changeful value compared to the other face parts. After determining the horizontal position and the face dimensions, a vertical projection is applied to each part of the horizontal position. Owing to the area's brightness between the left and right eyes, the peak of the vertical projection is considered as the face center. Based on the horizontal and vertical projections, two peaks are located as the left and right boundaries of the video frame, and the face width is calculated based on the two lines of the vertical projection. Based on the face segmentations resulted from both vertical and horizontal projections, the widths and heights of both eye regions can be estimated. And then, the regions of interest (ROIs) can be calculated.

b) *Pupil Centers Localization*: To localize the pupils centers, an eye template must be created to match the eye size on the template and the size of the actual eyes on the video frame. Assume that the two eye regions' created template is denoted as  $T[i, j]$ , and  $V[i, j]$  represents the size of the eyes on the video frame, which is required to be detected. To calculate  $V[i, j]$ , the template can be placed on the video frame by calculating the template intensity values and the corresponding points of the image. Since the template does not absolutely match the video frame, the dissimilarity between the template intensity values with the corresponding intensity values of the video frame is calculated, as follows:

$$\max_{[i,j] \in TR} |I - V|, \sum_{[i,j] \in TR} |I - V|, \text{ or } \sum_{[i,j] \in TR} (I - V)^2 \quad (1)$$

where TR is the template region.

If there is a match between the template and the video frame. The dissimilarity measure is calculated by Equation (2).

$$\sum_{[i,j] \in TR} (V - T)^2 = \sum_{[i,j] \in TR} V^2 + \sum_{[i,j] \in TR} T^2 - 2 \sum_{[i,j] \in TR} (V \times T)^2 \quad (2)$$

Reasonably, this calculation for determining the template instances is to create a general template that can be used for localizing the pupils' centers of the other video frames. This is to decrease the computational overhead of repeating the calculation of pupils' centers each time. If we have a template of  $M \times N$  dimensions, Equation (3) is used, which is known as cross-correlation.

$$M[i, j] = \sum_{a=1}^M \sum_{b=1}^N T[a, b] \times V[i + a, j + b] \quad (3)$$

where  $a$  and  $b$  are the offset between the video frame and the template.

The equations mentioned above are used to calculate the cross-correlation when  $V$  and  $T$  are fixed. However, in the case of  $T$  is fixed, while  $V$  is varying,  $M$  will depend on  $V$ . Therefore, the normalization of the cross-correlation is carried out to solve this problem, as shown in Equation (4) and (5).

$$corr[i, j] = \sum_{a=1}^M \sum_{b=1}^N T[a, b] \times V[i + a, j + b] \quad (4)$$

$$m[i, j] = \frac{corr_{TV}[i, j]}{\sqrt{\left\{ \sum_{a=1}^M \sum_{b=1}^N V^2[i + a, j + b] \right\}}} \quad (5)$$

2) *Eye Movement Classification*: Eye movements are classified into three categories: fixation, saccades, or smooth pursuit. The eye regions obtained from the previous stage are used in a multiclass classification for predicting the eye movement on the next stage.

a) *Classification Threshold Setting*: To classify the eye movements, the proposed system relies on velocity thresholds of eye gaze. It adopts an adaptive threshold for the saccade classification. The saccades are initialized by a user-defined threshold of the time series velocity to a certain value. Based on the specified initial value (TV1), the new threshold is adaptively determined by calculating the variance of sub-thresholds (SV), as given by Equation (6).

$$TV_n = \overline{SV}_{n-1} + St.dev \times \sqrt{\frac{\sum (SV_{n-1} - \overline{SV}_{n-1})^2}{N - 1}} \quad (6)$$

where St.dev represents the number of standard deviations higher than the average velocity.

This step is repeated until a threshold velocity is stabilized, as given by Equation (7).

$$|TV_n - TV_{n-1}| < 1^\circ / \text{sec} \quad (7)$$

The previous steps are carried out to determine the saccades classification. Regarding pursuit classification thresholding, if the velocity exceeds the minimum velocity threshold (pursuit threshold), it is classified as a pursuit. Otherwise, it is classified as a fixation.

b) *Convolutional Neural Network (CNN)*: CNN is known as a feed-forward neural network used for different machine learning purposes. Although one of the drawbacks of CNN is the huge time needed for training, its output accuracy compared to other deep learning models is better. Our proposed system adopts a CNN model by specifying three convolution stages as shown in Fig. 4:

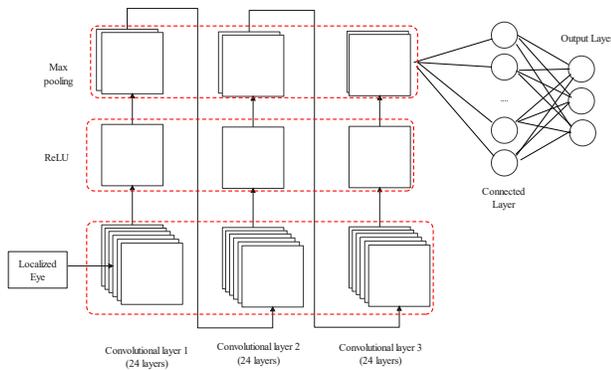

Fig. 4. The CNN Network Architecture.

- The input stage: the video frame is set to have a dimension of  $42 \times 50$ . The first layer utilizes 24 filters, and each filter is of  $7 \times 7$  dimensions.
- A rectified linear unit (ReLU) stage: In this stage, the ReLU layer is added, and a non-linearity to the activations is introduced, which is mathematically represented as given by Equation (8).

$$f(A) = \max(0, A) \quad (8)$$

where  $A$  is the input, and  $f(A)$  is the output of the ReLU layer.

- A max-pooling stage: In this stage, A max-pooling is followed the ReLU layer. It carries out a spatial sub-sampling of video frames. In this stage  $2 \times 2$  dimensional max-pooling layers have been used for the reduction of the spatial resolution of the video frames to half.

Moreover, two layers consisting of input, ReLU, and max-pooling layers are added after the previous stages with  $5 \times 5$  and  $3 \times 3$  dimensions, respectively. Then, a connected layer receives the output from the previous activation layer. In our case, the output layer consists of three nodes representing the eye movements: saccade, fixation, and smooth pursuit. The softmax loss function is used to measure the error, and the Cross entropy loss function is used as a loss function, which is reduced during the training phase. Equation (9) gives a mathematical representation of the Cross entropy loss function ( $L$ ).

$$L = -[t \log(f(A)) + (1 - t) \log(1 - f(A))] \quad (9)$$

where  $A$  is the classification vector,  $t$  is the truth value taking a value of 0 or 1, and  $f(A)$  is the softmax probability of  $i^{th}$  class

3) *Face Tracking and Detection*: This section is dedicated to elaborating on our solution for face tracking and detection. Fig. 5 presents an illustrative demonstration of the proposed solution for face tracking and detection.

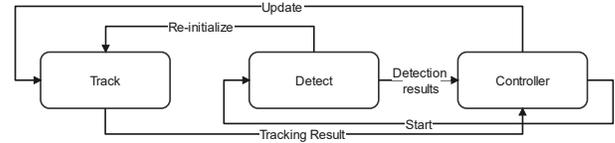

Fig. 5. Face Tracking and Detection Flowchart.

a) *Face Tracking*: Our proposed solution utilized a kernelized correlation filter (KCF) introduced in [51] for face tracking. Although there is a drawback of KCF when the face is not in the camera's view, it fails and hardly recovered. This challenge is solved using the detection unit, whose results are used to re-initialize the KCF algorithm and update the model with a specific learning rate. The procedure of KCF is summarized in the following steps:

- KCF uses a window that is 2.5 times larger than the given face to cycle shift to obtain training samples. Then, the extracted samples are labeled using Gaussian distribution and are saved in the filter model.
- KCF uses windows, which are 2.5 times larger than the best-obtained result to cycle shift to obtain the samples in the next frames. The similarity is calculated between the target in the KCF model and the samples. Then, the KCF is updated using the obtained result.

b) *Face detection*: For face detection, we adopt the lightweight multi-task cascade Convolution Neural Network. The following phases briefly describe the overall steps of face detection.

- Phase one: In this phase, a proposal Network is exploited to get the windows obtained from the face tracking unit and the related vector of their bounding boxes. Then. The regression vectors of bounding boxes are used to carry out the calibration of the candidates. The highly overlapping candidates are merged using non-maximum suppression.
- Phase two: The candidates obtained from phase one are used as an input to Refined Network to perform false candidate rejection. The non-rejected candidates with their boxes are calibrated using non-maximum suppression.
- Phase three: In this phase, the outputs of phase two are fed to O-net to obtain more accurate results. In this phase, we ignored the landmarks produced by O-net since we only need bounding surrounding the face to be used by the eye detection module.

The control unit controls the starting point of the face detection unit and updates the face tracking unit.

4) *Eye Movement Prediction*: This component's main task is to predict eye movement based on the output of head pose estimation and eye data of the classification component. This component works in conjunction with Head pose estimation, whose main task is to detect and estimate the pose direction in order to detect the eye position and direction. Eye movement

prediction can reliably track both eyes and detect the eye features in each video frame. However, by accurately detecting the number of head movements in each video frame, the user's eye movement estimation can be carried out accurately, as it is difficult for the users to keep their heads still.

In our proposed system, Kalman filter is modeled by two-state vectors to predict eye movements, as given by Equations (10) and (11), and the transitional state matrix is modeled as given by Equation (12).

$$x_n = \begin{bmatrix} \omega_x(n) \\ v_x(n) \end{bmatrix} \quad (10)$$

$$y_n = \begin{bmatrix} \omega_y(n) \\ v_y(n) \end{bmatrix} \quad (11)$$

$$A_n = \begin{bmatrix} 1 & \Delta s \\ 0 & 1 \end{bmatrix} \quad (12)$$

where  $\omega_x(n)$  and  $\omega_y(n)$  are the eyes' horizontal and vertical positions,  $v_x(n)$  and  $v_y(n)$  represent the horizontal and vertical velocities at time instance  $n$ , and  $\Delta s$  represents the sampling interval. The identity matrix for both state vectors is set as given by Equation (13).

$$H_n = [ 1 \quad 0 ] \quad (13)$$

To represent the noise resulted from Arduino board or the camera itself, The standard deviation of measurement noise  $R_n = \delta_v^2 = 1^\circ$ . Suppose there is a corruption in the eye signal position (the eye noise resulted from eye sub-movements, such as drifting). In that case, the estimation of system noise is done by the following covariance matrix, as given by Equation ((14)).

$$Q_n = \begin{bmatrix} \sigma_w^2 & 0 \\ 0 & \sigma_w^2 \end{bmatrix} \quad (14)$$

where  $\sigma_w^2$  represents the variance of the system noise.

For eye movements predictions, the following is carried out:

- **Saccades prediction:** The prediction of saccadic movement is carried out using the method presented in [52]. To detect saccades, the differences between the actual eye velocity and the predicted eye velocity are measured. Two-State Kalman Filter is used to measure the predicted eye-velocity, and a chi-square test is employed to measure the difference between the actual eye velocity and the Kalman-filter-based predicted eye velocity, as follows:

$$V^2 = \sum_{i=1}^p \frac{(\hat{v}_2^-(i) - \frac{(z_i - z_{i-1})}{\Delta t})^2}{\sigma^2} \quad (15)$$

where  $\hat{v}_2^-(i)$  is the predicted velocity and  $z_i$  is the measured coordinate of eye position.  $\Delta t$  is the sampling interval and  $\sigma^2$  is the standard deviation of the actual eye velocity during  $\Delta t$ . We adopted the proposed method in [53] for determining the saccade

amplitude using the chi-square value. The proposed method was based on the following formula:

$$Sac\_amp = -0.000024x^6 + 0.0536x^4 + 1.5 \quad (16)$$

$$Sac\_dur = (2.2 \times Sac\_amp\_21)/1000 \quad (17)$$

Once  $Sac\_amp$  is calculated, the saccade duration (in seconds) can be calculated by Equation (17).

- **Fixation prediction:** fixation analysis is carried on by updating eye positions. The fixation is predicted when the eye velocity threshold is exceeding  $0.5^\circ$  per second for a minimum of 100 ms.
- **Smooth prediction:** this eye movement is predicted when the eye position does not belong to fixation or saccade eye movements, and the velocity is not exceeding  $140^\circ$  per second.

#### IV. SYSTEM IMPLEMENTATION & EVALUATION

When examining the proposed system, the realistic implementation environment is essential because it is exploratory by nature. This section is devoted to describing the implementation of the proposed system. It clarifies the environment in which the proposed system has been implemented and presents the prototype's functionalities.

##### A. Implementation Programming Environment

MatLab has been used for the proposed system implementation. This is because most of the proposed system computation is based on arrays (lists), which is simple to be implemented in Matlab. The version used for implementation was MatLab R2018b, which works on Windows 10 platform.

##### B. System Evaluation

For evaluating the proposed system, many experiments have been carried out to investigate the solution's success in different scenarios. Since the main objective of the proposed system is to classify and predict the movements, it has been evaluated in terms of eye movement classification and prediction. Different evaluation metrics have been employed, and an actual training dataset has been used. The following subsections are devoted to the description of the training dataset and evaluation metrics.

*1) Training Dataset Description:* The GazeCom dataset is the largest available dataset [54]. The dataset includes 18 recorded videos, and each video has 47 subjects. Far from the screen by 40 cm, the subjects were placed looking at the screen. The size of the screen was 40x30 cm with a resolution of 1280x720. The visual angle covered by the stimulus was 48x27 degrees, and each degree corresponds to 26.7 pixels. The recordings contain only monocular data; the resulted mean validation error was 0.62 degrees. The ARFF format was used to store the recordings due to the access simplicity by programming languages, such as Python and MatLab. The ARFF files contain different data fields, the time in microseconds, x and y positions, the scoring, and combined scoring. The eye movement classes contained in the dataset are unknown, saccades, fixations, smooth pursuit, and noise

numbered from 0 to 4, respectively. Other fields presented in the dataset are the direction, velocity, and signal acceleration. The whole dataset has been used to train the Eye Movement Classification module, which runs based on the CNN and RNN models. For testing, we used the data frame recorded by the system camera described above.

2) *Evaluation Metrics*: The following metrics are used to evaluate the performance of the proposed system in terms of eye movement classification and prediction. It is essential to specify quantitative and qualitative scores for the performance assessment of the proposed system and its counterparts in terms of eye movement classification, which can evaluate the proposed system in terms of eye movement prediction. The following evaluation metrics are selected.

- **Pursuits quantitative score (PQnS)**:  
The PQnS metric is used to determine the number of detected eye smooth pursuit, while the smooth pursuit of the stimuli is given. It is calculated by comparing the eye position  $(x_e, y_e, t)$  with the corresponding coordinate of smooth pursuit of stimuli  $(x_s, y_s, t)$ . If the eye position is classified as smooth pursuit, then the smooth pursuit detection counter increases. Equation (18) shows the mathematical representation of PQnS [51][55].

$$PQnS = \frac{\text{Saccade\_detection\_counter}}{\text{stimulus\_saccade\_points}} \times 100 \quad (18)$$

The ideal PQnS is calculated by Equation (19).

$$\text{Ideal\_PQnS} = \frac{n \times s_t + \sum_{j=1}^n D_{cor\_sac\_dur_j}}{\sum_{j=1}^n D_{stim\_pur\_dur_i}} \quad (19)$$

where  $n$  donates the pursuits of stimulus,  $D_{stim\_pur\_dur_i}$  represents pursuit duration stimulus  $i$ ,  $D_{cor\_sac\_dur_j}$  is the corrective saccade duration and  $s_t$  is the pursuit latency.

- **Fixation quantitative score (FQnS)**:  
This metric measures the number of detected fixation behavior to the number of presented fixations of stimuli. FQnS is calculated by sampling the fixation stimulus using a similar frequency of eye position. Then, the stimulus fixation coordinate  $(x_s, y_s)$  is compared with the recorded eye position coordinates  $(x_e, y_e)$ . The mathematical representation of FQnS is given by Equation (20) [51][55].

$$FQnS = \frac{\text{fixation\_detection\_counter}}{\text{stimulus\_stimuli\_points}} \times 100 \quad (20)$$

Where  $\text{fixation\_detection\_counter}$  denote the number of fixation points, when  $\text{stimulus\_stimuli\_points}$  the number of fixation stimuli is given.

- **Saccade quantitative score (SQnS)**:  
The main idea behind SQnS is to measure the number of the detected saccades when the stimuli saccadic behavior is given. The stimuli metric is calculated by considering each jump in the fixation target as a stimuli saccade, and distances between targets are added to the  $\text{total\_stimuli\_saccade\_amplitude}$ . Correspondingly,  $\text{total\_detected\_saccade\_amplitude}$  is the total of the absolute values of the detected saccade

amplitudes. The mathematical representation of SQnS is given by Equation (21) [51], [55].

$$SQnS = \frac{\text{total\_detected\_saccade}}{\text{total\_stimuli\_saccade}} \times 100 \quad (21)$$

- **Fixation qualitative score (FQIS)**:  
FQIS measures how the detected fixation is approximate to the given stimuli. Therefore, it provides the detected fixation's positional accuracy. Like FQnS, FQIS is calculated for fixation coordinates  $(x_s, y_s)$  of the given stimuli compared to the coordinates of eye position. if such coordinates are considered as a fixation, the distance between the centroid of the detected fixation coordinates  $(x_e, y_e)$  and given fixation coordinates is calculated. Equation (22) gives the mathematical representation of FQIS [51], [55].

$$FQIS = \frac{\sum_{i=1}^n \text{fixation\_distance}_i}{N} \quad (22)$$

$$\text{fixation\_distance}_i = \sqrt{(x_s^i - x_c^i)^2 + (y_s^i - y_c^i)^2} \quad (23)$$

where  $N$  is the number of stimuli position coordinates. The Ideal FQIS is  $0^\circ$ , which indicates the absolute accuracy of the system equipment.

- **Misclassified fixation score (MisFix)**:  
MisFix is calculated by separately measuring  $SP\_fixation\_points$ , the number of fixation coordinates in eye position classified as smooth pursuit, and the total number of fixation coordinates in stimuli ( $\text{total\_stimuli\_fixation\_points}$ ). Equation (24) gives the mathematical representation of MisFix [51][55].

$$MisFix = \frac{\text{sp\_fixation\_points}}{\text{total\_stimuli\_fixation\_points}} \quad (24)$$

The Ideal MisFix is 0%, meaning that no smooth pursuit was classified during the fixational stimulus.

- **Pursuit qualitative scores (PQIS)**:  
PQIS measures how the detected smooth pursuit is approximate to smooth pursuit in the given stimulus. PQIS is measured by  $PQIS\_P$  for position and the  $PQIS\_V$  for velocity accuracy. The  $PQIS\_P$  and  $PQIS\_V$  are calculated in a similar way to FQnS. The mathematical representations of  $PQIS\_P$  and  $PQIS\_V$  are given in Equations (25) and (26) [51], [55].

$$PQIS\_P = \frac{\sum_{i=1}^N \text{pursuit\_distance}_i}{N} \quad (25)$$

$$PQIS\_V = \frac{\sum_{i=1}^N \text{pursuit\_speed\_difference}_i}{N} \quad (26)$$

$$\text{pursuit\_distance}_i = \sqrt{(x_s^i - x_c^i)^2 + (y_s^i - y_c^i)^2} \quad (27)$$

$$\text{pursuit\_speed\_difference}_i = |v_s^i - v_c^i| \quad (28)$$

where  $N$  is the number of points of stimuli position. The evaluation ideal scores of this paper is shown in Table I.

TABLE I. THE EVALUATION IDEAL BEHAVIOR SCORES

SQnS	FQnS	PQnS	MisFix	FQIS	PQIS_P	PQIS_V
100	81.599	52.04	7.1	0	0	0

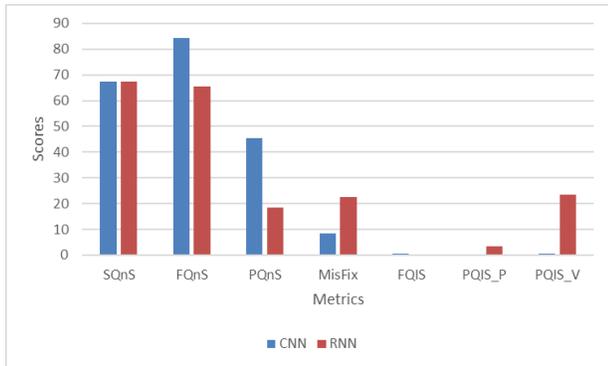

Fig. 6. The Behavioral Classification Scores of the Proposed System and RNN with Sampling Rate 30 Hz and Saccadic Threshold 75 Deg.

3) *Classification Evaluation:* In this section, the evaluation, in terms of eye movement classification, of the proposed system employing CNN against the RNN model is carried out based on the evaluation metrics given above. To evaluate the performance of the proposed system, the data frame was sampled using different frequencies (30 Hz, 100 Hz, 500 Hz, and 1000Hz).

The behavioral scores introduced in 4.2.2 were utilized to evaluate the effectiveness of the proposed system and its counterpart (RNN) in eye movement classifications.

Figs 6-9 display the obtained classification behavioral scores of both the CNN adopted in our proposed system and the RNN model, and the saccadic threshold is 75 deg. According to the obtained results for sampling rate 30 Hz, the CNN and RNN models achieve almost the same results for SQnS. However, the CNN model outperforms the RNN model in FQnS, PQnS, MisFix, FQIS, *PQIS\_P*, and *PQIS\_V*,

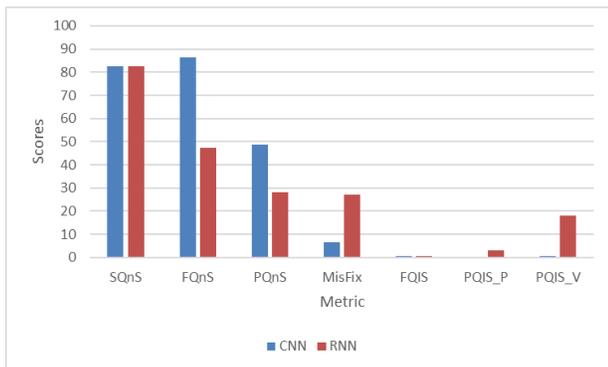

Fig. 7. The Behavioral Classification Scores of the Proposed System and RNN with Sampling Rate 100 Hz and Saccadic Threshold 75 Deg.

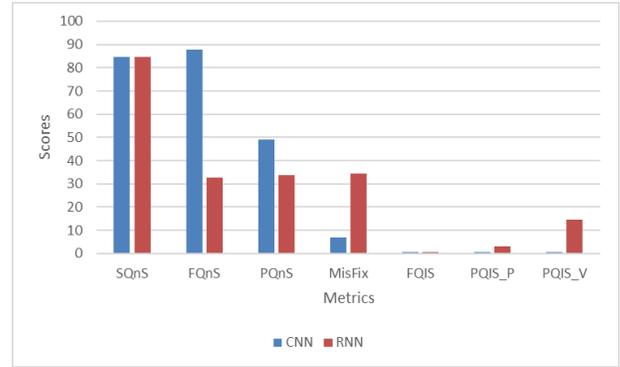

Fig. 8. The Behavioral Classification Scores of the Proposed System and RNN with Sampling Rate 500 Hz and Saccadic Threshold 75 Deg.

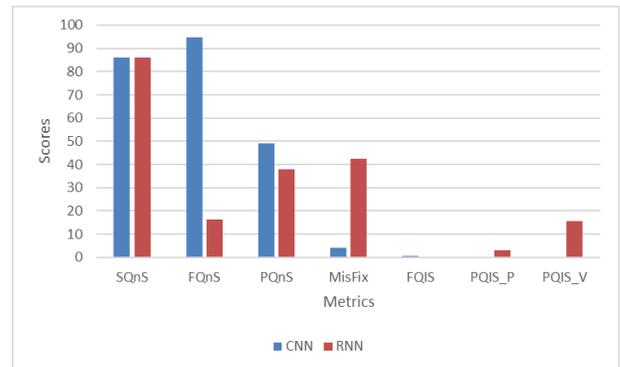

Fig. 9. The Behavioral Classification Scores of the Proposed System and RNN with Sampling Rate 1000 Hz and Saccadic Threshold 75 Deg.

respectively. For 100 Hz, it is noticeable the CNN model achieves better results than the RNN model, but are the close scores for saccades classification metric (SQnS). Similarly, for sampling rates (500 Hz and 1000 Hz), the CNN model shows better results than the RNN model. The RNN model shows an increase in MisFix as the value of the sampling rate increases. Besides, *PQIS\_P* and *PQIS\_V* show instability in measuring the pursuit position and velocity. It is worth mentioning that the CNN behavioral classification show proximity to ideal scores as the sampling rate frequency increases.

Moreover, the proposed system against the RNN model is evaluated in terms of eye movement classification with decreasing 10% of the saccadic threshold of the previous evaluation. As mentioned above, the evaluation is carried with different sampling rates, and the saccadic threshold is 65 degrees. We selected this slight change in the saccade threshold to determine the changes of eye movement classification that can take place with different classification thresholds of saccade movement. Fig. 10 to 13 depict the obtained classification behavioral scores of both the CNN adopted in our proposed system and the RNN model.

However, compared to the RNN model, the CNN model

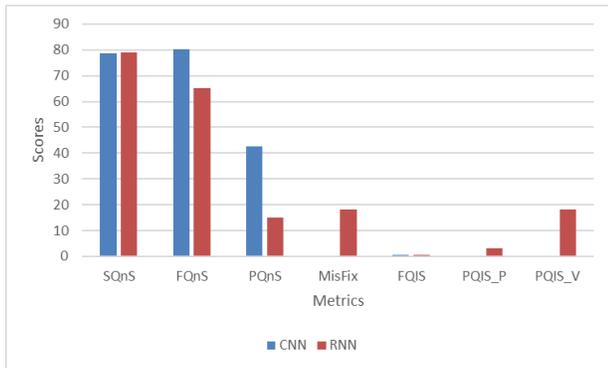

Fig. 10. The Behavioral Classification Scores of the Proposed System and RNN with Sampling Rate 30 Hz and Saccadic Threshold 65 Deg.

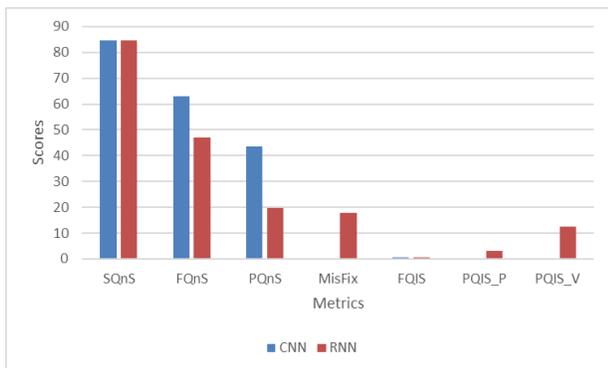

Fig. 11. The Behavioral Classification Scores of the Proposed System and RNN with Sampling Rate 100 Hz and Saccadic Threshold 65 Deg.

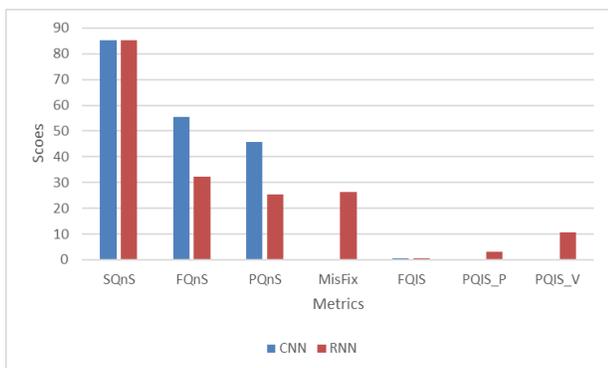

Fig. 12. The Behavioral Classification Scores of the Proposed System and RNN with Sampling Rate 500 Hz and Saccadic Threshold 65 Deg.

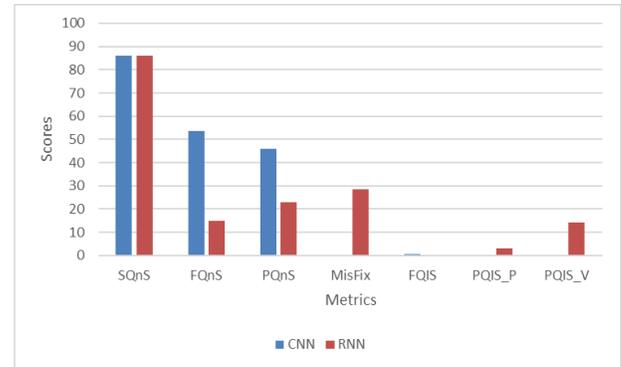

Fig. 13. The Behavioral Classification Scores of the Proposed System and RNN with Sampling Rate 1000 Hz and Saccadic Threshold 65 Deg.

achieves better results as indicated by the behavioral scores. Both models achieve almost the same SQnS scores for the given sampling frequencies. The other behavioral scores (FQnS, PQnS, FQIS, *PQIS\_P*, *PQIS\_V*) show that the achieved scores decrease as the sampling frequencies increase. This leads us to conclude that the saccadic threshold has effects on the behavioral classification scores as it decreases. It can be noticed that the CNN model outperforms the RNN model in achieving more reliable results. Table II gives the behavioral classification scores of the proposed system and RNN with various sampling rates, and the saccadic threshold is 75 deg.

Compared with the results listed in Table II, the eye movement classification performance of both the CNN and RNN models is notably decreased with the saccadic threshold decrease.

### C. Prediction Evaluation

The proposed system utilized the Kalman filter for eye-movement prediction with two states (velocity and position). The Kalman filter is applied to the recorded eye movement to predict the eye velocity and position. Then, the Chi-square test uses the measured and predicted position and velocity values to classify each positional value as fixation, saccade, and smooth pursuit. The eye movement prediction module of the proposed system is evaluated using two scenarios.

The first scenario was carried with a saccadic threshold of 75 degrees. The second scenario was carried out with a saccadic threshold of 65 degrees. Both scenarios were implemented with various sampling rate frequencies (30 Hz, 100 Hz, 500 Hz, and 1000 Hz). Figs 14-17 illustrate the behavioral scores of both scenarios.

As it can be seen, the different thresholds influence the Kalman filter prediction scores. The SQnS score has shown no changes in both scenarios for sampling frequencies (30 Hz, 100 Hz, and 500 Hz). As the sampling frequency increased to 1000Hz, the results have shown remarkable changes. For FQnS, it can be noticed that capability of the Kalman filter in classifying fixation is influenced by the increase in the sampling frequencies. This indicates that the accuracy of the

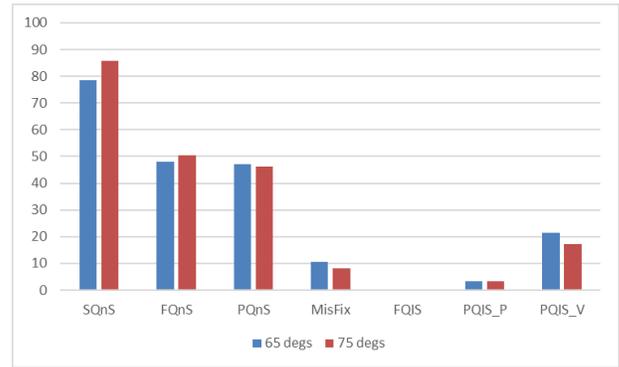

Fig. 17. The Behavioral Classification Scores with a Sampling Rate of 1000 Hz and Saccadic Threshold 75 and 65 Degs.

Kalman filter in fixation classification decreased as the sampling frequencies increase. Unlike FQnS, PQnS is increased in both scenarios. This indicates that the Kalman filter accuracy in pursuit classification as the sampling frequencies increase. However, the Kalman filter shows high fixation misclassification, as shown by MisFix scores. Moreover, the Kalman filter shows a deviation in predicting pursuit positional and velocity, as indicated by  $PQIS_P$  and  $PQIS_V$  scores, in both scenarios. This can happen in a case of a very high position detected before a very low position.

## V. CONCLUSION AND FUTURE WORK

### A. Conclusion

This paper proposed a system for eye movement analysis and prediction. The system proposed in this paper is a comprehensive system for three-type eye movement classification and prediction data consistency with a various and wide range of components. It combines two essential components: hardware and software. Each component encompasses different sub-components or modules, and each module has different func-

tions. The design of the proposed system relies on software designing architecture. We exploited one software architecture, namely, module architecture. As a result, the proposed system's design is highly flexible, and components can be accessed and used individually or collectively. Based on the obtained results, the proposed system accomplished good success in eye-movement classification and prediction.

### B. Future work

Eye movement classification and prediction is still an active research area. According to the work achieved in this paper, some research directions could be proposed.

- Empirical studies could cover a wide range of deep learning techniques to test and evaluate the behavior of the proposed system in eye-movement classification. Moreover, different lightweight techniques can be implemented to perform eye movement prediction.
- A recommended future research be done by employing different techniques for face tracking and detection to detect the face with different angles.
- Further recommended studies can be introduced to eye detection and localization. Besides, improvement of the developed prototype can be conducted. This includes the optimization of source Code and improvements of code speed, the implementation of the developed prototype in an implementation environment that support parallelization.

**Abstract**—The main purpose of this work is to propose a robust approach for dangerous sound events detection (e.g. gunshots) to improve recent surveillance systems. Despite the fact that the detection and classification of different sound events has a long history in signal processing, the analysis of environmental sounds is still challenging. The most recent works aim to prefer the time-frequency 2-D representation of sound as input to feed convolutional neural networks. This paper includes an analysis of known architectures as well as a newly proposed Independent Channel Residual Convolutional Network architecture based on standard residual blocks. Our approach consists of processing three different types of features in the individual channels. The UrbanSound8k and the Free Firearm Sound Library audio datasets are used for training and testing data generation, achieving a 98 % F1 score. The model was also evaluated in the wild using manually annotated movie audio track, achieving a 44 % F1 score, which is not too high but still better than other state-of-the-art techniques.

**Keywords**—Acoustic signal processing; gunshot detection systems; audio signal analysis; machine learning; deep learning; residual networks

## I. INTRODUCTION

In the field of signal processing, the audio data analysis takes an extensive part, which is constantly studied. Many machine learning-based algorithms were proposed for solving tasks such as classification, segmentation, and denoising. In many cases, the methods are adapted for a specific type of sound, mainly speech and music, which take an extensive part in the research. On the other hand, the environmental sounds are unstructured, and it is challenging to generalize their nature. Many environmental sound analysis applications, ranging from urban monitoring [1] to IoT [2] and surveillance system [3], [4], [5], have been developed within the past years.

However, in recent years it has become a topical task to use known techniques to classify environmental sounds like explosion, gunshot, siren, car alarm, baby crying, window breakage and other events associated with potential danger [6]. Usage of learning algorithms tends to increase personal safety. The possible implementations are in-home or industrial protection systems, in cars to alert deaf or poorly hearing drivers of the siren, in homes to alert a parent of a crying child, and in a wide range of assistive devices, especially for deaf people. Recent modern surveillance systems for risk prevention purposes focuses mainly on the analysis of video signals from

cameras using advanced computer vision techniques [7], [8], [9]. However, the analysis of audio signals has considerable potential in these systems as well. Especially gunshot detection technologies have been increasingly adopted by law enforcement agencies for mapping the spatial and temporal patterns of gun violence [10]. The general problem of gun detection technologies is a high rate of false alarms resulting in the waste of police resources when responding to those false alerts [11]. From a practical point of view, it is necessary to minimize the amount of false-positive predictions. Therefore, when setting the operating point of the system in practical applications, the false-positive rate must be taken into account.

The main objective of our work is to propose a method for detecting danger-related audio events (gunshots) that achieve high specificity in real conditions. We also aim to explore several types of feature spaces and neural architectures and discuss, what kind of setup is the most suitable for such an application.

The standard approach for sound analysis is to collect a single vector of features. The often used classifiers are Support Vector Machines (SVM), Deep Neural Networks (DNN), or multilayer perceptrons. When processing environmental sounds, the uniform structure can not be expected as in speech or music, where the signal contains a harmonic structure or repetitions. The features that perform well in specific applications may be inadequate for sounds with other nature and vice versa.

In our work we are using several 2-dimensional sound representations such as spectrograms as well as the standard 1-D approach and analyse the performance in the gunshot detection application. In addition to the frequently used spectrogram [12], [13], [14], also new visualizations and advanced methods for feature processing are used. The main contributions of our work are:

- Exploring the suitability of several state-of-the-art convolutional networks based approaches for gunshot detection.
- Proposing the convolutional model for boosting the performance on 2-dimensional independent feature spaces.

The signal is transformed into three independent audio feature sets forming an "RGB image" that is suitable for processing

by common 2-D convolutional networks used for image processing. Unlike image processing, where color channels are highly correlated and processed together after the first DNN layer, the three audio feature sets are processed independently by the first two DNN blocks. Our proposed architecture is based on standard residual units. The important task is not only increasing the number of true predictions but also reducing the number of false-positive gunshot predictions.

## II. RELATED WORK

Over the years several works dealing with gunshots detection from audio signal have been published. Most of them are based on the extraction of handcrafted acoustic features and the use of machine learning techniques for the task of classification. A combination of 7 Linear Predictive Coding (LPC) coefficients and 13 Mel Frequency Cepstral Coefficients (MFCC) with SVM classifier is used in work [15] providing 8 % false alarms rate on a custom dataset. The author of [16] extended the previous feature set by Linear Predictive Coding Cepstral (LPCC) and auto-correlation coefficients reaching 82 % accuracy and 70 % precision on a combination of public available datasets. The same author then evaluated the effect of individual features on the accuracy of the classification task [17], considering the features with the best score to be the first five coefficients of the 24<sup>th</sup> order LPC. A large set of various acoustic features with Hidden Markov Model (HMM) and Viterbi decoder is used in EAR-TUKE system [18] for detecting gunshots and glass breaking events with 98 % accuracy in records with Signal to Noise Ratio (SNR)  $\geq 20$  dB. In case of microphones arrays it is possible to use a two stage methodology comprising of a Blind System Identification and Deconvolution (BSID) stage followed by a SVM-based classification [19] for gunshot detection in a noisy urban environment. In [20] a method of classifying impulsive sounds based on a Weighted Majority Voting (WMV) strategy is described. In [21] Convolutional Neural Network (CNN) with temporal and spectral features is used for gunshot sound categories classification (pistol, rifle and shotgun of different calibres) reaching over 90 % accuracy. Another CNN approach detects gunshots with 99 % accuracy and low false alarm rate using the ResNet architecture [22]. Most of the above approaches work with database recordings that contain a low level of environmental noise. In the case of real applications, this condition can hardly be met. For this reason, dealing with the detection and classification of environmental noisy sounds is important.

The datasets of environmental sounds are made mainly for learning algorithms that perform Environmental Sound Classification (ESC) task. One of the widely used datasets for ESC is the UrbanSound8K [23], further described in Section III-E.

The signal representation of audio is related to the architecture of the learning algorithm and learning objective. The standard process that follows the approaches from speech and music analysis is to collect a single vector of features. Short-term or long-term features may not always generalize the unstructured nature of environmental sounds.

The direct solution of the feature extraction problem is to build a model that operates on the raw audio signals directly.

The 1-D CNNs can handle the internal representation of the input signal, which allows end-to-end usage. The important advantage is that there is no need to transform or pre-process the data, and such a model can adapt to a variety of audio signals. In the studies [24], [25], the first end-to-end ESC architecture called EnvNet was proposed in versions 1 and 2. Another 1-D architecture was proposed in [26], where the audio signal was processed at different time scales. The study [27] presents an end-to-end 1-D convolutional network that has fewer parameters compared to dense 2-D convolutional neural networks and does not require a large amount of training data. It reaches 87 % mean accuracy on the UrbanSound8K dataset with random weights initialization and 89 % with weights initialization by Gammatone filter bank coefficients [28] synthesizing an impulse response from nerve cells in the auditory fiber [29].

The 2-D CNN models operate on the pre-computed feature representations obtained by a fixed process of extraction. The study [13] is the first which deals with ESR using CNN trained on mel-scaled spectrograms. Such an approach is extended in study [12], where different augmentation methods are used. In work [14], the authors presented the model ESResNet based on STFT, that outperforms recently known approaches with ESC datasets achieving 82% accuracy when trained from scratch and 85% accuracy with ImageNet weights initialization on UrbanSound8K dataset. Since the Piczak's work [13], the research trend in environmental sound analysis seems to be the usage of 2-D feature matrices for feeding 2-D CNNs [30].

## III. MATERIALS AND METHODS

### A. Signal Model and Problem Formulation

Following the recent studies [12], [13], [14], [31], [32], [33], [34], the most suitable setup for environmental sound recognition employs a 2-D convolutional neural network fed by a Time-Frequency representation of the audio signal (further mentioned as audio features). In order to be processed by a 2-D convolutional network, these audio features need to be converted into a suitable uniform 2-D representation. Based on this 2-D representation, it is then necessary to choose an optimal architecture of the convolutional network for the classification task. The whole workflow from audio samples to predictions is depicted in Fig. 1.

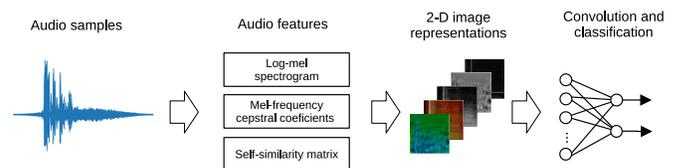

Fig. 1. Feature Extraction and Classification Workflow.

### B. Audio Features

In the case of audio signal processing, there is a large number of various audio features. The Log-Mel Spectrograms (LM Spec) and Mel Frequency Cepstral Coefficients (MFCC) are among the most commonly used audio features. In our work, we additionally include the Self-Similarity Matrix (SSM),

which is frequently used to analyze the global structure of musical works, to the audio feature list. The hyperparameters for feature extraction are detailed in Table I.

1) *Log-Mel Spectrogram*: The spectrogram is the most commonly used audio signal visualization. It shows the frequency spectrum change over time. A Short Time Fourier Transform (STFT) is used to convert the signal from time to frequency domain. Additional mel-frequency scale transform 1 is applied to embrace the psychoacoustic knowledge.

$$f_{mel} = 2595 \cdot \log_{10} \left( 1 + \frac{f_{Hz}}{700} \right) \quad (1)$$

2) *Mel Frequency Cepstral Coefficient*: MFCC reflects the non-linear and masking psychoacoustic characteristics of human hearing. MFCC coefficients are obtained by multiplying the signal spectrum by a mel-scale distributed filter bank, logarithm and Discrete Cosine Transform (DCT).

3) *Self-Similarity Matrix*: SSM is the measure of self-similarity of the signal based on distances. We use a self-similarity matrix to display signal correlation. To visualize the self-similarity, we use a matrix  $S$  defined by Equation 2. The matrix dimensions  $N \times N$  depend on the number of signal samples. For reducing the computational complexity, a self-similarity matrix  $S$  is computed on downsampled envelope  $s = (s_1, s_2, s_3, \dots, s_N)$  of input audio signal, obtained using the Hilbert transform. As a measure of similarity we are using the absolute distance.

$$S(i, j) = |s_i - s_j| \quad i, j = 1, \dots, N \quad (2)$$

The vertical and horizontal axes represent the time sequence. The matrix is symmetrical by the main diagonal where the similarity is maximal.

TABLE I. HYPERPARAMETERS FOR FEATURE EXTRACTION

Features	FFT length	Banks	Window
Log-mel spectrogram	2048	256	Hamming
MFCC	2048	20	Hamming
Self-similarity	-	-	-

### C. 2-D Feature Representation

Audio features are extracted as 2-D matrices and aligned for convolutional neural network input. Since most 2D convolutional network architectures were primarily designed for image processing, they expect 3 sets of 2-D feature matrices at the input (an analogy to RGB channels of images).

1) *Band-Splitted Spectrogram (BS Spec)*: In our experiments, we are using the log-mel spectrogram split to three frequency bands (high, middle, low) aligned with the RGB color channels (each band as one color channel). The band cutting frequencies depends the on maximal frequency  $f_{max} = \frac{f_s}{2}$  given by the sampling rate (Fig. 2).

The same principle was used in study [14], where authors explain the usage of the band-splitted spectrogram for avoiding redundancy. Other solutions are replicating the spectrogram or passing zeros.

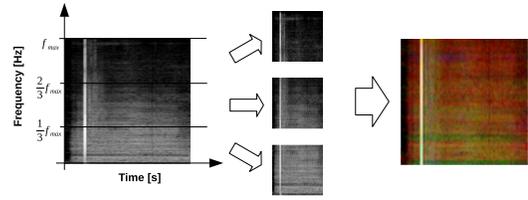

Fig. 2. Band-split Log-mel Spectrogram and Resulting RGB Image.

2) *Independent Feature Spaces (IFS)*: The combination of the log-mel spectrogram, MFCC and self-similarity matrix represents the independent feature spaces. The similar method was used in study [32]. We assume that the MFCC and SSM will help to classify non-impulsive background sounds. The harmonicity of the gunshot signal is low, so the SSM is almost empty, while the background noise results in a visible grid.

Three feature matrices are overlapped in matched time positions. It means, that the x-axis resolutions are approximately the same for all matrices. However, on the y-axis we have different dimensions when using spectrogram (frequency), MFCC (mel banks) and SSM (time) (Fig. 3).

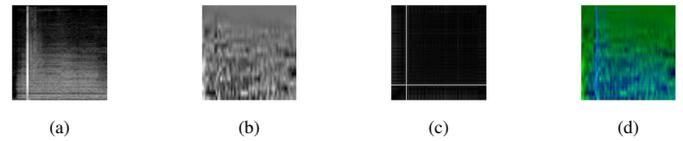

Fig. 3. Independent Feature Spaces as RGB Image Channels. (a) Red Channel, Log-mel Spectrogram. (b) Green Channel, MFCCs. (c) Blue Channel, Self-similarity Matrix. (d) Resulting RGB Image.

### D. Convolutional Neural Networks Architectures

The most widely used convolutional neural network models for 2-D feature space classification are based on the residual network architecture (ResNet). However, there is also an approach that uses only a 1-dimensional convolutional network fed directly by a raw audio signal to classify environmental sounds. In addition, we include a custom approach based on residual networks where individual channels are processed independently.

1) *Residual Networks*: Following recent studies [14], the residual models perform well on environmental sound classification. The residual network was designed as a network in a network, which means that the lower layer's inputs are connected to the outputs of the two higher layers. The example of the standard residual block is shown in Fig. 4.

The skip connections defined as

$$y = F(x) + x \quad (3)$$

are also called shortcut connections. The function  $F$  represents the convolution operations. The shortcut connections help to eliminate the problem of vanishing gradient in deep neural networks. The authors of [35] designed ResNets with a different number of layers, specifically 18, 34, 50, 101 and 152.

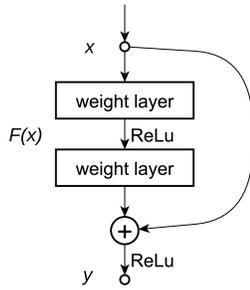

Fig. 4. Standard Residual Block [35].

2) *End-to-End Classification using a 1-D CNN*: In this approach, a 1-D convolutional (1-D CNN) neural network learns low-level and high-level information directly from the audio signal waveform. Since the size of the input data to the amount of data is in imbalance, it is not recommended to use too deep convolutional network architectures to avoid significant overfitting. The study [27] presents the optimal architecture with respect to the sampling frequency of the audio signal at different audio signal lengths. For the sampling frequency of 16 kHz considered further in this paper, it has been shown that the best score is achieved at the signal length of 1 second. The corresponding CNN architecture is shown in Table II consisting of 4 Convolutional Layers (CL), 2 Pooling Layers (PL) and 2 Fully Connected layers (FC). The Rectified Linear Unit (ReLU) activation function is used for all layers, except for the output layer where the softmax activation function is used with the output size equal to the number of classes being classified.

TABLE II. ARCHITECTURE OF 1-D CNN FOR 16 KHZ SAMPLING RATE AND AUDIO LENGTH OF 1 SECOND [27]

	CL1	PL1	CL2	PL2	CL3	CL4	FC1	FC2
Dimension	7969	996	483	60	23	8	128	64
Filters count	16	16	32	32	64	128	-	-
Filters size	64	8	32	8	16	8	-	-
Stride size	2	8	2	8	2	2	-	-

3) *Independent Channel Residual Convolutional Network*: We propose the Independent Channel Residual Convolutional Network (ICRCN), where the input RGB image is divided to the 2-D matrices in individual channels. The feature matrices share the dimension of the x-axis (time) but not the y-axis (frequency, mel banks, time). The system that combines different visual representations may suffer, when the features are combined as one input image. Therefore, we build the residual convolutional network, that processes different audio visualizations separately. The whole model architecture is shown in Table III.

The model input is a three channel RGB image. The separate channels contain residual blocks, where the number of filters is 32. The feature dimensions merging is made after the second residual block. From this point, the features are processed as in standard residual convolutional networks. The last convolutional block consists of 512 filters and it is followed by the classification layer. The proposed architecture is built up from standard residual blocks, as described in

TABLE III. PROPOSED INDEPENDENT CHANNEL RESIDUAL CONVOLUTIONAL NETWORK

Output size	ICRCN blocks		
(224, 224, 3)	Input RGB image		
(112, 112, 32)	7×7, 32	7×7, 32	7×7, 32

TABLE IV. COMPARISON OF ARCHITECTURES COMPLEXITY

Architecture	Number of trainable parameters
1-D CNN	256k
ResNet50	23.5M
ICRCN	11M

### E. Datasets

One of the most widely known datasets for environmental sound classification is the UrbanSound8K [23]. In this work we build our own gunshot detection dataset as a combination of the UrbanSound8k and The Free Firearm Sound Library [36].

- **UrbanSound8k** - 8732 tracks of 10 classes (air conditioner, car horn, children playing, dog barking, drilling, engine idling, gunshot, jackhammer, siren, street music), with varying sampling frequency file to file.
- **The Free Firearm Sound Library** - 2200 tracks of gunshots in a noise free environment including handguns (pistols, revolvers, semi-automatic pistols), rifles (lever-action, semi-automatic, fully automatic, machine guns, etc.) and shotguns. Recordings are in loss-less wav format with sampling frequency 44.1 kHz.

The examples from The Free Firearm Sound Library were combined with gunshots from the UrbanSound dataset. The other sounds from UrbanSound were used as negative examples (random background). Since UrbanSound records are not equal in length, the window size of our examples floats in the range from 1 s to 4 s.

In the field of supervised machine learning, the performance of algorithms strongly depends on the quality of the dataset. To some extent, it is possible to simulate a big dataset using augmentation methods. However, this approach will never be as good as the expansion of the dataset by real examples. The following augmentation techniques are applied to positive examples (gunshots) while training.

- **Random background mixing** - The gunshot were randomly mixed with background noise in a random SNR from 0 dB to 20 dB.
- **Random time shift** - The onset positions of gunshots within the processing window were chosen randomly from 0 to 0.8 % of the window length.
- **Random Gaussian noise addition** - SNR from 60 dB to 100 dB.

#### F. Evaluation Metrics

The softmax output activation function directly indicates the probability of the example belonging to a certain class. The softmax activation also guarantees that the sum of probabilities over classes (background and gunshot) is one. The examples are classified as positive or negative according to higher or lower activation of output neurons. The confusion matrix can be constructed using predicted and true labels. Thereafter, the performance is evaluated via known metrics.

For practical implementation of the system for dangerous sound detection (gunshots, explosion, ...) it is necessary to minimize the amount of false-positive predictions. In this case, the high accuracy value may be a little bit confusing and thus we have to choose a metric for relevant evaluation. Therefore, in our work we use the following evaluation metrics:

- **Accuracy:** It reflects the overall algorithm performance, so it also takes into account the true negative predictions (TN). The accuracy is high when the number of true positive (TP) and true negative predictions is large. False positives (FP) and false negatives (FN) are prediction errors.

$$Accuracy = \frac{TP + TN}{TN + TP + FN + FP} \quad (4)$$

- **Sensitivity:** The relative amount of true positive predictions against all positive examples. It is often called *recall* or True Positive Rate (TPR).

$$Sensitivity = \frac{TP}{TP + FN} \quad (5)$$

- **Specificity:** The relative amount of true negative predictions against all negative examples.

$$Specificity = \frac{TN}{FP + TN} \quad (6)$$

- **False-Positive Rate (FPR):** Reflects the relative amount of false positives against all negative examples.

$$FPR = \frac{FP}{FP + TN} \quad (7)$$

- **F1 score:** The balance value between sensitivity and precision, where precision is the amount of true positives against all positive predictions. This means that the F1 score is not distorted by a large number of true negative predictions and may be considered as decisive, when testing data are unbalanced.

$$F1 = \frac{2TP}{2TP + FP + FN} \quad (8)$$

- **Detection Error Tradeoff** - DET curve visualizes the false positive rate vs. the false negative rate. Standardly, the axes are scaled non-linearly. Unlike the ROC curve, the DET curves are more linear and situated in most of the plot area.
- **Equal Error Rate** - EER is defined as the point in DET or ROC where the errors are equal. The lower EER value reflects better performance of the system.

#### IV. RESULTS

All the networks were trained as long as validation loss was decreasing. Early stop was applied and only the best model was saved. Adam optimizer was used while training the models and the categorical cross-entropy loss was computed in each batch of 16 examples. Hardware used is NVIDIA GeForce GTX 1650, Intel Core i9-10900X CPU 3.7 GHz, RAM 64 GB. Fig. 5 shows the training and validation history of our ICRCN model when using 16 kHz sampling frequency.

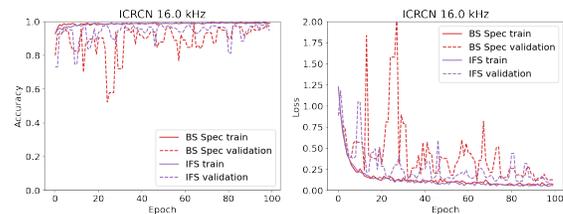

Fig. 5. Training and Validation History of ICRCN Model.

We use Tensorflow and Keras for building and training the models. For augmenting the audio we use the Audiomentations library. The Sci-kit learn is used for evaluation using described metrics.

##### A. 2-D Convolutional Networks

The training audio examples were generated in three sampling frequencies to test the effect of sampling on system performance. The overall F1 score and FPR is evaluated in Fig. 6. As the test subset is balanced, the F1 score and overall accuracy metrics are very similar. As seen, the high F1 score value does not necessarily guarantee good performance in the reduction of false-positives.

When looking at the F1 score of individual models, the difference between 44.1 kHz and 16 kHz is not significant. In several cases, the score drops significantly at the 8 kHz sampling. The significant drop of F1 score is seen in case of ICRCN trained on band-split spectrograms. Table V, Table VI, and Table VII show also the change in sensitivity and specificity over all combinations.

TABLE V. TESTING RESULTS FOR SAMPLING FREQUENCY 8 KHZ

Model	Features	F1 [%]	Sensitivity [%]	Specificity [%]

	SSM	95.9	94.6	97.3

As the softmax output activation function is used, the output gives the probabilities of the example belonging to a certain class. Nevertheless, the operating point can be moved by changing the threshold of positive predictions. Choosing the operating point is strongly related to the application of the developed system and there are different ways how to set up the operating point. The useful visualizations are the DET curves (Fig. 7), which tend to be more linear and highlight the differences in the operating region more clearly than the

ROC curves. The EER value represents the operating point, where the system performs equal in terms of the false-positive rate and false-negative rate. The false-positive rate can be interpreted as the false alarm probability and false-negative rate is the probability of missing the positive detection.

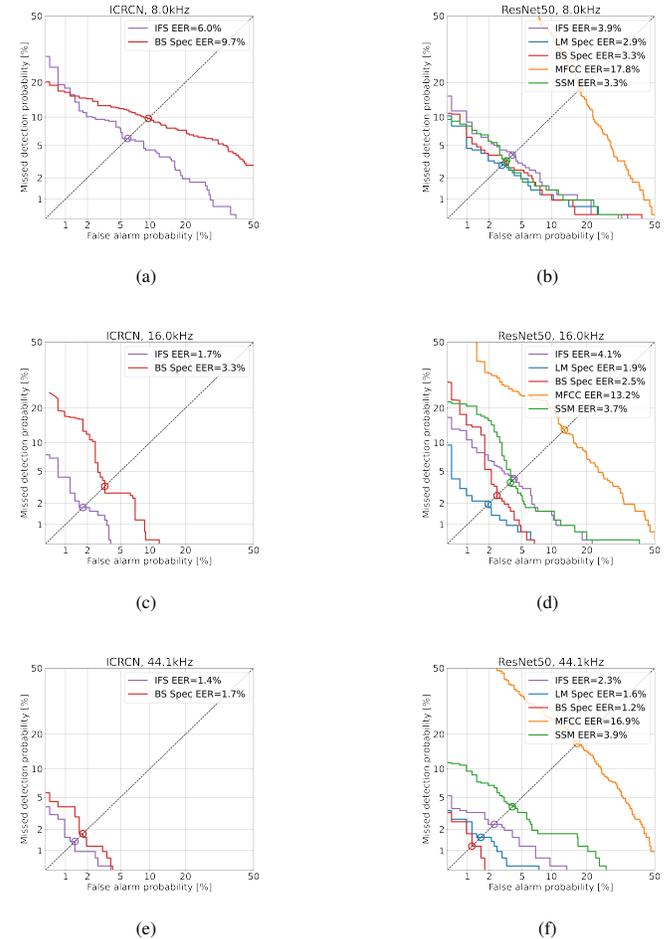

Fig. 7. Detection Error Tradeoff Curves for Different Models and Sampling Frequencies. (a) ICRCN, 8 kHz. (b) ResNet50, 8 kHz. (c) ICRCN, 16 kHz. (d) ResNet50, 16 kHz. (e) ICRCN, 44.1 kHz. (f) ResNet50, 44.1 kHz.

As seen in Table 7, the EER evaluation slightly correlates with the overall F1 score of the system. Though there is no evident regress over the parameters, we can highlight several findings from the results. Using the original sampling frequency when the data are clear and detailed, all architectures model the data well. The more trainable parameters seem to be useful as the system loses the information by audio downsampling. At 16 kHz sampling, the performance of architectures is closely comparable. The proposed ICRCN performs best with IFS feature combination. According to study [32], the single SSM performs worst on environmental sounds classification. Our results showed, that for gunshot detection, using the SSM only may leads to better scores than single MFCC, which surprisingly performs worst.

### B. 1-D Convolutional Network

In this part of work, we compare the 1-D CNN model to the best 2-D models. For this comparison we consider only the 16 kHz sampling frequency. As the best candidates from the previous test we choose two model-features combinations, namely ICRCN-IFS and ResNet50-LM Spec. The comparison is shown in Table VIII. The 1-D CNN model was trained on the same dataset as 2-D models.

TABLE VIII. THE RESULTS FOR 1-D CNN MODEL IN COMPARISON TO THE BEST 2-D MODELS

Model	Features	F1 [%]	Sensitivity [%]	Specificity [%]
ICRCN	IFS	97.9	98.4	97.3
ResNet50	LM Spec	97.8	98.8	96.7
1-D CNN	-	98.1	98.2	98.1

### C. Evaluation of Performance in the Wild

The results on artificially generated test subsets may not always meet the real performance in the wild. Therefore, we evaluate the models on a real audio track from action movie to simulate the real world conditions. On this stage we use only 16 kHz sampling frequency as the most suitable based on previous results. The audio track from the movie John Wick (2014) was manually annotated. We use a 4 seconds window length with 2 seconds overlap and third-order median filtering of the CNN output. Each segment is labeled as positive if there is an occurrence of a gunshot. The numbers of positive and negative segments is very unbalanced, therefore we use the F1 score as the evaluation metric. The evaluation results are shown in Table IX.

TABLE IX. EVALUATION ON REAL DATA IN THE WILD

Model	Features	Test	Evaluation		
		F1[%]	F1[%]	Sensitivity[%]	Specificity[%]
ICRCN	BS Spec	93.9	14.5	98.2	10.5
	IFS	97.9	<b>44.3</b>	59.2	91.6
ResNet50	LM Spec	97.8	26.4	89.0	62.5
	MFCC	87.0	16.5	47.2	67.0
	SSM	95.9	5.5	5.5	92.7
	BS Spec	97.1	17.6	98.2	29.2
1-D CNN	IFS	95.9	16.2	95.4	24.3
	-	98.1	4.2	7.8	96.5

As shown in Table IX, the performance on real data drops significantly. However, the evaluation test scores correlate in a relative way. The test score difference is slight in most cases, while the evaluation score difference is noticeable. We can see, that single SSM outperforms the MFCC features in test results, but fails in evaluation, where the sensitivity and specificity are very unbalanced. The results show, that the proposed ICRCN network architecture was able to model the in a data robust way and outperforms the standard residual network ResNet50 even using less trainable parameters. In the case of 1-D CNN, the bad final score was probably caused by the low number of parameters of the convolutional neural network. Thus the network was not able to generalize the extracted features sufficiently to deal with the high variability of real audio data.

The previous experiment mainly focused on the ability of the proposed algorithm to detect gunshot sounds in the

simulated real recording. However, in the case of surveillance systems, in addition to accuracy, a low frequency of false alarms is also required. This value cannot be derived from the above experiment because the soundtracks of the movies are sound-exposed. Thus, in this case, recordings from the QUT-NOISE database [37], which is the only suitable publicly available database containing continuous recordings of city sounds, were used to determine the false error rate. Since the total recording time is only a few hours, this database was supplemented with custom recordings from a busy city street. Within these recordings, the proposed algorithm did not detect a single false gunshot event.

### D. Processing Time

In Table X, we showed the mean processing time for each of the features used in the experiments. The generation of three feature matrices takes twice as much time than generation of a single spectrogram. This must be taken into account if the detector is implemented on the system with limited processing capacity.

TABLE X. FEATURE EXTRACTION TIME

Sampling frequency [kHz]	Features	Time [ms]
8	Spec	5.02
	MFCC	2.68
	SSM	2.31
16	Spec	6.23
	MFCC	3.62
	SSM	3.71
44.1	Spec	10.53
	MFCC	6.9
	SSM	10.58

When comparing processing time between multiple sampling frequencies, the good compromise is to prefer the 16 kHz sampling. It offers the comparable performance to original sampling while the feature extraction time is almost halved.

## V. DISCUSSION

When comparing the residual architectures and features using testing data, there is not a significant best setup. The evaluation on real data showed the benefit of independent features processing, where the difference in score is observable. The standard ResNet50 performs well with a single spectrogram. The feature combination works best with the proposed architecture with independent channels. Therefore, we prefer using the proposed ICRCN architecture and IFS for gunshot detection. Taking the feature extraction times into account, we prefer using the 16 kHz sampling.

We assume, that the ICRCN model fed by IFS matrices is the most suitable for gunshot detection systems, outperforming the other state-of-the-art approaches (in terms of F1 score). The combination of spectrogram, MFCC, and SSM was used in study [32], with conclusion that it does not improve the accuracy of environmental sounds classification. We assume, that the feature combination can be beneficial for gunshot detection applications and has a potential to lower the false-positive rate. The results showed, that there is a benefit of splitting the convolutional channels. The real performance of

the system relates on the operating point. In some applications the specificity may be a more important score than sensitivity, or vice versa. We visualized the DET curves, as they can help to fit the requirements of the system for particular applications.

## VI. CONCLUSION

In this paper, we analyzed the usage of several convolutional architectures for the gunshot detection task. We proposed a new architecture and compared its performance to standard ResNet50 and 1-D architectures. The effect of different features on the resulting performance was tested using several Time-Frequency audio representations. For training, validation and testing we collected the gunshots and random backgrounds audio clips from public datasets. In the training phase, the standard augmentation methods were used. Finally, we simulated the real world conditions by evaluation of a real audio track from the action movie.

We achieved the goal of our work by proposing a system for gunshot audio events detection. Our ICRCN approach is able to operate in noisy environments with high specificity (slightly over 90%), by maintaining fair sensitivity (almost 60%). The Detection Error Tradeoff analysis showed, that the real performance of the system strongly depends on the error tolerance and requirements. The operating point should be selected for specific applications. On our test data, the missed detection probability is about 10% when the false alarm probability is as minimal as possible. We expect the similar results also for explosion detection. Such a systems can be implemented in a complex application together with a smoke or fire detector. Due to the fact that the proposed approach has a relatively low computational time, it can be easily integrated into existing surveillance systems without the need to invest in expensive computing servers to operate in real time.

**Abstract**—Network security has become a serious issue since networks are vulnerable and subject to increasing intrusive activities. Therefore, network intrusion detection systems (IDSs) are an essential component to defend against these activities. One of the biggest issues encountered by IDSs is the class imbalance problem which leads to a biased performance by most machine learning models to normal activities (majority class). Several techniques were proposed to overcome the class-imbalance problem such as resampling, cost-sensitive, and ensemble learning techniques. Other issues related to intrusion detection data include mixed data types, and non-Gaussian and multimodal distributions. In this study, we employed a conditional tabular generative adversarial network (CTGAN) model with common machine learning algorithms to construct more effective detection systems while addressing the imbalance issue. CTGAN can generate samples of the minority class during training to make the dataset more balanced. To assess the effectiveness of the proposed IDS, we combined CTGAN with three machine learning algorithms: support vector machine (SVM), K-nearest neighbor (KNN), and decision tree (DT). The imbalanced NSL-KDD dataset was used and several experiments were conducted. The results showed that CTGAN can improve the performance of imbalance learning for intrusion detection with SVM and DT. On the other hand, KNN showed no improvement in the performance since it is less sensitive to the class imbalance problem. Moreover, the results proved that CTGAN can capture the distribution of discrete features better than continuous features.

**Keywords**—Intrusion detection; machine learning; imbalance learning; conditional tabular generative adversarial networks

## I. INTRODUCTION

In the current era of transformation to digital services and with the evolution of Internet technologies, cybersecurity has become a serious issue, especially with the growing volume and diversity of attacks. People utilize the Internet to conduct most of their work (e.g. online shopping, payment, banking, access to governmental services, file sharing, communication, and more). Moreover, it is a vital part of several cyber-physical systems in critical infrastructures such as Internet-of-Things (IoT) and smart grids. Therefore, intrusion detection systems are an essential component of cybersecurity and provide crucial services to protect information systems from cyberattacks that can lead to catastrophic consequences (e.g. sensitive data leakage, physical harm, and financial loss). It can monitor the system operations and network traffic to detect anomalous patterns [1].

Intrusion detection is a recurrent research topic due to the

emergence of more sophisticated adversarial incidents. One of the challenges facing intrusion detection is the scarcity of intrusive samples compared to the abundance of normal operation samples; resulting in insufficient data samples to train the model on a representative collection of attack scenarios. With such an imbalanced dataset, the number of samples in a majority (normal or negative) class is significantly higher than the number of samples in a minority (abnormal or positive) class. Training a machine learning algorithm on an imbalanced dataset can adversely impact the performance and lead to unsatisfactory results since it can be more biased towards the majority class, i.e. normal patterns.

Imbalanced learning is very common in several problems with rare events and different techniques have been proposed to address the imbalance issue. These techniques can be divided into five main categories: data-level, algorithm-level, cost-sensitive, ensemble-based, and hybrid techniques. The data level are preprocessing techniques known as re-sampling because they either increase the frequency of the minority class (oversampling) or reduce the frequency of the majority class (undersampling/downsampling). Random oversampling (ROS), random undersampling (RUS), synthetic minority oversampling technique (SMOTE), and generative adversarial networks (GAN) are examples of data-level techniques. A systematic literature review of the challenges and solutions for imbalanced data in machine learning is provided in [2].

The focus of our study is on oversampling techniques, specifically, an enhanced version of GAN, i.e. the conditional tabular GAN (CTGAN) [3]. CTGAN is a recent deep learning model and can be thought of as an oversampling technique. It can augment the tabular dataset and increase the frequency of the minority class samples while handling other issues such as mixed data types, multimodality, and non-Gaussian distributions. It proves its efficiency in addressing the imbalance problem and improving the classification accuracy in different domains.

This paper aims to investigate the role of CTGAN in improving the classification performance of support vector machines (SVM), K-nearest neighbors (KNN), and decision trees when applied to imbalanced data to detect various types of network intrusions. Different metrics have been computed to evaluate the quality of the generated data for various attacks in the multi-class NSL-KDD dataset. Moreover, the performance measures of the trained intrusion detection models have been computed and discussed.

The main contributions of this paper are:

- Handling the imbalance problem in intrusion detection datasets by employing CTGAN which is not investigated very well in the literature.
- Evaluating the quality of the generated data by CTGAN in terms of different metrics.

The rest of this paper is organized as follows: Section II provides a brief background about intrusion detection, class imbalance problem, and techniques to deal with this problem. Section III reviews related studies on intrusion detection. Section IV describes the methodology we followed in our study. Finally, Section V describes the experiments we conducted to evaluate the proposed prototype.

## II. BACKGROUND

### A. Intrusion Detection

An intrusion detection system is an essential component responsible for analyzing and monitoring networks to detect intrusions and alert administrators on ongoing attack activities [4]. Intrusion detection is still a significant research field for two reasons. First, there are continuous updates and changes of network intrusions resulting in continually changing patterns [5]. Second, the number of available intrusion detection datasets is increasing over time, making it possible to investigate and compare new approaches [5]. Examples of intrusion categories include Denial of Service (DoS) such as smurf, User to Root (U2R) such as buffer overflow, Probing (Prob) such as portsweep, and Root to Local (R2L) such as password guessing [6]. An effective intrusion detection system should have not only low false negative but also low false positive. These measures can be greatly affected by the quality of having a representative training dataset. However, real scenarios may have several challenges. For example, besides the class imbalance problem, the intrusion detection traces may have several other characteristics that need a special treatment, e.g. mixed data types (continuous, discrete, ordinal, and categorical) as well as non-Gaussian and multimodal distributions.

### B. Class Imbalance Problem

Most of the intrusion detection datasets are imbalanced datasets, which causes a degradation in the classification performance for certain types of intrusions [7]. Usually, the number of normal traces in intrusion detection datasets is much higher than the number of intrusion traces. Thus, as a minority class, the intrusion class might not be well-represented and hence not classified correctly.

The misclassification of the minority class costs more than the misclassification of the majority class, as it could cause a serious problem. Misclassifying a normal behavior class can lead to the need for more tests to explore the intrusion. On the other hand, misclassifying intrusions may lead to disaster impacts (e.g., privacy loss, unauthorized access to network assets, or damage of the whole system). Even if the detection rate of the minority class is low, classification accuracy could be high because the classification accuracy does not consider the distribution of classes. Consequently, machine-learning

based intrusion detection systems can be accuracy biased, since they can give more attention to the majority class (a.k.a. normal behavior).

### C. Imbalance Techniques

Many different techniques can be used to address the imbalance issue. These can be categorized into five categories, i.e. data-level, algorithm-level, cost-sensitive, ensemble-based, and hybrid techniques. Data-level techniques modify the class distributions before the training process. This modification is done either by removing some instances from the majority class or by adding more instances to the minority class [8]. The former method is known as undersampling while the latter is known as oversampling. Random oversampling (ROS), random undersampling (RUS) and synthetic minority oversampling technique (SMOTE) are examples of data-level preprocessing techniques.

Unlike data-level techniques, algorithm-level techniques do not modify the distribution of classes; but rather, they modify the algorithm [9]. In contrast, cost-sensitive techniques assign different costs to give the minority class higher importance than the majority class [10]. Ensemble methods combine more than one algorithm to achieve superior performance than would normally be attained separately such as bagging, boosting, stacking, and cascading classifiers [10]. Moreover, hybrid techniques combine two or more of the aforementioned techniques to produce an efficient technique for handling imbalance [9]. For instance, SMOTEENN combines oversampling by SMOTE with undersampling by the edited nearest neighbor (ENN) method [11].

### D. Conditional Tabular GAN

Generative Adversarial Network (GAN) is one of the top innovative deep learning models [12]. It has been widely used in various applications to process different types of data (e.g., images, voice, and text). Hence, it became one of the most critical research fields in deep learning. It combines two networks: generator and discriminator [13]. The generator is responsible for generating synthetic data that resemble to the original data whereas the discriminator is responsible for classifying the real or synthetic data with their corresponding classes [13]. GAN in tabular data has various challenges. One of the challenges is that the structured data can follow non-Gaussian and multimodal distributions. Tabular GAN (TGAN) resolved this issue by using mode-specific normalization [3].

In GAN, the generator does not consider the imbalance issue. Data that belong to the minority class will not be presented sufficiently as the data belong to the majority class do. Conditional generator in conditional GAN can be used to enforce the synthetic sample to match a specific class (category) [14]. Hence, it can generate more intrusive samples to overcome the imbalance issue in intrusion detection datasets. To use the conditional generator, in CGAN, instead of the original generator in GAN, three issues must be mitigated:

- A way must be found to represent the condition and the input to the generator.
- The generated samples must match the chosen category (condition).

- The conditional generator should learn the conditional distribution.

Conditional Tabular GAN (CTGAN) combines the advantages of CGAN and TGAN. Therefore, it can be used to solve the class imbalance issue by controlling the class labels of the generated samples. It also overcomes the non-Gaussian and multimodal distributions of structured data. Furthermore, CTGAN utilizes fully connected networks to enhance the quality of the model [3]. The conditional generator can be interpreted as

$$\hat{\mathbf{r}} \sim P_g(\text{row} | D_{i^*} = k^*)$$

where  $k^*$  is the chosen category from the discrete column  $D_{i^*}$  that must be generated by conditional generator and  $\hat{\mathbf{r}}$  is the sample generated by the generator. Fig. 1 shows a typical architecture of the CTGAN.

### III. RELATED WORK

With the growth of the amount of data related to intrusion detection, and the evolution in machine learning and deep learning techniques, many studies have been conducted in this field. Most of the previous studies ignore the class imbalance problem and use datasets of balanced distributions. In [1], the authors proposed a framework called scale-hybrid-IDS-AlertNet which can trace the network traffic and detect abnormal activities. The building of this framework came after a comprehensive analysis of different machine learning and deep learning models on different intrusion detection datasets. They found that the deep neural network (DNN) model outperforms other machine learning models such as Logistic Regression (LR), Naïve Bayes (NB), K-nearest neighbor (KNN), and support vector machines (SVM).

There are some researchers who have used imbalance techniques to deal with this problem in network intrusion detection systems. For example, Razan Abdulhammed et al. [15] compared the performance of different data-level techniques on the CIDDS-001 dataset. For data preprocessing, they considered ROS, RUS, class balanced and spread subsample. For classification, they utilized deep neural networks (DNN), random forest (RF), voting technique, stacking technique and variational autoencoder (VA). The superior performance was achieved by RF on the original distribution, class balancer and RUS (99.9%). Moreover, the accuracy of voting in the original distribution and using RUS was high (99.99%).

SMOTE is a known and effective oversampling technique, and many studies have been conducted to prove its efficiency. In [16], the imbalance issue was mitigated in a CICIDS2017 dataset using SMOTE oversampling. As SMOTE works only with binary classification, the researchers examined two classes at a time—a normal class with one of the minority classes (i.e., botnet, web attack, or brute force attack). Two experiments were conducted: one on the imbalanced dataset and one on the balanced dataset. Three algorithms were utilized to conduct the experiments (i.e., RF, NB, and KNN). On the imbalanced dataset, the accuracy was high with all classifiers, but the precision, recall, and F1-score were low. To mitigate this degradation, the researchers applied the SMOTE technique and the result showed better performance based on F1-score and recall.

Generative adversarial networks (GAN) is considered as a data-level technique because it modifies the distribution of data by generating new samples. It was applied in [17] by Yilmaz et al. to improve the performance of intrusion detection. The result after applying GAN was found to be more accurate than without using GAN. Different versions of GAN were proposed to enhance its performance. For example, Shuokang Huang and Kai Lei. [18] proposed Imbalanced GAN (IGAN) that includes a data imbalance filter, a generator, and a discriminator. It can force the generator to generate samples of the minority class only. IGAN with fuzzy neural network (FNN) obtained a superior performance over Convolutional Neural Network (CNN), RUS with SVM, FNN, and SMOTE with multilayer perception (MLP).

Punam Bedi et al. [19] proposed an intrusion detection system called Siam IDS which is based on Siamese Neural Network (Siamese-NN). It can handle the imbalance issue in intrusion detection systems. It achieved high recall values of the minority classes (U2R and R2L intrusions). Moreover, it outperformed CNN-based IDS and DNN-based IDS. In [20], m-RIGFS and RWIGFS were used with weighted-SVM to improve the imbalance learning for the intrusion detection systems. m-RIGFS and RWIGFS are feature selection techniques for imbalanced classes. This approach obtained a good performance in terms of the overall accuracy, sensitivity, and specificity. However, it should be noted that the sensitivity of the U2R, a rare class was low.

In [7], a CNN model was utilized to classify UNSW-NB15 and CICIDS2017, which are relatively recent intrusion detection datasets. They applied the CNN model, after addressing the class imbalance issue using their proposed approach, i.e. SGM which combines an oversampling technique (SMOTE) with an undersampling technique (Gaussian Mixture (GMM)). The proposed approach achieved a higher result (more than 96%) compared to other sampling techniques and classification models. Furthermore, in [21], SMOTE was combined with a genetic fuzzy system that includes a fitness function designed to deal with the imbalance problem. The proposed approach outperformed other approaches, which are the KDDCup-99 winner [22], GFS(Pittsburgh) [23], MOG-FIDS [24], EFRID [25] and RIPPER [26].

Data-level and cost-sensitive techniques can be combined to yield better performance. Alabdallah et al. in [27] combined a stratified sampling with a cost function. This approach assigns the minority class samples higher weights than the majority class samples to improve the classification performance and decrease the accuracy paradox.

To our knowledge and based on exploring earlier work in the literature, limited studies have used GAN-based methods to overcome the imbalance problem in intrusion detection systems. Moreover, none of the reviewed studies have evaluated the generated samples. Therefore, in our study, we explore CTGAN machine-learning based models to deal with the imbalance learning for intrusion detection. Moreover, we evaluated the generated samples in terms of different metrics (e.g. Chi-Squared test and Continuous Kullback–Leibler Divergence).

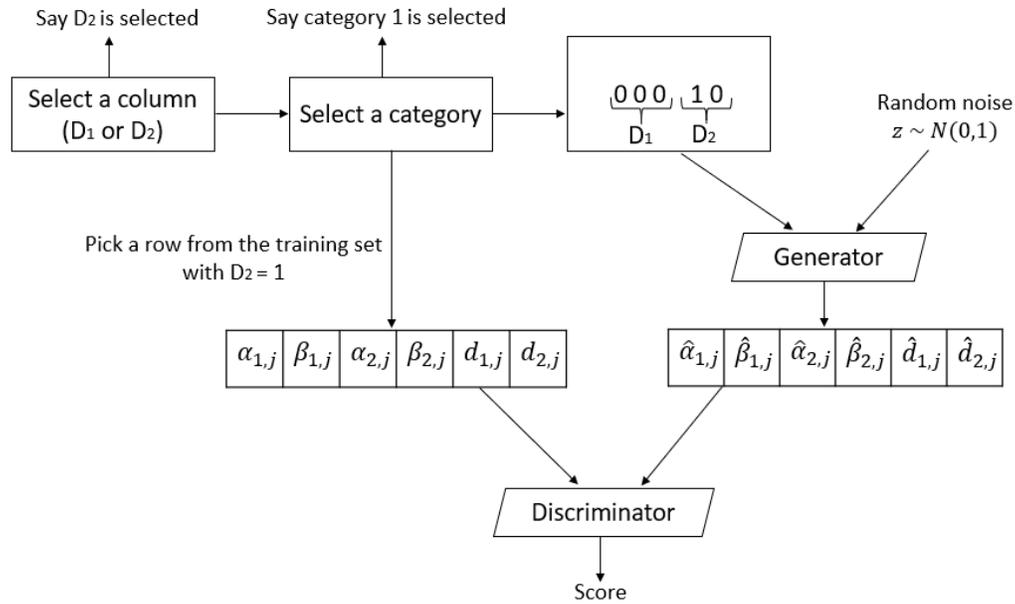

Fig. 1. CTGAN Architecture.

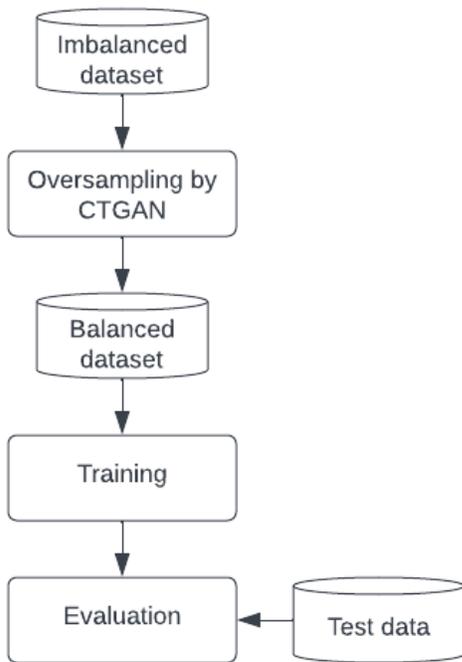

Fig. 2. General Layout of the Workflow.

#### IV. METHODOLOGY

Fig. 2 depicts the general layout of the workflow. The aim of this work is to investigate the performance of CTGAN in improving the detection rate of intrusive samples in intrusion detection systems. To achieve this aim, we applied the following steps:

- Oversampling by CTGAN: Since the intrusion data suffers from several issues including class imbalance, mixed data types, multimodality, and non-Gaussian distributions, we first applied CTGAN to increase the intrusive samples in the training dataset.
- Data preprocessing: The aim of this step is converting raw data into a suitable format for machine learning models. In this study, two preprocessing techniques were applied to the dataset before classification:
  - One-hot encoding: Some machine learning algorithms work only with numeric data, hence one-hot encoding is important when dealing with a dataset that contains categorical features. One-hot encoding is a method of sorting each categorical value into a distinct column and setting a value to it (either 0 or 1). Therefore, one-hot encoding was applied to the NSL-KDD dataset to convert its categorical features (i.e., protocol type, service, and flag).
  - Standard scalar: This is a significant step for some machine learning algorithms because features that are not scaled to have zero mean and unit variance could negatively affect the performance of the algorithm. This method scales the features to have a mean of zero and a standard deviation of one. Hence, all values will be in the same range. The following equation is used to perform standard scalar:

$$z = \frac{x - \mu}{\sigma}$$

where  $x$  is a sample,  $\mu$  is the mean of the samples and  $\sigma$  is the standard deviation of the samples.

- Machine learning training and testing: To assess the efficiency of using CTGAN to overcome the imbal-

ance problem and other data issues, three machine learning algorithms (i.e. SVM, DT, and KNN) were used to train and test the NSL-KDD dataset before and after applying CTGAN.

- **Evaluation:** To accurately evaluate the performance of the proposed framework, various metrics (e.g. F1-score, geometric mean (G-mean), and Matthews correlation coefficient (MCC)) were used. These metrics are appropriate for evaluating the performance of imbalance learning.

## V. EXPERIMENTS AND EVALUATION

### A. Dataset Description

NSL-KDD is an imbalanced dataset with huge amount of captured traffic under various normal and attack scenarios. It is an improved and revised version of the KDD99 dataset. It contains 41 features extracted from traffic traces of normal and abnormal activities as shown in Table I. Intrusion traffic is categorized into four main categories: Denial-of-Service (DoS), Probing (Probe), Remote-to-Local (R2L), and User-to-Root (U2R). Each category of these attacks contains several sub-categories as shown in Table II. In this study, only 20% of the dataset was used to conduct the experiments. Each class includes a different number of samples as shown in Table III. Therefore, this dataset is imbalanced because of the obvious difference in the number of samples in each class. The imbalance ratio of normal and attack classes in the dataset ranges from 1.44 to 305.77. Fig. 3 shows the distribution of intrusive and normal samples.

TABLE II. ATTACK CATEGORIES IN NSL-KDD

Attack category	Attack Types
DoS	Back, Apache2, Smurf, Neptune, Udpstorm, Land,Worm, Pod, Procestable, Teardrop
Prob	Satan, PortswEEP, Nmap, Ipsweep, Mscan, Saint
R2L	Warezmaster, Phf, Ftp_write, Named, Smpguess,Httptunnel, Xlock, Spy, Xsnoop, Sendmail, Imap,Guess_Password, Warezcilent, Multi-hop, Smpgetattack
U2R	Loadmodule, Buffer_overflow, Rootkit, Xterm,Sqlattack, Perl, PS

### B. Performance Measures

1) **Evaluation Metrics of Machine Learning Models:** The following metrics were used to evaluate the performance of the applied classifiers:

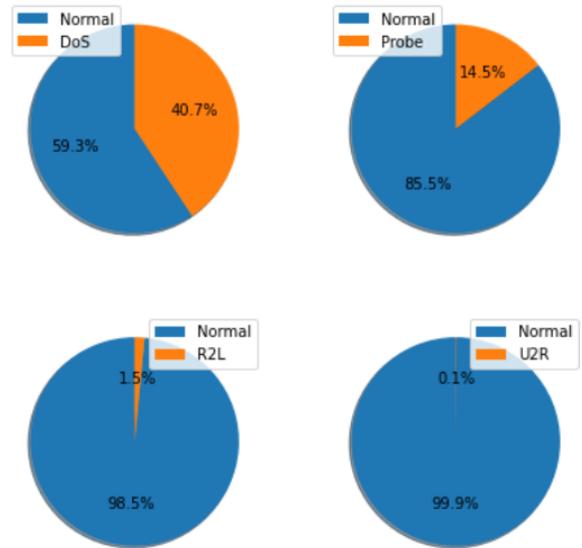

Fig. 3. Distribution of the Samples.

TABLE III. SAMPLES IN NSL-KDD

Class	Train set	Test set
Normal	13449	9711
DoS	9234	7458
Prob	2289	2421
R2L	209	2754
U2R	11	200
Total	25192	22544

a) **Accuracy (ACC):** This is the most common metric to evaluate the performance of a model. It is the number of samples that are correctly predicted over the number of all samples. It can be calculated using the following equation:

$$ACC = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

b) **Recall:** It refers to the ability of the model to predict positive samples. It can be calculated by dividing the number of the samples that are correctly classified as true positive over all positive samples. It can be calculated using the following equation:

$$Recall = \frac{TP}{TP+FN} \quad (2)$$

c) **Precision:** It is the number of samples that are correctly classified as true positive over the number of samples that are predicted as positive. The following equation can be used to calculate the precision:

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

d) **F1-score:** It is a way to combine recall and precision into a single metric. It is called the harmonic mean of recall and precision. It can be calculated using Equation 4:

$$F1\_score = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (4)$$

e) *Geometric mean (G-mean)*: It is based on the true positive rate (sensitivity or recall) and true negative rate (specificity). G-mean is a combination of sensitivity (recall), and specificity. Specificity and G-mean can be calculated using the following equations:

$$Specificity = \frac{TN}{FP+TN} \quad (5)$$

$$G\_mean = \sqrt{Sensitivity \times Specificity} \quad (6)$$

f) *Matthews correlation coefficient (MCC)*: It is a good performance metric for binary classification and combines all parts of the confusion matrix (i.e., true positives, false positives, true negatives, and false negatives). It can be calculated using the following equation:

$$MCC = \frac{(TP \times TN) - (FP \times FN)}{\sqrt{(TP+FP) \times (TP+FN) \times (TN+FP) \times (TN+FN)}} \quad (7)$$

### C. Synthetic Data Evaluation Metrics

The overall evaluation score of the synthetic data is an aggregation of the following metrics:

a) *Chi-Squared (CSTest)*: It is a statistical metric that compares the distributions of two discrete columns using the Chi-squared test.

b) *Inverted Kolmogorov-Smirnov D statistic (KSTest)*: It is a statistical metric that compares the distributions of the continuous columns using the Kolmogorov-Smirnov test.

c) *KSTestExtended*: It is an extension of the KSTest metric that transforms all columns into numerical columns before applying the KSTest.

d) *Continuous Kullback-Leibler Divergence (Continuous KLDivergence)*: This metric calculates the Kullback-Leibler (KL) divergence on all pairs of the numerical columns.

e) *Discrete Kullback-Leibler Divergence (Discrete KL-Divergence)*: This metric calculates the Kullback-Leibler divergence on all pairs of the Boolean and categorical columns.

### D. Experiments

In this study, one-vs-one classification was performed. We divided the dataset into four subsets. Each subset contains two class labels, i.e. normal and one of the intrusions (i.e., DoS, Prob, R2L, or U2R).

The experiments were conducted in Python and CTGAN was used to oversample the subsets using different number of epochs. Tuning epoch size in deep learning models is important, as it has a direct effect on the performance. It is the number of iterations the model performs over the training dataset. The default epoch size value in CTGAN is 300. In this study, different epoch size values (e.g., 300, 400, and 1600) were tested to obtain the best results.

Then, we evaluated the quality of the synthetic samples using multiple evaluation metrics that are combined to produce an overall score. This score provides a general indication of how good the synthetic samples are. Lastly, SVM, KNN, and decision tree models were run on the NSL-KDD dataset before and after implementing CTGAN.

### E. Result and Discussion

Table IV presents the evaluation scores of the synthetic data used to balance the subsets. The overall evaluation score is the average of multiple scores that evaluate the data from different aspects (e.g., statistical, detection, and likelihood). The overall score gives an estimation of how similar the synthetic data and the real data are (i.e., the quality of the generated data). This score ranges from 0 to 1, where 0 is the worst possible score and 1 is the best possible score. As shown in Table IV all synthetic data of all attack categories achieved overall scores around 0.5.

We observed that CSTest obtained high scores ranging from 0.85 to 0.99, whereas KSTest achieved fairly good scores ranging from 0.77 to 0.82. Moreover, KL Divergence scores for discrete columns are reasonable unless for DoS; it is slightly high. On the other hand, KL Divergence scores for Continuous columns are high which indicates worse performance. Therefore, we can conclude that CTGAN can fairly capture distributions of both continuous and discrete columns, but its performance is better in the discrete columns.

TABLE IV. EVALUATION SCORES OF THE SYNTHETIC SAMPLES

Metric	DoS	Probe	R2L	U2R
Overall evaluation score	0.54	0.50	0.49	0.51
CSTest	0.99	0.98	0.85	0.92
KSTest	0.80	0.77	0.82	0.80
KSTestExtended	0.79	0.76	0.81	0.80
ContinuousKLDivergence	0.83	0.73	0.80	0.84
DiscreteKLDivergence	0.40	0.29	0.28	0.21

TABLE V. RESULTS OF ONE-VS-ONE SVM CLASSIFICATION

Imbalanced dataset	Normal-vs-DoS	Normal-vs-Probe	Normal-vs-R2L	Normal-vs-U2R
Accuracy	0.90	0.92	0.79	0.98
Precision	0.99	0.87	0.99	0
Recall	0.77	0.69	0.07	0
F1-score	0.87	0.77	0.13	0
G-mean	0.87	0.81	0.26	0
MCC	0.80	0.72	0.231	-0.002
Balanced dataset	Normal-vs-DoS	Normal-vs-Probe	Normal-vs-R2L	Normal-vs-U2R
Accuracy	0.93	0.96	0.79	0.98
Precision	0.99	0.87	0.60	0.38
Recall	0.85	0.94	0.17	0.24
F1-score	0.91	0.90	0.26	0.30
G-mean	0.91	0.95	0.40	0.49
MCC	0.86	0.87	0.234	0.29

Although accuracy is the most common evaluation metric of machine learning models, it is an inappropriate metric for imbalanced classification because it does not distinguish between the number of correctly classified samples of the majority and minority classes. Therefore, it is obvious from Tables V, VI, and VII that there is a degradation in accuracy values of some attack categories after implementing CTGAN.

Moreover, the precision values of all classifiers decreased for some attacks categories, but improved for others. At the same time, recall values increased for all attack categories, except for DoS in the decision tree and KNN, where there was no improvement.

Precision and recall separately are not enough to evaluate the performance of the imbalanced classification. F1-score is

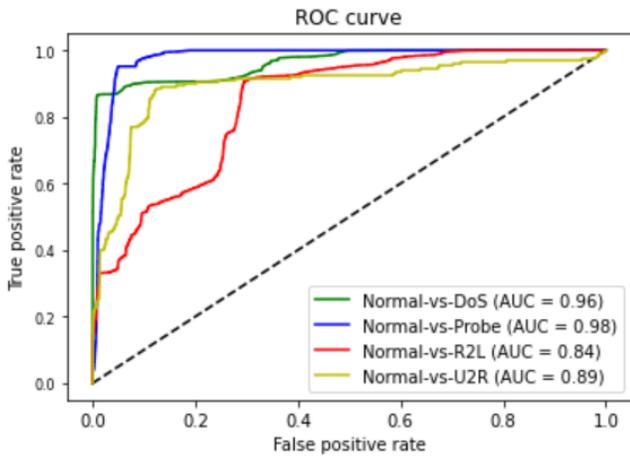

Fig. 4. ROC Curves of SVM on the Imbalanced Dataset.

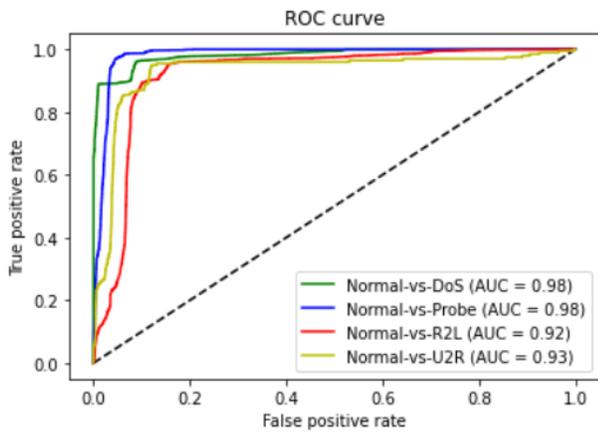

Fig. 5. ROC Curves of SVM on the Balanced Dataset.

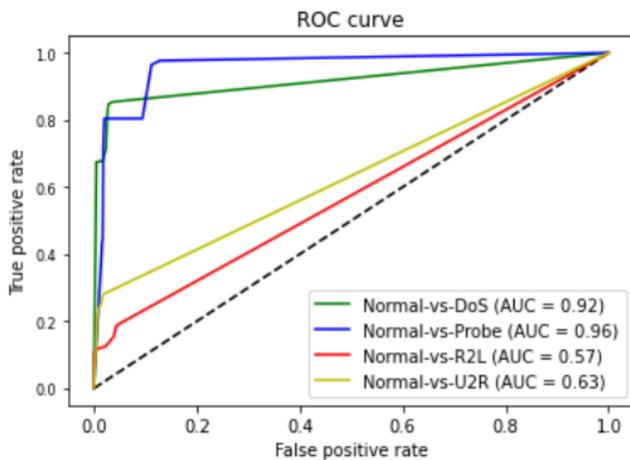

Fig. 6. ROC Curves of DT on the Imbalanced Dataset.

TABLE VI. RESULTS OF ONE-VS-ONE DT CLASSIFICATION

Imbalanced dataset	Normal-vs-DoS	Normal-vs-Probe	Normal-vs-R2L	Normal-vs-U2R
Accuracy	0.91	0.94	0.80	0.98
Precision	0.96	0.91	0.98	0
Recall	0.82	0.80	0.11	0
F1-score	0.88	0.85	0.20	0
G-mean	0.89	0.88	0.33	0
MCC	0.81	0.821	0.291	0
Balanced dataset	Normal-vs-DoS	Normal-vs-Probe	Normal-vs-R2L	Normal-vs-U2R
Accuracy	0.91	0.96	0.80	0.94
Precision	0.98	0.88	0.68	0.22
Recall	0.82	0.91	0.21	0.73
F1-score	0.89	0.86	0.32	0.33
G-mean	0.90	0.92	0.45	0.83
MCC	0.83	0.828	0.299	0.37

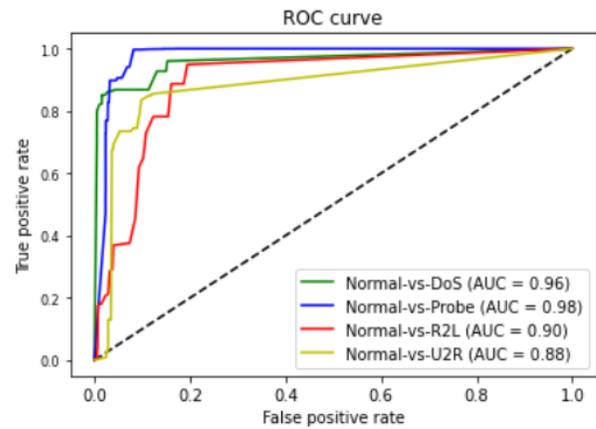

Fig. 7. ROC Curves of DT on the Balanced Dataset.

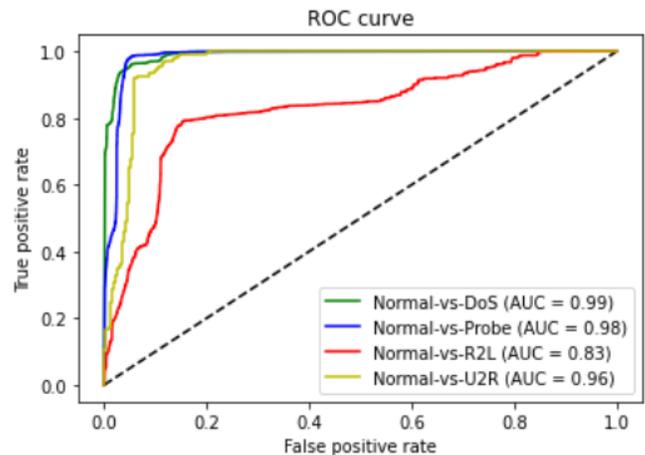

Fig. 8. ROC Curves of KNN on the Imbalanced Dataset.

a balance of precision and recall; thus, it is a good metric for the imbalanced classification. Tables V, VI, and VII show an improvement in the F1-score values in all attack categories after using CTGAN, except for DoS with KNN, where there was no improvement.

G-mean is the balance between the accuracy of the algorithm on the majority class and the accuracy of the algorithm on the minority class. Hence, it is an appropriate evaluation metric for imbalanced classification. We notice from Tables V, VI, and VII that there is an improvement in G-mean values of all classifiers on all attack categories after using CTGAN, except for DoS with KNN there was no improvement.

TABLE VII. RESULTS OF ONE-VS-ONE KNN CLASSIFICATION

Imbalanced dataset	Normal-vs-DoS	Normal-vs-Probe	Normal-vs-R2L	Normal-vs-U2R
Accuracy	0.90	0.93	0.79	0.98
Precision	0.99	0.88	0.99	0.75
Recall	0.78	0.77	0.04	0.03
F1-score	0.87	0.82	0.07	0.06
G-mean	0.87	0.86	0.19	0.17
MCC	0.80	0.78	0.17	0.14
Balanced dataset	Normal-vs-DoS	Normal-vs-Probe	Normal-vs-R2L	Normal-vs-U2R
Accuracy	0.90	0.96	0.78	0.97
Precision	0.99	0.86	0.48	0.21
Recall	0.78	0.93	0.09	0.11
F1-score	0.87	0.89	0.15	0.15
G-mean	0.87	0.94	0.29	0.33
MCC	0.80	0.86	0.12	0.14

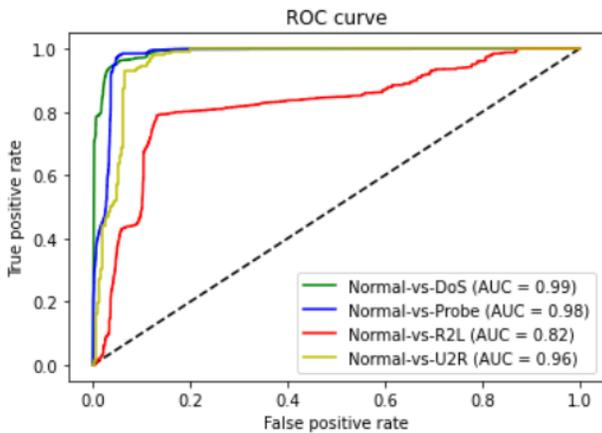

Fig. 9. ROC Curves of KNN on the Balanced Dataset.

While F1-score and G-mean are good evaluation metrics for imbalanced classification, MCC is more informative and reliable because it is determined based on the values of all of the cells of the confusion matrix. It is high only if all values of the confusion matrix are good. Moreover, MCC is the metric least affected by the imbalance issue. Thus, we notice from Tables V and VI that MCC values of SVM and decision tree increased on the balanced datasets for all attacks categories. On the other hand, there was no improvement in MCC values of KNN on DoS and U2R balanced datasets as shown in Table VII. Also, the MCC value of KNN was reduced on the balanced R2L dataset. One possible reason for this issue is that the KNN is less sensitive to the imbalance problem, which is consistent with [28]. Thus, oversampling the dataset did not improve the performance.

ROC curves and AUC scores are commonly used evaluation metrics for imbalanced classification. Fig. 4, Fig. 5 show the ROC curves and AUC scores of SVM on the imbalanced and balanced datasets of all attacks categories. We notice that AUC scores of all attack categories in the balanced datasets are clearly better than the AUC scores in the imbalanced datasets, which indicates an improved performance. Fig. 6 and Fig. 7 demonstrate the ROC curves and AUC scores of decision tree on the imbalanced and balanced datasets of all attacks categories. The AUC scores of all attacks categories are significantly higher after implementing CTGAN, especially for

the rare classes (i.e., R2L and U2R). Fig. 8 and Fig. 9 depict the ROC curves and AUC scores of KNN on the imbalanced and balanced datasets of all attacks categories. We observed that the AUC scores of KNN did not show an improvement after the balancing process except with R2L, where there was a slight reduction.

Based on the F1-score, G-mean, MCC and AUC values obtained, using CTGAN to generate synthetic samples has improved the performance of the SVM and decision tree models. At the same time, we notice that the positive impact of CTGAN was not obvious on KNN, instead it causes a slight reduction in some evaluation metrics. This is due to the insensitivity of the KNN to the imbalance problem.

## VI. CONCLUSION

Most of the intrusion detection datasets are imbalanced due to the natural difference between the number of intrusive and normal samples. There are many techniques to deal with the imbalance problem. One of these techniques is oversampling (e.g., ROS, SMOTE, and GAN-based methods). In this study, the focus is on CTGAN which can generate more samples of a specific class. CTGAN was applied on NSL-KDD to increase the number of intrusive samples and make the dataset balanced. The effectiveness of CTGAN was evaluated by running SVM, decision tree, and KNN models on the dataset before and after using CTGAN. Experiments using various types of attacks and one-vs-one classification were conducted in this study. CTGAN proved its effectiveness in generating synthetic data resembling real intrusions to improve the performance of SVMs and decision trees on the imbalanced datasets in terms of F1-score, G-mean, MCC, and AUC values. On the other hand, CTGAN did not show an improvement in KNN performance because it is less sensitive to class imbalance problem. For future work, more machine learning and deep learning models could be used. Furthermore, other imbalance techniques could be evaluated and compared with CTGAN.

**Abstract**—The growing and marketing of coffee is an important source of economic resources for many countries, especially those with economies dependent on agricultural production, as is the case of Colombia. Although the country has done a lot of research to develop the sector, the truth is that most of its cultivation is carried out by small coffee families without a high degree of technology, and without major resources to access it. The quality of the coffee bean is highly sensitive to diverse diseases related to environmental conditions, fungi, bacteria, and insects, which directly and strongly affect the economic income of the entire production chain. In many cases the diseases are transmitted rapidly, causing great economic losses. A quick and reliable diagnosis would have an immediate effect on reducing losses. In this sense, this research advances the development of an embedded system based on machine learning capable of performing on-site diagnoses by untrained personnel but taking advantage of the know-how of expert coffee growers. Such a system seeks to instrument the visual characteristics of the most common plant diseases on low-cost, robust, and highly reliable hardware. We identified a deep network architecture with high performance in disease categorization and adjusted the hyperparameters of the model to maximize its characterization capacity without incurring overfitting problems. The prototype was evaluated in the laboratory on real plants for recognized disease cases, tests that matched the performance of the model validation dataset.

## I. INTRODUCTION

For developing countries, agriculture is one of the most important economic sectors, both for foreign exchange earnings and for ensuring the food sustainability of their citizens. Colombian coffee enjoys great importance in the international markets because has characteristics that make it stand out, such as its excellent quality and its soft flavor [1]. The importance of coffee is so great that it has been the main source of foreign exchange for the country with 5.3 of the Gross Domestic Product (GDP) and with a production of one million fifty thousand sacks by January 2020. However, its cultivation is mainly carried out by low-income coffee families, with very little access to technologies that help reduce the effect of the plagues that affect the plant [2], [3]. While real-time image processing can be computationally expensive [4], a low-cost artificial system reduces costs for damage and care of the plant because farming families can access these tools at low cost and use them to reduce the spread of disease and artificial intelligence strategies can increase crop performance if they

are made accessible to people with modest education and purchasing power [5], [6].

The production and conservation of quality coffee are very difficult for small producers [7]. In Colombia, only Arabic coffees are cultivated, which differ from the Canephora coffees (Robusta coffees) because they are soft, and of greater acceptance in the world market. The harvest is mostly done by small coffee-growing families of medium and low profile. Some plagues attack and make the plant sick, reducing the production and affecting the quality and flavor [8]. These problems have increased considerably in the last decades worldwide, which has affected quality and quantity indicators [9]. Among the most important pests that affect the coffee plant are Coffee Leaf Rust (CLR) [10], the Coffee Borer Beetle (*Hypothenemus Hampei*) [11], the Coffee Leaf Miner (*Leucoptera Coffeella*) [11], the Citrus Mealybug (*Planococcus Citri*), the Coffee Stem, and Root Borer (*Plagiohammus Colombiensis*), and the red spider. Also of importance are the Iron Spot (*Cercospora Coffeicola*) [12], the Lint Disease (*Corticium Koleroga*), the Cock's Eye (*Mycena Citricolor*) [13], and the Anthracnose (*Colletotrichum Coffeanum*) [14]. The varieties of Arabic found in Colombia are Tipica (susceptible to CLR), Borbón, Maragogipe, Tabi (resistant to CLR), Caturra (susceptible to CLR), and Colombia variety (resistant to CLR).

Another important factor that negatively affects the cultivation of coffee, and that favors the propagation of plagues and their diseases, is related to the climatic variations of the planting areas [15], [16]. These climatic variations in addition to affecting the growth of the plants tend to increase the aggressiveness of the pests [17]. It has been observed that height affects the intensity of CLR aggression, which is greater in the lower areas with higher temperatures [18], [19].

Prevention and timely diagnosis are essential to stop the advance of pests [20]. Identifying pests at an early stage of infection greatly increases the chances of successful treatment. There are methods for determining the diseases of any plant, such as taking samples of vegetative tissue to a specialized laboratory or bringing an expert agronomist to the crop site. In any of these cases, the disadvantages for the farmer are centered on the time needed to obtain the results and the costs involved. This is why the design of autonomous systems using artificial vision and pattern recognition techniques, as well as some classification algorithms, has been considered for the development of preliminary diagnostic tasks [21], [22]. In this way, the coffee grower can identify the possible disease, its propagation, and with experts and specialists coordinate more

quickly and with less cost the correct treatment [23], [24].

Several of the diseases and plagues that are threatening the cultivation of coffee also produce visually detectable effects [25]. The visible effects have been studied as possible indicators of their presence, thanks to the fact that they present specific characteristics [26]. Among these specific characteristics are abnormal coloring of the leaves, deformation of the leaves, and signs of dehydration. These particular characteristics can be used for the process of diagnosis of the disease, or in the opposite case, to diagnose the plant as healthy. RLC is considered by many to be the most severe disease of the coffee crop since it causes the premature fall of the leaves, leading to the death of the plant. The disease has caused great production losses in countries in Asia, Africa, and the Americas. Once the disease appears and establishes itself in a place, it has not been possible to eradicate it, despite multiple strategies implemented by the producing families [27]. It is characterized by pale spots on the underside of the leaves that over time become large yellow or orange spots with the presence of a yellow powder (the spores of the fungus) [28].

In the case of the Cock's Eye disease (*Mycena Citricolor*), small circular or oval spots are observed, slightly sunken, with a diameter of 6-10 mm on the leaves [29], [13]. The lesions start as dark brown spots with an undefined border, which when reaching their final size present a well-marked border, with little or no chlorosis around them, and can be light brown, grayish, or reddish-brown, with a papery and dry appearance.

Iron Spot (*Cercospora Coffeicola*) is another important disease that attacks coffee cultivation. It is caused by a fungus that affects the plant in various stages, beginning in the nursery [12]. It is visually characterized by brown spots with a yellowish halo that contrasts with the normal leaf tissue. As the disease progresses, the size of the spot increases, causing the tissue to die. The most serious damage occurs to the fruit, but also affects the leaves. It is transmitted by the fungus *Cercospora Coffeicola*, and its spot is particularly prevalent in the nursery and on unshaded coffee plantations. In the fruits the infection starts through wounds or exposure to the sun forming lesions similar to those on the leaves, but which eventually stop being circular to become elongated and dark.

Each disease produces characteristic damage to the plant. These damages visually generate geometrical and colorimetric parameters that can be identified through digital image processing [30], [31]. One of the most powerful strategies for image categorization is the convolutional neural networks, which have demonstrated to have a very high capacity to identify information in unknown images after training with categorized cases [32], [33]. Therefore, it is possible to use a neural model to design an embedded, autonomous, and low-cost system capable of identifying in real-time diseases of the coffee plant leaves [34].

The rest of this article is organized as follows. Section II describes the functional characteristics of the embedded system and the working environment of the equipment, which define the design profile of the system. Section III describes the model developed for the detection of anomalies in the coffee leaf, as well as the characteristics of the hardware used, and its configuration. The results that demonstrate the behavior of the classification model are given in Section IV, and in Section V

the conclusions of the research and development are presented.

## II. PROBLEM STATEMENT

The sustainability of agriculture depends on many factors, including the ability to reduce food losses due to infections caused by bacteria, viruses, and fungi. In this sense, early detection of crop diseases drastically reduces the spread of illnesses, and therefore economic losses. Solution strategies should be developed focusing not only on the nature of the crop in question but also on the social conditions under which production takes place. Our research focuses on the identification of diseases common to the coffee plant, which is why we sought to develop a system that could examine in real-time the leaf of the plant, the place where diseases can be identified. This system aims to detect possible changes in the leaf of the plant that could signal an infection.

The objective of this research is to develop an embedded system for the autonomous and on-site diagnosis of coffee diseases. Other important features of the system include low cost and ease of operation. Among the design features, the need for autonomous operation stands out given the impossibility of connection for the deployment of complex models. In addition to these features, portability and high performance also limit the hardware characteristics to be used.

Among the machine learning schemes evaluated as automatic categorization schemes, those based on deep networks presented the highest values in the evaluation metrics. Consequently, a deep model that can be run in real-time on limited processing hardware should be chosen for implementation. Such a system should have a digital camera for image capture, and the appropriate framework for digital processing. The categorization model must extract the image parameters with the diseases to be identified, so a specific dataset for the problem is required. It should also facilitate the interpretation of results by the user, so the images captured by the user should be labeled according to the diagnosis (Fig. 1).

To design the model, the most frequent diseases that cause the most damage to the plant and coffee production were selected. For these images, we used public databases categorized by experts in the plant. We used 1250 images with a size of each of  $2048 \times 1024$  pixels, corresponding to Arabica coffee leaves separated into five categories, each category with 250 images. The number of images in each category was kept the same (250) to avoid bias in the model. The first category (category 1) corresponds to healthy leaves, the other four categories correspond to leaves affected by four common plant diseases (each leaf has only one of the diseases): Coffee Leaf Miner (CLM, category 2), Coffee Leaf Rust (CLR, category 3), Phoma Leaf Spot (Phoma Tarda, category 4), and Iron Spot (*Cercospora Coffeicola*, category 5). Fig. 2 show the detail of the images in each of the categories.

Before training the model, the images will be pre-processed using segmentation and labeling filters to remove the background of the image and keep only the leaf. Color adjustment filters will also be used to enhance the images. In this way, we seek to ensure that each image has the visual information that a human expert would identify. The same processing is applied to the images used in the training as well as those used for model validation (Fig. 3). The system must have a visual

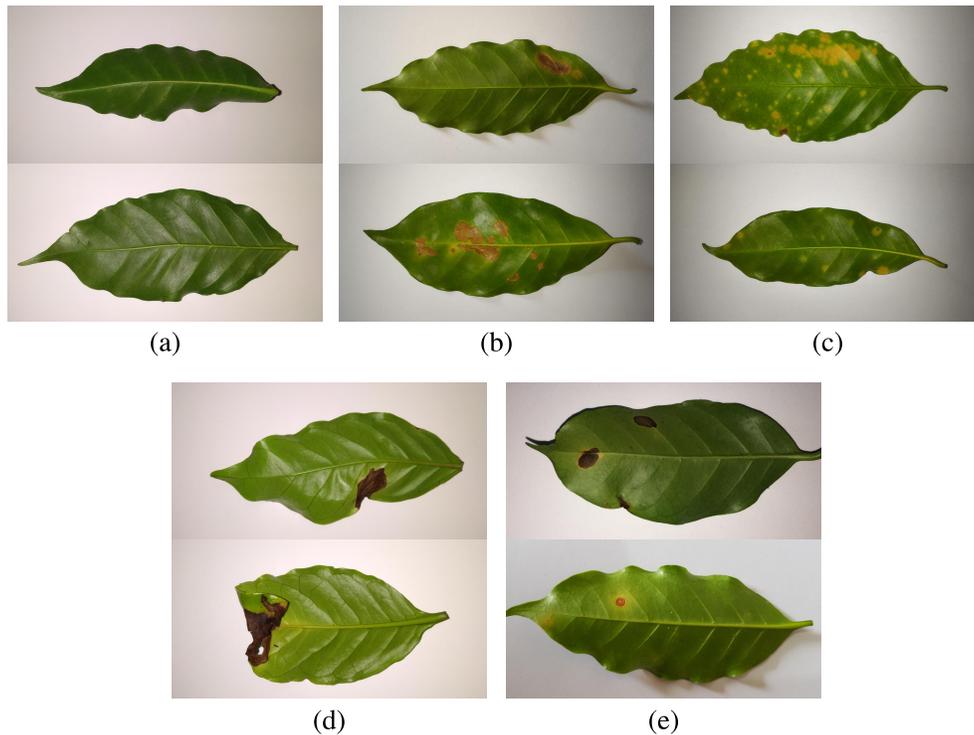

Fig. 2. Sample Images from the Dataset. (a) Healthy Leaves, (b) Coffee Leaf Miner (CLM), (c) Coffee Leaf Rust (CLR), (d) Phoma Leaf Spot (*Phoma Tarda*) and (e) Iron Spot (*Cercospora Coffeicola*)

output in which the user can observe the damage identified on the leaf in real-time. In principle, a screen should be available in which this image is constructed by superimposing on the frame captured by the camera the information related to this labeling and the information related to the categorization.

Among the possible deep models, the best performance was obtained with the ResNet (Residual Neural Network). Convolutional neural networks have convolution layers (convolution filters) that have the effect of filtering the image with a previously trained kernel, capable of detecting primitive features such as lines or curves. Over several layers, the neural network learns to identify these features along with the training data set. The ResNet50 architecture is selected as the topology given its smaller comparative size (fewer parameters), and high initial test results. This feature is achieved thanks to its design,

the network topology contemplates short forward connections from the previous layers, which has been observed to increase its accuracy.

### III. METHODS

The system is composed of three processing modules: leaf detection unit, preprocessing unit, and DNN (Deep Neural Network) based model (Fig. 1). These modules are sequential, the output of one functions as input to the next. The first one corresponds to a set of filters applied to the input image that seeks to identify the morphological characteristics of the leaf in the video frames. These filters look for leaf shape regardless of orientation or background, but prioritize shapes of relative size to the frame, thus requiring the user to focus on individual plant leaves. These initial filters reduce processing

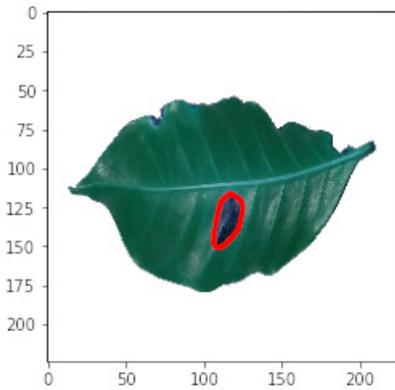

Fig. 3. Image after Segmentation, Labeling, Filtering and Scaling.

requirements by identifying an area in which the second module's preprocessing is applied. The preprocessing module receives as input an area in the frame on which segmentation and labeling are applied to identify areas of the region with characteristics different from those expected in a healthy leaf. This information is transferred to the output screen for user documentation but is also used to precisely delimit the region containing the leaf, which feeds the next module. Finally, this information enters the DNN module, which propagates the network in the trained model, and defines the most likely disease. This information is also displayed on the screen for the user.

The ResNet network was trained with public images corresponding to different databases. The selection of the images considered criteria related to the effect of the disease in the region of interest, the severity of leaf damage, and image capture conditions (real environment and/or laboratory). The images in the dataset were filtered to remove the background, center the leaf on the image, and improve its color level [35]. Also, they were randomly mixed within the stack to improve the performance of the network. To facilitate training and reduce resource consumption, the images were scaled to  $256 \times 256$  pixels in RGB format. Although the aspect ratio of the images was altered, this does not alter the visual information related to the images, but it does facilitate the design of the neural network.

For neural network training, the color matrices of the images, which make up the input parameters, were normalized to color depths in the range of zero to one. Besides, the 1250 images were randomly separated into two groups, the first group with 80% of the images (1000 images) for neural network training, and a second group with the remaining 20% (250 images) for model validation purposes. For the design of the network structure, the size of the input images is taken into account,  $256 \times 256 \times 3 = 196,608$ , which defines the total number of input nodes. The number of output nodes is defined by the number of network categories, which in our case are five categories, so five output nodes. In the output, a one-hot coding structure was defined to define these five output categories.

The ResNet50 model is a variant of ResNet with a total of 48 convolution layers, along with 1 MaxPool layer and 1 Average Pool layer. The network has a total of 23,597,957

parameters, of which 23,544,837 were adjusted during training. Of these parameters, 10245 corresponded to the dense output network. As optimization function in the model, we use the stochastic gradient descent function. In the optimization we use as error measure the categorical hinge function. During the training, we calculated in each epoch the values of accuracy (or hit rate) and MSE (mean quadratic errors) metrics to observe the performance of the network throughout the training. The final model was trained over 300 epochs with a batch size of 32. Throughout the training, the accuracy increased from 23.3% to 96.5% for the training data.

We selected Arrow Electronics' DragonBoard 410c development board as the platform to evaluate the performance of our neural model as an embedded system. We chose this board for both cost and performance. This board has a Qualcomm APQ8016e 64-bit quad-core processor, Wi-Fi, Bluetooth, and GPS connectivity, and support for Windows 10 IoT Core, Android 5.1, and Debian 8.0. To evaluate the performance of our model, we use Keras 2.4.3 and Tensorflow 2.3.0 installed above Linux Debian OS. Additionally, we used numpy 1.18.5, scipy 1.4.1, scikit-learn 0.22.2, Pillow 7.0.0, glob2 0.7, matplotlib 3.2.2, cv2 4.1.2.30, seaborn 0.11.0, and pandas 1.1.2.

#### IV. RESULT AND DISCUSSION

The performance of the model was evaluated based on the behavior of the categorization system with the validation images, in this way it was possible to quantify the performance under ideal conditions. The final tests of the prototype were performed in the laboratory with leaves collected directly in the field by the research group. These tests allowed validation of the detection and preprocessing modules.

For the case of the final DNN model tuned for implementation, training was performed over 300 epochs, and accuracy (Fig. 4) and loss values (Fig. 5) were recorded for both training and validation data. The error produced by the training data is continuously reduced throughout the whole process, reaching a final value of 0.07. An equivalent behavior is observed for the accuracy of the training data, which increases continuously throughout the training process from 23.3% to 96.5%. The behavior of the validation data is not as uniform, but an overall reduction of the error at the end of the training process is observed, which although it is lower than that achieved by the training data, keeps decreasing in parallel, guaranteeing the non-existence of overfitting (final loss value of 0.56). The accuracy of the validation data also has a uniformly increasing behavior, parallel to the training data, increasing continuously throughout the training process (final value of 71.5%). These data, while not guaranteeing a perfect classification, do provide for the application of an adequate classification of the analyzed images.

The confusion matrix provides a quick picture of the classification capability of the model as it explicitly shows when one category is confused with another. This allows working separately with different types of error, as well as calculating different model performance metrics. We calculate the confusion matrix for our model using the images from the validation group (unknown images for the model) and assign a heatmap with light colors for the highest number of true

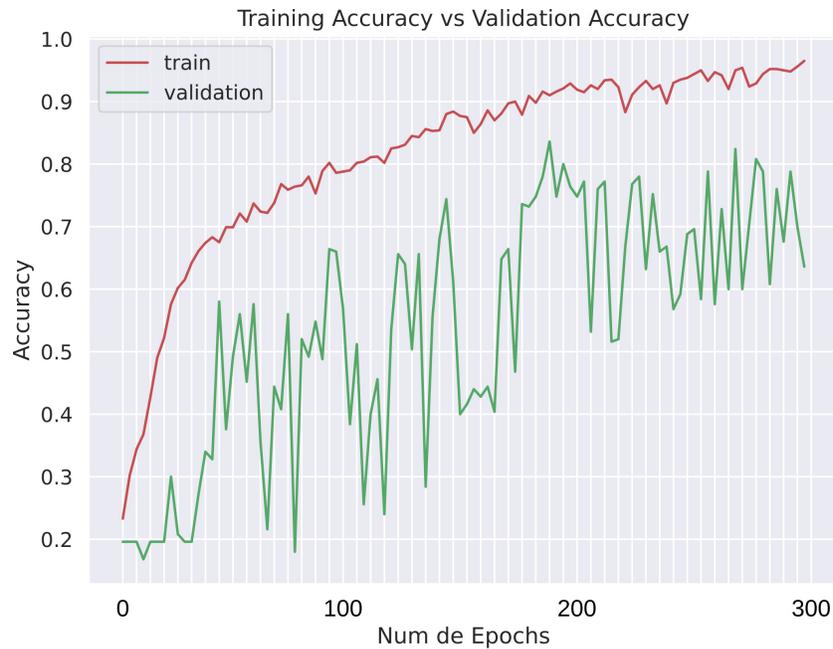

Fig. 4. Model Behavior: Training Accuracy vs Validation Accuracy.

positives, and dark colors for the opposite cases (Fig. 6). The diagonal of the curve clearly shows that the model correctly classifies most of the unknown images. For example, for the healthy leaves' category, 22 of the images were correctly classified in the first category, and for the CLM category, the best performing category, 45 of the images were correctly classified.

To evaluate the performance of the model in a specific way, we calculate the accuracy, recall, f1-score, and support metrics for each of the categories with the validation images (the 250 unknown images for the model). The average precision of the model (percentage of correct positive predictions among all positive predictions) was 73%, with an exceptional classification of diseased leaves with Phoma Leaf Spot (84% precision) and healthy leaves (92% precision). However, the classification of diseased leaves with Coffee Leaf Rust was considerably low (42% precision). The values of recall and f1-score show similar results to those shown by the precision, in the case of recall (percentage of correct positive predictions among all positive predictions that could have been made) some measure of the wrong positive predictions is presented, in this case, the average value drops a little to 64%, which is very similar to the precision value, but the recall for the leaves that are healthy drops to 41%, and the value for the leaves that are sick with Coffee Leaf Rust goes up to 88%. The f1-score corresponds to the harmonic mean of precision and recall, so the above peaks are averaged out at 64%. For the classification model of our project, these values are good enough to support the development of the prototype.

We also calculated the ROC curve (Receiver Operating Characteristic) of the neural model (Fig. 7). This curve graphically shows the sensitivity of the model (ratio of true positives to the ratio of false positives) to variations in the discrimination threshold between categories. In this sense, high average values

(0.87) and high values per category (0.85 to 0.93) of true positives versus false positives are observed.

Laboratory tests of the prototype showed not only the correct operation of the classification model within the metric margins but also how the leaf detection and preprocessing modules facilitate the work of the deep model. The need to evaluate the impact of these modules on the overall performance of the system is raised in future work. The capability of the DragonBoard 410c development board to run the software in real-time will also be verified.

## V. CONCLUSION

Early and on-site detection of diseases in coffee crops is of great importance to avoid harvest losses, and to schedule the correct spraying processes. In this sense, in this work, we propose an embedded system based on machine learning for the detection of diseases in the coffee plant. This system is intended to be used directly in crops by farmers without technical knowledge, so its design, in addition to the characteristics of the plant and its diseases, considers aspects of use, cost, and performance. These characteristics of the system constitute the major contribution of the authors in the research.

For the design of the classification model, we selected four high impact diseases for this crop: Coffee Leaf Miner (CLM), Coffee Leaf Rust (CLR), Phoma Leaf Spot (Phoma Tarda), and Iron Spot (Cercospora Coffeicola). Healthy leaves were also assigned a category. These diseases produce visible damage in the coffee leaf that can be identified and classified by image processing. In this sense, we selected a deep neural network type ResNet (Residual Neural Network) to identify and learn the characteristics of the leaves and their diseases. This neural network was selected due to its high performance and lower number of parameters compared to other topologies, including other larger ResNet models. The architecture of the

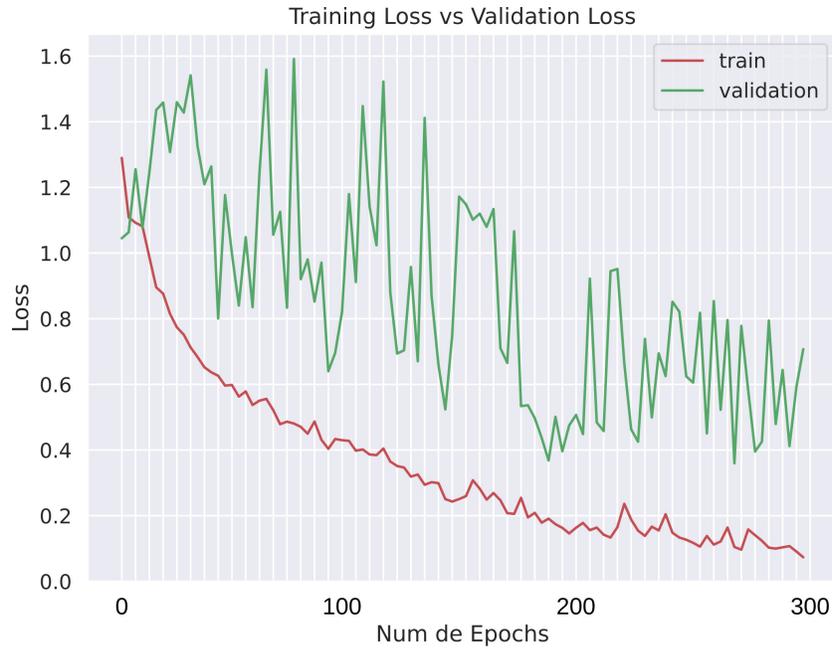

Fig. 5. Model Behavior: Training Loss vs Validation Loss.

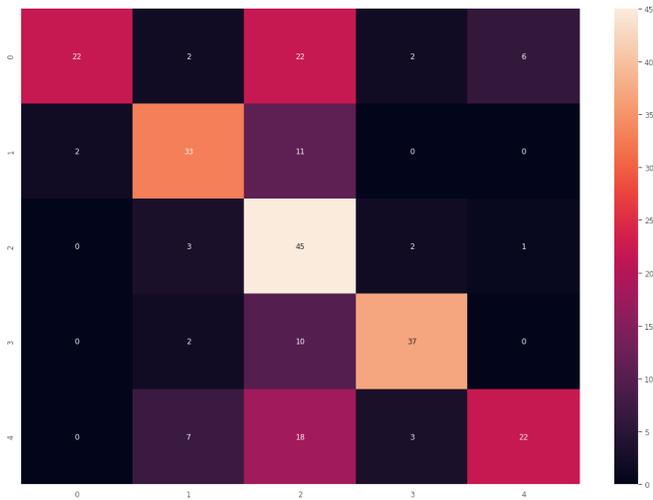

Fig. 6. Confusion Matrix.

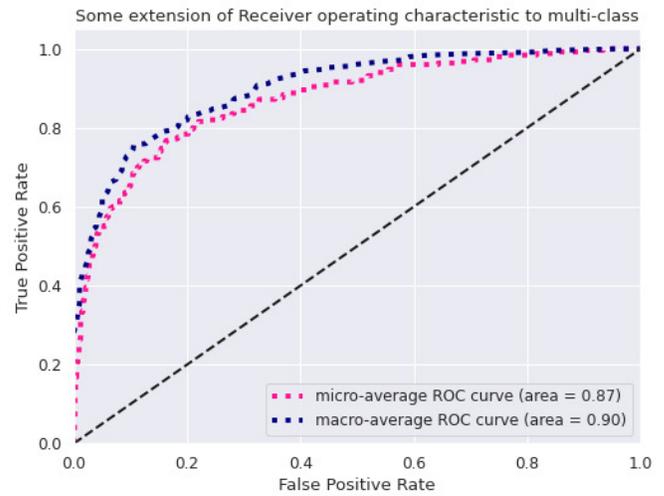

Fig. 7. ROC Curve.

ResNet network was adjusted for input images of  $256 \times 256$  pixels in RGB format, 50 layers of depth (ResNet50), and five output categories. The database was made up of 250 images in each category, and 80% of them were used for training (1000 images) and 20% for model validation. The training was carried out over 300 epochs taking care not to overfitting the network. To fine-tune the parameters, the error was evaluated using the categorical hinge function, and optimized using the stochastic gradient descent function. The final accuracy achieved by the model was 96.5% for the training data and 63.6% for the validation data (images unknown to the model). This model was implemented on a DragonBoard 410c from Arrow Electronics, running a Debian OS. Preliminary results

show low resource consumption and acceptable performance for real-world implementation. Detection of diseased leaves exceeds 91% of cases, and correct disease identification is 64% in the worst case. Research continues to strengthen the training database, apply further fine-tuning to the hyperparameters, and evaluate the impact on the performance of the digital image processing modules.

ACKNOWLEDGMENT

# Deep Learning-based Hybrid Model for Efficient Anomaly Detection

Frances Osamor, Briana Wellman  
Computer Science and Information Technology  
University of the District of Columbia, Washington, USA

**Abstract**—It is common among security organizations to run processes system call trace data to predict its anomalous behavior, and it is still a dynamic study region. Learning-based algorithms can be employed to solve such problems since it is typical pattern recognition problem. With the advanced progress in operating systems, some datasets became outdated and irrelevant. System calls datasets such as Australian Defense Force Academy Linux Dataset (ADFA-LD) are amongst the current cohort containing labeled data of system call traces for normal and malicious processes on various applications. In this paper, we propose a hybrid deep learning-based anomaly detection system. To advance the detection accurateness and competence of anomaly detection systems, Convolution Neural Network (CNN) with Long Short Term Memory (LSTM) is employed. The raw sequence of system call trace is fed to the CNN network first, reducing the traces' dimension. This reduced trace vector is further fed to the LSTM network to learn the sequences of the system calls and produce the concluding detection outcome. Tensorflow-GPU was used to implement and train the hybrid model and evaluated on the ADFA-LD dataset. Experimental results showed that the proposed method had reduced training time with an enhanced anomaly detection rate. Therefore, this method lowers the false alarm rates.

**Keywords**—Anomaly detection; system call sequence; convolution neural network; long short term memory

## I. INTRODUCTION

Intrusion detection is the procedure of recognizing malicious behaviors on the network [1]. There are two kinds of intrusion-based detection systems. They are network-based [2] and host-based [3] —network-based examines the traffic on the network and the set of protocols to govern the conceivable intrusions. Pattern matching procedures were used earlier by analysts [4]. Packet header of the data, string and port data are among the few matching features used. Such features improve the consistency and suitability. Particle swarm optimization, gray wolf algorithm, genetic algorithm are some of the current feature selection algorithms [5, 6]. The genetic algorithm runs to the issue of moderately outsized randomness; the gray wolf algorithm traps easily in the local optimum. Host-based intrusion detection system investigates the system maneuver data such as the log files and audits for anomalous pattern behavior. Learning-based methods are popular compare to the rule-based system with the increasing complexity of the environment [7]. Support Vector Machine, Decision Tree, and Random Forest are some of the traditional machine learning algorithms [8, 9, 10, and 11] applied for host-based intrusion detection systems. Hinton projected the idea of deep learning

first in 2006 [12]. Deep Learning learns the complex patterns of the data in both supervised and unsupervised ways. Hence, deep learning based algorithms are widely used in natural language processing areas, image processing areas, etc. In recent years, scholars started smearing deep Learning based algorithms to solve intrusion detection problems. To reduce the dimensionality of features and extract meaningful patterns, autoencoders are widely used. It encodes the high-dimensional input data into lower dimension subspace. Convolution Neural Network extracts the significant features from the image data (Gray Scale or Color). Chawla et al. [13] applied stacked CNN and achieved an accuracy of 0.81. Diep et al. [14] focused on custom CNN with word embedding followed by Bi-LSTM and achieved a score of 0.96. In this work, we study the application of learning-based Convolution Neural Network (CNN) and Long Short Term Memory (LSTM) algorithm with optimization of hyperparameters to detect the anomalies [15] with reduced and efficient neural architecture and in optimized training time. The second focus is on the training time of the hybrid model. The training time of the proposed hybrid model is significantly reduced compared to the baseline models. The rest of the divisions are as follows. In Section 2, we discuss the related work on anomaly detection systems. The dataset is explained in Section 3. Next, we provide explanation of proposed framework in Section 4. Next, in Section 5 we explain the experimental results and finally we conclude in section 6 with future work discussion.

## II. RELATED WORK

A system call is a call made by a program to the kernel for a service. Its system calls sequence can analyze the behavior of the process. Such traces are used to classify a process as normal or malicious in a host-based intrusion detection system. For such behavior classification of a process, numerous data representation methods can be found in the literature. Sequence n-gram model [16, 17] and pair-gram [18, 19] are among the few representations to extract the meaningful features from the trace of system call. Information retrieval and Natural language processing (NLP) techniques can be used by treating an individual system call as word and the trace of system call as the document. Vector space model and Boolean model-based document representation approach are used to extract the features from the traces. X. Wang et al. [20] extracted the feature using the Boolean model with n-gram approach and further applied the Support Vector Machine algorithm for classification purposes. Vector space model was used by K. Rieck et al. [21] with polynomial function for categorizing the traces of system call. As a distance metric, Y. Liao [22] used a

vector space model with a k-nearest neighbor classifier with cosine similarity. Nonetheless, such a classification system considers the system calls frequencies and not its sequence. System call trace datasets like DARPA [23] and University of New Mexico [24] were widely used by researchers for training the learning-based algorithms for analyzing the behavior of the processes. Nevertheless, with the advanced modernization of complex operating systems, these datasets are becoming irrelevant. ADFA datasets by G. Creech et al. [25, 26] are currently used to benchmark the evaluation of intrusion detection systems based on a system call. They used short sequences and a projected model for anomaly detection. It has an extensive pool of system call traces. They trained one-class SVM, Hidden Markov Model, and Extreme Learning Machine algorithms. With one-class SVM, the author achieved 80% accuracy and 90% with ELM [27]. It is a time-intensive task for learning a vocabulary of all sequences. Miao Xie et al. [28] uses principal component analysis [29] to reduce the dimensionality of features on the ADFA-LD dataset and further train k-means clustering and k-nearest neighbor algorithms. Their result showed an additional endeavor, they achieved an accuracy of 70% by training one-class SVM. The results and experiments in the proposed work are mostly on the supervised classification [30, 31]. Thus, in this work, we implemented a hybrid learning-based approach.

### III. ADFA-LD DATASET

Australian Defense Force Academy generated the ADFA-LD host-based intrusion detection dataset. Linux system calls are being recorded in this dataset. To communicate between the user and kernel mode, standard interfaces are provided by the Linux kernel. The programs in user-mode have very partial reference to hardware devices for accessing the resources of systems, read and write to the device, and new process creation. Every system call has a unique identifier number on the sequence trace. The host designed to characterize a recent Linux server which logs the traces of system calls during a specified period. Authentic programs functioned in normal behavior during such sampling period. The constituted Linux server comprises of file distribution, remote access, database, and web server type of functionality. Entirely patched Ubuntu 11.04 operating system with Linux kernel 2.6.38 was used. For access to services on the web, Apache 2.2.17 and PHP 5.3.5 were configured. Secure Shell Protocol, MySQL, and File Transfer Protocol with their default ports were permitted. As a collaborative web-based tool, TikiWiki 8.1 was installed. Subsequently, various cyberattacks listed in Table I are injected to generate the abnormal traces.

TABLE I. ADFA-LD DATASET

Trace Type	Count	Label
Hydra-FTP	162	Abnormal
Hydra-SSH	148	Abnormal
Webshell	118	Abnormal
Java Meterpreter	125	Abnormal
Meterpreter	75	Abnormal
Add user	91	Abnormal
Training	833	Normal
Validation	4373	Normal

### IV. PROPOSED FRAMEWORK

Fig. 1 depicts the overall framework. There are three phases. Dataset Collection, Data Engineering and Training of the Detection Algorithm with the final testing.

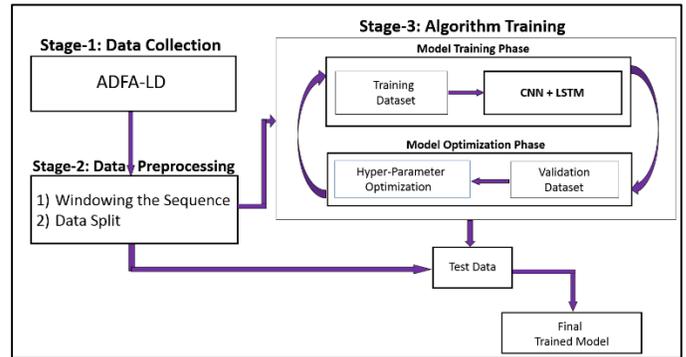

Fig. 1. Proposed Framework.

#### Phase-1: Data Collection

We employed the ADFA-LD dataset which is explained in Section 3.

#### Phase-2: Data Engineering (Preprocessing)

The following tasks are performed:

- Windowing the sequence of the system calls as input and output and performing the encoding of the target category [32].
- Applying stratified sampling and divide the dataset into train, validate, and test.

#### Phase-3: Algorithm Training.

In this phase, the hybrid model is trained as discussed below:

##### A. Training of the Model

A hybrid deep learning-based Convolution Neural Network with long short term memory algorithm is trained in this phase.

1) *Convolution neural network*: It is a type of neural network, as depicted in Fig. 2, which is widely used for images dataset. It is used for image segmentation, classification, etc.

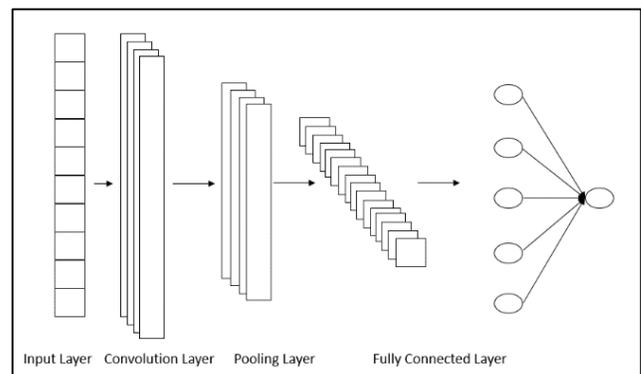

Fig. 2. Convolution Neural Network.

There are two layers in CNN architecture. They are:

a) *Convolution layer*: This layer applies convolution operation on the input image to extract the meaningful feature. Each pixel value of the image is multiplied by the corresponding filter value, and finally, all the values are added.

b) *Pooling layer*: This layer is used to reduce the dimensionality of the images. There are different types: Max-Pooling, Min-Pooling, Mean-Pooling, etc.

Rectifier Linear Unit (ReLu) activation function is applied to deal with the non-linearity of the data. Finally, a fully connected dense layer is employed to predict the outcome.

2) *Long short term memory*: LSTM has memory cells. Numerous gates are attached to the LSTM system to mitigate the vanishing gradient problem of the RNN [33]. These gates behave like a memory. The memory update occurs with the read of an input by the cell. It has the following four gates:

I gate: It enhances the updation of the new incoming memory.

O gate: It updates the new hidden state by selecting the new memory cell info.

F gate: It regulates the amount of old information to be discarded.

M gate: It creates new memory.

For a example dataset of  $U=(U_1, U_2, U_3, U_{N-1}, U_N)$  as input to network, it updates the above four gates values to learn the output variable. It is updated as follows:

$$(z_t, d_{t-1}, s_{t-1}) \rightarrow (d_t, s_t) \quad (1)$$

$$i_t = \sigma(k_{zi}z_t + k_{di}d_{t-1} + k_{si}a_{t-1} + j_i) \quad (2)$$

$$f_t = \sigma(k_{zf}z_t + k_{df}d_{t-1} + k_{af}a_{t-1} + j_f) \quad (3)$$

$$a_t = f_t * a_{t-1} + i_t * \tanh(k_{za}z_t + k_{da}d_{t-1} + j_a) \quad (4)$$

$$y_t = \sigma(k_{zy}z_t + k_{dy}d_{t-1} + k_{ay}a_t + j_y) \quad (5)$$

$$d_t = y_t * \tanh(a_t) \quad (6)$$

where  $j_i, j_f, j_y, j_a$  represents the bias units for I, F, O, and the memory cell, respectively. Next,  $k$  denotes the weight vector, and  $a$  denotes memory state with output of intermediate layer's as  $d$  as shown in Fig. 3.

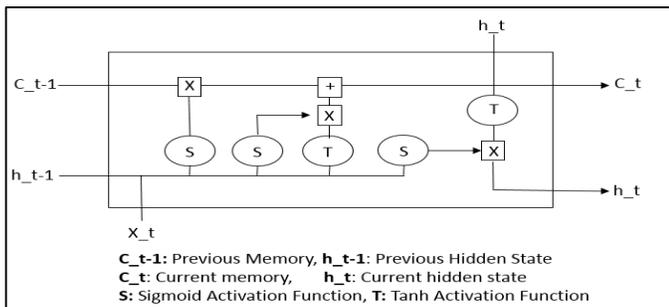

Fig. 3. Long Short Term Memory.

We developed and trained the hybrid CNN [34] with LSTM model architecture shown in Fig. 4. To optimize the hyper-parameters value, we use the K-fold technique with K being 10 [35]. The proposed architecture has a custom ConvLSTM2D layer. This layer takes the raw system call sequences of normal operation as input. The convolution layer applies the convolution operation followed by the pooling technique to extract the meaningful features from the sequences. We use a kernel size of (1,2) with 64 filters. Next, the extracted sequence is fed to the LSTM layer, which learns the patterns of the normal behavior of the sequences. TimeDistributed layer is applied to pass the hidden output at every time step. Finally, the output is flattened and passed to a fully connected dense layer, predicting the final result.

The following metric is used to evaluate the model.

Mean Squared Error (MSE): It finds the square deviations between predicted and actual value.

$$MSE = \frac{1}{N} \sum (Y - \bar{Y})^2 \quad (7)$$

N is the total data points, Y is the actual ground-truth label, and  $\bar{Y}$  is the predicted label.

### B. Optimization of the Model

We use the validation part of the dataset for optimizing the hyper-parameter [36, 37] for the hybrid model. Parameters that are tuned are as follows:

- Number of Epochs: Total amount of time, data is passed to the model.
- Batch-size: Total count of data sequence given to the model to calculate the loss and update the weight. After the fine-tune optimization, test data is used to evaluate the model.

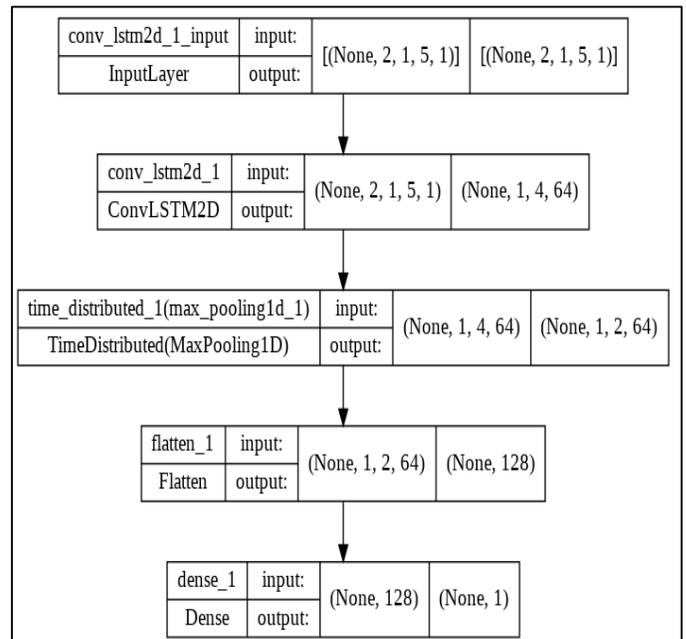

Fig. 4. Model Architecture.

### V. EXPERIMENTAL RESULTS

The hybrid model was trained with activation function namely Rectifier Linear Unit. The optimal accuracy rate is achieved with a batch-size of 128. While training the deep neural network, the size of the batch is one of the critical hyper-parameter to be tuned. Stochastic Batch, Batch, and Mini-Batch are the three variants of batch sizes. The model waits till the end of the processing to update the weights in batch variant. Next, model updates the weights after every input sequence in stochastic batch approach. Model updates the weights after every batch in minibatch approach. We train the hybrid model with mini-batch of {16, 32, 64, 128, and 256}. At each batch value, the accuracy value is shown in Fig. 5. The highest accuracy of 0.961 is achieved with a batch value of 128. Fig. 6 and 7 depicts the accuracy and loss at each epoch. After 100<sup>th</sup> Epoch, the accuracy and loss didn't change much. With the proposed hybrid approach, we achieved 96% accuracy rate and 0.04% loss. The comparison with baseline is given in Table II.

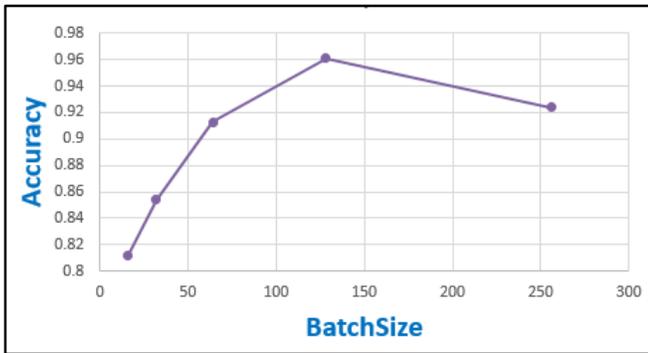

Fig. 5. Accuracy for Individual Batch.

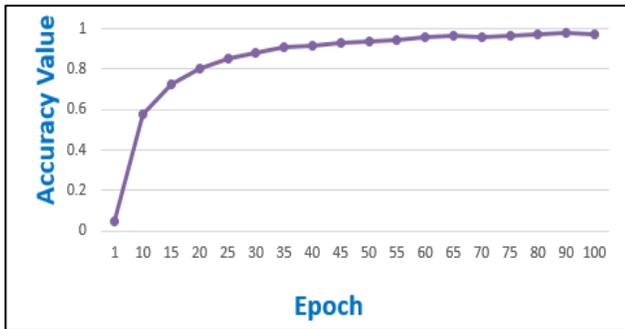

Fig. 6. Accuracy for Individual Epoch.

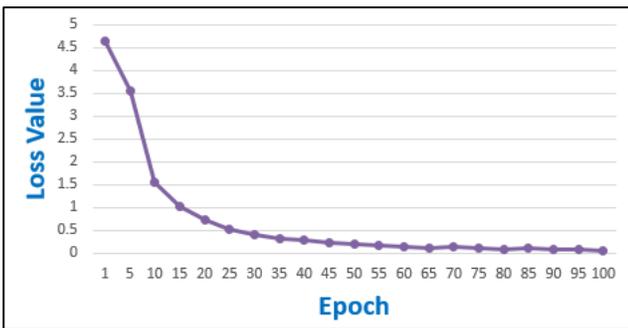

Fig. 7. Loss for Individual Batch.

TABLE II. COMPARISON WITH BASELINE

Model	Accuracy
CNN	0.81
LSTM	0.88
<b>CNN+LSTM</b>	<b>0.96</b>

### VI. CONCLUSION

Intrusion-based detection algorithms exert on the postulate that normal events differ from abnormal events. Anomaly detection algorithms learn a program's behavior during its normal operation. Process behavior is defined by the occurrence of the system call in a particular sequence. We proposed a hybrid deep learning-based CNN with an LSTM model to detect the anomaly in the sequence of system calls. CNN was used to extract the meaningful features, and LSTM was used to learn the patterns of the sequence from the reduced features. The model is trained with the normal process behavior and tested against the normal and malware-infected process. We use the ADFA-LD dataset to test our proposed hybrid model. We achieved an accuracy rate of 96% with a reduced time.

This work can be extended by applying the AutoEncoder neural network to reduce the dimensionality of the data further. Furthermore, numerous natural language processing-based algorithms can be trained, such as Bi-Directional LSTM and Transformers for comparative analysis.

# An Ensemble Deep Learning Approach for Emotion Detection in Arabic Tweets

Alaa Mansy, Sherine Rady, Tarek Gharib

Department of Information Systems, Faculty of Computers and Information, Ain Shams University, Cairo, Egypt

**Abstract**—Now-a-days people use social media websites for different activities such as business, entertainment, following the news, expressing their thoughts, feelings, and much more. This initiated a great interest in analyzing and mining such user-generated content. In this paper, the problem of emotion detection (ED) in Arabic text is investigated by proposing an ensemble deep learning approach to analyze user-generated text from Twitter, in terms of the emotional insights that reflect different feelings. The proposed model is based on three state-of-the-art deep learning models. Two models are special types of Recurrent Neural Networks (Bi-LSTM and Bi-GRU), and the third model is a pre-trained language model (PLM) based on BERT and it is called MARBERT transformer. The experiments were evaluated using the SemEval-2018-Task1-Ar-Ec dataset that was published in a multilabel classification task: Emotion Classification (EC) inside the SemEval-2018 competition. MARBERT PLM is compared to one of the most famous PLM for dealing with the Arabic language (AraBERT). Experiments proved that MARBERT achieved better results with an improvement of 4%, 2.7%, 4.2%, and 3.5% regarding Jaccard accuracy, recall, F1 macro, and F1 micro scores respectively. Moreover, the proposed ensemble model showed outperformance over the individual models (Bi-LSTM, Bi-GRU, and MARBERT). It also outperforms the most recent related work with an improvement ranging from 0.2% to 4.2% in accuracy, and from 5.3% to 23.3% in macro F1 score.

**Keywords**—Deep learning; emotion detection; transformers; RNNs; Bi-LSTM; Bi-GRU

## I. INTRODUCTION

Twitter is a famous 24/7 active social media platform with many signed users sharing their activities, thoughts, and feelings at any time. People post tweets, stream live videos, chat with each other, companies create and manage a lot of marketing campaigns to promote their products, and even much more services are provided.

These days no one can give up using online social networks because it makes them feel connected all the time. Also, they can express their feelings and emotions whether they are happy, sad, surprised, anticipated, or any other feelings during their online activities.

A lot of expressions and words in our daily written text over the web may reflect our feelings. Not only that but also it may affect other people significantly because we believe that every simple word reflects an impact. For example, posting a tweet like that:

“I got COVID-19 twice even though I have been vaccinated the vaccine is useless”,

Such simple words can kill a lot of people affected by that virus. Elderly people who have chronic diseases will realize that death is their next step because it makes them feel frustrated. By analyzing that content, everything that may affect a lot of people can be controlled. For Example, social networks can utilize a model for emotion detection in their platforms as an option to prevent such disappointing statuses from being appeared in their customers' timelines. In this way, they can control and restrict anxiety, frustration, and much more.

Emotion Detection or ED is one of the hottest research topics in the field of Natural Language Processing (NLP). ED is considered different from Sentiment Analysis (SA), where SA task is to recognize polarities from text such as positive, negative, or neutral. On the other hand, ED aims to get emotional insights from what has been typed [1].

When reading a tweet, it may reflect one of the following feeling polarities (positive, negative, or neutral). This study is not focusing on the detection of these polarities, but it goes deeper to detect different emotions like (joy, anger, surprise, etc.).

Scientists have summarized ED activities in a set of approaches that determine how exactly emotions are represented. The most famous emotional model is the Discrete Emotion Model (DEM) like Ekman's model which contains six basic emotions which are anger, fear, disgust, happiness, sadness, and surprise. The other models are Dimensional Emotion Model (DiEM) like Plutchik's Emotion Model and Russell's Circumplex Model [2][3].

Suppose a text presented in a user-generated tweet like this: “غضب دفين يفقد الاشياء الوانها لتصبح رمادية وتنعدم لذة الحياة”, humans can simply understand the context of this sentence by understanding each word based on the understanding of previous and next words. Also, they can understand the implied emotion of the user who posted the tweet (tweeter) which is sad or angry.

Words in a sentence are linked with each other's in a certain sequence to form a meaning, understanding that meaning is called “Contextual Understanding”. Traditional machine learning techniques cannot understand the context very well. Deep learning (DL) sequence models can be utilized to make machines simulate human understanding.

Sequence models such as Recurrent Neural Networks (RNNs) can understand the context by memorizing words and getting the relationships between them. But they have shown some shortages known by the problems of vanishing and

exploding gradients. Accordingly, new generations of RNNs have been developed to overcome that shortage. For example, LSTM and GRU models can deal with long-term dependencies and tackle the problems mentioned above.

Although there is a lack of Arabic resources and research studies on Arabic contextual understanding, different Arabic language models were developed to support this point. The most famous one is called AraBERT [4] which is an Arabic pre-trained language model (PLM) based on Bidirectional Encoder Representations from Transformers (BERT) [5]. AraBERT was pretrained using more than 20GB of Arabic text from different sources like Arabic Wikipedia, Arabic news websites, and others. It is based on Modern Standard Arabic (MSA), and it gets better results when fine-tuned using MSA datasets. PLMs are considered a part of Transfer Learning (TL) that support the research in this area and tackle the problem of limited resources. Other models were pretrained based on both MSA and Arabic Dialects (AD) like MARBERT PLM that is utilized in this study.

State-of-the-art neural networks (Bi-LSTM, Bi-GRU, and MARBERT) have been ensembled to deal with a multilabel classification task for emotion detection in user-generated Arabic tweets that were collected and shared during SemEval-2018 task-1: Affect in Tweets.

In Section II, related work is discussed. Section III discusses the proposed ensemble model. In Section IV, empirical results and discussion are investigated. Finally in Section V, the conclusion and future work.

## II. RELATED WORK

A lot of research studies have been conducted to get emotional insights and understand the context of English text. Unfortunately, there exist few studies related to the Arabic language because of different challenges related to the complexity of this language, the lack of existing Arabic resources, and different available Arabic dialects. Attention to the analysis of the Arabic language has increased in the last decade due to the need for digital transformation in Arab communities. The Arabic language has a lot of different dialects that are spoken by around 422 million speakers all over the world which is considered a big challenge in the analysis. In the following subsections, ED generic and closely related studies are discussed.

### A. Survey Studies

Alswaidan et al. [6] surveyed the state-of-the-art approaches related to emotion detection ED in the textual content for English and some other languages. They mentioned the available resources (corpora and lexicons) for working with ED tasks and addressed some challenges like (I) The challenge of detecting implicit emotions which are hidden in the text. (II) The problems related to size and quality in the available datasets. (III) Limited resources in some languages like Arabic.

Another survey study by Acheampong et al. [7] investigated the ED problem in text content by mentioning all available emotion-related datasets like (ISEAR, SemEval, EMOBANK, EmoInt, Cecilia Ovesdotter Alm's Affect data,

Daily Dialog, AMAN'S Emotion, Grounded Emotion data, Emotion-Stimulus data, Crowdsourcing, MELD, Emotion and Smile dataset). Also, they have mentioned the different approaches used to analyze and detect the emotional insights from that data (the rule construction approach, ML approach, and the hybrid approach). And they have made a comparison between different related works in terms of (used approaches, datasets, and limitations).

Similarly, a Systematic Literature Review (SLR) was introduced by William et al. [8] and listed the closely related studies used for text-based depression detection. Also, they aimed to identify and analyze different text-based approaches for the early detection of depression in social media posts. Their results showed that using BiLSTM along with the attention model performs well on depression-related textual data. They also made an experiment by using a BERT-based model and achieved better results compared to the studies mentioned in the SLR. Their experiments used a BERT-based model for the classification task. They also suggested a new method to deal with long sequences by summarizing the text before feeding it into the model. The model depends on a dataset crawled from Reddit.

### B. Utilizing Traditional ML and DL Models

Mohammad et al. [9] shared a task called "Affect in Tweets" in the SemEval-2018 competition, which includes a list of subtasks for detecting the emotional states of the tweeters from their text-based tweets. They streamed and annotated some Arabic tweets to form twitter-based labeled datasets represented in three different languages English, Arabic, and Spanish. About 200 team members participated in this competition. Different ML and DL algorithms like (Bi-LSTM, CNN, Gradient Boosting, Linear Regression, Logistic Regression, LSTM, Random Forest, RNN, and SVM) were used. Badaro et al. [10] improved the performance of the emotion classification task by utilizing a pre-trained word embedding model (Aravec) and achieved the best evaluation metrics for (Arabic EC subtask) by using SVC L1 classifier that achieved 48.9%, 61.8%, 46.1% for accuracy, micro f1, and macro F1 scores respectively.

Baali et al.[11] presented a study for classifying emotions in tweets written in the Arabic language. They have used Convolutional Neural Networks (CNN) trained on top of trained word vectors. They compared the results of their approach with three ML algorithms (SVM, NB, and MLP). Their proposed approach was evaluated on the Arabic dataset provided by Sem- Eval for the emotion intensity ordinal classification task (EI-oc). Their results were 99.90% as training accuracy, and 99.82% as validation accuracy.

Khalil et al. [12] proposed a Bi-LSTM deep learning model for the task of emotion classification (EC) in Arabic tweets that were shared SemEval-2018 competition. They have merged the dataset files into only one file to use in the cross-validation process. Aravec with CBOW for the word embedding phase has been used. Their results have shown [Jaccard Accuracy 0.498, Micro Precision 0.695, Micro Recall 0.551, and Micro F1 score 0.615].

### C. Utilizing Pre-Trained Language Models (PLMs)

One of the challenges of ED in Arabic text is the limited resources of the Arabic language. As a result, Transfer Learning have been emerged to help pre-train of an NLP model on one large dataset and then quickly fine-tune the model to adapt to other NLP tasks. Also, the nature of that dataset may affect the fine-tuning process i.e., if the model was pre-trained on a dataset containing emotional-related content it will give the best results in ED tasks compared to the model that was pre-trained using other natures of data. Also, some of the existing PLMs were pre-trained using Arabic MSA like AraBERT introduced by Antoun et al. [4] which gets lower results when compared to other PLMs like Abdul-Mageed et al. [13] who introduced MARBERT PLM that was pretrained using both Arabic MSA and different Arabic dialects. Another research study by Abdelali et al. [14] trained five different Arabic BERT models of QARiB using the original implementation of the BERT model implemented by google for both Arabic MSA and Arabic Dialects. Also, they have compared their results with three existing PLMs (mBERT, ARABERTv0.1&v1, ArabicBERT). And the evaluation was conducted using 5 different datasets represented in the following tasks (1) Named Entity Recognition (2) Emotion detection [SemEval2018-Ar-Ec] (3) QADI Arabic Dialects Identification (4) Offensive language detection (5) Sentiment Analysis. Macro-averaged F1 score was used as an evaluation metric, and the results related to the (EC task) using the dataset SemEval2018-Ar-Ec showed that the QARiB25 mix achieved the best macro-averaged F1 score equal to 46.8 %.

Researchers continued to investigate the development of Arabic language models thought conducting a lot of experiments like Al-Twairesh [15] who conducted ten experiments using different models starting from traditional TF-IDF to the recent state-of-the-art BERT models (TF-IDF, AraVecCBOW100, AraVecSG100, AraVecCBOW300, AraVecSG300, AraBertv01, AraBertv1, ArabicBertBase, ArabicBertLarge, Multi-Dialect Bert) on SemEval-2018 dataset. And the results showed that the Arabic BERT-Large model achieved the best results compared to other models.

Others utilized the contextualized embeddings of the PLMs to support other DL models like Elfaik et al. [2] who investigated the problem of Arabic Emotion detection (multilabel emotion classification) in tweets by combining the generated contextualized embeddings using AraBERT and an attention-based LSTM-BiLSTM deep model. The attention mechanism is applied to the output of LSTM-BiLSTM to guarantee different words. Their proposed approach was evaluated using the dataset of SemEval-2018-Task1-Ar-Ec (Affect in Tweets). Their results show that the proposed approach achieves accuracy (53.82%).

Samy et al. [16] researchers utilized some social intelligence and proposed a context-aware gated recurrent unit (C-GRU) to solve the problem of multi-label classification in Arabic-related tweets represented in the SemEval-2018-Task1-Affect in tweets (EC subtask). They have related each tweet with a specific topic, and they depend on what is called social influence where people in the same network can share topics and in the same topic, they can find similar emotions. They have used SemEval-2017 for the topic classification task and

SemEval-2018-Ec-Ar for the emotion detection task. They have used Jaccard-similarity for accuracy, F1 macro average, and F1 micro average which achieved results of 0.532, 0.648, and 0.495 respectively.

### D. Utilizing Ensemble Techniques

AlZoubi et al. [1] implemented an ensemble approach that contains [bidirectional GRU\_CNN (BiGRU\_CNN), conventional neural networks (CNN), and XGBoost regressor (XGB)] to be used in solving the emotion intensity (EI-reg) subtask of the SemEval-2018 Task1 (Affect in Tweets). Their proposed ensemble approach was evaluated using the dataset of the SemEval-2018 Task1 EI-reg. Results show that their model achieved a Pearson of (69.2%).

Alswaidan et al. [17] proposed three different models, a human-engineered feature-based (HEF) model, a deep feature-based (DF) model, and a hybrid of both models (HEF+DF) for the emotion detection task in Arabic text. And they measured the performance of the proposed models using three different datasets (SemEval2018-Ar-Ec, IAEDS, and AETD). Regarding the SemEval2018-Ar-Ec dataset, the hybrid model achieved the best results of 0.512, 0.631, and 0.502 for Jaccard accuracy,  $F^{micro}$ , and  $F^{macro}$  scores respectively.

Talafha et al. [18] investigated the Arabic dialect identification problem and trained Arabic-BERT [19] using 10M unlabeled tweets shared in Nuanced Arabic Dialect Identification Task 1 (NADI) and the result was a new pre-trained language model called Multi-dialect-Arabic-BERT. Also, they utilized an ensemble technique (element-wise average) to get the highest value of the predicted probabilities per class for each of the four models. Their results are 44.07 for accuracy and 29.03 for the F1 score.

Closely related studies have been analyzed and concluded in the chart area shown in Fig. 1 that presents the progress till now regarding the EC task using the SemEval-2018-Ar-Ec dataset. As shown in the figure, utilizing PLMs has shown some progress in accuracy compared to other models. Similar studies that use PLMs for the EC task of SemEval-2018 didn't use the most suitable PLMs because most of them have used models that were pre-trained using non-emotional related content. To the best of our knowledge, no one has fine-tuned the MARBERT model using the SemEval-2018-Task1-Ec-Ar dataset. Also, we have used the ensemble model to combine different contextual understanding experiences that can help in getting better results.

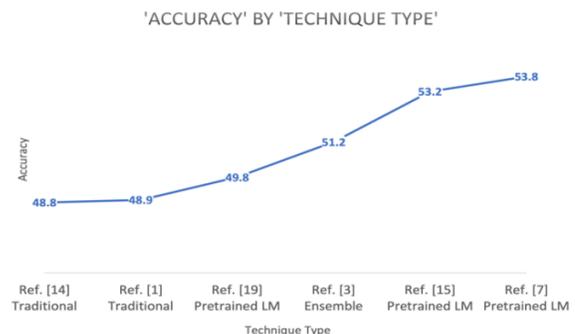

Fig. 1. Progress of Emotion Classification Task against SemEval-Ec Dataset.

### III. PROPOSED MODEL

The proposed ensemble model for multi-label emotion classification EC in the Arabic language is shown in Fig. 2 which consists of six layers (a) Preprocessing layer (b) Word embedding layer (c) Processing Layer (d) Testing Layer (e) Ensemble layer (f) Classification layer. The details of these layers are explained in the following subsections.

#### A. Preprocessing Phase

Data preprocessing is considered one of the most important phases in machine learning applications to avoid misleading

results and get better insights. In this section, the preprocessing steps will be discussed in detail with an example from our dataset.

As shown in Table I, a user-generated tweet from the SemEval2018-Ar-Ec dataset has been preprocessed using the most common preprocessing techniques like removing English characters, numbers, stop words, repeating chars, punctuation marks, and Arabic diacritics. Also, text normalization and emojis replacement steps have been added.

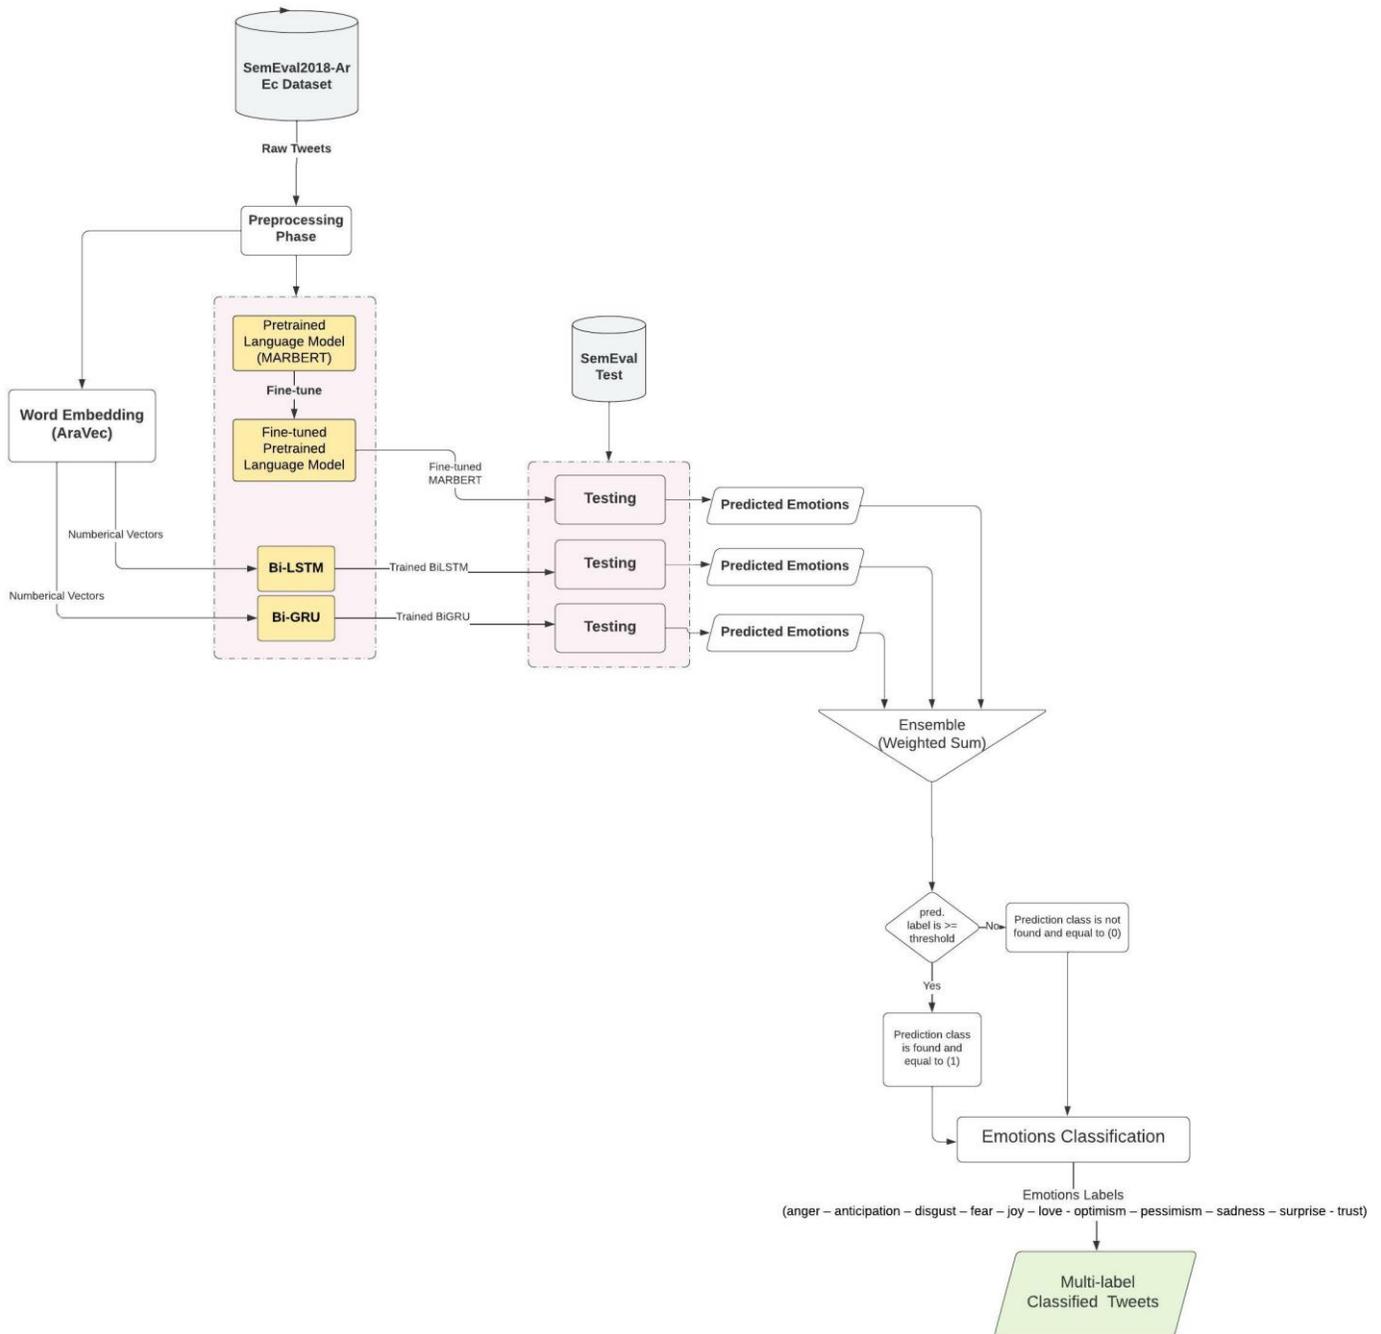

Fig. 2. The Proposed Ensemble Model.

categories (1) Sentiment Analysis SA (2) Named Entity Recognition NER (3) Dialect Identification DI (4) Topic Classification TC (5) Social Meaning SM like (emotion, irony, sarcasm, ...). Because MARBERT transformer was used before in the emotion detection task, it has an emotion-related contextual understanding experience. In this paper, a fine-tuned MARBERT on the SemEval-2018-Ec-Ar task has been proposed.

2) *Bi-LSTM model*: Bidirectional Long Short Term Memory Model or Bi-LSTM is an extension of the normal LSTM introduced by Hochreiter & Schmidhuber in 1997 [21]. LSTM was developed to avoid the short-term dependency problem as it can remember information for long periods, unlike traditional RNNs.

The core component in any LSTM cell is called “cell state”, which maintains information from previous time steps. Addition or deletion to the cell state is controlled by three main gates (forget gate, input gate, and output gate). The input of an LSTM cell is a combination of the input from the current time step and the previous hidden state. This combination outputs a numerical vector whose values are squished between 0 and 1 after applying a sigmoid function as shown in (1). Values closer to 0 will be forgotten while values closer to 1 will be kept and this is called the forget gate.

$$F_t = s ( W_f \cdot [h_{t-1}, x_t] + b_f ) \quad (1)$$

The same combination of input will be copied to be an input for two different activation functions (sigmoid and tanh) which are the main components of the input layer. The output of the sigmoid function is a vector whose values are squished between 0 and 1 by using (2) while the output of the tanh function is a vector whose values are squished between -1 and 1 by using (3). A pointwise multiplication is conducted between the output of these two activation functions which outputs a candidate cell state represented in a vector  $C_t$  after filtering non-important information using the sigmoid function.

$$i_t = s ( W_i \cdot [h_{t-1}, x_t] + b_i ) \quad (2)$$

$$C_t = \tanh ( W_c \cdot [h_{t-1}, x_t] + b_c ) \quad (3)$$

To calculate the updated cell state, (4) is used which represents a pointwise addition between two parts, the first part is the result of a pointwise multiplication between (the previous cell state and the output of forget gate) while the second part is the result of input gate.

$$C_t = f_t * C_{t-1} + i_t * C_t \quad (4)$$

The final step is to determine the new hidden state, and this is the output gate. To calculate the new hidden state  $h_t$ , (6) is used which includes two main parts, the first one is the output of a sigmoid activation function  $O_t$ , (5) that accepts a combined input from both the previous hidden state and the current input while the second part is the output of a tanh activation function whose input is the newly updated cell state  $C_t$ . As a result, the final output  $h_t$  of the LSTM cell will be filtered values from the cell state  $C_t$ .

$$O_t = s ( W_o \cdot [h_{t-1}, x_t] + b_o ) \quad (5)$$

$$h_t = O_t * \tanh ( C_t ) \quad (6)$$

Bi-LSTM is also a type of deep learning model that deals with sequential data. It is an extension of LSTM, and it accepts input data from both directions one from a forward direction and the other from a backward direction. Working in both directions can increase the contextual understanding of the user-generated text. In the following example, the word “احمد” in the first sentence is a noun (a person whose name is Ahmed) but in the second one, it is a verb (means thank). The model can understand the context by working in both directions to decide the meaning of each word in the context based on the next and previous words. In this way, Bi-LSTM can help more in a deep understanding of the user-generated text to get the emotional insights of the tweeter.

ابدعته الاعلان حلو اووي

دائماً ارفع راسي واحمد ربنا أنى من شعب مصر العظيم.

3) *Bi-GRU model*: GRU or Gated Recurrent Unit is a newer version of the LSTM neural network, and it was introduced by [22]. Unlike LSTM, GRU has fewer steps because it has only two gates (update and reset gates). Also, it has no cell state and the role of maintaining information lies in the hidden state. Update gate acts like forget and update gates in LSTM cell i.e., it decides what information to maintain and what to drop. In most cases, the results of Bi-GRU are slightly faster and better than Bi-LSTM.

#### D. Testing Layer

After finishing the processing layer, a fine-tuned version of MARBERT is available besides a trained version of Bi-LSTM and Bi-GRU. The SemEval-2018-Ar-Ec test dataset is used to test and evaluate the models. The output of the testing phase is three prediction files ready to enter the ensemble layer.

#### E. Ensemble Layer

After each model is tested using the SemEval-2018-EC-Ar-test dataset, three prediction files are generated, combined, and processed using a weighted sum equation that balances contextual understanding according to the performance of each model.

#### F. Classification Layer

Fraction results are generated from the ensemble layer. To get correct values, a certain threshold had been used to determine which values are one “1” meaning class label is found or zero “0” meaning class label is not found.

### IV. EMPIRICAL RESULTS AND DISCUSSION

In this section, the results of the proposed ensemble approach are discussed.

#### A. Dataset

The Arabic dataset has eleven class labels (anger – anticipation – disgust – fear – joy – love – optimism – pessimism – sadness – surprise – trust). For every class label in a tweet there is one of the two binary classification numbers

TABLE V. BI-LSTM MODEL PARAMETERS

Parameter	Value
Cell type	LSTM
Number of cells	2
bidirectional	True
Cell units	256
Max timesteps	64
Batch size	128
Embedding dimensions	300
Learning Rate (LR)	3e-4
No. of epochs	20
Number of classes	11

During the training and validation phases, the model monitors and saves the best checkpoints for different validation metrics like accuracy, precision, recall, and loss. The weights of each best checkpoint have been loaded and made our predictions using the test dataset.

As shown in Table VI, the best recall checkpoint achieved better results than other checkpoints with 0.485, 0.522, 0.559, 0.509, and 0.653 for Jaccard score, precision, recall, and F1 macro & micro scores respectively. Fig. 3, 4, and 5 show the relationship between training and validation for loss, accuracy, and recall at each epoch.

TABLE VI. BEST RESULTS OF BI-LSTM MODEL

Best Metrics	Evaluation Metrics				
	Jaccard Score	Precision	Recall	F1 Score	
				Macro	Micro
BiLSTM_best_precision	0.319	0.210	0.384	0.257	0.483
BiLSTM_best_loss	0.481	0.503	0.512	0.480	0.649
BiLSTM_best_accuracy	0.415	0.400	0.445	0.393	0.586
<b>BiLSTM_best_recall</b>	<b>0.485</b>	<b>0.522</b>	<b>0.559</b>	<b>0.509</b>	<b>0.653</b>

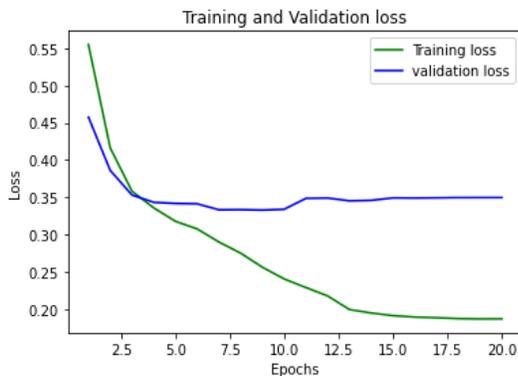

Fig. 3. BiLSTM Training and Validation Loss.

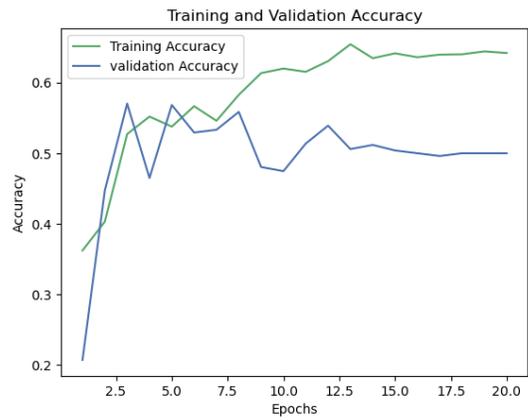

Fig. 4. BiLSTM Training and Validation Accuracy.

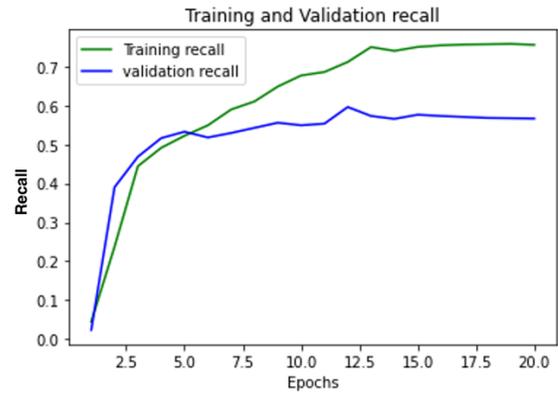

Fig. 5. BiLSTM Training and Validation Recall.

2) *Bi-GRU deep learning model*: The same work was done using Bi-GRU model with the parameters shown Table VII and the results of best checkpoints were compared in Table VIII.

As shown in the comparison, the best recall checkpoint achieved the best prediction results compared to other checkpoints with 0.498, 0.599, 0.503, 0.664 for Jaccard accuracy, precision, macro & micro F1 score, respectively. Fig. 6, 7, and 8 show the relationship between training and validation for loss, accuracy, and recall at each epoch.

TABLE VII. BI-GRU MODEL PARAMETERS

Parameter	Value
Cell type	GRU
Number of cells	2
bidirectional	True
Cell units	256
Max timesteps	64
Batch size	128
Embedding dimensions	300
Learning Rate (LR)	3e-4
No. of epochs	20
Number of classes	11

TABLE VIII. BEST RESULTS OF BI-GRU MODEL

Best Metrics	Evaluation Metrics				
	Jaccard Score	Precision	Recall	F1 Score	
				Macro	Micro
BiGRU_best_precision	0.267	0.248	0.269	0.223	0.422
BiGRU_best_loss	0.498	0.552	<b>0.545</b>	0.500	<b>0.664</b>
BiGRU_best_accuracy	0.431	0.395	0.475	0.426	0.602
<b>BiGRU_best_recall</b>	<b>0.498</b>	<b>0.599</b>	0.543	<b>0.503</b>	<b>0.664</b>

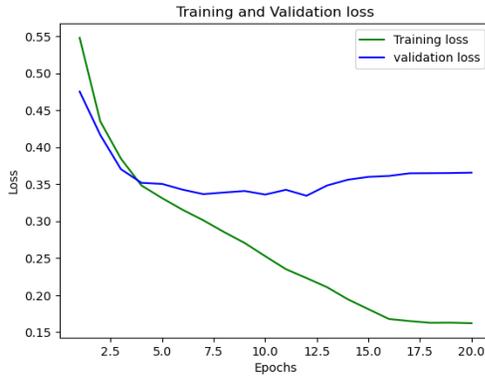

Fig. 6. Bi-GRU Training and Validation Loss.

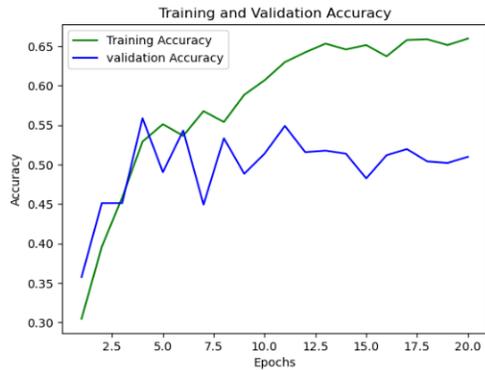

Fig. 7. Bi-GRU Training and Validation Accuracy.

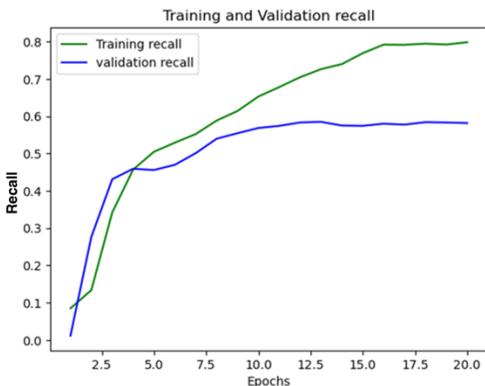

Fig. 8. Bi-GRU Training and Validation Recall.

3) *MARBERT deep learning model*: A pretrained language model “MARBERT” based on BERT was utilized. In [13] authors mentioned that the MARBERT transformer outperforms the recently used ARABERT transformer presented by [4] through their experiments using different datasets. They did not use SemEval-2018 E-c dataset for the emotion classification task. A comparison between the results of both ARABERT and MARBERT against the SemEval-2018-Ar-Ec dataset has been made and the results showed that MARBERT outperforms ARABERT by 4%, 2.7%, 4.2%, and 3.5% regarding Jaccard accuracy, recall, F1 macro, and F1 micro score respectively as shown in Table IX.

TABLE IX. COMPARISON BETWEEN MARBERT AND ARABERT AGAINST SEMEVAL-2018-EC-AR DATASET

Model	Evaluation Metrics				
	Jaccard Score	Precision	Recall	F1 Score	
				Macro	Micro
ARABERT	0.489	<b>0.545</b>	0.532	0.487	0.657
MARBERT	<b>0.529</b>	0.542	<b>0.559</b>	<b>0.529</b>	<b>0.692</b>

In fact, the outperformance is because MARBERT was pretrained on different tasks one of them is related to emotion recognition and it was pretrained on both MSA and Arabic dialects unlike ARABERT as mentioned in Section III.

4) *Ensemble model*: Because each model in the proposed ensemble model has its contextual understanding mechanism, there is a margin difference between the results of MARBERT transformer and the other two models. As a result, a weighted sum equation has been used to ensemble the results of all models i.e., predictions of each model are multiplied by weights according to the percentage of their understanding of the context as shown in (15). If the prediction of a single label is greater than or equal to a certain threshold, the predicted label will equal to “one” or the emotion is found otherwise the emotion is not found, and the predicted label will equal to “zero”. To determine the best threshold and weights a manual grid search was made and gave the best threshold equals 0.34 and the best weights are  $w_1 = 0.72$ ,  $w_2 = 0.1$ , and  $w_3 = 0.18$  for MARBERT, BiLSTM, and BiGRU respectively. The idea of manual grid search is that different weight values ranging from 0.01 to 1 are tested with different thresholds ranging from 0.01 to 1 to find the best result for the proposed ensemble model.

$$P^{total} = (p_1 * w_1 + p_2 * w_2 + p_3 * w_3) \quad (15)$$

where  $p_1$ ,  $p_2$ , and  $p_3$  are the predictions of MARBERT transformer, BiLSTM, and BiGRU respectively.  $P^{total}$  is the total result of the ensemble model after combining the results of the three models.

A comparison between the results of the closely related studies and the proposed ensemble model is shown in table X where it was found that the ensemble model has achieved the best results regarding Jaccard accuracy, and F1 macro score

with an improvement ranging from 0.2% to 4.2% in accuracy, and from 5.3% to 23.3% in macro F1 score.

Table XI presents a comparison between the proposed ensemble model and each of the separate models that constitute the ensemble model. The table indicates that the best

performance is for the MARBERT transformer model, while the ensemble approach combining all models still has a better effect on the overall performance compared to other models individually with an accuracy of 0.540 and a macro F1 score of 0.701.

## V. CONCLUSION AND FUTURE WORK

ED can help communities in different domains, especially for social networks which have many signed users sharing their feelings and thoughts. Understanding the context of user-generated Arabic text still has a lot of challenges because of the language complexity, the limited Arabic resources, and different available Arabic dialects. Recent research studies have used pre-trained language models to overcome the issue of limited resources. In this paper, a pretrained language model (MARBERT) is fine-tuned using the SemEval-2018-task1-ArEc dataset that was published in SemEval-2018-task1: Affect in Tweets to perform a multilabel classification task. Three state-of-the-art models (BiLSTM, BiGRU, and MARBERT) were ensembled and compared to recently published studies. The experimental results showed that the proposed ensemble model outperforms the best existing related work with an improvement ranging from 0.2% to 4.2% in accuracy, and from 5.3% to 23.3% in macro F1 score.

Also, it was noticed that the SemEval-2018 dataset we are using in this paper is not balanced. Three classes (anticipation, surprise, and trust) have low instances in the dataset making the dataset imbalanced. So, different data augmentation and oversampling techniques can be applied to solve this issue in future studies.

# Chatbots for the Detection of Covid-19: A Systematic Review of the Literature

Antony Albites-Tapia<sup>1</sup>, Javier Gamboa-Cruzado<sup>2</sup>, Junior Almeyda-Ortiz<sup>3</sup>, Alberto Moreno Lázaro<sup>4</sup>  
Facultad de Ingeniería Industrial y de Sistemas, Universidad Nacional Federico Villarreal, Lima, Perú<sup>1,2,3</sup>  
Facultad de Medicina Humana, Universidad Privada Antenor Orrego, Trujillo, Perú<sup>4</sup>

**Abstract**—At present, the development of chatbots is one of the key activities for the diagnosis of Covid-19. The aim is to understand how these chatbots operate in the health area to make a respective diagnosis. The purpose of the research is to determine the state of the art on the use of chatbots and its impact on Covid-19 diagnosis during the last 2 years. The data sources that have been consulted are IEEE Xplore, Taylor & Francis Online, ProQuest, World Wide Science, Science Direct, Microsoft Academic, Google Scholar, ACM Digital Library, Wiley Online Library, and ETHzurich. The search strategy identified 5701 papers, of which 101 papers were selected through 8 selection criteria and 7 quality assessments. This review presents discussions regarding the methodologies used for chatbot development, i.e., what are the purposes and impact of using chatbots for Covid-19 diagnosis. In addition, this presents the results of how important the development and implementation of chatbots are in the area of health in the face of this pandemic.

**Keywords**—Covid-19 diagnosis; chatbot; NLP; digital assistants; health; systematic review

## I. INTRODUCTION

The world is facing an unprecedented health crisis caused by the new coronavirus disease (Covid-19). Therefore, people are forced to go to health centers to rule out the disease, causing long queues. As a global pandemic, COVID-19 represents a problem in the care of patients in hospitals [107]. For this reason, many people initially turn to various sources on the Internet for self-diagnosis of their health before doing so with trained medical staff. The risk units of the Emergency Operations Center (EOC) attend online requests related to Covid-19 [108]. Direct telephone lines established by governments have collapsed due to the large volume of calls, generating long waiting times [109]. These health-related problematic situations are being solved with the help of Chatbots [110]. Thus, virtual agent applications are the latest inventions of the digital age. These applications are well known as conversational agents that run through programming or a type of artificial intelligence (AI) interaction between users and machines, with the intervention of natural language processing (NLP). Chatbots have been referred to as potentially the most promising and advanced form of human-machine interactions. It is therefore clear that chatbots play an important role in the process of Covid-19 diagnosis. These virtual agents (chatbots) are becoming involved in major global sectors such as health, banking, education, and agriculture. This paper focuses on the diagnosis of Covid-19 using chatbots. Likewise, the research is unique because a detailed review of the

methodologies used for the development of chatbots has been carried out, what are the purposes and the impact of using these virtual agents, and 101 high-impact articles have also been rigorously reviewed. Also, because the research questions are original and have not been raised by any other researcher. The document is organized as follows. The present research is to close the gap concerning the lack of knowledge of the progress of research related to Covid-19 detection using chatbots. Section II describes the background this study and previous related research. Section III reviews the methodology applied. Section IV presents a systematic review of the results. Finally, Section V presents some concluding remarks and areas of future research.

## II. BACKGROUND AND RELATED STUDIES

This section presents the background regarding the use of chatbots and discusses previous studies conducting systematic reviews of similar research.

### A. Chatbots

A chatbot is a computer program through which it is possible to have a conversation, ask the user for information, or perform an action. This technology has helped to streamline processes in different areas, giving a faster response to users.

Several studies [1], [50] have emphasized the results provided by chatbots and have agreed on the rapid response they provide to users.

Based on previous studies, we identified the characteristics that chatbots provide, as well as their different areas of application, including their use in Covid-19 diagnosis and its impact. In this review, we thoroughly search and explore their application in the health field and more specifically, their role in the Covid-19 pandemic.

### B. Previous Systematic Reviews

In recent months, reviews have been found on the use of AI for the diagnosis of Covid-19. A study was conducted on the use of AI for innovation in pandemic solutions [104]. Another study mapped the use of new technologies such as chatbots by health care organizations to improve mental health [103].

The authors investigated the use of various AI technologies for use in different solutions and the impacts they generate in times of pandemic. This shows the importance of AI in tackling the pandemic but does not mention much about the role of chatbots in diagnosing Covid-19. This review is then extended to the use of chatbots for the diagnosis of Covid-19 during this pandemic.

### III. METHODOLOGY OF REVIEW

The review method used in this study was developed by considering the guidelines of B. Kitchenham [102] for conducting a systematic literature review (SLR). The review method elaborates the research questions, data sources, search procedure, exclusion criteria, quality assessment, data extraction, and data synthesis.

#### A. Research Problems

Table I shows the research objectives of this study through the correspondence between each research question and each motivation.

TABLE I. RESEARCH OBJECTIVES

Research Questions	Motivation
RQ1: What methodologies are used for the development of chatbots diagnosing Covid-19?	Identify the methodologies to be used for the development of a chatbot.
RQ2: In what areas are chatbots mostly being applied?	Identify the areas where chatbots are being used.
Q3: What are the purposes of using a chatbot for Covid-19 diagnosis?	Identify the purposes of using chatbots for diagnosing Covid-19.
Q4: What are the most important tools for developing a chatbot?	Identify the most important tools for developing a chatbot.
Q5: What are the most widely used programming languages in chatbot development?	Identify the most widely used programming languages in chatbot development.

#### B. Search Sources and Search Strategy

The source of the referenced data includes prominent digital libraries such as Taylor & Francis Online, ProQuest, World Wide Science, Science Direct, IEEE Xplore, Microsoft Academic, Google Scholar, ACM Digital Library, Wiley Online Library, and ETHzurich. The search strategy includes searches by keywords relevant to our study. The search has been focused on research questions and commonly used terms corresponding to machine learning and estimations of the software effort.

The search procedure has been carried out using search threads written as (chatbot) AND (covid or covid-19 or covid-19 diagnosis) where the set of Ai represents the keywords related to the automatic learning methods, i.e., Ai chatbot} and Bi represents the keywords related to the dependent variables, i.e., Bi {covid, covid-19, covid-19 diagnosis}. The results of the search procedure have been reduced to 5701 items that are discussed in more details below (see Table II).

#### C. Selection Criteria

Exclusion criteria have been defined to accurately assess the quality of the available literature. Papers have been reviewed and discussed by the authors for the exclusion decision with the industry advisor. The papers were checked against the given criteria:

EC1: The papers do not mention a methodology, model, or method.

EC2: The papers are not less than 2 years old.

EC3: The papers are not written in English.

EC4: They are scientific papers.

EC5: Titles and keywords are inappropriate.

EC6: The papers are not related to the topic.

EC7: It contains few citations.

EC8: The summary of papers is irrelevant.

The result of this stage shows 101 items.

#### D. Studio Selection

At the outset, 5701 results were obtained. When applying criteria 1 and 2, 2914 items were excluded. Likewise, when applying criteria 3 and 4, 1369 papers were excluded. Furthermore, when applying criteria 5 and 6, 565 papers were excluded. Finally, when applying criteria 7 and 8, 752 papers were excluded. This results in a total of 101 items (see Fig. 1).

TABLE II. SEARCH SOURCES AND SEARCH STRATEGIES

Source	Search equations
IEEE Xplore	((("Full Text & Metadata": chatbot) AND "Full Text & Metadata": covid-19 or covid-19 diagnosis) AND "Full Text & Metadata": method or methodology or model)
Taylor & Francis Online	[All: chatbot] AND [All: covid-19 OR covid-19 diagnosis] AND [All: method OR methodology OR model]
ProQuest	(chatbot) AND (covid-19 diagnosis OR covid-19 diagnosis) AND (model OR method OR methodology)
World Wide Science	chatbot and (covid-19 OR covid-19 diagnosis) and (model or Methodology or method)
Science Direct	chatbot and (covid-19 OR covid-19 diagnosis) AND (model OR method OR methodology)
Microsoft Academic	(chatbot) AND (covid-19 OR covid-19 diagnosis) AND (model OR method OR methodology)
Google Scholar	chatbot AND (covid-19 OR covid-19 diagnosis) AND (model OR method OR methodology)
ACM Digital Library	(chatbot) AND (covid-19 OR covid-19 diagnosis) AND (model OR method OR methodology)
Wiley Online Library	(chatbot) AND (covid-19 OR covid-19 diagnosis) AND (model OR method OR methodology)
ETHzurich	(chatbot) AND (covid-19 OR covid-19 diagnosis) AND (model OR method OR methodology)

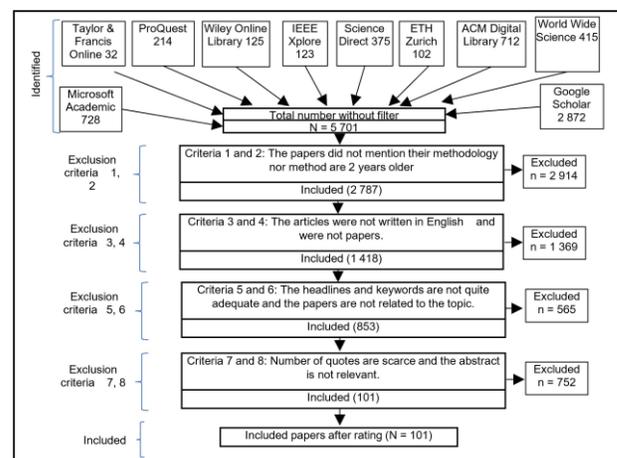

Fig. 1. Study Selection.

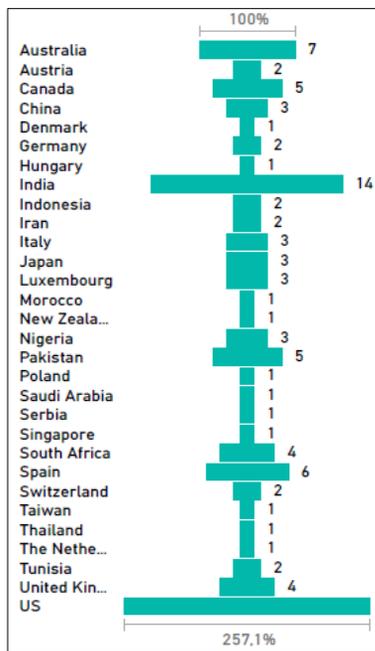

Fig. 5. Numbers of Papers by Country of Publication.

**B. Answers to Research Questions**

**RQ1:** What methodologies are being used for development?

The systematic review of the literature has resulted in 101 relevant papers. Each paper contains its own methodology for the development of chatbots used to diagnose Covid-19. We detected four different types of methodologies in the development of such chatbots. To provide a clearer view of our response, Table III was developed to answer the question more clearly.

The most widely used methodology for the development of chatbots is “sentence order prediction,” which is used to predict the sentences a user may write and use the information to prepare a more effective response. The second methodology is “mask language modelling,” which is used to predict the blank spaces in texts, which is necessary for the treatment of users. “Next sentence prediction” is being used because of the need to have a good user experience by speeding up the responses of the chatbots. The last methodology found is “learning based,” which is a method based on continuous learning, where a chatbot learns based on constant conversations with the user.

TABLE III. METHODOLOGIES APPLIED FOR THE DEVELOPMENT OF CHATBOTS

Applied methodologies	Papers	Qty. (%)
Sentence Order Prediction	[2] [3] [7] [8] [3] [17] [21] [27] [39] [42] [48] [58] [65] [68] [71] [81] [86] [94] [99]	19 (34.5)
Mask Language Modelling	[1] [4] [8] [3] [6] [14] [20] [24] [45] [52] [62] [89] [90] [100]	14 (25.5)
Next Sentence Prediction	[13] [4] [8] [9] [14] [19] [24] [37] [45] [59] [68] [76] [91] [99]	14 (25.5)
Learning Based	[3] [7] [31] [61] [69] [76] [80] [89]	8 (14.5)

The use of different methodologies provides excellent results, and depending on the chatbots to be developed, several methodologies can even be implemented together [104].

**RQ2:** In what areas are chatbots being mostly applied?

A literature review demonstrated that there were five most important areas where chatbots have been applied. Table IV shows the areas where chatbots are being used.

TABLE IV. AREAS WHERE CHATBOTS ARE APPLIED

Application Areas	Papers	Qty. (%)
Health	[1] [2] [3] [4] [5] [6] [7] [8] [9] [10] [11] [12] [13] [14] [15] [17] [18] [19] [20] [22] [23] [24] [25] [26] [27] [28] [29] [30] [31] [32] [33] [35] [36] [38] [39] [40] [41] [42] [43] [44] [45] [46] [47] [48] [49] [50] [51] [53] [54] [55] [56] [57] [58] [61] [62] [63] [64] [65] [66] [67] [68] [69] [70] [71] [72] [73] [74] [75] [76] [77] [78] [79] [81] [82] [83] [84] [85] [86] [87] [88] [90] [91] [92] [93] [94] [95] [96] [97] [98] [99] [100] [101]	93 (57.7)
Education	[1] [5] [7] [9] [12] [16] [19] [22] [26] [27] [30] [32] [34] [36] [37] [40] [42] [46] [51] [53] [54] [55] [57] [58] [77] [79] [81] [82] [84] [85] [89] [90] [98] [99]	34 (21.5)
Retail	[10] [12] [16] [33] [39] [43] [55] [60] [65] [59] [86] [89] [90] [97]	14 (8.8)
Banks	[12] [16] [27] [39] [55] [59] [72] [73] [80] [86] [90]	11 (8)
Tourism	[4] [22] [43] [59] [60] [65] [69] [77] [94]	9 (4)

One of the areas where chatbots are most applied is the health sector owing to its importance in human health and the impact it generates during the present pandemic. Another area where chatbots are applied is in the education sector where, through an agent that is able to respond to user needs 24 h a day, it is beneficial for different studies. In the banking and retail sectors, its application is increasing owing to the flexibility of chatbots to meet different business needs. Finally, in the tourism sector, the need to count on an agent that solves the frequent questions of the users and that is available at all times has led to the development of chatbots.

According to Alaa Ali Abd-Alrazaq [103], health is one of the areas where chatbots are most frequently applied, and the effectiveness and safety of chatbots in improving mental health has been measured.

**RQ3 -** What are the purposes of using chatbots for the diagnosis of covid-19?

As a result of a systematic review of the literature, we found three main purposes for using chatbots for the diagnosis of Covid-19. Table V shows the purposes of using chatbots for a Covid-19 diagnosis.

The most important purpose of using chatbots for Covid-19 is a high availability, in other words, to have a service that is always available to all users. User experience is one of the main reasons why we use chatbot for a Covid-19 diagnosis, which allows for a much faster, smoother, and better results. Agility is another extremely relevant reason because having a

space where one can obtain much more agile and personalized answers generates a positive impact for users.

According to Adam S. Miner [104], in line with our results in which we determined that a high availability is the main purpose for using a chatbot, the possibility to offer recommendations and diagnosis at any time has been observed.

Q4 - What are the most important tools for developing a chatbot?

When reviewing the relevant literature, it was observed that there are five important tools for the development of chatbots, which are the most widely used in the scientific field of AI. Table VI shows the most important tools for chatbot development.

The first and most widely used tool for developing a chatbot is DialogFlow, which is capable of understanding natural language and provides the infrastructure for creating conversations and building dialogue to interact with the user in a fluid manner. The second tool is Watson, which allows you to create, train, and implement conversational interactions in any application, device, or channel. Another tool used is Language Understanding, which is used for automatic learning that allows users to understand natural language and extract its meaning and understand what aspects are required. The latest tool found is AWS, in which previously trained AWS AI services provide ready-to-use intelligence in applications and workflows. AI services are easily integrated with applications to address common use cases, such as creating custom recommendations, upgrading a call center, improving security, and increasing customer involvement.

TABLE V. PURPOSES FOR USING A CHATBOT FOR COVID-19 DIAGNOSIS

Purpose of using chatbot	Papers	Qty. (%)
Availability	[1] [2] [8] [9] [10] [12] [16] [22] [25] [26] [27] [37] [39] [42] [44] [46] [49] [51] [52] [53] [55] [57] [65] [69] [70] [72] [73] [74] [77] [81] [91] [92] [97] [98]	34 (68)
User experience	[2] [4] [28] [39] [43] [45] [55] [71] [97]	9 (18)
Agility	[40] [54] [65] [79] [84] [85] [89]	7 (14)

TABLE VI. MOST IMPORTANT TOOLS FOR CHATBOT DEVELOPMENT

Tools for chatbot development	Papers	Qty. (%)
Amazon Web Services (AWS)	[9] [24] [35] [36] [37] [43] [46] [67] [69] [73] [75]	11 (52.38)
Language Understanding	[8] [20] [21] [25] [51] [74]	6 (28.57)
Watson	[34] [98]	2 (9.52)
Dialog Flow	[51] [100]	2 (9.52)

According to Pavel Smutny [105], the most important tools for the development of chatbots are DialogFlow together with Watson and Language Understanding, which are capable of understanding natural language for establishing fluid dialogues with users.

Q5 - What are the most widely used languages in the development of a chatbot?

Through the results of the SLR, we found the four most widely used programming languages in the development of chatbots, as listed in Table VII.

TABLE VII. MOST WIDELY USED PROGRAMMING LANGUAGES IN CHATBOT DEVELOPMENT

Most widely used programming languages	Papers	Qty. (%)
Python	[5] [6] [7] [8] [15] [20] [23] [28] [29] [48] [52] [58] [71] [76] [95]	15 (68.18)
Java	[22] [28] [71] [77] [99]	5 (22.73)
JavaScript	[28] [71]	2 (9.09)
PHP		0 (0)

The most widely used programming language in the development of chatbots is Python because it is one of the preferred languages used on the server side to create a back-end; it also has many interesting features, among them, an interpreter and a high-level object-oriented programming language. The second most widely used programming language found in our research is JavaScript, which is ideal for handling high user traffic applications and events where hundreds of thousands of interactions are to be sent every second. Java is another programming language that is widely used to create applications and processes in a great number of devices and allows executing the same program in different operating systems. The last programming language is PHP, which is used to develop web applications, favoring the connection between the servers and the user interface. This programming language is widely used because it is open source, which means that anyone can make changes to its structure.

According to Eleni Adamopoulou [106], these programming languages are the most recognized in the development of chatbots because they are open source and effective for high user traffic applications. In addition, these languages support all functionalities and guarantee quick and easy access to information and application services for users.

## V. CONCLUSION AND FUTURE RESEARCH

This study has managed to identify the impacts and purposes of Covid-19 diagnosis through chatbots, the areas where chatbots are most frequently applied, the methods used for their development, and the tools and languages needed for their implementation. The 101 papers reviewed for this analysis were chosen based on exclusion criteria and a quality evaluation. The results obtained indicate that the most widely used methodology for the development of chatbots is next

sentence prediction. The area where chatbots are mostly used is in retail owing to the high availability they offer to users. The most important purpose for using chatbots in the diagnosis of covid-19 is the agility of the response it provides to patients. The biggest impact generated is the satisfaction of the patients is by obtaining a fast response in their diagnoses. The most important tool for the development of a chatbot was found to be Watson Assistant owing to its easy integration with different communication channels. In addition, the most widely used language for the development of chatbots is Python owing to its easy integration and implementation. This review has certain limitations owing to the novelty of the topic; however, thanks to the motivation of the researchers regarding the topic because it is at a global level, a large number of papers were found to achieve a quality SLR.

The systematic review of the literature identified a new trend in the diagnosis of Covid-19, not only in the use of chatbot, but also on other technologies related to artificial intelligence, such as automatic and deep learning, which can contribute more efficiently to the diagnosis of Covid-19.

**Abstract**—Wireless Sensor Networks (WSNs) encounter a number of issues in terms of performance. In WSN, the majority of the energy is utilized to transfer data from sensor nodes to a central station or hub (BS). There have therefore been many different types of routing protocols devised to help with the distribution of data in WSNs. Large-scale networks have been designed with minimal power consumption and multipurpose processing due to recent improvements in wireless communication and networking technology. For the time being, sensor energy remains a restricted resource for constructing routing protocols between sensor nodes and the base station, despite advances in energy collection technologies. For wireless sensor networks with far-flung cluster heads and base stations, direct transmission is a critical component since it impacts the network's efficiency in terms of power consumption and lifespan. A new approach for identifying an effective multi-hop routing between a source (CH) and a destination (BS) is investigated in this study in order to decrease power consumption and hence increase the life of a network (OMPFM). The suggested technique utilizes a genetic algorithm and a novel fitness metric to discover the best route. For selecting CHs and enhancing the speed and quality of created chromosomes, they suggest two pre-processes, which they call CH-selection and Chromosome Quality Improvement (CHI). The proposed method is evaluated and compared to others of its kind using MATLAB simulator. It has been found that using the proposed method outperforms other methods such as LEACH, GCA, EAERP, GAECH, and HiTSeC in terms of the first node die metric by 35%, 34%, 26%, 19% and 50%, respectively. It also outperforms other methods by 100% in terms of the last node die metric.

**Keywords**—Cluster head; energy efficient; multi-hop path; enhanced genetic algorithm; wireless sensor network (WSN)

## I. INTRODUCTION

The development of micro electromechanical system technology has made compact, low-cost nodes practical in networks. The nodes are responsible for sensing, processing, and communicating wirelessly. A lot of the nodes in wireless sensor networks (WSNs) run on batteries and are connected to a base station (BS). It acts as a middleman between the end user and the other nodes[1] like figure1 represents the WSN's basic architecture. In any of the supervised areas, WSNs ensure continuous monitoring (CM) or engage in event detection. WSNs need non-rechargeable batteries to power the sensor nodes, therefore modelling an energy-efficient routing

algorithm is required. We need an energy-efficient routing strategy in places where battery recharging and replacement aren't an option. Energy is a big worry and as a result, there are several heuristics, however they all take longer to come into play. When it comes to WSN energy efficiency, clustering stands out as a viable option[2].

This probability-based clustering produces CHs, which can only communicate with other nodes in their immediate vicinity. So, multichip (MH) routing helps the network to route traffic beyond the communication range, which is limited by the energy factor. Multichip routing as an alternative, delay is reduced while energy consumption is increased, therefore the routing is more efficient. As a result, the researchers are working to create a better routing protocol that uses less energy[3]. MH transmission and direct transmission are the two most common conventional routing options (DT). Nodes in DT connect with the BS directly, but intermediate nodes in MH communicate with each other via subdivided communication distances, resulting in little energy and delay. Short-hop and long-hop routing are terms used to describe MH transmissions based on the number of hops. There are flat and hierarchical algorithm routing protocols in the literature that work to reduce the energy used by sensor nodes. This can be explained by comparing flat and hierarchical routing: in flat routing the communication takes place between nodes within the same communication range, while in hierarchical routing the communication takes place between a node and its nearest clustering hierarchy. Although hierarchical routing conserves energy, it places a heavy burden on the cluster's central hubs. To communicate outside of the regular radio range, all sensor nodes clamp themselves to a CH. This has an impact on QoS and performance[4],[33].

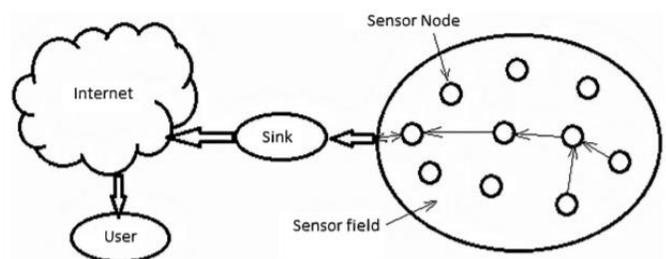

Fig. 1. The WSN's Basic Architecture.

A WSN is a network of micro-sensor-equipped nodes with a large number of spatially scattered communication infrastructures. These tiny sensors collect and interpret data from a specified area by sensing it and working together. A central station receives the data, which is subsequently processed. The relevance of WSNs in IoT-based goods and services is rising, but they have been around for a long. Things like health care, environmental monitoring, and smart cities will all need them in the future, due to the Internet of Things. [2, 3,5] It's easy to see that sensor networks have several orders of magnitude more nodes than ad hoc networks. Despite their extensive dispersion, sensor nodes have limited computing, memory, and power capabilities. The development of energy-efficient routing algorithms is a major problem in WSNs. It's impossible to delete or change sensor nodes after they've been set up in the network. Nodes' power usage and management have a strong impact on network performance. As the most energy-efficient systems in WSNs in recent years, hierarchical routing protocols have been frequently used [6]. Cluster heads operate as a go-between for the member nodes and the base station itself rather than having individual base stations for each member node [7]. Among the cluster's nodes, the CH utilises the least amount of network resources overall when gathering data, aggregating it, and transmitting it to the (BS).

It is the first hierarchically built protocol to use clustering for information routing (LEACH) [8]. When data are transported straight from the CHs to the BS, it is known as a single-hop routing protocol (SHR). It does, however, have significant drawbacks. In the first place, CHs positioned far from the BS lose more energy than those located nearby. As a result, populations in the furthest reaches of the galaxy are at greater risk of dying young. Large-scale networks can't employ LEACH's direct transmission method since it disrupts the distribution's load balancing and reduces the network's overall operating lifespan. It also depends on the relevance of the detected information at each point in time how often data is transferred between nodes. Due to the difference in activity, more active nodes die sooner than less active ones, causing an energy imbalance in the network[9].

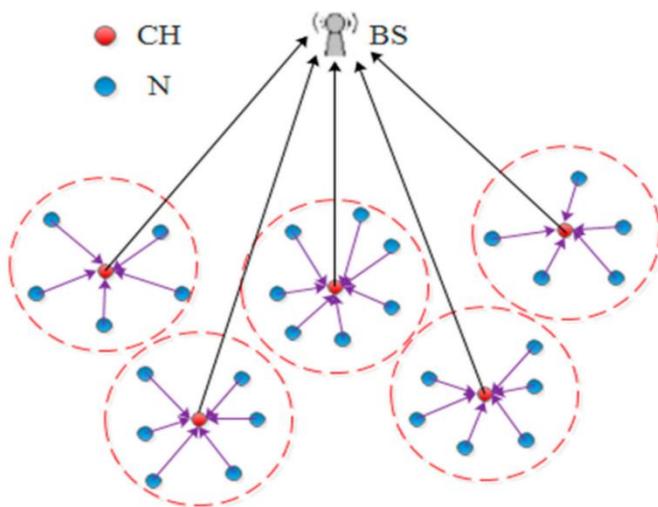

Fig. 2. The Wireless Sensor Network Architecture uses the Low Energy Adaptive Clustering Hierarchy (LEACH) Protocol.

Transmitting sensing data to the BS for analysis is critical in WSNs since this data helps the network meet its objectives. Making judgments that are in keeping with the network's aims is made easier with this strategy. With direct transmission, the LEACH protocol drains CHs quickly, especially if the distance between two CHs delivering data to BS is large. The additional energy used to transport data in a CH will have a negative influence on the network's overall lifetime factor performance. By determining the optimum route from a root CH to the BS, this research presents an improved way for increasing network lifetimes while using less power than the direct transmission process. The best transmission path is found using a genetic algorithm (GA). The proposed approach maximises the network's stability period during which all nodes are still operational. It also extends the network's lifespan in the event that all nodes fail. Maximizing the fitness function and improving the selection of cluster heads are two ways to accomplish this. The following is the paper's structure: It begins with a brief history of GA, followed by a discussion of similar works in Section 2, a detailed presentation of the proposed approach in Section 3, a quantitative assessment of the proposed method in addition to previous protocols in section 4, and a conclusion in Section 5.

## II. RELATED WORK

This section describes the LEACH and GA methods. Before discussing into GA optimization, let's take a look at the LEACH approach.

Wireless sensor networks have lately seen a slew of hierarchical routing methods [8,10,11–19]. To make the network last longer, several of them used multi-hop inter-cluster connection. WSN protocol LEACH [8,11] includes two phases: configuration and steady state operation. As a node is being set up, the distributed process employs a probabilistic method to assess whether or not it should be designated as a CH. Non-CH node will join the cluster based on the strength of the CH signal. The CH delivers the TDMA schedule to all cluster nodes at once to guarantee that it is received by all of them. Continuously sending one hop of data to the BS during the steady state phase is required. LEACH uses a CDMA coding to minimise inter-cluster interference. To maintain a fair distribution of burdens, the round concludes with a random rotation of CH. However, there are a number of disadvantages to using LEACH. During the CH election process, residual authority or position is not taken into consideration. Due to greater energy consumption and the death of remote CHs induced by direct data transfer from the sink node to the CH, this single-hop routing approach is unsuitable for large networks. With multi-hop communication between CHs and the BS, energy conservation and scaling were demonstrated to be higher [12, 20]. So, Zhang et al. [13] created the LEACH-WM WSN protocol, an intra-cluster multiple hop routing mechanism. In addition to the setup phase, LEACH contains an optimization phase. The BS receives data from the CH through a weight relay node during the final stage (WR). Because of its remaining energy and proximity to the backend server, this relay node is selected as a cluster member. Clusters located far away from the BS use their energy more quickly than clusters near to it, resulting in an uneven distribution of energy across the network.

Alnawaf et al. [14] employed a multi-hop approach to improve LEACH (MHT). CHs may be divided into two categories according to how far apart they are: internal and exterior. The CHs in the first group send data straight to the BS, whereas the CHs in the second group create a custom routing table to control data flow. CHs were distributed over two tiers while utilising the Improved MHT-LEACH protocol (IMHT). You can tell if you look at the distance between one CH level and the next by looking at how far one CH level is from BS. Despite the fact that these methods were developed to be as energy-efficient as possible, the majority of them solely consider the distance element when determining routes. Because data is always routed through the nodes nearest to the BS, those nodes use up their energy faster than the others. Defended routes cannot be changed for the network's whole operational life, affecting the network's ability to maintain a balanced load. Routing methods for WSNs will enhance load balancing by taking energy and distance into account when selecting the next hop. One way to increase the network's lifespan is to provide efficient data to the base station, as described by Biradar[15] et al. Each cluster has two means to connect with the others on the network, split into several clusters. Instead of using a backend server (BS), you may use a central hub (CH) to collect data from all cluster nodes and deliver it directly to the backend server instead (CHs). Second, the CH must use an inter-cluster channel to interact with both the BS and the CS, because it is located[16,17] in a remote location. When this occurs, it uses other CHs with a low hop count to deliver data to the BS. The optimal paths to the BS may be found using a multi-hop LEACH (MH-LEACH) protocol, according to Neto et al. [17]. Depending on the intensity of the received signal, each CH begins by sending an advertising message to create its routing table. However, the CH inspects the routes beforehand to make sure they won't cause a loop or send the incorrect way for individuals to go.

Wireless Sensor Networks (WSNs) may make use of EAACA, an ant colony algorithm that is energy-conscious and utilises the ACO to determine the most efficient route to the storage system's back end (sink node). When deciding on the next node, three factors are taken into account: the distance to BS, the remaining energy of the previous node, and the path's average power. Backward ants are used in the method to produce response packets in response to the legal routes built by forward ants. Using a lifespan aware routing method for wireless sensor networks, Mohajerani et al. developed a network topology where energy dissipation is uniformly spread among nodes (LTAWSN). When installing an energy-saving pheromone operator, it makes use of a phoney ant colony. When calculating the next step in the journey, a location function takes the distance to the destination into account, as well as nodes that are closer to the goal. Because they consume all of the network's energy, ACO's fat routing protocols require more energy than previous ACO versions and can quickly deplete the network's energy supply. In addition, they use two-step transmission systems, moving forward to investigate the route and returning to leave pheromones behind. As a result of increased transmission costs, nodes consume more energy.

Using the LEACH-C (LEACH-C) methodology was suggested in [14,20]. Centralized protocols have all choices

made by a single node and then relayed to all sensor nodes. Some of their duties include electing the network's chief executives (CH) and supervising clusters. A well-balanced distribution of nodes inside clusters is one of the goals of the LEACH-C protocol. Lifespan is the goal of the LEACH-Deterministic Cluster Head Selection (LEACH-DCHS) technique [15,34]. As a result, two changes have been recommended. To begin, the threshold equation must be adjusted to account for the residual energy in the sensor nodes when selecting the network's CHs. As part of the second update, new network lifetime standards will be established. To better understand the Threshold-LEACH (T-LEACH) approach, [16,21] provided an overview of the basic theory. According to this protocol, the network's CHs are selected based on their energy thresholds. The CHs can only be utilised in a certain number of rounds at a time. As long as the CH's residual energy is less than the threshold energy, this situation will persist. That would necessitate the appointment of a new House Speaker. For a one-hop connection, a technique known as Unequal Clustering LEACH has been suggested by [17,22]. (U-LEACH). One hop delivers all of the CH's data directly to the BS. The old method utilises more energy in CHs placed distant from the BS because of their location. As we travel away from the BS, the U-LEACH predicts that cluster sizes will become more unequal and then drop. There were imbalanced clusters in the original LEACH protocol, thus the LEACH-B protocol was developed to address that issue. For the purpose of choosing CHs and creating balanced clusters, this protocol takes into account not just a desired percentage of cluster members, but also the residual energy those members have left over once the election process is complete. The MHT-LEACH protocol was proposed in [11, 23] as a way of reducing network transmission distances. It divides all of the CHs into two groups of equal size. For starters, there's the internal level, which includes all the CHs that aren't too far from the BS. Also included in this level are any CHs that are located outside of a certain threshold distance from the base station (BS). A suitable CH from the internal level receives data from any external CH and routes it to the BS[24,35].

#### A. The Leach Protocol

The LEACH protocol's goal is to reduce the amount of power used by WSNs while increasing their efficiency [14,21,25,26]. To that end, a random factor has been used in a rotation strategy for CH selection. Each round of the LEACH procedure [14,20,27] has two stages, the first of which is the steady-state set-up. Along with the CHs selection, clusters are also established in the first stage. Random numbers between 0 and 1 are generated by nodes in each cluster to choose a CH [14,28]. In order to compare the generated numbers to, we use  $T(n)$ . As soon as the reference number is greater than the randomly generated number, the CH node becomes the active node for further calculations. Using Eq. (1), we can determine the value of the constant  $T(n)$ .

$$T(n) = \begin{cases} \frac{P}{1 - P * (\text{rmod} \frac{1}{P})} & : \text{if } n \in G \\ 0 & : \text{if } n \in G \end{cases} \quad (1)$$

To illustrate, consider the graph below, where G represents a group of nodes that have not yet become CHs in the

preceding 1/P rounds, and P represents the proportion of those nodes that have become CHs. All nodes in the cluster receive equal amounts of energy because of this. LEACH's power consumption is balanced across all nodes because the CH role is rotated, yet the protocol has significant drawbacks regardless of this benefit. The residual energy of a node, for example, is not taken into account by LEACH when choosing a CH. Equation (1) says that a node can become a CH at any time. All nodes have the same chance of becoming CHs after a certain number of rounds. Consequently, both high- and low-energy nodes are equally likely to become the CH. Another issue is the use of single-hop communications to transmit directly from a CH to a BS. This causes energy holes to form between CH and BS, making it impossible for isolated nodes to exchange data. When this is the case, network performance suffers as a result. As a result, an improvement to LEACH is proposed in this study to improve efficiency in the CH selection process and data transmission, as provided in the proposed mechanism, to address the issues raised above.

**B. Genetic Algorithm Optimization Technique**

GA is a solution-finding algorithm that mimics natural evolution by employing the same mechanisms as natural selection. GA is used to identify the best global solution to optimization and search problems. In GA, the most crucial techniques are selection [17,30], crossover and mutation. Starting with an initial sample of individuals, a random population is produced and each of those individuals is assessed according to their fitness level. Individuals with the best fitness values will be chosen from the initial population, and they will take part in the following generation [29,31]. An important part of GA is the objective function (fitness), which is used to assess the quality of individuals and pick the best contributors for future generations. By mixing the children of the parents, the crossover operator creates new ones, and these new ones will have a mix of qualities from both parents [18]. The new children are subjected to random swaps in the mutation operator, resulting in new solutions. When a certain condition is met, the algorithm comes to an end [8,19,25,26].

The crossover operation is demonstrated in Table 1. Pre-crossover chromosome presentation, followed by post-crossover chromosome presentation: that's how it works. The third position is designated as the crossing point. After that, a mutation operation depending on the mutation rate will be performed on one of the children, as detailed in the next section.

Given Table 2, when the mutation occurs at position 6, gene F in first part of table is not included in the old path (A D E F) and the new path is shown in the second part. The second offspring will be subjected to the same technique, and the fitness of the two new chromosomes will be determined. When the new offspring and their parents are compared to each other, a greedy selection is carried out to determine which has the highest fitness value. Chromosome fitness values are used in the selection process for future generations. Some are chosen for future generations based on the outcomes. In order to maintain a steady population size, chromosomes with lower fitness values will be picked for future generations rather than those with higher values. When the number of generations reaches a certain value, the process comes to a conclusion.

Using a suggested OMPFM, crossover and mutation algorithms have been tweaked to prevent the formation of erroneous routes by efficiently choosing the CHs that are participating in the GA while also ensuring that they are easily available in the network. By adopting binary representation to address the OMPFM's multi-hop route problem, the CH will never be duplicated along the way. Using GA and other evolutionary algorithms to maximise network longevity, we'll look at routing protocols that have been utilised to improve the LEACH protocol going forward.

**III. PROPOSED METHODOLOGY**

The GA technique is used by OMPFM (optimal multi-hop path finding methodology) to discover the shortest path between two network nodes: the source CH and the BS. Because of its simplicity, the GA is utilized in this study as an optimization strategy to find the optimal solution. The sections that follow include a lot more details on this technique. With the new approach, each chromosome identifies which CH source gave rise to BS. Chromosomes can vary in length depending on how many CHs are involved, but no more than 100 CHs should be used in a single cycle. The newly suggested approach uses binary representation to represent each gene on a chromosome as a CH in the route. Routing pathways include CHs with gene values of 1 by default. Otherwise, their gene expression levels are zero, as seen in the table below. The source CH is the CH with ID 1, and there are seven CHs in total, each with an ID from 1 to 7. As shown in Table 3, there is a direct link between the chromosomal in issue and the BS. Table 3 shows the IDs of the CHs in the first row, and the path's CHs are listed in the second row. To illustrate, let's get from CH1 to the BS via the following path.

TABLE III. THE SELECTED PATH

CH1	CH2	CH3	CH4	CH5	CH6	CH7
1	1	0	0	1	0	0

CH1 → CH2 → CH5 → BS

The proposed technique reduces energy consumption while increasing network lifespan by sending data from a source CH to a destination BS. A fitness function determines the optimum course of action. With the OMPFM protocol, you may send only the data you want from one CH to another. For example, it may identify which CHs have the most energy to follow a particular path and then utilize important attributes to narrow the pool of choices. It was shown that using two pre-processing techniques, the GA optimization strategy performed better than the fitness function's proposed parameters for determining the optimum direct path from a source CH to BS. Both examine the GA's chromosomal quality and the suggested fitness function, as stated in the next subsections.

#### A. Filter Pre-processing

In the GA's first generation, the quality of the chromosomes used will be taken into consideration in the second revision of the formula. Before GA operations begin, the best CHs will be picked based on their energy levels via a filtering pre-process. We'll start by calculating the global average CH energy. CHs with higher energy levels will be needed to help create the second generation when the first is finished. By starting with the best chromosomes, the GA will be more efficient since it will have better chromosomes to work with. Additionally, by reducing the chromosomal length, this change enhances the GA's speed. When four CHs have more energy than normal, they will take part in the GA, and the chromosome will only be three instead of six in length (save for the source CH). The following paragraphs go into detail on how energy affects chromosomal quality. Due to optimal route discovery being an important component, it is necessary in the proposed transmission technique to take into account how many CHs there are in transmission path. There will be less average energy spent to transport data from one CH to another as the number of CHs in the transmission channel increases Eq. (2) gives the average amount of transmission-related CHs energy utilized.

$$Avg_{CET} = (\sum_{i=1}^N E_{Tx}(i))/(N) \quad (2)$$

To convey data from one CH to another through the transmission channel, you need a certain amount of energy called  $E_{Tx}$ , whereas  $Avg_{CET}$  measures the average amount and  $N$  stands for the number CH involved.  $E_{Tx}$  can be calculated using the following formula [26].

$$E_{Tx} = E_{elec} * k + E_{amp} * k * d^m \quad (3)$$

Were  $n$  having a value of 2 in open space and a value of 4 in enclosed places where  $E_{elec}$  is the electronic energy and  $E_{amp}$  is the amplifier energy.

The same approach is used to determine the average amount of CHs consumed during the receiving process, which may be summarised as follows:

$$Avg_{CER} = (\sum_{i=1}^N E_{Rx}(i))/(N) \quad (4)$$

$Avg_{CER}$  is equal to the average energy necessary to receive data when  $N$  CHs are present in the transmission channel, where  $E_{Rx}$  is the average energy required to receive data from each CH. The energy model is used to determine  $E_{Rx}$  [26]:

$$E_{Rx} = E_{elec} * k \quad (5)$$

As a result of the calculations, the average CHs energy is as follows:

$$Avg_{RE} = (\sum_{i=1}^N E_r(i))/(N) \quad (6)$$

$Avg_{RE}$  is the average amount of remaining energy after all CHs have been spent in the current round? At the moment, the CH has an energy level of  $E_r$ . The effects of energy on data transmission to the BS are shown in Equations (2), (4), and (6), which are all found in the source code. This means that reducing participation in the GA by CHs will make the transmission process more efficient. The following section delves deeper into the fitness function that has been proposed.

With the suggested method, the major objective is to reduce the amount of energy used in the data transfer procedure from a CH to BS. Several fitness function factors are taken into consideration in order to reach this objective. One of the parameters of the fitness function is the distance from the BS to each participant CH. As the number of CHs increases, so does the fitness function. As a result, another fitness function parameter is the ratio of proposed CHs to total CHs on the path. Number of members in a cluster is a critical fitness function parameter since it impacts how much energy cluster members consume. The number of participants in each suggested CH is the final fitness function parameter. It's true that the efficiency of transmission is maximised when the distance between the source and destination is as short as possible, but this comes at the cost of increased energy consumption.

Using the fitness function below, we can minimise the fitness function's values to discover the best route:

$$F(i) = D(CH_s, BS) + \left(\frac{N_{par}}{N}\right) + NO_{ofpart} + members \quad (7)$$

With respect to which,  $F(i)$  signifies the number of homologous regions on the  $i^{th}$ , average distance between the origin CH and the BS is represented by chromosomal  $D$  (CHs, BS), as indicated in Chromosome homologs are represented by the letters  $N$ ,  $P$ , and  $O$ , and the number of parts they play in the transmission process is represented by the letters  $No$ ,  $P$ , and  $O$ , as described in the section on how they participate in the process [24,32].

In the first phase of the fitness function, the energy consumption is distributed across all CHs based on the distance between the source CH and the BS. It's important to note that this second section shows what percentage (really) of participants' CHs are actually employed in the transmission process. Because the suggested fitness function is a minimization function, when the percentage is low, the path's optimality improves. The optimality diminishes in direct proportion to the value. A CH that has engaged in the transmission process more than once would soon lose its energy, thus the third section shows the total number of CHs that have taken part in the transmission process along the way. In other words, when its value increases, the fitness function will become more valuable, and an inefficient path will result. The number of nodes in each cluster is the final consideration.

This is especially crucial because of its impact on energy usage.

#### IV. RESULT AND DISCUSSION

The decision was made to use a MATLAB simulation tool and the simulation parameters in Table 4 to test the fitness function. The effectiveness of the approach was evaluated by comparing the findings of the proposed technique with those of the LEACH process [26] and other comparable methods. Several tuning processes are used to specify the crossover and mutation rates after which the GA parameters provided in this paper are listed in Table 4.

The LEACH protocol is the most frequently used clustering method in the WSN community. As a consequence, referring to it as a guide is critical. On the other hand, the proposed OMPFM is pitted against several other protocols that are developed on top of LEACH. Before comparing the proposed OMPFM with the current methods, an assessment of the efficiency of the improved GA should be conducted in terms of chromosomal sizes and running time. This will indicate that the better GA is more efficient. A single round of comparison is shown in Figures 3 and 4 to demonstrate how conventional GA (NGA) compares to improved GA (EGA). For every additional round, the chart becomes increasingly jumbled; on the other hand, for every additional round less than ten, the comparison values get increasingly muddled. There will be a total of 10 rounds. Because all nodes in the selected rounds are still alive, the running time is precise and predictable, and the ideal chromosomal sizes have been attained. The chosen rounds are also the first ones. This is followed by ten tests in which the standard GA is compared to its upgraded counterpart (see Figures 3 and 4). Time required for 10 conventional GA rounds is shown in Figure 3, whereas time required for enhanced GA is shown in Figure 2. Figure 2 depicts the average chromosomal size throughout the first ten cycles. There is only one way to get the average chromosome size from the BS to each CH, thus the total number of CHs divided by the number of CHs each round gives the average chromosome size. Figure 3 demonstrates that the enhanced GA requires less time each round than the regular GA does. To improve efficiency, we used the suggested pre-processing steps. Furthermore, as seen in Figure 4, enhanced GA shrinks the size of the chromosomes when compared to regular GA. The graph below illustrates the average chromosomal size during the experiment. The improved version of GA's smaller chromosome sizes increases the effectiveness of the GA by finding the optimal solution by utilising short chromosomes, thanks to the suggested pre-process that picks the appropriate CHs to be included in the GA.

Figure 3 depicts how much faster the improved GA runs, on average, than the standard GA. (Number of intermediate CHs) is less for each run in the improved GA than it is for each run in the standard GA (Fig. 4). In terms of running time and chromosomal size, the results show that the proposed GA's pre-processes are more efficient than the standard GA. Various scenarios were developed in order to assess the OMPFM's feasibility. The simulations were run a total of 20 times to provide a fair comparison. Each sensor node in the network has its own array data structure that is used to calculate the fitness

value of the suggested strategy. To illustrate the array data structure, see Table 5.

TABLE IV. PARAMETERS AND VALUES USED IN THE SIMULATION

Representation	Declaration	Value
A	Size of the network	100×100
BS(i,j)	Base station location	area center (50×50)
N	The total no. of nodes	100
Et <sub>x</sub>	Transmission energy	51 nJ/bit
E <sub>o</sub>	Initial energy	0.5 Joule, 1 Joule
E <sub>elec</sub>	Consumption of electronic resources	51 nJ/bit
E <sub>r<sub>x</sub></sub>	Energy for reception	51 nJ/bit
E <sub>amp</sub>	amplified signal transmission	12 pJ/bit/m <sup>2</sup>
E <sub>da</sub>	energy used for data collection and analysis	6 nJ/bit
R <sub>max</sub>	Number of rounds allowed as a maximum	5000
Pack/CtrPack	Packet size for data and control	528 bytes/50 bytes
Indiv	No. of Individuals	50
Iter	No. of iterations	120
Cr	Ratio of changeover	0.9
Mr	Change rate	0.05

Table 6 and Fig. 5 show the outcomes of using the proposed technique in comparison to the comparable methods [5,14,16,22,36]. When compared to techniques based on the number of dead nodes, the recommended strategy leads in longer network lifetimes, as shown by the findings above. The recommended approach outperforms the LEACH protocol by 28%, the GCA by 25%, the EAERP by 18%, and the GAECH by 11% in dead node percentages of 10% compared to the LEACH protocol. As compared to the standard LEACH protocol, this one outperforms it by 35%, as well as the GCA (34%), EAERP (26%), and GAECH (19% when including HND, or 50% of dead nodes). The new approach beat the previous ones by a factor of 101 percent when compared to LEACH and a factor of 99 percent when compared to GCA and EAERP. Longevity gains are seen when employing the recommended technique, and these gains can be ascribed to using energy-efficient intermediate CHs in the selection process for the fitness function.

To simulate the second case, the starting energy of each node was reduced to 0.5 Joule from 1 Joule as per [11]. Table 7 shows the FND and LND of the proposed OMPFM. Table 7 shows the average values of the FND and LND parameters over tens of thousands of runs, which are 1695 and 3946, respectively. Figure 5 depicts the [11]'s FND and LND. Table 6 and Table. 7 [11] reveal that our OMPFM has superior FND and LND values than previous techniques. A FND of 1695 characterises the suggested OMPFM, while a FND of 800 characterises the techniques outlined in [11]. The LND in the OMPFM is 3946, but in the approaches in [11], it's roughly 2000. In terms of running time, the recommended OMPFM performs better thanks to better parameter selection in the fitness function and better utilisation of the pre-processing.

TABLE VI. PERCENTAGE OF DEAD NODES AND NUMBER OF ROUNDS

Dead nodes%	No. of Rounds				
	LEACH	CGA	EAERP	GAECH	OMPFM
10%	1898	2163	2244	2440	2646
20%	2013	2146	21782	2331	2713
40%	2057	22602	2334	2366	2644

### V. CONCLUSION AND FUTURE SCOPE

Data transmission in WSNs has a significant impact on a network's lifetime performance. It's difficult to use direct transmission in WSNs because of the increased energy usage. This is especially true when the source CH is far from the BS. Furthermore, choosing the right CHs is a problem that has a big impact on the network's lifespan. These issues have been the subject of a slew of investigations. A novel approach to the direct transmission problem, based on a modified GA, is given in this work. The settings of the boundary variables for the cluster head selection function can be altered to improve results based on the specific application. A change is recommended to the CHs selection threshold. Since the suggested technique is half as good as the LEACH protocol and other comparable methods presently in use in terms of network lifetimes and power consumption, this would lead to longer run times. Eventually, a new evolutionary algorithm will be implemented to speed up the processing time. Additionally, future mobile WSNs will consider a multi-hop routing method.
